Igor Pro

Version 9

WaveMetrics

Updates

Please check our website at <http://www.wavemetrics.com/> or the Igor Pro Help menu for minor updates, which we make available for you to download whenever bugs are fixed.

If there are features that you would like to see in future versions of Igor or if you find bugs in the current version, please let us know. We’re committed to providing you with a product that does the job reliably and conveniently.

Introduction to Igor Pro

Introduction to Igor Pro

Igor Pro is an integrated program for visualizing, analyzing, transforming and presenting experimental data.

Igor Pro's features include:

- Publication-quality graphics
- High-speed data display
- Ability to handle large data sets
- Curve-fitting, Fourier transforms, smoothing, statistics, and other data analysis
- Waveform arithmetic
- Image display and processing
- Combination graphical and command-line user interface
- Automation and data processing via a built-in programming environment
- Extensibility through modules written in the C and C++ languages

Some people use Igor simply to produce high-quality, finely-tuned scientific graphics. Others use Igor as an all-purpose workhorse to acquire, analyze and present experimental data using its built-in programming environment. We have tried to write the Igor program and this manual to fulfill the needs of the entire range of Igor users.

Igor 32-bit and 64-bit Versions

Igor is available in both 32-bit (Windows only) and 64-bit versions. When making a distinction between these versions, we sometimes refer to the 32-bit version as "IGOR32" and the 64-bit version as "IGOR64".

On Windows, both 32-bit and 64-bit applications are installed. The 64-bit version runs by default. You should run the 32-bit version only if compatibility with a 32-bit XOP (plug-in) is required.

On Macintosh, starting with Igor Pro 8.00, Igor is available only as a 64-bit application. If you need to run with a 32-bit XOP (plug-in) then you must run Igor Pro 7.

Igor Objects

The basic objects that all Igor users work with are:

- Waves
- Graphs
- Tables
- Page layouts

A collection of objects is called an "experiment" and is stored in an experiment file. When you open an experiment, Igor recreates the objects that comprise it.

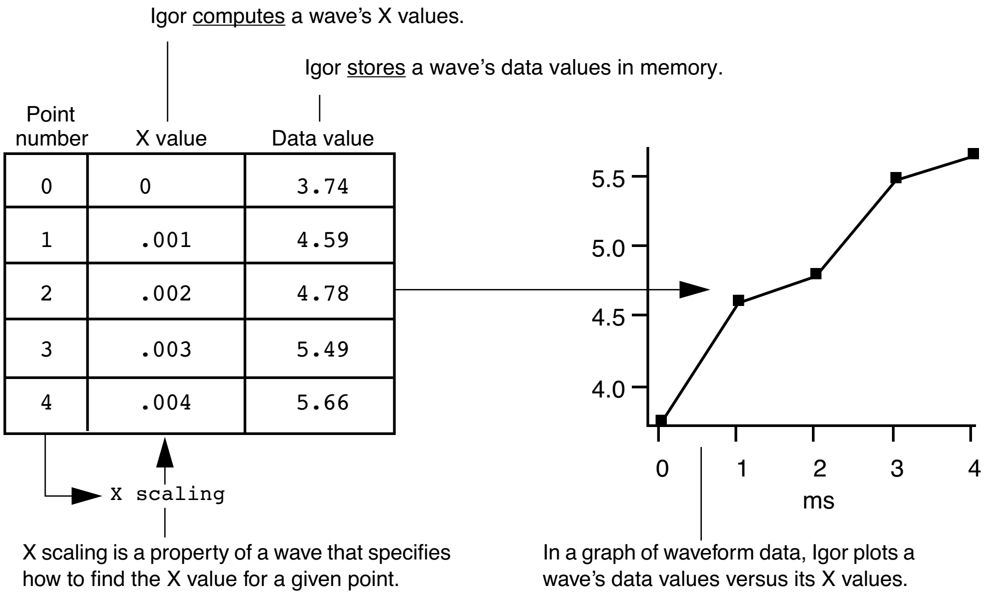
Waves — The Key Igor Concept

We use the term "wave" to describe the Igor object that contains an array of numbers. Wave is short for "waveform". The wave is the most important Igor concept.

Igor was originally designed to deal with waveform data. A waveform typically consists of hundreds to thousands of values measured at evenly-spaced intervals of time. Such data is usually acquired from a digital oscilloscope, scientific instrument or analog-to-digital converter card.

The distinguishing trait of a waveform is the *uniform spacing* of its values along an axis of time or other quantity. An Igor wave has an important property called "X scaling" that you set to specify the spacing of your data. Igor *stores* the Y component for each point of a wave in memory but it *computes* the X component based on the wave's X scaling.

In the following illustration, the wave consists of five data points numbered 0 through 4. The user has set the wave's X scaling such that its X values start at 0 and increment by 0.001 seconds per point. The graph displays the wave's stored data values versus its computed X values.



Igor computes a wave's X values.
Igor stores a wave's data values in memory.
X scaling
X scaling is a property of a wave that specifies how to find the X value for a given point.
5.5

4.5
4.0
0
1
2
3
4
ms
In a graph of waveform data, Igor plots a wave's data values versus its X values.

Point number	X value	Data value
0	0	3.74
1	.001	4.59
2	.002	4.78
3	.003	5.49
4	.004	5.66

Waves can have from one to four dimensions and can contain either numeric or text data.

Igor is also capable of dealing with data that does not fit the waveform metaphor. We call this XY data. Igor can treat two waves as an XY pair. In an XY pair, the data values of one wave supply the X component and the data values of another wave supply the Y component for each point in the pair.

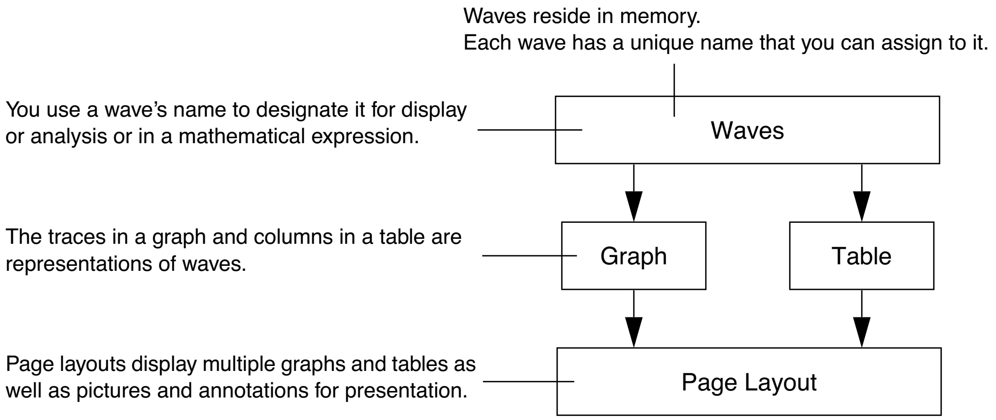
A few analysis operations, such as Fourier transforms, inherently work only on waveform data. They take a wave's X scaling into account.

Other operations work equally well on waveform or XY data. Igor can graph either type of data and its powerful curve fitting works on either type.

Most users create waves by loading data from a file. You can also create waves by typing in a table, evaluating a mathematical expression, acquiring from a data acquisition device, and accessing a database.

How Objects Relate

This illustration shows the relationships among Igor's basic objects. Waves are displayed in graphs and tables. Graphs and tables are displayed in page layouts. Although you can display a wave in a graph or table, a wave does not need to be displayed to exist.



Waves reside in memory.
Each wave has a unique name that you can assign to it.
You use a wave's name to designate it for display or analysis or in a mathematical expression.
Waves
The traces in a graph and columns in a table are representations of waves.
Graph
Table
Page layouts display multiple graphs and tables as well as pictures and annotations for presentation.
Page Layout

Each object has a name so that it can be referenced in an Igor command. You can explicitly set an object’s name or accept a default name created by Igor.

Graphs are used to visualize waves and to generate high-quality printouts for presentation. The traces in a graph are representations of waves. If you modify a wave, Igor automatically updates graphs. Igor labels the axes of a graph intelligently. Tick marks never run into one another and are always “nice” values no matter how you zoom in or pan around.

In addition to traces representing waveform or XY data, a graph can display an image or a contour plot generated from 2D data.

Tables are used to enter, inspect or modify wave data. A table in Igor is not the same as a spreadsheet in other graphing programs. A column in a table is a *representation* of the contents of a wave. The wave continues to exist even if you remove it from the table or close the table entirely.

Page layouts permit you to arrange multiple graphs and tables as well as pictures and annotations for presentation. If you modify a graph or table, either directly or indirectly by changing the contents of a wave, Igor automatically updates its representation in a layout.

Both graphs and layouts include drawing tools for adding lines, arrows, boxes, polygons and pictures to your presentations.

More Objects

Here are some additional objects that you may encounter:

- Numeric and string variables
- Data folders
- Notebooks
- Control panels
- 3D plots
- Procedures

A numeric variable stores a single number and a string variable stores a text string. Numeric and string variables are used for storing bits of data for Igor procedures.

A data folder can contain waves, numeric variables, string variables and other data folders. Data folders provide a way to keep a set of related data, such as all of the waves from a particular run of an experiment, together and separate from like-named data from other sets.

A notebook is like a text-editor or word-processor document. You can use a notebook to keep a log of results or to produce a report. Notebooks are also handy for viewing Igor technical notes or other text documentation.

A control panel is a window containing buttons, checkboxes and other controls and readouts. A control panel is created by an Igor user to provide a user interface for a set of procedures.

A 3D plot displays three–dimensional data as a surface, a scatter plot, or a path in space.

A procedure is a programmed routine that performs a task by calling Igor's built-in operations and functions and other procedures. Procedures range from very simple to very complex and powerful. You can run procedures written by WaveMetrics or by other Igor users. If you are a programmer or want to learn programming, you can learn to write your own Igor procedures to automate your work.

Igor’s Toolbox

Igor's toolbox includes a wide range of built-in routines. You can extend it with user-defined procedures written in Igor itself and with separately-compiled Igor extensions (plug-ins) that you obtain from WaveMetrics, from a colleague, from a third-party, or write yourself.

Built-In Routines

Each of Igor's built-in routines is categorized as a function or as an operation.

A built-in function is an Igor routine, such as sin, exp or ln, that directly returns a result. A built-in operation is a routine, such as Display, FFT or Integrate, that acts on an object and may create new objects but does not directly return a result.

A good way to get a sense of the scope of Igor's built-in routines is to scan the sections **Built-In Operations by Category** on page V-1 and **Built-In Functions by Category** on page V-7 in the reference volume of this manual.

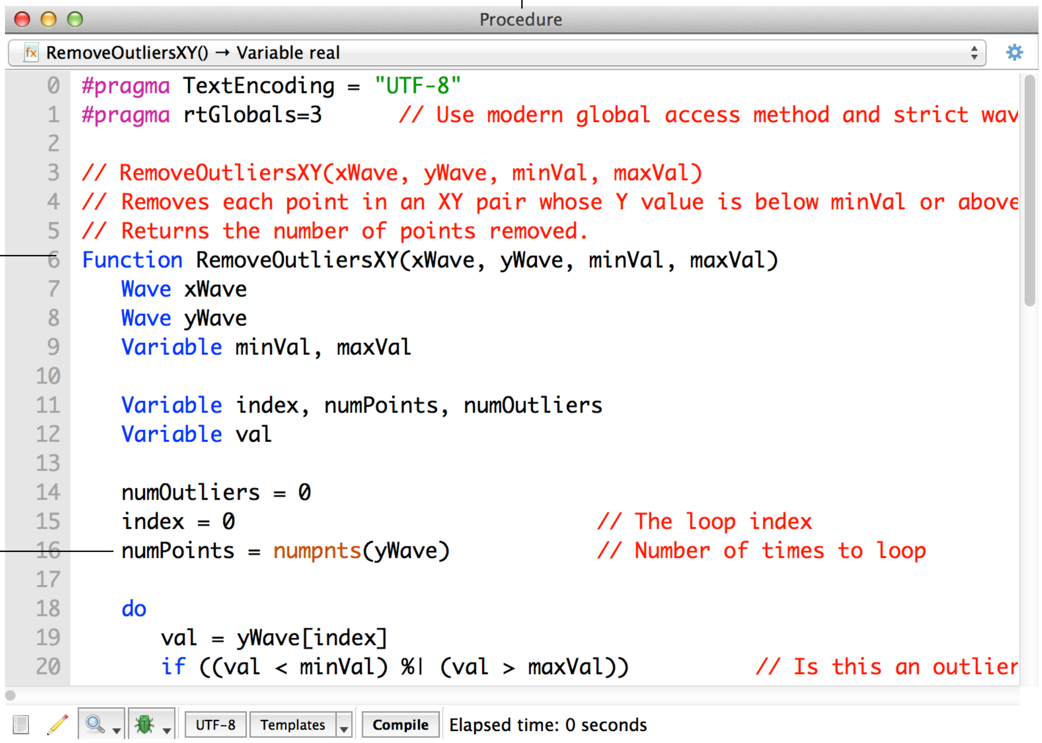
For getting reference information on a particular routine it is usually most convenient to choose Help→Command Help and use the Igor Help Browser.

User-Defined Procedures

A user-defined procedure is a routine written in Igor’s built-in programming language by entering text in a procedure window. It can call upon built-in or external functions and operations as well as other user-defined procedures to manipulate Igor objects. Sets of procedures are stored in procedure files.

You can create Igor procedures by entering text in a procedure window.

Each procedure has a name which you use to invoke it.



```
#pragma TextEncoding = "UTF-8"
#pragma rtGlobals=3      // Use modern global access method and strict wav

// RemoveOutliersXY(xWave, yWave, minVal, maxVal)
// Removes each point in an XY pair whose Y value is below minVal or above
// Returns the number of points removed.
Function RemoveOutliersXY(xWave, yWave, minVal, maxVal)
    Wave xWave
    Wave yWave
    Variable minVal, maxVal

    Variable index, numPoints, numOutliers
    Variable val

    numOutliers = 0
    index = 0                         // The loop index
    numPoints = numpnts(yWave)        // Number of times to loop

    do
        val = yWave[index]
        if ((val < minVal) %| (val > maxVal))         // Is this an outlier
```

Procedures can call operations, functions or other procedures. They can also perform waveform arithmetic.

Igor Extensions

An extension is a “plug-in” - a piece of external C or C++ code that adds functionality to Igor. For historical reasons, we use the term “XOP” to refer to an Igor extension. “XOP” is a contraction of “external operation”. The terms “XOP” and “Igor extension” are synonymous.

Originally XOPs were intended to allow adding operations only to Igor. Now XOPs can add much more, including functions, menus, dialogs, and windows, so “XOP” has the meaning “external module that extends Igor”.

To create an XOP, you must be a C or C++ programmer and you need the optional **Igor External Operations Toolkit**. See **Creating Igor Extensions** on page IV-208.

Although *creating* an extension is a job for a programmer, anyone can *use* an extension. The Igor installer automatically installs commonly used extensions in "Igor Pro Folder/Igor Extensions (64-bit)". These extensions are available for immediate use.

Less commonly used extensions are installed in "Igor Pro Folder/More Extensions (64-bit)". Available extensions are described in the “XOP Index” help file (choose Help→Help Windows→XOP Index.ihf). To activate an extension, see **Activating 64-bit Extensions** on page III-512.

Igor’s User Interface

Igor uses a combination of the familiar graphical user interface and a command-line interface. This approach gives Igor both ease-of-use and programmability.

The job of the user interface is to allow you to apply Igor’s operations and functions to objects that you create. You can do this in several ways:

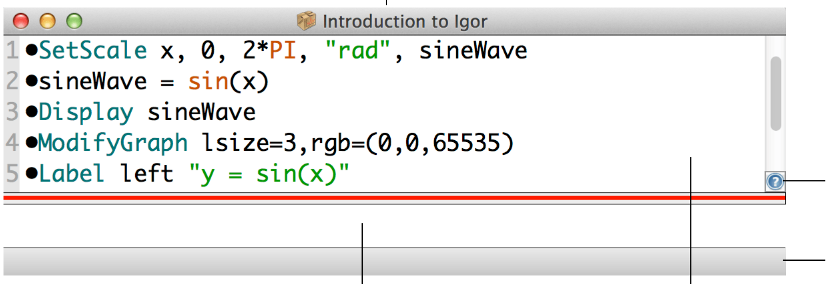
- Via menus and dialogs
- Using the main toolbar
- By typing Igor commands directly into the command line
- By writing Igor procedures

The Command Window

The command window is Igor’s control center. It appears at the bottom of the screen.

At the bottom of the command window is the command line. Above the red divider is the history area where executed commands are stored for review. Igor also uses the history area to report results of analyses like curve-fitting or waveform statistics.

The name of the current experiment appears as the title of the command window.



```
•SetScale x, 0, 2*PI, "rad", sineWave
•sineWave = sin(x)
•Display sineWave
•ModifyGraph lsize=3,rgb=(0,0,65535)
•Label left "y = sin(x)"
```

Help Browser button

Status area

You enter commands in the **command line**.

When Igor executes a command it transfers it to the **history area**.

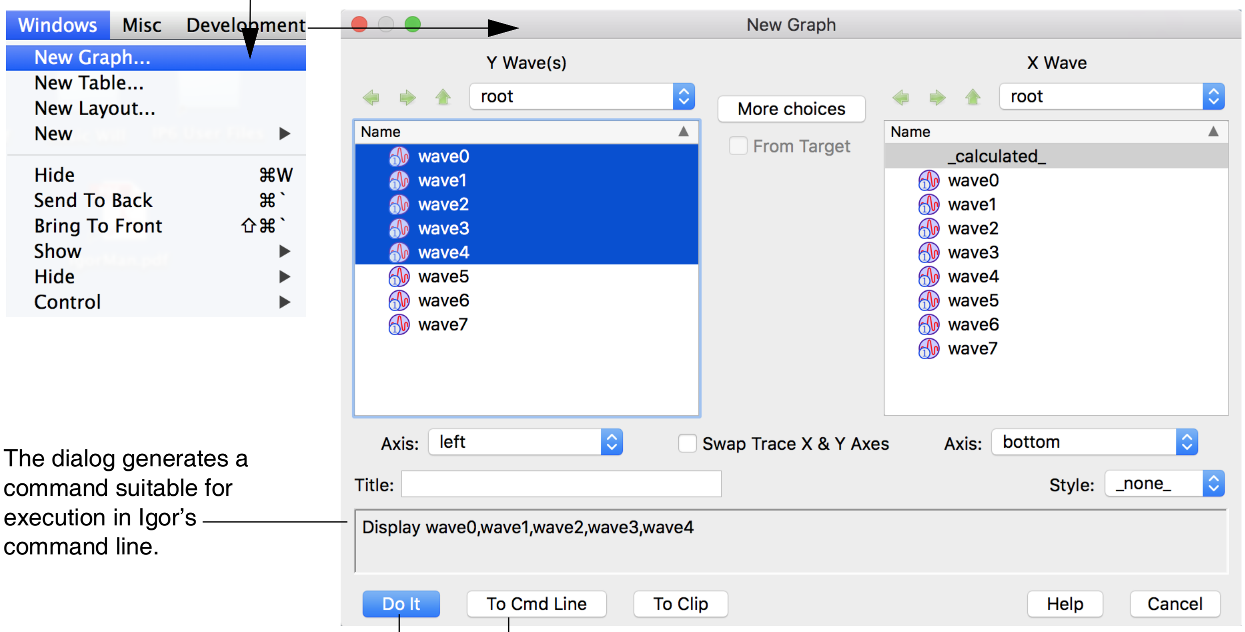
Menus, Dialogs and Commands

Menus and dialogs provide easy access to the most commonly-used Igor operations.

When you choose a menu item associated with an Igor operation, Igor presents a dialog. As you use the dialog, Igor generates a command and displays it in the **command box** near the bottom of the dialog. When you click the Do It button, Igor transfers the command to the command line where it is executed.

When you choose a menu item...

...Igor presents a dialog.



```
Display wave0,wave1,wave2,wave3,wave4
```

The dialog generates a command suitable for execution in Igor's command line.

Transfers the command to the command line and executes it.

Copies the command to the command line where you can edit it and then execute it.

As you get to know Igor, you will find that some commands are easier to invoke from a dialog and others are easier to enter directly in the command line.

There are some menus and dialogs that bypass the command line. Examples are the Save Experiment and Open Experiment items in the File menu.

The Igor Toolbar

The main toolbar provides quick access to frequently used features.

On Windows, the default location for the toolbar is just below the main menu bar. On Macintosh, it is at the top of the command window.

You can reposition the toolbar by clicking the dots at the left or top edge and dragging. You can either move it to a different edge of the outer frame window (*Windows*) or the command window (*Macintosh*), or you can drag it elsewhere to float the toolbar.

You can hide the toolbar by choosing Windows→Hide Toolbar and show it again by choosing Windows→Show Toolbar.

The visibility, position, and orientation of the toolbar is saved when you quit Igor.

Currently it is not possible to change which features are available on the toolbar.

Using Igor for Heavy-Duty Jobs

If you generate a lot of raw data or need to do custom technical computing, you will find it worthwhile to learn how to put Igor to heavy-duty use. It is possible to automate some or all of the steps involved in loading, processing, and presenting your data. To do this, you must learn how to write Igor procedures.

Igor includes a built-in programming environment that lets you manipulate waves, graphs, tables and all other Igor objects. You can invoke built-in operations and functions from your own procedures to build higher-level operations customized for your work.

Learning to write Igor procedures is easier than learning a lower-level language such as FORTRAN or C. The Igor programming environment is interactive so you can write and test small routines and then put them together piece-by-piece. You can deal with very high level objects such as waves and graphs but you also have fine control over your data. Nonetheless, it is still programming. To master it requires an effort on your part.

The Igor programming environment is described in detail in **Volume IV Programming**. You can get started by reading the first three chapters of that volume.

You can also learn about Igor programming by examining the WaveMetrics Procedures and example experiments that were installed on your hard disk.

Igor Documentation

Igor includes an extensive online help system and a comprehensive PDF manual.

The online help provides guided tours, tooltips, general usage information for all aspects of Igor, and reference information for Igor operations, functions and keywords.

The PDF manual contains the same information except for the tooltips.

The PDF manual, being in book format, is better organized for linear reading while the online help is usually preferred for reference information.

Tooltips

Igor displays tooltips when you hover the mouse over an icon or dialog item.

You can turn tooltips off using the Miscellaneous Settings dialog. Choose Misc→Miscellaneous Settings, click the Help icon on the left, and uncheck the Show Tooltips checkbox.

The Igor Help System

The Help menu provides access to Igor's help system, primarily through the Igor Help Browser.

- To display the Igor Help Browser, use the Help menu, click the question-mark icon in the command window, or press F1 (*Windows only*).
- Use the Igor Help Browser Help Topics tab to browse help topics.
- Use the Igor Help Browser Shortcuts tab to get a list of handy shortcuts and techniques.
- Use the Igor Help Browser Command Help tab to get reference information on Igor operations and functions. You can also right-click operation and function names in Igor windows to access the reference help.
- Use the Igor Help Browser Search tab to search Igor help, procedure and example files.

Most of the information displayed by the help browser comes from help files that are automatically loaded at launch time. The Help→Help Windows submenu provides direct access to these help files.

The Igor Manual

The Igor PDF manual resides in "Igor Pro Folder/Manual". You can access it by choosing Help→Manual.

The manual consists of five volumes and an index.

Volume I contains the Getting Started material, including the Guided Tour of Igor Pro.

Volumes II and III contain general background and usage information for all aspects of Igor other than programming.

Volume IV contains information for people learning to do Igor programming.

Volume V contains reference information for Igor operations, functions and keywords.

Hard copy of the manual is not available.

Learning Igor

To harness the power of Igor, you need to understand its fundamental concepts. Some of these concepts are familiar to you. However, Igor also incorporates a few concepts that will be new to you and may seem strange at first. The most important of these are *waves* and *experiments.*

In addition to this introduction, the primary resources for learning Igor are:

- The **Guided Tour of Igor Pro** in Chapter I-2

  The guided tour shows you how to perform basic Igor tasks step-by-step and reinforces your understanding of basic Igor concepts along the way.

  The guided tour provides an essential orientation to Igor and is highly-recommended for all Igor users.

- The Igor Pro PDF manual and online help files

  You can access the PDF manual through Igor's Help menu or by opening it directly from the Manual folder of the Igor Pro Folder where Igor is installed.

  You can access the help files through the Igor Help Browser (choose Help→Igor Help Browser) or directly through the Help→Help Windows submenu.

- The example experiments

  The example experiments illustrate a wide range of Igor features. They are stored in the Examples folder in the Igor Pro Folder. You can access them using the File→Example Experiments submenu or directly from the Examples folder of the Igor Pro Folder where Igor is installed.

You will best learn Igor through a combination of doing the guided tour, reading select parts of the manual (see suggestions following the guided tour), and working with your own data.

Videos of the guided tour are available at:

https://www.wavemetrics.com/igorpro/videotutorials.htm

Getting Hands-On Experience

This introduction has presented an overview of Igor, its main constituent parts, and its basic concepts. The next step is to get some hands-on experience and reinforce what you have learned by doing the **Guided Tour of Igor Pro** on page I-11.

Chapter

I-2

Guided Tour of Igor Pro

Overview

In this chapter we take a look at the main functions of Igor Pro by stepping through some typical operations. Our goal is to orient you so that you can comfortably read the rest of the manual or explore the program on your own. You will benefit most from this tour if you actually do the instructed operations on your computer as you read this chapter. Screen shots are provided to keep you synchronized with the tour.

Terminology

If you have read Chapter I-1, **Introduction to Igor Pro**, you already know these terms.

Experiment The entire collection of data, graphs and other windows, program text and other data that make up the current Igor environment or workspace.

Wave Short for waveform, this is basically a named array of data with optional extra information.

Name Because Igor contains a built-in programming and data transformation language, each object must have a unique name.

Command This is a line of text that performs some task. Igor is command-driven so that it can be easily programmed.

About the Tour

This tour consists of three sections: **Guided Tour 1 - General Tour** on page I-13, **Guided Tour 2 - Data Analysis** on page I-46, and **Guided Tour 3 - Histograms and Curve Fitting** on page I-53.

The General Tour is a rambling exploration intended to introduce you to the way things work in Igor and give you a general orientation.

The second and third tours guide you through Igor’s data analysis facilities including simple curve fitting.

When you’ve completed the first tour you may prefer to explore freely on your own before starting the second tour.

Guided Tour 1 - General Tour

In this exercise, we will generate data in three ways (typing, loading, and synthesizing) and we will generate graph, table, and page layout windows. We will jazz up a graph and a page layout with a little drawing and some text annotation. At the end, we will explore some of the more advanced features of Igor Pro.

Creating an Igor64 Alias or Shortcut

The 64-bit Igor Pro application is typically located at:

```
/Applications/Igor Pro 9 Folder/Igor64.app (Macintosh)
```

```
C:\Program Files\WaveMetrics\Igor Pro 9 Folder\IgorBinaries_x64\Igor.exe (Windows)
```

The ".app" and ".exe" extensions may be hidden on your system.

1. **Make an alias (Macintosh) or shortcut (Windows) for your Igor64 application file and put the alias or shortcut on your desktop. Name it Igor64.**

Launching Igor Pro

1. **Double-click your Igor64 alias or shortcut.**

   Igor starts up.

   On Windows, you an also launch Igor64 using the Start menu.

2. **Choose Misc→Preferences Off.**

   Turning preferences off ensures that the tour works the same for everyone.

Entering Data

1. **If a table window is showing, click it to bring it to the front.**

   When Igor starts up, it creates a new blank table unless this feature is turned off in the Miscellaneous Settings dialog. If the table is not showing, perform the following two steps:

2. **Choose the Windows→New Table menu item.**

   The New Table dialog appears.

3. **Click the Do It button.**

   A new blank table is created.

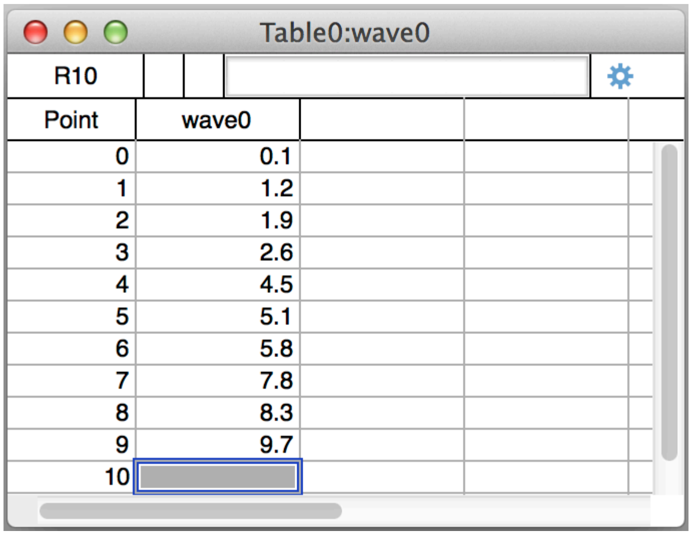
4. **Type "0.1" (without the quotes) and then press Return or Enter on your keyboard.**

   This creates a wave named "wave0" with 0.1 for the first point. Entering a value in the first row (point 0) of the first blank column automatically creates a new wave.

5. **Type the following numbers, pressing Return or Enter after each one:**

   1.2
   1.9
   2.6
   4.5
   5.1
   5.8
   7.8
   8.3
   9.7

   The table should look like this:



Point	wave0
0	0.1
1	1.2
2	1.9
3	2.6
4	4.5
5	5.1
6	5.8
7	7.8
8	8.3
9	9.7
10	

6. **Click in the first cell of the first blank column.**
7. **Enter the following numbers in the same way:**

   -0.12
   -0.08
   1.3
   1
   0.54
   0.47
   0.44
   0.2
   0.24
   0.13

8. **Choose Data→Rename.**
9. **Click “wave0” in the list and then click the arrow icon.**
10. **Replace “wave0” with “time”.**

    Notice that you can’t use the name “time” because it is the name of a built-in string function. We apologize for usurping such a common name.

11. **Change the name to “timeval”.**
12. **Click “wave1” in the list, click the arrow icon, and replace “wave1” with “yval”.**
13. **Click Do It.**

    The column headers in the table change to reflect the name changes.

Making a Graph

14. Choose the Windows→New Graph menu item.

The New Graph dialog appears. This dialog comes in a simple form that most people will use and a more complex form that you can use to create complex multi-axis graphs in one step.

15. If you see a button labeled Fewer Choices, click it.

16. In the Y Waves list, click “yval”.

17. In the X Wave list, click “timeval”.

18. Click Do It.

A simple graph is created.

Touching up a Graph

19. Position the cursor directly over the trace in the graph and double-click.

The Modify Trace Appearance dialog appears. You could also have chosen the corresponding menu item from the Graph menu.

Note: The Graph menu appears only when a graph is the target window. The *target* window is the window that menus and dialogs act on by default.

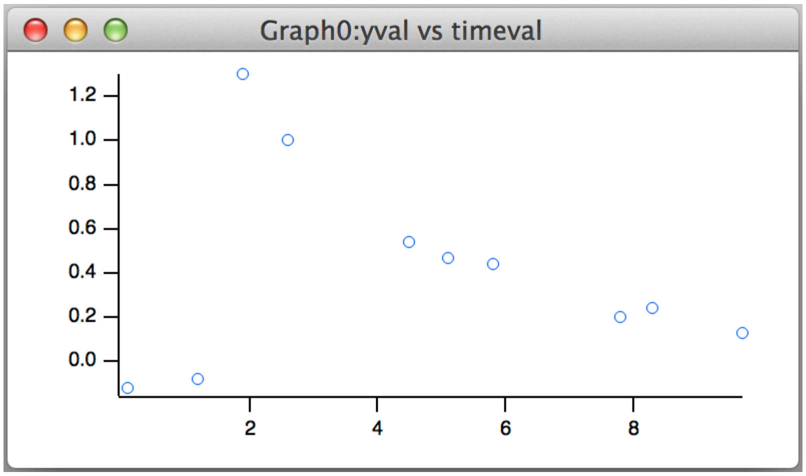
20. Choose Markers from the Mode pop-up menu.

21. Select the open circle from the Marker pop-up menu.

22. Set the marker color to blue.

23. Click Do It.

The graph should now look like this:



24. Position the cursor over the bottom axis line.

The cursor changes to this shape: ↕. This indicates the cursor is over the axis and also that you can offset the axis, and the corresponding plot area edge, to a new position.

25. Double-click directly on the axis.

The Modify Axis dialog appears. If another dialog appears, click Cancel and try again, making sure the ↕ cursor is showing when you double-click.

Note the Live Update checkbox in the top/right corner of the Modify Axis dialog. When it is checked, changes that you make in the dialog are immediately reflected in the graph. When it is unchecked, the changes appear only when you click Do It.

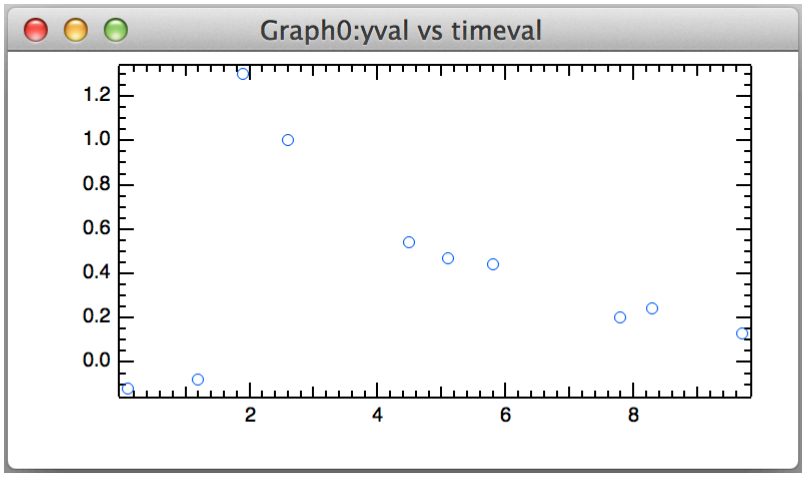
26. If it is not already showing, click the Axis tab.

27. Choose On from the Mirror Axis pop-up.

28. Click the Auto/Man Ticks tab.

29. **Click the Minor Ticks checkbox so it is checked.**
30. **Click the Ticks and Grids tab.**
31. **Choose Inside from the Location pop-up.**
32. **Choose the left axis from the Axis pop-up menu in the top-left corner of the dialog and then repeat steps 8 through 13.**
33. **Click Do It.**

    The graph should now look like this:



34. **Again double-click the bottom axis.**

    The Modify Axis dialog appears again.
35. **Click the Axis tab.**
36. **Uncheck the Standoff checkbox.**
37. **Choose the left axis from the Axis pop-up menu and repeat step 18.**
38. **Click Do It.**

    Notice that some of the markers now overlap the axes. The axis standoff setting offsets the axis so that markers and traces do not overlap it. You can use Igor's preferences to ensure that this and other settings default to your liking, as explained below.
39. **Double-click one of the tick mark labels (such as "6") on the bottom axis.**

    The Modify Axis dialog reappears, this time with the Axis Range tab showing. If another dialog or tab appears, cancel and try again, making sure to double click one of the tick mark labels on the bottom axis.
40. **Choose "Round to nice values" from the pop-up menu that initially reads "Use data limits".**
41. **Choose the left axis from the Axis pop-up menu and repeat step 22.**
42. **Click Do It.**

    Notice that the limits of the axes now fall on "nice" values.

Adding a Legend

1. **Choose the Graph→Add Annotation menu item.**

   The Add Annotation dialog appears.
2. **Click the Text tab if it is not already selected.**
3. **Choose Legend from the Annotation pop-up menu in the top-left corner of the dialog.**

   Igor inserts text to create a legend in the Annotation text entry area. The Preview area shows what the annotation will look like. The text `\s(yval)` generates the symbol for the yval wave. This is an "escape sequence" which creates special effects such as this.

4. **Change the second instance of “yval” to “Magnitude”.**

   The annotation annotation text should now be “\s(yval) Magnitude”.

5. **Click the Frame tab and choose Box from the Annotation Frame pop-up menu.**
6. **Choose Shadow from the Border pop-up menu.**
7. **Click the Position tab and choose Right Top from the Anchor pop-up menu.**

   Specifying an anchor point helps Igor keep the annotation in the best location as you make the graph window bigger or smaller.

8. **Click Do It.**

Adding a Tag

1. **Choose the Graph→Add Annotation menu item.**
2. **Choose Tag from the Annotation pop-up menu in the top-left corner of the dialog.**
3. **Click the Text tab, and in the annotation text entry area of the Text tab, type “When time is ”.**
4. **Choose Attach Point X Value from the Dynamic pop-up menu in the Insert area of the dialog.**

   Igor inserts the `\OX` escape code into the annotation text entry area.

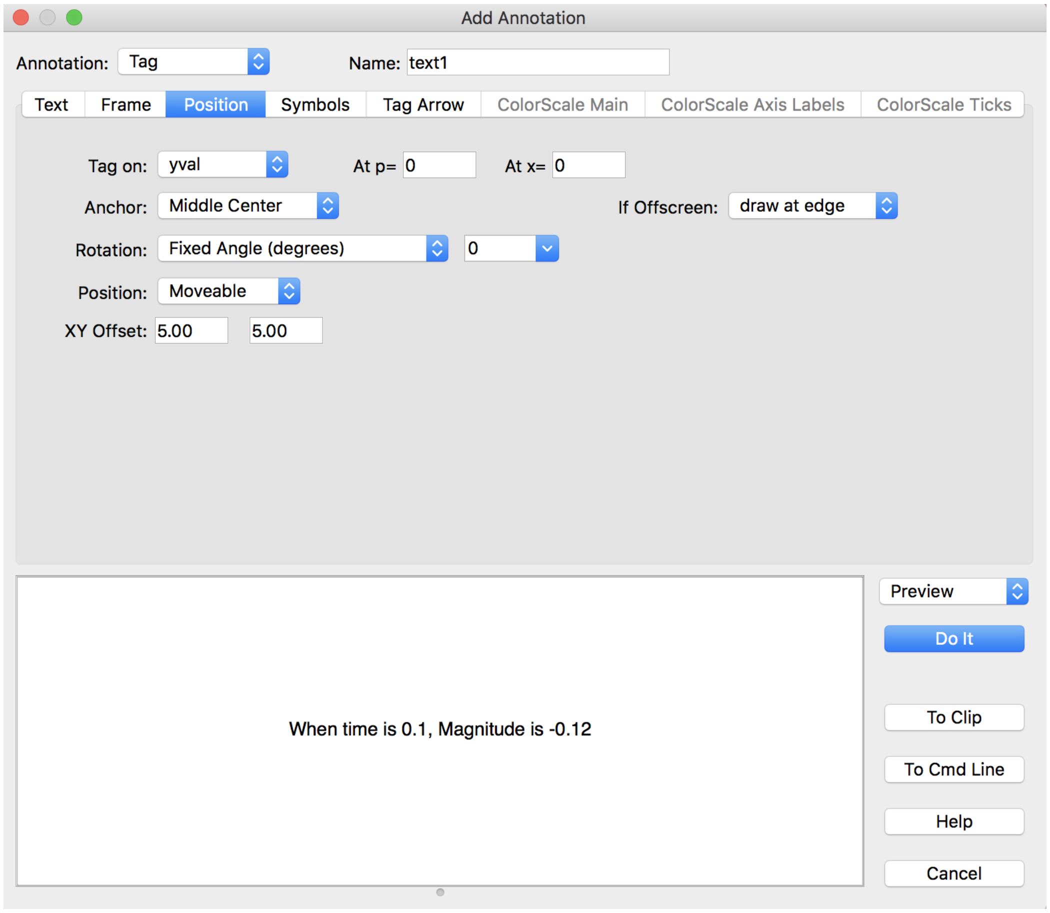
5. **In the annotation text entry area, add “, Magnitude is ”.**
6. **Choose Attach Point Y Value from the Dynamic pop-up menu.**

   Igor inserts the `\OY` escape code into the annotation text entry area.

7. **Click the Frame tab and choose None from the Annotation Frame pop-up menu.**
8. **Click the Tag Arrow tab and choose Arrow from the Connect Tag to Wave With pop-up menu.**

9. **Click the Position tab and choose “Middle center” from the Anchor pop-up menu.**

   The dialog should now look like this:



Annotation: Tag
Name: text1

Tag on: yval
At p= 0
At x= 0

Anchor: Middle Center
If Offscreen: draw at edge

Rotation: Fixed Angle (degrees) 0

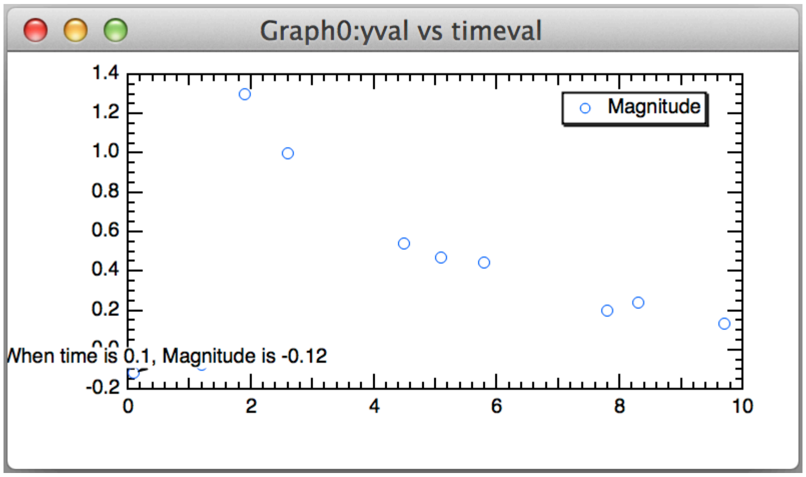
Position: Moveable

XY Offset: 5.00 5.00

When time is 0.1, Magnitude is -0.12

10. **Click Do It.**

    The graph should now look like this:



The tag is attached to the first point. An arrow is drawn from the center of the tag to the data point but you can’t see it because it is hidden by the tag text.

11. **Position the cursor over the text of the tag.**

    The cursor changes to a hand. This indicates you can reposition the tag relative to the data point it is attached to.

12. **Drag the tag up and to the right about 1 cm.**

    You can now see the arrow.

13. **With the cursor over the text of the tag, press Option (*Macintosh*) or Alt (*Windows*).**

    The cursor changes to this shape: ⊡ . (You may need to nudge the cursor slightly to make it change.)

14. **While pressing Option (*Macintosh*) or Alt (*Windows*), drag the box cursor to a different data point.**

    The tag jumps to the new data point and the text is updated to show the new X and Y values. Option-drag (*Macintosh*) or Alt-drag (*Windows*) the tag to different data points to see their X and Y values.

    Notice that the tip of the arrow touches the marker. This doesn't look good, so let's change it.

15. **Double-click the text part of the tag.**

    The Modify Annotation dialog appears.

16. **Click the Tag Arrow tab and change the Line/Arrow Standoff from "Auto" to "10".**

17. **Click the Change button.**

    The tip of the arrow now stops 10 points from the marker.

Using Preferences

If you have already set preferences to your liking and do not want to disturb them, you can skip this section.

1. **Choose Misc→Preferences On.**
2. **Click the graph window if it is not already active.**
3. **Choose the Graph→Capture Graph Prefs menu item.**

    The Capture Graph Preferences dialog appears.

4. **Click the checkboxes for XY plot axes and for XY plot wave styles.**
5. **Click Capture Preferences.**
6. **Choose Windows→New Graph.**
7. **Choose "yval" as the Y wave and "timeval" as the X wave.**
8. **Click Do It.**

    The new graph is created with a style similar to the model graph.

9. **Press Option (*Macintosh*) or Alt (*Windows*) while clicking the close button of the new graph.**

    The new graph is killed without presenting a dialog.

10. **Choose Graph→Capture Graph Prefs.**
11. **Click the checkboxes for XY plot axes and for XY plot wave styles.**
12. **Click Revert to Defaults.**
13. **Choose Misc→Preferences Off.**

    We turn preferences off during the guided tour to ensures that the tour works the same for everyone. This is not something you would do during normal work.

Making a Page Layout

1. **Choose the Windows→New Layout menu item.**

    The New Page Layout dialog appears. The names of all tables and graphs are shown in the list.

2. **In the Objects to Lay Out list, select Graph0.**
3. **Command-click (*Macintosh*) or Ctrl-click (*Windows*) on Table0.**

4. **Click Do It.**

   A page layout window appears with a Table0 object on top of a Graph0 object.

   The layout initially shows the page at 50% magnification but you may prefer to work at 100%. You can use the pop-up menu in the lower left corner of the window to change magnification.

5. **Click the Table0 object in the layout window.**

   The table object becomes selected, resize handles are drawn around the edges, and the cursor changes to a hand when over the table.

6. **Click in the middle of the table and drag it so you can see the right edge of the table.**

7. **Position the cursor over the handle (small black square) in the middle of the right edge of the table.**

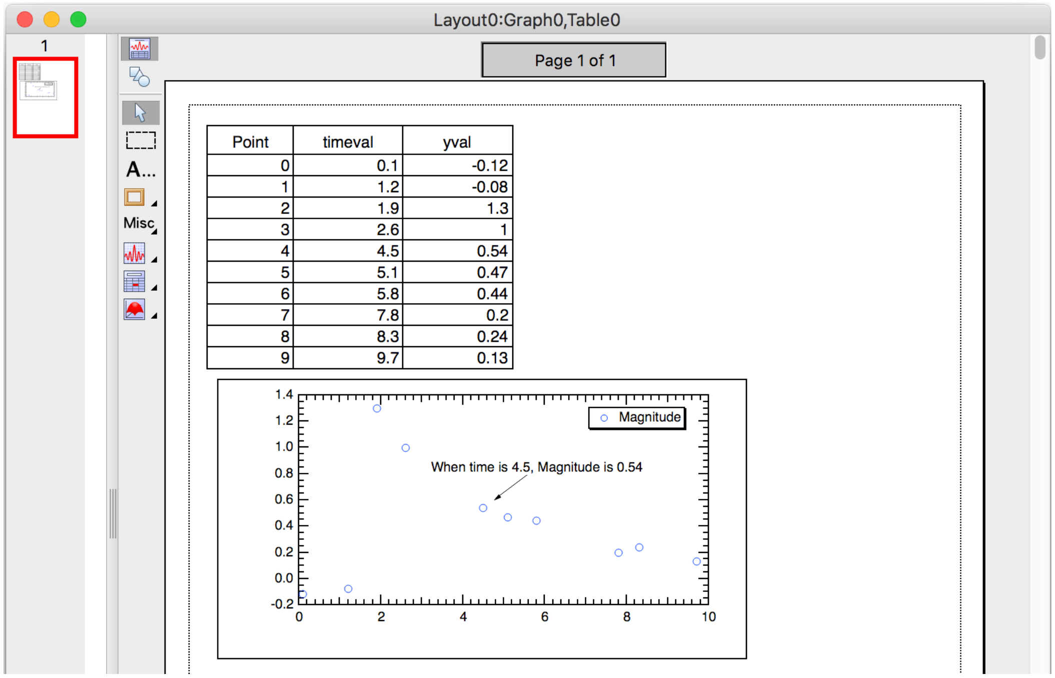
   The cursor changes to a two headed arrow indicating you can drag in the direction of the arrows.

8. **Drag the edge of the table to the left until it is close to the edge of the third column of numbers.**

   You need only get close — Igor snaps to the nearest grid line.

9. **In a similar fashion, adjust the bottom of the table to show all the data but without any blank rows.**

10. **Arrange the table and graph objects in the layout to approximately match this picture:**



Point	timeval	yval
0	0.1	-0.12
1	1.2	-0.08
2	1.9	1.3
3	2.6	1
4	4.5	0.54
5	5.1	0.47
6	5.8	0.44
7	7.8	0.2
8	8.3	0.24
9	9.7	0.13

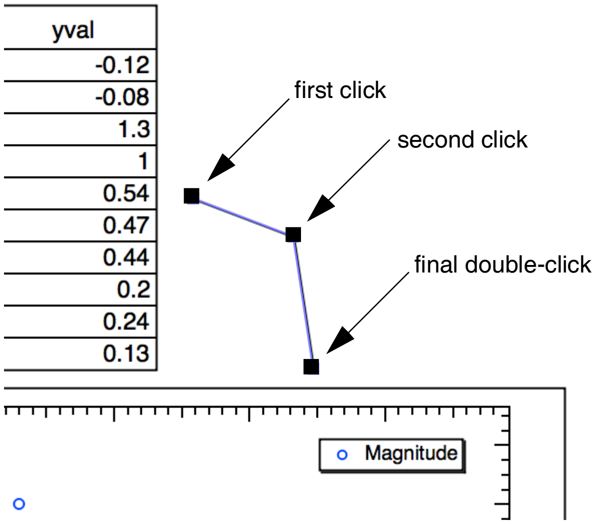
11. **Click this icon in the tool palette: .**

    This activates the drawing tools.

12. **Click this icon in the drawing tool palette: ⬠.**

    This is the polygon tool.

13. **Click once just to the right of the table, click again about 2 cm right and 1 cm down and finally double-click a bit to the right of the last click and just above the graph, as illustrated:**



The double-click exits the “draw polygon” mode and enters “edit polygon mode”. If you wish to touch up the defining vertices of the polygon, do so now by dragging the handles (the square boxes at the vertices).

14. **Click the Arrow tool in the palette.**

    This exits polygon edit mode.

15. **Click the polygon to select it.**

16. **Click the drawing environment icon ( ) and choose At End from the Line Arrow submenu.**

17. **Click this icon in the tool palette: .**

    This is the operate icon. The drawing tools are replaced by the normal layout tools.

    We are finished with the page layout for now.

18. **Choose Windows→Send To Back.**

Saving Your Work - Tour 1A

In this section, we will create a “Guided Tours” folder in which to save our work so far. Then we will save the current experiment in an Igor experiment file.

You can save Igor files anywhere. Here will will create the “Guided Tours” folder in the “Igor Pro User Files” folder. Igor creates “Igor Pro User Files” when it first starts. It is a good place to save Igor files.

1. **Choose Help→Show Igor Pro User Files.**

   Igor opens the "Igor Pro User Files" folder on the desktop.

   By default, this folder has the Igor Pro major version number in its name, for example, "Igor Pro 9 User Files", but it is generically called the "Igor Pro User Files" folder.

   Note where in the file system hierarchy this folder is located as you will need to know this in a subsequent step. The default locations are:

   Macintosh:
   `/Users/<user>/Documents/WaveMetrics/Igor Pro 9 User Files`

   Windows:
   `C:\Users\<user>\Documents\WaveMetrics\Igor Pro 9 User Files`

2. **Create a folder named “Guided Tours” in the “Igor Pro User Files” folder.**

3. **Activate Igor .**

4. **Choose File→Save Experiment As.**

   The save file dialog appears.

5. **Make sure that Packed Experiment File is selected as the file format.**

6. **Navigate to the “Guided Tours” folder.**

7. **Type “Tour 1A.pxp” in the name box.**

8. **Click Save.**

   The “Tour 1A.pxp” file contains all of your work in the current experiment, including waves that you created, graphs, tables and page layout windows.

   If you want to take a break, you can quit Igor Pro now.

Loading Data

Before loading data we will use a notebook window to look at the data file.

1. **If you are returning from a break, launch Igor and open your “Tour 1A.pxp” experiment file. Then turn preferences off using the Misc menu.**

   Opening the “Tour 1A.pxp” experiment file restores the Igor workspace to the state it was in when you saved the file. You can open the experiment file by using the Open Experiment item in the File menu. by double-clicking the experiment file, or by choosing File→Recent Experiments→Tour #1a.pxp.

2. **Choose the File→Open File→Notebook menu item.**

3. **Navigate to the folder “Igor Pro 9 Folder:Learning Aids:Sample Data” folder and open “Tutorial Data #1.txt.”**

   The Igor Pro 9 folder is typically installed in “/Applications” on Macintosh and in “C:/Program Files/WaveMetrics” on Windows.

   A notebook window showing the contents of the file appears. If desired, we could edit the data and then save it. For now we just observe that the file appears to be tab-delimited (tabs separate the columns) and contains names for the columns. Note that the name of the first column will conflict with the data we just entered and the other names have spaces in them.

4. **Click the close button or press Command-W (*Macintosh*) or Ctrl+W (*Windows*).**

   A dialog appears asking what you want to do with the notebook window.

5. **Click the Kill button.**

   The term “kill” means to “completely remove from the experiment”. The file will not be affected.

   Now we will actually load the data.

6. **Choose Data→Load Waves→Load Delimited Text.**

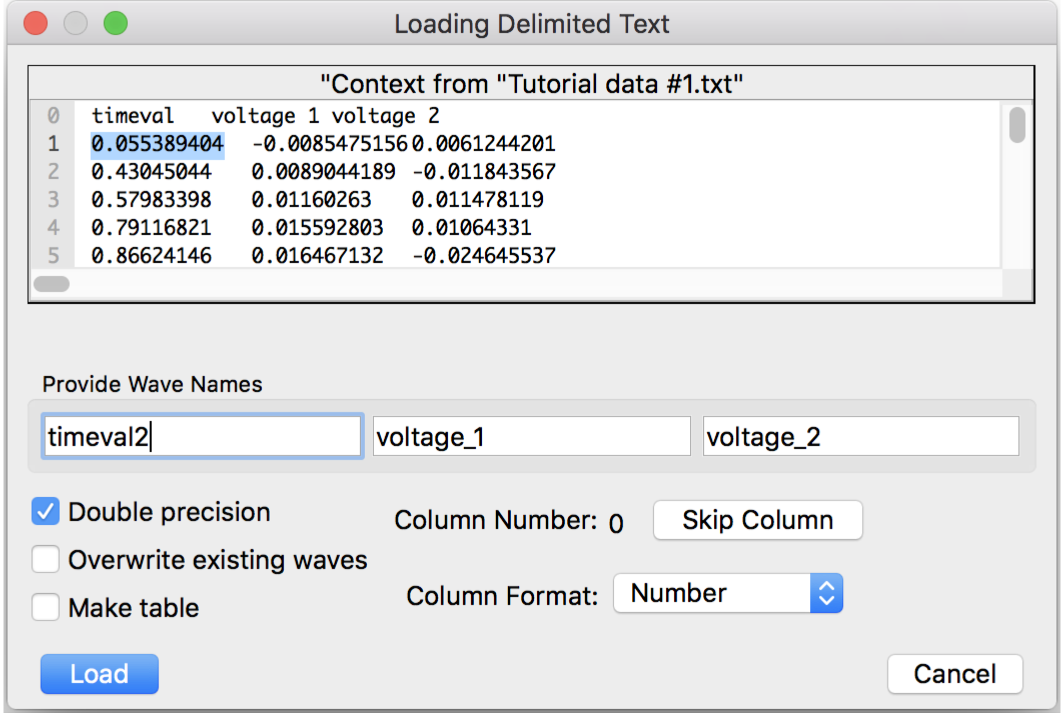
   An Open File dialog appears.

7. **Again choose “Tutorial Data #1.txt” and click Open.**

   The Loading Delimited Text dialog appears. The name “timeval” is highlighted and an error message is shown. Observe that the names of the other two columns were fixed by replacing the spaces with underscore characters.

8. **Change “timeval” to “timeval2”.**

   The dialog should now look like this:



"Context from "Tutorial data #1.txt"

```
0  timeval    voltage 1 voltage 2
1  0.055389404   -0.00854751560.0061244201
2  0.43045044   0.0089044189  -0.011843567
3  0.57983398   0.01160263    0.011478119
4  0.79116821   0.015592803   0.01064331
5  0.86624146   0.016467132   -0.024645537
```

Provide Wave Names

timeval2 | voltage_1 | voltage_2

☑ Double precision

□ Overwrite existing waves

□ Make table

Column Number: 0

Column Format: Number

9. **Click the Make Table box to check it and then click Load.**

   The data is loaded and a new table is created to show the data.

10. **Click the close button of the new table window.**

    A dialog is presented asking if you want to create a recreation macro.

11. **Click the No Save button.**

    The data we just loaded is still available in Igor. A table is just a way of viewing data and is not necessary for the data to exist.

The Load Delimited Text menu item that you used is a shortcut that uses default settings for loading delimited text. Later, when you load your own data files, choose Data→Load Waves→Load Waves so you can see all of the options.

Appending to a Graph

1. **If necessary, click in Graph0 to bring it to the front.**

   The Graph menu is available only when the target window is a graph.

2. **Choose the Graph→Append Traces to Graph menu item.**

   The Append Traces dialog appears. It is very similar to the New Graph dialog that you used to create the graph.

3. **In the Y Waves list, select voltage_1 and voltage_2.**
4. **In the X Wave list, select timeval2.**
5. **Click Do It.**

   Two additional traces are appended to the graph. Notice that they are also appended to the Legend.

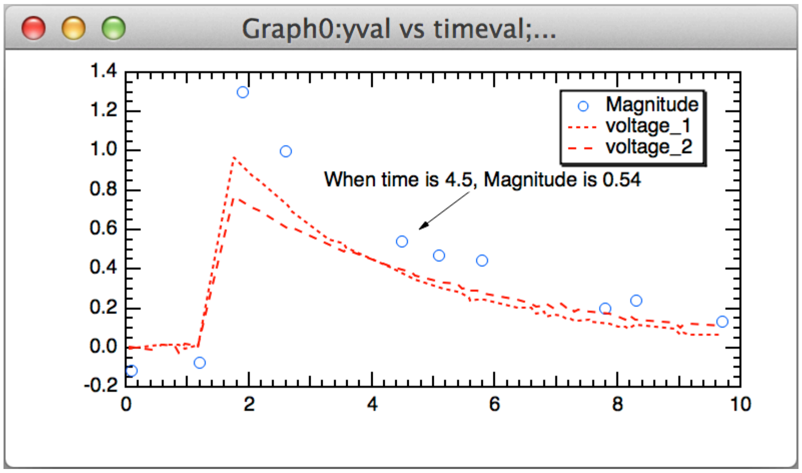
6. **Position the cursor over one of the traces in the graph and double-click.**

   The Modify Trace Appearance dialog appears with the trace you double-clicked already selected.

7. **If necessary, select voltage_1 in the list of traces.**

8. **Choose dashed line #2 from the Line Style pop-up menu.**
9. **Select voltage_2 in the list of traces.**
10. **Choose dashed line #3 from the Line Style pop-up menu.**
11. **Click Do It.**

    The graph should now look like this:



Offsetting a Trace

1. **Position the cursor directly over the voltage_2 trace.**

    The voltage_2 trace has the longer dash pattern.

2. **Click and hold the mouse button for about 1 second.**

    An XY readout appears in the lower-left corner of the graph and the trace will now move with the mouse.

3. **With the mouse button still down, press Shift while dragging the trace up about 1 cm and release.**

    The Shift key constrains movement to vertical or horizontal.

    You have added an offset to the trace. If desired, you could add a tag to the trace indicating that it has been offset and by how much. This trace offset does not affect the underlying wave data.

Unoffsetting a Trace

4. **Choose the Edit→Undo Trace Drag menu item.**

    You can undo many of the interactive operations on Igor windows.

5. **Choose Edit→Redo Trace Drag.**

    The following steps show how to remove an offset after it is no longer undoable.

6. **Double-click the voltage_2 trace.**

    The Modify Trace Appearance dialog appears with voltage_2 selected. (If voltage_2 is not selected, select it.) The Offset checkbox is checked.

7. **Click the Offset checkbox.**

    This turns offset off for the selected trace and the offset controls in the dialog are hidden.

8. **Click Do It.**

    The voltage_2 trace is returned to its original position.

Drawing in a Graph

1. **If necessary, click Graph0 to bring it to the front.**

2. **Choose the Graph→Show Tools menu item or press Command-T (*Macintosh*) or Ctrl+T (*Windows*).**

   A tool palette is added to the graph. The second icon from the top ( ) is selected indicating that the graph is in drawing mode as opposed to normal (or “operate”) mode.

3. **Click the top icon ( ) to go into normal mode.**

   Normal mode is for interacting with graph objects such as traces, axes and annotations. Drawing mode is for drawing lines, rectangles, polygons and so on.

4. **Click the second icon to return to drawing mode.**

5. **Click the drawing layer icon .**

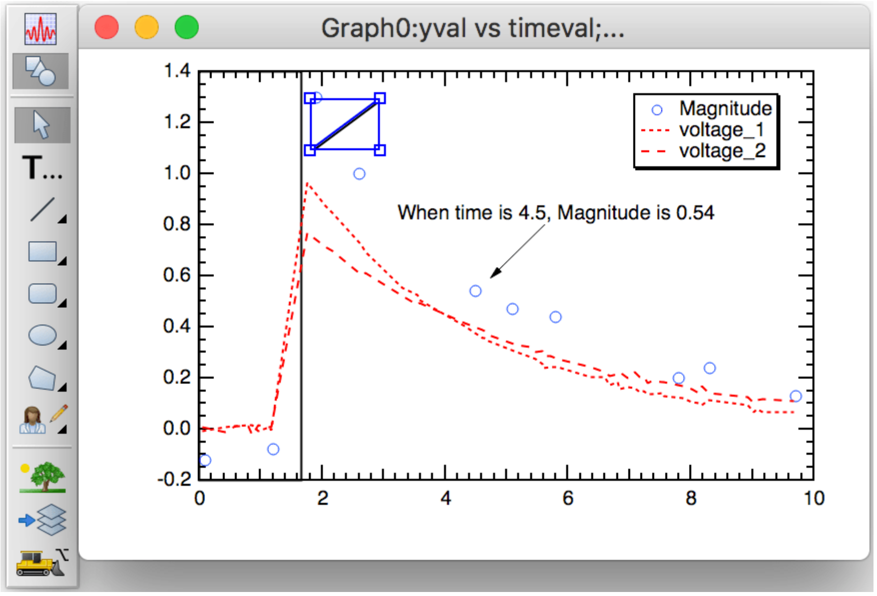
   A pop-up menu showing the available drawing layers and their relationship to the graph layers appears. The items in the menu are listed in back-to-front order.

6. **Choose UserBack from the menu.**

   We will be drawing behind the axes, traces and all other graph elements.

7. **Click the rectangle tool and drag out a rectangle starting at the upper-left corner of the plot area (y= 1.4, x=0 on the axes) and ending at the bottom of the plot area and about 1.5 cm in width (y= -0.2, x= 1.6).**

8. **Click the line tool and draw a diagonal line as shown, starting at the left, near the peak of the top trace, and ending at the right:**



9. **Click the drawing environment icon ( ) and choose At Start from the Line Arrow item.**

10. **Click the Text tool icon T... .**

11. **Click just to the right of the line you just drew.**

    The Create Text dialog appears.

12. **Type “Precharge”.**

13. **From the Anchor pop-up menu, choose Left Center.**

14. **Click Do It.**

15. **Click the graph's zoom button (*Macintosh*) or maximize button (*Windows*).**

To zoom the graph window on Macintosh, press the Option key while clicking the green button in the top/left corner of the window.

Notice how the rectangle and line expand with the graph. Their coordinates are measured relative to the plot area (rectangle enclosed by the axes).

16. **Click the graph's zoom button (*Macintosh*) or restore button (*Windows*).**

To restore the graph window on Macintosh, press the Option key while clicking the green button in the top/left corner of the window.

17. **Click the Arrow tool and then double-click the rectangle.**

The Modify Rectangle dialog appears showing the properties of the rectangle.

18. **Enter 0 in the Thickness box in the Line Properties section.**

This turns off the frame of the rectangle.

19. **Choose Solid from the Fill Mode pop-up menu.**

20. **Choose a light gray color from the Fore Color pop-up menu under the Fill Mode pop-up menu.**

21. **Click Do It.**

Observe that the rectangle forms a gray area behind the traces and axes.

22. **Again, double-click the rectangle.**

The Modify Rectangle dialog appears.

23. **From the X Coordinate pop-up menu, choose Axis Bottom.**

The X coordinates of the rectangle will be measured in terms of the bottom axis — as if they were data values.

24. **Press Tab until the X0 box is selected and type "0".**

25. **Tab to the X1 box and type "1.6".**

26. **Tab to the Y0 box and type "0".**

27. **Tab to Y1 and type "1".**

The X coordinates of the rectangle are now measured in terms of the bottom axis and the left side will be at zero while the right side will be at 1.6.

The Y coordinates are still measured relative to the plot area. Since we entered zero and one for the Y coordinates, the rectangle will span the entire height of the plot area.

28. **Click Do It.**

Notice the rectangle is nicely aligned with the axis and the plot area.

29. **Click the operate icon ( ) to exit drawing mode.**

30. **Press Option (*Macintosh*) or Alt (*Windows*), click in the middle of the plot area and drag about 2 cm to the right.**

The X axis range changes. Notice that the rectangle moved to align itself with the bottom axis.

31. **Choose Edit→Undo Modify.**

Making a Window Recreation Macro

1. **Click the graph's close button.**

Igor presents a dialog which asks if you want to save a window recreation macro. The graph's name is "Graph0" so Igor suggests "Graph0" as the macro name.

2. **Click Save.**

Igor generates a window recreation macro in the currently hidden procedure window. A window recreation macro contains the commands necessary to recreate a graph, table, page layout, control panel or 3D plot. You can invoke this macro to recreate the graph you just closed.

3. **Choose the Windows→Procedure Windows→Procedure Window menu item.**

   The procedure window is always present but is usually hidden to keep it out of the way. The window now contains the recreation macro for Graph0. You may need to scroll up to see the start of the macro. Because of the way it is declared:

   ```
   Window Graph0() : Graph
   ```

   this macro will be available from the Graph Macros submenu of the Windows main menu.

4. **Click the procedure window's close button.**

   This hides the procedure window. Most other windows display a dialog asking if you want to kill or hide the window, but the built-in procedure window and the help windows simply hide themselves.

Recreating the Graph

1. **Choose the Windows→Graph Macros→Graph0 menu item.**

   Igor executes the Graph0 macro which recreates a graph of the same name.

2. **Repeat step 1.**

   The Graph0 macro is executed again but this time Igor gave the new graph a slightly different name, Graph0_1, because a graph named Graph0 already existed.

3. **While pressing Option (*Macintosh*) or Alt (*Windows*), click the close button of Graph0_1.**

   The window is killed without presenting a dialog.

Using the Data Browser

The Data Browser lets you navigate through the data folder hierarchy and examine properties of waves and values of numeric and string variables.

1. **Choose the Data→Data Browser menu item.**

   The Data Browser appears.

2. **Make sure all of the checkboxes in the top-left corner of the Data Browser are checked.**

3. **Click the timeval wave icon to select it.**

   Note that the wave is displayed in the plot pane at the bottom of the Data Browser and the wave's properties are displayed just above in the info pane.

   If you don't see this, click the info icon (ⓘ) half-way down the left side fo the Data Browser window.

4. **Control-click (*Macintosh*) or right-click (*Windows*) on the timeval wave icon.**

   A contextual menu appears with a number of actions that you can perform on the selection.

5. **Press Escape to dismiss the contextual menu.**

   You can explore that and other Data Browser features later on your own.

6. **Click the Data Browser's close box to close it.**

Saving Your Work - Tour 1B

7. **Choose the File→Save Experiment As menu item.**

8. **Navigate to your "Guided Tours" folder.**

   This is the folder that you created under **Saving Your Work - Tour 1A** on page I-21.

9. **Change the name to "Tour 1B.pxp" and click Save.**

   If you want to take a break, you can quit from Igor now.

Using Igor Documentation

Now we will take a quick look at how to find information about Igor.

In addition to guided tours such as this one, Igor includes tooltips, general usage information, and reference information. The main guided tours, as well as the general and reference information, are available in both the online help files and in the Igor Pro PDF manual.

1. **Choose Misc→Miscellaneous Settings, click the Help icon on the left side, and verify that the Show Tooltips checkbox is checked.**

   If it is unchecked, check it..

2. **Click Save Settings to close the Miscellaneous Settings dialog.**

3. **Choose Data→Load Waves→Load Waves.**

   Igor displays the Load Waves dialog. This dialog provides an interface to the LoadWave operation which is how you load data into Igor from text data files.

4. **On Macintosh only, move the cursor over the Load Columns Into Matrix checkbox.**

   A tooltip appears in a yellow textbox. You can get a tip for most dialog items and icons this way.

5. **Click the Cancel button to quit the dialog.**

   Now let's see how to get reference help for a particular operation.

6. **Choose Help→Command Help.**

   The Igor Help Browser appears with the Command Help tab displayed.

   The information displayed in this tab comes from the Igor Reference help file - one of many help files that Igor automatically opens at launch. Open help files are directly accessible through Help→Help Windows but we will use the Igor Help Browser right now.

7. **If there is a Show All link above the left-hand list, click it.**

8. **Click any item in the list and then type "L".**

   Igor displays help for the first list item whose name starting with "L". We want the LoadWave operation.

9. **Press the down-arrow key until LoadWave is selected in the list.**

   Igor displays help for the LoadWave operation in the help area on the right.

   Another way to get reference help is to Control-click (Macintosh) or right-click (Windows) the name of an operation or function and choose the "Help For" menu item. This works in the command window and in procedure, notebook and help windows.

10. **In the Filter edit box just below the left-hand list, type “Matrix”.**

    The list now shows only operations, functions, and keywords whose names include “matrix”.

11. **Click Show All above the left-hand list.**

    The list shows all operations, functions, and keywords again.

12. **Click the Advanced Filtering control to reveal additional checkboxes and pop-up menus.**

    These controls provide other ways to filter what appears in the left-hand list.

    While we're in the Igor Help Browser, let's see what the other tabs are for.

13. **Click each of the Help Browser tabs and note their contents.**

    You can explore these tabs in more detail later.

    Next we will take a quick trip to the Igor Pro PDF manual. If you are doing this guided tour using the PDF manual, you may want to just read the following steps rather than do them to avoid losing your place.

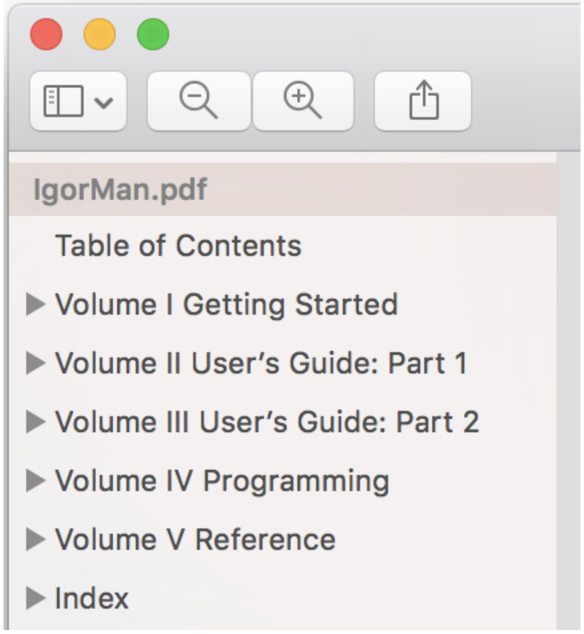
14. **Click the Manual tab and then click the Open Online Manual button.**

Igor opens the PDF manual in your PDF viewer - typically Adobe Reader or Apple's Preview program.

If you use Adobe Reader for viewing PDF files, you should have a Bookmarks pane on the left side of the PDF manual window. If not, choose View→Show/Hide→Navigation Panes→Bookmarks in Reader.

If you use Apple's Preview for PDF files, you should have a sidebar displaying the table of contents on one side of the main page. If not, choose View→Table of Contents in Preview.

Note in the Reader Bookmarks pane or the Preview table of contents that the PDF manual is organized into five volumes plus an index.



IgorMan.pdf

Table of Contents

▶ Volume I Getting Started

▶ Volume II User’s Guide: Part 1

▶ Volume III User’s Guide: Part 2

▶ Volume IV Programming

▶ Volume V Reference

▶ Index

15. **Use the bookmarks or table of contents to get a sense of what's in the manual.**

Expand the volume bookmarks to see the chapter names.

You may notice that the Igor PDF manual is rather large - over 2,000 pages at last count. You'll be happy to know that we don't expect you to read it cover-to-cover. Instead, read chapters as the need arises.

The information in the manual is also in the online help files. The manual, being in book format, is better organized for linear reading while the online help is usually preferred for accessing reference information.

In case you ever want to open it directly, you can find the PDF manual in "Igor Pro Folder/Manual".

That should give you an idea of where to look for information about Igor. Now let's get back to our hands-on exploration of Igor.

Graphically Editing Data

1. **If you quit Igor after the last save, open your “Tour 1B.pxp” experiment and turn preferences off.**
2. **Adjust the positions of the graph and table so you can see both.**

   Make sure you can see the columns of data in the table when the graph is the front window.
3. **If necessary, click the Graph0 window to bring it to the front.**
4. **Click the drawing mode icon ( ) to activate the drawing tools.**
5. **Move the cursor over the polygon icon ( ) and click and hold the mouse button.**

   A pop-up menu appears.

6. **Choose the Edit Wave menu item.**

7. **Click one of the open circles of the yval trace.**

   The trace is redrawn using lines and squares to show the location of the data points.

8. **Click the second square from the left and drag it 1 cm up and to the right.**

   Notice point 1 of yval and timeval changes in the table.

9. **Press Command-Z (*Macintosh*) or Ctrl+Z (*Windows*) or choose Edit→Undo.**

10. **Click midway between the first and second point and drag up 1 cm.**

    A new data point is added to the yval and timeval waves.

11. **Press Option (*Macintosh*) or Alt (*Windows*) and click the new data point.**

    The new data point is deleted.

    You could also have pressed Command-Z (*Macintosh*) or Ctrl+Z (*Windows*) to undo the insertion.

12. **Press Command (*Macintosh*) or Ctrl (*Windows*), click the line segment between the second and third point and drag a few cm to the right.**

    The line segment is moved and two points of yval and timeval are changed in the table.

13. **Press Command-Z (*Macintosh*) or Ctrl+Z (*Windows*) or choose Edit→Undo.**

14. **Click in the operate icon ( ) to exit drawing mode.**

15. **Choose File→Revert Experiment and answer *Yes* in the dialog.**

    This returns the experiment to the state it was in before we started editing the data.

16. **Choose File→New Experiment.**

    This clears the windows and data from the previously open experiment, creating a new, empty experiment.

Making a Category Plot (Optional)

Category plots show continuous numeric data plotted against non-numeric text categories.

1. **Choose the Windows→New Table menu item.**

2. **Click in the Do It button.**

   A new blank table is created.

3. **Type "Monday" (without the quotes) and then press Return or Enter.**

   A wave named "textWave0" was created with the text Monday as the value of the first point. Entering a non-numeric value in the first row of the first blank column automatically creates a new text wave.

4. **Type the following lines, pressing Enter after each one:**

   Tuesday
   Wednesday
   Thursday

5. **Click in the first cell of the next column and enter the following values:**

   10
   25
   3
   16

6. **Click in the first cell of the next column and enter the following values:**

   0
   12
   30
   17

7. **Choose Windows→New→Category Plot.**

   A dialog similar to the New Graph dialog appears. This dialog shows only text waves in the right-hand list.

8. **In the Y Waves list, select wave0 and wave1.**

9. **In the X Wave listm select textWave0.**

10. **Click Do It.**

    A category plot is created.

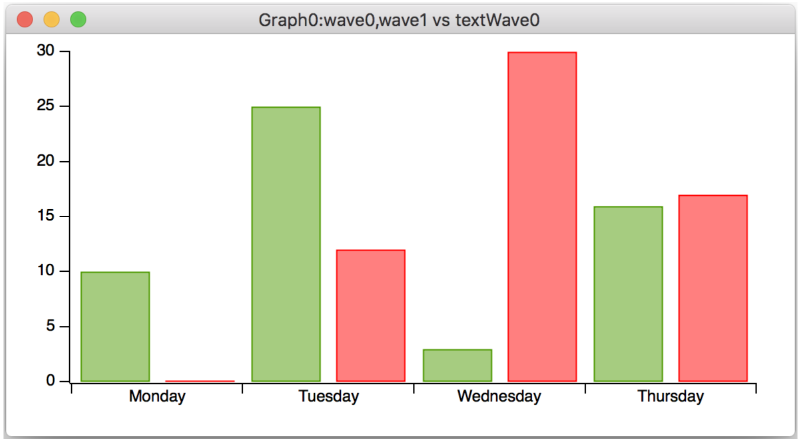
11. **Double-click one of the bars.**

    The Modify Trace Appearance dialog appears.

12. **Using the Color pop-up menu, set the color of the wave0 trace to green.**

13. **Click Do It.**

    The graph should now look like this:



14. **Choose File→Save Experiment As and save the current experiment as “Category Plots.pxp”.**

Category Plot Options (Optional)

This section explores various category-plot options. If you are not particularly interested in category plots, you can stop now, or at any point in the following steps, by skipping to the next section.

1. **Double-click one of the bars and, if necessary, select the wave0 in the list.**

2. **From the Grouping pop-up menu, choose Stack on Next.**

3. **Click Do It.**

   The left bar in each group is now stacked on top of the right bar.

4. **Choose the Graph→Reorder Traces menu item.**

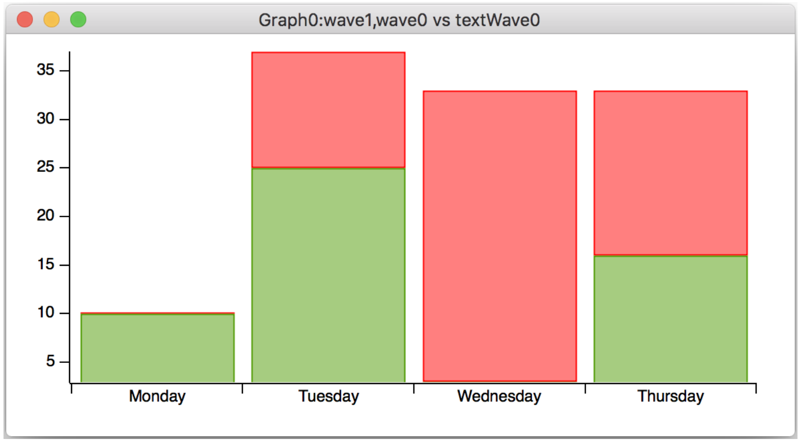
   The Reorder Traces dialog appears.

5. **Reverse the order of the items in the list by dragging the top item down and click Do It.**

   The bars are no longer stacked and the bars that used to be on the left are now on the right. The reason the bars are not stacked is that the trace that we set to Stack on Next mode is now last and there is no next trace.

6. **Using the Modify Trace Appearance dialog, set the wave1 trace to Stack on next. Click Do It.**

   The category plot graph should now look like this:



7. **Enter the following values in the next blank column in the table:**

   7
   10
   15
   9

   This creates a new wave named wave2.

8. **Click the graph to bring it to the front.**

9. **Choose Graph→Append to Graph→Category Plot.**

   The Append Category Traces dialog appears.

10. **In the Y Waves list, select wave2 and click Do It.**

    This adds a red bar underneath each green bar.

11. **Control-click (Macintosh) or right-click (Windows) one of the new red bars (underneath a green bar) to display the contextual pop-up menu and choose blue from the Color submenu.**

    The new bars are now blue.

12. **Using the Modify Trace Appearance dialog, change the grouping mode of the middle trace, wave0, to none.**

    We now have wave1 (red) stacked on wave0 (green) and wave0 not stacked on anything.

    Now the new wave2 bars (blue) are to the right of a group of two stacked bars. You can create any combination of stacked and side-by-side bars.

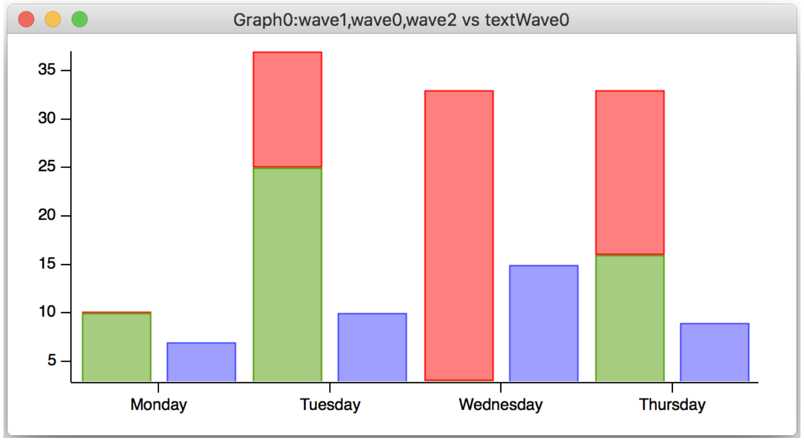
13. **Double-click the bottom axis.**

    The Modify Axis dialog appears with the bottom axis selected.

14. **Click the Auto/Man Ticks tab.**

15. **Click the Tick In Center checkbox and then click Do It.**

    Notice the new positions of the tick marks.



16. **Double-click the bottom axis again.**
17. **Click the Axis tab.**
18. **Change the value of Bar Gap to zero and then click Do It.**

    Notice that the bars within a group are now touching.

19. **Use the Modify Axis dialog to set the Category Gap to 50%.**

    The widths of the bars shrink to 50% of the category width.

20. **Choose Graph→Modify Graph.**
21. **Click the "Swap X & Y Axes" checkbox and then click Do It.**

    This is how you create a horizontal bar plot.

22. **Choose File→Save Experiment.**

The Command Window

Parts of this tour make use of Igor's command line to enter mathematical formulae. Let's get some practice now.

1. **Choose File→New Experiment.**

   This clears any windows and data left over from previous experimentation.

   Your command window should look something like this:

   If you don't see the command window, choose Windows→Command Window.

   The command line is the space below the red separator whereas the space above the separator is called the history area.

2. **Click in the command line, type the following line and press Return or Enter.**

```
Print 2+2
```

   The Print command as well as the result are placed in the history area.

3. **Press the Up Arrow key.**

   The line containing the print command is selected, skipping over the result printout line.

4. **Press Return or Enter.**

   The selected line in the history is copied to the command line.

5. **Edit the command line so it matches the following and press Return or Enter.**

   ```
   Print "The result is ", 2+2
   ```

   The Print command takes a list of numeric or string expressions, evaluates them and prints the results into the history.

6. **Choose the Help→Igor Help Browser menu item.**

   The Igor Help Browser appears.

   You can also display the help browser by clicking the question-mark icon near the right edge of the command window and, on Windows, by pressing F1.

7. **Click the Command Help tab in the Igor Help Browser.**

8. **Click Advanced Filtering if necessary to reveal the advanced options.**

9. **If there is a Show All link above the left-hand list, click it.**

10. **Uncheck the Functions and Programming checkboxes and check the Operations checkbox.**

    A list of operations appears.

11. **In the pop-up menu next to the Operations checkbox, choose About Waves.**

12. **Select PlaySound in the list.**

    Tip: Click in the list to activate it and then type “p” to jump to PlaySound.

    The reference help for the PlaySound operation appears in the help area on the right.

13. **Click the help area on the right, scroll down to the Examples section, and select the first four lines of example text (starting with “Make”, ending with “PlaySound sineSound).**

14. **Choose the Edit→Copy menu to copy the selection.**

15. **Close the Igor Help Browser.**

16. **Choose Edit→Paste to paste the command into the command line.**

    All four lines are pasted into the command line area.

17. **Make the command window taller and then drag the red divider line up so you can see the commands in the command line.**

18. **Press Return or Enter to execute the commands.**

    The four lines are executed and a short tone plays.

19. **Click once on the last line in the history area, on “PlaySound sineSound”.**

    The entire command is selected just as if you pressed the arrow key.

20. **Press Return or Enter once to transfer the command to the command line and a second time to execute it.**

    The tone plays again as the line executes.

    We are finished with the “sineSound” wave that was created in this exercise so let’s kill the wave to prevent it from cluttering up our wave lists.

21. **Choose Data→Kill Waves.**

    The Kill Waves dialog appears.

22. **Select “sineSound” and click Do It.**

    The sineSound wave is removed from memory.

23. **Again click once on the history line “PlaySound sineSound”.**

24. **Press Return or Enter twice to re-execute the command.**

    An error dialog is presented because the sineSound wave no longer exists.

25. **Click OK to close the error dialog.**

26. **Choose Edit→Clear Cmd Buffer or press Command-K (*Macintosh*) or Ctrl+K (*Windows*).**

    When a command generates an error, it is left in the command line so you can edit and re-execute it. In this case we just wanted to clear the command line.

Synthesizing Data

In this section we will make waves and fill them with data using arithmetic expressions.

1. **Choose File→New Experiment.**

   This clears any windows and data left over from previous experimentation.

2. **Choose the Data→Make Waves menu item.**

   The Make Waves dialog appears.

3. **Type "spiralY" in the first box, press the tab key, and type "spiralX" in the second box.**
4. **Change Rows to 1000.**
5. **Click Do It.**

   Two 1000 point waves have been created. They are now part of the experiment but are not visible because we haven't displayed them in a table or graph.

6. **Choose Data→Change Wave Scaling.**

   The Change Wave Scaling dialog appears. We will use it to set the X scaling of the waves.

7. **If a button labeled More Options is showing, click it.**
8. **In the Waves list, click spiralY and then Command-click (*Macintosh*) or Ctrl-click (*Windows*) spiralX.**
9. **Choose Start and Right in the SetScale Mode pop-up menu.**
10. **Enter "0" for Start and "50" for Right.**
11. **Click Do It.**

    This executes a **SetScale** command specifying the X scaling of the spiralX and spiralY waves. X scaling is a property of a wave that maps a point number to an X value. In this case we are mapping point numbers 0 through 999 to X values 0 through 50.

12. **Type the following on the command line and then press Return or Enter:**

    ```
    spiralY = x*sin(x)
    ```

    This is a waveform assignment statement. It assigns a value to each point of the destination wave (spiralY). The value stored for a given point is the value of the right-hand expression at that point. The meaning of *x* in a waveform assignment statement is determined by the X scaling of the destination wave. In this case, *x* takes on values from 0 to 50 as Igor evaluates the right-hand expression for points 0 through 999.

13. **Execute this in the command line:**

    ```
    spiralX = x*cos(x)
    ```

    Now both spiralX and spiralY have their data values set.

Zooming and Panning

1. **Choose the Windows→New Graph menu item.**
2. **If necessary, uncheck the From Target checkbox.**
3. **In the Y Waves list, select "spiralY".**
4. **In the X Wave list, select "_calculated_".**
5. **Click Do It.**

   Igor creates a graph of spiralY's data values versus its X values.

   Note that the X axis goes from 0 to 50. This is because the **SetScale** command we executed earlier set the X scaling property of spiralY which tells Igor how to compute an X value from a point number.

Choosing _calculated_ from the X Wave list graphs the spiralY data values versus these calculated X values.

6. **Position the cursor in the interior of the graph.**

   The cursor changes to a cross-hair shape.

7. **Click and drag down and to the right to create a marquee as shown:**

   You can resize the marquee with the handles (black squares). You can move the marquee by dragging the dashed edge of the marquee.

8. **Position the cursor inside the marquee.**

   The mouse pointer changes to this shape: ▬ , indicating that a pop-up menu is available.

9. **Click and choose Expand from the pop-up menu.**

   The axes are rescaled so that the area enclosed by the marquee fills the graph.

10. **Choose Edit→Undo Scale Change or press Command-Z (*Macintosh*) or Ctrl+Z (*Windows*).**

11. **Choose Edit→Redo Scale Change or press Command-Shift-Z (*Macintosh*) or Ctrl+Shift+Z (*Windows*).**

12. **Press Option (*Macintosh*) or Alt (*Windows*) and position the cursor in the middle of the graph.**

    The cursor changes to a hand shape. You may need to move the cursor slightly before it changes shape.

13. **With the hand cursor showing, drag about 2 cm to the left.**

14. **While pressing Option (*Macintosh*) or Alt (*Windows*), click the middle of the graph and gently fling it to the right.**

    The graph continues to pan until you click again to stop it.

15. **Click the plot area of the graph to stop panning.**

16. **Choose Graph→Autoscale Axes or press Command-A (*Macintosh*) or Ctrl+A (*Windows*).**

    Continue experimenting with zooming and panning as desired.

17. **Press Command-Option-W (*Macintosh*) or Ctrl+Alt+W (*Windows*).**

    The graph is killed. Option (*Macintosh*) or Alt (*Windows*) avoided the normal dialog asking whether to save the graph.

Making a Graph with Multiple Axes

1. **Choose the Windows→New Graph menu item.**

2. **If you see a button labeled More Choices, click it.**

   We will use the more complex form of the dialog to create a multiple-axis graph in one step.

3. **In the Y Waves list, select “spiralY”.**

4. **In the X Wave list, select “spiralX”.**

5. **Click Add.**

   The selections are inserted into the lower list in the center of the dialog.

6. **In the Y Waves list, again select “spiralY”.**

7. **In the X Wave list, select “_calculated_”.**

8. **Choose New from the Axis pop-up menu under the X Waves list.**

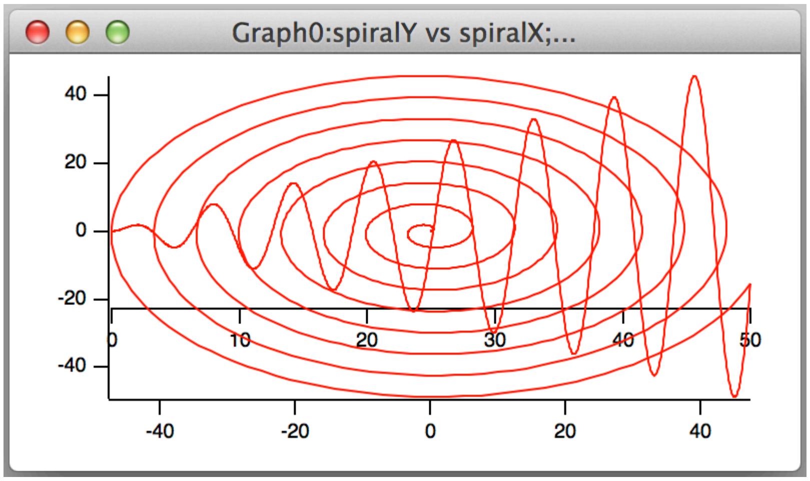
9. **Enter “B2” in the name box.**

10. **Click OK.**

    Note the command box at the bottom of the dialog. It contains two commands: a Display command corresponding to the initial selections that you added to the lower list and an AppendToGraph command corresponding to the current selections in the Y Waves and X Wave lists.

11. **Click Do It.**

    The following graph is created:



The interior axis is called a “free” axis because it can be moved relative to the plot rectangle. We will be moving it outside of the plot area but first we must make room by adjusting the plot area margins.

12. **Press Option (*Macintosh*) or Alt (*Windows*) and position the cursor over the bottom axis until the cursor changes to this shape: ╪.**

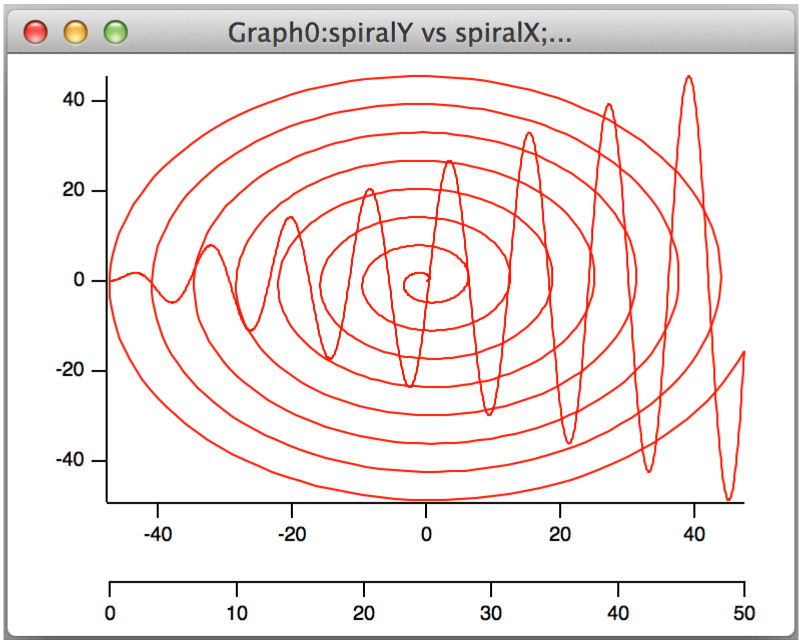
    This shape indicates you are over an edge of the plot area rectangle and that you can drag that edge to adjust the margin.

13. **Drag the margin up about 2 cm. Release the Option (*Macintosh*) or Alt (*Windows*).**

14. **Drag the interior axis down into the margin space you just created.**

15. **Resize the graph so the spiral is nearly circular.**

    The graph should now look like this:



Saving Your Work - Tour 1C

1. **Choose the File→Save Experiment As menu item.**
2. **Navigate to your "Guided Tours" folder.**

   This is the folder that you created under **Saving Your Work - Tour 1A** on page I-21.
3. **Type "Tour 1C.pxp" in the name box and click Save.**

   If you want to take a break, you can quit from Igor now.

Using Cursors

1. **If you are returning from a break, open your "Tour 1C.pxp" experiment and turn preferences off.**
2. **Click in the graph and choose the Graph→Show Info menu item.**

   A cursor info panel appears below the graph.
3. **Control-click (*Macintosh*) or right-click (*Windows*) in the name area for graph cursor A (the round one), where it says "A:".**
4. **Choose "spiralY" from the pop-up menu.**

   The A cursor is placed on point zero of spiralY.
5. **Repeat for cursor B but choose "spiralY#1" from the pop-up menu.**

   The wave spiralY is graphed twice. The #1 suffix is used to distinguish the second instance from the first. It is #1 rather than #2 because in Igor indices start from zero.
6. **Position the mouse pointer over the center of the cursor position control .**
7. **Click the blue slider and gently drag it to the right.**

   Both cursors move to increasing point numbers. They stop when one or both get to the end.

   You can also move the cursors using the left and right arrow keys on the keyboard or by clicking to the left or right of the blue slider.
8. **Practice moving the slider to the left and right.**

   Notice that the cursors move with increasing speed as the slider is displaced farther from the center.

9. **Click once on the dock for cursor A (the round black circle).**

   The circle turns white, indicating that cursor A is deselected.

10. **Move the slider to the left and right.**

    Notice that only cursor B moves.

11. **Click cursor B in the graph and drag it to another position on either trace.**

    You can also drag cursors from their docks to the graph.

12. **Click cursor A in the graph and drag it completely outside the graph.**

    The cursor is removed from the graph and returns to its dock.

13. **Choose Graph→Hide Info.**

14. **Click in the command window, type the following and press Return or Enter.**

    ```
    Print vcsr(B)
    ```

    The Y value at cursor B is printed into the history area. There are many functions available for obtaining information about cursors.

15. **Click in the graph and then drag cursor B off of the graph.**

Removing a Trace and Axis

16. **Choose the Graph→Remove from Graph menu item.**

    The Remove From Graph dialog appears with spiralY listed twice. When we created the graph we used spiralY twice, first versus spiralX to create the spiral and second versus calculated X values to show the sine wave.

17. **Click the second instance of spiralY (spiralY#1) and click Do It.**

    The sine wave and the lower axis are removed. An axis is removed when its last trace is removed.

18. **Drag the horizontal axis off the bottom of the window.**

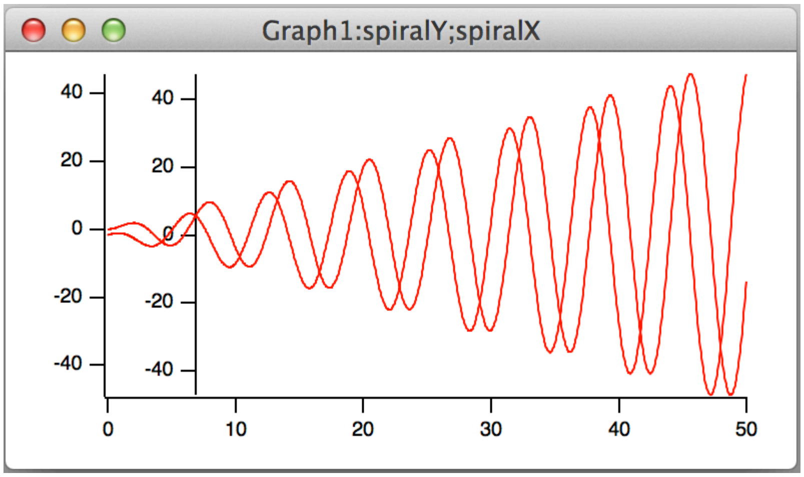
    This returns the margin setting to auto. We had set it to a fixed position when we option-dragged (*Macintosh*) or Alt-dragged (*Windows*) the margin in a previous step.

Creating a Graph with Stacked Axes

1. **Choose the Windows→New Graph menu item.**
2. **If you see a button labeled More Choices, click it.**
3. **In the Y Waves list, select “spiralY”.**
4. **In the X Wave list, select “_calculated_”.**
5. **Click Add.**
6. **In the Y Waves list, select “spiralX”.**
7. **In the X Wave list, select “_calculated_”.**
8. **Choose New from the Axis pop-up menu under the Y Waves list.**
9. **Enter “L2” in the name box.**
10. **Click OK.**

11. **Click Do It.**

    The following graph is created.



In the following steps we will stack the L2 axis on top of the left axis.

12. **Double-click the far left axis.**

    The Modify Axis dialog appears. If any other dialog appears, cancel and try again making sure the cursor is over the axis.

    The Left axis should be selected in the Axis pop-up menu in the upper-left corner of the dialog.

13. **Click the Axis tab.**

14. **Set the Left axis to draw between 0 and 45% of normal.**

15. **Choose L2 from the Axis pop-up menu.**

16. **Set the L2 axis to draw between 55 and 100% of normal.**

17. **In the Free Axis Position box, pop up the menu reading Distance from Margin and select Fraction of Plot Area.**

18. **Verify that the box labeled "% of Plot Area" is set to zero.**

    Steps 17 and 18 move the L2 axis so it is in line with the Left axis.

    Why don't we make this the default? Good question — positioning as percent of plot area was added in Igor Pro 6; the default behavior maintains backward compatibility.

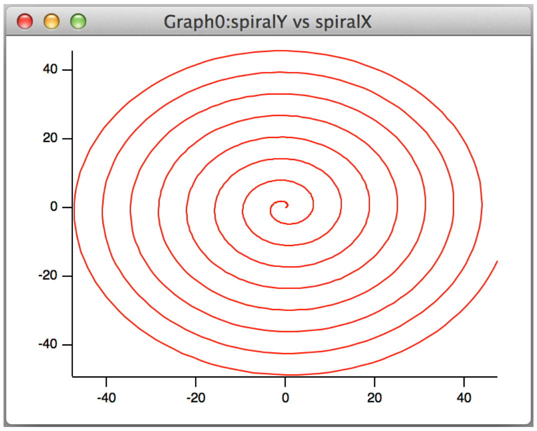
19. **Choose Bottom from the Axis pop-up menu.**

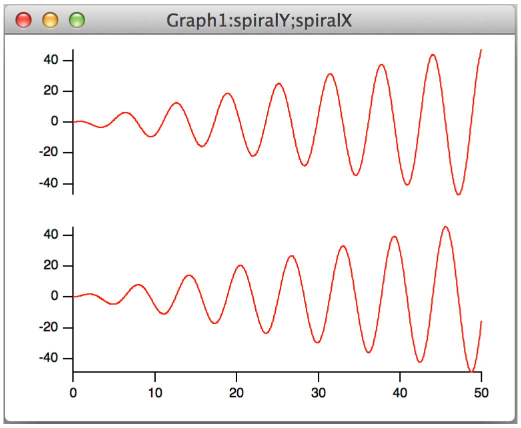
20. **Click the Axis Standoff checkbox to turn standoff off.**

21. **Click Do It.**

22. **Resize and reposition the Graph0 and Graph1 windows so they are side-by-side and roughly square.**

    The graphs should look like this:





Creating a Page Layout

1. **Choose the Windows→New Layout menu item and click Do It.**

   A new blank page layout window is created.

2. **Click in the graph icon ( ) and choose “Graph0”.**

   Graph0 is added to the layout.

3. **Again, click in the graph icon and choose “Graph1”.**

   Graph1 is added to the layout.

4. **Click the marquee icon ⬚.**

5. **Drag out a marquee that approximately fills the bottom half of the page.**

6. **Choose Layout→Arrange Objects.**

   The Arrange Objects dialog appears.

7. **Select both Graph0 and Graph1 and leave the Use Marquee checkbox checked.**

8. **Click Do It.**

   The two graphs are tiled inside the area defined by the marquee.

9. **Click in the page area outside the marquee to dismiss it.**

10. **Choose Windows→Send to Back.**

    This sends the page layout window behind all other windows.

Saving Your Work - Tour 1D

1. **Choose the File→Save Experiment As menu item.**

2. **Navigate to your “Guided Tours” folder.**

   This is the folder that you created under **Saving Your Work - Tour 1A** on page I-21.

3. **Type “Tour 1D.pxp” in the name box and click Save.**

   If you want to take a break, you can quit Igor Pro now.

Creating Controls

This section illustrates adding controls to an Igor graph — the type of thing a programmer might want to do. If you are not interested in programming, you can skip to the **End of the General Tour** on page I-45.

1. **If you are returning from a break, open your “Tour 1D.pxp” experiment and turn off preferences.**

2. **Click the graph with the spiral (Graph0) to bring it to the front.**

3. **Choose the Graph→Show Tools menu item or press Command-T (*Macintosh*) or Ctrl+T (*Windows*).**

   A tool palette is displayed to the left of the graph. The second icon is selected indicating that the graph is in the drawing as opposed to normal mode.

   The selector tool (arrow) is active. It is used to create, select, move and resize controls.

4. **Choose Graph→Add Control→Control Bar.**

   The Control Bar dialog appears.

5. **Enter a height of 30 points and click Do It.**

   This reserves a space at the top of the graph for controls.

6. **Click in the command line, type the following and press Return or Enter.**

   ```
   Variable ymult=1, xmult=1
   ```

   This creates two numeric variables and sets both to 1.0.

7. **Click Graph0 and then choose Graph→Add Control→Add Set Variable.**

   The SetVariable Control dialog appears.

   A SetVariable control provides a way to display and change the value of a variable.

8. **Choose ymult from the Value pop-up menu.**

9. **Enter 100 in the Width edit box.**

   This setting is back near the top of the scrolling list.

10. **Set the High Limit, Low Limit, and Increment values to 10, 0.1, and 0.1 respectively.**

    You may need to scroll down to find these settings.

11. **From the Font Size pop-up menu, choose 12.**

    You may need to scroll down to find this pop-up menu.

12. **Click Do It.**

    A SetVariable control attached to the variable ymult appears in the upper-left of the control bar.

13. **Double-click the ymult control.**

    The SetVariable Control dialog appears.

14. **Click the Duplicate button at the bottom of the dialog.**

15. **Choose xmult as the value.**

16. **Click Do It.**

    A second SetVariable control appears in the control bar. This one is attached to the xMult variable.

17. **Choose Graph→Add Control→Add Button.**

    The Button Control dialog appears.

18. **Tab to the Title edit box and enter “Update”.**

19. **Click the New button adjacent to Procedure.**

    The Control Procedure dialog appears in which you can create or edit the procedure to be called when control-related events occur. Such procedures are called “control action procedures”.

20. **Make sure the “Prefer structure-based procedures” checkbox is checked.**

21. **Edit the procedure text so it looks like this:**

    ```
    Function ButtonProc(ba) : ButtonControl
        STRUCT WMButtonAction& ba

        switch(ba.eventCode)
            case 2:                              // Mouse up
                WAVE spiralX
    ```

```
                NVAR xmult
                spiralX = x*cos(xmult*x)

                WAVE spiralY
                NVAR ymult
                spiralY = x*sin(ymult*x)

                break
        endswitch

        return 0
End
```

Proofread the function to make sure you entered it as shown above.

22. **Click the Save Procedure Now button.**

    The Control Procedure dialog disappears and the text you edited is inserted into the (currently hidden) procedure window.

23. **Click Do It.**

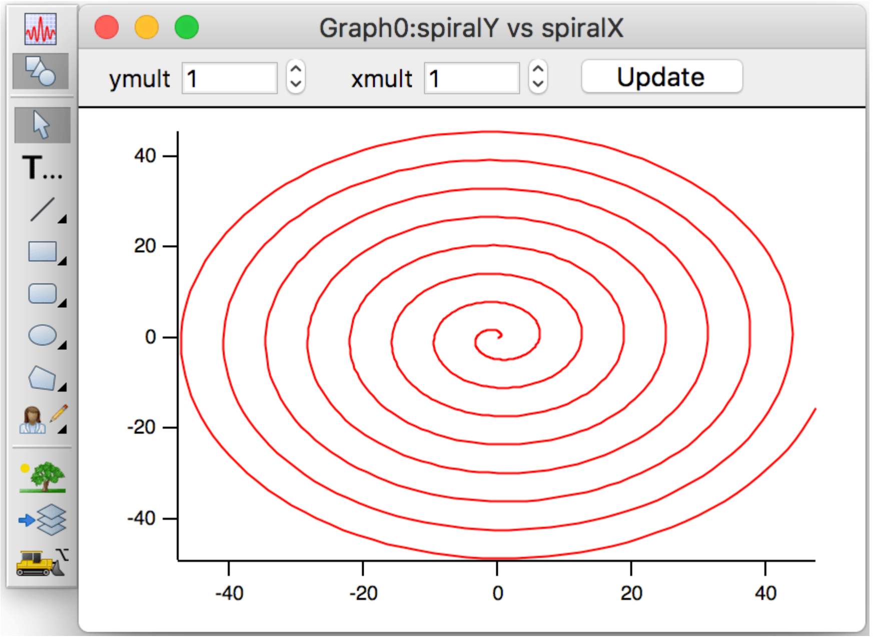
    A Button control is added to the control bar.

    The three controls are now functional but are not esthetically arranged.

24. **Use the Arrow tool to rearrange the three controls into a more pleasing arrangement. Expand the button so it doesn't crowd the text by dragging its handles.**

    After selecting a control with the arrow tool, you can drag it or use the arrow keys on the keyboard to finetune its position.

    The graph now looks like this:



25. **Click the top icon in the tool palette to enter "operate mode".**
26. **Choose Graph→Hide Tools or press Command-T (*Macintosh*) or Ctrl+T (*Windows*).**
27. **Click the up arrow in the ymult control.**

    The value changes to 1.1.

28. **Click the Update button.**

    The ButtonProc procedure that you created executes. The spiralY and spiralX waves are recalculated according to the expressions you entered in the procedure and the graphs are updated.

29. **Experiment with different ymult and xmult settings as desired.**

30. **Set both values back to 1 and click the Update button.**

    You can edit a value by typing in the SetVariable control and enter it by pressing Return or Enter.

Creating a Dependency

A dependency is a rule that relates the value of an Igor wave or variable to the values of other waves or variables. By setting up a dependency you can cause Igor to automatically update a wave when another wave or variable changes.

1. **Click the command window to bring it to the front.**
2. **Execute the following commands in the command line:**

    ```
    spiralY := x*sin(ymult*x)
    spiralX := x*cos(xmult*x)
    ```

    This is exactly what you entered before except here := is used in place of =. The := operator creates a dependency formula. In the first expression, the wave spiralY is made dependent on the variable ymult. If a new value is stored in ymult then the values in spiralY are automatically recalculated from the expression.
3. **Click Graph0 to bring it to the front.**
4. **Adjust the ymult and xmult controls but do not click the Update button.**

    When you change the value of ymult or xmult using the SetVariable control, Igor automatically executes the dependency formula. The spiralY or spiralX waves are recalculated and both graphs are updated.
5. **On the command line, execute this:**

    ```
    ymult := 3*xmult
    ```

    The ymult SetVariable control as well as the graphs are updated.
6. **Adjust the xmult value.**

    Again notice that ymult as well as the graphs are updated.
7. **Choose the Misc→Object Status menu item.**

    The Object Status dialog appears. You can use this dialog to examine dependencies.
8. **Click the the Current Object pop-up and choose spiralY from the Data Objects list.**

    The list on the right indicates that spiralY depends on the variable ymult.
9. **Double-click the ymult entry in the right-hand list.**

    ymult becomes the current object. The list on the right now indicates that ymult depends on xmult.
10. **Click the Delete Formula button.**

    Now ymult no longer depends on xmult.
11. **Click Done.**
12. **Adjust the xmult setting.**

    The ymult value is no longer automatically recalculated but the spiralY and spiralX waves still are.
13. **Click the Update button.**
14. **Adjust the xmult and ymult settings.**

    The spiralY and spiralX waves are no longer automatically recalculated. This is because the ButtonProc function called by the Update button does a normal assignment using = rather than := and that action removes the dependency formulae.

In real work, you should avoid using dependencies because they are hard to keep track of and debug. If a button can do the job then use it rather than the dependency.

Saving Your Work - Tour 1E

1. **Choose the File→Save Experiment As menu item.**

2. **Navigate to your “Guided Tours” folder.**

   This is the folder that you created under **Saving Your Work - Tour 1A** on page I-21.

3. **Type “Tour 1E.pxp” in the name box and click Save.**

End of the General Tour

This is the end of the general tour of Igor Pro.

If you want to take a break, you can quit from Igor Pro now.

Guided Tour 2 - Data Analysis

In this tour we will concentrate on the data analysis features of Igor Pro. We will generate synthetic data and then manipulate it using sorting and curve fitting.

Starting Guided Tour 2

1. **If Igor is already running, activate it and choose File→New Experiment.**

   In this case, skip to step 2.

2. **Double-click your Igor64 alias or shortcut.**

   Instructions for creating this alias or shortcut can be found under **Creating an Igor64 Alias or Shortcut** on page I-13.

   On Windows, you an also launch Igor64 using the Start menu.

3. **Choose Misc→Preferences Off.**

   Turning preferences off ensures that the tour works the same for everyone.

Creating Synthetic Data

We need something to analyze, so we generate some random X values and create some Y data using a math function.

1. **Type the following in the command line and then press Return or Enter:**

   ```
   SetRandomSeed 0.1
   ```

   This initializes the random number generator so you will get the same results as this guided tour.

2. **Type the following in the command line and then press Return or Enter:**

   ```
   Make/N=100 fakeX = enoise(5)+5,fakeY
   ```

   This generates two 100 point waves and fills fakeX with evenly distributed random values ranging from 0 to 10.

3. **Execute this in the same way:**

   ```
   fakeY = exp(-(fakeX-4)^2)+gnoise(0.1)
   ```

   This generates a Gaussian peak centered at 4.

4. **Choose the Windows→New Graph menu item.**
5. **If you see a button labeled Fewer Choices, click it.**
6. **In the Y Waves list, select “fakeY”.**
7. **In the X Wave list, select “fakeX”.**
8. **Click Do It.**

   The graph is a rat’s nest of lines because the X values are not sorted.

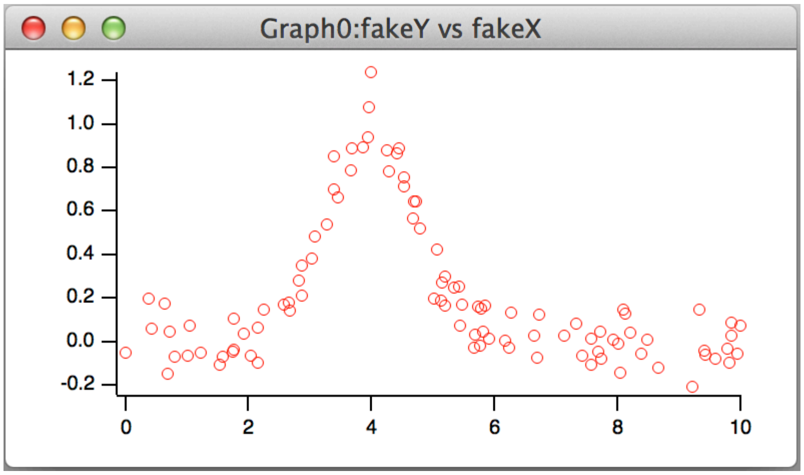
9. **Double-click the red trace.**

   The Modify Trace Appearance dialog appears.

10. **From the Mode pop-up choose Markers.**
11. **From the Markers pop-up menu choose the open circle.**

12. **Click Do It.**

    Now the graph makes sense.



Quick Curve Fit to a Gaussian

Our synthetic data was generated using a Gaussian function so let's try to extract the original parameters by fitting to a Gaussian of the form:

```
y = y0 + A*exp(-((x-x0)/width)^2)
```

Here y0, A, x0 and width are the parameters of the fit.

1. **Choose the Analysis→Quick Fit→gauss menu item.**

   Igor generated and executed a CurveFit command which you can see if you scroll up a bit in the history area of the command window. The CurveFit command performed the fit, appended a fit result trace to the graph, and reported results in the history area.

   At the bottom of the reported results we see the values found for the fit parameters. The amplitude parameter (A) should be 1.0 and the position parameter (x0) should be 4.0. We got 0.99222 ± 0.0299 for the amplitude and 3.9997 ± 0.023 for the position.

   Let's add this information to the graph.

2. **Choose Analysis→Quick Fit→Textbox Preferences.**

   The Curve Fit Textbox Preferences dialog appears.

   You can add a textbox containing curve fit results to your graph. The Curve Fit Textbox Preference dialog has a checkbox for each component of information that can be included in the textbox.

3. **Click the Display Curve Fit Info Textbox checkbox to check it and then click OK.**

   You have specified that you want an info textbox. This will affect future Quick Fit operations.

4. **Choose Analysis→Quick Fit→gauss again.**

   This time, Igor displays a textbox with the curve fit results. Once the textbox is made, it is just a textbox and you can double-click it and change it. But if you redo the fit, your changes will be lost unless you rename the textbox.

   That textbox is nice, but it's too big. Let's get rid of it.

   You could just double-click the textbox and click Delete in the Modify Annotation dialog. The next time you do a Quick Fit you would still get the textbox unless you turn the textbox feature off.

5. **Choose Analysis→Quick Fit→Textbox Preferences again. Click the Display Curve Fit Info Textbox checkbox to uncheck it. Click OK.**

6. **Choose Analysis→Quick Fit→gauss again.**

   The textbox is removed from the graph.

More Curve Fitting to a Gaussian

The Quick Fit menu provides easy access to curve fitting using the built-in fit functions, with a limited set of options, to fit data displayed in a graph. You may want more options. For that you must use the Curve Fitting dialog.

1. **Choose the Analysis→Curve Fitting menu item.**

   The Curve Fitting dialog appears.
2. **Click the Function and Data tab.**
3. **From the Function pop-up menu, choose gauss.**
4. **From the Y Data pop-up menu, choose fakeY.**
5. **From the X Data pop-up menu, choose fakeX.**
6. **Click the Data Options tab.**

   The Weighting and Data Mask pop-up menus should read "_none_".
7. **Click the Output Options tab.**

   The Destination pop-up menu should read "_auto_" and Residual should read "_none_".
8. **Click Do It.**

   During the fit a Curve Fit progress window appears. After a few passes the fit is finished and Igor waits for you to click OK in the progress window.
9. **Click OK.**

   The curve fit results are printed in the history. They are the same as in the previous section.

Sorting

In the next section we will do a curve fit to a subrange of the data. For this to work, the data must be sorted by X values.

1. **Double-click one of the open circle markers in the graph.**

   The Modify Traces Appearance dialog appears with fakeY selected. If fakeY is not selected, click it.
2. **From the Mode pop-up choose Lines between points and click Do It.**

   The fakeY trace reverts to a rat's nest of lines.
3. **Choose the Analysis→Sort menu item.**

   The Sorting dialog appears.
4. **If necessary choose Sort from the Operation pop-up menu.**
5. **Select "fakeX" in the Key Wave list and both "fakeX" and "fakeY" in the Waves to Sort list.**

   This will sort both fakeX and fakeY using fakeX as the sort key.
6. **Uncheck any checkboxes in the dialog that are checked, including the Display Output In checkbox.**
7. **Click Do It.**

   The rat's nest is untangled. Since we were using the lines between points mode just to show the results of the sort, we now switch back to open circles.
8. **Press Control and click (*Macintosh*) or right-click (*Windows*) on the fakeY trace (the jagged one).**

   A pop-up menu appears with the name of the trace at the top. If it is not "Browse fakeY" try again.
9. **Choose Markers from the Mode submenu.**

Fitting to a Subrange

Here we will again fit our data to a Gaussian but using a subset of the data. We will then extrapolate the fit outside of the initial range.

1. **Choose the Graph→Show Info menu item.**

   A cursor info panel is appended to the bottom of the graph.

   Two cursors are "docked" in the info panel, Cursor A and Cursor B.

2. **Place cursor A (the round one) on the fakeY trace.**

   One way to place the cursor is to drag it to the trace. Another way is to control-click (*Macintosh*) or right-click (*Windows*) on the name area which is just to the right of the cursor icon in the cursor info panel.

   Note that the cursor A icon in the dock is now black. This indicates that cursor A is selected, meaning that it will move if you use the arrow keys on the keyboard or the slider in the cursor info panel.

3. **Move cursor A to point #14.**

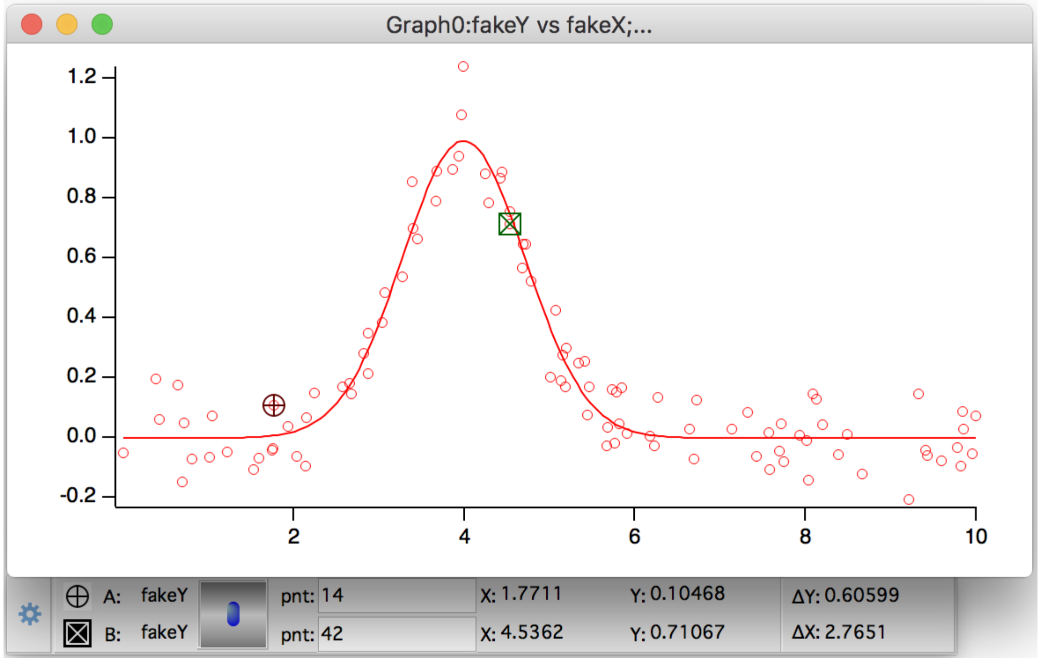
   To move the cursor one point at a time, use the arrow keys on the keyboard or click on either side of the slider in the cursor position control.

4. **Click the dock for cursor A in the cursor info panel to deselect it.**

   This is so you can adjust cursor B without affecting the position of cursor A.

5. **Place cursor B (the square one) on the fakeY trace and move it to point #42.**

   The graph should look like this:



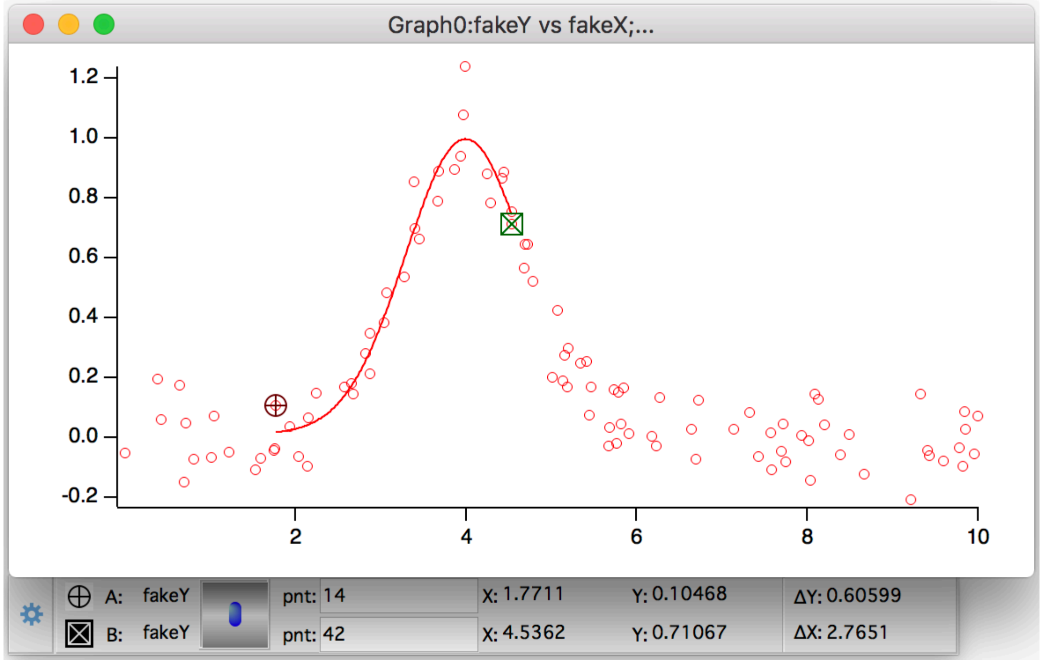
⊕ A: fakeY pnt: 14 X: 1.7711 Y: 0.10468 ΔY: 0.60599

☒ B: fakeY pnt: 42 X: 4.5362 Y: 0.71067 ΔX: 2.7651

6. **In the Analysis→Quick Fit menu make sure the Fit Between Cursors item is checked. If it is not, select it to check it.**

7. **Choose Analysis→Quick Fit→gauss.**

   Note that the fit curve is evaluated only over the subrange identified by the cursors.



A: fakeY pnt: 14 X: 1.7711 Y: 0.10468 ΔY: 0.60599

B: fakeY pnt: 42 X: 4.5362 Y: 0.71067 ΔX: 2.7651

We would like the fit trace to extend over the entire X range, while fitting only to the data between the cursors. This is one of the options available only in the Curve Fitting dialog.

8. **Choose Analysis→Curve Fitting and then click the Function and Data tab.**

   The curve fitting dialog appears and the settings should be as you left them. Check that the function type is gauss, the X data is fakeY, the X data is fakeX.

9. **Click the Data Options tab.**

10. **Click the Cursors button in the Range area.**

    This puts the text “pcsr(A)” and “pcsr(B)” in the range entry boxes.

    pcsr is a function that returns the wave point number at the cursor position.

11. **Select the Output Options tab and click the X Range Full Width of Graph checkbox to check it.**

12. **Click Do It.**

    The curve fit starts, does a few passes and waits for you to click OK.

13. **Click OK.**

    The fit was done using only the data between the cursors, but the fit trace extends over the entire X range.

    In the next section, we need the short version of the fit curve, so we will simply do the fit again:

14. **Choose Analysis→Quick Fit→gauss.**

Extrapolating a Fit After the Fit is Done

When you used the Quick Fit menu, and when you chose “_auto_” from the Destination pop-up menu in the Curve Fitting dialog, Igor created a wave named fit_fakeY to show the fit results. This is called the "fit destination wave." It is just an ordinary wave whose X scaling is set to the extent of the X values used in the fit.

In the preceding sections you learned how to make the curve fit operation extrapolate the fit curve beyond the subrange. Here we show you how to do this manually to illustrate some important wave concepts.

To extrapolate, we simply change the X scaling of fit_fakeY and re-execute the fit destination wave assignment statement which the CurveFit operation put in the history area.

1. **Choose the Data→Change Wave Scaling menu item.**
2. **If you see a button labeled More Options, click it.**
3. **From the SetScale Mode pop-up menu, choose Start and End.**
4. **Double-click "fit_fakeY" in the list.**

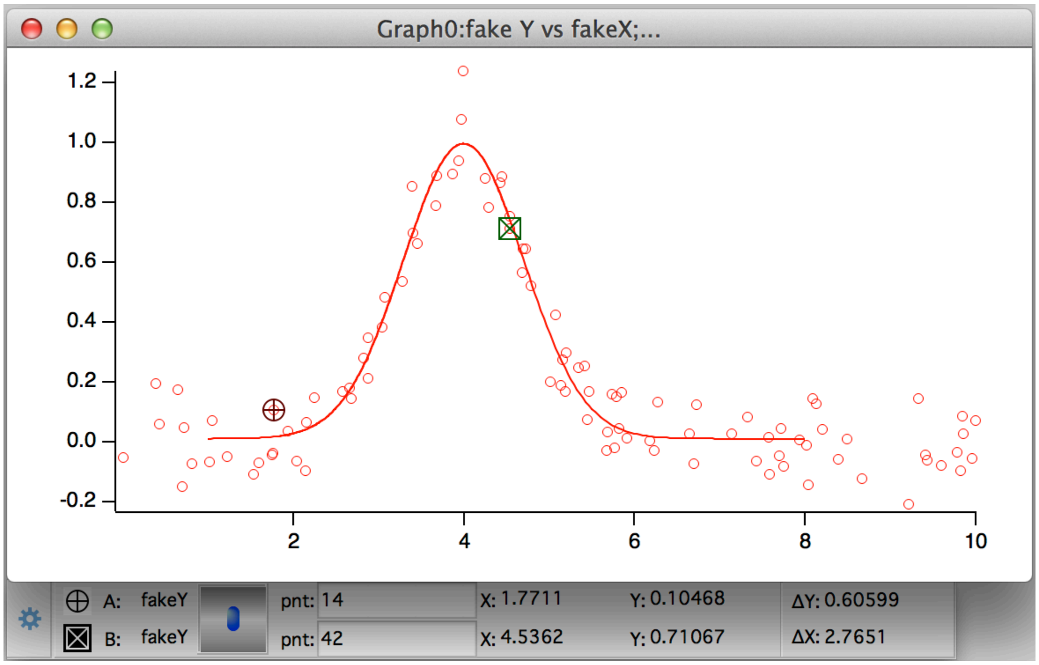
   This reads in the current X scaling values of fit_fakeY. The starting X value will be about 1.77 and the ending X will be about 4.53.
5. **Press Tab until the Start box is selected and enter 1.0.**
6. **Tab to the End box and type "8.0".**
7. **Click Do It**

   The fit_fakeY trace is stretched out and now runs between 1 and 8.

   Now we need to calculate new Y values for fit_fakeY using its new X values.
8. **In the history, find the line that starts "fit_fakeY=" and click it.**

   The entire line is selected. (The line in question is near the top of the curve fit report printed in the history.)
9. **Press Return or Enter once to copy the selection from the history to the command line and a second time to execute it.**

   The fit_fakeY wave now contains valid data between 1 and 8.



⊕ A: fakeY pnt: 14 X: 1.7711 Y: 0.10468 ΔY: 0.60599

☒ B: fakeY pnt: 42 X: 4.5362 Y: 0.71067 ΔX: 2.7651

Appending a Fit

The fit trace added automatically when Igor does a curve fit uses a wave named by adding "fit_" to the start of the Y data wave's name. If you do another fit to the same Y data, that fit curve will be overwritten. If you want to show the results of several fits to the same data, you will have to somehow protect the fit destination wave from being overwritten. This is done by simply renaming it.

1. **Choose the Data→Rename menu item.**
2. **Double-click the wave named fit_fakeY to move it into the list on the right.**
3. **Edit the name in the New Name box to change the name to "gaussFit_fakeY" and click Do It.**

4. **Position the A and B cursors to point numbers 35 and 61, respectively.**

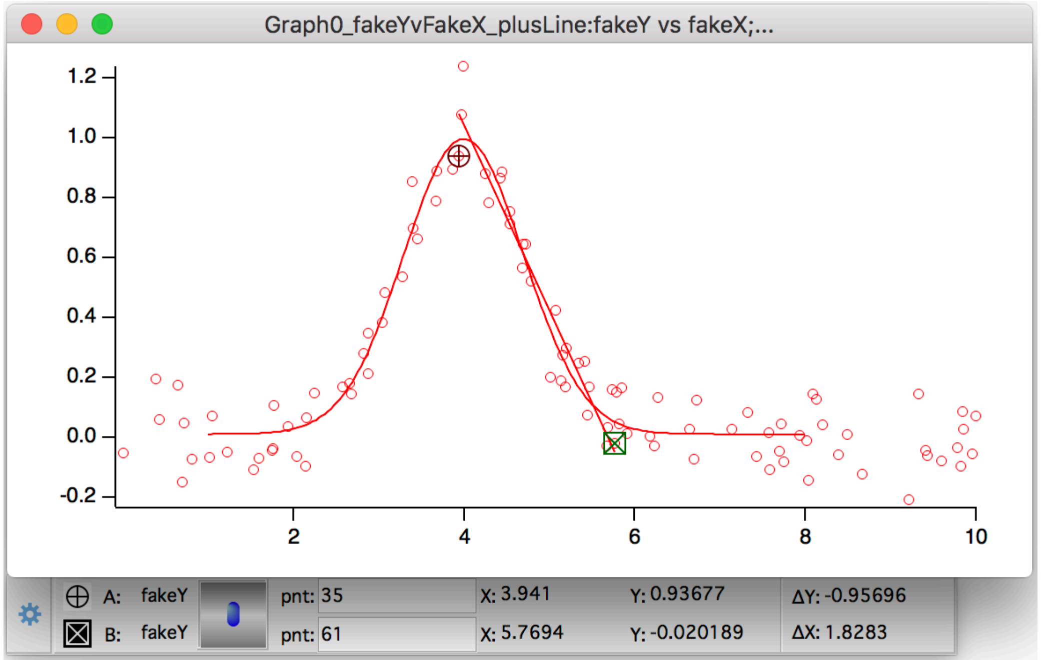
   A quick way to do this is to enter the numbers 35 and 61 in the edit boxes to the right of the cursor position control.

5. **Choose Analysis→Quick Fit→line.**

   Because there are two traces on the graph, Quick Fit doesn't know which one to fit and puts up the Which Data Set to Quick Fit dialog.

6. **Select fakeY from the list and click OK.**

   The line fit is appended to the graph:



⊕ A: fakeY pnt: 35 X: 3.941 Y: 0.93677 ΔY: -0.95696
☒ B: fakeY pnt: 61 X: 5.7694 Y: -0.020189 ΔX: 1.8283

This concludes Guided Tour 2.

Guided Tour 3 - Histograms and Curve Fitting

In this tour we will explore the Histogram operation and will perform a curve fit using weighting. The optional last portion creates a residuals plot and shows you how to create a useful procedure from commands in the history.

Starting Guided Tour 3

1. **If Igor is already running, activate it and choose File→New Experiment.**

   In this case, skip to step 2.

2. **Double-click your Igor64 alias or shortcut.**

   Instructions for creating this alias or shortcut can be found under **Creating an Igor64 Alias or Shortcut** on page I-13.

   On Windows, you an also launch Igor64 using the Start menu.

3. **Choose Misc→Preferences Off.**

   Turning preferences off ensures that the tour works the same for everyone.

Creating Synthetic Data

We need something to analyze, so let's generate some random values.

1. **Type the following in the command line and then press Return or Enter:**

   ```
   SetRandomSeed 0.1
   ```

   This initializes the random number generator so you will get the same results as this guided tour.

2. **Type the following in the command line and then press Return or Enter:**

   ```
   Make/N=10000 fakeY = enoise(1)
   ```

   This generates a 10,000 point wave filled with evenly distributed random values from -1 to 1.

Histogram of White Noise

Here we will generate a histogram of the evenly distributed "white" noise.

1. **Choose the Analysis→Histogram menu item.**

   The Histogram dialog appears.

2. **Select fakeY from the Source Wave list.**
3. **Verify that Auto is selected in the Output Wave menu.**
4. **Uncheck any checkboxes in the dialog that are checked, including the Display Output Wave checkbox.**
5. **Click the Auto-set Bin Range radio button.**
6. **Set the Number of Bins box to 100.**

   Note in the command box at the bottom of the dialog there are two commands:

   ```
   Make/N=100/O fakeY_Hist;DelayUpdate
   Histogram/B=1 fakeY,fakeY_Hist
   ```

   The first command makes a wave to receive the results, the second performs the analysis. The Histogram operation in the "Auto-set bin range" mode takes the number of bins from the output wave.

7. **Click the Do It button.**

   The histogram operation is performed.

   Now we will display the results.

8. **Choose Windows→New Graph.**
9. **Select fakeY_Hist in the Y Waves list and "_calculated_" in the X list.**

10. **Click the Do It button.**

    A graph is created showing the histogram results. Next we will touch it up a bit.

11. **Double-click the trace in the graph.**

    The Modify Trace Appearance dialog appears.

    "Left" is selected in the Axis pop-up menu in the top/left corner of the dialog indicating that changes made in the dialog will affect the left axis.

12. **Choose "Sticks to zero" from the Mode pop-up menu and click Do It.**

    The graph is redrawn using the new display mode.

13. **Double-click one of the tick mark labels (e.g., "100) of the left axis.**

    The Modify Axis dialog appears, showing the Axis Range tab.

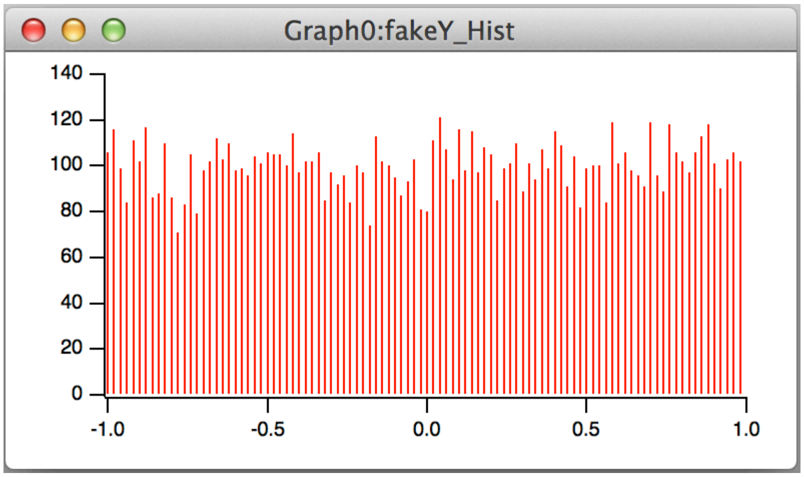
14. **From the two pop-up menus in the Autoscale Settings area, choose "Round to nice values" and "Autoscale from zero".**

15. **Choose Bottom from the Axis pop-up menu.**

16. **From the two pop-up menus in the Autoscale Settings area, choose "Round to nice values" and "Symmetric about zero".**

17. **Click the Do It button.**

    The graph should now look like this:



Saving Your Work - Tour 3A

1. **Choose the File→Save Experiment As menu item.**

2. **Navigate to your "Guided Tours" folder.**

   This is the folder that you created under **Saving Your Work - Tour 1A** on page I-21.

3. **Type "Tour 3A.pxp" in the name box and click Save.**

Histogram of Gaussian Noise

Now we'll do another histogram, this time with Gaussian noise.

1. **Type the following in the command line and then press Return or Enter:**

```
fakeY = gnoise(1)
```

2. **Choose the Analysis→Histogram menu item.**

   The dialog should still be correctly set up from the last time.

3. **Click the radio button labeled "Auto-set bins: 3.49*Sdev*N^-1/3".**

   The information text at the bottom of the Destination Bins box tells you that the histogram will have 48 bins.

   This is a method by Sturges for selecting a "good" number of bins for a histogram. See the **Histogram** operation on page V-349 for a reference.

4. **Click the Bin-Centered X Values checkbox to check it.**

   By default, the Histogram operation sets the X scaling of the output wave such that the X values are at the left edge of each bin, and the right edge is given by the next X value. This makes a nice bar plot.

   In the next section you will do a curve fit to the histogram. For curve fitting you need X values that represent the center of each bin.

5. **Click the Create Square Root(N) Wave checkbox to check it.**

   Counting data, such as a histogram, usually has Poisson-distributed values. The estimated mean of the Poisson distribution is simply the number of counts (N) and the estimated standard deviation is the square root of N.

   The curve fit will be biased if this is not taken into account. You will use this extra wave for weighting when you do the curve fit.

6. **Click the Do It button.**

   Note that the histogram output as shown in Graph0 has a Gaussian shape, as you would expect since the histogram input was noise with a Gaussian distribution.

7. **Choose Data→Data Browser.**

   The Data Browser shows you the waves and variables in your experiment. You should see three waves now: fakeY, fakeY_Hist, and W_SqrtN. FakeY_Hist contains the output of the Histogram operation and W_SqrtN is the wave created by the Histogram operation to receive the square root of N data.

8. **Close the Data Browser.**
9. **Click Graph0 and then double-click the trace to invoke the Modify Trace Appearance dialog.**
10. **Select Markers from the Mode menu, then select the open circle marker.**
11. **Click the Error Bars checkbox.**

    The Error Bars dialog appears.

12. **Select "+/- wave" from the Y Error Bars menu.**
13. **Pop up the Y+ menu and select W_SqrtN.**

    Note that the Y- menu is set to Same as Y+. You could now select another wave from the Y- menu if you needed asymmetric error bars.

14. **Click OK, then Do It.**

Saving Your Work - Tour 3B

1. **Choose the File→Save Experiment As menu item.**
2. **Navigate to your "Guided Tours" folder.**

   This is the folder that you created under **Saving Your Work - Tour 1A** on page I-21.

3. **Type "Tour 3B.pxp" in the name box and click Save.**

Curve Fit of Histogram Data

The previous section produces all the pieces required to fit a Gaussian to the histogram data, with proper weighting to account for the variance of Poisson-distributed data.

1. **Click the graph to make sure it is the target window.**

2. **In the Analysis→Quick Fit menu make sure the Weight from Error Bar Wave item is checked. If it is not, select it to check it.**
3. **Choose Analysis→Quick Fit→gauss.**

   The graph now looks like this:

   As shown in the history area, the fit results are:

```
Coefficient values ± one standard deviation
    y0     =-0.35284 ± 0.513
    A      =644.85 ± 7.99
    x0     =-0.0014111 ± 0.00997
    width  =1.406 ± 0.0118
```

   The original data was made with a standard deviation of 1. Why is the width 1.406? The way Igor defines its gauss fit function, width is sigma*$2^{1/2}$.

4. **Execute this command in the command line:**

```
Print 1.406/sqrt(2)
```

   The result, 0.994192, is pretty close to 1.0.

   It is often useful to plot the residuals from a fit to check for various kinds of problems. For that you need to use the Curve Fitting dialog.

5. **Choose Analysis→Curve Fitting.**
6. **Click the Function and Data tab and choose gauss from the Function menu.**
7. **Choose fakeY_Hist (not fakeY) from the Y Data menu.**
8. **Leave the X Data pop-up menu set to "_calculated_".**
9. **Click the Data Options tab. If there is text in the Start or End Range boxes, click the Clear button in the Range section.**
10. **Choose W_SqrtN from the Weighting pop-up menu.**
11. **Just under the Weighting pop-up menu there are two radio buttons. Click the top one which is labeled "Standard Dev".**
12. **Click the Output Options tab and choose "_auto_" from the Destination pop-up menu.**
13. **Set the Residual pop-up menu to "_auto trace_".**

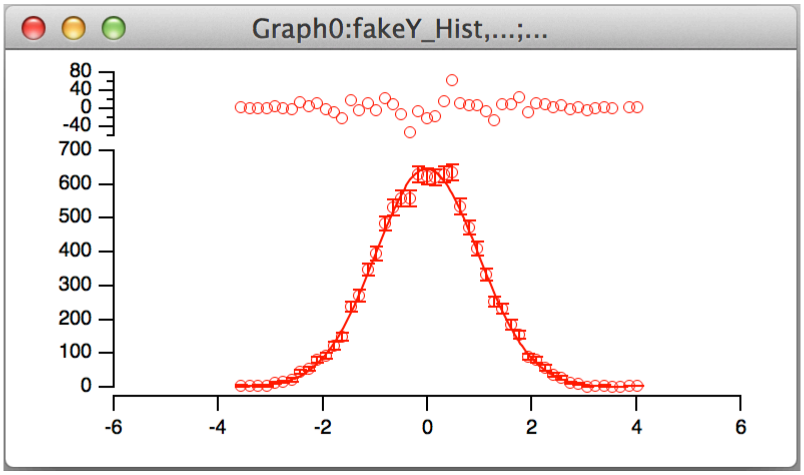
    Residuals will be calculated automatically and added to the curve fit in our graph.

14. **Uncheck the X Range Full Width of Graph checkbox.**

    This is appropriate only when we are fitting to a subset of the source wave.

15. **Click Do It.**

    The curve fit starts, does a few passes, and waits for you to click OK.



There is one small issue not addressed above. One of the bins contains zero; the square root of zero is, of course, zero. So the weighting wave contains a zero, which causes the curve fit to ignore that data point. It's not clear what is the best approach for fixing that problem. Some replace the zero with a one. These commands replace any zeroes in the weighting wave and re-do the fit:

```
W_SqrtN = W_SqrtN[p] == 0 ? 1 : W_SqrtN[p]
CurveFit/NTHR=0 gauss  fakeY_Hist /W=W_SqrtN /I=1 /D /R
```

This doesn't change the result very much, since there was just one zero in the histogram:

```
Coefficient values ± one standard deviation
    y0     =-0.40357 ± 0.464
    A      =644.76 ± 7.98
    x0     =-0.0014186 ± 0.00996
    width  =1.4065 ± 0.0115
```

Saving Your Work - Tour 3C

1. **Choose the File→Save Experiment As menu item.**
2. **Navigate to your "Guided Tours" folder.**

   This is the folder that you created under **Saving Your Work - Tour 1A** on page I-21.
3. **Type "Tour 3C.pxp" in the name box and click Save.**

Curve Fit Residuals (Optional)

The remaining guided tour sections are primarily of interest to people who want to use Igor programming to automate tasks. You may want to skip them and come back later. If so, jump ahead to **For Further Exploration** on page I-64.

In the next section, as an illustration of how the history area can be used as a source of commands to generate procedures, we will create a procedure that appends residuals to a graph. The preceding section illustrated that Igor is able to automatically display residuals from a curve fit, so the procedure that we write in the next section is not needed. Still, it demonstrates the process of creating a procedure. In preparation for writing the procedure, in this section we append the residuals manually.

If the curve fit to a Gaussian function went well and if the gnoise function truly produces noise with a Gaussian distribution, then a plot of the difference between the histogram data and the fitted function should not reveal any curvature.

1. **To remove the automatically generated residual from the Gaussian fit in the previous section, Control-click (*Macintosh*) or right-click (*Windows*) directly on the residual trace at the top of the graph and select Remove Res_fakeY_Hist from the pop-up menu.**

2. **Choose the Data→Duplicate Waves menu item.**

3. **Choose fakeY_Hist from the Template pop-up menu.**

4. **In the first Names box, enter "histResids".**

5. **Click Do It.**

   You now have a wave suitable for containing residuals.

6. **In the history area of the command window, find the line that reads:**

   ```
   fit_fakeY_Hist= W_coef[0]+W_coef[1]*exp(-((x-W_coef[2])/W_coef[3])^2)
   ```

   W_coef is a wave created by the CurveFit operation to contain the fit parameters. W_coef[0] is the y0 parameter, W_coef[1] is the A parameter, W_coef[2] is the x0 parameter and W_coef[3] is the width parameter.

   This line shows conceptually what the CurveFit operation did to set the data values of the fit destination wave.

7. **Click once on the line to select it and then press Return or Enter once.**

   The line is transferred to the command line.

8. **Edit the line to match the following:**

   ```
   histResids = fakeY_Hist -(W_coef[0]+W_coef[1]*exp(-((x-W_coef[2])/W_coef[3])^2))
   ```

   In other words, change `fit_fakeY_Hist` to `histResids`, click after the equals and type `fakeY_Hist - (` and then add a `)` to the end of the line.

   The expression inside the parentheses that you added represents the model value using the parameters determined by the fit. This command computes residuals by subtracting the model values from the data values on which the fit was performed.

   If the fit had used an X wave rather than calculated X values then it would have been necessary to substitute the name of the X wave for the "x" in the expression.

9. **Press Return or Enter.**

   This wave assignment statement calculates the difference between the measured data (the output of the Histogram operation) and the theoretical Gaussian (as determined by the CurveFit operation).

   Now we will append the residuals to the graph stacked above the current contents.

10. **Choose Graph→Append Traces to Graph.**

11. **Select histResids from the Y waves list and "_calculated_" from the X wave list.**

12. **Choose New from the Axis pop-up menu under the Y Waves list.**

13. **Enter "Lresid" in the Name box and click OK.**

14. **Click Do It.**

    The new trace and axis is added.

    Now we need to arrange the axes. We will do this by partioning the available space between the Left and Lresid axes.

15. **Double-click the far-left axis.**

    The Modify Axis dialog appears. If any other dialog appears, cancel and try again making sure the cursor is over the axis.

    If you have enough screen space you will be able to see the graph change as you change settings in the dialog. Make sure that the Live Update checkbox in the top/right corner of the dialog is selected.

16. **Click the Axis tab.**

    The Left axis should already be selected in the pop-up menu in the top-left corner of the dialog.

17. **Set the Left axis to draw between 0 and 70% of normal.**

18. **Choose Lresid from the Axis pop-up menu.**

19. **Set the Lresid axis to draw between 80 and 100% of normal.**

20. **Choose Fraction of Plot Area in the “Free axis position” menu.**

    The Lresid axis is a “free” axis. This moves it horizontally so it is in line with the Left axis.

21. **Choose Bottom from the Axis pop-up menu.**
22. **Click the Axis Standoff checkbox to turn standoff off.**

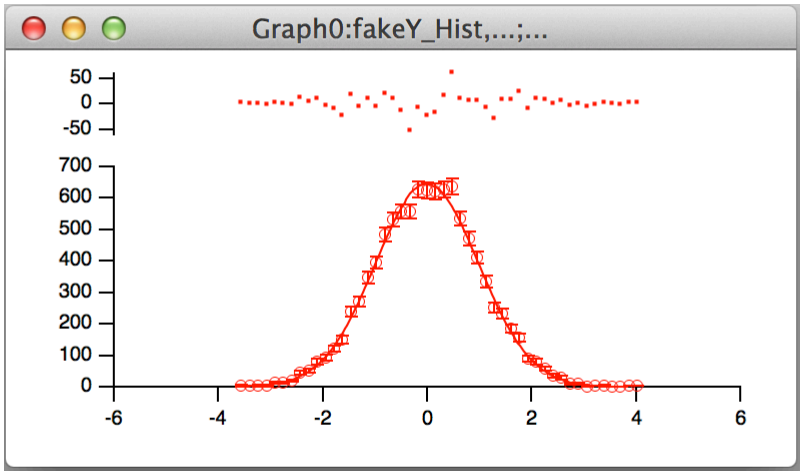
    Just a couple more touch-ups and we will be done. The ticking of the Lresid axis can be improved. The residual data should be in dots mode.

23. **Choose Lresid from the Axis pop-up menu again.**
24. **Click the Auto/Man Ticks tab.**
25. **Change the Approximately value to 2.**
26. **Click the Axis Range tab.**
27. **In the Autoscale Settings area, choose “Symmetric about zero” from the menu currently reading “Zero isn’t special”.**
28. **Click the Do It button.**
29. **Double-click the histResids trace.**

    The Modify Trace Appearance dialog appears with histResids already selected in the list.

30. **Choose Dots from the Mode pop-up menu**
31. **Set the line size to 2.00.**
32. **Click Do It.**

    The graph should now look like this:



Saving Your Work - Tour 3D

1. **Choose the File→Save Experiment As menu item.**
2. **Navigate to your “Guided Tours” folder.**

    This is the folder that you created under **Saving Your Work - Tour 1A** on page I-21.

3. **Type “Tour 3D.pxp” in the name box and click Save.**

Writing a Procedure (Optional)

In this section we will collect commands that were created as we appended the residuals to the graph. We will now use them to create a procedure that will append a plot of residuals to a graph.

1. **Make the command window tall enough to see the last 10 lines by dragging the top edge of the window upward.**

2. **Find the fifth line from the bottom that reads:**

```
•AppendToGraph/L=Lresid histResids
```

3. **Select this line and all the lines below it and copy them to the clipboard.**

4. **Choose the Windows→New→Procedure menu item.**

5. **Type "Append Residuals" (without the quotes) in the Document Name box and click OK.**

   A new procedure window appears. We could have used the always-present built-in procedure window, but we will save this new procedure window as a standalone file so it can be used in other experiments.

6. **Add a blank line to the window, type "Function AppendResiduals()", and press Return or Enter.**

7. **Paste the commands from the clipboard into the new window.**

8. **Type "End" and press Return or Enter.**

9. **Select the five lines that you pasted into the procedure window and then choose Edit→Adjust Indentation.**

   This removes the bullet characters copied from the history and prepends tabs to apply the normal indentation for procedures.

   Your procedure should now look like this:

```
Function AppendResiduals()
    AppendToGraph/L=Lresid histResids
    SetAxis/A/E=2 Lresid
    ModifyGraph nticks(Lresid)=2,standoff(bottom)=0,axisEnab(left)={0,0.7};DelayUpdate
    ModifyGraph axisEnab(Lresid)={0.8,1}, freePos(Lresid)=0;DelayUpdate
    ModifyGraph mode(histResids)=2,lsize(histResids)=2
End
```

10. **Delete the ";DelayUpdate" at the end of the two ModifyGraph commands.**

    DelayUpdate has no effect in a function.

    We now have a nearly functional procedure but with a major limitation — it only works if the residuals wave is named "histResids". In the following steps, we will change the function so that it can be used with any wave and also with an XY pair, rather than just with equally-spaced waveform data.

11. **Replace the first two lines of the function with the following:**

```
Function AppendResiduals(yWave, xWave)
    Wave yWave
    Wave xWave              // X wave or null if there is no X wave

    if (WaveExists(xWave))
       AppendToGraph/L=Lresid yWave vs xWave
    else
       AppendToGraph/L=Lresid yWave
    endif
    String traceName = NameOfWave(yWave)
```

12. **In the last ModifyGraph command in the function, change both "histResids" to "$traceName" (without the quotes).**

    The "$" operator converts the string expression that follows it into the name of an Igor object.

    Here is the completed procedure.

```
Function AppendResiduals(yWave,xWave)
    Wave yWave
    Wave/Z xWave            // X wave or null if there is no X wave

    if (WaveExists(xWave))
       AppendToGraph/L=Lresid yWave vs xWave
    else
       AppendToGraph/L=Lresid yWave
    endif
    String traceName = NameOfWave(yWave)
    SetAxis/A/E=2 Lresid
    ModifyGraph nticks(Lresid)=2,standoff(bottom)=0,axisEnab(left)={0,0.7}
    ModifyGraph axisEnab(Lresid)={0.8,1},freePos(Lresid)={0,kwFraction}
    ModifyGraph mode($traceName)=2,lsize($traceName)=2
End
```

Let's try it out.

13. **Click the Compile button at the bottom of the procedure window to compile the function.**

    If you get an error, edit the function text to match the listing above.

14. **Click the close button in the Append Residuals procedure window. A dialog asks if you want to kill or hide the window. Click Hide.**

    If you press Shift while clicking the close button, the window will be hidden without a dialog.

15. **Choose Windows→New Graph and click the Fewer Choices button if it is available.**

16. **Choose fakeY_Hist from the Y Waves list and _calculated_ from the X Wave list and click Do It.**

    A graph without residuals is created.

17. **In the command line, execute the following command:**

    ```
    AppendResiduals(histResids, $"")
    ```

    Because we have no X wave, we use $"" to pass NULL to AppendResiduals for the xWave parameter.

    The AppendResiduals function runs and displays the residuals in the graph, above the original histogram data.

    Next we will add a function that displays a dialog so we don't have to type wave names into the command line.

18. **Choose Windows→Procedure Windows→Append Residuals to show the Append Residuals procedure window.**

19. **Enter the following function below the AppendResiduals function.**

    ```
    Function AppendResidualsDialog()
        String yWaveNameStr, xWaveNameStr

        Prompt yWaveNameStr,"Residuals Data",popup WaveList("*",";","")
        Prompt xWaveNameStr,"X Data", popup "_calculated_;"+WaveList("*",";","")
        DoPrompt "Append Residuals", yWaveNameStr, xWaveNameStr
        if (V_flag != 0)
            return -1              // User canceled
        endif

        AppendResiduals($yWaveNameStr, $xWaveNameStr)

        return 0                   // Success
    End
    ```

    This function displays a dialog to get parameters from the user and then calls the AppendResiduals function.

    Let's try it out.

20. **Click the Compile button at the bottom of the procedure window to compile procedures.**

    If you get an error, edit the function text to match the listing above.

21. **Shift-click the close button to hide the procedure window. Then activate Graph1.**

22. **Control-click (*Macintosh*) or right-click (*Windows*) the residual trace at the top of the graph and select Remove histResids from the pop-up menu.**

    The Lresid axis is removed because the last wave graphed against it was removed.

23. **On the command line, execute this command:**

    ```
    AppendResidualsDialog()
    ```

    The AppendResidualsDialog function displays a dialog to let you choose parameters.

24. **Choose histResids from the Residuals Data pop-up menu.**

25. **Leave the X Wave pop-up set to "_calculated_".**

26. **Click Continue.**

    The graph should once again contain the residuals plotted on an axis above the main data.

    Next we will add a menu item to the Macros menu.

27. **Choose Windows→Procedure Windows→Append Residuals to show the Append Residuals procedure window.**

28. **Enter the following code before the AppendResiduals function:**

```
Menu "Macros"
    "Append Residuals...", AppendResidualsDialog()
End
```

29. **Click the Compile button.**

    Igor compiles procedures and adds the menu item to the Macros menu.

30. **Shift-click the close button to hide the procedure window. Then activate Graph1.**

31. **Control-click (*Macintosh*) or right-click (*Windows*) the residual trace at the top of the graph and select "Remove histResids" from the pop-up menu.**

32. **Click the Macros menu and choose the "Append Residuals" item**

    The procedure displays a dialog to let you choose parameters.

33. **Choose histResids from the Residuals Data pop-up menu.**

34. **Leave the X Wave pop-up menu set to "_calculated_".**

35. **Click the Continue button.**

    The graph should once again contain the residuals plotted on a new axis above the main data.

Saving a Procedure File (Optional)

Note: *If you are using the demo version of Igor Pro beyond the 30-day trial period, you cannot save a procedure file.*

Now that we have a working procedure, let's save it so it can be used in the future. We will save the file in the "Igor Pro User Files" folder - a folder created by Igor for you to store your Igor files.

More precisely, we will save the procedure file in the "User Procedures" subfolder of the Igor Pro User Files folder. You could save the file anywhere on your hard disk, but saving in the User Procedures subfolder makes it easier to access the file as we will see in the next section.

1. **Choose Help→Show Igor Pro User Files.**

   Igor opens the "Igor Pro User Files" folder on the desktop.

   By default, this folder has the Igor Pro major version number in its name, for example, "Igor Pro 9 User Files", but it is generically called the "Igor Pro User Files" folder.

   Note where in the file system hierarchy this folder is located as you will need to know this in a subsequent step. The default locations are:

   Macintosh:
   `/Users/<user>/Documents/WaveMetrics/Igor Pro 9 User Files`

   Windows:
   `C:\Users\<user>\Documents\WaveMetrics\Igor Pro 9 User Files`

   Note the "User Procedures" subfolder of the Igor Pro User Files folder. This is where we will save the procedure file.

2. **Back in Igor, choose Windows→Procedure Windows→Append Residuals to show the Append Residuals procedure window.**

3. **Choose File→Save Procedure As.**

4. **Enter the file name "Append Residuals.ipf".**

5. **Navigate to your User Procedures folder inside your Igor Pro User Files folder and click Save.**

   The Append Residuals procedure file is now saved in a standalone file.

6. **Click the close button on the Append Residuals procedure window.**

   Igor asks if you want to kill or hide the file.

7. **Click the Kill button.**

   This removes the file from the current experiment, but it still exists on disk and you can open it as needed.

   There are several ways to open the procedure file to use it in the future. One is to double-click it. Another is to choose the File→Open File→Procedure menu item. A third is to put a `#include` statement in the built-in procedure window, which is how we will open it in the next section.

Including a Procedure File (Optional)

The preferred way to open a procedure window that you intend to use from several different experiments is to use a #include statement. This section demonstrates how to do that.

Note: *If you are using the demo version of Igor Pro beyond the 30-day trial period, you did not create the Append Residuals.ipf file in the preceding section so you can't do this section.*

1. **In Igor, use the Windows→Procedure Windows→Procedure Window to open the built-in procedure window.**

2. **Near the top of the built-in procedure window, notice the line that says:**

   ```
   #pragma rtGlobals = 3
   ```

   This is technical stuff that you can ignore.

3. **Under the rtGlobals line, leave a blank line and then enter:**

   ```
   #include "Append Residuals"
   ```

4. **Click the Compile button at the bottom of the built-in procedure window.**

   Igor compiles the procedure window. When it sees the `#include` statement, it looks for the "Append Residuals.ipf" procedure file in the User Procedures folder and opens it. You don't see it because it was opened hidden.

5. **Use the Windows→Procedure Windows menu to verify that the Append Residuals procedure file is in fact open.**

   To remove the procedure file from the experiment, you would remove the `#include` statement from the built-in procedure window.

   #include is powerful because it allows procedure files to include other procedure files in a chain. Each procedure file automatically opens any other procedure files it needs.

   User Procedures is special because Igor searches it to satisfy #include statements.

   Another special folder is Igor Procedures. Any procedure file in Igor Procedures is automatically opened by Igor at launch time and left open till Igor quits. This is the place to put procedure files that you want to be open all of the time. It is the easiest way to make a procedure file available and is recommended for frequently-used files.

This concludes Guided Tour 3.

For Further Exploration

We developed the guided tours in this chapter to provide an overview of the basics of using Igor Pro and to give you some experience using features that you will likely need for your day-to-day work. Beyond these fundamentals, Igor includes a wide variety of features to facilitate much more advanced graphing and analysis of your data.

As you become more familiar with using Igor, you will want to further explore some of the additional learning and informational aids that we have included with Igor Pro.

- The Igor Pro manual is installed on your hard disk in PDF format. You can access it through the Igor Help Browser or open it directly from the Manual folder in the Igor Pro Folder.

  The material in the manual is the same as the material in the online help files but is organized in book format and is therefore better suited for linear reading. Unlike the help files, the PDF manual includes an index.

  The most important chapters at this point in your Igor learning curve are Chapter II-3, **Experiments, Files and Folders** and Chapter II-5, **Waves**. If you want to learn Igor programming, read Chapter IV-1, **Working with Commands**, Chapter IV-2, **Programming Overview**, and Chapter IV-3, **User-Defined Functions**.
- The Igor Help Browser provides online help, including reference material for all built-in operations, functions, and keywords, an extensive list of shortcuts, and the ability to search Igor help files, procedure files, examples and technical notes for key phrases. See **The Igor Help Browser** on page II-2 for more information.
- The Examples folder contains a wide variety of sample experiments illustrating many of Igor’s advanced graphing and programming facilities. You can access these most easily through the File→Example Experiments submenus.
- The Learning Aids folder contains additional guided tours and tutorials including a tutorial on image processing. You can access these through the File→Example Experiments→Tutorials submenus.
- A tutorial on 3D visualization can be found in the “3D Graphics” help window, accessible through the Help→Help Windows menu.
- The WaveMetrics Procedures folder contains a number of utility procedures that you may find useful for writing your own procedures and for your more advanced graphing requirements. For an overview of the WaveMetrics procedures and easy loading of the procedure files, choose Help→Help Windows→WM Procedures Index.
- The “More Extensions (64-bit)” folder contains a number of External Operations (XOPs), which add functionality not built into the Igor Pro application. Read the included help files to find out more about the individual XOPs and how to install them, or consult the External Operations Index in the XOP Index help file, which has brief description of each XOP.
- The Technical Notes folder contains additional information. Tech Note #000 contains an index to all of the other notes.
- The Igor Pro mailing list is an Internet mailing list where Igor users share ideas and help each other. See **Igor Mailing List** on page II-4 or select the Help→Support menu and then select Igor Mailing List from the Support Options list for information about the mailing list.
- **IgorExchange** is a user-to-user support web page and a repository for user-created Igor Pro projects. Choose Help→IgorExchange to visit it.

Chapter

II-1

Getting Help

Overview

There are a number of sources of information for learning about Igor Pro. The most important are:

- The Guided Tour
- The Igor help system
- The Igor Pro online manual
- The example experiments in the Examples folder
- The Igor mailing list
- The IgorExchange user-to-user support web page

The Guided Tour

The Igor guided tour is indispensible for learning Igor.

The time you spend doing the guided tour will be repaid many times over in productivity. To do the guided tour, choose Help→Getting Started.

The same material is available in the first two chapters of this manual: **Introduction to Igor Pro** on page I-1 and **Guided Tour of Igor Pro** on page I-11.

Online Manual

The Igor Pro installer installs the entire Igor Pro manual as an Adobe PDF file. The PDF manual contains the same information as the online help files but in the more familiar PDF format.

You can open the manual by choosing Help→Manual or by double-clicking the IgorMan.pdf file in "Igor Pro-Folder/Manual".

The manual is not available in hard-copy form.

Online Help

Igor's online help system consists of these components:

- The Igor help browser
- Igor help files
- Tooltips

The Igor Help Browser

The Igor Help Browser is designed to provide quick access to the most frequently-used Igor reference material and also to provide a starting point in searching for other kinds of information. You can display the Igor Help Browser by:

- Choosing Help→Igor Help Browser
- Pressing the help key (Macintosh only)
- Pressing the F1 key (Windows only)
- Clicking the question-mark icon in the lower/right corner of the command window

Igor Help Files

The Igor installer places help files primarily in "Igor Pro Folder/Igor Help Files" and in "Igor Pro Folder/More Help Files".

When Igor starts up, it automatically creates help windows by opening the Igor help files stored in "Igor Pro Folder/Igor Help Files" and in "Igor Pro User Files/Igor Help Files". You can display a help window using the Help Files tab of the Help Browser or by choosing it from the Help Windows submenu in the Help menu.

To see a list of topics in open help files, use the Igor Help Browser Help Topics tab.

To search all installed help files, whether open or not, use the Igor Help Browser Search Igor Files tab.

Hiding and Killing a Help Window

When you click the close button in a help window, Igor hides it.

Usually there is no reason to kill a help file, but if you want to kill one, you must press Option (*Macintosh*) or Alt (*Windows*) while clicking the close button.

Executing Commands from a Help Window

Help windows often show example Igor commands. To execute a command or a section of commands from a help window, select the command text and press Control-Enter or Control-Return. This sends the selected text to the command line and starts execution.

Tooltips

Igor provides tooltips for various icons, dialog items, and other visual features. You can turn these tips on or off using the Show Tooltips checkbox in the Miscellaneous Settings dialog. To display this setting, choose Misc→Miscellaneous Settings and select the Help category.

You can also use tooltips to get information about traces in graphs and columns in tables. Use Graph→Show Trace Info Tags and Table→Show Column Info Tags to turn these tips on and off.

Searching Igor Files

You can search Igor help files and procedure files using the Search Igor Files tab of the Igor Help Browser.

The search expression can consist of one or more (up to 8) terms. Terms are separated by the word “and”. Here are some examples:

interpolation	*One term*
spline interpolation	*One term*
spline and interpolation	*Two terms*
spline and interpolation and smoothing	*Three terms*

The second example finds the exact phrase “spline interpolation” while the third example finds sections that contain the words “spline” and “interpolation”, not necessarily one right after the other.

The only keyword supported in the search expression is “and”. Quotation marks in the search expression don’t mean anything special and should not be used.

If your search expression includes more than one term, a text box appears in which you can enter a number that defines what “and” means. For example, if you enter 10, this means that the secondary terms must appear within 10 paragraphs of the primary term to constitute a hit. A value of 0 means that the terms must appear in the same paragraph. In a plain text file, such as a procedure file, a paragraph is a single line of text. Blank lines count as one paragraph.

To speed up searches when entering multiple search terms, enter the least common term first. For example, searching help files for “hidden and axis and graph” is faster than searching for “graph and axis and hidden” because “hidden” is less common than “graph”.

Example Experiments

Igor Pro comes with a large collection of examples which demonstrate Igor features and techniques. You can access them using the File→Example Experiments submenu.

Igor Mailing List

The Igor mailing list is an Internet discussion list that provides a way for Igor Pro users to help one another and to share solutions and ideas. WaveMetrics also uses the list to post information on the latest Igor developments. For information about subscribing and other details about the mailing list, please visit this web page:

`http://www.wavemetrics.com/users/mailinglist.htm`

IgorExchange

IgorExchange is a user-to-user support and collaboration web site sponsored by WaveMetrics but run by and for Igor users. For information about IgorExchange, please visit this web page:

`http://www.igorexchange.com`

Updating Igor

WaveMetrics periodically releases free updates for Igor. Updates provide bug fixes and sometimes new features.

Igor Pro checks for available updates during startup by contacting one of our web sites. This update check is implemented to minimize any performance impact on starting Igor.

If an update is found, Igor presents a dialog in which you can choose to download the update, skip notifications about the current update, or be reminded later about the update. You can also choose to view the release notes for the update.

You can disable automatic update checking using the Updates section of the Miscellaneous Settings dialog. You can also enable checking for beta versions.

You can manually check for updates at any time by choosing Help→Updates for Igor Pro. This works regardless of whether automatic update checking is enabled.

If your Internet access requires a proxy server or other unusual configuration, Igor's update checking mechanism may fail. In those cases you can always go to http://www.wavemetrics.net to see if an update is available.

Technical Support

WaveMetrics provides technical support via email.

To send an email to WaveMetrics support, start by choosing Help→Contact Support. This creates an email containing information about your Igor installation, such as your Igor serial number and the Igor version, which we need to provide support.

In most cases, we need to reproduce your problem in order to solve it. It is best if you can provide a simplified example showing the problem.

For information on upgrades and other nontechnical information, send queries to:

`sales@wavemetrics.com`

World Wide Web

You will find our Web site at:

```
http://www.wavemetrics.com/
```

You can also choose Help→WaveMetrics Home Page.

Our Web site contains a page for searching our support database, and links to Igor-related FTP sites and to Igor users' Web pages. In addition, it contains a number of cool graphs. We are always grateful for new cool graphs. Contact us at sales@wavemetrics.com if you have a cool graph to share.

Help Shortcuts

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To activate the Igor Help Browser	Choose Help→Igor Help Browser or click the Igor Help Browser icon in the lower-right corner of the command window.	Press F1, choose Help→Igor Help Browser, or click the Igor Help Browser icon in the lower-right corner of the command window.
To get a contextual menu of commonly-used actions	Control-click the body of an Igor help window.	Right-click the body of an Igor help window.
To jump to a topic in an Igor help window	Click a blue underlined topic link in the help window.	Click a blue underlined topic link in the help window.
To execute commands in an Igor help window	Select the commands and press Control-Return or Control-Enter.	Select the commands and press Ctrl+Enter.
To kill a help window	Option-click the close button.	Press Alt and click the close button.
To insert a function or operation template in a procedure window or in the command line	Type or select the name of an Igor operation or function, Control-click it, and choose Insert Template.	Type or select the name of an Igor operation or function, right-click it, and choose Insert Template.
To get help for a function or operation from a procedure, notebook or help window or from the command line	Type or select the name of an Igor operation or function, Control-click it, and choose Help For <name> or choose Help→Help For <name>.	Type or select the name of an Igor operation or function, right-click it, and choose Help For <name> or choose Help→Help For <name>.
To revisit a previously-viewed location	Press Cmd-Option-Left Arrow (Go Back) or Cmd-Option-Right Arrow (Go Forward).	Press Alt+Left Arrow (Go Back) or Alt+Right Arrow (Go Forward).

Chapter

II-2

The Command Window

Overview

You can control Igor using menus and dialogs or using commands that you execute from the command window. Some actions, for example waveform assignments, are much easier to perform by entering a command. Commands are also convenient for trying variations on a theme — you can modify and reexecute a command very quickly. If you use Igor regularly, you may find yourself using commands more and more for those operations that you frequently perform.

In addition to executing commands in the Command window, you can also execute commands in a notebook, procedure or help window. These techniques are less commonly used than the command window. See **Notebooks as Worksheets** on page III-4 for more information.

This chapter describes the command window and general techniques and shortcuts. See Chapter IV-1, **Working with Commands**, for details on command usage and syntax.

The command window consists of a **command line** and a **history area.** When you enter commands in the command line and press Return (*Macintosh*) or Enter (*Windows and Macintosh*), the commands are executed. Then they are saved in the history area for you to review. If a command produces text output, that output is also saved in the history area. A bullet character is prepended to command lines in the history so that you can easily distinguish command lines from output lines.

The Command window includes a help button just below the History area scroll bar. Clicking the button displays the Help Browser window.

The total length of a command on the command line is limited to 2500 bytes. A command executed in the command line must fit in one line.

Command Window Example

Here is a quick example designed to illustrate the power of commands and some of the shortcuts that make working with commands easy.

1. **Choose New Experiment from the File menu.**
2. **Execute the following command by typing in the command line and then pressing Return or Enter.**

   ```
   Make/N=100 wave0; Display wave0
   ```

   This displays a graph.
3. **Press Command-J** (*Macintosh*) **or Ctrl+J** (*Windows*)**.**

   This activates the command window.
4. **Execute**

   ```
   SetScale x, 0, 2*PI, wave0; wave0 = sin(x)
   ```

   The graph shows the sine of x from 0 to 2π.

   Now we are going to see how to quickly retrieve, modify and reexecute a command.
5. **Press the Up Arrow key.**

   This selects the command that we just executed.
6. **Press Return or Enter.**

   This transfers the selection back into the command line.
7. **Change the “2” to “4”.**

   The command line should now contain:

   ```
   SetScale x, 0, 4*PI, wave0; wave0 = sin(x)
   ```
8. **Press Return or Enter to execute the modified command.**

   This shows the sine of x from 0 to 4π.
9. **While pressing Option** (*Macintosh*) **or Alt** (*Windows*)**, click the last command in the history.**

   This is another way to transfer a command from the history to the command line. The command line should now contain:

   ```
   SetScale x, 0, 4*PI, wave0; wave0 = sin(x)
   ```

10. **Press Command-K** (*Macintosh*) **or Ctrl+K** (*Windows*)**.**

    This “kills” the contents of the command line.

    Now let’s see how you can quickly reexecute a previously executed command.

11. **With Command and Option** (*Macintosh*) **or Ctrl and Alt** (*Windows*) **pressed, click the second-to-last command in the history.**

    This reexecutes the clicked command (the 2*PI command).

    Repeat this step a number of times, clicking the second-to-last command each time. This will alternate between the 2*PI command and the 4*PI command.

12. **Execute**

    ```
    WaveStats wave0
    ```

    Note that the WaveStats operation has printed its results in the history where you can review them. You can also copy a number from the history to paste into a notebook or an annotation.

There is a summary of all command window shortcuts at the end of this chapter.

The Command Buffer

The command line shows the contents of the **command buffer**.

Normally the command buffer is either empty or contains just one line of text. However you can copy multiple lines of text from any window and paste them in the command buffer and you can enter multiple lines by pressing Shift-Return or Shift-Enter to enter a line break. You can drag the red divider line up to show more lines or down to show fewer lines.

You can clear the contents of the command buffer by choosing the Clear Command Buffer item in the Edit menu or by pressing Command-K (*Macintosh*) or Ctrl+K (*Windows*).

When you invoke an operation from a typical Igor dialog, the dialog puts a command in the command buffer and executes it. The command is then transferred to the history as if you had entered the command manually.

If an error occurs during the execution of a command, Igor leaves it in the command buffer so you can edit and reexecute it. If you don’t want to fix the command, you should remove it from the command buffer by pressing Command-K (*Macintosh*) or Ctrl+K (*Windows*).

Because the command buffer usually contains nothing or one command, we usually think of it as a single line and use the term “command line”.

Command Window Title

The title of the command window is the name of the experiment that is currently loaded. When you first start Igor or if you choose New from the File menu, the title of the experiment and therefore of the command window is “Untitled”.

When you save the experiment to a file, Igor sets the name of the experiment to the file name minus the file extension. If the file name is “An Experiment.pxp”, the experiment name is “An Experiment”. Igor displays “An Experiment” as the command window title.

For use in procedures, the **IgorInfo**(1) function returns the name of the current experiment.

History Area

The history area is a repository for commands and results.

Text in the history area can not be edited but can be copied to the clipboard or to the command line. Copying text to the clipboard is done in the normal manner. To copy a command from the history to the command buffer, select the command in the history and press Return or Enter. An alternate method is to press Option (*Macintosh*) or Alt (*Windows*) and click in the history area.

To make it easy tocopy a command from the history to the command line, clicking a line in the history area selects the entire line. You can still select just part of a line by clicking and dragging.

Up Arrow and Down Arrow move the selection range in the history up or down one line selecting an entire line at a time. Since you normally want to select a line in the history to copy a command to the command line, Up Arrow and Down Arrow skip over non-command lines. Left Arrow and Right Arrow move the insertion point in the command line.

When you save an experiment, the contents of the history area are saved. The next time you load the experiment the history will be intact. Some people have the impression that Igor recreates an experiment by reexecuting the history. This is not correct. See **How Experiments Are Loaded** on page II-26 for details.

Limiting Command History

The contents of the history area can grow to be quite large over time. You can limit the number of lines of text retained in the history using the Limit Command History feature in the Command Window section of the Miscellaneous Settings dialog which is accessible through the Misc menu.

If you limit command history, when you save the experiment, Igor checks the number of history lines. If they exceed the limit, the oldest lines are deleted.

History Archive

When history lines are deleted through the Limit Command History feature, the History Archive feature allows you to tell Igor to write the deleted lines to a text file in the experiment's home folder.

To enable the History Archive feature for a given experiment, create a plain text file in the home folder of the experiment. The text file must be named

```
<Experiment Name> History Archive UTF-8.txt
```

where <Experiment Name> is the name of the current experiment. Now, when you save the experiment, Igor writes any deleted history lines to the history archive file.

Prior to Igor Pro 7 the history archive file was written in system text encoding and was named

```
<Experiment Name> History Archive.txt
```

If you used the history archive in Igor Pro 6 you need to create a new history archive file whose name includes “UTF-8”.

If the history archive file is open in another program, including Igor, the history archive feature may fail and history lines may not be written.

History Carbon Copy

This feature is expected to be of interest only in rare cases for advanced Igor programmers such as Bela Farago who requested it.

You can designate a notebook to be a "carbon copy" of the history area by creating a plain text or formatted notebook and setting its window name, via Windows->Window Control, to HistoryCarbonCopy. If the HistoryCarbonCopy notebook exists, Igor inserts history text in the notebook as well as in the history. However, if a command is initiated from the HistoryCarbonCopy notebook (see **Notebooks as Worksheets** on page III-4), Igor suspends sending history text to that notebook during the execution of the command.

If you rename the notebook to something other than HistoryCarbonCopy, Igor will cease sending history text to it. If you later rename it back to HistoryCarbonCopy, Igor will resume sending history text to it.

The history trimming feature accessed via the Miscellaneous Settings dialog does not apply to the HistoryCarbonCopy notebook. You must trim it yourself. Notebooks are limited to 16 million paragraphs.

When using a formatted notebook as the history carbon copy, you can control the formatting of commands and results by creating notebook rulers named Command and Result. When Igor sends text to the history carbon copy notebook, it always applies the Command ruler to commands. It applies the Result ruler to results if the current ruler is Normal, Command or Result. You must create the Command and Result rulers if you want Igor to use them when sending text to the history carbon copy.

This function creates a formatted history carbon copy notebook with the Command and Result rulers used automatically by Igor as well as an Error ruler which we will use for our custom error messages:

```
Function CreateHistoryCarbonCopy()
   NewNotebook /F=1 /N=HistoryCarbonCopy /W=(50,50,715,590)

   Notebook HistoryCarbonCopy backRGB=(0,0,0)// Set background to black

   Notebook HistoryCarbonCopy showRuler=0

   // Define ruler to govern commands.
   // Igor will automatically apply this to commands sent to history carbon copy.
   Notebook HistoryCarbonCopy newRuler=Command,
                        rulerDefaults={"Geneva",10,0,(65535,65535,0)}

   // Define ruler to govern results.
   // Igor will automatically apply this to results sent to history carbon copy.
   Notebook HistoryCarbonCopy newRuler=Result,
                        rulerDefaults={"Geneva",10,0,(0,65535,0)}

   // Define ruler to govern user-generated error messages.
   // We will apply this ruler to error messages that we send
   // to history carbon copy via Print commands.
   Notebook HistoryCarbonCopy newRuler=Error,
rulerDefaults={"Geneva",10,0,(65535,0,0)}
End
```

If the current ruler is not Normal, Command or Result, it is assumed to be a custom ruler that you want to use for special messages sent to the history using the Print operation. In this case, Igor does not apply the Result ruler but rather allows your custom ruler to remain in effect.

This function sends an error message to the history using the custom Error ruler in the history carbon copy notebook:

```
Function PrintErrorMessage(message)
   String message

   Notebook HistoryCarbonCopy, ruler=Error
   Print message

   // Set ruler back to Result so that Igor's automatic use of the Command
   // and Result rulers will take effect for subsequent commands.
   Notebook HistoryCarbonCopy, ruler=Result
End
```

XOP programmers can use the XOPNotice3 XOPSupport routine to control the color of text sent to the History Carbon Copy notebook.

Searching the Command Window

You can search the command line or the history by choosing Find from the Edit menu or by using the keyboard shortcuts as shown in the Edit menu. This displays the find bar.

Searching the command line is most often used to modify a previously executed command before reexecuting it. For example, you might want to replace each instance of a particular wave name with another wave name.

If the history area has keyboard focus, usually indicated by an active selection in the history, the find bar searches the history area. If the command window has keyboard focus, the find bar searches the command line. To be sure that Find will search the area that you want, you can click in that area before starting the search.

Command Window Magnification

You can magnify the size of text in the command line and history area.

To magnify the command line text, right-click in the command line and select an item from the Magnification submenu. To make the new magnification your default magnification for new experiments, right-click again and choose Set as Default for Command Line from the same submenu.

To magnify the history area text, right-click in the history area and select an item from the Magnification submenu. To make the new magnification your default magnification for new experiments, right-click again and choose Set as Default for History Area from the same submenu.

Command Window Formats

You can change the text format used for the command line. For example, you might prefer a different color. To do this, click in the command line and then choose Set Text Format from the Command Buffer submenu of the Misc menu. To set the text format for the history area, click in the history area and then choose Set Text Format from the History Area submenu of the Misc menu. To do this, the history area must have some text in it.

You can set other properties, such as background color, by choosing Document Settings from the Command Buffer or History Area submenus. The Document Settings dialog also sets the header and footer used when printing the history.

When you change the text format or document settings, you are changing the current experiment only. You may want to capture the new format and settings as a preference for new experiments. To do this, choose Capture Prefs from the Command Buffer and History Area submenus.

Getting Help from the Command Line

When working with the command line, you might need help in formulating a command. There are shortcuts that allow you to insert a template, view help, or find the definition of a user function. The command line also supports **Command Completion**.

To insert a template, type the name of the operation or function, Control-click (*Macintosh*) or right-click (*Windows*), and choose Insert Template.

To view help or to view the definition of a user function, type the name of the operation or function, Control-click (*Macintosh*) or right-click (*Windows*), and choose Help for <name>.

Command Window Shortcuts

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To activate the command window	Press Command-J.	Press Ctrl+J.
To clear the command buffer	Press Command-K.	Press Ctrl+K.
To get a contextual menu of commonly-used actions	Press Control and click the history area or command line	Right-click the history area or command line
To copy a line from the history to the command buffer	Click the line and press Return or Enter. Press Option and click the line.	Click the line and press Enter. Press Alt and click the line.
To reexecute a line from the history	Click the line and press Return or enter twice Press Command-Option and click the line.	Click the line and press Ctrl+Enter Press Ctrl+Alt and click the line.
To find a recently executed command in the history	Press the Up or Down Arrow keys.	Press the Up or Down Arrow keys.
To find text in the history	Click in the history area and press Command-F.	Click in the history area and press Ctrl+F.
To find text in the command line	Click in the command line and press Command-F.	Click in the command line and press Ctrl+F.
To insert a template	Type or select the name of an operation, Control-click, and choose Insert Template.	Type or select the name of an operation, right-click, and choose Insert Template.
To get help for a built-in or external operation or function	Type or select the name of an operation, Control-click, and choose Help for <name> or choose Help→Help For <name>.	Type or select the name of an operation, right-click, and choose Help for <name> or choose Help→Help For <name>.
To view the definition of a user-defined function	Type or select the name of an operation, Control-click, and choose Go to <name> or choose Edit→Help For <name>.	Type or select the name of an operation, right-click, and choose Go to <name> or choose Edit→Help For <name>.

Chapter

II-3

Experiments, Files and Folders

Experiments

An **experiment** is a collection of Igor objects, including waves, variables, graphs, tables, page layouts, notebooks, control panels and procedures. When you create or modify one of these objects you are modifying the **current experiment**.

You can save the current experiment by choosing File→Save Experiment. You can open an experiment by double-clicking its icon on the desktop or choosing File→Open Experiment.

Saving Experiments

There are two formats for saving an experiment on disk:

- As a packed experiment file. A packed experiment file has the extension .pxp.

  All waves, procedure windows, and notebooks are saved packed into the experiment file unless you explicitly save them separately.
- As an experiment file and an experiment folder (unpacked format). An unpacked experiment file has the extension .uxp.

  All waves, procedure windows, and notebooks are saved in separate files.

The packed format is recommended for most purposes. The unpacked format is useful for experiments that include very large numbers of waves (thousands or more).

Saving as a Packed Experiment File

In the packed experiment file, all of the data for the experiment is stored in one file. This saves space on disk and makes it easier to copy experiments from one disk to another. *For most work, we recommend that you use the packed experiment file format*.

The folder containing the packed experiment file is called the **home folder**.

To save a new experiment in the packed format, choose Save Experiment from the File menu.

Saving as an HDF5 Packed Experiment File

In Igor Pro 9 and later, you can save an Igor experiment in an HDF5 file. The main advantage is that the data is immediately accessible to a wide array of programs that support HDF5. The main disadvantage is that you will need Igor Pro 9 or later to open the file in Igor. Also HDF5 is considerably slower than PXP for experiments with very large numbers of waves.

To save an experiment in HDF5 packed experiment format, choose File→Save Experiment As. In the resulting Save File dialog, choose "HDF5 Packed Experiment Files (*.h5xp)" from the pop-up menu under the list of files. Then click Save.

If you want to make HDF5 packed experiment format your default format for saving new experiments, choose Misc→Miscellaneous Settings. In the resulting dialog, click the Experiment category on the left. Then choose "HDF5 Packed (.h5xp)" from the Default Experiment Format pop-up menu.

For normal use you don't need to know the details of how Igor stores data in HDF5 packed experiment files, but, if you are curious, you can get a sense by opening such a file using the HDF5 Browser (Data→Load Waves→New HDF5 Browser).

Programmers who want to read or write HDF5 packed experiment files from other programs can find technical details under **HDF5 Packed Experiment Files** on page II-223.

HDF5 Compression for Saving Experiment Files

If you are just starting with Igor, we recommend that you skip this section until you have more familiarity with it.

In Igor Pro 9 and later, you can save HDF5 packed experiment files in compressed form. This section provides a brief introduction to HDF5 compression as it relates to saving experiment files. For details on compression, see **HDF5 Compression** on page II-213.

Compression can reduce file size but also takes more time. Whether compression is worthwhile for you depends on the nature of your data and how you trade off file size versus time. If your experiments contain lots of relatively small waves with lots of noise, compression will save little disk space. If your experiments contain large waves with large sections containing one value (for example, an image that is mostly black), compression can save considerable disk space. The only way to tell if compression is worthwhile for you is to experiment with it.

To save an HDF5 packed experiment with compression via the File menu you need to enable HDF5 default compression and then provide three parameters via the Experiment section of the Miscellaneous Settings dialog. The parameters are:

- The minimum size a wave must be before compression is used
- A compression level from 0 (no compression) to 9 (max)
- Whether you want to enable shuffle (an optional process before compression)

Here are instructions for testing HDF5 compression with your experiment files. These instructions use the SaveExperiment operation via the TestHDF5ExperimentCompression function, not File->Save Experiment, and consequently are independent of the default compression settings in the Miscellaneous dialog.

1. Activate the "Test HDF5 Experiment Compression.ipf" procedure file as a global procedure file and restart Igor. The file is in WaveMetrics Procedures/File Input Output in your Igor Pro folder.
2. If you don't know how to do this, see **Activating WaveMetrics Procedure Files** on page II-33.
3. Open a typical experiment file.
4. Execute this:

   ```
   TestHDF5ExperimentCompression(10000, 2, 0)
   ```

   10000 is the minimum number of elements in a wave to be compressed. Smaller waves are saved uncompressed.

   2 is the zip compression level.

   0 means shuffle is off which is usually what you want.

The TestHDF5ExperimentCompression command saves copies of the current experiment in uncompressed form and in compressed form using the specified parameters and prints a message in the command window history area showing the effect of compression on the time to save the experiment and on the file size. The command deletes the copies so there is no junk left over.

Try different parameters for the minimum wave size and zip compression level to see how they affect save time and compression ratio. In most cases, higher zip compression levels provide small increases in compression and are not worth the time required.

Unless you find significant compression ratios, we recommend that you eschew compression. Disk space is abundant and time is precious.

By default, compression is disabled when you use the File menu to save an HDF5 packed experiment file. If you decide that you want to use compression, see **HDF5 Default Compression** on page II-214 to learn how to enable compression via the Miscellaneous Settings dialog.

Saving as an Unpacked Experiment File

In the unpacked format, an experiment is saved as an **experiment file** and an **experiment folder**. The file contains instructions that Igor uses to recreate the experiment while the folder contains files from which Igor loads data. The experiment folder is also called the **home folder**.

The main utility of this format is that it is faster for experiments that contain very large numbers of waves (thousands or more). However the unpacked format is more fragile and thus is not recommended for routine use.

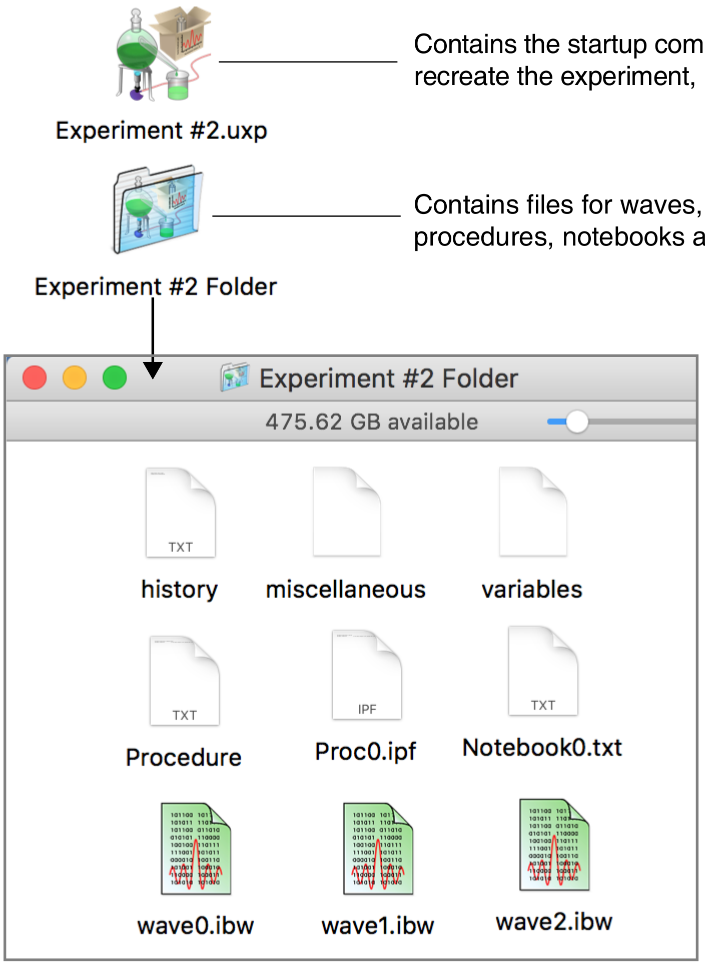
To save a new experiment in the unpacked format, choose Save Experiment from the File menu. At the bottom of the resulting Save File dialog, choose Unpacked Experiment Files from the popup menu. When you click Save, Igor writes the unpacked experiment file which as a ".uxp" extension.

Igor then automatically generates the experiment folder name by appending " Folder" or the Japanese equivalent, to the experiment file name. It then creates the unpacked experiment folder without further interaction. For example, if you enter "Test.uxp" as the unpacked experiment file name, Igor automatically uses "Test Folder", or the Japanese equivalent, as the unpacked experiment folder name.

If a folder named "Test Folder" already exists then Igor displays an alert asking if you want to reuse the folder for the unpacked experiment.

If the automatic generation of the unpacked experiment folder name causes a problem for you then you can save an experiment with the names of your choice using the **SaveExperiment** /F operation.

This illustration shows the icons used with an unpacked experiment and explains where things are stored.



Contains the startup commands that Igor executes to recreate the experiment, including all experiment windows.

Contains files for waves, variables, history, procedures, notebooks and other objects.

You normally have no need to deal with the files inside the experiment folder. Igor automatically writes them when you save an experiment and reads them when you open an experiment.

If the experiment includes data folders (see Chapter II-8, **Data Folders**) other than the root data folder, then Igor will create one subfolder in the experiment folder for each data folder in the experiment. The experiment shown in the illustration above contains no data folders other than root.

Note that there is one file for each wave. These are Igor Binary data files and store the wave data in a compact format. For the benefit of programmers, the Igor binary wave file format is documented in Igor Technical Note #003.

The “procedure” file holds the text in the experiment’s built-in procedure window. In this example, the experiment has an additional procedure window called Proc0 and a notebook.

The “variables” file stores the experiment’s numeric and string variables in a binary format.

The “miscellaneous” file stores pictures, page setup records, XOP settings, and other data.

The advantages of the unpacked experiment format are:

- Igor can save the experiment faster because it does not need to update files for waves, procedures or notebooks that have not changed.
- You can share files stored in one experiment with another experiment. However, sharing files can cause problems when you move an experiment to another disk. See **References to Files and Folders** on page II-24 for an explanation.

The disadvantages of the unpacked experiment format are:

- It takes more disk space, especially for experiments that have a lot of small waves.
- You need to keep the experiment file and folder together when you move the experiment to another disk.

Opening Experiments

You can open an experiment stored on disk by choosing Open Experiment from the File menu. You can first save your current experiment if it has been modified. Then Igor presents the Open File dialog.

When you select an experiment file and click the Open button, Igor loads the experiment, including all waves, variables, graphs, tables, page layouts, notebooks, procedures and other objects that constitute the experiment.

See **How Experiments Are Loaded** on page II-26 for details on how experiments are loaded.

Getting Information About the Current Experiment

You can see summary information about the current experiment by choosing File→Experiment Information. This displays the Experiment Information dialog.

The dialog shows when the current was last saved, whether it was modified since the last save, and other general information.

The dialog also shows whether the experiment uses long wave, variable, data folder, target window or symbolic path names. Experiments that use long names require Igor Pro 8.00 or later. See **Long Object Names** on page III-502 for details.

Merging Experiments

Normally Igor closes the currently opened experiment before opening a new one. But it is possible to merge the contents of an experiment file into the current experiment. This is useful, for example, if you want to create a page layout that contains graphs from two or more experiments. To do this, press Option (*Macintosh*) or Alt (*Windows*) and choose Merge Experiment from the File menu.

Note: *Merging experiments is an advanced feature that has some inherent problems and should be used judiciously*. If you are just learning to use Igor Pro, you should avoid merging experiments until you have become proficient. You may want to skim the rest of this section or skip it entirely. It assumes a high level of familiarity with Igor.

The first problem is that the merge operation creates a copy of data and other objects (e.g., graphs, procedure files, notebooks) stored in a packed experiment file. Whenever you create a copy there is a possibility that copies will diverge, creating confusion about which is the “real” data or object. One way to avoid this problem is to discard the merged experiment after it has served its purpose.

The second problem has to do with Igor’s use of names to reference all kinds of data, procedures and other objects. When you merge experiment B into experiment A, there is a possibility of name conflicts.

Igor prevents name conflicts for data (waves, numeric variables, string variables) by creating a new data folder to contain the data from experiment B. The new data folder is created inside the current data folder of the current experiment (experiment A in this case).

For other globally named objects, including graphs, tables, page layouts, control panels, notebooks, Gizmo plots, symbolic paths, page setups and pictures, Igor renames objects from experiment B if necessary to avoid a name conflict.

During the merge experiment operation, Igor looks for conflicts between target windows, between window recreation macros and between a target window and a recreation macro. If any such conflict is found, the window or window macro from experiment B is renamed.

Because page layouts reference graphs, tables, Gizmo plots, and pictures by name, renaming any of these objects may affect a page layout. The merge experiment operation handles this problem for page layouts that are open in experiment B. It does not handle the problem for page layout recreation macros in experiment B that have no corresponding open window.

If there are name conflicts in procedures other than window recreation macros, Igor will flag an error when it compiles procedures after finishing the merge experiment operation. You will have to manually resolve the name conflict by removing or renaming conflicting procedures.

Procedure windows have titles but do not have standard Igor names. The merge experiment operation makes no attempt to retitle procedure windows that have the same title.

The contents of the main procedure window from experiment B are appended to the contents of the main procedure window for experiment A.

During a normal experiment open operation, Igor executes experiment initialization commands. This is not done during an experiment merge.

Each experiment contains a default font setting that affects graphs and page layouts. When you do an experiment merge, the default font setting from experiment B is ignored, leaving the default font setting for experiment A intact. This may affect the appearance of graphs and layouts in experiment B.

The history from experiment B is not merged into experiment A. Instead, a message about the experiment merge process is added to the history area.

The system variables (K0…K19) from experiment B are ignored and not merged into experiment A.

Although the merge experiment operation handles the most common name conflict problems, there are a number problems that it can not handle. For example, a procedure, dependency formula or a control from experiment B that references data using a full path may not work as expected because the data from experiment B is loaded into a new data folder during the merge. Another example is a procedure that references a window, symbolic path or picture that is renamed by the merge operation because of a name conflict. There are undoubtedly many other situations where name conflicts could cause unexpected behavior.

Reverting an Experiment

If you choose Revert Experiment from the File menu, Igor asks if you’re sure that you want to discard changes to the current experiment. If you answer Yes, Igor reloads the current experiment from disk, restoring it to the state it was in when you last saved it.

New Experiments

If you choose New from the File menu, Igor first asks if you want to save the current experiment if it was modified since you last saved it. Then Igor creates a new, empty experiment. The new experiment has no experiment file until you save it.

By default, when you create a new experiment, Igor automatically creates a new, empty table. This is convenient if you generally start working by entering data manually. However, in Igor data can exist in memory without being displayed in a table. If you wish, you can turn automatic table creation off using the Experiment Settings category of the Miscellaneous Settings dialog (Misc menu).

Saving an Experiment as a Template

A template experiment provides a way to customize the initial contents of a new experiment. When you open a template experiment, Igor opens it normally but leaves it untitled and disassociates it from the template experiment file. This leaves you with a new experiment based on your prototype. When you save the untitled experiment, Igor creates a new experiment file.

Packed template experiments have ".pxt" as the file name extension instead of ".pxp". Unpacked template experiments have ".uxt" instead of ".uxp".

To make a template experiment, start by creating a prototype experiment with whatever waves, variables, procedures and other objects you would like in a new experiment. Then choose File→Save Experiment As, choose Packed Experiment Template or Unpacked Experiment Template from the file type pop-up menu, and save the template experiment.

You can convert an existing experiment file into a template file by changing the extension (".pxp" to ".pxt" or ".uxp" to ".uxt").

The Macintosh Finder’s file info window has a Stationery Pad checkbox. Checking it turns a file into a stationery pad. When you double-click a stationery pad file, Mac OS X creates a copy of the file and opens the copy. For most uses, the template technique is more convenient.

Browsing Experiments

You can see what data exists in the current experiment as well as experiments saved on disk using the Data Browser. To open the browser, choose Data→Data Browser. Then click the Browse Expt button. See **Data Folders** on page II-107 for details.

File Names and Paths

Igor supports file names up to 255 bytes long.

File paths can be up to 2000 byte long. Igor's 2000 byte limit applies even if the operating system supports longer paths.

As of this writing, on Macintosh, the operating system limits paths to 1026 bytes.

On Windows, prior to Windows 10 build 1607, released in August of 2016, the operating system limited paths to 260 bytes. Build 1607 raised this limit to 32767 characters. As of this writing, this feature is available only on systems that have "opted in" by setting the LongPathsEnabled registry setting. Using paths longer than 260 bytes may cause errors on some systems and with some software.

As described under **Path Separators** on page III-451, Igor accepts paths with either colons or backslashes on either platform.

The use of backslashes is complicated by the fact that Igor uses the backslash character as an escape character in literal strings. This is also described in detail under **Path Separators** on page III-451. The simplest solution to this problem is to use colon to separate path elements, even when you are running on Windows.

If you are writing procedures that need to extract sections of file paths or otherwise manipulate file paths, the **ParseFilePath** function may come in handy.

Symbolic Paths

A symbolic path is an Igor object that associates a short name with a folder on a disk drive. You can use this short name instead of a full path to specify a folder when you load, open or save a file. We recommend using symbolic paths instead of full paths when possible because they are more easily changed if your disk organization changes or if you want to access another location on disk.

Igor creates symbolic paths for the “Igor Pro Folder”, the “Igor Pro User Files” folder and for the current experiment’s home folder automatically. These symbolic paths exist in all experiments.

You can also create custom symbolic paths pointing to any folder on disk. These symbolic paths are part of the current experiment and cease to exist when you create a new experiment.

The New Symbolic Path Dialog

To access the New Symbolic Path dialog, choose New Path from the Misc menu. Use of this dialog is illustrated in the next section.

Symbolic Path Example

This example illustrate why you should use symbolic paths and how to use them. We assume that you have a folder full of text files containing data that you want to graph in Igor and that the organization of your hard disk is as follows:

```
hd or C:
   Users
      Jack
         Documents
            Data
               2016
                  May
                  June
                  July
```

Assume that we want to access files in the June folder.

To create a symbolic path for the folder:

1. Choose New Path from the Misc menu. This displays the New Symbolic Path dialog.
2. Enter Data in the Name field.
3. Click the Path button and locate the June folder.
4. Check the Overwrite checkbox.
5. Click Do It to create the symbolic path.

The NewPath command created by the dialog makes a symbolic path named Data which references:

```
hd:Users:Jack:Documents:Data:2016:June     (Macintosh)
C:\Users\Jack\Documents\Data\June          (Windows)
```

The command generated by the dialog uses Macintosh-style paths with colons separating components:

```
NewPath/O Data, "hd:Users:Jack:Documents:Data:2016:June"     // Macintosh

NewPath/O Data, "C:Users:Jack:Documents:Data:2016:June"      // Windows
```

The NewPath operation can also accept Windows-style paths with backslash characters, but this can cause problems and is not recommended. For details, see **Path Separators** on page III-451.

Once you have created it, you can select the Data path in dialogs where you need to choose a file. For example, in the Load Waves dialog, you can select Data from the Path list. You then click the File button and choose the file to be loaded. Igor generates a command like:

```
LoadWave /J /P=Data "Data1.txt"
LoadWave /J /P=Data "Data2.txt"
LoadWave /J /P=Data "Data3.txt"
```

These commands load data files from the June folder.

By using a symbolic path instead of the full path to the file to be loaded, you have isolated the location of the data files in one object - the symbolic path itself. This makes it easy to redirect commands or procedures that use the symbolic path. For example, you can re-execute the NewPath command replacing June with July:

```
NewPath/O Data, "hd:Users:Jack:Documents:Data:2016:July"    // Macintosh
```

```
NewPath/O Data, "C:Users:Jack:Documents:Data:2016:July"     // Windows
```

Now, if you re-execute the LoadWave commands, they will load data from July instead of June.

Isolating a specific location on disk in a symbolic path also simplifies life when you move from one user to another or from one machine to another. Instead of needing to change the full path in many commands, you can simply change the symbolic path.

Automatically Created Paths

Igor automatically creates a symbolic path named **Igor** which refers to the “Igor Pro 9 Folder”. The Igor symbolic path is useful only in rare cases when you want to access a file in the Igor Pro folder.

Igor also automatically creates a symbolic path named **IgorUserFiles** which refers to the Igor Pro User Files folder - see Special Folders for details. The IgorUserFiles symbolic path was added in Igor Pro 7.00.

Igor also automatically creates the **home** symbolic path. This path refers to the home folder for the current experiment. For unpacked experiments, this is the experiment folder. For packed experiments, this is the folder containing the experiment file. For new experiments that have never been saved, home is undefined.

Finally, Igor automatically creates a symbolic path if you do something that causes the current experiment to reference a file not stored as part of the experiment. This happens when you:

- Load an Igor binary wave file from another experiment into the current experiment
- Open a notebook file not stored with the current experiment
- Open a procedure file not stored with the current experiment

Creating these paths makes it easier for Igor to find the referenced files if they are renamed or moved. See **References to Files and Folders** on page II-24 for more information.

Symbolic Path Status Dialog

The Symbolic Path Status dialog shows you what paths exist in the current experiment. To invoke it, choose Path Status from the Misc menu.

The dialog also shows waves, notebook files, and procedure files referenced by the current experiment via a given symbolic path.

The Kill Paths Dialog

The Kill Symbolic Paths dialog removes from the current experiment symbolic paths that you no longer need. To invoke the dialog, choose Kill Paths from the Misc menu.

Killing a path does nothing to the folder referenced by the symbolic path. It just deletes the symbolic path name from Igor’s list of symbolic paths.

A symbolic path is in use — and Igor won’t let you kill it — if the experiment contains a wave, notebook window or procedure window linked to a file in the folder the symbolic path points to.

References to Files and Folders

An experiment can *reference* files that are not stored with the experiment. This happens when you load an Igor binary data file which is stored with a different experiment or is not stored with any experiment. It also happens when you open a notebook or procedure file that is not stored with the current experiment. We say the current experiment is *sharing* the wave, notebook or procedure file.

For example, imagine that you open an existing text file as a notebook and then save the experiment. The data for this notebook is in the text file somewhere on your hard disk. It is not stored in the experiment. What *is* stored in the experiment is a *reference* to that file. Specifically, the experiment file contains a command that will reopen the notebook file when you next reopen the experiment.

Note: When an experiment refers to a file that is not stored as part of the experiment, there is a potential problem. If you copy the experiment to an external drive to take it to another computer, for example, the experiment file on the external drive will contain a *reference* to a file on your hard disk. If you open the experiment on the other computer, Igor will ask you to find the referenced file. If you have forgotten to also copy the referenced file to the other computer, Igor will not be able to completely recreate the experiment.

For this reason, we recommend that you use references only when necessary and that you be aware of this potential problem.

If you transfer files between platforms file references can be particularly troublesome. See **Experiments and Paths** on page III-449.

Avoiding Shared Igor Binary Wave Files

When you load a wave from an Igor binary wave file stored in another experiment, you need to decide if you want to *share* the wave with the other experiment or *copy* it to the new experiment. Sharing creates a reference from the current experiment to the wave’s file and this reference can cause the problem noted above. Therefore, you should avoid sharing unless you want to access the same data from multiple experiments *and* you are willing to risk the problem noted above.

If you load the wave via the Load Igor Binary dialog, Igor will ask you if you want to share or copy. You can use the Miscellaneous Settings dialog to always share or always copy instead of asking you.

If you load the wave via the LoadWave operation, from the command line or from an Igor procedure, Igor will *not* ask what you want to do. You should normally use LoadWave’s /H flag, tells Igor to “copy the wave to home” and avoids sharing.

If you use the Data Browser to transfer waves from one experiment to another, Igor always copies the waves.

For further discussion, see **Home Versus Shared Waves** on page II-87 and **Home Versus Shared Text Files** on page II-56.

Adopting Files

Adoption is a way for you to copy a shared wave, notebook, or procedure file into the current experiment and break the connection to its original file. Adoption makes an experiment less fragile by being more self-contained. If you transfer it to another computer or send it to a colleague, all of the files needed to recreate the experiment will be stored in the experiment itself.

Adopting Waves

To adopt a wave file, select the wave in the Data Browser, right-click, and choose Adopt Wave. The Adopt Wave item is enabled only if the wave is shared. You can select multiple waves and adopt them in one step.

You can also adopt waves using File→Adopt All. See **Adopt All** below.

When you adopt a wave, Igor disconnects it from its original standalone file. The original file remains intact, but it is no longer referenced by the current experiment. The adoption is not final until you save the experiment.

If the current experiment is stored in packed form then, when you adopt a wave, it is saved in the packed experiment file. For an unpacked experiment, it is saved in the disk folder corresponding the waves data folder in the experiment folder.

Adopting Notebook and Procedure Files

To adopt a notebook or procedure file, choose Adopt Notebook or Adopt Procedure from the File menu. This item will be available only if the active window is a notebook or procedure file that is stored separate from the current experiment and the current experiment has been saved to disk.

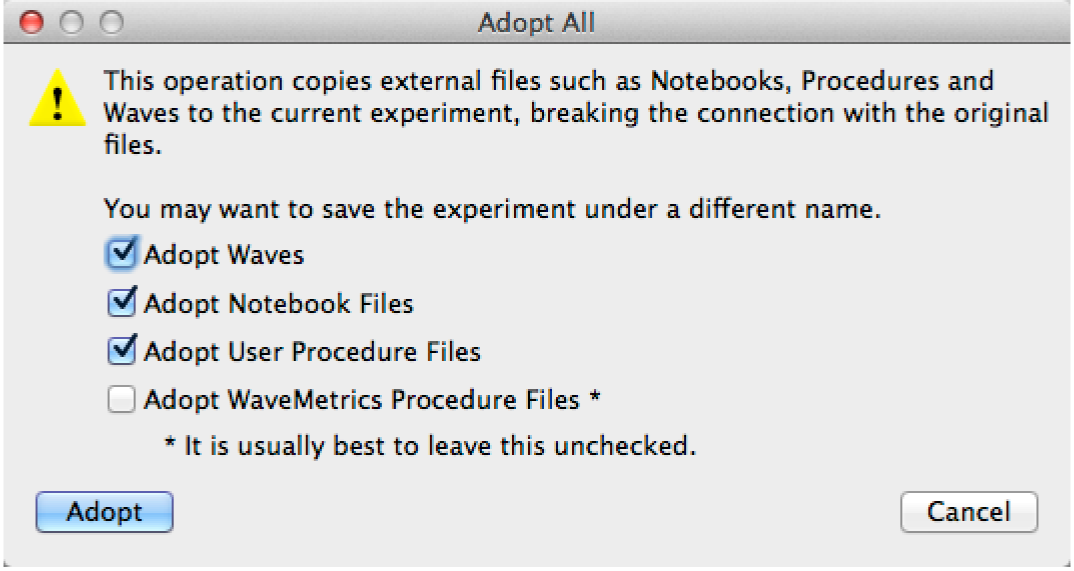
If the current experiment is stored in packed form then, when you adopt a file, Igor does a save-as to a temporary file. When you subsequently save the experiment, the contents of the temporary file are stored in the packed experiment file. Thus, the adoption is not finalized until you save the experiment.

If the current experiment is stored in unpacked form then, when you adopt a file, Igor does a save-as to the experiment's home folder. When you subsequently save the experiment, Igor updates the experiment's recreation procedures to open the new file in the home folder instead of the original file. Note that if you adopt a file in an unpacked experiment and then you do not save the experiment, the new file will still exist in the home folder but the experiment's recreation procedures will still refer to the original file. Thus, you should save the experiment after adopting a file.

To "unadopt" a procedure or notebook file, choose Save Procedure File As or Save Notebook As from the File menu.

Adopt All

You can adopt all referenced notebooks, procedure files and waves by pressing Shift and choosing File→Adopt All. This is useful when you want to create a self-contained packed experiment to send to someone else.



Adopt All

This operation copies external files such as Notebooks, Procedures and Waves to the current experiment, breaking the connection with the original files.

You may want to save the experiment under a different name.

☑ Adopt Waves

☑ Adopt Notebook Files

☑ Adopt User Procedure Files

□ Adopt WaveMetrics Procedure Files *

* It is usually best to leave this unchecked.

After clicking Adopt, choose File→Save Experiment As to save the packed experiment.

Saving All Standalone Files

Programmers may sometimes edit multiple procedure files while working on a given task. You can save all modified standalone procedure files in one step by choosing File→Save All Standalone Procedure Files. This saves standalone procedure files only, not packed procedure files including the built-in procedure window or new procedure windows that have not yet been saved to a file. The Save All Standalone Procedure Files menu item is available only when the active window is a procedure window.

Likewise you can save all modified notebook windows in one step by choosing File→Save All Standalone Notebook Files. This saves standalone notebook files only, not packed notebook files or new notebook windows that have not yet been saved to a file. The Save All Notebook Procedure Files menu item is available only when the active window is a notebook window.

How Experiments Are Loaded

It is not essential to know how Igor stores your experiment or how Igor recreates it. However, understanding this may help you avoid some pitfalls and increase your overall understanding of Igor.

Experiment Recreation Procedures

When you save an experiment, Igor creates procedures and commands, called “experiment recreation procedures” that Igor will execute the next time you open the experiment. These procedures are normally not visible to you. They are stored in the experiment file.

The experiment file of an unpacked experiment contains plain text, but its extension is not “.txt”, so you can’t open it with most word processors or editors.

As an example, let’s look at the experiment recreation procedures for a very simple unpacked experiment:

```
// Platform=Macintosh, IGORVersion=8.000, ...

// Creates the home symbolic path
NewPath home ":Unpacked Experiment Folder:"

// Reads the experiment variables from the "variables" file
ReadVariables

// Loads the experiment's waves
LoadWave/C /P=home "wave0.ibw"
LoadWave/C /P=home "wave1.ibw"
LoadWave/C /P=home "wave2.ibw"

DefaultFont "Helvetica"

MoveWindow/P 5,62,505,335         // Positions the procedure window
MoveWindow/C 2,791,1278,1018      // Positions the command window

Graph0()                          // Recreates the Graph0 window

// Graph recreation macro for Graph0
Window Graph0() : Graph
   PauseUpdate; Silent 1   // building window...
   Display /W=(35,44,430,252) wave0,wave1,wave2
EndMacro
```

When you open the experiment, Igor reads the experiment recreation procedures from the experiment file into the procedure window and executes them. The procedures recreate all of the objects and windows that constitute the experiment. Then the experiment recreation procedures are removed from the procedure window and your own procedures are loaded from the experiment’s procedure file into the procedure window.

For a packed experiment, the process is the same except that all of the data, including the experiment recreation procedures, is packed into the experiment file.

Experiment Initialization Commands

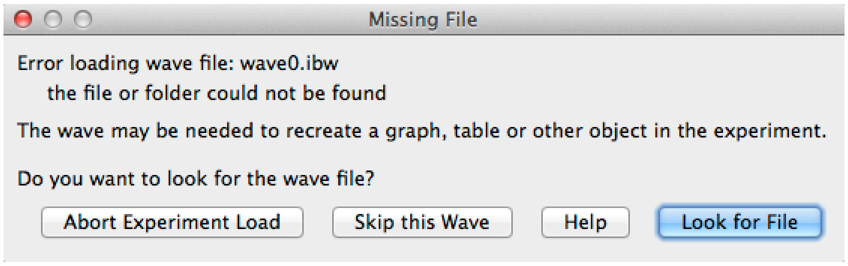
After executing the experiment recreation procedures and loading your procedures into the procedure window, Igor checks the contents of the procedure window. Any commands that precede the first macro, function or menu declaration are considered **initialization commands**. If you put any initialization commands in your procedure window then Igor executes them. This mechanism initializes an experiment when it is first loaded.

Savvy Igor programmers can also define a function that is executed whenever Igor opens any experiment. See **User-Defined Hook Functions** on page IV-280.

Errors During Experiment Load

It is possible for the experiment loading process to fail to run to a normal completion. This occurs most often when you move or rename a file or folder. It also happens if you move an experiment to a different computer and forget to also move referenced files or folders. See **References to Files and Folders** on page II-24 for details.

When a file is missing, Igor presents a dialog giving you several options:



Missing File

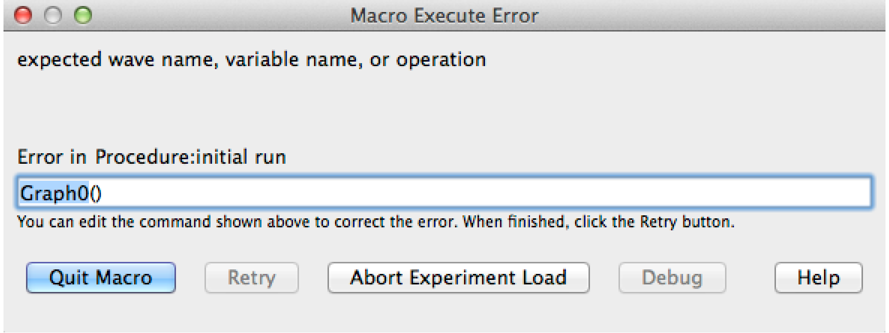
Error loading wave file: wave0.ibw
the file or folder could not be found

The wave may be needed to recreate a graph, table or other object in the experiment.

Do you want to look for the wave file?

If you elect to abort the experiment load, Igor will alert you that the experiment is in an inconsistent state. It displays some diagnostic information that might help you understand the problem and changes the experiment to Untitled. You should choose New Experiment or Open Experiment from the File menu to clear out the partially loaded experiment.

If you elect to skip loading a wave file, you may get another error later, when Igor tries to display the wave in a graph or table. In that case, you will see a dialog like this:



Macro Execute Error

expected wave name, variable name, or operation

Error in Procedure:initial run

Graph0()

You can edit the command shown above to correct the error. When finished, click the Retry button.

In this example, Igor is executing the Graph0 macro from the experiment recreation procedures in an attempt to recreate a graph. Since you elected to skip loading wave0, Igor can’t display it.

You have three options at this point, as explained in the following table.

Option	Effect
Quit Macro	Stops executing the current macro but continues experiment load. In this example, Graph0 would not be recreated. After the experiment load Igor displays diagnostic information.
Abort Experiment Load	Aborts the experiment load immediately and displays diagnostic information.
Retry	In this example, you could fix the macro by deleting “wave0,”. You would then click the Retry button. Igor would create Graph0 without wave0 and would continue the experiment load.

With the first two options, Igor leaves the experiment untitled so that you don’t inadvertently wipe out the original experiment file by doing a save.

How Igor Handles Missing Folders

When Igor saves an experiment, it stores commands in the experiment file that will recreate the experiment’s symbolic paths when you reopen the experiment. The commands look something like this:

```
NewPath home ":Test Exp Folder:"
NewPath/Z Data1 "::Data Folder #1:"
NewPath Data2 "::Data Folder #2:"
NewPath/Z Data3 "hd:Test Runs:Data Folder #3:"      // Macintosh
NewPath/Z Data3 "C:Test Runs:Data Folder #3:"       // Windows
```

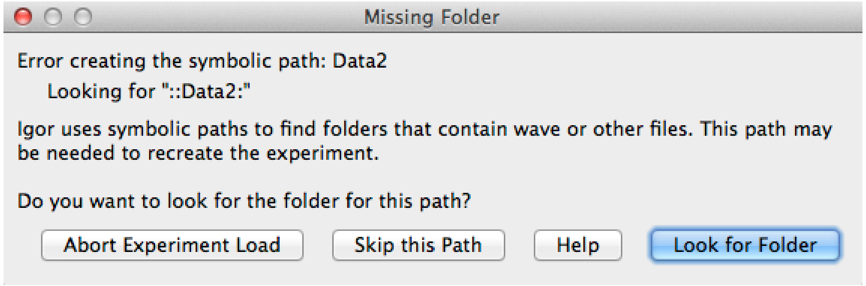
The location of the home folder is specified relative to the folder containing the experiment file. The locations of all other folders are specified relative to the experiment folder or, if they are on a different volume, using absolute paths. Using relative paths, where possible, ensures that no problems will arise if you move the experiment file and experiment folder *together* to another disk drive or another location on the same disk drive.

The /Z flags indicate that the experiment does not need to load any files from the Data1 and Data3 folders. In other words, the experiment has symbolic paths for these folders but no files need to be loaded from them to recreate the experiment.

When you reopen the experiment, Igor executes these NewPath commands. If you have moved or renamed folders, or if you have moved the experiment file, the NewPath operation will be unable to find the folder.

If the folder associated with the symbolic path is not needed to recreate the experiment, the NewPath command includes the /Z flag. In this case, Igor skips the creation of the symbolic path, generates no error, and just continues the load. The experiment will wind up without the missing symbolic path.

If the missing folder is needed to load waves, notebooks or procedure files then Igor asks if you want to look for the folder by displaying the Missing Folder dialog.



Error creating the symbolic path: Data2

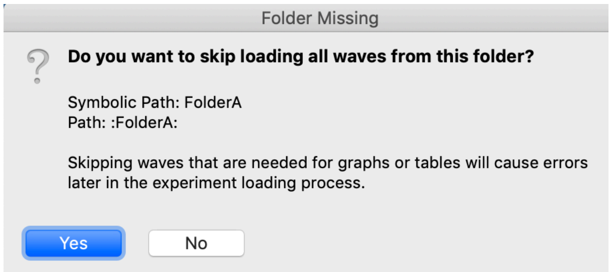
Looking for "::Data2:"

Igor uses symbolic paths to find folders that contain wave or other files. This path may be needed to recreate the experiment.

Do you want to look for the folder for this path?

If you click Look for Folder, Igor presents a Choose Folder dialog in which you can locate the missing folder.

If you click Skip This Path, Igor does not create the symbolic path. Igor then asks if you want to skip waves loaded using the symbolic path that is being skipped:



Folder Missing

Do you want to skip loading all waves from this folder?

Symbolic Path: FolderA
Path: :FolderA:

Skipping waves that are needed for graphs or tables will cause errors later in the experiment loading process.

If you click Yes, Igor skips all LoadWave commands using the symbolic path associated with the missing folder. This will cause errors later in the experiment loading process if the waves are needed for graphs, tables or other windows.

If you click No and the folder contains wave files referenced by the experiment, you will get Missing File dialogs later in the process giving you a chance to locate the wave files.

For example, if the experiment loads two waves using the Data2 path then the experiment's recreation commands would contain two lines like this:

```
LoadWave/C/P=Data2 "wave0.ibw"
LoadWave/C/P=Data2 "wave1.ibw"
```

If you elected to skip creating the Data2 path and clicked Yes when asked if you want to skip waves from that path, then Igor skips these LoadWave commands altogether.

If you elected to skip creating the Data2 path and clicked No when asked if you want to skip waves from that path, then each of these LoadWave commands presents the Missing File dialog.

If you were unable to find the Data2 folder then each of these LoadWave commands will present the Missing Wave File dialog.

If you are unable to find the wave file and if the wave is used in a graph or table, you will get more errors later in the experiment recreation process, when Igor tries to use the missing wave to recreate the graph or table.

How Experiments Are Saved

When you save an experiment for the first time, Igor just does a straight-forward save in which it creates a new file, writes to it, and closes it. However, when you resave a pre-existing experiment, which overwrites the previous version of the experiment file, Igor uses a "safe save" technique. This technique is designed to preserve your original file in the event of an error while writing the new version.

For purposes of illustration, we will assume that we are resaving an experiment file named "Experiment.pxp". The safe save proceeds as follows:

1. Rename the original file as "Experiment.pxp.T0.noindex". If an error occurs during this step, the save operation is stopped and Igor displays an error message.
2. Write the new version of the file as "Experiment.pxp".
3. If step 2 succeeds, delete the original file ("Experiment.pxp.T0.noindex").

   If step 2 fails, delete the new version of the file and rename the original version with the original name.

The ".noindex" suffix tells Apple's Spotlight program not to interfere with the save by opening the temporary file at an inopportune time.

The next three subsections are for use in troubleshooting file saving problems only. If you are not having a problem, you can skip them.

Experiment Save Errors

There are many reasons why an error may occur during the save of an experiment. For example, you may run out of disk space, the server volume you are saving to might be disconnected, or you may have a hardware failure, but these are uncommon.

The most common reason for a save error is that you cannot get write access to the file because:

1. The file is locked (Macintosh Finder) or marked read-only (Windows desktop).
2. You don't have permission to write to the folder containing the file.
3. You don't have permission to write to this specific file.
4. The file has been opened by another application. This could be a virus scanner, an anti-spyware program or an indexing program such as Apple's Spotlight.

Here are some troubleshooting techniques.

Macintosh File Troubleshooting

Open the file's Get Info window and verify that the file is not marked as locked. Also check the lock setting of the folder containing the file.

Next try doing a Save As to a folder for which you know you have write access, for example, to your home folder (e.g., "/Users/<user>" where <user> is your user name). If this works, the problem may be that you did not have sufficient permissions to write to the original folder or to the original file. Use the Finder Get Info window Sharing and Permissions section to make sure that you have read/write access for the file and folder.

If you are able to save a file to a new location but get an error when you try to resave the file, which overwrites the original file, then this may be an issue of another program opening the file at an inopportune time.

Windows File Troubleshooting

Open the file's Properties window and uncheck the read-only checkbox if it is checked. Do the same for the folder containing the file.

Next try doing a Save As to a folder for which you know you have write access, for example, to your Documents folder. If this works, the problem may be that you did not have sufficient permissions to write to the original folder or to the original file. This would happen, for example, if the folder was inside the Program Files folder and you are not running as an administrator.

If you think you should be able to write to the original file location, you will need to investigate permissions. You may want to enlist the help of a local expert as this can get complicated and works differently in different versions of Windows.

If you are able to save a file to a new location but get an error when you try to resave the file, which overwrites the original file, then this may be an issue of another program opening the file at an inopportune time. This typically happens in step 3 of the safe-save technique described above. Try disabling your antivirus software. For a technical explanation of this problem, see http://support.microsoft.com/kb/316609.

Special Folders

This section describes special folders that Igor automatically searches when looking for help files, Igor extensions (plug-ins that are also called XOPs) and procedure files.

Igor Pro Folder

The Igor Pro folder is the folder containing the Igor application on Macintosh and the IgorBinaries folder on Windows. By default, this folder has the Igor Pro major version number in its name, for example, “Igor Pro 9 Folder”, but it is generically called the “Igor Pro Folder”.

Igor looks inside the Igor Pro Folder for these special subfolders:

```
Igor Help Files
Igor Extensions
Igor Extensions (64-bit)
Igor Procedures
User Procedures
WaveMetrics Procedures
```

The Igor installer puts files in the special folders. Igor searches them when looking for help files, extensions and procedure files. *With very rare exceptions, you should not make any changes to the Igor Pro Folder.*

Igor Pro User Files

At launch time, Igor creates a special folder called the Igor Pro User Files folder. By default, this folder has the Igor Pro major version number in its name, for example, "Igor Pro 9 User Files", but it is generically called the "Igor Pro User Files" folder.

On Macintosh, the Igor Pro User Files folder is created by default in:

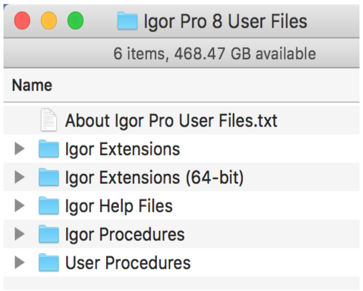
```
/Users/<user>/Documents/WaveMetrics
```

On Windows it is created by default in:

```
C:\Users\<user>\Documents\WaveMetrics
```

You can change the location of your Igor Pro User Files folder using Misc→Miscellaneous Settings but this should rarely be necessary.

The Igor Pro User Files folder looks like this:



Igor Pro 8 User Files

6 items, 468.47 GB available

Name

About Igor Pro User Files.txt
Igor Extensions
Igor Extensions (64-bit)
Igor Help Files
Igor Procedures
User Procedures

You can activate additional help files, extensions and procedure files that are part of the Igor Pro installation, that you create, or that you receive from third parties. To do this, add files, or aliases/shortcuts pointing to files, to the special subfolders within the Igor Pro User Files folder. See **Activating WaveMetrics Procedure Files** on page II-33 **Activating WaveMetrics XOPs** on page II-33 for details on activating additional WaveMetrics files.

You can display the Igor Pro User Files folder on the desktop by choosing Help→Show Igor Pro User Files. To display both the Igor Pro Folder and the Igor Pro User Files folder, which you typically want to do to activate a WaveMerics XOP or procedure file, press the shift key and choose Help→Show Igor Pro Folder and User Files.

Igor Help Files Folder

When Igor starts up, it opens any Igor help files in "Igor Pro Folder/Igor Help Files" and in "Igor Pro User Files/Igor Help Files". It treats any aliases, shortcuts and subfolders in "Igor Help Files" in the same way.

Standard WaveMetrics help files are pre-installed in "Igor Pro Folder/Igor Help Files".

If there is an additional help file that you want Igor to automatically open at launch time, put it or an alias/shortcut for it in "Igor Pro User Files/Igor Help Files".

Igor Extensions Folder

An Igor extension, also called an XOP (“external operation”), is a plug-in that adds functionality to Igor. WaveMetrics provides some extensions with Igor. Igor users and third parties can also create extensions. See **Igor Extensions** on page III-511 for details.

Igor extensions come in 32-bit and 64-bit versions. 32-bit extensions can run only with IGOR32 (the 32-bit version of Igor) and 64-bit extensions can run only with IGOR64 (the 64-bit version of Igor). As noted under **Igor 32-bit and 64-bit Versions** on page I-2, both IGOR32 and IGOR64 are installed on Windows but only IGOR64 is available on Macintosh.

When IGOR32 starts up, it searches "Igor Pro Folder/Igor Extensions" and "Igor Pro User Files/Igor Extensions" for 32-bit Igor extension files. These extensions are available for use in IGOR32. It treats any aliases, shortcuts and subfolders in "Igor Extensions" in the same way.

When IGOR64 starts up, it searches "Igor Pro Folder/Igor Extensions (64-bit)" and "Igor Pro User Files/Igor Extensions (64-bit)" for 64-bit Igor extension files. These extensions are available for use in IGOR64. It treats any aliases, shortcuts and subfolders in "Igor Extensions (64-bit)" in the same way.

Standard WaveMetrics extensions are pre-installed in "Igor Pro Folder/Igor Extensions" and "Igor Pro Folder/Igor Extensions (64-bit)".

Additional WaveMetrics extensions are described in the "XOP Index" help file, which you can access through the Help→Help Windows menu, and can be found in "Igor Pro Folder/More Extensions" and "Igor Pro Folder/More Extensions (64-bit)".

If there is an additional extension that you want to use, put it or an alias/shortcut pointing to it in "Igor Pro User Files/Igor Extensions" or "Igor Pro User Files/Igor Extensions (64-bit)".

Igor Procedures Folder

When Igor starts up, it automatically opens any procedure files in "Igor Pro Folder/Igor Procedures" and in "Igor Pro User Files/Igor Procedures". It treats any aliases, shortcuts and subfolders in "Igor Procedures" in the same way. Such procedure files are called "global" procedure files and are available for use from all experiments. See **Global Procedure Files** on page III-399 for details.

Standard WaveMetrics global procedure files are pre-installed in "Igor Pro Folder/Igor Procedures".

Additional WaveMetrics procedure files are described in the "WM Procedures Index" help file and can be found in "Igor Pro Folder/WaveMetrics Procedures". You may also create your own global procedure files or obtain them from third parties.

If there is an additional procedure file that you want Igor to automatically open at launch time, put it or an alias/shortcut pointing to it in "Igor Pro User Files/Igor Procedures".

User Procedures Folder

You can load a procedure file from another procedure file using a #include statement. This technique is used when one procedure file requires another. See **Including a Procedure File** on page III-401 for details.

When Igor encounters a #include statement, it searches for the included procedure file in "Igor Pro-Folder/User Procedures" and in "Igor Pro User Files/User Procedures". Any aliases, shortcuts and subfolders in "User Procedures" are treated the same way.

If there is an additional procedure file that you want to include from your procedure files, put it or an alias/shortcut pointing to it in "Igor Pro User Files/User Procedures".

WaveMetrics Procedures Folder

The "Igor Pro Folder/WaveMetrics Procedures" folder contains an assortment of procedure files created by WaveMetrics that may be of use to you. These files are described in the WM Procedures Index help file which you can access through the Help→Help Windows menu.

You can load a WaveMetrics procedure file from another procedure file using a #include statement. See **Including a Procedure File** on page III-401 for details.

There is no WaveMetrics Procedures folder in the Igor Pro User Files folder.

Activating Additional WaveMetrics Files

The following sections explain how to activate additional Igor Pro features.

Activating WaveMetrics Procedure Files

To activate a WaveMetrics-supplied procedure file that you want to be available in all experiments:

1. Press the shift key and choose Help→Show Igor Pro Folder and User Files. This displays the Igor Pro Folder and the Igor Pro User Files folder on the desktop.
2. Open the WaveMetrics Procedures folder in the Igor Pro Folder and identify the WaveMetrics procedure file that you want to activate.
3. Make an alias/shortcut for the file and put it in "Igor Pro User Files/Igor Procedures" folder. This causes Igor to automatically load the procedure file the next time Igor is launched.
4. Restart Igor.

The activated procedure file appears in the Windows→Procedure Windows submenu.

Activating WaveMetrics XOPs

To activate a WaveMetrics-supplied XOP (a plug-in also called an "extension") :

1. Press the shift key and choose Help→Show Igor Pro Folder and User Files. This displays the Igor Pro Folder and the Igor Pro User Files folder on the desktop.
2. Open the "More Extensions (64-bit)" folder in the Igor Pro Folder and identify the XOP that you want to activate. (If you are running IGOR32 on Windows, open the "More Extensions" folder.)
3. Make an alias/shortcut for the XOP file and put it in "Igor Pro User Files/Igor Extensions" folder. This causes Igor to automatically load the XOP the next time Igor is launched.
4. Restart Igor.

The activated XOP adds its operations and/or functions to the Igor Help browser and they are available for programmatic use. Some XOPs also add menu items.

Activating Other Files

You may create an Igor package or receive a package from a third party. You should store each package in its own folder in the Igor Pro User Files folder or elsewhere, at your discretion. You should not store such files in the Igor Pro Folder because it complicates backup and updating.

To activate files from the package, create aliases/shortcuts for the package files and put them in the appropriate subfolder of the Igor Pro User Files folder.

If you have a single procedure file or a single Igor extension that you want to activate, you may prefer to put it directly in the appropriate subfolder of the Igor Pro User Files folder.

Activating Files in a Multi-User Scenario

Our recommendation is that you activate files using the special subfolders in the Igor Pro User Files folder, not in the Igor Pro Folder. An exception to this is the multi-user scenario where multiple users are running the same copy of Igor from a server. In this case, if you want to activate a file for all users, put the file or an alias/shortcut for it in the appropriate subfolder of the Igor Pro Folder. Users will have to restart Igor for the change to take effect.

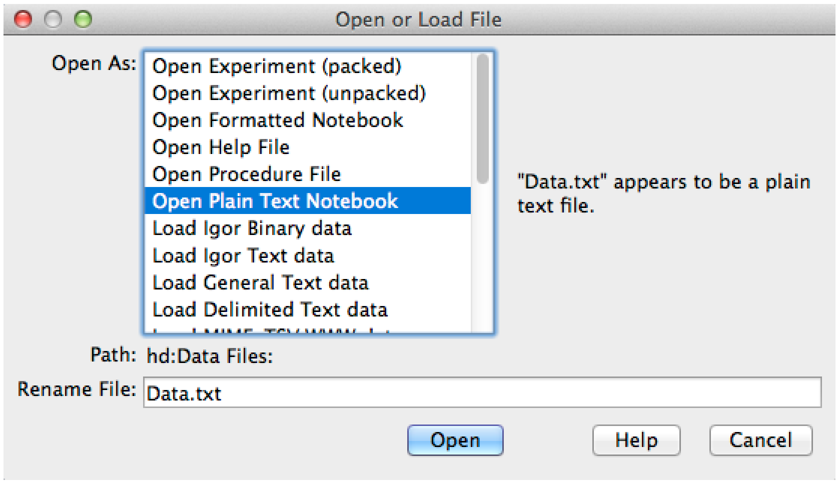
Igor File-Handling

Igor has many ways to open and load files. The following sections discuss some of the ways Igor deals with the various files it is asked to open.

The Open or Load File Dialog

When you open a file using menu item, such as File→Open File→Notebook, there is no question of how Igor should treat the file. This is not always the case when you drop a file onto the Igor icon or double-click a file on the desktop.

Often, Igor can determine how to open or load a file, and it will simply do that without asking the you about it. Sometimes Igor recognizes that a file (such as a plain text file or a formatted Igor notebook) can be appropriately opened several ways, and will ask you what to do by displaying the Open or Load File Dialog. The dialog presents a list of ways to open the file (usually into a window) or to load it as data.



"Data.txt" appears to be a plain text file.

Path: hd:Data Files:

Rename File: Data.txt

Tip: You can force this dialog to appear by holding down Shift when opening a file through the Recent Files or Recent Experiments menus, or when dropping a file onto the Igor icon.

This is especially useful for opening Igor help files as a notebook file for editing, or to open a notebook as a help file, causing Igor to compile it.

The list presents three kinds of methods for handling the file:

1. Open the file as a document window or an experiment.
2. Load the file as data without opening another dialog.
3. Load the file as data through the Load Waves Dialog or a File Loader Extension dialog.

If you choose one of the list items marked with an asterisk, Igor displays the selected dialog as if you had chosen the corresponding item from the Load Waves submenu of the Data menu.

Information about the file, or about how it was most recently opened, is displayed to the right of the list. The complete path to the file is shown below the list.

If you change the text in the Rename file edit box, Igor changes the file name before opening or loading the file.

Recent Files and Experiments

When you use a dialog to open or save an experiment or a file, Igor adds it to the Recent Experiments or Recent Files submenu in the File menu. When you choose an item from these submenus, Igor opens the experiment or file the same way in which you last opened or saved it.

For example, if you last opened a text file as an unformatted notebook, selecting the file from Recent Files will again open the file as an unformatted notebook. If you loaded it as a general text data file, Igor will load it as data again.

Igor does not remember all the details of how you originally load a data file, however. If you load a text data file with all sorts of fiddly tweaks about the format, Igor won't load it using the those same tweaks. To guarantee that Igor does load the data correctly, use the appropriate Load Data dialog.

Selecting an experiment or file while pressing Shift displays the Open or Load File dialog in which you can choose how Igor will open or load that file.

Desktop Drag and Drop

On Macintosh, you can drag and drop one or more files of almost any type onto the Igor icon in the dock or onto an alias for the Igor application on the desktop. On Windows, you must drag and drop files into an Igor window. One use for this feature is to load multiple data files at once.

If a dropped file was opened or loaded recently, it is listed in the Recent Files or Recent Experiments menu. In this case, Igor reopens or reloads it the same way.

If you press Shift while dropping a file on Igor, Igor displays the Open or Load File dialog in which you can choose how the file is to be handled.

Advanced programmers can customize Igor to handle specific types of files in different ways, such as automatically loading files with an XOP. See **User-Defined Hook Functions** on page IV-280.

IGOR64 Experiment Files

The 64 bit version of Igor can store waves larger than the 32-bit limit in packed experiment files but not in unpacked experiments. Huge wave storage uses a 64-bit capable wave record and is supported only for numeric waves.

The 32-bit versions of Igor, starting with version 6.20, supports 64-bit capable wave records. By default, IGOR32 attempts to read new these records and generates a lack of memory warning if they can not be loaded.

The rest of this section describes features for advanced users.

You can control some aspects of how Igor deals with 64-bit capable wave records using SetIgorOption. Remember that SetIgorOption settings last only until you quit Igor.

```
SetIgorOption UseNewDiskHeaderBytes = bytes
```

When bytes is non-zero, if the size of the wave data exceeds this value, the 64-bit capable wave record type is used. In IGOR32, the default value for bytes is 0 (off). In IGOR64, the default value for bytes is 100E6. If you want the 64-bit capable wave record type to be used only when absolutely necessary, use 2E9.

```
SetIgorOption UseNewDiskHeaderCompress = bytes
```

When bytes is non-zero, if the size of the wave data exceeds this value and if the 64-bit capable wave record type is used, the data is written compressed. The default value is 0 (off) because, although you can get substantial file size reduction for some kinds of data, there is also a substantial speed penalty when saving the experiment. In many cases, the compression actually results in a larger size than the original. If this occurs, Igor writes the original data instead of the compressed data.

```
SetIgorOption MaxBytesReadingWave = bytes
SetIgorOption BigWaveLoadMode = mode
```

These two options control how IGOR32 acts when loading experiments with the 64-bit capable wave record types.

mode can be 0 (default) for no special action. Igor attempts to read all the records.

If mode is 1, then any waves with data size exceeding bytes are silently skipped.

If mode is 2, then any waves with data size exceeding bytes are downgraded to a smaller size and only that portion of the data is loaded. Such partial waves are marked as locked and bit 1 of the lock flag is also set. In addition, the wave note contains the text "**PARTIAL LOAD**" and a warning dialog is presented after the experiment loads.

The default value for bytes is 500E6 in IGOR32.

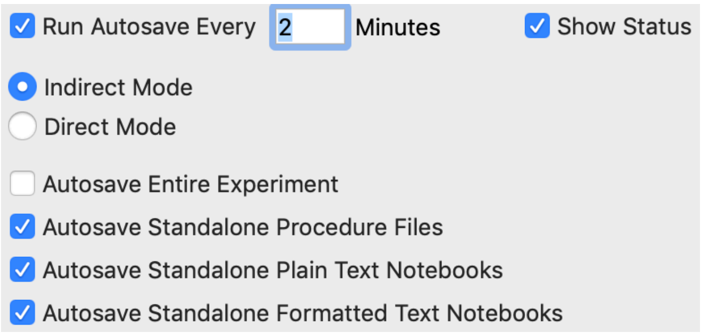
Autosave

Igor can autosave files while you work. This is of use in the event that Igor crashes or some other catastrophe occurs before you save.

If your habit is to save anytime you have made non-trivial changes that you want to keep then you don't need autosave. If your habit is to do a significant amount of work without saving, which is inherently risky, then autosave may prevent loss of work in the event of a crash.

Autosave is not foolproof and can cause confusing and unpredictable behavior if multiple users modify the same file or if you modify a file in multiple instance of Igor. For these and other reasons, you should consider autosave a last resort and always save when you have made progress and back up any work that would be painful to lose.

Autosave is turned off by default. You can turn it on and fine-tune how it works by choosing Misc→Miscellaneous Settings and clicking the Autosave icon in the lefthand list to display the Autosave pane of the Miscellaneous Settings dialog. The heart of it looks like this:



☑ Run Autosave Every 2 Minutes ☑ Show Status

● Indirect Mode
○ Direct Mode

□ Autosave Entire Experiment
☑ Autosave Standalone Procedure Files
☑ Autosave Standalone Plain Text Notebooks
☑ Autosave Standalone Formatted Text Notebooks

You turn autosave on by checking the Run Autosave checkbox. If turned on, autosave runs at the interval in minutes that you specify. Autosave runs when Igor is idling and not while procedures are running or if a modal dialog is displayed.

Alternatives to automatically autosaving include:

- Manually saving by choosing File→Save Experiment when you know the experiment is in good shape
- Running autosave manually when you know the experiment is in good shape by choosing File→Run Autosave Now
- Manually saving modified procedure files only using File→Save All Standalone Procedure Files

Igor can display information in its status bar showing the status of autosave. You can turn the autosave information on or off using the Show Status checkbox in the autosave pane of the Miscellaneous Settings dialog or by right-clicking the status bar. If autosave is enabled, the status bar information shows the time of the next autosave run. “Run” means “check if there are any files to be autosaved and autosave them if so.”

Modifying the same file in different instances of Igor while autosave is on will cause confusing and unpredictable behavior.

Igor programmers can query autosave settings using **IgorInfo**(13).

What Autosave Saves

Depending on the settings you choose, autosave can save the following types of files:

- Entire experiment files
- Standalone procedure files
- Standalone notebook files

In the sections below, we refer to the types of files you have chosen to autosave as "autosaveable files".

Autosave does not work on the following:

- Files that you have not yet saved to disk

  This includes experiment files, procedure files and notebook files that you have created but not yet saved to disk
- Unpacked experiment files (.uxp) in indirect mode
- Copies of procedure files #included into independent modules

  Such files should not be modified. See **Independent Modules and #include** on page IV-240 for details.

Autosave saves the following items only for packed experiments (.pxp and .h5xp) and **only if the Autosave Entire Experiment checkbox is checked**:

- The built-in procedure window
- Packed procedure files
- Packed notebook files
- Graphs, tables, page layouts, Gizmo plots, control panels and other windows
- Data folders and waves

Autosave Is Not A Substitute for Manual Saving or for Backing Up

The purpose of autosave is to increase the chance that you can recover work if Igor or your machine crashes or there is a power failure. Relying on autosave as a substitute for frequent saving backing up is courting disaster.

Depending on the autosave settings you choose, autosave may save at the wrong time (for example, just after you made a mistake) or may not save all of your work (see **What Autosave Saves** on page II-37).

A crash or other disaster may occur after you have made important changes but before autosave automatically runs.

You may realize that the work you saved today is wrong and you need to go back to yesterday's version of a file.

Your computer may fail catastrophically.

Your computer may be attacked by malware.

Your computer may be stolen.

Your computer may be damaged by fire, natural disaster, or some other mishap.

For these and other reasons, **you should always save when you have made progress and back up any work that would be painful to lose**. You should back up locally and also remotely for the case where your computer is destroyed or stolen.

Autosave Modes

You control the mode of operation of autosave using the Autosave pane of the Miscellaneous Settings dialog.

Autosave supports three modes. Each has its strengths and weaknesses.

- **Off**

  Autosave is off when the Run Autosave checkbox is unchecked.

  In this mode, Igor's autosave routine does not automatically run.

  Strengths

  Easy to understand.

  Takes no time.

  You are in complete control of when files are saved.

  Weaknesses

  You are in complete control of when files are saved.

  You are responsible for saving when you have made important changes.

- **Indirect Mode**

  Saves the current experiment (if it is packed, not if it is unpacked) and/or standalone procedure and standalone notebook files to .autosave files alongside the original files. For example, "Experiment.pxp" is autosaved to "Experiment.pxp.autosave" and "Proc0.ipf" is autosaved to "Proc0.ipf.autosave".

  Saving the current experiment is the same as choosing File→Save Experiment Copy.

  Saving a standalone procedure file is the same as choosing File→Procedure Copy.

  Saving a standalone notebook is the same as choosing File→Notebook Copy.

  You can choose whether to autosave the current experiment, standalone procedure files, and standalone notebooks.

  Indirect autosave of unpacked experiments is not supported.

  Strengths

  Does not risk overwriting your original files at the wrong time, for example just after you made a mistake.

  Weaknesses

  Saving the entire experiment can take a while for very large experiments.

  If you do not elect to save the entire experiment, many things are not autosaved, including the built-in procedure window, packed procedure files and notebooks, graphs, layouts and other windows, data folders and waves - see What Autosave Saves for details.

  Can interfere with sharing of files by multiple users or by multiple instances of Igor launched by a single user.

  Does not work with unpacked experiments.

  The .autosave files represent more clutter relative to direct mode.

  Recovering after a crash is more complicated compared to direct mode. Igor will ask if you want to use the .autosave file or the original file.

- **Direct Mode**

  Saves the current experiment and/or standalone procedure and standalone notebook files directly.

  Saving the current experiment is the same as choosing File→Save Experiment.

  Saving a standalone procedure file is the same as choosing File→Procedure.

  Saving a standalone notebook is the same as choosing File→Notebook.

  You can choose whether to autosave the current experiment, standalone procedure files, and standalone notebooks.

  Strengths

Simplicity.

Weaknesses

Saving the entire experiment can take a while for very large experiments.

Autosave may save a file at the wrong time, for example just after you made a mistake.

If you do not elect to save the entire experiment, many things are not autosaved, including the built-in procedure window, packed procedure files and notebooks, graphs, layouts and other windows, data folders and waves - see What Autosave Saves for details.

Can interfere with sharing of files by multiple users or by multiple instances of Igor launched by a single user.

Changes That Tee Up Autosaving the Entire Experiment

If you check the Autosave Entire Experiment checkbox and make a substantive change then Igor autosaves the entire experiment on the next autosave run.

Changes that are considered substantive include creating, killing or modifying waves and data folders, changing the content of a graph, table, layout, panel or Gizmo plot, and editing a procedure file or notebook.

Autosaving the entire experiment can be time-consuming. To prevent autosaving the entire experiment too often, some relatively minor changes do not tee up an experiment autosave. Among these are moving and resizing windows, changes to the history area that don't cause other objects to substantively change, and changes to global variables.

If the File→Run Autosave Now menu item is disabled, this indicates that no changes considered substantive were made since the last experiment save or last autosave.

Forcing Autosave to Run

You can force Igor to run its autosave routine when it is turned off or before it normally would run by choosing File→Run Autosave Now.

If the File→Run Autosave Now menu item is disabled, this means that there are no autosaveable files at present. This typically occurs because no autosaveable files were modified since the last time the autosave routine ran.

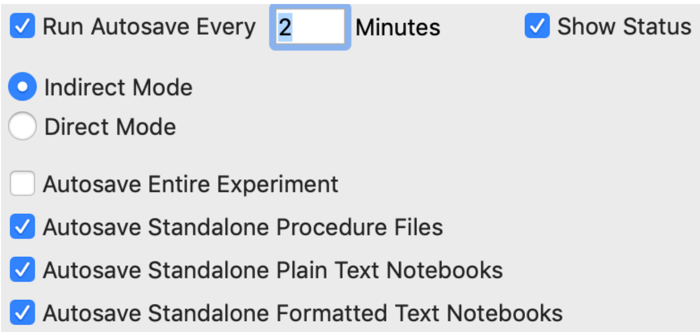
The Run Autosave Now menu command runs Igor's autosave procedure regardless of the state of the Run Autosave checkbox in the Autosave pane of the Miscellaneous Settings dialog. It does respect the other settings in that pane.

Saving Standalone Files Without Autosave

You can save all modified standalone procedure files or all modified standalone notebooks at once whether autosave is on or off. See **Saving All Standalone Files** on page II-26 for details.

Indirect Autosave Mode

The indirect autosave mode is more complicated than the direct mode. We will illustrate how indirect autosave works assuming the following settings in the Autosave pane of the Miscellaneous Settings dialog:



☑ Run Autosave Every 2 Minutes ☑ Show Status

● Indirect Mode
○ Direct Mode

□ Autosave Entire Experiment
☑ Autosave Standalone Procedure Files
☑ Autosave Standalone Plain Text Notebooks
☑ Autosave Standalone Formatted Text Notebooks

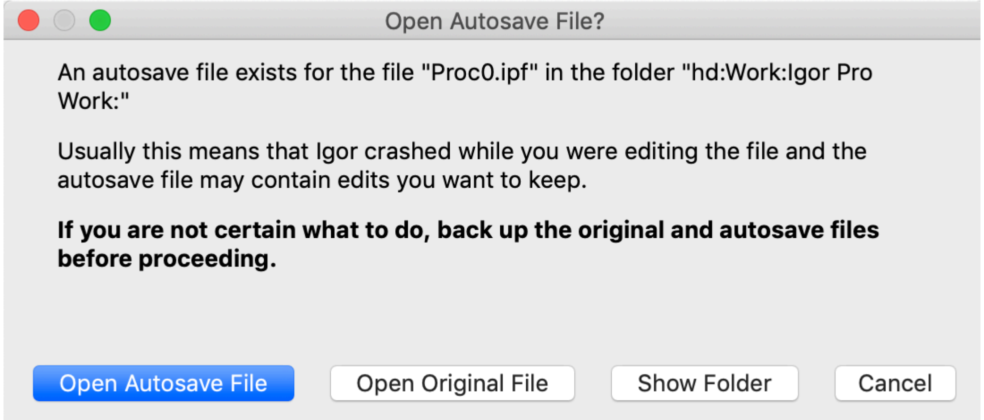
Now assume that you are editing a standalone procedure window that you previously saved to a file named "Proc0.ipf".

Every two minutes, Igor checks to see if there are autosaveable files that have been modified since the previous autosave. This check is performed when Igor is idling and not while procedures are running or if a modal dialog is displayed. If you have modified "Proc0.ipf" since the last autosave, Igor autosaves the file by writing its current contents to a file named "Proc0.ipf.autosave".

When you save "Proc0.ipf", close it without saving, or revert it, Igor deletes the corresponding "Proc0.ipf.autosave" file if it exists.

Recovering a File from a .autosave File

If Igor crashes or some other catastrophe occurs and Igor's indirect autosave routine executed before Igor was terminated, you will be left with the original file, "Proc0.ipf", and the .autosave file, "Proc0.ipf.autosave". If you attempt to open the original file, either manually or programmatically, Igor displays a dialog that looks like this:



Open Autosave File?

An autosave file exists for the file "Proc0.ipf" in the folder "hd:Work:Igor Pro Work:"

Usually this means that Igor crashed while you were editing the file and the autosave file may contain edits you want to keep.

If you are not certain what to do, back up the original and autosave files before proceeding.

NOTE: We recommend that you back up the original and autosave files before proceeding.

We recommend backing up in case you inadvertenly choose to open the wrong file.

If you click Cancel

The open operation is canceled and the original and autosave files are left unchanged.

If you click Open Original File

Igor opens the original file (e.g., "Proc0.ipf").

Igor then moves the autosave file (e.g., "Proc0.ipf.autosave") to the trash (Macintosh) or recycle bin (Windows). However, if the autosave file is open in Igor, it is not moved to the trash but may be overwritten by a subsequent autosave.

If you click Open AutoSave File

Igor renames the original file by appending a ".original" extension (e.g., "Proc0.ipf" is renamed as "Proc0.ipf.original").

Igor then renames the autosave file using the original file name (e.g., "Proc0.ipf.autosave" is renamed as "Proc0.ipf").

Igor then opens the autosave file which now has the original file name (e.g., "Proc0.ipf").

Igor then moves the original file, which now has the ".original" extension (e.g., "Proc0.ipf.original") to the trash (*Macintosh*) or recycle bin (*Windows*).

Indirect Autosave Mode Issues

Indirect mode can create confusing situations when files are shared by multiple users or by multiple instances of Igor launched by a single user.

For example, if a user is editing a shared procedure file with indirect autosave mode on, Igor creates a corresponding .autosave file. If another user directly or indirectly (e.g., via a #include statement) opens the original file, the existence of the .autosave file causes Igor to display the Open Autosave File dialog discussed in the preceding section. This will confuse the second user and potentially interfere with the first user's editing. A similar situation can occur with shared notebook and experiment files.

This kind of issue is mitigated by using a source code control system or by otherwise avoiding working directly on shared files or by turning autosave off.

Opening .autosave Files Explicitly

Normally you have no need to open an Igor .autosave file but you might want to do so to inspect it.

Igor opens procedure and notebook .autosave files for reading only. If you close a procedure or notebook file whose .autosave file you have also opened in Igor, Igor automatically closes the .autosave file before deleting it.

Igor does not allow you to open .autosave experiment files. If you want to open such a file, rename it without the .autosave extension before opening it in Igor.

Indirect Autosave and Unpacked Experiments

Indirect autosave of unpacked experiments is not supported.

If an unpacked experiment is open, autosaving of standalone procedure files and notebooks is still performed if enabled by the corresponding checkboxes in the Autosave pane of the Miscellaneous Settings dialog.

For background information on unpacked experiments, see **Saving as an Unpacked Experiment File** on page II-17.

Experimenting With Indirect Autosave Recovery

If you want to familiarize yourself with how indirect autosave works, you can use this function for experimentation. It writes files "Test Indirect Autosave.txt" and "Test Indirect Autosave.txt.autosave" to your Igor Pro User Files folder and then opens "Test Indirect Autosave.txt" as a notebook. Igor displays the "Open Autosave File?" dialog in which you can choose which file you want to open. The file not chosen is moved to the trash (*Macintosh*) or recycle bin (*Windows*).

```
Function TestOpenWithIndirectAutoSaveFilePresent()
   KillWindow/Z TestAutosaveNotebook

   String pathName = "IgorUserFiles"
   // Create original file
   String fileName = "Test Indirect Autosave.txt"
   Variable refNum
   Open/P=$pathName refNum as fileName
   fprintf refNum, "This is a test\r\n"
   Close refNum

   // Create the autosave file
   CopyFile /O /P=$pathName fileName as fileName + ".autosave"

   // Displays "Open Autosave File?" dialog
   OpenNotebook/P=$pathName/N=TestAutosaveNotebook fileName
   int err = GetRTError(1)       // Returns non-zero if user cancels
   Print err
End
```

Chapter

II-4

Windows

Windows

This section describes Igor's windows in general terms, the Windows menu, and window recreation macros.

Detailed information about each type of window can be found in these chapters:

Window Type	Chapter
Command window	Chapter II-2, **The Command Window** Chapter IV-1, **Working with Commands**
Procedure windows	Chapter III-13, **Procedure Windows**
Help windows	Chapter II-1, **Getting Help**
Graphs	Chapter II-13, **Graphs**
Tables	Chapter II-12, **Tables**
Layouts	Chapter II-18, **Page Layouts**
Notebooks	Chapter III-1, **Notebooks**
Control panels	Chapter III-14, **Controls and Control Panels**
Gizmo windows	Chapter II-17, **3D Graphics**
Camera windows	**NewCamera** on page V-678

The Command Window

When Igor first starts, the **command window** appears at the bottom of the screen.

Commands are automatically entered and executed in the command window's **command line** when you use the mouse to "point-and-click" your way through dialogs. You may optionally type the commands directly and press Return or Enter. Igor preserves a history of executed commands in the **history area**.

For more about the command window, see Chapter II-2, **The Command Window**, and Chapter IV-1, **Working with Commands**.

The Rest of the Windows

There are also a number of additional windows which are initially hidden:

- The main procedure window
- The Igor Help Browser
- Help windows for files in "Igor Pro Folder/Igor Help Files" and "Igor Pro User Files/Igor Help Files"

You can create additional windows for graphs, tables, page layouts, notebooks, control panels, Gizmos (3D plots), and auxiliary procedure windows, as well as more help windows.

The Target Window

Igor commands and menus operate on the **target window**. The target window is the top graph, table, page layout, notebook, control panel or XOP target window. The term "target" comes from the fact that these windows can be the target of command line operations such as ModifyGraph, ModifyTable and so on. The command window, procedure windows, help windows and dialogs can not be targets of command line operations and thus are not target windows.

Prior to version 4, Igor attempted to draw a special icon to indicate which window was the target. However, this special target icon is no longer drawn because of operating system conflicts.

The menu bar changes depending on the top window and the target window. For instance, if a graph is the target window the menu bar contains the Graph menu. However, you may type any command into the command line, including commands that do not apply to the target window. Igor will apply the command to the top window of the correct type.

Sometimes the top window isn't a target window, but it causes the menu bar to change. For example, if you activate a procedure window, the Procedure menu appears in the menu bar.

Window Names and Titles

Each graph, table, page layout, control panel, notebook, and Gizmo has a **title** and a **name**.

The title is what you see at the top of the window frame and in the Windows menu. Its purpose is to help you visually identify the window, and is usually descriptive of its contents or purpose.

The window *name* is not the same as the *title*. The purpose of the name is to allow you to refer to the window from a command, such as the DoWindow or AppendToGraph operations.

When you first create one of these windows, Igor gives it a name like Graph0, Table0, Layout0 or Panel0, and a title based on the name and window contents. You can change the window's title and name to something more descriptive using the Window Control dialog (Windows→Control submenu). Among other things, it renames and retitles the target window.

The Window Control dialog is also a good way to discover the name of the top window, since the window shows only the window title.

The command window, procedure windows, and help windows have *only* a title. The title is the name of the file in which they are stored. These windows do not have names because they can not be affected by command line operations.

Allowable Window Names

A window name is used for commands and therefore must follow the standard rules for naming Igor objects:

- The name must start with a letter.
- Additional characters can be alphanumeric or the underscore character.
- No other characters, including spaces, are allowed in standard Igor object names.
- No more than 255 bytes are allowed.
- The name must not conflict with other object names (you see a message if it does).

Prior to Igor Pro 8.00, window names were limited to 31 bytes. If you use long window names, your experiments will require Igor Pro 8.00 or later.

For more information, see **Object Names** on page III-501.

The Open File Submenu

The File menu contains the Open File submenu for opening an existing file as a notebook, Igor help window, or procedure window.

When you choose an item from the submenu, the Open File dialog appears for you to select a file.

The Windows Menu

You can use the Windows menu for making new windows, and for showing, arranging and closing (either hiding or "killing") windows. You can also execute "window recreation macros" that recreate windows that have been killed and "style macros" that modify an existing window's appearance.

Making a New Window

You can use the various items in the Windows menu and Windows→New submenu to create new windows. Most of these items invoke dialogs which produce commands that Igor executes to create the windows.

You can also create windows by typing these commands yourself directly in the command line. For example,

```
Display yData vs xData
```

creates a graph of the wave named yData on the Y axis, versus xData on the X axis.

You can create a new window by selecting the name of a window recreation macro from the Windows menu. See **Window Macros Submenus** on page II-48.

You can also create a window using the File→Open File submenu.

Activating Windows

To activate a window, click it, or choose an item from Windows menu or its submenus.

The Recent Windows submenu shows windows recently activated. This information is saved when you save an experiment to disk and restored when you later reopen the experiment.

By default, just the window’s title is displayed in the Windows menu. You can choose to display the title or the name for target windows using the Windows Menu Shows pop-up menu in the Miscellaneous section of the Miscellaneous Settings dialog.

Showing and Hiding Windows

All types of Igor windows can be hidden.

To hide a window, press Shift and choose Windows→Hide or use the keyboard shortcut Command-Shift-W (*Macintosh*) or Ctrl+Shift+W (*Windows*). You can also hide a window by pressing Shift and clicking the close button.

You can hide multiple windows at once using the Windows→Hide submenu. For example, to hide all graphs, choose Windows→Hide→All Graphs. If you press Shift while clicking the Windows menu, the sense of the menu items changes. For example, Hide→All Graphs changes to Hide→All Except Graphs.

The command window is not included in mass hides of any kind. If you want to hide it you must do so manually.

Similarly, you can show multiple windows at once using the Windows→Show submenu. For example, to show all graphs, choose Windows→Show→All Graphs. If you press Shift while clicking the Windows menu, the sense of the menu items changes. For example, Show→All Graphs changes to Show→All Except Graphs.

The Show All Except menu items do not show procedure windows and help files because there are so many of them that it would be counterproductive.

The Windows→Show→Recently Hidden Windows item shows windows recently hidden by a mass hide operation, such as Hide→All Graphs, or windows recently hidden manually (one-at-a-time using the close button or Command-Shift-W or Ctrl+Shift+W). In the case of manually hidden windows, “recently hidden” means within the last 30 seconds.

XOP windows do participate in Hide All XOP Windows and Show All XOP Windows only if XOP programmers specifically support these features.

Closing a Window

You can close a window by either choosing the Windows→Close menu item or by clicking in the window’s close button. Depending on the top window’s type, this will either kill or hide the window, possibly after a dialog asking for confirmation.

Killing Versus Hiding

“Killing” a window means the window is removed from the experiment. The memory used by the window is released and available for other purposes. The window’s title is removed from the Windows menu.

Killing a window that represents a file on disk does not delete the file. You can also kill a window with a **KillWindow** command.

“Hiding” a window simply means the window is made invisible, but is still part of the experiment and uses the same amount of memory. It can be made visible again by choosing its title from the Windows menu.

The command window and the built-in procedure window can be hidden but not killed. All other built-in windows can be hidden or killed.

When you create a window from a procedure, you can control what happens when the user clicks the close button using the `/K=<num>` flag in the command that creates the window.

You can hide a window programmatically using the `DoWindow/HIDE=1` operation.

Saving the Window Contents

Notebooks and procedure windows can be saved either in their own file, or in a packed experiment file with everything else. You can tell which is the case by choosing Notebook→Info or Procedure→Info. When you kill a notebook or a procedure window that contains unsaved information, a dialog will allow you to save it before killing the window.

Graph, table, control panel, page layout, and Gizmo windows are not saved as separate files, and are lost when you kill them unless you save a **window recreation macro** which you can execute to later recreate the window. Killing these windows and saving them as window recreation macros (stored in the built-in procedure window) frees up memory and reduces window clutter without losing any information. You can think of window recreation macros as “freeze-dried windows”.

Close Window Dialogs

When you close a graph, table, layout or control panel, or Gizmo window, Igor presents a Close dialog.

If you click the Save button Igor creates a window recreation macro in the main procedure window. It sets the macro’s subtype to Graph, Table, Layout, Panel, or Gizmo, so the name of the macro appears in the appropriate Macros submenu of the Windows menu. You can recreate the window using this menu.

If you don’t plan to use the window again, you should click the No Save button and no window recreation macro will be created.

If you have previously created a recreation macro for the window then the dialog will have a Replace button instead of a Save button. Clicking Replace replaces the old window recreation macro with a new one. If you know that you won’t need to recreate the window, you can delete the macro (see **Saving a Window as a Recreation Macro** on page II-47).

When you close a notebook or procedure window (other than the built-in procedure window), Igor presents a “hide or kill dialog”.

To hide a window, press Shift while clicking the close button.

To kill a graph, table, layout, control panel, or Gizmo window without the Close dialog, press Option (*Macintosh*) or Alt (*Windows*) while clicking the close button.

If you create a window programmatically using the Display, Edit, NewLayout, NewPanel, NewNotebook, or NewGizmo operation, you can modify the behavior of the close button using the /K flag.

Saving a Window as a Recreation Macro

When you close a window that can be saved as a recreation macro, Igor offers to create one by displaying the Close Window dialog. Igor stores the window recreation macro in the main procedure window of the current experiment. The macro uses much less memory than the window, and reduces window clutter. You can invoke the window recreation macro later to recreate the window. You can also create or update a window recreation macro using the Window Control dialog.

The window recreation macro contains all the necessary commands to reconstruct the window provided the underlying data is still present. For instance, a graph recreation macro contains commands to append waves to the graph, but does not contain any wave data. Similarly, a page layout recreation macro does not contain graphs or tables or the commands to create them. The macros refer to waves, graphs and tables in the current experiment by name.

Here is how you would use recreation macros to keep a graph handy, but out of your way:

The window recreation macro is evaluated in the context of the root data folder. This detail is of consequence only to programmers. See **Data Folders and Commands** on page II-111 for more information.

You can create or replace a window recreation macro without killing the window using **The Window Control Dialog** described on page II-49. The most common reason to replace a window recreation macro is to keep the macro consistent with the window that it creates.

When Igor displays the Close Window dialog, the proposed name of the window recreation macro is the same as the name of the window. You can save the window recreation macro under a different name, if you want, by entering the new name in the dialog. If you do this, Igor creates a new macro and leaves the original macro intact. You can run the new macro to create a new version of the window or you can run the old macro to recreate the old version. This way you can save several versions of a window, while displaying only the most recent one.

Window recreation macros stay in an experiment's procedure window indefinitely. If you know that you won't need to recreate a window for which a window recreation macro exists, you can delete the macro.

To locate a window recreation macro quickly:

- Activate any procedure window, press Option (*Macintosh*) or Alt (*Windows*), and choose the window recreation macro name from the appropriate macro submenu in the Windows menu.

To delete the macro, if you're sure you won't want it again, simply select all the text from the Macro declaration line to the End line. Press Delete to remove the selected text.

See **Saving and Recreating Graphs** on page II-350 for details specific to graphs.

Window Macros Submenus

The Windows menu has submenus containing graph, table, page layout, control panel, and Gizmo recreation macros. These menus also include graph, table, and page layout style macros.

Window recreation macros are created by the Close Window and Window Control dialogs, and by the DoWindow/R command. Style macros are created by the Window Control dialog and the DoWindow/R/S command.

Igor places macros into the appropriate macro submenu by examining the macro's subtype. The subtypes are Graph, Table, Layout, Panel, Gizmo, GraphStyle, TableStyle and LayoutStyle. See **Procedure Subtypes** on page IV-204 for details.

When you choose the name of a recreation macro from a macro submenu, the macro runs and recreates the window. Choosing a style macro runs the macro which changes the target window's appearance (its "style").

However, if a procedure window is the top window and you press Option (*Macintosh*) or Alt (*Windows*) and then choose the name of any macro, Igor displays that macro but does not execute it.

The Name of a Recreated Window

When you run a window recreation macro, Igor recreates the window with the same name as the macro that created it unless there is already a window by that name. In this case, Igor adds an underscore followed by a digit (e.g. _1) to the name of the newly created window to distinguish it from the preexisting window.

Changing a Window's Style From a Macro

When you run a style macro by invoking it from the Windows menu, from the command line or from another macro, Igor applies the commands in the macro to the top window. Usually these commands change the appearance of the window. For example, a graph style macro may change the color of graph traces or the axis tick marks.

Style macros are used most effectively with graph windows. For more information, see **Saving and Recreating Graphs** on page II-350 and **Graph Style Macros** on page II-350.

The Window Control Dialog

Choosing Control→Window Control displays the Window Control dialog which you can use to change the top window's title and name, and create or update its recreation and style macros. You can access this dialog quickly by pressing Command-Y (*Macintosh*) or Ctrl+Y (*Windows*).

You can also change the window's name. The window name is used to address the window from command line operations such as MoveWindow and also appears in the macro submenus of the Windows menu.

For more about names and titles, see **Window Names and Titles** on page II-45. Also see **Saving a Window as a Recreation Macro** on page II-47 for a discussion of window recreation macros, and see **Graph Style Macros** on page II-350 for details on style macros.

The Window Browser

The Window Browser allows you to find and manage windows of interest. Choose Windows→Window Browser to activate it.

The window list on the right side lists windows that meet the current filtering criteria. You can filter windows by name, by type, by visibility (visible or hidden), and based on whether they display a specific wave. Clicking the funnel icon at the bottom of the list toggles the display of advanced filtering controls. Clicking the gear icon displays the options menu in which you can set sorting and display options.

If a single window is selected in the window list, the controls on the left display information about the window. The buttons at the top of the Selection area control the types of information that are displayed. You can choose to display the following types of information:

- Window Information

  Includes the window name, window title, and window note. See **Window Names and Titles** on page II-45 for a discussion of the distinction between names and titles.

- Waves in Window

  Displays a list of waves used by the window. Right-click a wave icon to edit the wave in a table, view it in the Data Browser, or set the current data folder to the wave's data folder. You can also toggle display of full paths by right clicking anywhere in the list.

  You can select one or more waves in the list and drag them into an existing graph or table window to append them to the target window. See **Appending Traces by Drag and Drop** on page II-280 for details.

- Layout Objects

  Displays information about the pages in the selected page layout window and the objects on each page.

If multiple windows are selected, the Window Information control displays a list of window names.

The buttons above the window list allow you to show, hide, close the selected windows and to bring them to the front or send them to the back.

You can append selected graph, table, and Gizmo windows to a page layout by dragging them from the window list into a layout or by right clicking in the window list and choosing the appropriate item.

You can add menu items to the contextual menu in the window list. See **WindowBrowserWindowsPopup Menu** on page IV-140 for details.

Arranging Windows

You can tile or stack windows by choosing the appropriate items from the Control submenu in the Windows menu.

You can customize the behavior of the Tile and Stack items using the Tile or Stack Windows dialog.

You can also move windows around using the MoveWindow, StackWindows, and TileWindows commands.

The Tile or Stack Windows Dialog

The Tile or Stack Windows dialog is useful for tiling a few windows or even for setting the size and position of a single window.

Select individual windows from the Windows to Arrange list, and entire classes of windows with the checkboxes.

If you want subsequent selections of the Tile (or Stack) menu item to stack the same types of windows with the same rows, columns, grout, tiling area, etc., check the "Capture as pref" checkbox. Windows selected in the Windows to Arrange menu aren't remembered by the preferences; only the window type checkboxes are remembered. There are separate settings and preferences for Stack and for Tile.

Although the TileWindows and StackWindows operations can tile and stack panels, panels don't show up here because they don't resize very well.

The Window Tiling Area subdialog specifies the area where tiling *and stacking* take place.

You can specify the tiling area in one of four ways:

- By entering screen positions in units of points
- By dragging the pictorial representation of the tiling area
- By clicking the "Use default area" button to use the default tiling area
- By positioning any non-dialog window before you enter the dialog, and clicking the "Use top window" button

Window Position and Size Management

There are four items in the Control submenu of the Windows menu that help you manage the position and size of windows.

Move to Preferred Position

Moves the active window to the position and size determined by preferences. For each type of window, you can set the preferred position and size using the Capture Prefs dialog (e.g., Capture Graph Prefs for graphs).

Move to Full Size Position

Moves and sizes the active window to display as much of the content as practical. On Macintosh, this is the same as clicking the zoom button. On Windows, the size is limited to the size of the frame window.

Retrieve Window

Moves the active window and sizes it if necessary so that all of the window is visible.

Retrieve All Windows

Moves all windows and sizes them if necessary so that all of each window is within the screen on Macintosh or within the frame on Windows. This is often useful when you open an experiment that was created on a system with a larger screen or Windows frame than yours.

Send to Back — Bring to Front

The Send to Back item in the Windows menu sends the top window to the bottom of the desktop, behind all other windows. This function can also be accessed by pressing Command-' (*Macintosh*) or Ctrl+E (*Windows*). After sending a window behind, you can bring it to the front by choosing Bring to Front or by pressing Command-Shift-' (*Macintosh*) or Ctrl+Shift+E (*Windows*). You can also press these keys repeatedly to cycle through all windows.

You can also send a window to the back with the `DoWindow/B` command and bring it to the front with the `DoWindow/F` command.

Text Windows

Igor Pro displays text in procedure, notebook, and Igor help windows as well as in the command and history areas of the command window. This section discusses behavior common to all of these windows.

Executing Commands

You can execute commands selected in a notebook, procedure or help window by pressing Control-Enter or Control-Return. You can also execute selected commands by Control-clicking (*Macintosh*) or right-clicking (*Windows*) and choosing Execute Selection.

For more on this, see **Notebooks as Worksheets** on page III-4.

Text Window Navigation

The term "keyboard navigation" refers to selection and scrolling actions that Igor performs in response to the arrow keys and to the Home, End, Page Up, and Page Down keys. Macintosh and Windows have different conventions for these actions in windows containing text. You can use either Macintosh or Windows conventions on either platform.

By default, Igor uses Macintosh conventions on Macintosh and Windows conventions on Windows. You can change this using the Keyboard Navigation menu in the Misc Settings section of the Miscellaneous Settings dialog. If you use Macintosh conventions on Windows, use Ctrl in place of the Macintosh Command key. If you use Windows conventions on Macintosh, use Command in place of the Windows Ctrl key.

Macintosh Text Window Navigation

Key	No Modifier	Option	Command
Left Arrow	Move selection left one character	Move selection left one word *	Move selection to start of line
Right Arrow	Move selection right one character	Move selection right one word *	Move selection to end of line
Up Arrow	Move selection up one line	Move selection up one paragraph *	Move selection up one screen
Down Arrow	Move selection down one line	Move selection down one paragraph *	Move selection down one screen
Home	Scroll to start of document	Scroll to start of document	Not used
End	Scroll to end of document	Scroll to end of document	Not used
Page Up	Scroll up one screen	Scroll up one screen	Not used
Page Down	Scroll down one screen	Scroll down one screen	Not used

* If you choose Macintosh keyboard navigation on Windows, these Alt-Arrow key events are not supported. Alt-Left-Arrow is the keyboard shortcut for Edit→Go Back and Alt-Right-Arrow is the keyboard

shortcut for Edit→Go Forward. Alt-Up-Arrow nudges the selection up and Alt-Down-Arrow nudges the selection down.

Windows Text Window Navigation

Key	No Modifier	Ctrl
Left Arrow	Move selection left one character	Move selection left one word
Right Arrow	Move selection right one character	Move selection right one word
Up Arrow	Move selection up one line	Move selection up one paragraph
Down Arrow	Move selection down one line	Move selection down one paragraph
Home	Move selection to start of line	Move selection to start of document
End	Move selection to end of line	Move selection to end of document
Page Up	Scroll up 1 screen	Scroll up 1 screen
Page Down	Scroll down 1 screen	Scroll down 1 screen

Text Window Go Back and Go Forward

Certain actions add entries to a go-back stack that Igor maintains in memory. These actions include opening a text window, doing a find, clicking a help link, right-clicking and choosing the Help For and Go To menu items, and using the navigation bar.

You can return to locations in text windows that you recently visited using the Go Back and Go Forward buttons. These appear in the navigation bar of procedure and help windows and in the status area of notebook windows. The Go Back button looks like a "less-than" symbol and the Go Forward button looks like a "greater-than" symbol. You can also use the Edit menu Go Back and Go Forward items or their keyboard equivalents:

	Macintosh	Windows
Go Back	Cmd-Option-Left-Arrow	Alt+Left-Arrow
Go Forward	Cmd-Option-Right-Arrow	Alt+Right-Arrow

If your mouse has Go Back and Go Forward buttons, you can use them also.

Between the Go Back and Go Forward buttons is a button which when clicked displays the Go Back pop-up menu. You can return to a specific recently-visited location by choosing an item from a submenu in the Go Back pop-up menu.

Igor can keep the go back locations for all text windows in one stack or it can keep separate stacks for procedure windows, notebook windows and help windows. You control this using the "Separate stacks for procedure, notebook, help windows" menu item in the Go Back pop-up menu. When that item is checked, Igor maintains separate stacks. When it is unchecked, Igor maintains one stack for all three types of windows. Which you choose is a matter of taste. The advantage of keeping multiple stacks is that it most of the time you are interested in windows of the same type. The advantage of keeping just one stack is that it allows you to go back to a procedure file after right-clicking for help for an Igor operation or function.

Igor keeps a maximum of 25 locations in each stack and discards older locations when necessary.

Finding Text in the Active Window

You can find text active windowby choosing Edit→Find or by pressing Command-F (*Macintosh*) or Ctrl+F (*Windows*). This displays the Find bar.

On Macintosh, you can search for the next occurrence of a string by selecting the string and choosing Edit→Use Selection For Find or pressing Command-E to enter the selected text as the find string and Command-G to find it.

On Windows, you can search for the next occurrence of a string by selecting the string and choosing Edit→Find Selection or pressing Ctrl+H to enter the selected text as the find string and find it.

Find and Replace

You can find and replace text by choosing Edit→Replace Text or by pressing Command-R (*Macintosh*) or Ctrl+R (*Windows*). This displays the Find and Replace bar.

Here is another method for finding and replacing text:

1. Move the selection to the top of the active window.
2. Use Edit→Find to find the first instance of the target string.
3. Manually change the first instance, then copy the new text to the Clipboard.
4. Press Command-G (*Macintosh*) or Ctrl+G (*Windows*) to find the next occurrence.
5. Press Command-V (*Macintosh*) or Ctrl+V (*Windows*) to paste.
6. Repeat steps 4 and 5 until done.

Finding Text in Multiple Windows

You can find text in multiple windows by choosing Edit→Find Text in Multiple Windows. This displays the Find Text in Multiple Windows window which allows you to search all help windows, all procedure windows, and all notebooks.

You can also use the Igor Help Browser to search in multiple files, including files that are not open in your current experiment. See **The Igor Help Browser** on page II-2 for details.

Text Magnification

You can magnify the text in any window to make it bigger or smaller to suit your taste.

In help windows, procedure windows, plain text notebooks, and formatted text notebooks, you can use the magnifying glass icon in the bottom-left corner of the window. You can also use the Magnification submenu in the contextual menu for the window. To display the contextual menu, Control-click (*Macintosh*) or right-click (*Windows*) in the body of the window.

You can also set the magnification for the command line, history area, and the debugger. These areas do not display the magnifying glass icon so you must use the contextual menu.

You may notice some anomalies when you use text magnification. For example, in a formatted text notebook, text may wrap at a different point in the paragraph and may change in relation to tab stops. This happens because fonts are not available in fractional sizes and because the actual width of text does not scale linearly with font size.

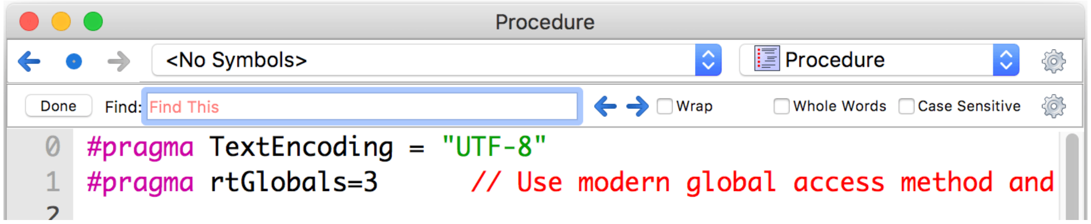
You can set the default magnification for each type of text area by choosing a magnification from the Magnification popup menu and then choosing Set As Default from the same popup menu. Any text areas whose magnification is set to Default will use the newly specified default magnification. For example, if you want text in all help files to appear larger, open any help file, choose a larger magnification, 125% for example, and then choose Set As Default For Help Files. All help files whose current magnification is set to Default will be updated to use the new default.

The default magnification for the command line and history area controls the magnification that will be used the next time you launch Igor Pro.

The magnification setting is saved in formatted notebooks and help files only. If you change the magnification setting for one of these files and then save and close the file, the magnification setting will be restored when you reopen the file. For all other types of text areas, including procedure windows and plain text notebooks, the magnification setting is not stored in the file. If you close and reopen such a file, it will reopen using the default magnification for that type of text area.

The Find Bar

The find bar is available in help, procedure and notebook windows, and other places where you might need to search for text. To display it, choose Edit→Find or press Command-F (Macintosh) or Ctrl+F (Windows). The Find Bar appears at the top of the host window:



```
#pragma TextEncoding = "UTF-8"
#pragma rtGlobals=3       // Use modern global access method and
```

Enter text in the Find edit box and press the right arrow icon to find the next occurrence of the text. Press the left arrow icon to find the preceding occurrence.

You can also find the next occurrence by pressing Command-G (Macintosh) or Ctrl+G (Windows). You can also find the preceding occurrence by pressing Command-Shift-G (Macintosh) or Ctrl+Shift+G (Windows).

You can set the text to be found by selecting it in the active window and pressing Command-E (Macintosh) or Ctrl+H (Windows).

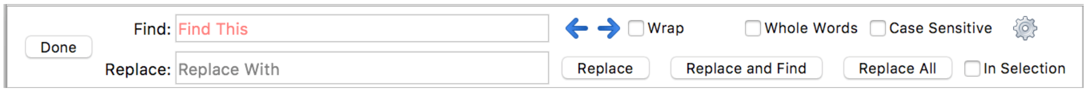
By default, when you use these keyboard equivalents, if the find bar is not showing, Igor displays it. If you prefer that Igor not display the find bar when you use these equivalents, click the gear icon and check the Show Find Bar on Edit→Find Only checkbox.

You can set the size of the find bar using the gear icon.

To hide the find bar, click the Done button or press the Esc key.

Search and Replace

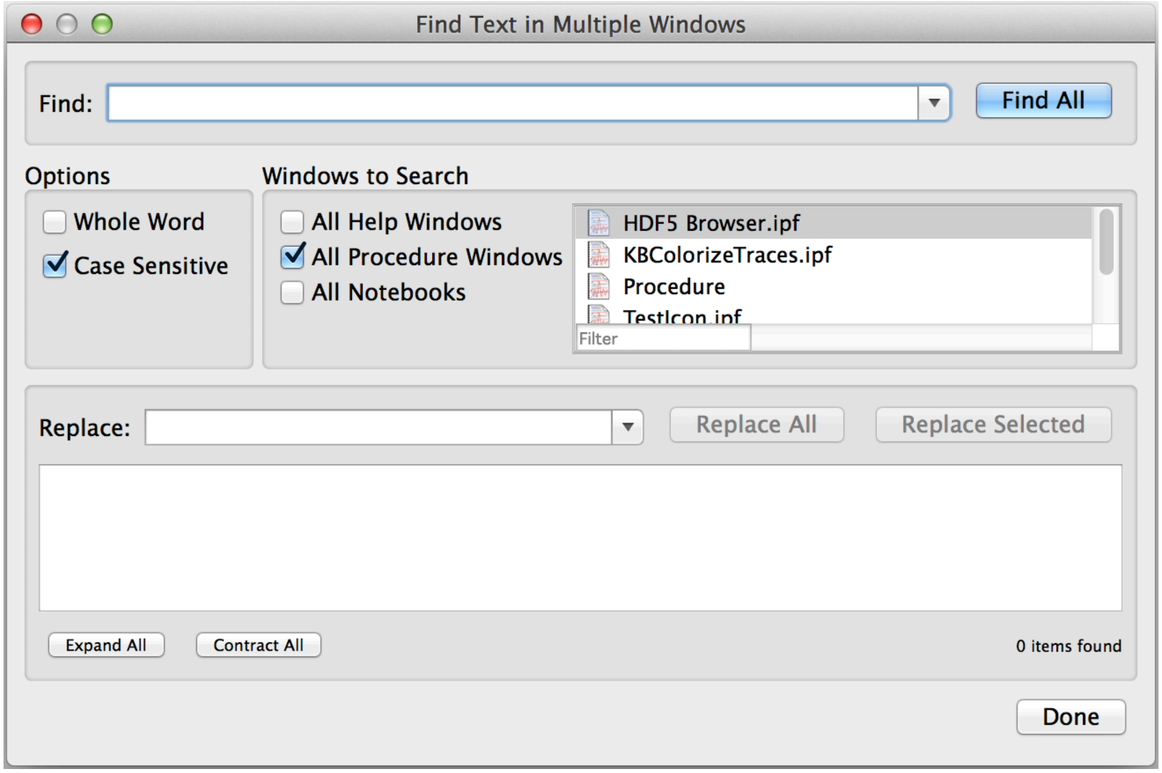
If the window you are working on contains editable text, you can choose Edit→Replace or press Command-R (Macintosh) or Ctrl+R (Windows) to display the replace text portion of the find bar:



While replacing text is undoable, the potential for unintended and wide-ranging consequences is such that we recommend saving the file before doing a mass replace using Replace All so you can revert-to-saved if necessary.

The Find Text in Multiple Windows Dialog

You can perform a Find on multiple help, procedure and notebook windows at one time by choosing Edit→Find in Multiple Windows or by pressing Command-Shift-F (Macintosh) or Ctrl+Shift+F (Windows). This invokes the Find Text in Multiple Windows dialog:



☐ Whole Word
☑ Case Sensitive

☐ All Help Windows
☑ All Procedure Windows
☐ All Notebooks

HDF5 Browser.ipf
KBColorizeTraces.ipf
Procedure
TestIcon.ipf

0 items found

Enter text to be found in the Find box. Use the checkboxes to select the types of windows to search. To narrow the list of files to search, you can enter a filter string in the Filter box at the bottom of the window list. The list then shows only list items whose names contain the filter string.

When you click the Find All button, Igor commences searching all the text in the listed windows. During the search, Igor displays a small progress dialog showing how far through the window list the search has gotten. You can stop the search by clicking the Cancel button.

For each window in which the text is found, an entry appears in the panel at the bottom of the dialog. A number in parentheses indicates how many instances of the search text were found in that window.

Each of these window entries can be opened using the disclosure control at the left end of the item. Then a snippet of text around the search string is shown, with the search string highlighted. The number at the left end of the found text snippet is the line number within the searched window.

Double-clicking a text snippet item takes you to the found text in the window containing the text.

Search and Replace in Multiple Windows

After a search is finished, you can use the found text items to replace all instances of the text that were found in editable windows. Enter the replacement text in the Replace edit box.

Clicking the Replace All button replaces all the found instances with the replacement text.

NOTE: Replace All in multiple windows cannot be undone. Use it with great care.

If you make a mistake, choose File→Revert Experiment, File→Revert Notebook, or File→Procedure and make sure you have reverted all affected windows. This is the only way to recover.

You can limit the replacement by selecting a subset of the found text items and clicking the Replace Selected button. Click a found text item to select it. Shift-click another item to select all items between that item and the one previously clicked. To select non-contiguous items, Command-click (Macintosh) or Ctrl-click (Windows). You can also click and drag over multiple items. It is still a good idea to save before replacing.

Home Versus Shared Text Files

A text file that is stored in a packed experiment file, or in the experiment folder for an unpacked experiment, is a "home" text file. Otherwise it is a "shared" text file.

Home text files are typically intended for use by their owning experiment only. Shared text files are typically intended for use by by multiple experiments.

When you create a text file in a packed experiment, it saved by default in the packed experiment file and is a home text file. It becomes a shared text file only if you explicitly save it to a standalone file.

When you create a text file in an unpacked experiment, it saved by default in the experiment folder and is a home text file. It becomes a shared text file only if you explicitly save it to a standalone file outside of its experiment folder.

When you save a packed experiment as unpacked, home text files are stored in the experiment folder.

When you save an unpacked experiment as packed, home text files are saved in the packed experiment file.

You can use the File Information dialog, which you access by choosing Procedure→Info or Notebook→Info, to determine if a text file is shared. For shared text files, the dialog says "This file is stored separate from the experiment file" for packed and unpacked experiments. For home text, the dialog says "This file is stored in packed form in the experiment file" for packed experiments and "This file is in the experiment folder" for unpacked experiments.

You can convert a shared text file to a home text file by adopting it. See **Adopting Notebook and Procedure Files** on page II-25 for details.

Using an External Text Editor

Igor supports the use of external editors for editing Igor procedure files and plain text notebooks. This allows you to use your favorite text editor rather than Igor for editing plain text files if you prefer. This is mostly intended for use by advanced programmers who are accustomed to using external editors in other programming environments.

Prior to Igor7, Igor kept plain text files open as long as the corresponding procedure or notebook window was open in Igor. This interfered with the use of external editors.

Now a procedure or plain text notebook window opens its file just long enough to read the text into memory and then close it. If you modify the text in Igor and do a save, Igor reopens the file, writes the modified text to it, and closes the file.

If you modify the file using an external text editor instead of Igor, Igor notices the change, reopens the file, reloads the modified text into memory, and closes the file.

Supporting external editors creates issues that Igor must deal with:

- If you modify the file in an external editor, the text is now out of sync with the text in Igor's window. In this case, Igor notices that the file has been changed and either reloads the text into memory or notifies you, depending on your external editor miscellaneous settings.
- If you save modifications to the file in an external editor and also edit the document in Igor, the text in Igor is in conflict with the external file. In this case Igor informs you of the conflict and lets you choose which version to keep.
- If you move the disk file to new location, delete the file or rename it, Igor's information about the

file is no longer valid. In this case Igor notices that the file has disappeared and gives you options for dealing with it.

The following sections explain how Igor deals with these issues in more detail.

A Plain Text File Has Been Modified Externally

Once per second Igor checks every procedure and plain text notebook window to see if its file has been modified externally. If so then it either automatically reloads the file into memory or notifies you about the external modification and allows you to reload the file at your leisure. The factory default behavior is to automatically reload externally modified files and to check for modified files only when Igor is the active application.

You can control Igor's behavior using the Miscellaneous Settings Dialog. Choose Misc→Miscellaneous Settings, click Text Editing in the lefthand pane, and click the External Editor tab.

If you select Ask Before Reloading, two things happen when the file is modified externally:

- Igor displays a **Reload** button in the status area at the bottom of the document window:

  The Reload button will be visible only if the window is visible.

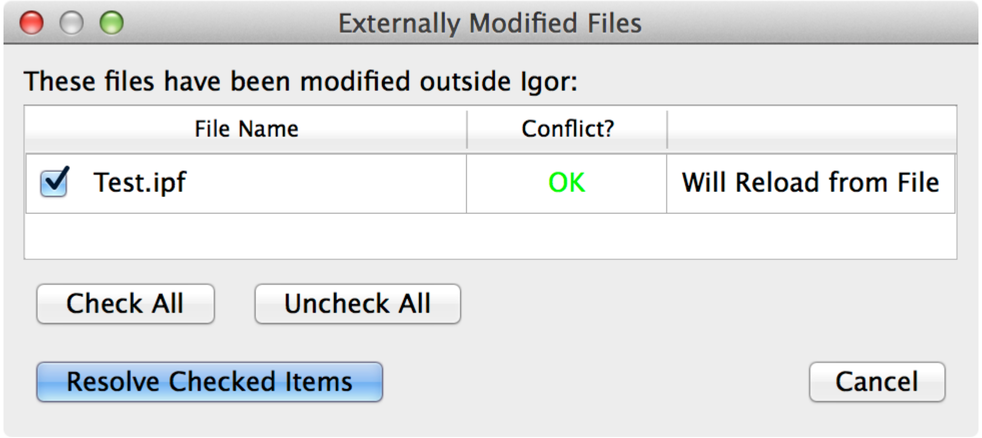
- Igor displays a small floating notification window:

    Files Were Modified Externally

  One or more files have been modified outside Igor.

Clicking the **Reload** button causes Igor to reload the file's text.

Clicking the **Review** button in the notification window displays a dialog in which you can review all the files that are currently modified externally:



Externally Modified Files

These files have been modified outside Igor:

File Name	Conflict?	
☑ Test.ipf	OK	Will Reload from File

Click **Resolve Checked Items** to reload the file into memory.

A Plain Text File Has Been Modified Externally and In Igor

When a file has been modified both in an external editor and by editing in an Igor window, we say it is "in conflict". Igor never automatically reloads a file that is in conflict.

When a file is in conflict, Igor displays a **Resolve Conflict** button in the status area in the Igor document window. Clicking that button brings up a dialog giving four choices to deal with the conflict:

- Reload External Changes

  Loads the contents of the file into memory, discarding changes made in Igor.

- Adopt Document

  Severs the tie between the document and the file, keeping the Igor changes and discarding the changes to the file. To learn more about adopting a file, see **Adopting Notebook and Procedure Files** on page II-25.

- Close the Window

  Closes the procedure or notebook window in Igor, discarding changes made in Igor.

- Save Igor Changes

  Writes changes made in Igor to the file. This resolves the conflict in Igor and creates a conflict in the external editor. Different external editors have different approaches to such conflicts.

Files that are in conflict also cause the notification window to appear. Clicking the Review button in the notification window displays a dialog which gives you the same options for resolving the conflict.

Editing a File with External Modifications

If a file has been modifed externally and not re-loaded in Igor, typing in the Igor window creates a conflict even if there wasn't one previously. This may be undesirable, so when Igor detects this situation, it displays a dialog, similar to the Resolve Conflict dialog, asking you what should be done. The choices are:

- Allow Typing

This choice tells Igor that you want to be allowed to modify the document in Igor. You are putting off resolving the conflict for later. You will have to decide at some point to resolve the conflict in one of the ways described above.

- Reload External Changes

The external modifications will be loaded into the Igor window. Modifications in Igor's copy are discarded.

- Adopt Document

Severs the tie between the document and the file. To learn more about adopting a file, see Adopting Notebook and Procedure Files.

You also have the option of clicking the Cancel button. In that case, the situation is not resolved, and any further attempt to type in the window will cause the dialog to be displayed again.

A Plain Text File Is Missing

If the file associated with an Igor plain text document window is moved, renamed or deleted, Igor will note that the file is missing. In this case, Igor displays a **File Missing** button in the status area in the Igor document window. Clicking that button displays a File Missing dialog giving four choices to deal with the conflict:

- Adopt Document

  Severs the tie between the document and the file. To learn more about adopting a file, see Adopting Notebook and Procedure Files.

- Close the Window

  Closes the procedure or notebook window in Igor.

- Find Missing File

  Displays an Open File dialog allowing you to locate the moved or renamed file.

- Save As

  Displays a Save As dialog allowing you to save the document to a new file.

Missing or Modified Text Files Dialog

A plain text file (procedure file or plain text notebook) may be missing because you deleted it, renamed it, or moved it, or it was deleted, renamed or moved by a program.

A plain text file may have been modified by another program if you edited it in an external editor, for example.

If you try to do a save while a plain text file is missing or modified, Igor displays the Missing or Modified file dialog which asks if you want to cancel the save or continue it. Usually you should cancel the save and use the Files Were Modified Externally window, which appears in the top/right corner of the screen, to review and address the situation.

If you elect to continue the save, it is likely that an error will occur.

To prevent an unattended procedure from hanging, the check for missing or modified files is not done if the save is invoked from a procedure.

Window Shortcuts

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To close a window	Click the close button or press Command-W.	Click the close button or press Ctrl+W.
To kill a window with no dialog	Press Option and click the close button or press Command-Option-W.	Press Alt and click the close button or press Ctrl+Alt+W.
To hide a window	Press Shift and click the close button or press Command-Shift-W.	Press Shift and click the close button or press Ctrl+Shift+W.
To invoke the Window Control dialog	Press Command-Y.	Press Ctrl+Y.
To send the top window behind all others	Press Control-Command-E.	Press Ctrl+E.
To bring the bottom window on top of all others	Press Shift-Control-Command-E.	Press Ctrl+Shift+E.
To send all windows that are completely visible behind all others	Press Command-Option-E.	Press Ctrl+Alt+E.
To activate a recently activated window	Press Command, click the main menu bar, and select from the Recent menu.	Press Ctrl, click the main menu bar, and select from the Recent menu.
To move a window to its preferred size and position	Click the zoom button.	Press Alt and click the maximize button.
To move a window to its full-size position	Press Shift-Option and click the zoom button.	Press Shift +Alt and click the maximize button.
To activate the command window	Press Command-J.	Press Ctrl+J.
To clear the command buffer	Press Command-K.	Press Ctrl+K.
To open the built-in procedure window	Press Command-M.	Press Ctrl+M.
To cycle through all procedure windows	Press Command-Option-M.	Press Ctrl+Alt+M.
To open the Igor help browser	Choose Help→Igor Help Browser.	Press F1.
To find a phrase in a text window	Press Command-F.	Press Ctrl+F.
To find the same phrase again	Press Command-G. Press Command-Shift-G to search backward.	Press Ctrl+G. Press Ctrl+Shift+G to search backward.
To find the selected phrase	Press Command-E and Command-G. Press Command-E and Command-Shift-G to search backward. This shortcut can be changed through the Miscellaneous Settings dialog.	Press Ctrl+H. Press Ctrl+Shift+H to search backward.

Chapter II-5

Waves

Overview

We use the term “wave” to describe the Igor object that contains an array of numbers. Wave is short for “waveform”. The main purpose of Igor is to store, analyze, transform, and display waves.

Chapter I-1, **Introduction to Igor Pro**, presents some fundamental ideas about waves. Chapter I-2, **Guided Tour of Igor Pro**, is designed to make you comfortable with these ideas. In this chapter, we assume that you have been introduced to them.

This chapter focuses on one-dimensional numeric waves. Waves can have up to four dimensions and can store text data. Multidimensional waves are covered in Chapter II-6, **Multidimensional Waves**. Text waves are discussed in this chapter.

The primary tools for dealing with waves are Igor’s built-in operations and functions and its waveform assignment capability. The built-in operations and functions are described in detail in Chapter V-1, **Igor Reference**.

This chapter covers:

- waves in general
- operations for making, killing and managing waves
- setting and examining wave properties
- waveform assignment

and other topics.

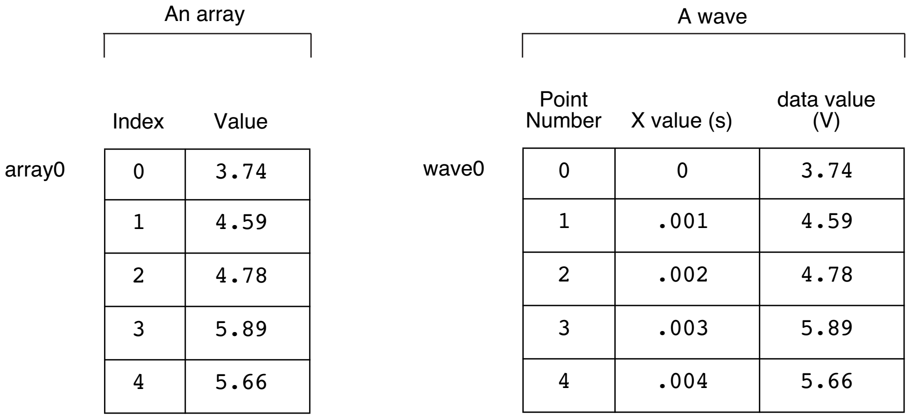
Waveform Model of Data

A wave consists of a number of components and properties. The most important are:

- the wave name
- the X scaling property
- X units
- an array of data values
- data units

The waveform model of data is based on the premise that there is a straight-line mapping from a point number index to an X value or, stated another way, that the data is uniformly spaced in the X dimension. This is the case for data acquired from many types of scientific and engineering instruments and for mathematically synthesized data. If your data is *not* uniformly spaced, you can use two waves to form an XY pair. See **XY Model of Data** on page II-63.

A wave is similar to an array in a standard programming language like FORTRAN or C.



Index	Value
0	3.74
1	4.59
2	4.78
3	5.89
4	5.66

Point Number	X value (s)	data value (V)
0	0	3.74
1	.001	4.59
2	.002	4.78
3	.003	5.89
4	.004	5.66

An array in a standard language has a **name** (array0 in this case) and a number of **values**. We can reference a particular value using an **index**.

A wave also has a **name** (wave0 in this case) and **data values**. It differs from the array in that it has *two* indices. The first is called the **point number** and is identical to an array index or row number. The second is called the **X value** and is in the natural X units of the data (e.g., seconds, meters). Like point numbers, X values are not stored in memory but rather are *computed*.

The X value is related to the point number by the wave's X scaling, which is a property of the wave that you can set. The X scaling of a wave specifies how to compute an X value for a given point number using the formula:

```
x[p] = x0 + p*dx
```

where x[p] is the X value for point p. The two numbers x0 and dx constitute the wave's X scaling property. x0 is the starting X value. dx is the difference in X value from one point to the next. X values are uniformly spaced along the data's X dimension.

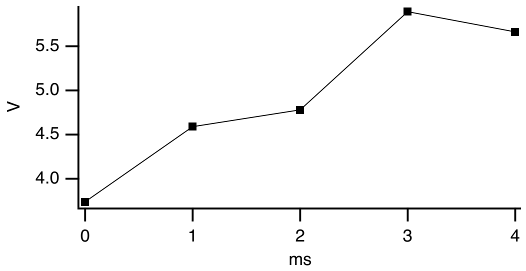
The **SetScale** operation (see page V-853) sets a wave's X scaling. You can use the Change Wave Scaling dialog to generate SetScale commands.

Why does Igor use this model for representing data? We chose this model because it provides all of the information that needed to properly display, analyze and transform waveform data.

By setting your data's X scaling, and X and data units in addition to its data values, you can make a proper graph in one step. You can execute the command

```
Display wave0
```

to produce a graph like this:



If your data is uniformly spaced on the X axis, it is *critical* that you understand and use X scaling.

The X scaling information is essential for operations such as integration, differentiation and Fourier transforms and for functions such as the **area** function (see page V-40). It also simplifies waveform assignment by allowing you to reference a single value or range of values using natural units.

Igor waves can have up to four dimensions. We call these dimensions X, Y, Z and T. X scaling extends to dimension scaling. For each dimension, there is a starting index value (x0, y0, z0, t0) and a delta index value (dx, dy, dz, dt). See Chapter II-6, **Multidimensional Waves**, for more about multidimensional waves.

XY Model of Data

If your data is not uniformly spaced along its X dimension then it can not be represented with a single wave. You need to use two waves as an XY pair.

In an XY pair, the data values of one wave provide X values and the data values of the other wave provide Y values. The X scaling of both waves is irrelevant so we leave it in its default state in which the x0 and dx components are 0 and 1. This gives us

```
x[p] = 0 + 1·p
```

This says that a given point's X value is the same as its point number. We call this "point scaling". Here is some sample data that has point scaling.

	X wave		
	Point Number	X value ()	data value (V)
xWave	0	0	0.0
	1	1	.0013
	2	2	.0021
	3	3	.0029
	4	4	.0042

	Y wave		
	Point Number	X value ()	data value (V)
yWave	0	0	3.74
	1	1	4.59
	2	2	4.78
	3	3	5.89
	4	4	5.66

The X values serve no purpose in the XY model. Therefore, we change our thinking and look at an XY pair this way.

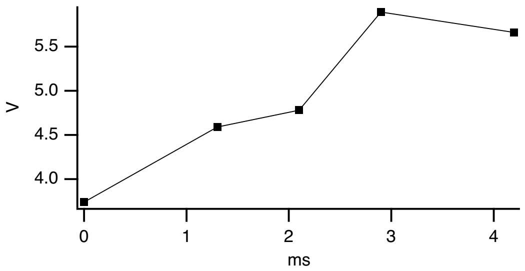
	X wave	
	Point Number	Value (s)
xWave	0	0.0
	1	.0013
	2	.0021
	3	.0029
	4	.0042

	Y wave	
	Point Number	Value (V)
yWave	0	3.74
	1	4.59
	2	4.78
	3	5.89
	4	5.66

We can execute

```
Display yWave vs xWave
```

and it produces a graph like this.



Some operations, such as Fast Fourier Transforms and convolution, require equally spaced data. In these cases, it may be desirable for you to create a uniformly spaced version of your data by interpolation. See **Converting XY Data to a Waveform** on page III-109.

Some people who have uniformly spaced data still use the XY model because it is what they are accustomed to. **This is a mistake**. If your data is uniformly spaced, it will be well worth your while to learn and use the waveform model. It greatly simplifies graphing and analysis and makes it easier to write Igor procedures.

Making Waves

You can make waves by:

- Loading data from a file
- Typing or pasting in a table
- Using the **Make** operation (via a dialog or directly from the command line)
- Using the **Duplicate** operation (via a dialog or directly from the command line)

Most people start by loading data from a file. Igor can load data from text files. In this case, Igor makes a wave for each column of text in the file. Igor can also load data from binary files or application-specific files created by other programs. For information on loading data from files, see **Importing Data** on page II-126.

You can enter data manually into a table. This is recommended only if you have a small amount of data. See **Using a Table to Create New Waves** on page II-239.

To synthesize data with a mathematical expression, you would start by making a wave using the **Make** operation (see page V-526). This operation is also often used inside an Igor procedure to make waves for temporary use.

The **Duplicate** operation (see page V-185) is an important and handy tool. Many built-in operations transform data in place. Thus, if you want to keep your original data as well as the transformed copy of it, use Duplicate to make a clone of the original.

Wave Names

All waves in Igor have names so that you can reference them from commands. You also use a wave's name to select it from a list or pop-up menu in Igor dialogs or to reference it in a waveform assignment statement.

You need to choose wave names when you use the **Make**, **Duplicate** or **Rename** operations via dialogs, directly from the command line, and when you use the Data Browser.

All names in Igor are case insensitive; wave0 and WAVE0 refer to the same wave.

The rules for the kind of characters that you can use to make a wave name fall into two categories: standard and liberal. Both standard and liberal names are limited to 255 bytes in length.

Prior to Igor Pro 8.00, wave names were limited to 31 bytes. If you use long wave names, your wave and experiment files will require Igor Pro 8.00 or later.

Standard names must start with an alphabetic character (A - Z or a-z) and may contain ASCII alphabetic and numeric characters and the underscore character only. Other characters, including spaces, dashes and periods and non-ASCII characters are not allowed. We put this restriction on standard names so that Igor can identify them unambiguously in commands, including waveform assignment statements.

Liberal names, on the other hand, can contain any character except control characters (such as tab or carriage return) and the following four characters:

```
   "  '  :  ;
```

Standard names can be used without quotation in commands and expressions but liberal names must be quoted. For example:

```
Make wave0; wave0 = p          // wave0 is a standard name
Make 'wave 0'; 'wave 0' = p    // 'wave 0' is a liberal name
```

Igor can not unambiguously identify liberal names in commands unless they are quoted. For example, in

```
wave0 = miles/hour
```

miles/hour could be a single wave or it could be the quotient of two waves.

To make them unambiguous, you must enclose liberal names in single straight quotes whenever they are used in commands or waveform arithmetic expressions. For example:

```
wave0 = 'miles/hour'
Display 'run 98', 'run 99'
```

NOTE: Writing procedures that work with liberal names requires extra effort and testing on the part of Igor programmers (See **Programming with Liberal Names** on page IV-168). We recommend that you avoid using liberal names until you understand the potential problems and how to solve them.

See **Object Names** on page III-501 for a discussion of object names in general.

Number of Dimensions

Waves can consist of one to four dimensions. You determine this when you make a wave. You can change it using the **Redimension** operation (see page V-788). See Chapter II-6, **Multidimensional Waves** for details.

Wave Data Types

Each wave has data type that determines the kind of data that it stores.You set a wave's data type when you create it. You can change it using the Data Browser, the **Redimension** operation (see page V-788) or the Redimension dialog.

There are three classes of wave data types:

- Numeric data types
- Text
- References (wave referencesand data folder references)

Each numeric data type can be either real or complex. Text and reference data types can not be complex.

Reference data types are used in programming only.

You can programmatically determine the data type of a wave using the **WaveType** function.

Numeric Wave Data Types

This table shows the numeric precisions available in Igor.

Precision	Range	Bytes per Point
Double-precision floating point	10^{-324} to 10^{+307} (~15 decimal digits)	8
Single-precision floating point	10^{-45} to 10^{+38} (~7 decimal digits)	4
Signed 64-bit integer	-2^63 to 2^63 - 1	8
Signed 32-bit integer	-2,147,483,647 to 2,147,483,648	4
Signed 16-bit integer	-32,768 to 32,767	2
Signed 8-bit integer	-128 to 127	1
Unsigned 64-bit integer	0 to 2^64 - 1	8
Unsigned 32-bit integer	0 to 4,294,967,295	4
Unsigned 16-bit integer	0 to 65,535	2
Unsigned 8-bit integer	0 to 255	1

The 64-bit integer types were added in Igor Pro 7.00.

For most work, single precision waves are appropriate.

Single precision waves take up half the memory and disk space of double precision. With the exception of the FFT and some special purpose operations, Igor uses double precision for calculations regardless of the numeric precision of the source wave. However, the narrower dynamic range and smaller precision of single precision is not appropriate for all data. If you are not familiar with numeric errors due to limited range and precision, it is safer to use double precision for analysis.

Integer waves are intended for data acquisition purposes and are not intended for use in analysis. See **Integer Waves** on page II-85 for details.

Default Wave Properties

When you create a wave using the **Make** operation (see page V-526) operation with no optional flags, it has the following default properties.

Property	**Default**
Number of points	128
Data type	Real, single-precision floating point
X scaling	x0=0, dx=1 (point scaling)
X units	Blank
Data units	Blank

These are the key wave properties. For a comprehensive list of properties, see **Wave Properties** on page II-88.

If you make a wave by loading it from a file or by typing in a table, it has the same default properties except for the number of points.

However you make waves, if they represent waveforms as opposed to XY pairs, you should use the Change Wave Scaling dialog to set their X scaling and units.

Make Operation

Most of the time you will probably make waves by loading data from a file (see **Importing Data** on page II-126), by entering it in a table (see **Using a Table to Create New Waves** on page II-239), or by duplicating existing waves (see **Duplicate Operation** on page II-70).

The **Make** operation is used for making new waves. See the **Make** operation (see page V-526) for additional details.

Here are some reasons to use Make:

- To make waves to play around with.
- For plotting mathematical functions.
- To hold the output of analysis operations.
- To hold miscellaneous data, such as the parameters used in a curve fit or temporary results within an Igor procedure.

The Make Waves dialog provides an interface to the **Make** operation. To use it, choose Make Waves from the Data menu.

Waves have a definite number of points. Unlike a spreadsheet program which automatically ignores blank cells at the end of a column, there is no such thing as an “unused point” in Igor. You can change the number of points in a wave using the Redimension Waves dialog or the **Redimension** operation (see page V-788).

The “Overwrite existing waves” option is useful when you don’t know or care if there is a wave with the same name as the one you are about to make.

Make Operation Examples

Make coefs for use in curve fitting:

```
Make/O coefs = {1.5, 2e-3, .01}
```

Make a wave for plotting a math function:

```
Make/O/N=200 test; SetScale x 0, 2*PI, test; test = sin(x)
```

Make a 2D wave for image or contour plotting:

```
Make/O/N=(20,20) w2D; w2D = (p-10)*(q-10)
```

Make a text wave for a category plot:

```
Make/O/T quarters = {"Q1", "Q2", "Q3", "Q4"}
```

It is often useful to make a clone of an existing wave. Don’t use Make for this. Instead use the **Duplicate** operation (see page V-185).

Make/O does not preserve the contents of a wave and in fact will leave garbage in the wave if you change the number of points, numeric precision or numeric type. Therefore, after doing a Make/O you should not assume anything about the wave’s contents. If you know that a wave exists, you can use the **Redimension** operation instead of Make. Redimension does preserve the wave’s contents.

Waves and the Miscellaneous Settings Dialog

The state of the Type popup menu in the Make Waves dialog, the precision of waves created by typing in a table, and the way Igor Binary waves are loaded (whether they are copied or shared) are preset with the Miscellaneous Settings dialog using the Data Loading Settings category; see **Miscellaneous Settings** on page III-500.

Changing Dimension and Data Scaling

When you make a 1D wave, it has default X scaling, X units and data units. You should use the **SetScale** operation (see page V-853) to change these properties.

The Change Wave Scaling dialog provides an interface to the **SetScale** operation. To use it, choose Change Wave Scaling from the Data menu.

Scaled dimension indices can represent ordinary numbers, dates, times or date&time values. In the most common case, they represent ordinary numbers and you can leave the Units Type pop-up menu in the Set X Properties section of the dialog on its default value: Numeric.

If your data is waveform data, you should enter the appropriate Start and Delta X values. If your data is XY data, you should enter 0 for Start and 1 for Delta. This results in the default “point scaling” in which the X value for a point is the same as the point number.

Normally you should leave the Set X Properties and Set Data Properties checkboxes selected. Deselect one of them if you want the dialog to generate commands to set only X or only Data properties. When working with multidimensional data, the X of Set X Properties can be changed to Y, Z or T via the pop-up menu. See Chapter II-6, **Multidimensional Waves**.

If you want to observe the properties of a particular wave, double-click it in the list or select the wave and then click the From Wave button. This sets all of the dialog items according to that wave’s properties.

Igor uses the dimension and data Units to automatically label axes in graphs. Igor can handle units consisting of 49 bytes or less. Typically, units should be short, standard abbreviations such as “m”, “s”, or “g”. If your data has more complex units, you can enter the complex units or you may prefer to leave the units blank.

Advanced Dimension and Data Scaling

If you click More Options, Igor displays some additional items in the dialog. They give you two additional ways to specify X scaling and allow you to set the wave’s “data full scale” values. These options are usually not needed but for completeness are described in this section.

In spite of the fact that there is only one way of calculating X values, there are three ways you can specify the x0 and dx values. The SetScale Mode pop-up menu changes the meaning of the scaling entries above. The simplest way is to simply specify x0 and dx directly. This is the Start and Delta mode in the dialog and is the only way of setting the scaling unless you click the More Options button. As an example, if you have data that was acquired by a digitizer that was set to sample at 1 MHz starting 150 µs after t=0, you would enter 150E-6 for Start and 1E-6 for Delta.

The other two ways of specifying X scaling are to set the starting and ending X values are and to calculate dx from the number of points. In the Start and End mode you specify the X value of the last data point. Using the Start and Right mode you specify the X at the end of the last interval. For example, assuming our digitizer (above) created a 100 point wave, we would enter 150E-6 as Start for either mode. If we selected the Start and End mode we would enter 249E-6 for End (150E-6 + 99*1E-6). If we selected Start and Right we would enter 250E-6 for Right.

The min and max entries allow you to set a property of a wave called its “data full scale”. This property doesn’t serve a critical purpose. Igor does not use it for any computation or graphing purposes. It is merely a way for you to document the conditions under which the wave data was acquired. For example, if your data comes from a digital oscilloscope and was acquired on the ±10v range, you could enter -10 for min and +10 for max. When you make waves, both of these will initially be set to zero. If your data has a meaningful data full scale, you can set them appropriately. Otherwise, leave them zero.

The data units, on the other hand *are* used for graphing purposes, just like the dimension units.

Date, Time, and Date&Time Units

The units “dat” are special, specifying that the scaled dimension indices or data values of a wave contain date, time, or date&time information.

If you have waveform data then set the X units of your waveform to "dat".

If you have XY data then set the data units of your X wave to "dat". In this case your X wave must be double-precision floating point in order to have enough precision to represent dates accurately.

For example, if you have a waveform that contains some quantity measured once per day, you would set the X units for the wave to “dat”, set the starting X value to the date on which the first measurement was done, and set the Delta X value to one day. Choosing Date from the Units Type pop-up menu sets the X units to “dat”. You can enter the starting value as a date rather than as a number of seconds since 1/1/1904, which is how Igor represents dates internally. When Igor graphs the waveform, it will notice that the X units are “dat” and will display dates on the X axis.

If instead of a waveform, you have an XY pair, you would set the data units of the X wave to “dat”, by choosing Date from the Units Type pop-up menu in the Set Data Properties section of the dialog. When you graph the XY pair, Igor will notice that the X wave contains dates and will display dates on the X axis.

The Units Type pop-up menus do not correspond directly to any property of a wave. That is, a wave doesn’t have a units type property. Instead, these menus merely identify what kind of values you are dealing with so that the dialog can display the values in the appropriate format.

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-85.

For information on dates and times in tables, see **Date/Time Formats** on page II-256.

For information on dates and times in graphs, see **Date/Time Axes** on page II-315.

Duplicate Operation

Duplicate is a handy and frequently-used operation. It can make new waves that are exact clones of existing waves. It can also clone a section of a wave and thus provides an easy way to break a big wave up into smaller waves.

Here are some reasons to use Duplicate:

- To hold the results of a transformation (e.g. integration, differentiation, FFT) while preserving the original data.
- To hold the “destination” of a curve fit.
- For holding temporary results within an Igor procedure.
- To extract a section of a wave.

The Duplicate Waves dialog provides an interface to the **Duplicate** operation (see page V-185). To use it, choose Duplicate Waves from the Data menu.

The cursors button is used in conjunction with a graph. You can make a graph of your template wave. Then put the cursors on the section of the template that you want to extract. Choose Duplicate Waves from the Data menu and click the cursors button. Then click Do It. This clones the section of the template wave identified by the cursors.

People sometimes make the mistake of using the **Make** operation when they should be using Duplicate. For example, the destination wave in a curve fit must have the same number of points, numeric type and numeric precision as the source wave. Duplicating the source wave insures that this will be true.

Duplicate Operation Examples

Clone a wave and then transform the clone:

```
Duplicate/O wave0, wave0_d1; Differentiate wave0_d1
```

Use Duplicate to inherit the properties of the template wave:

```
Make/N=200 wave0; SetScale x 0, 2*PI, wave0; wave0 = sin(x)
Duplicate wave0, wave1; wave1 = cos(x)
```

Make a destination wave for a curve fit:

```
Duplicate/O data1, data1_fit
CurveFit gauss data1 /D=data1_fit
```

Compare the first half of a wave to the second:

```
Duplicate/O/R=[0,99] data1, data1_1
Duplicate/O/R=[100,199] data1, data1_2
Display data1_1, data1_2
```

We often use the /O flag (overwrite) with Duplicate because we don’t know or care if a wave already exists with the new wave name.

Killing Waves

The **KillWaves** operation (see page V-471) removes waves from the current experiment. This releases the memory used by the waves. Waves that you no longer need clutter up lists and pop-up menus in dialogs. By killing them, you reduce this clutter.

Here are some situations in which you would use KillWaves:

- You are finished examining data that you loaded from a file.
- You are finished using a wave that you created for experimentation.

- You no longer need a wave that you created for temporary use in an Igor procedure.

The Kill Waves dialog provides an interface to the **KillWaves** operation. To use it, choose Kill Waves from the Data menu.

Igor will not let you kill waves that are used in graphs, tables or user-defined functions so they do not appear in the list.

Note: Igor can not tell if a wave is referenced from a macro. Thus, Igor will let you kill a wave that is referenced from a macro but not used in any other way. The most common case of this is when you close a graph and save it as a recreation macro. Waves that were used in the graph are now used only in the macro and Igor will let you kill them. If you execute the graph recreation macro, it will be unable to recreate the graph.

KillWaves can delete the Igor binary wave file from which a wave was loaded, called the “source file”. This is normally not necessary because the wave you are killing either has never been saved to disk or was saved as part of a packed experiment file and therefore was not loaded from a standalone file.

The “Kill all waves not in use” option is intended for those situations where you have created an Igor experiment that contains procedures which load, graph and process a batch of waves. After you have processed one batch of waves, you can kill all graphs and tables and then kill all waves in the experiment in preparation for loading the next batch. This affects only those waves in the current data folder; waves in any other data folders will not be killed.

KillWaves Operation Examples

Here are some simple examples using KillWaves.

```
// Kills all target windows and all waves.
// Does not kill nontarget windows (procedure and help windows).
Function KillEverything()
   String windowName

   do
      windowName = WinName(0, 1+2+4+16+64)// Get next target window
      if (CmpStr(windowName, "") == 0) // If name is ""
         break                        // we are done so break loop
      endif
      KillWindow $windowName          // Kill this target window
   while (1)

   KillWaves/A                        // Kill all waves
End

// This illustrates killing a wave used temporarily in a procedure
Function Median(w)                 // Returns median value of wave w
   Wave w

   Variable result

   Duplicate/O w, temp             // Make a clone of wave
   Sort temp, temp                 // Sort clone
   result = temp[numpnts(temp)/2]

   KillWaves temp                  // Kill clone

   return result
End
```

For more examples, see the “Kill Waves” procedure file in the “WaveMetrics Procedures” folder.

Browsing Waves

The Data Browser (Data menu) lets you see what waves (as well as strings and variables) exist at any given time. It also lets you see what data folders exist and set the current data folder. The Data Browser is described in detail in Chapter II-8, **Data Folders**.

Igor Pro 6 had a Browse Waves dialog which you accessed via the Data→Browse Waves menu item. Because it provided the same functionality as the Data Browser, the dialog and menu item were removed in Igor Pro 7.00.

Renaming Waves

You can rename a wave using:

- The Data Browser
- The Rename dialog (Data menu)
- The **Rename** operation from the command line

The **Rename** operation (see page V-796) renames waves as well as other objects.

Here are some reasons for renaming waves:

- You have loaded a bunch of waves from a file and Igor auto-named the waves.
- You have decided on a naming convention for waves and you want to make existing waves follow the convention.
- You are about to load a set of waves whose names will be the same as existing waves and you want to get the existing waves out of the way but still keep them in memory. (You could also achieve this by moving them to a new data folder.)

To use the **Rename** operation, choose Rename from the Data menu. This brings up the Rename Objects dialog.

Redimensioning Waves

The Redimension operation can change the following properties of a wave:

- The number of dimensions in the wave
- The number of elements in each dimension
- The numeric precision (e.g., single to double)
- The numeric type (e.g., real to complex)

The Redimension Waves dialog provides an interface to the **Redimension** operation (see page V-788). To use it, choose Redimension Waves from the Data menu.

When Redimension adds new elements to a wave, it sets them to zero for a numeric wave and to blank for a text wave.

The following commands illustrate two ways of changing the numeric precision of a wave. Redimension preserves the contents of the wave whereas Make does not.

```
Make/N=5 wave0=x
Edit wave0
Redimension/D wave0        // This preserves the contents of wave0
Make/O/D/N=5 wave0         // This does not
```

See **Vector (Waveform) to Matrix Conversion** on page II-98 for information on converting a 1D wave into a 2D wave while retaining the data (i.e., reshaping).

You cannot change a wave from numeric to text or vice versa. The following examples illustrate how you can make a text copy of a numeric wave and a numeric copy of a text wave:

```
Make/N=10 numWave = p
Make/T/N=(numpnts(numWave)) textWave = num2str(numWave)
Make/N=(numpnts(textWave)) numWave2 = str2num(textWave)
```

However, you can lose precision because num2str prints with only 6 digits of precision.

Inserting Points

There are two ways to insert new points in a wave. You can do this by:

- Using the **InsertPoints** operation
- Typing or pasting in a table

This section deals with the **InsertPoints** operation (see page V-443). For information on typing or pasting in a table, see Chapter II-12, **Tables**.

Using the **InsertPoints** operation, you can insert new data points at the start, in the middle or at the end of a 1D wave. You can also insert new elements in multidimensional waves. For example, you can insert new columns in a 2D matrix wave. The inserted values will be 0 for a numeric wave and "" for a text wave.

The Insert Points dialog provides an interface to the **InsertPoints** operation. To use it, choose Insert Points from the Data menu.

If the value that you enter for first point is greater than the number of elements in the selected dimension of a selected wave, the new points are added at the end of the dimension. InsertPoints can change the dimensionality of a wave. For example, if you insert a column in a 1D wave, you end up with at 2D wave.

If the top window is a table at the time that you select Insert Points, Igor will preset the dialog items based on the selection in the table.

Deleting Points

There are two ways to delete points from a wave. You can do this by:

- Using the **DeletePoints** operation
- Doing a cut in a table

This section deals with the **DeletePoints** operation (see page V-157). For information on cutting in a table, see Chapter II-12, **Tables**.

Using the **DeletePoints** operation, you can delete data points from the start, middle or end of a 1D wave. You can also delete elements from multidimensional waves. For example, you can delete columns from a 2D matrix wave.

The Delete Points dialog provides an interface to the **DeletePoints** operation. To use it, choose Delete Points from the Data menu.

If the value that you enter for first point is greater than the number of elements in the selected dimension of a selected wave, DeletePoints will do nothing to that wave. If the number of elements is too large, DeletePoints will delete from the specified first element to the end of the dimension.

Except for the case of removing all elements, which leaves the wave as 1D, DeletePoints does not change the dimensionality of a wave. Use **Redimension** for that.

If the top window is a table at the time that you choose Delete Points, Igor will preset the dialog items based on the selection in the table.

Waveform Arithmetic and Assignments

Waveform arithmetic is a very flexible and powerful part of Igor's analysis capability. You can write assignment statements that work on an entire wave or on a subset of a wave, much as you would write an assignment to a single variable in a standard programming language.

In a wave assignment statement, a wave appears on the left side and a mathematical expression appears on the right side. Here are some examples.

```
wave0 = sin(x)
wave0 = log(wave1/wave2)
wave0[0,99] = wave1[100 + p]
```

A wave on the left side is called the **destination wave**. A wave on the right side is called a **source wave**.

When Igor executes a wave assignment statement, it evaluates the expression on the right-hand side one time for each point in the destination wave. The result of each evaluation is stored in the corresponding point in the destination wave.

During execution, the symbol *p* has a value equal to the number of the point in the destination wave which is being set and the symbol *x* has a value equal to the X value at that point. The X value for a given point is determined by the number of the point and the X scaling for the wave. To see this, execute the following commands, one-at-a-time:

```
Make/N=5 wave0; SetScale/P x 0, .1, wave0; Edit wave0.xy
wave0 = p
wave0 = x
```

The first assignment statement sets the value of each point of wave0 to the point number. The second assignment statement sets the value of each point of wave0 to the X value for that point.

A source wave returns its data value at the point being evaluated. In the example

```
wave0 = log(wave1/wave2)
```

Igor evaluates the right-hand expression once for each point in wave0. During each evaluation of the expression, wave1 and wave2 return their data values at the point being evaluated. Consequently, these commands are equivalent:

```
wave0 = log(wave1/wave2)

wave0 = log(wave1[p]/wave2[p])
```

Understanding Wave Assignments

To understand wave assignments, it is critical to understand the meaning of p and x. To this end, it may be helpful to think of what happens inside Igor. A wave assignment statement causes a loop to run inside Igor.

p is the loop index of the internal loop and runs over the range of points being set in the destination wave. In the preceding example, p starts from 0 and is incremented each time through the internal loop, up to N-1, where N is the number of points in wave0. For each value of p, the right-hand expression is evaluated and the result is stored in the corresponding point of wave0.

When you see `wave1` or `wave1[p]` on the right-hand side of a waveform assignment statement, this returns the value of wave1 at point p, which is the point in the destination wave (wave0) that Igor is setting during the current iteration of the internal loop.

x is similar to p except that, instead of being the loop index of the internal Igor loop, it is calculated from the loop index using the X scaling of the destination wave:

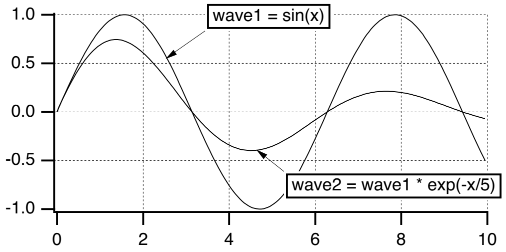
```
x = x0 + p*dx
```

Wave assignment is an important Igor feature and it will be worth your time to understand it. You may need to reread this material and do some experimentation on the command line. If you are new to Igor, you may prefer to return to this topic after you have gained experience.

Wave Assignment Example

This command sequence illustrates some of the ideas explained above.

```
Make/N=200 wave1, wave2                // Two waves, 200 points each
SetScale/P x, 0, .05, wave1, wave2     // Set X values from 0 to 10
Display wave1, wave2                   // Create a graph of waves
wave1 = sin(x)                         // Assign values to wave1
wave2 = wave1 * exp(-x/5)              // Assign values to wave2
```



Since wave1 has 200 points, the wave assignment statement `wave1=sin(x)` evaluates `sin(x)` 200 times, once for each point in wave1. The first point of wave1 is point number 0 and the last point of wave1 is point number 199. The symbol p, not used in this example, goes from 0 to 199. The symbol x steps through the 200 X values for wave1 which start from 0 and step by .05, as specified by the SetScale command. The result of each evaluation is stored in the corresponding point in wave1, making wave1 about 1.5 cycles of a sine wave.

Since wave2 also has 200 points, the wave assignment statement `wave2=wave1*exp(-x/5)` evaluates `wave1*exp(-x/5)` 200 times, once for each point in wave2. In this assignment, the right-hand expression contains a wave, wave1. As Igor executes the assignment, p goes from 0 to 199. Each of the 200 times the right side is evaluated, wave1 returns its data value for the corresponding point. The result of each evaluation is stored in the corresponding point in wave2 making wave2 about 1.5 cycles of a damped sine wave.

The effect of a wave assignment statement is to set the data values of the destination wave. Igor does not remember the functional relationship implied by the assignment. In this example, if you changed wave1, wave2 would not change automatically. If you wanted wave2 to have the same functional relationship to wave1 as it had before you changed wave1, you would have to reexecute the `wave2=wave1*exp(-x/5)` assignment.

There is a special kind of wave assignment statement that *does* establish a functional relationship. It should be used sparingly. See **Wave Dependency Formulas** on page II-84 for details.

More Wave Assignment Features

Just as the symbol p returns the current element number in the rows dimension, the symbols q, r and s return the current element number in the columns, layers and chunks dimensions of multidimensional waves. The symbol x in the rows dimension has analogs y, z and t in the columns, layers and chunks dimensions. See Chapter II-6, **Multidimensional Waves**, for details.

You can use multiple processors to execute a waveform assignment statement that takes a long time. See **Automatic Parallel Processing with MultiThread** on page IV-323 for details.

The right-hand expression is evaluated in the context of the data folder containing the destination wave. See **Data Folders and Assignment Statements** on page II-111 for details.

Usually source waves have the same number of points and X scaling as the destination wave. In some cases, it is useful to write a wave assignment statement where this is not true. This is discussed under **Mismatched Waves** on page II-83.

Indexing and Subranges

Igor provides two ways to refer to a specific point or range of points in a 1D wave: X value indexing and point number indexing. Consider the following examples.

```
wave0[54] = 92          // Sets wave0 at point 54 to 92
wave0(54) = 92          // Sets wave0 at X=54 to 92
wave0[1,10] = 92        // Sets wave0 from point 1 to point 10 to 92
wave0(1,10) = 92        // Sets wave0 from X=1 to X=10 to 92
```

Brackets tell Igor that you are indexing the wave using point numbers. The number or numbers inside the brackets are interpreted as point numbers of the indexed wave.

Parentheses tell Igor that you are indexing the wave using X values. The number or numbers inside the parentheses are interpreted as X values of the indexed wave. When you use an X value as an index, Igor first finds the point number corresponding to that X value based on the indexed wave's X scaling, and then uses that point number as the point index.

If the wave has point scaling then these two methods have identical effects. However, if you set the X scaling of the wave to other than point scaling then these commands behave differently. In both cases the range is inclusive.

You can specify not only a range but also a point number increment. For example:

```
wave0[0,98;2] = 1       // Sets even numbered points in wave0 to 1
wave0[1,99;2] = -1      // Sets odd numbered points in wave0 to -1
```

The number after the semicolon is the increment. Igor begins at the starting point number and goes up to and including the ending point number, skipping by the increment. At each resulting point number, it evaluates the right-hand side of the wave assignment statement and sets the destination point accordingly.

Increments can also be used when you specify a range in terms of X value but the increment is always in terms of point number. For example:

```
wave0(0,100;5) = PI     // Sets wave0 at specified X values to PI
```

Here Igor starts from the point number corresponding to x = 0 and goes up to and including the point number that corresponds to x = 100. The point number is incremented by 5 at each iteration.

You can take some shortcuts in specifying the range of a destination wave. The subrange start and end values can both be omitted. When the start is omitted, point number zero is used. When the end is omitted, the last point of the wave is used. You can also use a * character or INF to specify the last point. An omitted increment value defaults to a single point.

Here are some examples that illustrate these shortcuts:

```
wave0[ ,50] = 13           // Sets wave0 from point 0 to point 50

wave0[51,] = 27            // Sets wave0 from point 51 to last point

wave0[51,*] = 27           // Sets wave0 from point 51 to last point

wave0[51,INF] = 27         // Sets wave0 from point 51 to last point

wave0[ , ;2] = 18.7        // Sets every even point of wave0

wave0[1,*;2] = 100         // Sets every odd point of wave0
```

A subrange of a destination wave may consist of a single point or a range of points but a subrange of a source wave must consist of a single point. In other words the wave assignment statement:

```
wave1(4,5) = wave2(5,6)    // Illegal!
```

is not legal. In this assignment, x ranges from 4 to 5. You can get the desired effect using:

```
wave1(4,5) = wave2(x+1)    // OK!
```

By virtue of the range specified on the left hand side, x goes from 4 to 5. Therefore, x+1 goes from 5 to 6 and the right-hand expression returns the values of wave2 from 5 to 6.

Indexing with an index wave

You can set specific elements of the destination wave using another wave to provide index values using this syntax:

```
destWave[indexWave] = <expression>
```

This feature was added in Igor Pro 8.00.

When the destination wave is one dimensional, the index wave must contain a list of valid point numbers. For example:

```
Make/O/N=10 destWave = 0
Make/O indexWave = {2,5,8}
destWave[indexWave] = p; Print destWave
   destWave[0]= {0,0,2,0,0,5,0,0,8,0}
```

When the destination wave is multidimensional, the index wave can be two dimensional with a valid row index in the first column and a valid column index in the second column. The next example sets all elements of the destination wave to zero except for elements (3,2), (5,4), and (7,6) which it sets to 999.

```
Make/O/N=(10,10) destWave = 0
Make/O/N=(3,2) indexWave
indexWave[0][0] = {3,5,7}           // Store row indices in column 0
indexWave[0][1] = {2,4,6}           // Store column indices in column 1
Edit indexWave
destWave[indexWave] = 999
Edit destWave
```

When the destination wave is multidimensional, it is legal for the index wave to be 1D containing linear point numbers as if the destination wave were itself 1D. The assignment statement is evaluated as if the destination wave were 1D so q, r, s, y, z and t return zero on the righthand side. This example uses a 1D index wave to set the same elements as the preceding example:

```
Make/O/N=(10,10) destWave = 0
Make/O indexWave = {23,45,67}
destWave[indexWave] = 888
```

In addition to using an index wave on the left hand side, you can also use a value wave on the right with this syntax:

```
destWave[indexWave] = {valueWave}
```

The value wave is a 1D vector of values. It should contain the same number of values as there are index values and should have the same type (numeric, string, etc.) as the destination wave. Here is an example:

```
Make/O/N=10 destWave = 0
Make/O indexWave = {2,5,8}
Make/O valueWave = {777,776,775}
destWave[indexWave] = {valueWave}
```

When you use an index wave, a list of individual values is not supported:

```
destWave[indexWave] = {777,776,775}    // Error - value wave expected in braces
```

In the next example we treat a 2D destination wave as 1D by providing a 1D index wave:

```
Make/O/N=(10,10) destWave = 0
Make/O indexWave = {23,45,67}
Make/O valueWave = {666,665,664}
destWave[indexWave] = {valueWave}
```

In the next example we treat a 2D the destination wave as 2D by providing a 2D index wave:

```
Make/O/N=(10,10) destWave = 0
Make/O/N=(3,2) indexWave
indexWave[0][0] = {3,5,7}          // Store row indices in column 0
indexWave[0][1] = {2,4,6}          // Store column indices in column 1
Make/O valueWave = {555,554,553}
destWave[indexWave] = {valueWave}
```

Interpolation in Wave Assignments

If you specify a fractional point number or an X value that falls between two data points, Igor will return a linearly interpolated data value. For example, wave1[1.75] returns the value of wave1 three-quarters of the way from the data value of point 1 to the data value of point 2. This interpolation is done only for one-dimensional waves. See **Multidimensional Wave Assignment** on page II-96, for information on assignments with multidimensional data.

This is a powerful feature. Imagine that you have an evenly spaced calibration curve, called calibration, and you want to find the calibration values at a specific set of X coordinates as stored in a wave called xData. If you have set the X scaling of the calibration wave, you can do the following:

```
Duplicate xData, yData
yData = calibration(xData)
```

This uses the interpolation feature of Igor's wave assignment statement to find a linearly-interpolated value in the calibration wave for each X coordinate in the xData wave.

Lists of Values

You can assign values to a wave or to a subrange of a wave using a list of values in curly braces. You can also add rows and columns.

1D Lists of Values

This section shows how to set elements of a 1D wave and add rows using lists of values. As shown below a 1D list of values consists of a lists of row values in curly braces.

```
Make/O/N=5 wave0 = NaN        // Make 5 point wave and display in table
Edit/W=(5,45,450,350) wave0

wave0 = {0, 1, 2}             // Redimension wave0 to 3 rows and set Y values

Make/O/N=5 wave0 = NaN        // Restore to 5 points

wave0[1,3]= {1, 2, 3}         // Set points 1 through 3

wave0 = NaN
wave0[1]= {1, 2, 3}           // Set points 1 through 3 (same as previous)

wave0 = NaN
wave0[0,4;2]= {0, 2, 4}       // Set points 0, 2, and 4 using a step of 2

// Extend wave0 from 5 rows to 8 rows and set new Y values.
// Adds rows because the index, 5, is equal to the number of wave rows.
wave0 = NaN
wave0[5]= {5, 6, 7}

Make/O/N=5 wave0 = NaN        // Restore to 5 points
```

```
// Add a column changing wave0 from 1D to 2D. Adds a column
// because the column index, 1, is equal to the number of wave columns.
wave0[][1] = {10,11,12,13,14}
```

2D Lists of Values

This section shows how to set elements of a 2D wave and add rows and columns using lists of values. As shown below a 2D list of values consists of a a nested list of lists in curly braces. Each inner list defines the row values for one column.

```
Make/O/N=(4,3) w2D = NaN      // Make wave with 4 rows and 3 columns
Edit/W=(225,45,850,350) w2D

// Redimension w2D and set elements.
// Set column 0 to {1,2,3}, column 1 to {10,11,12}.
w2D = {{0,1,2}, {10,11,12}}

Make/O/N=(4,3) w2D = NaN      // Restore to 4 rows by 3 column

// Set column 0 to {0,1,2,3}, column 1 to {10,11,12,13}.
// Here [] can be read as "all rows" so this means set
// all rows of columns 0 through 1.
w2D[][0,1] = {{0,1,2,3}, {10,11,12,13}}

// Extend w2D from 4 rows to 5 rows and set new Y values.
// Adds a row because the row index, 4, is equal to the number of wave rows.
// Here [] can be read as "all columns" so this means set row 4, all columns.
w2D[4][] = {{4},{14},{24}}

// Extend w2D from 5 rows to 7 rows and set new Y values.
w2D[5][] = {{5,6},{15,16},{25,26}}

Make/O/N=(4,3) w2D = NaN      // Restore to 4 rows by 3 column

// Extend w2D from 3 columns to 4 columns and set new Y values.
// Adds a column because the column index, 3, is equal
// to the number of wave columns.
w2D[][3] = {{30,31,32,33}}

// Extend w2D from 4 columns to 6 columns and set new Y values.
w2D[][4] = {{40,41,42,43},{50,51,52,53}}
```

Wave Initialization

From Igor’s command line or in a procedure, you can make a wave and initialize it with a single command, as illustrated in the following examples:

```
Make wave0=sin(p/8)         // wave0 has default number of points
Make coeffs={1,2,3}         // coeffs has just three points
```

Example: Normalizing Waves

When comparing the shape of multiple waves you may want to normalize them so that the share a common range. For example:

```
// Create some sample data
Make waveA = 3*sin(x/8)
Make waveB = 2*sin(pi/16 + x/8)

// Display the waves
Display waveA, waveB
ModifyGraph rgb(waveB)=(0,0,65535)
```

```
// Normalize the waves
Variable aMin = WaveMin(waveA)
Variable bMin = WaveMin(waveB)
waveA -= aMin
waveB -= bMin
Variable aMax = WaveMax(waveA)
Variable bMax = WaveMax(waveB)
waveA /= aMax
waveB /= bMax
```

Note the use of the temporary variables aMin and bMin. They are needed for two reasons. First, if we wrote `waveA -= WaveMin(waveA)`, then **WaveMin** would be called once for each point in waveA, which would be a waste of time. Worse than that, the minimum value in waveA would change during the course of the waveform assignment statement, giving incorrect results.

There are sometimes faster ways to do waveform arithmetic. For large waves, the **FastOp** and **MatrixOp** operations provide increased speed:

```
waveA -= aMin                    // FastOp does not support wave-variable
FastOp waveA = (1/aMax) * waveA

MatrixOp/O waveA = waveA - aMin
MatrixOp/O waveA = waveA / aMax
```

Example: Converting XY Data to Waveform Data

There are some times when it is desirable to convert XY data to uniformly spaced waveform data. For example, the Fast Fourier Transform requires uniformly spaced data. If you have measured XY data in the time domain, you would need to do this conversion before doing an FFT on it.

We can make some sample XY data as follows:

```
Make/N=1024 xWave, yWave
xWave = 2*PI*x/1024 + gnoise(.001)
yWave = sin(xwave)
```

xWave has values from 0 to 2π with a bit of noise in them. Our data is not uniformly spaced in the x dimension but it is monotonic — always increasing, in this case. If it were not monotonic we could sort the XY pair.

We can create a waveform representing our XY data as follows:

```
Duplicate ywave, wave0
SetScale x 0, 2*PI, wave0
wave0 = interp(x, xwave, ywave)
```

The SetScale command sets the scaling of wave0 so that its X values run from 0 to 2π. Its data values are generated by picking a value off the curve represented by ywave versus xwave at each of these X values using linear interpolation.

See **Converting XY Data to a Waveform** on page III-109 for a discussion of other interpolation techniques.

Example: Concatenating Waves

Concatenating waves can be done much more easily using the **Concatenate** operation (see page V-82). This simple example serves mainly to illustrate a use of wave assignment statements.

Suppose we have three waves of 100 points each: wave1, wave2 and wave3. We want to create a fourth wave, wave4, which is the concatenation of the three original waves. Here is the sequence of commands to do this.

```
Make/N=300 wave4
wave4[0,99] = wave1[p]              // Set first third of wave4
wave4[100,199] = wave2[p-100]       // Set second third of wave4
wave4[200,299] = wave3[p-200]       // Set last third of wave4
```

In this example, we use a subrange of wave4 as the destination of our wave assignment statements. The right-hand expressions index the appropriate values of wave1, wave2 and wave3. Remember that p ranges over the points being evaluated in the destination. So, p ranges from 0 to 99 in the first assignment, from 100 to 199 in the second assignment and from 200 to 299 in the third assignment. In each of the assignments, the wave on the right-hand side has only 100 points, from point 0 to point 99. Therefore we must offset p on the right-hand side to pick out the 100 values of the source wave.

Example: Decomposing Waves

Suppose we have a 300 point wave, wave4, that we want to decompose into three waves of 100 points each: wave1, wave2 and wave3. Here is the sequence of commands to do this.

```
Make/N=100 wave1,wave2,wave3
wave1 = wave4[p]            // Get first third of wave4
wave2 = wave4[p+100]        // Get second third of wave4
wave3 = wave4[p+200]        // Get last third of wave4
```

In this example, we use a subrange of wave4 as the source of our data. We index the desired segment of wave4 using point number indexing. Since wave1, wave2 and wave3 each have 100 points, p ranges from 0 to 99. In the first assignment, we access points 0 to 99 of wave4. In the second assignment, we access points 100 to 199 of wave4. In the third assignment, we access points 200 to 299 of wave4.

You could also use the **Duplicate** operation (see page V-185) to make a wave from a section of another wave.

Example: Complex Wave Calculations

Igor includes a number of built-in functions for manipulating complex numbers and complex waves. These are illustrated in the following example.

We make a time domain waveform and do an FFT on it to generate a complex wave. The example function shows how to pick out the real and imaginary part of the complex wave, how to find the sum of squares and how to convert from rectangular to polar representation. For more information on frequency domain processing, see **Fourier Transforms** on page III-270.

```
Function ComplexWaveCalculations()
   // Make a time domain waveform
   Make/O/N=1024 wave0
   SetScale x 0, 1, "s", wave0            // Goes from 0 to 1 second
   wave0 = sin(2*PI*x) + sin(6*PI*x)/3 + sin(10*PI*x)/5 + sin(14*PI*x)/7
   Display wave0 as "Time Domain"

   // Do the FFT
   FFT/DEST=cwave0 wave0                  // cwave0 is complex, 513 points
   cwave0 /= 512;cwave0[0] /= 2           // Normalize amplitude
   Display cwave0 as "Frequency Domain";SetAxis bottom, 0, 25

   // Calculate magnitude and phase
   Make/O/N=513 mag0, phase0, power0      // These are real waves
   CopyScales cwave0, mag0, phase0, power0
   mag0 = real(r2polar(cwave0))
   phase0 = imag(r2polar(cwave0))
   phase0 *= 180/PI                       // Convert to Degrees
   Display mag0 as "Magnitude and Phase"; AppendToGraph/R phase0
   SetAxis bottom, 0, 25
   Label left, "Magnitude";Label right, "Phase"

   // Calculate power spectrum
   power0 = magsqr(cwave0)
   Display power0 as "Power Spectrum";SetAxis bottom, 0, 25
End
```

Example: Comparison Operators and Wave Synthesis

The comparison operators ==, >=, >, <= and < can be useful in synthesizing waves. Imagine that you want to set a wave so that its data values equal -π for x<0 and +π for x>=0. The following wave assignment statement accomplishes this:

```
wave1 = -pi*(x<0) + pi*(x>=0)
```

This works because the conditional statements return 1 when the condition is true and 0 when it is false, and then the multiplication proceeds.

You can also make such assignments using the conditional operator:

```
wave0 = (x>0) ? pi : -pi
```

A series of impulses can be made using the **mod** function and ==. This wave equation will assign 5 to every tenth point starting with point 0, and 0 to all the other points:

```
wave1 = (mod(p,10)==0) * 5
```

Example: Wave Assignment and Indexing Using Labels

Dimension labels can be used to refer to wave values by a meaningful name. Thus, for example, you can create a wave to store coefficient values and directly refer to these values by the name of the coefficient (e.g., coef[%Friction]) instead of a potentially confusing and less meaningful numeric index (e.g., coef[1]). You can also view the wave values and labels in a table.

You create wave dimension labels using the **SetDimLabel** operation (see page V-838); for details see **Dimension Labels** on page II-93. Dimension labels may be up to 255 bytes in length; if you use liberal names, such as those containing spaces, make certain to enclose these names within single quotation marks.

Prior to Igor Pro 8.00, dimension labels were limited to 31 bytes. If you use long dimension labels, your wave files and experiments will require Igor Pro 8.00 or later.

In this example we create a wave and use the **FindPeak** operation (see page V-247) to get peak parameters of the wave. Next we create an output parameter wave with appropriate labels and then assign the FindPeak results to the output wave using the labels.

```
// Make a wave and get peak parameters
Make test=sin(x/30)
FindPeak/Q test

// Create a wave with appropriate row labels
Make/N=6 PeakResult
SetDimLabel 0,0,'Peak Found', PeakResult
SetDimLabel 0,1,PeakLoc, PeakResult
SetDimLabel 0,2,PeakVal, PeakResult
SetDimLabel 0,3,LeadingEdgePos, PeakResult
SetDimLabel 0,4,TrailingEdgePos, PeakResult
SetDimLabel 0,5,'Peak Width', PeakResult

// Fill PeakResult wave with FindPeak output variables
PeakResult[%'Peak Found']   =V_flag
PeakResult[%PeakLoc]        =V_PeakLoc
PeakResult[%PeakVal]        =V_PeakVal
PeakResult[%LeadingEdgePos] =V_LeadingEdgeLoc
PeakResult[%TrailingEdgePos]=V_TrailingEdgeLoc
PeakResult[%'Peak Width']   =V_PeakWidth

// Display the PeakResult values and labels in a table
Edit PeakResult.ld
```

In addition to the method illustrated above, you can also create and edit dimension labels by displaying the wave in a table and showing the dimension labels with the data. See **Showing Dimension Labels** on page II-235 for further details on using tables with labels.

Mismatched Waves

For most applications you will not need to mix waves of different lengths. In fact, doing this is more often the result of a mistake than it is intentional. However, if your application requires mixing you will need to know how Igor handles this.

Let's consider the case of assigning the value of one wave to another with a command such as

```
wave1 = wave2
```

In this assignment, there is no explicit indexing, so Igor evaluates the expression as if you had written:

```
wave1 = wave2[p]
```

If wave2 has more points than wave1, the extra points have no effect on the assignment since p ranges from 0 to n-1, where n is the number of points in wave1.

If wave2 has fewer points than wave1 then Igor will try to evaluate wave2[p] for values of p greater than the length of wave2. In this case, it returns the value of the last point in wave2 during the wave assignment statement but also raises an "index out of range" error. Previous versions of Igor did not raise this error.

It may be that you actually want the values in wave1 to span the values in wave2 by interpolating between values in wave2. To get Igor to do this, you must explicitly index the appropriate X values on the right side. For instance, if you have two waves of different lengths, you can do this:

```
big = small[p*(numpnts(small)-1)/(numpnts(big)-1)]
```

NaNs, INFs and Missing Values

The data value of a point in a floating point numeric wave is normally a finite number but can also be a NaN or an INF. NaN means "not a number". An expression returns the value NaN when it makes no sense mathematically. For example, `log(-1)` returns the value NaN. You can also set a point to NaN, using a table or a wave assignment statement, to represent a missing value. An expression returns the value INF when it makes sense mathematically but has no finite value. `log(0)` returns the value -INF.

The IEEE floating point standard defines the representation and behavior of NaN values. There is no way to represent a NaN in an integer wave. If you attempt to store NaN in an integer wave, you will store a garbage value.

Comparison operators do not work with NaN parameters because, by definition, NaN compared to anything, even another NaN, is false. Use **numtype** to test if a value is NaN.

Igor ignores NaNs and INFs in curve fit and wave statistics operations. NaNs and INFs have no effect on the scaling of a graph. When plotting, Igor handles NaNs and INFs properly, as missing and infinite values respectively.

Igor does *not* ignore NaNs and INFs in many other operations, especially those that are DSP related such as FFT. In general, any operation that numerically combines all or most of the data points from a wave will give meaningless results if one or more points is a NaN or INF. Notable examples include the **area** and **mean** functions and the **Integrate** and **FFT** operations. Some operations that only mix a few points such as Smooth and Differentiate will "contaminate" only those points in the vicinity of the NaN or INF. You can use the Interpolate operation (Analysis menu) to create a NaN-free version of a wave.

If you get NaNs from functions such as **area** or **mean** or operations such as **Convolve** or any other functions or operations that sum points in waves, it indicates that some of the points in the wave are NaN. If you get NaNs from curve-fitting results, it indicates that Igor's curve fitting has failed. See **Curve Fitting Troubleshooting** on page III-266 for troubleshooting tips.

See **Dealing with Missing Values** on page III-112 for techniques for dealing with NaNs.

Don’t Use the Destination Wave as a Source Wave

You may get unexpected results if the destination of a wave assignment statement also appears in the right-hand expression. Consider these examples:

```
wave1 -= wave1(5)
wave1 -= vcsr(A)            // where cursor A is on wave1
```

Each of these examples is an attempt to subtract the value of wave1 at a particular point from every point in wave1. This will not work as expected because the value of wave1 at that particular point is altered during the assignment. At some point in the assignment, wave1(5) or vcsr(A) will return 0 since the value at that point in wave1 will have been subtracted from itself.

You can get the desired result by using a variable to store the value of wave1 at the particular point.

```
Variable tmp
tmp = wave1(5); wave1 -= tmp
tmp = vcsr(A); wave1 -= tmp
```

Wave Dependency Formulas

You can cause a wave assignment statement to “stick” to the wave by substituting “:=” for “=” in the statement. This causes the wave to become dependent upon the objects referenced in the expression. For example:

```
Variable/G gAngularFrequency = 5
wave1 := sin(gAngularFrequency*x)    // Note ":="
Display wave1
```

If you now execute “gAngularFrequency = 8” you will see the wave automatically update. Similarly if you change the wave’s X scaling using the **SetScale** operation (see page V-853), the wave will be automatically recalculated for the new range of X values.

Dependencies should be used sparingly if at all. Overuse creates a web of interactions that are difficult to understand and difficult to debug. It is better to explicitly update the target when necessary.

See Chapter IV-9, **Dependencies**, for further discussion.

Using the Wave Note

One of the properties of a wave is the **wave note**. This is just some plain text that Igor stores with each wave. The note is empty when you create a wave. There is no limit on its length.

You can inspect and edit a wave note using the Data Browser. You can set or get the contents of a wave note from an Igor procedure using the **Note** operation (see page V-694) or the **note** function (see page V-694).

Originally we thought of the wave note as a place for an experimenter to store informal comments about a wave and it is fine for that purpose. However, over time both we and many Igor users have found that the wave note is also a handy place to store additional, user-defined properties of a wave in a structured way. These additional properties are editable using the Data Browser but they can also be used and manipulated by procedures.

To do this, you store keyword-value pairs in the wave note. For example, a note might look like this:

```
CELLTYPE:rat hippocampal neuron
PATTERN:1VN21
TREATMENT:PLACEBO
```

You could then write Igor functions to set the CELLTYPE, PATTERN and TREATMENT properties of a wave. You can retrieve such properties using the **StringByKey** function.

Integer Waves

Igor provides support for integer waves primarily to aid in data acquisition projects. They allow people who are interfacing with hardware to write/read directly into integer waves. This allows for slightly quicker live display and also saves the programmer from having to convert integers to floating point.

Integer waves are also appropriate for storing images.

Aside from memory considerations there is no other reason to use integer waves. You might expect that wave assignment statements would evaluate more quickly when an integer wave is the destination. This is not the case, however, because Igor still uses floating point for the assignment and only converts to integer for storage.

Date/Time Waves

Dates are represented in Igor date format - as the number of seconds since midnight, January 1, 1904. Dates before that are represented by negative values. Igor supports dates from the year -32768 to the year 32767.

As of Igor7, Igor uses the Gregorian calendar convention in which there is no year 0. The year before year 1 is year -1.

A date can not be accurately stored in the data values of a single precision or integer wave. Make sure to use double precision to store dates and times.

You must set the data units of a wave containing date or date/time data to "dat". This tells Igor that the wave contains date/time data and affects the default display of axes in graphs and columns in tables.

The following example illustrates the use of date/time data. First we create some date/time data and view it in a table:

```
Make/D/N=10/O testDate = date2secs(2011,4,p+1)
SetScale d 0, 0, "dat", testDate // Tell Igor this wave stores date/time data
```

We used `SetScale d` to set the data units of the wave to "dat".

Next we view the wave in a table:

```
Edit testDate
ModifyTable width(testDate)=120  // Make column wider
```

The data is displayed as dates but it is stored as numbers - specifically the number of seconds since January 1, 1904. We can see this by changing the column format:

```
ModifyTable format=1             // Display as integer
```

Now we return to date format:

```
ModifyTable format(testDate)=6   // Display as date again
```

Next we create some time data. This wave will not store dates and therefore does not need to be double-precision:

```
Make/N=10/O testTime = 3600*p    // Data is stored in seconds
AppendToTable testTime
```

Now we create a date/time wave by adding the time data to the date data. Since this wave will store dates it must be double-precision and must have "dat" data units. We accomplish this by using the Duplicate operation to duplicate the original date wave:

```
Duplicate/O testDate, testDateTime
AppendToTable testDateTime
ModifyTable width(testDateTime)=120    // Make wider
```

Igor displays the date/time wave in date format because it has "dat" units and all of the time values are 00:00:00. We now change the column format to date/time:

```
ModifyTable format(testDateTime)=8     // Set column to date/time format
```

Finally, we add the time:

```
testDateTime = testDateTime + testTime // Add time to date
```

To check the data type of your waves, use the info pane in the Data Browser. The data type shown for date/time waves should be “Double Float 64 bit”. If not, use Data→Redimension Waves to redimension as double-precision.

So far we have looked at storing dates in the data of a wave. Typically such a date wave is used to supply the X wave of an XY pair. If your data is waveform in nature, you would store date data in the X values of a wave treated as a waveform. For example:

```
Make/N=100 wave0 = sin(p/8)
SetScale/P x date2secs(2011,4,1), 60*60*24, "dat", wave0
Display wave0
Edit wave0.id; ModifyTable format(wave0.x)=6
```

Here the SetScale command is used to set the X scaling and units of the wave, not the data units as before. In this case, the wave does not need to be double-precision because Igor always calculates X values using double-precision regardless of the wave's data type.

Text Waves

Text waves are just like numeric waves except they contain text rather than numbers. Like numeric waves, text waves can have one to four dimensions.

To create a text wave:

- Type anything but a number into the first unused cell of a table.
- Import data from a delimited text file that contains nonnumeric columns.
- Use the **Make** operation with the /T flag.

You can use the Make Waves dialog to generate text waves by choosing Text from the Type pop-up menu. Most often you will create text waves by entering text in a table. See **Using a Table to Create New Waves** on page II-239 for more information.

You can store anything in an element of a text wave. There is no length limit. You can edit text waves in a table or assign values to the elements of a text wave using a wave assignment statement.

You can use text waves in category plots, to automatically label individual data points in a graph (use markers mode and choose a text wave via the marker pop-up menu) and for storing notes in a table. Programmers may find that text waves are handy for storing a collection of diverse data, such as inputs to or outputs from a complex Igor procedure.

Here is how you can create and initialize text waves on the command line:

```
Make/T textWave= {"First element","Second and last element"}
```

To see the text wave, create a table:

```
Edit textWave
```

Now you can try some wave assignment statements and see the result in the table:

```
textWave[2] = {"Third element"}      // Create new row
textWave += "*"                      // Append asterisk to each point
textWave = "*" + textWave            // Prepend asterisk to each point
```

Text Wave Text Encodings

This section is of concern only if you store non-ASCII data in a text wave.

Igor interprets the bytes stored in a text wave in light of the wave's text content text encoding setting. This setting will be UTF-8 for waves created in Igor7 or later and, typically, MacRoman or Windows-1252 for waves created in previous versions.

Igor7 and later use Unicode, in the form of UTF-8, as the working text encoding. When you access the cont ents of a text wave element or store text in a text wave element, Igor does whatever text encoding conversion is required. For example, assume that macRomanTextWave is a wave created in Igor6 on Macintosh. Then:

```
String str = macRomanTextWave[0]       // Igor converts from MacRoman to UTF-8
str = "Area = 2πr"                     // π is a non-ASCII character
macRomanTextWave[0] = str              // Igor converts from UTF-8 to MacRoman
Make/O/T utf8TextWave                  // New waves use UTF-8 text encoding
utf8TextWave = macRomanTextWave        // Igor converts from MacRoman to UTF-8
macRomanTextWave = utf8TextWave        // Igor converts from UTF-8 to MacRoman
```

For further discussion, see **Text Encodings** on page III-459 and **Wave Text Encodings** on page III-472.

Using Text Waves to Store Binary Data

While a numeric wave stores a fixed number of bytes in each element, a text wave has the ability to store a different number of bytes in each point. This makes text waves handy for storing a variable number of variable-length blobs. This is something that an advanced Igor programmer might do in a sophisticated package of procedures.

If you do this, you need to mark the text wave as containing binary data. Otherwise Igor will try to interpret it as text, leading to errors. For details on this issue, see **Text Waves Containing Binary Data** on page III-475.

Wave Text Encoding Properties

Igor Pro 7 uses Unicode internally. Older versions of Igor used non-Unicode text encodings such as MacRoman, Windows-1252 and Shift JIS.

Igor Pro 7 must convert from the old text encodings to Unicode when opening old files. It is not always possible to get this conversion right. You may get incorrect characters or receive errors when opening files containing non-ASCII text.

For a discussion of these issues, see **Text Encodings** on page III-459 and **Wave Text Encodings** on page III-472.

Home Versus Shared Waves

A wave that is stored in a packed experiment file, or in the disk folder corresponding to its data folder for an unpacked experiment, is a "home" wave. Otherwise it is a "shared" wave.

Home waves are typically intended for use by their owning experiment only. Shared waves are typically intended for use by by multiple experiments.

When you create a wave in a packed experiment, it saved by default in the packed experiment file and is a home wave. It becomes a shared wave only if you explicitly save it to a standalone file.

When you create a wave in an unpacked experiment, it is saved by default in the disk folder corresponding to its data folder and is a home wave. For waves in root, the disk folder is the experiment folder. For waves in other data folders, the disk folder is a subfolder of the experiment folder. The wave becomes a shared wave only if you explicitly save it to a standalone file outside of its default disk folder.

When you save a packed experiment as unpacked, home waves are stored in their default disk folder in the experiment folder.

When you save an unpacked experiment as packed, home waves are saved in the packed experiment file.

You can use the Data Browser to determine if a wave is shared. For shared waves, the Data Browser info pane shows the path and file name of the wave file on disk. For home waves this information is omitted.

You can convert a shared wave to a home wave by adopting it. See **Adopting Files** on page II-24 for details.

Wave Properties

Here is a complete list of the properties that Igor stores for each wave.

Property	Comment
Name	Used to reference the wave from commands and dialogs. 1 to 255 bytes. Standard names start with a letter. May contain letters, numbers or underscores. Prior to Igor Pro 8.00, wave names were limited to 31 bytes. If you use long wave names, your wave files and experiments will require Igor Pro 8.00 or later. Liberal names may contain almost any character but must be enclosed in single quotes. See **Wave Names** on page II-65. The name is assigned when you create a wave. You can use the **Rename** operation (see page V-796) to change it.
Data type	A numeric, text or reference data type. See **Wave Data Types** on page II-66. Set when you create a wave. Use the **Redimension** operation (see page V-788) to change it.
Length	Number of data points in the wave. Also, size of each dimension for multidimensional waves. Set when you create a wave. Use the **Redimension** operation (see page V-788) to change it.
X scaling (x0 and dx)	Used to compute X values from point numbers. Also Y, Z and T scaling for multidimensional waves. The X value for point p is computed as X = x0 + p*dx. Set by **SetScale** operation (see page V-853).
X units	Used to auto-label axes. Also Y, Z and T units for multidimensional waves. Set by **SetScale** operation (see page V-853).
Data units	Used to auto-label axes. Set by **SetScale** operation (see page V-853).
Data full scale	For documentation purposes only. Not used. Set by **SetScale** operation (see page V-853).
Note	Holds arbitrary text related to wave. Set by **Note** operation (see page V-694) or via the Data Browser. Readable via **note** function (see page V-694).
Dimension labels	Holds a label up to 255 bytes in length for each dimension index and for each dimension. See **Dimension Labels** on page II-93. Prior to Igor Pro 8.00, dimension labels were limited to 31 bytes. If you use long dimension labels, your wave files and experiments will require Igor Pro 8.00 or later.

Property	Comment
Dependency formula	Holds right-hand expression if wave is dependent. Set when you execute a dependency assignment using := or the **SetFormula** operation (see page V-847). Cleared when you do an assignment using plain =.
Creation date/time	Date & time when wave was created.
Modification date/time	Date & time when wave was last modified.
Lock	Wave lock state. A locked wave can not be modified. Set by **SetWaveLock** operation (see page V-858).
Source folder	Identifies folder containing wave’s source file, if any.
File name	Name of wave’s source file, if any.
Text encodings	See **Wave Text Encodings** on page III-472.

Chapter

II-6

Multidimensional Waves

Overview

Chapter II-5, **Waves**, concentrated on one-dimensional waves consisting of a number of rows. In Chapter II-5, **Waves**, the rows were referred to as “points” and the symbol p stood for row number, which was called “point number”. Scaled row numbers were called X values and were represented by the symbol x.

This chapter now extends the concepts from Chapter II-5, **Waves**, to waves of up to four dimensions by adding the column, layer and chunk dimensions. The symbols q, r and s stand for column, layer and chunk numbers. Scaled column, layer and chunk numbers are called Y, Z and T values and are represented by the symbols y, z and t.

We call a two-dimensional wave a “matrix”; it consists of rows (the first dimension) and columns (the second dimension). After two dimensions the terminology becomes a bit arbitrary. We call the next two dimensions “layers” and “chunks”.

Here is a summary of the terminology:

Dimension Number	0	1	2	3
Dimension Name	row	column	layer	chunk
Dimension Index	p	q	r	s
Scaled Dimension Index	x	y	z	t

Each element of a 1D wave has one index, the row index, and one data value.

Each element of a 2D wave has two indices, the row index and the column index, and one data value.

Each element of a 3D wave has three indices (row, column, layer) and one data value.

Each element of a 4D wave has four indices (row, column, layer, chunk) and one data value.

Creating Multidimensional Waves

Multidimensional waves can be created using the Make operation:

```
Make/N=(numRows,numColumns,numLayers,numChunks) waveName
```

When making an N-dimensional wave, you provide N values to the /N flag. For example:

```
// Make a 1D wave with 20 rows (20 points total)
Make/N=20 wave1

// Make a matrix (2D) wave with 20 rows and 3 columns (60 elements total)
Make/N=(20,3) wave2
```

The Redimension operation’s /N flag works the same way.

```
// Change both wave1 and wave2 so they have 10 rows and 4 columns
Redimension/N=(10,4) wave1, wave2
```

The operations InsertPoints and DeletePoints take a flag (/M=*dimensionNumber*) to specify the dimension into which elements are inserted. For example:

```
InsertPoints/M=1 2,5,wave2    //M=1 means column dimension
```

This command inserts 5 new columns in front of column number 2. If the /M=1 had been omitted or if /M=0 had been used then 5 new rows would have been inserted in front of row number 2.

You can also create multidimensional waves using the Make operation with a list of data values. For example:

```
// Create a 1D wave consisting of a single column of 3 rows
Make wave1 = {1,2,3}
```

```
// Creates a 2D wave consisting of 3 rows and 2 columns
Make wave2 = {{1,2,3},{4,5,6}}
```

See **Lists of Values** on page II-78 for further discussion of the use of curly braces.

The Duplicate operation can create an exact copy of a multidimensional wave or, using the /R flag, extract a subrange. Here is the syntax of the /R flag:

```
Duplicate/R=[startRow,endRow][startCol,endCol] and so on...
```

You can use the character * for any end field to specify the last element in the given dimension or you can just omit the end field. You can also specify just [] to include all of a given dimension. If the source wave has more dimensions than you specify in the /R flag, then all of those dimensions are copied. For example:

```
// Make a 3D wave to play with
Make/N=(5,4,3) wave3A = p + 10*q + 100*r

// Duplicate rows 1 through 2, columns 2 through the end, and all layers
Duplicate/R=[1,2][2,*] wave3A, wave3B     // 2 rows, 2 columns, 3 layers

// Create a 3D wave consisting of all rows of column 2, layer 0
Duplicate/R=[][2,2][0,0] wave3A, wave3C   // 5 rows, 1 column, 1 layer
```

Igor considers wave3C to be 3 dimensional wave and not 1 dimensional, even though it consists of just one column of data, because the number of columns and layers are greater than zero. This is a subtle distinction and can cause confusion. For example, you may think you have extracted a 1D wave from a 3D object but you will find that wave3C will not show up in dialogs where 1D waves are required.

You can turn the 3D wave wave3C into a 1D wave using the following command:

```
Redimension/N=(-1,0) wave3C
```

The -1 value does not to change the number of rows whereas the 0 value for the number of columns indicates that there are no dimensions past rows (in other words, no columns, layers or chunks).

Programmer Notes

For historical reasons, you can treat the symbols x and p like global variables, meaning that you can store into them as well as retrieve their values by referencing them. But this serves no purpose and is not recommended.

Unlike x and p, y, z, t, q, r and s act like functions and you can’t store into them.

Here are some functions and operations that are useful in programming with multidimensional waves:

```
DimOffset, DimDelta, DimSize
FindDimLabel, SetDimLabel, GetDimLabel
```

Dimension Labels

A dimension label is a name associated with a dimension (rows, columns, layers or chunks) or with a specific dimension index (row number, column number, layer number or chunk number).

Dimension labels are primarily an aid to the Igor procedure programmer when dealing with waves in which certain elements have distinct purposes. Dimension labels can be set when loading from a file, and can be displayed, created or edited in a table (see **Showing Dimension Labels** on page II-235).

You can give names to individual dimension indices in multidimensional or 1D waves. For example, if you have a 3 column wave, you can give column 0 the name “red”, column 1 the name “green” and column 2 the name “blue”. You can use the names in wave assignments in place of literal numbers. To do so, you use the % symbol in front of the name. For example:

```
wave2D[][%red] = wave2D[p][%green]     //Set red column equal to green column
```

To create a label for a given index of a given dimension, use the SetDimLabel operation.

For example:

```
SetDimLabel 1, 0, red, wave2D
```

1 is the dimension number (columns), 0 is the dimension index (column 0) and red is the label.

The function GetDimLabel returns a string containing the name associated with a given dimension and index. For example:

```
Print GetDimLabel(wave2D,1,0)
```

prints “red” into the history area.

The FindDimLabel function returns the index value associated with the given label. It returns the special value -2 if the label is not found. This function is useful in user-defined functions so that you can use a numeric index instead of a dimension label when accessing a wave in a loop. Accessing wave data using a numeric index is much faster than using a dimension label.

In addition to setting the name for individual dimension index values, you can set the name for an entire dimension by using an index value of -1. For example:

```
SetDimLabel 1, -1, ColorComponents, wave2D
```

This sets the label for the columns dimension to “ColorComponents”. This label appears in a table if you display dimension labels.

You can copy dimension labels from one dimension to another or from one wave to another using **CopyDimLabels**.

Dimension labels can contain up to 255 bytes and may contain spaces and other normally illegal characters if you surround the name in single quotes or if you use the $ operator to convert a string expression to a name. For example:

```
wave[%'a name with spaces']
wave[%$"a name with spaces"]
```

Dimension labels have the same characteristics as object names. See **Object Names** on page III-501 for a discussion of object names in general.

Long Dimension Labels

Prior to Igor8, wave dimension labels were limited to 31 bytes. If you create dimension labels of length 31 bytes or fewer, waves saved by Igor8 or later are saved in a format that is compatible with Igor7 or before. If you create a dimension label longer than 31 bytes, that wave is saved in a format that is incompatible with Igor7 and before.

If you attempt to save an Igor binary wave file or an experiment file that has waves with long dimension labels, Igor displays a warning dialog telling you that the experiment will require Igor Pro 8.00 or later. The warning dialog is presented only when you save an Igor binary wave file or experiment interactively, not if you save it programmatically using SaveExperiment. You can suppress the dialog by clicking the "Do not show this message again" checkbox.

Graphing Multidimensional Waves

You can easily view two-dimensional waves as images and as contour plots using Igor’s built-in operations. See Chapter II-15, **Contour Plots**, and Chapter II-16, **Image Plots**, for further information about these types of graphs. You can also create waterfall plots where each column in the matrix wave corresponds to a separate trace in the waterfall plot. For more details, see **Waterfall Plots** on page II-326.

Additional facilities for displaying multi-dimensional waves in Igor Pro are provided by the Gizmo extension, which create surface plots, slices through volumes and many other 3D plots. To get started with Gizmo, see **3D Graphics** on page II-405.

It is possible to graph a subset of a wave, including graphing rows or columns from a multidimensional wave as traces. See **Subrange Display** on page II-321 for details.

Analysis on Multidimensional Waves

Igor Pro includes the following capabilities for analysis of multidimensional data:

- Multidimensional waveform arithmetic
- Matrix math operations
- Image processing
- Multidimensional Fast Fourier Transform
- The **MatrixOp** operation

There are many analysis operations for 1D data that we have not yet extended to support multiple dimensions. Multidimensional waves do not appear in dialogs for these operations. If you invoke them on multidimensional waves from the command line or from an Igor procedure, Igor treats the multidimensional waves as if they were 1D. For example, the Smooth operation treats a 2D wave consisting of n rows and m columns as if it were a 1D wave with n*m rows. In some cases the operation will be useful. In other cases, it will make no sense.

Multidimensional Wave Indexing

You can use multidimensional waves in wave expressions and assignment statements just as you do with 1D waves (see **Indexing and Subranges** on page II-76). To specify a particular element of a 4D wave, use the syntax:

`wave[`*`rowIndex`*`][`*`columnIndex`*`][`*`layerIndex`*`][`*`chunkIndex`*`]`

Similarly, to specify an element of a 4D wave using *scaled* dimension indices, use the syntax:

`wave(`*`xIndex`*`)(`*`yIndex`*`)(`*`zIndex`*`)(`*`tIndex`*`)`

To index a 3D wave, omit the chunk index. To index a 2D wave, omit the layer and chunk indices.

rowIndex is the number, starting from zero, of the row of interest. It is an unscaled index. *xIndex* is simply the row index, offset and scaled by the wave's X scaling property, which you set using the SetScale operation (Change Wave Scaling in Data menu).

Using scaled indices you can access the wave's data using its natural units. You can use unscaled or scaled indices, whichever is more convenient. column/Y, layer/Z and chunk/T indices are analogous to row/X indices.

Using bracket notation tells Igor that the index you are supplying is an unscaled dimension index. Using parenthesis notation tells Igor that you are supplying a scaled dimension index. You can even mix the bracket notation with parenthesis notation.

Here are some examples:

```
Make/N=(5,4,3) wave3D = p + 10*q + 100*r
SetScale/I x, 0, 1, "", wave3D
SetScale/I y, -1, 1, "", wave3D
SetScale/I z, 10, 20, "", wave3D
Print wave3D[0][1][2]
Print wave3D(0.5)[2](15)
```

The first Print command prints 210, the value in row 0, column 1 and layer 2. The second Print command prints 122, the value in row 2 (where x=0.5), column 2 and layer 1 (where z=15).

Since wave3D has three dimensions, we do not, and must not, specify a chunk index.

There is one important difference between wave access using 1D waves versus multidimensional waves. For 1D waves alone, Igor performs linear interpolation when the specified index value, whether scaled or unscaled, falls between two points. For multidimensional waves, Igor returns the value of the element whose indices are closest to the specified indices.

When a multidimensional wave is the destination of a wave assignment statement, you can specify a subrange for each dimension. You can specify an entire dimension by using []. For example:

```
wave3D[2][][1,2] = 3
```

This sets row 2 of all columns and layers 1 and 2 to the value 3.

Note that indexing of the form [] (entire dimension) or [1,2] (range of a dimension) can be used on the left-hand side only. This is because the indexing on the left side determines which elements of the destination are to be set whereas indexing on the right side identifies a particular element in the source which is to contribute to a particular value in the destination.

Multidimensional Wave Assignment

As with one-dimensional waves, you can assign a value to a multidimensional wave using a wave assignment statement. For example:

```
Make/O/N=(3,3) wave0_2D, wave1_2D, wave2_2D
wave1_2D = 1.0; wave2_2D = 2.0
wave0_2D = wave1_2D / wave2_2D
```

The last command sets all elements of wave0_2D equal to the quotient of the corresponding elements of wave1_2D and wave2_2D.

Important: Wave assignments as shown in the above example where waves on the right-hand side do not include explicit indexing are defined only when all waves involved have the same dimensionality. The result of the following assignment is undefined and may produce surprising results.

```
Make/O/N=(3,3) wave33
Make/O/N=(2,2) wave22
wave33 = wave22
```

Whenever waves of mismatched dimensionality are used you should specify explicit indexing as described next.

In a wave assignment, Igor evaluates the right-hand side one time for each element specified by the left-hand side. During this evaluation, the symbols p, q, r and s take on the value of the row, column, layer and chunk, respectively, of the element in the destination for which a value is being calculated. For example:

```
Make/O/N=(5,4,3) wave3D = 0
Make/O/N=(5,4) wave2D = 999
wave3D[][][0] = wave2D[p][q]
```

This stores the contents of wave2D in layer 0 of wave3D. In this case, the destination (wave3D) has three dimensions, so p, q and r are defined and s is undefined. The following discussion explains this assignment and presents a way of thinking about wave assignments in general.

The left-hand side of the assignment specifies that Igor is to store a value into all rows (the first []) and all columns (the second []) of layer zero (the [0]) of wave3D. For each of these elements, Igor will evaluate the right-hand side. During the evaluation, the symbol p will return the row number of the element in wave3D that Igor is about to set and the symbol q will return the column number. The symbol r will have the value 0 during the entire process. Thus, the expression wave2D[p][q] will return a value from wave2D at the corresponding row and column in wave3D.

As the preceding example shows, wave assignments provide a way of transferring data between waves. With the proper indexing, you can build a 2D wave from multiple 1D waves or a 3D wave from multiple

2D waves. Conversely, you can extract a layer of a 3D wave into a 2D wave or extract a column from a 2D wave into a 1D wave. Here are some examples that illustrate these operations.

```
// Build a 2D wave from multiple 1D waves (waveforms)
Make/O/N=5, wave0=p, wave1=p+1, wave2=p+2    // 1D waveforms
Make/O/N=(5,3) wave0_2D
wave0_2D[][0] = wave0[p]      // Store into all rows, column 0
wave0_2D[][1] = wave1[p]      // Store into all rows, column 1
wave0_2D[][2] = wave2[p]      // Store into all rows, column 2

// Build a 3D wave from multiple 2D waves
Duplicate/O wave0_2D, wave1_2D; wave1_2D *= -1
Make/O/N=(5,3,2) wave0_3D
wave0_3D[][][0]= wave0_2D[p][q]  // Store into all rows/cols, layer 0
wave0_3D[][][1]= wave1_2D[p][q]  // Store into all rows/cols, layer 1

// Extract a layer of a 3D wave into a 2D wave
wave0_2D = wave0_3D[p][q][0]     // Extract layer 0 into 2D wave

// Extract a column of a 2D wave into a 1D wave
wave0 = wave0_2D[p][0]           // Extract column 0 into 1D wave
```

To understand assignments like these, first figure out, by looking at the indexing on the left-hand side, which elements of the destination wave are going to be set. (If there is no indexing on the left then all elements are going to be set.) Then think about the range of values that p, q, r and s will take on as Igor evaluates the right-hand side to get a value for each destination element. Finally, think about how these values, used as indices on the right-hand side, select the desired source element.

To create such an assignment, first determine the indexing needed on the left-hand side to set the elements of the destination that you want to set. Then think about the values that p, q, r and s will take on. Then use p, q, r and s as indices to select a source element to be used when computing a particular destination element.

Here are some more examples:

```
// Extract a row of a 2D wave into a 1D wave
Make/O/N=3 row1
row1 = wave0_2D[1][p]         // Extract row 1 of the 2D wave
```

In this example, the *row* index (p) for the destination is used to select the source *column* while the source row is always 1.

```
// Extract a horizontal slice of a 3D wave into a 2D wave
Make/O/N=(2,3) slice_R2       // Slice consisting of all of row 2
slice_R2 = wave0_3D[2][q][p]  // Extract row 2, all columns/layers
```

In this example, the row data for slice_R2 comes from the layers of wave0_3D because the p symbol (row index) is used to select the layer in the source. The column data for slice_R2 comes from the columns of wave0_3D because the q symbol (column index) is used to select the column in the source. All data comes from row 2 in the source because the row index is fixed at 2.

You can store into a range of elements in a particular dimension by using a range index on the left-hand side. As an example, here are some commands that shift the horizontal slices of wave0_3D.

```
Duplicate/O wave0_3D, tmp_wave0_3D
wave0_3D[0][][] = tmp_wave0_3D[4][q][r]
wave0_3D[1,4][][] = tmp_wave0_3D[p-1][q][r]
KillWaves tmp_wave0_3D
```

The first assignment transfers the slice consisting of all elements in row 4 to row zero. The second assignment transfers slice n-1 to slice n. To understand this, realize that as p goes from 1 to 4, p-1 indexes into the preceding row of the source.

Vector (Waveform) to Matrix Conversion

Occasionally you will may need to convert between a vector form of data and a matrix form of the same data values. For example, you may have a vector of 16 data values stored in a waveform named sixteenVals that you want to treat as a matrix of 8 rows and 2 columns.

Though the Redimension operation normally doesn't move data from one dimension to another, in the special case of converting to or from a 1D wave Redimension will leave the data in place while changing the dimensionality of the wave. You can use the command:

```
Make/O/N=16 sixteenVals          // 1D
Redimension/N=(8,2) sixteenVals  // Now 2D, no data lost
```

to accomplish the conversion. When redimensioning from a 1D wave, columns are filled first, then layers, followed by chunks. Redimensioning from a multidimensional wave to a 1D wave doesn't lose data, either.

Matrix to Matrix Conversion

To convert a matrix from one matrix form to another, don't directly redimension it to the desired form. For instance, if you have a 6x6 matrix wave, and you would like it to be 3x12, you might try:

```
Make/O/N=(6,6) thirtySixVals        // 2D
Redimension/N=(3,12) thirtySixVals  // This loses the last three rows
```

But Igor will first shrink the number of rows to 3, discarding the data for the last three rows, and then add 6 columns of zeroes.

The simplest way to work around this is to convert the matrix to a 1D vector, and then convert it to the new matrix form:

```
Make/O/N=(6,6) thirtySixVals        // 2D
Redimension/N=36 thirtySixVals      // 1D vector preserves the data
Redimension/N=(3,12) thirtySixVals  // Data preserved
```

Multidimensional Decimation

You can create reduced-size representations of 2D and 3D waves.

The ImageInterpolate operation with the pixelate keyword can create a reduced-size representation of a 2D wave, or of the layers of a 3D wave, by averaging blocks of rows and columns. Use ImageInterpolate/PXSZ={*nx*,*ny*} pixelate where *nx* and *ny* are the number of rows and columns respectively to average.

The ImageInterpolate operation with the pixelate keyword can also create a reduced-size representation of a 3D wave by averaging 3D subsections. Use ImageInterpolate/PXSZ={*nx*,*ny*,*nz*} pixelate where *nx*, *ny*, and *nz* are the number of rows, columns, and layers respectively to average.

The ReduceMatrixSize function, provided by the "Reduce Matrix Size.ipf" WaveMetrics procedure file which was added in Igor Pro 9.00, creates a reduced-size representation of a 2D wave, or of the layers of a 3D wave, by sampling rows and columns or by averaging blocks of rows and columns. It uses a wave assignment for sampling and ImageInterpolate pixelate for averaging and provides a convenient wrapper for both techniques. To use ReduceMatrixSize, activate it as a global procedure file or #include it using:

```
#include <Reduce Matrix Size>
```

See **Decimation** on page III-135 for a discussion of decimating 1D waves.

Multidimensional Fourier Transform

Igor's FFT and IFFT routines are mixed-radix and multidimensional. Mixed-radix means you do not need a power of two number of data points (or dimension size).

There is only one restriction on the dimensions of a wave: when performing a forward FFT on real data, the number of rows must be even. Note, however, that if a given dimension size is a prime number or contains a large prime in its factorization, the speed will be reduced to that of a normal Discrete Fourier Transform (i.e., the number of operations will be on the order of N^2 rather than N*log(N)).

For more information about the FFT, see **Fourier Transforms** on page III-270 and the **FFT** operation on page V-222.

Treating Multidimensional Waves as 1D

Sometimes it is useful to treat a multidimensional wave as if it were 1D. For example, if you want to know the number of NaNs in a 2D wave, you can pass the wave to **WaveStats**, even though WaveStats treats its input as 1D.

In other cases, you need to understand the layout of data in memory in order to treat a multidimensional wave as 1D.

A 2D wave consists of some number of columns. In memory, the data is laid out column-by-column. This is called "column-major order". In column-major order, consecutive elements of a given column are contiguous in memory.

For example, execute:

```
Make/N=(2,2) mat = p + 2*q
Edit mat
```

The wave mat consists of two columns. The first column contains the values 0 and 1. The second column contains the values 2 and 3.

You can pass this wave to an operation or function that is not multidimensional-aware and it will treat the wave as if it were one column containing 0, 1, 2, 3. For an example:

```
Print WaveMax(mat)       // Prints 3
```

Here is an example of using the knowledge of how a multidimensional wave is laid out in memory:

```
Function DemoMDAs1D()
   // Make a 2D wave
   Make/O/N=(5,3) mat = p + 10*q
   Variable numRows = DimSize(mat,0)

   // Find the sum of each column
   Variable numColumns = DimSize(mat,1)
   Make/O/N=(numColumns) Sums
   Sums = sum(mat, p*numRows, (p+1)*numRows-1)
   Edit mat, Sums
End
```

The statement

```
Sums = sum(mat, p* numRows, (p+1)* numRows-1)
```

passes the 2D wave mat to the **sum** function which is not multidimensional-aware. Because sum is not multidimensional-aware, it requires that we formulate the startX and endX parameters treating mat as if it were a 1D wave with the data arranged in column-major order.

You can also treat 3D and 4D waves as 1D. In a 3D wave, the data for layer n+1 follows the data for layer n. In a 4D wave, the data for chunk n+1 follows the data for chunk n.

Chapter

II-7

Numeric and String Variables

Overview

This chapter discusses the properties and uses of global numeric and string variables. For the fine points of programming with global variables, see **Accessing Global Variables and Waves** on page IV-65.

Numeric variables are double-precision floating point and can be real or complex. String variables can hold an arbitrary number of bytes. Igor stores all global variables when you save an experiment and restores them when you reopen the experiment.

Numeric variables or numeric expressions containing numeric variables can be used in any place where literal numbers are appropriate including as operands in assignment statements and as parameters to operations, functions, and macros.

When using numeric variables in operation flag parameters, you need parentheses. See **Reference Syntax Guide** on page V-15.

String variables or string expressions can be used in any place where strings are appropriate. String variables can also be used as parameters where Igor expects to find the name of an object such as a wave, variable, graph, table or page layout. For details on this see **Converting a String into a Reference Using $** on page IV-62.

In Igor7 or later, Igor assumes that the contents of string variables are encoded as UTF-8. If you store non-ASCII text in string variables created by Igor6 or before, you need to convert it for use in Igor7 or later. See **String Variables and Text Encodings** on page II-106 for details.

Creating Global Variables

There are 20 built-in numeric variables (K0 … K19), called system variables, that exist all the time. Igor uses these mainly to return results from the CurveFit operation. We recommend that you refrain from using system variables for other purposes.

All other variables are user variables. User variables can be created in one of two ways:

- Automatically in the course of certain operations
- Explicitly by the user, via the Variable/G and String/G operations

When you create a variable directly from the command line using the Variable or String operation, it is always global and you can omit the /G flag. You need /G in Igor procedures to make variables global. The /G flag has a secondary effect — it permits you to overwrite existing global variables.

Uses For Global Variables

Global variables have two properties that make them useful: globalness and persistence. Since they are global, they can be accessed from any procedure. Since they are persistent, you can use them to store settings over time.

Using globals for their globalness creates non-explicit dependencies between procedures. This makes it difficult to understand and debug them. Using a global variable to pass information from one procedure to another when you could use a parameter is bad programming and should be avoided except under rare circumstances. Consequently, you should use global variables when you need persistence.

A legitimate use of a global variable for its globalness is when you have a value that rarely changes and needs to be accessed by many procedures.

Variable Names

Variable names consist of 1 to 255 bytes. Only ASCII characters are allowed. The first character must be alphabetic. The remaining characters can be alphabetic, numeric or the underscore character. Names in Igor are case insensitive.

Prior to Igor Pro 8.00, variable names were limited to 31 bytes. If you use long variable names, your experiments will require Igor Pro 8.00 or later.

Variable names must be standard names, not liberal names. See **Object Names** on page III-501 for details.

Variable names must not conflict with the names of other Igor objects, functions or operations.

You can rename a variable using the Rename operation, or the Rename Objects dialog via the Misc menu.

System Variables

System variables are built in to Igor. They are mainly provided for compatibility with older versions of Igor and are not recommended for general use. You can see a list of system variables and their values by choosing the Object Status item in the Misc menu.

There are 20 system variables named K0,K1...K19 and one named veclen. The K variables are used by the curve fitting operations.

System variables can be used only from the normal "main thread", not from premptive theads. For more about preemptive threads, see **ThreadSafe Functions and Multitasking** on page IV-329 and **Thread Data Environment** on page IV-330.

The `veclen` variable is present for compatibility reasons. In previous versions of Igor, it contained the default number of points for waves created by the Make operation. This is no longer the case. Make will always create waves with 128 points unless you explicitly specify otherwise using the /N=(<number of points>) flag.

Although the CurveFit operation stores results in the K variables, it does so only for compatibility reasons and it also creates user variables and waves to store the same results.

However, the CurveFit operation does use system variables for the purpose of setting up initial parameter guesses if you specify manual guess mode. You can also use a wave for this purpose if you use the kwCWave keyword. See the **CurveFit** operation on page V-124.

It is best to not rely on system variables unless necessary. Since Igor writes to them at various times, they may change when you don’t expect it.

The Data Browser does not display system variables.

System variables are stored on disk as single precision values so that they can be read by older versions of Igor. Thus, you should store values that you want to keep indefinitely in your own global variables.

User Variables

You can create your own global variables by using the `Variable/G` (see **Numeric Variables** on page II-104) and `String/G` operations (see **String Variables** on page II-105). Variables that you create are called “user variables” whether they be numeric or string. You can browse the global user variables by choosing the Object Status item in the Misc menu. You can also use the Data Browser window (Data menu) to view your variables.

Global user variables are mainly used to contain persistent settings used by your procedures.

Special User Variables

In the course of some operations, Igor automatically creates special user variables. For example, the CurveFit operation creates the user variable `V_chisq` and others to store various results generated by the curve fit. The names of these variables always start with the characters “`V_`” for numeric variables or “S_” for string variables. The meaning of these variables is documented along with the operations that generate them in Chapter V-1, **Igor Reference**.

In addition, Igor sometimes checks for `V_` variables that you can create to modify the default operation of certain routines. For example, if you create a variable with the name V_FitOptions, Igor will use that to control the CurveFit, FuncFit and FuncFitMD operations. The use of these variables is documented along with the operations that they affect.

When an Igor operation creates V_ and S_ variables, they are global if the operation was executed from the command line and local if the operation was executed in a procedure. See **Accessing Variables Used by Igor Operations** on page IV-123 for details.

Numeric Variables

You create numeric user variables using the `Variable` operation from the command line or in a procedure. The syntax for the Variable operation is:

```
Variable [flags] varName [=numExpr] [,varName [=numExpr]]...
```

There are three optional flags:

/C	Specifies complex variable.
/D	Obsolete. Used in previous versions to specify double-precision. Now all variables are double-precision.
/G	Specifies variable is to be global and overwrites any existing variable.

The variable is initialized when it is created if you supply the initial value with a numeric expression using `=numExpr`. If you create a numeric variable and specify no initializer, it is initialized to zero.

You can create more than one variable at a time by separating the names and optional initializers for multiple variables with a comma.

When used in a procedure, the new variable is local to that procedure unless the /G flag is used. When used on the command line, the new variable is always global.

Here is an example of a variable creation with initialization:

```
Variable v1=1.1, v2=2.2, v3=3.3*sin(v2)/exp(v1)
```

Since the /C flag was not specified, the data type of v1, v2 and v3 is double-precision real.

Since the /G flag was not specified, these variables would be global if you invoked the `Variable` operation directly from the command line or local if you invoked it in a procedure.

`Variable/G varname` can be invoked whether or not a variable of the specified name already exists. If it does exist as a variable, its contents are not altered by the operation unless the operation includes an initial value for the variable.

To assign a value to a complex variable, use the `cmplx()` function:

```
Variable/C cv1 = cmplx(1,2)
```

You can kill (delete) a global user variable using the Data Browser or the `KillVariables` operation. The syntax is:

```
KillVariables [flags] [variableName [,variableName]...]
```

There are two optional *flags*:

/A	Kills all global variables in the current data folder. If you use /A, omit variableName.
/Z	Doesn't generate an error if a global variable to be killed does not exist.

For example, to kill global variable `cv1` without worrying about whether it was previously defined, use the command:

```
KillVariables/Z cv1
```

Killing a global variable reduces clutter and saves a bit of memory. You can not kill a system variable or local variable.

To kill all global variables in the current data folder, use KillVariables/A/Z.

String Variables

You create user string variables by calling the `String` operation from the command line or in a procedure. The syntax is:

```
String [/G] strName [=strExpr] [,strName [=strExpr]... ]
```

The optional /G flag specifies that the string is to be global, and it overwrites any existing string variable.

The string variable is initialized when it is created if you supply the initial value with a string expression using =*strExpr*. If you create a string variable and specify no initializer it is initialized to the empty string ("").

When you call String from the command line or from a macro, the string variable is initialized to the specified initial value or to the empty string ("") if you provide no initial value.

When you declare a local string variable in a user-defined function, it is null (has no value) until you assign a value to it, via either the initial value or a subsequent assignment statement. Igor generates an error if you use a null local string variable in a user-defined function.

When you call String in a procedure, the new string is local to that procedure unless you include the /G flag. When you call String from the command line, the new string is always global.

You can create more than one string variable at a time by separating the names and optional initializers for multiple string variables with a comma.

Here is an example of variable creation with initialization:

```
String str1 = "This is string 1", str2 = "This is string 2"
```

Since /G was not used, these strings would be global if you invoked String directly from the command line or local if you invoked it in a procedure.

`String/G strName` can be invoked whether or not a variable of the given name already exists. If it does exist as a string, its contents are not altered by the operation unless the operation includes an initial value for the string.

You can kill (delete) a global string using the Data Browser or the `KillStrings` operation. The syntax is:

```
KillStrings [flags] [stringName [,stringName ]...]
```

There are two optional *flags*:

A	Kills all global strings in the current data folder. If you use /A, omit stringName.
/Z	Doesn't generate an error if a global string to be killed does not exist.

For example, to kill global string `myGlobalString` without worrying about whether it was previously defined, use the command:

```
KillStrings/Z myGlobalString
```

Killing a string reduces clutter and saves a bit of memory. You can not kill a local string.

To kill all global strings in the current data folder, use KillStrings/A/Z.

Local and Parameter Variables in Procedures

You can create variables in procedures as parameters or local variables. These variables exist only while the procedure is running. They can not be accessed from outside the procedure and do not retain their values from one invocation of the procedure to the next. See **Local Versus Global Variables** on page IV-61 for more information.

String Variables and Text Encodings

Igor uses Unicode internally. Prior to Igor7, Igor used non-Unicode text encodings such as MacRoman, Windows-1252 and Shift JIS.

If you have string variables containing non-ASCII text in old experiments, they will be misinterpreted. For a discussion of this issues, see **String Variable Text Encodings** on page III-478.

Chapter

II-8

Data Folders

Overview

Using data folders, you can store your data within an experiment in a hierarchical manner. Hierarchical storage is useful when you have multiple sets of similar data. By storing each set in its own data folder, you can organize your data in a meaningful way and also avoid name conflicts.

Data folders contain four kinds of **data objects**:

- Waves
- Numeric variables
- String variables
- Other data folders

Igor's data folders are very similar to a computer's hierarchical disk file system except they reside wholly in memory and not on disk. This similarity can help you understand the concept of data folders but you should take care not to confuse them with the computer's folders and files.

Data folders are particularly useful when you conduct several runs of an experiment. You can store the data for each run in a separate data folder. The data folders can have names like "run1", "run2", etc., but the names of the waves and variables in each data folder can be the same as in the others. In other words, the information about which run the data objects belong to is encoded in the data folder name, allowing the data objects themselves to have the same names for all runs. You can write procedures that use the same wave and variable names regardless of which run they are working on.

Data folders are very handy for programmers who need to store private data between one invocation of their procedures and the next. This use of data folders is discussed under **Managing Package Data** on page IV-249.

The Data Browser window allows you to examine the data folder hierarchy. You display it by choosing Data→Data Browser.

One data folder is designated as the "current" data folder. Commands that do not explicitly target a particular data folder operate on the current data folder. You can see and set the current data folder using the Data Browser or using the **GetDataFolder** and **GetDataFolderDFR** functions and the **SetDataFolder** operation.

You can use the Data Browser not only to see the hierarchy and set the current data folder but also to:

- Create new data folders.
- Move, duplicate, rename and delete objects.
- Browse other Igor experiment files and load data from them into memory.
- Save a copy of data in the current experiment to an experiment file or folder on disk.
- See and edit the contents of variables, strings, and waves in the info pane by selecting an object
- See a simple plot of 1D or 2D waves by selecting one wave at a time in the main list while the plot pane is visible.
- See a simple plot of a wave while browsing other Igor experiments.
- See variable, string and wave contents by double-clicking their icons.
- See a simple histogram or wave statistics for one wave at a time.

A similar browser is used for wave selection in dialogs. For details see **Dialog Wave Browser** on page II-228.

Before using data folders, be sure to read **Using Data Folders** on page II-112.

Programmers should read **Programming with Data Folders** on page IV-169.

Data Folder Syntax

Data folders are named objects like other Igor objects such as waves and variables. Data folder names follow the same rules as wave names. See **Liberal Object Names** on page III-501.

Igor Pro's data folders use the colon character (:) to separate components of a path to an object.

A data folder named "root" always exists and contains all other data folders.

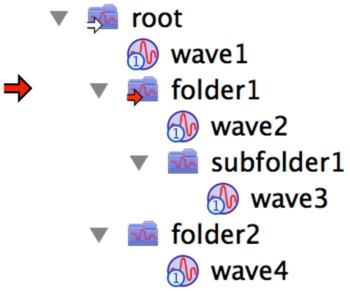
A given object can be specified in a command using:

- A full path
- A partial path
- Just the object name

The object name alone can only be used when the current data folder contains the object.

A full path starts with "root" and does not depend on the current data folder. A partial path starts with ":" and is relative to the current data folder.

Assume the data folder structure shown below, where the arrow indicates that folder1 is the current data folder.



Each of the following commands creates a graph of one of the waves in this hierarchy:

```
Display wave2
Display :subfolder1:wave3
Display root:folder1:subfolder1:wave3
Display ::folder2:wave4
```

The last example illustrates the rule that you can use multiple colons to walk back up the hierarchy: from folder1 (the current data folder), up one level, then down to folder2 and wave4. Here is another valid, though silly, example:

```
Display root:folder1:subfolder1:::folder2:wave4
```

Occasionally you need to specify a data folder itself rather than an object in a data folder. In that case, just leave off the object name. The path specification should therefore have a trailing colon. However, Igor will generally understand what you mean if you omit the trailing colon.

If you need to specify the current data folder, you can use just a single colon. For example:

```
KillDataFolder :
```

kills the current data folder, and all its contents, and then sets the current data folder to the parent of the current. Non-programmers might prefer to use the Data Browser to delete data folders.

Recall that the $ operator converts a string expression into a single name. Since data folders are named, the following is valid:

```
String df1 = "folder1", df2="subfolder1"
Display root:$(df1):$(df2):wave3
```

This is a silly example but the technique would be useful if df1 and df2 were parameters to a procedure.

Note that parentheses must be used in this type of statement. That is a result of the precedence of $ relative to :.

When used at the beginning of a path, the $ operator works in a special way and must be used on the entire path:

```
String path1 = "root:folder1:subfolder1:wave3"
Display $path1
```

When liberal names are used within a path, they must be in single quotes. For example:

```
Display root:folder1:'subfolder 1':'wave 3'
String path1 = "root:folder1:'subfolder 1':'wave 3'"
Display $path1
```

However, when a simple name is passed in a string, single quotes must not be used:

```
Make 'wave 1'
String name
name = "'wave 1'"       // Wrong.
name = "wave 1"         // Correct.
Display $name
```

Data Folder Operations and Functions

Most people will use the Data Browser to create, view and manipulate data folders. The following operations will be mainly used by programmers, who should read **Programming with Data Folders** on page IV-169.

NewDataFolder *path*
SetDataFolder *path*
KillDataFolder *path*
DuplicateDataFolder *srcPath*, *destPath*
MoveDataFolder *srcPath*, *destPath*
MoveString *srcPath, destPath*
MoveVariable *srcPath*, *destPath*
MoveWave *wave*, *destPath* [*newname*]
RenameDataFolder *path*, *newName*
Dir

The following are functions that are used with data folders.

GetDataFolder(*mode* [, *dfr*])
CountObjects(*pathStr*,*type*)
GetIndexedObjName(*pathStr*,*type*,*index*)
GetWavesDataFolder(*wave*,*mode*)
DataFolderExists(*pathStr*)
DataFolderDir(*mode*)

Data Folders Reference Functions

Programmers can utilize data folder references in place of paths. Data folder references are lightweight objects that refer directly to a data folder whereas a path, consisting of a sequence of names, has to be looked up in order to find the actual target folder.

Here are functions that work with data folder references:

GetDataFolder(*mode* [, *dfr*])
GetDataFolderDFR()
GetIndexedObjNameDFR(*dfr*, *type*, *index*)
GetWavesDataFolderDFR(*wave*)
CountObjectsDFR(*dfr*, *type*)
DataFolderRefChanges(*dfr*, *changeType*)
DataFolderRefStatus(*dfr*)

```
DataFolderRefsEqual(dfr1, dfr2)
NewFreeDataFolder()
```

For information on programming with data folder references, see **Data Folder References** on page IV-78.

Data Folders and Commands

Igor normally evaluates commands in the context of the current data folder. This means that, unless qualified with a path to a particular data folder, object names refer to objects in the current data folder. For example:

```
Function Test()
   Make wave1
   Variable/G myGlobalVariable
End
```

This function creates wave1 and myGlobalVariable in the current data folder. Likewise executing:

```
WaveStats wave1
```

operates on wave1 in the current data folder.

Data Folders and User-Defined Functions

To access global variables and waves from a user-defined function, you must first create an NVAR, SVAR or WAVE reference. These references are local objects that point to global objects. See **Accessing Global Variables and Waves** on page IV-65 for details.

Data Folders and Window Recreation Macros

Window recreation macros begin with the Window keyword. They are used to recreate graphs, tables, and other Igor windows and are explained under **Saving a Window as a Recreation Macro** on page II-47.

Window recreation macros are evaluated in the context of the root data folder. In effect, Igor sets the current data folder to root when the window macro starts and restores it when the window macro ends.

Macros that begin with the Macro or Proc keywords evaluate their commands in the context of the *current* data folder.

Evaluating window recreation macros this way ensures that a window is recreated correctly regardless of the current data folder, and provides some compatibility with window macros created with prior versions of Igor Pro which didn’t have data folders.

This means that object names within window recreation macros that don’t explicitly contain a data folder path refer to objects in the root data folder.

Data Folders and Assignment Statements

Wave and variable assignment statements are evaluated in the context of the data folder containing the wave or variable on the left-hand side of the statement:

```
root:subfolder:wave0 = wave1 + var1
```

is a shorter way of writing the equivalent:

```
root:subfolder:wave0 = root:subfolder:wave1 + root:subfolder:var1
```

This rule also applies to dependency formulae which use := instead of = as the assignment operator.

Data Folders and Controls

ValDisplay controls evaluate their value expression in the context of the root data folder.

SetVariable controls remember the data folder in which the controlled global variable exists, and continue to function properly when the current data folder is different from the controlled variable.

See Chapter III-14, **Controls and Control Panels**, for details about controls.

Data Folders and Traces

You cannot tell by looking at a trace in a graph which data folder it resides in.

The easiest way to find out what data folder a trace's wave resides in is to use the trace info help. Choose Graph→Show Trace Info Tags and then hover the mouse over the trace to get trace info.

Another method is to use the Modify Trace Appearance dialog. Double-click the trace to display the dialog. The Traces list shows the full data folder path for each trace.

Finally, you can create and examine the graph window recreation macro. See **Saving a Window as a Recreation Macro** on page II-47 for details.

Using Data Folders

You can use data folders for many purposes. Here are two common uses of data folders.

Hiding Waves, Strings, and Variables

Sophisticated Igor procedures may need a large number of global variables, strings and waves that aren't intended to be directly accessed by the user. The programmer who creates these procedures should keep all such items within data folders they create with unique names designed not to conflict with other data folder names.

Users of these procedures should leave the current data folder set to the data folder where their raw data and final results are kept, so that the procedure's globals and waves won't clutter up the dialog lists.

Programmers creating procedures should read **Managing Package Data** on page IV-249.

Separating Similar Data

One situation that arises during repeated testing is needing to keep the data from each test run separate from the others. Often the data from each run is very similar to the other runs, and may even have the same name. Without data folders you would need to choose new names after the first run.

By making one data folder for each test run, you can put all of the related data for one run into each folder. The data can use identical names, because other identically named data is in different data folders.

Using data folders also keeps the data from various runs from being accidently combined, since only the data in the current data folder shows up in the various dialogs or can be used in a command without a data folder name.

The WaveMetrics-supplied "Multipeak Fitting" example experiment's procedures work this way: they create data folders to hold separate peak curve fit runs and global state information.

Using Data Folders Example

This example will use data folders to:

- Load data from two test runs into separate data folders
- Create graphs showing each test run by itself
- Create a graph comparing the two test runs

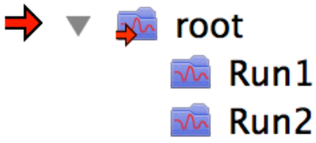
First we'll use the Data Browser to create a data folder for each test run.

Open the Data Browser, and set the current data folder to root by right-clicking the root icon and choosing Set as Current Data Folder.

Click the root data folder, and click the New Data Folder button. Enter "Run1" for the new data folder's name and click OK.

Click New Data Folder again. Enter “Run2” for the new data folder’s name and click OK.

The Data Browser window should look like this:



Now let’s load sample data into each data folder, starting with Run1.

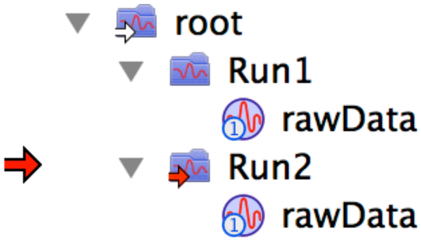
Set the current data folder to Run1, then choose Data→Load Waves→Load Delimited. Select the CSTATIN.ASH file from the Sample Data subfolder of the Learning Aids folder, and click Open. In the resulting Loading Delimited Text dialog, name the loaded wave “rawData” and click Load. We will pretend this data is the result of Run 1. Type “Display rawData” on the command line to graph the data.

Set the current data folder to Run2, and repeat the wave loading steps, selecting the CSTATIN.ASV file instead. In the resulting Loading Delimited Text dialog, name the loaded wave “rawData”. We will pretend this data is the result of Run 2. Repeat the “Display rawData” command to make a graph of this data.

Notice that we used the same name for the loaded data. No conflict exists because the other rawData wave is in another data folder.

In the Data Browser, set the current data folder to root.

In the Data Browser, uncheck the Variables and Strings checkboxes in the Display section. Open the Run1 and Run2 icons by clicking the disclosure icons next to them. At this point, the Data Browser should look something like this:



You can easily make a graph displaying both rawData waves to compare them better. Choose Windows-New Graph to display the New Graph dialog. Use the dialog wave browser controls (see **Dialog Wave Browser** on page II-228) to select both `root:Run1:rawData` and `root:Run2:rawData`. Click Do It.

You can change the current data folder to anything you want and the graphs will continue to display the same data. Graphs remember which data folder the waves belong to, and so do graph recreation macros. This is often what you want, but not always.

Suppose you have many test runs in your experiment, each safely tucked away in its own data folder, and you want to “visit” each test run by looking at the data using a single graph which displays data from the test run’s data folder only. When you visit another test run, you want the graph to display data from that other data folder only.

Additionally, suppose you want the graph characteristics to be the same (the same axis labels, annotations, line styles and colors, etc.). You could:

- Create a graph for the first test run
- Kill the window, and save the graph window macro.
- Edit the recreation macro to reference data in another data folder.
- Run the edited recreation macro.

The recreated graph will have the same appearance, but use the data from the other data folder. The editing usually involves changing a command like:

```
SetDataFolder root:Run1:
```

to:

```
SetDataFolder root:Run2:
```

If the graph displays waves from more than one data folder, you may need to edit commands like:

```
Display rawData,::Run1:rawData
```

as well.

However, there is another way that doesn't require you to edit recreation macros: use the ReplaceWave operation to replace waves in the graph with waves from the other folder.

- Set the current data folder to the one containing the waves you want to view
- Activate the desired graph
- Execute in the command line:

```
ReplaceWave allinCDF
```

This replaces all the waves in the graph with identically named waves from the current data folder, if they exist. See the **ReplaceWave** for details. You can choose Graph→Replace Wave to display a dialog in which you can generate ReplaceWave commands interactively.

Though we have only one wave per data folder, we can try it out:

- Set the current data folder to Run1.
- Select the graph showing data from Run2 only (CSTATIN.ASV).
- Execute in the command line:

```
ReplaceWave allinCDF
```

The graph is updated to show the rawData wave from Run1.

For another Data Folder example, choose File→Example Experiments→Tutorials→Data Folder Tutorial.

The Data Browser

The Data Browser lets you navigate through the data folder hierarchy, examine properties of waves and values of numeric and string variables, load data objects from other Igor experiments, and save a copy of data from the current experiment to an experiment file or folder on disk.

To open the browser choose Data Browser from the Data menu.

The user interface of the Data Browser is similar to that of the computer desktop. The basic Igor data objects (variables, strings, waves and data folders) are represented by icons and arranged in the main list based on their hierarchy in the current experiment. The browser also sports several buttons that provide you with additional functionality.

The main components of the Data Browser window are:

- The main list which displays icons representing data folders, waves, and variables
- The Display checkboxes which control the types of objects displayed in the main list
- The buttons for manipulating the data hierarchy
- The info pane which displays information about the selected item
- The plot pane which displays a graphical representation of the selected wave

The Main List

The main list occupies most of the Data Browser when it is first invoked.

At the top of the data tree is the root data folder which by default appears expanded. By double-clicking a data folder icon you can change the display so that the tree is displayed with your selection as the top data folder instead of root. You can use the pop-up menu above the main list to change the current top data folder to another data folder in the hierarchy.

Following the top data folder are all the data objects that it contains. Objects are grouped by type and by default are listed in creation order. You can change the sort order using the gear icon. You can filter the list using the filter textbox.

You can select data objects with the mouse. You can select multiple contiguous data objects by shift-clicking. You can select multiple discontiguous data objects by Command-clicking (*Macintosh*) or Ctrl-clicking (*Windows*).

Note: Objects remain selected even when they are hidden inside collapsed data folders. If you select a wave, collapse its data folder, Shift-select another wave, and drag it to another data folder, both waves will be moved there.

However, when a selected object is hidden by deselecting the relevant Display checkbox, actions, such as deletion and duplication, are not taken upon it.

You can rename data objects by clicking the name of the object and editing the name.

The Data Browser also supports icon dragging to move or copy data objects from one data folder to another. You can move data objects from one data folder to another by dragging them. You can copy data objects from one data folder to another by pressing Option (*Macintosh*) or Alt (*Windows*) while dragging.

You can duplicate data objects within a data folder by choosing Duplicate from the Edit menu or by pressing Command-D (*Macintosh*) or Ctrl+D (*Windows*).

You can copy the full paths of all selected data objects, quoted if necessary, to the command line by dragging the objects onto the command line.

You can select one or more waves in the list and drag them into an existing graph or table window to append them to the target window. See **Appending Traces by Drag and Drop** on page II-280 for details.

The Current Data Folder

The “current data folder” is the data folder that Igor uses by default for storing newly-created variables, strings, waves and other data folders. Commands that create or access data objects operate in the current data folder unless you use data folder paths to specify other data folders.

Above the main list there is a textbox that shows the full path to the current data folder. The main list displays a red arrow overlayed on the icon of the current data folder. When the current data folder is contained inside another data folder, a white arrow indicator is overlayed on the icons of the ancestors of the current data folder.

To set the current data folder, right-click any data folder and select Set Current Data Folder. You can also set the current data folder by dragging the red arrow or by Option-clicking (*Macintosh*) or Alt-clicking (*Windows*) a data folder icon.

The Display Checkboxes

The Display checkbox group lets you control which object types are shown in the main list. Data folders are always shown. They also allow you to show or hide the info pane and the plot pane.

The Info Pane

To view the info pane, check the Info checkbox.

The info pane appears below the main list. When you select an object in the main list, its properties or contents appear in the info pane. For example, when you select a variable, its name and value are displayed in the info pane.

If you select a wave in the main list, the info pane displays various properties of the wave, such as type, size, dimensions, units, start X, delta Xand note. Each of these fields is displayed as a blue label followed by a plain text value. You can control which properties are displayed using the Data Browser category of the Miscellaneous Settings Dialog.

If you select a data folder, the info pane may display notes for the data folder. See **Data Folder Notes** on page II-120 for details.

You can edit the name and value of a numeric or string variable, or the name and properties of a wave, by clicking the Edit Object Properties button at the top right corner of the info pane. The button appears only when a single object is selected. Clicking it displays the Edit Object Properties dialog.

The info pane can also display statistics for any selected wave. To show wave statistics, click the sigma icon at the top of the info pane. To change back to normal mode, click the i icon.

You can copy the text displayed in the info pane to the clipboard by clicking the clipboard button at the top of the info pane.

You can control various aspects of the info pane display by right-clicking and choosing an item from the Settings submenu. The options include how white space is displayed, parenthesis matching, syntax coloring, and word wrap.

The Plot Pane

To view the plot pane, check the Plot checkbox.

The plot pane provides a graphical display of a single selected wave. The plot pane is situated below the main list and the info pane. It displays a small graph or image of a wave selected in the main list above it. The plot pane does not display text waves or more than one wave at a time.

You can control various properties of the plot pane by right-clicking and using the resulting pop-up menu.

You can toggle the display of axes by choosing Show Axes from the pop-up menu. You can also toggle between showing a plot of the selected wave and a plot of a 1D histogram by choosing Show Plot or Show Histogram.

Simple 1D real waves are drawn in red on a white background. Complex 1D waves are drawn as two traces with the real part drawn in red and the imaginary in blue. The mode, line style, line size, marker, marker size, and color of the trace can all be configured using the pop-up menu.

2D waves are displayed as an image that by default is scaled to the size of the plot pane and uses the Rainbow color table by default. You can change the aspect ratio and color table via the pop-up menu.

By default, images are displayed with the left axis reversed - that is, the Y value increases from top to bottom, consistent with the behavior of the **NewImage** operation. You can disable this by choosing Reverse Left Axis from the pop-up menu.

When you select a 3D or 4D wave in the main list, the plot pane displays one layer of the wave at a time. Controls at the top of the plot pane allow you to choose which layer is displayed. You can start the plot pane cycling through the layers using the play button and stop it using the stop button.

If the dimensionality of the selected wave is such that it could be interpreted as containing RGB or RGBA data, Igor displays the Automatically Detect RGB(A) checkbox. If you check it, Igor displays the data as an RGB(A) composite image. Otherwise the image data is displayed using a color table, just as with 2D data.

The New Data Folder Button

The New Data Folder button creates a new data folder inside the current data folder. The Data Browser displays a simple dialog to ask for the name of the new data folder and tests that the name provided is valid. When entering liberal object names in the dialog, do not use single quotes around the name.

The Browse Expt Button

The Browse Expt button loads data objects from an Igor packed experiment file or from a folder on disk into the current experiment.

To browse a packed experiment file, click Browse Expt. The Data Browser displays the Open File dialog from which you choose the packed experiment file to browse.

To browse a folder on disk, which may contain packed experiment files, standalone Igor wave (.ibw) files, and other folders, press Option (*Macintosh*) or Alt (*Windows*) while clicking Browse Expt. The Data Browser displays the Choose Folder dialog from which you choose the folder to browse.

Once you select the packed experiment file or the folder to browse, the Data Browser displays an additional list to the right of the main list. The righthand list displays icons representing the data in the file or folder that you selected for browsing. To load data into the current experiment, select icons in the righthand list and drag them into a data folder in the lefthand list.

Click the Done Browsing button to close the righthand list and return to normal operating mode.

The Save Copy Button

The Save Copy button copies data objects from the current experiment to an Igor packed experiment file on disk or as individual files to a folder on disk. Most users will not need to do this because the data is saved when the current experiment is saved.

Before clicking Save Copy, select the items that you want to save. When you click Save Copy, the Data Browser presents a dialog in which you specify the name and location of the packed Igor experiment file which will contain a copy of the saved data.

If you press Option (*Macintosh*) or Alt (*Windows*) while clicking Save Copy, the Data Browser presents a dialog for choosing a folder on disk in which to save the data in unpacked format. The unpacked format is intended for advanced users with specialized applications.

When saving as unpacked, the Data Browser uses "mix-in" mode. This means that the items saved are written to the chosen disk folder but pre-existing items on disk are not affected unless they conflict with items being saved in which case they are overwritten.

When saving as unpacked, if you select a data folder in the Data Browser, it and all of its contents are written to disk. The name of the disk folder is the same as the name of the selected data folder except for the root data folder which is written with the name Data. If you don't select a data folder but just select some items, such as a few waves, the Data Browser writes files for those items but does not create a disk folder.

By default, objects are written to the output without regard to the state of the Waves, Variables and Strings checkboxes in the Display section of the Data Browser. However, there is a preference that changes this behavior in the Data Browser category of the Miscellaneous Settings Dialog. If you check the 'Save Copy saves ONLY displayed object types' checkbox, then Save Copy writes a particular type of object only if the corresponding Display checkbox is checked.

The Data Browser does not provide a method for adding or deleting data to or from a packed experiment file on disk. It can only overwrite an existing file. To add or delete, you need to open the experiment, make additions and deletions and then save the experiment.

The Delete Button

The Delete button is enabled whenever data objects are selected in the main list. If you click it, the Data Browser displays a warning listing the number of items that will be deleted.

To skip the warning, press Option (*Macintosh*) or Alt (*Windows*) when clicking in the Delete button.

Warning: Use this skip feature with great care. If you accidentally delete something, you cannot undo it except by reverting the entire experiment to its last saved state.

Clicking the Delete button when the root data folder is selected deletes all data objects in the current experiment.

Warning: If you accidentally delete something, you cannot undo it except by reverting the entire experiment to its last saved state.

If you try to delete an object that cannot be deleted, such as a wave used in a graph or table, Igor displays a warning message that some objects could not be deleted. Click the Show Details button in this dialog to get a list of objects that were not deleted.

The Execute Cmd Button

The Execute Cmd button provides a shortcut for executing a command on selected items in the Data Browser window. When you click the Execute Cmd button, Igor displays a dialog in which you can specify the command to be executed and the execution mode. Once you have set the command, you can skip the dialog and just execute the command by pressing Option (*Macintosh*) or Alt (*Windows*) while clicking the button.

The format of the command is the same as other Igor commands except that you use %s where the selection is to be inserted. For example:

```
Display %s
```

For the case where the command to be executed exceeds the maximum length for an Igor command, you can specify a secondary command. For example:

```
AppendToGraph %s
```

When 'Execute for each selected item' is enabled, Igor executes the primary command once for each selected item, substituting the full path to the item in place of %s. So, for example, if you select wave0, wave1 and wave2 in the root data folder, Igor executes:

```
Display root:wave0
Display root:wave1
Display root:wave2
```

When 'Execute once for all selected items' is enabled, Igor executes the primary command once, like this:

```
Display root:wave0, root:wave1, root:wave2
```

If the command would exceed the maximum length of the command line, Igor executes the primary and secondary commands, like this:

```
Display root:wave0, root:wave1
AppendToGraph root:wave2
```

Data Browser Command String Limitations

The command strings set in the Execute Cmd dialog, as well as those set via the **ModifyBrowser** operation, must be shorter than the maximum command length of 2500 bytes and may not contain "printf", "sprintf" or "sscanf".

When executing the command on all selected objects at once, the primary and secondary command strings may contain at most one "%s" token.

The commands must not close the Data Browser window.

The command string mechanism is sometimes convenient but somewhat kludgy. It is cleaner and more transparent to get the list of selected objects using the **GetBrowserSelection** function and then process the list using normal list-processing techniques.

Using the Find in Data Browser Dialog

If you choose the Edit→Find, the Data Browser displays the Find in Data Browser dialog. This dialog allows you to find waves, variables and data folders that might be buried in sub-data folders. It also provides a convenient way to select a number of items at one time, based on a search string. You can then use the Execute Cmd button to operate on the selection.

The Find in Data Browser dialog allows you to specify the text used for name matching. Any object whose name contains the specified text is considered a match.

You can also use the wildcard character "*" to match zero or more characters regardless of what they are. For example, "w*3" matches "wave3", and "w3", ""

The dialog also allows you to specify whether the search should be case sensitive, use whole word matching, and wrap around.

DataBrowser Pop-Up Menu

You can apply various Igor operations to objects by selecting the objects in the Data Browser, right-clicking, and choosing the operation from the resulting pop-up menu.

Using the Display and New Image pop-up items, you can create a new graph or image plot of the selected wave. You can select multiple waves, in the same or different data folders, to display together in the same graph.

The Copy Full Path item copies the complete data folder paths of the selected objects, quoted if necessary, to the clipboard.

The Show Where Object Is Used item displays a dialog that lists the dependencies in which the selected object is used and, for waves, the windows in which the wave is used. This item is available only when just one data object is selected.

The Adopt Wave item adopts a shared wave into the current experiment.

Data Browser Preferences

Various Data Browser settings are controlled from the Data Browser category of the Miscellaneous Settings Dialog. You access them by choosing Misc→Miscellaneous Settings and clicking Data Browser in the lefthand list.

Programming the Data Browser

The Data Browser can be controlled from Igor procedures using the following operations and functions:

CreateBrowser, **ModifyBrowser**, **GetBrowserSelection**, **GetBrowserLine**

Advanced Igor programmers can use the Data Browser as an input device via the **GetBrowserSelection** function. For an example, choose File→Example Experiments→Tutorials→Data Folder Tutorial.

Using the Data Browser as a Modal Dialog

You can use the Data Browser as a modal dialog to let the user interactively choose one or more objects to be processed by a procedure. The modal Data Browser is separate from the regular Data Browser that you invoke by choosing Data→Data Browser. The modal Data Browser normally exists only briefly, while you solicit user input from a procedure.

There are two methods for creating and displaying the modal Data Browser. Examples are provided in the help for the **CreateBrowser** operation.

The first and simplest method is to use the **CreateBrowser** operation with the prompt keyword. You can optionally use any of the other keywords supported by CreateBrowser.

The second method is to use the CreateBrowser operation with the /M flag. This creates the modal Data Browser but does not display it. You then call **ModifyBrowser** with the /M flag to configure the modal browser as you like. When you are ready to display the browser, call ModifyBrowser with the /M flag and the showModalBrowser keyword.

Using either method, when the user clicks OK or Cancel or closes the modal browser using the close box, the browser sets the V_Flag and S_BrowserList variables. If the user clicks OK, V_Flag is set to 1 and S_BrowserList is set to contain a semicolon-separated list of the full paths of the selected items. If the user clicks Cancel or the close box, V_Flag is set to 0 and S_BrowserList is set to "".

The Data Browser stores full paths, quoted if necessary, in S_BrowserList. Each full path is followed by a semicolon. You can extract the full paths one-by-one using the **StringFromList** function.

The output variables are local when CreateBrowser is executed from a procedure. There is no reason for you to create the modal Data Browser from the command line, but if you do, the output variables are global and are created in the current data folder at the time the CreateBrowser operation was invoked.

The user can change the current data folder in the modal browser. In most cases this is not desirable. The examples for the **CreateBrowser** operation show how to save and restore the current data folder.

When the user clicks the OK button, the Data Browser executes the commands that you specify using the command1 and command2 keywords to **CreateBrowser** or **ModifyBrowser**. If you omit these keywords, it does not execute any commands.

Managing Data Browser User-Defined Buttons

User-defined buttons allow you to customize your work environment and provide quick access to frequently-used operations. You add a button using ModifyBrowser appendUserButton and delete a button using ModifyBrowser deleteUserButton. The appendUserButton keyword allows you to specify the button name as well as the command to be executed when the button is clicked.

The user button command allows you to invoke operations or functions on the objects that are currently selected in the Data Browser or to invoke some action that is completely unrelated to the selection. For example, the command string "Display %s" will display each of the currently selected waves while the command string "Print IgorInfo(0)" prints some general information in the history window.

When you click a user button, the command is executed once for each selected item if the command string contains a %s. Otherwise the command is executed once regardless of the current selection. If you want to operate once on the whole selection you must not use %s but instead call GetBrowserSelection from your function.

User buttons are drawn in the order that they are appended to the window. If you want to change their position you must delete them and then append them in the desired order.

Buttons are not saved with the experiment or in preferences so they must be added to the Data Browser when Igor starts. To add a set of buttons so that they are available in any experiment, you must write an **IgorStartOrNewHook** hook function. See **User-Defined Hook Functions** on page IV-280 for more information.

Data Folder Notes

You can store notes describing a particular data folder in a string variable in that data folder and view those notes in the Data Browser.

When a single data folder is selected in the Data Browser and the info pane is visible, if the data folder contains a string whose name matches a preset list, the contents of the string are displayed in the info pane. You can edit the list of string names in the Info Pane tab of the Data Browser category of the Miscellaneous Settings dialog. The default list of names is "readme;notes;".

For example, execute the following commands on the command line:

```
NewDataFolder/O TestDF
String root:TestDF:readme = "This is a data folder note"
```

Now open the Data Browser, make sure the Info Pane checkbox is checked, and select TestDF in the main list. The contents of root:TestDF:readme are displayed in the info pane.

If a data folder contains more than one string matching the list of string names to use as data folder notes, only the first matching string in the list is used.

This feature was added in Igor Pro 9.00. To disable it, set the list of names in the Miscellaneous Settings dialog to an empty string.

Data Browser Shortcuts

Action	Shortcut
To set the current data folder	Control-click (*Macintosh*) or right-click (*Windows*) the desired data folder and choose Set Current Data Folder.
To reveal the current data folder in the main list	Click the arrow button at the right end of the Current Data Folder readout.
To display a graph, image or 3D plot of a wave	Control-click (*Macintosh*) or right-click (*Windows*) and select an option from the pop-up menu.
To select contiguous objects	Click the first object and Shift-click the last object.
To select discontiguous objects	Command-click (*Macintosh*) or Ctrl-click (*Windows*) the objects to be selected.
To move objects from one data folder to another	Select the objects and drag them onto the destination data folder.
To copy an object from one data folder to another	Drag the object while pressing Option (*Macintosh*) or Alt (*Windows*).
To duplicate an object	Select the object and press Command-D (*Macintosh*) or Ctrl+D (*Windows*).
To rename an object	Click the object's name and type a new name. To finish, press Return or Enter, or click outside the name.
To edit the properties of the selected object	Click the Edit Object Properties icon in the top/right corner of the info pane.
To view a wave in a table	Double-click the wave's icon.
To append a wave to an existing graph or table	Drag the wave's icon to the graph or table window.
To delete an object without the confirmation dialog	Press Option (*Macintosh*) or Alt (*Windows*) while clicking the Delete button.
To find objects in the browser list	Choose Find from the Edit menu, or press Command-F (*Macintosh*) or Ctrl+F (*Windows*).
To find the same thing again	Choose Find Same from the Edit menu, or press Command-G (*Macintosh*) or Ctrl+G (*Windows*).
To execute a command on a set of waves	Select the icon for each wave that the command is to act on and click the Execute Cmd button.
To execute a command on a set of waves without going through the Execute Cmd dialog	Select the icon for each wave that the command is to act on, press Option (*Macintosh*) or Alt (*Windows*), and click the Execute Cmd button. This reexecutes the command entered previously in the Execute Cmd dialog.
To see statistics for a selected wave	Click the sigma icon in the info pane.
To change styles used in the plot pane	Control-click (*Macintosh*) or right-click (*Windows*) in the plot pane and select an option from the pop-up menu.
To start or stop the animation in the plot pane	Click the Start or Stop button in the plot pane.

Action	Shortcut
To navigate between displayed layers or chunks	Stop the animation in the plot pane and use the up and down cursor keys to change the displayed layer and the right and left cursor keys to change the displayed chunk.
To browse a folder containing unpacked Igor data such as waves	Press Option (*Macintosh*) or Alt (*Windows*) while clicking the Browse Expt button.
To save a copy of selected data in unpacked format	Press Option (*Macintosh*) or Alt (*Windows*) while clicking the Save Copy button.

Chapter

II-9

Importing and Exporting Data

Importing Data

Most Igor users create waves by loading data from a file created by another program. The process of loading a file creates new waves and then stores data from the file in them. Optionally, you can overwrite existing waves instead of creating new ones. The waves can be numeric or text and of dimension 1 through 4.

Igor provides a number of different routines for loading data files. There is no single file format for numeric or text data that all programs can read and write.

There are two broad classes of files used for data interchange: text files and binary files. Text files are usually used to exchange data between programs. Although they are called text files, they may contain numeric data, text data or both. In any case, the data is encoded as plain text that you can read in a text editor. Binary files usually contain data that is efficiently encoded in a way that is unique to a single program and can not be viewed in a text editor.

The closest thing to a universally accepted format for data interchange is the “delimited text” format. This consists of rows and columns of numeric or text data with the rows separated by carriage return characters (CR - *Macintosh*), linefeed return characters (LF - *Unix*), or carriage return/linefeed (CRLF - *Windows*) and the columns separated by tabs or commas. The tab or comma is called the “delimiter character”. The CR, LF, or CRLF characters are called the “terminator”. Igor can read delimited text files written by most programs.

FORTRAN programs usually create fixed field text files in which a fixed number of bytes is used for each column of data with spaces as padding between columns. The Load Fixed Field Text routine is designed to read these files.

Text files are convenient because you can create, inspect or edit them with any text editor. In Igor, you can use a notebook window for this purpose. If you have data in a text file that has an unusual format, you may need to manually edit it before Igor can load it.

Text files generated by scientific instruments or custom programs often have “header” information, usually at the start of the file. The header is not part of the block of data but contains information associated with it. Igor’s text loading routines are designed to load the block of data, not the header. The Load General Text routine can usually automatically skip the header. The Load Delimited Text and Load Fixed Field Text routines needs to be told where the block of data starts if it is not at the start of the file.

An advanced user could write an Igor procedure to read and parse information in the header using the Open, FReadLine, StrSearch, sscanf and Close operations as well as Igor’s string manipulation capabilities. Igor includes an example experiment named Load File Demo which illustrates this.

If you will be working on a Macintosh, and loading data from files on a PC, or vice-versa, you should look at **File System Issues** on page III-450.

The following table lists the data loading routines available in Igor and their salient features.

File Type	Description
Delimited text	Created by spreadsheets, database programs, data acquisition programs, text editors, custom programs. This is the most commonly used format for exchanging data between programs. Row Format: `<data><delimiter><data><terminator>` Contains one block of data with any number of rows and columns. A row of column labels is optional. Can load numeric, text, date, time, and date/time columns. Can load columns into 1D waves or blocks into 2D waves. Columns may be equal or unequal in length. See **Loading Delimited Text Files** on page II-129.

File Type	Description
Fixed field text	Created by FORTRAN programs. Row Format: <data><padding><data><padding><`terminator`> Contains one block of data with any number of rows and columns. Each column consists of a fixed number of bytes including any space characters which are used for padding. Can load numeric, text, date, time and date/time columns. Can load columns into 1D waves or blocks into 2D waves. Columns are usually equal in length but do not have to be. See **Loading Fixed Field Text Files** on page II-137.
General text	Created by spreadsheets, database programs, data acquisition programs, text editors, custom programs. Row Format: `<number><white space><number><terminator>` Contains one or more blocks of numbers with any number of rows and columns. A row of column labels is optional. Can not handle columns containing non-numeric text, dates and times. Can load columns into 1D waves or blocks into 2D waves. Columns must be equal in length. Igor's Load General Text routine has the ability to automatically skip nonnumeric header text. See **Loading General Text Files** on page II-138.
Igor Text	Created by Igor, custom programs. Used mostly as a means to feed data and commands from custom programs into Igor. Format: See **Igor Text File Format** on page II-151. Can load numeric and text data. Can load data into waves of dimension 1 through 4. Contains one or more wave blocks with any number of waves and rows. Consists of special Igor keywords, numbers and Igor commands. See **Loading Igor Text Files** on page II-150.
Igor Binary	Created by Igor, custom programs. Used by Igor to store wave data. Each file contains data for one Igor wave of dimension 1 through 4. Format: See Igor Technical Note #003, "Igor Binary Format". See **Loading Igor Binary Data** on page II-154.
Image	Created by a wide variety of programs. Format: Always binary. Varies according to file type. Can load JPEG, PNG, TIFF, BMP, Sun Raster graphics files. Can load data into matrix waves, including TIFF image stacks. See **Loading Image Files** on page II-157.
General binary	General binary files are binary files created by other programs. If you understand the binary file format, it is possible to load the data into Igor. See **Loading General Binary Files** on page II-166.

File Type	Description
Excel	Supports the .xls and .xlsx file formats. See **Loading Excel Files** on page II-159.
HDF4	Requires activating an Igor extension. For help, execute this in Igor: `DisplayHelpTopic "HDF Loader XOP"`
HDF5	For help, execute this in Igor: `DisplayHelpTopic "HDF5 in Igor Pro"`
Matlab	See **Loading Matlab MAT Files** on page II-163.
JCAMP-DX	The JCAMP-DX format is used primarily in infrared spectroscopy. See **Loading JCAMP Files** on page II-168.
Sound	Supports a variety of sound file formats. See **Loading Sound Files** on page II-170.
TDMS	Loads data from National Instruments TDMS files. Requires activating an extension. Supported on Windows only. See the “TDM Help.ihf” help file for details.
Nicolet WFT	Loads data written by old Nicolet oscilloscopes. Requires activating an extension. See the “NILoadWave Help.ihf” help file for details.
SQL Databases	Loads data from SQL databases. Requires activating an extension and expertise in database programming. See **Accessing SQL Databases** on page II-181.

Load Waves Submenu

You access all of these routines via the Load Waves submenu of the Data menu.

The Load Waves item in this submenu leads to the Load Waves dialog. This dialog provides access to the built-in routines for loading Igor binary wave files, Igor text files, delimited text files, general text files, and fixed field text files, and provides access to all available options.

The Load Igor Binary, Load Igor Text, Load General Text, and Load Delimited Text items in the Load Waves submenu are shortcuts that access the respective file loading routines with default options. We recommend that you start with the Load Waves item so that you can see what options are available.

The precision of numeric waves created by Data→Load General Text and Data→Load Delimited Text is controlled by the Default Data Precision setting in the Data Loading section of the Miscellaneous Settings dialog.

There are no shortcut items for loading fixed field text or image data because these formats require that you specify certain parameters.

The Load Image item leads to the Load Image dialog which provides the means to load various kinds of image files.

Line Terminators

The character or sequence of characters that marks the end of a line of text is known as the “line terminator” or “terminator” for short. Different computer systems use different terminator.

Mac OS 9 used the carriage-return character (CR).

Unix uses linefeed (LF).

Windows uses a carriage-return and linefeed (CRLF) sequence.

When loading waves, Igor treats a single CR, a single LF, or a CRLF as the end of a line. This allows Igor to load text data from file servers on a variety of computers without translation.

LoadWave Text Encodings

This section applies to loading a text file using Load General Text, Load Delimited Text, Load Fixed Field Text, or Load Igor Text.

If your file uses a byte-oriented text encoding (i.e., a text encoding other than UTF-16 or UTF-32), and if the file contains just numbers or just ASCII text, then you don't need to be concerned with text encodings.

If your file uses UTF-16, UTF-32, or contains non-ASCII text, you may neeed to tell the LoadWave operation which text encoding the file uses. For details, see **LoadWave Text Encoding Issues** on page II-149.

Loading Delimited Text Files

A delimited text file consists of rows of values separated by tabs or commas with a carriage return, linefeed or carriage return/linefeed sequence at the end of the row. There may optionally be a row of column labels. Igor can load each column in the file into a separate 1D wave or it can load all of the columns into a single 2D wave. There is no limit to the number of rows or columns except that all of the data must fit in available memory.

In addition to numbers and text, the delimited text file may contain dates, times or date/times. The Load Delimited Text routine attempts to automatically determine which of these formats is appropriate for each column in the file. You can override this automatic determination if necessary.

A numeric column can contain, in addition to numbers, NaN and [±]INF. NaN means "Not a Number" and is the way Igor represents a blank or missing value in a numeric column. INF means "infinity". If Igor finds text in a numeric or date/time column that it can't interpret according to the format for that column, it treats it as a NaN.

If Igor encounters, in any column, a delimiter with no data characters preceding it (i.e., two tabs in a row) it takes this as a missing value and stores a blank in the wave. In a numeric wave, a blank is represented by a NaN. In a text wave, it is represented by an element with zero characters in it.

Determining Column Formats

The Load Delimited Text routine must determine the format of each column of data to be loaded. The format for a given column can be numeric, date, time, date/time, or text. Text columns are loaded into text waves while the other types are loaded into numeric waves with dates being represented as the number of seconds since 1904-01-01.

There are four methods for determining column formats:

- Auto-identify column type
- Treat all columns as numeric
- Treat all columns as text
- Use the LoadWave /B flag to explicitly specify the format of each column

You can choose from the first three of these methods using the Column Types pop-up menu in the Tweaks subdialog of the Load Waves dialog. To use the /B flag, you must manually add the flag to a LoadWave command. This is usually done in a procedure.

In the "auto-identify column type" method, Igor attempts to determine the format of each column by examining the file. This is the default method when you choose Data→Load Waves→Load Delimited Text. Igor looks for the first non-blank value in each column and makes a determination based on the column's content. In most cases, the auto-identify method works and there is no need for the other methods.

In the "treat all columns as numeric" method, Igor loads all columns into numeric waves. If some of the data is not numeric, you get NaNs in the output wave. For backward compatibility, this is the default method when you use the LoadWave/J operation from the command line or from an Igor procedure. To use the "auto-identify column type" method, you need to use LoadWave/J/K=0.

In the "treat all columns as text" method, Igor loads all columns into text waves. This method may have use in rare cases in which you want to do text-processing on a file by loading it into a text wave and then using Igor's string manipulation capabilities to massage it.

For details on the /B method, see the section **Specifying Characteristics of Individual Columns** on page II-145.

Date/Time Formats

The Load Delimited Text routine can handle dates in many formats. A few "standard" formats are supported and in addition, you can specify a "custom" format (see **Custom Date Formats** on page II-130).

The standard date formats are:

mm/dd/yy	(month/day/year)
mm/yy	(month/year)
dd/mm/yy	(day/month/year)

To use the dd/mm/yy format instead of mm/dd/yy, you must set a tweak. See **Delimited Text Tweaks** on page II-136.

You can also use a dash or a dot as a separator instead of a slash.

Igor can also handle times in the following forms:

[+][-]hh:mm:ss [AM PM]	(hours, minutes, seconds)
[+][-]hh:mm:ss.ff [AM PM]	(hours, minutes, seconds, fractions of seconds)
[+][-]hh:mm [AM PM]	(hours, minutes)
[+][-]hhhh:mm:ss.ff	(hours, minutes, seconds, fractions of seconds)

As of Igor Pro 6.23, Igor also accepts a colon instead of a dot before the fractional seconds.

The first three forms are time-of-day forms. The last one is the elapsed time. In an elapsed time, the hour is in the range 0 to 9999.

The year can be specified using two digits (99) or four digits (1999). If a two digit year is in the range 00 … 39, Igor treats this as 2000 … 2039. If a two digit year is in the range 40 … 99, Igor treats this as 1940 … 1999.

The Load Delimited Text routine can also handle date/times which consist of one of these date formats, a single space or the letter T, and then one of the time formats. To load <date><space><time> as a date/time value, space must not be specified as a delimiter character.

Custom Date Formats

If your data file contains dates in a format other than the "standard" format, you can use Load Delimited Text to specify exactly what date format to use. You do this using the Delimited Text Tweaks dialog which you access through the Tweaks button in the Load Waves dialog. Choose Other from the Date Format pop-up menu. This leads to the Date Format dialog.

By clicking the Use Common Format radio button, you can choose from a pop-up menu of common formats. After choosing a common format, you can still control minor properties of the format, such as whether to use 2 or 4 digits years and whether to use leading zeros or not.

In the rare case that your file's date format does not match one of the common formats, you can use a full custom format by clicking the Use Custom Format radio button. It is best to first choose the common format that is closest to your format and then click the Use Custom Format button. Then you can make minor changes to arrive at your final format.

When you use either a common format or a full custom format, the format that you specify must match the date in your file exactly.

When loading data as delimited text, if you use a date format containing a comma, such as "October 11, 1999", you must make sure that LoadWave operation does not treat the comma as a delimiter. You can do this using the Delimited Text Tweaks dialog.

When loading a date format that consists entirely of digits, such as 991011, you should use the LoadWave/B flag to specify that the data is a date. Otherwise, LoadWave will treat it as a regular number. The /B flag can not be generated from the dialog — you need to use the LoadWave operation from the command line. Another approach is to use the dialog to generate a LoadWave command without the /B flag and then specify that the column is a date column in the Loading Delimited Text dialog that appears when the LoadWave operation executes.

Column Labels

Each column may optionally have a column label. When loading 1D waves, if you read wave names and if the file has column labels, Igor will use the column labels for wave names. Otherwise, Igor will automatically generate wave names of the form wave0, wave1 and so on.

Igor considers text in the label line to be a column label if that text can not be interpreted as a data value (number, date, time, or datetime) or if the text is quoted using single or double quotes.

When loading a 2D wave, Igor optionally uses the column labels to set the wave's column dimension labels. The wave name does not come from column labels but is automatically assigned by Igor. You can rename the wave after loading if you wish.

Igor expects column labels to appear in a row of the form:

```
<label><delimiter><label><delimiter>…<label><terminator>
```

where <column label> may be in one of the following forms:

<label>	(label with no quotes)
"<label>"	(label with double quotes)
'<label>'	(label with single quotes)

The default delimiter characters are tab and comma. There is a tweak (see **Delimited Text Tweaks** on page II-136) for using other delimiters.

Igor expects that the row of column labels, if any, will appear at the beginning of the file. There is a tweak (see **Delimited Text Tweaks** on page II-136) that you can use to specify if this is not the case.

Igor cleans up column labels found in the file, if necessary, so that they are legal wave names using standard name rules. The cleanup consists of converting illegal characters into underscores and truncating long names to the maximum of 255 bytes.

Examples of Delimited Text

Here are some examples of text that you might find in a delimited text file. These examples are tab-delimited.

Simple delimited text

```
ch0          ch1          ch2          ch3          (optional row of labels)
2.97055      1.95692      1.00871      8.10685
3.09921      4.08008      1.00016      7.53136
3.18934      5.91134      1.04205      6.90194
```

Loading this text would create four waves with three points each or, if you specify loading it as a matrix, a single 3 row by 4 column wave.

Delimited text with missing values

```
ch0          ch1          ch2          ch3          (optional row of labels)
2.97055      1.95692                   8.10685
3.09921      4.08008      1.00016      7.53136
             5.91134      1.04205
```

Loading this text as 1D waves would create four waves. Normally each wave would contain three points but there is an option to ignore blanks at the end of a column. With this option, ch0 and ch3 would have two points. Loading as a matrix would give you a single 3 row by 4 column wave with blanks in columns 0, 2 and 3.

Delimited text with a date column

```
Date         ch0          ch1          ch2          (optional row of labels)
2/22/93      2.97055      1.95692      1.00871
2/24/93      3.09921      4.08008      1.00016
2/25/93      3.18934      5.91134      1.04205
```

Loading this text as 1D waves would create four waves with three points each. Igor would convert the dates in the first column into the appropriate number using the Igor system for storing dates (number of seconds since 1/1/1904). This data is not suitable for loading as a matrix.

Delimited text with a nonnumeric column

```
Sample       ch0          ch1          ch2          (optional row of labels)
Ge           2.97055      1.95692      1.00871
Si           3.09921      4.08008      1.00016
GaAs         3.18934      5.91134      1.04205
```

Loading this text as 1D waves would normally create four waves with three points each. The first wave would be a text wave and the remaining would be numeric. You could also load this as a single 3x3 matrix, treating the first row as column labels and the first column as row labels for the matrix. If you loaded it as a matrix but did not treat the first column as labels, it would create a 3 row by 4 column text wave, not a numeric wave.

Delimited text with quoted strings

Sample	ch0	ch1	ch2	Comment
Ge	2.97055	1.95692	1.00871	"Run 17, station 1"
Si	3.09921	4.08008	1.00016	"Run 17, station 2"
GaAs	3.18934	5.91134	1.04205	"Run 17, station 3"

Starting with Igor Pro 8.00, Load Delimited Text (LoadWave/J) recognizes ASCII double-quote characters as enclosing a string that may contain delimiter characters. In this case, the Comment column contains text which contains commas. Comma is normally a delimiter character but, because the column text is quoted, LoadWave does not treat it as a delimiter. See **Quoted Strings in Delimited Text Files** on page II-135 for details.

The Load Waves Dialog for Delimited Text — 1D

The basic process of loading 1D data from a delimited text file is as follows:

1. Choose Data→Load Waves→Load Waves to display the Load Waves dialog.
2. Choose Delimited Text from the File Type pop-up menu.

3. Click the File button to select the file containing the data.
4. Click Do It.

When you click Do It, the LoadWave operation runs. It executes the Load Delimited Text routine which goes through the following steps:

1. Optionally, determine if there is a row of column labels.
2. Determine the number of columns.
3. Determine the format of each column (number, text, date, time or date/time).
4. Optionally, present another dialog allowing you to confirm or change wave names.
5. Create waves.
6. Load the data into the waves.

Igor looks for a row of labels only if you enable the “Read wave names” option. If you enable this option and if Igor finds a row of labels then this determines the number of columns that Igor expects in the file. Otherwise, Igor counts the number of data items in the first row in the file and expects that the rest of the rows have the same number of columns.

In step 3 above, Igor determines the format of each column by examining the first data item in the column. Igor tries to interpret all of the remaining items in a given column using the format that it determines from the first item in the column.

If you choose Data→Load Waves→Load Delimited Text instead of choosing Data→Load Waves→Load Waves, Igor displays the Open File dialog in which you can select the delimited text file to load directly. This is a shortcut that skips the Load Waves dialog and uses default options for the load. This always loads 1D waves, not a matrix. The precision of numeric waves is controlled by the Default Data Precision setting in the Data Loading section of the Miscellaneous Settings dialog. Before you use this shortcut, take a look at the Load Waves dialog so you can see what options are available.

Editing Wave Names

The “Auto name & go” option is used mostly when you are loading 1D data under control of an Igor procedure and you want everything to be automatic. When loading 1D data manually, you normally leave the “Auto name & go” option deselected. Then Igor presents an additional Loading Delimited Text dialog in which you can confirm or change wave names.

The context area of the Loading Delimited Text dialog gives you feedback on what Igor is about to load. You can’t edit the file here. If you want to edit the file, abort the load and open the file as an Igor notebook or open it in a text editor.

Set Scaling After Loading Delimited Text Data

If your 1D numeric data is uniformly spaced in the X dimension then you will be able to use the many operations and functions in Igor designed for waveform data. You will need to set the X scaling for your waves after you load them, using the Change Wave Scaling dialog.

Note: If your 1D data is uniformly spaced it is *very important* that you set the X scaling of your waves. Many Igor operations depend on the X scaling information to give you correct results.

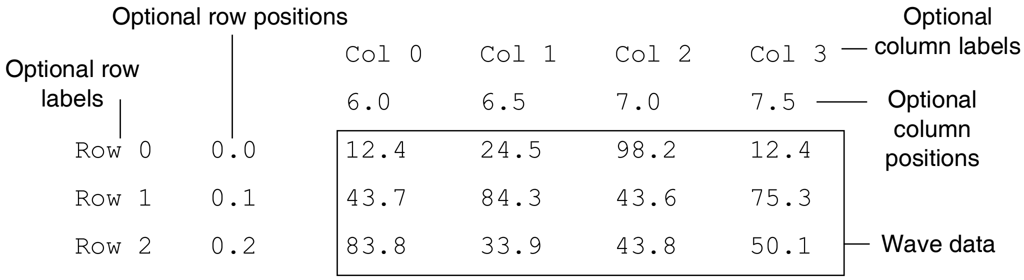
If your 1D data is not uniformly spaced then you will use XY pairs and you do not need to change X scaling. You may want to use Change Wave Scaling to set the data units.

The Load Waves Dialog for Delimited Text — 2D

To load a delimited text file as a 2D wave, choose the Load Waves menu item. Then, select the “Load columns into matrix” checkbox.

When you load a matrix (2D wave) from a text file, Igor creates a single wave. Therefore, there is no need for a second dialog to enter wave names. Instead, Igor automatically names the wave based on the base name that you specify. After loading, you can then rename the wave if you want.

To understand the row/column label/position controls, you need to understand Igor's view of a 2D delimited text file:



```
                Col 0    Col 1    Col 2    Col 3
                6.0      6.5      7.0      7.5
Row 0    0.0    12.4     24.5     98.2     12.4
Row 1    0.1    43.7     84.3     43.6     75.3
Row 2    0.2    83.8     33.9     43.8     50.1
```

In the simplest case, your file has just the wave data — no labels or positions. You would indicate this by deselecting all four label/position checkboxes.

2D Label and Position Details

If your file does have labels or positions, you would indicate this by selecting the appropriate checkbox. Igor expects that row labels appear in the first column of the file and that column labels appear in the first line of the file unless you instruct it differently using the Tweaks subdialog (see **Delimited Text Tweaks** on page II-136). Igor loads row/column labels into the wave's dimension labels (described in Chapter II-6, **Multidimensional Waves**).

Igor can treat column positions in one of two ways. It can use them to set the dimension scaling of the wave (appropriate if the positions are uniformly-spaced) or it can create separate 1D waves for the positions. Igor expects row positions to appear in the column immediately after the row labels or in the first column of the file if the file contains no row labels. It expects column positions to appear immediately after the column labels or in the first line of the file if the file contains no column labels unless you instruct it differently using the Tweaks subdialog.

A row position wave is a 1D wave that contains the numbers in the row position column of the file. Igor names a row position wave "RP_ " followed by the name of the matrix wave being loaded. A column position wave is a 1D wave that contains the numbers in the column position line of the file. Igor names a column position wave "CP_" followed by the name of the matrix wave being loaded. Once loaded (into separate 1D waves or into the matrix wave's dimension scaling), you can use row and column position information when displaying a matrix as an image or when displaying a contour of a matrix.

If your file contains header information before the data, column labels and column positions, you need to use the Tweaks subdialog to specify where to find the data of interest. The "Line containing column labels" tweak specifies the line on which to find column labels. The "First line containing data" tweak specifies the first line of data to be stored in the wave itself. The first line in the file is considered to be line zero.

If you instruct LoadWave to read column positions, it determines which line contains them in one of two ways, depending on whether or not you also instructed it to read column labels. If you do ask LoadWave to read column labels, then LoadWave assumes that the column positions line immediately follows the column labels line. If you do not ask LoadWave to read column labels, then LoadWave assumes that the column positions line immediately precedes the first data line.

Loading Text Waves from Delimited Text Files

There are a few issues relating to special characters that you may need to deal with when loading data into text waves.

By default, the Load Delimited Text operation considers comma and tab characters to be delimiters which separate one column from the next. If the text that you are loading may contain commas or tabs as values rather than as delimiters, you will need to change the delimiter characters. You can do this using the Tweaks subdialog of the Load Delimited Text dialog.

The Load Delimited Text operation always considers carriage return and linefeed characters to mark the end of a line of text. It would be quite unusual to find a data file that uses these characters as values. In the extremely rare case that you need to load a carriage return or linefeed as a value, you can use an escape sequence. Replace the carriage return value with "\r" (without the quotes) and the linefeed value with "\n". Igor will convert these to carriage return and linefeed and store the appropriate character in the text wave.

In addition to "\r" and "\n", Igor will also convert "\t" into a tab value and do other escape sequence conversions (see **Escape Sequences in Strings** on page IV-14). These conversions create a possible problem which should be quite rare. You may want to load text that contains "\r", "\n" or "\t" sequences which you do not want to be treated as escape sequences. To prevent Igor from converting them into carriage return and tab, you will need to replace them with "\\r", "\\n" and "\\t".

Igor does not remove quotation marks when loading data from delimited text files into text waves. If necessary, you can do this by opening the file as a notebook and doing a mass replace before loading or by displaying the loaded waves in a table and using Edit→Replace.

Quoted Strings in Delimited Text Files

Comma-separated values (CSV) text files can be loaded in Igor as delimited text files with comma as the delimiter. Here is some text that might appear in a CSV text file:

```
1,London
2,Paris
3,Rome
```

Sometimes double-quotes are used in CSV files to enclose an item. For example:

```
1,"London"
2,"Paris"
3,"Rome"
```

In Igor6 and Igor7, double-quotes in a delimited text file received no special treatment. Thus, when loading the second example, Igor would create a numeric wave containing 1, 2, and 3, and a text wave containing "London", "Paris", and "Rome". The text wave would include the double-quote characters.

In Igor8 and later, by default, the Load Delimited Text routine treats plain ASCII double-quote characters as enclosing characters that are not loaded into the wave. So, in the second example, the text wave contains London, Paris, and Rome, with no double-quote characters.

This feature is especially useful when the quoted strings contain commas, as in this example:

```
1,"123 First Street, London, England"
2,"59 Rue Poncelet, Paris, France"
3,"Viale Europa 22, 00144 Rome, Italy"
```

Prior to Igor8, Igor would treat this text as containing four columns, because double-quotes received no special treatment and comma is a delimiter character by default. Igor8 loads this as two columns creating a numeric wave with three numbers and a text wave with three addresses.

Because of previously-established rules regarding column names in delimited text files, if you specify that the file includes column names using the LoadWave /W flag, LoadWave interprets quoted text as column names even if the text is all numeric. For example, if you use LoadWave/W and the file contains:

```
"1","2","3"
"4","5","6"
```

LoadWave treats the first line as column names. However, if you use LoadWave/W and the file contains:

```
1,2,3
4,5,6
```

LoadWave treats the first line as data, not column names. So, if your file contains quoted strings, you must omit the /W flag if the file does not contain column names.

Delimited Text Compatibility With Igor7

As of Igor8, LoadWave/J provides better handling of quoted strings in delimited text files, such as comma-separated values files. See **Quoted Strings in Delimited Text Files** on page II-135 for details.

As a side-effect, in rare cases, Igor8 and later may produce different results for a given file compared to Igor7. For example, Igor7 would automatically identify this data as containing two numeric columns:

```
1;,2;
```

Igor8 automatically identifies this as containing two text columns, because of the unexpected semicolons.

If this change interferes with your file loading, you can cause Igor8 and later to work like Igor7 by setting bit 4 of the loadFlags parameter of the LoadWave /V flag. For example:

```
LoadWave/J/V={",", " ", 0, 16}       // 16 means bit 4 is set
```

This disables Igor8's support for quoted strings which causes LoadWave to behave more like it did in Igor7.

Another workaround is to force LoadWave to use a given data type for a given column. You can do this using the Column Format popup menu in the Loading Delimited Text dialog (see **Editing Wave Names** on page II-133) or by using the LoadWave /B flag.

Delimited Text Tweaks

There are many variations on the basic form of a delimited text file. We've tried to provide tweaks that allow you to guide Igor when you need to load a file that uses one of the more common variations. To do this, use the Tweaks button in the Load Waves dialog.

The Tweaks dialog can specify the space character as a delimiter. Use the LoadWave operation to specify other delimiters as well.

The main reason for allowing space as a delimiter is so that we can load files that use spaces to align columns. This is a common format for files generated by FORTRAN programs. Normally, you should use the fixed field text loader to load these files, not the delimited text loader. If you do use the delimited text loader and if space is allowed as a delimiter then Igor treats any number of consecutive spaces as a single delimiter. This means that two consecutive spaces do not indicate a missing value as two consecutive tabs would.

When loading a delimited file, by default Igor expects the first line in the file to contain either column labels or the first row of data. There are several tweaks that you can use for a file that doesn't fit this expectation.

Lines and columns in the tweaks dialog are numbered starting from zero.

Using the "Line containing column labels" tweak, you can specify on what line column labels are to be found if not on line zero. Using this and the "First line containing data" tweak, you can instruct Igor to skip garbage, if any, at the beginning of the file.

The "First line containing data", "Number of lines containing data", "First column containing data", and "Number of columns containing data" tweaks are designed to allow you to load any block of data from anywhere within a file. This might come in handy if you have a file with hundreds of columns but you are only interested in a few of them.

If "Number of lines containing data" is set to "auto" or 0, Igor will load all lines until it hits the end of the file. If "Number of columns containing data" is set to "auto" or 0, Igor will load all columns until it hits the last column in the file.

The proper setting for the "Ignore blanks at the end of a column" tweak depends on the kind of 1D data stored in the file. If a file contains some number of similar columns, for example four channels of data from a digital oscilloscope, you probably want all of the columns in the file to be loaded into waves of the same length. Thus, if a particular column has one or more missing values at the end, the corresponding points in the wave should contain NaNs to represent the missing value. On the other hand, if the file contains a number of dissimilar columns, then you might want to ignore any blank points at the end of a column so that the resulting waves will not necessarily be of equal length. If you enable the "Ignore blanks at the end of a column" tweak then LoadWave will not load blanks at the end of a column into the 1D wave. If this option is enabled and a particular column has nothing but blanks then the corresponding wave is not loaded at all.

Troubleshooting Delimited Text Files

You can examine the waves created by the Load Delimited Text routine using a table. If you don't get the results that you expected, you can to try other LoadWave options or inspect and edit the text file until it is in a form that Igor can handle. Remember the following points:

- Igor expects the file to consist of numeric values, text values, dates, times or date/times separated by tabs or commas unless you set tweaks to the contrary.
- Igor expects a row of column labels, if any, to appear in the first line of the file unless you set tweaks to the contrary. It expects that the column labels are also delimited by tabs or commas unless you set tweaks to the contrary. Igor will not look for a line of column labels unless you enable the Read Wave Names option for 1D waves or the Read Column Labels options for 2D waves.
- Igor determines the number of columns in the file by inspecting the column label row or the first row of data if there is no column label row.

If merely inspecting the file does not identify the problem then you should try the following troubleshooting technique.

- Copy just the first few lines of the file into a test file.
- Load the test file and inspect the resulting waves in a table.
- Open the test file as a notebook.
- Edit the file to eliminate any irregularities, save it and load it again. Note that you can load a file as delimited text even if it is open as a notebook. Make sure that you have saved changes to the notebook before loading it.
- Inspect the loaded waves again.

This process usually sheds some light on what aspect of the file is irregular. Working on a small subset of your file makes it easier to quickly do some trial and error investigation.

If you are unable to get to the bottom of the problem, email a zipped copy of the file or of a representative subset of it to support@wavemetrics.com along with a description of the problem. Do not send the segment as plain text because email programs may strip out or replace unusual control characters in the file.

Loading Fixed Field Text Files

A fixed field text file consists of rows of values, organized into columns, that are a fixed number of bytes wide with a carriage return, linefeed, or carriage return/linefeed sequence at the end of the row. Space characters are used as padding to ensure that each column has the appropriate number of bytes. In some cases, a value will fill the entire column and there will be no spaces after it.

FORTRAN programs typically generate fixed field text files. A normal Fortran data file contains consists of values followed by spaces to pad to the field width. For example, the contents of a file using a field width of 10 might look like this (using dashes to represent spaces for clarity):

```
0.000-----1.000-----2.000-----<CRLF>
1.000-----2.000-----3.000-----<CRLF>
```

Non-Fortran programs sometimes write fixed-field data right-justified instead of left-justified, like this (using dashes to represent spaces for clarity):

```
-----0.000-----1.000-----2.000<CRLF>
-----1.000-----2.000-----3.000<CRLF>
```

To accommodate such files, Igor's Load Fixed Field routine strips leading and trailing spaces from the field before reading the value.

Stripping leading and trailing spaces also allows Igor's Load Fixed Field routine to load values that are left-justified or right-justified, so long as each value for a given row is in a consistent width field.

Igor’s Load Fixed Field Text routine works just like the Load Delimited Text routine except that, instead of looking for a delimiter character to determine where a column ends, it counts the number of bytes in the column. All of the features described in the section **Loading Delimited Text Files** on page II-129 apply also to loading fixed field text.

The Load Waves Dialog for Fixed Field Text

To load a fixed field text file, invoke the Load Waves dialog by choosing Data→Load Waves→Load Waves. The dialog is the same as for loading delimited text except for three additional items.

In the Number of Columns item, you must enter the total number of columns in the file. In the Field Widths item, you must enter the number of bytes in each column of the file, separated by commas. The last value that you enter is used for any subsequent columns in the file. If all columns in the file have the same number of bytes, just enter one number.

If you select the All 9’s Means Blank checkbox then Igor will treat any column that consists entirely of the digit 9 as a blank. If the column is being loaded into a numeric wave, Igor sets the corresponding wave value to NaN. If the column is being loaded into a text wave, Igor sets the corresponding wave value to "" (empty string).

Specifying Fixed Field Widths Programmatically

If all of the columns in the file consist of the same number of bytes, you can specify this number using the LoadWave /F flag. If different columns consist of different numbers of bytes, you have to use the LoadWave /B flag to specify the width of each column.

Loading General Text Files

We use the term “general text” to describe a text file that consists of one or more blocks of numeric data. A block is a set of rows and columns of numbers. Numbers in a row are separated by one or more tabs or spaces. One or more consecutive commas are also treated as white space. A row is terminated by a carriage return character, a linefeed character, or a carriage return/linefeed sequence.

The Load General Text routine handles numeric data only, not date, time, date/time or text. Use Load Delimited Text or Load Fixed Field Text for these formats. Load General Text can handle 2D numeric data as well as 1D.

The first block of data may be preceded by header information which the Load General Text routine automatically skips.

If there is a second block, it is usually separated from the first with one or more blank lines. There may also be header information preceding the second block which Igor also skips.

When loading 1D data, the Load General Text routine loads each column of each block into a separate wave. It treats column labels as described above for the Load Delimited Text routine, except that spaces as well as tabs and commas are accepted as delimiters. When loading 2D data, it loads all columns into a single 2D wave.

The Load General Text routine determines where a block starts and ends by counting the number of numbers in a row. When it finds two rows with the same number of numbers, it considers this the start of a block. The block continues until a row which has a different number of numbers.

Examples of General Text

Here are some examples of text that you might find in a general text file.

Simple general text

```
ch0         ch1         ch2         ch3         (optional row of labels)
2.97055     1.95692     1.00871     8.10685
3.09921     4.08008     1.00016     7.53136
```

```
3.18934     5.91134     1.04205     6.90194
```

The Load General Text routine would create four waves with three points each or, if you specify loading as a matrix, a single 3 row by 4 column wave.

General text with header

```
Date: 3/2/93
Sample: P21-3A
ch0         ch1         ch2         ch3         (optional row of labels)
2.97055     1.95692     1.00871     8.10685
3.09921     4.08008     1.00016     7.53136
3.18934     5.91134     1.04205     6.90194
```

The Load General Text routine would automatically skip the header lines (Date: and Sample:) and would create four waves with three points each or, if you specify loading as a matrix, a single 3 row by 4 column wave.

General text with header and multiple blocks

```
Date: 3/2/93
Sample: P21-3A
ch0_1       ch1_1       ch2_1       ch3_1       (optional row of labels)
2.97055     1.95692     1.00871     8.10685
3.09921     4.08008     1.00016     7.53136
3.18934     5.91134     1.04205     6.90194

Date: 3/2/93
Sample: P98-2C
ch0_2       ch1_2       ch2_2       ch3_2       (optional row of labels)
2.97055     1.95692     1.00871     8.10685
3.09921     4.08008     1.00016     7.53136
3.18934     5.91134     1.04205     6.90194
```

The Load General Text routine would automatically skip the header lines and would create eight waves with three points each or, if you specify loading as a matrix, two 3 row by 4 column waves.

Comparison of General Text, Fixed Field and Delimited Text

You may wonder whether you should use the Load General Text routine, Load Fixed Field routine or the Load Delimited Text routine. Most commercial programs create simple tab-delimited files which these routines can handle. Files created by scientific instruments, mainframe programs, custom programs, or exported from spreadsheets are more diverse. You may need to try these routines to see which works better. To help you decide which to try first, here is a comparison.

Advantages of the Load General Text compared to Load Fixed Field and to Load Delimited Text:

- It can automatically skip header text.
- It can load multiple blocks from a single file.
- It can tolerate multiple tabs or spaces between columns.

Disadvantages of the Load General Text compared to Load Fixed Field and to Load Delimited Text:

- It can not handle blanks (missing values).
- It can not tolerate columns of non-numeric text or non-numeric values in a numeric column.
- It can not load text values, dates, times or date/times.
- It can not handle comma as the decimal point (European number style).

The Load General Text routine *can* load missing values if they are represented in the file explicitly as “NaN” (Not-a-Number). It can not handle files that represent missing values as blanks because this confounds the technique for determining where a block of numbers starts and ends.

The Load Waves Dialog for General Text — 1D

The basic process of loading data from a general text file is as follows:

1. Choose Data→Load Waves→Load Waves to display the Load Waves dialog.
2. Choose General Text from the File Type pop-up menu.
3. Click the File button to select the file containing the data.
4. Click Do It.

When you click Do It, Igor's LoadWave operation runs. It executes the Load General Text routine which goes through the following steps:

1. Locate the start of the block of data using the technique of counting numbers in successive lines. This step also skips the header, if any, and determines the number of columns in the block.
2. Optionally, determine if there is a row of column labels immediately before the block of numbers.
3. Optionally, present another dialog allowing you to confirm or change wave names.
4. Create waves.
5. Load data into the waves until the end of the file or a until a row that contains a different number of numbers.
6. If not at the end of the file, go back to step 1 to look for another block of data.

Igor looks for a row of column labels only if you enable the "Read wave names" option. It looks in the line immediately preceding the block of data. If it finds labels and if the number of labels matches the number of columns in the block, it uses these labels as wave names. Otherwise, Igor automatically generates wave names of the form wave0, wave1 and so on.

If you choose Data→Load Waves→Load General Text instead of choosing Data→Load Waves→Load Waves, Igor displays the Open File dialog in which you can select the general text file to load directly. This is a shortcut that skips the Load Waves dialog and uses default options for the load. This will always load 1D waves, not a matrix. The precision of numeric waves is controlled by the Default Data Precision setting in the Data Loading section of the Miscellaneous Settings dialog. Before you use this shortcut, take a look at the Load Waves dialog so you can see what options are available.

Editing Wave Names for a Block

In step 3 above, the Load General Text routine presents a dialog in which you can change wave names. This works exactly as described above for the Load Delimited Text routine except that it has one extra button: "Skip this block".

Use "Skip this block" to skip one or more blocks of a multiple block general text file.

Click the Skip Column button to skip loading of the column corresponding to the selected name box. Shift-click the button to skip all columns except the selected one.

The Load Waves Dialog for General Text — 2D

Igor can load a 2D wave using the Load General Text routine. However, Load General Text does not support the loading of row/column labels and positions. If the file has such rows and columns, you must load it as a delimited text file.

The main reason to use the Load General Text routine rather than the Load Delimited Text routine for loading a matrix is that the Load General Text routine can automatically skip nonnumeric header information. Also, Load General Text treats any number of spaces and tabs, as well as one comma, as a single delimiter and thus is tolerant of less rigid formatting.

Set Scaling After Loading General Text Data

If your 1D data is uniformly spaced in the X dimension then you will be able to use the many operations and functions in Igor designed for waveform data. You will need to set the X scaling for your waves after you load them, using the Change Wave Scaling dialog.

Note: If your data is uniformly spaced it is *very important* that you set the X scaling of your waves. Many Igor operations depend on the X scaling information to give you correct results.

If your 1D data is not uniformly spaced then you will use XY pairs and you do not need to change X scaling. You may want to use Change Wave Scaling to set the waves' data units.

General Text Tweaks

The Load General Text routines provides some tweaks that allow you to guide Igor as it loads the file. To do this, use the Tweaks button in the Load Waves dialog.

The items at the top of the dialog are hidden because they apply to the Load Delimited Text routine only. Load General Text always skips any tabs and spaces between numbers and will also skip a single comma. The "decimal point" character is always period and it can not handle dates.

The items relating to column labels, data lines and data columns have two potential uses. You can use them to load just a part of a file or to guide Igor if the automatic method of finding a block of data produces incorrect results.

Lines and columns in the tweaks dialog are numbered starting from zero.

Igor interprets the "Line containing column labels" and "First line containing data" tweaks differently for general text files than it does for delimited text files. For delimited text, zero means "the first line". For general text, zero for these parameters means "auto".

Here is what "auto" means for general text. If "First line containing data" is auto, Igor starts the search for data from the beginning of the file without skipping any lines. If it is not "auto", then Igor skips to the specified line and starts its search for data there. This way you can skip a block of data at the beginning of the file. If "Line containing column labels" is auto then Igor looks for column labels in the line immediately preceding the line found by the search for data. If it is not auto then Igor looks for column labels in the specified line.

If the "Number of lines containing data" is not "auto" then Igor stops loading after the specified number of lines or when it hits the end of the first block, whichever comes first. This behavior is necessary so that it is possible to pick out a single block or subset of a block from a file containing more than one block.

If a general text file contains more than one block of data and if "Number of lines containing data" is "auto" then, for blocks after the first one, Igor maintains the relationship between the line containing column labels and first line containing data. Thus, if the column labels in the first block were one line before the first line containing data then Igor expects the same to be true of subsequent blocks.

You can use the "First column containing data" and "Number of columns containing data" tweaks to load a subset of the columns in a block. If "Number of columns containing data" is set to "auto" or 0, Igor loads all columns until it hits the last column in the block.

Troubleshooting General Text Files

You can examine the waves created by the Load General Text routine using a table. If you don't get the results that you expected, you will need to inspect and edit the text file until it is in a form that Igor can handle. Remember the following points:

- Load General Text can not handle dates, times, date/times, commas used as decimal points, or blocks of data with non-numeric columns. Try Load Delimited Text instead.
- It skips any tabs or spaces between numbers and will also skip a single comma.
- It expects a line of column labels, if any, to appear in the first line before the numeric data unless you set tweaks to the contrary. It expects that the labels are also delimited by tabs, commas or spaces. It will not look for labels unless you enable the Read Wave Names option.
- It works by counting the number of numbers in consecutive lines. Some unusual formats (e.g., 1,234.56 instead of 1234.56) can throw this count off, causing it to start a new block prematurely.
- It can not handle blanks or non-numeric values in a column. Each of these cause it to start a new block of data.

- If it detects a change in the number of columns, it starts loading a new block into a new set of waves.

If merely inspecting the file does not identify the problem then you should try the technique of loading a subset of your data. This is described under **Troubleshooting Delimited Text Files** on page II-137 and often sheds light on the problem. In the same section, you will find instructions for sending the problem file to WaveMetrics for analysis, if necessary.

LoadWave Generation of Wave Names

When loading an Igor binary file or an Igor Text file, LoadWave uses the wave name or names stored in the file being loaded.

When loading files as delimited text (/J), as fixed field text (/F), and as general text (/G), wave names are determined by the /A, /N, /W, /B, and /NAME flag. This section provides describes how these naming flags work.

If you omit all of the naming flags, LoadWave generates wave names like wave0, wave1, and wave2 but if such wave already exist, it generates unique names like wave3, wave4, and wave5. LoadWave then displays a dialog in which you can edit the names.

The /A flag behaves the same except that it turns on "auto name and go" which skips the dialog in which you can edit the names. /A=baseName is the same as /A except that allows you to specify a base name other than 'wave'.

The /N flag is the same as /A except that it always uses suffix numbers starting from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten. For example, /N=wave gives wave names like wave0, wave1, and wave2.

The /W flag loads wave names from the file itself. By default, LoadWave expects the wave names to be in the first line of the file but the /L flag allows you to specify another line. If the names in the file conflict with existing waves and you specify overwrite (/O), the existing waves are overwritten; if you do not specify overwrite, LoadWave displays a dialog in which you can enter unique names.

The /B flag, used when calling LoadWave from a user-defined function, allows you to specify explicit names for each column. See **Specifying Characteristics of Individual Columns** on page II-145 for details.

The /NAME flag provides an easy way to incorporate the file name in the wave names. See the next section for details.

/NAME overrides /B which overrides /W which overrides /N which overrides /A.

Using the File Name in Wave Names

The LoadWave /NAME flag was added in Igor Pro 9.00 primarily to provide an easy way to incorporate the file name in the wave names.

The Load Waves dialog (Data→Load Waves→Load Waves) supports the /NAME flag through the Use File Name in Wave Names and Include Normal Name checkboxes. The dialog does not provide access to all features of /NAME but is sufficient for most common uses.

This section provides a general description of the /NAME flag. Subsequent sections with examples which should clarify how to use it.

The format of the flag is:

```
/NAME={namePrefix, nameSuffix, nameOptions}
```

The generated wave names consist of the following components:

```
<namePrefix><normal name><nameSuffix><suffix number>
```

namePrefix and *nameSuffix* can be empty (""), literal text like "Run1_", the special pattern ":filename:" or a combination of literal text and the special pattern like ":filename:_". LoadWave replaces the special pattern ":filename:" with the name of the file being loaded minus the file name extension. If both *namePrefix* and *nameSuffix* are empty, LoadWave acts as if the /NAME flag were omitted.

<normal name> refers to the wave name that would be used if /NAME were omitted.

The rest of this section discusses the nameOptions bitwise parameter (see **Setting Bit Parameters** on page IV-12) which provides flexibility in naming across various scenarios. In the abstract, *nameOptions* may be confusing; examples shown in subsequent sections should clarify its meaning and use.

If bit 0 of *nameOptions* is set, LoadWave includes <normal name>. If cleared, it omits <normal name>.

Bits 1, 2, and 3 control the use of suffix numbers. A suffix number is a number like 0, 1, 2, and so on, used to make the wave names unique. When loading a single wave, LoadWave includes <suffix number> if bit 1 of *nameOptions* is set unless it is suppressed by bit 3 as explained below. When loading multiple waves, LoadWave includes <suffix number> if bit 2 of *nameOptions* is set unless it is suppressed by bit 3 as explained below. Often you want to include suffix numbers when loading multiple waves, because the numbers are necessary to distinguish the names of the waves you are loading, but you want to exclude the suffix number when loading a single wave. For that case you would leave bit 1 cleared and set bits 2 and 3.

Bit 3 of *nameOptions* overrides bits 1 and 2 to prevent prevent appending suffix numbers if they are not needed to prevent name conflicts. When loading a single wave, bit 3 overrides bit 1 to prevent appending a suffix number if there is no name conflict. When loading multiple waves, bit 3 overrides bit 2 to prevent appending a suffix numbers if there are no name conflicts.

If bit 4 of *nameOptions* is set, LoadWave chooses the suffix number, if enabled, to avoid conflicts with existing waves and other objects. If it is cleared, the suffix number, if enabled, starts from 0 and increments for each wave being loaded.

If bit 5 of *nameOptions* is cleared, LoadWave cleans up the wave name to make it a standard name. Otherwise it allows liberal names. We recommend standard names because programming with liberal names is tricky. See **Object Names** on page III-501 for details.

Loading a Single Wave Using the File Name

In this section, we assume that we are loading a file named "Data.txt" and that we are loading a single wave from the file.

```
// nameOptions=0 means omit the normal name
/NAME={":filename:","",0}
```

LoadWave creates a wave named Data if it does not already exist. If it exists and you include the /O (overwrite) flag, Data is overwritten. If it exists and you omit /O, LoadWave displays a dialog in which you can enter a unique name.

```
// nameOptions=26 means include a unique suffix number
// but only if there is a name conflict
/NAME={":filename:","",26}          // 26 = 2 | 8 | 16 (bits 1, 3, and 4 set)
```

LoadWave creates a wave named Data if it does not already exist. If it exists LoadWave creates a wave named Data0, or Data1, or ... where the suffix number is chosen so that the resulting wave name is unique.

Loading Multiple Waves Using the File Name

In this section, we assume that we are loading a file named "Data.txt" and that we are loading three waves from the file.

```
// nameOptions=0 means omit the normal name
/NAME={":filename:","",0}
```

In this case, since we requested no suffix number, all of the generated wave names are Data and LoadWave displays a dialog in which you can enter unique names.

```
// nameOptions=4 means always include a sequential suffix number
/NAME={":filename:","",4}           // Bit 2 set
```

LoadWave generates wave names Data0, Data1, and Data2. If any of these waves exist and you include the /O (overwrite) flag, they are overwritten. If they exist and you omit /O, LoadWave displays a dialog in which you can enter unique names.

```
// nameOptions=20 means always include a unique suffix number
/NAME={":filename:","",20}          // 20 = 4 | 16 (bits 2 and 4 set)
```

LoadWave generates wave names like Data0, Data1, and Data2 where the suffix numbers are chosen to make the names unique. If you execute the same command on the same file a second time, LoadWave generates wave names Data3, Data4, and Data5.

Loading Multiple Waves Using the File Name and the Normal Name

In this section, we assume that we are loading a file named "Data.txt" and that we are loading three waves from the file. We further assume that the file contains the column names ColumnA, ColumnB, and ColumnC and that we include the /W flag to load the column names from the file.

```
// nameOptions=1 means include the normal name
/W /NAME={":filename:_","",1}
```

This generates wave names Data_ColumnA, Data_ColumnB, and Data_ColumnC. If any of these waves exist and you include the /O (overwrite) flag, they are overwritten. If they exist and you omit /O, LoadWave displays a dialog in which you can enter unique names.

```
// nameOptions=21 means always include the normal name and a unique suffix number
/W /NAME={":filename:_","",21}      // 21 = 1 | 4 | 16 (bits 0, 2 and 4 set)
```

LoadWave generates wave names Data_ColumnA0, Data_ColumnB0, and Data_ColumnC0 where the suffix numbers are chosen to make the wave names unique. If you execute the same command on the same file a second time, LoadWave generates wave names Data_ColumnA1, Data_ColumnB1, and Data_ColumnC1.

This technique could also be used with the /B flag instead of the /W flag to create wave names combining the file name and additional names explicitly specified by /B. See **Setting Wave Names When Loading Data Files** on page II-176 for a functional example.

Other LoadWave Features

This section discusses other issues that apply to loading text data files.

Loading Custom Date Formats

This section applies to loading delimited text (/J), fixed field text (/F) and general text (/G) files.

Here are some examples showing custom date formats and how you would specify them using the **LoadWave** /R flag:

October 11, 1999	/R={English, 2, 4, 1, 1, "Month DayOfMonth, Year", 40}
Oct 11, 1999	/R={English, 2, 3, 1, 1, "Month DayOfMonth, Year", 40}
11 October 1999	/R={English, 2, 4, 1, 1, "DayOfMonth Month Year", 40}
11 Oct 1999	/R={English, 2, 3, 1, 1, "DayOfMonth Month Year", 40}
10/11/99	/R={English, 1, 2, 1, 1, "Month/DayOfMonth/Year", 40}
11-10-99	/R={English, 1, 2, 2, 1, "DayOfMonth-Month-Year", 40}
11-Jun-99	/R={English, 1, 3, 2, 1, "DayOfMonth-Month-Year", 40}
991011	/R={English,1,2,2,1,"YearMonthDayOfMonth", 40}

When loading data as delimited text, if you use a date format containing a comma, such as "October 11, 1999", you must use the /V flag to make sure that LoadWave will not treat the comma as a delimiter.

When loading a date format that consists entirely of digits, such as 991011, you must use the LoadWave/B flag to tell LoadWave that the data is a date. Otherwise, LoadWave will treat it as a regular number.

Specifying Characteristics of Individual Columns

The LoadWave /B=*columnInfoStr* flag provides information to LoadWave for each column in a delimited text (/J), fixed field text (/F) or general text (/G) file. The flag overrides LoadWave's normal behavior. In most cases, you will not need to use it. /B is useful in user-defined functions when you need additional control.

columnInfoStr is constructed as follows:

```
"<column info>;<column info>; . . .;<column info>;"
```

where <column info> consists of one or more of the following:

C=<number> The number of columns controlled by this column info specification. <number> is an integer greater than or equal to one.

F=<format> A code that specifies the data type of the column or columns. <format> is an integer from -2 to 10. The meaning of the <format> is:

-2: Text. The column will be loaded into a text wave.

-1: Format unknown. Igor will deduce the format.

0 to 5: Numeric.

6: Date

7: Time

8: Date/Time

9: Octal number

10: Hexadecimal number

The F= flag is used for delimited text and fixed field text files only. It is ignored for general text files.

N=<name> A name to use for the column. <name> can be a standard name (e.g., wave0) or a quoted liberal name (e.g., 'Heart Rate'). If <name> is '_skip_' then LoadWave will skip the column.

The N= flag works for delimited text, fixed field text and general text files.

See **LoadWave Generation of Wave Names** on page II-142 for further discussion.

T=<numtype> A number that specifies what the numeric type for the column should be. This flag overrides the LoadWave/D flag. It has no effect on columns whose format is text. <numtype> must be one of the following:

2: 32-bit float

4: 64-bit float

8: 8-bit signed integer

16: 16-bit signed integer

32: 32-bit signed integer

72: 8-bit unsigned integer

80: 16-bit unsigned integer

96: 32-bit unsigned integer

W=<width> The column field width for fixed field files. <width> is an integer greater than or equal to one. Fixed width files are FORTRAN-style files in which a fixed number of bytes is allocated for each column and spaces are used as padding.

The W= flag is used for fixed field text only.

Here is an example of the /B=*columnInfoStr* flag:

```
/B="C=1,F=-2,T=2,W=20,N=Factory;  C=1,F=6,W=16,T=4,N=MfgDate;
C=1,F=0,W=16,T=2,N=TotalUnits;  C=1,F=0,W=16,T=2,N=DefectiveUnits;"
```

This example is shown on two lines but in a real command it would be on a single line. In a procedure, it could be written as:

```
String columnInfoStr = ""
columnInfoStr += "C=1,F=-2,T=2,W=20,N=Factory;"
columnInfoStr += "C=1,F=6,T=4,W=16,N=MfgDate;"
columnInfoStr += "C=1,F=0,T=2,W=16,N=TotalUnits;"
columnInfoStr += "C=1,F=0,T=2,W=16,N=DefectiveUnits;"
columnInfoStr += "C=1,F=0,T=2,W=16,N=DefectiveUnits;"
```

Note that each flag inside the quoted string ends with either a comma or a semicolon. The comma separates one flag from the next within a particular column info specification. The semicolon marks the end of a column info specification. The trailing semicolon is required. Spaces and tabs are permitted within the string.

This example provides information about a file containing four columns.

The first column info specification is "C=1;F=-2,T=2,W=20,N=Factory;". This indicates that the specification applies to one column, that the column format is text, that the numeric format is single-precision floating point (but this has no effect on text columns), that the column data is in a fixed field width of 20 bytes, and that the wave created for this column is to be named Factory.

The second column info specification is "C=1;F=6,T=4,W=16,N=MfgDate;". This indicates that the specification applies to one column, that the column format is date, that the numeric format is double-precision floating point (double precision should always be used for dates), that the column data is in a fixed field width of 16 bytes, and that the wave created for this column is to be named MfgDate.

The third column info specification is "C=1;F=0,T=2,W=16,N=TotalUnits;". This indicates that the specification applies to one column, that the column format is numeric, that the numeric format is single-precision floating point, that the column data is in a fixed field width of 16 bytes, and that the wave created for this column is to be named TotalUnits.

The fourth column info specification is the same as the third except that the wave name is DefectiveUnits.

All of the items in a column specification are optional. The default value for each item in the column info specification is as follows:

C=<number> C=1. Specifies that the column info describes one column.

F=<format> F=-1. Determines the format as dictated by the /K flag. If /K=0 is used, LoadWave will automatically determine the column format.

N=<name> N=_auto_. Generates the wave name as it would if the /B flag were omitted.

T=<numtype> Defaults to T=4 (double precision) if the LoadWave/D flag is used or to T=2 (single precision) if the /D flag is omitted.

W=<width> W=0. For a fixed width file, LoadWave will use the default field width specified by the /F flag unless you provide an explicit field width greater than 0 using W=<width>.

Taking advantage of the default values, we could abbreviate the example as follows:

```
/B="F=-2,W=20,N=Factory;  F=6,T=4,W=16,N=MfgDate;
W=16,N=TotalUnits; W=16,N=DefectiveUnits;"
```

If the file were not a fixed field text file, we would omit the W= flag and the example would become:

```
/B="F=-2,N=Factory;  F=6,T=4,N=MfgDate;  N=TotalUnits;  N=DefectiveUnits;"
```

Here are some more examples and discussion that illustrate the use of the /B=*columnInfoStr* flag.

In this example, the /B flag is used solely to specify the name to use for the waves created from the columns in the file:

```
/B="N=WaveLength;  N=Absorbance;"
```

The wave names in the previous example are standard names. If you want to use liberal names, such as names containing spaces or dots, you must use single quotes. For example:

```
/B="N='Wave Number';  N='Reflection Angle';"
```

The name that you specify via N= can not be used if overwrite is off and there is already a wave with this name or if the name conflicts with a macro, function or operation or variable. In these cases, LoadWave generates a unique name by adding one or more digits to the name specified by the N= flag for the column in question. You can avoid the problem of a conflict with another wave name by using the overwrite (/O) flag or by loading your data into a newly-created data folder. You can minimize the likelihood of a name conflict with a function, operation or variable by avoiding vague names.

If you specify the same name in two N= flags, LoadWave will generate an error, so make sure that the names are unique.

Except if the specified name is '_skip_', the N= flag generates a name for one column only, even if the C= flag is used to specify multiple columns. Consider this example:

```
/B="C=10,N=Test;"
```

This ostensibly uses the name Test for 10 columns. However, wave names must be unique, so LoadWave will not do this. It will use the name Test for just the first column and the other columns will receive default names.

You can load a subset of the columns in the file using the /L flag. Even if you do this, the column info specifications that you provide via the /B flag start from the first column in the file, not from the first column to be loaded. For example, if you are using /L to skip columns 0 and 1, you must skip columns 0 and 1 in the column info specification, like this:

```
// Skip column 0 and 1 and name the successive columns
/L={0,0,0,2,0} /B="C=2;N=Column2;N=Column3;"
```

The "C=2;" part accepts default specifications for columns 0 and 1 and the subsequent specifications apply to subsequent columns.

You can achieve the same thing using /B without /L, like this:

```
/B="C=2,N='_skip_';N=Column2;N=Column3;"
```

Also, when loading data into a matrix wave, LoadWave uses only one name. If you specify more than one name, only the first is used. If you are loading data into a matrix and also skipping columns, the explanation above about skipping applies.

In this example, the /B flag solely specifies the format of each column in the file. The file in question starts with a text column, followed by a date column, followed by 3 numeric columns.

```
/B="F=-2;  F=6;  C=3,F=0"
```

In most cases, it is not necessary to use the F= flag because LoadWave can automatically deduce the formats. The flag is useful for those cases where it deduces the column formats incorrectly. It is also useful to force LoadWave to interpret a column as octal or hexadecimal because LoadWave can not automatically deduce these formats.

The numeric codes (0...10) used by the F= flag are the same as the codes used by the ModifyTable operation. If you create a table using the /E flag, the F= flag controls the numeric format of table columns.

The code -1 is not a real column format code. If you use F=-1 for a particular column, LoadWave will deduce the format for that column from the column text.

In this example, the /B flag is used solely to specify the width of each column in a fixed field file. This file contains a 20 byte column followed by ten 16 byte columns followed by three 24 byte columns.

```
/B="C=1,W=20;  C=10,W=16;  C=3,W=24"
```

The field widths specified via W= override the default field width specified by the /F flag. If all of the columns in the file have the same field width then you can use just the /F flag.

You can load a subset of the columns in the file using the /L flag. Even if you do this, the column info specifications that you provide via the /B flag start from the first column in the file, not from the first column to be loaded.

Other LoadWave Issues

This section discusses other issues that apply to the LoadWave operation.

LoadWave Text Encoding Issues

This section discusses LoadWave text encoding issues of interest to advanced users. It assumes that you are familiar with the general topic of text encodings as explained under **Text Encodings** on page III-459.

Since Igor stores all text internally as UTF-8, it must convert text read from a file from the source text encoding to UTF-8. In order to do this it needs to know the source text encoding.

When loading an Igor binary wave file LoadWave ignores the /ENCG=*textEncoding* flag. The loaded wave's text encoding is determined as described under **LoadWave Text Encodings for Igor Binary Wave Files** on page III-475. The rest of this section applied to loading data from plain text files, not from Igor binary wave files.

When loading a text data file you can use the /ENCG=*textEncoding* flag to tell Igor what that text encoding is. See **Text Encoding Names and Codes** on page III-490 for a list of accepted values for textEncoding.

LoadWave uses the text encoding specified by /ENCG and the rules described under **Determining the Text Encoding for a Plain Text File** on page III-467 to determine the source text encoding for conversion of the text file's data to UTF-8. If you omit /ENCG or specify /ENCG=0, the specified text encoding is unknown and does not factor into the determination of the source text encoding. If following the rules does not identify a text encoding that works for converting the file's text to UTF-8, Igor displays the Choose Text Encoding dialog.

If the file contains nothing but ASCII characters, as is often the case, then any byte-oriented text encoding will work and there is no need to use the /ENCG flag.

When you are loading a huge file (e.g., hundreds of megabytes), finding a valid source text encoding may add a noticeable amount to the time it takes to load the file. If you know that the file is either all ASCII or is valid UTF-8, you can tell LoadWave to skip text encoding conversion altogether using an optional parameter, like this:

```
/ENCG={1,4}
```

"1" tells LoadWave that the text is valid as UTF-8, meaning that it is all ASCII or, if it contains non-ASCII characters, they are properly encoded as UTF-8.

"4" tells LoadWave to assume that the text is valid as UTF-8 and skip all validation and conversion.

In testing with a 200 MB delimited text file containing 1 million rows and 20 columns, we found that using /ENCG={1,4} saved about 10% of the time.

NOTE: If you use this flag but the file is not valid UTF-8 and you are loading data into text wave, the text waves will wind up with invalid data which will result in errors when you use the waves later.

As noted above, if following the rules does not identify a text encoding that works for converting the file's text to UTF-8, Igor displays the Choose Text encoding dialog. If you are loading many files using an unattended, automated procedure, displaying this dialog will cause your procedure to grind to a halt. You can prevent this by using another optional flag, like this:

```
/ENCG={1,8}
```

If you use this flag and LoadWave can not determine the source text encoding for a file, it will return an error. If you want your procedure to continue with other files you must check for and handle the error using GetRTError.

Loading Very Large Files

The number of waves (columns) or points (rows) that LoadWave can handle when loading a text file is limited only by available memory.

You can improve the speed and efficiency of loading very large files (i.e., more than 50,000 lines of data) using the *numLines* parameter of the /L flag. Normally this parameter is used to load a section of the file instead of the whole file. However, in delimited, general text and fixed field text loads, the *numLines* parameter also specifies how many rows the waves should initially have. Thus all of the required memory is allocated at the start of the load, rather than increasing the number of wave rows over and over as more lines of data are loaded. When loading very large files, if you know the exact number of lines of data in the file, use the *numLines* parameter of the /L flag. If you don't know the exact number of lines, you can provide a number that is guaranteed to be larger.

If you omit the /L flag or if the *numLines* parameter is zero, and if you are loading a file greater than 500,000 bytes, LoadWave automatically counts the lines of data in the file so that the entire wave can be allocated before data loading starts. This acts as if you used /L and set *numLines* to the exact correct value which normally speeds the loading process considerably. You can disable this feature by using the /V flag and setting bit 2 of the *loadFlags* parameter to 1.

Escape Sequences

An escape sequence is a two-character sequence used to represent special characters in plain text. Escape sequences are introduced by a backslash character.

By default, in a text column, LoadWave interprets the following escape sequences: \t (tab), \n (linefeed), \r (carriage-return), \\ (backslash), \" (double-quote) and \' (single-quote). This works well with Igor's Save operation which uses escape sequences to encode the first four of these characters.

If you are loading a file that does not use escape sequences but which does contain backslashes, you can disable interpretation of these escape sequences by setting bit 3 of the loadFlags parameter of the /V flag. This is mainly of use for loading a text file that contains unescaped Windows file system paths.

Loading Igor Text Files

An Igor Text file consists of keywords, data and Igor commands. The data can be numeric, text or both and can be of dimension 1 to 4. Many Igor users have found this to be an easy and powerful format for exporting data from their own custom programs into Igor.

The file name extension for an Igor Text file is ".itx". Old versions of Igor used ".awav" and this is still accepted.

Examples of Igor Text

Here are some examples of text that you might find in an Igor Text file.

Simple Igor Text

```
IGOR
WAVES/D unit1, unit2
BEGIN
      19.7  23.9
      19.8  23.7
      20.1  22.9
END
X SetScale x 0,1, "V", unit1; SetScale d 0,0, "A", unit1
X SetScale x 0,1, "V", unit2; SetScale d 0,0, "A", unit2
```

Loading this would create two double-precision waves named unit1 and unit2 and set their X scaling, X units and data units.

Igor Text with extra commands

```
IGOR
WAVES/D/O xdata, ydata
BEGIN
      98.822      486.528
      109.968     541.144
      119.573     588.21
      133.178     654.874
      142.906     702.539
END
X SetScale d 0,0, "V", xdata
X SetScale d 0,0, "A", ydata
X Display/N=TempGraph ydata vs xdata
X ModifyGraph mode=2,lsize=5
X CurveFit line ydata /X=xdata /D
X Textbox/A=LT/X=0/Y=0 "ydata= \\{W_coef[0]}+\\{W_coef[1]}*xdata"
X PrintGraphs TempGraph
X KillWindow TempGraph              // Kill the graph
X KillWaves xdata, ydata, fit_ydata // Kill the waves
```

Loading this would create two double-precision waves and set their data units. It would then make a graph, do a curve fit, annotate the graph and print the graph. The last two lines do housekeeping.

Igor Text File Format

An Igor Text file starts with the keyword **IGOR**. The rest of the file may contain blocks of data to be loaded into waves or Igor commands to be executed and it must end with a blank line.

A block of data in an Igor Text file must be preceded by a declaration of the waves to be loaded. This declaration consists of the keyword **WAVES** followed by optional flags and the names of the waves to be loaded. Next the keyword **BEGIN** indicates the start of the block of data. The keyword **END** marks the end of the block of data.

A file can contain any number of blocks of data, each preceded by a declaration. If the waves are 1D, the block can contain any number of waves but waves in a given block must all be of the same data type. Multidimensional waves must appear one wave per block.

A line of data in a block consists of one or more numeric or text items with tabs separating the numbers and a terminator at the end of the line. The terminator can be CR, LF, or CRLF. Each line should have the same number of items.

You can’t use blanks, dates, times or date/times in an Igor Text file. To represent a missing value in a numeric column, use “NaN” (not-a-number). To represent dates or times, use the standard Igor date format (number of seconds since 1904-01-01).

There is no limit to the number of waves or number of points except that all of the data must fit in available memory.

The WAVES keyword accepts the following optional flags:

Flag	Effect
/N=(…)	Specifies size of each dimension for multidimensional waves.
/O	Overwrites existing waves.
/R	Makes waves real (default).
/C	Makes waves complex.
/S	Makes waves single precision floating point (default).

Flag	Effect
/D	Makes waves double precision floating point.
/I	Makes waves 32 bit integer.
/W	Makes waves 16 bit integer.
/B	Makes waves 8 bit integer.
/U	Makes integer waves unsigned.
/T	Specifies text data type.

Normally you should make single or double precision floating point waves. Integer waves are normally used only to contain raw data acquired via external operations. They are also appropriate for storing image data.

The /N flag is needed only if the data is multidimensional but the flag is allowed for one-dimensional data, too. Regardless of the dimensionality, the dimension size list must always be inside parentheses. Examples:

```
WAVES/N=(5) wave1D
WAVES/N=(3,3) wave2D
WAVES/N=(3,3,3) wave3D
```

Integer waves are signed unless you use the /U flag to make them unsigned.

If you use the /C flag then a pair of numbers in a line supplies the real and imaginary value for a single point in the resulting wave.

If you specify a wave name that is already in use and you don’t use the overwrite option, Igor displays a dialog so that you can resolve the conflict.

The /T flag makes text rather than numeric waves. See **Loading Text Waves from Igor Text Files** on page II-154.

A command in an Igor Text file is introduced by the keyword **X** followed by a space. The command follows the X on the same line. When Igor encounters this while loading an Igor Text file it executes the command.

Anything that you can execute from Igor’s command line is acceptable after the X. Introduce comments with “X //”. There is no way to do conditional branching or looping. However, you can call an Igor procedure defined in a built-in or auxiliary procedure window.

Commands, introduced by X, are executed as if they were entered on the command line or executed via the Execute operation. Such command execution is not thread-safe. Therefore, you can not load an Igor text file containing a command from an Igor thread.

Setting Scaling in an Igor Text File

When Igor writes an Igor Text file, it always includes commands to set each wave’s scaling, units and dimension labels. It also sets each wave’s note.

If you write a program that generates Igor Text files, you should set at least the scaling and units. If your 1D data is uniformly spaced in the X dimension, you should use the SetScale operation to set your waves X scaling, X units and data units. If your data is not uniformly spaced, you should set the data units only. For multidimensional waves, use SetScale to set Y, Z and T units if needed.

The Load Waves Dialog for Igor Text

The basic process of loading data from an Igor Text file is as follows:

1. Choose Data→Load Waves→Load Waves to display the Load Waves dialog.
2. Choose Igor Text from the File Type pop-up menu.
3. Click the File button to select the file containing the data.

4. Click Do It.

When you click Do It, Igor’s LoadWave operation runs. It executes the Load Igor Text routine which loads the file.

If you choose Data→Load Waves→Load Igor Text instead of choosing Data→Load Waves→Load Waves, Igor displays the Open File dialog in which you can select the Igor Text file to load directly. This is a shortcut that skips the Load Waves dialog.

Loading MultiDimensional Waves from Igor Text Files

In an Igor Text file, a block of wave data is preceded by a WAVES declaration. For multidimensional data, you must use a separate block for each wave. Here is an example of an Igor Text file that defines a 2D wave:

```
IGOR
WAVES/D/N=(3,2) wave0
BEGIN
      1     2
      3     4
      5     6
END
```

The “/N=(3,2)” flag specifies that the wave has three rows and two columns. The first line of data (1 and 2) contains data for the first row of the wave. This layout of data is recommended for clarity but is not required. You could create the same wave with:

```
IGOR
WAVES/D/N=(3,2) wave0
BEGIN
      1     2     3     4     5     6
END
```

Igor merely reads successive values and stores them in the wave, storing a value in each column of the first row before moving to the second row. All white space (spaces, tabs, return and linefeed characters) are treated the same.

When loading a 3D wave, Igor expects the data to be in column/row/layer order. You can leave a blank line between layers for readability but this is not required.

Here is an example of a 3 rows by 2 columns by 2 layers wave:

```
IGOR
WAVES/D/N=(3,2,2) wave0
BEGIN
      1     2
      3     4
      5     6

      11    12
      13    14
      15    16
END
```

The first 6 numbers define the values of the first layer of the 3D wave. The second 6 numbers define the values of the second layer. The blank line improves readability but is not required.

When loading a 4D wave, Igor expects the data to be in column/row/layer/chunk order. You can leave a blank line between layers and two blank lines between chunks for readability but this is not required.

If loading a multidimensional wave, Igor expects that the dimension sizes specified by the /N flag are accurate. If there is more data in the file than expected, Igor ignores the extra data. If there is less data than expected, some of the values in the resulting waves will be undefined. In either of these cases, Igor prints a message in the history area to alert you to the discrepancy.

Loading Text Waves from Igor Text Files

Loading text waves from Igor Text files is similar to loading them from delimited text files except that in an Igor Text file you declare a wave's name and type. Also, text strings are quoted in Igor Text files as they are in Igor's command line. Here is an example of Igor Text that defines a text wave:

```
IGOR
WAVES/T textWave0, textWave1
BEGIN
      "This"      "Hello"
      "is"        "out"
      "a test"    "there"
END
```

All of the waves in a block of an Igor Text file must have the same number of points and data type. Thus, you can not mix numeric and text waves in the same block. You can have any number of blocks in one Igor Text file.

As this example illustrates, you must use double quotes around each string in a block of text data. If you want to embed a quote, tab, carriage return or linefeed within a single text value, use the escape sequences \", \t, \r or \n. Use \\ to embed a backslash. For less common escape sequences, see **Escape Sequences in Strings** on page IV-14.

Loading Igor Binary Data

This section discusses loading Igor Binary data into memory.

Igor stores Igor Binary data in two ways: one wave per Igor binary wave file in unpacked experiments and multiple waves within a packed experiment file.

When you open an experiment, Igor *automatically* loads the Igor Binary data to recreate the experiment's waves. The main reason to *explicitly* load an Igor binary wave file is if you want to access the same data from multiple experiments. The easiest way to load data from another experiment is to use the Data Browser (see **The Data Browser** on page II-114).

Warning: You can get into trouble if two Igor experiments load data from the same Igor binary wave file. See **Sharing Versus Copying Igor Binary Wave Files** on page II-156 for details.

There are a number of ways to load Igor Binary data into the current experiment in memory. Here is a summary. For most users, the first and second methods — which are simple and easy to use — are sufficient.

Method	Loads	Action	Purpose
Open Experiment	Packed and unpacked files	Restores the experiment to the state in which it was last saved.	To restore experiment.
Data Browser	Packed and unpacked files	Copies data from one experiment to another. See **The Browse Expt Button** on page II-117 for details.	To collect data from different sources for comparison.
Desktop Drag and Drop	Unpacked files only	Copies data from one experiment to another or shares between experiments.	To collect data from different sources for comparison.
Load Waves Dialog	Unpacked files only	Copies data from one experiment to another or shares between experiments.	To create a LoadWave command that can be used in an Igor procedure.
LoadWave Operation	Unpacked files only	Copies data from one experiment to another or shares between experiments. See **LoadWave** on page V-508 for details.	To automatically load data using an Igor Procedure.

Method	Loads	Action	Purpose
LoadData Operation	Packed and unpacked files	Copies data from one experiment to another. See **LoadData** on page V-500 for details.	To automatically load data using an Igor Procedure.

The Igor Binary Wave File

The Igor binary wave file format is Igor's native format for storing waves. This format stores one wave per file very efficiently. The file includes the numeric contents of the wave (or text contents if it is a text wave) as well as all of the auxiliary information such as the dimension scaling, dimension and data units and the wave note. In an Igor packed experiment file, any number of Igor Binary wave files can be packed into a single file.

The file name extension for an Igor binary wave file is ".ibw". Old versions of Igor used ".bwav" and this is still accepted. The Macintosh file type code is IGBW and the creator code is IGR0 (last character is zero).

The name of the wave is stored *inside* the Igor binary wave file. It does not come from the name of the file. For example, wave0 might be stored in a file called "wave0.ibw". You could change the name of the file to anything you want. This does not change the name of the wave stored in the file.

The Igor binary wave file format was designed to save waves that are part of an Igor experiment. In the case of an unpacked experiment, the Igor binary wave files for the waves are stored in the experiment folder and can be loaded using the LoadWave operation. In the case of a packed experiment, data in Igor Binary format is packed into the experiment file and can be loaded using the **LoadData** operation.

.ibw files do not support waves with more than 2 billion elements. you can use the **SaveData** operation or the Data Browser Save Copy button to save very large waves in a packed experiment file (.pxp) instead.

Some Igor users have written custom programs that write Igor binary wave files which they load into an experiment. Igor Technical Note #003, "Igor Binary Format", provides the details that a programmer needs to do this. See also Igor Pro Technical Note PTN003.

The Load Waves Dialog for Igor Binary

The basic process of loading data from an Igor binary wave file is as follows:

1. Choose Data→Load Waves→Load Waves to display the Load Waves dialog.
2. Choose Igor Binary from the File Type pop-up menu.
3. Click the File button to select the file containing the data.
4. Check the "Copy to home" checkbox.
5. Click Do It.

When you click Do It, Igor's LoadWave operation runs. It executes the Load Igor Binary routine which loads the file. If the wave that you are loading has the same name as an existing wave or other Igor object, Igor presents a dialog in which you can resolve the conflict.

Notice the "Copy to home" checkbox in the Load Waves dialog. It is very important.

If it is checked, Igor will disassociate the wave from its source file after loading it into the current experiment. When you next save the experiment, Igor will store a new copy of the wave with the current experiment. The experiment will not reference the original source file. We call this "copying" the wave to the current experiment.

If "Copy to home" is unchecked, Igor will keep the connection between the wave and the file from which it was loaded. When you save the experiment, it will contain a *reference* to the source file. We call this "sharing" the wave between experiments.

We strongly recommend that you copy waves rather than share them. See **Sharing Versus Copying Igor Binary Wave Files** on page II-156 for details.

If you choose Data→Load Waves→Load Igor Binary instead of choosing Data→Load Waves→Load Waves, Igor displays the Open File dialog in which you can select the Igor binary wave file to load directly. This is a shortcut that skips the Load Waves dialog. When you take this shortcut, you lose the opportunity to set the “Copy to home” checkbox. Thus, during the load operation, Igor presents a dialog from which you can choose to copy or share the wave.

The LoadData Operation

The LoadData operation provides a way for Igor programmers to automatically load data from packed Igor experiment files or from a file-system folder containing unpacked Igor binary wave files. It can load not only waves but also numeric and string variables and a hierarchy of data folders that contains waves and variables.

The Data Browser’s Browse Expt button provides interactive access to the LoadData operation and permits you to drag a hierarchy of data from one Igor experiment into the current experiment in memory. To achieve the same functionality in an Igor procedure, you need to use the LoadData operation directly. See the **LoadData** operation (see page V-500).

LoadData, accessed from the command line or via the Data Browser, has the ability to overwrite existing waves, variables and data folders. Igor automatically updates any graphs and tables displaying the overwritten waves. This provides a very powerful and easy way to view sets of identically structured data, as would be produced by successive runs of an experiment. You start by loading the first set and create graphs and tables to display it. Then, you load successive sets of identically named waves. They overwrite the preceding set and all graphs and tables are automatically updated.

Sharing Versus Copying Igor Binary Wave Files

There are two reasons for loading a binary file that was created as part of another Igor experiment: you may want your current experiment to *share* data with the other experiment or, you may want to *copy* data to the current experiment from the other experiment.

There is a potentially serious problem that occurs if two experiments share a file. The file can not be in two places at one time. Thus, it will be stored *with* the experiment that created it but *separate from* the other. The problem is that, if you move or rename files or folders, the second experiment will be unable to find the binary file.

Here is an example of how this problem can bite you.

Imagine that you create an experiment at work and save it as an unpacked experiment file on your hard disk. Let’s call this “experiment A”. The waves for experiment A are stored in individual Igor binary wave files in the experiment folder.

Now you create a new experiment. Let’s call this “experiment B”. You use the Load Igor Binary routine to load a wave from experiment A into experiment B. You elect to share the wave. You save experiment B on your hard disk. Experiment B now contains a *reference* to a file in experiment A’s home folder.

Now you decide to use experiment B on another computer so you copy it to the other computer. When you try to open experiment B, Igor can’t find the file it needs to load the shared wave. This file is back on the hard disk of the original computer.

A similar problem occurs if, instead of moving experiment B to another computer, you change the name or location of experiment A’s folder. Experiment B will still be looking for the shared file under its old name or in its old location and Igor will not be able to load the file when you open experiment B.

Because of this problem, we recommend that you *avoid file sharing* as much as possible. If it is necessary to share a binary file, you will need to be very careful to avoid the situation described above.

The Data Browser always copies when transferring data from disk into memory.

For more information on the problem of sharing files, see **References to Files and Folders** on page II-24.

Copy or Share Wave Dialog

When you load an Igor binary wave file interactively (i.e., not via a command), by default Igor displays the Copy or Share Wave dialog which allows you to choose to copy the wave into the current experiment or to share it with other experiments. You can change the default behavior to always copy or always share using the Data Loading section of the Miscellaneous Settings dialog.

If you interactively load multiple Igor binary wave files at one time, by default, you will see the Copy or Share Wave dialog once for each file being loaded. In Igor Pro 9 and later, you can apply your choice to all of the files by checking the Apply to All Igor Binary Wave Files in the Batch Currently Being Loaded checkbox. This feature is available only when you:

- Choose Data→Load Waves→Load Igor Binary
- Drag multiple Igor binary wave files into the Igor command window
- Drag multiple Igor binary wave files into the Igor frame window (Windows only)
- Drag multiple Igor binary wave files into the Data Browser (Windows only)

The Copy or Share Wave dialog is not displayed when you load Igor binary wave files using the Data Browse Browse Expt button. In that case, the waves are always copied to the current experiment.

When loading multiple Igor binary wave files, the output variables V_Flag, S_waveNames, S_path, and S_fileName reflect only the last file loaded.

Loading Image Files

You can load JPEG, PNG, TIFF, BMP, and Sun Raster image files into Igor Pro using the Load Image dialog.

You can load numeric plain text files containing image data using the Load Waves dialog via the Data menu. Check the "Load columns into matrix" checkbox.

You can load images from HDF5 files. For help, execute this in Igor:

```
DisplayHelpTopic "HDF5 in Igor Pro"
```

You can load images from HDF4 files. For help, execute this in Igor:

```
DisplayHelpTopic "HDF Loader XOP"
```

You can also load images by grabbing frames. See the **NewCamera** operation.

The Load Image Dialog

To load an image file into an Igor wave, choose Data→Load Waves→Load Image to display the Load Image dialog.

When you choose a particular type of image file from the File Type pop-up menu, you are setting a file filter that is used when displaying the image file selection dialog. If you are not sure that your image file has the correct file name extension, choose “Any” from the File Type pop-up menu so that the filter does not restrict your selection.

The name of the loaded wave can be the name of the file or a name that you specify. If you enter a wave name in the dialog that conflicts with an existing wave name and you do not check the Overwrite Existing Waves checkbox, Igor appends a numeric suffix to the new wave name.

Loading PNG Files

There are two menu choices for the PNG format: Raw PNG and PNG. When Raw PNG is selected, the data is read directly from the file into the wave. When PNG is selected, the file is loaded into memory, an offscreen image is created, and the wave data is set by reading the offscreen image. In nearly all cases, you should choose Raw PNG.

When loading a PNG file, the image data is loaded into a 3D Igor RGB wave containing unsigned byte RGB elements in layers 0, 1, and 2. If the image file includes an alpha channel, the resulting 3D RGBA wave includes an alpha layer.

You can convert a 3D waves containing an RGB image into a grayscale image using the **ImageTransform** operation with the rgb2gray keyword.

Loading JPEG File

When loading a JPEG file, the image data is loaded into a 3D Igor RGB wave containing unsigned byte RGB elements in layers 0, 1, and 2. JPEG does not support alpha.

You can convert a 3D waves containing an RGB image into a grayscale image using the **ImageTransform** operation with the rgb2gray keyword.

Loading BMP Files

When loading a BMP file, the image data is loaded into a 3D Igor RGB wave containing unsigned byte RGB elements in layers 0, 1, and 2. BMP does not support alpha.

You can convert a 3D waves containing an RGB image into a grayscale image using the **ImageTransform** operation with the rgb2gray keyword.

Loading TIFF Files

A TIFF file can store one or more images in many formats. The most common formats are:

- Bilevel
- Grayscale
- Palette color
- Full color (RGB, RGBA, CMYK)

A bilevel image consists of one plane of data in which each pixel can represent black or white. Igor loads a bilevel image into a 2D wave.

A grayscale image consists of one plane of data in which each pixel can represent a range of intensities. Igor loads a grayscale image into a 2D wave.

A palette color image is like a grayscale but includes a color palette. Igor loads the grayscale image into a 2D wave and also creates a colormap wave named with the suffix "_CMap".

RGB, RGBA, and CMYK images are loaded into 3D waves with 3 or 4 layers. Each layer stores the pixels for one color component.

TIFF files that contain multiple images are called TIFF stacks. There are two options for loading them:

- Load the images into a single 3D wave.

  This works with grayscale images only. Each grayscale image is loaded into a layer of the 3D output wave.
- Load each image into its own wave.

  This works with any kind of image. Each grayscale image is loaded into its own 2D wave. Each RGB, RGBA, or CMYK image is loaded into its own 3D wave.

You can specify a particular image, or range of images, to be loaded from a multi-image TIFF file. In the Load Image dialog, enter the zero-based index of the first image to load and the number of images to load from the TIFF stack.

You can display TIFF images using the NewImage operation and convert image waves into other forms using the ImageTransform operation.

You can convert a 3D waves containing an RGB image into a grayscale image using the **ImageTransform** operation with the rgb2gray keyword.

You can convert a number of 2D image waves into a 3D stack using the **ImageTransform** operation with the stackImages keyword.

Loading Sun Raster Files

Sun Raster files are loaded as 2D waves.

If the Sun Raster file includes a color map, Igor creates, in addition to the image wave, a colormap wave, named with the suffix "_CMap".

Loading Row-Oriented Text Data

All of the built-in text file loaders are column-oriented — they load the columns of data in the file into 1D waves. There is a row-oriented format that is fairly common. In this format, the file represents data for one wave but is written in multiple columns. Here is an example:

```
350         2.97         1.95         1.00         8.10         2.42
351         3.09         4.08         1.90         7.53         4.87
352         3.18         5.91         1.04         6.90         1.77
```

In this example, the first column contains X values and the remaining columns contain data values, written in row/column order.

Igor Pro does not have a file-loader extension to handle this format, but there is a WaveMetrics procedure file for it. To use it, use the Load Row Data procedure file in the “WaveMetrics Procedures:File Input Output” folder. It adds a Load Row Data item to the Macros menu. When you choose this item, Igor presents a dialog that offers several options. One of the options treats the first column as X values or as data. If you specify treating the column as X values, Igor will use it to determine the X scaling of the output wave, assuming that the values in the first column are evenly spaced. This is usually the case.

Loading Excel Files

You can load data from Excel files into Igor using the **XLLoadWave** operation directly or by choosing Data→Load Waves→Load Excel File which displays the Load Excel File dialog.

XLLoadWave loads numeric, text, date, time and date/time data from Excel files into Igor waves. It can load data from .xls and .xlsx files. It does not support .xlsb (binary format for large files) files. It also can not load password-protected Excel files.

On Macintosh, it is possible to have a worksheet open in Excel and to use XLLoadWave to load the worksheet into Igor at the same time. When you do this, Igor loads the most recently saved version of the worksheet. On Windows, you must close the worksheet in Excel before loading it in Igor.

Some programs unfortunately save tab-delimited or other non-Excel type files using the ".xls" extension. If you try to load one of these files, XLLoadWave will tell you that it is not an Excel binary file.

What XLLoadWave Loads

A worksheet can be very simple, consisting of just a rectangular block of numbers, or it can be very complex, with blocks of numbers, strings, and formulas mixed up in arbitrary ways. XLLoadWave is designed to pick a rectangular block of cells out of a worksheet, converting the columns into Igor waves.

XLLoadWave can load both numeric and text (string) data. An Excel column can contain a mix of numeric and text cells. An Igor wave must be all numeric or all text. When you load an Excel column into an Igor wave, you need to decide whether to load the data into a numeric wave or into a text wave. XLLoadWave can also load date, time, and date/time data into numeric waves.

Column and Wave Types

XLLoadWave provides the following methods of determining the type of wave that it will create for a given column. These methods are presented in the Load Excel File dialog and are controlled by the /C and /COLT flags of the XLLoadWave command line operation.

Treat all columns as numeric

This is the default method. If you have a simple block of numbers that you want to load into waves, this is the method to use, and you can forget about the others.

XLLoadWave creates a numeric wave for each Excel column that you are loading. If the column contains numeric cells, their values are stored in the corresponding point of the wave. If the column contains text cells, XLLoadWave stores NaNs (blanks) in the corresponding point of the wave.

Treat all columns as date

This is the same as the preceding method except that XLLoadWave converts the numeric data from Excel date/time format into Igor date/time format. See Excel Date/Time Versus Igor Date/Time for details.

When XLLoadWave creates a numeric wave that is to store dates or times, it always creates a double-precision wave, because double precision is required to accurately store dates. Also, XLLoadWave sets the data units of the wave to "dat". Igor recognizes "dat" as signifying that the wave contains dates and/or times when you use the wave in a graph as the X part of an XY pair.

In this method, when XLLoadWave displays the wave in a table, it uses date/time formatting for the table column. You can change the column format to just date or just time using the ModifyTable operation.

Treat all columns as text

XLLoadWave loads all columns into text waves.

If you load a column containing numeric cells into a text wave, Igor converts the numeric cell value into text and stores the resulting text in the wave.

Deduce from row

This is a good method to use for loading a mix of columns of different types (numeric and/or date and/or text) into Igor.

You tell XLLoadWave what row to look at. XLLoadWave examines the cells in that row. For a given column, if the cell is numeric then XLLoadWave creates a numeric wave and if the cell is text then XLLoadWave creates a text wave.

If a numeric cell uses an Excel built-in date, time, or date/time format, XLLoadWave converts the numeric data from Excel date/time format into Igor date/time format. XLLoadWave can not deduce date and time formatting for cells that are governed by custom cell formats. In this case, see Excel Date/Time Versus Igor Date/Time for details on manually conversion.

When XLLoadWave deduces the column type using this method, it sets the Igor table column format for date/time waves to either date, time or date/time, depending on the built-in cell format for the corresponding column in the Excel file.

Use column type string

Use this method if you have a mix of columns of different types (numeric and/or date and/or text) and the "deduce from row" method does not make the correct deduction. For example, in some files there may be no single row that is suitable for deducing the column type.

In this method, you provide a string that identifies the type of each column to be loaded. For example, the string "1T1D3N" tells XLLoadWave that the first column loaded is to be loaded into a text wave, the next column is to be loaded into a numeric date/time wave, and the next three columns are to be loaded into numeric waves. If you load more columns than are covered by the string, extra columns are loaded as numeric. Also, the string "N" means all columns are numeric, the string "D" means all columns are numeric date/time, and the string "T" means all columns are text. The string must not contain any blanks or other extraneous characters.

Here are examples of suitable strings:

"N"	All columns are numeric.
"T"	All columns are text.
"1T1D3N"	One text column followed by one numeric date/time column followed by three or more numeric columns.
"1T1N3T25N"	One text column followed by one numeric column followed by three text columns followed by 25 or more numeric columns.

When loading numeric columns, the "use column type string" method differs from the "treat all columns as numeric" method in one way. In the "Treat all columns as numeric" method, any text cells in the numeric column are treated as blanks. This behavior is compatible with previous versions of XLLoadWave. In the "use column type string" method, if XLLoadWave encounters a text cell in a numeric column, it converts the text cell into a number. If the text represents a valid number (e.g., "1.234"), this will produce a valid number in the Igor wave. If the text does not represent a valid number (e.g., "January"), this will produce a blank in the Igor wave. This is useful if you have a file that inadvertently contains a text cell in a numeric column.

XLLoadWave and Wave Names

As you can see in the Load Excel File dialog, XLLoadWave uses one of three ways to generate names for the Igor waves that it creates. First, it can take wave names from a row that you specify in the worksheet. In this case XLLoadWave expects that the row contains string values. Second, it can generate default wave names of the form ColumnA, ColumnB and so on, where the letter at the end of the name indicates the column in the worksheet from which the wave was created. Third, XLLoadWave can generate wave names of the form wave0, wave1 and so on using a base name, "wave" in this case, that you specify.

XLLoadWave supports a fourth wave naming method that is not available from the dialog: the /NAME flag. This flag allows you to specify the desired name for each column using a semicolon-separated string list.

There are several situations, described below, in which XLLoadWave changes the name of the wave that it creates from what you might expect. When this happens, XLLoadWave prints the original and new names in Igor's history area. After the load, you can use Igor's Rename operation to pick another name of your choice, if you wish.

If a name in the worksheet is too long, XLLoadWave truncates it to a legal length. If a name contains characters that are not allowed in standard Igor wave names, XLLoadWave replaces them with the underscore character.

If two names in the worksheet conflict with each other, XLLoadWave makes the second name unique by adding a prefix such as “D_” where the letter indicates the Excel column from which the wave is being loaded.

If a name in the worksheet conflicts with the name of an existing wave, XLLoadWave makes the name of the incoming wave unique by adding one or more digits unless you use the overwrite option. With the overwrite option on, the incoming data overwrites the existing wave.

If XLLoadWave needs to add one or more digits to a name to make it unique and if the length of the name is already at the limit for Igor wave names, XLLoadWave removes one or more characters from the middle of the name.

It is possible that a name taken from a cell in the worksheet might conflict with the name of an Igor operation, function or macro. For example, Date and Time are built-in Igor functions so a wave can not have these names. If such a conflict occurs, XLLoadWave changes the name and prints a message in Igor's history area showing the original and the new names.

XLLoadWave Output Variables

XLLoadWave sets the standard Igor file-loader output variables, V_flag, S_path, S_fileName, and S_waveNames. In addition it sets S_worksheetName to the name of the loaded worksheet within the workbook file.

Excel Date/Time Versus Igor Date/Time

Excel stores date/time information in units of days since January 1, 1900 or January 1, 1904. 1900 is the default on Windows and 1904 is the default on Macintosh. Igor stores dates in units of seconds since January 1, 1904.

If you use the Treat all columns as date, Deduce from row, or Use column type string methods for determining the column type, XLLoadWave automatically converts from the Excel format into the Igor format. If you use the Treat all columns as numeric method, you need to manually convert from Excel to Igor format.

If the Excel file uses 1904 as the base year, the conversion is:

```
wave *= 24*3600              // Convert days to seconds
```

If the Excel file uses 1900 as the base year, the conversion is:

```
wave *= 24*3600              // Convert days to seconds
wave -= 24*3600*365.5*4      // Account for four year difference
```

The use of 365.5 here instead of 365 accounts for a leap year plus the fact that the Microsoft 1900 date system represents 1/1/1900 as day 1, not as day 0.

When displaying time data, you may see a one second discrepancy between what Excel displays and what Igor displays in a table. For example, Excel may show "9:00:30" while Igor shows "9:00:29". The reason for this is that the Excel data is just short of the nominal time. In this example, the Excel cell contains a value that corresponds to, "9:00:30" minus a millisecond. When Excel displays times, it rounds. When Igor displays times, it truncates. If this bothers you, you can round the data in the Igor wave:

```
wave = round(wave)
```

In doing this rounding, you eliminate any fractional seconds in the data. That is why XLLoadWave does not automatically do the rounding.

Loading Excel Data Into a 2D Wave

XLLoadWave creates 1D waves. Here is an Igor function that converts the 1D waves into a 2D wave.

```
Function LoadExcelNumericDataAsMatrix(pathName, fileName, worksheetName,
                        startCell, endCell)
   String pathName         // Name of Igor symbolic path or "" to get dialog
   String fileName         // Name of file to load or "" to get dialog
   String worksheetName
   String startCell        // e.g., "B1"
   String endCell          // e.g., "J100"

   if ((strlen(pathName)==0) || (strlen(fileName)==0))
      // Display dialog looking for file.
      Variable refNum
      String filters = "Excel Files (*.xls,*.xlsx,*.xlsm):.xls,.xlsx,.xlsm;"
      filters += "All Files:.*;"
      Open/D/R/P=$pathName /F=filters refNum as fileName
      fileName = S_fileName         // S_fileName is set by Open/D
      if (strlen(fileName) == 0)    // User cancelled?
         return -2
      endif
   endif
   // Load row 1 into numeric waves
   XLLoadWave/S=worksheetName/R=($startCell,$endCell)/COLT="N"/O/V=0/K=0/Q fileName
   if (V_flag == 0)
      return -1                    // User cancelled
   endif

   String names = S_waveNames       // S_waveNames is created by XLLoadWave
   String nameOut = UniqueName("Matrix", 1, 0)
   Concatenate /KILL /O names, $nameOut   // Create matrix and kill 1D waves

   String format = "Created numeric matrix wave %s containing cells %s to %s in
                    worksheet \"%s\"\r"
   Printf format, nameOut, startCell, endCell, worksheetName
End
```

Loading Matlab MAT Files

The MLLoadWave operation loads Matlab MAT-files into Igor Pro. You can access it directly via the MLLoadWave operation or by choosing Data→Load Waves→Load Matlab MAT File which displays the Load Matlab MAT File dialog.

MLLoadWave relies on dynamic libraries provided by the Matlab application. You must have a compatible version of Matlab installed on your machine to use MLLoadWave. If you don't have Matlab or if your Matlab version is not compatible with Igor, or if you simply prefer to work with HDF5 files, see **Loading Version 7.3 MAT Files as HDF5 Files** on page II-165 for a workaround.

The MLLoadWave operation was incorporated into Igor for Igor Pro 7.00. In earlier versions it was implemented as an XOP. The XOP was originally created by Yves Peysson and Bernard Saoutic.

Finding Matlab Dynamic Libraries

MLLoadWave dynamically links with libraries supplied by The Mathworks when you install Matlab. You will need to tell Igor where to look as follows:

1. Choose Data→Load Waves→Load Matlab MAT File.

   This displays the Load Matlab MAT File dialog.
2. Click the Find 32-bit Matlab Libraries button or the Find 64-bit Matlab Libraries button.

   The button title depends on whether you are running IGOR32 (Windows only) or IGOR64. Clicking it displays the Find Matlab dialog.
3. Click the Folder button to display a Choose Folder dialog.
4. Navigate to your Matlab folder and select it.

   This will be something like:

   ```
   C:\Program Files\MATLAB\<version>                  // 64-bit Windows
   C:\Program Files (x86)\MATLAB\<version>            // 32-bit Windows
   /Applications/MATLAB_<version>.app/bin/maci64      // 64-bit Macintosh
   ```

   where <version> is your Matlab version, for example, R2015a.
5. Click the Choose button.

   Igor searches your Matlab folder to find the required dynamic libraries. If found, Igor attempts to load them. If the search and loading succeeds, the Accept button is enabled. If the search and loading fails, the Accept button is disabled. The search will fail if Igor can not find the required Matlab dynamic libraries or if the system can not find other dynamic libraries required by the Matlab dynamic libraries.

   If you have selected a valid Matlab folder but the Accept button remains disabled, see **Matlab Dynamic Library Issues**.

6. Click the Accept button.

   Igor records the location of the Matlab dynamic libraries in preferences for use in future sessions.

If you call MLLoadWave before you specify the Matlab dynamic library locations, MLLoadWave displays the Find Matlab dialog. Follow the steps above to locate your Matlab installation.

Matlab Dynamic Library Issues

NOTE: MLLoadWave requires compatible Matlab dynamic libraries built for the same architecture as your version of Igor Pro. IGOR32 (32-bit Igor Pro, Windows only) requires the 32-bit Matlab libraries, while IGOR64 (64-bit Igor Pro) requires the 64-bit Matlab libraries.

If you don't have Matlab or if your Matlab version is not compatible with Igor, or if you simply prefer to work with HDF5 files, see **Loading Version 7.3 MAT Files as HDF5 Files** on page II-165 for a workaround.

Matlab Dynamic Library Issues on Macintosh

On Macintosh, MLLoadWave has been verified to work with Matlab version 2010b and 2015b. It should work with later versions. It may or may not work with earlier versions.

For Matlab 2010b, you need to create an alias to the libraries as described next. Matlab 2015b does not require the alias. We do not know whether the alias is necessary for versions between 2010b and 2015b.

On Macintosh it sometimes happens that you point Igor to valid Matlab dynamic libraries but Igor still can't link with them. This occurs when the dynamic libraries to which Igor directly links cannot find other dynamic libraries which they require. To address this problem, create an alias pointing to the Matlab libraries directory as follows:

1. In the Finder, open the Applications folder and locate the 64-bit Matlab application.
2. Right click on the Matlab application and open it by selecting "Show Package Contents".
3. Inside the Matlab package, navigate to the folder containing your Matlab dynamic libraries. This will be one of the following:

   ```
   /Applications/MATLAB_<version>.app/bin/maci64    // 64-bit Macintosh
   ```

   where <version> is your Matlab version, for example, R2010b.
4. Right click the maci64 folder and select Make Alias.
5. Rename the alias as MLLoadWave64Support.
6. Move the alias to your Applications folder.
7. Restart Igor and try Finding Matlab Dynamic Libraries again.

Matlab Dynamic Library Issues on Windows

Prior to Igor Pro 7.02, it was required that the path to the Matlab dynamic libraries directory be in the Windows PATH environment variable. As of 7.02, this should no longer be necessary.

However, we can not test with all versions of Matlab and future versions may behave differently. If you follow the steps listed under **Finding Matlab Dynamic Libraries** on page II-163 but Igor is still unable to link with the Matlab dynamic libraries, try adding the Matlab libraries path to your Windows PATH environment variable. Remember that IGOR32 requires 32-bit Matlab libraries and IGOR64 requires 64-bit Matlab libraries. Restart Igor before re-testing.

We have received reports that Matlab 2021 is not compatible with Igor Pro 9. This appears to be caused by a dynamic library conflict. See **Loading Version 7.3 MAT Files as HDF5 Files** on page II-165 for a workaround.

Supported Matlab Data Types

MLLoadWave can load 1D, 2D, 3D and 4D numeric and string data. MLLoadWave can not load data of dimension greater than 4.

When loading Matlab string data into an Igor wave, the Igor wave will be of dimension one less than the Matlab data set. This is because each element in a Matlab string data set is a single byte whereas each element in an Igor string wave is a string (any number of bytes).

MLLoadWave does not support loading of the following types of Matlab data: cell arrays, structures, sparse data sets, objects, 64 bit integers.

Numeric Data Loading Modes

The Load Matlab MAT File dialog presents a popup menu that controls how numeric data is loaded into Igor. The items in the menu are:

Load columns into 1D wave	Each column of the Matlab matrix is loaded into a separate 1D Igor wave.
Load rows into 1D wave	Each row of the Matlab matrix is loaded into a separate 1D Igor wave.
Load matrix into one 1D wave	The entire Matlab matrix is loaded into a single 1D Igor wave.
Load matrix into matrix	The Matlab matrix is loaded into an Igor multi-dimensional wave*.
Load matrix into transposed matrix	The Matlab matrix is loaded into an Igor multi-dimensional wave* but the rows and columns are transposed.

* Starting with Igor Pro 8.00, after loading a matrix that results in an Mx1 2D wave, MLLoadWave automatically redimensions the wave as an M-row 1D wave.

When loading data of dimension 3 or 4, the first three modes treat each layer (“page” in Matlab terminology) as a separate matrix. For 3D Matlab data, this gives the following behavior:

Load columns into 1D wave	Each column of each layer of the Matlab data set is loaded into a separate 1D Igor wave.
Load rows into 1D wave	Each row of each layer of the Matlab data set is loaded into a separate 1D Igor wave.
Load matrix into one 1D wave	The layer of the Matlab data set is loaded into a 1D Igor wave.
Load matrix into matrix	The Matlab 3D data set is loaded into an Igor 3D wave.
Load matrix into transposed matrix	The Matlab 3D data set is loaded into an Igor 3D wave but the rows and columns are transposed.

When loading 3D or 4D data sets, the term "matrix" in the last two modes is not really appropriate. MLLoadWave loads the entire 3D or 4D data set into a 3D or 4D Igor wave.

Loading Version 7.3 MAT Files as HDF5 Files

In 2006 Matlab added version 7.3 of their MAT file format. A version 7.3 MAT file is an HDF5 file with 512 bytes of Matlab-specific information at the start of the file. The HDF5 library allows applications to prepend application-specific data, so version 7.3 MAT files can be loaded as HDF5 files.

You may find it useful to load such files as HDF5 files because Igor has better HDF5 support than MAT-file support, because you don't have Matlab on your machine, or because Igor's Matlab support does not work with your Matlab installation. See **Igor HDF5 Guide** on page II-183 for information on Igor's HDF5 support.

A version 7.3 MAT file contains an HDF5 signature at byte offset 512. The HDF5 signature is an 8-byte pattern described at https://support.hdfgroup.org/HDF5/doc/H5.format.html.

In order to open a 7.3 MAT file in the HDF5 Browser you will need to select All Files from the popup menu in the HDF5 Browser Open File dialog. If you try to open a MAT file that is not version 7.3 as an HDF5 file, the HDF5 library will return an error.

For an example of saving Matlab data in the version 7.3 format, see https://www.mathworks.com/help/matlab/ref/save.html. You can also set a preference in Matlab to make version 7.3 your default format.

Loading General Binary Files

General binary files are binary files created by other programs. If you understand the binary file format, it is possible to load the data into Igor. However, you must understand the binary file format *precisely*. This is usually possible only for relatively simple formats.

There are two ways to load data from general binary files into Igor:

- Using the **FBinRead** operation
- Using the **GBLoadWave** operation

Using FBinRead is somwhat more difficult and more flexible than using GBLoadWave. It is especially useful for loading data stored as structures into Igor. For details, see **FBinRead**. This section focuses on using the GBLoadWave operation.

GBLoadWave loads data from general binary files into Igor waves. "GB" stands for "general binary".

You can invoke the GBLoadWave operation directly or by choosing Data→Load Waves→Load General Binary File which displays the Load General Binary dialog.

You need to know the format of the binary file precisely in order to successfully use GBLoadWave. Therefore, it is of use mostly to load binary files that you have created from your own program. You can also use GBLoadWave to load third party files if you know the file format precisely.

Files GBLoadWave Can Handle

GBLoadWave handles the following types of binary data:

- 8 bit, 16 bit, 32 bit, and 64 bit signed and unsigned integers
- 32 and 64 bit IEEE floating point numbers
- 32 and 64 bit VAX floating point numbers

In addition, GBLoadWave handles high-byte-first (Motorola) and low-byte-first (Intel) type binary numbers.

GBLoadWave currently can not handle IEEE or VAX extended precision values. See **VAX Floating Point** for more information.

GBLoadWave can create waves using any of numeric data types that Igor supports (64-bit and 32-bit IEEE floating point, 64-bit, 32-bit, 16-bit and 8-bit signed and unsigned integers). The data type of the wave does not need to be the same as the data type of the file. For example, if you have a file containing integer A/D readings, you can load that data into a single-precision or double-precision floating point wave.

In general, it is best to load waves as floating point since nearly all Igor operations work faster on floating point. One exception is when you are dealing with images, especially stacks of images. For example, if you have a 512x512x1024 byte image stack in a file, you should load it into a byte wave. This takes one quarter of the memory and disk space of a single-precision floating point wave.

GBLoadWave knows nothing about Igor multi-dimensional waves. It knows about 1D only. The term "array", used in the GBLoadWave dialog, means "1D array". However, after loading data as a 1D wave, you can redimension it as required.

GBLoadWave can load one or more 1D arrays from a file. When multiple arrays are loaded, they can be stored sequentially in the file or they can be interleaved. Sequential means that all of the points of one array appear in the file followed by all of the points of the next array. Interleaved means that point zero of each array appears in the file followed by point one of each array.

GBLoadWave And Very Big Files

Most data files are not so large as to present major issues for GBLoadWave or Igor. However, if your data file approaches hundreds of millions or billions of bytes, size and memory issues may arise.

If you want GBLoadWave to convert the type of the data, for example from 16-bit signed to 32-bit floating point, this requires an extra buffer during the load process which takes more memory.

When dealing with extremely large files, you may need to load part of your data file into Igor at a time using the GBLoadWave /S and /U flags.

The Load General Binary Dialog

When you choose Data→Load Waves→Load General Binary File, Igor displays the Load General Binary dialog. This dialog allows you to choose the file to load and to specify the data type of the file and the data type of the wave or waves to be created.

A few of the items in the dialog require some explanation.

The Number of Arrays in File textbox and the Number of Points in Array textbox are both initially set to 'auto'. Auto means that GBLoadWave automatically determines these based on the number of bytes in the file.

If you leave both on auto, GBLoadWave assumes that there is one array in the file with the number of points determined by the number of bytes in the file and the data length of each point.

If you set Number of Arrays in File to a number greater than zero and leave Number of Points in Array on auto, GBLoadWave determines the number of points in each array based on the total number of bytes in the file and the specified number of arrays in the file.

If you set Number of Points in Array to a number greater than one and leave Number of Arrays in File on auto, GBLoadWave determines the number of arrays in the file based on the total number of bytes in the file and the specified number of points in each array.

You can also specify the number of arrays in the file and the number of points in each array explicitly by entering a number in place of 'auto' for each of these settings.

GBLoadWave creates one or more 1D waves and gives the waves names which it generates by appending a number to the specified base name. For example, if the base name is "wave", it creates waves with names like wave0, wave1, etc.

If the Overwrite Existing Waves checkbox is checked, GBLoadWave uses names of existing waves, overwriting them. If it is unchecked, GBLoadWave skips names already in use.

Checking the Apply Scaling checkbox allows you to specify an offset and multiplier so that GBLoadWave can scale the data into meaningful units. If this checkbox is unchecked, GBLoadWave does no scaling.

VAX Floating Point

GBLoadWave can load VAX "F" format (32 bit, single precision) and "G" format (64 bit, double precision) numbers.

Do not use the GBLoadWave byte-swapping feature (/B flag) for VAX data. This does Intel-to-Motorola byte swapping, also called little-endian to big-endian. VAX data is byte-swapped relative to the way Igor stores data, but not in the same sense. Specifically, each 16-bit word is big-endian but each 8-bit byte is little-endian. When you specify that the input data is VAX data, using /J=2, GBLoadWave does the swapping required for VAX data.

GBLoadWave can not currently read VAX "D" (another 64 bit format). However, VAX D format is the same as F with an additional 4 bytes of fraction. This makes it possible to load VAX D format as F format, throwing away the extra fractional bits. Here is an example:

```
GBLoadWave/W=2/V/P=VAXData/T={2,2}/J=2/N=temp "VAX D File"
KillWaves temp1
Rename temp0, VAXDData_WithoutExtraFractBits
```

The /W=2 flag tells GBLoadWave that there are two arrays in the file. The /V flag tells it that they are interleaved. The first four bytes of each data point in the file wind up in the temp0 wave. The seconds four bytes, which contain the extra fractional bits in the D format, wind up in temp1 which we discard.

Loading JCAMP Files

Igor can load JCAMP-DX files using the **JCAMPLoadWave** operation. The JCAMP-DX format is used primarily in infrared spectroscopy. It is a plain text format that uses only ASCII characters.

You can invoke the JCAMPLoadWave operation directly or by choosing Data→Load Waves→Load JCAMP-DX File which displays the Load JCAMP-DX File dialog.

JCAMPLoadWave understands JCAMP-DX file headers well enough to read the data and set the wave scaling appropriately. Because JCAMP-DX is intended primarily for evenly-spaced data, a single wave is produced for each data set. The wave's X scaling is set based on information in the JCAMP-DX file header. The header information is optionally stored in the wave note, and optionally in a series of Igor variables. If you choose to create these variables, there will be one variable for each JCAMP-DX label in the header.

Files JCAMPLoadWave Can Handle

JCAMPLoadWave can load one or more waves from a single file. The JCAMP-DX standard calls for each new data set to start with a new header. Each header should start with the ##TITLE= label. As far as we can tell, most spectrometer systems write only one data set per file.

In addition, the JCAMP-DX standard includes simple optional compression techniques which JCAMPLoadWave supports. Files that do not use compression are human-readable.

We believe that JCAMPLoadWave should load most files stored in standard JCAMP-DX format. If you have a JCAMP-DX file that does not load correctly, please send it to support@wavemetrics.com.

Some systems produce a hybrid format in which the data itself is stored in a binary file, accompanied by an ASCII file that contains just a JCAMP-DX style header. We know that certain Bruker NMR spectrometers do this. To accomodate these systems, it is possible to select an option to load the header information only. You would then have to load the data separately, most likely using **GBLoadWave**.

Loading JCAMP Header Information

JCAMPLoadWave provides two mechanisms to load the header information into Igor:

- Storing all header text in the wave note
- Creating one Igor variable for each JCAMP label encountered in the header

In the Load JCAMP-DX File dialog, checking the Make Wave Note checkbox invokes the /W flag which stores the entire header in the wave note.

Checking Set JCAMP Variables invokes the /V flag which creates one Igor variable for each JCAMP label encountered in the header. This is explained in the next section.

Variables Set By JCAMPLoadWave

JCAMPLoadWave sets the standard Igor file-loader output variables: S_fileName, S_path, V_flag and S_waveNames. These are described in the JCAMPLoadWave reference documentation.

If you use the /V flag, which corresponds to the the Set JCAMP Variables checkbox in the dialog, it also sets "header variables". Header variables are variables that contain data which JCAMPLoadWave gleans from the JCAMP header.

When JCAMPLoadWave is called from a macro, it creates the header variables as local variables. When it is called from the command line or from a user-defined function, it creates the header variables as global variables. The section **Using Header Variables From a Function** on page II-169 explains this in more detail.

The header variable names are set based on the JCAMP label with a prefix of "SJC_" for string variables or "VJC_" for numeric variables. Thus, when it encounters the ##TITLE label, JCAMPLoadWave creates a string variable named SJC_TITLE which contains the label.

Certain JCAMP labels are parsed for numeric information and a numeric variable is created. Numeric variables that might be created include:

VJC_NPOINTS Set to the number of points in the data set. This is set from the header information. If the actual number of data points in the file is different, this variable will not reflect this fact.

VJC_FIRSTX Set to the X value of the first data point in the data set.

VJC_LASTX Set to the X value of the last data point in the data set.

VJC_DELTAX Set to the interval between successive abscissa values. This is calculated from (VJC_LASTX -VJC_FIRSTX)/ (VJC_NPOINTS - 1), and so might be slightly different from the value given by the ##DELTAX=label.

VJC_XFACTOR Set to the multiplier that must be applied to the X data values in the file to give real-world values.

VJC_YFACTOR Set to the multiplier that must be applied to the Y data values in the file to give real-world values.

VJC_MINY Set to the minimum Y value found in the data set.

VJC_MAXY Set to the maximum Y value found in the data set.

If you are loading Fourier domain data, these variables may be created to reflect the fact that the data represent optical retardation and amplitude: VJC_FIRSTR, VJC_LASTR, VJC_DELTR, VJC_RFACTOR, VJC_AFACTOR.

Any other labels found in the header result in a string variable with name SJC_<label> where <label> is replaced with the name of the JCAMP label. For instance, the ##YUNITS label results in a string variable named SJC_YUNITS.

Since successive data sets in a single file have the same standard labels, the contents of the variables are set by the last instance of a given label in the file.

Using Header Variables From a Function

If you execute JCAMPLoadWave from a user-defined function and tell it to create header variables via the /V flag, the variables are created as global variables in the current data folder. To access these variables, you must use **NVAR** and **SVAR** references. These references must appear *after* the call to JCAMPLoadWave. For example:

```
Function LoadJCAMP()
   JCAMPLoadWave/P=JCAMPFiles "JCAMP1.dx"
   if (V_Flag == 0)
      Print "No waves were loaded"
      return -1
   endif

   NVAR VJC_NPOINTS
   Printf "Number of points: %d\r", VJC_NPOINTS
   SVAR SJC_YUNITS
   Printf "Y Units: %s\r", SJC_YUNITS

   return 0
End
```

The code above assumes that the header contains the ##NPOINTS label from which the variables VJC_NPOINTS and SJC_YUNITS are created. If you can't guarantee that the file contains such a label, then you must use **NVAR**/Z and **NVAR_Exists** to test for the existence of the variable before using it.

If you need to determine which variables were created at runtime, use the **GetIndexedObjName** function and test each name for the SJC_ or VJC_ prefix.

Another problem with header variables in functions is that they leave a lot of clutter around. You can clean up like this:

```
KillVariables/Z VJC_NPOINTS
KillStrings/Z SJC_YUNITS
```

Loading Sound Files

The **SoundLoadWave** operation, which was added in Igor Pro 7, loads data from various sound file formats.

See **Sound** on page IV-245 for general information on Igor's sound-related features.

Loading Waves Using Igor Procedures

One of Igor's strong points is that it you can write procedures to automatically load, process and graph data. This is useful if you have accumulated a large number of data files with identical or similar structures or if your work generates such files on a regular basis.

The input to the procedures is one or more data files. The output might be a printout of a graph or page layout or a text file of computed results.

Each person will need procedures customized to his or her situation. In this section, we present some examples that might serve as a starting point.

Variables Set by File Loaders

The LoadWave operation creates the numeric variable V_flag and the string variables S_fileName, S_path, and S_waveNames to provide information that is useful for procedures that automatically load waves. When used in a function, the LoadWave operation creates these as local variables.

Most other file loaders create the same or similar output variables.

LoadWave sets the string variable S_fileName to the name of the file being loaded. This is useful for annotating graphs or page layouts.

LoadWave sets the string variable S_path to the full path to the folder containing the file that was loaded. This is useful if you need to load a second file from the same folder as the first.

LoadWave sets the variable V_flag to the number of waves loaded. This allows a procedure to process the waves without knowing in advance how many waves are in a file.

LoadWave also sets the string variable S_waveNames to a semicolon-separated list of the names of the loaded waves. From a procedure, you can use the names in this list for subsequent processing.

Loading and Graphing Waveform Data

Here is a very simple example designed to show the basic form of an Igor function for automatically loading and graphing the contents of a data file. It loads a delimited text file containing waveform data and then makes a graph of the waves.

This example uses an Igor symbolic path. If you are not familiar with the concept, see **Symbolic Paths** on page II-22.

In this function, we make the assumption that the files that we are loading contain three columns of waveform data. Tailoring the function for a specific type of data file allows us to keep it very simple.

```
Function LoadAndGraph(fileName, pathName)
   String fileName      // Name of file to load or "" to get dialog
   String pathName      // Name of path or "" to get dialog

   // Load the waves and set the local variables.
   LoadWave/J/D/O/P=$pathName fileName
   if (V_flag==0)       // No waves loaded. Perhaps user canceled.
      return -1
   endif

   // Put the names of the three waves into string variables
   String s0, s1, s2
   s0 = StringFromList(0, S_waveNames)
   s1 = StringFromList(1, S_waveNames)
   s2 = StringFromList(2, S_waveNames)

   Wave w0 = $s0                 // Create wave references.
   Wave w1 = $s1
   Wave w2 = $s2

   // Set waves' X scaling, X units and data units
   SetScale/P x, 0, 1, "s", w0, w1, w2
   SetScale d 0, 0, "V", w0, w1, w2

   Display w0, w1, w2            // Create a new graph

   // Annotate graph
   Textbox/N=TBFileName/A=LT "Waves loaded from " + S_fileName

   return 0                      // Signifies success.
End
```

s0, s1 and s2 are local string variables into which we place the names of the loaded waves. We then use the $ operator to create a reference to each wave, which we can use in subsequent commands.

Once the function is entered in the procedure window, you can execute it from the command line or call it from another function. If you execute

```
   LoadAndGraph("", "")
```

the LoadWave operation displays an Open File dialog allowing you to choose a file. If you call LoadAndGraph with the appropriate parameters, LoadWave loads the file without presenting a dialog.

You can add a “Load And Graph” menu item by putting the following menu declaration in the procedure window:

```
Menu "Macros"
   "Load And Graph...", LoadAndGraph("", "")
End
```

Because we have not used the “Auto name & go” option for the LoadWave operation, LoadWave displays another dialog in which you can enter names for the new waves. If you want the procedure to be more automatic, use /A or /N to turn “Auto name & go” on. If you want the procedure to specify the names of the loaded waves, use the /B flag. See the description of the **LoadWave** operation (see page V-508) for details.

To keep the function simple, we have hard-coded the X scaling, X units and data units for the new waves. You would need to change the parameters to the SetScale operation to suit your data. For more flexibility, you would add additional parameters to the function.

It is possible to write LoadAndGraph so that it can handle files with any number of columns. This makes the function more complex but more general.

For more advanced programmers, here is the more general version of LoadAndGraph.

```
Function LoadAndGraph(fileName, pathName)
   String fileName      // Name of file to load or "" to get dialog
   String pathName      // Name of path or "" to get dialog

   // Load the waves and set the variables.
   LoadWave/J/D/O/P=$pathName fileName
   if (V_flag==0)       // No waves loaded. Perhaps user canceled.
      return -1
   endif

   Display              // Create a new graph

   String theWave
   Variable index=0
   do                   // Now append waves to graph
      theWave = StringFromList(index, S_waveNames) // Next wave
      if (strlen(theWave) == 0)             // No more waves?
            break                           // Break out of loop
      endif
      Wave w = $theWave
      SetScale/P x, 0, 1, "s", w            // Set X scaling
      SetScale d 0, 0, "V", w               // Set data units
      AppendToGraph w
      index += 1
   while (1)         // Unconditionally loop back up to “do”

   // Annotate graph
   Textbox/A=LT "Waves loaded from " + S_fileName

   return 0          // Signifies success.
End
```

The do-loop picks each successive name out of the list of names in S_waveNames and adds the corresponding wave to the graph. S_waveNames will contain one name for each column loaded from the file.

There is one serious shortcoming to the LoadAndGraph function. It creates a very plain, default graph. There are four approaches to overcoming this problem:

- Use preferences
- Use a style macro
- Set the graph formatting directly in the procedure
- Overwrite data in an existing graph

Normally, Igor does not use preferences when a procedure is executing. To get preferences to take effect during the LoadAndGraph function, you would need to put the statement “Preferences 1” near the beginning of the function. This turns preferences on just for the duration of the function. This will cause the Display and AppendToGraph operations to use your graph preferences.

Using preferences in a function means that the output of the function will change if you change your preferences. It also means that if you give your function to a colleague, it will produce different results. This dependence on preferences can be seen as a feature or as a problem, depending on what you are trying to achieve. We normally prefer to keep procedures independent of preferences.

Using a style macro is a more robust technique. To do this, you would first create a prototype graph and create a style macro for the graph (see **Graph Style Macros** on page II-350). Then, you would put a call to the style macro at the end of the LoadAndGraph macro. The style macro would apply its styles to the new graph.

To make your code self-contained, you can set the graph formatting directly in the code. You should do this in a subroutine to avoid cluttering the LoadAndGraph function.

The last approach is to overwrite data in an existing graph rather than creating a new one. The simplest way to do this is to always use the same names for your waves. For example, imagine that you load a file with three waves and you name them wave0, wave1, wave2. Now you make a graph of the waves and set everything in the graph to your taste. You now load another file, use the same names and use LoadWave's overwrite option. The data from the new file will replace the data in your existing waves and Igor will automatically update the existing graph. Using this approach, the function simplifies to this:

```
Function LoadAndGraph(fileName, pathName)
   String fileName      // Name of file to load or "" to get dialog
   String pathName      // Name of path or "" to get dialog

   // load the waves, overwriting existing waves
   LoadWave/J/D/O/N/P=$pathName fileName
   if (V_flag==0)       // No waves loaded. Perhaps user canceled.
      return -1
   endif

   Textbox/C/N=TBFileName/A=LT "Waves loaded from " + S_fileName

   return 0             // Signifies success.
End
```

There is one subtle change here. We have used the /N option with the LoadWave operation, which autonames the incoming waves using the names wave0, wave1, and wave2.

You can see that this approach is about as simple as it can get. The downside is that you wind up with uninformative names like wave0. You can use the LoadWave /B flag to provide better names.

If you are loading data from Igor binary wave files or from packed Igor experiments, you can use the LoadData operation instead of LoadWave. This is a powerful operation, especially if you have multiple sets of identically structured data, as would be produced by multiple runs of an experiment. See **The LoadData Operation** on page II-156 above.

Loading and Graphing XY Data

In the preceding example, we treated all of the columns in the file the same: as waveforms. If you have XY data then things change a bit. We need to make some more assumptions about the columns in the file. For example, we might have a collection of files with four columns which represent two XY pairs. The first two columns are the first XY pair and the second two columns are the second XY pair.

Here is a modified version of our function to handle this case.

```
Function LoadAndGraphXY(fileName, pathName)
   String fileName   // Name of file to load or "" to get dialog
   String pathName   // Name of path or "" to get dialog

   // load the waves and set the globals
   LoadWave/J/D/O/P=$pathName fileName
   if (V_flag==0)    // No waves loaded. Perhaps user canceled.
      return -1
   endif
   // Put the names of the waves into string variables.
   String sx0, sy0, sx1, sy1
   sx0 = StringFromList(0, S_waveNames)
   sy0 = StringFromList(1, S_waveNames)
   sx1 = StringFromList(2, S_waveNames)
   sy1 = StringFromList(3, S_waveNames)

   Wave x0 = $sx0                    // Create wave references.
   Wave y0 = $sy0
   Wave x1 = $sx1
   Wave y1 = $sy1

   SetScale d 0, 0, "s", x0, x1      // Set wave data units
   SetScale d 0, 0, "V", y0, y1

   Display y0 vs x0                  // Create a new graph
   AppendToGraph y1 vs x1

   Textbox/A=LT "Waves loaded from " + S_fileName  // Annotate graph

   return 0          // Signifies success.
End
```

The main difference between this and the waveform-based LoadAndGraph function is that here we append waves to the graph as XY pairs. Also, we don’t set the X scaling of the waves because we are treating them as XY pairs, not as waveforms.

It is possible to write a more general function that can handle any number of XY pairs. Once again, adding generality adds complexity. Here is the more general version of the function.

```
Function LoadAndGraphXY(fileName, pathName)
   String fileName      // Name of file to load or "" to get dialog
   String pathName      // Name of path or "" to get dialog

   // Load the waves and set the globals
   LoadWave/J/D/O/P=$pathName fileName
   if (V_flag==0)       // No waves loaded. Perhaps user cancelled.
      return -1
   endif

   Display              // Create a new graph

   String sxw, syw
   Variable index=0
   do       // Now append waves to graph
      sxw=StringFromList(index, S_waveNames) // Next name
      if (strlen(sxw) == 0)                  // No more?
            break       // break out of loop
      endif
      syw=StringFromList(index+1, S_waveNames)// Next name

      Wave xw = $sxw                    // Create wave references.
      Wave yw = $syw

      SetScale d 0, 0, "s", xw          // Set X wave's units
      SetScale d 0, 0, "V", yw          // Set Y wave's units
      AppendToGraph yw vs xw

      index += 2
   while (1)         // Unconditionally loop back up to “do”

   // Annotate graph
   Textbox/A=LT "Waves loaded from " + S_fileName
   return 0          // Signifies success.
End
```

Loading All of the Files in a Folder

In the next example, we assume that we have a folder containing a number of files. Each file contains three columns of waveform data. We want to load each file in the folder, make a graph and print it. This example uses the LoadAndGraph function as a subroutine.

```
Function LoadAndGraphAll(pathName)
   String pathName      // Name of symbolic path or "" to get dialog

   String fileName
   String graphName
   Variable index=0

   if (strlen(pathName)==0)      // If no path specified, create one
      NewPath/O temporaryPath    // This will put up a dialog
      if (V_flag != 0)
         return -1               // User cancelled
      endif
      pathName = "temporaryPath"
   endif

   Variable result
   do       // Loop through each file in folder
      fileName = IndexedFile($pathName, index, ".dat")
      if (strlen(fileName) == 0)    // No more files?
         break                      // Break out of loop
      endif
      result = LoadAndGraph(fileName, pathName)
      if (result == 0)              // Did LoadAndGraph succeed?
                                    // Print the graph
         graphName = WinName(0, 1)  // Get the name of the top graph
         String cmd
         sprintf cmd, "PrintGraphs %s", graphName
         Execute cmd                // Explained below

         KillWindow $graphName      // Kill the graph
         KillWaves/A/Z              // Kill all unused waves
      endif
      index += 1
   while (1)

   if (Exists("temporaryPath"))     // Kill temp path if it exists
      KillPath temporaryPath
   endif
   return 0          // Signifies success.
End
```

This function relies on the IndexedFile function to find the name of successive files of a particular type in a particular folder. The last parameter to IndexedFile says that we are looking for files with a ".dat" extension.

Once we get the file name, we pass it to the LoadAndGraph function. After printing the graph, we kill it and then kill all the waves in the current data folder so that we can start fresh with the next file. A more sophisticated version would kill only those waves in the graph.

To print the graphs, we use the PrintGraphs operation. PrintGraphs is one of a few built-in operations that can not be directly used in a function. Therefore, we put the PrintGraphs command in a string variable and call Execute to execute it.

If you are loading data from Igor binary wave files or from packed Igor experiments, you can use the LoadData operation. See **The LoadData Operation** on page II-156 above.

Setting Wave Names When Loading Data Files

In this section we show how to programmatically set the names of waves loaded from a delimited text file. For background information, see **LoadWave Generation of Wave Names** on page II-142.

We assume that the file contains three columns of numbers with no column labels and we want to create waves named Stimulus, CellA, and CellB. We use the LoadWave /B flag to set the wave names.

```
Function/S GetColumnInfoStr1()
   String columnInfoStr = ""
   columnInfoStr += "N='Stimulus';"
   columnInfoStr += "N='CellA';"
   columnInfoStr += "N='CellB';"
   return columnInfoStr
End

Function LoadAndSetNames1(pathName, fileName)
   String pathName      // Name of symbolic path or "" to get dialog
   String fileName      // Name of file or "" to get dialog

   String columnInfoStr = GetColumnInfoStr1()
   LoadWave/J/O/P=$pathName/B=columnInfoStr fileName
   if (V_Flag == 0)
      return -1         // Failure
   endif

   return 0             // Success
End
```

Next we include the name of the file being loaded, minus the file name extension, in the wave names. Given a file named "Data.txt", this creates waves named Data_Stimulus, Data_CellA, and Data_CellB.

```
Function/S GetColumnInfoStr2(String baseName)
   String columnInfoStr = ""
   columnInfoStr += "N='" + baseName + "_" + "Stimulus';"
   columnInfoStr += "N='" + baseName + "_" + "CellA';"
   columnInfoStr += "N='" + baseName + "_" + "CellB';"
   return columnInfoStr
End

Function LoadAndSetNames2(pathName, fileName)
   String pathName      // Name of symbolic path
   String fileName      // Name of file

   // This version does requires that you provide the actual symbolic path
   // and file name.
   if (strlen(pathName)==0 || strlen(fileName)==0)
      return -1         // Failure
   endif

   String fileNameMinusExtension = ParseFilePath(3, fileName, ":", 0, 0)
   String baseName = CleanupName(fileNameMinusExtension, 0)

   String columnInfoStr = GetColumnInfoStr2(baseName)
   LoadWave/J/A/O/P=$pathName/B=columnInfoStr fileName
   if (V_Flag == 0)
      return -1         // Failure
   endif

   return 0             // Success
End
```

Finally we include the name of the file being loaded, minus the file name extension, in the wave names using the LoadWave /NAME flag which requires Igor Pro 9.00 or later. Given a file named "Data.txt", this creates waves named Data_Stimulus, Data_CellA, and Data_CellB, the same as the preceding example.

```
Function/S GetColumnInfoStr3()
   String columnInfoStr = ""
   columnInfoStr += "N='Stimulus';"
   columnInfoStr += "N='CellA';"
   columnInfoStr += "N='CellB';"
   return columnInfoStr
End

Function LoadAndSetNames3(pathName, fileName)
   String pathName      // Name of symbolic path or "" to get dialog
   String fileName      // Name of file or "" to get dialog

   String columnInfoStr = GetColumnInfoStr3()
   LoadWave/J/A/O/P=$pathName/B=columnInfoStr/NAME={":filename:_","",1} 
fileName
   if (V_Flag == 0)
      return -1      // Failure
   endif

   return 0          // Success
End
```

See **Using the File Name in Wave Names** on page II-142 for details on the /NAME flag.

Exporting Data

Igor automatically saves the waves in the current experiment on disk when you save the experiment. Many Igor users load data from files into Igor and then make and print graphs or layouts. This is the end of the process. They have no need to explicitly save waves.

You can save waves in an Igor packed experiment file for archiving using the SaveData operation or using the Save Copy button in the Data Browser. The data in the packed experiment can then be reloaded into Igor using the LoadData operation or the Load Expt button in Data Browser. Or you can load the file as an experiment using File→Open Experiment. See the **SaveData** operation on page V-815 for details.

The main reason for saving a wave separate from its experiment is to export data from Igor to another program. To explicitly save waves to disk, you would use Igor's Save operation.

You can access all of the built-in routines via the Save Waves submenu of the Data menu.

The following table lists the available data saving routines in Igor and their salient features.

File type	Description
Delimited text	Used for archiving results or for exporting to another program. Row Format: `<data><delimiter><data><terminator>`* Contains one block of data with any number of rows and columns. A row of column labels is optional. Columns may be equal or unequal in length. Can export 1D or 2D waves. See **Saving Waves in a Delimited Text File** on page II-178.

File type	Description
General text	Used for archiving results or for exporting to another program. Row Format: `<number><tab><number><terminator>`* Contains one or more blocks of numbers with any number of rows and columns. A row of column labels is optional. Columns in a block must be equal in length. Can export 1D or 2D waves. See **Saving Waves in a General Text File** on page II-179.
Igor Text	Used for archiving waves or for exporting waves from one Igor experiment to another. Format: See **Igor Text File Format** on page II-151 above. Contains one or more wave blocks with any number of waves and rows. A given block can contain either numeric or text data. Consists of special Igor keywords, numbers and Igor commands. Can export waves of dimension 1 through 4. See **Saving Waves in an Igor Text File** on page II-179.
Igor Binary	Used for exporting waves from one Igor experiment to another. Contains data for one Igor wave. Format: See Igor Technical Note #003, “Igor Binary Format”. See **Sharing Versus Copying Igor Binary Wave Files** on page II-156.
Image	Used for exporting waves to another program. Format: TIFF, PNG, raw PNG, JPEG. See **Saving Waves in Image Files** on page II-180.
HDF4	Igor does not support exporting data in HDF4 format.
HDF5	For help, execute this in Igor: `DisplayHelpTopic "HDF5 in Igor Pro"`
Sound	Used for exporting waves to another program. Format: AIFC, WAVE. See **Saving Sound Files** on page II-180.
TDMS	Saves data to National Instruments TDMS files. Requires activating an extension. Supported on Windows only. See the “TDM Help.ihf” help file for details.
SQL Databases	Writes data to SQL databases. Requires activating an extension and expertise in database programming. See **Accessing SQL Databases** on page II-181.

* `<terminator>` can be carriage return, linefeed or carriage return/linefeed. You would use carriage return for exporting to a Macintosh program, carriage return/linefeed for Windows systems, and linefeed for Unix systems.

Saving Waves in a Delimited Text File

To save a delimited text file, choose Data→Save Waves→Save Delimited Text to display the Save Delimited Text dialog.

The Save Delimited Text routine writes a file consisting of numbers separated by tabs, or another delimiter of your choice, with a selectable line terminator at the end of each line of text. When writing 1D waves, it can optionally include a row of column labels. When writing a matrix, it can optionally write row labels as well as column labels plus row and column position information.

Save Delimited Text can save waves of any dimensionality. Multidimensional waves are saved one wave per block. Data is written in row/column/layer/chunk order. Multidimensional waves saved as delimited text can not be loaded back into Igor as delimited text because the Load Delimited Text routine does not support multiple blocks. They can be loaded back in as general text. However, for data that is intended to be loaded back into Igor later, the Igor Text, Igor Binary or Igor Packed Experiment formats are preferable.

The order of the columns in the file depends on the order in which the wave names appear in the Save command. This dialog generates the wave names based on the order in which you select waves in the Source Waves list.

By default, the Save operation writes numeric data using the "%.15g" format for double-precision data and "%.7g" format for data with less precision. These formats give you up to 15 or 7 digits of precision in the file.

To use different numeric formatting, create a table of the data that you want to export. Set the numeric formatting of the table columns as desired. Be sure to display enough digits in the table because the data will be written to the file as it appears in the table. In the Save Delimited Text dialog, select the "Use table formatting" checkbox. When saving a multi-column wave (1D complex wave or multi-dimensional wave), all columns of the wave are saved using the table format for the first table column from the wave.

The **SaveTableCopy** and **wfprintf** operations can also be used to save waves to text files using a specific numeric format.

The Save operation is capable of appending to an existing file, rather than overwriting the file. This is useful for accumulating results of a analysis that you perform regularly in a single file. You can also use this to append a block of numbers to a file containing header information that you generated with the fPrintf operation. The append option is not available through the dialog. If you want to do this, see the discussion of the **Save** operation (see page V-812).

Saving Waves in a General Text File

Saving waves in a general text file is very similar to saving a delimited text file. The Save General Text dialog is identical to the Save Delimited Text dialog.

All of the columns in a single block of a general text file must have the same length. The Save General Text routine writes as many blocks as necessary to save all of the specified waves. For example, if you ask it to save two 1D waves with 100 points and two 1D waves with 50 points, it will write two blocks of data. Multidimensional waves are written one wave per block.

Saving Waves in an Igor Text File

The Igor Text format is capable of saving not only the data of a wave but its other properties as well. It saves each wave's dimension scaling, units and labels, data full scale and units and the wave's note, if any. All of this data is saved more efficiently as binary data when you save as an Igor packed experiment using the SaveData operation.

As in the general text format, all of the columns in a single block of an Igor Text file must have the same length. The Save Igor Text routine handles this requirement by writing as many blocks as necessary.

Save Igor Text can save waves of any dimensionality. Multidimensional waves are saved one wave per block. The /N flag at the start of the block identifies the dimensionality of the wave. Data is written in row/column/layer/chunk order.

Saving Waves in Igor Binary Wave Files

Igor's Save Igor Binary routine saves waves in Igor binary wave files, one wave per file. Most users will not need to do this since Igor automatically saves waves when you save an Igor experiment. You might want to save a wave in an Igor binary wave file to send it to a colleague.

The Save Igor Binary dialog is similar to the Save Delimited Text dialog. There is a difference in file naming since, in the case of Igor Binary, each wave is saved in a separate file. If you select a single wave from the dialog's list, you can enter a name for the file. However, if you select multiple waves, you can not enter a file name. Igor will use default file names of the form "wave0.ibw".

When you save an experiment in a packed experiment file, all of the waves are saved in Igor Binary format. The waves can then be loaded into another Igor experiment using **The Data Browser** (see page II-114) or **The LoadData Operation** (see page II-156).

.ibw files do not support waves with more than 2 billion elements. you can use the **SaveData** operation or the Data Browser Save Copy button to save very large waves in a packed experiment file (.pxp) instead.

Saving Waves in Image Files

To save a wave in TIFF, PNG, raw PNG, or JPEG format, choose Data→Save Waves→Save Image to display the Save Image dialog.

JPEG uses lossy compression. TIFF, PNG and raw PNG use lossless compression. To avoid compression loss, don't use JPEG.

JPEG supports only 8 bits per sample.

PNG supports 24 and 32 bits per sample. Raw PNG supports 8 and 16 bits per sample.

The extended TIFF file format supports 8, 16, and 32 bits per sample and you can use image stacks to export 3D and 4D waves.

See the **ImageSave** operation on page V-405 for details.

Saving Sound Files

You can save waves as sound files using the **SoundSaveWave** operation.

Exporting Text Waves

Igor does not quote text when exporting text waves as a delimited or general text file. It does quote text when exporting it as an Igor Text file.

Certain special characters, such as tabs, carriage returns and linefeeds, cause problems during exchange of data between programs because most programs consider them to separate one value from the next or one line of text from the next. Igor Text waves can contain any character, including special characters. In most cases, this will not be a problem because you will have no need to store special characters in text waves or, if you do, you will have no need to export them to other programs.

When Igor writes a text file containing text waves, it replaces the following characters, when they occur within a wave, with their associated escape codes:

Character	**Name**	**ASCII Code**	**Escape Sequence**
CR	carriage return	13	\r
LF	linefeed	10	\n
tab	tab	9	\t
\	backslash	92	\\

Igor does this because these would be misinterpreted if not changed to escape sequences. When Igor loads a text file into text waves, it reverses the process, converting escape sequences into the associated ASCII code.

This use of escape codes can be suppressed using the /E flag of the **Save** operation (see page V-812). This is necessary to export text containing backslashes to a program that does not interpret escape codes.

At present, the Save operation always uses the UTF-8 text encoding when writing text files. If your waves contain non-ASCII text, and if you need to import into a program that does not support UTF-8, you will need to convert the file's text encoding after saving it. You can do this by opening the file as a notebook, changing the text encoding, and saving it again, or using an external text editor.

Exporting MultiDimensional Waves

When exporting a multidimensional wave as a delimited or general text file, you have the option of writing row labels, row positions, column labels and column positions to the file. Each of these options is controlled by a checkbox in the Save Waves dialog. There is a discussion of row/column labels and positions under **2D Label and Position Details** on page II-134.

Igor writes multidimensional waves in column/row/layer/chunk order.

Accessing SQL Databases

Igor Pro includes an XOP, called SQL XOP, which provides access to relational databases from IGOR procedures. It uses ODBC (Open Database Connectivity) libraries and drivers on Mac OS X and Windows to provide this access.

For details on configuring and using SQL XOP, open the SQL Help file in "Igor Pro 7 Folder:More Extensions:Utilities".

Chapter

II-10

Igor HDF5 Guide

HDF5 in Igor Pro

HDF5 is a widely-used, very flexible data file format. The HDF5 file format is a creation of the National Center for Supercomputing Applications (NCSA). HDF5 is now supported by The HDF Group (http://www.hdfgroup.org).

Igor Pro includes deep support for HDF5, including:

- Browsing HDF5 files
- Loading data from HDF5 files
- Saving data to HDF5 files
- Saving Igor experiments as HDF5 files
- Loading Igor experiments from HDF5 files

Prior to Igor Pro 9.00, HDF5 support was provided by an XOP that you had to activate. HDF5 support is now built into Igor and activation is no longer required.

Support for saving and loading Igor experiments as HDF5 files was added in Igor Pro 9.00. For details see **HDF5 Packed Experiment Files** on page II-223.

Index of HDF5 Topics

Here are the main sections in the following material on HDF5:

HDF5 Guided Tour on page II-183

The HDF5 Browser on page II-193

HDF5 Operations and Functions on page II-197

HDF5 Procedure Files on page II-198

HDF5 Attributes on page II-198

HDF5 Dataset Subsets on page II-202

Igor Versus HDF5 on page II-203

Advanced HDF5 Data Types on page II-207

Other HDF5 Issues on page II-219

HDF5 Packed Experiment Files on page II-223

HDF5 Guided Tour

This section will get you off on the right foot using HDF5 in Igor Pro.

In the following material you will see numbered steps that you should perform. Please perform them exactly as written so you stay in sync with the guided tour.

This tour in intended to help experienced Igor users learn how to access HDF5 files from Igor but also to entice non-Igor users to buy Igor. Therefore the tour is written assuming no knowledge of Igor.

HDF5 Overview

HDF5 is a very powerful but complex file format that is designed to be capable of storing almost any imaginable set of data and to encapsulate relationships between data sets.

An HDF5 file can contain within it a hierarchy similar to the hierarchy of directories and files on your hard disk. In HDF5, the hierarchy consists of "groups" and "datasets". There is a root group named "/". Each group can contain datasets and other groups.

An HDF5 dataset is a one-dimensional or multi-dimensional set of elements. Each element can be an "atomic" datatype (e.g., 16-bit signed integer or a 32-bit IEEE float) or a "composite" datatype such as a structure or an array. A "compound" datatype is a composite datatype similar to a C structure. Its members can be atomic datatypes or composite datatypes. For now, forget about composite datatypes - we will deal with atomic datatypes only.

Each dataset can have associated with it any number of "attributes". Attributes are like datasets but are attached to datasets, or to groups, rather than being part of the hierarchy.

Igor Pro HDF5 Support

The Igor Pro HDF5 package consists of built-in HDF5 support and a set of Igor procedures.

The Igor procedures, which are automatically loaded when Igor is launched, implement an HDF5 browser in Igor. The browser supports:

- Previewing HDF5 file data
- Loading HDF5 datasets and groups into Igor
- Saving Igor waves and data folders in HDF5 files

In Igor Pro 9 and later, Igor can save Igor experiments as HDF5 packed experiment files and reload experiments from them.

Using the HDF5 Browser

1. **Choose Data→Load Waves→New HDF5 Browser.**

   This displays an HDF5 browser control panel.

   As you can see, the HDF5 Browser takes up a bit of screen space. You will need to arrange it and this help window so you can see both.

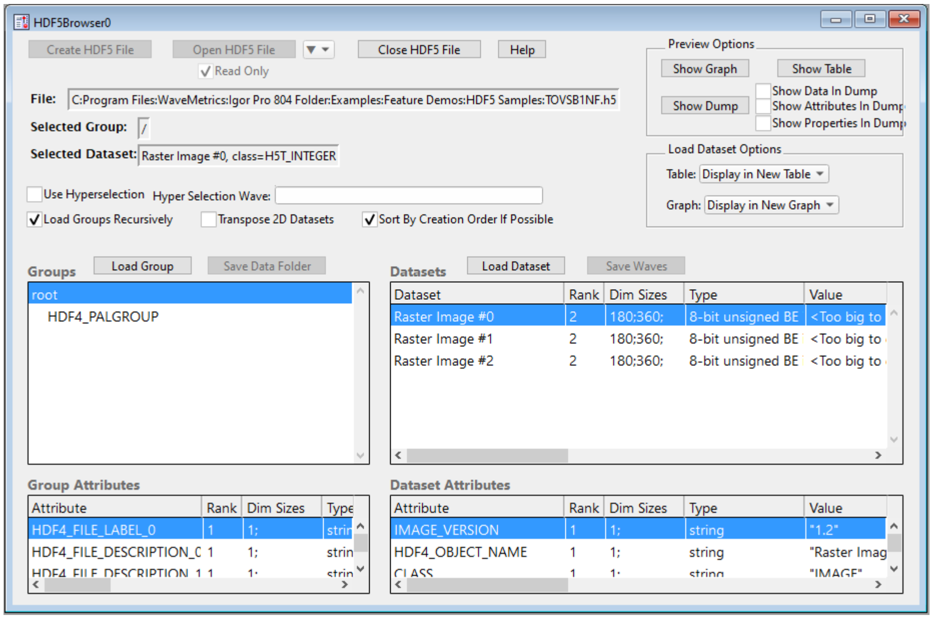
2. **Click the Open HDF5 File button and open the following file:**

   ```
   Igor Pro Folder\Examples\Feature Demos\HDF5 Samples\TOVSB1NF.h5
   ```

   (If you're not sure where your Igor Pro Folder is, choose Misc→Path Status, click on the Igor symbolic path, and note the path to the Igor Pro Folder.)

   We got this sample from the NCSA web site.

You should now see something like this:



☑ Read Only

File: C:Program Files:WaveMetrics:Igor Pro 804 Folder:Examples:Feature Demos:HDF5 Samples:TOVSB1NF.h5

Selected Group: /

Selected Dataset: Raster Image #0, class=H5T_INTEGER

□ Use Hyperselection   Hyper Selection Wave:

☑ Load Groups Recursively   □ Transpose 2D Datasets   ☑ Sort By Creation Order If Possible

□ Show Data In Dump
□ Show Attributes In Dump
□ Show Properties In Dump

Table: Display in New Table

Graph: Display in New Graph

Groups:

root
HDF4_PALGROUP

Dataset	Rank	Dim Sizes	Type	Value
Raster Image #0	2	180;360;	8-bit unsigned BE	<Too big to
Raster Image #1	2	180;360;	8-bit unsigned BE	<Too big to
Raster Image #2	2	180;360;	8-bit unsigned BE	<Too big to

Attribute	Rank	Dim Sizes	Type
HDF4_FILE_LABEL_0	1	1;	strin
HDF4_FILE_DESCRIPTION_C	1	1;	strin
HDF4_FILE_DESCRIPTION_1	1	1;	strin

Attribute	Rank	Dim Sizes	Type	Value
IMAGE_VERSION	1	1;	string	"1.2"
HDF4_OBJECT_NAME	1	1;	string	"Raster Imag
CLASS	1	1;	string	"IMAGE"

The browser contains four lists.

The top/left list is the Groups list and shows the groups in the HDF5 file. Groups in an HDF5 file are analogous to directories in a hard disk hierarchy. In this case there are two groups, root (which is called "/" in HDF5 terminology) and HDF4_PALGROUP. HDF4_PALGROUP is a subgroup of root.

This file contains a number of objects with names that begin with HDF4 because it was created by converting an HDF4 file to HDF5 format using a utility supplied by The HDF Group.

Below the Groups list is the Group Attributes list. In the picture above, the root group is selected so the Group Attributes list shows the attributes of the root group. An attribute is like a dataset but is attached to a group or dataset instead of being part of the HDF5 file hierarchy. Attributes are usually used to save small snippets of information related to a group or dataset.

The top/right list is the Datasets list. This lists the datasets in the selected group, root in this case. In the root group of this file we have three datasets all of which are images.

Below the Datasets list is the Dataset Attributes list. It shows the attributes of the selected dataset, Raster Image #0 in this case.

Three of the lists have columns that show information about the items in the list.

3. **Familiarize yourself with the information listed in the columns of the lists.**

   To see all the information you will need to either scroll the list and/or resize the entire HDF5 browser window to make it larger.

4. **In the Groups list, click the subgroup and notice that the information displayed in the other lists changes.**

5. **In the Groups list, click the root group again.**

   Now we will see how to browse a dataset.

6. **Click the Show Graph, Show Table and Show Dump buttons and arrange the three resulting windows so that they can all be seen at least partially.**

   These browser preview windows should typically be kept fairly small as they are intended just to provide a preview. It is usually convenient to position them to the right of the HDF5 browser.

   The three windows are blank now. They display something only when you click on a dataset or attribute.

7. **In the Datasets list, click the top dataset (Raster Image #0).**

The dataset is displayed in each of the three preview windows.

The dump window shows the contents of the HDF5 file in "Data Description Language" (DDL). This is useful for experts who want to see the format details of a particular group, dataset or attribute. The dump window will be of no interest in most everyday use.

If you check the Show Data in Dump checkbox and then click a very large dataset, it will take a very long time to dump the data into the dump window. Therefore you should avoid checking the Show Data in Dump checkbox.

The preview graph and table, not surprisingly, allow you to preview the dataset in graphical and tabular form.

This dataset is a special case. It is an image formatted according to the HDF5 Image and Palette Specification which requires that the image have certain attributes that describe it. You can see these attributes in the Dataset Attributes list. They are named CLASS, IMAGE_VERSION, IMAGE_SUBCLASS and PALETTE. The HDF5 Browser uses the information in these attributes to make a nice preview graph.

An HDF5 file can contain a 2D dataset without the dataset being formatted according to the HDF5 Image and Palette Specification. In fact, most HDF5 files do not follow that specification. We use the term "formal image" to make clear that a particular dataset is formatted according to the HDF5 Image and Palette Specification and to distinguish it from other 2D datasets which may be considered to be images.

8. **In the Dataset Attributes list, click the CLASS attribute.**

   The value of the selected attribute is displayed in the preview windows.

   Try clicking the other image attributes, IMAGE_VERSION, IMAGE_SUBCLASS and PALETTE.

   So far we have just previewed data, we have not loaded it into Igor. (Actually, it was loaded into Igor and stored in the root:Packages:HDF5Browser data folder, but that is an HDF5 Browser implementation detail.)

   Now we will load the data into Igor for real.

9. **Make sure that the Raster Image #0 dataset is selected, that the Table popup menu is set to Display In New Table and that the Graph popup menu is set to Display In New Graph. Then click the Load Dataset button.**

   The HDF5 Browser loads the dataset (and its associated palette, because this is a formal image with an associated palette dataset) into the current data folder in Igor and creates a new graph and a new table.

10. **Choose Data→Data Browser and note the two "waves" in the root data folder.**

    "Wave" is short for "waveform" and is our term for a dataset. This terminology stems from our roots in time series signal processing.

    The two waves, 'Raster Image #0' and 'Raster Image #0Pal' were loaded when you clicked the Load Dataset button. The graph was set up to display 'Raster Image #0' using 'Raster Image #0Pal' as a palette wave.

11. **Back in the HDF5 Browser, with the root group still selected, click the Load Group button.**

    The HDF5 Browser created a new data folder named TOVSB1NF and loaded the contents of the HDF5 root group into the new data folder which can be seen in the Data Browser. The name TOVSB1NF comes from the name of the HDF5 file whose root group we just loaded.

    When you load a group, the HDF5 Browser does not display the loaded data in a graph or table. That is done only when you click Load Dataset and also depends on the Load Dataset Options controls.

12. **Click the Close HDF5 File button and then click the close box on the HDF5 Browser.**

    If you had closed the HDF5 browser without clicking the Close HDF5 File button, the browser would have closed the file anyway. It will also automatically close the file if you choose File→New Experiment or File→Open Experiment or if you quit Igor.

Next we will learn how to write an Igor procedure to access an HDF5 file programmatically. Before you start that, feel free to play with the HDF5 Browser on your own HDF5 files. Start by choosing Data→Load Waves→New HDF5 Browser.

Igor can handle most HDF5 files that you will encounter, but it can not handle all possible HDF5 files. If you receive an error while examining your own files, it may be because of a bug or because Igor does not support a feature used in your file. In this case you can send the file along with a brief explanation of the problem to support@wavemetrics.com and we will determine whether the problem is a bug or just a limitation.

Loading HDF5 Data Programmatically

Igor includes a number of operations and functions for accessing HDF5 files. To get an idea of the range and scope of the operations, click the link below. Then return here to continue the guided tour.

HDF5 Operations and Functions on page II-197

In this section, we will load an HDF5 dataset using a user-defined function.

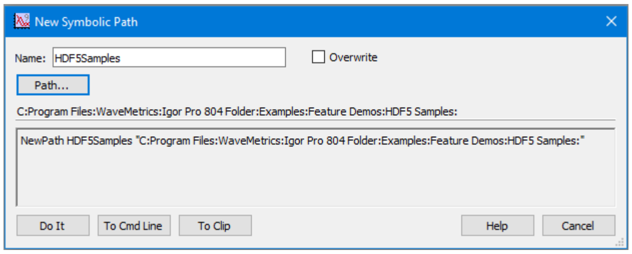
1. **Choose File→New Experiment.**

   You will be asked if you want to save the current experiment. Click No (or Yes if you want to save your current work environment).

   This closes the current experiment, killing any waves and windows.

2. **Choose Misc→New Path and create an Igor symbolic path named HDF5Samples and pointing to the HDF5 Samples directory which contains the TOVSB1NF.h5 file that we used in the preceding section.**

   The New Path dialog will look something like this:



Name: HDF5Samples

C:Program Files:WaveMetrics:Igor Pro 804 Folder:Examples:Feature Demos:HDF5 Samples:

NewPath HDF5Samples "C:Program Files:WaveMetrics:Igor Pro 804 Folder:Examples:Feature Demos:HDF5 Samples:"

   Click Do It to create the symbolic path.

   An Igor symbolic path is a short name that references a specific directory on disk. We will use this symbolic path in a command that opens an HDF5 file.

   In HDF5, you must first open a file or create a new file. The HDF5 library returns a file ID that you use in subsequent calls to the library. When you are finished, you must close the file. The following example illustrates this three step process.

3. **Choose Windows→Procedure Window and paste the following into the Procedure window:**

```
Function TestLoadDataset(datasetName)
    String datasetName              // Name of dataset to be loaded

    Variable fileID                 // HDF5 file ID will be stored here

    Variable result = 0             // 0 means no error

    // Open the HDF5 file
    HDF5OpenFile /P=HDF5Samples /R /Z fileID as "TOVSB1NF.h5"
    if (V_flag != 0)
        Print "HDF5OpenFile failed"
        return -1
    endif

    // Load the HDF5 dataset
```

```
	HDF5LoadData /O /Z fileID, datasetName
	if (V_flag != 0)
		Print "HDF5LoadData failed"
		result = -1
	endif

	// Close the HDF5 file
	HDF5CloseFile fileID

	return result
End
```

Read through the procedure. Notice that we use the symbolic path HDF5Samples created above as a parameter to the HDF5OpenFile operation.

The /R flag was used to open the file for read-only so that we don't get an error if the file can not be opened for writing.

The /Z flag tells HDF5OpenFile that, if there is an error, it should set the variable V_flag to a non-zero value but return to Igor as if no error occurred. This allows us to handle the error gracefully rather than having Igor abort execution and display an error dialog.

HDF5OpenFile sets the local variable fileID to a value returned from the HDF5 library. We pass that value to the HDF5LoadData operation. We also provide the name of a dataset within that file to be loaded. Again we check the V_flag variable to see if an error occurred.

Finally we call HDF5CloseFile to close the file that we opened. It is important to always close files that we open. If, during development of a procedure, you forget to close a file or fail to close a file because of an error, you can close all open HDF5 files by executing:

```
HDF5CloseFile /A 0
```

Also, Igor automatically closes all open files if you choose File→New Experiment, File→Revert Experiment or File→Open Experiment or if you quit Igor.

4. **Click the Compile button at the bottom of the Procedure window.**

   If you don't see a Compile button at the bottom of the Procedure window, that is because the procedures were already automatically compiled when you deactivated the Procedure window.

   If you get a compile error then you have not pasted the right text into the Procedure window or you have entered other incorrect text. Try going back to step 1 of this section.

   Now we are ready to run our procedure.

5. **Execute the following command in the Igor command line either by typing it and pressing Enter, by copy/paste followed by Enter, or by selecting it and pressing Control-Enter (Macintosh) or Ctrl-Enter (Windows):**

   ```
   TestLoadDataset("Raster Image #0")
   ```

   At this point the procedure should have correctly executed and you should see no error messages printed in the history area (just above the command line). This history area of the command window should contain:

   ```
   Waves loaded by HDF5LoadData: Raster Image #0
   ```

   Now we will verify that the data was loaded.

6. **Choose Data→Data Browser. Then double-click the wave named 'Raster Image #0'.**

   This creates a table showing the data just loaded.

   At this point Igor's root data folder contains just one wave, 'Raster Image #0', and does not contain the corresponding palette wave. That's because we loaded the dataset as a plain dataset, not as a formal image. The HDF5LoadData operation does not know about formal images. For that we need to use HDF5LoadImage.

7. **In the Data Browser, Control-click (Macintosh) or right-click (Windows) the 'Raster Image #0' wave and choose New Image.**

   Igor creates an image plot of the wave.

Because we loaded 'Raster Image #0' as a plain dataset, not as a formal image, the image plot is gray instead of colored. Also, it is rotated 90 degrees relative to the image plot we saw earlier in the tour. That's because Igor plots 2D data different from most programs and the HDF5LoadData operation does not compensate by default.

Our procedure is of rather limited value because it is hard-coded to use a specific symbolic path and a specific file name. We will now make it more general.

Before we do that, we will save the current work environment so that, if you make a mistake, you can revert to a version of it that worked.

8. **Choose File→Save Experiment As and save the current work environment in a new Igor experiment file named "HDF5 Tour.pxp" in a directory where you store your own files.**

   This saves all of your data and procedures in a single file. If need be, later you can revert to the saved state by choosing File→Revert Experiment.

9. **Open the Procedure window (Windows→Procedure Window) and replace the first two lines of the TestLoadDataset function with this:**

```
Function TestLoadDataset(pathName, fileName, datasetName)
    String pathName         // Name of symbolic path
    String fileName         // Name of HDF5 file
    String datasetName      // Name of dataset to be loaded
```

10. **Change the HDF5OpenFile command to this:**

```
HDF5OpenFile /P=$pathName /R /Z fileID as fileName
```

   Here we replaced HDF5Samples with $pathName. $pathName tells Igor to use the contents of the string parameter pathName as the parameter for the /P flag. We also replaced "TOVSB1NF.h5" with fileName so that we can specify the file to be loaded when we call the function instead of when we code it.

11. **Click the Compile button and then execute this in the command line:**

```
TestLoadDataset("HDF5Samples", "TOVSB1NF.h5", "Raster Image #0")
```

   This does the same thing as the earlier version of the function but now we have a more general function that can be used on any file in any directory.

   The command above reloaded the 'Raster Image #0' dataset into Igor, overwriting the previous contents. Since the new contents is identical to the previous contents, the graph and table did not change.

12. **Choose File→Save Experiment to save your current work environment in the HDF5 Tour.pxp experiment file that you created earlier.**

   You can now take a break and quit Igor if you want.

Saving HDF5 Data Programmatically

Now that we have seen how to programmatically load HDF5 data we will turn our attention to saving Igor data in an HDF5 file.

In this section, we will create some Igor data and save it in an HDF5 dataset from a user-defined function.

1. **If the HDF5 Tour.pxp experiment that you previously saved is not already open, open it by choosing File→Recent Experiments→HDF5 Tour.pxp.**

   Next we will create some data that we can save in an HDF5 file. We will create the data in a new Igor data folder to keep it separate from our other data.

2. **Choose Data→Data Browser. Click the New Data Folder button. Enter the name Test Data, click the Set As Current Data Folder and click OK.**

   The Data Browser shows the new data folder and a red arrow pointing to it. The red arrow indicates the current data folder. Operations that do not explicitly address a specific data folder work in the current data folder.

3. **On Igor's command line, execute these commands:**

```
Make/N=100 data0, data1, data2
```

```
SetScale x 0, 2*PI, data0, data1, data2
data0=sin(x); data1=2*sin(x+PI/6); data2=3*sin(x+PI/4)
Display data0, data1, data2
```

The SetScale operation set the X scaling for each wave to run from 0 to 2π. The symbol x in the wave assignment statements takes on the X value for each point in the destination wave as the assignment is executed.

(If you have not already done it, later you should do the Igor guided tour by choosing Help→Getting Started. It explains X scaling and wave assignment statements as well as many other Igor features.)

4. **Choose Misc→New Path and create an Igor symbolic path named HDF5Data pointing to a directory on your hard disk where you will save data.**

   Choose Misc→Path Status and verify that the HDF5Data symbolic path exists and points to the intended directory.

   Now that we have done some more work worth saving we will save the current experiment so we can revert to a known good state if necessary.

5. **Choose File→Save Experiment to save your current work environment in the HDF5 Tour.pxp experiment file that you created earlier.**

   If need be, later you can revert to the saved state by choosing File→Revert Experiment.

6. **Choose Windows→Procedure Window and paste the following into the Procedure window below the TestLoadDataset function:**

```
Function TestSaveDataset(pathName, fileName, w)
    String pathName         // Name of symbolic path
    String fileName         // Name of HDF5 file
    Wave w                  // The wave to be saved

    Variable result = 0     // 0 means no error

    Variable fileID

    // Create a new HDF5 file, overwriting if same-named file exists
    HDF5CreateFile/P=$pathName /O /Z fileID as fileName
    if (V_flag != 0)
        Print "HDF5CreateFile failed"
        return -1
    endif

    // Save wave as dataset
    HDF5SaveData /O /Z w, fileID
    if (V_flag != 0)
        Print "HDF5SaveData failed"
        result = -1
    endif

    // Close the HDF5 file
    HDF5CloseFile fileID

    return result
End
```

Read through the procedure. It should look familiar as it is similar to the TestLoadDataset function we wrote before. Again it has parameters that specify a symbolic path and file name. It does not have a parameter to specify the dataset name because HDF5SaveData uses the wave name as the dataset name unless instructed otherwise. This function has a wave parameter through which we will specify the wave whose data is to be written to the HDF5 file.

Here we use HDF5CreateFile to create a new file rather than HDF5OpenFile. HDF5CreateFile creates a new file and opens it, returning a file ID. If you wanted to add a dataset to an existing file you would use HDF5OpenFile instead of HDF5CreateFile.

HDF5CreateFile sets the local variable fileID to a value returned from the HDF5 library. We pass that value to the HDF5SaveData operation. The /O flag means that, if there is already a dataset with the same name, it will be overwritten.

Finally we call HDF5CloseFile to close the file that we opened via HDF5CreateFile.

7. **Click the Compile button at the bottom of the Procedure window.**

   If you get an error then you have not pasted the right text into the Procedure window or you have entered other incorrect text. If you can not find the error, choose File→Revert Experiment and go back to step 6 of this section.

   Now we are ready to run our procedure.

8. **Execute the following command in the Igor command line either by typing it and pressing Enter, by copy/paste followed by Enter, or by selecting it and pressing Control-Enter (Macintosh) or Ctrl-Enter (Windows):**

```
TestSaveDataset("HDF5Data", "SaveTest.h5", data0)
```

   At this point the procedure should have correctly executed and you should see no error messages printed in the history area of the command window (just above the command line).

   Now we will verify that the data was saved.

9. **Choose Data→Load Waves→New HDF5 Browser. Click the Open HDF5 File button and open the SaveTest.h5 file that we just created.**

   Verify that the file contains a dataset named data0.

   The data0 dataset has some attributes. These attributes allow HDF5LoadData to fully recreate the wave and all of its properties if you ever load it back into Igor. If you don't want to save these attributes you can use the /IGOR=0 flag when calling HDF5SaveData.

10. **Click the Close HDF5 File button.**

    We can't write more data to the file while it is open in the HDF5 Browser.

    The TestSaveDataset function is rather limited because it saves just one wave. We will now make it more general so that it can save any number of waves. But first we will save our work since it is in a known good state.

11. **Choose File→Save Experiment to save your current work environment in the HDF5 Tour.pxp experiment file that you created earlier.**

    If need be, later you can revert to the saved state by choosing File→Revert Experiment.

    Next we will create a new, more general user function with a different name (TestSaveDatasets instead of TestSaveDataset).

12. **Choose Windows→Procedure Window and paste the following into the Procedure window below the TestSaveDataset function:**

```
Function TestSaveDatasets(pathName, fileName, listOfWaves)
    String pathName            // Name of symbolic path
    String fileName            // Name of HDF5 file
    String listOfWaves         // Semicolon-separated list of waves

    Variable result = 0        // 0 means no error

    Variable fileID

    // Create a new HDF5 file, overwriting if same-named file exists
    HDF5CreateFile/P=$pathName /O /Z fileID as fileName
    if (V_flag != 0)
        Print "HDF5CreateFile failed"
        return -1
    endif

    String listItem
    Variable index
    index = 0
    do
        listItem = StringFromList(index, listOfWaves)
        if (strlen(listItem) == 0)
            break  // No more waves
        endif

        // Create a local reference to the wave
        Wave w = $listItem

        // Save wave as dataset
        HDF5SaveData /O /Z w, fileID
        if (V_flag != 0)
            Print "HDF5SaveData failed"
            result = -1
            break
        endif

        index += 1
    while(1)

    // Close the HDF5 file
    HDF5CloseFile fileID

    return result
End
```

Read through the procedure. It is similar to the TestSaveDataset function.

The first difference is that, instead of passing a wave, we pass a list of wave names in a string parameter. This parameter is a semicolon-separated list which is a commonly-used programming technique in Igor.

The next difference is that we have a do-while loop which extracts a name from the list and saves the corresponding wave as a dataset in the HDF5 file.

The statement

```
Wave w = $listItem
```

creates a local "wave reference" and allows us to use w to refer to a wave whose identity is determined by the contents of the listItem string variable. This also is a common Igor programming technique and is explained in detail in the Programming help file.

13. **Click the Compile button at the bottom of the Procedure window.**

    If you get an error then you have not pasted the right text into the Procedure window or you have entered other incorrect text. If you can not find the error, choose File→Revert Experiment and go back to step 12 of this section.

    Now we are ready to run our procedure.

14. **Enter the following command in the Igor command line either by typing it and pressing enter, by copy/paste followed by Enter, or by selecting it and pressing Control-Enter (Macintosh) or Ctrl-Enter (Windows):**

    ```
    TestSaveDatasets("HDF5Data", "SaveTest.h5", "data0;data1;data2;")
    ```

    The third parameter is a string in this function. In the previous example, it was a name, specifically the name of a wave. Strings are entered in double-quotes but names are not.

    At this point the procedure should have correctly executed and you should see no error messages printed in the history area of the command window (just above the command line).

    Now we will verify that the data was saved.

15. **Activate the HDF5 Browser window. Click the Open HDF5 File button and open the SaveTest.h5 file that we just created.**

    Verify that the file contains datasets named data0, data1 and data2.

16. **Click the Close HDF5 File button.**

17. **Choose File→Save Experiment and save the current work environment in the HDF5 Tour.pxp experiment file.**

    This concludes the HDF5 Guided Tour.

Where To Go From Here

If you are new to Igor or have never done it you should definitely do the **Guided Tour of Igor Pro** on page I-11. If you are in a hurry, do just the first half of it.

You should also read the following chapters which explain the basics of Igor in more detail:

Getting Help on page II-1

Experiments, Files and Folders on page II-15

Windows on page II-43

Waves on page II-61

To get started with Igor programming you need to read these chapters:

Working with Commands on page IV-1

Programming Overview on page IV-23

User-Defined Functions on page IV-29

For HDF5-specific programming, you need to have at least a basic understanding of HDF5. See the links in the next section. Then you need to familiarize yourself with the HDF5-related operations and functions listed in **HDF5 Operations and Functions** on page II-197.

If you run into problems, send a sample HDF5 file along with a description of what you are trying to do to support@wavemetrics.com and we will try to get you started in the right direction.

Learning More About HDF5

In order to use HDF5 operations, you must have at least a basic understanding of HDF5. The HDF5 web site provides an abundance of material. To get started, visit this web page:

```
https://portal.hdfgroup.org/display/HDF5/Learning+HDF5
```

The HDF Group provides a Java-based program called HDFView. You may want to download and install HDFView so that you can easily browse HDF5 files as you read the introductory material. Or you may prefer to use the HDF5 browser provided by Igor.

The HDF5 Browser

Igor Pro includes an automatically-loaded procedure file, "HDF5 Browser.ipf", which implements an HDF5 browser. The browser lets you interactively examine HDF5 files to get an idea of what is in them. It also lets you load HDF5 datasets and groups into Igor and save Igor waves and data folders in HDF5 files.

The browser currently does not support creating attributes. For that you must use the **HDF5SaveData** operation.

The HDF5 browser includes lists which display:

- All groups in the file
- All attributes of the selected group
- All datasets in the selected group
- All attributes of the selected dataset

In addition, the HDF5 browser optionally displays:

- A graph displaying the selected dataset or attribute
- A table displaying the selected dataset or attribute
- A notebook window containing a dump of the selected group, dataset or attribute

Using The HDF5 Browser

To browse HDF5 files, choose Data→Load Waves→New HDF5 Browser. This creates an HDF5 browser control panel. You can create additional browsers by choosing the same menu item again.

Each browser control panel lets you browse one HDF5 file at a time. For most users, one browser will be sufficient.

After creating a new browser, click the Open HDF5 File button to choose the file to browse.

The HDF5 browser contains four lists which display the groups, group attributes, datasets and dataset attributes in the file being browsed.

HDF5 Browser Basic Controls

Here is a description of the basic controls in the HDF5 browser that most users will use.

Create HDF5 File

Creates a new HDF5 file and opens it for read/write.

Open HDF5 File

Opens an existing HDF5 file for read-only or read/write, depending on the state of the Read Only checkbox.

Close HDF5 File

Closes the HDF5 file.

Show Graph

If you click the Show Graph button, the browser displays a preview graph of subsequent datasets or attributes that you select.

Show Table

If you click the Show Table button, the browser displays a preview table of subsequent datasets or attributes that you select.

Load Dataset

The Load Dataset button loads the currently selected dataset into the current data folder.

Load Dataset Options

This section of the browser contains two popup menus that determine if data that you load by clicking the Load Dataset button is displayed in a table or graph.

The Table popup menu contains three items: No Table, Display in New Table, and Append To Top Table. If you choose Append To Top Table and there are no tables, it acts as if you chose Display in New Table.

The Graph popup menu contains three items: No Graph, Display in New Graph, and Append To Top Graph. If you choose Append To Top Graph and there are no graphs, it acts as if you chose Display in New Graph. Appending is useful when you are loading 1D data but of little use when appending multi-dimensional data. Multi-dimensional data is appended as an image plot which obscures anything that was already in the graph.

Text waves are not displayed in graphs even if Display in New Graph or Append To Top Graph is selected.

Save Waves

Displays a panel that allows you to select and save waves in the HDF5 file, provided the file was open for read/write.

Transpose 2D

If the Transpose 2D checkbox is checked, 2D datasets are transposed to compensate for the difference in how Igor and other programs treat rows and columns in an image plot. See **HDF5 Images Versus Igor Images** on page II-204 for details. This does not affect the loading of "formal" images (images formatted according to the HDF5 Image and Palette Specification).

Sort By Creation Order If Possible

If checked, and if the file supports listing by creation order, the HDF5 Browser displays and loads groups and datasets in creation order.

Most HDF5 files do not include creation-order information and so are listed and loaded in alphabetical order even if this checkbox is checked. However, HDF5 files written by Igor Pro 9 or later include creation-order information and so can be listed and loaded in creation order.

Load Group

The Load Group button loads all of the datasets in the currently selected group into a new data folder inside current data folder.

The Load Group button calls the **HDF5LoadGroup** operation using the /IMAG flag. This means that, if the group contains a formal image (see **HDF5 Images Versus Igor Images** on page II-204), it is be loaded as a formal image.

The Hyperselection controls do not apply to the operation of the Load Group button.

Load Groups Recursively

If the Load Groups Recursively checkbox is checked, when the Load Group button is pressed any sub-groups in the currently selected group are loaded as sub-datafolders.

Load Group Only Once

Because an HDF5 file is a "directed graph" rather than a strict hierarchy, a given group in an HDF5 file can appear in more than one location in the file's hierarchy.

If the Load Group Only Once checkbox is checked, the Load Group button loads a given group only the first time it is encountered. If it is unchecked, the Load Group button loads a given group each time it appears in the file's hierarchy resulting in duplicated data. If in doubt, leave Load Group Only Once checked.

Save Data Folder

Displays a panel that allows you to select a single data folder and save it in the HDF5 file, provided the file was open for read/write.

HDF5 Browser Contextual Menus

If you right-click a row in the Datasets, Dataset Attributes or Group Attributes lists, the browser displays a contextual menu that allows you to perform the following actions:

- Copy the selected dataset or attribute's value to the clipboard as text

- Load the selected dataset or attribute as a wave

- Load all datasets or attributes as a waves

These popup menus also appear if you click the triangle icons above the lists. They work the same as the HDF5 Browser contextual menus described above.

When the Datasets list is active, choosing Load Selected Dataset as Wave does the same thing as clicking the Load Dataset button.

When copying data to the clipboard, the data is copied as text and consequently may not represent the full precision of the underlying dataset or attribute. Not all datatypes are supported. If the browser supports the datatype that you right clicked, the contextual menu shows "Copy to Clipboard as Text". If the datatype is not supported, it shows "Can't Copy This Data Type".

When loading as waves, any pre-existing waves with the same names are overridden.

When loading waves from datasets, the table and graph options in the Load Dataset Options section of the browser apply. If you check Apply to Attributes also, the options apply when loading waves from attributes.

HDF5 Browser Advanced Controls

Here is a description of the advanced controls in the HDF5 browser. These are for use by people familiar with the HDF5 file format.

Show Dump

If you click the Show Dump button, the browser displays a notebook in which you can see additional details about subsequent groups, datasets or attributes that you select. The dump window is updated each time you select a group, dataset or attribute from any of the lists.

Show Data In Dump

When unchecked, the dump shows header information but not the actual data of a dataset. When checked it shows data as well as header information for a dataset.

WARNING: If you check the Show Data In Dump checkbox and choose to dump a very large dataset, the dump could take a very long time. If the dump seems to be taking forever, clicking the Abort button in the Igor status bar.

Even if the Show Data In Dump checkbox is checked, the dump for a group consist of the header information only and omits the actual data for datasets and attributes.

Show Attributes In Dump

The Show Attributes In Dump checkbox lets you determine whether attributes are dumped when you select a group or dataset. When checked, information about any attributes associated with the dataset is included in the dump. This checkbox does not affect what is dumped when you select an item in the group or dataset attribute lists.

Show Properties In Dump

The Show Properties In Dump checkbox lets you see properties such as storage layout and filters (compression). This information is usually of little interest but is useful when investigating the effects of compression.

Use Hyperselection

If you check the Use Hyperselection checkbox and enter a path to a "hyperslab wave", the HDF5 Browser uses the hyperselection in the wave to load a subset of subsequent datasets or attributes that you click. This is a feature for advanced users who understand HDF5 hyperselections and have read the **HDF5 Dataset Subsets** discussion below.

The hyperselection is used when you click the Load Dataset button but not when you click the Load Group button.

HDF5 Browser Dump Technical Details

The dump notebook displays a dump of the selected group, dataset or attribute in "Data Description Language" (DDL) format. For most purposes you will not need the dump window. It is useful for experts who are trying to debug a problem or for people who are trying to understand the nuts and bolts of HDF5.

Sometimes strings in HDF5 files contain a large number of trailing nulls. These are not displayed in the dump window.

Sometimes strings in HDF5 files contain the literal strings "\r", "\n" and "\t" to represent carriage return, linefeed and tab. To improve readability, in the dump window these literal strings are displayed as actual carriage returns, linefeeds and tabs.

HDF5 Operations and Functions

This section lists Igor's HDF5-related operations and functions:

HDF5CreateFile	Creates a new HDF5 file or overwrites an existing file.
HDF5OpenFile	Opens an HDF5 file, returning a file ID that is passed to other operations and functions.
HDF5CloseFile	Closes an HDF5 file or all open HDF5 files.
HDF5FlushFile	Flushes an HDF5 file or all open HDF5 files.
HDF5CreateGroup	Creates a group in an HDF5 file, returning a group ID that can be passed to other operations and functions.
HDF5OpenGroup	Opens an existing HDF5 group, returning a group ID that can be passed to other operations and functions.
HDF5ListGroup	Lists all objects in a group.
HDF5CloseGroup	Closes an HDF5 group.
HDF5LinkInfo	Returns information about an HDF5 link.
HDF5ListAttributes	Lists all attributes associated with a group, dataset or datatype.
HDF5AttributeInfo	Returns information about an HDF5 attribute.
HDF5DatasetInfo	Returns information about an HDF5 dataset.
HDF5LoadData	Loads data from an HDF5 dataset or attribute into Igor.
HDF5LoadImage	Loads an image written according to the HDF5 Image and Palette Specification.
HDF5LoadGroup	Loads an HDF5 group and its datasets into an Igor Pro data folder.
HDF5SaveData	Saves Igor waves in an HDF5 file.
HDF5SaveImage	Saves an image in the HDF5 Image and Palette Specification format.
HDF5SaveGroup	Saves an Igor data folder in an HDF5 group.
HDF5TypeInfo	Returns information about an HDF5 datatype.
HDF5CreateLink	Creates a new hard, soft or external link.
HDF5UnlinkObject	Unlinks an object (a group, dataset, datatype or link) from an HDF5 file. This deletes the object from the file's hierarchy but does not free up the space in the file used by the object.
HDF5DimensionScale	Supports the creation and querying of HDF5 dimension scales.

HDF5LibraryInfo	Returns information about the HDF5 library used by Igor. This is of interest to advanced programmers only.
HDF5Control	Provides control of aspects of Igor's use of the HDF5 file format.
HDF5Dump	Returns a DDL-format dump of a group, dataset or attribute.
HDF5DumpErrors	Returns information about HDF5-related errors encountered by Igor. This is a diagnostic tool for experts that is needed only in rare cases.

HDF5 Procedure Files

Igor ships with two procedure files to support HDF5 use and programming. Both files are automatically loaded by Igor on launch and consequently are always available.

"HDF5 Browser.ipf" implements the HDF5 Browser. This procedure file is an independent module and consequently is normally hidden. If you are an Igor programmer who wants to inspect the procedure file, see Independent Modules for background information. However, there is no reason for you to call routines in "HDF5 Browser.ipf" from your own code.

"HDF5 Utilities.ipf" is a public procedure file (i.e., not an independent module) that defines HDF5-related constants and provides HDF5-related utility routines that may be of use if you write procedures that use HDF5 features.

If you write your own procedure file, you can use the constants and utility routines in "HDF5 Utilities.ipf" without #including anything. However, if you are creating your own independent module for HDF5 programming, you will need to #include "HDF5 Utilities.ipf" into your independent module - see "HDF5 Browser.ipf" for an example.

HDF5 Attributes

An attribute is a piece of data attached to an HDF5 group, dataset or named datatype.

To load an attribute, you need to use the HDF5LoadData operation with the /A=attributeNameStr flag and the /TYPE=objectType flag.

Loading attributes of type H5T_COMPOUND (compound - i.e., structure) is not supported.

Loading an HDF5 Numeric Attribute

This function illustrates how to load a numeric attribute of a group or dataset. The function result is an error code. The value of the attribute is returned via the pass-by-reference attributeValue numeric parameter.

```
Function LoadHDF5NumericAttribute(pathName, filePath, groupPath, objectName,
                        objectType, attributeName, attributeValue)
   String pathName            // Symbolic path name - or ""
   String filePath            // File name, relative path or full path
   String groupPath           // Path to group, such as "/", "/my_group"
   String objectName          // Name of group or dataset
   Variable objectType        // 1=group, 2=dataset
   String attributeName       // Name of attribute
   Variable& attributeValue   // Output - pass-by-reference parameter

   attributeValue = NaN

   Variable result = 0

   // Open the HDF5 file
   Variable fileID            // HDF5 file ID will be stored here
   HDF5OpenFile /P=$pathName /R /Z fileID as filePath
   if (V_flag != 0)
      Print "HDF5OpenFile failed"
      return -1
   endif

   Variable groupID           // HDF5 group ID will be stored here
   HDF5OpenGroup /Z fileID, groupPath, groupID
   if (V_flag != 0)
      Print "HDF5OpenGroup failed"
      HDF5CloseFile fileID
      return -1
   endif

   HDF5LoadData /O /A=attributeName /TYPE=(objectType) /N=tempAttributeWave /Q
                      /Z groupID, objectName
   result = V_flag                  // 0 if OK or non-zero error code

   if (result == 0)
      Wave tempAttributeWave
      if (WaveType(tempAttributeWave) == 0)
         attributeValue = NaN       // Attribute is string, not numeric
         result = -1
      else
         attributeValue = tempAttributeWave[0]
      endif
      KillWaves/Z tempAttributeWave
   endif

   // Close the HDF5 group
   HDF5CloseGroup groupID

   // Close the HDF5 file
   HDF5CloseFile fileID

   return result
End
```

Loading an HDF5 String Attribute

This function illustrates how to load a string attribute of a group or dataset. The function result is an error code. The value of the attribute is returned via the pass-by-reference attributeValue string parameter.

```
Function LoadHDF5StringAttribute(pathName, filePath, groupPath, objectName,
                        objectType, attributeName, attributeValue)
   String pathName            // Symbolic path name - or ""
   String filePath            // File name, relative path or full path
   String groupPath           // Path to group, such as "/", "/metadata_group"
   String objectName          // Name of group or dataset
   Variable objectType        // 1=group, 2=dataset
   String attributeName       // Name of attribute
   String& attributeValue     // Output - pass-by-reference parameter

   attributeValue = ""

   Variable result = 0

   // Open the HDF5 file
   Variable fileID               // HDF5 file ID will be stored here
   HDF5OpenFile /P=$pathName /R /Z fileID as filePath
   if (V_flag != 0)
      Print "HDF5OpenFile failed"
      return -1
   endif

   Variable groupID              // HDF5 group ID will be stored here
   HDF5OpenGroup /Z fileID, groupPath, groupID
   if (V_flag != 0)
      Print "HDF5OpenGroup failed"
      HDF5CloseFile fileID
      return -1
   endif

   HDF5LoadData /O /A=attributeName /TYPE=(objectType) /N=tempAttributeWave /Q
                        /Z groupID, objectName
   result = V_flag               // 0 if OK or non-zero error code

   if (result == 0)
      Wave/T tempAttributeWave
      if (WaveType(tempAttributeWave) != 0)
         attributeValue = ""     // Attribute is numeric, not string
         result = -1
      else
         attributeValue = tempAttributeWave[0]
      endif
      KillWaves/Z tempAttributeWave
   endif

   // Close the HDF5 group
   HDF5CloseGroup groupID

   // Close the HDF5 file
   HDF5CloseFile fileID

   return result
End
```

Loading All Attributes of an HDF5 Group or Dataset

This function illustrates loading all of the attributes of a given group or dataset. The attributes are loaded into waves in the current data folder.

```
Function LoadHDF5Attributes(pathName, filePath, groupPath, objectName,
                        objectType, verbose)
   String pathName            // Symbolic path name - or ""
   String filePath            // File name, relative path or full path
   String groupPath           // Path to group, such as "/", "/metadata_group"
   String objectName          // Name of object whose attributes you want or "."
                        for the group specified by groupPath
   Variable objectType        // The type of object referenced by objectPath:
                              // 1=group, 2=dataset
   Variable verbose           // Bit 0: Print errors; Bit 1: Print warnings;
                              // Bit 2: Print routine info

   Variable printErrors = verbose & 1
   Variable printWarnings = verbose & 2
   Variable printRoutine = verbose & 4

   Variable result = 0        // 0 means no error

   // Open the HDF5 file
   Variable fileID            // HDF5 file ID will be stored here
   HDF5OpenFile /P=$pathName /R /Z fileID as filePath
   if (V_flag != 0)
      if (printErrors)
         Print "HDF5OpenFile failed"
      endif
      return -1
   endif

   Variable groupID           // HDF5 group ID will be stored here
   HDF5OpenGroup /Z fileID, groupPath, groupID

      if (V_flag != 0)
         if (printErrors)
            Print "HDF5LoadData failed"
         endif
         result = -1
         break
      endif
      if (printRoutine)
         Printf "Loaded attribute %d, name=%s\r", i, attributeNameStr
      endif
   endfor

   // Close the HDF5 group
   HDF5CloseGroup groupID

   // Close the HDF5 file
   HDF5CloseFile fileID

   return result
End
```

HDF5 Dataset Subsets

It is possible, although usually not necessary, to load a subset of an HDF5 dataset using a "hyperslab". To use this feature, you must have a good understanding of hyperslabs which are explained in the HDF5 documentation. The examples below assume that you have read and understood that documentation.

HDF5 does not support loading a subset of an attribute.

To load a subset of a dataset, use the /SLAB flag of the **HDF5LoadData** operation. The /SLAB flag takes as its parameter a "slab wave". This is a two-dimensional wave containing exactly four columns and at least as many rows as there are dimensions in the dataset you are loading.

The four columns of the slab wave correspond to the start, stride, count and block parameters to the HDF5 H5Sselect_hyperslab routine from the HDF5 library.

The following examples illustrate how to use a hyperslab. The examples use a sample file provided by NCSA and stored in Igor's HDF5 Samples directory.

Create an Igor symbolic path (Misc→New Symbolic Path) named HDF5Samples which points to the folder containing the i32le.h5 file (Igor Pro X Folder:Examples:Feature Demos:HDF5 Samples).

In the first example, we load a 2D dataset named "TestArray" which has 6 rows and 5 columns. We start by loading the entire dataset without using a hyperslab.

```
Variable fileID
HDF5OpenFile/P=HDF5Samples /R fileID as "i32le.h5"
HDF5LoadData /N=TestWave fileID, "TestArray"
Edit TestWave
```

Now we create a slab wave and set its dimension labels to make it easier to remember which column holds which type of information. We will use a utility routine in the automatically-loaded "HDF5 Utiliies.ipf" procedure file which is automatically loaded when Igor is launched:

```
HDF5MakeHyperslabWave("root:slab", 2   )  // In HDF5 Utilities.ipf
Edit root:slab.ld
```

Now we set the values of the slab wave to give the same result as before, that is, to load the entire dataset, and then we load the data again using the slab.

```
slab[][%Start] = 0          // Start at zero for all dimensions
slab[][%Stride] = 1         // Use a stride of 1 for all dimensions
slab[][%Count] = 1          // Use a count of 1 for all dimensions
slab[0][%Block] = 6         // Set block size for the dimension 0 to 6
slab[1][%Block] = 5         // Set block size for the dimension 1 to 5
TestWave = -1               // So we can see the next command change it
HDF5LoadData /N=TestWave /O /SLAB=slab fileID, "TestArray"
```

Here we set the stride, count and block parameters to load every other element from both dimensions.

```
slab[][%Start] = 0          // Start at zero for all dimensions
slab[][%Stride] = 2         // Use a stride of 2 for all dimensions
slab[0][%Count] = 3         // Load three blocks of dimension 0
slab[1][%Count] = 2         // Load two blocks of dimension 1
slab[0][%Block] = 1         // Set block size for dimension 0 to 1
slab[1][%Block] = 1         // Set block size for dimension 1 to 1
TestWave = -1               // So we can see the next command change it
HDF5LoadData /N=TestWave /O /SLAB=slab fileID, "TestArray"
```

Finally we close the file.

```
HDF5CloseFile fileID
```

Each row of the slab wave holds a set of parameters (start, stride, count and block) for the corresponding dimension of the dataset in the file. Row 0 of the slab wave holds the parameters for dimension 0 of the dataset, and so on.

The start values must be greater than or equal to zero. All of the other values must be greater than or equal to 1. All values must be less than 2 billion.

HDF5LoadData clips the values supplied for the block sizes to the corresponding sizes of dataset being loaded.

HDF5LoadData requires that the slab wave have exactly four columns. The HDF5MakeHyperslabWave function, from the automatically-loaded "HDF5 Utiliies.ipf" procedure file, creates a four-column wave with the column dimension labels Start, Stride, Count, and Block. HDF5LoadData does not require the column dimension labels. As of Igor Pro 9.00, HDF5MakeHyperslabWave returns a free wave if you pass "" for the path parameter. It also returns a wave reference as the function result whether the wave is free or not.

The slab wave must have at least as many rows as the dataset has dimensions. Extra rows are ignored.

HDF5LoadData creates a wave just big enough to hold all of the loaded data. So in the first example, it created a 6 x 5 wave whereas in the last example it created a 3 x 2 wave.

Igor Versus HDF5

This section documents differences in how Igor and HDF5 organize data and how Igor reconciles them.

Case Sensitivity

Igor is not case-sensitive but HDF5 is. So, for example, when you specify the name of an HDF5 data set, case matters. "/Dataset1" is not the same as "/dataset1".

If you load /Dataset1 and /dataset1 into Igor using the default wave name, the second load overwrites the wave created by the first.

HDF5 Object Names Versus Igor Object Names

The forward slash character is not allowed in HDF5 object names. If you create an Igor wave or data folder with a name containing a forward slash and attempt to save the object to an HDF5 file, you will get an error. An object name that starts with a dot may also create an error.

As of this writing, the section 4.2.3, "HDF5 Path Names" of the HDF5 User's Guide says:

Component link names may be any string of ASCII characters not containing a slash or a dot ("/"and ".", which are reserved as noted above). However, users are advised to avoid the use of punctuation and non-printing characters, as they may create problems for other software.

HDF5 Data Types Versus Igor Data Types

HDF5 supports many data types that Igor does not support. When loading such data types, Igor attempts to convert to a data type that it supports, if possible. In the process, precision may be lost.

By default and for backward compatibility, Igor saves and loads HDF5 64-bit integer data as double-precision floating point. Precision may be lost in this conversion. To save and load 64-bit integer data as 64-bit integer, use /OPTS=1 with **HDF5SaveData**, **HDF5SaveGroup**, **HDF5LoadData** and **HDF5LoadGroup**. Because most operations are carried out in Igor in double-precision floating point, we recommend loading 64-bit integer as double if it fits in 53 bits and as 64-bit integer if it may exceed 53 bits.

Since Igor does not currently support 128-bit floating point data (long double), Igor loads HDF5 128-bit floating point data as double-precision floating point. Precision is lost in this conversion.

HDF5 Max Dimensions Versus Igor Max Dimensions

The HDF5 library supports data with up to 32 dimensions. Igor supports only four dimensions. If you load HDF5 data whose dimensionality is greater than four, the **HDF5LoadData** operation creates a 4D wave with enough chunks to hold all of the data. ("Chunk" is the name of the fourth dimension in Igor, after "row", "column" and "layer".)

For example, if you load a dataset whose dimensions are 7x6x5x4x3x2, HDF5LoadData creates a wave with dimensions 7x6x5x24. The wave has 24 chunks. The number 24 comes from multiplying the number of chunks in the HDF5 dataset (4 in this case) by the size of each higher dimension (3 and 2 in this case).

Row-major Versus Column-major Data Order

HDF5 and Igor store multi-dimensional data differently in memory. For almost all purposes, this difference is immaterial. For those rare cases in which it matters, here is an explanation.

HDF5 stores multi-dimensional data in "row-major" order. This means that the index associated with the highest dimension changes fastest as you move in memory from one element to the next. For example, if you have a two-dimensional dataset with 5 rows and 4 columns, as you move sequentially through memory, the column index changes fastest and the row index slowest.

Igor stores data in "column-major" order. This means that the index associated with the lowest dimension changes fastest as you move in memory from one element to the next. For example, if you have a two-dimensional dataset with 5 rows and 4 columns, as you move sequentially through memory, the row index changes fastest and the column index slowest.

To work around this difference, after the **HDF5LoadData** or **HDF5LoadGroup** operation initially loads data with two or more dimensions, it shuffles the data around in memory. The result is that the data when viewed in an Igor table looks just as it would if viewed in the HDF Group's HDFView program although its layout in memory is different. A similar accomodation occurs when you save Igor data using **HDF5SaveData** or **HDF5SaveGroup**.

HDF5 Images Versus Igor Images

The HDF5 Image and Palette Specification provides detailed guidelines for storing an image and its associated information (e.g., palette, color model) in an HDF5 file. However many HDF5 users do not follow the specification and just write image data to a regular 2D dataset. To distinguish between these two ways of storing an image, we use the term "formal image" to refer to an image written to the specification and "regular image" to refer to regular 2D datasets which the user thinks of as an image.

In an Igor image plot the wave's column data is plotted horizontally while in HDFView and most other programs the row data is plotted horizontally. Therefore, without special handling, a regular image would appear rotated in Igor relative to most programs.

The **HDF5LoadImage** and **HDF5SaveImage** operations handle loading and saving formal images. These operations automatically compensate for the difference in image orientation.

If you are dealing with a regular image, you will use the **HDF5LoadData** and **HDF5SaveData** operations, or **HDF5LoadGroup** and **HDF5SaveGroup**. These operations have a /TRAN flag which causes 2D data to be transposed. When you use /TRAN with HDF5LoadData, images viewed in Igor and in programs like HDFView will have the same orientation but will appear transposed when viewed in a table.

The /TRAN flag works with 2D and higher-dimensioned data. When used with higher-dimensioned data (3D or 4D), each layer of the data is treated as a separate image and is transposed. In other words, /TRAN treats higher-dimensioned data as a stack of images.

Saving and Reloading Igor Data

The **HDF5SaveData** and **HDF5SaveGroup** operations can save Igor waves, numeric variables and string variables in HDF5 files. All of these Igor objects are written as HDF5 datasets.

The datasets saved from Igor waves are, by default, marked with attributes that store wave properties such as the wave data type, the wave scaling and the wave note. The attributes have names like IGORWaveType and IGORWaveScaling. This allows **HDF5LoadData** and **HDF5LoadGroup** to fully recreate the Igor wave if it is later read from the HDF5 file back into Igor. You can suppress the creation of these attributes by using the /IGOR=0 flag when calling HDF5SaveData or HDF5SaveGroup.

Wave text is always written using UTF-8 text encoding. See **HDF5 Wave Text Encoding** on page II-221 for details.

Wave reference waves and data folder reference waves are read as such when you load an HDF5 packed experiment but HDF5LoadData and HDF5LoadGroup load these waves as double-precision numeric. The reason for this is that restoring such waves so that they point to the correct wave or data folder is is possible only when an entire experiment is loaded.

The datasets saved by HDF5SaveGroup from Igor variables are marked with an "IGORVariable" attribute. This allows **HDF5LoadData** and **HDF5LoadGroup** to recognize these datasets as representing Igor variables if you reload the file. In the absence of this attribute, these operations load all datasets as waves.

The value of the IGORVariable attribute is the data type code for the Igor variable. It is one of the following values:

0:	Igor string variable
4:	Igor real numeric variable
5:	Igor complex numeric variable

See also **HDF5 String Variable Text Encoding** on page II-221.

Handling of Complex Waves

Igor Pro supports complex waves but HDF5 does not support complex datasets. Therefore, when saving a complex wave, **HDF5SaveData** writes the wave as if its number of rows were doubled. For example, HDF5SaveData writes the same data to the HDF5 file for these waves:

```
Make wave0 = {1,-1,2,-2,3,-3}                              // 6 scalar points
Make/C cwave0 = {cmplx(1,-1),cmplx(2,-2),cmplx(3,-3)}     // 3 complex points
```

When reading an HDF5 file written by HDF5SaveData, you can determine if the original wave was complex by checking for the presence of the IGORComplexWave attributes that HDF5SaveData attaches to the dataset for a complex wave. **HDF5LoadData** and **HDF5LoadGroup** do this automatically if you use the appropriate /IGOR flag.

Handling of Igor Reference Waves

Igor Pro supports wave reference waves and data folder reference waves. Each element of a wave reference wave is a reference to another wave. Each element of a data folder reference wave is a reference to a data folder.

Igor correctly writes Igor reference waves when you save an experiment as HDF5 packed format, but the **HDF5SaveData** and **HDF5SaveGroup** do not support saving Igor reference waves.

The HDF5SaveData operation returns an error if you try to save a reference wave.

The behavior of the HDF5SaveGroup operation when it is asked to save a reference wave depends on the /CONT flag. By default (/CONT=1), it prints a note in the history saying it can not save the wave and then continues saving the rest of the objects in the data folder. If /CONT=0 is used, HDF5SaveGroup returns an error if asked to save a reference wave.

HDF5 Multitasking

You can call HDF5 operations and functions from an Igor preemptive thread.

The HDF5 library is limited to accessing one HDF5 file at a time. This precludes loading multiple HDF5 files concurrently in a given Igor instance but it does allow you to load an HDF5 file in a preemptive thread while you do something else in Igor's main thread. If you create multiple threads that attempt to access HDF5 files, one of your threads will gain access to the HDF5 library. Your other HDF5-accessing threads will wait until the first thread finishes at which time another thread will gain access to the HDF5 library.

For further information on multitasking and for examples, see the Demo Thread Safe HDF5 example experiment.

Igor HDF5 Capabilities

Igor supports only a subset of all of the HDF5 capability.

Here is a partial list of HDF5 features that Igor does support:

- Loading of all atomic datatypes.
- Loading of strings.
- Loading of array datatypes.
- Loading of variable-length datasets where the base type is integer or float.
- Loading of compound datasets (datasets consisting of C-like structures), including compound datasets containing members that are arrays.
- Use of hyperslabs to load subsets of datasets.
- Loading and saving object references.
- Loading dataset region references.

Igor HDF5 Limitations

Here is a partial list of HDF5 features that Igor does not support:

- Creating or appending to VLEN datasets (ragged arrays).
- Loading of deeply-nested datatypes. See **HDF5 Nested Datatypes** below.
- Saving dataset region references.

If Igor does not work with your HDF5 file, it could be due to a limitation in Igor. Send a sample file along with a description of what you are trying to do to support@wavemetrics.com and we will try to determine what the problem is.

Advanced HDF5 Data Types

This section is mostly of interest to advanced HDF5 users.

HDF5 Variable-Length Data

Most HDF5 files do not use variable-length datatypes so most users do not need to know this information.

Variable-length data consists of an array where each element is a 1D set of elements of another datatype, called the "base" datatype. The number of elements of the base datatype in each set can be different. For example, a 5 element variable-length dataset whose base type is H5T_STD_I32LE contains 5 1D sets of 32-bit, little-endian integers and the length of each set is independent.

HDF5LoadData loads variable-length datasets where the base type is integer or float only. The data for each element is loaded into a separate wave.

When loading most types of data, HDF5LoadData creates just one wave. When loading a variable-length dataset or attribute, one wave is created for each loaded element. If more than one element is to be loaded, the proposed name for the wave (the name of the dataset or attribute being loaded or a name specified by /N=name) is treated as a base name. For example, if the dataset or attribute has three elements and name is test and the /O flag is used, waves named test0, test1 and test2 are created. If the /O flag is not used, names of the form test<n> are created where <n> is a number chosen to make the wave names unique.

HDF5LoadData operation supports loading a subset of a variable-length dataset. You do this by supplying a slab wave using the HDF5LoadData /SLAB flag. In the example from the previous paragraph, if you loaded just one element, its name would be test, not test0. If you loaded two elements, they would be named test0 and test1, regardless of which two elements you loaded.

This function demonstrates loading one element of a variable-length dataset. We assume that a symbolic path named Data and a file named "Vlen.h5" exist and that the file contains a 1D variable-length dataset named TestVlen that contains at least two elements. The function loads the second variable-length element into a wave named TestWave.

```
Function DemoVlenLoad()
   Variable fileID
   HDF5OpenFile /P=Data /R fileID as "Vlen.h5"

   HDF5MakeHyperslabWave("root:slab", 1)  // In HDF5 Utilities.ipf
   Wave slab = root:slab
   slab[0][%Start] = 1                    // Start at second vlen element
   slab[0][%Stride] = 1                   // Use a stride of 1
   slab[0][%Count] = 1                    // Load 1 block
   slab[0][%Block] = 1                    // Set block size to 1
   HDF5LoadData /N=TestWave /O /SLAB=slab fileID, "TestVlen"

   HDF5CloseFile fileID
End
```

HDF5 Array Data

Most HDF5 files do not use array datatypes so most users do not need to know this information.

An HDF5 dataset (or attribute) consists of elements organized in one or more dimensions. Each element can be an atomic datatype, such as an unsigned short or a double-precision float, or it can be a composite datatype, such as a structure or an array. Thus, an HDF5 dataset can be an array of unsigned shorts, an array of doubles, an array of structures or an array of arrays. This section discusses loading this last type - an array of arrays.

In this case, the class of the dataset is H5T_ARRAY. The type of the dataset is something like "5 x 4 array of signed long" and "signed long" is said to be the "base type" of the array datatype. If the dataset itself is 1D with 10 rows then you would have a 10-row dataset, each element of which consists of one 5 x 4 array of signed longs.

In Igor this could be treated as a 3D wave consisting of 5 rows, 4 columns and 10 layers. However, since Igor supports only 4 dimensions while HDF5 supports 32, you could easily run out of dimensions in Igor. Therefore when you load an H5T_ARRAY-type dataset, HDF5LoadData creates a wave whose dimensionality is that of the array type, not that of the underlying dataset, except that the highest dimension is increased to make room for all of the data. This reduces the likelihood of running out of dimensions.

HDF5LoadData can not load array data whose base type is compound or array (see **HDF5 Nested Datatypes** on page II-211 for details).

The following example illustrate how to load an array datatype. The example uses a sample file provided by NCSA and stored in Igor's HDF5 Samples directory.

Create an Igor symbolic path (Misc→New Symbolic Path) named HDF5Samples which points to the folder containing the SDS_array_type.h5 file (Igor Pro X Folder:Examples:Feature Demos:HDF5 Samples).

The sample file contains a 10 row 1D data set, each element of which is a 5 row by 4 column matrix of 32-bit signed big-endian integers (a.k.a., big-endian signed longs or I32BE).

When we load the dataset, we get 5 rows and 40 columns.

```
Variable fileID
HDF5OpenFile/P=HDF5Samples /R fileID as "SDS_array_type.h5"
HDF5LoadData fileID, "IntArray"
HDF5CloseFile fileID
Edit IntArray
```

The first four columns contain the 5x4 matrix from row zero of the dataset. The next four columns contain the 5x4 matrix from row one of the dataset. And so on.

In this case, Igor has enough dimensions so that you could, if you want, reorganize it as a 3D wave consisting of 10 layers of 5x4 matrices. You would do that using this command:

```
Redimension /N=(5,4,10) /E=1 IntArray
```

The /E=1 flag tells Redimension to change the dimensionality of the wave without actually changing the stored data. In Igor, the layout in memory of a 5x4x10 wave is the same as the layout of a 5x40 wave. The redimension merely changes the way we look at the wave from 40 columns of 5 rows to 10 layers of 4 columns of 5 rows.

Although you can load a dataset with an array datatype, Igor currently provides no way to write a datatype with an array datatype.

Loading HDF5 Reference Data

Most HDF5 files do not use reference datatypes so most users do not need to know this information.

An HDF5 dataset or attribute can contain references to other datasets, groups and named datatypes. There are two types of references: "object references" and "dataset region references". **HDF5LoadData** loads both types of references into text waves.

An element of an object reference dataset can refer to a dataset in the same or in another file. An element of a dataset region reference dataset can refer only to a dataset in the same file.

Loading HDF5 Object Reference Data

For each object reference to a dataset, HDF5LoadData returns "D:" plus the full path of the dataset within the HDF5 file, for example, "D:/GroupA/DatasetB".

For references to groups and named datatypes, HDFLoadData returns "G:" and "T:" respectively, followed by the path to the object.

Loading HDF5 Dataset Region Reference Data

This section is for advanced HDF5 users. A demo experiment, "HDF5 Dataset Region Demo.pxp", provides examples and utilities for dealing with dataset region references.

Prior to Igor Pro 9.00, HDF5LoadData returned the same thing when loading an object reference or a dataset region reference. It had this form:

```
<object type character>:<full path>
```

For a dataset, this might be something like

```
D:/Group1/Dataset3
```

In Igor Pro 9.00 and later, HDF5LoadData returns additional information for a dataset region reference. It has this form with the additional information shown in red:

```
<object type character>:<full path>.<region info>
```

For a dataset, this might be something like this with the additional information shown in red:

```
D:/Group1/Dataset3.REGIONTYPE=BLOCK;NUMDIMS=2;NUMELEMENTS=2;COORDS=0,0-
0,2/0,11-0,13;
```

If you have code that depends on the pre-Igor9 behavior, you can make it work with Igor9 by using StringFromList with "." as list separator string to obtain the text preceding the dot character.

The region info string is a semicolon-separated keyword-value string constructed for ease of programmatic parsing. It consists of these parts:

```
REGIONTYPE=<type>
NUMDIMS=<number of dimensions>
NUMELEMENTS=<number of elements>
COORDS=<list of points> or <list of blocks>
```

<type> is POINT for a region defined as a set of points, BLOCK for a region defined as a set of blocks.

<number of dimensions> is the number of dimensions in the dataset.

<number of elements> is the number of points in a region defined as a set of points or the number of blocks in a region defined as a set of blocks.

<list of points> has the following format:

```
<point coordinates>/<point coordinates>/...
```

where <point coordinates> is a comma-separated list of coordinates.

For a 2D dataset with three selected points, this might look like this:

```
3,4/11,13/21,30
```

which specifies these three points:

```
row 3, column 4
row 11, column 13
row 21, column 30
```

<list of blocks> has the following format:

```
<coordinates>-<coordinates>/<coordinates>-<coordinates>/...
```

where <coordinates> is a comma-separated list of coordinates.

A dash appears between pairs of <coordinates>. The first set of coordinates of a pair specifies the starting coordinates of a block while the second set of coordinates of a pair specifies the ending coordinates of the block.

For a 2D dataset with three selected blocks, this might look like this:

```
3,4-6,7/11,13-15,17/21,30-37,38
```

which specifies these three blocks:

```
row 3, column 4 to row 6, column 7
row 11, column 13 to row 15, column 17
row 21, column 30 to row 37, column 38
```

Here is an example of a complete point dataset region info string with the additional information shown in red:

```
D:/Group1/Dataset3.REGIONTYPE=POINT;NUMDIMS=2;NUMELEMENTS=3;COORDS=3,4/11,13/2
1,30;
```

Here is an example of a complete block dataset region info string with the additional information shown in red:

```
D:/Group1/Dataset4.REGIONTYPE=BLOCK;NUMDIMS=2;NUMELEMENTS=3;COORDS=3,4-
6,7/11,13-15/17/21,30-37/38;
```

The wave returned after calling HDF5LoadData on a two-row dataset region reference dataset would contain two rows of text like the examples just shown. Each row in the dataset region reference dataset refers to one dataset and to a set of points or blocks within that dataset.

The "HDF5 Dataset Region Demo.pxp" experiment provides further information including examples and utilities for dealing with dataset region references.

Saving HDF5 Object Reference Data

Most HDF5 files do not use reference datatypes so most users do not need to know this information.

An HDF5 dataset or attribute can contain references to other datasets, groups and named datatypes. These are called "object references". You can instruct HDF5SaveData to save a text wave as an object reference using the /REF flag. The /REF flag requires Igor Pro 8.03 or later.

The text to save as a reference must be formatted with a prefix character identifying the type of the referenced object followed by a full or partial path to the object: "G:", "D", or "T:" for groups, datatypes, and datasets respectively. For example:

```
Function DemoSaveReferences(pathName, fileName)
   String pathName         // Name of symbolic path
   String fileName         // Name of HDF5 file

   Variable fileID
   HDF5CreateFile/P=$pathName /O fileID as fileName

   // Create a group to target using a reference
   Variable groupID
   HDF5CreateGroup fileID, "GroupA", groupID

   // Create a dataset to target using a reference
   Make/O/T textWave0 = {"One", "Two", "Three"}
   HDF5SaveData /O /REF=(0) /IGOR=0 textWave0, groupID

   // Write reference dataset to root using full paths
   Make/O/T refWaveFull = {"G:/GroupA", "D:/GroupA/textWave0"}
   HDF5SaveData /O /REF=(1) /IGOR=0 refWaveFull, fileID
   HDF5CloseGroup groupID
   HDF5CloseFile fileID
End
```

Partial paths are relative to the file ID or group ID passed to HDF5SaveData.

Saving HDF5 Dataset Region Reference Data

Igor Pro does not currently support saving dataset region references.

HDF5 Enum Data

Most HDF5 files do not use enum datatypes so most users do not need to know this information.

Enum data values are stored in an HDF5 file as integers. The datatype associated with an enum dataset or attribute defines a mapping from an integer value to a name. HDF5LoadData can load either the integer data or the name for each element of enum data. You control this using the /ENUM=enumMode flag.

If /ENUM is omitted or enumMode is zero, HDF5LoadData creates a numeric wave with data type signed long and loads the integer enum values into it.

If enumMode is 1, HDF5LoadData creates a text wave and loads the name associated with each enum value into it. This is slower than loading the integer enum values but the speed penalty is significant only if you are loading a very large enum dataset or very many enum datasets.

HDF5 Opaque Data

Most HDF5 files do not use opaque datatypes so most users do not need to know this information.

Opaque data consists of elements that are treated as a string of bytes of a specified length. HDF5LoadData loads opaque data into an unsigned byte wave. If an element of opaque data is n bytes then each element occupies n contiguous rows in the wave.

HDF5 Bitfield Data

Most HDF5 files do not use bitfield datatypes so most users do not need to know this information.

Bitfield data consists of elements that are a sequence of bits treated as individual values. HDF5LoadData loads bitfield data of any length into an unsigned byte wave with as many bytes per element as are needed. For example, if the bitfield is two bytes then two rows of the unsigned byte wave are used for each element.

The data is loaded using the byte order as stored in the file. This is appropriate if you think of the data as a stream of bytes. If you think of the data as a short (2 bytes) or long (4 bytes), you can use the Redimension command. For example, if you just loaded a 2D data set containing 5 two-byte bitfields per row and 3 columns, you wind up with a 10x3 unsigned byte wave. You can change it to a 5x3 wave of shorts like this:

```
Redimension /N=(5,3) /W /E=1 bitfieldWave
```

If you need to change the byte order, use /E=2 instead of /E=1.

HDF5 Nested Datatypes

Most HDF5 files do not use nested datatypes so most users do not need to know the following information.

HDF5 supports "atomic" data classes, such as integers (called class H5T_INTEGER in the HDF5 library) and floats (class H5T_FLOAT), and "composite" data classes, such as structures (class H5T_COMPOUND), arrays (class H5T_ARRAY) and variable-length (class H5T_VLEN) types.

In a dataset whose datatype is atomic, each element of the dataset is a single value. In a dataset whose datatype is composite, each element is a collection of elements of one or more other datatypes.

For example, consider a 5x3 array of data of type H5T_STD_I16BE. H5T_STD_I16BE is a built-in atomic datatype of class H5T_INTEGER. Each element of such an array is a 16-bit, big-endian integer value. This dataset has an atomic datatype.

Now consider a 4 row dataset of class H5T_ARRAY where each element of the dataset is a 5x3 array of data of type H5T_STD_I16BE. This dataset has a composite datatype. Each of the 4 elements of the dataset is an array, in this case, an array of 16-bit, big-endian integer values. H5T_STD_I16BE is the "base datatype" of each of the 4 arrays.

Now consider a 4 row dataset of class H5T_COMPOUND with one integer member, one float member and one string member. This dataset has a composite datatype. Each of the 4 elements of this dataset is a structure with members of three different datatypes.

In HDF5 it is possible to nest datatypes to any depth. For example, you can create an H5T_ARRAY dataset where each element is an H5T_COMPOUND dataset where the members are H5T_ARRAY datasets of H5T_STD_I16BE, H5T_STD_I32BE and other datatypes.

Igor does not support indefinitely nested datasets. It supports only the following:

- Atomic datasets of almost any type.
- Array datasets where the base type is integer, float, string, bitfield, opaque or enum.
- Compound datasets where the member's base type is integer, float, string, bitfield, opaque, enum or reference.
- Compound datasets with array members where the base type of the array is integer, float, string, bitfield, opaque, enum or reference.
- Variable-length datasets where the base type is integer or float.

HDF5 Compound Data

This is an advanced feature that most users will not need.

In an HDF5 compound dataset, each element of the dataset consists of a set of named fields, like an instance of a C structure. Loading compound datasets is problematic because their structure can be arbitrarily complex.

A compound data set may contain a collection of disparate datatypes, arrays of disparate datatypes, and sub-compound structures.

HDF5LoadData can load either a single member from a compound dataset into a single wave, or it can load all members of the compound dataset into a set of waves. However, if a member is too complex, HDF5LoadData can not load it and returns an error. For the most part, "too complex" means that the member is itself compound (a sub-structure).

You instruct the HDF5LoadData operation to load a single member from each element of the compound dataset by using the /COMP flag with a mode parameter set to one and with the name of the member to load. The member must be an atomic datatype or an array datatype but can not be another compound datatype (see HDF5 Nested Datatypes for details). HDF5LoadData creates an Igor wave with a data type that is compatible with the datatype of the HDF5 dataset. The name of the wave is based on the name of the dataset or attribute being loaded or on the name specified by the /N flag.

You instruct HDF5LoadData to load all members into separate waves by omitting the /COMP flag or specifying /COMP={0,""}. The names of the waves created consist of a base name concatenated with a possibly cleaned up version of the member name. The base name is based on the name of the dataset or attribute being loaded or on the name specified by the /N flag.

Although you can load an HDF5 dataset with a compound datatype, Igor currently provides no way to write a datatype with a compound datatype.

HDF5 Compression

Igor can use compression when writing datasets to HDF5 files. Compressed datasets usually take less space on disk but more time to write and more time to read.

The amount of disk space saved by compression depends on the size and nature of your data. If your data is very noisy, compression may save little disk space or even increase the amount of disk space required. If your data is nearly all zero or some other constant value, compression may save 99 percent of disk space. With typical real-world data, compression may save from 10 to 50 percent of disk space.

The time required to save a compressed dataset is typically in the range of 2 to 10 times the time required to save an uncompressed dataset. The time required to load a compressed dataset is typically 2 times the time required to load an uncompressed dataset. These times can vary widely depending on your data.

Compression may be performed when you

- Save an HDF5 packed experiment file
- Save a dataset or group using the HDF5 Browser
- Call the HDF5SaveData operation
- Call the HDF5SaveGroup operation

To enable compression Igor must provide certain parameters to the HDF5 library:

- The level of compression for GZIP from 0 to 9
- Whether shuffling should be performed or not
- The chunk size to use for each dimension of the wave being saved

Compression parameters for a given dataset are set when the dataset is created and can not be changed when appending to an existing dataset.

There are several ways through which Igor obtains these parameters:

- From the HDF5SaveData operation /GZIP and /LAYO flags
- From the HDF5SaveGroup, SaveExperiment, and SaveData operation /COMP flags
- From the SaveGraphCopy, SaveTableCopy, and SaveGizmoCopy operation /COMP flags
- From the HDF5SaveDataHook (see **Using HDF5SaveDataHook** on page II-215 for details)
- Via HDF5 default compression for manual saves (see **HDF5 Default Compression** on page II-214 for details)

HDF5 supports compression of datasets through three categories of filters:

- Internal filters: Shuffle, Fletcher32, ScaleOffset, and NBit

  Internal filters are implemented in the HDF5 library source code.
- External filters: GZIP, SZIP

  External filters are linked to the HDF5 library when the library is compiled.
- Third-party filters

  Third-party filters are detected and loaded by the HDF5 library at runtime.

Igor Pro currently supports the following HDF5 filters:

- GZIP
- SZIP for reading only - not supported for writing
- Shuffle

  Shuffle reorders the bytes of multi-byte data elements and can result in higher compression ratios.

HDF5 Layout Chunk Size

Layout refers to how data for a given dataset is arranged on disk. The HDF5 library supports three types of layout: contiguous, compact, chunked. The HDF5SaveData and HDF5SaveGroup operations default to contiguous layout which is appropriate for uncompressed datasets.

The HDF5 library requires that compressed datasets use the chunked layout. This means that the data for the dataset is written in some number of discrete chunks rather than in one contiguous block. In the context of compression, chunking is mainly useful for speeding up accessing subsets of a dataset. Without chunking, the entire dataset has to be read and decompressed to read any subset. If the dataset is always read in its entirety, such as when Igor loads an HDF5 packed experiment file, chunking does not enhance speed.

Chunked storage requires telling the HDF5 library the size of a chunk for each dimension of the dataset. There is no general way to choose appropriate chunk sizes because it depends on the dimensions and nature of the data as well as tradeoffs that require the judgement of the user. In Igor chunk sizes can be specified

- Using the HDF5SaveData operation /LAYO flag (see HDF5SaveData for details)
- Using HDF5SaveDataHook (see **Using HDF5SaveDataHook** on page II-215 for details)

The HDF5SaveGroup, SaveExperiment, SaveData, SaveGraphCopy, SaveTableCopy, and SaveGizmoCopy operations and HDF5 default compression always save a compressed dataset in one chunk, as described in the following sections.

Compression parameters for a given dataset are set when the dataset is created and can not be changed when appending to an existing dataset.

HDF5SaveGroup Compression

In Igor Pro 9.00 and later, you can tell the HDF5SaveGroup operation to compress numeric datasets using the /COMP flag.

HDF5SaveGroup applies compression only to numeric waves, not to text waves or other non-numeric waves nor to numeric waves with fewer than the number of elements specified by the /COMP flag.

HDF5SaveGroup compression uses chunk sizes equal to the size of each dimension of the wave. Such chunk sizes mean that the entire wave is written using chunked layout as one chunk. This is fine for datasets that are to be read all at once. For finer control you can use the HDF5SaveDataHook function to override compression specified by /COMP but this is usually not necessary.

SaveExperiment Compression

In Igor Pro 9.00 and later, you can tell the SaveExperiment operation to compress numeric datasets using the /COMP flag. This works the same as HDF5SaveGroup compression discussed in the preceding section.

The same is true for the SaveData, SaveGraphCopy, SaveTableCopy, and SaveGizmoCopy operations.

See **HDF5 Compression for Saving Experiment Files** on page II-16 for step-by-step instructions.

HDF5 Default Compression

Igor can perform default dataset compression when you save HDF5 files via the user interface. Default compression does not apply when saving HDF5 files via the HDF5SaveData, HDF5SaveGroup, SaveExperiment, SaveData, SaveGraphCopy, SaveTableCopy, or SaveGizmoCopy operations. HDF5 default compression was added in Igor Pro 9.00.

Default compression is disabled by default because compression can significantly increase the time required to save. Whether compression is worthwhile depends on the size and nature of your data and on how you trade off time versus disk space.

You can enable default compression by choosing Misc→Miscellaneous Settings and clicking the Experiment icon. This allows you to set the following settings:

- Whether default compression is enabled or disabled
- The minimum size a wave must be before compression is used
- A compression level from 0 (no compression) to 9 (max)
- Whether you want to enable shuffle (an optional process before compression)

You can programmatically determine the default compression currently in effect like this:

```
Print IgorInfo(14)      // Print default compression settings
```

Once you have turned default compression on, it applies to saving HDF5 packed experiment files via the user interface, namely via the Data Browser Save Copy button, via the HDF5 Browser Save Waves and Save Data Folder buttons, and via the following File menu items: Save Experiment, Save Experiment As, Save Experiment Copy, Save Graph Copy, Save Table Copy, and Save Gizmo Copy.

The HDF5SaveDataHook function, if it exists, can override default compression settings.

Igor applies default compression only to numeric waves, not to text waves or other non-numeric waves nor to numeric waves with fewer than the number of elements specified by the settings.

Default compression uses chunk sizes equal to the size of each dimension of the wave. Such chunk sizes mean that the entire wave is written using chunked layout as one chunk. This is fine for datasets that are to be read all at once.

Igor's HDF5 default compression is sufficient for most purposes. If necessary, for example if you intend to read subsets rather than the entire dataset at once, you can override it using the HDF5SaveData operation or an HDF5SaveDataHook function.

Using HDF5SaveDataHook

HDF5SaveDataHook is a user-defined function that Igor calls to determine what kind of compression, if any, should be applied when saving a given wave as a dataset.

Support for HDF5SaveDataHook was added in Igor Pro 9.00.

NOTE: HDF5SaveDataHook is an experimental feature for advanced users only. The feature may be changed or removed. If you find it useful, please let us know, and send your function and an explanation of what purpose it serves.

The hook function takes a single HDF5SaveDataHookStruct parameter containing input and output fields. The version, operation, and waveToSave fields are inputs. The gzipLevel, shuffle, and chunkSizes fields are outputs.

The main use for HDF5SaveDataHook is to provide a way by which you can specify chunk sizes on a wave-by-wave basis taking into account the wave dimension sizes and your tradeoff of disk space versus save time. The HDF5SaveData operation allows you to specify chunk sizes via the /LAYO flag. However, the other operations that support HDF5 compression through the /COMP flag (HDF5SaveGroup, SaveExperiment, SaveData, SaveGraphCopy, SaveTableCopy, and SaveGizmoCopy) always save datasets as one chunk as does HDF5 default compression. HDF5SaveDataHook allows you to change that, though in most cases there is no need to.

If the operation field is non-zero, then the hook function is being called from the HDF5SaveData or HDF5SaveGroup operations. You should respect the compression settings specified to those operations unless there is good reason to override them.

To set the compression parameters for the specified wave, set the output fields and return 1. To allow the save to proceed without altering compression, return 0.

Here is an example:

```
ThreadSafe Function HDF5SaveDataHook(s)
   STRUCT HDF5SaveDataHookStruct& s
   // Print "Global ThreadSafe HDF5SaveDataHook called"// For debugging only
   // return 0             // Uncomment this to make this hook a NOP

   if (s.version >= 2000)  // Structure version is 1000 as of this writing
      return 0             // The structure changed in an incompatible way
   endif

   if (s.operation != 0)   // Called from HDF5SaveData or HDF5SaveGroup?
      return 0             // Respect their settings unless we have
   endif                   // good reason to change them

   // Set compression parameters only for numeric waves
   int isNumeric = WaveType(s.waveToSave) == 1
   if (!isNumeric)
      return 0
   endif

   // Set compression parameters only if the total number of elements
   // in the wave exceeds a particular threshold
   int numElements = numpnts(s.waveToSave)
   if (numElements < 10000)
      return 0
   endif

   // Set compression parameters
   s.gzipLevel = 5         // 0 (no compression) to 9 (max compression)
   s.shuffle = 0           // 0=shuffle off, 1=shuffle on
   s.chunkSizes[0] = 200   // These values are arbitrary. Igor clips them.
   s.chunkSizes[1] = 200   // In a real function you would have some more
   s.chunkSizes[2] = 50    // systematic way to choose them.
   s.chunkSizes[3] = 50

   // Indicate that we want to set compression parameters for this wave
   return 1
End
```

The HDF5SaveDataHook function must be threadsafe. If it is not threadsafe, Igor will not call it.

The HDF5SaveDataHook function is called when a dataset is created and not when appending to an existing dataset.

The HDF5SaveDataHook function must not alter the state of Igor. That is, it must have no side effects such as creating waves or variables, modifying waves or variables, or killing waves or variables. It is called when HDF5SaveData is called, when HDF5SaveGroup is called, and also when Igor is saving an HDF5 packed experiment file. If you change the state of Igor in your HDF5SaveDataHook function, this may cause file corruption or a crash.

It is possible but not recommended to define more than one HDF5SaveDataHook function. For example, you can define one in the ProcGlobal context, another in a regular module and a third in an independent module. If you do this, each function is called until one returns 1. The order in which the functions are called is not defined.

We recommend that you define your HDF5SaveDataHook function in an independent module so that it can be called when normal procedures are in an uncompiled state. Otherwise, if you save an HDF5 packed experiment while procedures are not compiled, for example because of an error, your HDF5SaveDataHook function will not be called and all datasets will be saved with default compression or uncompressed.

For testing purposes, you can prevent Igor from calling any HDF5SaveDataHook function by executing:

```
SetIgorOption HDF5SaveDataHook=0
```

This prevents Igor from calling the hook function via HDF5SaveData and HDF5SaveGroup operations and when saving an HDF5 packed experiment file.

You can re-enable calling the hook function by executing:

```
SetIgorOption HDF5SaveDataHook=1
```

HDF5 Compression Troubleshooting

HDF5 Dynamically Loaded Filters

The HDF5 library can use third-party dynamically loaded filter plugins which are used for forms of compression that are not built into the library itself. "Dynamically loaded" means that the filter plugins are not compiled into the HDF5 library but reside in separate library files. The HDF5 library looks for these plugins and, if it finds them, loads them, and their features become available. (For HDF5 experts, dynamically loaded filter plugins are described at https://portal.hdfgroup.org/display/HDF5/HDF5+Dynamically+Loaded+Filters.)

The default locations where the HDF5 libraries look for filter plugins are:

Macintosh: `/usr/local/hdf5/lib/plugin`

Windows: `%ALLUSERSPROFILE%/hdf5/lib/plugin`
(%ALLUSERSPROFILE% is `C:\ProgramData` on most systems)

The user can override the default locations by setting the HDF5_PLUGIN_PATH environment variable to the path to the user's plugins prior to launching Igor.

Starting with Igor Pro 9.01, Igor Pro ships with the plugins provided by The HDF Group at https://www.hdfgroup.org/downloads/hdf5. These plugins include:

BLOSC, BSHUF, BZ2, JPEG, LZ4, LZF, and ZFP

Igor supports decoding datasets written with these filters. It does not yet support encoding with these filters. Also, this is supported with the 64 bit version of Igor, not with the 32 bit version because we have not found 32 bit filter plugin libraries.

On Macintosh, the filter libraries as provided by The HDF Group's download page (https://www.hdfgroup.org/downloads/hdf5) do not work with Igor Pro. The filter libraries that ship with Igor are tweaked to allow them to work with Igor Pro. (For Macintosh programming experts, this is explained at https://forum.hdfgroup.org/t/dynamically-loaded-filters-on-mac-os/9159/2.)

On Macintosh, the filters are shipped in "Igor64.app/MacOS/hdf5plugins". On Windows they are shipped in "IgorBinaries_x64/hdf5plugins". When Igor starts, it tells the HDF5 library to look in these locations first for plugins, before looking in the default filter location or in the locations specified by the HDF5_PLUGIN_PATH environment variable if it exists. This means that the HDF5 library will find the filter plugins that ship with Igor, not those in other locations.

There are other "registered filtered plugins" besides the ones listed above. A comprehensive list can be found at https://portal.hdfgroup.org/display/support/Registered+Filter+Plugins. It is unlikely that you will need other filter plugins. If you do, you can put them in the default location or the location specified by the HDF5_PLUGIN_PATH environment variable. The HDF5 library will look for them there after not finding them in Igor's hdf5plugins folder.

As noted above, filter plugin libraries on Macintosh need to be tweaked to work with Igor. Consequently, on Macintosh, other filter plugins will probably not work no matter where you put them.

HDF5 Dimension Scales

The HDF5 library supports dimension scales through the H5DS API. A dimension scale is a dataset that provides coordinates for another dataset. A dimension scale for dimension 0 of a dataset is analogous to an X wave in an Igor XY pair. The analogy applies to higher dimensions also.

Dimension scales are primarily of use in connection with the netCDF-4 format which is based on HDF5. Most Igor users do not need to know about dimension scales.

In the netCDF file format, the term "variable" is used like the term "dataset" in HDF5. Each variable of dimension n is associated with n named dimensions. Another variable, called a "coordinate variable", can supply values for the indices of a dimension, like an X wave supplies values for an XY pair in Igor.

The association between a variable and its coordinate variables is established when the variable is created. A given coordinate variable typically provides values for a given dimension of multiple variables. For example, a netCDF file may define coordinate variables named "latitude" and "longitude" and multiple 2D variables (images) whose X and Y dimensions are associated with "latitude" and "longitude".

The netCDF-4 file format is implemented using HDF5. The netCDF library uses the HDF5 dimension scale feature to implement coordinate variables and their associations with variables.

HDF5 Dimension Scale Support in Igor

The HDF5DimensionScale operation supports the creation and querying of HDF5 dimension scales. It was added in Igor Pro 9.00.

The operation is implemented using keyword=value syntax for setting parameters and simple keywords without values for invoking an action. For example, these commands convert a particular dataset into a dimension scale and then attach that dimension scale to another dataset:

```
// Convert a dataset named XScale into a dimension scale with name "X"
HDF5DimensionScale dataset={fileID,"XScale"}, dimName="X", setScale

// Attach dimension scale XScale to dimension 0 of dataset Data0
HDF5DimensionScale scale={fileID,"XScale"}, dataset={fileID,"Data0"},
                                                    dimIndex=0, attachScale
```

For details, see HDF5DimensionScale in Igor’s online help.

HDF5 Dimension Scale Implementation Details

If you view netCDF-4 files using Igor's HDF5 Browser, this section will help you to understand what you see in the browser.

The H5DS (dimension scale) API, which is part of the HDF5 "high-level" library, uses attributes to designate a dataset as a dimension scale, to associate a dimension scale with other datasets, and to keep track of the associations.

The most important attributes of a dimension scale are:

CLASS	Set to "DIMENSION_SCALE" to indicate that the dataset is a dimension scale.
NAME	Name of dimension such as "X".
REFERENCE_LIST	An array of structures used to keep track of the datasets and dimensions to which the dimension scale is attached. Each element of the structure includes a reference to a dataset and a dimension index.

The most important attributes of a dataset to which a dimension scale is attached are are:

DIMENSION_LIST	A variable-length array of references used to keep track of the dimensions used by each dimension of the dataset. The array has one column for each dataset dimension. Each column has one row for each dimension scale attached to the corresponding dataset dimension. A given dataset dimension can have multiple attached dimension scales.
DIMENSION_LABELS	An 1D array containing labels for the dimensions of the dataset.

HDF5 Dimension Scale Reference

For experts, some sources of additional information on HDF5 dimension scales and related netCDF-4 features are available in Igor’s online help topic "HDF5 Dimension Scale Reference".

Other HDF5 Issues

This section is mostly of interest to advanced HDF5 users.

HDF5 String Formats

Strings can be written to HDF5 files as datasets or as attributes using several formats:

- Variable length
- Fixed length with null termination
- Fixed length with null padding
- Fixed length with space padding

In addition, strings can be marked as either ASCII or UTF-8.

Usually you do not need to know or care about the format used to write strings. However, some programs do not support all of the formats. If you attempt to load an HDF5 file written by Igor into one of those programs, you may get an error. In that event, you may be able to fix the problem by controlling the string format used to write the file. The rest of this section provides information that may help in that event.

The variable-length string format is most useful when writing a dataset or attribute containing multiple strings of different lengths. For example, when a dataset containing the two strings "ABC" and "DEFGHIJKLMNOP" is written as variable length, each string and its length is stored in the HDF5 file. That requires 3 bytes for "ABC" and 13 bytes for "DEFGHIJKLMNOP" plus the space required to store the length for each string. If these strings were written as fixed length, the fixed length for the dataset or attribute would have to be at least 13 bytes and at least 10 bytes would be wasted by padding when writing "ABC".

The fixed-length string format is most useful when writing a dataset or attribute consisting of a single string. For example, "ABC" can be written using a 3-byte fixed-length datatype with 0 padding bytes.

If more than one string is written as fixed length, the padding mode determines how extra bytes are filled. In null-terminated mode, the extra bytes are filled with null (0) and the first null marks the end of a string. In null-padded mode, the extra bytes are filled with null (0) all consecutive nulls at the end of the string mark the end of the string. In space-padded mode, the extra bytes are filled with space all consecutive spaces at the end of the string mark the end of the string.

In addition to the variable-length versus fixed-length issue, there is a text encoding issue with HDF5. A string dataset or attribute is marked as either ASCII or UTF-8 depending on the software that wrote it. The marking does not guarantee that the text is valid ASCII or valid UTF-8 as the HDF5 library does not check to make sure that written text is valid as marked nor does it do any text encoding conversions. The marking is merely a statement of the intended text encoding. Some software may fail when reading datasets or attributes marked as ASCII or UTF-8 because the HDF5 library does require that the reading program use a compatible datatype.

With some exceptions explained below, you can control the string format used to save datasets and attributes using the /STRF={*fixedLength*,*paddingMode*,*charset*} flag with the **HDF5SaveData** and **HDF5SaveGroup** operations. The /STRF flag was added in Igor Pro 9.00.

If *fixedLength* is 0, HDF5SaveData writes strings using a variable-length HDF5 string datatype. If *fixedLength* is greater than 0, HDF5SaveData writes strings using a fixed-length HDF5 string datatype of the specified length with padding specified by padding mode. If *fixedLength* is -1, HDF5SaveData determines the length of the longest string to be written for a given dataset or attribute and writes strings using a fixed-length HDF5 string datatype of that length with padding specified by *paddingMode*.

If *paddingMode* is 0, HDF5SaveData writes fixed-length strings as null terminated strings. If *paddingMode* is 1, HDF5SaveData writes fixed-length strings as null-padded strings. If *paddingMode* is 2, HDF5SaveData writes fixed-length strings as space-padded strings. When writing strings as variable length (*fixedLength*=0), *paddingMode* is ignored.

If *charset* is 0, HDF5SaveData writes strings marked as ASCII. If *charset* is 1, HDF5SaveData writes strings marked as UTF-8.

An exception is zero-length datasets or attributes which are always written as variable-length UTF-8. Another exception is string variables written by HDF5SaveGroup which are always written as fixed-length null padded UTF-8.

This table shows the default string format used for various situations if you omit /STRF and whether or not HDF5SaveData and HDF5SaveGroup honor the /STRF flag for the corresponding situation:

	HDF5SaveData Default	**HDF5SaveData Behavior**
Text Wave Zero Element as Dataset	Variable,NULLPAD,UTF-8	Ignores /STRF
Text Wave Single Element as Dataset	Variable,NULLPAD,UTF-8	Honors /STRF
Text Wave Multiple Elements as Dataset	Variable,NULLPAD,UTF-8	Honors /STRF
String Variable	N/A	HDF5SaveData can not save string variables
Text Wave Zero Element as Attribute	Variable,NULLPAD,UTF-8	Ignores /STRF
Text Wave Single Element as Attribute	Fixed,NULLPAD,UTF-8	Honors /STRF
Text Wave Multiple Elements as Attribute	Variable,NULLPAD,UTF-8	Honors /STRF

	HDF5SaveGroup Default	**HDF5SaveGroup Behavior**
Text Wave Zero Element as Dataset	Variable,NULLPAD,UTF-8	Ignores /STRF
Text Wave Single Element as Dataset	Variable,NULLPAD,UTF-8	Honors /STRF
Text Wave Multiple Elements as Dataset	Variable,NULLPAD,UTF-8	Honors /STRF
Zero-Length String Variable	Variable,NULLPAD,UTF-8	Ignores /STRF
String Variable > Zero-Length	Fixed,NULLPAD,UTF-8	Ignores /STRF

Text Wave Zero Element as Attribute	N/A	HDF5SaveGroup can not save attributes
Text Wave Single Element as Attribute	N/A	HDF5SaveGroup can not save attributes
Text Wave Multiple Elements as Attribute	N/A	HDF5SaveGroup can not save attributes

HDF5 String Variable Text Encoding

Igor writes string variables as UTF-8 fixed-length string datasets.

String variables may contain null bytes and text that is invalid as UTF-8. This would occur, for example, if a variable were used to contain binary data. Such string variables are still written as UTF-8 fixed-length string datasets.

HDF5 Wave Text Encoding

For background information on wave text encoding, see **Wave Text Encodings** on page III-472.

Igor text wave contents are written as variable-length string datasets using UTF-8 text encoding. Other wave elements (units, note, dimension labels) are written as UTF-8 fixed-length string attributes.

Text wave contents may contain null bytes and text that is invalid as UTF-8. This would occur, for example, if a text wave were used to contain binary data. Such contents are still written as UTF-8 variable-length string datasets.

Wave text elements can be marked in Igor as using any supported text encoding. No matter how a wave's text elements are marked, they are written to HDF5 as UTF-8 strings. Consequently, if you save a wave that uses non-UTF-8 text encodings to an HDF5 file and the load it back into Igor, its text encodings change but the characters represented by the text do not.

An exception applies to wave elements marked as binary (see **Text Waves Containing Binary Data** on page III-475 for background information). When you save a wave containing one or more binary elements as an HDF5 dataset, Igor adds the IGORWaveBinaryFlags attribute to the dataset. This attribute identifies the wave elements marked as binary using bits as defined for the **WaveTextEncoding** function. When you load the dataset from an HDF5 file, Igor restores the binary marking for the wave elements corresponding to the bits set in the attribute. The IGORWaveBinaryFlags attribute was added in Igor Pro 9.00.

In Igor Pro 9.00 and later, the HDF5LoadData and HDF5LoadGroup operations can check for binary data loaded into text waves from string datasets and mark such text waves as containing binary. If you load binary data from string datasets, see bit 1 of the /OPTS flag of those operations for details.

HDF5 File Paths on Windows

The HDF5 library does not support Unicode file paths on Windows. This is explained under "Filenames" at

https://support.hdfgroup.org/HDF5/doc/Advanced/UsingUnicode/index.html

Instead, on Windows the HDF5 library uses system text encoding (also known as "system locale" and "language for non-Unicode programs").

This worked fine with Igor6 because Igor6 also used system text encoding internally. However, Igor7 and later store all text internally as UTF-8. Consequently, on Windows Igor converts file paths from UTF-8 to system text encoding before passing those paths to HDF5 library routines. This allows you to use paths containing non-ASCII characters. However, you are limited to those characters that are supported by the current system text encoding on your system. For example, if your system is set to use Windows-1252 ("western" code page) as the system text encoding, then you will get an error if the path to your file contains, for example, Japanese, because Windows-1252 does not support Japanese characters.

This issue does not affect Macintosh because both Igor7 or later and the HDF5 library use UTF-8 on Macintosh.

Igor Compatibility With HDF5

This section discusses issues relating to various HDF5 library versions.

You don't need to know this information unless you are using very old software based on HDF5 library versions earlier than 1.8.0.

The following table lists various Igor and HDF5 versions:

Igor Version	**HDF5 Library Version**
Igor Pro 6.03	1.6.3 (released on 2004-09-22)
Igor Pro 6.10 to 6.37	1.8.2 (released on 2008-11-10)
Igor Pro 7.00 to 7.08	1.8.15 (released on 2015-05-04)
Igor Pro 8.00 to 8.04	1.10.1 (released on 2017-04-27)
Igor Pro 9.00 to 9.0x	1.10.7 (released on 2020-09-15)

HDF5 Compatibility Terminology

For the purposes of this discussion, the term "old HDF5 version" means a version of the HDF5 library earlier than 1.8.0. The term "old HDF5 program" means a program that uses an old HDF5 version. The term "old HDF5 file" means an HDF5 file written by an old HDF5 program.

Reading Igor HDF5 Files With Old HDF5 Programs

By default, Igor Pro 9 and later create HDF5 files that work with programs compiled with HDF5 library version 1.8.0 or later. HDF5 1.8.0 was released in February of 2008. For most uses, this default compatibility will work fine.

The rest of this section is of interest only if you need to read Igor HDF5 files using very old HDF5 programs which use HDF5 library versions earlier than 1.8.0.

As explained at https://support.hdfgroup.org/HDF5/faq/bkfwd-compat.html#162unable, software compiled with HDF5 1.6.2 (released on 2004-02-12) or before is incompatible with HDF5 files produced by HDF5 1.8.0 or later.

If you need to read files written by Igor Pro 9 and later using software that uses HDF5 1.6.3 (released on 2004-09-22) through 1.6.10 (released on 2009-11-10), you need to tell Igor to use compatible HDF5 formats. You do this by executing this command:

```
SetIgorOption HDF5LibVerLowBound=0
```

When you do this, you lose these features:

- The ability to save attributes larger than 65,535 bytes ("large attributes")

  You will get an error in the unlikely event that you attempt to write a large attribute to a group or dataset.

  This includes saving a wave with a very large wave note or with a very large number of dimension labels via HDF5SaveData or HDF5SaveGroup or by saving an HDF5 packed experiment file. It also includes adding a large attribute using HDF5SaveData/A.
- The ability to sort groups and datasets by creation order

  This feature is provided by the HDF5 browser but is supported only for files in which it is enabled when the file is created.
- The ability to write attributes so that they can be read in creation order

To restore Igor to normal operation, execute:

```
SetIgorOption HDF5LibVerLowBound=1
```

The effect of SetIgorOption lasts only until you restart Igor.

Typically, if you need to set HDF5LibVerLowBound at all, you would do this once at startup. Do not call SetIgorOption to set HDF5LibVerLowBound while an Igor preemptive thread is making HDF5 calls.

Writing to Old HDF5 Files

The HDF5 documentation does not spell out all of the myriad compatibility issues between various HDF5 library versions. The information in this section is based on our empirical testing.

See **HDF5 Compatibility Terminology** on page II-222 for a definition of terms used in this section.

If you use Igor to open an old HDF5 file and write a dataset to it, the new dataset is not readable by old HDF5 programs. Also, the group containing the new dataset can not be listed by old HDF5 programs. In other words, writing to an old file in new format makes the old file at least partially unreadable by old software.

If you have old HDF5 files and you rely on old HDF5 programs to read them, open such files for read only, not for read/write. Also make sure the files are thoroughly backed up.

HDF5 Packed Experiment Files

In Igor Pro 9 and later, you can save an Igor experiment in an HDF5 file. The main advantage is that the data is immediately accessible to a wide array of programs that support HDF5. The main disadvantage is that you will need Igor Pro 9 or later to open the file in Igor. Also HDF5 is considerably slower than PXP for experiments with very large numbers of waves.

To save an experiment in HDF5 packed experiment format, choose File→Save Experiment As. In the resulting Save File dialog, choose "HDF5 Packed Experiment Files (*.h5xp)" from the pop-up menu under the list of files. Then click Save.

If you want to make HDF5 packed experiment format your default format for saving new experiments, choose Misc→Miscellaneous Settings. In the resulting dialog, click the Experiment category on the left. Then choose "HDF5 Packed (.h5xp)" from the Default Experiment Format pop-up menu.

For normal use you don't need to know the details of how Igor stores data in HDF5 packed experiment files, but, if you are curious, you can get a sense by opening such a file using the HDF5 Browser (Data→Load Waves→New HDF5 Browser).

The rest of this topic is for the benefit of programmers who want to read or write HDF5 packed experiment files from other programs. It is assumed that you are an experienced Igor and HDF5 user.

HDF5 Packed Experiment File Organization

An HDF5 packed experiment file has the following general organization:

```
/
   History
      History                 // Contents of the history area window
   Packed Data
      <Waves, variables and data folders here>
   Shared Data
      <Paths to shared wave files here>
   Free Waves
      <Free waves here>
   Free Data Folders
      <Free data folders here>
   Packed Procedure Files
      Procedure              // Contents of the built-in procedure window
      <Zero or more packed procedure files>
   Shared Procedure Files
      <Paths to shared procedure files>
   Packed Notebooks
      <Packed notebook files>
   Shared Notebooks
      <Paths to shared notebook files>
   Symbolic Paths
      <Paths to folders associated with symbolic paths>
   Recreation
      Recreation Procedures   // Experiment recreation procedures
   Miscellaneous
         Dash Settings (dataset)
         Recent Windows Settings (dataset)
         Running XOPs (dataset)
         Pictures
            <Picture datasets here>
         Page Setups
            Page Setup for All Graphs (dataset)
            Page Setup for All Tables (dataset)
            Page Setup for Built-in Procedure Window (dataset)
            <Datasets for page layout page setups here>
         XOP Settings
            <XOP settings datasets here>
```

Any of the top-level groups can be omitted if it is not needed. For example, if the experiment has no free waves, Igor writes no Free Waves group.

The Shared Data group contains datasets containing full paths to Igor binary wave (.ibw) files referenced by the experiment. The paths are expressed as Posix paths on Macintosh, Windows paths on Windows.

The Shared Procedure Files group contains datasets containing full paths to procedure (.ipf) files referenced by the experiment. The paths are expressed as Posix paths on Macintosh, Windows paths on Windows. Global procedure files and #included procedure files are not part of the expeirment and are not included.

The Shared Notebooks group contains datasets containing full paths to notebook (.ifn or any plain text file type) files referenced by the experiment. The paths are expressed as Posix paths on Macintosh, Windows paths on Windows.

The Symbolic Paths group includes only user-created symbolic paths, not the built-in symbolic paths Igor, IgorUserFiles, or home which by definition points to the folder containing the packed experiment file. The paths are expressed as Posix paths on Macintosh, Windows paths on Windows. If there are no user-created symbolic paths, Igor writes no Symbolic Paths group.

The Recreation Procedures dataset contains the experiment recreation procedures written by Igor to recreate the experiment.

The Miscellaneous group contains datasets and subgroups. Any of these objects can be omitted if not needed. The format of the data in the Miscellaneous group is subject to change and not documented. If your program reads or writes HDF5 packed experiment files, we recommend that you not attempt to read or write these objects.

HDF5 Packed Experiment File Hierarchy

An HDF5 file is a "directed graph" rather than a strict hierarchy. This means that it is possible to create strange relationships between objects, such as a group being a child of itself, or a dataset being a child of more than one group. Such strange relationships are not allowed for HDF5 packed experiment files - they must constitute a strict hierarchy.

Storage of Plain Text in HDF5 Packed Experiment Files

Several kinds of plain text items are stored in experiment files, including:

- The contents of the built-in procedure window
- The contents of the built-in history window
- The contents of packed procedure files
- The contents of packed plain text notebook files
- Text data contents of text waves
- Text properties of numeric waves (e.g., units, wave note, dimension labels)
- String variables

Igor stores such text as strings (HDF5 class H5T_STRING) using UTF-8 text encoding (H5T_CSET_UTF8) when writing an HDF5 packed experiment file.

Occasionally an item that is expected to be valid UTF-8 will contain byte sequences that are invalid in UTF-8 or contain null bytes. Examples include text waves and string variables that are being used to carry binary rather than text data. Such data is still written as UTF-8 string datasets.

Plain Text Files

"Plain text files" in this context refers to history text, recreation procedures, procedure files, and plain text notebooks. Igor writes plain text files as UTF-8 string datasets.

Waves

Igor writes text waves as UTF-8 string datasets. For details, see **HDF5 Wave Text Encoding** on page II-221.

String Variables

Igor writes string variables as UTF-8 fixed-length string datasets. For details, see **HDF5 String Variable Text Encoding** on page II-221.

Writing HDF5 Packed Experiments

This section is for programmers who want to write HDF5 packed experiment files from programs other than Igor. This section assumes that you understand the information presented in the preceding sections of **HDF5 Packed Experiment Files** on page II-223.

If you open an HDF5 packed experiment using the HDF5 Browser you will see that the file (top-level group displayed as "root" in the HDF5 file) has a number of attributes. The only required attribute is the IGORRequiredVersion attribute which specifies the minimum version of Igor required to open the experiment. Write 9.00 for this attribute, or a larger value if your HDF5 packed experiment requires a later version of Igor.

Waves in HDF5 Files

Igor writes waves to HDF5 files as datasets with attributes representing wave properties. For example, the IGORWaveType attribute represents the data type of the wave - see **WaveType** for a list of data types. See the discussion of the /IGOR flag of the **HDF5SaveData** operation for a list of HDF5 wave attributes.

Wave Reference Waves and Data Folder Reference Waves

A wave reference wave (see **Wave Reference Waves** on page IV-77), or "wave wave" for short, is a wave whose elements are references to other waves. Each wave referenced by a wave wave has an IGORWaveID attribute that specifies the wave ID of the referenced wave. The contents of each element of a wave wave is the wave ID for the referenced wave. A wave ID of zero indicates a null wave reference. On loading the experiment, Igor restore each element of each wave wave so that it points to the appropriate wave.

A data folder reference wave (see **Data Folder Reference Waves** on page IV-82), or "DFREF wave" for short, is a wave whose elements are references to data folders. Each data folder referenced by a DFREF wave has an IGORDataFolderID attribute that specifies the data folder ID of the referenced data folder. The contents of each element of a DFREF wave is the data folder ID for the referenced data folder. A data folder ID of zero indicates a null data folder reference. On loading the experiment, Igor restore each element of each DFREF wave so that it points to the appropriate data folder.

Writing and restoring wave waves and DFREF waves is complicated and tricky. If your program writes HDF5 packed experiment files, we recommend that you not attempt to write these objects. If your program loads HDF5 packed experiment files, we recommend that you ignore ignore wave waves (IGORWaveType=16384) and DFREF waves (IGORWaveType=256).

Free Waves and Free Data Folders

Igor writes representations of **Free Waves** and **Free Data Folders** to HDF5 packed experiment files and restores free waves and free data folders when the experiment is loaded.

Each free wave is written as a dataset in the Free Waves group. For a free wave to exist, it must be referenced by a wave wave in the experiment.

Each free root data folder and its descendents are written as a group and subgroups in the Free Data Folders group. For a free root data folder to exist, it must be referenced by a DFREF wave in the experiment.

Writing and restoring free waves and free data folders is a complicated and tricky. If your program writes HDF5 packed experiment files, we recommend that you not attempt to write these objects. If your program loads HDF5 packed experiment files, we recommend that you ignore the Free Waves and Free Data Folders groups.

HDF5 Packed Experiment Issues

In rare cases, Igor experiments can not be written in HDF5 packed format because of name conflicts. For details, see **Object Name Conflicts and HDF5 Files** on page III-505.

Chapter

II-11

Dialog Features

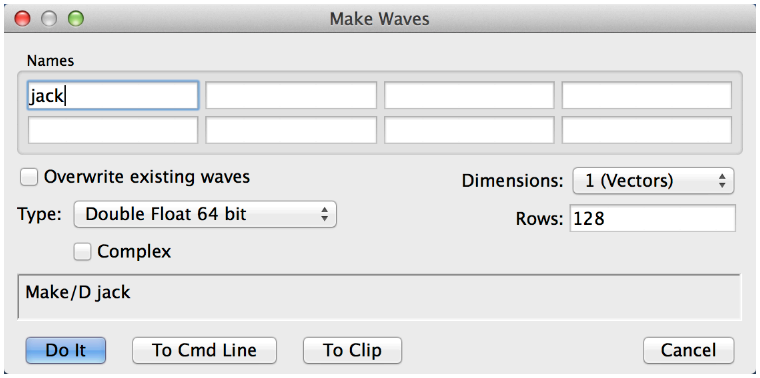
Overview

Most Igor Pro dialogs are designed with common features. This chapter describes some of those common features.

Operation Dialogs

Menus and dialogs provide easy access to many of Igor Pro's operations.

When you choose a menu item, like Data-Make waves, Igor presents a dialog:



Names: jack

□ Overwrite existing waves

Dimensions: 1 (Vectors)

Type: Double Float 64 bit

Rows: 128

□ Complex

```
Make/D jack
```

As you click and type in the items in the dialog, Igor generates an appropriate command. The command being generated is displayed in the command box near the bottom of the dialog.

As you become more proficient, you will find that some commands are easier to invoke from a dialog and others are easier to enter directly in the command line. There are some menus and dialogs that bypass the command line, usually because they perform functions that have no command line equivalents.

Dialog Wave Browser

In dialogs in which a wave must be selected, Igor presents a list of suitable waves in a dialog wave browser. The browser also lets you navigate through the data folder hierarchy.

Double-click a data folder icon to make that data folder the top level for the hierarchical display. To return to levels closer to the root, use the menu at the top of the browser.

In dialogs that support selection of multiple items, you can drag the mouse over items to select more than one. Press Shift while clicking to add additional contiguous items to a selection. Press Command (*Macintosh*) or Ctrl (*Windows*) while clicking to add additional discontiguous items to a selection.

You can change the columns that are displayed in the browser by right-clicking the header and enabling or disabling the different columns. If you click on a column in the header area, the waves in the browser are sorted by that column. Click the column in the header area again to reverse the sort direction.

After toggling the display of one or more columns, you may wish to right-click the header again and choose Size All Columns to Fit. You can also resize the columns by dragging the vertical bar that separates columns.

Click the gear icon at the bottom of the browser to display the options menu. It allows you to control whether data folders are displayed and how the waves are sorted and grouped.

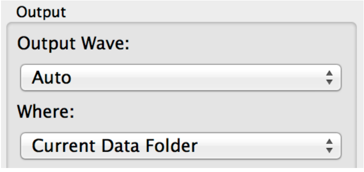
To filter waves by name, type a name in the Filter edit box. Only waves whose name match the filter string are displayed. The filtering algorithm supports the following features:

?	Matches any single character.
*	Matches zero or more of any characters. For example, "w*3" matches wave3, wave30 and wave300.
[...]	Matches a single character if it is included in the set of characters specified in square brackets. For example, [A-Z] matches any character from A to Z, case-insensitive. [0-9] matches any single digit.

Click the question mark icon at the bottom right corner of the browser to display a tooltip containing information about the current filter. This tip shows you the filtering criteria currently in place and may help you to figure out why waves you expect to be able to select are not displayed in the browser.

Operation Result Chooser

In most Igor dialogs that perform numeric operations (Analysis menu: Integrate, Smooth, FFT, etc.) there is a group of controls allowing you to choose what to do with the result. Here is what the Result Chooser looks like in the Integrate dialog:



Output

Output Wave: Auto

Where: Current Data Folder

The Output Wave menu offers choices of a wave to receive the result of the operation:

Auto	Igor will create a new wave to receive the results. The source wave is not changed. The new wave will have a name derived from the source wave by adding a suffix that depends on the operation. choosing Auto makes the Where menu available.
Overwrite Source	The source wave (the wave that contains the input data) will be overwritten with the results of the operation. This will destroy the original data. The Where menu will not be available.
Make New Wave	This is like the Auto choice, but an edit box is presented that you use to type a name of your own choosing. Igor will make a new wave with this name to receive the results of the operation. This selection makes the Where menu available.
Select Existing Wave	A Wave Browser will be presented allowing you to choose any existing wave to be overwritten with the results. This choice preserves the contents of the source wave, but destroys the contents of the wave chosen to receive the results.

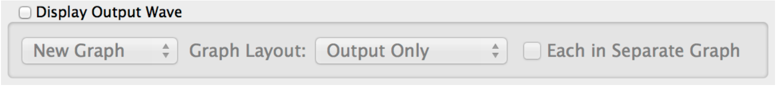
The Where menu offers choices for the location of a new wave created when you choose Auto or Make New Wave. Usually you will want to choose Current Data Folder.

Current Data Folder	The new wave is created in the current data folder. If you don't know about data folders, this is probably the best choice.
Source Wave Data Folder	The new wave is created in the same data folder as the source wave. It is quite likely that the source wave will be in the current data folder, in which case this choice is the same as choosing Current Data Folder.
Select Data Folder	This choice presents a Wave Browser in which you can choose a data folder where the new wave will be created.

Operation Result Displayer

In some Igor dialogs that perform numeric operations (Analysis menu: Integrate, Smooth, FFT, etc.) there is a group of controls allowing you to choose how to display the result. Choices are offered to put the result into the top graph, a new graph, the top table, or a new table. For two-dimensional results, New Image and New Contour are also offered. If the result is complex, as is the case for an FFT, New Contour is not available.

Here is what the Result Displayer looks like in the Smooth dialog:

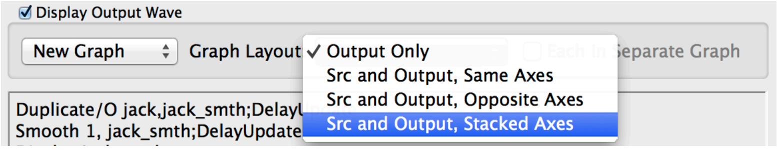


☐ Display Output Wave

New Graph   Graph Layout: Output Only   ☐ Each in Separate Graph

The contents of the displayer are not available here because the Display Output Wave checkbox is not selected. This is the default state.

When you choose New Graph, there are four choices in the Graph menu for the contents and layout of the new graph. In this menu, *Src* stands for Source. It is the wave containing the input data; Output is the wave containing the result of the operation.



☑ Display Output Wave

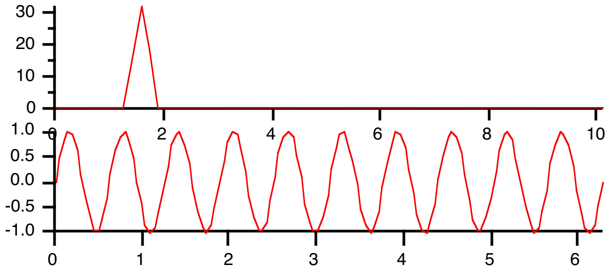
New Graph   Graph Layout

✓ Output Only
Src and Output, Same Axes
Src and Output, Opposite Axes
Src and Output, Stacked Axes
Each in Separate Graph

```
Duplicate/O jack,jack_smth;DelayU
Smooth 1, jack_smth;DelayUpdate
```

In many cases, the second choice, Src and Output, Same Axes, will not be appropriate because the operation changes the magnitude of data values or the range of the X values.

This picture shows the result of an FFT operation when Src and Output, Stacked Axes is chosen:

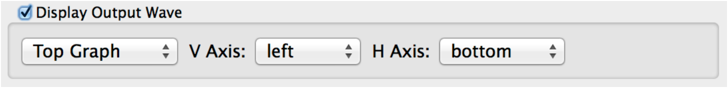


When you choose New Image or New Contour to display matrix results, the Graph Layout menu allows only Output Only or Src and Output, Stacked Axes. The axes aren't really stacked - it makes side-by-side graphs. It makes little sense to put two images or two contours on one set of axes.

The Result Displayer doesn't give you many options for formatting the graph, and doesn't allow any control over trace style, placement of axes, etc. It is intended to be a convenient way to get started with a graph. You can then modify the graph in any way you choose.

If you want a more complex graph, you may need to use the New Graph dialog (choose New Graph from the Windows menu) after you have clicked Do It in an operation dialog.

If you choose Top Graph instead of New Graph, the output wave will be appended to the top graph. It is assumed that this graph will already contain the source wave, so there is no option to append the source wave to the top graph. The Graph layout menu disappears, and two menus are presented to let you choose axes for the new wave:



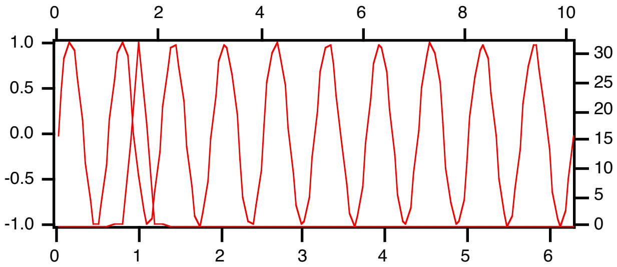
☑ Display Output Wave

Top Graph V Axis: left H Axis: bottom

The menus allow you to choose the standard axes: left and right in the V Axis menu; top and bottom in the H Axis menu. If the top graph includes any free axes (axes you defined yourself) they will be listed in the appropriate menu as well.

In most cases the source wave will be plotted on the left and bottom axes. You will usually want to select the right axis because of the differing magnitude of data values that result from most operations. You may also want to select the top axis if the operation (like the FFT) changes the X range as well.

Here is the result of choosing right and top when doing an FFT (this is the same input data as in the graph above):



Note that the format of the graph is poor. We leave it to you to format it as you wish. If you want a stacked graph, it may be better to choose the New Graph option.

Chapter

II-12

Tables

Overview

Tables are useful for entering, modifying, and inspecting waves. You can also use a table for presentation purposes by exporting it to another program as a picture or by including it in a page layout. However, it is not optimized for this purpose.

If your data has a small number of points you will probably find it most convenient to manually enter it in a table. In this case, creating a new empty table will be your first step.

If your data has a large number of points you will most likely load it into Igor from a file. In this case it is not necessary to make a table. However, you may want to display the waves in a table to inspect them. Igor Pro tables can handle virtually any number of rows and columns provided you have sufficient memory.

A table in Igor is similar to but not identical to a spreadsheet in other graphing programs. The main difference is that in Igor data exists independent of the table. You can create new waves in Igor's memory by entering data in a table. Once you have entered your data, you may, if you wish, kill the table. The waves exist independently in memory so killing the table does not kill the waves. You can still display them in a graph or in a new table.

In a spreadsheet, you can create a formula that makes one cell dependent on another. You can not create cell-based dependencies in Igor. You can create dependencies that control entire waves using Analysis→Compose Expression, Misc→Object Status, or the **SetFormula** operation (see page V-847), but this is not recommended for routine work.

To make a table, choose Windows→New Table.

When the active window is a table, the Table menu appears in Igor's menu bar. Items in this menu allow you to append and remove columns, change the formatting of columns, and sets table preferences.

Waves in tables are updated dynamically. Whenever the values in a wave change, Igor automatically updates any tables containing that wave. Because of this, tables are often useful for troubleshooting number-crunching procedures.

Creating Tables

Table Creation with New Experiment

By default, when you create a new experiment, Igor automatically creates a new, empty table. This is convenient if you generally start working by entering data manually. However, in Igor data can exist in memory without being displayed in a table. If you wish, you can turn automatic table creation off using the Experiment Settings category of the Miscellaneous Settings dialog (Misc menu).

Creating an Empty Table for Entering New Waves

Choose Windows→New Table and click the Do It button.

If you enter a numeric value in the table, Igor creates a numeric wave. If you enter a non-numeric value, Igor creates a text wave.

To create multidimensional waves you must use the Make Waves dialog (Data menu).

After creating the wave, you may want to rename it. Choose Rename from the Table pop-up menu or from the Data menu in the main menu bar.

Creating a Table to Edit Existing Waves

Choose Windows→New Table.

Select the waves to appear in the table from the Columns to Edit list. Press Shift while clicking to select a range of waves. Press Cmd (*Macintosh*) or Ctrl (*Windows*) to select an individual list item.

Click the Do It button to create the table.

Showing Index Values

As described in Chapter II-5, **Waves**, waves have built-in scaled index values. The New Table and Append to Table dialogs allow you to display just the data in the wave or the index values and the data. If you click the Edit Index And Data Columns radio button in either of these dialogs, Igor displays both index and data columns in the table.

A 1D wave's X index values are determined by its X scaling which is a property that you set using the Change Wave Scaling dialog or SetScale operation. A 2D wave has X and Y scaling, controlling X and Y scaled index values. Higher dimension waves have additional scaling properties and scaled index values. Displaying index values in a table is of use mostly if you are not sure what a wave's scaling is or if you want to see the effect of a SetScale operation.

Showing Dimension Labels

As described in **Dimension Labels** on page II-93, waves have dimension labels. The New Table and Append Columns to Table dialogs allow you to display just the data in the wave or the dimension labels and the data. If you click the Edit Dimension Label And Data Columns radio button in either of these dialogs, Igor displays both label and data columns in the table.

Dimension labels are of use only when individual rows or columns of data have distinct meanings. In an image, for example, this is not the case because the significance of one row or column is the same as any other row or column. It is the case when a multidimensional wave is really a collection of related but disparate data.

A 2D wave has row and column dimension labels. A 1D wave has row dimension labels only.

You can display dimension labels or dimension indices in a table, but you can not display both at the same time for the same wave.

The Horizontal Index Row

When a multidimensional wave is displayed in a table, Igor adds the horizontal index row, which appears below the column names and above the data cells. This row can display numeric dimension indices or textual dimension labels.

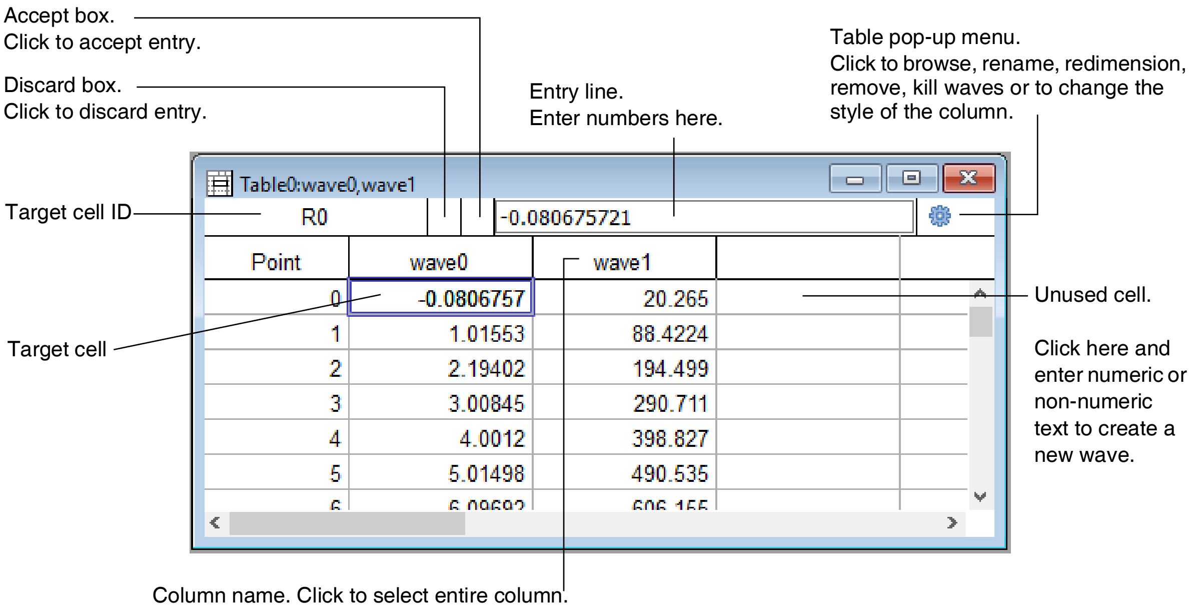
By default, the horizontal index row displays dimension labels if the wave's dimension label column is displayed in the table. Otherwise it displays numeric dimension indices. You can override this default using the Table→Horizontal Index submenu.

Creating a Table While Loading Waves From a File

The Load Waves dialog (Data menu) has an option to create a table to show the newly loaded waves.

Parts of a Table

This diagram shows the parts of a table displaying 1D waves. If you display multidimensional waves, Igor adds some additional items to the table, described under **Editing Multidimensional Waves** on page II-261.



Accept box.
Click to accept entry.

Discard box.
Click to discard entry.

Entry line.
Enter numbers here.

Table pop-up menu.
Click to browse, rename, redimension, remove, kill waves or to change the style of the column.

Target cell ID

Target cell

Unused cell.

Click here and enter numeric or non-numeric text to create a new wave.

Column name. Click to select entire column.

Table0:wave0,wave1

R0 -0.080675721

Point	wave0	wave1
0	-0.0806757	20.265
1	1.01553	88.4224
2	2.19402	194.499
3	3.00845	290.711
4	4.0012	398.827
5	5.01498	490.535
6	6.09692	606.155

The bulk of a table is the **cell area**. The cell area contains columns of numeric or text data values as well as the column of point numbers on the left. If you wish, it can also display index columns or dimension label columns. To the right are unused columns into which you can type or paste new data.

If the table displays multidimensional waves then it will include a row of column indices or dimension labels below the row of names. Use the Append Columns to Table dialog to switch between the indices and labels.

In the top left corner is the **target cell ID** area. This identifies a wave element corresponding to the target cell. For example, if a table displays a 2D wave, the ID area might show “R13 C22”, meaning that the target cell is on row 13, column 22 of the 2D wave. For 3D waves the target cell ID includes the layer (“L”) and for a 4D wave it includes the chunk (“Ch”).

If you scroll the target cell out of view you can quickly bring it back into view by clicking in the target cell ID

There is a special cell, called the **insertion cell**, at the bottom of each column of data values. You can add points to a wave by entering a value or pasting in the insertion cell.

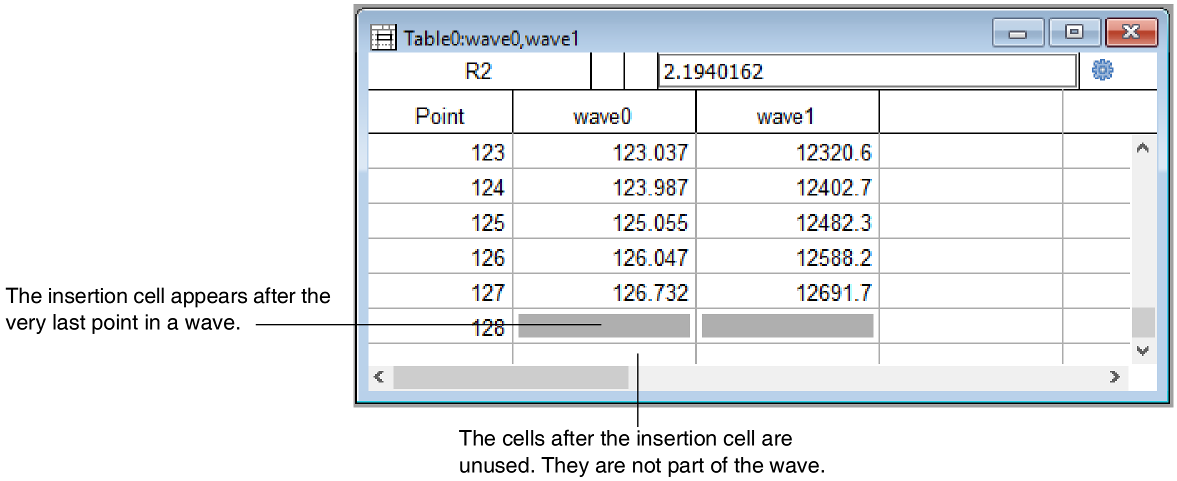


Table0:wave0,wave1

R2 2.1940162

Point	wave0	wave1
123	123.037	12320.6
124	123.987	12402.7
125	125.055	12482.3
126	126.047	12588.2
127	126.732	12691.7
128		

The insertion cell appears after the very last point in a wave.

The cells after the insertion cell are unused. They are not part of the wave.

The **Table pop-up menu** provides a quick way to inspect or change a wave, remove or kill a wave and change the formatting of one or more columns. You can invoke the Table pop-up menu by clicking the gear icon or right-clicking (*Windows*) or Control-clicking (*Macintosh*) a column.

For waves displayed in multiple columns (complex waves and multidimensional waves), if you change the display format of any data column from the wave, Igor changes the format for all data columns from that wave.

One of the items in the pop-up menu is Delay Update. Normally, when you change the value of a cell in the table, Igor immediately updates any other tables or graphs to reflect the new value. Enabling Delay Update forces this updating of other tables and graphs to be postponed until you click in another window or disable Delay Update. When Delay Update has been enabled, there is a checkmark next to the menu item. You can do this if you have a list of values to enter into a table and you don't want other tables or graphs to be updated until you are finished.

Delay Update does not delay updates when you remove or add cells to a wave. It only delays updates when you change the value of a cell.

Showing and Hiding Parts of a Table

The Table menu has a Show submenu that shows or hides various parts of a table. This is of use only in specialized situations such as when you are using a table subwindow in a control panel to display data but don't want the user to enter data. For normal use you should leave all of the items in the Show submenu checked so that all parts of the table will be visible.

When the entry line is hidden, the user can not change values in the table.

Arrow Keys in Tables

By default, if you are in the process of entering data, the arrow keys accept the entry as if you pressed Enter and then move the selected cell.

Some users prefer to use the arrow keys to move the selection in the entry line when an entry is in progress. You can specify your preference via the Table Settings category in the Miscellaneous Settings dialog (Misc menu).

Table Keyboard Navigation

The term "keyboard navigation" refers to selection and scrolling actions in response to the arrow keys and to the Home, End, Page Up, and Page Down keys. Macintosh and Windows have different conventions for these actions in windows containing text. You can use either Macintosh or Windows conventions on either platform.

By default, Macintosh conventions apply on Macintosh and Windows conventions apply on Windows. You can change this using the Keyboard Navigation menu in the Misc Settings section of the Miscellaneous Settings Dialog. If you use Macintosh conventions on Windows, use Ctrl in place of Command. If you use Windows conventions on Macintosh, use Command in place of Ctrl.

Macintosh Table Navigation

Key	No Modifier	Option	Command
Left Arrow	Move selection left one cell	Not used	Move selection to first column
Right Arrow	Move selection right one cell	Not used	Move selection to last column
Up Arrow	Move selection up one cell	Show previous layer	Scroll and move selection to first row
Down Arrow	Move selection down one cell	Show next layer	Scroll and move selection to last row
Home	Scroll to start of document	Scroll to start of document	Scroll to start of document
End	Scroll to end of document	Scroll to end of document	Scroll to end of document

Macintosh Table Navigation

Key	No Modifier	Option	Command
Page Up	Scroll up one screen	Scroll left one screen	Scroll up one screen
Page Down	Scroll down one screen	Scroll right one screen	Scroll down one screen

When viewing a 3D or 4D wave, Option-Up Arrow and Option-Down Arrow change the currently viewed layer.

When viewing a 4D wave, Command-Option-Up Arrow and Command-Option-Down Arrow change the currently viewed chunk.

Pressing shift-arrow-key extends the selection in the direction of the arrow key. Pressing cmd-shift-arrow-key extends selection as far as possible in the direction of the arrow key.

Windows Table Navigation

Key	No Modifier	Alt	Ctrl
Left Arrow	Move selection left one cell	Not used	Move selection to first column
Right Arrow	Move selection right one cell	Not used	Move selection to last column
Up Arrow	Move selection up one cell	Show previous layer	Scroll and move selection to first row
Down Arrow	Move selection down one cell	Show next layer	Scroll and move selection to last row
Home	Move selection to first visible cell	Not used	Scroll and move selection to first cell
End	Move selection to last visible cell	Not used	Scroll and move selection to last cell
Page Up	Scroll up one screen	Scroll left one screen	Scroll up one screen
Page Down	Scroll down one screen	Scroll right one screen	Scroll down one screen

When viewing a 3D or 4D wave, Alt+Up Arrow and Alt+Down Arrow change the currently viewed layer.

When viewing a 4D wave, Ctrl+Alt+Up Arrow and Ctrl+Alt+Down Arrow change the currently viewed chunk.

Pressing shift-arrow-key extends the selection in the direction of the arrow key. Pressing cmd-shift-arrow-key extends selection as far as possible in the direction of the arrow key.

Decimal Symbol and Thousands Separator in Tables

By default, the decimal symbol for entering a number in a table is period. You can change this to comma or Per System Setting using the Table→Table Misc Settings menu. The selected decimal symbol is used for entering, copying, and pasting data in tables.

The Decimal Symbol setting controls the character that is produced when you press the decimal key on the numeric keypad while entering a value in the entry area of a table.

If comma is selected as the decimal symbol then it is not supported as a column separator when creating new waves by pasting text into a table.

When you choose Per System Setting, the decimal symbol is determined by your system settings as of when Igor was launched. Only period and comma are supported as the decimal symbol. If you choose any decimal symbol other than comma, period will be used as the decimal symbol for tables.

When creating a new wave by entering data into an unused table cell, there are some rare situations when what you are trying to enter cannot be properly interpreted unless you first choose the appropriate column numeric format from the Table menu. For example, if the decimal symbol is comma and you want to enter a time or date/time value with fractional seconds, you must choose Time or Date/Time from the Table→Formats menu before entering the data.

If the decimal symbol is period then the thousands separator is comma. If the decimal symbol is comma then the thousands separator is period. The thousands separator is permitted when entering data in a table. You can also choose a column numeric format that displays thousands separators. However thousands separators are not permitted when creating new waves by pasting text into a table.

Using a Table to Create New Waves

If you click in any unused column, Igor selects the first cell in the first unused column. You can then create new waves by entering a value or pasting data that you have copied to the clipboard.

Creating a New Wave by Entering a Value

When you enter a data value in the first unused cell, Igor creates a single new 1D wave and displays it in the table. This is handy for entering a small list of numbers or text items. If you enter a numeric value, including date/time values, Igor creates a numeric wave. If you enter a nonnumeric value, Igor creates a text wave.

Igor gives the wave a default name, such as wave0 or wave1. You can rename the wave using the Rename item in the Data menu or the Rename item in the Table pop-up menu. You can also rename the wave from the command line by simply executing:

```
Rename oldName, newName
```

When you create a new wave, the wave has one data point — point 0. The cell in point number 1 appears gray. This is the **insertion cell**. It indicates that the preceding cell is the last point of the wave. You can click in the insertion cell and enter a value or do a paste. This adds one or more points to the wave.

If the new wave is numeric, it will be single or double precision, depending on the Default Data Precision setting in the Miscellaneous Settings dialog. The number of digits displayed, however, depends on the numeric format. See **Numeric Formats** on page II-255.

When entering a date, you must use the format selected in the Table Date Format dialog, accessible via the Table menu. The setting in this dialog affects all tables.

If you enter a date (e.g., 1993-01-26), time (e.g., 10:23:30) or date/time (e.g., 1993-01-26 10:23:30) value, Igor notices this. It sets the column's numeric format to display the value properly. It also forces the new wave to be double precision, regardless the Default Data Precision setting in the Miscellaneous Settings dialog. This is necessary because single precision does not have enough range to store date and time values.

Creating New Waves by Pasting Data from Another Program

If you have data in a spreadsheet program or other graphing program, you may be able to import that data into Igor using copy and paste.

This will work if the other program can copy its data to the clipboard as tab-delimited text or comma-delimited text. Most programs that handle data in columns can do this. Tab-delimited data consists of a number of lines of text with following format:

```
value <tab> value <tab> value <terminator>
```

It may start with a line containing column names. The end of a line is marked by a terminator which may be a carriage return, a linefeed, or a carriage return/linefeed combination. If pasted into a word processor, tab delimited text would look something like this:

```
column1     column2     column3     (this line is optional)
27.95       -13.738     12.74e3
31.37       -12.89      13.97e3
```

.	.	.
.	.	.
.	.	.

In the other program, select the cells containing the data of interest and copy them to the clipboard. In Igor, select the first cell in the first unused column in a table and then select Paste from Igor's Edit menu.

Igor scans the contents of the clipboard to determine the number of rows and columns of numeric text data. It also checks the first line of text in the clipboard to see if it contains column names. It creates waves and displays them in the table using the names found in the clipboard or default names. If the text contains names which conflict with existing names, Igor presents a dialog in which you can correct the problem.

If you paste text-only data, which does not contain numbers,dates, times or date/time values, Igor treats all of the pasted text as data instead of treating the first line as column names. This will usually produce the desired results. If you want to treat the first line as column names, use the Load Delimited Text routine to load the text from the clipboard and specify that you want to load wave names. See **Loading Delimited Text Files** on page II-129 for details.

Troubleshooting Table Copy and Paste

If the waves that are created when you paste don't contain the values you expect, chances are that the clipboard does not contain tab-delimited text. In this case you will need to undo the paste. To examine the contents of the clipboard, paste it into an Igor plain text notebook or into the word processor of your choice. After editing the text, copy it to the clipboard again and repaste it into the table.

Creating New Waves by Pasting Data from Igor

You can also create new waves by copying data from existing waves. When you copy wave data in a table, Igor stores not only the raw data but also the following properties of the wave or waves:

- Data units and dimension units
- Data full scale and dimension scaling
- Dimension labels
- The wave note

Thus you can duplicate a wave by copying it in a table and pasting into the unused area of the same table or a different table. You can also copy from a table in one experiment and paste in a table in another experiment.

You can copy and paste the wave note only if you copy the entire wave. If you copy part of the wave, it does not copy the wave note.

Table Names and Titles

Every table that you create has a name. The name is a short Igor object name that you or Igor can use to reference the table from a command or procedure. When you create a new table, Igor assigns it a name of the form Table0, Table1 and so on. You will most often use a table's name when you kill and recreate the table, as described in the next section.

A table also has a title. The title is the text that appears at the top of the table window. Its purpose is to identify the table visually. It is not used to identify the table from a command or procedure. The title can consist of any text, up to 255 bytes.

You can change the name and title of a table using the Window Control dialog. This dialog is a collection of assorted window-related things. Choose Windows→Control→Window Control to display the dialog.

Hiding and Showing a Table

You can hide a table by Shift-clicking the close button.

You can show a table by choosing its name from the Windows→Tables submenu.

Killing and Recreating a Table

Igor provides a way for you to kill a table and then later to recreate it. Use this to temporarily get rid of a table that you expect to be of use later.

You kill a table by clicking the table window's close button or by using the Close item in the Windows menu. When you kill a table, Igor offers to create a **window recreation macro**. Igor stores the window recreation macro in the procedure window of the current experiment. The name of the window recreation macro is the same as the name of the table. You can invoke the window recreation macro later to recreate the table by choosing its name from Windows→Table Macros.

A table does not contain waves but is just a way of viewing them. Killing a table does not kill the waves displayed in a table. If you want to kill the waves in a table, select all of them (Select All in Edit menu) and then choose Kill All Selected Waves from the Table pop-up menu.

For further details, see **Closing a Window** on page II-46 and **Saving a Window as a Recreation Macro** on page II-47.

Index Columns

There are two kinds of numeric values associated with a numeric wave: the stored data values and the computed index values. For example, each point in a real 1D wave has two values: a data value and an X index value. The data value is stored in memory. The X value is computed based on the point number and the wave's X scaling property. The correspondence between point numbers and X values is discussed in detail under **Waveform Model of Data** on page II-62.

Because the index values for a wave are computed, a value in an index column in a table can not be altered by editing the wave. Only values in data columns of a table can be edited. To alter the index values of a wave, use the Change Wave Scaling dialog.

Column Names

Column names are related to but not identical to wave names. You need to use column names to append, remove or modify table columns from the command line or from an Igor procedure.

A column name consists of a wave name and a suffix that identifies which part of the wave the column displays. For each real 1D wave there can be two columns: one for the X index values or dimension labels of the wave and one for the data values of the wave. For complex waves there can be three columns: one for the X index values or dimension labels of the wave, one for the real data values of the wave and one for the imaginary data values of the wave.

If we have a real 1D wave named "test" then there are three column names associated with that wave: test.i ("i" for "index"), test.l ("l" for "label") and test.d ("d" for "data"). If we have a complex 1D wave named "ctest" then there are four column names associated with that wave:ctest.i, ctest.l, ctest.d.real and ctest.d.imag.

Wave Name	Column Name	Column Contents
test	test.i	Index values of test
test	test.l	Dimension labels of test

Wave Name	Column Name	Column Contents
test	test.d	Data values of test
ctest	ctest.i	Index values of ctest
ctest	ctest.d.real	Real part of data values of ctest
ctest	ctest.d.imag	Imaginary part of data values of ctest

For multidimensional waves, the ".i" and ".l" suffixes still specify a single column of index values or dimension labels while the ".d" suffix specifies all of the data columns.

In the table-related commands, you can abbreviate column names as follows:

Full Column Specification	Abbreviated Column Specification
test.d	test
test.i, test.d	test.id
test.l, test.d	test.ld
ctest.d.real, ctest.d.imag	ctest.d or ctest
ctest.i, ctest.d.real	ctest.id.real
ctest.l, ctest.d.real	ctest.ld.real
ctest.i, ctest.d.imag	ctest.id.imag
ctest.l, ctest.d.imag	ctest.ld.imag
ctest.i,ctest.d.real,ctest.d.imag	ctest.id
ctest.l,ctest.d.real,ctest.d.imag	ctest.ld

A 2D wave has X and Y index values. A 3D wave has X, Y and Z index values. A 4D wave has X, Y, Z and T index values. Regardless of the dimensionality of the wave, however, it has only one index column in a table. The index column for a 2D wave, for example, may show the X values or the Y values, depending on how you are viewing the data. The index column will be labeled "wave.x" or "wave.y", depending on the view. However, when referring to the column from an Igor command, you can always use the generic column name "wave.i" as well as the specific column name "wave.x" or "wave.y". A dimension label column is always called "wave.l", regardless of which dimension is showing in the table.

See **Edit** on page V-192 for some examples of commands using column names.

Appending Columns

To append columns to a table, choose Table→Append Columns to Table. This displays the Append Columns dialog.

Igor appends columns to the right end of the table. You can drag a column to a new position by pressing Option (*Macintosh*) or Alt (*Windows*) and dragging the column name.

Removing Columns

To remove columns from a table, choose Table→Remove Columns from Table. This displays the Remove Columns dialog.

You can also select the columns in the table, and use the Table pop-up menu to remove the selected columns.

Removing a column from a table does not kill the underlying wave. The column is not the wave but just a *view* of the wave. Use the Kill Waves item in the Table pop-up menu to remove waves from the table and kill them. Use the Kill Waves item in the Data menu to kill waves you have already removed from a table.

Selecting Cells

If you click in a cell, it becomes the target cell. The old target cell is deselected and the cell you clicked on is highlighted. The target cell ID changes to reflect the row and column of the new target cell and the value of the target cell is shown in the entry line. You click in a cell and make it the target when you want to enter a new value for that cell or because you want to select a range of cells starting with that cell.

Here are the selections that you can make:

Click	Action
Click	Selects a single cell and makes it the target cell
Shift-click	Extends or reduces the selection range
Click in the point column	Selects the entire row
Click in a column name	Selects the entire column
Click in an unused column	Selects the first unused cell
Choose Select All (Edit menu)	Selects all cells (if possible)

The selection in a table must be rectangular. Igor will not let you select a range that is not rectangular. If you choose Select All, Igor will attempt to select all of the cells in the table. However, if you have columns of different length, Igor will be limited to selecting a rectangular array of cells.

If, after clicking in a cell to make it the target cell, you drag the mouse, the cells over which you drag are selected and highlighted to indicate that they are selected. You select a range of cells in preparation for copying, cutting, pasting or clearing those cells. While you drag, the cell ID area shows the number of rows and columns that you have currently selected. If you drag beyond the edges of the table, the cell area scrolls so that you can select as many cells as you want.

Moving the target cell accepts any data entry in progress.

You can change which cell is the target cell using Return, Enter, Tab, or arrow keys. If you are entering a value, these keys also accept the entry.

Key	Action (When a Single Cell is Selected)
Return, Enter, Down Arrow	Moves target cell down
Shift-Return, Shift-Enter, Up Arrow	Moves target cell up
Tab, Right Arrow	Moves target cell right
Shift-Tab, Left Arrow	Move target cell left

If you have a range of cells selected, these keys keep the target cell within that selected range. If it is at one extreme of the selected range it will wrap around to the other extreme.

By default, the arrow keys move the target cell. You can change it so they move the insertion point in the entry line using Table→Table Misc Settings.

The used columns in a table are always contiguous. If you click in any unused column, Igor selects the first unused cell. There are just two things you can do when the first unused cell is selected: create a new wave by entering a value or create new waves by pasting data from the clipboard. Igor will not allow you to select any unused cell other than the first cell in the first unused column.

The Insertion Cell

At the bottom of every column of data values is a special cell called the **insertion cell**. It appears as a gray box below the very last point in a wave.

Sometimes you know the number of points that you want a wave to contain and don't need to insert additional points into the wave. However, if you want to enter a short list of values into a table or to add new data to an existing wave, you can do this by entering data in the insertion cell.

When you enter a value in an insertion cell, Igor extends the wave by one point. Then the insertion cell moves down one position and you can insert another point.

The insertion cell can also be used to a extend a wave or waves by more than one point at a time. This is described under **Pasting Values** on page II-248.

You can also insert points in waves using the Insert Points item which appears in both the Table pop-up menu and the Data menu or using the InsertPoints operation from the command line.

Entering Values

You can alter the data value of a point in a wave by making the cell corresponding to that value the target cell, typing the new value in the entry line, and then confirming the entry.

You can also accept the entry by clicking in any cell or by pressing any of the keys that move the target cell: Return, Enter, Tab, or arrow keys. You can discard the entry by pressing Escape or by clicking the X icon.

If a range of cells is selected when you confirm an entry, the target cell will move within the range of selected cells unless you click in a cell outside this range.

While you are in the process of entering a value, the Clear, Copy, Cut and Paste items in the Edit menu as well as their corresponding command key shortcuts affect the entry line. If you are not in the process of entering, these operations affect the cells.

Entering a value in an insertion cell is identical to entering a value in any other cell except that when the entry is confirmed the wave is extended by one point.

Igor will not let you enter a value in an index column since index values are computed based on a waves dimension scaling.

Dimension labels are limited to 255 bytes. If you paste into a dimension label cell, Igor clips the pasted data to 255 bytes.

Prior to Igor Pro 8.00, dimension labels were limited to 31 bytes. If you use long dimension labels, your wave files and experiments will require Igor Pro 8.00 or later.

When entering a value in a numeric column, if what you have entered in the entry line is not a valid numeric entry, Igor will not let you confirm it. The check icon will be dimmed to indicate that the value can not be entered. To enter a date in a date column, you must use the date format specified in the Table Date Format dialog.

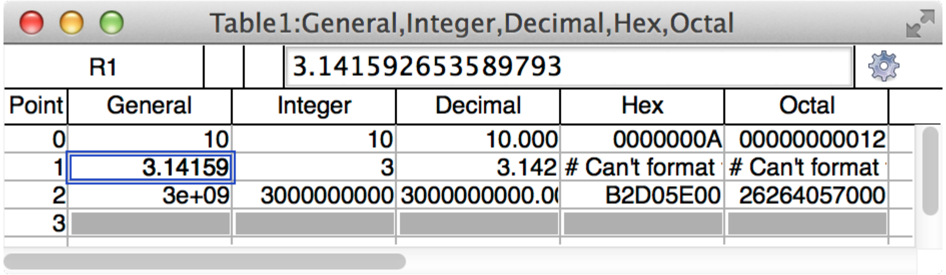
If you edit a text wave or dimension label which contains bytes that are not valid in the wave's text encoding, Igor displays a warning and substitutes escape codes for the invalid bytes. See **Editing Invalid Text** on page II-259 for details.

If you attempt to enter a character that can not be represented in the text encoding controlling a text wave or dimension label, Igor displays an error message. See **Entering Special Characters** on page II-261 for details.

Table Display Precision

The display of data in a column of a table depends on the data type of the displayed wave, the values stored in the wave, and the numeric format settings applied to the column. In some cases, the cell area displays less than full precision but the entry line always displays full precision.

For example, this table displays five double-precision floating point waves using different display formats. Each of the waves contains the values 10, 3.141592653589793, and 3 billion.



Point	General	Integer	Decimal	Hex	Octal
0	10	10	10.000	0000000A	00000000012
1	3.14159	3	3.142	# Can't format	# Can't format
2	3e+09	3000000000	3000000000.0	B2D05E00	26264057000
3					

The first column is set to general format with six digits of precision which is the factory default format for new table columns. The general format chooses either integer, floating point or scientific notation depending on the displayed value.

The value of General[1] is displayed in the body of the table as 3.14159 since the format specifies six digits of precision. Since this cell is selected as the target cell, its value appears in the entry line. However, the entry line displays the value using full 16-digit precision rather than using the column's format. This guarantees that, if you click in the entry line and accept the text that is already there, no precision is lost.

If the General wave were single-precision floating point instead of double-precision, the entry line would show 8 digits for non-integer values since 8 digits are sufficient for single-precision. Integer values from single-precision waves are displayed using up to 16 digits.

Because the Integer column is formatted to display as integer, 3.141592653589793 is displayed as 3. If you clicked on Integer[1], the entry line would show the full precision.

The story is the same for Decimal[1]. The cell area of the table follows the column's formatting but if you clicked Decimal[1], the full precision would appear in the entry line.

The Hex and Octal columns are set to hexadecimal and octal display respectively. The hex and octal formats do not support the display of fractional data so Hex[1] and Decimal[1] display error messages instead of values. This is further discussed under **Hexadecimal Numeric Formats** on page II-257 and **Octal Numeric Formats** on page II-257.

Date Values

Dates and times are represented in Igor date format — as a number of seconds since midnight, January 1, 1904. Dates before that are represented by negative values.

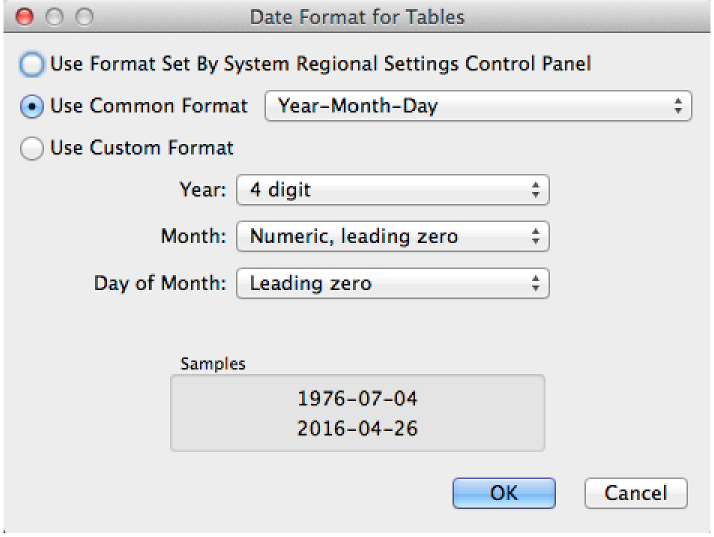
A date can not be accurately stored in the data values of a single precision wave. Make sure to use double precision to store dates and times.

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-85.

The way you enter dates in tables and the way that Igor displays them is controlled by the Table Date Format dialog which you invoke through the Table menu. This dialog sets a global preference that determines the date format for all tables.

If in the Table Date Format dialog you choose to use the system date format, which is the factory default setting, Igor displays dates in a table using the short date format as set by the Language & Region control panel (*Macintosh*) or by the Region control panel (*Windows*).

Alternatively, you can choose to use a common date format or a custom date format. Here is what the dialog looks like if the Use Common Format radio button is selected:



Date Format for Tables

○ Use Format Set By System Regional Settings Control Panel

● Use Common Format: Year-Month-Day

○ Use Custom Format

Year: 4 digit

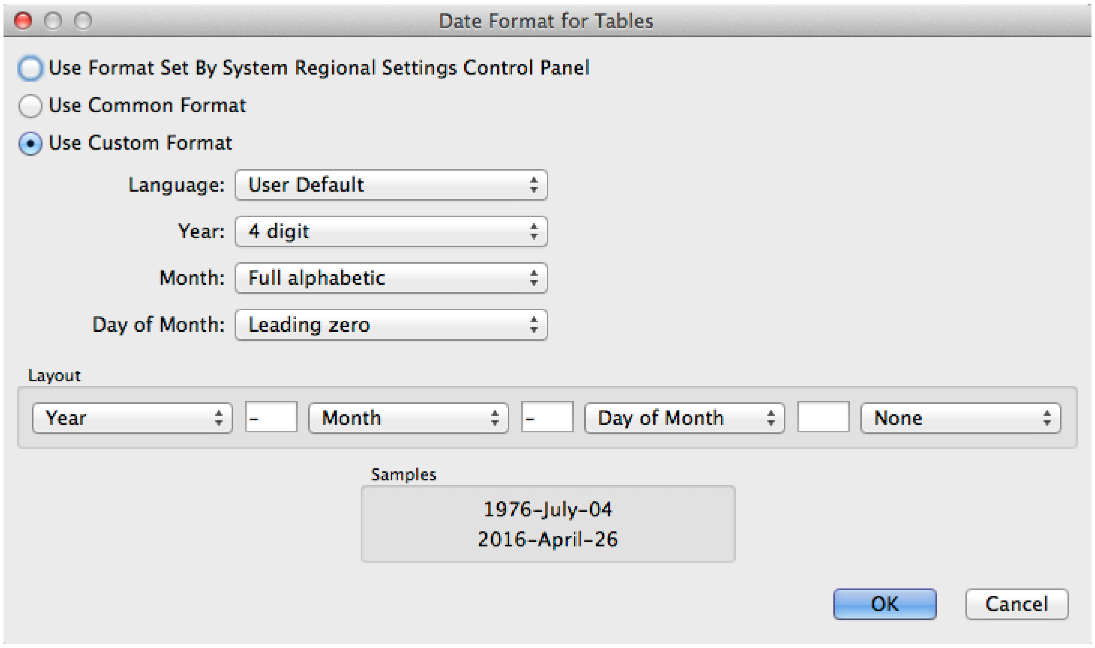
Month: Numeric, leading zero

Day of Month: Leading zero

Samples

1976-07-04
2016-04-26

You can access even more flexibility in those rare cases where it's needed by clicking the Use Custom Format radio button:



Date Format for Tables

○ Use Format Set By System Regional Settings Control Panel

○ Use Common Format

● Use Custom Format

Language: User Default

Year: 4 digit

Month: Full alphabetic

Day of Month: Leading zero

Layout

Year | - | Month | - | Day of Month | | None

Samples

1976-July-04
2016-April-26

When using a common or custom date format that includes separators (e.g., 10/05/99 or 10.05.99), Igor is lenient about the number of digits in the year and whether or not leading zeros are used. Igor will accept two or four digit years and leading zeros or no leading zeros for the year, month, and day of month. However, when using a format with no separators (e.g., 991005 or 19991005), Igor requires that you enter the date exactly as the format specifies.

When you enter a value in the first unused column in a table, Igor must deduce what kind of value you are entering (number, date, time, date/time, or text). It then sets the column format appropriately and interprets what you have entered accordingly. An ambiguity occurs if you use date formats with no separators. For example, if you enter 991005, are you trying to enter a date or a number? Igor has no way to know. Therefore, if you want to create a new column consisting of dates with no separators, you must choose Date from the Table Format submenu before you enter the value. This is not necessary for dates that include separators because Igor can distinguish them from numbers.

If you choose a date format that includes alphabetic characters, such as “October 11, 1999”, you must enter dates exactly as the format indicates, including spaces.

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-85.

Special Values

There are two special values that can be entered in any numeric data column. They are NaN and INF.

Missing Values (NaNs)

NaN stand for “Not a Number” and is the value Igor uses for missing or blank data. Igor displays NaNs in a table as a blank cell. NaN is a legal number in a text data file, in text pasted from the clipboard, and in a numeric expression in Igor’s command line or in a procedure.

A point will have the value NaN when a computation has produced a meaningless result, for example if you take the log of a negative number. You can enter a missing value in a cell of a table by entering NaN or by deleting all of the text in the entry line and confirming the entry.

You can also get NaNs in a wave if you load a delimited text data file or paste delimited text which contains two delimiters with no number in between.

Infinities (INFs)

INF stands for “infinity”. Igor displays infinities in a table as “INF”. INF is a legal number in a text data file, in text pasted from the clipboard and in a numeric expression in Igor’s command line or in a procedure.

A point will have the value INF or -INF when a computation has produced an infinity, for example if you divide by zero. You can enter an infinity in a cell of a table by entering INF or -INF.

Clearing Values

You invoke the clear operation by choosing Edit→Clear from. Clear sets all selected cells in numeric columns to zero. It sets all selected cells in text and dimension label columns to "" (empty string). It has no effect on selected cells in index columns.

To set a block of numeric values to NaN (or any other numeric value), select the block and then choose Analysis→Compose Expression. In the resulting dialog, choose “_table selection_” from the Wave Destination pop-up menu. Enter “NaN” as the expression and click Do It.

Copying Values

You invoke the copy operation by choosing Edit→Copy. This copies all selected cells to the clipboard as text and as Igor binary. It is useful for copying ranges of points from one wave to another, from one part of a wave to another part of that wave, and for exporting data to another application or to another Igor experiment (see **Exporting Data from Tables** on page II-252).

Copying and pasting in Igor tables uses the binary version of the data which represents the data with full precision and also includes wave properties such as scaling and units. If you paste anywhere other than an Igor table, for example to an Igor notebook or to another program, the text version of the data is used.

For technical reasons relating to 64-bit support, the binary clipboard format is different from the Igor Pro 6 format. Consequently you can not copy/paste binary table data between these versions.

The text version of the copied data uses as many digits as needed to represent the data with full precision. If you want to export text exactly as shown in the table you must use the Save operation with the /F flag, or File→Save Table Copy, or the **SaveTableCopy** operation.

You can also create new waves by copying data from existing waves. This is described earlier in this chapter under **Creating New Waves by Pasting Data from Igor** on page II-240.

See also **Multidimensional Copy/Cut/Paste/Clear** on page II-265.

Cutting Values

You invoke the cut operation by choosing Edit→Cut. Cut starts by copying all selected cells to the clipboard as text and as Igor binary. Then it deletes the selected points from their respective waves, thereby shortening the waves.

You cannot cut sections of an index column since index values are computed based on point numbers, not stored. However, if you cut a section of a data or dimension label column, the index column corresponding to the data column will also be shortened.

Pasting Values

You invoke the paste operation by choosing Edit→Paste. There are three kinds of paste operations: a replace-paste, an insert-paste and a create-paste.

Paste Type	What You Do	What Igor Does
Replace-paste	Choose Paste.	Replaces the selected cells with data from the clipboard.
Insert-paste	Press Shift and choose Paste.	Inserts data from clipboard as new cells.
Create-paste	Select the first cell in the first unused column and then choose Paste.	Creates new waves containing clipboard data.

When dealing with multidimensional waves, there are other options. See **Multidimensional Copy/Cut/Paste/Clear** on page II-265 for details.

When you do a paste, Igor starts by figuring out how many rows and columns of values are in the clipboard. The clipboard may contain binary data that you just copied from an Igor table or it may contain plain text data from another application such as a spreadsheet or a text editor.

If the data in the clipboard is plain text, Igor expects that rows of values be separated by carriage return characters, linefeed characters, or carriage return/linefeed pairs and that individual values in a row be separated by tabs or commas. This is normally no problem since most applications export data as tab-delimited text. If you have trouble with a paste and are not sure about the format of the data in the clipboard, you can paste it into an Igor notebook to inspect or edit it.

Once Igor has figured out how many rows and columns are in the clipboard, it proceeds to paste those values into the table and therefore into the waves that the table displays.

If you select the first cell in the first unused column, the paste will be a create-paste. In this case, Igor makes new waves, appends them to the table and then stores the data in the clipboard in the new waves. It makes one new wave for each column of text in the clipboard. If the text starts with a row of column names, Igor uses this row as the basis for the names of the new waves. Otherwise Igor uses default wave names.

Mismatched Number of Columns

If the number of columns in the clipboard is not the same as the number of columns selected in the table then Igor asks you how many columns to paste. This applies to the replace-paste but not to the insert-paste or create-paste.

For example, if you have M columns of text in the clipboard but you select N columns and then do a paste, Igor presents presents the Columns to Paste dialog which gives you two options:

- Paste M columns using the current selection
- Change the selection and paste N columns

Mismatched Number of Rows

If the number of rows in the clipboard is not the same as the number of rows selected in the table then Igor asks you how many rows to paste. This applies to the replace-paste but not to the insert-paste or create-paste.

For example, if you have M rows of text in the clipboard but you select N rows and then do a paste, Igor presents the Rows to Paste dialog which gives you three options:

- Paste M rows using the current selection
- Change the selection and paste N rows
- Replace the selected N rows with M rows from the clipboard

Pasting and Index Columns

Since the values of an index column are computed based on point numbers, they can not be altered by pasting. However, if index columns and data columns are adjacent in a range of selected cells, a paste can still be done. The data values will be altered by the paste but the index values will not be altered.

Pasting and Column Formats

When you paste plain text data into existing numeric columns, Igor tries to interpret the text in the clipboard based on the numeric format of the columns. For example, if a column is formatted as dates then Igor tries to interpret the data according to the table date format. If the column is formatted as time then Igor tries to interpret the text as a time values (e.g., 10:00:00). If the column has a regular number format, Igor tries to intrepret the text as regular numbers.

When you paste plain text data into unused columns, Igor does a create-paste. In this case, Igor inspects the text in the clipboard to determine if the data is in date format, time format, date and time format or regular number format. When it appends new columns to the table, it applies the appropriate numeric format.

When pasting octal or hexadecimal text in a table, you must first set the column format to octal or hexadecimal so that Igor will correctly interpret the text.

If the column does not appear to be in any of these formats, Igor creates a text wave rather than a numeric wave.

See **Date Values** on page II-245 for details on entering dates.

Copy-Paste Waves

You can copy and paste entire waves within Igor. This is described under **Creating New Waves by Pasting Data from Igor** on page II-240.

Inserting and Deleting Points

In addition to pasting and cutting, you can also insert and delete points from waves using the Insert Points and Delete Points dialogs via the Data menu or via the Table pop-up menu. You can use these dialogs to modify waves without using a table but they do work intelligently when a table is the top window.

Finding Table Values

You can search tables for specific contents by choosing Edit→Find. This displays the Find In Table dialog.

Find In Table can search the current selection in the active table, the entire active table or all table windows. You control this using the right-hand pop-up menu at the top of the dialog.

The All Table Windows mode searches standalone table windows only. It does not search table subwindows. It is possible to search a table subwindow in a control panel using the Top Table mode. Searching in tables embedded in graphs and page layouts is not supported.

Find In Table can search for the following types of values which you control using the left-hand pop-up menu.

Find Type	Description
Row	Displays the specified row but does not select it.
Text String	Finds the specified text string in any type of column: text, numeric, date, time, date/time, and dimension labels. For example, searching for “-1” would find numeric cells containing -1.234 and -1e6. A given cell is found only once, even if the search string occurs more than once in that cell. The target string is limited to 254 bytes.
Blank Cell	Finds blank cells in any type of column: text, numeric, date, time, date/time, and dimension labels. Finds blank cells in numeric columns (NaNs) and text columns (text elements containing zero characters).
Numeric Value	Finds numeric values within the specified range in numeric columns only. Does not search the following types of columns: text, date, time, date/time, and dimension labels.
Date	Finds date values within the specified range in date and date/time columns only. Does not search the following types of columns: text, numeric, time and dimension labels. Accepts input of dates in the format specified by Table Date Format dialog (Table menu).
Time of Day	Finds a time of day within the specified range in time and date/time columns only. Does not search the following types of columns: text, numeric, date and dimension labels. A time of day is a time between 00:00:00 and 24:00:00. Times are entered as hh:mm:ss.ff with the seconds part and fractional part optional.
Elapsed Time	Finds an elapsed time within the specified range in time columns only. Does not search the following types of columns: text, numeric, date, date/time and dimension labels. Unlike a time of day, an elapsed time can be negative and can be greater than 24:00:00. Times are entered as hh:mm:ss.ff with the seconds part and fractional part optional.
Date/Time	Finds a date/time within the specified range in date/time columns only. Does not search the following types of columns: text, numeric, date, time and dimension labels. Date/time values consist of a date, a space and a time.

Find In Table does not search the point column.

The search starts from the “anchor” cell. If you are searching the top table or the current selection, the anchor cell is the target cell. If you are searching all tables, the anchor cell is the first cell in the first-opened table, or the last cell in the last-opened table if you are doing a backward search.

When you do an initial search via the Find dialog, the search includes the anchor cell. When you do a subsequent search using Find Again, the search starts from the cell after the anchor cell, or before it if you are doing a backward search.

A find in the top table starts from the target cell and proceeds forward or backward, depending on the state of the Search Backwards checkbox. The search stops when it hits the end or beginning of the table, unless Wrap Around Search is enabled, in which case the whole table is searched.

A find in the current selection also starts from the target cell and proceeds forward or backward, depending on the state of the Search Backwards checkbox. The search stops when it hits the end or beginning of the selection, unless Wrap Around Search is enabled, in which case the whole selection is searched.

If Search Rows First is selected, all rows of a given column are searched, then all rows of the next column. If Search Columns First is selected, all columns of a given row are searched, then all columns of the next row.

To do a search of a 3D or 4D wave, you must create a table containing just that wave. Then the Table Find will search the entirety of the wave. If the table contains more than one wave, the Table Find will not search the parts (e.g. other layers of a 3D wave) of a 3D or 4D wave that are not shown in the table.

Choosing the Edit→Find Selection menu sets the Find mode to Find Text String, Find Blank Cells, Find Numeric Value, Find Date, Find Time Of Day, Find Elapsed Time, or Find Date/Time based on the format of the target cell except that, if the target cell is blank, the mode is set to Find Blank Cells regardless of the cell's format.

You may find it convenient to use Find Again (Command-G on Macintosh, Ctrl+G on Windows) after doing an initial find to find subsequent cells with the specified contents. Pressing Shift (Comand-Shift-G on Macintosh, Ctrl+Shift+G on Windows) does a Find Again in the opposite direction.

Replacing Table Values

You can perform a mass replace in a table by choosing Edit→Replace. This displays the Replace In Table dialog.

Unlike Find In Table, which can search all tables, Replace In Table is limited to the top table or the current selection, as set by the right-hand pop-up menu.

When you click Replace All, Replace In Table first finds the specified cell contents using the same rules as Find In Table. It then replaces the contents with the specified replace value. It then continues searching and replacing until it hits the end of the table or selection, unless Wrap Around Search is enabled, in which case the whole table or selection is searched.

You can undo all of the replacements by choosing Edit→Undo Replace.

Replace In Table does not affect X columns. You must use the Change Wave Scaling dialog (Data menu) for that.

Replace In Table goes through each candidate cell looking for the specified search value. If it finds the value, it extracts the text from the cell and does the replacement on the extracted text. If the resulting text is legal given the format of the cell, the replacement is done. If it is not legal, Replace In Table stops and displays an error dialog showing where the error occurred.

Here are some additional considerations regarding Replace In Table.

Find Type	Description
Text String	In each cell, all occurrences of the find string are replaced with the replace string. For example, if you replacing "22" with "33" and a cell contains the value 122.223, the resulting value will be 133.333. The replace string is limited to 254 bytes. Using text string replace, it is possible to come up with a value that is not legal given a cell's formatting. For example, if you replace "22" with "9.9" in the example above, you get "19.9.9.93". This is not a legal numeric value so Replace In Table displays an error dialog.
Date	You can replace a date in a date column or a date/time column. When replacing a date in a date/time column, the time component is not changed. Dates must use the format specified by the Table Date Format dialog (Table menu).
Time of Day	You can replace a time of day in a time column or a date/time column. When replacing a time of day in a date/time column, the date component is not changed.

Selectively Replacing Table Values

The Replace In Table dialog is designed to do a mass replace. You can do a selective replace using the Find In Table dialog followed by a series of Find Again and Paste operations. Here is the process:

1. Choose Edit→Find and find the first cell containing the value you want to replace.
2. Edit that cell so it contains the desired value.
3. Copy that cell’s contents to the clipboard.
4. Do Find Again (Command-G on Macintosh, Ctrl+G on Windows) to find the next cell you might want to replace.
5. If you want to replace the found cell, do Paste (Command-V on Macintosh, Ctrl+V on Windows).
6. If not done, go back to step 4.

Exporting Data from Tables

You can use the clipboard to export data from an Igor table to another application. If you do this you must be careful to preserve the precision of the exported data.

When you copy data from an Igor table, Igor puts the data into the clipboard in two formats: tab-delimited text and Igor binary.

If you later paste that data into an Igor table, Igor uses the Igor binary data so that you retain all precision through the copy-paste operation.

If you paste the data into another application, the other application uses the text data that Igor stored in the clipboard. To prevent losing precision, Igor uses enough digits to represent the data with full precision.

You can also export data via files by choosing Data→Save Waves→Save Delimited Text or File→Save Table Copy.

Changing Column Positions

You can rearrange the order of columns in the table. To do this, position the cursor over the name of the column that you want to move. Press Option (*Macintosh*) or Alt (*Windows*) and the cursor changes to a hand. If you now click the mouse you can drag an outline of the column to its new position.

When you release the mouse the column will be redrawn in its new position. Igor always keeps all of the columns for a particular wave together so if you drag a column, you will move all of the columns for that wave.

The point column can not be moved and is always at the extreme left of the cell area.

Changing Column Widths

You can change the width of a column by dragging the vertical boundary to the right of the column name.

You can influence the manner in which column widths are changed by pressing certain modifier keys.

If Shift is pressed, all table columns except the Point column are changed to the same width.

The Command (*Macintosh*) or Ctrl (*Windows*) key determines what happens when you drag the boundary of a data column of a multidimensional wave. If that key is not pressed, all data columns of the wave are set to the same width. If that key is pressed then just the dragged column is changed.

Autosizing Columns By Double-Clicking

You can autosize a column by double-clicking the vertical boundary to the right of the column name.

You can influence the manner in which column widths are changed by pressing certain modifier keys.

If the no modifier keys are pressed and you double-click the boundary of a data column of a multidimensional wave then the width of each data column is set individually.

When pressing Option (*Macintosh*) or Alt (*Windows*) and you double-click the boundary of a data column of a multidimensional wave then the width of all data columns are set the same.

If Shift is pressed, all table columns except the Point column are autosized. Shift pressed with Option (*Macintosh*) or Alt (*Windows*) will autosize all data columns of a given wave to the same width.

When pressing Command (*Macintosh*) or Ctrl (*Windows*), only the double-clicked column is autosized, not all data columns of a multidimensional wave.

Autosizing Columns Using Menus

You can autosize columns by selecting them and choosing Autosize Columns from the Table menu or from the table popup menu in the top-right corner of the table. You can also choose Autosize Columns from the contextual menu that you get when you Control-click (*Macintosh*) or right-click (*Windows*) on a column.

You can influence the manner in which column widths are changed by pressing certain modifier keys.

If the no modifier keys are pressed and a data column of a multidimensional wave is selected, all data columns of that wave are set individually.

If Option (*Macintosh*) or Alt (*Windows*) is pressed and a data column of a multidimensional wave is selected, all data columns of that wave are set the same.

If Shift is pressed, all table columns except the Point column are autosized. Shift pressed with Option (*Macintosh*) or Alt (*Windows*) will autosize all data columns of a given wave to the same width.

When pressing Command (*Macintosh*) or Ctrl (*Windows*), only the selected columns are autosized, not all data columns of a multidimensional wave.

Autosizing Limitations

When you autosize a column, the width of every cell in that column must determined. For very long columns (100,000 points or more), this may take a very long time. When this happens, cell checking stops and the autosize is based only on the checked cells.

Similarly, if you autosize the data columns of a multidimensional wave with a very large number of columns (10,000 or more columns), this could take a very long time. When this happens, columns checking stops and the autosize is based only on the checked columns.

If the default time limits are not suitable, use the ModifyTable autosize keyword to set the time limits.

Changing Column Styles

You can change the presentation style of columns in a table using the Modify Columns dialog, the Table menu in the main menu bar, the Table pop-up menu (gear icon), or the contextual menu that you get by right-clicking.

You can invoke the Modify Columns dialog from the Table menu, from the Table pop-up menu, from the contextual menu, or by double-clicking a column name.

You can select one or more columns in the Columns to Modify list. If you select more than one column, the items in the dialog reflect the settings of the first selected column.

Once you have made your selection, you can change settings for the selected columns. After doing this, you can then select a different column or set of columns and make more changes. Igor remembers all of the changes you make, allowing you to do everything in one trip to the dialog.

There is a shortcut for changing a setting for all columns at once without using the dialog: Press Shift while choosing an item from the Table menu, from the Table pop-up menu, or from the contextual menu.

Tables are primarily intended for on-screen data editing. You can use a table for presentation purposes by exporting it to another program as a picture or by including it in a page layout. However, it is not ideal for this purpose. For example, there no way to change the background color or the appearance of gridlines.

You can capture your favorite styles as preferences. See **Table Preferences** on page II-272.

Modifying Column Properties

You can independently set properties, such as color, column width, font, etc., for the index or dimension label column and the data column of 1D waves. Except in rare cases all of the data columns of a multidimensional wave should have the same properties. When you set the properties of one data column of a multidimensional wave using Igor's menus or using the Modify Columns dialog, Igor sets the properties of all data columns the same.

For example, if you are editing a 3 x 3 2D wave and you set the first data column to red, Igor will make the second and third data columns will red too.

Despite Igor's inclination to set all of the data columns of a multidimensional wave the same, it is possible to set them differently. Select the columns to be modified. Press Command (*Macintosh*) or Ctrl (*Windows*) before clicking the Table menu or Table pop-up menu and make a selection. Your selection will be applied to the selected columns only instead of to all data columns from the selected waves.

The ModifyTable operation supports a column number syntax that designates a column by its position in the table. Using this operation, you can set any column to any setting. For example:

```
Make/O/N=(3,3) mat
Edit mat
ModifyTable rgb[1]=(50000,0,0), rgb[2]=(0,50000,0)
```

This sets mat's first data column to red and its second to blue.

You can specify a range of columns using column number syntax:

```
ModifyTable rgb[1,3]=(50000,0,0)
```

The Modify Columns dialog sets the properties for both the real and imaginary columns of complex waves at the same time. If you really want to set the properties of the real and imaginary columns differently, you must use the column number syntax shown above.

Column Titles

The column title appears at the top of each column. By default, Igor automatically derives the column title from the name of the wave displayed in the column. For example, if we display the X index and data values of wave1 and data values of wave2, the table will have columns titled wave0.x, wave0.d, and wave1.

Igor uses the suffixes ".x" and ".d" only if this is necessary to distinguish columns. If there is no index column displayed, Igor omits the suffix.

Using the Title setting in the Modify Columns dialog, you can replace the automatically derived title with a title of your own. Remove all text from this item to turn the automatic title back on.

The title setting changes *only* the title of the column in this table. It does not change wave name. We provide the column title setting primarily to make tables look better in presentations (in layouts and exported pictures). If you are not using a table for a presentation, it is better to let Igor automatically generate column titles since this has less potential for confusion. If you want to rename a wave, use the Rename items in the Data and Table pop-up menus.

If you really need to use column titles for multidimensional waves, use the techniques described in **Modifying Column Properties** on page II-254 to set the title for individual columns.

Numeric Formats

Columns in tables display either text or numeric waves. For numeric waves, the column format determines how the data values in the wave are entered and displayed. The column format has no effect on data columns of text waves.

In addition to regular number formats, tables support date, time and date&time formats. The format is merely a way of displaying a number. Even dates and times are stored internally in Igor as numbers. You can enter a value in a numeric column of a table as a number, date, time or date&time if you set the format for the column appropriately.

The following table lists all of the numeric formats.

Numeric Format	Description
General	Displays numbers in a format appropriate to the number itself. Very large or small numbers are displayed in scientific notation. Other numbers are displayed in decimal form (e.g. 1234.567). The Digits setting controls the number of significant digits. Integers are displayed with no fractional digits.
Integer	Numbers are displayed as the nearest integer number. For example, 1234.567 is displayed as 1235.
Integer with comma	Numbers are displayed as the nearest integer number. In addition, commas are used to separate groups of three digits. For example, 1234.567 is displayed as 1,235.
Decimal	As many digits to the left of the decimal point as are required are used to display the number. The Digits setting controls the number of digits to the right of the decimal point. For example, if the number of digits is specified as two, 1234.567 is displayed as 1234.57.
Decimal with comma	Identical to the decimal format except that commas are used to separate groups of three digits to the left of the decimal point.
Scientific	Numbers are displayed in scientific notation. The Digits setting controls the number of digits to the right of the decimal point.
Date	Dates are displayed using the format set in the Table Date Format dialog. See **Date/Time Formats** on page II-256.
Time	[+][-]hhhh:mm:ss[.ff] [AM/PM]. See **Date/Time Formats** on page II-256.
Date & Time	Date format plus space plus time format. See **Date/Time Formats** on page II-256.
Octal	Numbers are displayed in octal (base 8) notation. Only integers are supported. The number of digits displayed depends on the wave data type and the Digits setting is ignored. See **Octal Numeric Formats** on page II-257 for details.
Hexadecimal	Numbers are displayed in hexadecimal (base 16) notation. Only integers are supported. The number of digits displayed depends on the wave data type and the Digits setting is ignored. See **Hexadecimal Numeric Formats** on page II-257 for details.

When you enter a number in a table, Igor expects either dot or comma as the decimal symbol, as determined by the Decimal Symbol setting in the Table Misc Settings dialog. The factory default is dot. This setting applies only to entering numbers in tables. To change it, choose Table→Table Misc Settings. If it is set to Per System Setting and you change the system decimal symbol, you must restart Igor for the change to take effect.

For most numeric formats you can control the number of digits displayed. You can set this using the Modify Columns dialog or using the Digits submenu of the Table menu, table pop-up menu (gear icon), or table contextual menu. The meaning of the number that you choose from the Digits submenu depends on the numeric format.

Numeric Format	You Specify
General	Number of displayed digits
Decimal (0.0...0)	Number of digits after the decimal point
Decimal with comma (0.0...0)	Number of digits after the decimal point
Time and Date&Time	Number of digits after the decimal point when displaying fractional seconds
Scientific (0.0...0E+00)	Number of digits after the decimal point
Octal	Total number of octal digits to display.
Hexadecimal	Total number of hexadecimal digits to display.

The Digits setting has no effect on columns displayed using the integer, octal and hexadecimal formats and also has no effect on columns displaying text waves. It affects time and date/time formats only if the display of fractional seconds is enabled.

With the General format, you can choose to display trailing zeros or not.

With the time format, Igor accepts and displays times from -9999:59:59 to +9999:59:59. This is the supported range of elapsed times. If you are entering a time-of-day rather than an elapsed time, you should restrict yourself to the range 00:00:00 to 23:59:59.

With the Time and Date&Time formats, you can choose to display fractional seconds. Most people dealing with time data use whole numbers of seconds. Therefore, by default, a table does not show fractional seconds. If you want to see fractional seconds in a table, you must choose Show Fractional Seconds from the Table→Format menu. Once you do this, the Table→Digits menu controls the number of digits that appear in the fractional part of the time.

If you always want to see fractional seconds, use the Capture Table Prefs dialog to capture columns whose Show Fractional Seconds setting is on. This applies to tables created after you capture the preference.

When displaying fractional seconds, Igor always displays trailing zeros and the Show Trailing Zeros menu item in the Table→Format menu has no effect.

When choosing a format, remember that single precision floating point data stores about 7 decimal digits and double-precision floating point data stores about 16 decimal digits. If you want to inspect your data down to the last decimal place, you need to select a format with enough digits.

The format does not affect the precision of data that you export via the clipboard from a table to another application. See **Exporting Data from Tables** on page II-252.

Date/Time Formats

As described under **Date Values** on page II-245, the way you enter dates in tables and the way Igor displays them is controlled by the Table Date Format dialog which you invoke through the Table menu. This dialog sets a global preference that determines the date format for all tables. By factory default, the table date format is controlled by the system Regional Settings control panel.

If you set the column format to time, then Igor displays time in elapsed time format. You can enter elapsed times from -9999:59:59 to +9999:59:59. You can precede an elapsed time with a minus sign to enter a negative elapsed time. You can also enter a fractional seconds value, for example 31:35:20.19. To view fractional seconds, choose Show Fractional Seconds from the Format submenu of the Table menu.

You can also enter times in time-of-day format, for example 1:45 PM or 1:45:00 PM or 13:45 or 13:45:00. A space before the AM or PM is allowed but not required. AM and am have no effect on the resulting time. PM adds 12 hours to the time. PM has no effect if the hour is already 12 or greater.

Igor stores times the same way whether they are time-of-day times or elapsed times. The difference is in how you think of the value and how you choose to display it in a graph.

Here are some valid time-of-day times:

```
00:00:00 (midnight)           12:00:00 (noon)
06:30:00 (breakfast time)     18:30:00 (dinner time)
06:30 (breakfast time)        18:30 (dinner time)
06:30 PM (dinner time)        18:30 PM (dinner time)
```

Here are some valid elapsed times:

```
-00:00:10    (T minus 10 and counting)
72:00:00     (an elapsed time covering three days)
4:17:33.25   (an elapsed time with fractional seconds)
```

The format for a date/time wave in a table defaults to Date, Time, or Date/Time depending on the content of the wave.

For displaying date/time data in a graph, see **Date/Time Axes** on page II-315.

Octal Numeric Formats

You can format any numeric column in a table as octal. Igor ignores the digits setting for columns displayed as octal and always displays all digits required for the supported range of values.

For floating point waves (single-precision and double-precision), negative values are displayed using a minus sign as this is necessary to accurately present the wave value. For example, -1 is displayed as -00000001.

It is possible to store in floating point waves a value that can't be displayed in octal because the value is fractional or exceeds the supported range of values. In these cases, the table will display an error message such as "# Can't format fractional value as octal" or "# Value too large to display as octal".

If you are using a floating point wave for data you think of as integer data of a given size, consider redimensioning the wave to the appropriate integer type using the **Redimension** operation. For example, if you are storing 16-bit signed integer data in a floating point wave, consider redimensioning the wave as 16-bit signed integer to get a more appropriate octal display in a table.

Hexadecimal Numeric Formats

You can format any numeric column in a table as hexadecimal. Igor ignores the digits setting for columns displayed as hexadecimal and always displays all digits required for the supported range of values.

For floating point waves (single-precision and double-precision), negative values are displayed using a minus sign as this is necessary to accurately present the wave value. For example, -1 is displayed as -00000001.

It is possible to store in floating point waves a value that can't be displayed in hexadecimal because the value is fractional or exceeds the supported range of values. In these cases, the table will display an error message such as "# Can't display fractional value as hex" or "# Value too large to display as hex".

Although SP waves are displayed as 32 bits using 8 hex digits, they have only 24 bits of precision so not all values greater than 2^24 (16,777,216) can be represented by an SP wave.

If you are using a floating point wave for data you think of as integer data of a given size, consider redimensioning the wave to the appropriate integer type using the **Redimension** operation. For example, if you are storing 16-bit signed integer data in a floating point wave, consider redimensioning the wave as 16-bit signed integer to get a more appropriate hexadecimal display in a table.

Object Reference Wave Formatting

This section is for advanced users only.

In addition to text and numeric waves, tables can also display object reference waves. An object reference wave is a WAVE wave or a DFREF wave.

The elements of object reference waves are displayed with full precision either as decimal integer, hexadecimal, or octal. If the column format is integer or octal, the column is displayed as integer or octal. If the column format is any other format, including general, decimal, scientific, date, time, and date&time, the column is displayed as hexadecimal.

Editing Text Waves

You can create a text wave in a table by clicking in the first unused cell and entering non-numeric text. For the most part, editing a text wave is self-evident. However, there are some issues, mostly relating to special characters or large amounts of text, that you may run into.

Large Amounts of Text in a Single Cell

A text wave is handy for storing short descriptions of corresponding data in numeric waves. In some cases, you may find it useful to store larger amounts of text. There is no limit on the number of characters in a point of a text wave. However, the entry area of a table can display no more than 100,000 bytes. You cannot edit in a table a cell containing more than 100,000 bytes.

The Edit Text Cell Dialog

You edit numeric wave data using the table entry line. To edit text wave data, you can use the the table entry line or the Edit Text Cell dialog. The dialog is convenient for editing multi-line data. It is also convenient for editing text to be used for annotations.

When a text wave cell is selected, an icon appears at the right end of the table entry line. Click the icon to invoke the dialog.

The next section discusses using the Edit Text Cell dialog to edit tabs and terminators.

Tabs, Terminators and Other Control Characters

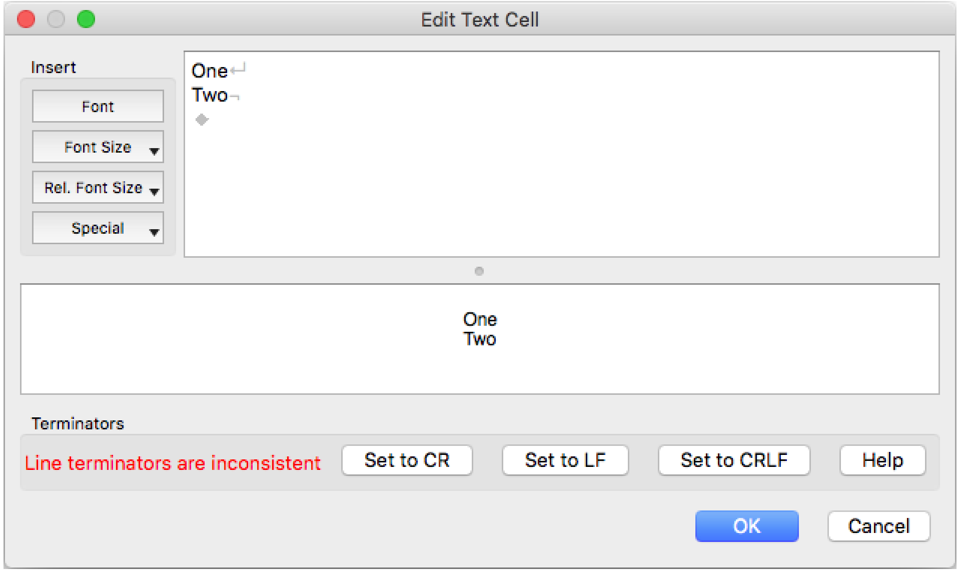
In rare cases, you may want to store text containing control characters such as tabs and terminators (carriage-returns and linefeeds) in text waves. You can’t enter such characters in the table entry line, but you can enter them using the Edit Text Cell dialog. To display the dialog, click the icon at the right end of the table entry line. This icon appears only when you are editing an existing text wave.

You can display whitespace characters (tabs, spaces, and terminators) in the Edit Text Cell dialog by right-clicking in the text entry area and choosing Settings→Show Whitespace. This is recommended for editing multi-line text. Tabs and terminators are identified with these symbols:

→	Tab
↵	Carriage-return (CR) For historical reasons, CR is the Igor-standard line terminator. Text for use within Igor should have CR terminators.

¬	Linefeed (LF) LF is the Unix-standard line terminator. Text for use with Unix programs should have LF terminators.
¶	Carriage-return/linefeed (CRLF) CRLF is the Windows-standard line terminator. Text for use with Windows programs should have CRLF terminators.

When the dialog's text entry area includes one or more terminators, buttons appear that allow you to change terminators:



Edit Text Cell

```
One↵
Two¬
```

One
Two

Terminators

Line terminators are inconsistent

You can also enter control characters by executing a command. For example:

```
textWave0[0] = "Hello\tGoodbye"      // Text with tab character
```

Use \t for tab, \r for carriage-return, and \n for linefeed.

You can examine what is in a text wave by printing it from the command line:

```
Print textWave0
```

This displays tabs, carriage-returns and linefeeds using escape sequences.

Editing Invalid Text

Some patterns of bytes are invalid in some text encodings. For example, this command creates a UTF-8 text wave with invalid text:

```
// "\xFE" represents a single byte with value 0xFE
Make/O/T test = {"A", "\xFE", "C"}
```

Point 1 of the wave is invalid because, in UTF-8, any byte outside the range 0x00..0x7F must be part of a multi-byte character. Invalid bytes are displayed in table cells using the Unicode replacement character.

The most likely way for this situation to arise is if you have a text wave containing MacRoman, Windows-1252 or Shift JIS text but the wave's text encoding is mistakenly set to UTF-8. In this case, you can either edit the wave to remove the invalid text or correct Igor's notion of the wave's text encoding using Misc→Text Encodings→Set Wave Text Encoding. In this section we assume that you want to edit the wave.

If you click a cell containing invalid text, Igor displays a yellow warning icon. If you attempt to edit the cell contents, Igor displays a warning dialog.

When the yellow warning icon is visible, the entry line works in a special mode. Each invalid byte in the cell is represented by a `\x` escape code. In the example above, if you click the cell representing point 1 of the wave, Igor displays `\xFE` in the entry area.

While editing the text, in most cases you will want to remove the escape sequences.

If you accept the text in the entry area, Igor converts any remaining `\x` escape sequences back to the bytes which they represent. In the example above, assuming that you started the editing process, made no changes in the entry line, and accepted the text, the contents of the cell would be the same after editing as they were before.

This use of escape sequences in tables applies only when the yellow warning icon is visible, indicating that the cell contained invalid text when you selected it. It applies only to `\x` escape sequences, not to other escape sequences such as `\t` (tab), `\r` (carriage-return) or `\n` (linefeed). If the yellow warning icon is not visible, there is no special treatment of escape sequences.

For expert debugging purposes, you can get a hex dump of text wave and dimension label cell contents by double-clicking the yellow warning icon. You can also get a hex dump whether the warning icon is visible or not by pressing Cmd (*Macintosh*) or Ctrl (*Windows*) and double-clicking a cell. The hex dump is printed in the history area of the command window.

See also Chapter III-16, **Text Encodings**, **Wave Text Encodings** on page III-472.

Editing Control Characters

Control characters are special non-printing characters created in olden times for controlling teletype machines and similar equipment. The ASCII codes for control characters, expressed as hexadecimal, fall in the range 0x00 to 0x1F, except for 0x7F which is the delete control character.

Other than tab (0x09), CR (carriage-return-0x0D) and LF (linefeed-0x0A), control characters have little use and rarely appear in modern computer text. When they do appear, it is often the result of an error or bug. Null (0x00) is used internally in many programs to mean “end-of-string” but should not appear in text documents.

In nearly all computer fonts, control characters are displayed as blanks. This makes it difficult to recognize and edit them, if they happen to appear in text whether on purpose or by error.

When Igor displays a control character in a table cell, it displays a “stand-in” symbol so that you can see what is there instead of seeing a blank. Here are some examples:

Character	ASCII Code	Stand-in Symbol (Unicode)
Tab	0x09	→ (U+2192)
CR	0x0D	↵ (U+21B5)
LF	0x0A	¬ (U+00AC)
CRLF	0x0D, 0x0A	¶ (U+00B6)
Null	0x00	␀ (U+2400)
Escape	0x1B	␛ (U+241B)

If you click a cell containing a control character, Igor displays a yellow warning icon. If you attempt to edit the cell contents, Igor displays a warning dialog.

When the yellow warning icon is visible, the entry line works in a special mode. If you edit and accept the text in the entry line, Igor converts any remaining stand-in symbols back to the control characters which they represent.

This use of stand-in symbols in tables applies only when the yellow warning icon is visible. If the yellow warning icon is not visible, there is no special treatment of these symbols.

You can disable use of stand-in symbols by unchecking the Use Special Symbols for Control Characters checkbox in the Tables section of the Miscellaneous Settings dialog. Except in rare cases, you should leave that setting checked.

Entering Special Characters

While editing a cell, you can enter special characters, such as Greek letters and math symbols, by choosing Edit→Characters to enter commonly-used characters such as Greek letters and math symbols or Edit→Special Characters to enter other characters.

If the wave whose element you are editing uses the UTF-8 text encoding, which is the default for waves created in Igor7 or later, then you can enter any character.

If the wave uses another text encoding then it is not possible to represent all characters. For example, the triple integral character, U+222D, can not be represented in MacRoman, Windows-1252, Shift JIS, or any other non-Unicode text encoding.

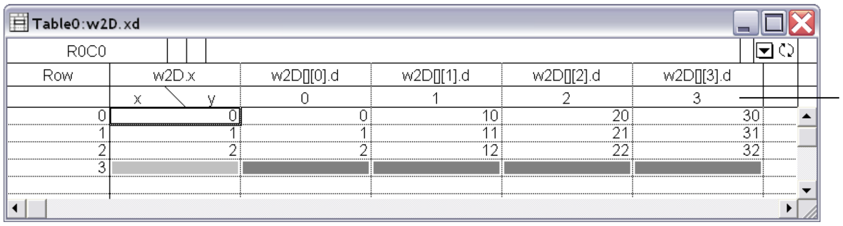
If you attempt to enter a character that can not be represented in the wave's text encoding, Igor displays an alert informing you of the problem. Your options are to omit that character or to convert the wave to UTF-8, using Misc→Text Encoding→Set Wave Text Encoding.

See also Chapter III-16, **Text Encodings**, **Wave Text Encodings** on page III-472.

Editing Multidimensional Waves

If you view a multidimensional wave in a table, Igor adds some items to the table that are not present for 1D waves. To see this, execute the following commands which create and display a 2D wave:

```
Make/O/N=(3,4) w2D = p + 10*q; Edit w2D.id
```



Row	w2D.x	w2D[][0].d	w2D[][1].d	w2D[][2].d	w2D[][3].d
	x y	0	1	2	3
0	0	0	10	20	30
1	1	1	11	21	31
2	2	2	12	22	32
3					

Horizontal index row.

The first column in the table is labeled Row, indicating that it shows row numbers. The second column contains the scaled row indices, which in this case are the same as the wave row numbers. The remaining columns show the wave data. Notice the name at the top of the first column of wave data: “w2D[][0].d”. The “w2D” identifies the wave. The “.d” specifies that the column shows wave data rather than wave indices. The “[][0]” identifies the part of the wave shown by this column. The “[]” means “all rows” and the “[0]” means column 0. This is derived from the syntax that you would use from Igor’s command line to store values into all rows of column 0 of the wave:

```
w2D[][0] = 123        // Set all rows of column 0 to 123
```

When displaying a multidimensional wave in a table, Igor adds a row to the table below the row of names. This row is called the horizontal index row. It can display either the scaled indices or the dimension labels for the wave elements shown in the columns below.

By default, if you view a 2D wave in a table and append the wave’s index column, Igor displays the wave’s row indices in a column to the left of the wave data and displays the wave’s column indices in the horizontal index row, above the wave data.

If you append the wave's dimension label column, Igor displays the wave's row labels in a column to the left of the wave data and displays the wave's column labels in the horizontal index row, above the wave data.

If you display neither index columns nor dimension labels, Igor still displays the wave's column indices in the horizontal index row.

If you want to show numeric indices horizontally and dimension labels vertically or vice versa, you can use the Table→Horizontal Index submenu to override the default behavior. For example, if you want dimension labels vertically and numeric indices horizontally, append the wave's dimension label column to the table and then choose Table→Horizontal Index→Numeric Indices.

In the example above, the row and column indices are equal to the row and column element numbers. You can set the row and column scaling of your 2D data to reflect the nature of your data. For example, if the data is an image with 5 mm resolution in both dimensions, you should use the following commands:

```
SetScale/P x 0, .005, "m", w2D; SetScale/P y 0, .005, "m", w2D
```

When you do this, you will notice that the row and column indices in the table reflect the scaling that you have specified.

1D waves have no column indices. Therefore, if you have no multidimensional waves in the table, Igor does not display the horizontal index row. If you have a mix of 1D and multidimensional waves in the table, Igor does display the horizontal index row but displays nothing in that row for the 1D waves.

When showing 1D data, Igor displays a column of point numbers at the left side of the table. This is called the Point column. When showing a 2D wave, Igor titles the column Row or Column depending on how you are viewing the 2D wave. If you have 3D or 4D waves in the table, Igor titles the column Row, Column, Layer or Chunk, depending on how you are viewing the waves.

It is possible to display a mix of 1D waves and multidimensional waves such that none of these titles is appropriate. For example, you could display two 2D waves, one with the wave rows shown vertically (the normal case) and one with the wave rows shown horizontally. In this case, Igor will title the Point column "Element".

You can edit dimension labels in the main body of the table by merely clicking in the cell and typing. However, you can't edit dimension labels in the horizontal index row this way. Instead you must double-click a label in this row. Igor then displays a dialog into which you can enter a dimension label. You can also set dimension labels using the SetDimLabel operation from the command line.

Changing the View of the Data

A table can display waves of dimension 1 through 4. A one dimensional wave appears as a simple column of numbers, or, if the wave is complex, as two columns, one real and one imaginary. A two dimensional wave appears as a matrix. In the one and two dimensional cases, you can see all of the wave data at once.

If you display a three dimensional wave in a table, you can view and edit only one slice at a time. To see this, execute the following commands:

```
Make/O/N=(5,4,3) w3D = p + 10*q + 100*r; Edit w3D.id
```

Initially you see the slice of the wave whose layer index is 0 — layer zero of the wave. You can change which layer you are viewing using the next layer and previous layer icons that appear in the top/right corner of the table or using keyboard shortcuts.

By analogy with the up-arrow and down-arrow keys as applied to the row dimension of a 1D wave, "up" means "previous layer" (lower index) and "down" means "next layer" (higher index).

To change the layer from the keyboard, press Option-Up Arrow (*Macintosh*) or Alt+Up Arrow (*Windows*) to view the previous layer and Option-Down Arrow (*Macintosh*) or Alt+Down Arrow (*Windows*) to view the next layer.

Pressing the Shift key reverses the direction for both the icons and the arrow keys.

If you know the index of the layer you want to view you can enter it directly in a dialog by pressing Command (*Macintosh*) or Ctrl (*Windows*) while clicking the next or previous layer icon.

If you display a four dimensional wave in a table, you can still view and edit only one layer at a time. You can change which layer you are viewing by using the icons or keyboard shortcuts described above. To view the previous chunk in the 4D wave, press Option (*Macintosh*) or Alt (*Windows*) while clicking the up icon or press Command-Option-Up Arrow (*Macintosh*) or Ctrl+Alt+Up Arrow (*Windows*). To view the next chunk, press Option or Alt while clicking the down icon or press Command-Option-Down Arrow or Ctrl+Alt+Down Arrow.

In addition to using the keyboard shortcuts, you can specify the layer and chunk that you want to use using the ModifyTable elements operation.

Changing the Viewed Dimensions

When you initially view a 3D wave in a table, Igor shows a slice of the wave in the rows-columns plane. The wave's rows dimension is mapped to the table's vertical dimension and the wave's columns dimension is mapped to the table's horizontal dimension.

Using the Choose Dimensions icon, which appears to the right of the layer icons, you can instruct Igor to map any wave dimension to the vertical table dimension and any other wave dimension to the horizontal table dimension. This is primarily of interest if you work with waves of dimension three or higher because you can view and edit any orthogonal plane in the wave. You can, for example, create a new wave that contains a slice of data from the 3D wave.

When you click the Choose Dimensions icon, Igor displays the Choose Dimensions dialog. This dialog allows you to specify how the dimensions in the wave are to be displayed in the table.

ModifyTable Elements Command

This section discusses choosing viewed dimensions using the ModifyTable "elements" keyword. You do not need to know about this unless you want a thorough understand of editing 3D and 4D waves and viewing them from different perspectives.

The best way to understand this section is to execute all of the commands shown.

Igor needs to know which wave dimension to map to the vertical table dimension and which wave dimension to map to the horizontal table dimension. In addition, for waves of dimension three or higher, Igor needs to know which element of the remaining dimensions to display.

The form of the command is:

```
ModifyTable elements(<wave name>) = (<row>,<column>,<layer>,<chunk>)
```

The parameters specify which element of the wave's rows, columns, layers and chunks dimensions you want to view. The value of each parameter may be an element number (0 or greater) or it may be a special value. There are three special values that you can use for any of the parameters:

-1	Means no change from the current value.
-2	Means map this dimension to the table's vertical dimension.
-3	Means map this dimension to the table's horizontal dimension.

In reading the following discussion, remember that the first parameter specifies how you want to view the wave's rows, the second parameter specifies how you want to view the wave's columns, the third parameter specifies how you want to view the wave's layers and the fourth parameter specifies how you want to view the wave's chunks.

If you omit a parameter, it takes the default value of -1 (no change). Thus, if you are dealing with a 2D wave, you can supply only the first two parameters and omit the last two.

To get a feel for this command, let’s start with the example of a simple matrix, which is a 2D wave.

```
Make/O/N=(3,3) wave0 = p + 10*q
Edit wave0.id
```

As you look down in the table, you see the rows of the matrix and as you look across the table, you see its columns. Thus, initially, the rows dimension is mapped to the vertical table dimension in the and the columns dimension is mapped to the horizontal table dimension. This is the default mapping. You can change this with the following command:

```
ModifyTable elements(wave0) = (-3, -2)
```

The first parameter specifies how you want to view the wave’s rows and the second parameter specifies how you want to view the wave’s columns. Since the wave has only two dimensions, the third and fourth parameters can be omitted.

The -3 in this example maps the wave’s rows to the table’s horizontal dimension. The -2 maps the wave’s columns to the table’s vertical dimension.

You can return the wave to its default view using:

```
ModifyTable elements(wave0) = (-2, -3)
```

When you consider a 3D wave, things get a bit more complex. In addition to the rows and columns dimensions, there is a third dimension — the layers dimension. When you initially create a table containing a 3D wave, it shows all of the rows and columns of layer 0 of the wave. Thus, as with the 2D wave, the rows dimension is mapped to the vertical table dimension and the columns dimension is mapped to the horizontal table dimension. You can control which layer of the 3D wave is displayed in the table using the icons and keyboard shortcuts described above, or using the ModifyTable elements keyword.

For example:

```
Make/O/N=(5,4,3) wave0 = p + 10*q + 100*r
ModifyTable elements(wave0)=(-2, -3, 1)   //Shows layer 1 of 3D wave
ModifyTable elements(wave0)=(-2, -3, 2)   //Shows layer 2 of 3D wave
```

In these examples, the wave’s layers dimension is fixed to a specific value whereas the wave’s rows and columns dimensions change as you look down or across the table. The term “free dimension” refers to a wave dimension that is mapped to either of the table’s dimensions. The term “fixed dimension” refers to a wave dimension for which you have chosen a fixed value.

In the preceding example, we viewed a slice of the 3D wave in the rows-columns plane. We can view any orthogonal plane. For example, this command shows us the data in the layers-rows plane:

```
ModifyTable elements=(-3, 0, -2)    // Shows column 0 of 3D wave
```

The first parameter says that we want to map the wave’s rows dimension to the table’s horizontal dimension. The second parameter says that we want to see column 0 of the wave. The third parameter says that we want to map the wave’s layers dimension to the table’s vertical dimension.

Dealing with a 4D wave is similar to the 3D case, except that, in addition to the two free dimensions, you have two fixed dimension.

```
Make/O/N=(5,4,3,2) wave0 = p + 10*q + 100*r + 1000*s
ModifyTable elements(wave0)=(-2, -3, 1, 0)   //Shows layer 1/chunk 0
ModifyTable elements(wave0)=(-2, -3, 2, 1)   //Shows layer 2/chunk 1
```

If you change a wave (using Make/O or Redimension) such that one or both of the free dimensions has zero points, Igor automatically resets the view to the default — the wave’s rows dimension mapped to the table’s vertical dimension and the wave’s column dimension mapped to the table’s horizontal dimension. Here is an example:

```
Make/O/N=(5,4,3) wave0 = p + 10*q + 100*r
Edit wave0.id
```

```
Modify elements(wave0) = (0, -2, -3)// Map layers to horizontal dim
Redimension/N=(5,4) wave0           // Eliminate layers dimension!
```

This last command has eliminated the wave dimension that is mapped to the table horizontal dimension. Thus, Igor will automatically reset the table view.

If you use a dimension with zero points as a free dimension, Igor will also reset the view to the default:

```
Make/O/N=(3,3) wave0 = p + 10*q
Edit wave0.id
Modify elements(wave0) = (0, -2, -3)   // Map layers to horizontal dim
```

This last command maps the wave's layers dimension to the table's horizontal dimension. However, the wave has no layers dimension, so Igor will reset the view to the default.

The initial discussion of changing the view using keyboard shortcuts was incomplete for the sake of simplicity. It said that Option-Down Arrow (*Macintosh*) or Alt+Down Arrow (*Windows*) displayed the next layer and that Command-Option-Down Arrow or Ctrl+Alt+Down Arrow displayed the next chunk. This is true if rows and columns are the free dimensions. A more general statement is that Option-Down Arrow or Alt+Down Arrow changes the viewed element of the first fixed dimension and Command-Option-Down Arrow or Ctrl+Alt+Down Arrow changes the viewed element of the second fixed dimension. Here is an example using a 4D wave:

```
Make/O/N=(5,4,3,2) wave0 = p + 10*q + 100*r + 1000*s
Edit wave0.id
ModifyTable elements(wave0)=(0, -2, 0, -3)
```

The ModifyTable command specifies that the columns and chunks dimensions are the free dimensions. The rows and layers dimensions are fixed at 0. If you now press Option-Down Arrow or Alt+Down Arrow, you change the element of the first fixed dimension — the rows dimension in this case. If you press Command-Down Arrow or Ctrl+Alt+Down Arrow, you change the element of the second fixed dimension — the layers dimension in this case.

Multidimensional Copy/Cut/Paste/Clear

The material in this section is primarily of interest if you intend to edit 3D and 4D data in a table. There are also a few items that deal with 2D data.

When you copy table cells, Igor copies the data in two formats:

- Igor binary, for pasting into another Igor wave
- Plain text, for pasting into another program

For 1D and 2D waves, the subset that you copy and paste is obvious from the table selection. In the case of 3D and 4D waves, you can only see two dimensions in the table at one time and you can select a subset of those two dimensions.

When copying as plain text, Igor always copies just the visible cells to the clipboard.

When copying as Igor binary, if you press Option (*Macintosh*) or Alt (*Windows*), Igor copies cells from all dimensions.

Consider the following example. We make a wave with 5 rows, 4 columns and 3 layers and display it in a table:

```
Make/O/N=(5,4,3) w3D = p + 10*q + 100*r; Edit w3D.id
```

The table now displays all rows and all columns of layer 0 of the wave. If you select all of the visible data cells and do a copy, Igor copies all of layer 0 to the clipboard. However, if you do an Option-copy or Alt-copy, Igor copies all three layers to the clipboard — layer 0 plus the two layers that are currently not visible — in Igor binary format.

This table shows the effect of the Option (*Macintosh*) or Alt (*Windows*) key.

	Copy	**Paste**	**Clear**
No modifiers	Copies visible	Replace-pastes visible	Clears visible
Option or Alt	Copies all	Replace-pastes all	Clears all

The middle column of the preceding table mentions “replace-pasting”. When you do a paste, Igor normally replaces the selection in the table with the data in the clipboard. However, if you press Shift while pasting, Igor inserts the data as new cells in the table. This is called an “insert-paste”. This table shows the effect of the Shift and Option (*Macintosh*) or Alt (*Windows*) keys on a paste.

	Paste
No modifiers	Replace-pastes visible
Option	Replace-pastes all
Shift	Insert-pastes visible
Shift and Option or Alt	Insert-pastes all

Replace-Paste of Multidimensional Data

If you copy data in a table, and then select cells in the table or in another table, and do a paste, you are doing a replace-paste. The copied data replaces the selection when you do the paste.

For 1D and 2D waves, the subset that you copy and paste is obvious from the table selection. In the case of 3D and 4D waves, you can only see two dimensions in the table at one time and you can select a subset of those two dimensions.

When you do a normal replace-paste involving waves of dimension 3 or higher, the data in the clipboard replaces the data in the currently visible slice of the selected wave.

Copying a Layer of a 3D Wave to Another Layer

Here is an example that illustrates replace-paste.

1. Make a wave with 5 rows, 4 columns and 3 layers and display it in a table:

   ```
   Make/O/N=(5,4,3) w3D = p + 10*q + 100*r; Edit w3D
   ```

   The table now displays all rows and all columns of layer 0 of the wave. Let’s look at layer 1 of the wave.
2. Press Option-Down Arrow (*Macintosh*) or Alt+Down Arrow (*Windows*) while the table is active.

   This changes the view to show layer 1 instead of layer 0.
3. Select all of the visible cells and choose Edit→Copy.

   This copies all of layer 1 to the clipboard.
4. Press Option-Down Arrow or Alt+Down Arrow again to view layer 2 of the wave.
5. With all of the cells still selected, choose Edit→Paste.

   The data copied from layer 1 replaces the data in layer 2 of the wave.
6. Choose Edit→Undo.

   Layer 2 is restored to its original state.
7. Press Option-Up Arrow or Alt+Up Arrow two times.

   We are now looking at layer 0.
8. Choose Edit→Paste.

The data that we copied from layer 1 replaces the data in layer 0.

9. Choose Edit→Undo to return layer 0 to the original state.

Copying and Pasting All Data of a 3D Wave

Now let's consider an example in which we copy and paste all of the wave data, not just one layer.

1. Make a wave with 5 rows, 4 columns and 3 layers and display it in a table:

   ```
   Make/O/N=(5,4,3) w3D = p + 10*q + 100*r; Edit w3D
   ```

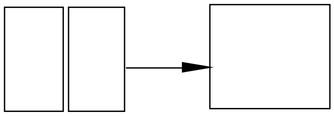
2. Select all of the visible cells.
3. Press Option (*Macintosh*) or Alt (*Window*) and choose Edit→Copy All Layers.

   This copies the entire wave, all three layers, to the clipboard.
4. Press Option or Alt and choose Edit→Clear All Layers.

   This clears all three layers.
5. Use Option-Down Arrow or Alt+Down Arrow and Option-Up Arrow or Alt+Up Arrow to verify that all three layers were cleared.
6. Press Option or Alt and choose Edit→Paste All Layers.

   This pastes all three layers from the clipboard into the selected wave.
7. Use Option-Down Arrow and Option-Up Arrow or Alt+Down Arrow and Alt+Up Arrow to verify that all three layers were pasted.

Making a 2D Wave from Two 1D Waves



In this example, we make a 2D wave from two 1D waves. Execute:

```
Make/O/N=5 w1DA=p, w1DB=100+p; Edit w1DA, w1DB
```

1. Select all of the first 1D wave and choose Edit→Copy.
2. Click in the first unused cell in the table and choose Edit→Paste.

   Because you pasted into the unused cell, Igor created a new wave. This is a "create-paste".
3. Choose Redimension w1DA1 from the Table pop-up menu (gear icon).
4. In the Redimension Waves dialog, enter 2 for the number of columns and click Do It.
5. Right-click the column name of the redimensioned wave and choose Rename.
6. Rename w1DA1 as w2D.
7. Select all of the second 1D wave, w1DB, and choose Edit→Copy.
8. Select all of the second column of the 2D wave, w2D, and choose Edit→Paste.

We now have a 2D wave generated from two 1D waves.

Insert-Paste of Multidimensional Data

If you copy data in a table, and then select in the table or in another table, and do a paste while pressing Shift, you are doing an insert-paste. The copied data is inserted into the selected wave or waves before the selected cells. As in the case of the replace-paste, the insert-paste works on just the visible layer of data if Option (*Macintosh*) or Alt (*Windows*) is not pressed or on all layers if the Option or Alt is pressed. Next is an example that illustrates this.

Inserting New Rows in a 3D Wave

1. Make a wave with 5 rows, 4 columns and 3 layers and display it in a table:

   ```
   Make/O/N=(5,4,3) w3D = p + 10*q + 100*r; Edit w3D
   ```

2. Select all of the cells in rows 1 and 2 of the table.

   An easy way to do this is to click the "1" in the Row column and drag down to the "2".

3. Choose Edit→Copy to copy the selected cells.

   Since you did not press Option or Alt, this copies just the visible layer.
4. Press shift and choose Edit→Insert Paste to insert-paste the copied data.

   Notice that two new rows were inserted, pushing the pre-existing rows down.
5. Press Option-Down Arrow or Alt+Down Arrow to see what was inserted in layers 1 and 2 of the 3D wave.

   Notice that zeros were inserted. This is because the paste stored data only in the visible layer.
6. Press Option-Up Arrow or Alt+Up Arrow to view layer 0 again.
7. Choose Edit→Undo from the Edit menu to undo the paste.
8. Use Option-Down Arrow or Alt+Down Arrow to check the other layers of the wave and then use Option-Up Arrow or Alt+Up Arrow to come back to layer zero.

   The wave is back in its original state.

   Now we will do an insert-paste in all layers.
9. Select rows 1 and 2 of the wave.
10. Press Option or Alt and choose Edit→Copy All Layers.

    This copies data from all three layers to the clipboard.
11. Press Shift-Option or Shift+Alt and choose Edit→Insert Paste All Layers.

    This pastes data from the clipboard into all three layers of the wave. By pressing Shift, we did an insert-paste rather than a replace-paste and by pressing Option or Alt, we pasted into all layers, not just the visible layer.
12. Use Option-Down Arrow or Alt+Down Arrow to verify that we have pasted data into all layers.

Cutting and Pasting Rows Versus Columns

Normally, you cut and paste rows of data. However, there may be cases where you want to cut and paste columns. For example, if you have a 2D wave with 5 rows and 3 columns, you may want to cut the middle column from the wave. Here is how Igor determines if you want to cut rows or columns.

If the selected wave is 2D or higher, *and* if one or more *entire* columns is selected, Igor cuts the selected column or columns. In all other cases Igor cuts rows.

After copying or cutting wave data, you have data in the clipboard. Normally, a paste overwrites the selected rows or inserts new rows (if you press Shift).

To insert columns, you need to do the following:

1. Copy the column that you want to insert.
2. Select exactly one entire column. You can do this quickly by clicking the column name.
3. Press Shift and choose Edit→Insert Paste or press Command-Shift-V (*Macintosh*) or Ctrl+Shift+V (*Windows*).

If the wave data is real (not complex), Igor normally pastes the new column or columns before the selected column. This behavior would provide you with no way to paste columns after the last column of a wave. Therefore, if the selected column is the last column, Igor presents a dialog to ask you if you want to paste the new columns before or after the last column.

If the wave data is complex, Igor pastes the new columns before the selected column if the selected column is real or after the selected column if it is imaginary.

If you select more than one column or if you do not select all of the column, Igor will insert rows instead of columns.

Create-Paste of Multidimensional Data

When you copy data in a table and then select the first unused cell in the table and then do a paste, Igor creates one or more new waves.

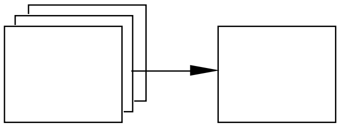
The number of waves created and the number of dimensions in each wave are the same as for the copied data. Igor also copies and pastes the following wave properties:

- Data units and dimension units
- Data full scale and dimension scaling
- Dimension labels
- The wave note

Igor copies and pastes the wave note only if you copy the entire wave. If you copy part of the wave, it does not copy the wave note.

You can use a create-paste to create a copy of a subset of the data displayed in the table. For 1D and 2D waves, the subset that you copy and paste is obvious from the table selection. In the case of 3 and higher dimension waves, you can only see two dimensions in the table at one time and you can choose a subset of those two dimensions. If you do a copy and then a create-paste, Igor creates a new 2D wave containing just the data that was visible when you did the copy. If you do an Option-copy (*Macintosh*) or Alt-copy (*Windows*) to copy all and then a create-paste, Igor creates a new wave with the same number of dimensions and same data as what you copied.

Making a 2D Wave from a Slice of a 3D Wave



1. Make a 3D wave and display it in a table:

```
Make/O/N=(5,4,3) w3D = p + 10*q + 100*r; Edit w3D
```

2. Select all of the cells of the 3D wave and choose Edit→Copy.
3. Click in the first unused cell and choose Edit→Paste.

You now have a 2D wave consisting of the data from layer 0 of the 3D wave.

Making a 3D Wave from a 3D Wave

1. Make a 3D wave and display it in a table:

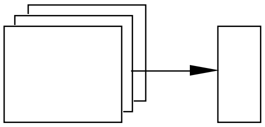
```
Make/O/N=(5,4,3) w3D = p + 10*q + 100*r; Edit w3D
```

2. Select all of the cells of the 3D wave.
3. Press Option or Alt, and choose Edit→Copy All Layers.
4. Click in the first unused cell and choose Edit→Paste.

   You now have a 3D wave consisting of the data from all layer2 of the original 3D wave.

   To confirm this, we will inspect all layers of the new wave.
5. To demonstrate this, view the other layers of the new wave by pressing Option-Down Arrow or Alt+Down Arrow (to go to the next layer) and Option-Up Arrow or Alt+Up Arrow (to go to the previous layer).

Making a 1D Wave from a Column of a 3D Wave



1. Make a 3D wave and display it in a table:

```
Make/O/N=(5,4,3) w3D = p + 10*q + 100*r; Edit w3D
```

2. Select a single column of the 3D wave and choose Edit→Copy.
3. Click the first unused cell in the table and choose Edit→Paste.

   You have created a single-column wave but it is a 2D wave, not a 1D wave.
4. Choose Redimension w3D1 from the Table pop-up menu (gear icon) to display the Redimension Waves dialog.

5. Enter 0 for the number of columns and click Do It.

   You now have a 1D wave created from a column of a 3D wave.

Save Table Copy

You can save the active table as an Igor packed experiment file or as a tab or comma-delimited text file by choosing File→Save Table Copy.

The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the table starting from the “top” data folder, which is the data folder that encloses all waves displayed in the table. The top data folder becomes the root data folder of the resulting experiment file. Only the table and its waves are saved in the packed experiment file, not variables or strings or any other objects in the experiment.

Save Table Copy does not know about dependencies. If a table contains a wave, wave0, that is dependent on another wave, wave1 which is not in the table, Save Table Copy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

The main use for saving as a tab or comma-delimited text file is for exporting data to another program.

The point column is never saved.

When saving as text, the data format matches the format shown in the table. This causes truncation if the underlying data has more precision than shown in the table.

To save data as text with full precision, choose Data→Save Waves→Save Delimited Text or use the **SaveTableCopy** operation with /F=1.

When saving 3D and 4D waves as text, only the visible layer is saved. To save the entirety of a 3D or 4D wave, choose Data→Save Waves→Save Delimited Text.

The **SaveTableCopy** provides options that are not available using the Save Table Copy menu command.

Object Reference Waves in Tables

This topic is for advanced users.

Object reference waves are waves containing wave references (WAVE waves) or data folder references (DFREF waves).

Object reference wave elements are formatted as hexadecimal by default. See **Object Reference Wave Formatting** on page II-258 for details.

Because entering an invalid reference may cause a crash, you can not modify the elements of an object reference wave by editing in the table.

If you display an object reference wave in a table, turn column info tags on via the Table menu, and hover the mouse over an element of the object reference wave, Igor displays in the column info tag information about the wave or data folder referenced by the element. This feature works in the debugger if you have column info tags turned on.

Editing Waves Referenced by WAVE Waves

This is a feature for advanced users.

If you have a WAVE wave displayed in table, you can select one or more cells of that wave, right-click, and choose Edit Waves. Igor creates a new table showing the waves referenced by the selected wave references in the table.

You can do the same using the table popup menu (gear icon in top/right corner of the table). The Edit Waves item does not appear in the Table menu in the main menu bar.

The Edit Waves item appears in the contextual menu or table popup menu only if one or more editable wave references are selected. NULL waves (wave reference=0) and free waves can not be edited in a table.

This feature is not available in the table subwindow in the debugger.

Printing Tables

Before printing a table you should bring the table to the top of the desktop and set the page size and orientation using the Page Setup dialog. Choose the Page Setup for All Tables item from the Files menu.

In each experiment, Igor stores one page setup for all tables. Thus, changing the page setup while a table is active changes the page setup for all tables in the current experiment.

When you invoke the Page Setup dialog you must make sure that the table that you want to print is the top window. Changing the page setup for graphs, page layouts or other windows does not affect the page setup for tables.

You can print all or part of a table. To print the whole table, select just one cell and choose File-Print Table. To print the selection, select multiple cells and choose File→Print Table Selection.

Exporting Tables as Graphics

Although Igor tables are intended primarily for editing data, you can also use them for presentation purposes. You can put a table into an Igor page layout, as discussed in Chapter II-18, **Page Layouts**. This section deals with exporting a table to other applications as a picture.

Typically you would do this if you are preparing a report in a word processor or page layout program or making an illustration in a drawing program. If you are exporting to a program that has strong text formatting features, it may be better to copy the data from the table as text, using the Copy item in the Edit menu. You can paste the text into the other program and then format it as you wish.

Exporting a Table as a Picture

To export a table as a Macintosh picture via the clipboard, choose Export Graphics from the Edit menu. This copies the table to the clipboard as a picture.

The picture that Igor puts into the clipboard contains just the visible cells in the table window. You can scroll, expand or shrink the window to control which cells will appear in the picture.

Igor can write a picture out to a file instead of copying it to the clipboard. To do this, use the Save Graphics submenu of the File menu.

Most word processing, drawing and page layout programs permit you to import a picture via the clipboard or via a file.

Although we have not optimized tables for presentation purposes, we did put two features into tables specifically for presentation. First, you can hide the point column by setting its width to zero. Second, you can replace the automatic column titles with column titles of your own. Use the Modify Columns dialog for both of these.

There are some features lacking that would be nice for presentation. You can’t change the background color of a table. You can’t change or remove the grid lines. If you want to do these things, export the table to a drawing program for sprucing up.

Table Preferences

Table preferences allow you to control what happens when you create a new table or add new columns to an existing table. To set preferences, create a table and set it up to your taste. We call this your *prototype* table. Then choose Capture Table Prefs from the Table menu.

Preferences are normally in effect only for *manual* operations, not for automatic operations from Igor procedures. This is discussed in more detail in **How to Use Preferences** on page III-516.

When you initially install Igor, all preferences are set to the factory defaults. The dialog indicates which preferences you have changed, and which are factory defaults.

The Window Position and Size preference affects the creation of new tables only.

The Column Styles preference affects the formatting of newly created tables and of columns added to an existing table. This preference stores column settings for the point column and for one additional column - the first column after the point column in the prototype table. When you create a new table or add columns to a table, these settings determine the formatting of the columns.

The page setup preference affects what happens when you create a new *experiment*, not when you create a new *table*. Here is why.

Each experiment stores *one* page setup for *all* tables in that experiment. The preferences also store one page setup for tables. When you set the preferred page setup for tables, Igor stores a copy of the current experiment's page setup for tables in the preferences file. When you create a new experiment, Igor stores a copy of the preferred page setup for tables in the experiment.

Table Style Macros

The purpose of a table style macro is to allow you to create a number of tables with the same stylistic properties. Using the Window Control dialog, you can instruct Igor to automatically generate a style macro from a prototype table. You can then apply the macro to other tables.

Igor can generate style macros for graphs, tables and page layouts. However, their usefulness is mainly for graphs. See **Graph Style Macros** on page II-350. The principles explained there apply to table style macros also.

Table Shortcuts

To view table keyboard navigation shortcuts, see **Table Keyboard Navigation** on page II-237.

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To add columns for existing waves	Choose Append to Table from the Table menu.	Choose Append to Table from the Table menu.
To create new numeric waves	Click in the first unused column and enter a number or paste numeric data from the clipboard.	Click in the first unused column and enter a number or paste numeric data from the clipboard.
	Copy all or part of an existing numeric wave and paste in the first unused column.	Copy all or part of an existing numeric wave and paste in the first unused column.
To create new text waves	Click in the first unused column and enter nonnumeric text or paste text data from the clipboard.	Click in the first unused column and enter nonnumeric text or paste text data from the clipboard.
	Copy all or part of an existing text wave and paste in the first unused column.	Copy all or part of an existing text wave and paste in the first unused column.
To kill one or more waves	Select the waves in the table and choose Kill Waves from the Table pop-up menu.	Select the waves in the table and choose Kill Waves from the Table pop-up menu.
To rename a wave	Select one or more cells from the wave and choose Rename from the Table pop-up menu.	Select one or more cells from the wave and choose Rename from the Table pop-up menu.
To redimension a wave	Select one or more cells from the wave and choose Redimension from the Table pop-up menu.	Select one or more cells from the wave and choose Redimension from the Table pop-up menu.
To add cells to a column	Click in a row and choose Insert Points from the Table pop-up.	Click in a row and choose Insert Points from the Table pop-up.
	Press Command-Shift-V. This does an insert-paste.	Press Ctrl+Shift+V. This does an insert-paste.
	Click in the insertion cell at the end of the column and enter a value or paste.	Click in the insertion cell at the end of the column and enter a value or paste.
To remove cells from a column	Select the cells to be removed and choose Delete Points from the Table pop-up.	Select the cells to be removed and choose Delete Points from the Table pop-up.
	Press Command-X (Cut).	Press Ctrl+X (Cut).
To identify a particular column	Press Command-Option-Control and click in the column.	Press Shift-F1 to summon context-sensitive help and then click in the column.
To modify column styles	Double-click a column title (goes to Modify Columns dialog).	Double-click a column title (goes to Modify Columns dialog).
	Select one or more columns and click the Table pop-up menu.	Select one or more columns and click the Table pop-up menu.
	Press Control and click the column title.	Right-click the column title.
To modify the style of all columns at once	Press Shift while using the Table pop-up menu.	Press Shift while using the Table pop-up menu.
	Press Shift-Option to modify all but the Point column.	Press Alt+Shift to modify all but the Point column.

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To modify the style of a subset of the data columns of multidimensional wave	Select the columns to modify, press Command, then click the Table menu or the Table pop-up menu, then make a selection.	Select the columns to modify, press Ctrl, then click the Table menu or the Table pop-up menu, then make a selection.
To select entire rows	Drag in the point number column.	Drag in the point number column.
To select entire columns	Drag on the column titles.	Drag on the column titles.
To select all of the columns of a given wave	Press Command and click the column title of a data column from the wave. This selects all data columns from the wave. Press Command and click the column title of an index or label column from a wave to select that column plus all data columns.	Press Ctrl and click the column title of a data column from the wave. This selects all data columns from the wave. Press Ctrl and click the column title of an index or label column from a wave to select that column plus all data columns.
To change a wave's position	Press Option and drag the column title to the new position.	Press Alt and drag the column title to the new position.
To adjust the width of a column	Drag the border at the right of the column title. Press Shift to resize all columns except the point column. Press Command while clicking to set the width of a single data column of a multidimensional wave.	Drag the border at the right of the column title. Press Shift to resize all columns except the point column. Press Ctrl while clicking to set the width of a single data column of a multidimensional wave.
To bring the target cell into view	Click in the cell ID in the top left corner of the table.	Click in the cell ID in the top left corner of the table.

Chapter II-13

Graphs

Overview

Igor graphs are simultaneously:

- Publication quality presentations of data.
- Dynamic windows for exploratory data analysis

This chapter describes how to create and modify graphs, how to adjust graph features to your liking, and how to use graphs for data exploration. It deals mostly with general graph window properties and with waveform and XY plots.

These other chapters discuss material related to graphs:

Category Plots on page II-355, **Contour Plots** on page II-365, **Image Plots** on page II-385
3D Graphics on page II-405, **Drawing** on page III-61, **Annotations** on page III-33
Exporting Graphics (Macintosh) on page III-95, **Exporting Graphics (Windows)** on page III-101
Graphics Technology on page III-506

A single graph window can contain one or more of the following:

Waveform plots	Wave data versus X values (scaled point number)
XY plots	Y wave data versus X wave data
Category plots	Numeric wave data versus text wave data
Image plots	Display of a matrix of data
Contour plots	Contour of a matrix or an XYZ triple
Axes	Any number of axes positioned anywhere
Annotations	Textboxes, legends and dynamic tags
Cursors	To read out XY coordinates
Drawing elements	Arrows, lines, boxes, polygons, pictures …
Controls	Buttons, pop-up menus, readouts …

The various kinds of plots can be overlaid in the same plot area or displayed in separate regions of the graph. Igor also provides extensive control over stylistic factors such as font, color, line thickness, dash pattern, etc.

Graph Features

Igor graphs are smart. If you expand a graph to fill a large screen, Igor will adjust all aspects of the graph to optimize the presentation for the larger graph size. The font sizes will be scaled to sizes that look good for the large format and the graph margins will be optimized to maximize the data area without fouling up the axis labeling. If you shrink a graph down to a small size, Igor will automatically adjust axis ticking to prevent tick mark labels from running into one another. If Igor’s automatic adjustment of parameters does not give the desired effect, you can override the default behavior by providing explicit parameters.

Igor graphs are dynamic. When you zoom in on a detail in your data, or when your data changes, perhaps due to data transformation operations, Igor will automatically adjust both the tick mark labels and the axis labels. For example, before zooming in, an axis might be labeled in milli-Hertz and later in micro-Hertz. No matter what the axis range you select, Igor always maintains intelligent tick mark and axis labels.

If you change the values in a wave, any and all graphs containing that wave will automatically change to reflect the new values.

You can zoom in on a region of interest (see **Manual Scaling**), expand or shrink horizontally or vertically, and you can pan through your data with a hand tool (see **Panning**). You can offset graph traces by simply dragging them around on the screen (see **Trace Offsets**). You can attach cursors to your traces and view data readouts as you glide the cursors through your data (see **Info Panel and Cursors**). You can edit your data graphically (see **Drawing and Editing Waves** on page III-73).

Igor graphs are fast. They are updated almost instantly when you make a change to your data or to the graph. In fact, Igor graphs can be made to update in a nearly continuous fashion to provide a real-time oscilloscope-like display during data acquisition (see **Live Graphs and Oscilloscope Displays**)

You can also control virtually every detail of a graph. When you have the graph just the way you like it, you can create a template called a "style macro" to make it easy to create more graphs of the same style in the future (see **Graph Style Macros**). You can also set preferences from a reference graph so that new graphs will automatically be created with the settings you prefer (see **Graph Preferences**).

You can print or export graphs directly, or you can combine several graphs in a page layout window prior to printing or exporting. You can export graphs and page layouts in a wide variety of graphics formats.

A graph can exist as a standalone window or as a subwindow of another graph, a page layout, or a control panel (see **Embedding and Subwindows** on page III-79).

The Graph Menu

The Graph menu contains items that apply only to graph windows. The menu appears in the menu bar only when the active or target window is a graph.

When you choose an item from the Graph menu it affects the top-most graph.

Typing in Graphs

If you type on the keyboard while a graph is the top window, Igor brings the command window to the front and your typing goes into the command line. (The only exception to this is when a graph contains a selected SetVariable control.)

Graph Names

Every graph that you create has a window name which you can use to manipulate the graph from the command line or from a procedure. When you create a new graph, Igor assigns it a name of the form "Graph0", "Graph1" and so on. When you close a graph, Igor offers to create a window recreation macro which you can invoke later to recreate the graph. The name of the window recreation macro is the same as the name of the graph.

The graph *name* is not the same as the graph *title* which is the text that appears in the graph's window frame. The name is for use in procedures but the title is for display purposes only. You can change a graph's name and title using the Window Control dialog which you can access by choosing Windows→Control→Window Control.

Creating Graphs

You create a graph by choosing New Graph from the Windows menu.

You can also create a graph by choosing New Category Plot, New Contour Plot or New Image Plot from the New submenu in the Windows menu.

You select the waves to be displayed in the graph from the Y Waves list. The wave is displayed as a **trace** in the graph. A trace is a visual representation of a wave or an XY pair. By default a trace is drawn as a series of lines joining the points of the wave or XY pair.

Each trace has a name so you can refer to it from a procedure. By default, the trace name is he same as the wave name or Y wave in the case of an XY pair. However, there are exceptions. If you display the same wave multiple times in a given graph, the traces will have names like wave0, wave0#1, and wave0#2. wave0 is equivalent to wave0#0. Such names are called *trace instance names*.

You can also programmatically specify a trace's name using the **Display** or **AppendToGraph** operations. This is something an Igor programmer would do, typically to better distinguish multiple traces with the same Y wave.

Often the data values of the waves that you select in the Y Waves list are plotted versus their calculated X values. This is a **waveform trace**. The calculated X values are derived from the wave's X scaling; see **Waveform Model of Data** on page II-62.

If you want to plot the data values of the Y waves versus the data values of another wave, select the other wave in the X Wave list. This is an **XY trace**. In this case, X scaling is ignored; see **XY Model of Data** on page II-63.

If the lengths of the X and Y waves are not equal, then the number of points plotted is determined by the shorter of the waves.

The New Graph dialog has a simple mode and an advanced mode. In the simple mode, you can select multiple Y waves but just one X wave. If you have multiple XY pairs with distinct X waves, click the More Choices button to use the advanced mode. This allows you to select a different X wave for each Y wave.

You can specify a **title** for the new window. The title is not used except to form the title bar of the window. It is *not* used to identify windows and does not appear *in* the graph. If you specify no title, Igor will choose an appropriate title based on the traces in the graph and the graph name. Igor automatically assigns graph names of the form "Graph0". The name of a window is important because it is used to identify windows in commands. The title is for display purposes only and is not used in commands.

If you have created style macros for the current experiment they will appear in the Style pop-up menu. See **Graph Style Macros** on page II-350 for details.

Normally, the new graph is created using left and bottom axes. You can select other axes using the pop-up menus under the X and Y wave lists. Picking L=VertCrossing automatically selects B=HorizCrossing and vice versa. These **free axes** are used when you want to create a Cartesian type plot where the axes cross at (0,0).

You can create additional free axes by choosing New from the pop-up menu. This displays the New Free Axis dialog. Axes created this way are called "free axes" because they can be freely positioned nearly anywhere in the graph window. The standard left, bottom, right, and top axes always remain at the edge of the plot area.

You should give the new axis a name that describes its intended use. The name must be unique within the current graph and can't contain spaces or other nonalphanumeric characters. The Left and Right radio buttons determine the side of the axis on which tick mark labels will be placed. They also define the edge of the graph from which axis positioning is based.

You can create a blank graph window containing no traces or axes by clicking the Do It button without selecting any Y waves to plot. Blank graph windows are mostly used in programming when traces are appended later using **AppendToGraph**.

The New Graph dialog comes in two versions. The simpler version shown above is suitable for most purposes. If, however, you have multiple pairs of XY data or when you will be using more than one pair of axes, you can click the More Choices button to get a more complex version of the dialog.

Using the advanced mode of the New Graph dialog, you can create complex graphs in one step. You select a wave or an XY pair using the Y Waves and X Wave lists, and then click the Add button. This moves your selection to the trace specification list below. You can then add more trace specifications using the Add button. When you click Do It, your graph is created with all of the specified traces.

The advanced version of the dialog includes two-dimensional waves in the Y Waves and X Wave lists. You can edit the range values for waves in the holding pen to specify individual rows or columns of a matrix or to specify other subsets of data. See **Subrange Display** on page II-321 for details.

Waves and Axes

Axes are dependent upon waves for their existence. If you remove from a graph the last wave that uses a particular axis then that axis will also be removed.

In addition, the first wave plotted against a given axis is called the **controlling wave** for the axis. There is only one thing special about the controlling wave: its units define the units that will be used in creating the axis label and occasionally the tick mark labels. This is normally not a problem since all waves plotted against a given axis will likely have the same units. You can determine which wave controls an axis with the AxisInfo function.

Types of Axes

The four axes named left, right, bottom and top are termed **standard axes**. They are the only axes that many people will ever need.

Each of the four standard axes is always attached to the corresponding edge of the **plot area**. The plot area is the central rectangle in a graph window where traces are plotted. Axis and tick mark labels are plotted outside of this rectangle.

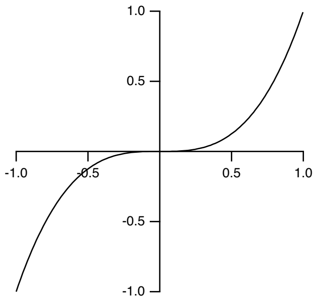
You can also add unlimited numbers of additional user-named axes termed **free axes**. Free axes are so named because you can position them nearly anywhere within the graph window. In particular, vertical free axes can be positioned anywhere in the horizontal dimension while horizontal axes can be positioned anywhere in the vertical dimension.

The Axis pop-up menu entries L=VertCrossing and B=HorizCrossing in the New Graph dialog create free axes that are each preset to cross at the numerical zero location of the other. They are also set to suppress the tick mark and label at zero. For example, create this data:

```
Make yWave; SetScale/I x,-1,1,yWave; yWave= x^3
```

Now, using the New Graph dialog, select yWave from the Y list and then L=VertCrossing from the Y axis pop-up menu. This generates the following command and the resulting graph:

```
Display/L=VertCrossing/B=HorizCrossing yWave
```



You could remove the tick mark and label at -0.5 by double-clicking the axis to reach the Modify Axis dialog, choosing the Tick Options tab, and finally typing -0.5 in one of the unused Inhibit Ticks boxes.

The free axis types described above all require that there be at least one trace that uses the free axis. For special purposes Igor programmers can also create a free axis that does not rely on any traces by using the **NewFreeAxis** operation (page V-679). Such an axis will not use any scaling or units information from any associated waves if they exist. You can specify the properties of a free axis using the **SetAxis** operation (page V-835) or the **ModifyFreeAxis** operation (page V-609), and you can remove them using the **KillFreeAxis** operation (page V-470).

Appending Traces

You can append waves to a graph as a waveform or XY plot by choosing Append Traces to Graph from the Graph menu. This presents a dialog identical to the New Graph dialog except that the title and style macro items are not present. Like the New Graph dialog, this dialog provides a way to create new axes and pairs of XY data. The Append to Graph submenu in the Graph menu allows you to append category plots, contour plots and image plots.

Appending Traces by Drag and Drop

You can append waves to a graph by dragging them from the Data Browser or from the Waves in Window list of the Window Browser.

The following sections present a guided tour showing how to use drag and drop. You can execute the example commands by selecting the line or lines and pressing Control-Enter (*Macintosh*) or Ctrl+Enter (*Windows*).

Drag and Drop Tour

1. **Choose File->New Experiment.**
2. **Execute this command to create waves used in the tour:**

```
Make/O wave0=sin(x/8), wave1=cos(x/8), wave2=wave0*wave1, xwave=x/8
```

3. **Choose Data->Data Browser.**

   We will drag icons from the Data Browser into a graph window.

4. **Execute this command to create an empty graph:**

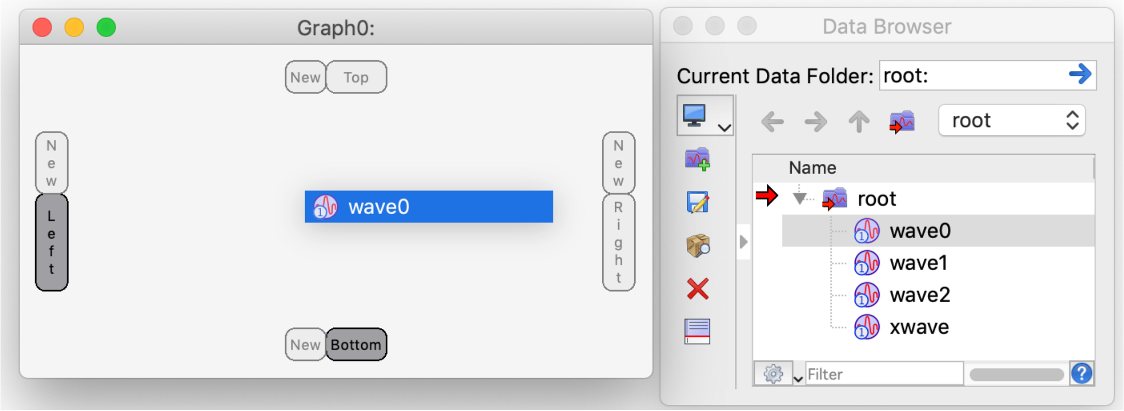
```
Display
```

Appending Traces to Standard Axes by Drag and Drop

You can append a trace using any of the four standard axes by dragging and hovering over the Left, Top, Right, or Bottom drop targets shown below. Dropping a wave in the middle of the graph appends a trace using the left and bottom axes.

1. **Select wave0 in the Data Browser and drag it to the middle of the graph.**

   When the mouse enters the graph, a number of drop targets appear.



2. **Release the mouse to drop the wave in the middle of the graph window.**

   Dropping the wave in the middle of the graph adds a trace to the left and bottom axes. An AppendToGraph command appears in the history area of the command window.

3. **Remove the trace from the graph by executing:**

   ```
   RemoveFromGraph wave0
   ```

   When you remove the last trace plotted against a given axis, Igor removes that axis from the graph.

   Next we will show how to append a trace using any of the four standard axes.

4. **Select wave0 in the Data Browser, drag it to the Top drop target and pause until Top turns blue. Then drag the wave to the Right drop target and release the mouse.**

   A trace is appended to the graph using the standard right and top axes.

5. **Remove the trace from the graph by executing:**

   ```
   RemoveFromGraph wave0
   ```

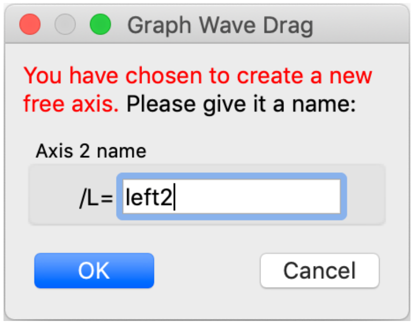
You can cancel a drag and drop operation that you have not yet completed by dragging the wave out of the graph or by pressing the escape key.

Creating Free Axes by Drag and Drop

You can append a trace to a new free axis by dragging and hovering over one of the New drop targets. In this section, we will append a trace to a new free left axis versus the standard bottom axis. For background information on free axes, see Types of Axes.

1. **Select wave0 in the Data Browser, drag it to the New drop target on the left side of the graph, and pause until New turns blue. Then drag the wave to the Bottom drop target and release the mouse.**

   A dialog appears asking for a name for the new free axis:



You have chosen to create a new free axis. Please give it a name:

Axis 2 name

/L= left2

2. **Enter left2 as the name for the new free axis an click OK.**

   The trace is appended versus the left2 and bottom axes.

   In the history area of the command window you can see AppendToGraph and ModifyGraph commands that were executed to create the new free axis and set its position.

3. **Select wave1 in the Data Browser, drag it to the New drop target on the left side of the graph, and pause until New turns blue. Then drag the wave to the Bottom drop target and release the mouse.**

   A dialog appears asking for a name for the new free axis. Enter left3.

   A wave1 trace is appended versus the left3 and bottom axes. The left2 and left3 axes are identical at this point so you can see only one of them. In the next step we will make them distinct.

4. **Stack the left2 and left3 axes by executing:**

   ```
   ModifyGraph axisEnab(left2)={0,0.45}, axisEnab(left3)={0.55,1.0}
   ```

   You now have a stacked graph.

   You can also use the Draw Between settings of the Axis tab of the Modify Graph dialog to generate the axisEnab commands.

Dragging to Existing Axes

Axes that already exist in the graph, whether standard or free, act as drop targets. To append a new trace to an existing axis, you drag onto the existing axis and pause until it turns blue, then drag onto another drop target.

1. **Select wave2 in the Data Browser, drag it to the left3 axis (the upper left axis) in the graph, and pause until New turns blue. Then drag the wave to the Bottom drop target and release the mouse.**

   Wave2 is appended versus the left3 and bottom axes.

2. **Remove the traces from the graph by executing:**

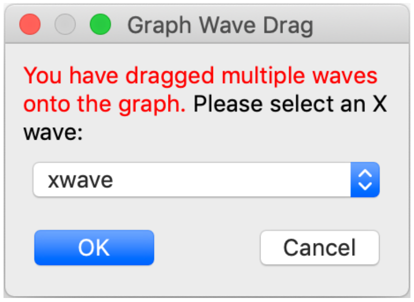
   ```
   RemoveFromGraph wave0, wave1, wave2
   ```

Appending XY Traces by Drag and Drop

To append an XY pair to a graph, you select the X and Y waves in the browser and drag to the graph as described above. When you release the mouse, Igor displays a dialog that allows you to identify one of the waves as the X wave.

1. **Select wave0, wave1, and xwave in the Data Browser, and drag and drop them in the middle of the graph.**

   Igor displays a dialog asking you to select an X wave:



Graph Wave Drag

You have dragged multiple waves onto the graph. Please select an X wave:

xwave

2. **Select xwave from the pop-up menu and click OK.**

   Igor displays wave0 and wave1 versus xwave using the left and bottom axes.

   If you wanted to plot all dragged waves as waveforms rather than as XY pairs, you would choose _calculated_ from the popup menu and click OK.

3. **Remove the traces from the graph by executing:**

   ```
   RemoveFromGraph wave0, wave1
   ```

It is not supported to create multiple XY traces with one drag. For example, if you have waves named wave0 and xwave0 and wave1 and xwave1, you have to do two drags to create two XY pairs. If you have many such XY pairs, use the command line or the advanced mode of the New Graph or Append Traces dialog; see Creating Graphs for details.

Trace Names

Each trace in a graph has a name. Trace names are displayed in graph dialogs and popup menus and used in graphing operations. Some of the operations that take trace names as parameters are **ModifyGraph (traces)**, **RemoveFromGraph**, **ReorderTraces**, **ErrorBars** and **Tag**.

The name of the trace is usually the same as the name of the wave displayed in the trace, but not always. If two traces display the same wave, or waves with the same name from different data folders, **Instance Notation** such as #1and #2, is used to distinguish between the traces. For example:

```
Make wave0 = sin(x/8)

// Create first trace displaying wave0. The trace name is wave0.
Display wave0

// Create second trace displaying of wave0. The trace name is wave0#1.
AppendToGraph wave0
```

Trace names like wave0#1 are automatically generated by Igor based on the name of the wave and the position of the trace in the graph.

It is also possible to assign a user-defined name to a trace that is not derived from the name of the wave being displayed:

```
// Create third instance of wave0. The trace name is thirdInstance.
AppendToGraph wave0/TN=thirdInstance
```

This creates a graph with three traces named wave0, wave0#1 and thirdInstance. The trace name wave0 is equivalent to wave0#0.

As of Igor Pro 9.00, you can change the name of an existing trace using ModifyGraph with the traceName keyword.

User-defined trace names are helpful in graphs that display same-named waves from different data folders. They are also useful for assigning names to be used programmatically which indicate the purpose of the trace rather than the wave supplying the data for it. User-defined trace names can be set only via the Display and AppendToGraph operations.

User-defined trace names are particularly useful for box plots and violin plots, as these plot types often take a list of waves instead of just one wave. Unless you specify a user-defined trace name, the name is taken from the first wave in the list.

See also **User-defined Trace Names** on page IV-89.

Automatically-generated trace names can create surprises. Imagine that three waves from different data folders all having the name "wave0" are added to a graph:

```
Make :df1:wave0
Make :df2:wave0
Make :df3:wave0
Display :df1:wave0,:df2:wave0,:df3:wave0
```

Now the list of traces is wave0, wave0#1, wave0#2. Now remove the first trace:

```
RemoveFromGraph wave0
```

This is equivalent to removing wave0#0. Because the automatically-generated instance number is the based on position in the list of traces, the name of trace wave0#1 changes to wave0 and wave0#2 changes to wave0#1.

For information on programming with trace names, see **Programming With Trace Names** on page IV-87.

Moving Traces

You can move a trace from the left axis to the right axis or vice versa by right-clicking the trace and choosing Move to Opposite Axis. You can do other types of moves using the **ReorderTraces** operation with the /L or /R flags.

Removing Traces

You can remove traces, as well as image plots and contour plots, from a graph by choosing Remove from Graph from the Graph menu. Select the type of item that you want to remove from the pop-up menu above the list.

A contour plot has traces that you can remove, but they will come back when the contour plot is updated. Rather than removing the contour traces, use the pop-up to select Contours, and remove the contour plot itself, which automatically removes all of the contour-related traces. See **Removing Contour Traces from a Graph** on page II-374.

If you remove the last item associated with a given axis then that axis will also be removed.

Replacing Traces

You can “replace” a trace in the sense of changing the wave that the trace is displaying in a graph. All the other characteristics of the trace, such as mode, line size, color, and style, remain unchanged. You can use this to update a graph with data from a wave other than the one originally used to create the trace.

To replace a trace, use the Replace Wave item in the Graph menu to display the Replace Wave in Graph dialog:

A special mode allows you to browse through groups of data sets composed of identically-named waves residing in different data folders. For instance, you might take the same type of data during multiple runs on different experimental subjects. If you store the data for each run in a separate data folder, and you give the same names to the waves that result from each run, you can select the Replace All in Data Folder checkbox and then select one of the data folders containing data from a single run. All the waves in the chosen data folder whose names match the names of waves displayed in the graph will replace the same-named waves in the graph.

You can also replace waves one at a time with any other wave. With the Replace All in Data Folder checkbox unchecked, choose a trace from the list below the menu. To replace the Y wave used by the trace, check the Y checkbox; to replace the X wave check the X checkbox. You can replace both if you wish. Select the waves to use as replacements from the menus to the right of the checkboxes. You can select _calculated_ from the X wave menu to remove the X wave of an XY pair, converting it to a waveform display.

The menus allow you to select waves having lengths that don’t match the length of the corresponding X or Y wave. In that case, use the edit boxes to the right to select a sub-range of the wave’s points. You can also use these boxes to select a single row or column from a two-dimensional wave.

The dialog creates command lines using the **ReplaceWave** operation (page V-801).

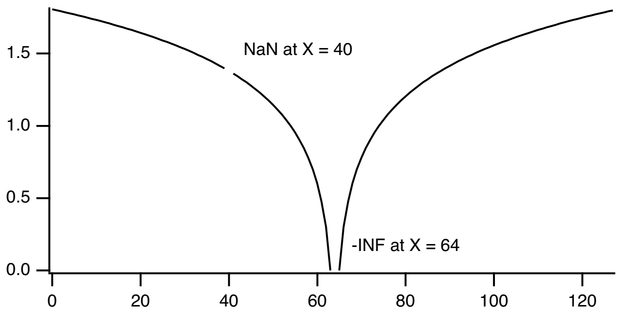
Plotting NaNs and INFs

The data value of a wave is normally a finite number but can also be a NaN or an INF. NaN means “Not a Number”, and INF means “infinity”. An expression returns the value NaN when it makes no sense mathematically. For example, `log(-1)` returns the value NaN. You can also set a point to NaN, using a table or a wave assignment, to represent a missing value. An expression returns the value INF when it makes sense mathematically but has no finite value. `log(0)` returns the value -INF.

Igor ignores NaNs and INFs when scaling a graph. If a wave in a graph is set to lines between points mode then Igor draws lines toward an INF. By default, it draws no line to or from a NaN so a NaN acts like a missing value. You can override the default, instructing Igor to draw lines through NaNs using the Gaps checkbox in the Modify Trace Appearance dialog.

The following graph illustrate these points. It was created with these commands:

```
Make wave1= log(abs(x-64))
wave1(40)=log(-1)
Display wave1
```



You can override the default, instructing Igor to draw lines through NaNs. See **Gaps** on page II-303 for details.

Scaling Graphs

Igor provides several ways of scaling waves in graphs. All of them allow you to control what sections of your waves are displayed by setting the range of the graph's axes. Each axis is either autoscaled or manually scaled.

Autoscaling

When you first create a graph all of its axes are in **autoscaling** mode. This means that Igor automatically adjusts the extent of the axes of the graph so that all of each wave in the graph is fully in view. If the data in the waves changes, the axes are automatically rescaled so that all waves remain fully in view.

If you manually scale any axis, that axis changes to **manual scaling** mode. The methods of manual scaling are described in the next section. Axes in manual scaling mode are never automatically scaled.

If you choose Autoscale Axes from the Graph menu all of the axes in the graph are autoscaled and returned to autoscaling mode. You can set individual axes to autoscaling mode and can control properties of autoscaling mode using the Axis Range tab of the Modify Axis dialog described in **Setting the Range of an Axis** on page II-286.

Manual Scaling

You can manually scale one or more axes of a graph using the mouse. Start by clicking the mouse and dragging it diagonally to frame the region of interest. Igor displays a dashed outline around the region. This outline is called a marquee. A marquee has handles and edges that allow you to refine its size and position.

To refine the size of the marquee move the cursor over one of the handles. The cursor changes to a double arrow which shows you the direction in which the handle moves the edge of the marquee. To move the edge click the mouse and drag.

To refine the position of the marquee move the cursor over one of the edges away from the handles. The cursor changes to a hand. To move the marquee click the mouse and drag.

When you click inside the region of interest Igor presents a pop-up menu from which you can choose the scaling operation.

Choose the operation you want and release the mouse. These operations can be undone and redone; just press Command-Z (*Macintosh*) or Ctrl+Z (*Windows*).

The **Expand** operation scales all axes so that the region inside the marquee fills the graph (zoom in). It sets the scaling mode for all axes to manual.

The **Horiz Expand** operation scales only the horizontal axes so that the region inside the marquee fills the graph horizontally. It has no effect on the vertical axes. It sets the scaling mode for the horizontal axes to manual.

The **Vert Expand** operation scales only the vertical axes so that the region inside the marquee fills the graph vertically. It has no effect on the horizontal axes. It sets the scaling mode for the vertical axes to manual.

The **Shrink** operation scales all axes so that the waves in the graph appear smaller (zoom out). The factor by which the waves shrink is equal to the ratio of the size of the marquee to the size of the entire graph. For example, if the marquee is one half the size of the graph then the waves shrink to one half their former size. The point at the center of the marquee becomes the new center of the graph. The shrink operation sets the scaling mode for all axes to manual.

The **Horiz Shrink** operation is like the shrink operation but affects the horizontal axes only. It sets the scaling mode for the horizontal axes to manual.

The **Vert Shrink** operation is like the shrink operation but affects the vertical axes only. It sets the scaling mode for the vertical axes to manual.

Another way to manually scale axes is to use the Axis Range tab of the Modify Axis dialog (see **Manual Axis Ranges** on page II-287), or the **SetAxis** operation (page V-835).

Scaling Using the Mouse Wheel

You can manually scale a graph axis using the mouse wheel. The scaling performed is determined by where along the axis you position the mouse. Start by positioning the mouse over the axis until the cursor changes to a double-ended arrow.

If you position the mouse over the middle of the axis and rotate the wheel, both ends of the axis are scaled equally.

If you position the mouse over one end of the axis and rotate the wheel, that end remains fixed and the other end of the axis is scaled.

If you position the mouse between the middle and one end of the axis and rotate the wheel, more of the scaling is applied to the other end.

Panning

After zooming in on a region of interest, you may want to view data that is just off screen. To do this, press Option (*Macintosh*) or Alt (*Windows*) and move the mouse to the graph interior where the cursor changes to a hand. Now drag the body of the graph. Pressing Shift will constrain movement to the horizontal or vertical directions.

This operation is undoable.

Fling Mode

If, while panning, you release the mouse button while the mouse is still moving, the panning will automatically continue. While panning, release the Option or Alt key and change the force or direction of the mouse-click gesture to change the panning speed or direction. Click the mouse button once to stop.

Panning Using the Mouse Wheel

You can pan a graph using the mouse wheel. Start by positioning the mouse over the axis until the cursor changes to a double-ended arrow.

Press the shift key and rotate the wheel. The axis range is changed to pan the graph. The axis value over which you position the mouse remains fixed while the axis range is changed.

Panning is triggered by "horizontal scrolling" with the mouse wheel. With most mice, you trigger horizontally scrolling by pressing the shift key and rotating the scroll wheel, but some mice may behave differently.

Setting the Range of an Axis

You can set the range and other scaling parameters for individual axes using the Axis Range tab in the Modify Axis dialog. You can display the dialog with this tab selected by choosing Set Axis Range from the

Graph menu or by double-clicking a tick mark label of the axis you wish to modify. Information on the other tabs in this dialog is available in **Modifying Axes** on page II-306.

Start by choosing the axis that you want to adjust from the Axis pop-up menu. You can adjust each axis in turn, or a selection of axes, without leaving this dialog.

Manual Axis Ranges

When a graph is first created, it is in autoscaling mode. In this mode, the axis limits automatically adjust to just include all the data. The controls in the Autoscale Settings section provide autoscaling options.

You can set the axis limits to fixed values by editing the minimum and maximum parameters in the Manual Range Settings section. You can return the minimum or maximum axis range to autoscaling mode by unchecking the corresponding checkbox. These settings are independent, so you can fix one end of the axis and autoscale the other end.

There are a number of other ways to set the minimum and maximum parameters. Clicking the Expand 5% button expands the range by 5 percent. This has the effect of shrinking the traces plotted on the axis by 5%.

Clicking the Swap button exchanges the minimum and maximum parameters. This has the effect of reversing the ends of the axis, allowing you to plot waves upside-down or backwards with fixed limits.

An additional way to set the minimum and maximum parameters is to select a wave from the list and use the Quick Set buttons. If you click the X Min/Max quick set button then the minimum and maximum X values of the selected wave are transferred to the parameter boxes. If you click the Y Min/Max quick set button then the minimum and maximum Y values of the selected wave are transferred to the parameter boxes. If you specified the full scale Y values for the wave then you can click the Full Scale quick set button. This transfers the wave’s Y full scale values to the parameter boxes. The full scale Y values can be set using the Change Wave Scaling item in the Data menu.

Automatic Axis Ranges

When the manual minimum and maximum checkboxes are unchecked, the axis is in autoscaling mode. In this mode the axis limits are determined by the data values in the waves displayed using the selected axis. The items in the Autoscale Settings section control the method used to determine the axis range:

The Reverse Axis checkbox swaps the minimum and maximum axis range values, plotting the trace upside-down or backwards.

The top pop-up menu controls adjustments to the minimum and maximum axis range values.

The default mode is “Use data limits”. The axis range is set to the minimum and maximum data values of all waves plotted against the axis.

The “Round to nice values” mode extends the axis range to include the next major tick mark.

The “Nice + inset data” mode extends the axis range to include the next major tick mark and also ensures that traces are inset from both ends of the axis.

The bottom pop-up menu controls the treatment f the value zero.

The default mode is “Zero isn’t special”. The axis range is set to the minimum and maximum data values.

The “Autoscale from zero” mode forces the end of the axis that is closest to zero to be exactly zero.

The “Symmetric about zero” mode forces zero to be in the middle of the axis range.

The “Autoscale from zero if not bipolar” mode behaves like “Autoscale from zero” if the data is unipolar (all positive or all negative) and like “Zero isn’t special” if the data is bipolar.

Autoscaling mode usually sets the axis limits using all the data in waves associated with the traces that use the axis. This can be undesirable if the associated horizontal axis is set to display only a portion of the total

X range. Select the Autoscale Only Visible Data checkbox to have Igor use only the data included within the horizontal range for autoscaling. This checkbox is available only if the selected axis is a vertical axis.

Overall Graph Properties

You can specify certain overall properties of a graph by choosing Modify Graph from the Graph menu. This brings up the Modify Graph dialog. You can also get to this dialog by double-clicking a blank area outside the plot rectangle.

Normally, X axes are plotted horizontally and Y axes vertically. You can reverse this behavior by checking the “Swap X & Y Axes” checkbox. This is commonly used when the independent variable is depth or height. This method swaps X and Y for all traces in the graph. You can cause individual traces to be plotted vertically by selecting the “Swap X & Y Axes” checkbox in the New Graph and Append Traces dialogs as you are creating your graph.

Initially, the graph font is determined by the default font which you can set using the Default Font item in the Misc menu. The graph font size is initially automatically calculated based on the size of the graph. You can override these initial settings using the “Graph font” and “Font size” settings. Igor uses the font and size you specify in annotations and axis labels unless you explicitly set the font or size for an individual annotation or label.

Initially, the graph marker size is automatically calculated based on the size of the graph. You can override this using the “Marker size” setting. You can set it to “auto” (or 0 which is equivalent) or to a number from -1 to 99. Use -1 to make a graph subwindow get is default font size from its parent. Igor uses the marker size you specify unless you explicitly set the marker size for an individual wave in the graph.

The “Use comma as decimal separator” checkbox determines whether dot or comma is used as the decimal separator in tick mark labels.

Graph Margins

The margin is the distance from an outside edge of the graph to the edge of the plot area of the graph. The plot area, roughly speaking, is the area inside the axes. See **Graph Dimensions** on page II-288 for a definition. Initially, Igor automatically sets each margin to accommodate axis and tick mark labels and exterior textboxes, if any. You can override the automatic setting of the margin using the Margins settings. You would do this, for example, to force the left margins of two graphs to be identical so that they align properly when stacked vertically in a page layout. The Units pop-up menu determines the units in which you enter the margin values.

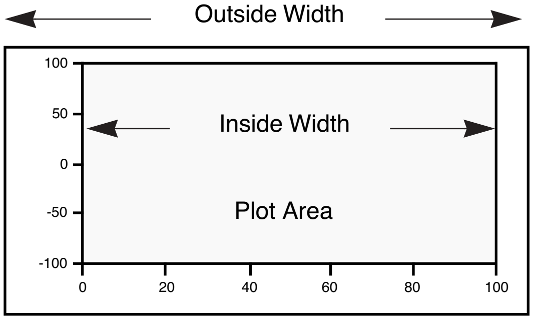
You can also set graph margins interactively. If you press Option (*Macintosh*) or Alt (*Windows*) and position the cursor over one of the four edges of the plot area rectangle, you will see the cursor change to this shape: ⇹ . Use this cursor to drag the margin. You can cause a margin to revert to automatic mode by dragging the margin all the way to the edge of the graph window or beyond. If you drag to within a few pixels of the edge, the margin will be eliminated entirely. If you double click with this cursor showing, Igor displays the Modify Graph dialog with the corresponding margin setting selected.

If you specify a margin for a given axis, the value you specify solely determines where the axis appears. Normally, dragging an axis will adjust its offset relative to the nominal automatic location. If, however, a fixed margin has been specified then dragging the axis will drag the margin.

Graph Dimensions

The Modify Graph dialog provides several ways of controlling the width and height of a graph. Usually you don’t need to use these. They are intended for certain specialized applications.

These techniques are powerful but can be confusing unless you understand the algorithms, described below, that Igor uses to determine graph dimensions.



The graph can be in one of five modes with respect to each dimension: auto, absolute, per unit, aspect, or plan. These modes control the width and height of the **plot area** of the graph. The plot area is the shaded area in the illustration. The width mode and height mode are independent.

In this graph, the axis standoff feature, described in the **Modifying Axes** section on page II-306, is off so the plot area extends to the center of the axis lines. If it were on, the plot area would extend only to the inside edge of the axis lines.

Auto mode automatically determines the width or height of the plot area based on the outside dimensions of the graph and other factors that you specify using Igor's dialogs. This is the normal default mode which is appropriate for most graphing jobs. The remaining modes are useful for special purposes such as matching the axis lengths of two or more graphs or replicating a standard graph or a graph from a journal.

If you select any mode other than auto, you are putting a constraint on the width or height of the plot area which also affects the outside dimensions of the graph. If you adjust the outside size of the graph, by dragging the window's size box, by tiling, by stacking or by using the MoveWindow operation, Igor first determines the outside dimensions as you have specified them and then applies the constraints implied by the width/height mode that you have selected. A graph dimension can be changed by dragging with the mouse only if it is auto mode.

With **Absolute** mode, you specify the width or height of the plot area in absolute units; in inches, centimeters or points. For example, if you know that you want your *plot area* to be exactly 5 inches wide and 3.5 inches high, you should use those numbers with an absolute mode for both the width and height.

If you want the *outside* width and height to be an exact size, you must also specify a fixed value for all four margins. For instance, setting all margins to 0.5 inches in conjunction with an absolute width of 5 inches and a height of 3.5 inches yields a graph whose outside dimensions will be 6 inches wide by 4.5 inches high.

The **Aspect** mode maintains a constant aspect ratio for the plot area. For example, if you want the width to be 1.5 times longer than the height, you would set the width mode to aspect and specify an aspect ratio of 1.5.

The remaining modes, per unit and plan, are quite powerful and convenient for certain specialized types of graphs, but are more difficult to understand. You should expect that some experimentation will be required to get the desired results.

In **Per unit** mode, you specify the width or height of the plot area in units of length per axis unit. For example, suppose you want the plot width to be one inch per 20 axis units. You would specify 1/20 = 0.05 inches per unit of the bottom axis. If your axis spanned 60 units, the plot width would be three inches.

Igor allows you to select a horizontal axis to control the vertical dimension or a vertical axis to control the horizontal direction, but it is very unlikely that you would want to do that.

In **Plan** mode, you specify the length of a unit in the horizontal dimension as a scaling factor times the length of a unit in the vertical dimension, or vice versa. The simplest use of plan scaling is to force a unit in one dimension to be the same as in the other, such as would be appropriate for a map. To do this, you select plan scaling for one dimension and set the scaling factor to 1.

Until you learn how to use the per unit and plan modes, it is easy to create a graph that is ridiculously small or large. Since the size of the graph is tied to the range of the axes, expanding, shrinking or autoscaling the graph makes its size change.

Applying plan or aspect mode to both the X and Y dimensions of a graph is a bad idea. Interactions between the dimensions cause huge or tiny graphs, or other bizarre results. The Modify Graph dialog does not allow both dimensions to be plan or aspect, or a combination of the two. However, the ModifyGraph operation permits it and it is left to you to refrain from doing this.

Sometimes you can end up with a graph whose size makes it difficult to move or resize the window. Use the Graph menu's Modify Graph dialog to reset the size of the graph to something more manageable.

You can change a graph dimension by dragging with the mouse only if it is in auto mode. If you want to resize a graph but can't, use the Modify Graph dialog to check the width and height modes.

If you want to fully understand how Igor arrives at the final size of a graph when the width or height is constrained, you need to understand the algorithm Igor uses:

1. The initial width and height are calculated. When you adjust a window by dragging, the initial width and height are based on the width and height to which you drag the window.
2. If you are exporting graphics, the width and height are as specified in the Export Graphics dialog or in the **SavePICT** command.
3. If you are printing, the width and height are modified by the effects of the printing mode, as set by the **PrintSettings** graphMode keyword.
4. The width modes absolute and per unit are applied which may generate a new width.
5. The height mode is applied which may generate a new height.
6. The width modes aspect and plan are applied which may generate a new width.

Because there are many interactions, it is possible to get a graph so big that you can't adjust it manually. If this occurs, use the Modify Graph dialog to set the width and height to a manageable size, using absolute mode.

Modifying Traces

You can specify each trace's appearance in a graph by choosing Modify Trace Appearance from the Graph menu or by double-clicking a trace in the graph. This brings up the following dialog:

For image plots, choose Modify Image Appearance from the Graph menu, rather than Modify Trace Appearance.

For contour plots, you normally should choose Modify Contour Appearance. Use this to control the appearance of all of the contour lines in one step. However, if you want to make one contour line stand out, use the Modify Trace Appearance dialog.

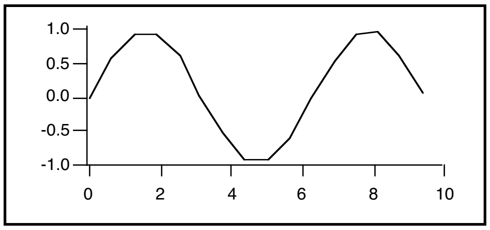
Selecting Traces to be Modified

Select the trace or traces whose appearance you want to modify from the Trace list. If you got to this dialog by double-clicking a trace in the graph then that trace will automatically be selected. If you select more than one trace, the items in the dialog will show the settings for the *first* selected trace.

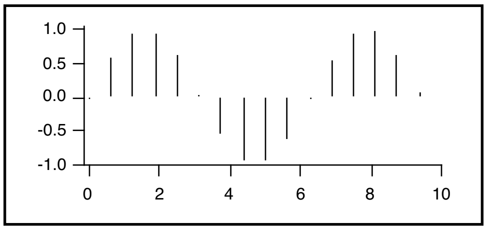
Once you have made your selection, you can change settings for the selected traces. After doing this, you can then select a different trace or set of traces and make more changes. Igor remembers all of the changes you make, allowing you to do everything in one trip to the dialog.

Display Modes

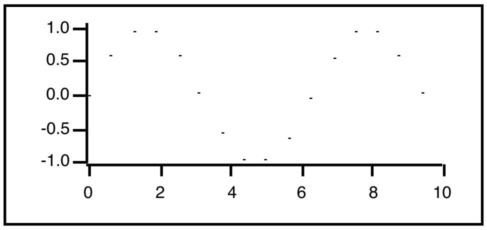
Choose the **mode** of presentation for the selected trace from the Mode pop-up menu. The commonly-used modes are Lines Between Points, Dots, Markers, Lines and Markers, and Bars. Other modes allow you to draw sticks, bars and fills to Y=0 or to another trace.



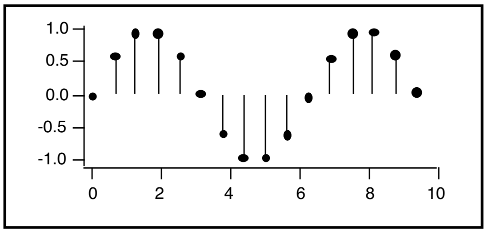
Lines between points mode



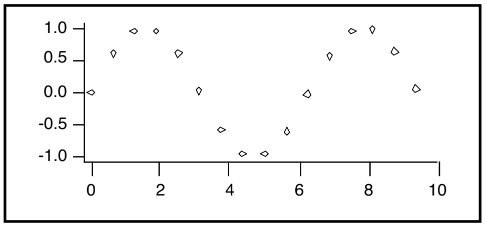
Sticks to zero mode



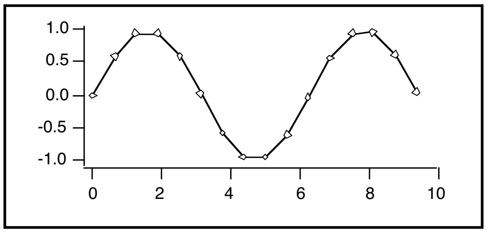
Dots mode



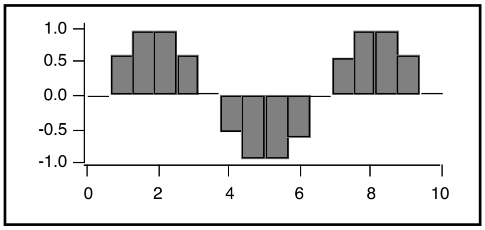
Sticks and markers mode



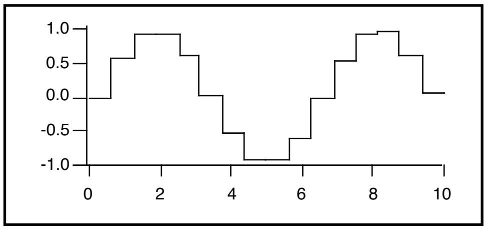
Markers mode



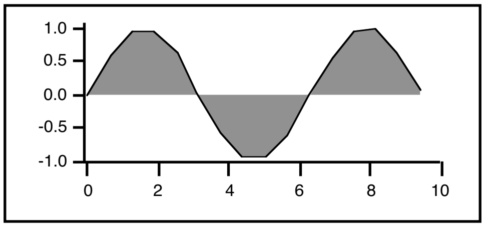
Lines and markers mode



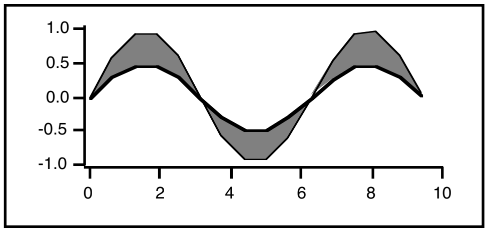
Bars mode



Cityscape mode



Fill to zero mode



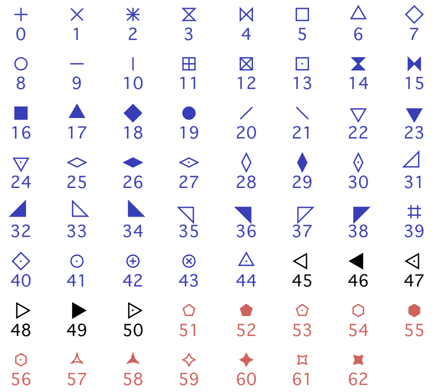
Fill to next mode

Markers

If you choose the Markers or Lines and Markers mode you also can choose the marker, marker size, marker thickness, and whether the marker is transparent or filled with color. The marker size is a fractional number from 0 to 200. 0 means “auto”, which chooses a marker size appropriate to the size of the graph. The marker thickness is in a fractional number from 0 to 50 points. Fractional points may not be evident on screen but can be seen in exported and printed graphics. Setting the marker thickness to 0 makes the markers disappear.

There is an interaction between marker size and marker thickness: Igor will adjust the marker size if this is needed to make the marker symmetrical. The unadjusted width and height of the marker is 2*s+1 points where s is the marker size setting.

Here is a table of the markers and the corresponding marker codes:



You can also create custom markers. See the **SetWindow** operation's markerHook keyword.

Marker Colors

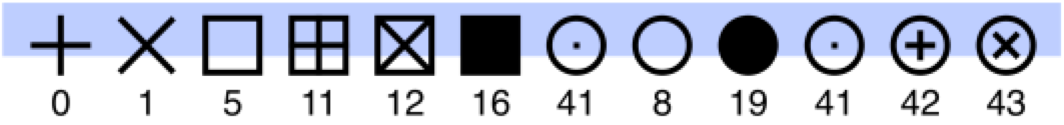
Igor provides control of three colors for graph markers: the trace color, the stroke color and the fill color.

The trace color is simply the color selected for the trace overall and is the same for any trace mode.

The stroke color is the color of the lines making the outlines of the markers. By default the stroke color is the same as the trace color.

The fill color is used to fill the background space of hollow markers. By default there is no fill color so that you see background objects through the interiors of hollow markers.

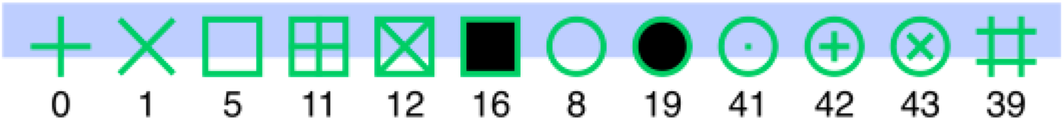
Here is a sample of some of Igor's markers with the trace color set to black, the marker size set to 10 and the marker stroke thickness set to 2 points. A blue rectangle is drawn beneath the markers:



The blue rectangle shows through the interior of the hollow markers (5, 11, 12, 8, 41, 42, 43). The solid markers (16, 19) are solid black because the trace color is black.

You can set the stroke color using the Modify Trace Appearance dialog: turn on the Stroke checkbox and select a color. You can also use the command ModifyGraph mrkStrokeRGB. In the next figure, the stroke color was set to green using the command

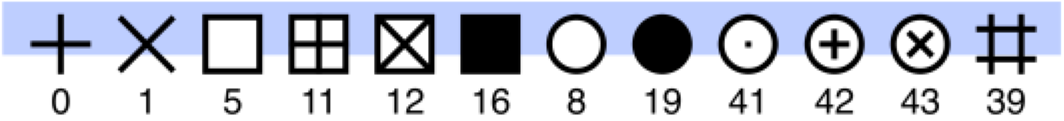
```
ModifyGraph mrkStrokeRGB=(1,52428,26586)
```



The stroke color overrides the trace color, so the outlines of all the markers are now green. The solid markers are black with green outlines.

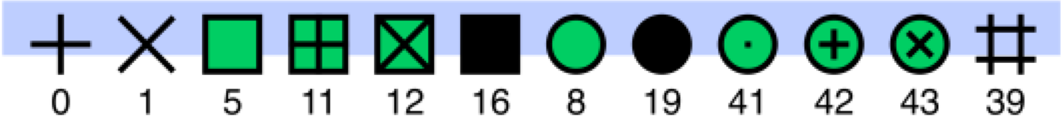
You can choose to make the interiors of hollow markers opaque. In the Modify Trace Appearance dialog, turn on the Fill checkbox. The command is

```
ModifyGraph opaque=1
```



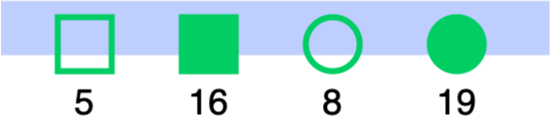
By default, the interior color of opaque hollow markers is white. You can change the interior color by selecting a fill color in the Modify Trace Appearance dialog or with the ModifyGraph mrkFillRGB keyword. Here the fill is set using the command

```
ModifyGraph mrkFillRGB=(1,52428,26586)
```

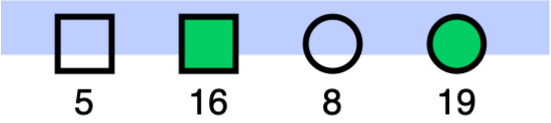


It is possible to achieve identical results by setting the stroke color of a solid marker or the fill color of a hollow marker, as in the following example.

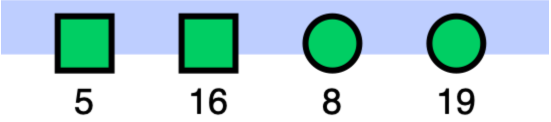
Trace color set to green:



Now set the stroke color set to black, resulting in solid markers having a black outline and green interior:



Finally set the fill color to green resulting in hollow markers being filled with green:



Now the solid and hollow markers look the same. This is a historical oddity - the fill color could not be changed from white before Igor Pro 9.00. Before Igor9 the hollow markers with interior markings such as 11 or 42 could not be filled with a color.

Text Markers

In addition to the built-in drawn markers, you can also instruct Igor to use one of the following as text markers:

- A single character from a font
- The contents of a text wave
- The contents of a numeric wave

A single character from a font is mainly of interest if you want to use a special symbol that is available in a font but is not included among Igor’s built-in markers. The specified character is used for all data points.

The remaining options provide a way to display a third value in an XY plot. For example, a plot of earthquake magnitude versus date could also show the location of the earthquake using a text wave to supply text markers. Or, a plot of earthquake location versus date could also show the magnitude using a numeric wave to supply text markers. For each data point in the XY plot, the corresponding point of the text or numeric wave supplies the text for the marker. The marker wave must have the same number of points as the X and Y waves.

To create a text marker, choose the Markers or Lines and Markers display mode. Then click the Markers pop-up menu and choose the Text button. This leads to the Text Markers subdialog in which you can specify the source of the text as well as the font, style, rotation and other properties of the markers.

You can offset and rotate all the text markers by the same amount but you can not set the offset and rotation for individual data points — use tags for that. You may find it necessary to experimentally adjust the X and Y offsets to get character markers exactly centered on the data points. For example, to center the text just above each data point, choose Middle bottom from the Anchor pop-up menu and set the Y offset to 5-10 points. If you need to offset some items differently from others, you will have to use tags (see **Tags** on page III-43).

Igor determines the font size to use for text markers from the marker size, which you set in the Modify Trace Appearance dialog. The font size used is 3 times the marker size.

You may want to show a text marker *and* a regular drawn marker. For this, you will need to display the wave twice in the graph. After creating the graph and setting the trace to use a drawn marker, choose Graph→Append Traces to Graph to append a second copy of the wave. Set this copy to use text markers.

Arrow Markers

Arrow markers can be used to create vector plots illustrating flow and gradient fields, for example. Arrow markers are fairly special purpose and require quite a bit of advance preparation.

Here is a very simple example:

```
// Make XY data
Make/O xData = {1, 2, 3}, yData = {1, 2, 3}
Display yData vs xData              // Make graph
ModifyGraph mode(yData) = 3         // Marker mode

// Make an arrow data wave to control the length and angle for each point.
Make/O/N=(3,2) arrowData            // Controls arrow length and angle
Edit /W=(439,47,820,240) arrowData

// Put some data in arrowData
arrowData[0][0]= {20,25,30}                  // Col 0: arrow lengths in points
arrowData[0][1]= {0.523599,0.785398,1.0472}  // Col 1: arrow angle in radians

// Set trace to arrow mode to turn arrows on
ModifyGraph arrowMarker(yData) = {arrowData, 1, 10, 1, 1}

// Make an RGB color wave
Make/O/N=(3,3) arrowColor
Edit /W=(440,272,820,439) arrowColor

// Store some colors in the color wave
arrowColor[0][0]= {65535,0,0}       // Red
arrowColor[0][1]= {0,65535,0}       // Green
arrowColor[0][2]= {0,0,65535}       // Blue

// Turn on color as f(z) mode
ModifyGraph zColor(yData)={arrowColor,*,*,directRGB,0}
```

To see a demo of arrow markers choose File→Example Experiments→Graphing Techniques→Arrow Plot.

See the reference for a description of the arrowMarker keyword under the **ModifyGraph (traces)** operation on page V-613 for further details.

Line Styles and Sizes

If you choose the “Lines between points”, “Lines and markers”, or Cityscape mode you can also choose the line style. You can change the dash patterns using the Dashed Lines item in the Line section.

For any mode except the Markers mode you can set the line size. The line size is in points and can be fractional. If the line size is zero, the line disappears.

For more information see **Dashed Lines** on page III-496.

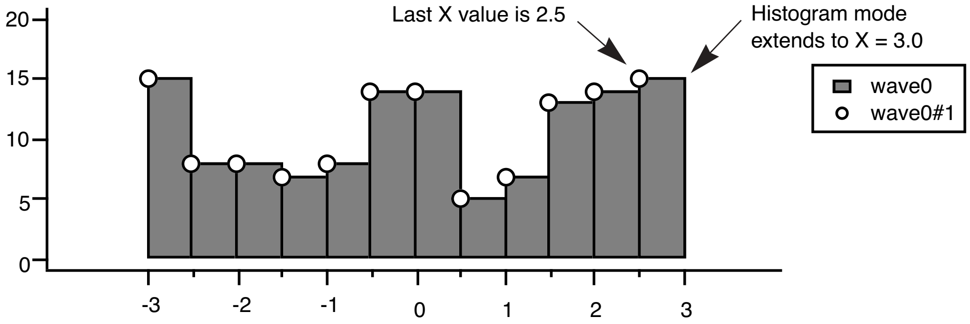
Fills

For traces in the Bars and “Fill to zero” modes, Igor presents a choice of fill type. The fill type can be None, which means the fill is transparent, Erase, which means the fill is white and opaque, Solid, or three patterns of gray. You can also choose a pattern from a palette and can choose the fill types and colors for positive going regions and negative going regions independently.

For more information see **Fill Patterns** on page III-498 and **Gradient Fills** on page III-498.

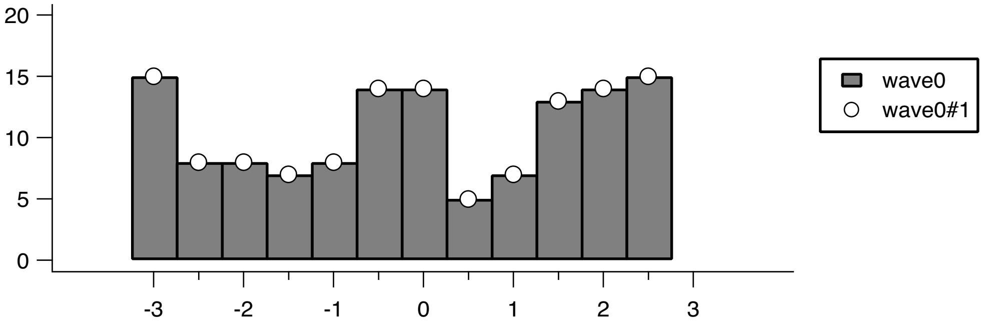
Bars With Waveforms

When Bars mode is used for a waveform plotted on a normal continuous X axis (rather than a category axis, see Chapter II-14, **Category Plots**), the X values are computed from the wave’s X scaling. The bars are drawn from the X value for a given point up to *but not including* the X value for the next point. Such bars are commonly called “histogram bars” because they are usually used to show the number of counts in a histogram that fall between the two X values.



If you want your bars centered on their X values, then you should create a Category Plot, which is more suited for traditional bar charts (see Chapter II-14, **Category Plots**). You can, however, adjust the X values for the wave so that the flat areas appear centered about its original X value as for a traditional bar chart. One way to do this without actually modifying any data is to offset the trace in the graph by one half the bar width. You can just drag it, or use the Modify Trace Appearance dialog to generate a more precise offset command. In our example, the bars are 0.5 X units wide:

```
ModifyGraph offset(wave0)={-0.25,0}
```



Bars With XY Pairs

If your X axis is controlled by an XY pair, the width of each bar is determined by two X values. One X value provides the location of the left edge of the bar and the next X value provides the location of the right edge of the bar.

If you imagine a bar plot with one bar, this requires an XY pair with two points - one X value to set the left edge of the bar and the next X value to set the right edge.

Generalizing, for a bar plot with N bars, you need N+1 points in your X and Y waves. Here is an example using 3 XY points to produce two bars:

```
Make/O barX={0,1,3}, barY = {1,2,2}
Display barY vs barX
ModifyGraph mode=5, hbFill=4
SetAxis left 0,*
```

Grouping, Stacking and Adding Modes

For the four modes that normally draw to y=0 (“Sticks to zero”, “Bars”, “Fill to zero”, and “Sticks and markers”) you can choose variants that draw to the Y values of the next trace. The four variant modes are: “Sticks to next”, “Bars to next”, “Fill to next” and “Sticks&markers to next”. *Next* in this context refers to the trace listed after (below) the selected trace in the list of traces in the Modify Trace Appearance and the Reorder Traces dialogs.

If you choose one of these four modes, Igor automatically selects “Draw to next” from the Grouping pop-up menu. You can also choose “Add to next” and “Stack on next” modes.

The Grouping pop-up menu the Modify Trace Appearance dialog is used to create special effects such as layer graphs and stacked bar charts. The available modes are “Keep with next”, None, “Draw to next”, “Add to next”, and “Stack on next.

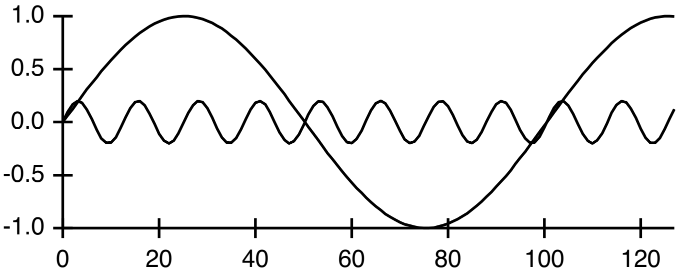
“Keep with next” is used only with category plots and is described in Chapter II-14, **Category Plots**.

“Draw to next” modifies the action of those modes that normally draw to y=0 so that they draw to the Y values of the next trace that is plotted against the same pair of axes as the current trace. The X values for the next trace should be the same as the X values for the current trace. If not, the next trace will not line up with the bottom of the current trace.

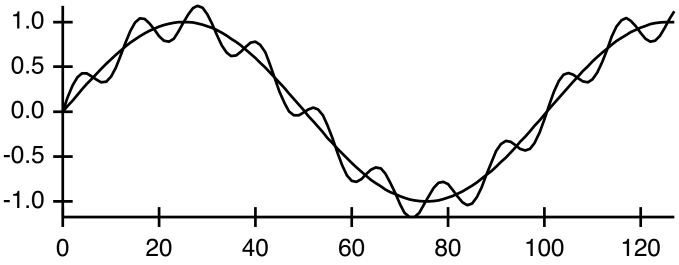
“Add to next” adds the Y values of the current trace to the Y values of the next trace before plotting. If the next trace is also using “Add to next” then that addition is performed first and so on. When used with one of the four modes that normally draw to y=0, this mode also acts like “Draw to next”.

“Stack on next” works just like “Add to next” except Y values are not allowed to backtrack. On other words, negative values act like zero when the Y value of the next trace is positive and positive values act like zero with a negative next trace.

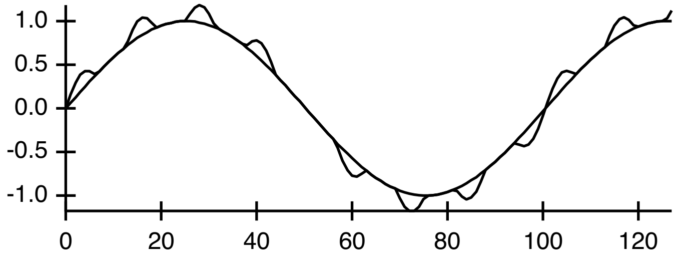
Here is a normal plot of a small sine wave and a bigger sine wave:



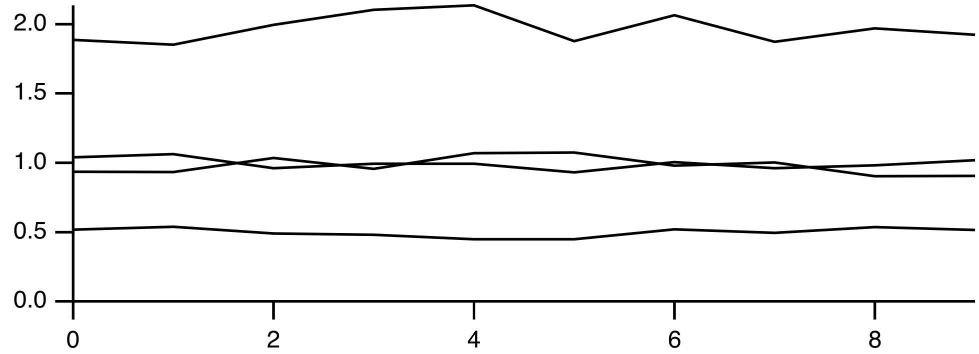
In this version, the small sine wave is set to “Add to next” mode:



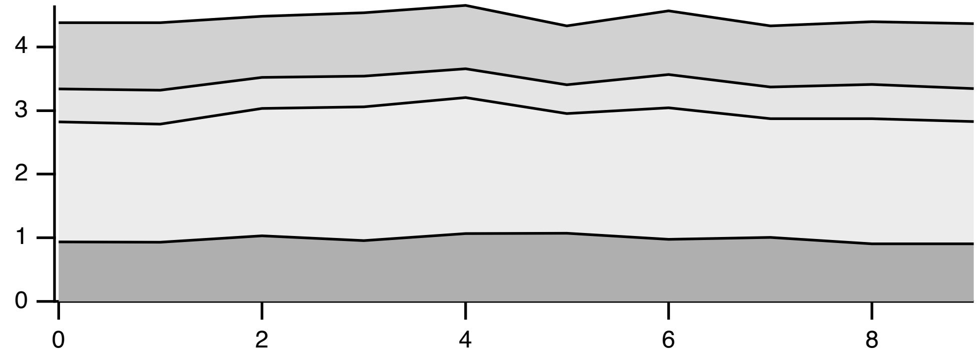
And here we use “Stack on next”:



You can create layer graphs by plotting a number of waves in a graph using the fill to next mode. Depending on your data you may also want to use the add to next grouping mode. For example, in the following normal graph, each trace might represent the thickness of a geologic layer:



We can show the layers in a more understandable way by using fill to next and add to next modes:



Because the grouping modes depend on the identity of the next trace, you may need to adjust the order of traces in the graph. You can do this using the Reorder Traces dialog. Choose Graph→Reorder Traces. Select the traces you want to move. Adjust the order by dragging the selected traces up and down in the list, dropping them in the appropriate spot.

Note: All of the waves you use for the various grouping, adding, and stacking modes should have the same numbers of points, X scaling, and should all be displayed using the same axes.

Trace Color

You can choose a color for the selected trace from the color pop-up palette of colors.

In addition to color, you can specify opacity using the color pop-up via the “alpha” property. An alpha of 1.0 makes the trace fully opaque. An alpha of 0.0 makes it fully transparent.

Setting Trace Properties from an Auxiliary (Z) Wave

You can set the color, marker number, marker size, and pattern number of a trace on a point-by-point basis based on the values of an auxiliary wave. The auxiliary wave is called the “Z wave” because other waves control the X and Y position of each point on the trace while the Z wave controls a third property.

For example, you could position markers at the location of earthquakes and vary their size to show the magnitude of each quake. You could show the depth of the quake using marker color and show different types of quakes as different marker shapes.

To set a trace property to be a function of a Z wave, click the “Set as f(z)” button in the Modify Trace Appearance dialog to display the “Set as f(z)” subdialog.

Color as f(z)

Color as f(z) has four modes: Color Table, Color Table Wave, Color Index Wave, and Three or Four Column Color Wave. You select the mode from the Color Mode menu.

In Color Table mode, the color of each data point on the trace is determined by mapping the corresponding Z wave value into a built-in color table. The mapping is logarithmic if the Log Colors checkbox is checked and linear otherwise. The Log Colors option is useful when the zWave spans many decades and you want to show more detailed changes of the smaller values.

The zMin and zMax settings define the range of values in your Z wave to map onto the color table. Values outside the range take on the color at the end of the range. If you choose Auto for zMin or zMax, Igor uses the smallest or largest value it finds in your Z wave. If any of your Z values are NaN, Igor treats those data points in the same way it does if your X or Y data is NaN. This depends on the Gaps setting in the main dialog.

Color Table Wave mode is the same as Color Table mode except that the colors are determined by a color table wave that you provide instead of a built-in color table. See **Color Table Waves** on page II-399 for details.

In Color Index Wave mode, the color of data points on the trace is derived from the Z wave you choose by mapping its values into the X scaling of the selected 3-column color index wave. This is similar to the way **ModifyImage** cindex maps image values (in place of the Z wave values) to a color in a 3-column color index matrix. See **Indexed Color Details** on page II-400.

In Three or Four Column Color Wave mode, data points are colored according to Red, Green and Blue values in the first three columns of the selected wave. Each row of the three column wave controls the color of a data point on the trace. This mode gives absolute control over the colors of each data point on a trace. If the wave has a fourth column, it controls opacity. See **Direct Color Details** on page II-401 for further information.

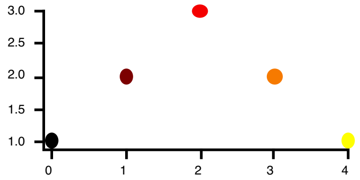
Color as f(z) Example

Create a graph:

```
Make/N=5 yWave = {1,2,3,2,1}
Display yWave
ModifyGraph mode=3, marker=19, msize=5
```

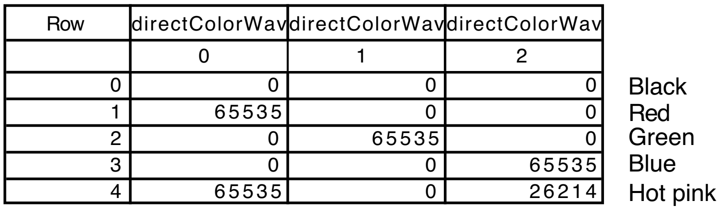
```
Make/N=5 zWave = {1,2,3,4,5}
ModifyGraph zColor(yWave)={zWave,*,*,YellowHot}
```

The commands generate this graph:



If instead you create a three column wave and edit it to enter RGB values:

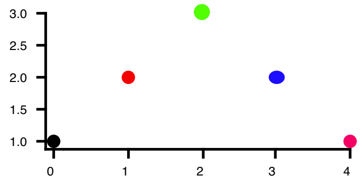
```
Make/N=(5,3) directColorWave
```



Row	directColorWav	directColorWav	directColorWav	
	0	1	2	
0	0	0	0	Black
1	65535	0	0	Red
2	0	65535	0	Green
3	0	0	65535	Blue
4	65535	0	26214	Hot pink

You can use this wave to directly control the marker colors:

```
ModifyGraph zColor(yWave)={directColorWave,*,*,directRGB}
```

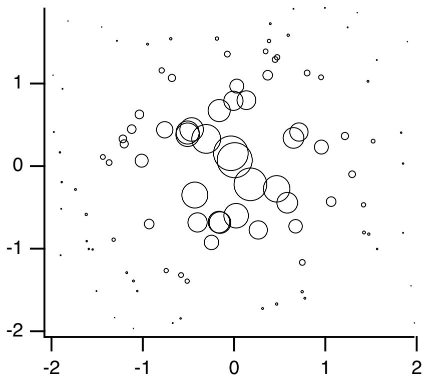


Marker Size as f(z)

“Marker size as f(z)” works just like “Color as f(z)” in Color Table mode except the Z values map into the range of marker sizes that you define using the min and max marker settings.

This example presents a third value as a function of marker size:

```
Make/N=100 xData,yData,zData
xData=enoise(2); yData=enoise(2); zData=exp(-(xData^2+yData^2))
Display yData vs xData; ModifyGraph mode=3,marker=8
ModifyGraph zmrkSize(yData)={zData,*,*,1,10}
```

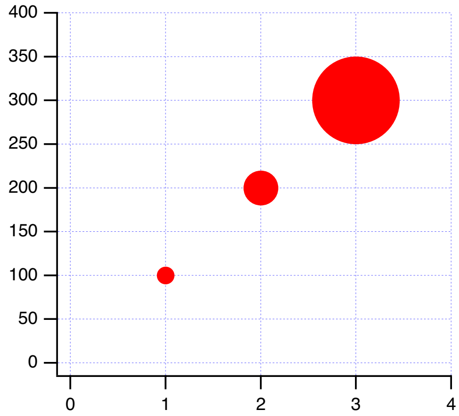


Marker Size as f(z) in Axis Units

In Igor Pro 9.00 or later, you can specify the marker size in units of an axis. For example:

```
Make/O xData2 = {1,2,3}
Make/O yData2 = {100,200,300}
Make/O zData2 = {10, 20, 50}
Display/W=(400,50,700,300) yData2 vs xData2
ModifyGraph mode=3, marker=19, msize=6 // Markers mode, filled circle marker
ModifyGraph grid=1
ModifyGraph nticks(left)=10
SetAxis left,0,400
SetAxis bottom,0,4
ModifyGraph zmrkSize(yData2)={zData2,*,*,6,10,left}
```

The last command sets the marker size to be controlled by the wave zData2 whose values are scaled to the left axis. For example, zData2[2] is 50 and sets the radius of the marker for point 2 of yData2 to be 50 units on the left axis. This produces this graph:



The axis specified can be any axis on the graph. If that axis is later removed, the marker size, the marker size goes back to the "no axis" state as if you never specified an axis.

When scaling marker sizes in axis units, the values that you specify for the zMin, zMax, mrkMin, and mrkMax parameters of the zmrkSize keyword have no impact on the marker size unless you remove the specified axis in which case those parameters control the trace's marker sizes.

If the marker size scale is independent of the scales of the axes against which the trace is plotted, you can use a free axis to show the scale. You do this by creating a free axis with the desired range and setting it as the axis for the zmrkSize keyword. See **Types of Axes** on page II-279 for a discussion of free axes.

If the axis that you specify is a log axis, the interpretation of Z values changes. Think of a conceptual axis of the same length in points as the log axis. Conceptually set the min and max of the conceptual axis to the log of the min and log of the max of the log axis. The marker size for a given Z value is the length of Z units on the conceptual axis. To help visualize this, you can create a free axis representing this conceptual axis.

For a demo, choose File→Example Experiments→Graphing Techniques→Marker Size in Axis Units Demo.

Marker Number as f(z)

In"Marker Number as f(z)" mode, you must create a Z wave that contains the actual marker numbers for each data point. See **Markers** on page II-291 for the marker number codes.

Pattern Number as f(z)

In “Pattern Number as f(z)” mode, you must create a Z wave that contains the actual pattern numbers for each data point. See **Fill Patterns** on page III-498 for a list of pattern numbers.

Color as f(z) Legend Example

If you have a graph that uses the color as f(z) mode, you may want to create a legend that identifies what the colors correspond to. This section demonstrates using the features of the Legend operation for this purpose.

Execute these commands, one-at-a-time:

```
// Make test data
Make /O testData = {1, 2, 3}

// Display in a graph in markers mode
Display testData
ModifyGraph mode=3,marker=8,msize=5

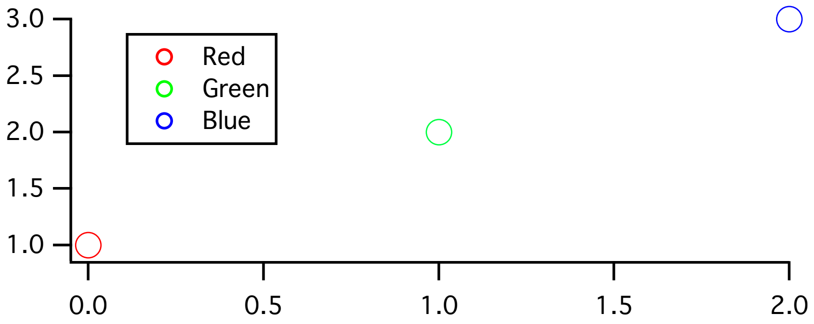
// Create a normal legend where the symbol comes from the trace
Legend/C/N=legend0/J/A=LT "\\s(testData) First\r\\s(testData)
Second\r\\s(testData) Third"

// Make a color index wave to control the marker color
Make /O testColorIndex = {0, 127, 225}

// Change the graph trace to use color as f(z) mode.
// Rainbow256 is the name of a built-in color table.
// The numbers 0 and 255 set the color index values that correspond to the
// first and last entries in the color table.
ModifyGraph zColor(testData)={testColorIndex,0,255,Rainbow256,0}

// Change the legend so that it shows the colors
Legend/C/N=legend0/J/A=LT "\\k(65535,0,0)\\W608 Red\r\\k(0,65535,0)\\W608
Green\r\\k(0,0,65535)\\W608 Blue"
```

The result is this graph:



The last command used the \W escape sequence to specify which marker to use in the legend (08 for the circle marker in this case) and the marker thickness (6 means 1.0 points).

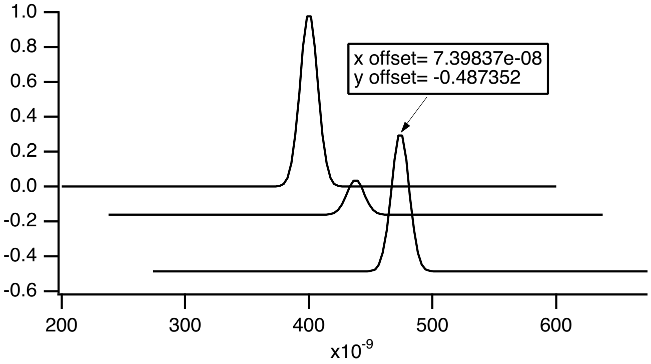
The \k escape sequence specifies the color to use for stroking the marker specified by \W. You would use \K to specify the marker fill color. Colors are specified in RGB format where each component falls in the range 0 to 65535.

This example uses double-backslashes because a single backslash is an escape character in Igor literal strings. Since we want a backslash in the final text, because that is what Igor requires for \k and \W, we need to use a double-backslash in the literal strings.

If you were to enter the legend text in the Add Annotation dialog, you would use just a single backslash and the dialog would generate the requires command, with double-backslashes.

Trace Offsets

You can offset a trace in a graph in the horizontal or vertical direction without changing the data in the associated wave. This is primarily of use for comparing the shapes of traces or for spreading overlapping traces out for better viewing.



Each trace has an X and a Y offset, both of which are initially zero. If you check the Offset checkbox in the Modify Trace Appearance dialog, you can enter an X and Y offset for the trace.

You can also set the offsets by clicking and dragging in the graph. To do this, click the trace you want to offset. Hold the mouse down for about a second. You will see a readout box appear in the lower left corner of the graph. The readout shows the X and Y offsets as you drag the trace. If it doesn't take too long to display the given trace, you will be able to view the trace as you drag it around on the screen.

If you press Shift while offsetting a wave, Igor constrains the offset to the horizontal or vertical dimension.

You can disable trace dragging by pressing Caps Lock, which may be useful for trackball users.

Offsetting is undoable, so if you accidently drag a trace where you don't want it, choose Edit →Undo.

It is possible to attach a tag to a trace that will show its current offset values. See **Dynamic Escape Codes for Tags** on page III-38, for details.

If autoscaling is in effect for the graph, Igor tries to take trace offsets into account. If you want to set a trace's offset without affecting axis scaling, use the Set Axis Range item in the Graphs menu to disable autoscaling.

When offsetting a trace that uses log axes, the trace offsets by the same distance it does when the axis is not log. The shape of the trace is not changed — it is simply moved. If you were to try to offset a trace by adding a constant to the wave's data, it would distort the trace.

Trace Multipliers

In addition to offsetting a trace, you can also provide a multiplier to scale a trace. The effective value used for plotting is then *multiplier*data+offset*. The default value of zero means that no multiplier is provided, not that the data should be multiplied by zero.

With normal (not log) axes, you can interactively scale a trace using the same click and hold technique described for trace offsets. First place Cursor A somewhere on the trace to act as a reference point. Then, after entering offset mode by clicking and holding, press Option (*Macintosh*) or Alt (*Windows*) to adjust the multiplier instead of the offset. You can press and release the key as desired to alternate between scaling and offsetting.

With log axes, the trace multiplier provides an alternative method of offsetting a trace on a log axis (remember: log(*a***b*)=log(*a*)+log(*b*)). For compatibility reasons and because the trace offset method better handles switching between log and linear axis modes, Igor uses the multiplier method when you drag a trace only if the offset is zero and the multiplier is not zero (the default meaning "not set"). Consequently, to use the multiplier technique, you must use the command line or the Offset controls in the Modify Trace Appearance dialog to set a nonzero multiplier. 1 is a good setting for this purpose.

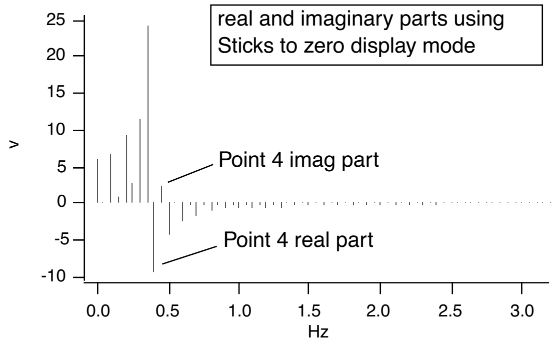
Hiding Traces

You can hide a trace in a graph by checking the Hide Trace checkbox in the Modify Trace Appearance dialog. When you hide a trace, you can use the Include in Autoscale checkbox to control whether or not the data of the hidden trace should be used when autoscaling the graph.

Complex Display Modes

When displaying traces for complex data you can use the Complex Mode pop-up menu in the Modify Trace Appearance dialog to control how the data are displayed. You can display the complex and real components together or individually, and you can also display the magnitude or phase.

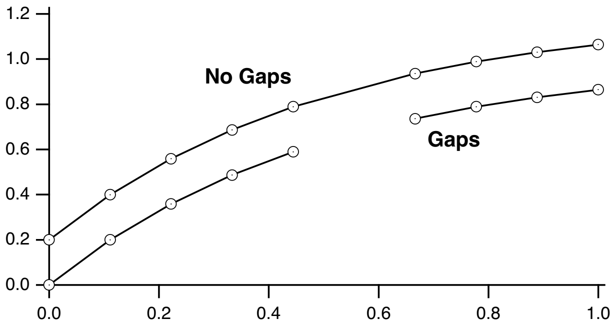
The default display mode is Lines between points. To display a wave's real and imaginary parts side-by-side on a point-for-point basis, use the Sticks to zero mode.



Gaps

In Igor, a missing or undefined value in a wave is stored as the floating point value NaN ("Not a Number"). Normally, Igor shows a NaN in a graph as a gap, indicating that there is no data at that point. In some circumstances, it is preferable to treat a missing value by connecting the points on either side of it.

You can control this using the Gaps checkbox in the Modify Trace Appearance dialog. If this checkbox is checked (the default), Igor shows missing values as gaps in the data. If you uncheck the checkbox, Igor ignores missing values, connecting the available data points on either side of the missing value.



Error Bars

The Error Bars checkbox in the Modify Trace Appearance dialog adds error bars to the selected trace. When you select this checkbox or click the Options button, Igor presents the Error Bars subdialog.

Error bars are a style that you can add to a trace in a graph. Error values can be a constant number, a fixed percent of the value of the wave at the given point, the square root of the value of the wave at the given point, or they can be arbitrary values taken from other waves. In this last case, the error values can be set independently for the up, down, left and right directions.

Choose the desired mode from the Y Error Bars and X Error Bars pop-up menus.

The dialog changes depending on the selected mode. For the “% of base” mode, you enter the percent of the base wave. For the “sqrt of base” mode, you don’t need to enter any further values. This mode is meaningful only when your data is in counts. For the “constant” mode, you enter the constant error value for the X or Y direction. For the “+/- wave” mode, you select the waves to supply the positive and negative error values.

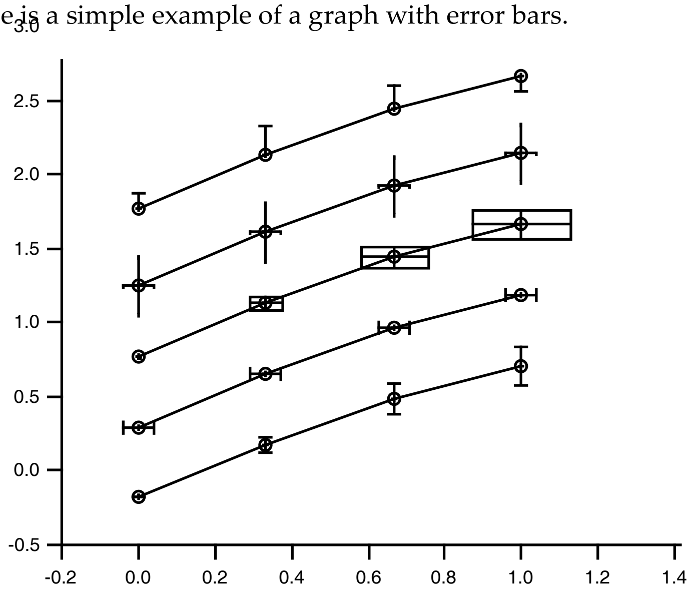
If you select “+/- wave”, pop-up menus appear from which you can choose the waves to supply the upper and lower or left and right error values. These waves are called **error waves**. The values in error waves should normally all be positive since they specify the length of the line from each point to its error bar. This is the only mode that supports single-sided error bars. Error waves do not have to have the same numeric type and length as the base wave. If the value of a point in an error wave is NaN then the error bar corresponding to that point is not drawn.

The Cap Width setting sets the width of the cap on the end of an error bar as an integral number of points. You can also set the cap width to “auto” (or to zero) in which case Igor picks a cap width appropriate for the size of the graph. In this case the cap width is set to twice the size of the marker plus one. For best results the cap width should be an odd number.

You can set the thickness of the cap and the thickness of the error bar. The units for these settings are points. These can be fractional numbers. Nonintegral thicknesses are properly produced when exporting or printing. If you set Cap Thickness to zero no caps are drawn. If you set Bar Thickness to zero no error bars are drawn.

If you enable the “XY Error box” checkbox then a box is drawn rather than an error bar to indicate the region of uncertainty. No box is drawn for points for which one or more of the error values is NaN.

Here is a simple example of a graph with error bars.



The top trace used the “+/- Wave” mode with only a +wave. The last value of the error wave was made negative to reverse the direction of the error bar.

Error Shading

In Igor Pro 7 or later, you can use shading in place of error bars. In the Error Bars subdialog, check the "Use shading instead of bars" checkbox to enable shading.

Shading mode fills between either the +error to -error levels or from +error to data and data to -error depending on the parameters used with the shade keyword.

These commands illustrate multiple and overlapping error shading with transparency:

```
Make/O/N=200 jack=sin(x/8), sam=cos(x/9) + (100-x)/30
Display /W=(64,181,499,520) jack,jack,sam
ModifyGraph lsize(jack)=0,rgb(sam)=(0,0,65535)
ErrorBars jack shade={0,0,(0,65535,0,10000),(0,0,0)},const=2
ErrorBars jack#1 shade={0,0,(0,65535,0,10000),(0,0,0)},const=1
ErrorBars sam shade={0,0,(65535,0,0,10000),(0,0,0)},const=1
```

On Windows shading does not work with the old GDI graphics technology. See **Graphics Technology** on page III-506 for details.

These commands illustrate different +error and -error shading as well as the use of pattern:

```
Make/O jack=sin(x/8)
Display /W=(64,181,499,520) jack
ErrorBars jack shade={0,73,(0,65535,0),(0,0,65535),11,(65535,0,0),(0,65535,0)},const=0.5
```

See the shade keyword for the **ErrorBars** operation for details.

Error Ellipses

In Igor Pro 9.00 and later, you can specify error ellipses instead of bars or boxes. Error ellipses show both X and Y errors along with correlation between X and Y.

You must provide the data for error ellipses via a three-column wave with a row for each data point. This wave is labelled Ellipse Wave in the Error Bars dialog. It is identified by ewave=*ew* in the **ErrorBars** operation.

Each row of *ew* contains information for the error ellipse for one data point. The interpretation of the columns of *ew* depends on the mode, labelled Data Type in the ErrorBars dialog and identified by the mode parameter of the ELLIPSE keyword in the ErrorBars operation.

mode=0: *ew* contains the standard deviation in X, the standard deviation in Y, and the correlation between X and Y.

mode=1: *ew* contains the variance in X, the variance in Y, and the covariance of X and Y.

When specified via the ErrorBars operation ew, may include a subrange specification so long as it results in effectively a 2D wave with three columns and a row for each trace data point. See **Subrange Display Syntax** on page II-321.

Error Ellipse Color

The color of each error ellipse is taken from the color of the data point to which the ellipse is attached. Usually that is simply the trace color. You can change the color of individual data points and their corresponding ellipses using the trace **Color as f(z)**, or by point customization (see **Customize at Point** on page II-306).

You can specify the opacity of all error ellipses for a given trace using the Fill Alpha setting in the Error Bars dialog which ranges from 0 (fully transparent) to 1.0 (fully opaque). This specifies the fill color alpha for all error ellipses, overriding the data points' alpha. In the ErrorBars operation, you specify alpha as a value from 0 (fully transparent) to 65535 (fully opaque) using the ELLIPSE keyword. For background information on alpha, see **RGBA Values** on page IV-13.

Error Ellipse Example

This example illustrates the use of error ellipses:

```
Function ErrorEllipseDemo()
   Make/O/N=5 data = 5*sin(x)
   Display data
   ModifyGraph mode=3, marker=19    // Markers mode, solid circle marker

   Make/O/N=(5,3) ellipseData       // Error ellipse parameters

   // Column 0: Standard deviation in X
   ellipseData[0][0]={0.944527,1.19611,0.32858,1.64494,1.71742}

   // Column 1: Standard deviation in Y
   ellipseData[0][1]={0.357613,0.680198,0.665561,0.581878,0.948245}

   // Column 2: Correlation in X and Y. Must be in the range [-1, 1].
   ellipseData[0][2]={0.562396,0.707809,0.396551,-0.516456,0.554322}

   ErrorBars data, ELLIPSE={0, .95, .3*65535}, ewave=ellipseData

   // Make point 2 blue
   ModifyGraph rgb(data[2])=(0,0,65535)
End
```

Customize at Point

You can customize the appearance of individual points on a trace in a graph displayed in bar, marker, dot and lines to zero modes. To do this interactively, right-click the desired point on a trace and choose Customize at Point→Customize at Point from the contextual menu. The Modify Trace dialog appears with an entry in the trace list shown with the point number in square brackets. When such an entry is selected, only those properties that can be customized are shown in the dialog.

You can remove customizations for a single point by right-clicking on the point and selecting Customize at Point→Remove Customization Here. You can remove all customizations from a trace by right-clicking on the trace and choosing Customize at Point→Remove Customizations from Trace.

Modifying Axes

You can modify the style of presentation of each axis in a graph by choosing Graph→Modify Axis or by double-clicking an axis. This displays the Modify Axis dialog.

The dialog has tabs for various aspects of axis appearance, plus a few controls outside the tabs. These global controls include the standard Igor dialog controls: Do It, To Cmd Line, To Clip, Help and Cancel buttons, plus a box to display the commands generated by the dialog. At the top are the Axis pop-up menu and the Live Update checkbox.

The Axis pop-up menu shows all axes that are in use in the top graph. Choose the axis that you want to change from the Axis menu, or choose Multiple Selection if you want to affect more than one axis. Below the Multiple Selection item are items that provide shortcuts for selecting certain classes of axes.

You select the appropriate tab for the types of changes you want to make. The dialog provides these tabs:

Axis Tab

Tick Options Tab

Axis Range Tab

Auto/Man Ticks Tab

Axis Label Tab

Ticks and Grids Tab

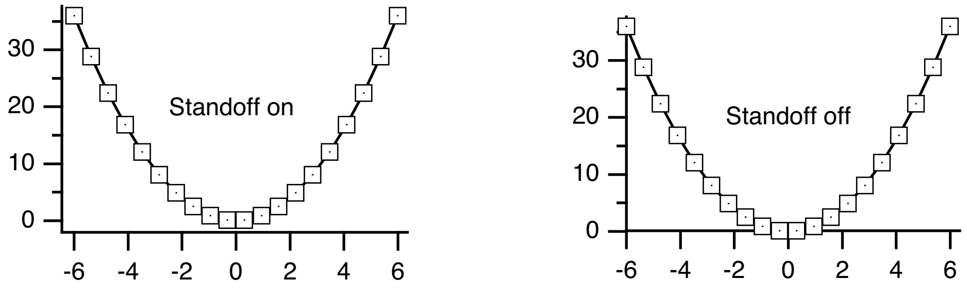
Label Options Tab

Axis Tab

You can set the axis Mode for the selected axis to linear, log base 10, log base 2, or Date/Time.

The Date/Time mode is special. When drawing an axis, Igor looks at the controlling wave's units to decide if it should be a date/time axis. Consequently, if you select Date/Time axis, the dialog immediately changes the units of the controlling wave. See **Date/Time Axes** on page II-315 for details on how date/time axes work.

The Standoff checkbox controls offsetting of axes. When standoff is on, Igor offsets axes so that traces do not cover them:

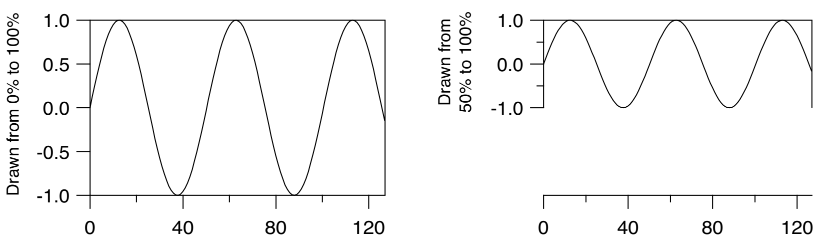


If a free axis is attached to the same edge of the plot rectangle as a normal axis then the standoff setting for the normal axis is ignored. This is to make it easy to create stacked plots.

Use the Mirror Axis pop-up menu to enable the mirror axis feature. A mirror axis is an axis that is the mirror image of the opposite axis. You can mirror the left axis to the right or the bottom axis to the top. The normal state is Off in which case there is no mirror axis. If you choose On from the pop-up, you get a mirror axis with tick marks but no tick mark labels. If you choose No Ticks, you get a mirror axis with no tick marks. If you choose Labels you get a mirror axis with tick marks and tick mark labels. Mirror axes may not do exactly what you want when using free axes, or when you shorten an axis using Draw Between. An embedded graph may be a better solution if free axes don't do what you need; see Chapter III-4, **Embedding and Subwindows**.

Free axes can also have mirror axes. Unlike the free axis itself, the mirror for a given free axis can not be moved — it is always attached to the opposite side of the plot area. This feature can create stacked plots; see **Creating Stacked Plots** on page II-324.

The "Draw between" items are used to create stacked graphs. You will usually leave these at 0 and 100%, which draws the axis along the entire length or width of the plot area. You could use 50% and 100% to draw the left axis over only the top half of the plot area (mirror axes are on in this example to indicate the plot area):



For additional examples using "Draw between", see **Creating Stacked Plots** on page II-324 and **Creating Split Axes** on page II-347.

The Offset setting provides a way to control the distance between the edge of the graph and the axis. It specifies the distance from the default axis position to the actual axis position. This setting is in units of the size of a zero character in a tick mark label. Because of this, the axis offset adjusts reasonably well when you change the size of a graph window. The default axis offset is zero. You can restore the axis offset to zero by dragging the axis to or beyond the edge of the graph. If you enter a graph margin (see **Overall Graph Properties** on page II-288), the margin overrides the axis offset.

Normally you will adjust the axis offset by dragging the axis in the graph. If the mouse is over an axis, the cursor changes to a double-ended arrow indicating that you can drag the axis. If the axis is a mirror axis you will not be able to drag it and the cursor will not change to the double-ended arrow.

The Offset setting does not affect a free axis. To adjust the position of a free axis, use the settings in the Free Position section.

The Thickness setting sets the thickness of an axis and associated tick marks in points. The thickness can be fractional and if you set it to zero the axis and ticks disappear.

The free position can be adjusted by dragging the axis interactively. This is the recommended way to adjust the position when using the absolute distance mode but it is not recommended when using the “crossing at” mode. This is because the crossing value as set interactively will not be exact. You should use the Free Position controls to specify an exact crossing value.

The Font section of the Axis tab specifies the font, font size, and typeface used for the tick labels and the axis label. You should leave this setting at “default” unless you want this particular axis to use a font different from the rest of the graph. You can set the default font for all graphs using the Default Font item in the Misc menu. You can set the default font for a particular graph using the Modify Graph item in the Graph menu. The axis label font can be controlled by escape codes within the axis label text. See **Axis Labels** on page II-318.

Colors of axis components are controlled by items in the Color area.

Auto/Man Ticks Tab

The items in the Auto/Man Ticks tab control the placement of tick marks along the axis. You can choose one of three methods for controlling tick mark placement from the pop-up menu at the top of the tab.

Choose Auto Ticks to have Igor compute nice tick mark intervals using some hints from you.

Choose Computed Manual Ticks to take complete control over the origin and interval for placing tick marks. See **Computed Manual Ticks** on page II-312 for details.

Choose User Ticks from Waves to take complete control over tick mark placement and labelling. See **User Ticks from Waves** on page II-313 for details.

In Auto Ticks mode, you can specify a *suggested* number of major ticks for the selected axis by entering that number in the Approximately parameter box. The actual number of ticks on the axis may vary from the suggested number because Igor juggles several factors to get round number tick labels with reasonable spacing in a common numeric sequence (e.g., 1, 2, 5). In most cases, this automatically produces a correct and attractive graph. The Approximately parameter is not available if the selected axis is a log axis.

You can turn minor ticks on or off for the selected axis using the Minor Ticks checkbox.

The Minimum Sep setting controls the display of minor ticks if minor ticks are enabled. If the distance between minor ticks would be less than the specified minimum tick separation, measured in points, then Igor picks a less dense ticking scheme. For log axes Minor Ticks and Tick Separation affect the drawing of subminor ticks.

Ticks and Grids Tab

The Ticks and Grids tab provides control over tick marks, tick mark labels, and grid lines.

Exponential Labels

When numbers that would be used to label tick marks become very large or very small, Igor switches to exponential notation, displaying small numbers in the tick mark labels and a power of 10 in the axis label. The use of the power of 10 in the axis label is covered under **Axis Labels** on page II-318. In the case of log axes, the tick marks include the power.

With the Low Trip and High Trip settings, you can control the point at which tick mark labels switch from normal notation to exponential notation. If the absolute value of the larger end of the axis is between the low trip and the high trip, then normal notation is used. Otherwise, exponential is used. However, if the exponent would be zero, normal notation is always used.

There are actually two independent sets of low trip and high trip parameters: one for normal axes and one for log axes. The low trip point can be from 1e-38 to 1 and defaults to 0.1 for normal axes and to 1e-4 for log axes. The high trip point can be from 1 to 1e38 and defaults to 1e4.

Under some circumstances, Igor may not honor your setting of these trip points. If there is no room for normal tick mark labels, Igor will use exponential notation, even if you have requested normal notation.

The Engineering and Scientific radio buttons allow you to specify whether tick mark labels should use engineering or scientific notation when exponential notation is used. It does not affect log axes. Engineering notation is just exponential notation where the exponent is always a multiple of three.

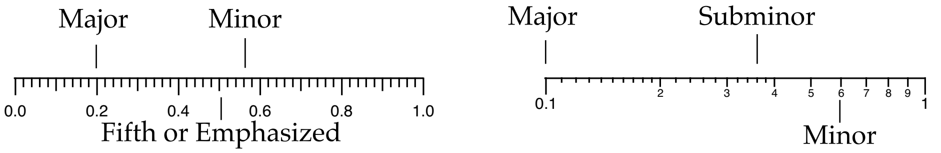
With the Exponent Prescale setting, you can force the tick and axis label scaling to values different from what Igor would pick. For example, if you have data whose X scaling ranges from, say, 9pA to 120pA and you display this on a log axis, Igor will label the tick marks with 10pA and 100pA. But if you really want the tick marks labeled 10 and 100 with pA in the axis label, you can set the Exponent Prescale to 12. For details, see **Axis Labels** on page II-318.

Date/Time Tick Labels

The Date/Time Tick Labels area of the Ticks and Grids tab is explained under **Date/Time Axes** on page II-315.

Tick Dimensions

You can control the length and thickness of each type of tick mark and the location of tick marks relative to the axis line using items in the Tick Dimensions area. Igor distinguishes four types of tick marks: major, minor, “fifth”, and subminor:



Normal Axis **Log Axis**

The tick mark thicknesses normally follow the axis thickness. You can override the thickness of individual tick types by replacing the word “Auto” with your desired thickness specified in fractional points. A value of zero is equivalent to “Auto”.

The tick length is normally calculated based on the font and font size that will be used to label the tick marks. You can enter your own values in fractional points. For example you might enter a value of 6 for the major tick mark, 3 for the minor tick mark and 4.5 for the 5th or emphasized minor tick marks. The subminor tick mark only applies to log axes.

Use the Location pop-up menu to specify that tick marks for the selected axis be outside the axis, crossing the axis or inside the axis or you can specify no tick marks for the axis at all.

Grid

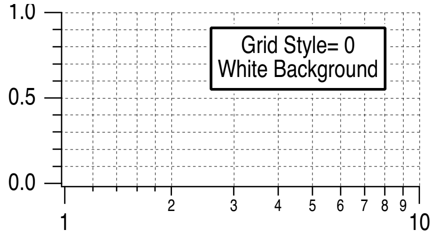
Choose Off from the Grid pop-up menu if you do not want grid lines. Choose On for grid lines on major and minor tick marks. Choose Major Only for grid lines on major tick marks only.

Igor provides five grid styles identified with numbers 1 through 5. Different grid styles have major and minor grid lines that are light, heavy, dotted or solid. If the style is set to zero (the default) and the graph background is white then grid style 2 is used. If the graph background is not white then grid style 5 is used.

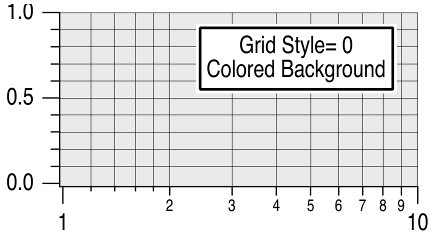
Use the Grid Color palette to set the color of the grid lines. They are by default light blue.

The grid line thickness is specified as a fraction of the axis line thickness. Since the axis line thickness is usually one point, and computer monitors usually have a resolution of about a point, it generally is not possible to see the differences in thickness on your screen. You can see the difference in exported and printed graphs.

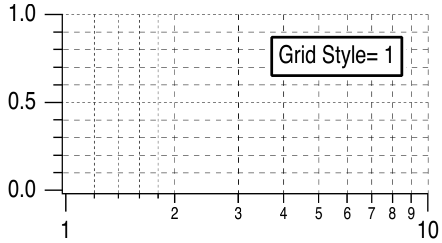
The examples here show graphs with thicker than normal axis lines and the thickest grid lines:

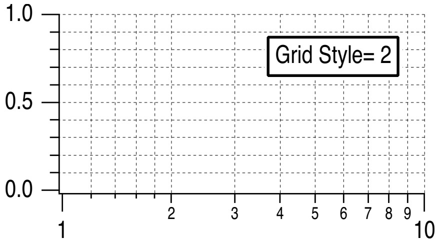


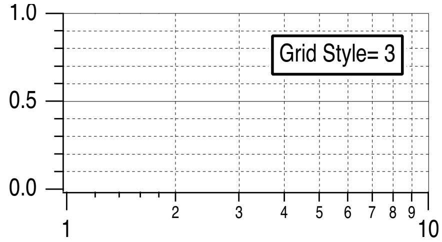
(same as gridStyle=2)

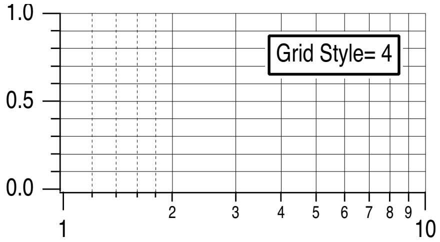


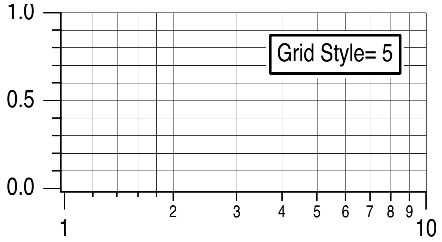
(same as gridStyle=5)











Using the settings "Draw from" and "to" you can restrict the length of the grid lines. This is useful if you have used the similar settings on the Axis tab to shorten one of your axes, and you want grid lines to match.

Zero Line

You can control the zero line for the selected axis using the Zero Line checkbox.

The zero line is a line perpendicular to the axis extending across the graph at the point where the value of the axis is zero. The Zero Line checkbox is not available for log axes.

If you turn the zero line on then you will be able to choose the line style from the Style pop-up menu. The thickness of the line can be set in fractional points from 0 to 5. The zero line has the same color as the axis.

Tick Options Tab

The Tick Options tab provides fine control over tick marks and tick mark labels.

The Enable/Inhibit Ticks section allows you to limit tick marks to a specific range and to suppress specific tick marks.

The Log Ticks section provides control over minor tick marks and labels on log axes.

The Tick Label Tweaks section provides the following settings:

Checkbox	Result
Thousands separator	Tick labels like 10000 are drawn as 10,000.
Zero is '0'	Select this to force the zero tick mark to be drawn as 0 where it would ordinarily be drawn as 0.0 or 0.00.
No trailing zeroes	Tick labels that would normally be drawn as 1.50 or 2.00 are drawn as 1.5 or 2.
No leading zero	Select if you want tick labels such as 0.5 to be drawn as .5
Tick Unit Prefix is Exponent	If tick mark would have prefix and units (µTorr), force to exponential notation (10^{-6} Torr).
No Units in Tick Labels	If tick mark would have units, suppress them.
Units in Every Tick Label	If normal axis, force exponent or prefix and units into each label.

Axis Label Tab

See **Axis Labels** on page II-318.

Label Options Tab

The Label Options tab provides control of the placement and orientation of axis and tick mark labels. You can also hide these labels completely.

Normally, you will adjust the position of the axis label by simply dragging it around on the graph. The “Axis label position” or “Axis label margin” and the “Axis label lateral offset” settings are useful when you want precise numeric control over the position.

The calculations used to position the axis label depend on the setting in the Label Position Mode menu. By default this is set to Compatibility, which will work with older versions of Igor. The other modes may allow you to line up labels on multiple axes more accurately. The choice of positioning mode affects the meaning of the three settings below the menu.

In Compatibility mode, the method Igor uses to position the axis label depends on whether or not a free axis is attached to the given plot rectangle edge. If no free axis is attached then the label position is measured from the corresponding window edge. We call this the axis label margin. Thus if you reposition an axis the axis label will not move. On the other hand, if a free axis is attached to the given plot rectangle edge then the label position is measured from the axis and when you move the axis, the label will move with it.

Because the method used to set the axis label varies depending on circumstances, one or the other of the “Axis label margin” or “Axis label position” settings may be unavailable. If you have selected an axis on the same edge as a free axis, the “Axis label position” setting is made available. If you have selected an axis that does not share an edge with a free axis, the “Axis label margin” setting is made available. If you have selected multiple axes it is possible for both settings to be available.

The axis label position is the distance from the axis to the label and is measured in points.

The axis label margin is the distance from the edge of the graph to the label and is measured in points. The default label margin is zero which butts the axis label up against the edge of the graph.

The margin modes measure relative to an edge of the graph while the axis modes measure relative to the position of the axis. Using an axis mode causes the label to follow a free axis when you move the axis. The margin modes are useful for aligning labels on stacked graphs. The “Axis label margin” setting applies to margin modes while the “Axis label position” setting applies to axis modes.

The absolute modes measure distance in points. Scaled modes have similar numerical values but are scaled to respond to changes in the font size.

The Labels pop-up menu controls which labels are drawn. On gives normal axis labeling. Axis Only leaves the axis label in place but removes the tick mark labels. Off removes the axis labels and tick mark labels.

Axis and Tick label rotations can be set to any value between -360 and 360 degrees.

Axis Range Tab

See **Scaling Graphs** on page II-285.

Manual Ticks

If Igor’s automatic selection of ticks does not suit you, and you can’t find any adjustments that make the tick marks just the way you want them, Igor provides two methods for specifying the tick marks yourself. On the Auto/Man Ticks tab of the Modify Axis dialog, you can choose either Computed Manual Ticks or User Ticks from Waves.

Computed Manual Ticks

Use Computed Manual Ticks to enter a numeric specification of the increment between tick marks and the starting point for calculating where the tick marks fall. This style of manual ticking is available for normal axes and date/time axes. It is not available for normal log axes but is available in LogLin mode.

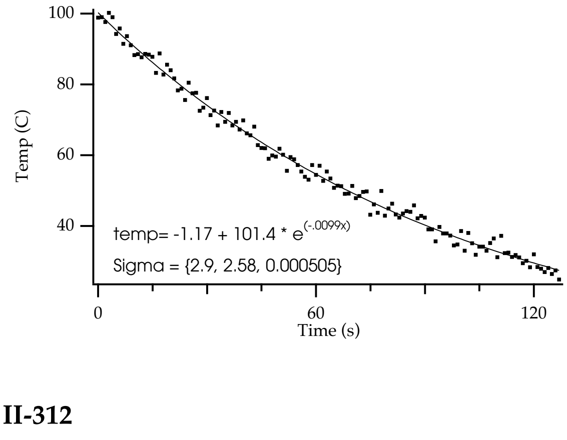
When you choose Computed Manual Ticks, the corresponding settings in theAuto/Man Ticks tab becomes available.

If you click the “Set to auto values” button, Igor sets all of the items in the Compute Manual Ticks section to the values they would have if you let Igor automatically determine the ticking. This is usually a good starting point.

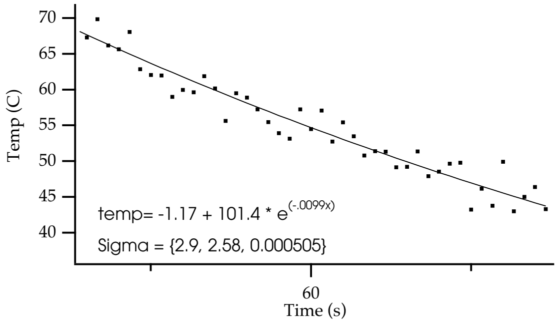
Using the “Canonic tick” setting, you specify the value of any major tick mark on the axis. Using the “Tick increment” setting, you specify the number of axis units per major tick mark. Both of these numbers are specified as a mantissa and an exponent. The canonic tick is not necessarily the first major tick on the axis. Rather, it is a major tick on an infinitely long axis of which the axis in the graph is a subset. That is, it can be *any* major tick whether it shows on the graph or not.

When you use computed manual ticks on a large range logarithmic axis in LogLin mode, the settings in the dialog refer to the exponent of the tick value.

Imagine that you want to show the temperature of an object as it cools off. You want to show time in seconds but you want it to be clear where the integral minutes fall on the axis. You would turn on manual ticking for the bottom axis and set the canonic tick to zero and the tick increment to 60. You could show the half and quarter minute points by specifying three minor ticks per major tick (“Number per major tick” in the Minor Ticks section) with every second minor tick emphasized (“Emphasize every” setting). This produces the following graph:



Now, imagine that you want to zoom in on t = 60 seconds.



The canonic tick, at t = 0, does not appear on the graph but it still controls major tick locations.

User Ticks from Waves

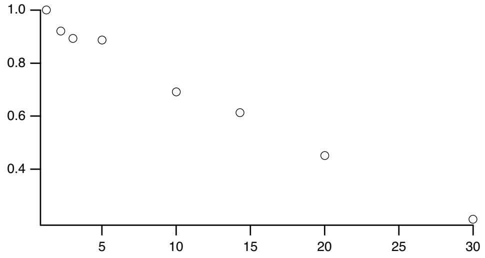
With Computed Manual Ticks you have complete control over ticking as long as you want equally-spaced ticks. If you want to specify your own ticking on a normal log axis, or you want ticks that are not equally spaced, you need User Ticks from Waves.

The first step in setting up User Ticks from Waves is to create two waves: a 1D numeric wave and a text wave. Numbers entered in the numeric wave specify the positions of the tick marks in axis units. The corresponding rows of the text wave give the labels for the tick marks.

Perhaps you want to plot data as a function of Tm/T (melting temperature over temperature, but you want the tick labels to be at nice values of temperature. Starting with this data:

Point	InverseTemp	Mobility
0	30	0.211521
1	20	0.451599
2	14.2857	0.612956
3	10	0.691259
4	5	0.886406
5	3.0303	0.893136
6	2.22222	0.921083
7	1.25	1

you might have this graph:



Create the waves for labelling the axes:

```
Make/N=5 TickPositions
Make/N=5/T TickLabels
```

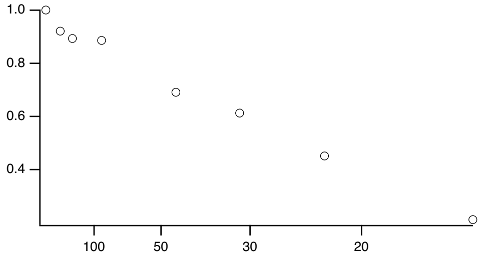
Assuming that Tm is 450 degrees and that you have determined that tick marks at 20, 30, 50, 100, and 400 degrees would look good, you would enter these numbers in the text wave, TickLabels. At this point, a convenient way to enter the tick positions in the TickPositions wave is a wave assignment that embodies the relationship you think is appropriate:

```
TickPositions = 450/str2num(TickLabels)
```

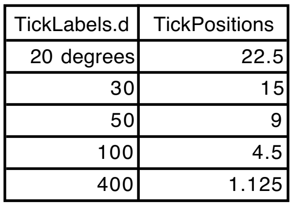
Note that the str2num function was used to interpret the text in the label wave as numeric data. This only works, of course, if the text includes only numbers.

Finally, double-click the bottom axis to bring up the Modify Axis dialog, select the Auto/Man Ticks tab and select User Ticks from Waves. Choose the TickPositions and TickLabels waves:

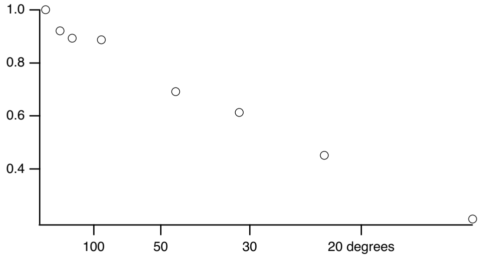
The result is this graph:



You can add other text to the labels, including special marks. For instance:

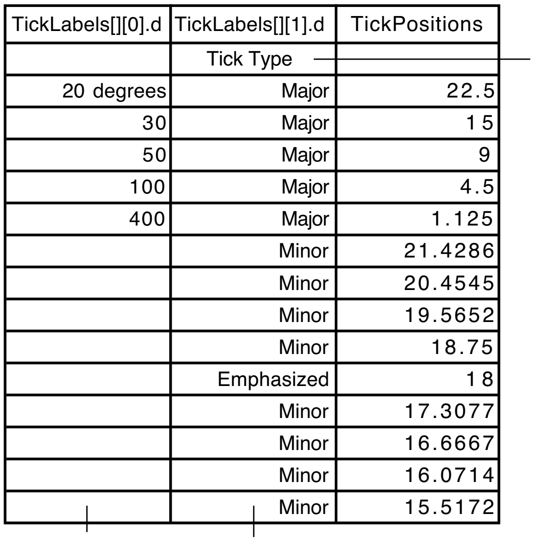


TickLabels.d	TickPositions
20 degrees	22.5
30	15
50	9
100	4.5
400	1.125



Finally, you can add a column to the text wave and add minor, subminor and emphasized ticks by entering appropriate keywords in the other column. To add a column to a wave, select Redimension Waves from the Data menu, select your text wave in the list and click the arrow. Then change the number of columns from 0 to 2.

This extra column must have the column label 'Tick Type'. For instance:



TickLabels[][0].d	TickLabels[][1].d	TickPositions
	Tick Type	
20 degrees	Major	22.5
30	Major	15
50	Major	9
100	Major	4.5
400	Major	1.125
	Minor	21.4286
	Minor	20.4545
	Minor	19.5652
	Minor	18.75
	Emphasized	18
	Minor	17.3077
	Minor	16.6667
	Minor	16.0714
	Minor	15.5172

Dimension label "Tick Type" has keywords to set tick types

Blank entries make ticks with no labels.

Use keyword "Subminor" for subminor ticks such as Igor uses on log axes.

Dimension labels allow you (or Igor) to refer to a row or column of a wave using a name rather than a number. Thus, the Tick Type column doesn't have to be the second column (that is, column 1). For instructions on showing dimension labels in a table, see **Showing Dimension Labels** on page II-235.

An easy way to get started is to let the Modify Axis dialog generate waves for you. Double-click the axis for which you want user ticks. Click the Auto/Man Ticks tab and select User Ticks from Waves from the pop-up menu. Click the New from Auto Ticks button. Igor immediately generates waves with names of the form <graphname>_<axisname>_labels and <graphname>_<axisname>_values and selects them in the Labels and Locations pop-up menus. Click Do It. If you now edit the generated waves, the ticks in the graph will change. You can achieve the same thing programmatically using the **TickWavesFromAxis** operation.

Log Axes

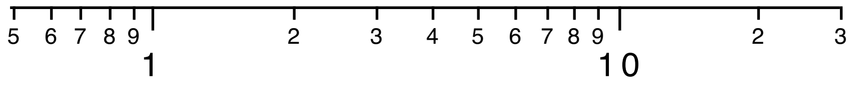
To create a logarithmic axis, set the axis mode to Log in the Axis tab of the Modify Axis dialog.

Computed manual ticks and zero lines are not supported for normal log axes.

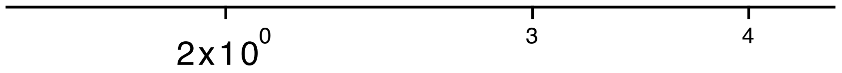
Igor has three ways of ticking a log axis that are used depending on the range (number of decades) of the axis: normal, small range and large range. The normal mode is used when the number of decades lies between about one third to about ten. The exact upper limit depends on the physical size of the axis and the font size.

If the number of decades of range is less than two or greater than five, you can force Igor to use the small/large range methods by checking the LogLin checkbox, which may give better results for log axes with small or very large range. When you do this, all of the settings of a linear axis are enabled including manual ticking.

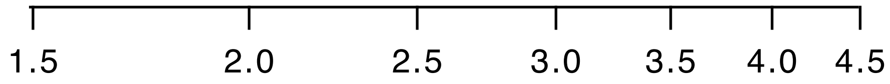
Here is a normal log axis with a range of 0.5 to 30:



If we zoom into a range of 1.5 to 4.5 we get this:



But if we then check the LogLin checkbox, we get better results:



Selecting a log axis makes the Log Ticks box in the Tick Options tab available.

The "Max log cycles with minor ticks" setting controls whether minor ticks appear on a log axis. This setting can range from 0 to 20 and defaults to 0. If it is 0 or "auto", Igor automatically determines if minor ticks are appropriate. Otherwise, if the axis has more decades than this number, then the minor ticks are not displayed. Minor ticks are also not displayed if there is not enough room for them.

Similarly, you can control when Igor puts labels on the minor ticks of a log axis using the "Max log cycles with minor tick labels" item. This is a number from 0 to 8. 0 disables the minor tick labels. As long as the axis has fewer decades than this setting, minor ticks are labeled.

Date/Time Axes

In addition to numeric axes, Igor supports axes labeled with dates, times or dates and times.

Dates and date/times are represented in Igor as the number of seconds since midnight, January 1, 1904.

In Igor, a date can not be accurately represented in a single precision wave. Make sure you use double precision waves to store dates and date/times. (A single precision wave can provide dates and date/times calculated from its X scaling, but not from its data values.)

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-85.

Times without dates can be thought of in two ways: as time-of-day times and as elapsed times.

Time-of-day times are represented in Igor as the number of seconds since midnight.

Elapsed times are represented as a number of seconds in the range -9999:59:59 to +9999:59:59. For integral numbers of seconds, this range of elapsed times can be precisely represented in a signed 32-bit integer wave. A single-precision floating point wave can precisely represent integral-second elapsed times up to about +/-4600 hours.

Igor displays dates or times on an axis if the appropriate units for the wave controlling the axis is “dat”. This is case-sensitive — “Dat” won’t work. You can set the wave’s units using the Change Wave Scaling item in the Data menu, or the **SetScale** operation.

To make a horizontal axis a date or time axis for a waveform graph, you must set the X units of the wave controlling the axis to “dat”. For an XY graph you must set the data units of the wave supplying the X coordinates for the curve to “dat”. To make the vertical axis a date or time axis in either type of graph, you must set the data units of the wave controlling the axis to “dat”.

If you choose Date/Time as the axis mode in the Axis tab of the Modify Axis dialog, the dialog sets the appropriate wave units to “dat”.

For Igor to display an axis as date or time, the following additional restrictions must be met: the axis must span at least 2 seconds and both ends must be within the legal range for a date/time value. If any of these restrictions is not met, Igor displays a single tick mark.

When an axis is in the date/time mode, the Date/Time Tick Labels box in the Ticks and Grids tab of the Modify Axis dialog is available.

From the Time Format pop-up menu, you can choose Normal, Military, or Elapsed. Use Normal or Military for time-of-day times and Elapsed for elapsed times. In normal mode, the minute before midnight is displayed as 11:59:00 PM and midnight is displayed as 12:00:00 AM. In military mode, they are displayed as 23:59:00 and 00:00:00.

Elapsed mode can display times from -9999:59:59 to +9999:59:59. This mode makes sense if the values displayed on the axis are actually elapsed times (e.g., 23:59:00). It makes no sense and will display no tick labels if the values are actually date/times (e.g., 7/28/93 23:59:00).

Custom Date Formats

In the short, long and abbreviated modes, dates are displayed according to system date/time settings. If you choose Other from the Date Format pop-up, a dialog is displayed giving you almost complete control over the format of the tick labels. The dialog allows you to choose from a variety of built-in formats or to create a fully custom format.

Depending on the extent of the axis, the tick mark labels may show date or date and time. You can suppress the display of the date when both the date and time are showing by selecting the Suppress Date checkbox. This checkbox is irrelevant when you choose the elapsed time mode in which dates are never displayed.

Date/Time Example

The following example shows how you can create a date/time graph of a waveform whose Y values are temperature and whose X values, as set via the SetScale operation, are dates:

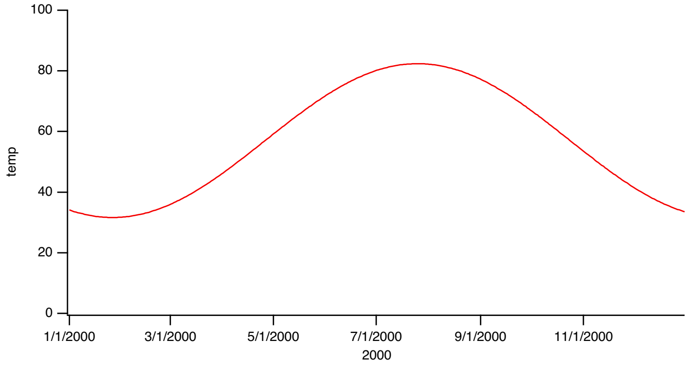
```
// Make a wave to contain temperatures for the year
Make /N=365 temperature             // single precision data values
```

```
// Set its scaling so X values are dates
Variable t0, t1
t0 = Date2Secs(2000,1,1); t1 = Date2Secs(2001,1,1)
SetScale x t0, t1, "dat", temperature  // double-precision X scaling

// Enter the temperature data in the wave's Y values
t0 = Date2Secs(2000,1,1); t1 = Date2Secs(2000,3,31)    // winter
temperature(t0, t1) = 32                               // it's cold
t0 = Date2Secs(2000,4,1); t1 = Date2Secs(2000,6,30)    // spring
temperature(t0, t1) = 65                               // it's nice
t0 = Date2Secs(2000,7,1); t1 = Date2Secs(2000,9,31)    // summer
temperature(t0, t1) = 85                               // it's hot
t0 = Date2Secs(2000,10,1); t1 = Date2Secs(2000,12,31) // fall
temperature(t0, t1) = 45                               // cold again

// Smooth the data out
CurveFit sin temperature
temperature= K0+K1*sin(K2*x+K3)

// Graph the wave
Display temperature
SetAxis left, 0, 100;Label left "temp"
Label bottom "2000"
```



The SetScale operation sets the temperature wave so that its X values span the year 2000. In this example, the date/time information is in the *X values* of the wave. X values are always double precision. The wave itself is not declared double precision because we are storing temperature information, not date/time information in the Y values.

Manual Ticks for Date/Time Axes

Just as with regular axes, there are times when Igor’s automatic choices of ticks for date/time axes simply are not what you want. For these cases, you can use computed manual ticks with date/time axes.

To use computed manual ticks, display the Modify Axis dialog by double-clicking the axis, or by choosing Graph→Modify Axis. Select the Auto/Man Ticks tab, and choose Computed Manual Ticks from the menu in that tab.

The first step is to click the Set to Auto Values button. Choose Date, Time, or Date&Time from the pop-up menu below the Canonic Tick setting. This will depend on the range of the data. Choose the units for the Tick Increment setting and enter an increment value.

“Fake” Axes

It is sometimes necessary to create an axis that is not related to the data in a simple way. One method uses free axes that are not associated with a wave (see **NewFreeAxis**). The Transform Axis package uses this technique to make a mirror axis reflecting a different view of the data. An example would be a mirror axis showing wave number to go with a main axis showing wavelength. For an example, choose File→Example Experiments→Graphing Techniques→Transform Axis Demo.

Another technique is to use Igor's drawing tools to create fake axes. For an example, choose File→Example Experiments→Graphing Techniques→New Polar Graph Demo or File→Example Experiments→Graphing Techniques→Ternary Diagram Demo.

Axis Labels

The text for an axis label in a graph can come from one of two places. If you specify units for the wave which controls an axis, using the Change Wave Scaling dialog, Igor uses these units to label the axis. You can override this labeling by explicitly entering axis label text using the Axis Label tab of the Modify Axis dialog.

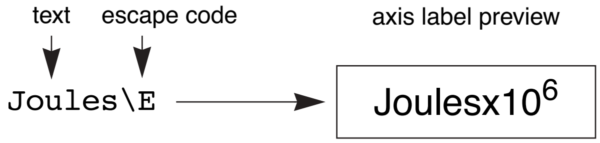
To display the dialog, choose Graph→Label Axis or double-click an axis label. Select the axis that you want to label from the Axis pop-up menu and then enter the text for the axis label in the Axis Label area. Further label formatting options are available in the **Label Options Tab**.

There are two parts to an axis label: the text for the label and the special effects such as font, font size, superscript or subscript. You specify the text by typing in the Axis Label area. At any point in entering the text, you can choose a special effect from a pop-up menu in the Insert area.

The Label Preview area shows what the axis label will look like, taking the text and special effects into account. You can not enter text in the preview. You can also see your label on the graph if you check the Live Update checkbox.

Axis Label Escape Codes

When you choose a special effect, Igor inserts an **escape code** in the text. An escape code consists of a backslash character followed by one or more characters. It represents the special effect you chose. The escape codes are cryptic but you can see their effects in the Label Preview box.



You can insert special affects at any point in the text by clicking at that point and choosing the special effect from the Insert pop-ups.

Choosing an item from the Font pop-up menu inserts a code that changes the font for subsequent characters in the label. The font pop-up also has a "Recall font" item. This item is used to make elaborate axis labels. See **Elaborate Annotations** on page III-51.

Choosing an item from the Font Size pop-up menu inserts a code that changes the font size for subsequent characters in the label. The font size pop-up also has a "Recall size" item used to make elaborate axis labels.

Axis Label Special Effects

The **Special** pop-up menu includes items for controlling many features including superscript, subscript, justification, and text color, as well as items for inserting special characters, markers and pictures.

The Store Info, Recall Info, Recall X Position, and Recall Y Position items are used to create elaborate annotations. See **Elaborate Annotations** on page III-51.

The most commonly used items are Superscript, Subscript and Normal. To create a superscript or subscript, use the Special pop-up menu to insert the desired code, type the text of the superscript or subscript and then finish with the Normal code. For example, suppose you want to create an axis label that reads "Phase space density (s^{3}m^{-6})". To do this, type "Phase space density (s", choose the Superscript item from the Special pop-up menu, type "3", choose Normal, type "m", choose Superscript, type "-6", choose Normal and then type ")". See Chapter III-2, **Annotations**, for a complete discussion of these items.

The "Wave controlling axis" item inserts a code that prints the name of the first wave plotted on the given axis.

The Trace Symbol submenu inserts a code that draws the symbol used to plot the selected trace.

The Character submenu presents a palette from which you can select special characters to add to the axis label.

The Marker submenu inserts a code to draw a marker symbol. These symbols are independent of any traces in the graph.

Axis Label Units

The items in the Units pop-up menu insert escape codes that allow you to create an axis label that automatically changes when the extent of the axis changes.

For example, if you specified units for the controlling wave of an axis, you can make those units appear in the axis label by choosing the Units item from the Units pop-up menu. If appropriate Igor will automatically add a prefix (µ for micro, m for milli, etc.) to the label and will change the prefix appropriately if the extent of the axis changes. The extent of the axis changes when you explicitly set the axis or when it is autoscaled.

If you choose the Scaling or Inverse Scaling items from the Units pop-up menu, Igor automatically adds a power of 10 scaling (x10^3, x10^6, etc.) to the axis label if appropriate and changes this scaling if the extent of the axis changes. The Trial Exponent buttons determine what power is used *only* in the label preview so you can see what your label will look like under varying axis scaling conditions. Both of these techniques can be ambiguous — it is never clear if the axis has been multiplied by the scale factor or if the units contain the scale factor.

A less ambiguous method is to use the Exponential Prefix escape code. This is identical to the Scaling code except the “x” is missing. You can then use it in a context where it is clear that it is a multiplier of units. For example, if your axis range is 0 to 3E9 in units of cm/s, typing “Speed, \ucm/s” would create “Speed, 10^9cm/s”.

It is common to parenthesize scaling information in an axis label. For example the label might say “Joules (x10^6)”. You can do this by simply putting parentheses around the Scaling or Inverse Scaling escape codes. If the scaling for the axis turns out to be x10^0 Igor omits it and also omits the parentheses so you get “Joules” instead of “Joules (x10^0)” or “Joules()”.

If you do not specify scaling but the range of the axis requires it, Igor labels one of the tick marks on the axis to indicate the axis scaling. This is an emergency measure to prevent the graph from being misleading. You can prevent this from happening by inserting the Manual Override escape code, \u#2, into your label. No scaling or units information will be added at the location of the escape code or on the tick marks.

The situation with log axes is a bit different. By their nature, log axes never have to be scaled and units/scaling escape codes are not used in axis labels. If the controlling wave for a log axis has units then Igor automatically uses the units along with the appropriate prefix for each major tick mark label.

Annotations in Graphs

You can add text annotation to a graph by choosing Graph→Add Annotation. This displays the Add Annotation dialog. If text annotation is already on the graph you can modify it by double-clicking it. This brings up the Modify Annotation dialog. See Chapter III-2, **Annotations**, for details.

Info Panel and Cursors

You can display an information panel (“info panel” for short) for a graph by choosing Graph→Show Info. An info panel displays a precise readout of values for waves in the graph. To remove the info panel from a graph while the graph is the target window choose Graph→Hide Info.

You can use up to five different pairs of cursors (AB through IJ). To control which pairs are available, click the gear icon and select select cursor pairs from the Show Cursor Pairs submenu. By default, cursors beyond B use the cross and letter style.

Cursors provide a convenient way to specify a range of points on a wave which is of particular interest. For example, if you want to do a curve fit to a particular range of points on a wave you can start by putting cursor A on one end of the range and cursor B on the other. Then you can summon the Curve Fitting dialog from the Analysis menu. In this dialog on the Data Options tab there is a range control. If you click the “cursors” button then the range of the fit will be set to the range from cursor A to cursor B.

Using Cursors

When you first show the info panel, the cursors are at home and not associated with any wave. The slide control is disabled and the readout area shows no values.

To activate a cursor, click it and drag it to the desired point on the wave whose values you want to examine. Now the cursor appears on the graph and the cursor’s home icon turns black indicating that the cursor is active. The name of the wave which the cursor is on appears next to the cursor’s name. You can drag the cursor to any point on a trace or image plot.

To move the cursor by one element, use the arrow keys. If the cursor is on a trace, you can use the left and right arrow keys. If it is on an image, you can use the left, right, up, and down arrow keys. If you press Shift plus an arrow key, the cursor moves 10 times as far.

If the cursor is on a trace, you can drag the slide control left or right. If it is on an image, you can drag it in any direction.

If you have both cursors of a pair on the graph and both are active, then the slide control moves both cursors at once. If you want to move only one cursor you can use the mouse to drag that cursor to its new location. Another way to move just one cursor is to deactivate the cursor that you don’t want to move. You do this by clicking in the cursor’s home icon. This makes the home icon change from black to white indicating that the cursor is not active. Then the slide control moves only the active cursor.

You can also move both cursors of a pair at once by dragging. With both cursors on the graph, press the Shift key before clicking and dragging one of the cursors.

When you use the mouse to drag a cursor to a new location, Igor first searches for the trace the cursor is currently attached to. Only if the new location is not near a point on the current trace are all the other traces searched. You can use this preferential treatment of the current trace to make sure the cursor lands on the desired trace when many traces are overlapping in the destination region.

You can attach a cursor to a particular trace by right-clicking the cursor home icon and choosing a trace name from the pop-up menu.

To remove a cursor from the graph, drag it outside the plot area or right-click the cursor home icon and choose Remove Cursor.

Free Cursors

By default, cursors are attached to a particular point on a trace or to a particular element of an image plot. By contrast, you can move a free cursor anywhere within the plot area of the graph. To make a cursor free, right-click the cursor home icon in the info panel and choose Style→Free from the resulting pop-up menu.

Cursor Styles

By default, cursors A and B are displayed in the graph using a circular icon for A and a square icon for B. For all other cursors, the default style is a cross. You can change the style for any cursor by right-clicking the cursor home icon in the info panel and using the resulting pop-up menu.

You can create a cursor style function which you can invoke later to apply a given set of cursor style settings Right-click the cursor home icon in the info panel and, from the resulting pop-up menu, choose Style→Style Function→Save Style Function. Igor creates a cursor style function in the built-in procedure window. You can edit the function to give it a more meaningful name than the default name that Igor uses.

To apply your style function to a cursor, right-click the cursor home icon in the info panel and choose choose Style→Style Function→<Your Style Function>.

Programming With Cursors

These functions and operations are useful for programming with cursors.

The **ShowInfo** and **HideInfo** operations show and hide the info panel.

The **Cursor** operation sets the position of a cursor. It can also be used to change characteristics of the cursor such as the color, hair style, and number of digits used in the Graph Info Panel display.

The **CsrInfo** function returns information about a cursor.

These functions return the current position of a cursor:

pcsr	qcsr	hcsr	vcsr	xcsr	zcsr

These functions return information about the wave to which a cursor is attached, if any:

CsrWave	CsrWaveRef	CsrXWave	CsrXWaveRef

The **CursorStyle** keyword marks a user-defined function for inclusion in the Style Function submenu of the cursor pop-up menu.

The section **Cursors — Moving Cursor Calls Function** on page IV-339 explains how to trigger a user-defined function when a cursor is moved.

Identifying a Trace

Igor can display a tooltip that identifies a trace when you hover the mouse over it. To enable this mode, choose Graph→Show Trace Info Tags.

Subrange Display

In addition to displaying an entire wave in a graph, you can specify a subrange of the wave to display. This feature is mainly intended to allow the display of columns of a matrix as if they were extracted into individual 1D waves but can also be used to display other subsets or to skip every *n*th data point.

To display a subrange of a graph using the New Graph and Append Traces dialogs, you must be in the more complex version of the dialogs which appears when you click the More Choices button. Select your Y wave and optionally an X wave and click the Add button. This adds the trace to the list below. You can then edit the subrange in the list.

Subrange Display Syntax

The **Display** operation (page V-161), **AppendToGraph** operation (page V-35), and **ReplaceWave** operation (page V-801) support the following subrange syntax for a wave list item:

```
wavename[rdspec][rdspec][rdspec][rdspec]
```

where *rdspec* is a range or dimension specification expressed as dimension indices (point numbers for 1D waves). For an n-dimensional wave, enter n specifications and omit the rest.

Only one *rdspec* can be a range spec. The others must be a single numeric element index or dimension label value.

You can enter `[]` or `[*]` to indicate the entire range of the dimension, or `[start,stop]` for a contiguous subrange, or `[start,stop;inc]` where `start`, `stop`, and `inc` are dimension indices. Entering * for `stop` is the same as enteringthe index of the last element in the dimension.

For example:

```
Make/N=100 w1D = p
Display w1D[0,*;10]                // Display every tenth point
ModifyGraph mode=3, marker=19

Make/N=(10,8) w2D = p + 10*q
Display w2D[0][0,*;2]              // Display every other column of row 0
ModifyGraph mode=3, marker=19
```

The subrange syntax rules can be restated as:

1. Only one dimension specifier can contain the range to be displayed.

   Legal syntax for range is: `[]` or `[*]` for an entire dimension

   `[start,stop]` for a subrange

   `stop` may be *

   `stop` must be >= `start`

   The range is inclusive

   `[start,stop;inc]` for a subrange with a positive increment

2. Other dimensions must contain a single numeric index or dimension label using % syntax.

   Legal syntax for nonrange specifier is: `[index]`

   `[%label]`

3. Unspecified higher dimensions are treated as if [0] was specified.

For non-XY plots, the X-axis label uses the dimension label (if any) for the active dimension (the one with a range).

When cursors or tags are placed on a subranged trace, the point number used is the virtual point number as if the subrange had been extracted into a 1D wave.

Subrange syntax is also supported for waves used with error bars and with color, marker size and marker number as f(Z). These correspond to the **ErrorBars** operation (page V-199) with the wave keyword and to the **ModifyGraph (traces)** operation (page V-613) with the zmrkSize, zmrkNum, and zColor keywords.

Subrange Display Limitations

In category plots, the category wave (the text wave) may not be subranged. Waves used to specify text using ModifyGraph textMarker mode may not be subranged.

Subranged traces may not be edited using the draw tools (such as: option click on the edit poly icon in the tool palette on a graph).

Waterfall plots may not use subranges.

When multiple subranges of the same wave are used in a graph, they are distinguished only using instance notation and not using the subrange syntax. For example, given `display w[][0],w[][1]`, you must use `ModifyGraph mode(w#0)=1,mode(w#1)=2` and not `ModifyGraph mode(w[][0])=1,mode(w[][1])=2` as you might expect.

The trace instance and subrange used to plot given trace is included in trace info information. See **Identifying a Trace** on page II-321.

Printing Graphs

Before printing a graph you should set the page size and orientation using the Page Setup dialog. Choose Page Setup from the Files menu. Often graphs are wider than they are tall and look better when printed using the horizontal orientation.

When you invoke the Page Setup dialog you must make sure that the graph that you want to print is the top window. Igor stores one page setup in each experiment for all graphs and stores other page setups for other types of windows. You can set the default graph page setup for new experiments using the Capture Graph Preferences dialog.

To print a graph, choose File→Print while the graph is the active window. You can also choose File→Print Preview to display a preview.

Graphs by default print at the same size as the graph window unless they do not fit in which case they are scaled down at the same aspect ratio.

Prior to Igor Pro 7, the Print dialog supported scaling modes such as Fill Page and Same Aspect. These are no longer available in the Print dialog. You can use **PrintSettings** with the graphMode and graphSize keywords prior to printing to achieve the same effects.

Printing Poster-Sized Graphs

Using the **PrintGraphs** operation, you can specify a size for a graph that is too big for a single sheet of paper. When you do this, Igor uses multiple sheets of paper to print the graph. Use this to make very large, poster-sized printouts.

To make the multiple sheets into one big poster, you need to trim the edges of the sheets and tape them together. Igor prints tiny alignment marks on the edges so you can line the pages up. You should trim the unneeded borders so that the alignment marks are flush against the edge of the trimmed sheet. Then align the sheets so that the alignment marks butt up against each other. All of the alignment marks should still be visible. Then tape the sheets together.

Other Printing Methods

You can also print graphs by placing them in page layouts. See Chapter II-18, **Page Layouts** for details.

You can print graphs directly from macros using the **PrintGraphs** (see page V-773) operation.

Save Graph Copy

You can save the active graph as an Igor packed experiment file by choosing File→Save Graph Copy. The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the graph starting from the “top” data folder, which is the data folder that encloses all waves displayed in the graph. The top data folder becomes the root data folder of the resulting experiment file. Only the graph, its waves, dashed line settings, and any pictures used in the graph are saved in the packed experiment file, not procedures, variables, strings or any other objects in the experiment.

Save Graph Copy does not work well with graphs containing controls. First, the controls may depend on waves, variables or FIFOs (for chart controls) that Save Graph Copy will not save. Second, controls typically rely on procedures which are not saved by Save Graph Copy.

Save Graph Copy does not know about dependencies. If a graph contains a wave, wave0, that is dependent on another wave, wave1 which is not in the graph, Save Graph Copy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

The **SaveGraphCopy** operation on page V-821 provides options that are not available using the Save Graph Copy menu command.

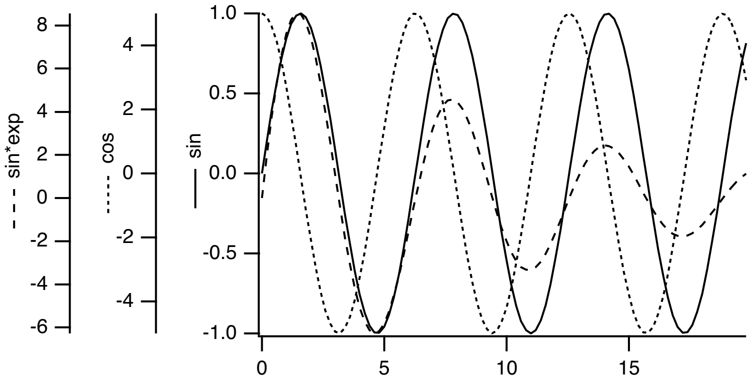
Exporting Graphs

You can export a graph to another application through the clipboard or by creating a file. To export via the clipboard, choose Edit→Export Graphics. To export via a file, choose File→Save Graphics.

The process of exporting graphics from a graph is very similar to exporting graphics from a layout. Because of this, we have put the details in Chapter III-5, **Exporting Graphics (Macintosh)**, and Chapter III-6, **Exporting Graphics (Windows)**. These chapters describe the various export methods you can use and how to choose a method that will give you the best results.

Creating Graphs with Multiple Axes

This section describes how to create a graph that has many axes attached to a given plot edge. For example:



To create this example we first created some data:

```
Make/N=100 wave1,wave2,wave3; SetScale x,0,20,wave1,wave2,wave3
wave1=sin(x); wave2=5*cos(x); wave3=10*sin(x)*exp(-0.1*x)
```

We then followed these steps:

1. Use the New Graph dialog to display the following

   wave1 versus the built-in left axis and the built-in bottom axis

   wave2 versus a free left axis, L1, and the built-in bottom axis

   wave3 versus another free left axis, L2, and the built-in bottom axis

   Use the Axis pop-up menu under the Y Waves list to create the L1 and L2 axes.
2. Use the Modify Graph dialog to set the left margin to 1.5 inches.

   This moves the built-in left axis to the right, creating room for the free axes.
3. Drag the L1 axis to the left of the left axis.
4. Drag the L2 axis to the left of the L1 axis.
5. Use the Modify Trace Appearance dialog to set the trace dash patterns.
6. Use the Axis Label tab of the Modify Axis dialog to set the axis labels.

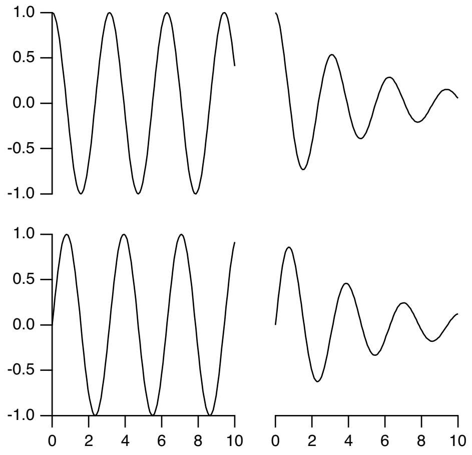
   We used Wave Symbol from the Special pop-up menu to include the line style.
7. Drag the axis labels into place.

Creating Stacked Plots

Igor's ability to use an unlimited number of axes in a graph combined with the ability to shrink the length of an axis makes it easy to create stacked plots. You can even create a matrix of plots and can also create inset plots.

Another way to make a stacked graph is to use subwindows. See **Layout Mode and Guide Tutorial** on page III-86 for an example. It is also possible to do make stacked graphs in page layouts, using either graph subwindows or graph layout objects.

In this section we create stacked plot areas in a single graph window using Igor's ability to limit a plot to a portion of a graph. As an example, we will create the following graph:



First we create some data:

```
Make wave1,wave2,wave3,wave4
SetScale/I x 0,10,wave1,wave2,wave3,wave4
wave1=sin(2*x); wave2=cos(2*x)
wave3=cos(2*x)*exp(-0.2*x)
wave4=sin(2*x)*exp(-0.2*x)
```

We then followed these steps:

1. Use the New Graph dialog to display the following

   wave1 versus the built-in left axis and the built-in bottom axis

   wave2 versus a free left axis, L2, and the built-in bottom axis

   wave3 versus L2 and a free bottom axis, B2

   wave4 versus the built-in left axis and B2

   Use the Axis pop-up menu under the Y Waves list to create the L2 axis.

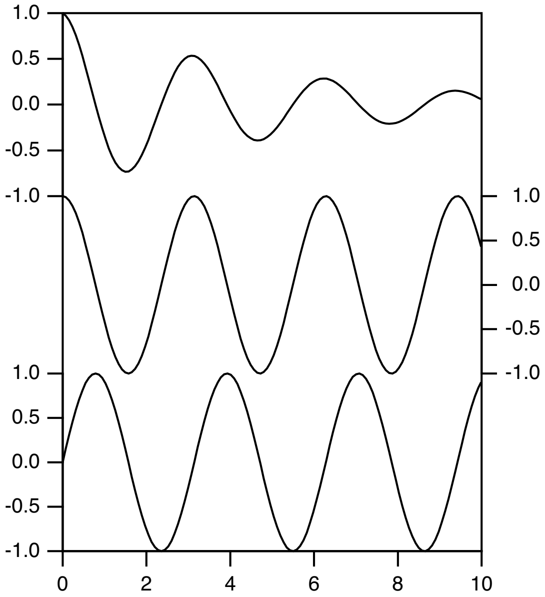
   Use the Axis pop-up menu under the X Waves list to create the B2 axis.

   This creates a graph consisting of a jumble of axes and traces.
2. Choose Graph→Modify Graph and click the Axis tab.

   The next four steps use the "Draw between" settings in the Axis section of the Axis tab.
3. From the Axis pop-up menu, select left and set the left axis to draw between 0% and 45% of normal.
4. From the Axis pop-up menu, select bottom and set the bottom axis to draw between 0% and 45% of normal.
5. From the Axis pop-up menu, select L2 and set the L2 axis to draw between 55% and 100% of normal. Also, in the Free Position section, choose Distance from Margin from the pop-up menu and set the Distance setting to 0.
6. From the Axis pop-up menu, select B2 and set the B2 axis to draw between 55% and 100% of normal. Also, in the Free Position section, choose Distance from Margin from the pop-up menu and set the Distance setting to 0.
7. Click Do It.

Staggered Stacked Plot

Here is a common variant of the stacked plot:



This example was created from three of the waves used in the previous plot. Wave1 was plotted using the left and bottom axes, wave2 used the right and bottom axes and wave3 used L2 and bottom axes. Then the Axis tab of the Modify Axis dialog was used to set the left axis to be drawn from 0% to 33% of normal, the right axis from 33% to 66% and the L2 axis from 66% to 100%. The Axis Standoff checkbox was unchecked for the bottom axis. This was not necessary for the other axes as axis standoff is not used when axes are drawn on a reduced extent.

After returning from the Modify Axis dialog, the graph was resized and the frame around the plot area was drawn using a polygon in plot-relative coordinates.

Waterfall Plots

You can create a graph displaying a sequence of traces in a perspective view. We refer to these types of graphs as waterfall plots, which can be created and modified using the **NewWaterfall** operation or by choosing Windows→New→Packages→Waterfall Plot.

To display a waterfall plot, you must first create or load a matrix wave. (If your data is in 1D waveform or XY pair format, you may find it easier to create a fake waterfall plot - see **Fake Waterfall Plots** on page II-328.) In this 2D matrix, each of the individual matrix columns is displayed as a separate trace in the waterfall plot. Each column from the matrix wave is plotted in, and clipped by, a rectangle defined by the X and Z axes with the plot rectangle displaced along the angled Y axis, which is the right-hand axis, as a function of the Y value.

You can display only one matrix wave per plot.

The traces can be plotted evenly-spaced, in which case their X and Y positions are determined by the X and Y dimension scaling of the matrix. Alternatively they can be plotted unevenly-spaced as determined by separate 1D X and Y waves.

To modify certain properties of a waterfall plot, you must use the ModifyWaterfall operation. For other properties, you will need to use the usual axis and trace dialogs.

Because the traces in the waterfall plot are from a single wave, any changes to the appearance of the waterfall plot using the Modify Trace Appearance dialog or ModifyGraph operation will globally affect all of the waterfall traces. For example, if you change the color in the dialog, then all of the waterfall traces will change to the same color. If you want each of the traces to have a different color, then you will need to use a separate wave to specify (as f(z)) the colors of the traces. See the example in the next section for an illustration of how this can be done.

The X and Z axes of a waterfall are always at the bottom and left while the Y axis runs at a default 45 degrees on the right-hand side. The angle and length of the Y axis can be changed using ModifyWaterfall. Except when hidden lines are active, the traces are drawn in back to front order. Note that hidden lines are active only when the trace mode is lines between points.

Marquee expansion is based only on the bottom and right (waterfall) axes. The marquee is drawn as a box with the bottom face in the ZY plane at zmin and the top face is drawn in the ZY plane at zmax.

Cursors may be used and the readout panel provides X, Y and Z axis information. The hcsr and xcsr functions are unchanged; the vcsr function returns the Y data value (waterfall) and the zcsr returns the data (Z axis) value.

Evenly-Spaced Waterfall Plot Example

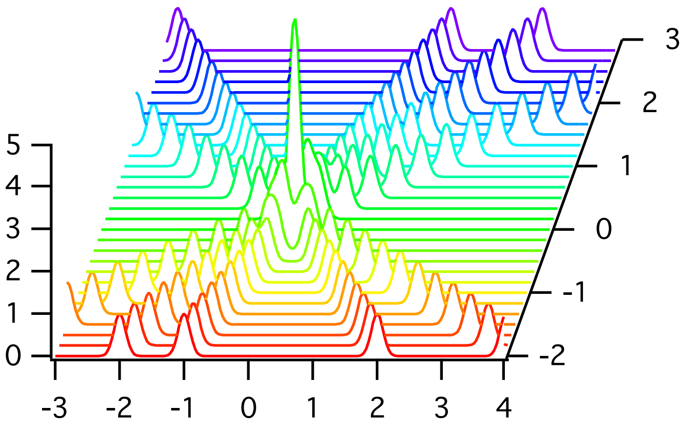
In this example we create a waterfall plot with evenly-spaced X and Y values that come from the X and Y scaling of the matrix being plotted.

```
Function EvenlySpacedWaterfallPlot()
   // Create matrix for waterfall plot
   Make/O/N=(200,30) mat1
   SetScale x,-3,4,mat1
   SetScale y,-2,3,mat1
   mat1=exp(-((x-y)^2+(x+3+y)^2))
   mat1=exp(-60*(x-1*y)^2)+exp(-60*(x-0.5*y)^2)+exp(-60*(x-2*y)^2)
   mat1+=exp(-60*(x+1*y)^2)+exp(-60*(x+2*y)^2)

   // Create waterfall plot
   NewWaterfall /W=(21,118,434,510) mat1
   ModifyWaterfall angle=70, axlen= 0.6, hidden= 3

   // Apply color as a function of Z
   Duplicate mat1,mat1ColorIndex
   mat1ColorIndex=y
   ModifyGraph zColor(mat1)={mat1ColorIndex,*,*,Rainbow}

End
```



Unevenly-Spaced Waterfall Plot Example

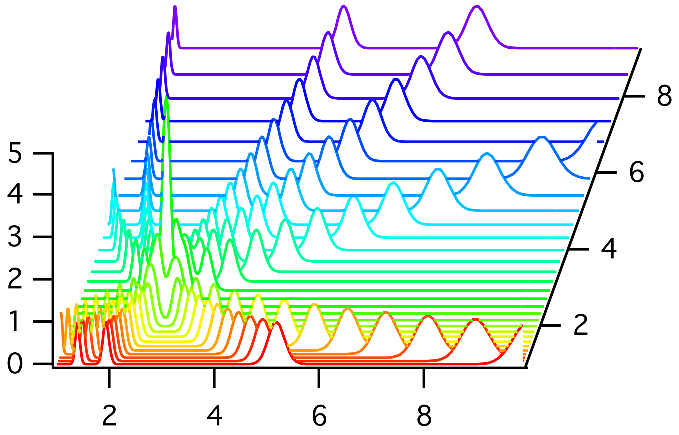
In this example we create a waterfall plot with unevenly-spaced X and Y values that come from separate 1D waves.

```
Function UnvenlySpacedWaterfallPlot()
   // Create matrix for waterfall plot
   Make/O/N=(200,30) mat2
   SetScale x,-3,4,mat2        // Scaling is needed only to generate
   SetScale y,-2,3,mat2        // the fake data
   mat2=exp(-((x-y)^2+(x+3+y)^2))
   mat2=exp(-60*(x-1*y)^2)+exp(-60*(x-0.5*y)^2)+exp(-60*(x-2*y)^2)
   mat2+=exp(-60*(x+1*y)^2)+exp(-60*(x+2*y)^2)
   SetScale x,0,0,mat2         // Scaling no longer needed because we will
   SetScale y,0,0,mat2         // use X and Y waves in waterfall plot

   // Make X and W waves
   Make/O/N=200 xWave = 10^(p/200)
   Make/O/N=30 yWave = 10^(p/30)

   // Create waterfall plot
   NewWaterfall /W=(21,118,434,510) mat2 vs {xWave,yWave}
   ModifyWaterfall angle=70, axlen= 0.6, hidden= 3

   // Apply color as a function of Z
   Duplicate mat2,mat2ColorIndex
   mat2ColorIndex=y
   ModifyGraph zColor(mat2)={mat2ColorIndex,*,*,Rainbow}
End
```

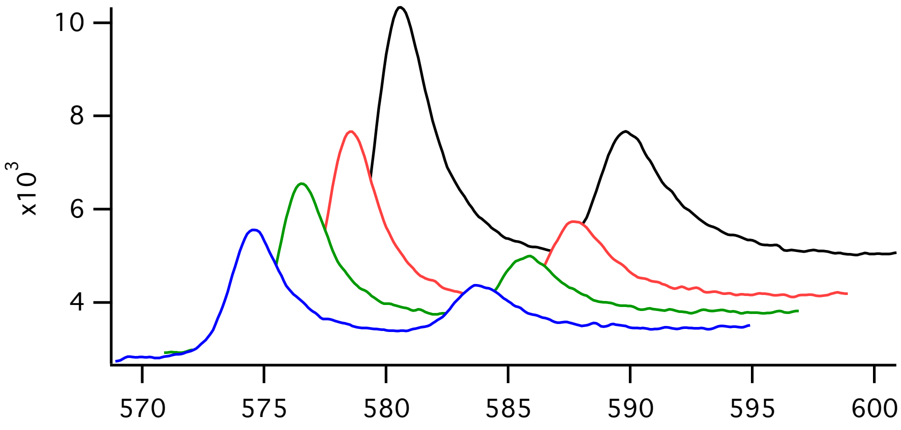


Fake Waterfall Plots

Creating a real waterfall plot requires a 2D wave. If your data is in the form of 1D waveforms or XY pairs, it may be simpler to create a "fake waterfall plot".

In a fake waterfall plot, you plot your waveform or XY data using a regular graph and then create the waterfall effect by offsetting the traces. Since fake waterfall plots use regular Igor traces, you can control their appearance the same as in a regular graph.

The result, with hidden line removal, looks like this:



Because of the offsetting in the X and Y directions, the axis tick mark labels can be misleading.

Igor includes a demo experiment showing how to create a fake waterfall plot. Choose File→Example Experiments→Graphing Techniques→Fake Waterfall Plot.

Wind Barb Plots

You can create a wind barb plot by creating an XY plot and telling Igor to use wind barbs for markers. You turn markers into wind barbs using "ModifyGraph arrowMarker", passing to it a wave that specifies the length, angle and number of barbs for each point.

If you want to color-code the wind barbs, you turn on color as f(z) mode using "ModifyGraph zColor", passing to it a wave that specifies the color for each point.

Here is an example. Execute the commands one section at at time to see how it works.

```
// Make XY data
Make/O xData = {1, 2, 3}, yData = {1, 2, 3}
Display yData vs xData          // Make graph
ModifyGraph mode(yData) = 3     // Marker mode

// Make a barb data wave to control the length, angle
// and number of barbs for each point.
// To control the number of barbs, column 2 must have a column label of WindBarb.
Make/O/N=(3,3) barbData         // Controls barb length, angle and number of barbs
SetDimLabel 1, 2, WindBarb, barbData          // Set column label to WindBarb
Edit /W=(439,47,820,240) barbData

// Put some data in barbData
barbData[0][0]= {20,25,30}      // Column 0: Barb lengths in points
barbData[0][1]= {0.523599,0.785398,1.0472}    // Column 1: Barb angle in radians
barbData[0][2]= {10,20,30}      // Column 2: Wind speed code from 0 to 40

// Set trace to arrow mode to turn barbs on
ModifyGraph arrowMarker(yData) = {barbData, 1, 10, 1, 1}

// Make an RGB color wave
Make/O/N=(3,3) barbColor
Edit /W=(440,272,820,439) barbColor

// Store some colors in the color wave
barbColor[0][0]= {65535,0,0}          // Red
```

```
barbColor[0][1]= {0,65535,0}        // Green
barbColor[0][2]= {0,0,65535}        // Blue

// Turn on color as f(z) mode
ModifyGraph zColor(yData)={barbColor,*,*,directRGB,0}
```

To see a demo of wind barbs choose File→Example Experiments→Feature Demos2→Barbs and Arrows.

See the arrowMarker keyword under **ModifyGraph (traces)** on page V-613 for details on the construction of the barb data wave.

The various color as f(z) modes are explained under **Setting Trace Properties from an Auxiliary (Z) Wave** on page II-298. You can eliminate the barbColor wave by using a color table lookup instead of a color wave.

Box Plots and Violin Plots

When you have multiple measurements that all represent the same conditions, it is useful to know how those measurements are distributed—tightly or loosely clustered, grouped around a central value or more loosely clustered with outliers, and many other possibilities. It is difficult for the eye to comprehend a simple cluster of dots, so plots that summarize the distribution are helpful. Box plots and violin plots are two ways to summarize a distribution of data points.

In Igor, box plots and violin plots are a special kind of graph trace. Each "point" of the trace represents an entire dataset. The data may be stored in individual waves, one wave for each dataset, in which case the input for the trace is a list of waves. Alternately, each dataset may be a column in a single two-dimensional matrix wave.

A normal XY graph trace is named for the wave containing the Y data. Thus, if the Y data is in a wave called "wave0", the trace is also called "wave0". But a box or violin plot may represent data coming from a number of waves. By default the box or violin plot trace is named for the first wave in the list of waves unless you specify a custom trace name. We recommend choosing a custom trace name that describes the nature of the collection of waves.

Box Plot and Violin Plot Terminology

To illustrate this terminology, consider these commands:

```
Make/N=10 wave0, wave1, wave2
Make/T labels = {"Run 1", "Run 2", "Run 3"}
Display; AppendBoxPlot/TN=trace0 wave0, wave1, wave2 vs labels
```

This creates a box plot with one trace named trace0. The trace consists of three datasets named wave0, wave1, and wave2. If we omitted /TN=trace0, the trace would have the default name wave0.

We can achieve the same thing using a 2D three-column 2D wave instead of three 1D waves:

```
Make/N={10,3} mat
Make/T labels = {"Run 1", "Run 2", "Run 3"}
Display; AppendBoxPlot/TN=trace0 mat vs labels
```

This creates a box plot with one trace named trace0. The trace consists of three datasets named mat[0], mat[1], and mat[2]. If we omitted /TN=trace0, the trace would have the default name mat.

Creating Box Plots and Violin Plots

To create a box plot, choose either Windows→New→Box Plot. To create a violin plot, choose Windows→New→Violin Plot. This displays a dialog in which you can choose datasets and set other parameters.

You choose datasets to be used for the plot from the list on the left, and transfer them to the list on the right by clicking the arrow button. Initially, the dialog shows only 1D waves and you need to select one wave for each box or violin to be displayed in the trace. If your data is in a 2D wave, turn on the One Multicolumn Wave checkbox below the list on the left.

If you are using 1D waves, after you have transferred the list of waves to the righthand list, you can reorder the waves by dragging up or down. The order of the waves in the list sets the order of the plots in the trace. If you use a multicolumn wave, the order is set by the columns in the wave.

You may also need to select an X wave. If you select _calculated_, the positions of the plots along the X axis are computed by Igor. For a list of 1D waves, the plots are positioned at 0, 1, 2, ... If your datasets are columns in a multicolumn wave, choosing _calculated_ results in plots positioned according to the Y scaling of the wave, that is, the scaled values of the column dimension indices.

The X Wave menu contains both numeric and text waves. Choosing a numeric wave allows you to position each plot at an arbitrary point on the X axis. Choosing a text wave results in a category X axis (see **Category Plots** on page II-355). The waves shown in the X Wave menu are limited to those waves that have the one point for each selected dataset.

The New Box Plot or New Violin Plot dialog can also make a new text wave for you. Selecting "_new text wave_" from the X Wave menu causes the dialog to generate commands which make a new text wave of the appropriate length, fill it with placeholder text, and display it in a table for editing. The result is a category X axis using the new text wave.

You can give your new trace a custom name by checking the Trace Name checkbox and entering the name in the associated edit box. A custom name is especially useful when you use a list of 1D waves because the default trace name, based on the name of the first data wave, is confusing.

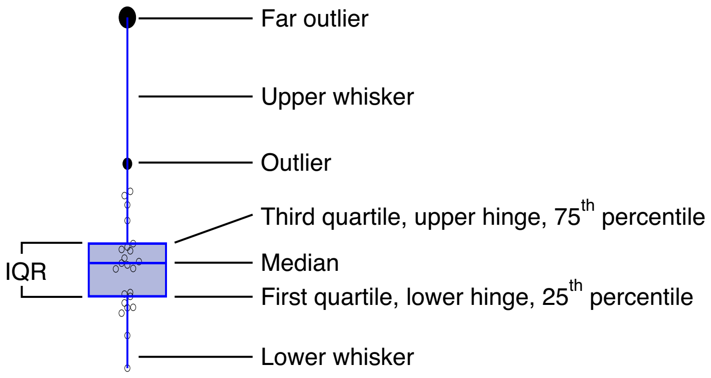
The X Axis, Y Axis and Swap XY Axes controls work the same way as they do in the New Graph dialog (see **Creating Graphs** on page II-277).

A graph can hold more than one box plot or violin plot trace and you can mix the two. To add another box plot or violin plot, choose Graph→Append to Graph→Box Plot or Graph→Append to Graph→Violin Plot.

Box Plots

The box plot, or box and whisker plot, was invented by John W. Tukey to present an easy-to-understand display of the distribution of the data points (see **Box Plot Reference** on page II-337).

A box plot has several parts:



Far outlier
Upper whisker
Outlier
Third quartile, upper hinge, 75th percentile
IQR
Median
First quartile, lower hinge, 25th percentile
Lower whisker

The bottom and top of the box are at the first and third quartiles of the dataset, with a line drawn across the box to represent the median value. Thus, the box gives an indication of the width of the distribution and the median line an indication of the central location of the distribution. The whiskers represent more information about the width of the data distribution such as the length of tails or the symmetry of the distribution. By default, Igor draws the whiskers to the extreme data points, but there are eight different options for whisker length.

The width of the box is not meaningful, but you can control it to make a pleasing display. The width can be expressed as a fraction, in which case it is the fraction of the width of the plot area. If the width is greater than one, it is taken to be an absolute width in points. By default the width is 1/(2*N), where N is the number of datasets or box plots included in the trace.

It is common to show the actual data points when they are far from the center of the distribution. Tukey defines "outliers" and "far outliers". Igor allows you to show all data points, only outliers and far outliers, or only far outliers. You can also select different markers, sizes and colors for each category of data points.

Box Plot Fences

Some options use Tukey's "fences" to define the length of the whiskers and the boundaries defining outliers and far outliers. Tukey also uses the term "hinge" to refer to the the 25th and 75th percentiles.

Inner fences are defined as

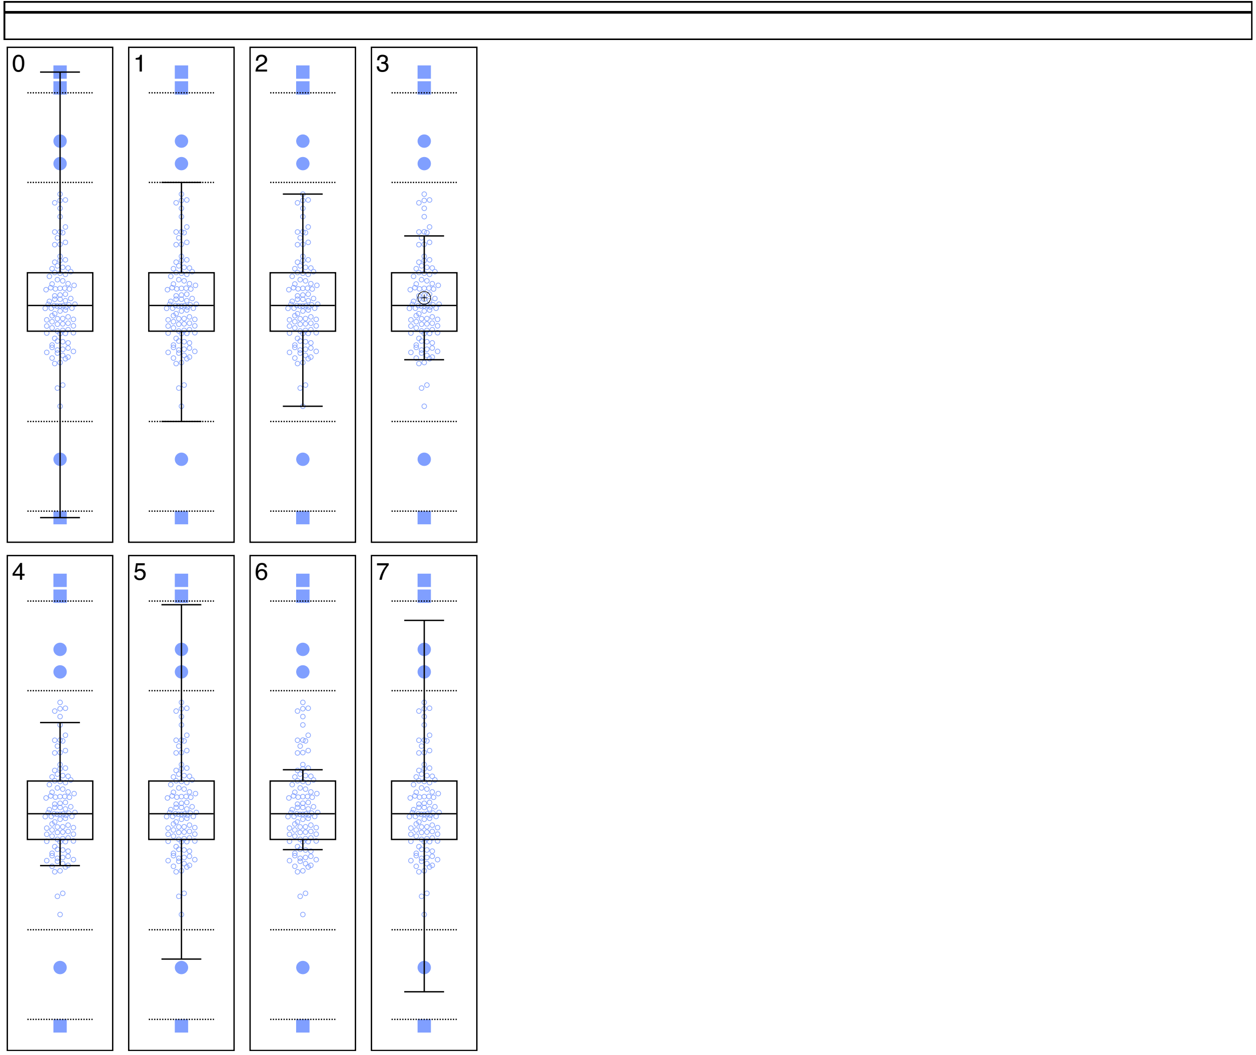
```
inner fence = upper hinge + 1.5*IQR and lower hinge - 1.5*IQR
```

Outer fences are defined as

```
outer fence = upper hinge + 3*IQR and lower hinge - 3*IQR
```

Box Plot Whisker Length

The following figure shows the options for defining the whisker length. The fences are shown for reference to Tukey's definitions, and the outlier method (see **Box Plot Outlier Methods** on page II-334) is option 0:



Option 0: Minimum and maximum data points (the default).

Option 1: Inner fences.

Option 2: "Adjacent points", which Tukey defines as the most extreme data points inside the inner fences. That is, the most extreme data points that are not outliers, if you define outliers the way Tukey does.

Option 3: One standard deviation from the mean of the data. The light circle with plus shows the mean value.

Option 4: The 9th and 91st percentiles.

Option 5: The 2nd and 98th percentiles.

Option 6: Arbitrary percentiles. Here the ends are set to the 20th and 80th percentiles in order to make it look different from the other options.

Option 7: An arbitrary factor times one standard deviation from the mean. In this case, the factor is 3.

If the data are normally distributed, the 2nd, 9th, 25th, 50th, 75th, 91st, and 98th percentiles should be equally spaced.

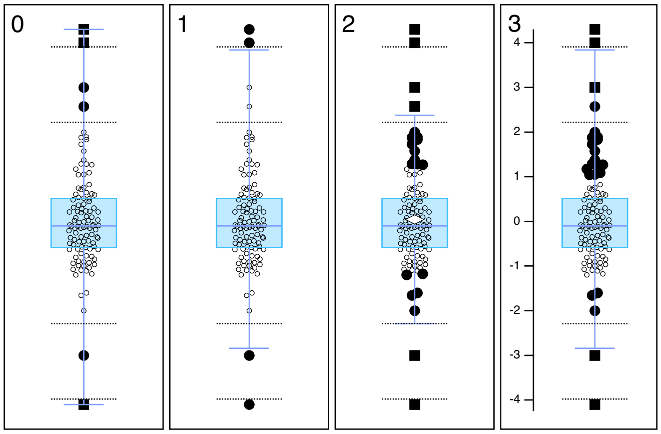
The examples show all the data points but it is common to show only outliers and far outliers. The data points are displayed with "jitter"—data points that would overlap are offset horizontally so that each data point can be seen. You can control the maximum offset by specifying the jitter amount in units of fractions of the box width. If the specified width is insufficient to separate the points, they will overlap as needed. If the width is greater than necessary, only as much offset as necessary is applied.

In usual practice the fences are not shown.

Box Plot Outlier Methods

By default, Igor follow Tukey in defining outliers and far outliers based on the fences, with "outliers" being points outside the inner fences and "far outliers" being points beyond the outer fences. While not usually shown in practice, you can tell Igor to include the fences on the plot using the command ModifyBoxPlot showFences=1. The outliers are shown as filled circles and the far outliers are large filled squares.

Igor offers four options to control which data points are outliers and far outliers:



Option 0: Tukey's definition. Outliers are any data points beyond the inner fences, far outliers are any data points beyond the outer fences.

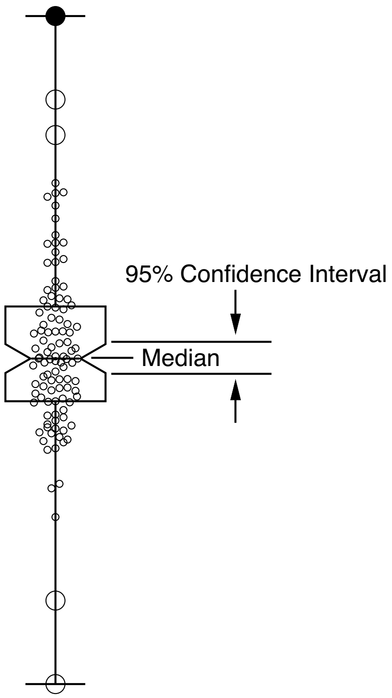
Option 1: Any points beyond the ends of the whiskers are outliers. There are no far outliers. For this option, the whiskers were set to option 6, 2nd and 98th percentiles.

Option 2: Outliers and far outliers are points beyond an arbitrary factor times the standard deviation of the mean. In this case, those factors are 1 and 2. The whisker lengths are set to option 7, arbitrary factor times the standard deviation of the mean. The factor is set to 2. The white diamond shows the mean value.

Option 3: Outliers and far outliers are determined by four arbitrary data values. In this case the values are -2, -1.5, 1 and 2.6.

Notched Box Plots

A notched box plot shows the 95% confidence interval of the median in addition to the various percentiles usually shown:



The notches are at median ± 1.57 * IQR/sqrt(n) where n is the number of data points in the dataset represented by the box plot. Two box plots have a high probability of significantly different median values if the notches don't overlap.

You make a notched box plot by right-clicking on the box plot trace and selecting Modify Box Plot. In the Modify Box Plot dialog, General tab, turn on the Notched checkbox.

Appearance Options for Box Plots

To change the appearance of a box plot, select Modify Box Plot from the Graph menu or right-click on a box plot trace and select Modify Box Plot from the contextual menu.

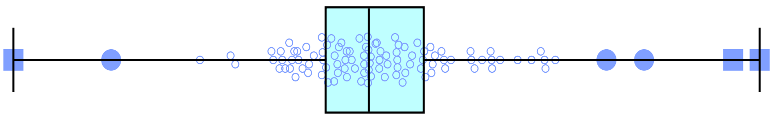
You can change the color, width and dash style for the lines. Those settings can be made individually for each component: the box, the whiskers, the median line and whisker caps.

We regard the fences as an incidental detail. You can show the fences in order to understand the display better, but we have not seen them used for publication purposes. Consequently, the lines for the fences are not modifiable.

You can control the width of the whisker caps—to omit the caps (the default), set the width to zero. A fractional width sets the size of the cap as a fraction of the box width. This is useful to make the cap width consistent when resizing the graph. A width greater than 1 is taken to be an absolute width in points.

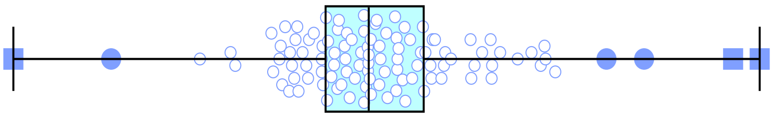
The plots that follow are drawn horizontally to save space. You can achieve that effect by choosing Modify Graph from the Graph menu, and then turning on the Swap XY checkbox. Alternately, you can turn on the Swap X Y Axes checkbox in the New Box Plot or the Append Box Plot dialog to apply the swap to just one box plot trace.

The box can be filled with a color. The box fill color is drawn before the markers so that whatever choices you make for the markers will not be overdrawn by the fill color.

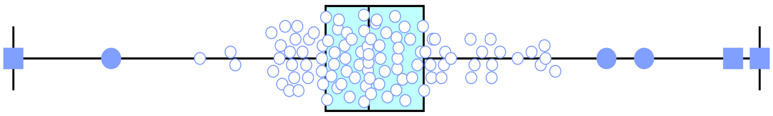


You can select a different marker for non-outlier data, outliers and far outliers. In the plot above, regular data points and outliers are drawn with the hollow circle marker, and outliers have been made larger than the regular data points to emphasize them. The far outlier (there is just one) is drawn with a filled circle marker.

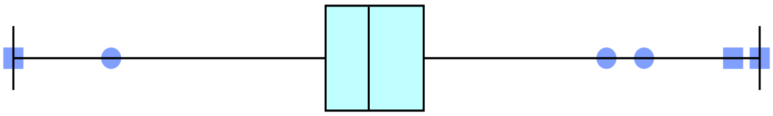
You can achieve some special effects by using a hollow marker and selecting a fill color for the marker For instance, in this plot the hollow circle marker is used for the regular data points, and the fill color is enabled and set to white:



The lines making the box, median and whiskers are on top of the markers so that the markers don't obscure the lines. Sometimes you may wish to have the markers on top. With this dataset, that may obscure the lines too much. To achieve this effect, on the Markers tab turn on the Draw Data Points on Top checkbox. You can separately control drawing the mean marker and median marker:

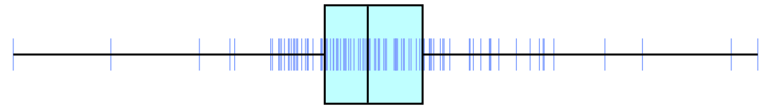


You can choose to show all the raw data, as above, or you can choose to show no raw data points, only outliers and far outliers, or just the far outliers. This plot shows outliers and far outliers:

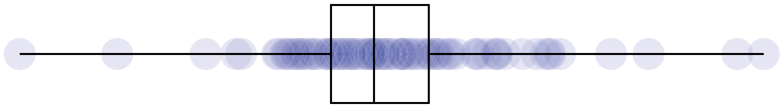


The plots above apply jitter to the data points; that is, if the markers would overlap a lateral offset is applied so that you can see all of them. You can specify a width for the jitter that sets a maximum lateral offset. If the offset is too small to completely separate the markers, they will overlap to some degree. If an offset is not required for a given marker, it is not offset.

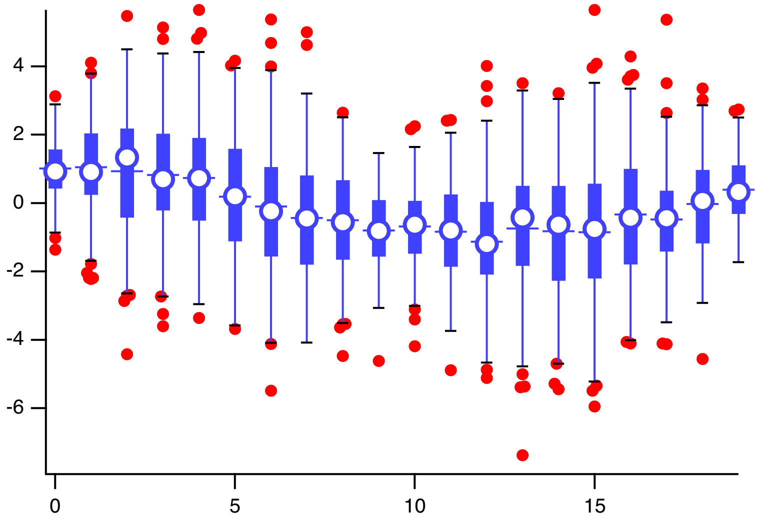
You will sometimes see a box plot in which the data points are shown as a "rug plot", that is, each data point is represented by a thin line. That is another way to allow all the data points to be seen, as long as there aren't too many. To do this, use the line marker and set the jitter to zero. In this plot the marker for normal points, outliers and far outliers is the same vertical line marker (marker 10) with the size set to 8. The caps were set to zero and the extreme data points look like caps.



Large markers with transparency can also give a sense of data density. This plot uses the solid circle marker (number 19) with a blue color with alpha set to 0.1. The fill color for the box is turned off, as the background will show through the transparent markers and affect the color.



Sometimes the number of datasets and data points can be overwhelming. Here is an alternative look that makes a more compact display:



The whisker method is set to Mean ± f*SD, with the factor set to 2, so the whiskers show a span of 2 standard deviations about the mean. The outlier method is set to Whiskers, so only data points beyond the ends of the whiskers are shown. That limits the shear number of data points on the plot.

There are many datasets, so the boxes are quite narrow and filled to make a solid box. Instead of a hard-to-see median line, the median is shown as a white-filled circle marker. To prevent the box outlines from showing on top of the white marker fill, the Draw Median Marker On Top checkbox is turned on in the Markers tab of the Modify Box Plot dialog.

Finally, the mean is shown as a horizontal bar marker. The marker size is set large enough that it shows outside the median circle marker.

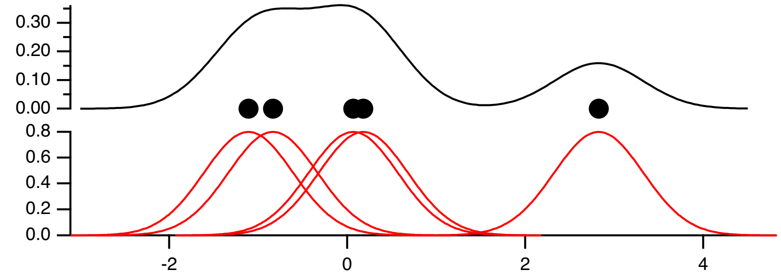
Box Plot Reference

Tukey, John W., Exploratory Data Analysis, Addison-Wesley Publishing Company, 1977.

Violin Plots

A violin plot, also called a bean plot, is a way to summarize the distribution of data. A violin plot shows the distribution of a dataset using a kernel density estimate (KDE). The KDE creates a smooth estimate of the underlying data distribution by summing some kernel function, one function per data point. The summed curve is then normalized to an area of 1.0 so that it is an estimate of the probability distribution function for the dataset.

Suppose you have five points drawn from a Gaussian distribution, such as the points represented by the black dots here:

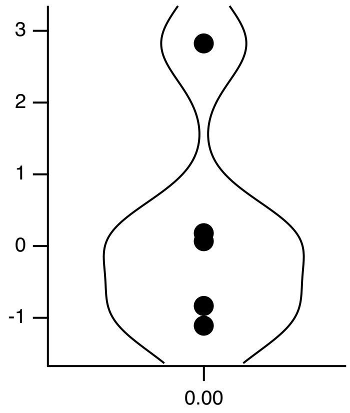


Generate a Gaussian curve for each point (the red curves), then sum the curves and normalize for an area of one (the black curve). In this plot we have arbitrarily selected a standard deviation for the red curves of 0.5; this is referred to as the bandwidth when computing a KDE curve or violin plot.

Now we have a smooth curve that gives a possible representation of the underlying distribution from which the data points were drawn. Quite possibly the kernel bandwidth we used was too small, and unjustified by the small number of points. The choice of kernel function, Gaussian in this example, and the width of the kernel are somewhat arbitrary. The Gaussian kernel is in some sense "smooth" and reflects our bias that most data follow a Gaussian distribution. Others are possible.

You can compute a KDE for your datasets yourself using the **StatsKDE** operation, but to get from there to a violin plot is quite tedious. Igor does a lot of this work for you when you create a violin plot trace by executing the steps described under **Creating Box Plots and Violin Plots** on page II-330.

In a violin plot, the curve is in general plotted vertically and reflected across the midline to give a plot that looks somewhat like a violin or a green bean pod with lumps for each seed. Here is Igor's violin plot of the five points shown above, modified to show the raw data points and to use black coloring:



In this plot, the width of the curves is not meaningful except in a relative way. The centerline indicates zero estimated probability density. Because it is the only dataset included in the trace, and it is not a category plot, it is positioned at zero on the X axis.

For the following illustrations, we made two representative fake datasets:

```
Make/N=(50,3) run1      // 50 points per dataset, three datasets
Make/N=(50,3) run2      // Another with three datasets with 50 points
run1 = gnoise(q+1)      // Gaussian data with standard deviation
run2 = gnoise(1) + q    // Gaussian data with constant width and location
Make/N=3/T categories="Dataset "+num2str(p+1)    // Text wave for category plot
```

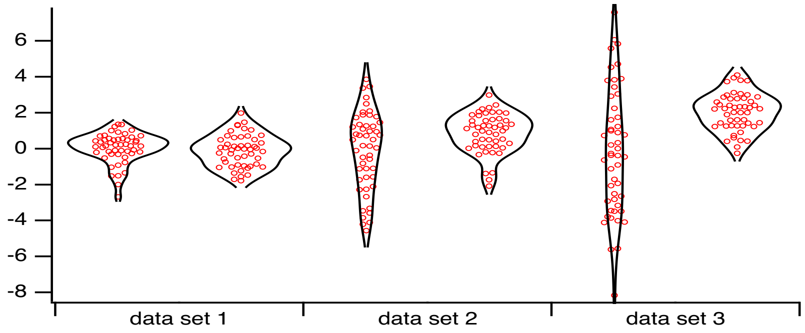
At this point you could select Windows→New Violin Plot, turn on the Multicolumn checkbox, select run1 as the data and categories as the X wave. That would result in these commands:

```
Display;AppendViolinPlot run1 vs categories
```

Now select Graph→Append Violin Plot, turn on the Multicolumn checkbox, select run2 as the data and accept categories as the X wave. That would result in this command:

```
AppendViolinPlot run2
```

The resulting graph looks like this:



Appearance Options for Violin Plots

To change the appearance of a violin plot, select Graph→Modify Violin Plot or right-click and select Modify Violin Plot.

Igor's violin plot has six kernel shapes to choose from. The default is Gaussian and we don't anticipate that other shapes will be used much.

There are three methods for automatically estimating the best bandwidth to use. If you don't like the results of the automatic bandwidths, you can set your own, with a separate bandwidth for each dataset. The automatic estimate assumes a Gaussian kernel.

Each plot of a violin trace occupies a horizontal space equivalent to the box width of a box plot, and that box width can be set in the same way as a box plot—fractions give a width that is a fraction of the plot area, values larger than one are absolute sizes in points. If the X axis is a category axis, Igor sets the box width, overriding whatever you may have chosen.

When Igor makes a violin trace containing more than one dataset, the curves are all normalized to the largest peak amongst all the KDE curves so only one of the violin plots occupies the full box width. You can see this in the plot above, where the third dataset in the Run1 trace (left plots in each category) represents a dataset with broader distribution, which means that to achieve an area of one it must have a smaller amplitude. Compare it with the short, fat distributions in the other categories.

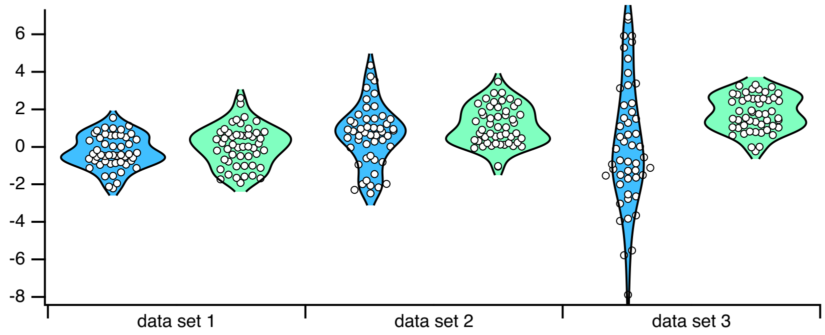
If you have more than one set of violin plots, as in this example where there are two violin traces—one from run1 and one from run2, by default the widest plot in each trace fills the box. The two traces are normalized separately. If you want all the plots in both traces to use the same normalization, you can set the normalization yourself so that the relative amplitudes of all the curves represent the same relative values. This is done using the Distribution Max setting in the General tab of the Modify Violin Plot dialog. The value computed by Igor is shown next to the edit box.

It is common to show the raw data with markers. By default, the raw data points are shown using hollow circles drawn half the size of the default markers for a normal trace. You can choose a marker for the raw data points, plus one for the mean and the median if desired. Violin plots do not distinguish outliers. Jitter can be applied to the data point markers so that they don't overlap.

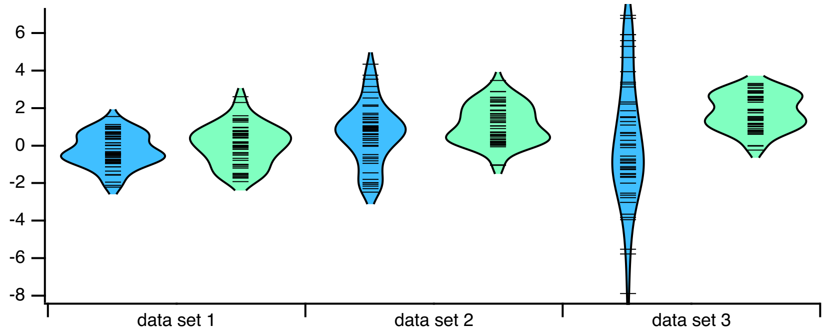
To make a rug plot of the raw data, use the appropriate line marker and set the jitter to 0. Most violin plots are plotted vertically, and the horizontal line marker would be appropriate.

The space between the KDE curves can be filled with color. The fill color is drawn behind the markers so that special effects can be achieved with marker color, marker stroke color and marker fill color.

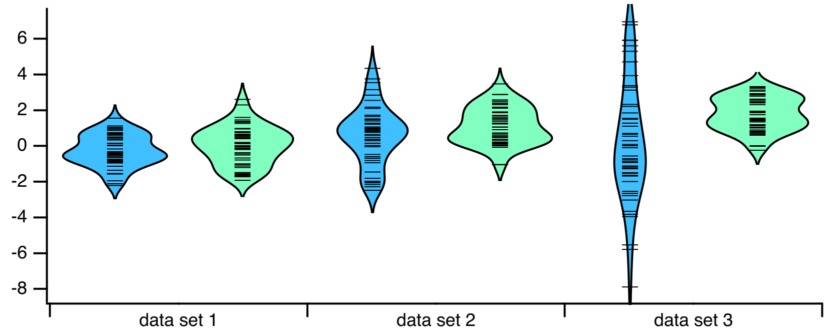
Here is the plot above, re-worked with fill color and hollow round markers with white fill:



And here it is as a rug plot:



You may notice that some of the curves appear to be a bit truncated. That is particularly true of the dataset 3 plot in the right-hand trace. By default, Igor plots the KDE curves one bandwidth beyond the last data point. In this case, it appears that it might be nice to have the curves extend a bit farther. To achieve that, right-click the trace and select Modify Violin Plot. On the General tab, find the Curve Extension edit box and enter a more pleasing amount of extension. The units are kernel bandwidths. Here we have set 2 for the plot above:

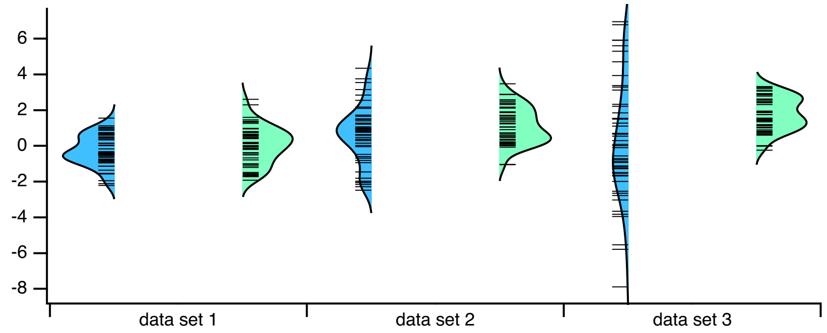


Asymmetric Violin Plots

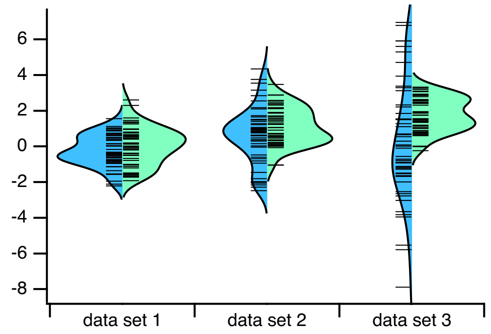
A common variation on a standard violin plot uses just half the violin. This is usually done to compare two conditions or two runs. One condition provides the left half and the other provides the right half.

Let's make the plot above into an asymmetric plot.

The first step is to right-click one of the traces in the plot and choose Modify Violin Plot from the contextual menu. Select the trace that you want for the left half, say the Run1 trace. On the General tab, find the Plot Side menu and select Left Side. Select Run2 and select Right Side in the Plot Side menu. Click Do It and you now have a plot that looks like this:

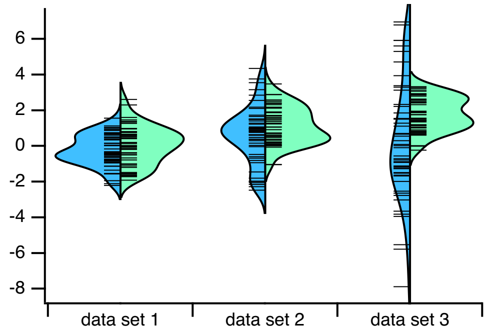


Because the X axis is a category axis, each plot occupies its own slot in the category. To bring them together, double-click the Run1 trace to bring up the Modify Trace Appearance dialog. Make sure the first trace in the trace list is selected. In the Grouping menu, select Keep With Next. We also made the graph window narrower for aesthetic reasons:



If your X axis is a numeric axis, you don't need the last step of setting the Grouping mode. The two violin plot traces draw the plots at the numeric value set by the X wave, or at 0, 1, 2, and so on, if you chose Calculated.

Finally, you may decide that the plot looks better with a line enclosing the entire color-filled area. On the General tab of the Modify Violin Plot dialog, turn on the Close Outline checkbox:



Violin Plot References

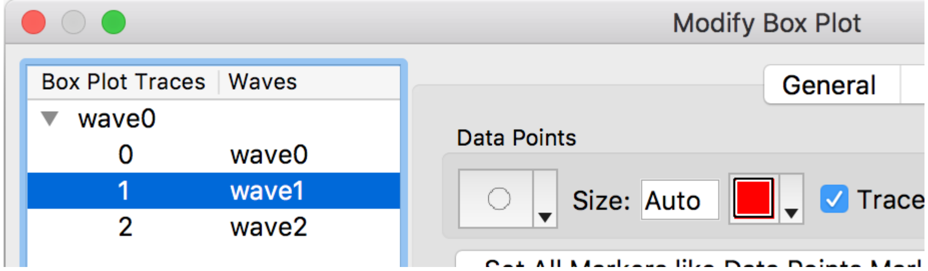
Making Boxes and Violins Look Different

At times you may want one of the boxes or violins in a trace to have a different appearance to distinguish the corresponding dataset from others in the trace. The Modify Box Plot and Modify Violin Plot dialogs support this by allowing you to select a single dataset from a trace.

This graphic shows the Modify Box Plot dialog with a box plot trace made with a list of three waves. The first wave in the list was wave0, so the name of the trace is "wave0". Clicking the triangle icon for the wave0 trace discloses a list of the three datasets, one for each wave.

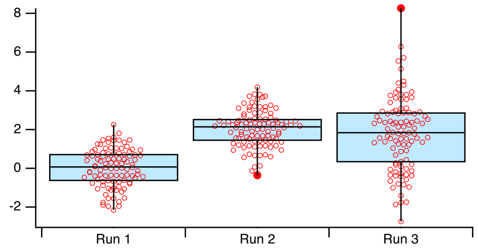


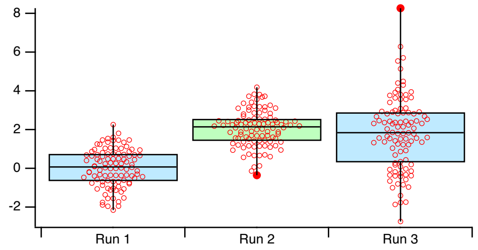
Box Plot Traces	Waves
▼ wave0	
0	wave0
1	wave1
2	wave2

○ Size: Auto 🟥 ☑ Trace

If the top wave0 item were selected, changes made in the dialog would apply to all datasets in the trace. Here we have selected the second dataset corresponding to wave1 so changes made in the dialog apply only to the dataset and consequently to the second box in the box plot.

These graphs show before and after setting the box fill color for the wave1 dataset only to light blue:



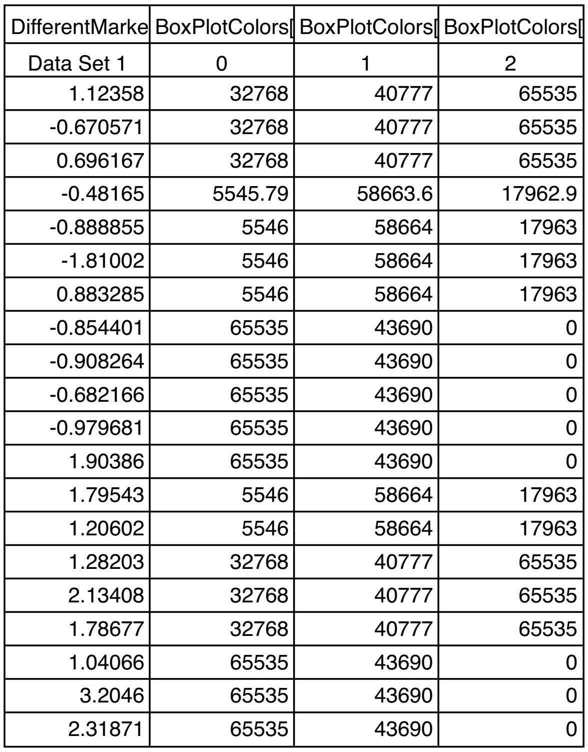


The order in which you make these settings is important. If you change an overall setting, any corresponding values for individual datasets are reset to the overall value. So to make the box plot above with light blue overall, and light green for the second dataset, you need to first set the light blue color for the entire trace followed by setting the light green color for the second dataset only. You do not need to close the dialog between these two changes.

Making Each Data Point Look Different

Sometimes the data points in a single dataset come from different sources, or represent different conditions, and you would like to show that in the graph. Using an auxiliary wave you can set the marker color, marker size or marker style for each data point. Controls for these settings appear in the Markers tab of the Modify Box Plot dialog.

For instance, this table shows a fake dataset in the first column and a corresponding three-column wave to specify the marker color for each data point:



DifferentMarke	BoxPlotColors[	BoxPlotColors[	BoxPlotColors[
Data Set 1	0	1	2
1.12358	32768	40777	65535
-0.670571	32768	40777	65535
0.696167	32768	40777	65535
-0.48165	5545.79	58663.6	17962.9

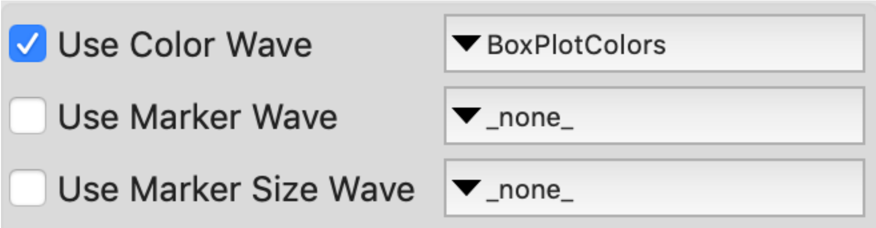
-0.854401	65535	43690	0
-0.908264	65535	43690	0
-0.682166	65535	43690	0
-0.979681	65535	43690	0
1.90386	65535	43690	0
1.79543	5546	58664	17963
1.20602	5546	58664	17963
1.28203	32768	40777	65535
2.13408	32768	40777	65535
1.78677	32768	40777	65535
1.04066	65535	43690	0
3.2046	65535	43690	0
2.31871	65535	43690	0

We made a box plot with that dataset and selected the wave BoxPlotColors to set the marker colors for the data points:

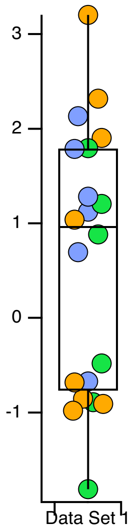


☑ Use Color Wave ▼ BoxPlotColors

☐ Use Marker Wave ▼ _none_

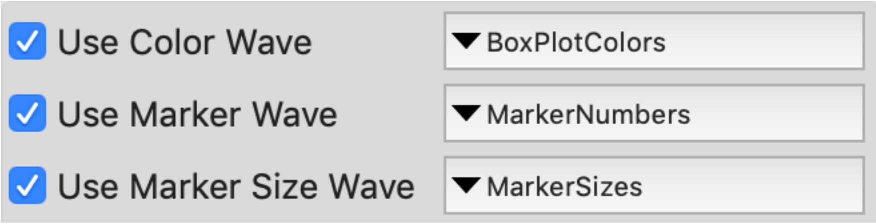
☐ Use Marker Size Wave ▼ _none_

The result is this box plot:



The color wave for this figure was created using the Color Wave Editor package, accessed by choosing Data→Packages→Color Wave Editor.

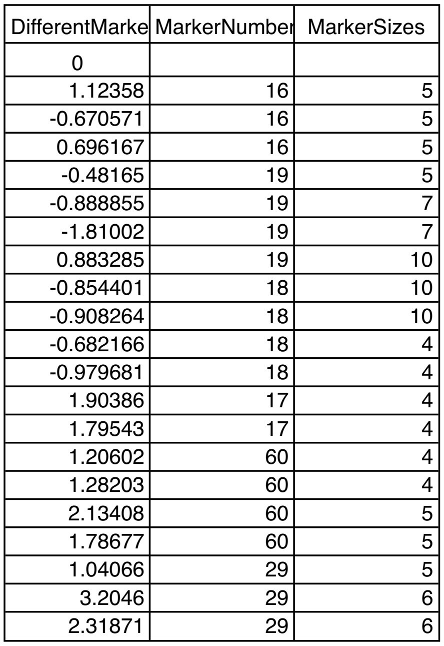
Similarly, you can set each data point marker to a different size or to a different marker style using a 1D wave with a size or marker number for each data point. For instance:



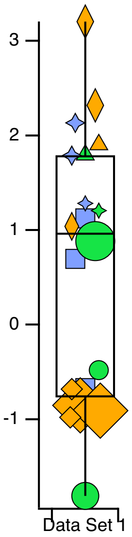
☑ Use Color Wave ▼ BoxPlotColors

☑ Use Marker Wave ▼ MarkerNumbers

☑ Use Marker Size Wave ▼ MarkerSizes



DifferentMarke	MarkerNumber	MarkerSizes
0		
1.12358	16	5
-0.670571	16	5
0.696167	16	5
-0.48165	19	5
-0.888855	19	7
-1.81002	19	7
0.883285	19	10
-0.854401	18	10
-0.908264	18	10
-0.682166	18	4
-0.979681	18	4
1.90386	17	4
1.79543	17	4
1.20602	60	4
1.28203	60	4
2.13408	60	5
1.78677	60	5
1.04066	29	5
3.2046	29	6
2.31871	29	6



Marker sizes can range from 0 to 200. See **Markers** on page II-291 for a table of marker styles and the associated marker numbers.

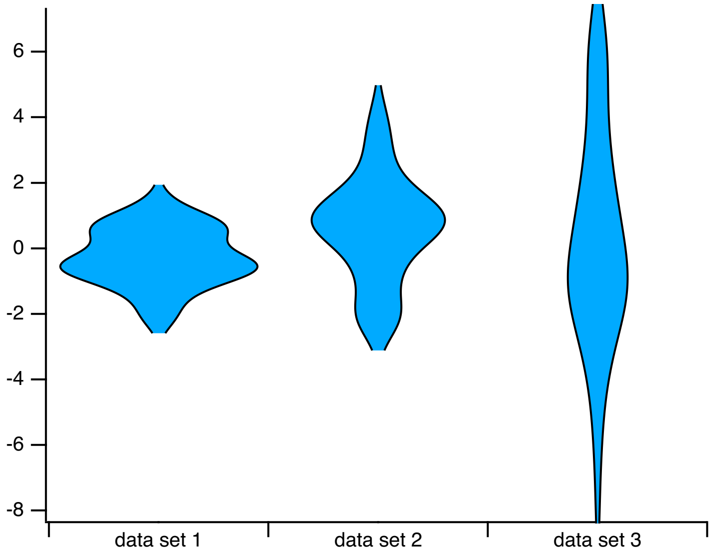
The marker colors, marker sizes and marker styles set by these waves override whatever other settings have been made. So if you have selected a particular marker for box plot outliers, for instance, but an outlier data point has a marker set via a marker wave, the marker is taken from the wave.

The marker color, marker size and marker style waves are not required to have the same number of rows as the dataset wave. If there are extra rows the extras are ignored. If there are too few rows, the extra data points take their color, size, color and style from the normal color, size and style settings.

Combining Box Plots and Violin Plots

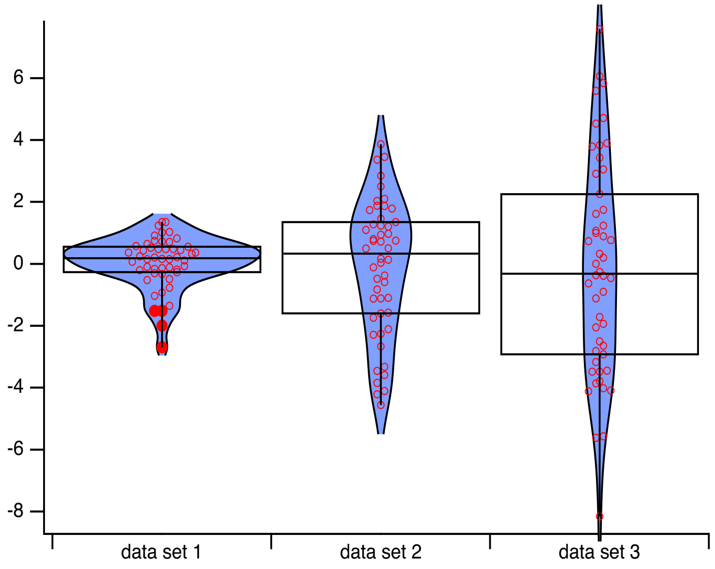
One problem with a box plot is that it hides the true distribution of your data. If your data is bimodal, it still shows you only a box with a median line and whiskers. But a violin plot lacks the statistical information contained in a box plot. A common solution is to combine the two—put a box plot in the middle of a violin plot.

To do this in Igor, first create a violin plot using Windows→New→New Violin Plot. We did this with the Run1 dataset from the violin plot example:

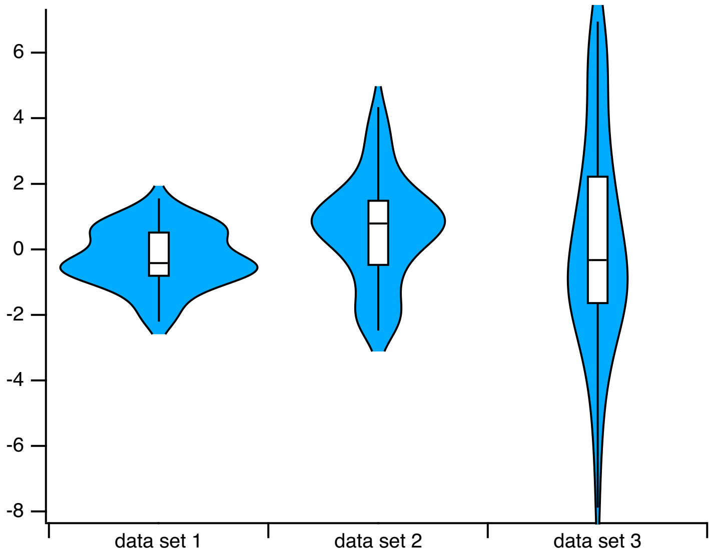


We have chosen a fill color and we are not showing the data points.

Now add a box plot by choosing Graph→Append→Box Plot. Because we are using a category X axis, the plots are side-by-side. Double-click the violin plot trace and select Keep With Next as the grouping mode:



For best appearance, you should make the box plot narrower, and most likely fill the box with contrasting color. Here we set the box width to 0.1 and chose to fill the box with white. We don't show the data points, but if you wish to, it is best to show the data points using the box plot trace so that fills don't obscure the data points.



Creating Split Axes

You can create split axes using the same techniques described above for creating stacked plots. Simply plot your data twice using different axes and then adjust the axes so they are stacked. You can then adjust the range of the axes independently. You can use draw tools to add cut marks.

WaveMetrics supplies a procedure package to automate all aspects of creating split axes except setting the range and adjusting the ticking details of the axes. To use the package, choose Graph→Packages→Split Axes. For an example, choose File→Example Experiments→Graphing Techniques→Split Axes.

Before using the package, you should create the graph in near final form using just the main axes. For best results, especially if you will be using cut marks, you should work with the graph at actual size before adding the split axes. It is recommended that you create a recreation macro just before executing the split axis macros. This is so you can easily revert in case you need to change the pre-split setup.

After creating the split, you can execute the AddSplitAxisMarks procedure to add cut marks between the two axes. You can then use the drawing tools to duplicate the cut marks if you want marks on the traces as well as the axes. Of course, you can also draw your own cut marks. You should use the default Plot Relative coordinate system for cut marks so they will remain in the correct location should you resize the graph.

Some programs draw straight lines between data points on either side of the split. While such lines provide the benefit of connecting traces for the viewer, they also are misleading and inaccurate. This package accurately plots both sections and does not attempt to provide a bridge between them. If you feel it is necessary, you can use drawing tools to add a connecting bridge.

Live Graphs and Oscilloscope Displays

This section will be of interest mainly if you use Igor for data acquisition.

Normally, when the data in a wave is modified, all graphs containing traces derived from that wave are redrawn from scratch. Although fast compared to other programs, this process may noticeably limit the graph update rate.

Live Mode

If you specify one or more traces in a graph as being “live” then Igor takes some shortcuts, resulting in faster than normal updates. Fast update is obtained when certain conditions are observed.

Note: When graphs are redrawn in live mode, *autoscaling is not done.*

To specify a trace in a graph as being live you must use the **live** keyword with the ModifyGraph command. There is no dialog support for this setting.

```
ModifyGraph live(traceName)= mode
```

Mode can be 0 or 1. Zero turns live mode off for the given trace.

WaveMetrics provides a demo experiment that generates and displays synthetic data. You should use this experiment to get a feel for the performance you might expect on your particular computer as a function of the window size, number of points in the live wave, and the live modes. To run the demo, choose File→Example Experiments→Feature Demos→Live Mode.

Although live mode 1 is not restricted to unity thickness solid lines or dots modes, you will get the best performance if you do use these settings.

Quick Append

Another feature that may be of use is the quick append mode. It is intended for applications in which a data acquisition task creates new waves periodically. It permits you to add the new waves to a graph very quickly. To invoke a quick append, use the /Q flag in an AppendToGraph command. There is no dialog support for this setting.

A side effect of quick append is that it marks the wave as not being modified since the last update of graphs and therefore prevents other graphs containing the same wave, if any, from being updated. For a demo, choose File→Example Experiments→Feature Demos→Quick Append.

Graph Preferences

Graph preferences allow you to control what happens when you create a new graph or add new traces to an existing graph. To set preferences, create a graph and set it up to your taste. We call this your *prototype* graph. Then choose Capture Graph Prefs from the Graph menu.

Preferences are normally in effect only for *manual* operations, not for automatic operations from Igor procedures. This is discussed in more detail in Chapter III-18, **Preferences**.

When you initially install Igor, all preferences are set to the factory defaults. The dialog indicates which preferences you have not changed by displaying “default” next to them.

The Window Position and Size preference affects the creation of new graphs only. New graphs will have the same size and position as the prototype graph.

The Page Setup preference is somewhat unusual because all graphs share the same page setup settings, as shown in the Page Setup dialog. The captured page setup is already in use by all other graphs. The utility of this category is that new *experiments* will use the captured page setup for graphs.

The “XY Plots:Wave Styles” preference category refers to the various wave-specific settings in the graph, such as the line type, markers and line size, set with the Modify Trace Appearance dialog. This category also includes settings for waveform plots. Each captured wave style is associated with the index of the wave it was captured from. The index of the first wave displayed or appended to a graph is 0, the second appended wave has an index of 1, and so on.These indices are the same as are used in style macros. See **Graph Style Macros** on page II-350.

If preferences are on when a new graph with waves is created or when a wave is appended to an existing graph, the wave style assigned to each is based on its index. The wave with an index of 2 is given the captured style associated with index 2 (the third wave appended to the captured graph).

You might wonder what style is applied to the fifth and sixth waves if only four waves appeared in the graph from which wave style preferences were captured. You have two choices; either the factory default style is used, or the styles repeat with the first wave style and then the second style. You make this choice in the Miscellaneous Settings dialog, with the Repeat Wave Style Prefs in Graphs checkbox. With that box selected, the fifth and sixth waves would get the first and second captured styles; if deselected, they would both get the factory default style, as would any other waves subsequently appended to the graph.

The XY Plots:Axes and Axis Labels preferences category captures all of the axis-related settings for axes in the graph. Only axes used by XY or waveform plots have their settings captured. Axes used solely for a category, image, or contour plot are ignored. The settings for each axis are associated with the name of the axis it was captured from.

Even if preferences are on when a new graph with waves is created or when a wave is newly appended to an existing graph, the wave is still displayed using the usual default left and bottom axes unless you explicitly specify another named axis. The preferred axes are not automatically applied, but they are listed by name in the New Graph, and the various Append to Graph dialogs, in the two Axis pop-up menus so that you may select them.

For example, suppose you capture preferences for an XY plot using axes named MyRightAxis and MyTopAxis. These names will appear in the X Axis and Y Axis pop-up menus in the New Graph and Append Traces to Graph dialogs.

- If you choose them in the New Graph dialog and click Do It, a graph will be created containing *newly-created* axes named MyRightAxis and MyTopAxis and having the axis settings you captured.
- If you have a graph which already uses axes named MyRightAxis and MyTopAxis and choose these axes in the Append Traces to Graph dialog, the traces will be appended to those axes, as usual, but no captured axis settings will be applied to these *already-existing* axes.

Captured axes may also be specified by name on the command line or in a procedure, provided preferences are on:

```
Function AppendWithCapturedAxis(wav)
   Wave wav
   Variable oldPrefState
   Preferences 1; oldPrefState = V_Flag   // Turn preferences on
   Append/L=MyCapturedAxis wav      // Note: MyCapturedAxis must
                                    //       be vertical to use /L
   Preferences oldPrefState         // Restore old prefs setting
End
```

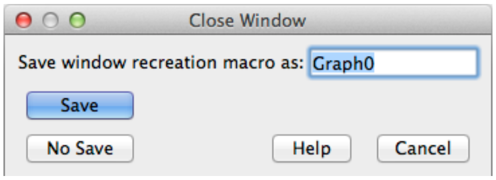
The Category Plots:Axes and Axis Labels and Category Plots:Wave Styles are analogous to the corresponding settings for XY plots. Since they are separate preference categories, you have can independent preferences for category plots and for XY plots. Similarly, preferences for image and contour plots are independent of preferences for other types. See Chapter II-14, **Category Plots**, Chapter II-15, **Contour Plots**, and Chapter II-16, **Image Plots**.

How to use Graph Preferences

Here is our recommended strategy for using graph preferences:

1. Create a new graph containing a single trace. Use the axes you will normally use.
2. Make the graph appear as you prefer using the Modify Graph dialog, Modify Trace Appearance dialog, the Modify Axis dialog, etc. Move the graph to where you prefer it be positioned.
3. Choose the Graph→Capture Graph Prefs menu to display the Capture Graph Preferences dialog. Check the checkboxes corresponding to the categories you want to capture, and click Capture Prefs.
4. Choose Misc→Miscellaneous Settings to display the Miscellaneous Settings dialog. In the Graphs section, check the Repeat Wave Style Prefs checkbox, and click Save Settings.

Saving and Recreating Graphs



If you click in the close button of a graph window, Igor asks you if you want to save a **window recreation macro**.

Igor presents the graph's name as the proposed name for the macro. You can replace the proposed name with any valid macro name.

If you want to make a macro so you can recreate the graph later, click Save. Igor then creates a macro which, when invoked, will recreate the graph with its size, position and presentation intact. Igor saves the recreation macro is placed in the procedure window where you can inspect, modify or delete it as you like.

The macro name appears in the Graph Macros submenu of the Windows menu. You can invoke the macro by choosing it from that submenu or by executing the macro from the command line. The window name of the recreated graph will be the same as the name of the macro that recreated it.

If you are sure that you never want to recreate the graph, you can press Option (*Macintosh*) or Alt (*Windows*) while you click the close button of the graph window. This closes the graph without presenting the dialog and without saving a recreation macro.

For a general discussion of saving, recreating, closing windows, see Chapter II-4, **Windows**.

Graph Style Macros

The purpose of a graph style macro is to allow you to create a number of graphs with the same stylistic properties. Igor can automatically generate a style macro from a prototype graph. You can manually tweak the macro if necessary. Later, you can apply the style macro to a new graph.

For example, you might frequently want to make a graph with a certain sequence of markers and colors and other such properties. You could use preferences to accomplish this. The style macro offers another way and has the advantage that you can have any number of style macros while there is only one set of preferences.

You create a graph style macro by making a prototype graph, setting each of the elements to your taste and then, using the Window Control dialog, instructing Igor to generate a style macro for the window.

You can apply the style macro when you create a graph using the New Graph dialog. You can also apply it to an existing graph by choosing the macro from the Graph Macros submenu of the Windows menu.

Example of Creating a Style Macro

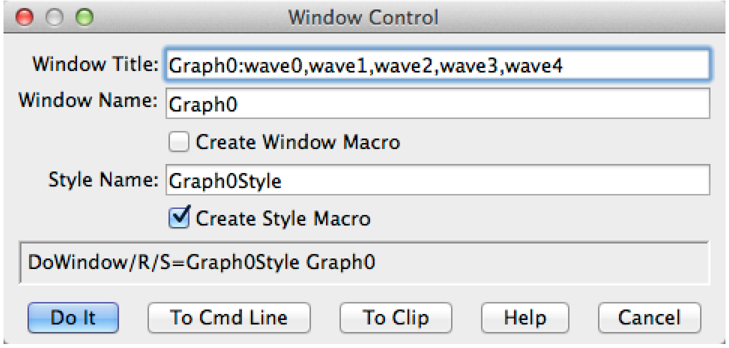
As an example, we will create a style macro that defines the color and line type of five traces.

Since we want our style macro to define a style for five traces, we start by making a graph with five waves:

```
Make wave0=p, wave1=10+p, wave2=20+p, wave3=30+p, wave4=40+p
Display wave0, wave1, wave2, wave3, wave4
```

Now, using the Modify Trace Appearance dialog, we set the color and line style for each of the waves to our liking.

Now we're ready to generate the style macro. With the graph the active window, we choose Windows→Control→Window Control to display the Window Control dialog in which we check the Create Style Macro checkbox.



Window Title: Graph0:wave0,wave1,wave2,wave3,wave4
Window Name: Graph0
□ Create Window Macro
Style Name: Graph0Style
☑ Create Style Macro

```
DoWindow/R/S=Graph0Style Graph0
```

When we click Do It, Igor generates a graph style macro and saves it in the procedure window.

The graph style macro for this example is:

```
Proc Graph0Style() : GraphStyle
   PauseUpdate; Silent 1      // modifying window...
   ModifyGraph/Z lStyle[1]=1,lStyle[2]=2,lStyle[3]=3,lStyle[4]=4
   ModifyGraph/Z rgb[0]=(0,0,0)
   ModifyGraph/Z rgb[1]=(3,52428,1)
   ModifyGraph/Z rgb[2]=(1,12815,52428)
   ModifyGraph/Z rgb[3]=(52428,1,41942)
   ModifyGraph/Z rgb[4]=(65535,21845,0)
EndMacro
```

Notice that the graph style macro does not refer to wave0, wave1, wave2, wave3 or wave4. Instead, it refers to traces by index. For example,

```
ModifyGraph rgb[0]=(0,0,0)
```

sets the color for the trace whose index is 0 to black. A trace's index is determined by the order in which the traces were displayed or appended to the graph. In the Modify Trace Appearance dialog, the trace whose index is zero appears at the top of the list.

The /Z flag used in the graph style macro tells Igor not to worry if the command tries to modify a trace that is not actually in the graph. For example, if you make a graph with three traces (indices from 0 to 2) and apply this style macro to it, there will be no trace whose index is 3 at the time you run the macro. The command:

```
ModifyGraph rgb[3]=(52428,1,41942)
```

would generate an error in this case. Adding the /Z flag continues macro execution and ignores the error.

Style Macros and Preferences

When Igor generates a graph style macro, it generates commands to modify the target graph according to the prototype graph. It assumes that the objects in the target will be in their factory default states at the time the style macro is applied to the target. Therefore, it generates commands only for the objects in the prototype which have been modified. If Igor did not make this assumption, it would have to generate commands for every possible setting for every object in the prototype and style macros would be very large.

Because of this, you should create the new graph with preferences off and then apply the style macro.

Applying the Style Macro

To use this macro, you would perform the following steps.

1. Turn preferences off by choosing Preferences Off from the Misc menu.
2. Create a new graph, using the New Graph dialog and optionally the Append Traces to Graph dialog.
3. Choose Graph0Style from the Graph Macros submenu in the Windows menu.
4. Turn preferences back on by choosing Preferences On from the Misc menu.

If you use only the New Graph dialog, you can use the shorter method:

1. Open the New Graph dialog, select the waves to be displayed in the graph, and choose Graph0Style from the Style pop-up menu in the dialog. Click Do It.

Igor automatically generates the Preferences Off and Preferences On commands to apply the style to the new graph without being affected by preferences.

Limitations of Style Macros

Igor automatically generates style macro commands to set all of the properties of a graph that you set via the ModifyGraph, Label and SetAxis operations. These are the properties that you set using the Modify Trace Appearance, Modify Graph, and Modify Axis dialogs.

It does not generate commands to recreate annotations or draw elements. Igor's assumption is that these things will be unique from one graph to the next. If you want to include commands to create annotations and draw elements in a graph, you must add the appropriate commands to the macro.

Where to Store Style Macros

If you want a style macro to be accessible from a single experiment only, you should leave them in the main procedure window of that experiment. If you want a style macro to be accessible from any experiment then you should store it in an auxiliary procedure file. See Chapter III-13, **Procedure Windows** for details.

Graph Pop-Up Menus

There are a number of contextual pop-up menus that you can use to quickly set colors and other graph properties. To display a contextual menu on Macintosh, press the Control key and click. On Windows, click using the right mouse button.

Different contextual menus are available for clicks on traces, the interior of a graph (but not on a trace) and axes. If you press the Shift key before a contextual click on a trace or axis, the menu will apply to all traces or axes in the graph.

Sometimes it is difficult to contextual click in the plot area of a graph and not hit a trace. In this case, try clicking outside the plot area, but not on an axis.

Graph Expansion

Normally, graphs are shown actual size but sometimes, when working with very small or very large graphs, it is easier to work with an expanded or contracted screen representation. You can set an expansion or contraction factor for a graph using the Expansion submenu in the Graph menu or using the contextual menu for the graph body, away from traces or axes.

The expansion setting affects only the screen representation. It does not affect printing or exporting.

Graph Shortcuts

Action	Shortcut (*Macintosh*)	Shortcut (*Windows*)
To autoscale a graph	Press Command-A.	Press Ctrl+A.
To modify the appearance or front-to-back drawing order of a trace	Press Control and click the trace to get a contextual menu. Press Shift-Control to modify all traces. Double-click the trace to summon a dialog.	Right-click the trace to get a contextual menu. Press Shift while right-clicking to modify all traces. Double-click the trace to summon a dialog.
To modify the appearance of an axis, axis labels, grid lines, tick marks	Press Control and click the axis. Press Shift-Control to modify all axes. Double-click an axis to summon a dialog.	Right-click the axis. Press Shift and right-click to modify all axes. Double-click an axis to summon a dialog.
To modify the appearance of a contour plot	Control-click and choose Modify Contour from the contextual menu or press Shift and double-click the contour plot. See also Chapter II-15, **Contour Plots**.	Right-click and choose Modify Contour from the contextual menu or press Shift and double-click the contour plot. See also Chapter II-15, **Contour Plots**.
To modify the appearance of an image plot	Control-click and choose Modify Image from the contextual menu. See also Chapter II-16, **Image Plots**.	Right-click and choose Modify Image from the contextual menu. See also Chapter II-16, **Image Plots**.
To set background colors	Press Control and click in the graph body, away from any traces.	Press Ctrl and click in the graph body, away from any traces.
To set the range of an axis	Double-click tick mark labels to summon a dialog.	Double-click tick mark labels to summon a dialog.
To pan the graph	Press Option and drag the body of the graph. Press Shift also to constrain the direction of panning.	Press Alt and drag the body of the graph. Press Shift also to constrain the direction of panning.
To offset a trace	Click and hold the trace for about a second, then drag. You can avoid inadvertently triggering this feature by pressing Caps Lock before clicking a trace.	Click and hold the trace for about a second, then drag. You can avoid inadvertently triggering this feature by pressing Caps Lock before clicking a trace.
To adjust the position of an axis or axis label	Drag the axis or label.	Drag the axis or label.
To change a graph margin	Press Option and click the axis and drag. Drag beyond edge of graph to return to default position. Press Option and double-click an axis or just double-click outside of the graph body and axes to summon a dialog.	Press Alt and click the axis and drag. Drag beyond edge of graph to return to default position. Press Alt and double-click an axis or just double-click outside of the graph body and axes to summon a dialog.
To change an axis label	Double-click the label to summon a dialog.	Double-click the label to summon a dialog.

Action	Shortcut (*Macintosh*)	Shortcut (*Windows*)
To change an annotation	Double-click the annotation to summon a dialog.	Double-click the annotation to summon a dialog.
To connect a tag to a different point	Press Option and drag the tag to the new point. Don't drag the arrow or line; drag the tag body. Drag it off the graph window to remove it.	Press Alt and drag the tag to the new point. Don't drag the arrow or line; drag the tag body. Drag it off the graph window to remove it.
To attach a cursor to a particular trace	Drag the cursor from the info panel to the trace or click the cursor name in the info panel and choose a trace name from the pop-up menu.	Drag the cursor from the info panel to the trace or click the cursor name in the info panel and choose a trace name from the pop-up menu.
To get information about a particular trace	Press Command-Option-I to turn on Trace Info tags.	Press Ctrl+Alt+I to turn on Trace Info tags.
To show or hide a graph's tool palette	Press Command-T.	Press Ctrl+T.
To move or resize a user-defined control without using the tool palette	Press Command-Option and click the control. With Command-Option still pressed, drag or resize it. See also Chapter III-14, **Controls and Control Panels**.	Press Ctrl+Alt and click the control. With Ctrl+Alt still pressed, drag or resize it. See also Chapter III-14, **Controls and Control Panels**.
To modify a user-defined control	Press Command-Option and double-click the control. This displays a dialog that you use to modify all aspects of the control. If the control is already selected, you don't need to press Command-Option.	Press Ctrl+Alt and double-click the control. This displays a dialog that you use to modify all aspects of the control. If the control is already selected, you don't need to press Ctrl+Alt.
To edit a user-defined control's action procedure	With the graph in modify mode (tools showing, second icon from the top selected) press Option and double-click the control. This displays the procedure window containing the action procedure or beeps if there is no action procedure.	With the graph in modify mode (tools showing, second icon from the top selected) press Alt and double-click the control. This displays the procedure window containing the action procedure or beeps if there is no action procedure.
To nudge a user-defined control's position	Select the control and press Arrow keys. Press Shift to nudge faster.	Select the control and press Arrow keys. Press Shift to nudge faster.

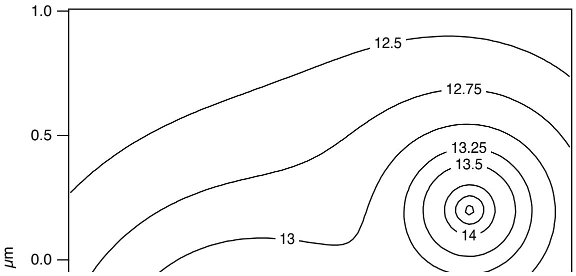
Chapter

II-14

Category Plots

Overview

Category plots are two-dimensional plots with a continuous numeric variable on one axis and a non-numeric (text) category on the other. Most often they are presented as bar charts with one or more bars occupying a category slot either side-by-side or stacked or some combination of the two. You can also combine them with error bars:



Category plots are created in ordinary graphs when you use a text wave or dimension labels as the X data. For more on graphs, see Chapter II-13, **Graphs**.

Creating a Category Plot

To create a category plot, first create your numeric wave(s) and your text category wave.

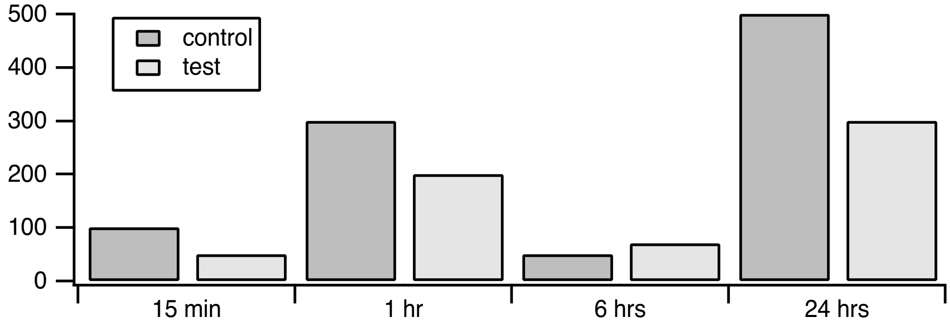
The numeric waves used to create a category plot should have “point scaling” (X scaling with Offset = 0 and Delta = 1). See **Category Plot Pitfalls** on page II-362 for an explanation.

Then invoke the Category Plot dialog by choosing Windows→New→Category Plot. You can append to an existing graph by choosing Graph→Append to Graph→Category Plot.

Select the numeric waves from the Y Waves list, and the category (text) wave from the X Wave list.

You can use also the Display command directly to create a category plot:

```
Make/O control={100,300,50,500},test={50,200,70,300}
Make/O/T sample={"15 min","1 hr","6 hrs","24 hrs"}
Display control,test vs sample   //vs text wave creates category plot
ModifyGraph hbFill(control)=5,hbFill(test )=7
SetAxis/A/E=1 left
Legend
```



Category Plot Commands

The **Display** operation that creates a category plot is the same Display operation that creates an XY plo t. When you use a text wave for the X wave, Igor creates a category plot. When you use a numeric wave for tthe X wave, Igor creates an XY plot. The same applies to the **AppendToGraph** operation.

You can control the gap between categories and the gap between bars within a single category using the ModifyGraph operation with the barGap and catGap keywords. You can create a stacked category plot using the ModifyGraph toMode keyword. See Bar and Category Gaps.

Combining Category Plots and XY Plots

You can have ordinary XY plots and category plots in the same graph window. However, once an axis has been used as either numeric or category, it is not usable as the other type.

For example, if you tried to append an ordinary XY plot to the graph shown above, you would find that the bottom (category) axis was not available in the Axis pop-up menu. If you try to append data to an existing category plot using a different text wave as the category wave, the new category wave is ignored.

The solution to these problems is to create a new axis using the Append Traces to Graph dialog or the Append Category Plot dialog.

Category Plot Using Dimension Labels

An alternative to using a text wave to create a category plot is to use the dimension labels from the Y wave. This feature was added in Igor Pro 8.00.

The easiest way to create the dimension labels is to edit the dimension labels in a table (see **Showing Dimension Labels** on page II-235). This example shows how to programmatically make a category plot using dimension labels:

```
Function DemoCategoryPlotUsingDimensionLabels()
   Make/O control={100,300,50,500}, test={50,200,70,300}
   SetDimLabel 0, 0, '15 min', control
   SetDimLabel 0, 1, '1 hour', control
   SetDimLabel 0, 2, '6 hrs', control
   SetDimLabel 0, 3, '24 hrs', control
   Display /W=(35,45,430,253) control, test vs '_labels_'
   ModifyGraph hbFill(control)=5,hbFill(test)=7
   SetAxis/A/E=1 left
   Legend
End
```

The _labels_ keyword must be enclosed in single quotes because it has the form of a liberal name and it is used in a place where a wave name is expected.

Using the Y wave's dimension labels is convenient for category plots having just one Y wave because it keeps the category labels and the numeric Y data in one place. If you are making the graph manually, you can enter the labels in a table, instead of executing a separate command for each label.

When you have more than one Y wave, the first trace added to a category axis controls the category labels. If you remove the first trace or change the order of traces, the labels may change or become blank. You can prevent this by setting the dimension labels for all the Y waves.

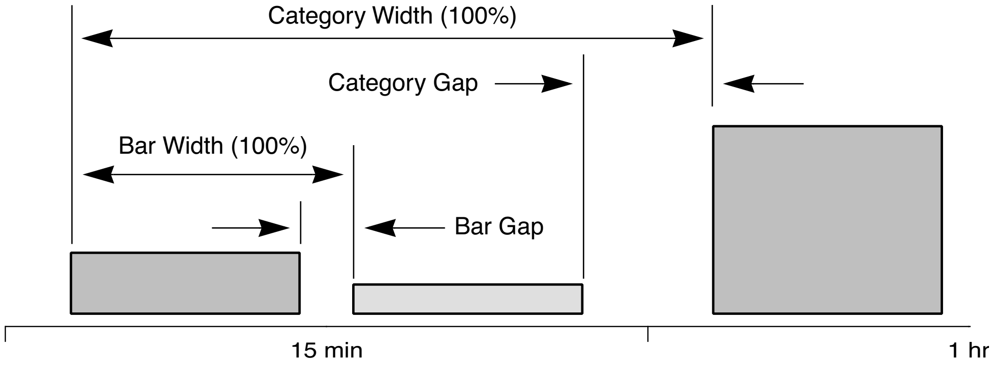
Modifying a Category Plot

Because category plots are created in ordinary graph windows, you can change the appearance of the category plot using the same methods you use for XY plots. For example, you can modify the bar colors and line widths using the Modify Trace Appearance dialog. For information on traces, XY plots and graphs, see **Modifying Traces** on page II-290.

The settings unique to category plots are described in the following sections.

Bar and Category Gaps

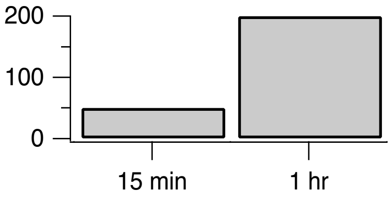
You can control the gap size between bars and between categories.



Generally, the category gap should be larger than the bar gap so that it is clear which bars are in the same category. However, a category gap of 100% leaves no space for bars.

The gap sizes are set in the Modify Axis dialog which you can display by choosing Graph→Modify Axis or by double-clicking the category axis.

Tick Mark Positioning



You can cause the tick marks to appear in the center of each category slot rather than at the edges. Double-click the category axis to display the Modify Axis dialog and check the “Tick in center” checkbox in the “Auto/Man Ticks” pane. This looks best when there is only one bar per category.

Fancy Tick Mark Labels

Tick mark labels on the category axis are drawn using the contents of your category text wave. In addition to simple text, you can insert special escape codes in your category text wave to create multiline labels and to include font changes and other special effects. The escape codes are exactly the same as those used for axis labels and for annotation text boxes — see **Annotation Text Content** on page III-35.

There is no point-and-click way to insert the codes in this version of Igor Pro. You will have to either remember the codes or use the Add Annotation dialog to create a string you can paste into a cell in a table.

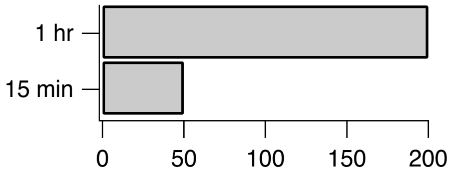
To enter multi-line text in a table cell, click the text editor widget at the right end of the table entry line.

You can also make a multi-line label from the command line, like this:

```
Make/T/N=5 CatWave         // Mostly you won't need this line
CatWave[0]="Line 1\rLine2" // "\r" Makes first label with two lines
```

Multiline labels are displayed center-aligned on a horizontal category axis and right-aligned on a left axis but left-aligned on a right axis. You can override the default alignment using the alignment escape codes as used in the Add Annotation dialog. See the **Annotation Text Escape Codes** operation on page III-35 for a description of the formatting codes.

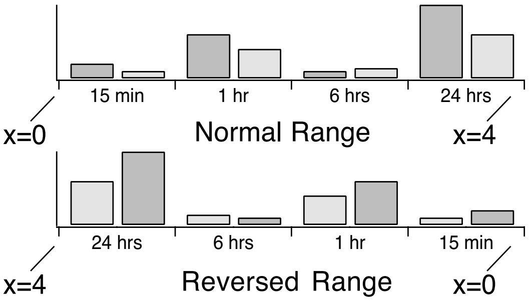
Horizontal Bars



To create a category plot in which the category axis runs vertically and the bars run horizontally, create a normal vertical bar plot and then select the Swap XY checkbox in the Modify Graph dialog.

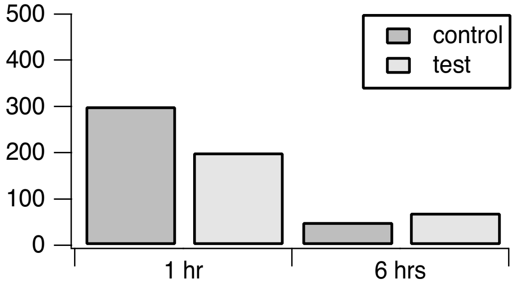
Reversed Category Axis

Although the ordering of the categories is determined by the ordering of the value (numeric) and category (text) waves, you can reverse a category axis just like you can reverse a numeric axis. Double-click one of the category axis tick labels or choose the Set Axis Range from the Graph menu to access the Axis Range pane in the Modify Axes dialog. When the axis is in autoscale mode, select the Reverse Axis checkbox to reverse the axis range.



Category Axis Range

You can also enter numeric values in the min and max value items of the Axis Range pane of the Modify Axes dialog. The X scaling of the numeric waves determine the range of the category axis. We used "point" X scaling for the numeric waves, so the numeric range of the category axis for the 15 min, 1 hr, 6 hrs, 24hrs example is 0 to 4. To display only the second and third categories, set the min to 1 and the max to 3.



Bar Drawing Order

When you plot multiple numeric waves against a single category axis, you have multiple bars within each category group. In the examples so far, there are two bars per category group.

The order in which the bars are initially drawn is the same as the order of the numeric waves in the Display or AppendToGraph command:

```
Display control,test vs elapsed     //control on left, test on right
```

You can change the drawing order in an existing graph using the **Reorder Traces dialog** and the Trace pop-up menu (see **Graph Pop-Up Menus** on page II-352).

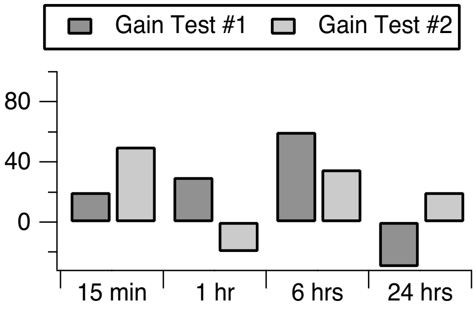
The ordering of the traces is particularly important for stacked bar charts.

Stacked Bar Charts

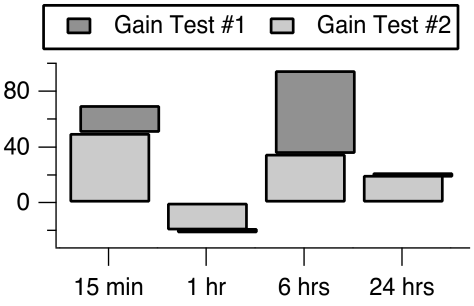
You can stack one bar on top of the next by choosing one of several grouping modes in the Modify Trace Appearance dialog which you can invoke by double-clicking a bar. The Grouping pop-up menu in the dialog shows the available modes. The choices are:

Mode	Mode Name	Purpose
-1	Keep with next	For special effects
0	None	Side-by-side bars (default)
1	Draw to next	Overlapping bars
2	Add to next	Arithmetically combined bars
3	Stack on next	Stacked bars

For most uses, you will use the **None** and “Stack on next” modes which produce the familiar bar and stacked bar chart:



None Mode

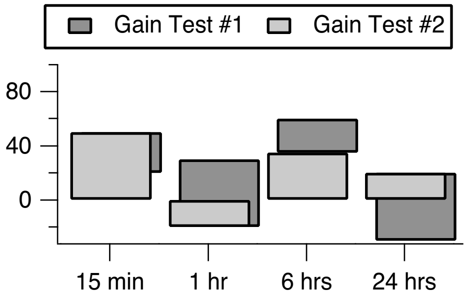


Stack on Next Mode

In all of the Stacked Bar Chart examples that follow, the stacking mode is applied to the Gain Test #1 bar and Gain Test #2 is the “next” bar.

We have offset Gain Test #1 horizontally by 0.1 so that you can see what is being drawn behind Gain Test #2.

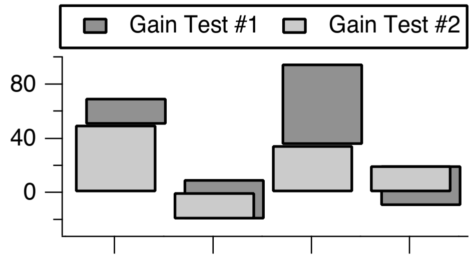
Choosing “**Draw to next**” causes the current bar to be in the same horizontal position as the next bar and to be drawn from the y value of this trace to the Y value of the next trace.



Draw to Next Mode

If the next bar is taller than the current bar then the current bar will not be visible because it will be hidden by the next bar. The result is as if the current bar is drawn behind the next bar, as is done when bars are displayed using a common numeric X axis.

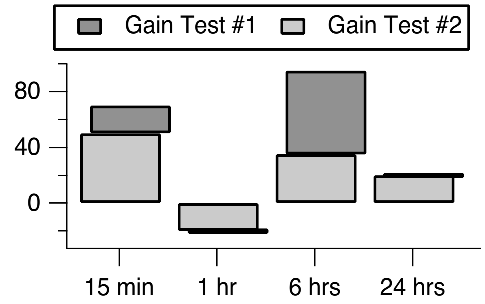
“**Add to next**” is similar to “Draw to next” except the Y values of the current bar are added to the Y values of the next bar(s) before plotting.



Add to Next Mode

If the current Y value is negative and the next is positive then the final position will be shorter than the next bar, as it is here for the 24 hrs bar.

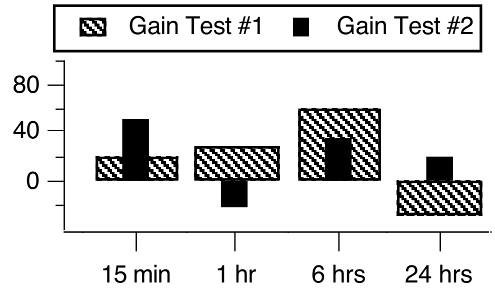
"**Stack on next**" is similar to "Add to next" except bars are allowed only to grow, not shrink.



Stack on Next Mode

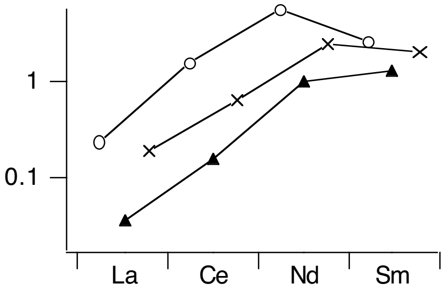
Negative values act like zero when added to a positive next trace (see the 24 hrs bar) and positive values act like zero when added to a negative next trace (see the 1 hr bar). Zero height bars are drawn as a horizontal line. Normally the values are all positive, and the bars stack additively, like the 15 min and 6 hrs bars.

"**Keep with next**" creates special effects in category plots. Use it when you want the current trace to be plotted in the same horizontal slot as the next but you don't want to affect the length of the current bar. For example, if the current trace is a bar and the next is a marker then the marker will be plotted on top of the bar. Here we set the Gain Test #2 wave to Lines from Zero mode, using a line width of 10 points.

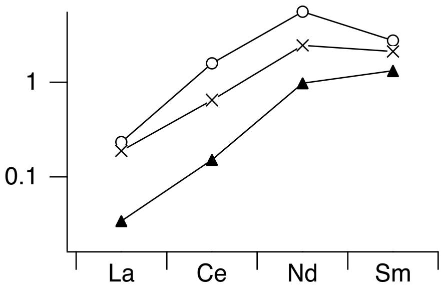


Keep with Next Mode

"Keep with next" mode is also useful for category plots that don't use bars; you can keep markers from different traces vertically aligned within the same category:



None mode



Keep with Next Mode

More details about these modes can be found in **Grouping, Stacking and Adding Modes** on page II-296.

Numeric Categories

You can create category plots with numeric categories by creating a text wave from your numeric category data. Create a text wave containing the numeric values by using the num2str function. For example, if we have years in a numeric wave:

```
Make years={1993,1995,1996,1997}
```

we can create an equivalent text wave:

```
Make/T/N=4 textYears= num2str(years)
```

Then create your category plot using textYears:

```
Display ydata vs textYears       // vs 1993, 1995, 1996, 1997 (as text)
```

Combining Numeric and Category Traces

Normally when you create a category plot, you can append only another category trace (a numeric wave plotted versus a text wave) to that plot. In rare cases, you may want to add a numeric trace to a category plot. You can do this using the /NCAT flag. Here is an example:

```
Make/O/T catx = {"cat0", "cat1", "cat2"}
Make/O caty = {1, 3, 2}
Display caty vs catx
SetAxis/A/E=1 left

// Plot simulated original data for a category
Make/N=10/O cat1over = gnoise(1) + 1.5
SetScale/P x, 1.5, 1e-5, cat1over      // Delta x can not be zero
AppendToGraph/NCAT cat1over
ModifyGraph mode(cat1over)=3, marker(cat1over)=19, rgb(cat1over)=(0,0,65535)
```

The /NCAT flag, used with AppendToGraph, tells Igor to allow adding a numeric trace to a category plot. This flag was added in Igor Pro 6.20.

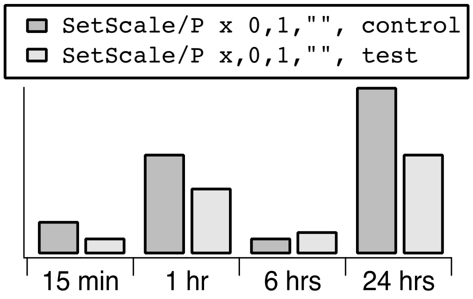
In Igor Pro 6.37 or later, the Display operation also supports the /NCAT flag. This allows you to create a numeric plot and then append a category trace.

Category Plot Pitfalls

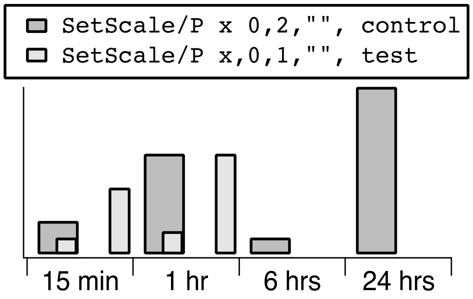
You may encounter situations in which the category plot doesn't look like you expect it to.

X Scaling Moves Bars

Category plots position the bars using the X scaling of the value (numeric) waves. The X scaling of the category (text) wave is completely ignored. It is usually best if you leave the X scaling of the category plot waves at the default “point scaling.” In any event, the X scaling of the value (numeric) waves should be identical. Differing X scaling causes the bars to become separated in category plots containing multiple bars per category. In the graph on the right the numeric waves have different X scaling



Same X scaling



Different X scaling

Changing the Drawing Order Breaks Stacked Bars

Stacked bar charts are heavily dependent on the concept of the “current bar” and the “next bar”. The modes describe how the current bar is connected to the next bar, such as “Stack on next”.

If you change the drawing order of the traces, using the Reorder Traces dialog or the Trace pop-up menu, one or more bars will have a new “next bar” (a different trace than before). Usually this means that a bar will be stacking on a different bar. This is usually a problem only when the stacking modes of the traces differ, or when smaller bars become hidden by larger bars.

After you change the drawing order, you may have to change the stacking modes. Bars hidden by larger bars may have to be moved forward in the drawing order with the Reorder Traces dialog or the Trace pop-up menu.

Bars Disappear with “Draw to next” Mode

In “Draw to next” mode, if the next bar is taller than the current bar then the current bar will not be visible because it will be hidden by the next bar.

You can change the drawing order with the Reorder Traces dialog or the Trace pop-up menu to move the shorter bars forward in the drawing order, so they will be drawn in front of the larger bars.

Category Plot Preferences

You can change the default appearance of category plots by capturing preferences from a prototype graph containing category plots. Create a graph containing a category plot (or plots) having the settings you use most often. Then choose Graph→Capture Graph Prefs. Select the Category Plots categories, and click Capture Prefs.

Preferences are normally in effect only for *manual* operations, not for automatic operations from Igor procedures. This is discussed in more detail in Chapter III-18, **Preferences**.

Category Plot Axes and Axis Labels

When creating category plots with preferences turned on, Igor uses the Category Plot axis settings for the text wave axis and XY plot axis settings for the numeric wave axis.

Only axes used by category plot *text waves* have their settings captured. Axes used solely for an XY plot, image plot, or contour plot are ignored. Usually this means that only the bottom axis settings are captured.

The category plot axis preferences are applied only when axes having the same name as the captured axis are created by a Display or AppendToGraph operation when creating a category plot. If the axes existed before the operation is executed, they are not affected by the category plot axis preferences.

The names of captured category plot axes are listed in the X Axis pop-up menu of the New Category Plot and Append Category Plot dialogs.

For example, suppose you capture preferences for a category plot that was created with the command:

```
AppendToGraph/R=myRightAxis/T=myTopAxis ywave vs textwave
```

Since only the X axis is a category axis, “myTopAxis” appears in the X Axis pop-up menu in the category plot dialogs. The Y Axis pop-up menu is unaffected.

- If you choose “myTopAxis” in the X Axis pop-up menu of the New Category Plot dialog and click Do It, a graph is created containing a *newly-created* X axis named “myTopAxis” and having the axis settings you captured.
- If you have a graph which already uses an axis named “myTopAxis” *as a category axis* and you choose it from the X Axis pop-up menu in the Append Category Plot dialog, the category plot uses the axis, but no captured axis settings are applied to it.

You can capture category plot axis settings for the standard left or bottom axis, and Igor will save the settings separately from left and bottom axis preferences captured for XY, image, and contour plots.

Category Plot Wave Styles

The captured category plot wave styles are automatically applied to a category plot when it is first created provided preferences are turned on — see **How to Use Preferences** on page III-516. “Wave styles” refers to the various trace-specific settings for category plot numeric waves in the graph. The settings include trace mode, line style, stacking mode, fill pattern, colors, etc., as set by the Modify Trace Appearance dialog.

If you capture the category plot preferences from a graph with more than one category plot, the first category plot appended to a graph gets the wave style settings from the category first appended to the prototype graph. The second category plot appended to a graph gets the settings from the second category plot appended to the prototype graph, etc. This is similar to the way XY plot wave styles work.

How to Use Category Plot Preferences

Here is our recommended strategy for using category preferences:

1. Create a new graph containing a single category plot.
2. Use the Modify Trace Appearance dialog and the Modify Axes dialogs to make the category plot appear as you prefer.
3. Choose Capture Graph Prefs from the Graph menu. Select the Category Plot checkboxes, and click Capture Prefs.

Chapter

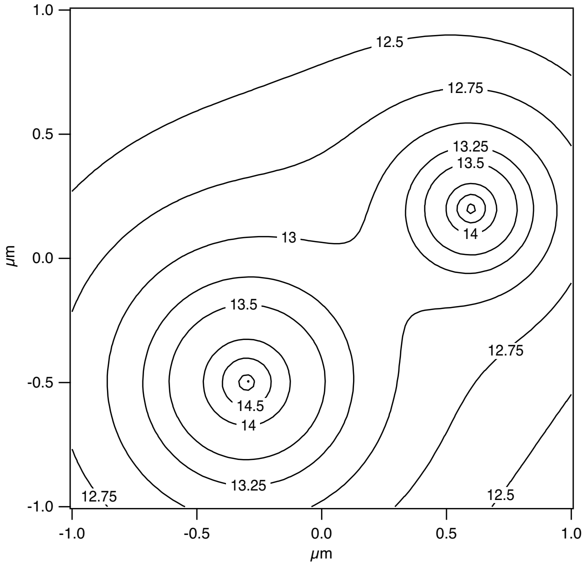
II-15

Contour Plots

Overview

A contour plot is a two-dimensional XY plot of a three-dimensional XYZ surface showing lines where the surface intersects planes of constant elevation (Z).

One common example is a contour map of geographical terrain showing lines of constant altitude, but contour plots are also used to show lines of constant density or brightness, such as in X-ray or CT images, or to show lines of constant gravity or electric potential.



Contour Data

The contour plot is appropriate for data sets of the form:

$$z = f(x,y)$$

meaning there is only one Z value for each XY pair. This rules out 3D shapes such as spheres, for example.

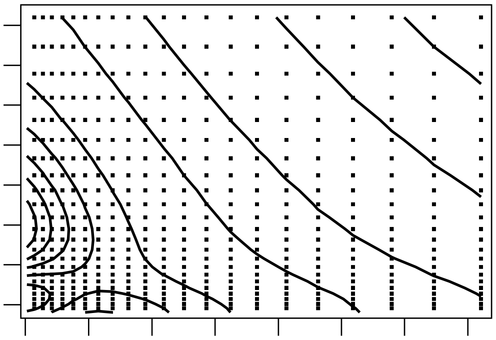
You can create contour plots from two kinds of data:

- Gridded data stored in a matrix
- XYZ triplets

Gridded Data

Gridded data is stored in a 2D wave, or “matrix wave”. By itself, the matrix wave defines a regular XY grid. The X and Y coordinates for the grid lines are set by the matrix wave’s row X scaling and column Y scaling.

You can also provide optional 1D waves that specify coordinates for the X or Y grid lines, producing a non-linear rectangular grid like the one shown here. The dots mark XY coordinates specified by the 1D waves:



Contouring gridded data is computationally much easier than XYZ triplets and consequently much faster.

XYZ Data

XYZ triplets can be stored in a matrix wave of three columns, or in three separate 1D waves each supplying X, Y, or Z values. You must use this format if your Z data does not fall on a rectangular grid. For example, you can use the XYZ format for data on a circular grid or for Z values at random X and Y locations.

XYZ contouring involves the generation of a Delaunay triangulation of your data, which takes more time than is needed for gridded contouring. You can view the triangulation by selecting the Show Triangulation checkbox in the Modify Contour Appearance dialog.

For best results, you should avoid having multiple XYZ triplets with the same X and Y values. If the contour data is stored in separate waves, the waves should be the same length.

If your data is in XYZ form and you want to convert it to gridded data, you can use the **ContourZ** function on an XYZ contour plot of your data to produce a matrix wave. The AppendImageToContour procedure in the WaveMetrics Procedures folder produces such a matrix wave, and appends it to the top graph as an image. Also see the Voronoi parameter of the **ImageInterpolate** operation on page V-382 for generating an interpolated matrix.

Creating a Contour Plot

Contour plots are appended to ordinary graph windows. All the features of graphs apply to contour plots: axes, line styles, drawing tools, controls, etc. See Chapter II-13, **Graphs**.

You can create a contour plot in a new graph window by choosing Windows→New→Contour Plot. This displays the New Contour Plot dialog. This dialog creates a blank graph to which the plot is appended.

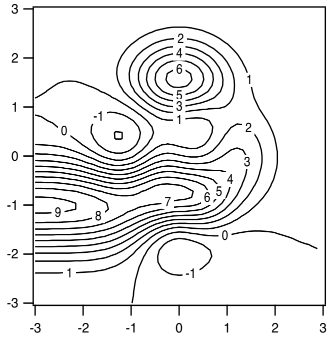
To add a contour plot to an existing graph, choose Graph→Append To Graph→Contour plot. This displays the Append Contour Plot dialog.

You can also use the **AppendMatrixContour** or **AppendXYZContour** operations.

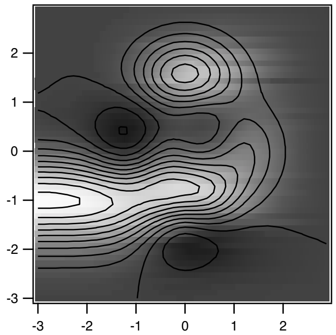
You can add a sense of depth to a gridded contour plot by adding an image plot to the same graph. To do this, choose Graph-Append To Graph-Image Plot. This displays the Append Image Plot dialog. If your data is in XYZ form, use the AppendImageToContour WaveMetrics procedure to create and append an image.

These commands generate a gridded contour plot with an image plot:

```
Make/O/D/N=(50,50) mat2d            // Make some data to plot
SetScale x,-3,3,mat2d
SetScale y,-3,3,mat2d
mat2d =  3*(1-y)^2 * exp(-((x*(x>0))^2.5) - (y+0.5)^2)
mat2d -= 8*(x/5 - x^3 - y^5) * exp(-x^2-y^2)
mat2d -= 1/4 * exp(-(x+.5)^2 - y^2)
Display;AppendMatrixContour mat2d   //This creates the contour plot
AppendImage mat2d
```



AppendMatrixContour mat2d



AppendMatrixContour mat2d
AppendImage mat2d

Instead of displaying an image plot with the contour plot, you can instruct Igor to add a color fill between contour levels. You can see this using these commands:

```
RemoveImage mat2d
ModifyContour mat2d ctabFill={*,*,Grays256,0}
```

Modifying a Contour Plot

You can change the appearance of the contour plot choosing Graph→Modify Contour Appearance. This displays the Modify Contour Appearance dialog. This dialog is also available as a subdialog of the New Contour Plot and Append Contour Plot dialogs.

You can open the Modify Contour Appearance by Shift-double-clicking the contour plot or by right-clicking it but not on a contour and choosing Modify Contour Appearance from the contextual menu.

Use preferences to change the default contour appearance, so you won’t be making the same changes over and over. See **Contour Preferences** on page II-380.

The Modify Contour Appearance Dialog

The following sections describe some of the contour plot parameters you can change using the Modify Contour Appearance dialog.

Contour Data Pop-Up Menu

The Contour Data pop-up menu shows the “contour instance name” of the contour plot being modified. The name of the contour plot is the same as the name of the Z wave containing the contour data.

If the graph contains more than one contour plot, you can use this pop-up menu to change all contour plots in the target graph.

If the graph contains two contour plots *using the same Z wave name*, an instance number is appended to those Z wave names in this pop-up menu. See **Instance Notation** on page IV-20, and **Contour Instance Names** on page II-376.

Contour Levels

Each contour trace draws lines at one constant Z level. The Z levels are assigned automatically or manually as specified in this part of the dialog.

Igor computes automatic levels by subdividing the range of Z values into approximately the number of requested levels. You can instruct Igor to compute the Z range automatically from the minimum and maximum of the Z data, or to use a range that you specify in the dialog. Igor attempts to choose “nice” contour levels that minimize the number of significant digits in the contour labels. To achieve this, Igor may create more or fewer levels than you requested.

You can specify manual levels directly in the dialog in several ways:

- Linearly spaced levels (constant increment) starting with a first level and incrementing by a specified amount.
- A list of arbitrary levels stored in a wave you choose from a pop-up Wave Browser.
- A list of arbitrary levels you enter in the More Contour Levels dialog that appears when you click the More Contour Levels checkbox. These levels are *in addition to* automatic, manual, or from-wave levels.

The More Levels dialog can be used for different purposes:

- To add a contour level to those already defined by the automatic, manual, or from-wave levels. You might do this to indicate a special feature of the data.
- As the only source of arbitrary contour levels, for complete control of the levels. You might do this to slightly change a contour level to avoid problems (see **Contouring Pitfalls** on page II-379). Disable the auto or manual levels by entering 0 for the number of levels. The only contour levels in effect will be those entered in the More Levels dialog.

WaveMetrics provides some utility procedures for dealing with contour levels. See “WaveMetrics Contour Plot Procedures” in the “WM Procedures Index” help file for details.

Update Contours Pop-Up Menu

Igor normally recalculates and redraws the contour plot whenever any change occurs that might alter its appearance. This includes changes to any data waves and the wave supplying contour levels, if any. Since calculating the contour lines can take a long time, you may want to disable this automatic update with the Update Contours pop-up menu.

“Off” completely disables updating of the contours for any reason. Choose “once, now” to update the contour when you click the Do It button. “Always” selects the default behavior of updating whenever the contour levels change.

Contour Labels Pop-Up Menu

Igor normally adds labels to the contour lines, and updates them whenever the contour lines change (see **Update Contours Pop-Up Menu** on page II-369). Since updating plots with many labels can take a long time, you may want to disable or modify this automatic update with the Labels pop-up menu.

“None” removes any existing contour labels, and prevents any more from being generated.

“Don’t update any more” keeps any existing labels, and prevents any more updates. This is useful if you have moved, removed, or modified some labels and you want to keep them that way.

“Update now, once” will update the labels when you click the Do It button, then prevents any more updates. Use this if updating the labels takes too long for you to put up with automatic updates.

“If contours change”, the default, updates the labels whenever Igor recalculates the contour lines.

“Always update” is the most aggressive setting. It updates the labels if the graph is modified in almost any way, such as changing the size of the graph or adjusting an axis. You might use this setting temporarily while making adjustments that might otherwise cause the labels to overlap or be too sparse.

Click Label Tweaks to change the number format and appearance of the contour labels with the Contour Labels dialog. See **Modifying Contour Labels** on page II-378.

For more than you ever wanted to know about contour labels, see **Contour Labels** on page II-377.

Line Colors Button

Click the Line Colors button to assign colors to the contour lines according to their Z level, or to make them all the same color, using the Contour Line Colors dialog.

Autoscaled color mapping assigns the first color in a color table to the minimum Z value of the contour data (not to the minimum contour level), and the last color to the maximum Z value.

See **The Color of Contour Traces** on page II-371 for further discussion of contour colors.

Show Boundary Checkbox

Click this to generate a trace along the perimeter of the contour data in the XY plane. For a matrix contour plot, the perimeter is simply a rectangle enclosing the minimum and maximum X and Y. The perimeter of XYZ triplet contours connects the outermost XY points. This trace is updated at the same time as the contour level traces.

Show XY Markers Checkbox

Click this to generate a trace that shows the XY locations of the contour data. For a matrix contour plot, the locations are by default marked with dots. For XYZ triplet contours, they are shown using markers. As with any other contour trace, you can change the mode and marker of this trace with the Modify Trace Appearance dialog. This trace is updated at the same time as the contour level traces.

Fill Contours Checkbox

Click this to fill between contour levels with solid colors. Click the Fill Colors button to adjust the colors in the same manner as described under **Line Colors Button** on page II-369.

Warning: Solid fills can sometimes fail.

You can set the fill and color for individual levels using the Modify Trace Appearance dialog even if the Fill Contours checkbox is off.

See **Contour Fills** on page II-373 for more information.

Show Triangulation Checkbox

Click this to generate a trace that shows the Delaunay triangulation of the contour data. This is available only for XYZ triplet contours. This trace is updated at the same time as the contour level traces.

Interpolation Pop-Up Menu

XYZ triplet contours can be interpolated to increase the apparent resolution, resulting in smoother contour lines. The interpolation uses the original Delaunay triangulation. Increasing the resolution requires more time and memory; settings higher than x16 are recommended only to the very patient.

Contour Traces

Igor creates XY pairs of double-precision waves to contain the contour trace data, and displays them as ordinary graph traces. Each trace draws all the curves for one Z level. If a single Z level generates more than one contour line, Igor uses a blank (NaN) at the end of each contour line to create a gap between it and the following line.

The same method is used to display markers at the data’s XY coordinates, the XY domain’s boundary, and, for XYZ triplet contours only, the Delaunay triangulation.

The names of these traces are fabricated from the name of the Z data wave or matrix. See **Contour Trace Names** on page II-371.

One important special property of these waves is that they are private to the graph. These waves do not appear in the Data Browser or in any other dialog, and are not accessible from commands. There is a trick you can use to copy these waves, however. See **Extracting Contour Trace Data** on page II-376.

The contour traces, which are the visible manifestation of these private waves, *do* show up in the Modify Trace Appearance dialog, and *can* be named in commands just like other traces.

There is often no need to bother with the individual traces of a contour plot because the Modify Contour Appearance dialog provides adequate control over the traces for most purposes. However, if you want to distinguish one or more contour levels, to make them dashed lines, for example, you can do this by modifying the traces using the Modify Trace Appearance dialog. For further discussion, see **Overriding the Color of Contour Traces** on page II-373.

Contour Trace Names

The name of a contour trace is usually something like “zwave=2.5”, indicating that the trace is the contour of the z data set “zwave” at the z=2.5 level. A name like this must be enclosed in single quotes when used in a command:

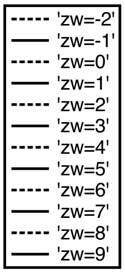
```
ModifyGraph mode('zwave=2.5')=2
```

This trace naming convention is the default, but you can create a different naming convention when you first append a contour to a graph using the /F flag with AppendMatrixContour or AppendXYZContour. The contour dialogs do not generate /F flags and therefore create contours with default names. See the **AppendMatrixContour** operation on page V-33 and the **AppendXYZContour** operation on page V-39 for a more thorough discussion of /F.

Example: Contour Legend with Numeric Trace Names

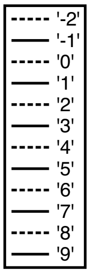
To make a legend contain slightly nicer wording you can omit the “zwave=” portion from trace names with `/F="%g"`:

```
AppendMatrixContour/F="%g" zw    // trace names become just numbers
```



```
----- 'zw=-2'
————— 'zw=-1'
----- 'zw=0'
————— 'zw=1'
----- 'zw=2'
————— 'zw=3'
----- 'zw=4'
————— 'zw=5'
----- 'zw=6'
————— 'zw=7'
----- 'zw=8'
————— 'zw=9'
```

`/F="%s=%g"` (default)



```
----- '-2'
————— '-1'
----- '0'
————— '1'
----- '2'
————— '3'
----- '4'
————— '5'
----- '6'
————— '7'
----- '8'
————— '9'
```

`/F="%g"`

You can manually edit the legend text to remove the single quotes around the trace names. Double-click the legend to bring up the Modify Annotation dialog.

For details on creating contour plot legends, see **Contour Legends** on page II-377.

Contour Trace Programming Notes

The **TraceNameList** function returns a string which contains a list of the names of contour traces in a graph. You can use the name of the trace to retrieve a wave reference for the private contour wave using **TraceNameToWaveRef**. See also **Extracting Contour Trace Data** on page II-376.

If a graph happens to contain two traces with the same name, “instance notation” uniquely identifies them. For example, two traces named “2.5” would show up in the Modify Trace Appearance dialog as “2.5” and “2.5#1”. On the command line, you would use something like:

```
ModifyGraph mode('2.5'#1)=2
```

Notice how the instance notation (the “#1” part) is outside the single quotes. This instance notation is needed when the graph contains two contour plots that generate identically named traces, usually when they use the same /F parameters and draw a contour line at the same level (z=2.5).

See **Instance Notation** on page IV-20. Also see **Contour Instance Names** on page II-376.

The Color of Contour Traces

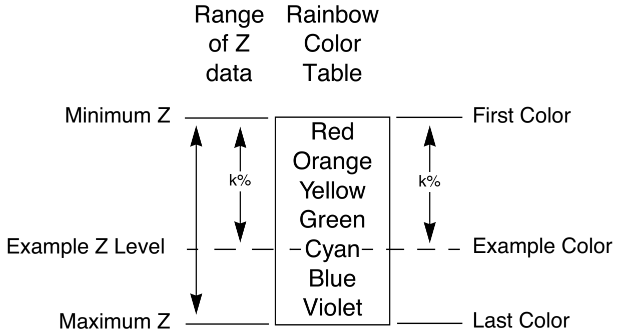
By default, contour traces are assigned a color from the Rainbow color table based on the contour trace’s Z level. You can choose different colors in the Contour Line Colors subdialog of the Modify Contour Appearance dialog.

The Contour Line Colors dialog provides four choices for setting the contour trace colors:

1. All contour traces can be set to the same color.
2. The color for a trace can be selected from a “color index wave” that you created, by matching the trace’s Z level with the color index wave X index.
3. The color for a trace can be computed from a chosen built-in color table or from a color table wave that you created, by matching the trace’s Z level with the range of available colors.

Color Tables

When you use a color table to supply colors, Igor maps the Z level to an entry in the color table. By default, Igor linearly maps the entire range of Z levels to the range of colors in the table by assigning the minimum Z value of the contour data to the first color in the table, and the maximum Z value to the last color:



Automatic Mode Color Table Mapping

With the Modify Contour Appearance dialog, you can assign a specific Z value to the color table’s first and last colors. For example, you can use the first half of the color table by leaving First Color on Auto, and typing a larger number (2*(ZMax -ZMin), to be precise) for the Last Color.

To see what the built-in color tables look like, see **Color Table Details** on page II-395.

You can create your own color table waves that act like custom color tables. See **Color Table Waves** on page II-399 for details.

Color Index Wave

You can create your own range of colors by creating a color index wave. The wave must be a 2D wave with three columns containing red, green, and blue values that range from 0 (zero intensity) to 65535 (full intensity), and a row for each color. Igor finds the color for a particular Z level by choosing the row in the color index wave whose X index most closely matches the Z level.

To choose the row, Igor converts the Z level into a row number as if executing:

```
colorIndexWaveRow= x2pnt(colorIndexWave,Z)
```

which rounds to the nearest row and limits the result to the rows in the color index wave.

When the color index wave has default X scaling (the X index is equal to row number), then row 0 contains the color for z=0, row 1 contains the color for z=1, etc. By setting the X scaling of the wave (Change Wave Scaling dialog), you can control how Igor maps Z level to color. This is similar to setting the First Color and Last Color values for a color table.

Color Index Wave Programming Notes

Looking up a color in a color index wave can be expressed programmatically as:

```
red=   colorIndexWave (Z level)[0]
green= colorIndexWave (Z level)[1]
blue=  colorIndexWave (Z level)[2]
```

where ( ) indexes into rows using X scaling, and [ ] selects a column using Y point number (column number).

Here is a code fragment that creates a color index wave that varies from blue to red:

```
Function CreateBlueRedColorIndexWave(numberOfColors,zMin,zMax)
   Variable numberOfColors
   Variable zMin,zMax              // From min, max of contour or image data

   Make/O/N=(numberOfColors,3) colorIndexWave
   Variable white = 65535          // black is zero
   Variable colorStep = white / (numberOfColors-1)

   colorIndexWave[][0]= colorStep*p // red increases with row number,
   colorIndexWave[][1]= 0          // no green
   colorIndexWave[][2]= colorStep*(numberOfColors-1-p)    // blue decreases

   SetScale/I x,zMin,zMax,colorIndexWave// Match X scaling to Z range
End
```

Log Color for Contour Traces

You can obtain a logarithmic mapping of z level values to colors using the Log Color checkbox in the Contour Line Colors dialog. This generates a `ModifyContour logLines=1` command. In this mode, the colors change more rapidly at smaller contour z level values than at larger values.

For a color index wave, the colors are mapped using the log(color index wave's x scaling) and log(contour z level) values this way:

```
colorIndexWaveRow = (nRows-1)*(log(Z)-log(xMin))/(log(xmax)-log(xMin))
```

where,

```
nRows = DimSize(colorIndexWave,0)
xMin = DimOffset(colorIndexWave,0)
xMax = xMin + (nRows-1) * DimDelta(colorIndexWave,0)
```

The colorIndexWaveRow value is rounded before it is used to select a color from the color index wave.

A similar mapping is performed with color tables, where the xMin and xMax are replaced with the automatically determined or manually provided zMin and zMax values.

Overriding the Color of Contour Traces

You can override the color set by the Line Color subdialog by using the Modify Trace Appearance dialog, the **ModifyGraph** command, or by Control-clicking (*Macintosh*) or right-clicking (*Windows*) the graph's plot area to pop up the **Trace Pop-Up Menu**. The color you choose will continue to be used until either:

1. The trace is removed when the contours are updated, because the levels changed, for instance.
2. You choose a new setting in the Line Color subdialog.

Contour Fills

You can specify colors or patterns to fill contour levels. To fill all contour levels with colors, check the Fill Contours checkbox in the Modify Contour dialog. To fill individual contour levels with colors or patterns, use the Contour Fill controls in the Modify Trace Appearance dialog. You can use the Add Annotation dialog to create a legend for contour fills.

Programatically, to turn contour fills on for all contour levels, execute:

```
ModifyContour <contour instance name>, fill=1
```

To control the color use one of these ModifyContour keywords:

ctabFill	Fills using a color table
cindexFill	Fills using a color index wave
rgbFill	Fills with a specific color

These keywords have the same syntax as `ctabLines`, **cindexLines** and `rgbLines` which control the colors of the contour lines themselves.

To turn on an individual contour level fill, execute:

```
ModifyContour <contour instance name>, fill=0         // Global fill mode off
ModifyGraph usePlusRGB(<contour level trace name>)=1  // Trace fill mode on
ModifyGraph hbFill(<contour level trace name>)=2      // Solid fill for trace
```

For example, in the Contour Demo example experiment, select Macros→Matrix Contour plot to display the Demo Matrix Contour graph. Double-click one of the traces to display the Modify Trace Appearance dialog. Choose Solid for +Fill Type; this automatically checks the Custom Fill checkbox. Select a yellow color from the associated popup menu. This gives the following commands:

```
ModifyGraph usePlusRGB('RealisticData=6')=1
ModifyGraph hbFill('RealisticData=6')=2
ModifyGraph plusRGB('RealisticData=6')=(65535,65532,16385)
```

You can also fill all contour levels, using `ModifyContour fill=1`, and then customize one or more levels using this technique.

You can create a color bar for contour fills using the **ColorScale** operation with the `contourFill` keyword. The syntax is the same as for the ColorScale `contour` keyword.

Solid fills can sometimes fail because Igor can not determine a closed path for a contour line. Be sure to visually inspect the results and turn off fills if they are not correct. The success or failure of a contour fill is highly dependent on the data and is more likely with XYZ data. To see this, choose File→Example Experiments→Sample Graphs→Contour Demo and choose the XYZ Contour Plot from the Macros menu. Turn on Fill Levels and experiment with the number of points and the z-function. Occasionally you may see a warning in the history area saying that a contour level is not closeable. There is not much you can do about this other than trying a different data set or converting your XYZ data to a matrix. Although rare, even matrix data can be sufficiently pathological as to cause the contour fill to fail.

If automatic fills do not work with your data, you can use a background image to provide the fill effect using the WaveMetrics procedure FillBetweenContours. See Image and Contour Plots in the WM Procedures Index for information.

To support fills, Igor needs the boundary trace which it creates and then sets as hidden. When loading an experiment into Igor6, you will encounter an error on the command to hide this trace. You can continue the load by simply commenting out this command in the error dialog.

Removing Contour Traces from a Graph

Removing traces from a contour plot with the RemoveFromGraph operation or the Remove from Graph dialog will work only temporarily. As soon as Igor updates the contour traces, any removed traces may be replaced.

You can prevent this replacement by disabling contour updates with the Modify Contour Appearance dialog. It is better, however, to use the Modify Contour Appearance dialog to control which traces are drawn in the first place.

To permanently remove a particular automatic or manual contour level, you are better off not using manual levels or automatic levels at all. Use the More Contour Levels dialog to explicitly enter all the levels, and enter zero for the number of manual or automatic levels.

Tip: Make a legend in the graph to list the contour traces. The trace names normally contain the contour levels. To do this, select the command window, type `Legend`, and press Return or Enter.

Similarly, if you don't want the triangulation or XY marker traces to be drawn, use the Modify Contour Appearance dialog to turn them off, rather than removing them with the Remove from Graph dialog.

Cursors on Contour Traces

You can attach cursors to a contour trace. Just like any other trace, the X and Y values are shown in the graph info panel (choose Show Info from the Graph menu). When the cursor is attached to a contour line the Z value (contour level) of the trace is also shown in the info panel.

There are several additional methods for displaying the Z value of a contour trace:

- The zcsr function returns the Z value of the trace the cursor is attached to. zcsr returns a NaN if the cursor is attached to a noncontour trace. You can use this in a procedure, or print the result on the command line using: `Print zcsr(A)`.
- If you add an image behind the contour, you can use cursors to display the X, Y, and Z values at any point.
- The name of the trace the cursor is attached to shows up in the info panel, and the name usually contains the Z value.
- Contour labels show the Z value. Contour labels are tags that contain the \OZ escape code or TagVal(3). See **Contour Labels** on page II-377. You can drag these labels around by pressing Option (*Macintosh*) or Alt (*Windows*) while dragging a tag. See **Changing a Tag's Attachment Point** on page III-45.

Contour Trace Updates

Igor normally updates the contour traces whenever the contour data (matrix or XYZ triplets) changes or whenever the contour levels change. Because creating the contour traces can be a lengthy process, you can prevent these automatic updates through a pop-up menu item in the Modify Contour Appearance dialog. See **Update Contours Pop-Up Menu** on page II-369.

Preventing automatic updates can be useful when you are repeatedly editing the contour data in a table or from a procedure. Use the "once, now" pop-up item to manually update the traces.

Contour Trace Update Programming Note

Programmers should be aware of another update issue: contour traces are created in two steps. To understand this, look at this graph recreation macro that appends a contour to a graph and then defines the contour levels, styles and labels:

```
Window Graph1() : Graph
   PauseUpdate; Silent 1      // building window...
   Display /W=(11,42,484,303)
   AppendMatrixContour zw
   ModifyContour zw autoLevels={*,*,5}, moreLevels={0.5}
   ModifyContour zw rgbLines=(65535,0,26214)
   ModifyContour zw labels=0
   ModifyGraph lSize('zw=0')=3
   ModifyGraph lStyle('zw=0')=3
   ModifyGraph rgb('zw=0')=(0,0,65535)
   ModifyGraph mirror=2
EndMacro
```

First, the AppendMatrixContour operation runs and creates stub traces consisting of zero points. The ModifyContour and ModifyGraph operations that follow act on the stub traces. Finally, after all of the commands that define the graph have executed, Igor does an update of the entire graph, when the effect of the PauseUpdate operation expires when the graph recreation macro returns. This is the time when Igor does the actual contour computations which convert the stub traces into fully-formed contour traces.

This delayed computation prevents unnecessary computations from occurring when ModifyContour commands execute in a macro or function. The ModifyContour command often changes default contour level settings, rendering any preceding computations obsolete. For the same reason, the New Contour Plot dialog appends ";DelayUpdate" to the Append Contour commands when a ModifyContour command is also generated.

The DoUpdate operation updates graphs and objects. You can call DoUpdate from a macro or function to force the contouring computations to be done at the desired time.

Drawing Order of Contour Traces

The contour traces are drawn in a fixed order. From back-to-front, that order is:

1. Triangulation (Delaunay Triangulation trace, only for XYZ contours),
2. Boundary
3. XY markers
4. Contour trace of lowest Z level

... intervening contour traces are in order from low-to-high Z level...

N. Contour of highest Z level

You can temporarily override the drawing order with the **Reorder Traces Dialog**, the **Trace Pop-Up Menu**, or the **ReorderTraces** operation. The order you choose will be used until the contour traces are updated. See **Contour Trace Updates** on page II-375.

The order of a contour plot's traces relative to any other traces (the traces belonging to another contour plot for instance) is *not* preserved by the graph's window recreation macro. Any contour trace reordering is lost when the experiment is closed.

Extracting Contour Trace Data

Advanced users may want to create a copy of a private XY wave pair that describes a contour trace. You might do this to extract the Delaunay triangulation, or simply to inspect the X and Y values in a table, for example. To extract contour wave pair(s), include the Extract Contours As Waves procedure file:

```
#include <Extract Contours As Waves>
```

which adds "Extract One Contour Trace" and "Extract All Contour Traces" menu items to the Graph menu.

Another way to copy the traces into a normal wave is to use the Data Browser to browse the saved experiment. The contour traces are saved as waves in a temporary data folder whose name begins with "WM_CTraces_" and ends with the contour's "contour instance name". See **The Browse Expt Button** on page II-117 for details about browsing experiment files.

Contour Instance Names

Igor identifies a contour plot by the name of the wave providing Z values (the matrix wave or the Z wave). This "contour instance name" is used in commands that modify the contour plot.

Contour instance names are not the same as contour trace instance names. Contour instance names refer to an entire contour plot, not to an individual contour trace.

The Modify Contour Appearance dialog generates the correct contour instance name automatically.

Contour instance names work much the same way wave instance names for traces in a graph do. See **Instance Notation** on page IV-20.

Examples

In the first example the contour instance name is "zw":

```
Display; AppendMatrixContour zw                    // New contour plot
ModifyContour zw ctabLines={*,*,BlueHot}           // Change color table
```

In the unusual case that a graph contains two contour plots of the same data, an instance number must be appended to the name to modify the second plot: zw#1 is the contour instance name of the second contour plot:

```
Display
AppendMatrixContour zw; AppendMatrixContour zw     // Two contour plots
ModifyContour zw ctabLines={*,*,RedWhiteBlue}      // Change first plot
ModifyContour zw#1 ctabLines={*,*,BlueHot}         // Change second plot
```

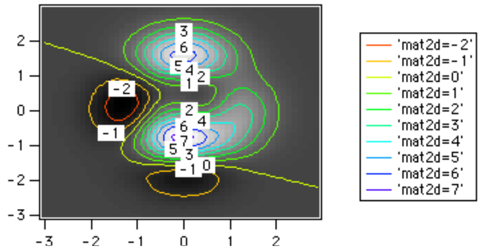
You might have two contour plots of the same data to show different subranges of the data side-by-side. This example uses separate axes for each plot.

The **ContourNameList** function returns a string containing a list of contour instance names. Each name corresponds to one contour plot in the graph. **ContourInfo** (see page V-85) returns information about a particular named contour plot.

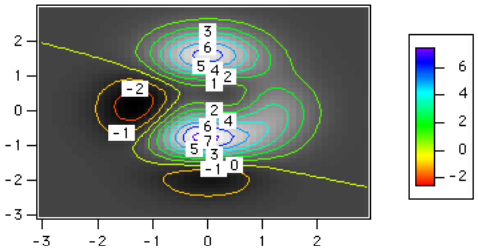
Contour Legends

You can create two kinds of legends appropriate for contour plots using the Add Annotation dialog: a Legend or a ColorScale. For more details about the Add Annotation dialog and creating legends, see Chapter III-2, **Annotations**, and the **Legends** (see page III-42) and **Color Scales** (see page III-47) sections.

A Legend annotation will display the contour traces with their associated color. A ColorScale will display the entire color range as a color bar with an axis that spans the range of colors associated with the contour data.



Legend



Color Scale

Contour Labels

Igor uses specialized tags to create the numerical labels for contour plots. Igor puts one label on every contour curve. Usually there are several contour curves drawn by one contour trace. The tag uses the \OZ escape code or the TagVal(3) function to display the contour level value in the tag instead of displaying the literal value. See **Annotation Text Content** on page III-35 for more about escape codes and tags.

You can select the rotation of contour labels using the Label Tweaks subdialog of the Modify Contour Appearance Dialog. You can request tangent, horizontal, vertical or both orientations. If permitted, Igor will prefer horizontal labels. The "Snap to" alternatives convert horizontal or vertical labels within 2 degrees of horizontal or vertical to exactly horizontal or vertical.

Igor positions the labels so that they don't overlap other annotations and aren't outside the graph's plot area. Contour labels are slightly special in that they are always drawn below all other annotations, so that they will never show up on top of a legend or axis label. Igor chooses label locations and tangent label orientations based on the slope of the contour trace on the screen.

Controlling Contour Label Updates

By default, Igor automatically relabels the graph only when the contour data or contour levels change, but you can control when labels update with the Labels pop-up menu in the Modify Contour Appearance dialog. See **Contour Labels Pop-Up Menu** on page II-369. Be aware that updating a graph containing many labels can be slow.

Repositioning and Removing Contour Labels

Contour labels are “frozen” so that they can’t be dragged, but since they are tags, you *can* Option-drag (*Macintosh*) or Alt-drag (*Windows*) them to a new attachment point. See **Changing a Tag’s Attachment Point** on page III-45. The labels are frozen to make them harder to accidentally move.

You can reposition contour labels, but they will be moved back, moved to a completely new position, or deleted when labels are updated. If you want full manual control of labels, turn off label updating before that happens. See **Controlling Contour Label Updates** on page II-377.

Here’s a recommended strategy for creating contour labels to your liking:

1. Create the contour plot and set the graph window to the desired size.
2. Choose Graph→Modify Contour Appearance, click the Label Tweaks button, and choose the rotation for labels, and any other label formatting options you want.
3. Choose “update now, once” from the Labels pop-up menu, and then click the Do It button.
4. Option-drag or Alt-drag any labels you don’t want completely off the graph.
5. Option-drag or Alt-drag any labels that are in the wrong place to another attachment point. You can drag them to a completely different trace, and the value printed in the label will change to the correct value.

To drag a label away from its attachment point, you must first unfreeze it with Position pop-up menu in the **Annotation Tweaks** dialog. See **Overriding the Contour Labels** on page II-378.

Adding Contour Labels

You can add a contour label with a Tag command like:

```
Tag/Q=ZW#1/F=0/Z=1/B=2/I=1/X=0/Y=0/L=1 'zw#1=2', 0 , "\\OZ"
```

An easier alternative is to use the Modify Annotation dialog to duplicate the annotation and then drag it to a new location.

Modifying Contour Labels

You can change the label font, font size, style, color, and rotation of all labels for a contour plot by clicking Label Tweaks in the Modify Contour Appearance dialog. This brings up the Contour Labels subdialog.

You can choose the rotation of contour labels from tangent, horizontal, vertical or both orientations. If both vertical and horizontal labels are permitted, Igor will choose vertical or horizontal with a preference for horizontal labels. Selecting one of the Tangent choices creates labels that are rotated to follow the contour line. The "Snap to" alternatives convert labels within 2 degrees of horizontal or vertical to exactly horizontal or vertical.

You can choose a specific font, size, and style. The “default” font is the graph’s default font, as set by the Modify Graph dialog.

The background color of contour labels is normally the same as the graph background color (usually white). With the Background pop-up menu, you can select a specific background color for the labels, or choose the window background color or the transparent mode.

You can choose among general, scientific, fixed-point, and integer formats for the contour labels. These correspond to printf conversion specifications, “%g”, “%e”, “%f”, and “%d”, respectively (see the **printf**). These specifications are combined with TagVal(3) into a dynamic text string that is used in each tag.

For example, choosing a Number Format of “###0.0...0” with 3 Digits after Decimal Point in the Contour-Labels dialog results in the contour tags having this as their text: `\{"%.3f",tagVal(3)}`. This format will create contour labels such as “12.345”.

Overriding the Contour Labels

Since Igor implements contour labels using standard tags, you can adjust labels individually by simply double-clicking the label to bring up the Modify Annotation dialog.

However, once you modify a label, Igor no longer considers it a contour label and will not automatically update it any more. When the labels are updated, the modified label will be ignored, which may result in two labels on a contour curve.

You may want to take complete, manual control of contour labels. In this case, set the Labels pop-up menu in the Modify Contour Appearance dialog to “no more updates” so that Igor will no longer update them. You can then make any desired changes without fear that Igor will undo them.

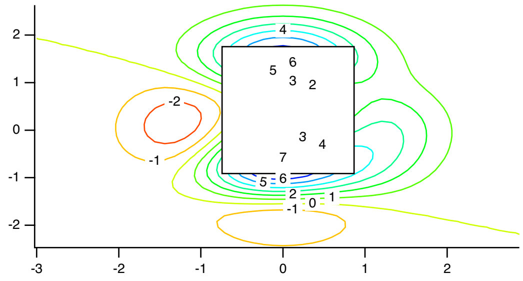
Contour labels are distinguished from other tags by means of the /Q flag. Tag/Q=*contourInstanceName* assigns the tag to the named contour. Igor uses the /Q flag in recreation macros to assign tags to a particular contour plot.

When you edit a contour label with the Modify Annotation dialog, the dialog adds a plain /Q flag (with no =*contourInstanceName* following it) to the Tag command to divorce the annotation from its contour plot.

Add the `/Q=ContourInstanceName` to Tag commands to temporarily assign ownership of the annotation to the contour so that it is deleted when the contour labels are updated.

Contour Labels and Drawing Tools

One problem with Igor’s use of annotations as contour labels is that normal drawing layers are below annotations. If you use the drawing tools to create a rectangle in the same location as some contour labels, you will encounter something like the following window.



You can solve this by putting the drawing in the overlay layer. See **Drawing Layers** on page III-68 for details.

Another solution is to remove the offending labels as described under **Repositioning and Removing Contour Labels** on page II-378.

Contouring Pitfalls

You may encounter situations in which the contour plot doesn’t look as you expect. This section discusses these pitfalls.

Insufficient Resolution

Contour curves are generally closed curves, or they intersect the data boundary. Under certain conditions, typically when using XYZ triplet data, the contouring algorithm may generate what appears to be an open curve (a line rather than a closed shape). This open curve typically corresponds to a peak ridge or a valley trough in the surface. At times, an open curve may also correspond to a line that intersects a nonobvious boundary.

The line may actually be a very narrow closed curve: zoom in by dragging out a marquee, clicking inside, and choosing “expand” from the pop-up menu.

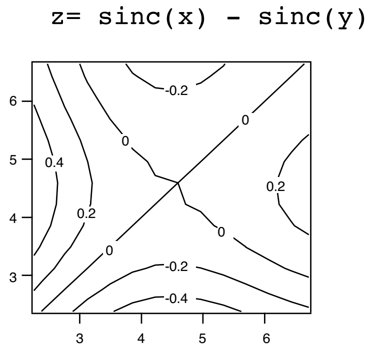
If it really is a line, increasing the resolution of the data in that region, by adding more X, Y, Z triplets, may result in a closed curve. Selecting a higher interpolation setting using the Modify Contour Appearance dialog may help.

Another solution is to shift the contour level slightly down from a peak or up from a valley. Or you could choose a new set of levels that don’t include the level exhibiting the problem. See **Contour Levels** on page II-368.

Crossing Contour Lines

Contour lines corresponding to different levels will not cross each other, but contour lines of the same level may appear to intersect. This typically happens when a contour level is equal to a “saddle point” of the surface. An example of this is a contour level of zero for the function:

```
z= sinc(x) - sinc(y)
```



You should shift the contour level away from the level of the saddle point. See **Contour Levels** on page II-368.

Flat Areas in the Contour Data

Patches of constant Z values in XYZ triplet data don’t contour well at those levels. If the data has flat areas equal to 2.0, for example, a contour level at Z=2.0 may produce ambiguous results. Gridded contour data does not suffer from this problem.

You should shift the contour level above or below the level of the flat area. See **Contour Levels** on page II-368.

Contour Preferences

You can change the default appearance of contour plots by capturing preferences from a prototype graph containing contour plots.

Create a graph containing one or more contour plots having the settings you use most often. Then choose Capture Graph Prefs from the Graph menu. Select the Contour Plots category, and click Capture Prefs.

Preferences are normally in effect only for *manual* operations, not for automatic operations from Igor procedures. This is discussed in more detail in Chapter III-18, **Preferences**.

The Contour Plots category includes both contour appearance settings and axis settings.

Contour Appearance Preferences

The captured contour appearance settings are automatically applied to a contour plot when it is first created, provided preferences are turned on. They are also used to preset the Modify Contour Appearance dialog.

If you capture the contour plot preferences from a graph with more than one contour plot, the first contour plot appended to a graph gets the settings from the contour first appended to the prototype graph. The second contour plot appended to a graph gets the settings from the second contour plot appended to the prototype graph, etc. This is similar to the way XY plot wave styles work.

Contour Axis Preferences

Only settings for axes used by the contour plot are captured. Axes used solely for an XY, category, or image plot are not captured when the Contour Plots category is selected.

The contour axis preferences are applied only when axes having the same name as the captured axis are created by AppendMatrixContour or AppendXYZContour commands. If the axes existed before those commands are executed, they are not affected by the axis preferences. The names of captured contour axes are listed in the X Axis and Y Axis pop-up menus of the New Contour Plot and Append Contour Plot dialogs. This is similar to the way XY plot axis preferences work.

You can capture contour axis settings for the standard left and bottom axes, and Igor will save these separately from left and bottom axis preferences captured for XY, category, and image plots. Igor will use the contour axis settings for AppendMatrixContour or AppendXYZContour commands only.

How to Use Contour Plot Preferences

Here is our recommended strategy for using contour preferences:

1. Create a new graph containing a single contour plot. If you want to capture the triangulation and interpolation settings, you must make an XYZ contour plot. Use the axes you will want for a contour plot.
2. Use the Modify Contour Appearance dialog and the Modify Axis dialog to make the contour plot appear as you prefer.
3. Choose Graph→Capture Graph Prefs, select the Contour Plots category, and click Capture Prefs.

Contour Plot Shortcuts

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To modify the appearance of the contour plot as a whole	Control-click and choose Modify Contour from the pop-up menu or press Shift and double-click the plot area of the graph, away from any labels or traces. This brings up the Modify Contour Appearance dialog.	Right-click and choose Modify Contour from the pop-up menu or press Shift and double-click the plot area of the graph, away from any labels or traces. This brings up the Modify Contour Appearance dialog.
To modify a contour label	Press Shift and double-click the plot area, and click Label Tweaks in the Modify Contour Appearance dialog. Don't double-click the label to use the Modify Annotation dialog unless you intend to maintain the label yourself. See **Overriding the Contour Labels** on page II-378.	Press Shift and double-click the plot area, and click Label Tweaks in the Modify Contour Appearance dialog. Don't double-click the label to use the Modify Annotation dialog unless you intend to maintain the label yourself. See **Overriding the Contour Labels** on page II-378.
To remove a contour label	Press Option, click on the label, and drag it completely off the graph.	Press Alt, click on the label, and drag it completely off the graph.
To move a contour label to another contour trace	Press Option, click on the label and drag it to another contour trace.	Press Alt, click on the label and drag it to another contour trace.
To duplicate a contour label	Double-click any label, click the Duplicate button, and click Do It.	Double-click any label, click the Duplicate button, and click Do It.
To modify the appearance or front-to-back drawing order of a contour trace	Control-click the trace to get a contextual menu. Press Shift-Control to modify all traces. Double-click the trace to summon the Modify Trace Appearance dialog.	Right-click the trace to get a contextual menu. Press Shift while right-clicking to modify all traces. Double-click the trace to summon the Modify Trace Appearance dialog.

Contour Plot Shortcuts

Because contour plots are drawn in a normal graph, all of the **Graph Shortcuts** (see page II-353) apply. Here we list those which apply specifically to contour plots.

Action	**Shortcut** (Macintosh)	**Shortcut** (Windows)
To modify the appearance of the contour plot as a whole	Control-click and choose Modify Contour from the pop-up menu **or** Press Shift and double-click the plot area of the graph, away from any labels or traces. This brings up the Modify Contour Appearance dialog.	Right-click and choose Modify Contour from the pop-up menu **or** Press Shift and double-click the plot area of the graph, away from any labels or traces. This brings up the Modify Contour Appearance dialog.
To modify a contour label	Press Shift and double-click the plot area, and click Label Tweaks in the Modify Contour Appearance dialog. Don't double-click the label to use the Modify Annotation dialog unless you intend to maintain the label yourself. See **Overriding the Contour Labels** on page II-378.	Press Shift and double-click the plot area, and click Label Tweaks in the Modify Contour Appearance dialog. Don't double-click the label to use the Modify Annotation dialog unless you intend to maintain the label yourself. See **Overriding the Contour Labels** on page II-378.
To remove a contour label	Press Option, click in the label, and drag it completely off the graph.	Press Alt, click in the label, and drag it completely off the graph.
To move a contour label to another contour trace	Press Option, click in the label and drag it to another contour trace.	Press Alt, click in the label and drag it to another contour trace.
To duplicate a contour label	Double-click any label, click the Duplicate button, and click the Do It button.	Double-click any label, click the Duplicate button, and click the Do It button.
To modify the appearance or front-to-back drawing order of a contour trace	Press Control and click the trace to get a pop-up menu. Press Command-Shift to modify all traces. Double-click the trace to summon the Modify Trace Appearance dialog. Also see **Overriding the Color of Contour Traces** on page II-373 and **Drawing Order of Contour Traces** on page II-376.	Right-click the trace to get a contextual menu. Press Shift while right-clicking to modify all traces. Double-click the trace to summon the Modify Trace Appearance dialog. Also see **Overriding the Color of Contour Traces** on page II-373 and **Drawing Order of Contour Traces** on page II-376.

Chapter

II-16

Image Plots

Overview

You can display image data as an image plot in a graph window. The image data can be a 2D wave, a layer of a 3D or 4D wave, a set of three layers containing RGB values, or a set of four layers containing RGBA values where A is “alpha” which represents opacity.

When discussing image plots, we use the term *pixel* to refer to an element of the underlying image data and *rectangle* to refer to the representation of a data element in the image plot.

Each image data value defines a the color of a rectangle in the image plot. The size and position of the rectangles are determined by the range of the graph axes, the graph width and height, and the X and Y coordinates of the pixel edges.

If your image data is a floating point type, you can use NaN to represent missing data. This allows the graph background color to show through.

Images are displayed behind all other objects in a graph except the ProgBack and UserBack drawing layers and the background color.

An image plot can be false color, indexed color or direct color.

False Color Images

In false color images, the data values in the 2D wave or layer of a 3D or 4D wave are mapped to colors using a color table. This is a powerful way to view image data and is often more effective than either surface plots or contour plots. You can superimpose a contour plot on top of a false color image of the same data.

Igor has many built-in color tables as described in **Image Color Tables** on page II-392. You can also define your own color tables using waves as described in **Color Table Waves** on page II-399. You can also create color index waves that define custom color tables as described in **Indexed Color Details** on page II-400.

Indexed Color Images

Indexed color images use the data values stored in a 2D wave or layer of a 3D or 4D wave as indices into an RGB or RGBA wave of color values that you supply. “True color” images, such as those that come from video cameras or scanners generally use indexed color. Indexed color images are more common than direct color because they consume less memory. See **Indexed Color Details** on page II-400.

Direct Color Images

Direct color images use a 3D RGB or RGBA wave. Each layer of the wave represents a color component - red, green, blue, or alpha. A set of component values for a given row and column specifies the color for the corresponding image rectangle. With direct color, you can have a unique color for every rectangle. See **Direct Color Details** on page II-401.

Loading an Image

You can load TIFF, JPEG, PNG, BMP, and Sun Raster image files into matrix waves using the **ImageLoad** or the Load Image dialog via the Data menu.

You can also load images fom plain text files, HDF5 files, GIS files, and from camera hardware.

For details, see **Loading Image Files** on page II-157.

Creating an Image Plot

Image plots are displayed in ordinary graph windows. All the features of graphs apply to image plots: axes, line styles, drawing tools, controls, etc. See Chapter II-13, **Graphs**.

You can create an image plot in a new graph window by choosing Windows→New→Image Plot which displays the New Image Plot dialog. This dialog creates a blank graph to which the plot is appended.

The dialog normally generates two commands — a Display command to make a blank graph window, and an AppendImage command to append a image plot to that graph window. This creates a graph like any other graph but, for most purposes, it is more convenient to use the NewImage operation.

Checking the "Use NewImage command" checkbox replaces Display and AppendImage with NewImage. NewImage automatically sizes the graph window to match the number of pixels in the image and reverses the vertical axis so that pictures are displayed right-side-up.

You can show lines of constant image value by appending a contour plot to a graph containing an image. Igor draws contour plots above image plots. See **Creating a Contour Plot** on page II-367 for an example of combining contour plots and images in a graph.

X, Y, and Z Wave Lists

The Z wave is the wave that contains your image data and defines the color for each rectangle in the image plot.

You can optionally specify an X wave to define rectangle edges in the X dimension and a Y wave to define rectangle edges in the Y dimension. This allows you to create an image plot with rectangles of different widths and heights.

When you select a Z wave, Igor updates the X Wave and Y Wave lists to show only those waves, if any, that are suitable for use with the selected Z wave. Only those waves with the proper length appear in the X Wave and Y Wave lists. See **Image X and Y Coordinates** on page II-388 for details.

Choosing _calculated_ from the X Wave list uses the row scaling (X scaling) of the Z wave selected in the Z Wave list to provide the X coordinates of the image rectangle centers.

Choosing _calculated_ from the Y Wave list uses the column scaling (Y scaling) of the Z wave to provide Y coordinates of the image rectangle centers.

Modifying an Image Plot

You can change the appearance of the image plot by choosing Image-Modify Image Appearance. This displays the Modify Image Appearance dialog, which is also available as a subdialog of the New Image Plot dialog.

Tip: Use the preferences to change the default image appearance, so you won't be making the same changes over and over. See **Image Preferences** on page II-403.

The Modify Image Appearance Dialog

The Modify Image Appearance dialog applies to false color and indexed color images, but not direct color images. See **Direct Color Details** on page II-401.

To use indexed color, click the Color Index Wave radio button and choose a color index wave. For color index wave details, see **Indexed Color Details** on page II-400.

To use false color, click the Color Table radio button and choose a built-in color table or click the Color Table Wave radio button and choose a color table wave. Autoscaled color mapping assigns the first color in a color table to the minimum value of the image data and the last color to the maximum value. The dialog uses "Z" to refer to the values in the image wave. For more information, see **Image Color Tables** on page II-392.

Indexed and color table colors are distributed between the minimum and maximum Z values either linearly or logarithmically, based on the `ModifyImage log` parameter, which is set by the Log Colors checkbox.

Use Explicit Mode to select specific colors for specific Z values in the image. If an image element is exactly equal to the number entered in the dialog, it is displayed using the assigned color. This is not very useful for images made with floating-point data; it is intended for integer data. It is almost impossible to enter exact matches for floating-point data.

When you select Explicit Mode for the first time, two entries are made for you assigning white to 0 and black to 255. A third blank line is added for you to enter a new value. If you put something into the blank line, another blank line is added.

To remove an entry, click in the blank areas of a line in the list to select it and press Delete (*Macintosh*) or Backspace (*Windows*).

Image X and Y Coordinates

Images display wave data elements as rectangles. They are displayed versus axes just like XY plots.

The intensity or color of each image rectangle is controlled by the corresponding data element of a matrix (2D) wave, or by a layer of a 3D or 4D wave, or by a set of layers of a 3D RGB or RGBA wave.

When discussing image plots, we use the term *pixel* to refer to an element of the underlying image data and *rectangle* to refer to the representation of a data element in the image plot.

For each of the spatial dimensions, X and Y, the edges of each image rectangle are defined by one of the following:

- The dimension scaling of the wave containing the image data or
- A 1D auxiliary X or Y wave

In the simplest case, all pixels have the same width and height so the pixels are squares of the same size. Another common case consists of rectangular but not square pixels all having the same width and the same height. Both of these are instances of evenly-spaced data. In these cases, you specify the rectangle centers using dimension (X and Y) scaling. This is discussed further under **Image X and Y Coordinates - Evenly Spaced** on page II-389.

Less commonly, you may have pixels of unequal widths and/or unequal heights. In this case you must supply auxiliary X and/or Y waves that specify the edges of the image rectangles. This is discussed further under **Image X and Y Coordinates - Unevenly Spaced** on page II-389.

It is possible to combine these cases. For example, your pixels may have uniform widths and non-uniform heights. In this case you use one technique for one dimension and the other technique for the other dimension.

Sometimes you may have data that is not really image data, because there is no well-defined pixel width and/or height, but is stored in a matrix (2D) wave. Such data may be more suitable for a scatter plot but can be plotted as an image. This is discussed further under **Plotting a 2D Z Wave With 1D X and Y Center Data** on page II-389.

In other cases you may have 1D X, Y and Z waves. These cases are discussed under **Plotting 1D X, Y and Z Waves With Gridded XY Data** on page II-390 and **Plotting 1D X, Y and Z Waves With Non-Gridded XY Data** on page II-391.

The following sections include example commands. If you want to execute the commands, find the corresponding section in the Igor help files by executing:

```
DisplayHelpTopic "Image X and Y Coordinates"
```

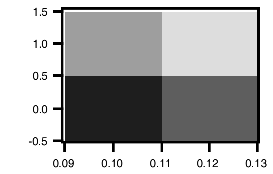
Image X and Y Coordinates - Evenly Spaced

When your data consists of evenly-spaced pixels, you use the image wave's dimension scaling to specify the image rectangle coordinates. You can set the scaling using the Change Wave Scaling dialog (Data menu) or using the **SetScale** operation.

The scaled dimension value for a given pixel specifies the center of the corresponding image rectangle.

Here is an example that uses a 2x2 matrix to exaggerate the effect:

```
Make/O small={{0,1},{2,3}}        // Set X dimension scaling
SetScale/I x 0.1,0.12,"", small
SetScale/P y 0.0,1.0,"", small    // Set Y dimension scaling
Display
AppendImage small    // _calculated_ X & Y
ModifyImage small ctab={-0.5,3.5,Grays}
```



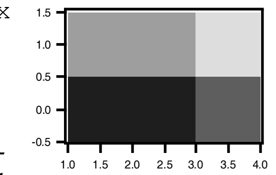
Note that on the X axis the rectangles are centered on 0.10 and 0.12, the matrix wave's X (row) indices as defined by its X scaling. On the Y axis the rectangles are centered on 0.0 and 1.0, the matrix wave's Y (column) indices as defined by its Y scaling. In both cases, the rectangle edges are one half-pixel width from the corresponding index value.

Image X and Y Coordinates - Unevenly Spaced

If your pixel data is unevenly-spaced in the X and/or Y dimension, you must supply X and/or Y waves to define the coordinates of the image rectangle edges. *These waves must contain one more data point than the X (row) or Y (column) dimension of the image wave in order to define the edges of each rectangle.*

In this example, the matrix wave is evenly-spaced in the Y dimension but unevenly-spaced in the X dimension:

```
Make/O small={{0,1},{2,3}}
SetScale/P y 0.0,1.0,"", small    // Set Y dimension scaling
Make smallx={1,3,4}               // Define X edges with smallx
Display
AppendImage small vs {smallx,*}
ModifyImage small ctab={-0.5,3.5,Grays,0}
```



The X coordinate wave (smallx) now controls the vertical edges of each image rectangle. smallx consists of three data points which are necessary to define the vertical edges of the two rectangles in the image plot. The values of smallx are interpreted as follows:

Point 0: 1.0	Sets left edge of first rectangle
Point 1: 2.75	Sets right edge of first rectangle and left edge of second rectangle
Point 2: 4.0	Sets right edge of last rectangle

The 1D edge wave must be either strictly increasing or strictly decreasing.

If you have X and/or Y waves that specify edges but they do not have an extra point, you may be able to proceed by simply adding an extra point. You can do this by editing the waves in a table or using the **InsertPoints** operation. If this is not appropriate, see the next section for another approach.

Plotting a 2D Z Wave With 1D X and Y Center Data

In an image, each pixel has a well-defined width and height. If your data is sampled at specific X and Y points and there is no well-defined pixel width and height, or if you don't know the width and height of each pixel, you don't really have a proper image.

However, because this kind of data is often stored in a matrix wave with associated X and Y waves, it is sometimes convenient to display it as an image, treating the X and Y waves as containing the center coordinates of the pixels.

To do this, you must create new X and Y waves to specify the image rectangle edges. The new X wave must have one more point than the matrix wave has rows and the new Y wave must have one more point than the matrix wave has columns.

A set of image rectangle centers does not uniquely determine the rectangle edges. To see this, think of a 1x1 image centered at (0,0). Where are the edges? They could be anywhere.

Without additional information, the best you can do is to generate a set of plausible edges, as we do with this function:

```
Function MakeEdgesWave(centers, edgesWave)
   Wave centers            // Input
   Wave edgesWave          // Receives output

   Variable N=numpnts(centers)
   Redimension/N=(N+1) edgesWave

   edgesWave[0]=centers[0]-0.5*(centers[1]-centers[0])
   edgesWave[N]=centers[N-1]+0.5*(centers[N-1]-centers[N-2])
   edgesWave[1,N-1]=centers[p]-0.5*(centers[p]-centers[p-1])
End
```

This function demonstrates the use of MakeEdgesWave:

```
Function DemoPlotXYZAsImage()
   Make/O mat={{0,1,2},{2,3,4},{3,4,5}}   // Matrix containing Z values
   Make/O centersX = {1, 2.5, 5}          // X centers wave
   Make/O centersY = {300, 400, 600}      // Y centers wave
   Make/O edgesX; MakeEdgesWave(centersX, edgesX)  // Create X edges wave
   Make/O edgesY; MakeEdgesWave(centersY, edgesY)  // Create Y edges wave
   Display; AppendImage mat vs {edgesX,edgesY}
End
```

If you have additional information that allows you to create edge waves you should do so. Otherwise you can use the MakeEdgesWave function above to create plausible edge waves.

Plotting 1D X, Y and Z Waves With Gridded XY Data

In this case we have 1D X, Y and Z waves of equal length that define a set of points in XYZ space. The X and Y waves constitute an evenly-spaced sampling grid though the spacing in X may be different from the spacing in Y.

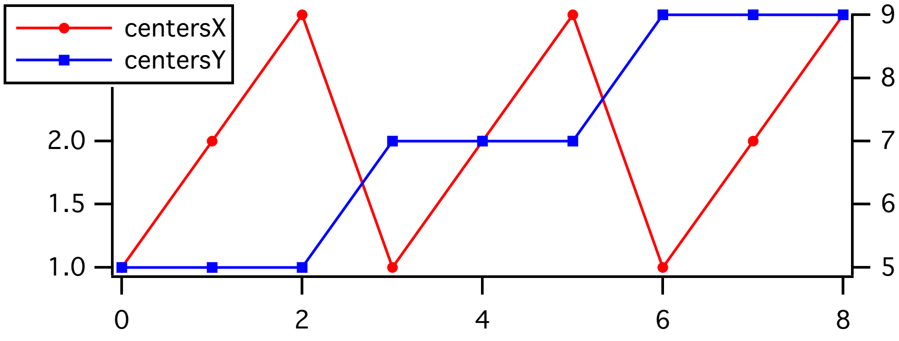
A good way to display such data is to create a scatter plot with color set as a function of the Z data. See **Setting Trace Properties from an Auxiliary (Z) Wave** on page II-298.

It is also possible to transform your data so it can be plotted as an image, as described under **Plotting a 2D Z Wave With 1D X and Y Center Data**. To do this you must convert your 1D Z wave into a 2D matrix wave and then convert your X and Y waves to contain the horizontal an vertical centers of your pixels.

For example, we start with this X, Y and Z data:

```
Make/O centersX = {1,2,3,1,2,3,1,2,3}
Make/O centersY = {5,5,5,7,7,7,9,9,9}
Make/O zData = {1,2,3,4,5,6,7,8,9}
```

If we display the X and Y data in a graph we can see that the X and Y waves exhibit repeating patterns:



To display this as an image, we transform the data so that the Z wave becomes a 2D matrix representing pixel values and the X and Y waves describe the centers of the rows and columns of pixels:

```
Redimension/N=(3,3) zData
Make/O/N=3 xCenterLocs = centersX[p]      // 1, 2, 3
Make/O/N=3 yCenterLocs = centersY[p*3]    // 5, 7, 9
```

We now have data as described under **Plotting a 2D Z Wave With 1D X and Y Center Data** on page II-389.

Plotting 1D X, Y and Z Waves With Non-Gridded XY Data

In this case you have 1D X, Y and Z waves of equal length that define a set of points in XYZ space. The X and Y waves do not constitute a grid, so the method of the previous section will not work.

A 2D scatter plot is a good way to graphically represent such data:

```
Make/O/N=20 xWave=enoise(4),yWave=enoise(5),zWave=enoise(6)  // Random points
Display yWave vs xWave
ModifyGraph mode=3,marker=19
ModifyGraph zColor(yWave)={zWave,*,*,Rainbow,0}
```

Although the data does not represent a proper image, you may want to display it as an image instead of a scatter plot. You can use the **ImageFromXYZ** operation to create a matrix wave corresponding to your XYZ data. The matrix wave can then be plotted as a simple image plot.

You can also Voronoi interpolation to create a matrix wave from the XYZ data:

```
Concatenate/O {xWave,yWave,zWave}, tripletWave
ImageInterpolate/S={-5,0.1,5,-5,0.1,5} voronoi tripletWave
AppendImage M_InterpolatedImage
```

Note that the algorithm for Voronoi interpolation is computationally expensive so it may not be practical for very large waves. See also **Loess** on page V-515 and **ImageInterpolate** on page V-382 kriging as alternative approaches for generating a smooth surface from unordered scatter data.

Additional options for displaying this type of data as a 3D surface are described under "Scatter Plots" in the "Visualization.ihf" help file and in the video tutorial "Creating a Surface Plot from Scatter Data" at http://www.youtube.com/watch?v=kggo0B43n_c.

Image Orientation

By default, the AppendImage operation draws increasing Y values (matrix column indices) upward, and increasing X (matrix row indices) to the right. Most image formats expect Y to increase downward. As a result, if you create an image plot using

```
Display; AppendImage <image wave>
```

your plot appears upside down.

You can flip an image vertically by reversing the Y axis, and horizontally by reversing the X axis, using the Axis Range tab in the Modify Axes dialog:

You can also flip the image vertically by reversing the Y scaling of the image wave.

A simpler alternative is to use NewImage instead of AppendImage. You can do this in the New Image Plot dialog by checking the “Use NewImage command” checkbox. NewImage automatically reverses the left axes.

Image Rectangle Aspect Ratio

By default, Igor does not make the image rectangles square. Use the Modify Graph dialog (in the Graph menu) to correct this by choosing Plan as the graph’s width mode. You can use the Plan height mode to accomplish the same result.

If DimDelta(*imageWave*,0) does not equal DimDelta(*imageWave*,1), you will need to enter the ratio (or inverse ratio) of these two values in the Plan width or height:

```
SetScale/P x 0,3,"", mat2dImage
SetScale/P y 0,1,"", mat2dImage
ModifyGraph width=0, height={Plan,3,left,bottom}
// or
ModifyGraph height=0, width={Plan,1/3,bottom,left}
```

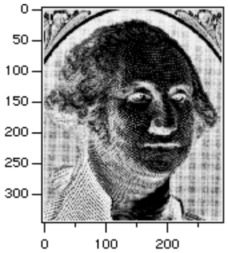
Do not use the Aspect width or height modes; they make the entire image plot square even if it shouldn’t be.

Plan mode ensures the image rectangles are square, but it allows them to be of any size. If you want each image rectangle to be a single point in width and height, use the per Unit width and per Unit height modes. With point X and Y scaling of an image matrix, use one point per unit:

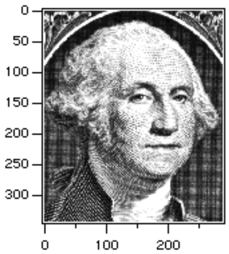
You can also flip an image along its diagonal by setting the Swap XY checkbox.

Image Polarity

Sometimes the image’s pixel values are inverted, too. False color images can be inverted by reversing the color table. Select the Reverse Colors checkbox in the Modify Image Appearance dialog. See **Image Color Tables** on page II-392. To reverse the colors in an index color plot is harder: the rows of the color index wave must be reversed.



After SetAxis/A/R left
ModifyGraph width={Plan,1,bottom,left}



After reversing
the Grays color table

Image Color Tables

In a false color plot, the data values in the 2D image wave are normally linearly mapped into a table of colors containing a set of colors that lets the viewer easily identify the data values. The data values can be logarithmically mapped by using the `ModifyImage log=1` option, which is useful when they span multiple orders of magnitude.

There are many built-in color tables you can use with false color images. Also, you can create your own color table waves - see **Color Table Waves** on page II-399.

The **CTabList** returns a list of all built-in color table names. You can create a color index wave or a color table wave from any built-in color table using **ColorTab2Wave**.

The ColorsMarkersLinesPatterns example Igor experiment, in “Igor Pro Folder:Examples:Feature Demos 2”, demonstrates all built-in color tables. These color tables are summarized in the section **Color Table Details** on page II-395.

Image Color Table Ranges

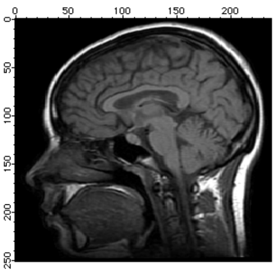
The range of data values that maps into the range of colors in the table can be set either manually or automatically using the Modify Image Appearance dialog.

When you choose to autoscale the first or last color, Igor examines the data in your image wave and uses the minimum or maximum data value found.

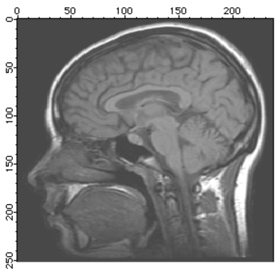
By changing the “First Color at Z=” and “Last Color at Z=” values you can examine subtle features in your data.

For example, when using the Grays color table, you can lighten the image by assigning the First Color (which is black) to a number lower than the image minimum value. This maps a lighter color to the minimum image value. To darken the maximum image values, assign the Last Color to a number higher than the image maximum value, mapping a darker color to the maximum image value.

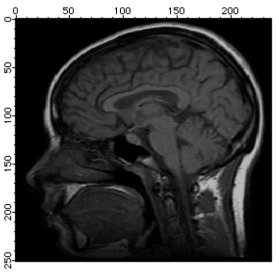
You can adjust these settings interactively by choosing Image→Image Range Adjustment.



`ctab = {0,255,Grays}`



`ctab = {-100,255,Grays}`



`ctab = {0,355,Grays}`

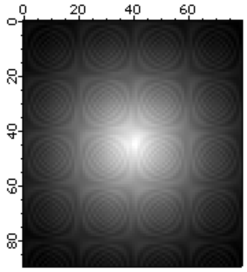
Data values greater than the range maximum are given the last color in the color table, or they can all be assigned to a single color or made transparent. Similarly, data values less than the range minimum are given the first color in the color table, or they can all be assigned to a single color (possibly different from the max color), or made transparent.

Example: Overlaying Data on a Background Image

By setting the image range to render small values transparent, you can see the underlying image in those locations, which helps visualize where the nontransparent values are located with reference to a background image. Here’s a fake weather radar example.

First, we create some “land” to serve as a background image:

```
Make/O/N=(80,90) landWave
landWave = 1-sqrt((x-40)*(x-40)+(y-45)*(y-45))/sqrt(40*40+45*45)
landWave = 7000*landWave*landWave
landWave += 200*sin((x-60)*(y-60)*pi/10)
landWave += 40*(sin((x-60)*pi/5)+sin((y-60)*pi/5))
NewImage landWave
```

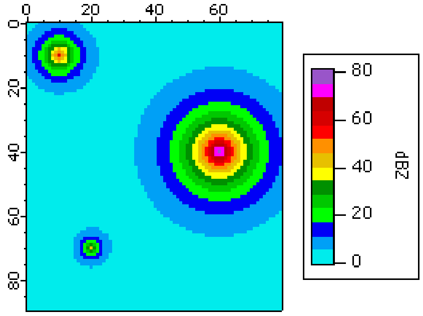


Then we create some “weather” radar data ranging from about 0 to 80 dBZ:

```
Duplicate/O landWave overlayWeather                        // "weather" radar values
overlayWeather=60*exp(-(sqrt((x-10)*(x-10)+(y-10)*(y-10))/5))      // storm 1
overlayWeather+=80*exp(-(sqrt((x-60)*(x-60)+(y-40)*(y-40)))/10)    // storm 2
overlayWeather+=40*exp(-(sqrt((x-20)*(x-20)+(y-70)*(y-70)))/3)     // storm 3
SetScale d, 0, 0, "dBZ", overlayWeather
```

We append the overlayWeather wave using the same axes as the landWave to overlay the images. With the default color table range, the landWave is totally obscured:

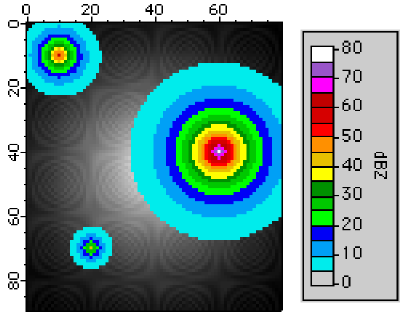
```
AppendImage/T overlayWeather
ModifyImage overlayWeather ctab= {*,*,dBZ14,0}
// Show the image's data range with a ColorScale
ModifyGraph width={Plan,1,top,left}, margin(right)=100
ColorScale/N=text0/X=107.50/Y=0.00 image=overlayWeather
```



We calibrate the image plot colors to National Weather Service values for precipitation mode by selecting the dBZ14color table for data values ranging from 5 to 75, where values below 5 are transparent and values above 75 are white:

We modify the ColorScale to show a range larger than the color table values (0-80):

```
ColorScale/C/N=text0 colorBoxesFrame=1,heightPct=90,nticks=10
ColorScale/C/N=text0/B=(52428,52428,52428) axisRange={0,80},tickLen=3.00
```



Color Table Ranges - Lookup Table (Gamma)

Normally the range of data values and the range of colors are linearly related or logarithmically related if the `ModifyImage log` parameter is set to 1. You can also cause the mapping to be nonlinear by specifying a lookup (or "gamma") wave, as described in the next example.

Example: Using a Lookup for Advanced Color/Contrast Effects

The **ModifyImage** operation (see page V-635) with the lookup parameter specifies a 1D wave that modifies the mapping of scaled Z values into the current color table. Values in the lookup wave should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the colormap. Used to apply gamma correction to grayscale images or for special effects.

```
Make luWave=0.5*(1+sin(x/30))
Make /n=(50,50) simpleImage=x*y
NewImage simpleImage
ModifyImage simpleImage ctab= {*,*,Rainbow,0}

// After inspecting the simple image, apply the lookup:
ModifyImage simpleImage lookup=luWave
```

Specialized Color Tables

Some of the color tables are designed for specific uses and specific numeric ranges.

The BlackBody color table shows the color of a heated "black body", though not the brightness of that body, over the temperature range of 1,000 to 10,000 K.

The Spectrum color table is designed to show the color corresponding to the wavelength of visible light as measured in nanometers over the range of 380 to 780 nm.

The SpectrumBlack color table does the same thing, but over the range of 355 to 830 nm. The fading to black is an attempt to indicate that the human eye loses the ability to perceive colors at the range extremities.

The GreenMagenta16, EOSOrangeBlue11, EOSSpectral11, dBZ14, and dBZ21 tables are designed to represent discrete levels in weather-related images, such as radar reflectivity measures of precipitation and wind velocity and discrete levels for geophysics applications.

The LandAndSea, Relief, PastelsMap, and SeaLandAndFire color tables all have a sharp color transition which is intended to denote sea level. The LandAndSea and Relief tables have this transition at 50% of the range. You can put this transition at a value of 0 by setting the minimum value to the negative of the maximum value:

```
ModifyImage imageName, ctab={-1000,1000,LandAndSea,0}     // image plot
ColorScale/C/N=scale0 ctab={-1000,1000,LandAndSea,0}      // colorscale
```

The PastelsMap table has this transition at 2/3 of the range. You can put this transition at a value of 0 by setting the minimum value to twice the negative of the maximum value:

```
ModifyImage imageName, ctab={-2000,1000,PastelsMap,0}     // image plot
ColorScale/C/N=scale0  ctab={-2000,1000,PastelsMap,0}     // colorscale
```

This principle can be extended to the other color tables to position a specific color to a desired value. Some trial-and-error is to be expected.

The BlackBody, Spectrum, and SpectrumBlack color tables are based on algorithms from the Color Science web site:

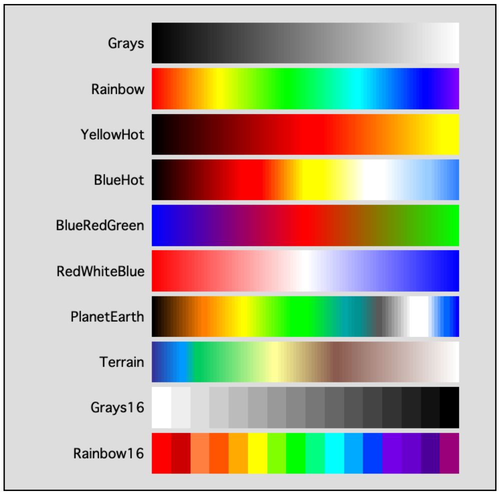
<`http://www.physics.sfasu.edu/astro/color.html`>.

Color Table Details

The built-in color tables can be grouped into several categories.

Igor Pro 4-Compatible Color Tables

Igor Pro 4 supported 10 built-in color tables: Grays, Rainbow, YellowHot, BlueHot, BlueRedGreen, RedWhiteBlue, PlanetEarth, Terrain, Grays16, and Rainbow16. These color tables have 100 color levels except for Grays16 and Rainbow16, which only have 16 levels.



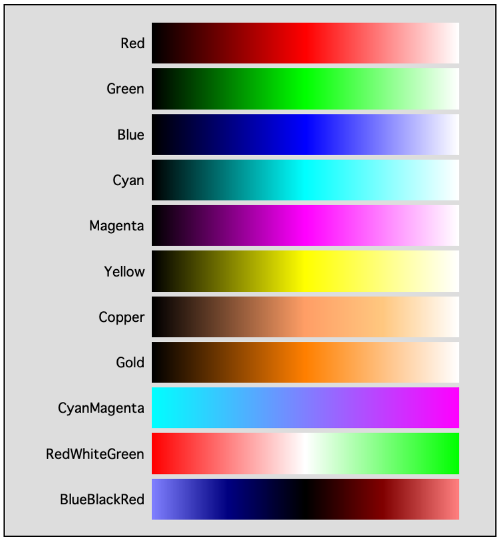
Igor Pro 5-Compatible Color Tables

Igor Pro 5 added 256-color versions of the eight 100-level color tables in Igor Pro 4 (Grays256, Rainbow256, etc.), new gradient color tables, and new special-purpose color tables.

Igor Pro 5 Gradient Color Tables

These are 256-color transitions between two or three colors.

Color Table Name	Colors	Notes
Red	256	Black → red → white.
Green	256	Black → green → white.
Blue	256	Black → blue → white.
Cyan	256	Black → cyan → white.
Magenta	256	Black → magenta → white.
Yellow	256	Black → yellow → white.
Copper	256	Black → copper → white.
Gold	256	Black → gold → white.
CyanMagenta	256	
RedWhiteGreen	256	
BlueBlackRed	256	

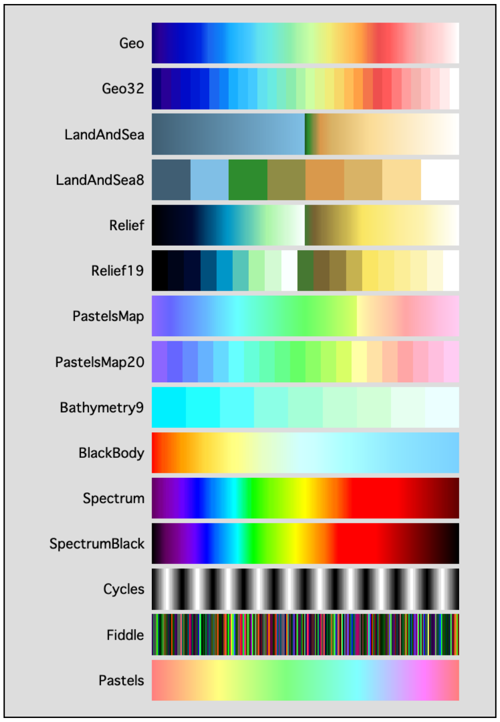


Igor Pro 5 Special-Purpose Color Tables

The special purpose color tables are ones that will find use for particular needs, such as coloring a digital elevation model (DEM) of topography or for spectroscopy. These color tables can have any number of color entries.

The following table summarizes the various special-purpose color tables.

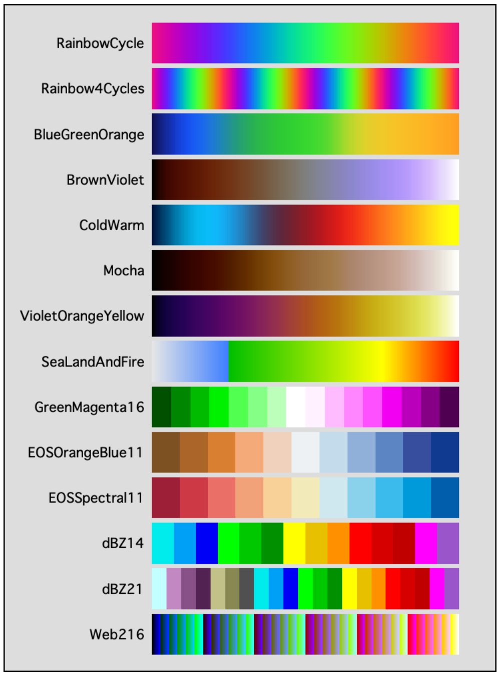
Color Table Name	Colors	Notes
Geo	256	Popular mapping color table for elevations. Sea level is around 50%.
Geo32	32	Quantized to classify elevations. Sea level is around 50%.
LandAndSea	255	Rapid color changes above sea level, which is at exactly 50%. Ocean depths are blue-gray.
LandAndSea8	8	Quantized, sea level is at about 22%.
Relief	255	Slower color changes above sea level, which is at exactly 50%. Ocean depths are black.
Relief19	19	Quantized, sea level is at about 47.5%.
PastelsMap	301	Desaturated rainbow-like colors, having a sharp green→yellow color change at sea level, which is around 66.67%. Ocean depths are faded purple.
PastelsMap20	20	Quantized. Sea level is at about 66.67%.
Bathymetry9	9	Colors for ocean depths. Sea level is at 100%.
BlackBody	181	Red → Yellow → Blue colors calibrated to black body radiation colors (neglecting intensity). The color table range is from 1,000 K to 10,000 K. Each color table entry represents a 50 K interval.
Spectrum	201	Rainbow-like colors calibrated to the visible spectrum when the color table range is set from 380 to 780 nm (wavelength). Each color table entry represents 2nm. Colors do not completely fade to black at the ends of the color table.
SpectrumBlack	476	Rainbow-like colors calibrated to the visible spectrum when the color table range is set from 355 to 830 nm (wavelength). Each color table entry represents 1 nm. Colors fade to black at the ends of the color table.
Cycles	201	Ten grayscale cycles from 0 to 100% to 0%.
Fiddle	254	Some randomized colors for “fiddling” with an image to detect faint details in the image.
Pastels	256	Desaturated Rainbow.



Igor Pro 6-Compatible Color Tables

Igor Pro 6 added 14 new color tables.

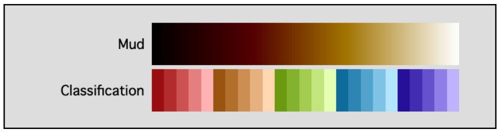
Color Table Name	Colors	Notes
RainbowCycle	360	Red, green, blue vary sinusoidally, each 120 degrees (120 values) out of phase. The first and last colors are identical.
Rainbow4Cycles	360	4 cycles with one quarter of the angular resolution.
BlueGreenOrange	300	Three-color gradient.
BrownViolet	300	Two-color gradient.
ColdWarm	300	Multicolor gradient for temperature.
Mocha	300	Two-color gradient.
VioletOrangeYellow	300	Multicolor gradient for temperature.
SeaLandAndFire	256	Another topographic table. Sea level is at 25%.
GreenMagenta16	16	Similar to the 14-color National Weather Service Motion color tables (base velocity or storm relative values), but friendly to red-green colorblind people.
EOSOrangeBlue11	11	Colors for diverging data (friendly to red-green colorblind people).
EOSSpectral11	11	Modified spectral colors (friendly to red-green colorblind people).
dBZ14	14	National Weather Service Reflectivity (radar) colors for Clear Air (-28 to +24 dBZ) or Precipitation (5 to 70 dBZ) mode.
dBZ21	21	National Weather Service Reflectivity (radar) colors for combined Clear Air and Precipitation mode (-30 to 70 dBZ).
Web216	216	The 216 “web-safe” colors, provides a wide selection of standard colors in a single color table. Intended for trace f(z) coloring using the ModifyGraph zColor parameter.



Igor Pro 6.2-Compatible Color Tables

Igor Pro 6.2 added 2 new color tables:

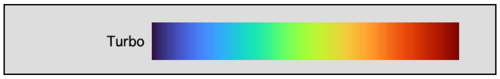
Color Table Name	Colors	Notes
Mud	256	Dark brown to white, without the pink cast of the Mocha color table. For Veeco atomic force microscopes.
Classification	25	5 hues for classification, 5 saturations for variations within each class.



Igor Pro 9-Compatible Color Tables

Igor Pro 9 added one new color table:

Color Table Name	Colors	Notes
Turbo	256	A reversed Rainbow-like color table with smoother transitions to avoid overly emphasizing features only because they map to a certain color. Designed by Anton Mikhailov, Senior Software Engineer, Daydream. See https://ai.googleblog.com/2019/08/turbo-improved-rainbow-colormap-for.html



Color Table Waves

You can use color index waves (see **Indexed Color Details** on page II-400) as if they were color tables.

With a color index wave, the image wave data value is used as an X index into the color index wave to select the color for a given point. The resultant color depends on the data value and the X scaling of the color index wave.

With a color table wave, the image wave's full range of data values, or a range that you explicitly specify, is mapped to the entire color table wave. The resultant color depends on the data value and the operative range only, not on the color table wave's X scaling.

A trivial way to generate a color table wave is to call the ColorTab2Wave operation which creates a 3 column RGB wave named M_Colors, where column 0 is the red component, column 1 is green, and column 2 is blue, and each value is between 0 (dark), and 65535 (bright).

With a 3 column RGB color table wave, all colors are opaque. You can add a fourth column to control transparency, making it an RGBA wave. The fourth column of an RGBA wave represents "alpha", where 0 is fully transparent and 65535 is fully opaque.

Many color table waves are included in the Color Tables folder in the Igor Pro folder, along with a help file that describes them.

The syntaxes for using color table waves for image plots, contour plots, graph traces, and colorscales vary and are detailed in their respective commands. See **ModifyImage** (ctab keyword), **ModifyContour** (ctabFill and ctabLines keywords), **ModifyGraph (traces)** (zColor keyword) and **ColorScale** (ctab keyword).

See the "ColorTableWavesHelp.ihf" help file in the "Color Tables" folder of the Igor Pro folder to preview and load color table waves that ship with Igor Pro.

Indexed Color Details

An indexed color plot uses a 2D image wave, or a layer of a 3D or 4D wave, and a color index wave. The image wave data value is used as an X index into the color index wave to select the color for a given image rectangle. The resulting color depends on the data value and the X scaling of the color index wave.

A color index wave is a 2D RGB or RGBA wave. An RGB wave has three columns and each row contains a set of red, green, and blue values that range from 0 (zero intensity) to 65535 (full intensity). An RGBA wave has three color columns plus an alpha column whose values range from 0 (fully transparent) to 65535 (fully opaque).

Linear Indexed Color

For the normal linear indexed color, Igor finds the color for a particular image data value by choosing the row in the color index wave whose X index corresponds to the image data value. Igor converts the image data value zImageValue into a row number colorIndexWaveRow using the following computation:

```
colorIndexWaveRow = floor(nRows*(zImageValue-xMin)/xRangeInclusive)
```

where,

```
nRows = DimSize(colorIndexWave,0)
xMin = DimOffset(colorIndexWave,0)
xRangeInclusive = (nRows-1) * DimDelta(colorIndexWave,0)
```

If colorIndexWaveRow exceeds the row range, then the Before First Color and After Last Color settings are applied.

By setting the X scaling of the color index wave, you can control how Igor maps the image data value to a color. This is similar to setting the First Color at Z= and Last Color at Z= values for a color table.

Logarithmic Indexed Color

For logarithmic indexed color (the ModifyImage log parameter is set to 1), colors are mapped using the log(x scaling) and log(image z) values this way:

```
colorIndexWaveRow = floor(nRows*(log(zImageValue)-log(xMin))/(log(xmax)-log(xMin)))
```

where,

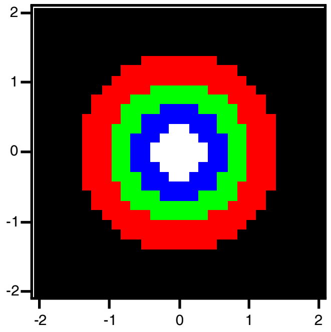
```
nRows = DimSize(colorIndexWave,0)
xMin = DimOffset(colorIndexWave,0)
xMax = xMin + (nRows-1) * DimDelta(colorIndexWave,0)
```

Displaying image data in log mode is slower than in linear mode.

Example: Point-Scaled Color Index Wave

```
// Create a point-scaled, unsigned 16-bit integer color index wave
Make/O/W/U/N=(1,3) shortindex          // initially 1 row; more will be added
shortindex[0][]= {{0},{0},{0}}               // black in first row
shortindex[1][]= {{65535},{0},{0}}           // red in new row
shortindex[2][]= {{0},{65535},{0}}           // green in new row
shortindex[3][]= {{0},{0},{65535}}           // blue in new row
shortindex[4][]= {{65535},{65535},{65535}}   // white in new row

// Generate sample data and display it using the color index wave
Make/O/N=(30,30)/B/U expmat   // /B/U makes unsigned byte image
SetScale/I x,-2,2,"" expmat
SetScale/I y,-2,2,"" expmat
expmat= 4*exp(-(x^2+y^2))      // test image ranges from 0 to 4
Display;AppendImage expmat
ModifyImage expmat cindex=shortindex
```



Direct Color Details

Direct color images use a 3D RGB wave with 3 color planes containing absolute values for red, green and blue or a 3D RGBA wave that adds an alpha plane. Generally, direct color waves are either unsigned 8 bit integers or unsigned 16 bit integers.

For 8-bit integer waves, 0 represents zero intensity and 255 represents full intensity. For alpha, 0 represents fully transparent and 255 represents fully opaque.

For all other number types, 0 represents zero intensity but 65535 represents full intensity. For alpha, 0 represents fully transparent and 65535 represents fully opaque. Out-of-range values are clipped to the limits.

Try the following example, executing each line one at a time:

```
Make/O/B/U/N=(40,40,3) matrgb
NewImage matrgb
matrgb[][][0]= 127*(1+sin(x/8)*sin(y/8))  // Specify red,   0-255
matrgb[][][1]= 127*(1+sin(x/7)*sin(y/6))  // Specify green, 0-255
matrgb[][][2]= 127*(1+sin(x/6)*sin(y/4))  // Specify blue,  0-255
```

```
// Switch to floating point, image turns black
Redimension/S matrgb

// Scale floating point to 0..65535 range
matrgb *= 256
```

Because the appearance of a direct color image is completely determined by the image data, the Modify Image Appearance dialog has no effect on direct color images, and the dialog appears blank.

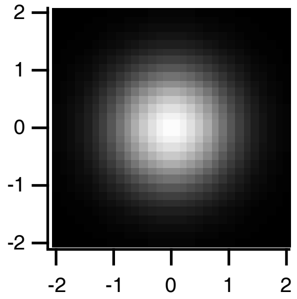
Creating Color Legends

You can create a color legend using a color scale annotation. For background information, see **Legends** on page III-42 and **Color Scales** on page III-47 sections.

We will demonstrate with a simple image plot:

```
Make/O/N=(30,30) expmat
SetScale/I x,-2,2,"" expmat; SetScale/I y,-2,2,"" expmat
expmat= exp(-(x^2+y^2))        // data ranges from 0 to 1
Display;AppendImage expmat     // by default, left and bottom axes
ModifyGraph width={Plan,1,bottom,left},mirror=0
```

This creates the following image, using the autoscaled Grays color table:



Choose Graph→Add Annotation to display the Add Annotation dialog.

Choose “ColorScale” from the Annotation pop-up menu.

Switch to the Frame tab and set the Color Bar Frame Thickness to 0 and the Annotation Frame to None.

Switch to the Position tab, check the Exterior checkbox, and set the Anchor to Right Center.

Click Do It. Igor executes:

```
ColorScale/C/N=text0/F=0/A=RC/E image=expmat,frame=0.00
```

This generates the following image plot:

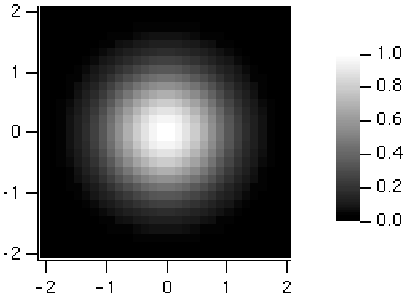


Image Instance Names

Igor identifies an image plot by the name of the wave providing Z values (the wave selected in the Z Wave list of the Image Plot dialogs). This “image instance name” is used in commands that modify the image plot.

In this example the image instance name is “zw”:

```
Display; AppendImage zw             // new image plot
ModifyImage zw ctab={*,*,BlueHot}   // change color table
```

In the unusual case that a graph contains two image plots of the same data, to show different subranges of the data side-by-side,for example, an instance number must be appended to the name to modify the second plot:

```
Display; AppendImage zw; AppendImage/R/T zw  // two image plots
ModifyImage zw ctab={*,*,RedWhiteBlue}       // change first plot
ModifyImage zw#1 ctab={*,*,BlueHot}          // change second plot
```

The Modify Image Appearance dialog generates the correct image instance name automatically. Image instance names work much the same way wave instance names for traces in a graph do. See **Instance Notation** on page IV-20.

The **ImageNameList** function (see page V-397) returns a string list of image instance names. Each name corresponds to one image plot in the graph. The **ImageInfo** function (see page V-380) returns information about a particular named image plot.

ImageNameList returns strings, but ModifyImage uses names. The $ operator turns a string into a name. For example:

```
Function SetFirstImageToRainbow(graphName)
   String graphName
   String imageInstNames = ImageNameList(graphName, ";")
   String firstImageName = StringFromList(0,imageInstNames) // Name in a string
   if (strlen(firstImageName) > 0)
      // $ converts string to name
      ModifyImage/W=$graphName $firstImageName ctab={,,Rainbow}
   endif
End
```

Image Preferences

You can change the default appearance of image plots by capturing preferences from a prototype graph containing image plots. Create a graph containing an image plot with the settings you use most often. Then choose Capture Graph Prefs from the Graph menu. Select the Image Plots category, and click Capture Prefs.

Preferences are normally in effect only for *manual* operations, not for automatic operations from Igor procedures. Preferences are discussed in more detail in Chapter III-18, **Preferences**.

The Image Plots category includes both Image Appearance settings and axis settings.

Image Appearance Preferences

The captured Image Appearance settings are automatically applied to an image plot when it is first created, provided preferences are turned on. They are also used to preset the Modify Image Appearance dialog when it is invoked as a subdialog of the New Image Plot dialog.

If you capture the Image Plot preferences from a graph with more than one image plot, the first image plot appended to a graph gets the settings from the image first appended to the prototype graph. The second image plot appended to a graph gets the settings from the second image plot appended to the prototype graph, etc. This is similar to the way XY plot wave styles work.

Image Axis Preferences

Only axes used by the image plot have their settings captured. Axes used solely for an XY, category, or contour plot are ignored.

The image axis preferences are applied only when axes having the same name as the captured axis are created by an AppendImage command. If the axes existed before AppendImage is executed, they are not affected by the image axis preferences.

The names of captured image axes are listed in the X Axis and Y Axis pop-up menus of the New Image Plot and Append Image Plot dialogs. This is similar to the way XY plot axis preferences work.

For example, suppose you capture preferences for an image plot using axes named “myRightAxis” and “myTopAxis”. These names will appear in the X Axis and Y Axis pop-up menus in image plot dialogs.

If you choose them in the New Image Plot dialog and click Do It, a graph will be created containing *newly-created* axes named “myRightAxis” and “myTopAxis” and having the axis settings you captured.

If you have a graph which already uses axes named “myRightAxis” and “myTopAxis” and choose these axes in the Append Image Plot dialog, the image will be appended to those axes, as usual, but no captured axis settings will be applied to these *already-existing* axes.

You can capture image axis settings for the standard left and bottom axes, and Igor will save these separately from left and bottom axis preferences captured for XY, category, and contour plots. Igor will use the image axis settings for AppendImage commands only.

How to Use Image Preferences

Here is our recommended strategy for using image preferences:

1. Create a new graph containing a single image plot. Use the axes you will normally use, even if they are left and bottom. You can use other axes, too (select New Axis in the New Image Plot and Append Image Plot dialogs).
2. Use the Modify Image Appearance, Modify Graph, and Modify Axis dialogs to make the image plot appear as you prefer.
3. Choose Capture Graph Prefs from the Graph menu. Select the Image Plots category, and click Capture Prefs.

Image Plot Shortcuts

Since image plots are drawn in a normal graph, all of the **Graph Shortcuts** (see page II-353) apply. Here we list those which apply specifically to image plots.

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To modify the appearance of the image plot as a whole	Control-click in the plot area of the graph and choose Modify Image from the pop-up menu.	Right-click in the plot area of the graph and choose Modify Image from the pop-up menu.

Chapter

II-17

3D Graphics

Overview

Igor can create various kinds of 3D graphics including:

- **Surface Plots**
- **3D Scatter Plots**
- **3D Bar Plots**
- **Path Plots**
- **Ribbon Plots**
- **Isosurface Plots**
- **Voxelgram Plots**

Image Plots, **Contour Plots** and **Waterfall Plots** are considered 2D graphics and are discussed in other sections of the help.

Igor's 3D graphics tool is called "Gizmo". Most 3D graphics that you produce with Gizmo will be based on data stored in waves. It's important to understand what type of wave data is required for what type of 3D graphic, as explained in the following sections explain.

1D Waves

1D waves can not be used for 3D plots.

If you have three 1D waves that represent X, Y and Z coordinates which you want to display as a 3D plot, you must convert them into a triplet wave. For example:

```
Concatenate {xWave,yWave,zWave}, tripletWave
```

Now you can plot the triplet wave using one of the methods described below.

The conversion of three 1D waves into a triplet wave is appropriate when the data are not sampled on a rectangular grid. If you know that your data are sampled on a rectangular grid you should convert the wave that contains your Z data into a 2D wave using the Redimension operation and then proceed to plot the surface using the 2D wave. You can perform this conversion, for example, using the commands:

```
Duplicate/O zWave, zMatrixWave
Redimension/N=(numRows,numColumns) zMatrixWave
```

2D Waves

A 2D wave, sometimes called a "matrix of Z values", is an M-row by N-column wave where each element represents a scalar Z value. You can apply wave scaling (see **Waveform Model of Data** on page II-62) to associate an X value with each row and a Y value with each column.

2D waves can be displayed as 3D graphics in **Surface Plots** and **3D Bar Plots**.

(2D waves can also be displayed as 2D graphics in **Image Plots**, **Contour Plots**, and **Waterfall Plots**.)

Triplet Waves

A triplet wave is an M-row by 3-column wave containing an XYZ triplet in each row. The X value appears in the first column, the Y value in the second and the Z value in the third. A triplet wave is a 2D wave interpreted as containing X, Y and Z coordinates.

Triplet waves can be displayed as 3D graphics in **3D Scatter Plots**, **Surface Plots**, **Path Plots** and **Ribbon Plots**. In a surface plot the triplet wave defines triangles on a surface.

(Triplet waves can also be displayed as 2D graphics in **Contour Plots**.)

3D Waves

A 3D wave, sometimes called a "volume", is an M-row by N-column by L-layer wave where each element represents a scalar Z value. To be used in 3D graphics, 3D waves must contain at least two elements in each dimension.

3D waves can be displayed as 3D graphics in **Surface Plots**, **Isosurface Plots**, and **Voxelgram Plots**.

(3D waves can also be displayed as 2D graphics in **Image Plots** where a single layer of a 3D wave is displayed as an image.)

Gizmo Overview

Igor's 3D plotting tool is called "Gizmo".

Gizmo is based on OpenGL, an industry standard system for 3D graphics. Gizmo converts Igor data and commands into OpenGL data and instructions and displays the result in an Igor window called a "Gizmo window".

You create a Gizmo window by choosing Windows→New→3D Plot and then appending graphic objects using the Gizmo menu. You can do this without any knowledge of OpenGL. At this level you can create surface plots, scatter plots, path plots, voxelgrams, isosurface plots, 3D bar plots and 3D pie charts. Such objects are called "wave-based objects" or "data objects" to differentiate them from drawing objects, discussed next. After creating the basic plot you can modify various properties using Gizmo's "info" window.

Advanced users can also construct graphics using a set of 3D primitives including lines, triangles, quadrangles, cubes, spheres, cylinders, disks, tetrahedra and pie wedges. Such objects are called "drawing objects" to differentiate them from wave-based objects. If you apply proper scaling you can combine drawing objects and wave-based objects in the same Gizmo window.

Gizmo supports advanced OpenGL features such as lighting effects, shininess and textures. Advanced users who want to create sophisticated 3D graphics will benefit from some familiarity with 3D graphics in general and OpenGL in particular.

System Requirements

Much of Gizmo's operation depends on your computer's graphics hardware and its graphics driver software. We suggest running Gizmo on hardware that includes a dedicated graphics card with at least 512MB of VRAM. Gizmo should also work on computers with onboard graphics and shared memory but you will experience slower performance and may encounter errors when exporting graphics.

Hardware Compatibility

Gizmo graphics may be affected by the version of OpenGL that you are running. This depends on your graphics hardware, graphics driver version and graphics acceleration settings.

Gizmo Guided Tour

The tutorials in the following sections will give you a sense of Gizmo's basic capabilities, how you create basic Gizmo plots, and the type of data that you need for a given type of plot.

At various points in the tour you are instructed to execute Igor commands. The easiest way to do this is to open the “3D Graphics” help file using the Help→Help Windows submenu and do the tour from the help file rather than from this manual. Then you can execute the commands by selecting them in the help file and pressing Ctrl-Enter.

Gizmo 3D Scatter Plot Tour

In this tour we will create a triplet wave containing XYZ data which we will plot as a 3D scatter plot.

1. **Start a new experiment by choosing File→New Experiment.**

2. **To create a triplet wave containing XYX scatter data, execute:**

```
Make/O/N=(20,3) data = gnoise(5)
data[][2] = 2*data[p][0] - 3*data[p][1] + data[p][0]^2 + gnoise(0.05)
```

   This scatter data represents random locations in the XY plane with Z values that are approximately equal to a polynomial function in X and Y.

   As we see next, the quickest way to display this data in Gizmo is by right-click selecting "Gizmo Plot" in the Data Browser.

3. **Choose Data→Data Browser.**

   The Data Browser window appears.

4. **Right-click the data wave icon and choose New Gizmo Plot.**

   Igor created a Gizmo 3D scatter plot from the data wave in a new window named Gizmo0.

   It also created the Gizmo info window entitled "Gizmo0 Info".

   (If you don't see the "Gizmo0 Info" window, choose Gizmo→Show Info.)

   You can rotate the Gizmo scatter plot by dragging the contents of the Gizmo0 window and using the arrow keys. Feel free to play.

   ...

   That was entirely too easy and not very instructive so we will redo it without using the Data Browser shortcut.

5. **Start a new experiment by choosing File→New Experiment.**

6. **To create a triplet wave containing XYX scatter data, execute:**

```
Make/O/N=(20,3) data = gnoise(5)
data[][2] = 2*data[p][0] - 3*data[p][1] + data[p][0]^2 + gnoise(0.05)
```

7. **Choose Windows→New→3D Plot.**

   Notice from the history area of the command window that Igor has executed:

```
NewGizmo
```

   Igor also created an empty Gizmo0 window and the Gizmo0 Info window.

   (If you don't see the "Gizmo0 Info" window, choose Gizmo→Show Info.)

8. **Click the + icon at the bottom of the object list in the Gizmo0 Info window and choose Scatter.**

   Igor displays the Scatter Properties dialog.

9. **Choose data from the Scatter Wave menu.**

   This menu displays only triplet waves. If you want to create a 3D scatter plot, you must have a triplet wave.

   There are several additional options but we will leave them in their default states for now.

10. **Click Do It.**

    Igor created a 3D scatter object named scatter0 and added it to the object list in the info window. It is not yet visible in the Gizmo0 window because we have not yet added it to the display list.

11. **Drag the scatter0 object from the object list to the display list.**

    Spheres representing the XYZ data appear in the Gizmo0 window. Although the plot is by no means complete, you can click and drag the body of the Gizmo0 window to rotate the display.

12. **In the Gizmo0 Info window, click the "+" icon at the bottom of the object list and choose Axes.**

    The Axes Properties dialog appears.

13. **Click the Axis tab if it is not already selected.**

    The Axis Type pop-up menu should be set to Box and all of the axis checkboxes (X0, X1...Z2, Z3) should be checked.

14. **Click Do It.**

    Igor created an axes object named axes0 and added it to the object list in the info window. It is not yet visible in the Gizmo0 window because we have not yet added it to the display list.

15. **Drag the axes0 object from the object list to the display list.**

    You now have box axes around the scatter spheres.

16. **Double-click the axes0 object in either the object list or the display list.**

    The Axes Properties dialog reopens.

17. **Click the Ticks and Labels tab.**

18. **Select X0 from the Axis pop-up menu and check the Show Tick Marks and Show Numerical Labels checkboxes.**

19. **Select Y0 from the Axis pop-up menu and check the Show Tick Marks and Show Numerical Labels checkboxes.**

20. **Select Z0 from the Axis pop-up menu and check the Show Tick Marks and Show Numerical Labels checkboxes.**

21. **Click Do It.**

    You now have labeled tick marks for the X0, Y0 and Z0 axes.

    But which axis is which?

22. **Right-click the body of the Gizmo0 window and select Show Axis Cue.**

    Igor adds an axis cue that shows you which dimension is which.

    Rotate the display a bit to get a sense of the axis cue.

    You can also double click the axes0 object and select the Axis tab. The properties dialog displays the box axes. If you now hover with the mouse cursor over any axis you see a tooltip that identifies the axis.

23. **Click the close box of the Gizmo0 Info window.**

    The Gizmo0 Info window is hidden. It is usually of interest while you are constructing or tweaking a 3D plot and can be hidden when you just want to view the plot. You can make it visible at any time by choosing Gizmo→Show Info or by right-clicking the Gizmo0 window and choosing Show Info Window.

24. **Click the close box of the Gizmo0 window.**

    Igor displays the Close Window dialog asking if you want to save the window as a window recreation macro. This works the same as a graph recreation macro.

25. **Click the Save button to save the window recreation macro.**

    The recreation macro is saved in the main procedure window.

26. **Choose Windows→Procedure Windows→Procedure Window.**

    This displays the main procedure window containing the Gizmo0 recreation macro. You may need to scroll up to see the beginning of it which starts with:

    ```
    Window Gizmo0() : GizmoPlot
    ```

27. **Close the procedure window by clicking its close box.**

28. **Choose Windows→Other Macros→Gizmo0.**

    Igor executes the Gizmo0 recreation macro which recreates the Gizmo0 window.

29. **Choose File→Save Experiment and save the experiment as "Gizmo 3D Scatter Plot Tour.pxp".**

    This is just in case you want to revisit the tour later and is not strictly necessary.

At this point, you have completed the construction of a 3D scatter plot. As you may have noticed, there are many scatter plot and axis options that we did not explore. You can do that now, by double-clicking the scatter0 and axes0 icons in the Gizmo Info window, or you can leave that for later and continue with the next section of the tutorial.

Gizmo Surface Plot Tour

In this tour we will create a 2D wave containing Z values which we will plot as a surface plot.

1. **Start a new experiment by choosing File→New Experiment.**
2. **To create a 2D matrix of Z values, execute:**

   ```
   Make/O/N=(100,100) data2D = Gauss(x,50,10,y,50,15)
   ```

   This matrix data represents Z values on a regular grid.

   As you saw in the first tour, the quickest way to display this data in Gizmo is by right-clicking an appropriate wave in the Data Browser and selecting Gizmo Plot. The same shortcut works with a matrix of Z values. But we will do it the hard way as this will give you a better understanding of Gizmo.
3. **Choose Windows→New→3D Plot.**

   Notice from the history area of the command window that Igor has executed:

   ```
   NewGizmo
   ```

   Igor also created an empty Gizmo0 window and the Gizmo0 Info window.
4. **Click the + icon at the bottom of the object list in the Gizmo0 Info window and choose Surface.**

   Igor displays the Surface Properties dialog.
5. **Choose Matrix from the Source Wave Type pop-up menu and data2D from the Surface Wave pop-up menu.**

   There are several additional options but we will leave them in their default states for now.
6. **Click Do It.**

   Igor created a surface object named surface0 and added it to the object list in the info window. It is not yet visible in the Gizmo0 window because we have not yet added it to the display list.
7. **Drag the surface0 object from the object list to the display list.**

   The surface appears in the Gizmo0 window. You are now looking at it from the top.
8. **Using the mouse, rotate the surface in the Gizmo0 window to reorient it so you can see the side view of the Gaussian peak.**
9. **In the Gizmo info window, click the "+" icon at the bottom of the object list and choose Axes.**

   The Axes Properties dialog appears. Click the Axis tab if it is not already selected.
10. **Click the Axis tab if it is not already selected.**

    The Axis Type pop-up menu should be set to Box and all of the axis checkboxes (X0, X1...Z2, Z3) should be checked.
11. **1Click Do It.**

    Igor created an axis object named axes0 and added it to the object list in the info window. It is not yet visible in the Gizmo0 window because we have not yet added it to the display list.
12. **Drag the axes0 object from the object list to the display list.**

    You now have box axes around the surface plot.
13. **Double-click the axes0 object in the display list. Using the resulting Axes Properties dialog, turn on tick marks and tick mark labels for the X0, Y0 and Z0 axes.**

    This is the same as what we did in the preceding tour.

    Now we will add a colorscale annotation.
14. **Choose Gizmo→Add Annotation.**

    The Add Annotation dialog appears.
15. **From the Annotation pop-up menu in the top/left corner of the dialog, choose ColorScale.**
16. **Click the Position tab and set the Anchor pop-up menu to Right Center.**

17. **Click the ColorScale Main tab and set the following controls as indicated:**

    Color Table: Rainbow

    Axis Range/Top: 100

    Axis Range/Bottom: 0

18. **Click Do It.**

    Igor creates the colorscale annotation.

    Note that its tick mark labels don't agree with the Z axis tick mark labels in the surface plot. We need to set the colorscale range to match the range of the data. We will do this by re-executing the command that created the colorscale.

19. **Click on the last command in the history area of the command window and press Enter to copy it to the command line.**

    The command line should now show this:

    ```
    ColorScale/C/N=text0/M/A=RC ctab={0,100,Rainbow,0}
    ```

20. **Edit the command as shown next and press Enter to execute it:**

    ```
    ColorScale/C/N=text0/M/A=RC ctab={WaveMin(data2D),WaveMax(data2D),Rainbow,0}
    ```

    Now the colorscale tick mark labels agree with the Z axis tick mark labels in the surface plot.

    Next we will add an image plot beneath the surface plot.

21. **In the Gizmo info window, click the "+" icon at the bottom of the object list and choose Image.**

    The Gizmo Image Properties dialog appears.

22. **Set the Source Type to 2D Matrix of Z Values, and select data2D from the Source Wave pop-up menu.**

    We will use the same wave as the source for both the surface plot and the image.

23. **From the Intitial Orientation pop-up menu, choose XY Plane Z=0.**

24. **Uncheck all checkboxes except Translate and set the X, Y, and Z components of the translation to 0, 0, and -1 respectively.**

    The translation in the Z direction moves the image from the center of the display volume to the bottom of the display volume, placing it on the "floor" of the surface plot.

25. **Click Do It.**

    Igor created an image object named image0 and added it to the object list in the info window. It is not yet visible in the Gizmo0 window because we have not yet added it to the display list.

26. **Drag the image0 object from the object list to the display list.**

    You now have an image plot below the surface plot. You may need to rotate the display to see it.

27. **Double-click the image0 object in the object list, set the Z translation to -1.5, then click Do It.**

28. **This separates the image plot from the surface plot, making it easier to see.**

    The translation parameters are in +/-1 display volume units, not in the units of the axes. Display volume units are used in many instances, especially when dealing with drawing objects such as spheres and boxes.

29. **Choose File→Save Experiment and save the experiment as "Gizmo Surface Plot Tour.pxp".**

    This is just in case you want to revisit the tour later and is not strictly necessary.

Gizmo 3D Scatter Plot and Fitted Surface Tour

In this tour we will create a 3D scatter plot from a triplet wave, perform a curve fit, and append a surface showing how the curve fit output relates to the original scatter data.

1. **Start a new experiment by choosing File→New Experiment.**
2. **To create a triplet wave containing XYX scatter data, execute:**

```
Make/O/N=(20,3) data = gnoise(5)
data[][2] = 2*data[p][0] - 3*data[p][1] + data[p][0]^2 + gnoise(0.05)
```

This scatter data represents random locations in the XY plane with Z values that are approximately equal to a polynomial function in X and Y.

3. **Choose Data→Data Browser.**

   The quickest way to display this data in Gizmo is by right-click selecting "Gizmo Plot" in the Data Browser.

4. **Right-click the data wave icon and choose New Gizmo Plot.**

   Igor created a Gizmo 3D scatter plot from the data wave in a new window named Gizmo0.

5. **In the command line, execute:**

   ```
   CurveFit/Q poly2d 2, data[][2]/X=data[][0,1] /D
   ```

   Igor performs a 2D polynomial curve fit and produces output waves and variables. The main output is in the wave fit_data.

6. **Close the Data Browser window.**

   This is just to reduce clutter on your screen.

   Next we will now add a surface to the Gizmo plot.

7. **Click the + icon at the bottom of the object list in the Gizmo0 Info window and choose Surface.**

   Igor displays the Surface Properties dialog.

8. **Choose Matrix from the Source Wave Type pop-up menu and fit_data from the Surface Wave pop-up menu.**

   There are several additional options but we will leave them in their default states for now.

9. **Click Do It.**

   Igor created a surface object named surface0 and added it to the object list in the info window. It is not yet visible in the Gizmo0 window because we have not yet added it to the display list.

10. **Drag the surface0 object from the object list to the display list.**

    The surface appears in the Gizmo0 window and appears to fit the scatter objects pretty well.

11. **Using the mouse, rotate the contents of the Gizmo plot to inspect the fit from various angles.**

12. **Choose File→Save Experiment and save the experiment as "Gizmo 3D Scatter Plot and Fitted Surface Tour.pxp".**

    This is just in case you want to revisit the tour later and is not strictly necessary.

Gizmo Surface Using Voronoi Interpolation Tour

We have already seen how to create a surface plot from a 2D matrix of Z values. In this tour we illustrate the how to plot a 3D surface representation of XYZ scatter data. The process involves triangulation of the XYZ data using Voronoi interpolation.

1. **Start a new experiment by choosing File→New Experiment.**

2. **To create a triplet wave containing XYZ scatter data, execute:**

   ```
   Make/O/N=(20,3) data = enoise(5)
   data[][2] = 2*data[p][0] - 3*data[p][1] + data[p][0]^2 + gnoise(0.05)
   ```

3. **Choose Data→Data Browser.**

4. **Right-click the data wave icon and choose New Gizmo Plot.**

   Igor created a Gizmo 3D scatter plot from the data wave in a new window named Gizmo0.

   Next we will triangulate the scatter data using Voronoi interpolation.

5. **Execute this in the command line:**

```
ImageInterpolate/S={-5,0.1,5,-5,0.1,5}/CMSH Voronoi data
```

The Voronoi interpolation created two waves: M_ScatterMesh and M_InterpolatedImage. M_ScatterMesh consists of a series of XYZ coordinates that define polygons in 3D space which fit the scatter data. We will use M_ScatterMesh to append a surface to the 3D plot.

6. **Click the + icon at the bottom of the object list in the Gizmo0 Info window and choose Surface.**

Igor displays the Surface Properties dialog.

7. **Choose Triangles from the Source Wave Type pop-up menu and M_ScatterMesh from the Surface Wave pop-up menu.**

There are several additional options but we will leave them in their default states for now.

8. **Click Do It.**

Igor created a surface object named surface0 and added it to the object list in the info window. It is not yet visible in the Gizmo0 window because we have not yet added it to the display list.

9. **Drag the surface0 object from the object list to the display list.**

The surface appears in the Gizmo0 window.

10. **Using the mouse, rotate the contents of the Gizmo plot to inspect the fit from various angles.**

The surface fits the scatter objects pretty well.

11. **Double-click the surface0 object in the display list, click the Grid Lines and Points tab, check the Draw Grid Lines checkbox, and click Do It.**

This shows the polygons created by Voronoi interpolation and represented by the M_ScatterMesh wave.

12. **Clean up by executing:**

```
KillWaves M_InterpolatedImage
Rename M_ScatterMesh, VoronoiMesh
```

It's a good idea to rename waves that Igor creates with default wave names so that, if you later execute another command that uses the same default wave name, you will not inadvertently overwrite data. Also we don't need the M_InterpolatedImage wave.

13. **Choose File→Save Experiment and save the experiment as "Gizmo Surface Using Voronoi Interpolation Tour.pxp".**

This is just in case you want to revisit the tour later and is not strictly necessary.

That concludes the Gizmo guided tour. There are more examples below. Also choose File→Example Experiments→Visualization for sample experiments.

Gizmo Windows

For each 3D plot, Gizmo creates a display window and its associated info window. The display window presents a rotatable representation of your 3D objects. You use the info window to control which objects are displayed, the order in which they are drawn, and their properties. You can hide both windows to reduce clutter when you do not need them. You can also kill and recreate Gizmo windows like you kill and recreate graphs.

You can create any number of Gizmo display windows. Keeping multiple Gizmo display windows open has some drawbacks. Even inactive and hidden Gizmo display windows consume graphics resources that could otherwise be used for the active Gizmo display window. Also, in some laptop computers you may be able to reduce power consumption by closing Gizmo display windows that include rotating objects. Depending on your hardware, saving unused Gizmo display windows as recreation macros may be beneficial.

For brevity, we sometimes use the term "Gizmo window" to refer to the Gizmo display window. We use "Gizmo info window" or "info window" to refer to the Gizmo info window.

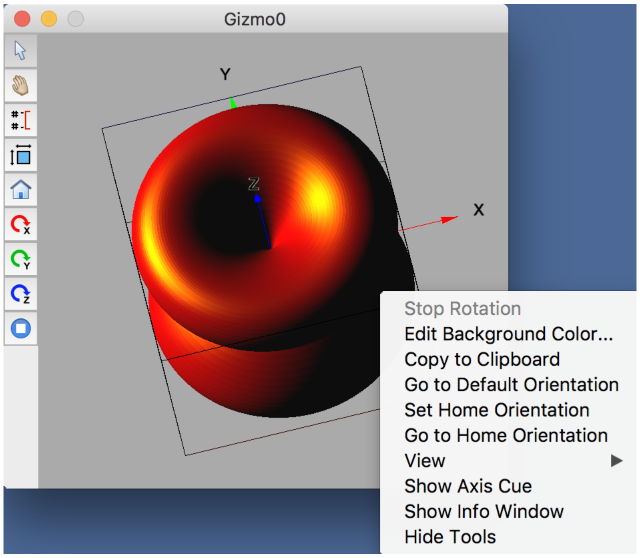
The Gizmo Display Window

The Gizmo display window presents a rotatable 3D display of objects representing waves and 3D drawing primitives as specified by the display list in the associated Gizmo info window.

You can display a palette of tools by choosing Gizmo→Show Tools.

You can access a pop-up menu to modify the appearance of the Gizmo display window by right-clicking (Windows) or Ctrl-clicking (Macintosh) in the display window.

Here is what the display window looks like with the tool palette and pop-up menu showing:



You can rotate the scene in the window by clicking and dragging the mouse as if you were rotating a virtual trackball positioned at the center of the window. You can also use the tool palette, mouse wheel, cursor keys and the x, y, z keys on your keyboard to rotate the scene.

Gizmo Display Window Tool Palette

To display the Gizmo tool palette, choose Gizmo→Show Tools or right-click and choose Show Tools. The tool palette contains the following icons, from top to bottom:

Arrow Tool

When the arrow tool is selected, dragging the body of the display window rotates the 3D scene. The arrow tool and the hand tool are mutually exclusive.

Hand Tool

When the hand tool is selected, dragging the body of the display window pans the 3D scene. The arrow tool and the hand tool are mutually exclusive.

Axis Tool

Clicking the axis tool displays the Axis Range dialog. This is equivalent to choosing Gizmo→Axis Range.

Aspect Ratio Tool

Toggles "aspect ratio" mode.

When aspect ratio mode is off, the length of each axis is the same.

When aspect ratio mode is on, the length of each axis is proportional to the range of data displayed against that axis.

Home Tool

Clicking the home tool sets the X, Y and Z rotation angles to 0 or to some other orientation that you designated as "home".

Rotate About X

Clicking the Rotate About X tool starts the 3D scene rotating about the X axis. To stop it, click the Stop tool or click once in the body of the display window.

Rotate About Y

Clicking the Rotate About Y tool starts the 3D scene rotating about the Y axis. To stop it, click the Stop tool or click once in the body of the display window.

Rotate About Z

Clicking the Rotate About Z tool starts the 3D scene rotating about the Z axis. To stop it, click the Stop tool or click once in the body of the display window.

Stop Tool

Clicking the stop tool stops all rotation.

Gizmo Display Window Contextual Menu

The Gizmo Display contextual menu provides shortcuts for common tasks. It contains the following items, from top to bottom:

Stop Rotation

Stops the rotation of the 3D scene, if any.

Edit Background Color

Sets the background color for the Gizmo window.

Copy to Clipboard

Copies the Gizmo plot to the clipboard using the format set in the Export Graphics dialog (Edit menu).

Go to Default Orientation

Sets the orientation of the 3D space to the orientation in effect when a new Gizmo window is first created.

Set Home Orientation

Stores the current orientation as the orientation to be used when Go to Home Orientation is selected or the Home icon in the tool palette is clicked.

Go to Home Orientation

Rotates the 3D scene to the home orientation.

View

Rotates the 3D scene to one of several preset orientations.

Show Axis Cue

Displays arrows showing the X, Y and Z directions.

Show Info Window

Shows the Gizmo info window associated with the active Gizmo display window.

Show Tools

Shows the Gizmo tool palette.

Match Window Size

Sets another Gizmo display window to the same size as the active Gizmo display window.

This item appears only if you have multiple Gizmo display windows.

Rotate to Match

Rotates another Gizmo display window to the same orientation as the active Gizmo display window.

This item appears only if you have multiple Gizmo display windows.

Sync to Gizmo

Locks the rotation of the current Gizmo plot to the same orientation as the another Gizmo plot. If you rotate the other plot, both rotate to the same orientation.

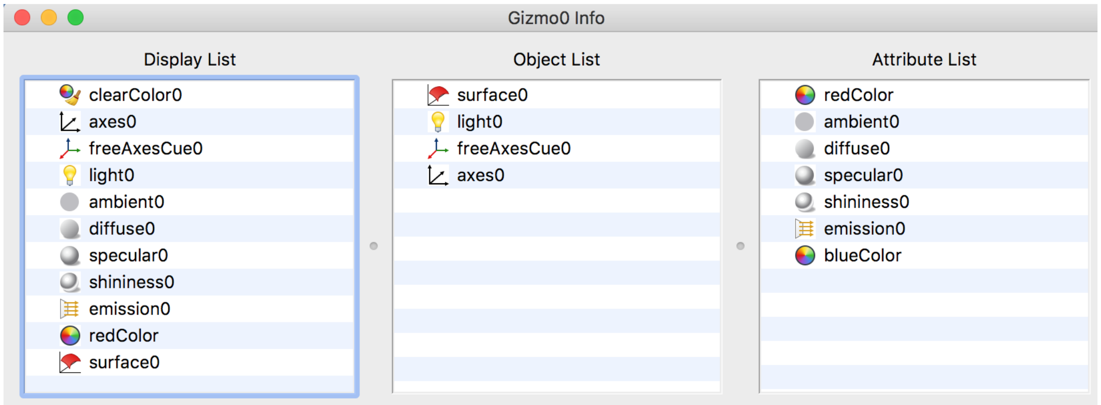
To have mutual syncing you must set each window to be synced to the other.

This item appears only if you have multiple Gizmo display windows.

The Gizmo Info Window

The Gizmo info window is the main user interface for controlling the display of objects in the Gizmo display window. Each info window has an associated Gizmo display window that shows the resulting graphical plot.

The info window contains three lists: the display list, the object list, and the attribute list. You use these lists to add objects and to modify their appearance in the Gizmo display window. Only items that appear in the display list are actually drawn in the Gizmo display window.



Gizmo0 Info

Display List	Object List	Attribute List
clearColor0	surface0	redColor
axes0	light0	ambient0
freeAxesCue0	freeAxesCue0	diffuse0
light0	axes0	specular0
ambient0		shininess0
diffuse0		emission0
specular0		blueColor
shininess0		
emission0		
redColor		
surface0		

You can create objects using the + icon at the bottom of the object list. Clicking the + icon displays a menu from which you choose the type of object to add. The + icon below the attribute list adds attributes while the + icon below the display list adds operations.

The object list contains only objects and the attribute list contains only attributes. The display list can contain objects dragged in from the object list, attributes dragged in from the attribute list, and operations.

You can edit an item's properties by double-clicking its icon or by selecting it and clicking the gear icon below the list. You can remove an item from a list by selecting it and pressing the delete key or by clicking the - icon.

If you have two or more open Gizmo windows in one experiment you can have two or more open info windows. You can then drag an attribute from the attribute list of one Info window and drop it in the attribute list of another info window. You can drag an object from the object list of one info window and drop it in the object list of another info window. If you drag an object from the object list of one info window and drop it in the display list of another info window, Igor also creates the corresponding entry in the object list of the receiving window.

It is not possible to drag and drop objects between info windows belonging to two instances of Igor.

The Gizmo Object List

The middle list in the info window is the object list. It lists all of the objects that you have created which are then available for use in the display list.

Gizmo supports many types of objects including wave-based objects such as surface plots and drawing primitives such as spheres. If you click the + icon under that object list you see a menu of the available object types. See **Gizmo Objects** on page II-418 for details.

For an object to appear in the Gizmo plot, you must drag it to the display list.

The Gizmo Display List

The display list controls what actually appears in the Gizmo display window. Gizmo processes the items in the display list in the order in which they appear.

In addition to objects that you drag in from the object list and attributes that you drag in from the attribute list, you can add the following operations to the display list:

ClearColor, ColorMaterial, Translate, Rotate, Scale, Main Transformation, Enable, Disable and Ortho.

Using the ColorMaterial, Enable and Disable operations requires some familiarity with OpenGL.

The Main Transformation item is used in conjunction with lighting. This is described under **Gizmo Positional Lights** on page II-434.

The Ortho operation controls the projection of the 3D space onto the 2D screen. This is described under **Gizmo Projections** on page II-422.

If you are familiar with OpenGL, you should note that Gizmo automatically generates a small number of OpenGL instructions e.g., viewing transformation, default lighting, etc., that are not visible on the list. If you provide your own alternatives the various defaults are simply not executed. For example, by default Gizmo provides a neutral ambient light to illuminate the scene. However, if you add one or more lights to the display list, the default ambient light is omitted.

Item Ordering in the Gizmo Display List

You can reorder items in the display list by dragging and dropping them in the desired locations. The order of items in the display list is important because it determines the order of execution of OpenGL drawing instructions which govern the appearance of the plot. This becomes obvious when you use operations such as translation, rotation, or scaling.

There are a few items for which the exact position in the list does not make any difference, but in the majority of cases a change in the order of items produces a visible change in the display. For example, if you switch the order of rotation and translation operations you will get a completely different result; see **Gizmo Object Rotation** on page II-424 for an example.

The Gizmo Attribute List

The attribute list appears on the right side of the info window.You create an attribute by clicking the + icon and selecting the type of attribute you want. You then drag that attribute into the display list as a global attribute or on top of an item in the object list as an embedded attribute.

The order of items in the attribute list is unimportant.

Attributes are discussed in detail under **Gizmo Attributes** on page II-419.

Gizmo Objects

There are five main categories of Gizmo objects: wave-based objects, axis objects, drawing primitive objects, lights, and miscellaneous objects.

Wave-based Gizmo objects, also called "data objects", get their data from waves and include the following types:

- **Path Plots**
- **Ribbon Plots**
- **Surface Plots**
- **Isosurface Plots**
- **Voxelgram Plots**
- **3D Scatter Plots**
- **3D Bar Plots**
- **Gizmo Image Plots**

Axis object types include:

- **Axis Objects**
- **Axis Cue Objects**

Drawing primitive object types include:

- **Line Objects**
- **Triangle Objects**
- **Quad Objects**
- **Box Objects**
- **Sphere Objects**
- **Cylinder Objects**
- **Disk Objects**
- **Tetrahedron Objects**
- **Pie Wedge Objects**

There is only one light object type:

- Light Objects (see **Gizmo Colors, Material and Lights** on page II-428)

Miscellaneous object types include:

- **Group Objects**
- **Texture Objects**
- **Matrix4x4 Objects**

You create an object by clicking the + icon below the object list in the info window for a given Gizmo display window.

An object of a given type has a set of internal properties that you can edit when you first create the object. You can edit them later by double-clicking the object in the object or display lists.

Creating a Gizmo object puts it in the object list. It is not displayed until you drag it to the display list. You can drag a given object to the display list multiple times. This creates an new display object each time.

Gizmo Attributes

A Gizmo attribute encapsulates a setting which you can then apply to the Gizmo display list as a global attribute or to a specific Gizmo object as an embedded attribute.

Gizmo supports the following types of attributes:

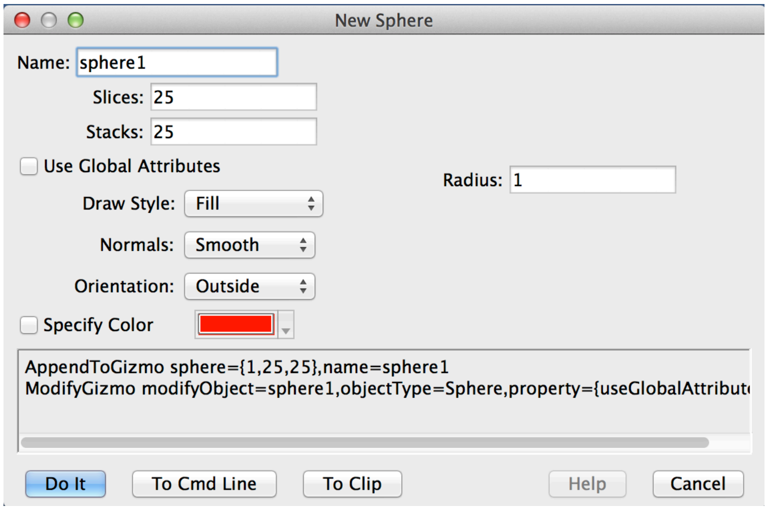
- Color
- Ambient
- Diffuse
- Specular
- Shininess
- Emission
- Blending
- Point size
- Line width
- Alpha test function

You create an attribute using the attribute list in the info window. You can then drag the attribute to the display list as a global attribute or into an object in the object list as an embedded attribute.

In addition to global and embedded attributes, Igor7 added internal attributes, described in the next section.

Internal Attributes

Internal attributes are built into objects. For example, the New Sphere dialog looks like this:



Name: sphere1

Slices: 25

Stacks: 25

□ Use Global Attributes

Radius: 1

Draw Style: Fill

Normals: Smooth

Orientation: Outside

□ Specify Color 🟥

```
AppendToGizmo sphere={1,25,25},name=sphere1
ModifyGizmo modifyObject=sphere1,objectType=Sphere,property={useGlobalAttribut
```

The draw style, normals, orientation and color settings are internal attributes of the sphere object.

The Use Global Attributes checkbox disables the controls under it and enables the use of the respective global attributes for the object in question. It does not affect the use of other global attributes.

The Specify Color checkbox does the same for color. If unchecked, the object has no intrinsic color. In this case you must add a color material operation and a color attribute to the display list before the object. If Specify Color is checked, Gizmo creates a default color material for the object and uses the specified internal color attribute.

Prior to Igor7 Gizmo supported no internal attributes so you had to use global or embedded attributes. We now recommend that you use internal attributes if they are available in preference to global or embedded attributes.

Global Attributes

When you drag an attribute to the display list, it acts as a global attribute that affects all objects later in the display list.

If you place an attribute such as color in the display list, OpenGL draws all subsequent objects that do not have an internal color specification using this global color. You also need a color material operation in order to see the applied color.

Internal attributes and embedded attributes override global attributes.

Embedded Attributes

Embedded attributes are deprecated and are supported mainly for backward compatibility. We don't recommend their use in new projects because primitive obects now have their own internal attributes which should be used instead.

When you drag an attribute on top of an object in the object list, it becomes embedded in that object. You can embed a given attribute in any number of objects and you can embed any number of attributes in a given object.

For example, if you create a sphere object and you want it to appear in blue, you can create a blue color attribute in the attribute list and drop it on top of the sphere object in the object list. The advantage of doing so, as opposed to directly setting the internal color attribute of the sphere object, is in allowing you to reuse the same color attribute with multiple objects. With this approach, by changing a single attribute you can change the color of all associated objects.

Internal attributes override embedded attributes and global attributes.

When an object with embedded attributes is drawn, Gizmo first stores the state of the drawing environment. It then executes the embedded attributes immediately before the object is drawn and finally it restores the state of the drawing environment. As a result, embedded attributes affect only the object in which they are embedded.

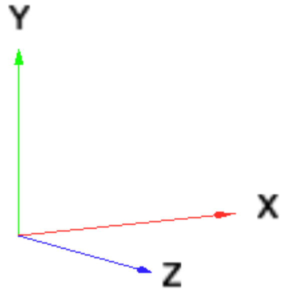
If you apply conflicting attributes to a given object, only the last attribute in the embedded list affects the object appearance. For example, if you have a sphere object with the following embedded attributes: red color, blue color and green color, the sphere is drawn in green.

Gizmo Display Environment

Gizmo constitutes an environment for displaying 3D graphics. This section discusses the main properties of that environment.

Gizmo Coordinate System

Gizmo uses a right-handed, 3D coordinate system. If the positive X axis points to the right and the positive Y axis points up then, by the right-hand rule, the positive Z axis points out of the screen towards you.



Gizmo Dimensions

The default Gizmo viewing volume is a space that is 4 units wide in all three dimensions. The actual display volume is two units in each dimension, centered in the middle of the viewing volume. Each dimension of the display volume extends from -1 to +1 about the origin. The display volume is smaller than the viewing volume to avoid clipping at the corners when the plot is rotated.

All drawing objects, such as spheres and cylinders, are sized in units of the +/-1 display volume. So, for example, if you create a box that is 2 units on a side, it completely fills the display volume. If you create a cylinder that is 3 units high, then the top of the cylinder is clipped because it extends outside the viewing volume boundary.

Superimposed on the display volume and precisely filling it is an axis coordinate system against which wave-based data objects such as scatter and surface plots are plotted. You can set the axis coordinate range for each dimension by choosing Gizmo→Axis Range. The axis coordinate system exists even though, by default, no axes are visible.

The axis coordinate system is autoscaled by default. Consequently, when you initially display a wave-based object, it fills the range of each axis. Since the axis coordinate system fills the display volume, the displayed wave-based object also fills the display volume.

When you display two or more wave-based objects at the same time while the axes are set to autoscale, Gizmo sets the range of each axis based on the minimum and maximum in the respective dimension of all data objects combined.

Once you turn autoscaling off, the axis range that you set determines the extent to which wave-based objects fill the display volume.

When you combine drawing objects and wave-based objects, the dimensions and positions of the drawing objects remain in +/-1 display volume units whereas the wave-based objects are displayed against the axis coordinate system.

Gizmo Clipping

When you set the range of any axis, you may use values that do not include the full range of the data. To display the results correctly in this case, Gizmo creates clipping planes on the relevant sides of the display volume. Once created, these clipping planes affect both wave-based data objects and drawing objects. The clipping planes are not created unless a data object extends beyond the range of the axes.

If you want to do your own clipping, this automatic Gizmo clipping may intefere. To disable automatic clipping, for example for a surface object named surface0, you can execute:

```
ModifyGizmo modifyObject=surface0, objectType=surface, property={Clipped,0}
```

If you are working in advanced mode (see **Advanced Gizmo Techniques** on page II-466), you can create custom clipping planes to create special effects such as gaps in a surface plot. To use clipping planes, make sure that you are not using an axis range that is smaller than the span of the data in any dimension. Current graphics hardware support 6 to 8 clipping planes and axis-range clipping planes have a priority. For an example, open the Clipping Demo experiment.

Gizmo Projections

A number of different projections can be used to control the display of 3D objects in a 2D Gizmo window.

By default Gizmo uses a built-in default orthographic projection which does not appear in the display list. The default orthographic projection is ideal for most applications.

Gizmo calculates the parameters to use with the default orthographic projection by scanning all objects in the display list and computing their largest extent. The default orthographic projection will be 2 units in all directions which allows full rotation of wave-based objects without clipping.

The automatic scanning of objects on the display list does not take into account optional translation, rotation, or scaling operations. If you use any of these in the display list you should also provide a separate ortho operation with the appropriate definition of the projected space.

To add a projection operation, click the + icon under the display list. By default the only projection offered is Ortho and this is sufficient for nearly all purposes. In order to choose another type of projection you must check the Display Advanced Options Menus checkbox in the Gizmo section of the Miscellaneous Settings dialog which you can access via the Misc menu.

You can have any number of projection operations on the display list. When there is more than one projection Gizmo executes only the last one.

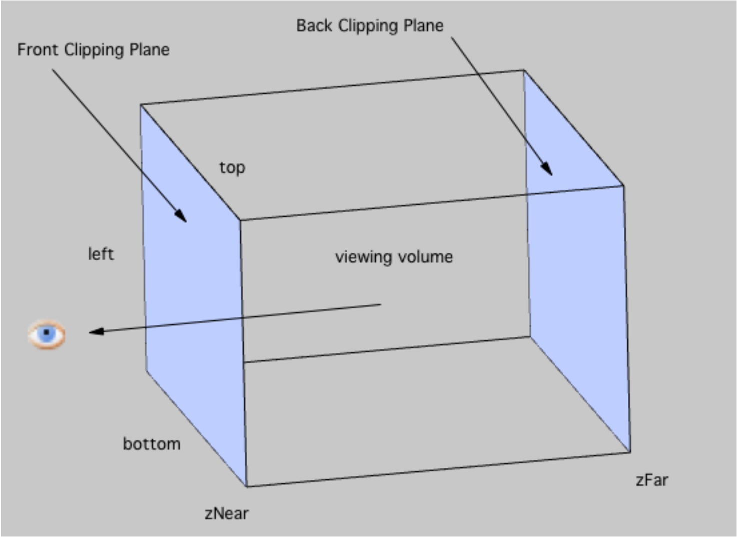
When you are using a projection other than Ortho you must also specify the viewing angle. As a result, the standard mouse rotation and mouse wheel zoom do not apply.

Orthographic

The orthographic projection maintains the geometric orientations and scalings of 3D objects. This is the default projection for the Gizmo display window and is recommended for most purposes.

Unlike perspective projection, discussed in the next section, orthographic projection preserves object parallelism and there is no object foreshortening. Orthographic projection is analogous to an arrangement where dimensions of objects in the displayed scene are small compared to the viewing distance. Another way to think of it is that the image plane is perpendicular to one of the coordinate axes. Only objects contained within the viewing volume are visible. This projection is also faster than perspective.

As shown in this diagram, the ortho projection depends on 6 parameters: left, right, bottom, top, zNear and zFar. The parameters are measured from the center of the display volume and are expressed in +/-1 display volume units.

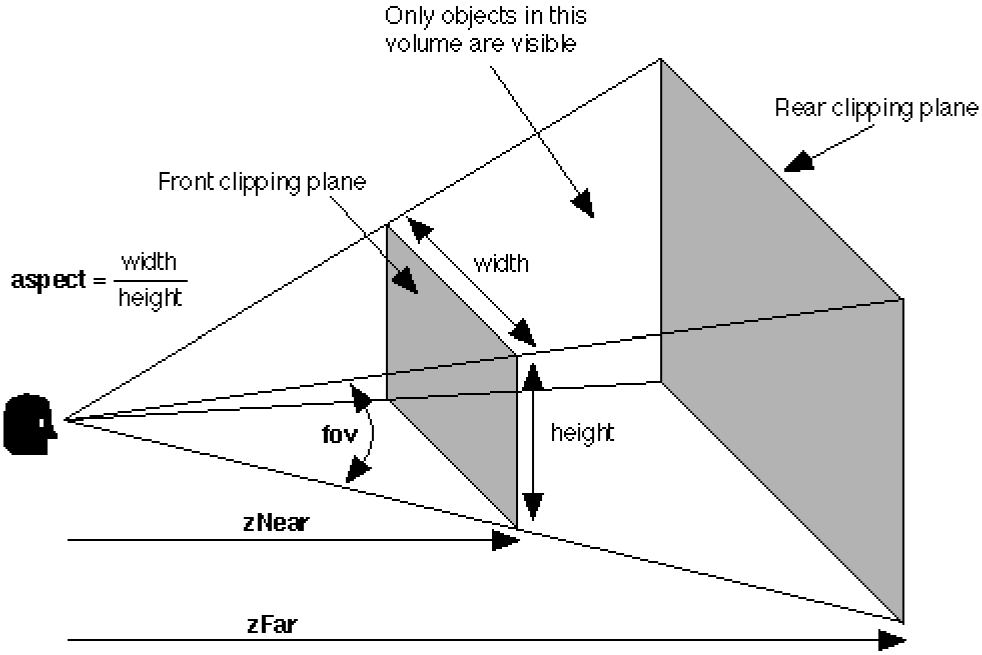


The zoom (using the mouse wheel) and pan tools are implemented by modifying the default ortho projection. If you add your own projection to the display list, the zoom tool is disabled.

Perspective

The perspective projection simulates the way your eye sees 3D objects. Although this is a realistic projection, it does not preserve the exact orientations or shapes of objects; for example, parallel lines may diverge or converge and there is foreshortening of objects. The viewing area is in the shape of a truncated pyramid in which the top has been cut off parallel to the base. Only objects within the viewing volume are visible. This is a symmetric perspective view of the viewing volume; a frustum, discussed in the next section, supports an asymmetric volume.

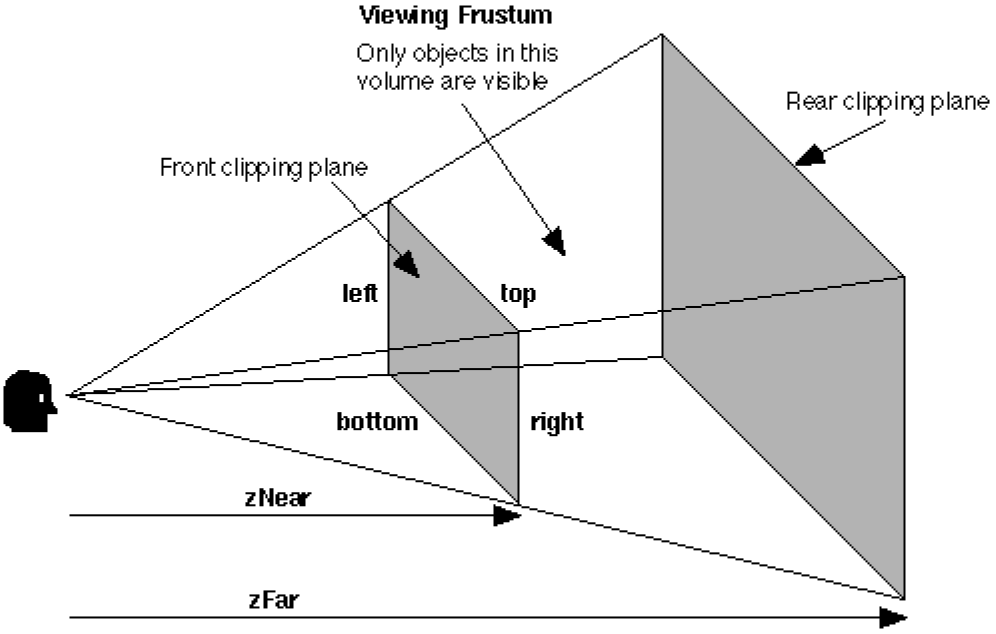
As shown in this diagram, the perspective projection depends on 4 parameters: fov, aspect, zNear and zFar.



Frustum

The frustum projection is essentially the same as the perspective projection, but in this case it has more flexible settings, which means that it does not have to be symmetrical or aligned with the Z axis.

As shown in this diagram, the frustrum projection depends on 6 parameters: left, right, bottom, top, zNear and zFar.



Viewport

A viewport is the rectangular 2D region of the window where the projected scene is drawn. You can use this to scale and distort the scene in the Gizmo display window.

The viewport projection depends on 4 parameters: left, bottom, width and height.

LookAt

A LookAt projection maps the center point to the negative Z axis, the eye point to the center, and the up vector to the Y axis. It may be useful if you want to change the origin of the coordinate system and the basic orientation.

Gizmo Object Rotation

You can click in a Gizmo display and drag the mouse to rotate the plot. The default rotation is implemented as if there is a virtual trackball in the center of the Gizmo window. Rotation through a positive angle is in a counterclockwise direction when viewed along the ray from the origin.

When experimenting with rotation it is helpful to display the axis cue which shows the X, Y and Z directions. Right-click and choose Show Axis Cue. The axis cue shows the orientation of the main Gizmo axes.

You can rotate the plot using the keyboard when a Gizmo display window is active. Press the x, y, or z keys to rotate the display counterclockwise in 1-degree increments about the respective axis. Press the shift key along with x, y, or z to rotate clockwise.

The up arrow and down arrow keys rotate the plot about a horizontal line drawn through the middle of the display area. The left arrow and right arrow keys rotate the plot about a vertical line drawn through the middle of the display area.

By default the mouse scroll wheel zooms the plot. You can change it to rotate the plot using a miscellaneous setting. Choose Misc→Miscellaneous Settings and click Gizmo in the list on the left to see the Gizmo miscellaneous settings. Using the mouse scroll wheel for scrolling behaves the same as using the arrow keys.

You can start the 3D scene rotating continuously by clicking and gently flinging with the mouse. This requires releasing the mouse button before stopping mouse movement. Click the plot once to stop continuous rotation. If the display pans instead of rotates then click the arrow tool in the Gizmo tool palette to enable rotation.

You can also start continuous rotation using the tool palette. Choose Gizmo→Show Tools and then click one of three rotation icons to start rotation about the X, Y or Z axis. Click the plot once or click the stop icon in the tool palette to stop rotation.

The Home icon in the tool palette rotates the scene to the home orientation. By default the home orientation is X=0, Y=0, Z=0. In this case, the positive X axis points to the right, the Y axis points up and the Z axis points out of the plane of the window toward you. You can set the home orientation by right-clicking and choosing Set Home Orientation.

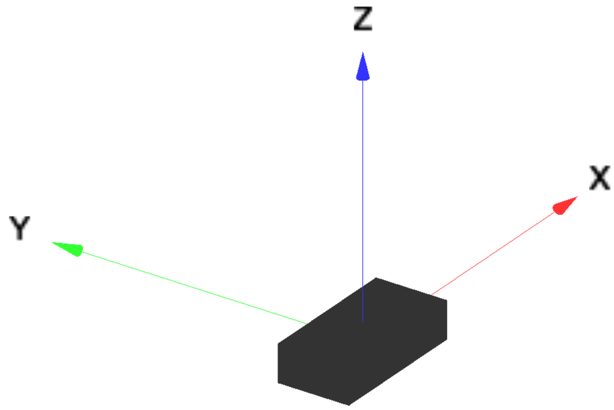
During continuous rotation you can use the x, y and z keys to tweak the orientation.

Gizmo Object Rotation and Translation

In the preceding section we discussed rotation of the entire Gizmo plot about the main Gizmo axes. Each Gizmo object has its own set of axes which, by default, correspond to the main axes. Though this is less frequently needed, it is possible to rotate a Gizmo object's axes independent of the main Gizmo axes. You do this by adding a rotate operation to the display list.

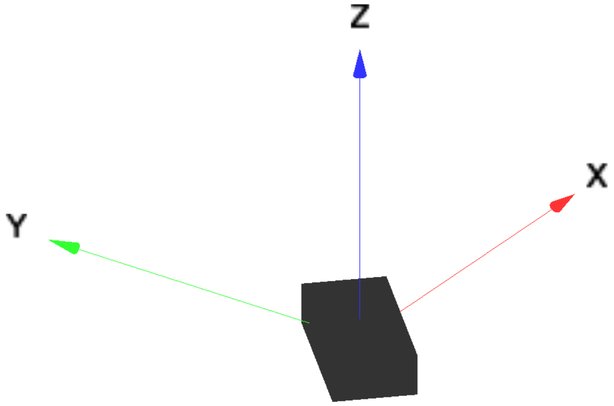
To see this we create a Gizmo with an axis cue and an unrotated box:

```
NewGizmo
ModifyGizmo showAxisCue=1
ModifyGizmo setQuaternion={0.435,-0.227,-0.404,0.777}
AppendToGizmo box={0.5,0.25,0.15}, name=box0
ModifyGizmo setDisplayList=0, object=box0
```



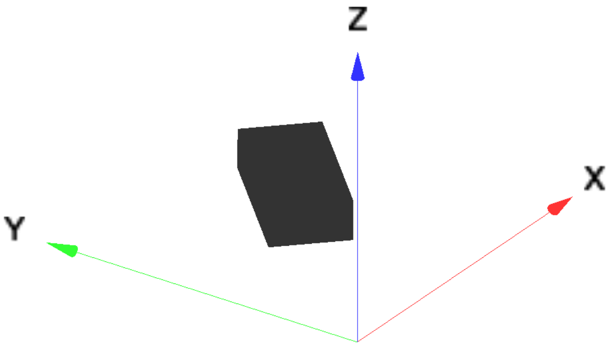
We then add a rotate operation to the display list, before the box object. This rotates the box object's axes by 45 degrees:

```
ModifyGizmo insertDisplayList=0, opName=rotate0, operation=rotate,
      data={45,0,0,1}
```



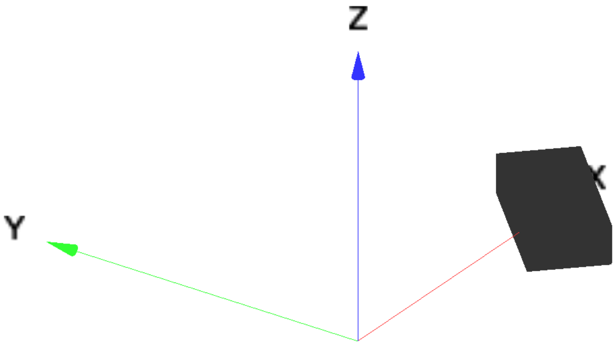
Now we insert a translation along the X axis:

```
ModifyGizmo insertDisplayList=1, opName=translate0, operation=translate,
      data={1,0,0}
```



The translation is along to the object's X axis, not the main X axis. Because of this, rotation followed by translation gives a different result than translation followed by rotation. To illustrate this we switch the order of the operations:

```
ModifyGizmo setDisplayList=0, opName=translate0, operation=translate,
      data={1,0,0}
ModifyGizmo setDisplayList=1, opName=rotate0, operation=rotate, data={45,0,0,1}
```



In this last case, at the time the translation was done, the object's axes were aligned with the main axes. The translation was along the object's X axis which pointed in the same direction as the main X axis.

Translate and rotate operations apply to all objects below them on the display list. They are cumulative. In other words, a translate or rotate operation on a given object starts from the current position or rotation of the object when the operation is applied.

Programming Rotations in Gizmo

The orientation of the Gizmo plot is stored internally as a quaternion. A quaternion is analogous to a complex number but extended to 3 dimensions.

When you manually rotate the plot you are changing the internal quaternion. You can query it using **GetGizmo** curQuaternion.

There are a number of **ModifyGizmo** keywords that programmatically set the orientation. The setQuaternion, setRotationMatrix, and euler keywords set the orientation in absolute terms and take a quaternion parameter, a transformation matrix, or a set of Euler angles, respectively. The appendRotation keyword applies a rotation specified by a quaternion to the current orientation. The goHome keyword goes to the home orientation. The idleEventQuaternion and idleEventRotation keywords change the orientation periodically. The matchRotation keyword sets the orientation to match another Gizmo window. The syncRotation keyword syncs one Gizmo window's rotation to that of another. The stopRotation keyword stops rotation.

No matter how you set the orientation it is stored internally as a quaternion.

If you want to rotate Gizmo's display so that the X axis points to the right, the Y axis points away from you, and the Z axis points up, you need a quaternion for rotation of 90 degrees about the X axis. This can be accomplished using the command

```
ModifyGizmo setQuaternion={sin(pi/4),0,0,cos(pi/4)}
```

If you want to rotate the plot to the orientation specified by an axis of rotation and an angle about that axis, you first need to convert those inputs into a quaternion. For an axis of rotation given by Ax, Ay, Az and an angle theta in radians, the rotation quaternion consists of the four elements:

```
Qx = Ax*sin(theta/2)/N
Qy = Ay*sin(theta/2)/N
Qz = Az*sin(theta/2)/N
Qw = cos(theta/2)
```

where we normalized the rotation vector using N=sqrt(Ax^2+Ay^2+Az^2).

To compute a rotation quaternion that represents two consecutive rotations, i.e., a rotation specified by quaternion q1 followed by a rotation specified by quaternion q2, we need to compute the product quaternion qr=q2*q1 using quaternion multiplication, which is not commutative. This can be computed using the following function:

```
// q1 and q2 are 4 elements waves corresponding to {x,y,z,w} quaternions.
// The function computes a new quaternion in qr which represents quaternion
// product q2*q1.
Function MultiplyQuaternions(q2,q1,qr)
   Wave q2,q1,qr

   Variable w1=q1[3]
   Variable w2=q2[3]
   qr[3]=w1*w2-(q1[0]*q2[0]+q1[1]*q2[1]+q1[2]*q2[2])
   Make/N=4/FREE vcross=0
   vcross[0]=(q2[1]*q1[2])-(q2[2]*q1[1])
   vcross[1]=(q2[2]*q1[0])-(q2[0]*q1[2])
   vcross[2]=(q2[0]*q1[1])-(q2[1]*q1[0])
   MatrixOP/FREE aa=w1*q2+w2*q1+vcross
   qr[0]=aa[0]
   qr[1]=aa[1]
   qr[2]=aa[2]
   Variable NN=norm(qr)
   qr/=NN
End
```

Assume you want to set the Gizmo orientation to the rotation produced by the preceding example (X axis points to the right, Y axis points away from you, and the Z axis points up) followed by a 90-degree rotation about the Z axis, producing the orientation where the X axis points to toward you, the Y axis points to the right, and the Z axis points up. You could execute this:

```
Make/O/N=4 q1={sin(pi/4),0,0,cos(pi/4)}       // Z up, X right, Y away
Make/O/N=4 q2={0,0,sin(pi/4),cos(pi/4)}       // 90 degree rotation about Z
Make/O/N=4 qr// Resultant orientation
MultiplyQuaternions(q2,q1,qr)                 // Compute resultant orientation
Print qr
 qr[0]= {0.5,0.5,0.5,0.5}
ModifyGizmo setQuaternion={0.5,0.5,0.5,0.5}
```

Another way to do this is to use the ModifyGizmo appendRotation command which does the quaternion multiplication for you:

```
ModifyGizmo setQuaternion={sin(pi/4),0,0,cos(pi/4)}    // Z up, X right, Y away
ModifyGizmo appendRotation={0,0,sin(pi/4),cos(pi/4)}
```

The last command rotates 90 degrees about the Z axis starting from the current orientation.

Locking Rotation

In some situations you want to prohibit rotation of the Gizmo plot. You can do this by executing:

```
ModifyGizmo lockMouseRotation = 1
```

This locks the rotation without providing any visible clue that it is locked.

A more complicated approach is to set a fixed viewing transformation on the display list, then add all the objects to be drawn, and end with a MainTransformation operation. All objects in the display list above the main transformation will be drawn with fixed rotation and scaling.

Gizmo Colors, Material and Lights

The rendered color of a Gizmo object depends on its internal color, color attributes, material as specified by a color material operation and lighting. The following sections discuss these topics.

Gizmo Color Specification

Colors of objects and lights are specified using four floating point numbers: RGBA.

The first three are the primary colors red, green, and blue which combine additively to give the final color. The intensity of each component is a number in the range [0.0 to 1.0].

The fourth component is alpha, which determines the opacity of an object. Values are between 1.0, a completely opaque color, and 0.0, a completely transparent or colorless object.

To conserve graphics resources, alpha blending for a Gizmo window is turned off by default. To create objects that have some degree of transparency, in addition to setting the alpha component of their color, you must enable transparency blending by choosing Gizmo Menu→Enable Transparency Blend.

By default the blendFunc0 and enableBlend items are inserted at the top of the display list and therefore affect the drawing of all items that follow them. You may be able to improve drawing speed by moving this pair of entries immediately above the items that require transparency blending. You would then also add a disable operation to disable the blending right after the last entry that uses transparency. For details see **Transparency and Translucency** on page II-432.

Here is an example showing color specification with transparency:

```
// Create a new Gizmo with axis cue and set rotation
NewGizmo
```

```
ModifyGizmo showAxisCue=1
ModifyGizmo setQuaternion={0.435,-0.227,-0.404,0.777}

// Append a red, opaque sphere
AppendToGizmo/D sphere={0.25,25,25}, name=sphere0
ModifyGizmo modifyObject=sphere0, objectType=Sphere, property={colorType,1}
ModifyGizmo modifyObject=sphere0, objectType=Sphere,
      property={color,1.0,0.0,0.0,1.0}

// Append a blue, translucent box
AppendToGizmo/D box={0.5,0.5,0.5}, name=box0
ModifyGizmo modifyobject=box0, objectType=Box, property={colorType,1}
ModifyGizmo modifyobject=box0, objectType=Box,
      property={colorValue,0,0.0000,0.2444,1.0000,0.5000}
```

You now have a translucent blue box surrounding a red sphere but you can not see the red sphere because alpha blending is disabled by default. Now we enable it:

```
// Enable transparency blend
AppendToGizmo attribute blendFunc={770,771}, name=blendFunc0
ModifyGizmo insertDisplayList=0, opName=enableBlend, operation=enable,
      data=3042
ModifyGizmo insertDisplayList=0, attribute=blendFunc0
```

The last set of commands is what is executed when you choose Gizmo Menu→Enable Transparency Blend.

Converting Igor Colors to Gizmo Colors

For historical reasons, Igor represents color components as integer values from 0 to 65535. OpenGL, and consequently Gizmo, represent color components as floating point values from 0.0 to 1.0. To convert from an Igor color component value, such as you might receive from the ColorTab2Wave operation, to a Gizmo color component value for use in a Gizmo command, you need to divide the Igor color component value by 65535.

Here is an example of such a conversion:

```
ColorTab2Wave Rainbow                          // Creates M_colors
MatrixOP/O gizmoRainbowColors = M_colors/65535  // Convert to SP and scale
Redimension/N=(-1,4) gizmoRainbowColors        // Add a column for alpha
gizmoRainbowColors[][3] = 1                    // Set the alpha to 1 (opaque)
```

Colors, Materials and Lighting

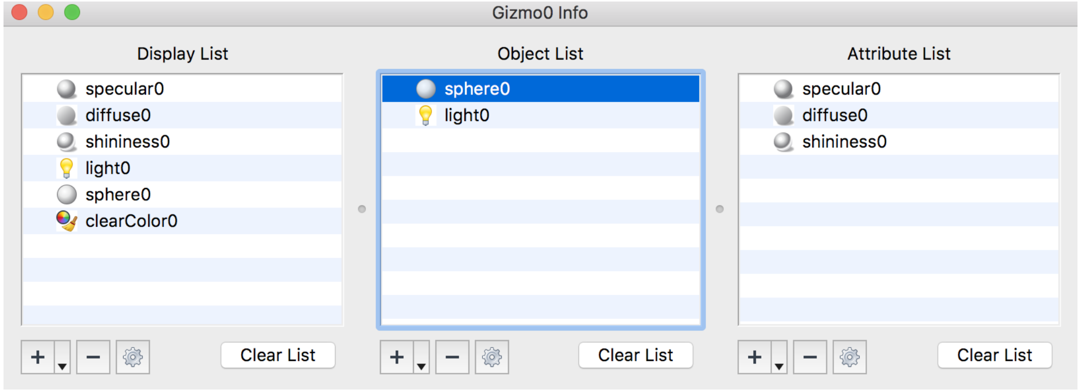
The perceived color of an object depends on the combination of the color, the material and the lighting.

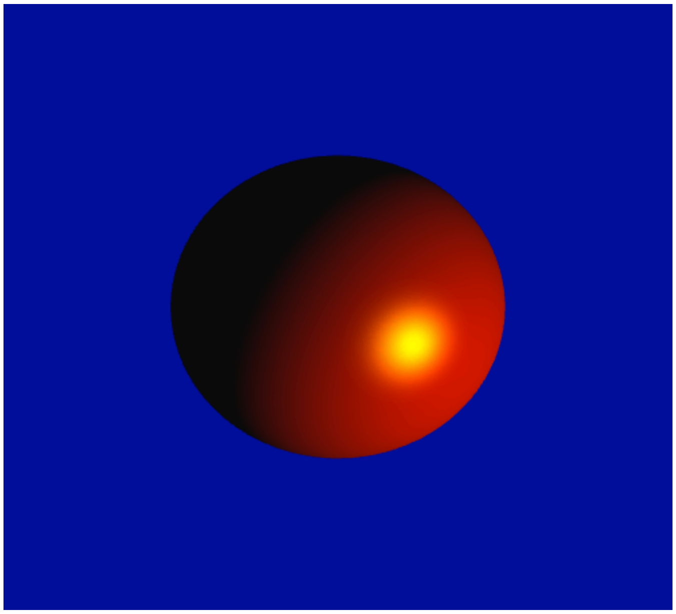
A color material specifies which faces of an object are to be colored by OpenGL and the way the object emits or responds to light. The "face" property can be set to GL_FRONT, GL_BACK or GL_FRONT_AND_BACK. The "mode" property can be set to GL_EMISSION, GL_AMBIENT, GL_DIFFUSE, GL_SPECULAR or GL_AMBIENT_AND_DIFFUSE.

When you create a Gizmo object you have the option to specify a color or to leave it unspecified. If you specify a color, Gizmo creates a default color material for the object. The default color material has the GL_FRONT_AND_BACK and GL_AMBIENT_AND_DIFFUSE settings. If you don't specify a color then Gizmo does not create a default color material and you must create a color material yourself. This color material affects all objects that appear later in the display list if they have no default color material.

Whatever color material is in effect for a given object, you can modify it by adding ambient, diffuse, specular, shininess or emission attributes above it in the display list.

To create a shiny object (e.g., sphere), start with a sphere object, add to it shininess and specular attributes and then add the sphere to the display list following a light object that has matching diffuse and specular components. In this case the info window and display window like this:





For an example, open this demo experiment: Material Attributes.

Color Waves

Wave-based objects can be drawn in fixed colors or using the built-in Igor color tables. You can also use your own color waves to specify the colors of the objects in the Gizmo display window. The format of a color wave is similar to that of the corresponding data wave except that each data node (vertex) has red, green, blue and alpha color components associated with it.

One situation where a color wave is useful is when you want to display a set of scalar values (e.g., temperature measurements) corresponding to points on a 3D surface. In this case you have one wave that describes the shape of the surface and another wave containing the scalar measurements. The application of a color wave gives you complete freedom to represent the scalar data distributed on the surface. In most cases you can create an appropriate color wave using the **ModifyGizmo** makeColorWave and makeTripletColorWave keywords to create a color wave for the data based on one of the built-in tables and then specifying an appropriate alpha in the color wave.

The required color wave format depends on the format of the data wave that describes the object to which the color is to be applied. This table shows some of the various data wave formats with their corresponding color wave formats. Dimensionality is indicated in parenthesis:

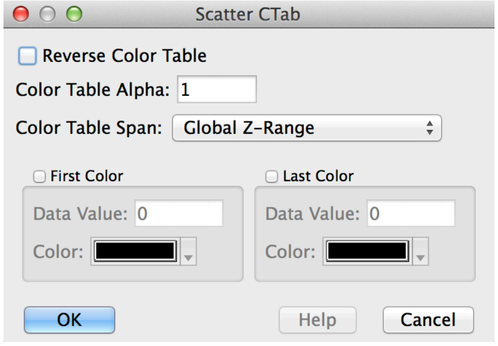
Data Wave	**Color Wave**
Triplet (Mx3) Used in path, ribbon and scatter plots	(Mx4) with RGBA in successive columns
Matrix of Z values (MxN) Used in surface and 3D bar chart plots	(MxNx4) with RGBA in successive layers
Sequential Quads (Mx4x3) Used in parametric surface plots	(Mx4x4) with RGBA in successive layers
Disjoint Quads (Mx12) Used in parametric surface plots	(Mx4x4) with RGBA in successive layers
Triangles (Mx3) Used in parametric surface plots	(Mx4) with RGBA in successive columns
Parametric (MxNx3) Used in parametric surface plots	(MxNx4) with RGBA in successive layers

Color Tables in Gizmo

You can use Igor's built-in color tables to specify the colors of surface, scatter, path and ribbon objects. Isosurface, voxelgram, 3D bar chart, and image objects do not support the use of color tables.

For surface, scatter, path and ribbon objects, you can select the color table in the properties dialog for a given type of object. To see a list of available color tables, see **CTabList** and for more information, see **Color Table Details** on page II-395.

When you choose a color table you can also set related options. In the properties dialog you set these options using the Details button which displays a subdialog that looks like this:



Scatter CTab

□ Reverse Color Table

Color Table Alpha: 1

Color Table Span: Global Z-Range

□ First Color

Data Value: 0

Color: ■

□ Last Color

Data Value: 0

Color: ■

The Color Table Alpha setting applies to all colors in the color table. If you want to apply a variable alpha, set the object color using a color wave where you specify the alpha value for each data point. Color waves are not supported for isosurface objects. Remember that alpha effects require that blending is enabled and that there is a blend function on the display list - see Transparency and Translucency for details.

The Color Table Span setting determines the numeric quantity used to select a color from the color table. For a scatter plot the most common choice is Global Z Range. By default this means that the lowest Z value displayed in the plot is mapped to the first color and the highest Z value is mapped to the last color. The color for a specific scatter element is chosen based on that element's Z value.

This mapping can be tweaked using the First Color and Last Color settings. If you enable First Color and enter a corresponding data value then that data value is mapped to the first color in the color table and any scatter element whose data value is less than the entered value is displayed using the color selected from the color pop-up menu below. If you enable Last Color and enter a corresponding data value then that data value is mapped to the last color in the color table and any scatter element whose data value is greater than the entered value is displayed using the color selected from the color pop-up menu below.

Reflection

Gizmo supports four types of surface object interactions with lights: ambient, diffuse, specular, and shininess.

Lights have ambient, diffuse and specular components.

Materials have ambient, diffuse, specular and shininess attributes.

Ambient

Ambient reflectance determines the overall color of the object. Ambient reflectance is most noticeable in object shadows. The total ambient reflectance is determined by the global ambient light and ambient light from individual light sources. It is unaffected by the viewpoint position.

Diffuse

A diffuse surface reflection scatters light evenly in all directions. This is the most important factor determining the color of an object. It is affected by the incident diffuse light color and by the angle of the incident light relative to the normal direction. It is most intense where the incident light falls perpendicular to the surface. It is unaffected by the viewpoint position.

Specular

Specular reflection governs the appearance of highlights on an object. The amount of specular reflection depends on the location of the viewpoint, being brightest along the direct angle of reflection.

Shininess

Shininess controls the size and brightness of a specular highlight. The shinier the object, the smaller and brighter (more focused) the highlight.

Normals, Lighting and Shading

When you display a scene with lighting effects, make sure to enable the calculation of normals for all objects in the display list. You can do this in the properties dialog for each object. Depending on the type of object, check the Calculate Normals checkbox or choose from the Normals pop-up menu. These settings are off by default to conserve graphics processing resources.

Normals are required because the shading of every pixel depends on the angle between the normal to the surface and the direction of the light source. In the special case of quadric objects (sphere, cylinder and disk) there are internal settings that let you choose between flat, smooth and no normals. All objects draw much slower when normals are calculated.

Transparency and Translucency

Proper implementation of transparency in OpenGL requires that objects be drawn from the back to the front of the scene, starting with the object that is farthest from the viewer and ending with the nearest object. For any fixed viewing transformation it is possible to sort the displayed objects as long as they consist of primitive non-intersecting elements. If you are drawing compound objects such as quadrics you have no control over the order of their constituent segments. Most wave-based objects are transformed into triangle arrays which can be distance-sorted as long as there are no intersecting triangles.

Distance sorting is computationally expensive so most applications avoid it using various tricks. The "poor man's" solution is to use alpha blending. This type of translucency can provide the desired effect for a restricted range of viewing angles and may require re-ordering the objects on the display list.

To use alpha blending, assign colors to two distinct objects on the display list. The translucent object should have an alpha value that corresponds to its opacity. An opaque object has alpha=1, whereas a transparent object has alpha=0. The final steps required for translucency are the addition of the blending function attribute and the enable operation. Select Gizmo→Enable Transparency Blend menu to create the blending function and the enable operation and add both to the display list.

The isosurface is a special case because by construction it consists of non-intersecting triangles. In most applications it is sufficient to sort the triangles in the order of the distance of the viewing point from the centroid of the triangle. You can obtain the triangles corresponding to an isosurface object using **ModifyGizmo** with the saveToWave keyword and establish a sample viewing point. The standard orthographic projection implies infinite distance to viewing point. An example of this type of sorting can be found in the Depth Sorting demo experiment.

Gizmo Lights

Gizmo supports both directional and positional light sources. The type and color of the lights that you add to the display affect the appearance of objects in the display window.

You create lights like any other object by selecting Light from the object list pop-up menu. Using the Light Properties dialog, shown below, you can specify the light type and various light parameters. For the light to have any effect, you must add it to the display list above any object that you want to illuminate.

Lighting effects are defined in terms of their ambient, diffuse, and specular components. The distribution of light intensity is described by the location of the light source, direction, cone angle, and attenuation. The final appearance of an object depends on the combination of the properties of the light and the properties of the object material.

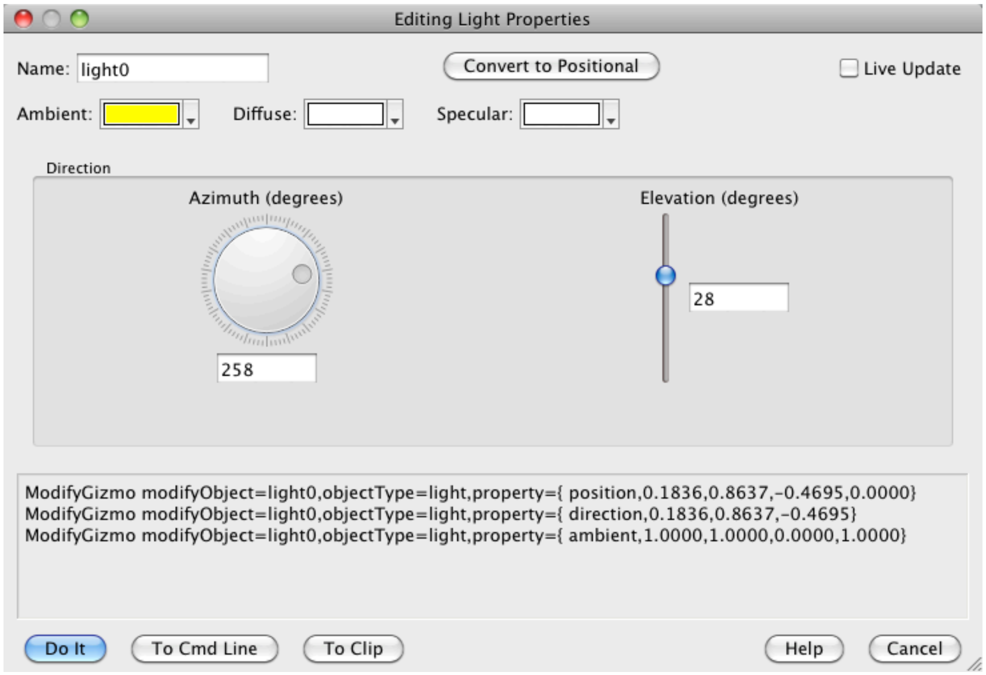
Lighting effects are computed in hardware on a per pixel basis. Therefore, when you want smooth shading, you must describe the object using a sufficiently large number of vertices. For simple objects, such as a single quad (4 vertices), you will likely not see much variation in lighting across the quad. Shading is computed using the dot product between the normal to the surface at each vertex and the direction of the light source. There is no accounting for objects obscuring other objects from the light source or for multiple reflections of light.

If you add no lights to the display list, Gizmo uses default, color-neutral ambient light. If you add a light to the display list, Gizmo removes the default lighting.

Gizmo Directional Lights

You can think of a directional light as a light positioned very far away from the scene so that its rays are essentially parallel within the display volume. The sun is a good example of a directional light. New light objects are directional by default.

The Light Properties dialog contains the controls you need to specify the light's position, color properties and distribution. When editing a light object that is already in the display list, you can click the Live Update checkbox to see how your changes affect the Gizmo Display.



Name: light0

Ambient: 🟨 Diffuse: □ Specular: □

Azimuth (degrees): 258

Elevation (degrees): 28

```
ModifyGizmo modifyObject=light0,objectType=light,property={ position,0.1836,0.8637,-0.4695,0.0000}
ModifyGizmo modifyObject=light0,objectType=light,property={ direction,0.1836,0.8637,-0.4695}
ModifyGizmo modifyObject=light0,objectType=light,property={ ambient,1.0000,1.0000,0.0000,1.0000}
```

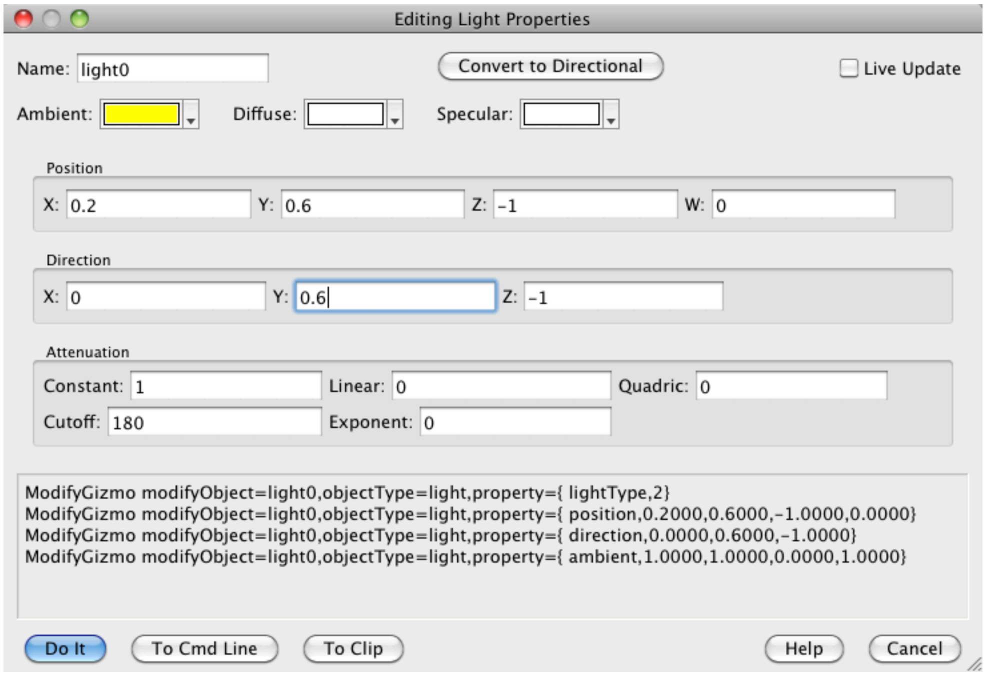
The position of the light is specified via two angles: azimuth and elevation. Elevation is also called "altitude", especially in astronomy. The meaning of these angles is described at http://en.wikipedia.org/wiki/Azimuth. When the elevation is +90 or -90 degrees, the azimuth is undefined.

Ambient, diffuse and specular lighting are described at http://en.wikipedia.org/wiki/Phong_reflection_model. Ambient light illuminates all parts of all objects equally regardless of their orientation and of the position of the light. Diffuse light is reflected off a surface in all directions, as when light hits a rough surface. Specular light is reflected in a specific direction, as when light hits a shiny surface. The illumination created by diffuse and specular light at a given point on an object depends on the angle of the light ray relative to the normal to the surface of that point.

Gizmo Positional Lights

A positional light is a light source that originates at a finite distance from the illuminated scene. A desk lamp is a typical example of a positional light. It can be placed somewhere above the desk and it produces non-uniform illumination as its intensity falls off as a function of distance from the center of the illumination spot.

When you create a light object, it is initialized as a directional light. You can click click the Convert to Positional button in the dialog to get the corresponding positional light settings which you can then adjust as desired.



Editing Light Properties

Name: light0

□ Live Update

Ambient: 🟨 Diffuse: □ Specular: □

Position

X: 0.2 Y: 0.6 Z: -1 W: 0

Direction

X: 0 Y: 0.6 Z: -1

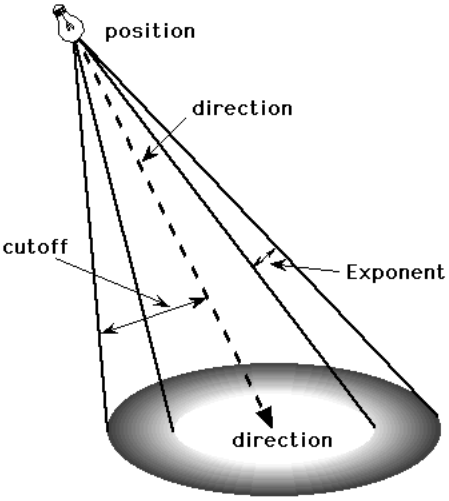
Attenuation

Constant: 1 Linear: 0 Quadric: 0

Cutoff: 180 Exponent: 0

```
ModifyGizmo modifyObject=light0,objectType=light,property={ lightType,2}
ModifyGizmo modifyObject=light0,objectType=light,property={ position,0.2000,0.6000,-1.0000,0.0000}
ModifyGizmo modifyObject=light0,objectType=light,property={ direction,0.0000,0.6000,-1.0000}
ModifyGizmo modifyObject=light0,objectType=light,property={ ambient,1.0000,1.0000,0.0000,1.0000}
```

The parameters for specifying positional lights are illustrated here:



Positional Light Geometry

The top three controls in the directional light dialog specify the RGBA values of each of the ambient, diffuse and specular light components. You should provide some ambient component in at least one of the lights in the display list. This requirement holds even if you are trying to create a predominantly diffuse or specular effect.

When you create a Gizmo object you have the option to specify a color or to leave it unspecified. If you specify a color, Gizmo creates a default color material for the object. The default color material has the GL_FRONT_AND_BACK and GL_AMBIENT_AND_DIFFUSE settings. If you are interested in specular effects you must add specular and shininess attributes (see **Gizmo Colors, Material and Lights** on page II-428).

The Position and Direction controls in the dialog describe the position and direction of the light source. The position is expressed in homogeneous coordinates where the last element (w) is used to normalize the X, Y and Z components. Therefore, if you set w=1, then the X, Y, and Z components specify the absolute position of the light in space. If you set w=0, your light source is infinitely far away and you effectively created a directional light source.

We suggest that you set w=1, and set the direction using the next group of controls in the dialog, which describes the direction of the light as the three components of a vector pointing from the position of the light source to the point that you want the center of the specular spot to illuminate. The typical error here is entering the position of the illuminated spot instead of the direction vector.

The specified position of the light source is subject to the same transformations that apply to any other objects in the display list. In particular, as you rotate display objects, the lights will likewise rotate. If you want to keep the lights stationary so they illuminate different part of the rotating display, you must add a main transformation operation to the display list immediately after the last light object and before all the rotating objects. This will keep all objects listed above the main transformation stationary, and apply the rotation only to all subsequent display list items.

Using the main transformation operation allows you to have some things fixed and other things rotatable. The main transformation operation sets the point in the display list after which coordinate transformations are applied. Coordinate transformations affect translation and scaling in addition to rotation. No transformations are applied to everything above the main transformation in the display list and therefore those items are drawn in their default view, unless you insert explicit translate, rotate or scale operations.

By default, the spot cutoff angle (the light cone half-angle) is 180 degrees which means that the light provides uniform illumination in all directions. If you take the trouble to specify position and direction it will be useful to reduce the cutoff angle to something more realistic - less than 90-degrees.

The constant, linear and quadratic attenuations combine to attenuate positional lights (i.e., for which w is non-zero). The exponent value, in the range 0 to128, determines the intensity falloff from the center of the spot by multiplying the center intensity by the cosine of the angle between the direction of the light and the vertex in question, raised to the power of the exponent value. This can be used to make the light highly specular.

The Positional Light Demo experiment contains a control panel that you can use to explore the interplay between the various positional light parameters and how they affect the lighting on an object.

Gizmo Drawing Objects

Gizmo provides access to a number of drawing primitives. These include **Line Objects**, **Triangle Objects**, **Quad Objects**, **Box Objects**, **Sphere Objects**, **Cylinder Objects**, **Disk Objects**, **Tetrahedron Objects** and **Pie Wedge Objects**. You can use the dialogs associated with the different objects to set the various object properties.

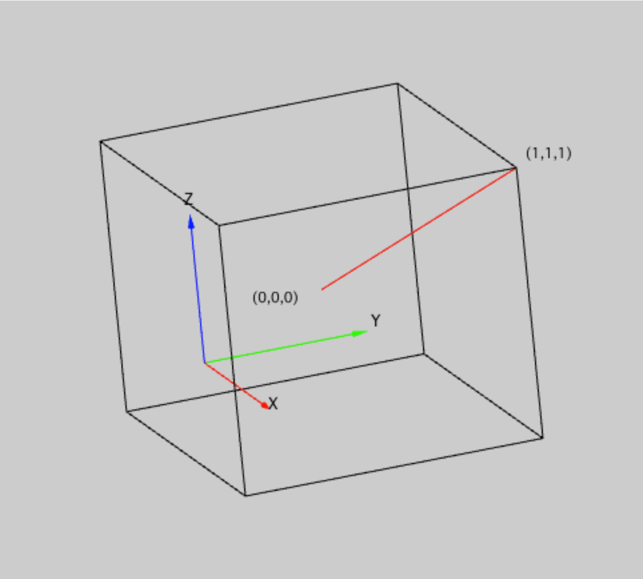
As explained under **Gizmo Dimensions** on page II-421, the size of a drawing object is expressed in display volume units. The display volume extends from the origin to +/- 1 in each dimension. A box of size 1 centered at the origin extends halfway from the origin the edge of the display volume in each dimension.

Unlike drawing objects, wave-based objects such as scatter plots and surface plots are displayed against a separate coordinate system. If you combine drawing objects with wave-based objects, remember that drawing object positions and sizes are always expressed in terms of the +/-1 display volume. If you draw a 2D wave as a surface and you would like to draw a box around it, just add a box whose length, width and height are two units.

Line Objects

A line object is a straight line that connects the two endpoint coordinates. You can add an arrowhead at the start or end of the line or at the mid point. This example shows a line from (1,1,1) to (0,0,0) created by the command

```
AppendToGizmo/D line={1,1,1,0,0,0}
```



You can make the line into a 3D cylinder using:

```
ModifyGizmo modifyObject=line0,objectType=line,property={arrowMode,16}
ModifyGizmo modifyObject=line0,objectType=line,property={cylinderStartRadius,0.05}
ModifyGizmo modifyObject=line0,objectType=line,property={cylinderEndRadius,0.05}
```

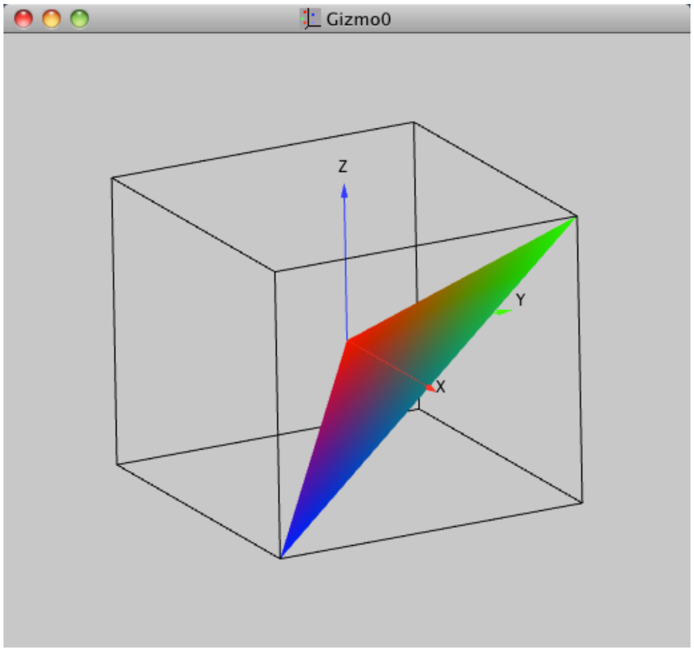
Triangle Objects

A triangle is a planar object bounded by a simple polygon connecting its three vertices. A triangle object is always drawn filled. The fill color is determined by the internal color attribute, an embedded color attribute, or a global color attribute, in that order of precedence. All lighting attributes also apply.

In some situations, it may be more straightforward to create the triangle in a simple orientation and then use translate and rotate operations to position the triangle in its final orientation.

You can set the color of the triangle on a vertex by vertex basis and OpenGL will interpolate the colors between the vertices. Here is an example:

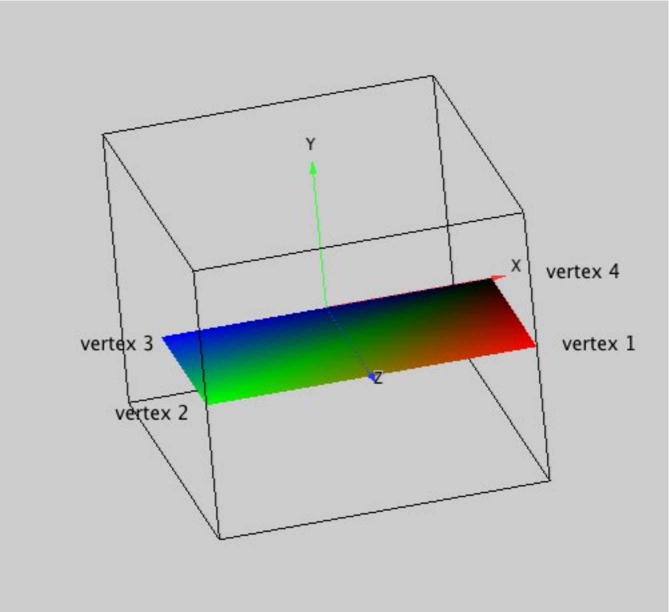
```
AppendToGizmo/D triangle={0,0,0,1,1,1,1,-1,-1}
ModifyGizmo modifyobject=triangle0, objectType=triangle,
      property={colorType,2}
ModifyGizmo modifyobject=triangle0, objectType=triangle,
      property={colorValue,0,1,0,0,1}
ModifyGizmo modifyobject=triangle0, objectType=triangle,
      property={colorValue,1,0,1,0,1}
ModifyGizmo modifyobject=triangle0, objectType=triangle,
      property={colorValue,2,0,0,1,1}
```



Quad Objects

A quad object fills the sheet connecting the four vertices that are positioned sequentially in any direction starting from the first vertex. A quad object is always drawn filled. The fill color is determined by the internal color attribute, an embedded color attribute, or a global color attribute, in that order of precedence. Normals to the quad are calculated on a per-vertex basis. This gives rise to gradual shading when lighting calculations are enabled. For example, here are commands to create a quad:

```
AppendToGizmo/D quad={1,0,1,-1,0,1,-1,0,0,1,0,0}
ModifyGizmo modifyObject=quad0, objectType=quad, property={colorType,2}
ModifyGizmo modifyObject=quad0, objectType=quad,
      property={colorValue,0,1,0,0,1}
ModifyGizmo modifyObject=quad0, objectType=quad,
      property={colorValue,1,1.5259e-05,0.6,0.30425,1}
ModifyGizmo modifyObject=quad0, objectType=quad,
      property={colorValue,2,1.5259e-05,0.244434,1,1}
ModifyGizmo modifyObject=quad0, objectType=quad,
      property={colorValue,3,0,0,0,1}
```

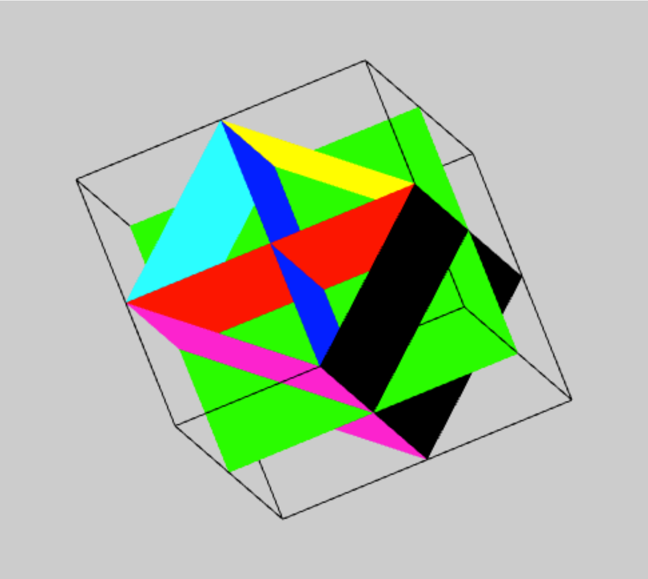


When creating a quad, you may find it easier to create the quad using simple coordinates in either the X, Y, or Z planes and then use translate and rotate operations to position the quad in the desired final orientation.

This table lists some basic quad examples with unit dimensions.

Quad Orientation	Command
XZ Plane	quad={1,0,1,-1,0,1,-1,0,-1,1,0,-1}
XY Plane	quad={1,1,0,-1,1,0,-1,-1,0,1,-1,0}
YZ Plane	quad={0,1,1,0,1,-1,0,-1,-1,0,-1,1}
Oblique Z Plane, +X, +Y	quad={1,0,1,1,0,-1,0,1,-1,0,1,1}
Oblique Z Plane, -X, +Y	quad={-1,0,1,-1,0,-1,0,1,-1,0,1,1}
Oblique Z Plane, -X, -Y	quad={-1,0,1,-1,0,-1,0,-1,-1,0,-1,1}
Oblique Z Plane, +X, -Y	quad={1,0,1,1,0,-1,0,-1,-1,0,-1,1}

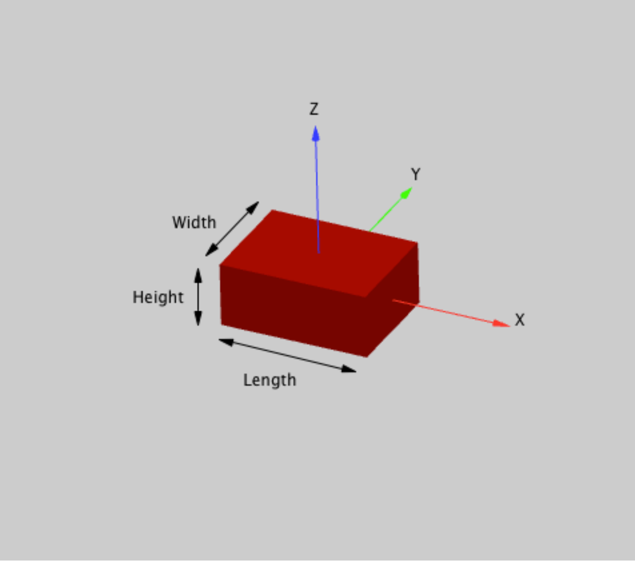
Here is what the seven quads described in the table look like after applying different colors:



Box Objects

A box object is defined by length along the X direction, width along the Y direction, and height along the Z direction. Boxes are centered on the origin and are always drawn filled. The fill color is determined by the internal color attribute, an embedded color attribute, or a global color attribute, in that order of precedence.

This illustration shows a box with length = 1, width = 0.75, height = 0.5:



To position a box in orientations where the sides are not parallel to the axes or not centered on the origin, add rotate and/or translate operations to the display list before the box item.

Sphere Objects

A sphere is a quadric object, meaning that it can be generated by a quadratic polynomial. Internally a quadric object is composed of a list of triangles and quads that approximate the curved surface.

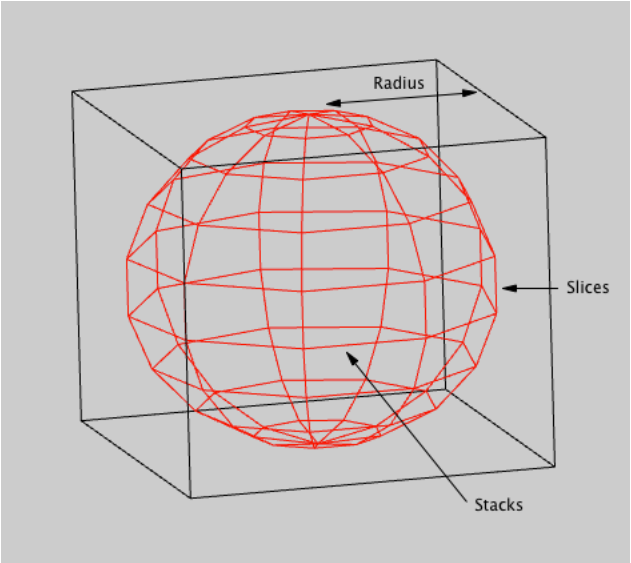
A newly-created sphere is centered on the origin and both poles are on the Z axis. The numbers of slices (subdivisions around the Z axis; divisions of longitude) and stacks (subdivisions along the Z axis; divisions of latitude) determine the smoothness of the sphere. The greater the numbers of subdivisions, the smoother the sphere's appearance. Small values produce other geometric objects (see illustrations below). The more subdivisions you use, the more time it takes to draw the sphere, but in most applications this is not important unless the sphere is replicated many times, such as when used as a marker in a scatter plot.

By default, spheres are initially drawn filled. The fill color is determined by the internal color attribute, an embedded color attribute, or a global color attribute, in that order of precedence.

Use translate and rotate operations to position the sphere in other locations and orientations.

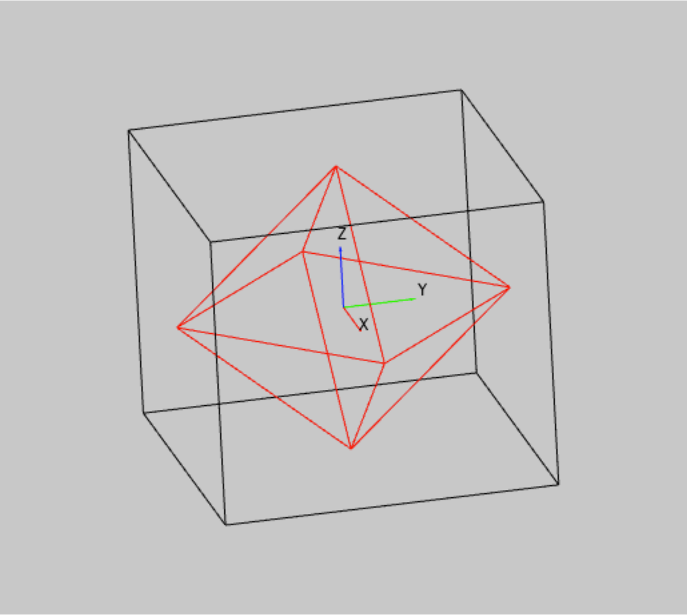
These commands generate a sphere with radius=1, stacks=10, and slices=10 and set its drawing style to lines:

```
AppendToGizmo/D sphere={1,10,10}
ModifyGizmo modifyObject=sphere0, objectType=Sphere,
      property={useGlobalAttributes,0}
ModifyGizmo modifyObject=sphere0, objectType=Sphere,
      property={drawStyle,100011}
```



Create other geometric shapes by using small values for the number of stacks and keeping slices = 2. These commands generate an octahedron with radius=1, stacks=4 and slices=2 and set its drawing style to lines:

```
AppendToGizmo/D sphere={1,4,2}
ModifyGizmo modifyObject=sphere0, objectType=Sphere,
      property={useGlobalAttributes,0}
ModifyGizmo modifyObject=sphere0, objectType=Sphere,
      property={drawStyle,100011}
```



You can create other geometric shapes by increasing the number of stacks and keeping slices=2.

Cylinder Objects

A cylinder is a quadric object, meaning that it can be generated by a quadratic polynomial. Cylinders are constructed from slices and rings. Specifying more slices creates a smoother cylinder. Initially, the cylinder axis is centered on the Z axis, height is in the positive Z direction, and the cylinder base is in the XY-plane.

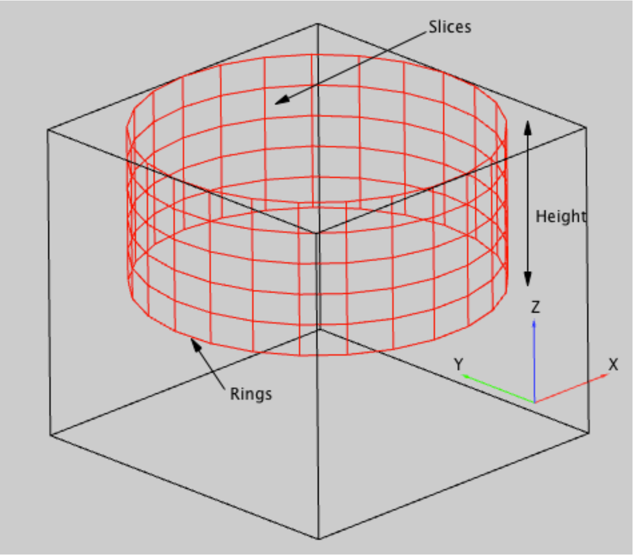
Create conical objects (see illustration below) by specifying different values for the base radius and top radius parameters.

By default, cylinders are initially drawn filled. The fill color is determined by the internal color attribute, an embedded color attribute, or a global color attribute, in that order of precedence.

Use translate and rotate operations to position the cylinder in other locations and orientations.

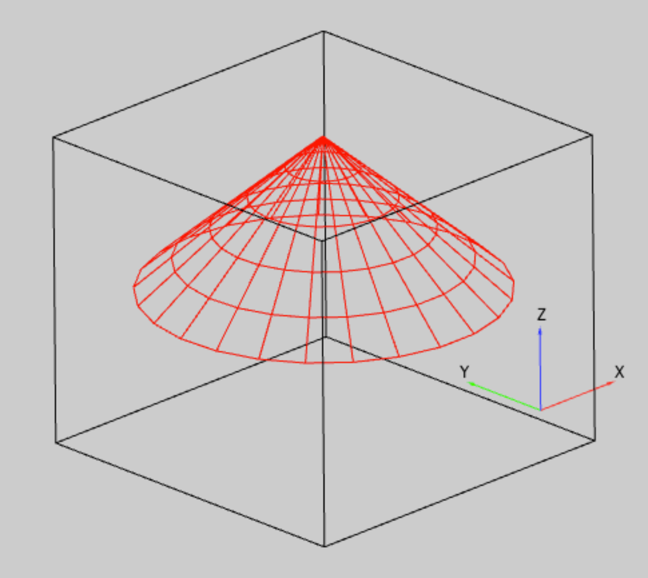
These commands generate a cylinder with baseRadius=1, topRadius=1, height=1, slices=25, and rings=5 and set its drawing style to lines:

```
AppendToGizmo/D cylinder = {1,1,1,25,5}
ModifyGizmo modifyObject=cylinder0, objectType=Cylinder,
      property={useGlobalAttributes,0}
ModifyGizmo modifyObject=cylinder0, objectType=Cylinder,
      property={drawStyle,100011}
```



A cone created using the same command but with topRadius=0:

```
AppendToGizmo/D cylinder = {1,0,1,25,5}, name=cone0
ModifyGizmo modifyObject=cone0, objectType=Cylinder,
      property={useGlobalAttributes,0}
ModifyGizmo modifyObject=cone0, objectType=Cylinder,
      property={drawStyle,100011}
```



You can create other types of cylindrical object shapes by specifying a small number for slices. Create a triangular cylinder with slices = 3; create a square cylinder or open-ended box with slices = 4. Use different values for baseRadius or topRadius to create pyramid shapes.

Disk Objects

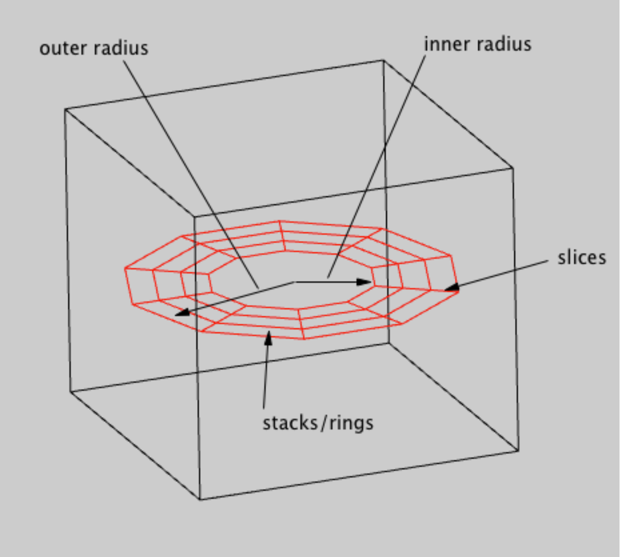
A disk is a quadric object, meaning that it can be generated by a quadratic polynomial. The disk is initially located in the XY plane centered on the origin. Create a smoother disk by specifying a greater number for slices.

By default, disks are initially drawn filled. The fill color is determined by the internal color attribute, an embedded color attribute, or a global color attribute, in that order of precedence.

Use translate and rotate operations to position the disk in other locations and orientations.

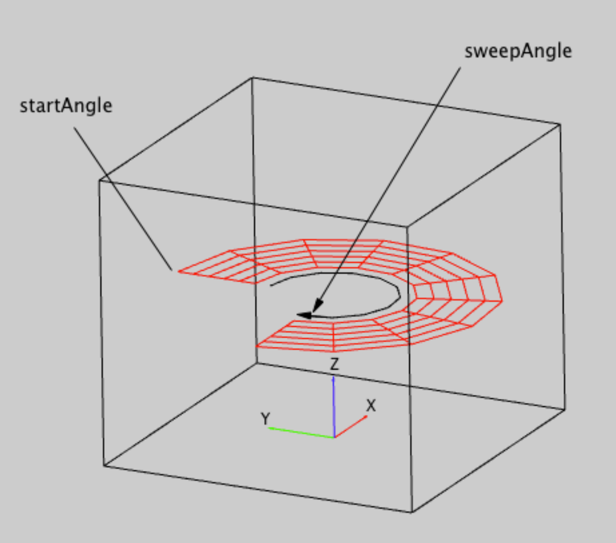
These commands generate a disk with innerRadius=0.5, outerRadius=1, slices=10, stacks=5, startAngle=0, sweepAngle=360 and set its drawing style to lines:

```
AppendToGizmo/D disk={0.5,1,10,5,0,360}
ModifyGizmo modifyObject=disk0, objectType=Disk,
      property={useGlobalAttributes,0}
ModifyGizmo modifyObject=disk0, objectType=Disk, property={drawStyle,100011}
```



This command changes the disk to a partial disk with sweepAngle set to 270 instead of 360. SweepAngle is specified in degrees clockwise from startAngle:

```
ModifyGizmo modifyObject=disk0, objectType=Disk, property={sweepAngle,270}
```



String Objects

You can use standard Igor annotations in Gizmo as you do in graphs.

Annotations are 2D text graphics that lie flat in a plane in front of all 3D graphics. They are well suited for general labeling purposes. To create an annotation choose Gizmo→Add Annotation and choose TextBox from the Annotation pop-up menu. For backward compatibility, Gizmo still supports string objects and they are useful if you want 3D graphics. Annotations are preferrable for general labeling.

For further discussion of annotations versus string objects, see **Changes to Gizmo Text** on page II-471. The rest of this section describes the original Gizmo string object feature.

String objects can be used for short text labels or annotations. You can create a string object using a command such as:

```
AppendToGizmo string="Hello", strFont="Geneva", name=string0
```

Like the primitive objects described above, string objects are 3D objects that are drawn in +/-1 display volume coordinates. You can use translate and rotate operations in order to place the string at the appropriate part of the graph and in the desired orientation.

The key to orienting strings correctly is understanding that they originate at the origin, character advance is in the X direction and text height is in the Y direction.

Multiple lines are not supported so a given string object results in a single line of text only.

ColorScale Objects

Gizmo colorscale objects were used in Igor Pro 6 and before to create 3D color scale graphics. You can now use standard Igor annotations as you do in graphs.

Annotations are 2D graphics that lie flat in a plane in front of all 3D graphics. They are well suited for general labeling purposes. To create a color scale as an annotation choose Gizmo→Add Annotation and choose ColorScale from the Annotation pop-up menu. For backward compatibility, Gizmo still supports colorscale objects and they are useful if you want 3D graphics. Annotations are preferrable for general labeling.

The rest of this section describes the original Gizmo ColorScale object.

Color scale objects are designed to provide an association between a sequence of colors and a numeric scale. You can create a color scale object using a command such as:

```
AppendToGizmo colorScale=colorScale0
```

You would typically following this with ModifyGizmo commands.

Color scales are also drawn in +/-1 display volume coordinates and by default appear planar though you can assign to them a positive depth value to make the color scale into a full 3D object.

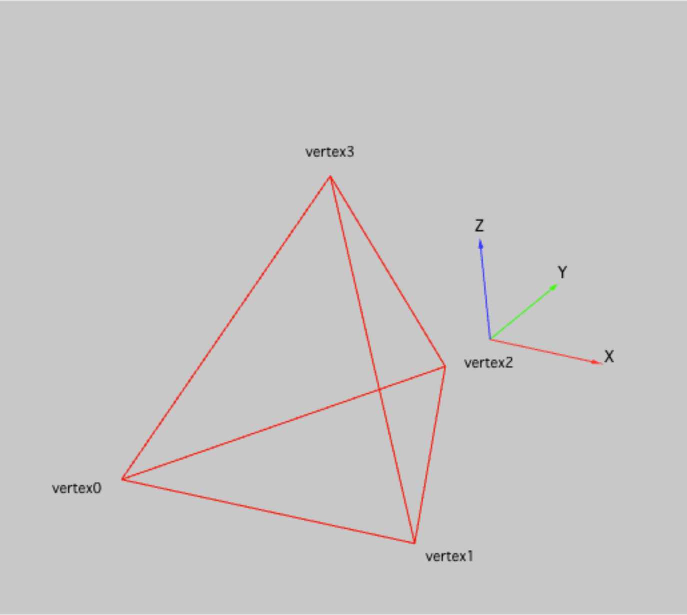
You can choose the sequence of colors to be based on a built-in color table or provide your own sequence using a color wave.

A color scale can be tied to a wave-based data object such as a surface plot but can also be independent on all objects in the plot. You can create multiple color scale objects in the same plot.

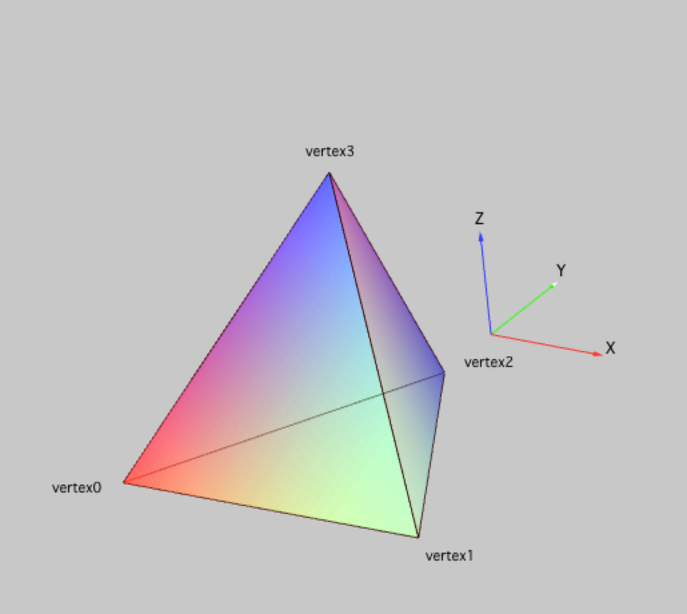
Tetrahedron Objects

A tetrahedron is defined by 4 vertices. These commands generate a tetrahedron and set its drawing style to lines:

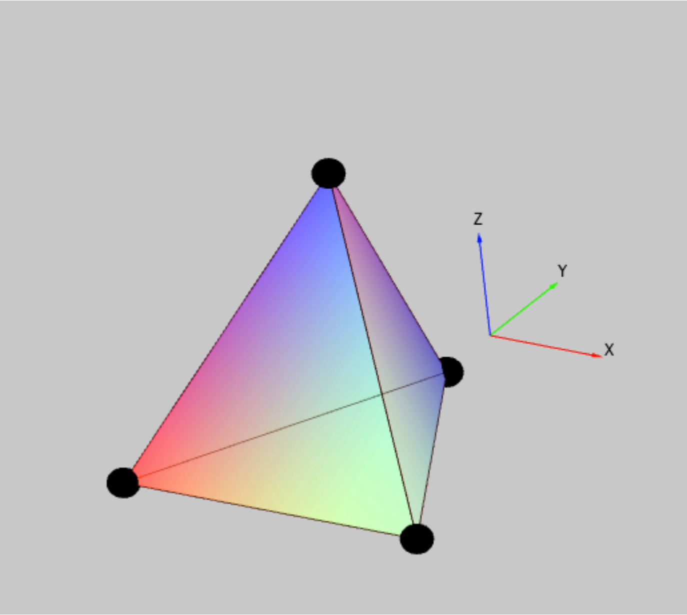
```
AppendToGizmo/D tetrahedron=tetrahedron0
ModifyGizmo ModifyObject=tetrahedron0, objectType=tetrahedron,
      property={vertex0,-1,-1,-1}
ModifyGizmo ModifyObject=tetrahedron0, objectType=tetrahedron,
      property={vertex1,1,-1,-1}
ModifyGizmo ModifyObject=tetrahedron0, objectType=tetrahedron,
      property={vertex2,0,1,-1}
ModifyGizmo ModifyObject=tetrahedron0, objectType=tetrahedron,
      property={vertex3,0,0,1}
```



You can turn on filling and specify a color for each vertex to produce a tetrahedron like this:



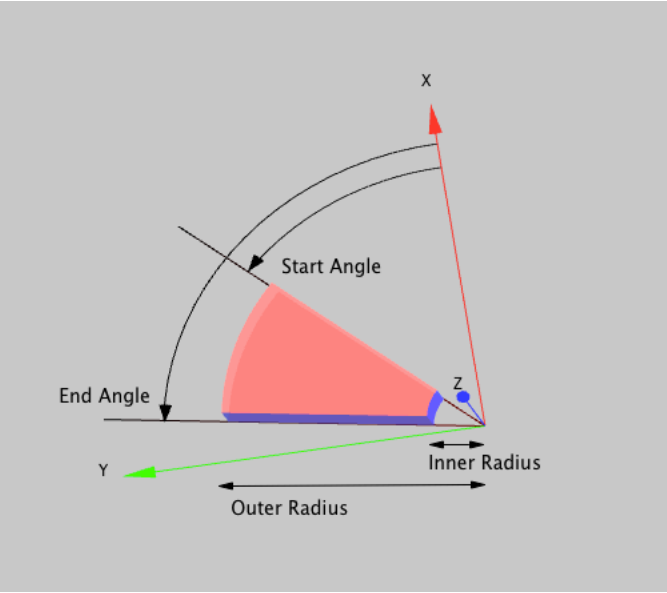
You can also specify that a sphere is to be drawn at each tetrahedron vertex:



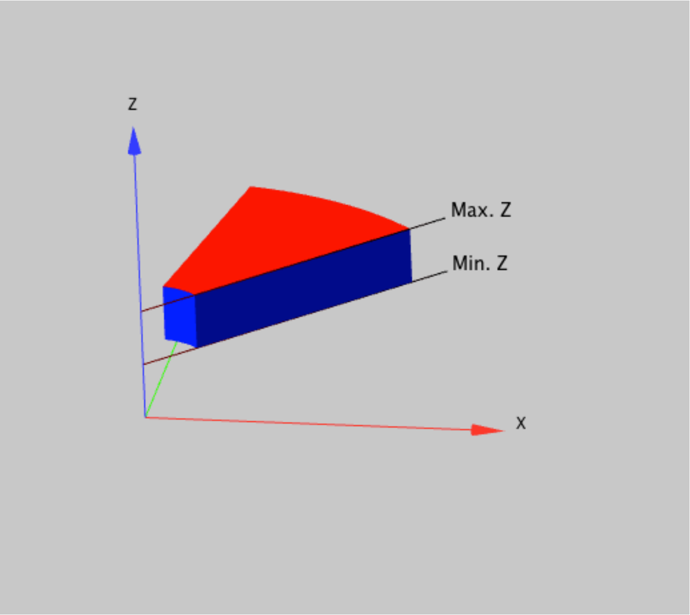
Pie Wedge Objects

A pie wedge object is defined by two angles, two radii and two Z values. You can use multiple pie wedge objects to create many types of 3D pie charts.

This illustration shows a pie wedge from the top:



This illustration shows a pie wedge from the side:



Gizmo Axis and Axis Cue Objects

Gizmo axis objects are used mostly with wave-based data objects such as surface plots and scatter plots. They allow you to indicate the range of data values and to set the scale of data objects.

Axis cue objects show the orientation of the X, Y and Z directions. Axis objects show both orientation and numeric range.

Axis Cue Objects

Gizmo supports two axis cue objects: the default axis cue and the free axis cue. These objects indicate the orientation of the X, Y and Z axes.

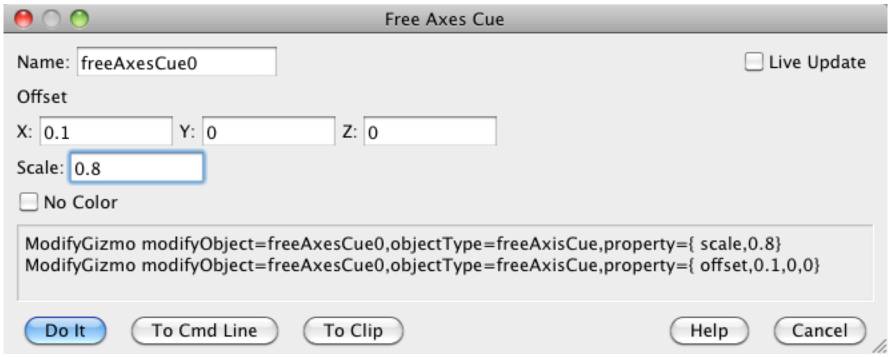
The default axis cue is a triplet axis object that is centered at the display volume origin. The X, Y and Z cue lines extend in the positive X, Y and Z directions of the display volume respectively.

There is just one default axis cue. It is used only to provide an indication of which direction is which. It does not support tick marks, tick mark labels or axis labels. To display the default axis cue, right-click the Gizmo display window and select Show Axis Cue.

The default axis cue object is drawn with the X axis in red, the Y axis in green and the Z axis in blue. The characters labeling the three axes are all drawn in black. Internally, the axes are drawn with emission color material which helps differentiate the axis cue from the background.

A free axis cue object can be drawn at any offset from the origin and at any scale. By default it has the same orientation as the default axis cue. Use a rotate operation if you want to rotate it.

You can create multiple free axis cues and even use them as markers in scatter plots. To add a free axis cue, click the + icon in the object list of the Gizmo info window and choose Free Axis Cue.



Name: freeAxesCue0

□ Live Update

Offset

X: 0.1 Y: 0 Z: 0

Scale: 0.8

□ No Color

```
ModifyGizmo modifyObject=freeAxesCue0,objectType=freeAxisCue,property={ scale,0.8}
ModifyGizmo modifyObject=freeAxesCue0,objectType=freeAxisCue,property={ offset,0.1,0,0}
```

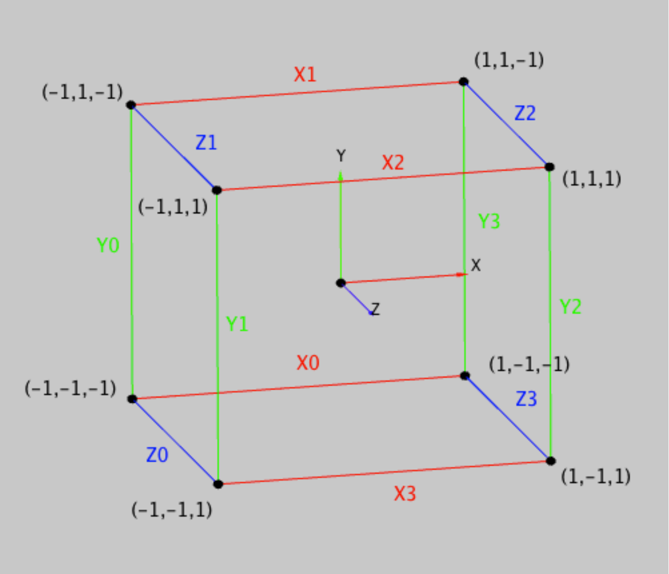
The free axis cue is colored the same as the default axis cue unless you disable its color by checking the No Color checkbox in the Free Axis Cue dialog. In this case it takes on the current color of the drawing environment as set by the previous color attribute in the display list. You also need a color material operation in the display list to apply a color to a free axis.

Axis Objects

As explained under **Gizmo Dimensions** on page II-421, a Gizmo display has an axis coordinate system that is superimposed on the +/-1 display volume. You set the range of this axis coordinate system using the Axis Range dialog, accessible via the Gizmo menu. Wave-based objects, such as scatter plots and surface plots, are displayed against this axis coordinate system. An axis object is a visual representation of it.

Gizmo supports three types of axis objects: box, triplet, and custom. Gizmo treats axis objects just like other objects that you add to the Gizmo display window with one exception: you must have at least one data object or drawing object on the display list for an axis object to be meaningful.

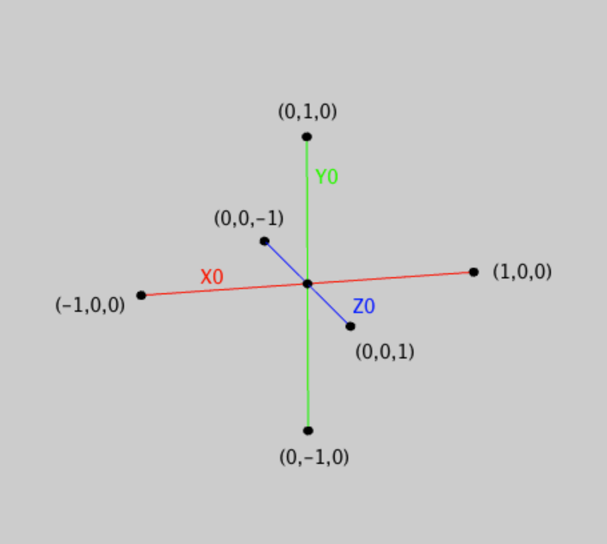
The corners of the box axis object correspond to the corners of the display volume. Thus the location of each corner in display volume space is -1 or +1 in each dimension. In this diagram the coordinates shown are the display volume coordinates of the corners of the box axes.



Box axes consist of 12 axes named X0, X1, X2, X3, Y0, Y1, Y2, Y3, Z0, Z1, Z2 and Z3. You can control each axis individually, assign it a color, range, tick marks, and tick mark labels. You can also add grid lines or paint any of the six sides of the box.

Triplet axes are a system of three orthogonal axes that intersect at the origin and span the +/-1 display volume. You can control each axis individually, assign its tick marks, tick mark labels and color. The origin of the axes is the center of the -/+1 display cube.

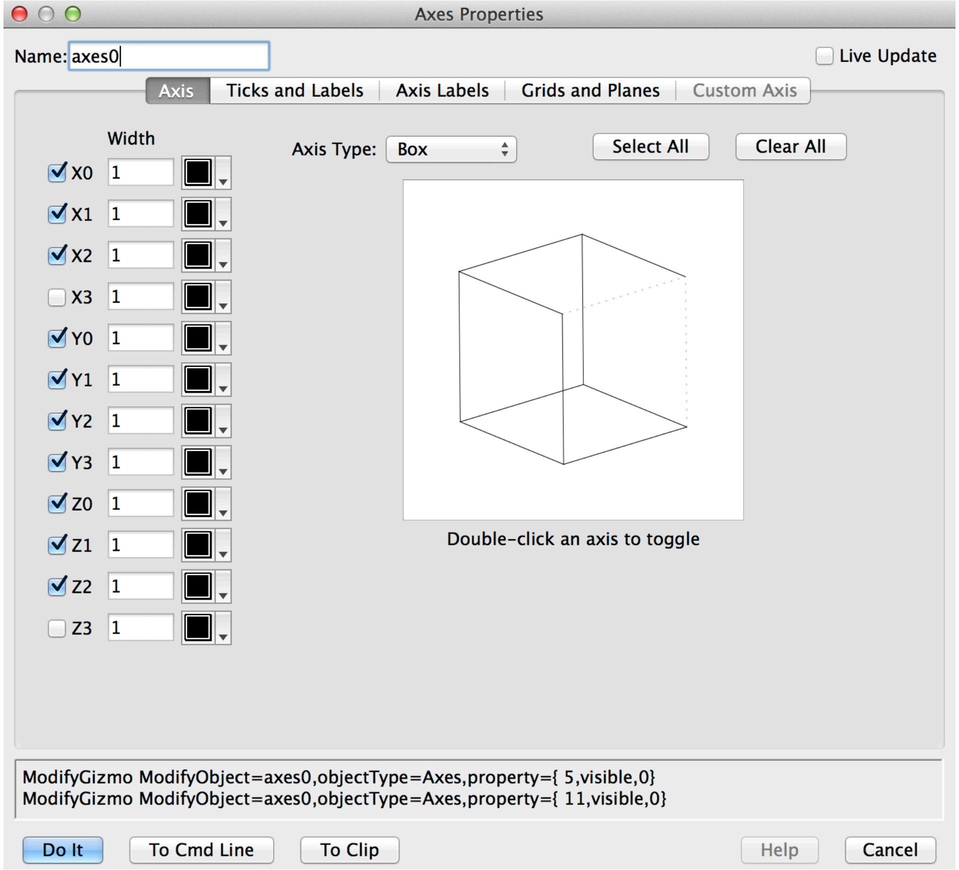
Each triplet axis is identified by name, X0, Y0, and Z0. This diagram shows display volume coordinates for triplet axes and the name of each axis:



A custom axis is a single line in space connecting your chosen start and end points as specified in -1/+1 display volume coordinates. Unlike box and triplet axes which reflect the global axis range as set by Gizmo→Axis Range, a custom axis has its own, independent axis range. You can add tick marks and tick mark labels to the custom axis as to any other axis.

By default, Gizmo attempts to find an appropriate position for tick mark labels. Using the manual position mode, you can take control over their position and orientation.

In most cases you will control the various axis settings using the Axes Properties dialog. When using the dialog it is important to keep track of the different axes that you can select with the checkboxes. To help you identify the various axes in your plot, the Axis tab of the dialog displays an outline of the axes in the same orientation as they appear in the Gizmo window. You can toggle the display of axes by double-clicking them.



```
ModifyGizmo ModifyObject=axes0,objectType=Axes,property={ 5,visible,0}
ModifyGizmo ModifyObject=axes0,objectType=Axes,property={ 11,visible,0}
```

See **AppendToGizmo** and **ModifyGizmo** for programming details.

Gizmo Wave Data Formats

Objects like surface plots, path plots, isosurfaces and voxelgrams are based on the data in a wave and are therefore called "wave-based data objects" or "data objects" for short. The wave supplying the data is called the "data wave" or the "source wave".

The following sections describe the data format requirements for the different data objects.

Scatter, Path, and Ribbon Data Formats

Scatter and path plots require a triplet wave, which is a 2D wave containing 3 columns for the X, Y, and Z coordinates of each vertex. A color wave for a scatter or path plot is a 2D wave in which each row specifies the color of the corresponding vertex in the data wave. The color wave has 4 columns which specify RGBA entries in the range of [0,1].

A ribbon plot also requires a triplet wave. A color wave for ribbon plot is the same as for scatter or path plots with one row of RGBA values per vertex. See also **ModifyGizmo** with the keyword pathToRibbon and **Ribbon Plots** on page II-462.

Surface Object Data Formats

The data wave format depends on the type of surface plot.

A simple surface plot is created from a 2D wave also known as a "matrix" or "matrix of Z values". The color wave for this type of surface plot is a 3D RGBA wave where the four layers in the wave contain the R, G, B and A components in the range of [0,1].

If you are plotting a parametric surface then the data wave is 3D wave containing three layers. At each row/column position, layer 0 contains the X coordinate, layer 1 the Y coordinate, and layer 2 the Z coordinate. The color wave for a parametric surface is a 3D RGBA wave that has the same number of elements in the X and Y dimensions as the data wave and where layer 0 contains the red component, layer 1 the green component, layer 2 the blue component and layer 3 the alpha component.

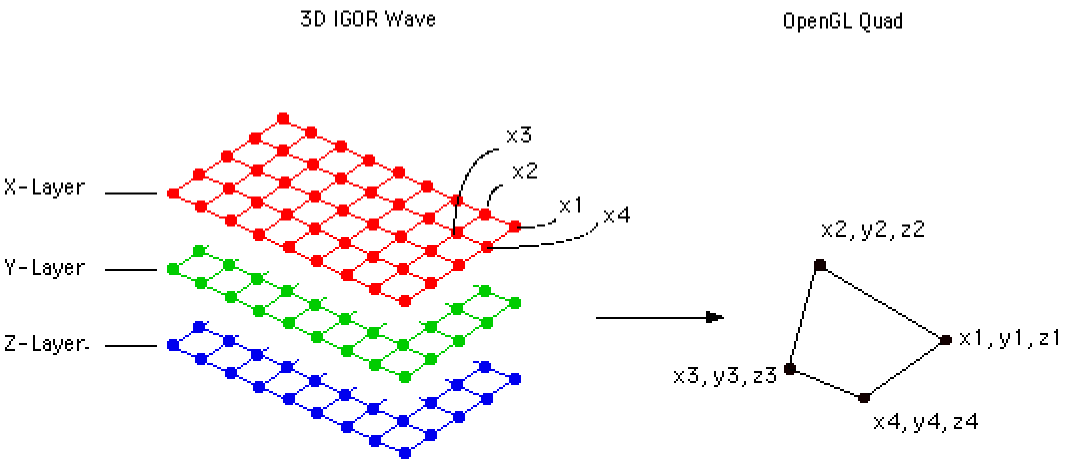
If you are plotting sequential quads (they could be the **ImageTransform** output of a Catmull-Clark B-Spline), the data wave is a 3D wave with four rows and three layers. Each row contains stores the four vertices of a quad and the three layers contain the X, Y, and Z coordinates.

If you are plotting disjoint quads the data wave is 2D with 12 columns corresponding to the X, Y, and Z values of the quad vertices taken in a counterclockwise direction.

The color wave for sequential quads and disjoint quads is a 4 column 2D wave in which the columns correspond to RGBA values in the range [0,1].

Parametric Surface Data Formats

A parametric surface is defined by equations in which the X, Y, and Z coordinates are calculated for, usually, a pair of parameters. To define a parametric surface for Gizmo you need to have a 3D wave containing X, Y, and Z layers. The only restriction on the dimensions of this wave is that it must not have 4 columns. Gizmo constructs the parametric surface from quads. Each quad is defined by four neighboring vertices as shown in the diagram below.



You can find examples of parametric surfaces in these demo experiments:

```
Igor Pro Folder:Examples:Visualization:Mobius Demo
Igor Pro Folder:Examples:Visualization:Spherical Harmonics Demo
Igor Pro Folder:Examples:Visualization:Gizmo Sphere Demo
```

Image Object Data Format

The data wave for an image object can be in one of three formats:

- A 2D matrix of Z values
- A 3D RGB wave of type unsigned byte with 3 layers
- A 3D RGBA wave of type unsigned byte with 4 layers

In the 3D formats, the red component is stored in layer 0, the green component in layer 1, and the blue component in layer 2. The alpha component, if any, is stored in layer 3. Each component value ranges from 0 to 255.

Isosurface and Voxelgram Object Data Formats

The data for an isosurface or a voxelgram object is a 3D volumetric wave.

Isosurfaces and voxelgrams do not use color waves.

NaN Values in Waves

In general, you should avoid using NaNs in data waves plotted in Gizmo. NaNs appears as holes in surfaces or as discontinuities in path plots. A surface object whose data wave contains one or more NaN values is drawn in the usual way except that all constituent triangles for which at least one vertex is a NaN are not drawn. When possible, it is best to display missing data in Gizmo using transparency (see **Transparency and Translucency** on page II-432).

Gizmo Data Objects

Data objects, also called "wave-based objects", are display objects representing data in Igor waves. They include **3D Scatter Plots**, **Path Plots**, **Surface Plots**, **Ribbon Plots**, **Isosurface Plots**, **Voxelgram Plots** and **3D Bar Plots**.

Data Object Scaling

Data objects are displayed against a set of X, Y and Z data axes. These data axes exist whether or not you add an axis object to the plot. The data axes fill the +/-1 display volume.

By default, the data axes are autoscaled to the range of data in all data objects in the plot. You can change the range of the data axes using Gizmo→Set Axis Range.

The following commands illustrate these points. Execute them in a new experiment to follow along:

```
// Create a Gizmo plot with a surface object
NewGizmo
ModifyGizmo showAxisCue=1
Make/O/N=(100,100) data2D = Gauss(x,50,10,y,50,15)
AppendToGizmo/D surface=data2D, name=surface0
ModifyGizmo setQuaternion={0.206113,0.518613,0.772600,0.302713}
```

If you now choose Gizmo→Set Axis Range, you can see that all data axes, which are now invisible, are in autoscale mode (Manual checkboxes are unchecked) and that the X and Y axes range from 0 to 99. These values come from the fact that the default X and Y values of the data2D wave range from 0 to 99 (default wave scaling). The Z axis range is based on the range of Z values in data2D. (If you opened the Axis Range dialog, click Cancel to dismiss it now.)

To help us visualize these data axes we add a box axis object with tick marks and tick mark labels:

```
// Add box axes with tick marks and tick mark labels
AppendToGizmo/D Axes=BoxAxes, name=axes0
ModifyGizmo ModifyObject=axes0, objectType=Axes, property={4,ticks,3}
ModifyGizmo ModifyObject=axes0, objectType=Axes, property={8,ticks,3}
ModifyGizmo ModifyObject=axes0, objectType=Axes, property={9,ticks,3}
```

If we change the values in the data, since the data axes are in autoscaling mode, the data still fills the axes (which always fill the display volume) after the change:

```
// Change the X and Y range of the data
SetScale x, 0, 10, "", data2D; SetScale y, 0, 10, "", data2D
```

Now we set the X and Y data axes to manual scaling mode but leave their ranges unchanged:

```
// Set the X and Y axes to manual scaling mode
ModifyGizmo setOuterBox={0,9.9,0,9.9,1.5286241e-11,0.001061033}
ModifyGizmo scalingOption=48
```

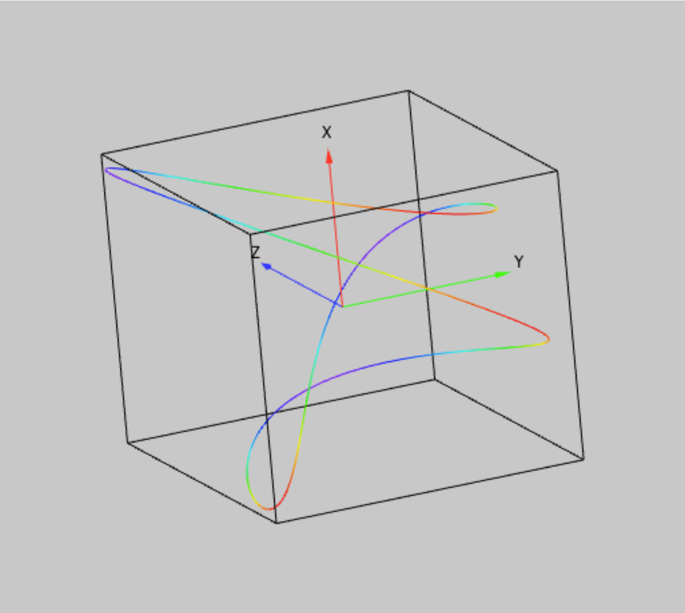
If we now change the range of the data, the data axes remain unchanged and the data no longer fills the axes:

```
// Change the X and Y range of the data
SetScale x, 0, 5, "", data2D; SetScale y, 0, 5, "", data2D
```

To recap, X, Y and Z data axes always exist, whether they are displayed or not. They always fill the +/-1 display volume. Data objects are displayed against the data axes which, by default, are autoscaled. Consequently, by default, data objects fill the display volume. If you change the data axes to manual scaling and change their range or change the range of the data, the data axes still fill the +/-1 display volume but the data objects no longer exactly fit.

Path Plots

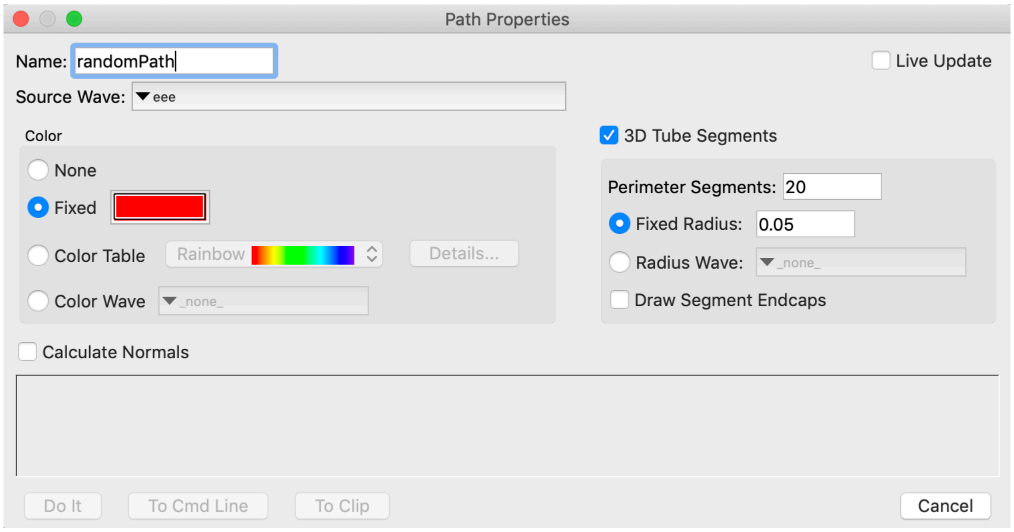
Each data point in a path plot is connected in sequential order by a straight line to each adjacent point.



To draw markers at the individual points, you need to append a scatter plot based on the same data wave.

A path plot requires a triplet wave, which is a 2D wave of 3 columns for X, Y, Z coordinates, respectively, of each vertex. A color wave for a path plot is a 2D wave in which each row specifies the color of the corresponding vertex in the data wave. The color wave has 4 columns which specify RGBA entries in the range of [0,1].

The Path Properties dialog looks like this:



Path Properties

Name: randomPath

□ Live Update

Source Wave: eee

○ None

● Fixed 🟥

○ Color Table Rainbow

○ Color Wave _none_

☑ 3D Tube Segments

Perimeter Segments: 20

● Fixed Radius: 0.05

○ Radius Wave: _none_

□ Draw Segment Endcaps

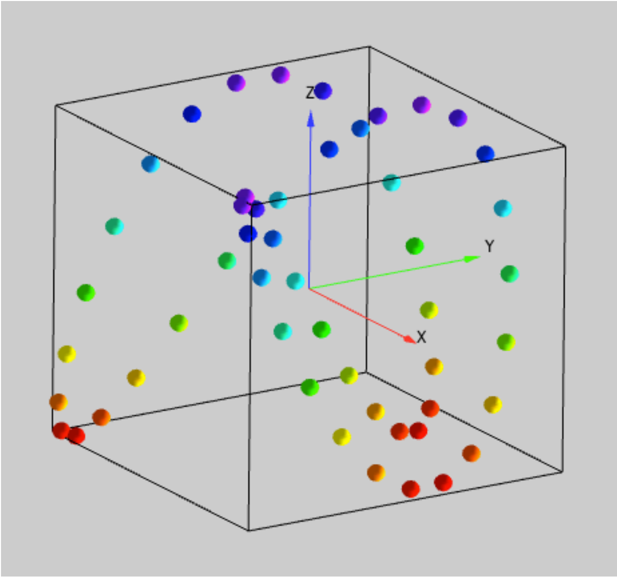
□ Calculate Normals

The full list of available options is given under **ModifyGizmo**.

You can find an example of 3D tube segments where the tube segments are used to display chemical bonds by choosing File→Example Experiments→Visualization→Molecule.

3D Scatter Plots

Each data point in a scatter plot is displayed as 3D marker.



If you want to connect the markers, you need to append a path plot object that uses the same triplet wave.

A scatter plot requires a triplet wave, which is a 2D wave of 3 columns for X, Y, Z coordinates, respectively, of each marker.

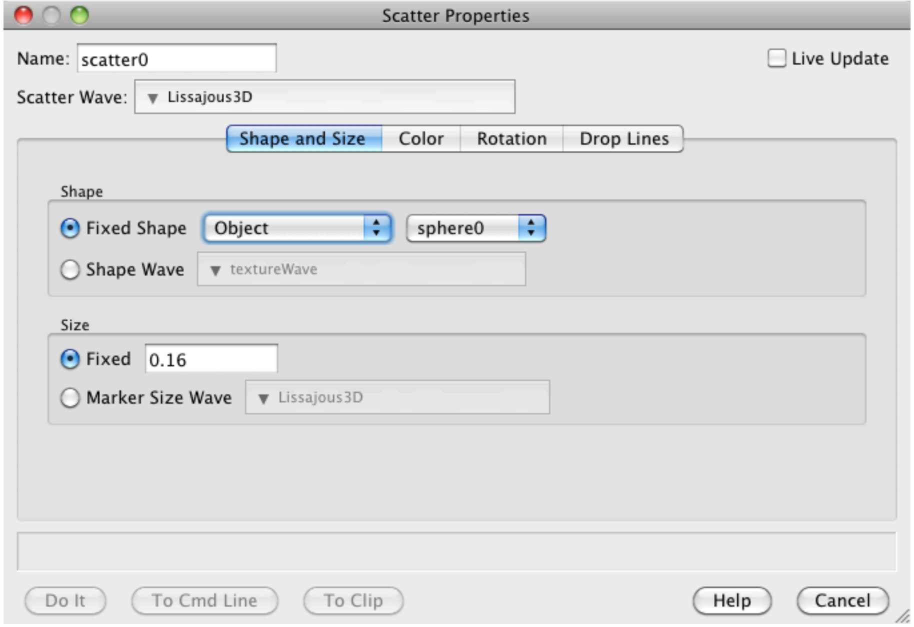
Each marker can be represented by a Gizmo object. You can select any one of the built-in drawing objects (e.g., box, sphere, cylinder or disk) or you can also select any object in the object list. This is useful when you have a very small number of points and you want to display each marker at high resolution. In that case you would add an object to the display list that has the required resolution and then choose this object as your marker for the path plot. Choose File→Example Experiments→Visualization→Molecule for an example.

You can specify the size of the scatter objects to be a constant size, or provide a wave that contains a size specification for each scatter point. The size is specified by a triplet wave where each row contains scale factors for the X, Y and Z dimensions of each marker.

You can also specify the rotation of each scatter point. The rotation is specified by a 2D wave containing four columns. The first column specifies the rotation angle in degrees and the remaining three columns specify the normalized rotation axis vector, just as in the rotate operation.

A scatter plot can be colored using a constant color, a color taken from one of the built-in color tables, or a user-specified color wave. A color wave for a scatter plot is a 2D wave in which each row specifies the color of the corresponding element in the data wave. The color wave has 4 columns which specify RGBA entries in the range of [0,1].

The Scatter Properties dialog allows you to set all properties of the object. If you use the dialog when the object is already in the display list then checking the Live Update box lets you to see all changes as you make them.



Scatter Properties

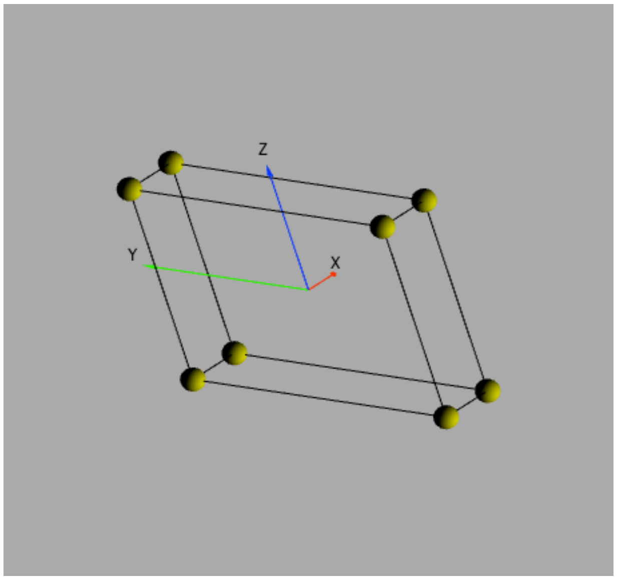
□ Fixed Drop Lines Color ■

The full list of available options is given under **ModifyGizmo**.

You can display crystal structures in Gizmo using scatter plots. Here is an example:



Crystals are easy to display as scatter objects that are centered at coordinates provided in a triplet wave. For example, you can use a sphere as the object drawn at each center. You can specify additional waves to control the color and size of each sphere.

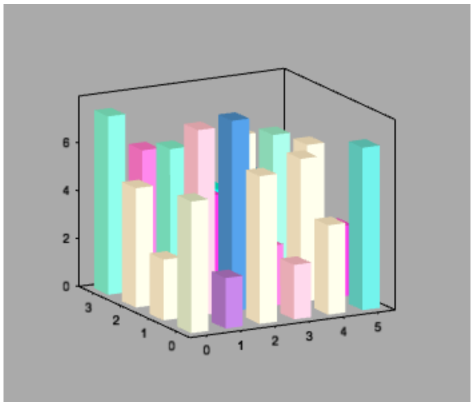
Igor provides two built-in transformations that convert triplet waves from crystallography coordinates to rectangular coordinates and vice versa. See the Crystal Demo experiment and the **WaveTransform** operation with the keywords crystalToRect and rectToCrystal.

3D Bar Plots

A 3D bar plot consists of a number of straight (parallel to all three axes) rectangular bars. The bars may be arranged on a regular grid or may be completely scattered within the volume.

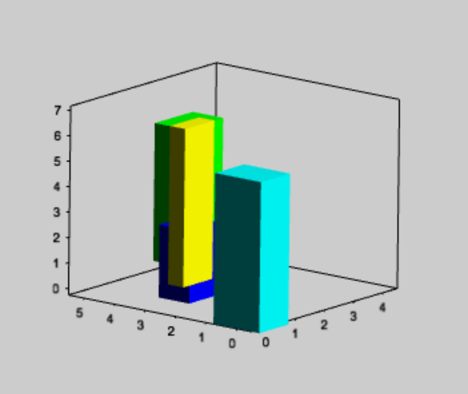
There are two modes for 3D bar plots: basic and refined.

In a basic 3D bar plot, the bars all start at zero and extend in the positive Z direction. Here is an example:



The basic 3D bar plot represents a 2D matrix of positive values. Each value is displayed as a zero-based bar according to its row/column in the matrix. All bars have the same width.

In a refined bar plot, bars can be drawn at arbitrary positions and all bar dimensions are under your control. Here is an example:



The refined 3D Bar plot displays requires a 6-column input wave where each row represents a single bar and the columns contain the following information:

Column 0:	The X center of the bar
Column 1:	The Y center of the bar
Column 2:	The lower Z value
Column 3:	The upper Z value
Column 4:	The width of the bar in the X direction
Column 5:	The width of the bar in the Y direction

Using the refined mode it is possible to create stacked and overlapping 3D bars plots as well as bars of varying sizes.

To find out more open the 3D Bar Plot Demo experiment.

Gizmo Image Plots

A Gizmo Image is a form of a quad object that is internally textured by image data.

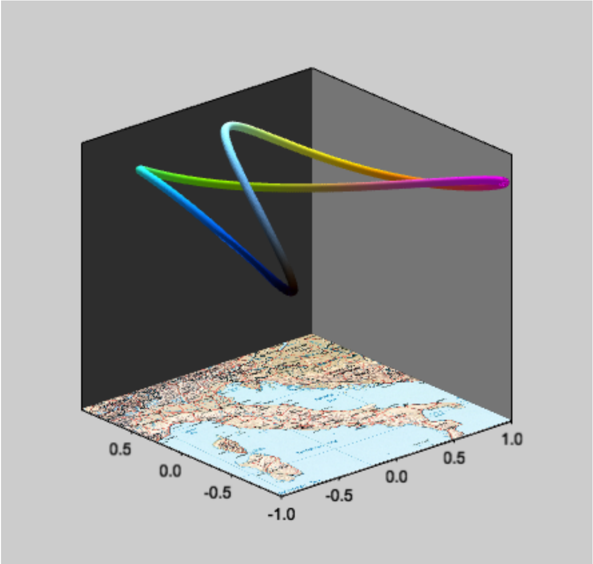
The image source wave can be in one of three formats:

- A 2D matrix of Z values
- A 3D RGB wave of type unsigned byte with 3 layers
- A 3D RGBA wave of type unsigned byte with 4 layers

The latter two formats are created by the **ImageLoad** operation.

By default, the image is displayed at the bottom of the display volume but using rotation, translation and scaling options you can place the image anywhere within it. If you need to register the image relative to the data you can modify the axis range of the Gizmo display or change the scaling of the image. The scaling is uniform about the center of the image.

Igor includes a flight path example that combines a dense scatter plot with a Gizmo image object. In this case the image consists of a map:



To find out more open the Flight Path Demo experiment.

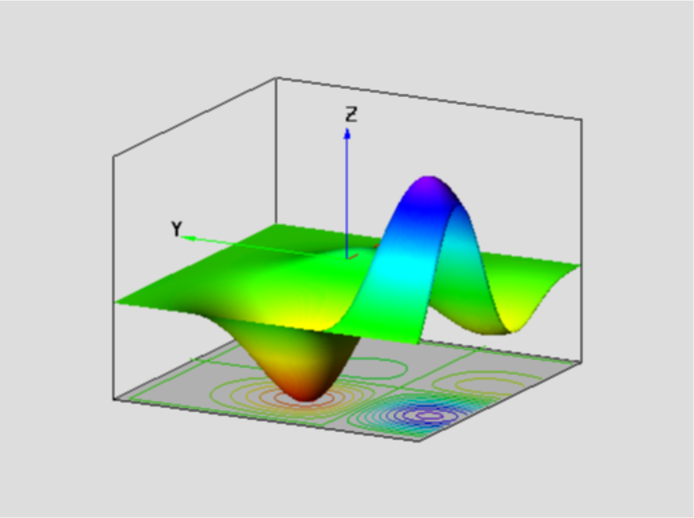
Surface Plots

A surface plot consists of a sheet connecting a grid of data values. You can specify surface colors from built-in color tables or custom color waves; see **Color Waves** on page II-430 for details. In addition to the surface, data values can also be displayed as points or as grid lines which can have their own color specification.

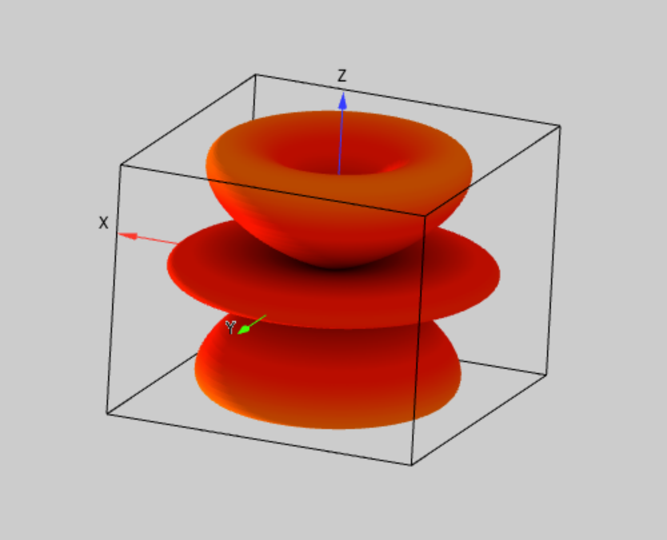
Typically data consist of an MxN 2D matrix of Z values which comprise the surface; see Surface Object Data Formats for details. Also supported are parametric surfaces which are 3D waves where each successive layer contains of the X, Y, and Z values in order; see **Parametric Surface Data Formats** on page II-452 for details.

The full list of available options is documented under **ModifyGizmo**.

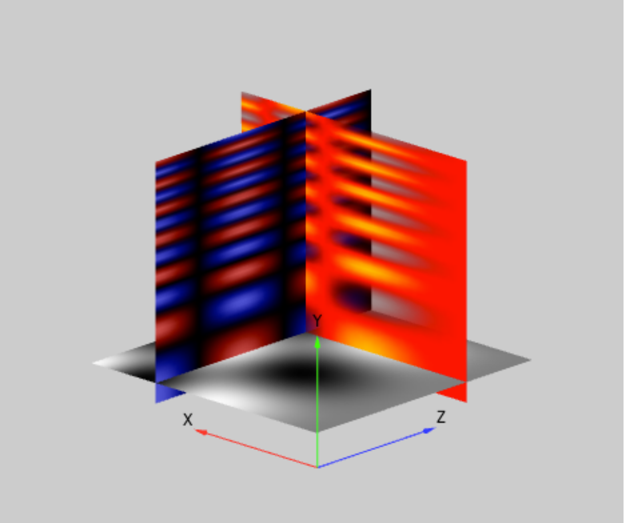
This example shows a surface plot with a contour map at the bottom:



This example shows a parametric surface plot of a spherical harmonic function:



This example shows orthogonal slices of volumetric data:



To display the data by sampling on non-orthogonal slices you can create an arbitrary parametric surface and color it using data sampled at the vertices of the parametric surface. Here is an example.

Suppose you have the following simple 3D data set:

```
Make/O/N=(100,100,100) ddd=z
```

Now create a parametric surface that describes a sphere in this range of data. Here is the MakeSphere function from the GizmoSphere demo experiment:

```
Function MakeSphere(pointsx,pointsy)
   Variable pointsx,pointsy

   Variable i,j,rad
   Make/O/N=(pointsx,pointsy,3) sphereData
   Variable anglePhi,angleTheta
   Variable dPhi,dTheta

   dPhi=2*pi/(pointsx-1)
   dTheta=pi/(pointsy-1)
   Variable xx,yy,zz
   Variable sig

   for(j=0;j<pointsy;j+=1)
      angleTheta=j*dTheta
      zz=sin(angleTheta)
      if(angleTheta>pi/2)
         sig=-1
      else
         sig=1
      endif
      for(i=0;i<pointsx;i+=1)
         anglePhi=i*dPhi
         xx=zz*cos(anglePhi)
         yy=zz*sin(anglePhi)
         sphereData[i][j][0]=xx
         sphereData[i][j][1]=yy
         sphereData[i][j][2]=sig*sqrt(1-xx*xx-yy*yy)
      endfor
   endfor
End
```

You can execute the function like this:

```
MakeSphere(100,100)
```

Then shift the result to the limits of the sample data using

```
sphereData*=48          // Slightly inside the boundary
sphereData+=50
```

Next create a scale wave that will contain the samples of the data at the vertices of the parametric surface:

```
Make/N=(100,100)/O scaleWave
scaleWave=Interp3D(ddd,sphereData[p][q][0],sphereData[p][q][1],sphereData[p][q][2])
```

To create a color wave we first open a Gizmo window and then have Gizmo create the color wave:

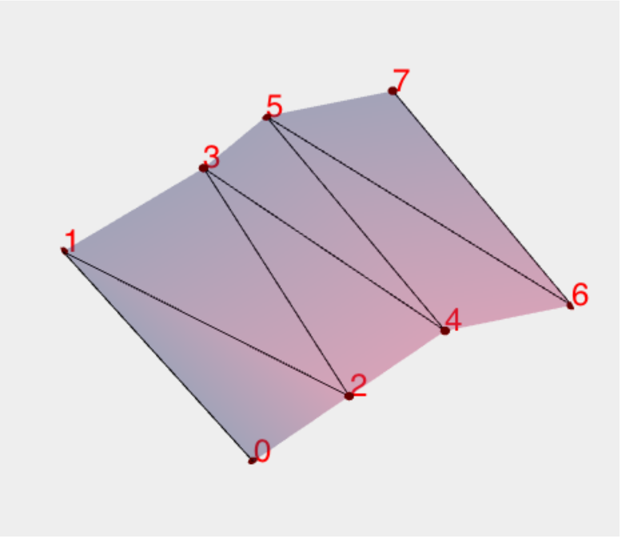
```
NewGizmo
AppendToGizmo surface=root:sphereData,name=surface0
ModifyGizmo modifyObject=surface0,objectType=surface,property={ srcMode,4}
ModifyGizmo makeParametricColorWave={sphereData,scaleWave,Rainbow,0}
```

Apply the color wave to the surface:

```
ModifyGizmo modifyObject=surface0,objectType=surface,
                         property={ surfaceColorType,3}
ModifyGizmo modifyObject=surface0,objectType=surface,
                         property={ surfaceColorWave,root:sphereData_C}
```

Ribbon Plots

In a ribbon plot, data points are connected by a surface that defines the ribbon object. A ribbon is constructed from a list of triangles with alternating vertices as shown here:



To display the individual points or connections, you need to append a scatter plot or a path plot.

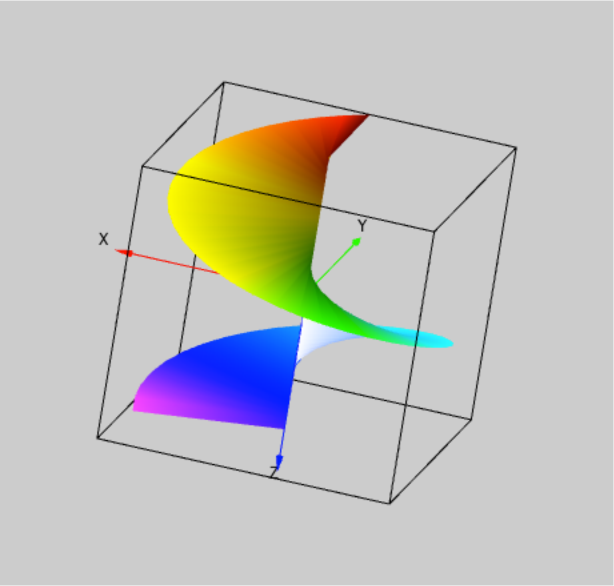
Data for a ribbon plot consist of a Nx3 matrix of values. Each row contains the X, Y, and Z values for the spatial coordinates of a point on the edge of the ribbon. The coordinates for each alternating edge of the ribbon follow in sequential order. The order of vertices for a ribbon is shown in the illustration above.

A ribbon must have at least four vertices and the total number of vertices must be even.

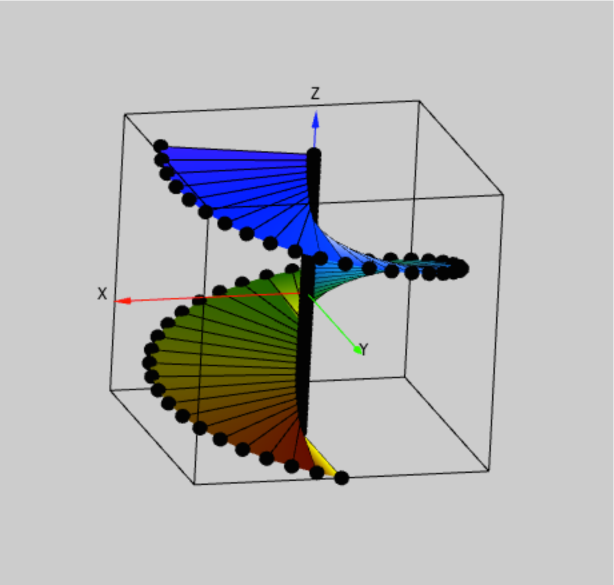
A ribbon plot can be colored using a constant color, a color taken from one of the built-in color tables, or a user-specified color wave. A color wave for a ribbon plot is a 2D wave in which each row specifies the color of the corresponding element in the data wave. The color wave has 4 columns which specify RGBA entries in the range of [0,1].

The full list of available options is given under **ModifyGizmo**.

This is an example of a simple ribbon plot:



This is an example of a ribbon plot overlayed with path and scatter plots of the same data in order to show the positioning of data points along the ribbon edges:



Voxelgram Plots

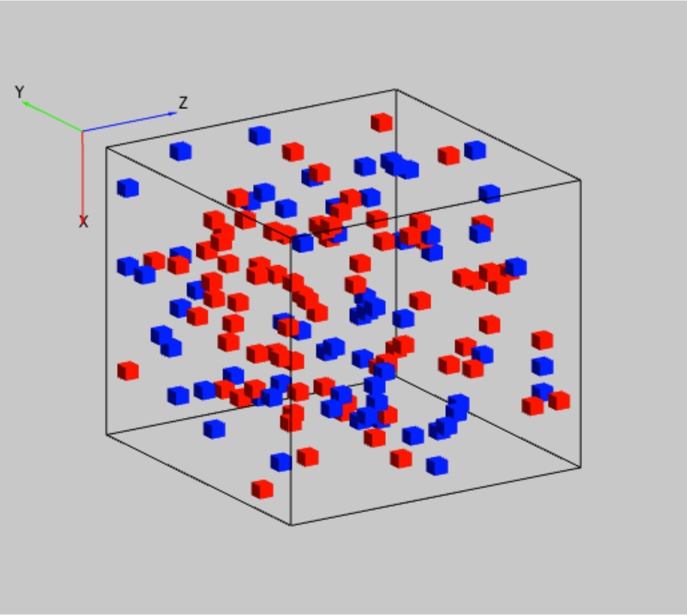
"Voxel" is short for "volume element".

A voxelgram is a representation of a 3D wave that uses color to indicate the wave elements containing certain values. You specify 1 to 5 values and, for each value, an associated RGBA color. If a given wave element's value matches one of the specified values within a specified tolerance, Gizmo displays that element using the associated RGBA color. If a wave element matches none of the specified levels then it is not displayed at all.

Voxels can be represented by cubes or points.

The full list of available options is given under **ModifyGizmo**.

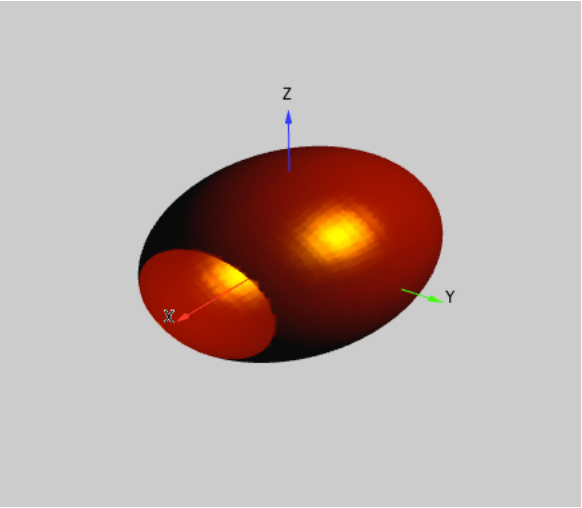
This example shows a voxelgram that uses two specified values:



Isosurface Plots

An isosurface is a 3D analog of 2D contour line. It is a surface drawn at the specified scalar value called the "isovalue". The surface may be represented by any combination of colors, grids, or points.

Here is an example of a translucent isosurface:



Isosurface generation is computationally intensive because it subdivides the volume into tetrahedra. If the isovalue is found in any tetrahedron, the intersection (one or two triangles) is calculated. The isosurface itself is composed of the collections of these triangles.

Isosurfaces are constructed from 3D volumetric data waves.

The full list of available options is given under **ModifyGizmo**.

Printing Gizmo Windows

You can print the image in the Gizmo display window by choosing File→Print when the Gizmo display window is the front window.

The window is printed at a multiple of screen resolution. The multiple is controlled by the Default Output Resolution Factor in the Gizmo section of the Miscellaneous Settings dialog which you can access via the Misc menu. The factory default value for this multiple is 2.

You can override the default printing resolution by executing:

```
ModifyGizmo outputResFactor = n
```

where n is a positive integer, typically 1, 2, 4 or 8. This applies to the active window only. It affects subsequent printing and overrides the Default Output Resolution Factor setting. This setting is not stored in the recreation macro for the Gizmo window and therefore does not persist. The maximum value of n that will work depends on the amount of video memory (VRAM) that you have in your graphics hardware.

You can also improve the output by anti-aliasing objects. To do this, add to the display list a blend function with GL_SRC_ALPHA and GL_ONE_MINUS_SRC_ALPHA and add an enable operation with GL_LINE_SMOOTH. You can also enable the GL_POINT_SMOOTH to smooth points in a scatter object.

If you are unable to print an image from Gizmo you may have run out of VRAM. This may produce a blank or distorted graphic. Some of the things that you should try are:

- Close any other Gizmo window that you might have open.
- Reduce the size of the Gizmo display window.
- Reduce the resolution as set by the Default Output Resolution Factor setting or via ModifyGizmo outputResFactor.
- If you are working on a system with more than one monitor move the display window to the one driven by a graphics card with the most VRAM.
- Run the experiment on hardware that has more VRAM.

Exporting Gizmo Windows

You can export a Gizmo plot using one of these techniques:

- Choose File→Save Graphics to export to a PNG, JPEG or TIFF file. This generates a **SavePICT** command.
- Choose Edit→Export Graphics to export to the clipboard as PNG, JPEG or TIFF.
- Choose Edit→Copy. This exports to the clipboard using the settings last set in the Export Graphics dialog.
- Right-click and choose Copy to Clipboard from the contextual pop-up menu. This is the same as choosing Edit→Copy.

The **ExportGizmo** operation is also available for backward compatibility only. It is obsolete and you should use SavePICT instead.

The Export Graphics dialog and the SavePICT operation give you control of the output resolution as a multiple of screen resolution. Exporting at high resolution requires sufficient video memory (VRAM). Most hardware supports 2x (two times screen resolution). You may be able to increase resolution further depending on the available VRAM.

If you are unable to export an image from Gizmo you may have run out of VRAM. This may produce a blank or distorted graphic. Some of the things that you should try are:

- Close any other Gizmo window that you might have open.
- Reduce the size of the Gizmo display window.
- Reduce the resolution as set in the Export Graphics or Save Graphics dialogs.
- If you are working on a system with more than one monitor move the display window to the one

driven by a graphics card with the most VRAM.

- Run the experiment on hardware that has more VRAM.

Advanced Gizmo Techniques

There are many advanced Gizmo options that are, by default, hidden. To display them you need to check the Display Advanced Options Menus checkbox in the Gizmo section of the Miscellaneous Settings dialog which you can access via the Misc menu. Most Gizmo users will not need these options.

Group Objects

A Gizmo group object is an encapsulation of existing Gizmo objects and operations that are treated as a single object in the top-level Gizmo.

To work with group objects you must enable advanced Gizmo menus in Miscellaneous Settings options. If you want to try the example in this section, make sure that the Display Advanced Options in Menus checkbox is checked in the Gizmos section of the Miscellaneous Settings dialog (Misc menu).

The following example illustrates how you can use a group object to create a custom marker for a scatter plot.

Start a new Igor experiment and execute this command:

```
NewGizmo/JUNK=3
```

This creates a simple scatter plot with default red sphere markers.

Create a group object using the + icon below the object list in the info window.

Double-click the group0 object in the object list. This opens a new info window for the group with display, object and attribute lists. Add a blue sphere object with a radius of 0.15 and a red cylinder object with top and bottom radii of 0.05 and a height of 0.3 to the group. Drag the sphere and cylinder objects to the group's display list.

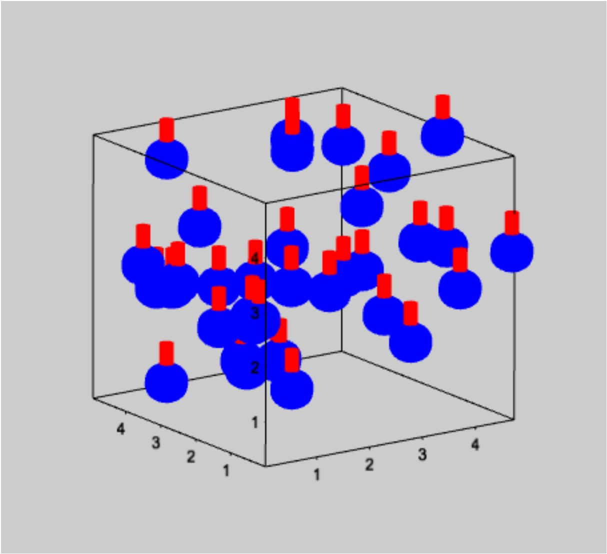
In the Gizmo0 Info window, drag the group0 object from the object list to the bottom of the display list. The sphere+cylinder group appears in the Gizmo plot.

Select the group0 object in the Gizmo0 Info window display list and delete it by clicking the - icon. The sphere+cylinder group disappears from the Gizmo plot.

Close the group0 info window.

In the Gizmo0 Info window, double-click the randomScatter object to open the Scatter Properties dialog. In the Shape and Size tab of the dialog, select Object from the Fixed Shape pop-up menu and group0 from the pop-up menu just to the right of it. Click Do It.

The resulting graph should look something like this:



A similar example of scatter objects can be found in the Scatter Arrows demo experiment where the marker object is a line that has a cylindrical body and cone head.

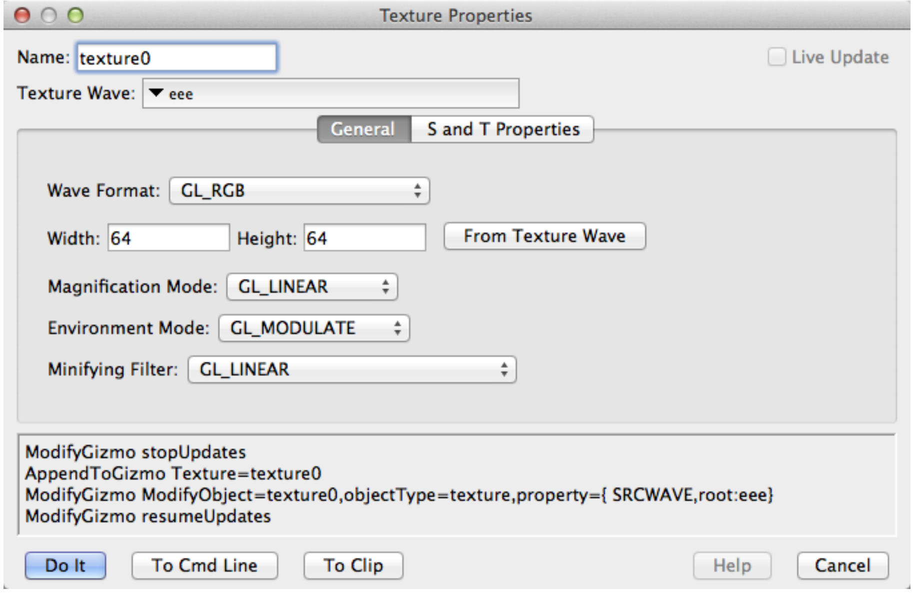
Texture Objects

Textures are used extensively in OpenGL so most graphics hardware are optimized to use them. An in-depth discussion of texture is beyond the scope of this document so we will focus on the use of textures in Gizmo. To work with texture objects you must enable the advanced Gizmo menus in Miscellaneous Settings.

A Gizmo texture object represents an OpenGL object that allows you to apply image information to surfaces of arbitrary shape. Textures in Gizmo are 1D or 2D. They can be applied to quad objects, quadric objects (spheres, cylinders and disks) and parametric surfaces. If you intend to use a texture on a simple quad you should use an image plot instead; see **Gizmo Image Plots** on page II-458.

You usually create a texture from an image that was loaded using **ImageLoad** and is in the form of an unsigned byte 3D RGB wave where the color for each pixel is stored in sequential layers. Before you create a Gizmo texture you need to convert the standard image format into a 1D wave where the color entries for each pixel are stored sequentially as RGB or RGBA. This conversion can be accomplished by **ImageTransform** with the keyword imageToTexture.

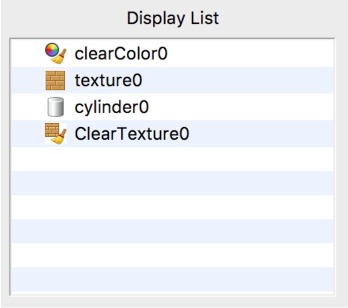
The Texture Properties dialog determines how the texture wave is converted into a texture object and how the texture is applied in a drawing.



```
ModifyGizmo stopUpdates
AppendToGizmo Texture=texture0
ModifyGizmo ModifyObject=texture0,objectType=texture,property={ SRCWAVE,root:eee}
ModifyGizmo resumeUpdates
```

Before invoking the dialog it is useful to know the dimensions of the texture wave, its packing format and the original image size. ImageTransform stores this information in the wave note of the texture wave. The dialog loads the texture information from the wave note if you click the From Texture Wave button.

Once you create a texture object you can apply it to other objects. For example, to apply texture0 to cylinder0 your display list should contain the following sequence:



clearColor0
texture0
cylinder0
ClearTexture0

where cylinder0 is preceeded by texture0 and followed by clearTexture0. You must check the Uniform Texture Coordinates checkbox in the Cylinder Properties dialog. The texture object is placed just before the cylinder and the clear texture operation follows so that subsequent drawings are free of textures.

The Gizmo Earth demo experiment illustrates the use of textures. In this case a high-resolution rectangular texture is added to a parametric surface representing the sphere. The parametric surface consists of 61x61 vertices.

Matrix4x4 Objects

Matrix4x4 objects are used with Gizmo operations that affect the transformation matrix. The encapsulate a 2D wave with 4 rows and 4 columns.

Gizmo Subwindows

You can embed a Gizmo subwindow in a graph, panel or layout window. Here is a simple example:

```
NewPanel/N=MyPanel
NewGizmo/HOST=MyPanel/JUNK=2
```

You can direct any ModifyGizmo commands using full subwindow specification. For example, to change the colormap of the demo surface you can execute:

```
ModifyGizmo/N=MyPanel#GZ0 modifyObject=sampleSurface, objectType=surface,
      property={surfaceCTab,Blue}
```

For more information see **Subwindow Syntax** on page III-92.

Gizmo Troubleshooting

This section provides tips for resolving problems you may encounter while using Gizmo.

Troubleshooting Gizmo Lighting Problems

1. Make sure that the light object appears in the display list above the objects that you expect to be illuminated.
2. Check that your light specifies non-black colors for the ambient, diffuse and specular components.
3. Start with directional light which has fewer options than positional light with less to go wrong. Open the Light Properties dialog, check the Live Update checkbox, change the direction controls and check for changes in the scene. If you do not see changes in the scene then the direction of the light is more than likely not the problem.
4. Verify that you have checked the Compute Normals checkbox for each object that you expect to be illuminated.
5. Check that the normal orientation is what you expect. In the case of quadric objects, toggle the normals orientation between inside and outside. For other objects, consider the definitions of front and back surfaces. If you have doubt, add a front face operation to the display list right before an object. The operation allows you to define the direction representing front and back surfaces.

6. If you are drawing an object that looks fine at normal scale but appears to have the wrong lighting effects when drawn after a scale operation you should compute the object at the final size and avoid scaling. For example, a scatter plot draws markers by default with an isotropic scaling factor of 1 (no scaling). If you create a sphere object with radius 1 for use in a scatter plot, you would need to reduce its size somewhere. You can do so by setting the scale in the Scatter Properties dialog or by reducing the radius of the sphere.

Troubleshooting Gizmo Transparency Problems

1. Check the display list to make sure that there is a GL_BLEND enable operation above the transparent objects and that a blend function exists and has the correct parameters. See **Transparency and Translucency** on page II-432 for details.
2. Check the drawing order of objects. Transparent objects must be after opaque objects in the display list.
3. If you have transparent surfaces that have some overlapping facets, you have no choice but to decompose the surface into triangles and order them according to depth. You can find an example of this in the Depth Sorting demo experiment.

Troubleshooting Gizmo Clipping Problems

Try these tips if an object or part of an object is clippled or not visible.

1. Set the axis range to auto for all axes using Gizmo Menu→Axis Range.
2. Make sure that the display list does not contain any clipping planes.
3. Make sure that the object in question does not follow in the display list after translate, rotate or scale operations.
4. Check the zoom level and the main transformation. If you do not have any transformation operations on the display list insert a default ortho operation (+/-2 for all axes) at the top of the display list.

Gizmo Compatibility

Before Igor7 Gizmo was implemented based on the original OpenGL 1.0 specification. Changes in OpenGL, especially since OpenGL 3.0, required that we modify various features of Gizmo. We have made an effort to allow Gizmo windows in old Igor experiments to open without error and to appear as close as possible to their original form. Notable exceptions include the orientation of string objects, axis labels and tick mark labels; see **Changes to Gizmo Text** on page II-471.

We have also marked in the Gizmo reference documentation some features as "obsolete" or "deprecated". "Obsolete" means that the feature is no longer supported. "Deprecated" means that it may be removed from a future version of Igor and you should use an alternative feature if possible.

Gizmo Commands in User-Defined Functions

In Igor7 and later Gizmo commands can be used in user-defined functions. Supporting this required some changes to the command syntax. The main syntax change is the addition of the objectType keyword in ModifyGizmo. Prior to Igor7 you could use:

```
ModifyGizmo modifyObject=quad0, property={calcNormals,1}
```

The Igor7 syntax requires adding the objectType=<type> keyword as in:

```
ModifyGizmo modifyObject=quad0, objectType=Quad, property={calcNormals,1}
```

So that Igor can interpret Gizmo recreation macros created by Igor6, the objectType keyword is required only in user-defined functions, not from the command line or in macros.

For backward compatibility, the Gizmo XOP as of Igor Pro 6.30 accepts the objectType keyword.

Gizmo Recreation Macro Changes

Prior to Igor7 every Gizmo recreation macro contained the line:

```
ModifyGizmo startRecMacro
```

In Igor7 and later the syntax includes a version number e.g.,

```
ModifyGizmo startRecMacro=700
```

For backward compatibility, the Gizmo XOP as of Igor Pro 6.30 accepts the new startRecMacro syntax.

In Igor7 and later Gizmo uses counter-clockwise as the front face default except when executing Gizmo recreation macros from previous versions. This is unlikely to affect most you but if it does, you can override this default by specifying an explicit frontFace operation in the Gizmo display list.

Use of GL Constants in Gizmo Commands

Previous versions of Gizmo supported the use of OpenGL constants in commands. For example, you could write:

```
AppendToGizmo attribute blendFunc={GL_SRC_ALPHA,GL_ONE_MINUS_SRC_ALPHA},
      name=blend0
```

In Igor7 and later the GL constants, such as GL_SRC_ALPHA, are not recognized and you must use the numeric equivalent instead. For example:

```
AppendToGizmo attribute blendFunc={770,771}, name=blend0
```

You can execute GetGizmo to determine what numeric value represents a given constant. For example:

```
GetGizmo constant="GL_SRC_ALPHA"
```

This prints "770" to the history. You can copy the printed number and past it into your procedure.

Exporting Gizmo Graphics

In Igor7 and later you can export Gizmo graphics using File→Save Graphics which generates a **SavePICT** command. The **ExportGizmo** operation is only partially supported for some degree of backward compatibility. It can export to the clipboard or to an Igor wave and it can print but it can no longer export to a file. Use SavePICT instead.

Changes to Gizmo Text

Prior to Igor7 Gizmo displayed axis labels, tick mark labels, and string objects by composing a 3D filled polygon for each character. The polygon representation allowed Gizmo to handle each string as a true 3D object which could be drawn at any position in the display volume independent of the orientation of the axes. This approach had three disadvantages:

- Labels were not always legible and could disappear completely in some orientations
- The conversion into polygons made it impractical to use anti-aliasing to smooth the characters
- Font sizes were inconsistent across platforms

In Igor7 we moved Gizmo to a new text rendering technology that generates 2D smooth text. While this technology addresses the three issues mentioned, it does not produce text objects that match those produced by previous versions. Consequently you will see differences when loading pre-Igor7 experiments that use text, such as axis labels, with offsets and rotations which are no longer supported.

In Igor7 and later you can use formatted text to construct complex axis labels. Double-click an axis item in the Display or object list to display the Axis Properties dialog and click the Axis Labels tab.

In Igor7 and later you can add standard Igor annotations, including textboxes and colorscales, to a Gizmo window using Gizmo→Add Annotation. These annotations appear in an overlay in front of the 3D graphics and behave like annotations in a graph window.

Miscellaneous Gizmo Changes

In Igor7 and later arguments to the shininess attribute have changed to front and back values.

In Igor7 and later a Gizmo object optionally has an internal color attribute. When you create an object you have the option to specify a color or to leave it unspecified. If you specify a color, Gizmo creates a default color material for the object. The default color material has the GL_FRONT_AND_BACK and GL_AMBIENT_AND_DIFFUSE settings. If you don't specify a color then Gizmo does not create a default color material and you must create a color material yourself. This color material affects all objects that appear later in the display list if they have no default color material. This change was necessary in order to support creation of shiny surfaces.

Gizmo Hook Functions

This section is for advanced programmers only.

A hook function is a user-defined function called by Igor when certain events occur. It allows a programmer to react to events and possibly modify Igor's behavior. A window hook function is a hook function that is called for events in a particular window.

Igor's support for this feature is described under **Window Hook Functions** on page IV-293 and, as of Igor7, applies to Gizmo as well as other types of windows.

Because Gizmo was previously implemented as an XOP, it has its own hook function mechanism separate from the Igor mechanism. This section describes Gizmo's specific hook function support.

You can use either Igor hook functions or Gizmo hook functions or both for a Gizmo window. However using both may lead to confusion. If you install both an Igor hook function and a Gizmo hook function on a given Gizmo window, the Igor hook function is called first.

As in Igor itself, Gizmo originally had just one window hook function, installed by the ModifyGizmo hookFunction keyword. Later a named hook function, installed by ModifyGizmo namedHook, was added. Unnamed hooks are obsolete. We recommend that you use named hooks.

Gizmo Named Hook Functions

A named Gizmo window hook function takes one parameter - a WMGizmoHookStruct structure. This built-in structure provides your function with information about the status of various window events.

You install a named Gizmo hook function using **ModifyGizmo** with the namedHook or namedHookStr keywords. The hookEvents keyword is not relevant for named hook functions.

The hook function should usually return 0. In the case of mouse wheel hook events returning a non-zero value prevents Gizmo from rotating in response to the wheel.

The named window hook function has this format:

```
Function MyGizmoHook(s)
   STRUCT WMGizmoHookStruct &s

   strswitch(s.eventName)
      case "mouseDown":
         break
      case "mouseMoved":
         break
      case "rotation":
         break
      case "killed":
         break
      case "scaling":
         break
   endswitch

   return 0
End
```

See **WMGizmoHookStruct** for details on the structure.

As of this time the following event names are defined: mouseDown, mouseMoved, rotation, killed and scaling.

For an example using a named Gizmo window hook, open the Gizmo Window Hook demo experiment and look at the GizmoRotationNamedHook function in the GizmoRotation.ipf procedure file. This is a packed procedure file. It is in an independent module so you need to enable **Independent Modules** to see it.

Gizmo Unnamed Hook Functions

Unnamed hooks are obsolete though still supported for backward compatibility. Use named hooks instead. The following documentation is for historical reference only.

Each Gizmo window can have one and only one unnamed Gizmo window hook function. You designate a function as the unnamed window hook function using the **ModifyGizmo** operation with the hookFunction keyword.

The unnamed hook function is called when various window events take place. The reason for the hook function call is stored as an event code in the hook function's infoStr parameter. Certain events must be enabled using the **ModifyGizmo** operation with the hookEvents keyword.

The unnamed hook function has the following syntax:

```
Function functionName(infoStr)
   String infoStr

   String event = StringByKey("EVENT",infoStr)
   ...
   return 0          // Return value is ignored
End
```

infoStr is a string which containing a semicolon-separated list of keyword:value pairs. For documentation see “Gizmo Unnamed Hook Functions” in the “3D Graphics” help file.

Chapter

II-18

Page Layouts

Overview

A page layout, or layout for short, is a type of window that you can use to compose pages containing:

- Graphs
- Tables
- 3D Gizmo plots
- Annotations (textboxes and legends)
- Pictures
- Drawing elements (lines, arrows, rectangles, polygons, etc.)

You create a layout by choosing New Layout from the Windows menu.

When the active window is a page layout window, the Layout menu appears in the menu bar. It contains items that apply to page layout windows only.

You can use a page layout to make complex graphics for publication and slide shows for presentation. A layout can have multiple pages. You can have as many layouts as memory allows.

Each page layout page has a number of layers. One layer, the layout layer, is for graphs, tables, 3D Gizmo plots, annotations and pictures. The other layers are for drawing elements. Drawing is discussed in detail in Chapter III-3, **Drawing**. This chapter is primarily devoted to the layout layer.

Here are the notable features of page layouts:

- You can combine graphs, tables, 3D Gizmo plots, pictures, annotations and drawing elements.
- Graphs, tables, Gizmo plots and legends in layouts are updated automatically.
- Layouts can contain multiple pages.
- You can export all or part of a layout page to another program as a graphics file.
- You can use a layout to create a full-screen slide show.

There are two ways to add a graph, table or Gizmo plot to a page layout:

- By creating a layout *object* in the layout layer. A layout object represents the contents of a standalone graph window, table window, or 3D Gizmo plot window. Layout objects are described under **Page Layout Objects** on page II-485.
- By creating an graph, table or Gizmo *subwindow* in a drawing layer. Subwindows are described under **Page Layout Subwindows** on page II-497.

The subwindow is a power-user feature. It is described in detail in Chapter III-4, **Embedding and Subwindows**. Graph, table and Gizmo objects are less powerful but simpler to use and more intuitive. We recommend using objects until you have had time to read and understand Chapter III-4.

In this chapter, the term “object” refers to a graph, table, 3D Gizmo plot, annotation or picture object, not to a subwindow.

The following documentation discusses page layouts from the top down, covering these objects:

- Windows
- Pages
- Layers
- Layout objects (in the layout layer)
- Drawing elements (in the drawing layers)
- Subwindows (in the drawing layers)

Page Layout Windows

To create a page layout window, choose Windows→New Layout.

Page Layout Names and Titles

Every page layout window that you create has a name. This is a short Igor-object name that you or Igor can use to reference the layout from a command or procedure. When you create a new layout, Igor assigns it a name of the form Layout0, Layout1 and so on. You will most often use a layout's name when you kill and recreate the layout, see **Killing and Recreating a Layout** on page II-477.

A layout also has a title. The title is the text that appears at the top of the layout window. Its purpose is to identify the layout visually. It is not used to identify the layout from a command or procedure. The title can consist of any text, up to 255 bytes.

You can change the name and title of a layout using the Window Control dialog. This dialog is a collection of assorted window-related things. Choose Window Control from the Control submenu of the Windows menu.

Hiding and Showing a Layout

You can hide a layout window by pressing the Shift key while clicking the close button.

You can show a layout window by choosing its name from the Windows→Layouts submenu.

Killing and Recreating a Layout

Igor provides a way for you to kill a layout and then later to recreate it. This temporarily gets rid of a layout that you expect to be of use later.

You kill a layout by clicking the layout window's close button or by using the Close item in the Windows menu. When you kill a layout, Igor offers to create a **window recreation macro**. Igor stores the window recreation macro in the procedure window of the current experiment. You can invoke the window recreation macro later to recreate the layout. The name of the window recreation macro is the same as the name of the layout.

For further details, see **Closing a Window** on page II-46 and **Saving a Window as a Recreation Macro** on page II-47.

Page Layout Zooming

You can zoom the page using the Zoom submenu in the Layout menu or the Zoom submenu in the Layout menu or the Zoom pop-up menu in the lower-left corner of the layout window.

By zooming out you see the entire page at once. You can zoom in to place drawing elements with higher precision.

Igor stores the position of layout objects with a precision of one point (nominally 1/72th of an inch, about 0.35 mm).

Page Layout Background Color

You can choose a background color for a page layout. This is useful for creating slides.

The background color applies to all pages of the page layout.

You can specify thebackground color by:

- Using the Background Color submenu in the Layout menu.
- Using the Background Color submenu in the Misc pop-up menu.
- Using the NewLayout command line operation.
- Using the ModifyLayout command line operation.

The background color is white by default. If you wish, after selecting a background color, you can capture your preferred background color by choosing Capture Layout Prefs from the Layout menu.

Page Layout Pages

Each page can have any number of pages. You use the page sorter to add and delete pages.

The Page Sorter

The page sorter occupies the left side of the layout window. It provides an overview of all pages in the layout by displaying a thumbnail view of each page.

Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the page sorter area displays a contextual menu from which you can add a page, insert a new page between existing pages, or delete existing pages. You can also add or delete pages using the controls at the bottom of the page sorter.

The editing area of the layout displays only one page at a time. The displayed page is called the "active page". You set the active page by clicking one of the thumbnails in the sorter. Igor identifies the active page by drawing a red outline around its thumbnail.

Although only one page can be active, you can select multiple pages. You would do this to delete or reorder multiple pages at a time. Igor identifies selected pages by drawing a darker outline around their thumbnails.

Starting from a single selected page, you can select a range of pages by clicking on a non-selected thumbnail while pressing the shift key. Alternatively, you can select or deselect individual pages by pressing the command key (*Macintosh*) or control key (*Windows*) while clicking the corresponding thumbnail.

To change the order of pages, select one or more thumbnails and drag them to the desired place in the sorter.

You can also manipulate the pages in a layout programatically using the **LayoutPageAction** operation.

You can resize the page sorter by dragging the divider between it and the page editing area to the left or right. Dragging the divider all the way to the left hides the page sorter entirely.

Page Layout Page Sizes

Each layout stores a global page size and page margins. You can also set the size and margins for specific individual pages. The global page size and margins apply to any page in the layout for which you have not set an explicit size. You can set both the global and the per-page dimensions using the Layout Page Size dialog via the Layout menu, or using the **LayoutPageAction** operation.

When it is created, a layout is given a default page size and page margins based on preferences. You can change these default dimensions by setting the global dimensions for a page layout and choosing Layout→Capture Layout Prefs.

Compatibility with Previous Versions of Igor

Page layouts were originally conceived, decades ago, primarily for use in printing hard copy. Because of this, in Igor Pro 6 and earlier versions, the layout page size was controlled using the system Page Setup dialog, which is part of the printing system.

Over time, the use of hard copy has diminished, replaced by on-screen formats such as HTML and PDF. It is more common now to create graphics for display in a web page or for inclusion in an electronic document to be sent to a journal editor. For these purposes, you usually need to control the size of the graphics independent of any paper size.

Consequently, in Igor Pro 7 and later, each layout has its own size setting that is independent of the page setup. The page setup affects printing of the layout only, not the size of the page on the screen or when exported. Because of this change, a layout created in Igor7 or later may appear with a different size when opened in Igor6.

You may be accustomed to controlling the size and orientation of a page layout page using File→Page Setup. In Igor7 and later, you need to use Layout→Page Size instead.

An ancillary benefit of this change is that it eliminates operating-system dependencies, making behavior across platforms more consistent.

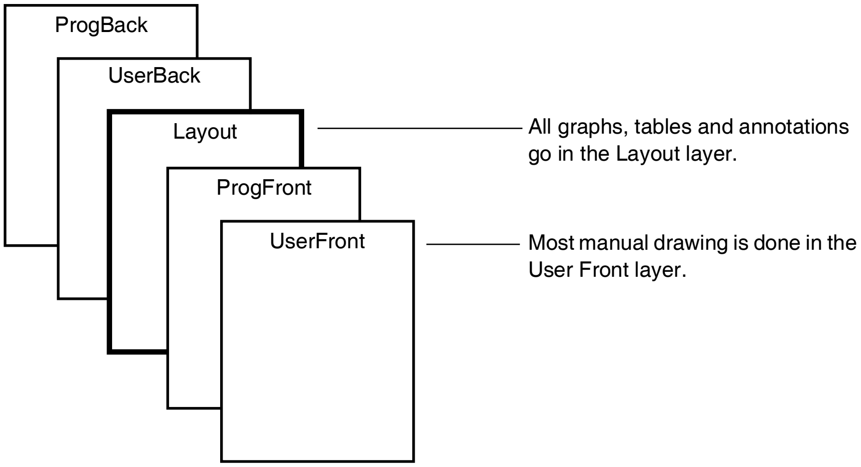
Printing Page Layouts

When you print a page layout, Igor aligns the top/left corner of the layout page, as set in the Layout Page Size dialog, with the top/left corner of the printer's printable area, as set in the Page Setup dialog. The printer's printable area is controlled by the printer margins as set in the Page Setup dialog.

You can preview the printed output using the Print Preview dialog from the File menu.

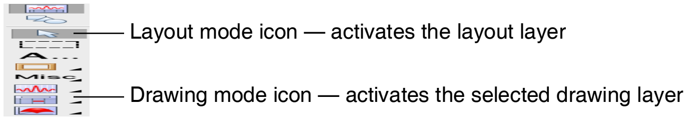
Page Layout Layers

A page in a layout has six layers. There is one layer for layout objects, four layers for drawing elements, and one layer (not shown in this graphic) for user-interface elements.



ProgBack
UserBack
Layout
ProgFront
UserFront
All graphs, tables and annotations go in the Layout layer.
Most manual drawing is done in the User Front layer.

The two icons in the top-left corner of the layout window control whether you are in layout mode or drawing mode.



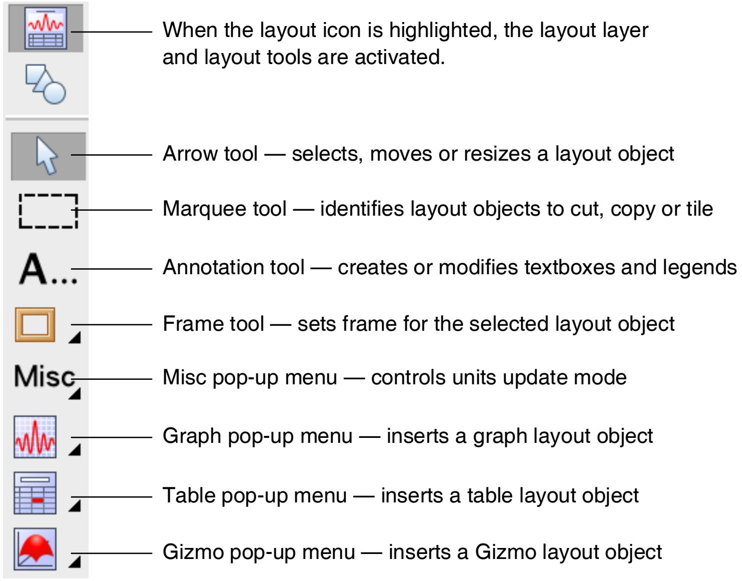
Layout mode icon — activates the layout layer
Drawing mode icon — activates the selected drawing layer

The layout layer is most useful for presenting multiple graphs and for annotations that refer to multiple graphs. The drawing layers are useful for adding simple graphic elements such as arrows between graphs.

The top layer (not shown in the graphic above) is the Overlay layer. It is provided for programmers who wish to add user-interface drawing elements without disturbing graphic elements. It is not included when printing or exporting graphics. This layer was added in Igor Pro 7.00.

Activating the Layout Layer

When you click the layout mode icon, the layout layer is activated. You can use the layout tools to add objects to or modify objects in the layout layer only.



When the layout icon is highlighted, the layout layer and layout tools are activated.

Arrow tool — selects, moves or resizes a layout object

Marquee tool — identifies layout objects to cut, copy or tile

Annotation tool — creates or modifies textboxes and legends

Frame tool — sets frame for the selected layout object

Misc pop-up menu — controls units update mode

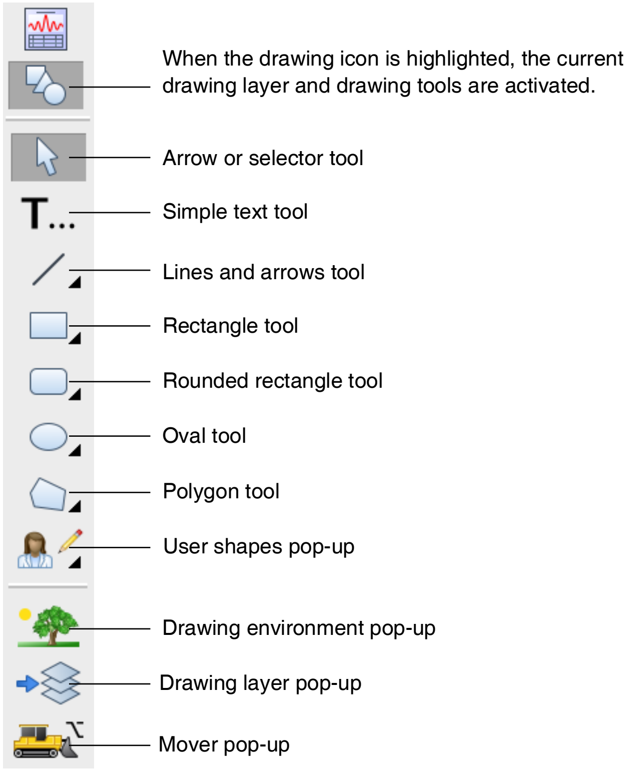
Graph pop-up menu — inserts a graph layout object

Table pop-up menu — inserts a table layout object

Gizmo pop-up menu — inserts a Gizmo layout object

Activating the Current Drawing Layer

When you click the drawing mode icon, the current drawing layer is activated. You can use the drawing tools to add elements to or modify elements in the current drawing layer only.



When the drawing icon is highlighted, the current drawing layer and drawing tools are activated.

Arrow or selector tool

Simple text tool

Lines and arrows tool

Rectangle tool

Rounded rectangle tool

Oval tool

Polygon tool

User shapes pop-up

Drawing environment pop-up

Drawing layer pop-up

Mover pop-up

Changing the Current Drawing Layer

Initially, the UserFront drawing layer will be the current drawing layer. To select a different drawing layer, click the layer tool and select the layer from the pop-up menu.

You may never need to use the drawing layer pop-up menu. Most users will need to use just the layout layer and the UserFront drawing layer. The ProgFront and ProgBack layers are intended to be used from Igor procedures only.

If you click an element that is not in the active layer, Igor ignores the click.

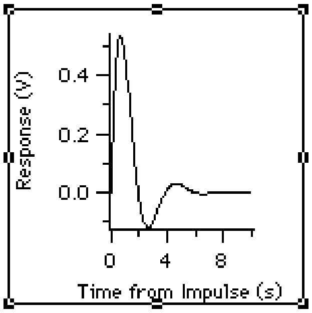
The Layout Layer Tool Palette

When you click the top icon in the tool palette, Igor displays the tools for the layout layer.

Arrow Tool

When you click the arrow tool, it becomes highlighted. The arrow tool is used to select, move or resize a graph, table, annotation or picture object. To select an object, click it. Adjustment handles appear on the selected object.

When you position the cursor over an object, the info panel shows the name of the object under the cursor. If you click and drag, the object will follow the cursor as you drag it. While you drag, the info panel shows the left and top coordinates of the object as well as its width and height. If you press Shift while dragging an object, the direction of movement is constrained either horizontally, vertically, or diagonally, depending on the motion direction. You must press Shift after clicking the object - otherwise the Shift-click will deselect it.



If you press Shift while dragging an object, the direction of movement is constrained either horizontally or vertically, depending on the first motion direction.

You can set the object's width and height by dragging the selected object's handles. While you drag, the info panel shows the width and height of the object.

When you adjust the size of a table and then release the mouse, the table is auto-sized to an appropriate integral number of rows and columns.

You can quickly force an annotation or picture back to its unadjusted size (100% by 100%) by pressing Option (*Macintosh*) or Alt (*Windows*) and double-clicking the object.

Double-clicking an object while the arrow tool is selected brings up the Modify Objects dialog, described in **Modifying Layout Objects** on page II-487. Use this dialog to set the object's properties.

To select multiple objects, click to select the first object and Shift-click to select other objects. Alternatively, you can click in the page and drag diagonally. If you Shift-click an object that is already selected, it becomes deselected.

When two or more objects are selected, you can align them using the Align submenu in the Layout menu. You can also make the widths, heights, or widths and heights of the selected objects the same using items in the Layout menu. In all of these actions, the first object that you select is used as the basis for aligning or resizing other objects. Click in a blank area of the page to deselect all objects. Then click the object whose position or size you want to replicate. Now Shift-click to select additional objects. Finally, choose the desired action from the Layout menu.

While an object is selected, you can control its front-to-back ordering in the layout layer by choosing Bring to Front, Move Forward, Send to Back or Move Backward from the Layout menu. This changes the order of objects *within the layout layer only*. It has no effect on the drawing layers.

If you select a graph, table or 3D Gizmo object, you can then double-click the name of the object in the info panel at the bottom of the layout window. This activates the associated graph or table window.

With multiple objects selected, you can perform the following actions:

- Delete the objects, using the Delete key or the Edit→Clear menu item.
- Copy the objects, using Edit→Copy.
- Cut the objects, using Edit→Cut.
- Drag the objects to a new location.

- Nudge the objects with the arrow keys.
- Change the frame on the objects using the frame tool.

You can not do the following actions on multiple objects:

- Change the order of the objects in the object list (move to front, move to back).
- Adjust the size of the objects using the mouse.

Marquee Tool

When you click the marquee tool, it becomes highlighted and the cursor changes to a crosshair. You can use the marquee tool to identify multiple objects for cutting, copying, clearing or arranging. You can also use it to indicate a part of the layout for export to another application and to control pasting of objects from the clipboard.

To use the marquee tool, click the mouse and drag it diagonally to indicate the region of interest. Igor displays a dashed outline around the region. This outline is called a marquee. A marquee has handles and edges that allow you to refine its size and position.

To refine the size of the marquee, move the cursor over one of the handles. The cursor changes to a double arrow which shows you the direction in which the handle adjusts the edge of the marquee. To adjust the edge, simply drag it to a new position.

To refine the position of the marquee, move the cursor over one of the edges away from the handles. The cursor changes to a hand. To move the marquee, drag it.

To make it possible to export any section of a layout, an object is considered selected if it intersects the marquee. This is in contrast to selection with the arrow tool, which requires that you completely enclose the object.

This table shows how to use the marquee.

To Accomplish This	Do This
Cut, copy or clear multiple objects	Drag a marquee around them and then use the Edit menu to cut, copy or clear.
Paste objects into a particular area	Drag a marquee where you want to paste and then use the Edit menu to paste.
Tile or stack objects	Drag a marquee to indicate the area into which you want to tile or stack and then choose Arrange Objects from the Layout menu.
Export a section of the layout as a picture	Drag a marquee to indicate the section that you want to export and then choose Export Graphics from the Edit menu (to use the clipboard) or choose Save Graphics from the File menu (to save in a disk file).

When you click inside the marquee Igor presents a pop-up menu, called the Layout Marquee menu, from which you can choose Cut, Copy, Paste, or Clear. This cuts, copies, pastes or clears the all objects that intersect the marquee. These marquee items do the same thing as the corresponding items in the Edit menu.

The Marquee menu also contains items that allow you to insert a subwindow.

It is possible to add your own menu items to the Layout Marquee menu. See **Marquee Menus** on page IV-137 for details.

See **Copying Objects from the Layout Layer** on page II-493 and **Pasting Objects into the Layout Layer** on page II-493 for more details on copying and pasting. See **Arranging Layout Objects** on page II-487 for details on tiling and stacking.

When the marquee tool is selected, any selected object is deselected. Double-clicking while the marquee tool is selected has no effect.

Annotation Tool

When you click the annotation tool, it becomes highlighted and the cursor changes to an I-beam. The annotation tool creates new annotations or modifies existing annotations. Annotations include textboxes, legends, and colorscales.

Clicking an existing annotation invokes the Modify Annotation dialog. Clicking anywhere else on the page invokes the Add Annotation dialog which you use to create a new annotation. See **Page Layout Annotations** on page II-494 for details.

Frame Pop-Up Menu

When an object is selected, you can change its frame by choosing an item from the Frame pop-up menu. Each object can have no frame or a single, double, triple or shadow frame.

When you change the frame of a graph, table or picture object, its outer dimensions (width and height) do not change. Since the different frames have different widths, the inner dimensions of the object *do* change. In the case of graphs this is usually the desired behavior. For tables, changing the frame shows a non-integral number of rows and columns. You can restore the table to an integral number of rows and columns by pressing Option (*Macintosh*) or Alt (*Windows*) and double-clicking the table. For pictures, changing the frame slightly resizes the picture to fit into the new frame. To restore the picture to 100% sizing, press Option (*Macintosh*) or Alt (*Windows*) and double-click the picture.

When you change the frame of an annotation object, Igor *does* change the outer dimensions of the object to compensate for the change in width of the frame.

Misc Pop-Up Menu

The Misc pop-up menu adjusts some miscellaneous settings related to the layout.

You can choose Points, Inches, or Centimeters. This sets the units used in the info panel.

You can enable or disable the DelayUpdate item. If DelayUpdate is on, when a graph or table which corresponds to an object in the layout changes, the layout is not updated until you activate it (make it the front window). If you disable DelayUpdate then changes to graphs or tables are reflected immediately in the layout. This also affects drawing commands. If you want to see the effect of drawing commands immediately, turn the DelayUpdate setting off.

DelayUpdate does not affect embedded graph and table subwindows.

DelayUpdate is a global setting that affects all existing and future layouts. When you change it in one layout, you change it for all layouts in all experiments.

You can use the Background Color submenu to change the layout's background color. See **Page Layout Background Color** on page II-477 for details.

Graph Pop-Up Menu

The Graph pop-up menu provides a handy way to append a graph object to the layout layer. It contains a list of all the graph windows that are currently open. Choosing the name of a graph appends the graph object to the layout layer. The initial size of the graph object in the layout is taken from the size of the graph window.

Table Pop-Up Menu

The Table pop-up menu provides a handy way to append a table object to the layout layer. It contains a list of all the table windows that are currently open. Choosing the name of a table appends the table object to the layout layer.

Gizmo Pop-Up Menu

The Gizmo pop-up menu provides a handy way to append a 3D Gizmo plot object to the layout layer. It contains a list of all the Gizmo windows that are currently open. Choosing the name of a Gizmo window appends the Gizmo object to the layout layer.

The Layout Layer Contextual Menu

When the layout layer is active, Control-clicking (*Macintosh*) or right-clicking (*Windows*) displays the Layout Layer contextual menu. The contents of the menu depend on whether you click directly on an object or on a part of the page where there is no object.

Layout Contextual Menu for a Single Object

If you Control-click (*Macintosh*) or right-click (*Windows*) directly on an object, the layout contextual menu includes these items:

Activate Object's Window

Activates the graph, table or 3D Gizmo plot window associated with the object.

Recreate Object's Window

Recreates the graph, table or 3D Gizmo plot window associated with the object by running the window recreation macro that was created when the window was killed.

Kill Object's Window

Kills the graph, table or 3D Gizmo plot window associated with the object. Before it is killed, Igor displays a dialog that you can use to create or update its window recreation macro.

If you press the Option key on Macintosh while selecting this item, the window is killed with no dialog and without creating or updating the window recreation macro. Any changes you made to the window will be lost so use this feature carefully. This feature does not work on Windows because the Alt key interferes with menu behavior.

Show Object's Window

Shows the corresponding window if it is hidden.

Hide Object's Window

Hides the corresponding if it is visible.

Scale Object

Changes the size of the layout object in terms of percent of its current size or percent of its normal size. Although this can work on any type of object, it is most useful for scaling pictures relative to their normal size.

For a picture or annotation object, "normal" size is the inherent size of the picture or annotation before any shrinking or expanding. For a graph, table or Gizmo object, "normal" size means the size of the corresponding window.

If a graph's size is hardwired via the Modify Graph dialog, the corresponding layout object can not be scaled.

Tip: You can quickly return a picture or annotation to its normal size by double-clicking it while pressing Option (*Macintosh*) or Alt (*Windows*).

Convert Object to Embedded

This item converts a graph, table or Gizmo object to an embedded subwindow. In doing so, the standalone window which the object represented is killed, leaving just the embedded subwindow.

Layout Contextual Menu for a Selected Object

If you Control-click or right-click on a part of the page where there is no object while objects are selected, the Layout contextual menu includes these items:

Recreate Selected Objects' Windows

Runs the recreation macro for each selected graph, table or Gizmo object for which the corresponding window was killed.

Kill Selected Objects' Windows

Kills the window corresponding to each selected graph, table, and Gizmo object. Before each window is killed, Igor displays a dialog that you can use to create or update its window recreation macro.

If you press the Option key on Macintosh while selecting this item, each window is killed with no dialog and without creating or updating the window recreation macro. Any changes you made to the window will be lost so use this feature carefully. This feature does not work on Windows because the Alt key interferes with menu behavior.

Show Selected Objects' Window

Shows the corresponding windows if they are hidden.

Hide Selected Objects' Window

Hides the corresponding windows if they are visible.

Scale Selected Objects

Changes the size of each selected layout object in terms of percent of its current size or percent of its normal size.

Page Layout Objects

The layout layer of a page layout page can contain five kinds of objects: graph windows, table windows, 3D Gizmo plot windows, annotations, and pictures. The term "layout object" references these objects in the layout layer only, not drawing elements or subwindows in other layers.

This table shows how you can add each of these objects to the layout layer.

Object Type	To Add Object to the Layout Layer
Graph	Use the Graph pop-up menu in the layout window. Use the Append to Layout dialog. Use the **AppendLayoutObject** operation.
Table	Use the Table pop-up menu in the layout window. Use the Append to Layout dialog. Use the **AppendLayoutObject** operation.
3D Gizmo Plots	Use the Gizmo pop-up menu in the layout window. Use the Append to Layout dialog. Use the **AppendLayoutObject** operation.

Object Type	To Add Object to the Layout Layer
Annotations	Click the text (“A”) tool and then click in the page area. Use the Add Annotation dialog. Use the **TextBox** or **Legend** operations.
Pictures	Paste from the clipboard. Use the Pictures dialog (Misc menu). Use the **AppendLayoutObject** operation if the picture already exists in the current experiment’s picture gallery.

Layout Object Names

Each object in the layout layer has a name so that you can manipulate it from the command line or from an Igor procedure as well as with the mouse. When you position the cursor over an object, its name, position and dimensions are shown in the info panel at the bottom of the layout window.

For a graph, table, or Gizmo object, the object name is the same as the name of the corresponding window. For an annotation, the object name is determined by the Textbox or Legend operation that created the annotation. When you paste a picture from the clipboard into a page layout, Igor automatically gives it a name like PICT_0 and adds it to the current experiment’s picture gallery which you can see by choosing Misc→Pictures.

Layout Object Properties

This table shows the properties of each object in the layout layer.

Object Property	Comment
Left coordinate	Measured from the left edge of the paper. Set using mouse or Modify Objects dialog.
Top coordinate	Measured from the top edge of the paper. Set using mouse or Modify Objects dialog.
Width	Set using mouse or Modify Objects dialog.
Height	Set using mouse or Modify Objects dialog.
Frame	None, single, double, triple, or shadow. Set using Frame pop-up menu or Modify Objects dialog.
Transparency	Set using Modify Objects dialog.

All of the properties can also be set using the ModifyLayout operation from the command line or from an Igor procedure.

Appending a Graph, Table, or Gizmo Plot to the Layout Layer

You can append a graph, table, or 3D Gizmo plot to a layout by choosing the Append to Layout item from the Layout menu or by using the pop-up menus in the layout’s tool palette.

Removing Objects from the Layout Layer

You can remove objects from a layout by choosing the Remove from Layout item from the Layout menu.

You can also remove objects by selecting them and choosing Edit→Clear or Edit→Cut.

Removing a picture from a layout does not remove it from the picture gallery. To do that, use the Pictures dialog.

Modifying Layout Objects

You can modify the properties of layout objects using the Modify Objects dialog. To invoke it, choose Modify Objects from the Layout menu or double-click an object with the layout layer arrow tool.

The effect of each property is described under **Layout Object Properties** on page II-486.

Once you have modified an object you can select another object from the Object list and modify it.

Automatic Updating of Layout Objects

Graph, table and Gizmo objects are dynamic. When the corresponding window changes, Igor automatically updates the layout object. Also, if you change the symbol for a wave in a graph and if that symbol is used in a layout legend, Igor automatically updates the legend.

Normally, Igor waits until the layout window is activated before doing an automatic update. You can force Igor to do the update immediately by deselecting the DelayUpdate item in the Misc pop-up menu in the layout's tool palette.

Dummy Objects

If you append a graph, table, or 3D Gizmo plot to the layout layer, this creates a layout object corresponding to the window. If you then kill the original window, the layout object remains and is said to be a "dummy object". A dummy object can be moved, resized or changed just as any other object.

If you later recreate the window or create a new window with the same name as the original, the object is reassociated with the window and ceases to be a dummy object.

Arranging Layout Objects

This section applies to layout objects in the layout layer only, not to drawing elements or subwindows.

Front-To-Back Relationship of Objects

New objects added to the layout layer are added in front of existing objects. You can move objects in front of or in back of other objects using the Layout menu after selecting a single object with the arrow tool.

These menu commands affect the layout layer only. To put drawing elements in front of the layout layer, use the User Front drawing layer. To put drawing elements behind the layout layer, User Back drawing layer.

Tiling Layout Objects

You can tile or stack objects in a layout by choosing the Arrange Objects item from the Layout menu. This displays the Arrange Objects dialog. The rest of this section refers to that dialog.

Click the Tile radio button to do tiling instead of stacking.

When you tile objects, Igor needs to know the following:

- Which objects you want to tile
- The area of the page into which you want to tile the objects
- The number of rows and columns of tiles that you want
- The spacing between tiles (grout)

You can specify all of this information via the Arrange Objects dialog.

In most cases, it is worthwhile for you pre-arrange the objects to be tiled in roughly the desired sizes and positions and select those objects before summoning the dialog. This facilitates using features of the dialog to precisely arrange the objects.

Before we get into details, we will look at a simple example that demonstrates tiling concepts.

Layout Tiling Guided Tour

In this tour, we will create a page layout displaying some graphs and arrange them using tiling.

We assume that we are creating the layout to produce a graphic of a specific size for use on a web page or in a paper, not for printing hard copy.

We start by making some graphs to tiled and then create a page layout containing the graphs.

1. **In a new experiment, execute the following commands:**

```
Make/O jack=sin(x/8), fred=cos(x/8), bob=jack*fred
Display/W=(35,50,300,175) jack
Display/W=(35,200,300,325) fred
Display/W=(35,350,300,475) bob
Layout/W=(350,50,850,650) Graph0, Graph1, Graph2
ModifyLayout mag=1, units=0
```

2. **If necessary, adjust the layout magnification and window size so you can see the entire page.**

   Next we will set the page size and margins appropriate for using in a web page or paper.

3. **Choose Layout→Page Size, enter the following settings, and click Do It:**

   Units: Points

   Width: 432

   Height: 360

   Margins: 0 for all

   Margins are useful when printing but usually serve no purpose when creating graphics for a paper or web page.

4. **Choose Layout→Append to Layout and append Graph0, Graph1, and Graph2.**

5. **Use Edit→Select All to select all of the graph objects in the layout.**

6. **Choose Layout→Arrange Objects.**

   Click the Tile radio button.

   Set the other settings as follows:

   Grout: 8

   Rows: Auto

   Columns: Auto

   Click Do It.

   The graphs are tiled in a 2 row by 2 column arrangment leaving the bottom/right tile empty.

   Suppose we want to leave the bottom/left tile empty rather than the bottom right.

7. **Drag the bottom/left graph and position it roughly in the bottom/right position.**

   Use Edit→Select All to select all of the graph objects.

   Choose Layout→Arrange Objects.

   Check the Preserve Arrangement checkbox.

   Click Do It.

   The Preserve Arrangement feature tiled the last graph in the bottom/right position as you had roughly positioned it.

   Next we will assume that you want to use just a portion of the page rather than the whole thing, perhaps to leave room for textboxes or other objects.

8. **Click the Misc icon in the tool palette and choose Points.**

   Click a blank area of the page to deselect all objects.

Drag the top/left graph down until its top edge is at 72 points (as displayed in the T section of the layout status panel)

Shift-click to select the top/right graph also and choose Layout→Align→Top Edges.

Shift-click to select the bottom/right graph also.

Choose Layout→Arrange Objects.

Check the Use Bounding Box checkbox.

Click Do It.

Now Igor has tiled the objects into the bounding box surrounding the selected graph objects. The bounding box is the smallest rectangle that encompasses all of the objects to be tiled.

We have left the top 72 points of the layout open for use by textboxes or other objects.

Next we will see how to do the same thing but using the marquee instead of the bounding box and leaving 36 points instead of 72 points of free space at the top.

The marquee tool is a dashed rectangle. It appears below the arrow tool and above the Annotation tool in the page layout tool palette.

To drag out a marquee, click in the page and drag diagonally. The marquee coordinates are displayed in the layout status panel at the bottom of the layout window.

The marquee has draggable handles on the corners and in the middle of each side that you can use for fine tuning its position.

9. **Click the Marquee tool and drag out a marquee that roughly fills the entire page.**

Position the mouse over the top handle and drag it so that the top is positioned at 36 points as shown in the T section of the layout status panel.

Drag the left, bottom, and right marquee handles to the corresponding page edges.

Choose Layout→Arrange Objects.

Uncheck the Use Bounding Box checkbox to enable the Use Marquee checkbox.

Click Do It.

Now Igor has tiled the objects into the area specified by the marquee.

This concludes the layout tiling guided tour.

Selecting Tiling Objects

There are several ways to specify which objects to arrange. The easiest is to select the objects in the page layout before summoning the Arrange Objects dialog. The selected objects will then be selected in the Objects to Arrange list.

Alternatively, you can select objects in the list directly. Objects are tiled in the order in which you select them.

Finally you can include objects to be tiled using the various dialog checkboxes such as All Graphs Too and All Tables Too.

If you select no objects in the list and select none of the checkboxes, then all of the objects in the layout will be arranged.

Specifying the Tiling Area

You can specify the tiling area by clicking the marquee tool and dragging out a marquee. Then when you enter the dialog, the Use Marquee checkbox will be checked and enabled.

Alternatively, you can pre-position the objects so that their bounding box defines the tiling area. The bounding box is the smallest rectangle that completely encloses all of the objects to be tiled. To use this technique, roughly pre-position the objects. Next precisely adjust the positions of the left-most, top-most, right-most, bottom-most edges. Select the objects to be tiled, summon the dialog, and check the Use Bounding Box and Preserve Arrangement checkboxes. See **Layout Tiling Guided Tour** on page II-488 for an example.

If you uncheck both Use Marquee and Use Bounding Box, the tiling area is the entire page.

Setting the Number of Rows and Columns

You can set the number of rows and columns of tiles or you can leave them both on auto. If auto, Igor figures out a nice arrangement based on the number of objects to be tiled and the available space. Setting rows or columns to zero is the same as setting it to auto.

If you set both the rows and columns to a number between 1 and 100, Igor tiles the objects in a grid determined by your row/column specification. If you set either rows *or* columns to a number between 1 and 100 but leave the other setting on auto, Igor figures out what the other setting should be to properly tile the objects. In all cases, Igor tiles starting from the top-left cell in a grid defined by the rows and columns, moving horizontally first and then vertically.

If the grid that you specify has fewer tiles than the number of objects to be tiled, once all of the available tiles have been filled, Igor starts tiling from the top-left corner again.

Setting the Space Between Tiles

To set the space between tiles, enter a value in points in the Grout edit box.

Preserving Your Rough Arrangement

If you check the Preserve Arrangement checkbox, Igor tries to keep the tiled objects in the same approximate positions as your rough pre-positioning. See **Layout Tiling Guided Tour** on page II-488 for an example.

If your approximate positioning is not close enough and if you have left the number of rows and columns as Auto, Preserve Arrangement may get the wrong row/column arrangement. In this case, enter specific values for the number of rows and columns and try again.

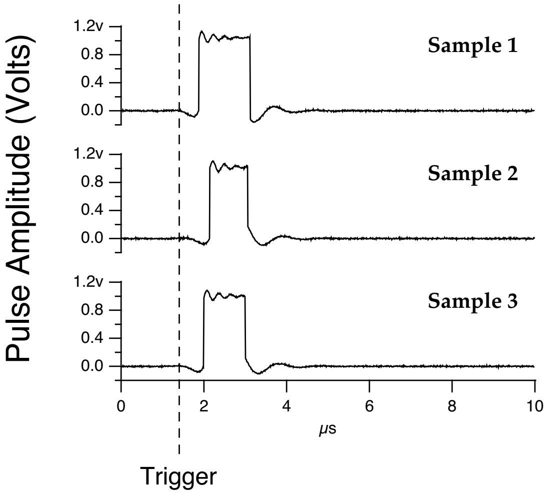
Other Tiling Issues

Regardless of the parameters you specify, Igor clips coordinates so that a tiled object is never completely off the page. Also, objects are never set smaller than a minimum size or larger than the page.

If Preserve Arrangement is unchecked, objects are tiled from left to right, top to bottom. If you select objects in the Objects to Arrange list, they are tiled in the order in which you selected them. If you select no objects in the list, the order in which objects are tiled is determined by the front to back ordering of the objects in the layout.

Aligning Layout Objects

It is a common practice to stack a group of graphs vertically in a column. Sometimes, only one X axis is used for a number of vertically stacked graph. Here is an example.



This section gives step-by-step instructions for creating a layout like the one above. It is also possible to do this using a single graph (see **Creating Stacked Plots** on page II-324 for details) or using subwindows (see Chapter III-4, **Embedding and Subwindows**).

To align the axes of multiple graph objects in a layout, it is critical to set the graph margins. This is explained in detail as follows.

The basic steps are:

1. Prepare the graphs.
2. Append the graph objects to the layout.
3. Align the left edges of the graph objects.
4. Set the width and height of the graph objects.
5. Set the vertical positions of the graph objects.
6. Set the graph plot areas and margins to uniform values.

It is possible to do steps 3, 4, and 5 at once by using the Arrange Objects dialog. However, in this section, we will do them one-at-a-time.

Prepare the Graphs

It is helpful to set the size of the graph windows approximately to the size you intend to use in the layout so that what you see in the graph window will resemble what you get in the layout. You can do this manually or you can use the MoveWindow operation. For example, here is a command that sets the target window to 5 inches wide by 2 inches tall, one inch from the top-left corner of the screen.

```
MoveWindow/I 1, 1, 1 + 5, 1 + 2
```

In the example shown above, we wanted to hide the X axes of all but the bottom graph. We used the Axis tab of the Modify Graph dialog to set the axis thickness to zero and the Label Options tab to turn the axis labels off.

Append the Graphs to the Layout

Click in the layout window or create a new layout using the New Layout item in the Windows menu. If necessary, activate the layout tools by clicking the layout icon in the top-left corner of the layout. Use the Graph pop-up menu or the Append to Layout item in the Layout menu to add the graph objects to the layout. Drag each graph object to the general area of the layout page where you want it.

Align Left Edges of Layout Objects

Drag one of the graphs to set its left position to the desired location. Then Shift-click the other graphs to select them. Now choose Align→Left Edges from the Layout menu.

Set Width and Height of Layout Objects

Set the width and height of one of the graph objects by selecting it and dragging the resulting handles or by double-clicking it and entering values in the Modify Objects dialog.

Click in a blank part of the page to deselect all objects. Now click the object whose dimensions you just set. Now Shift-click to select the other graph objects. With all of the graph objects selected, choose Make Same Width And Height from the Layout menu.

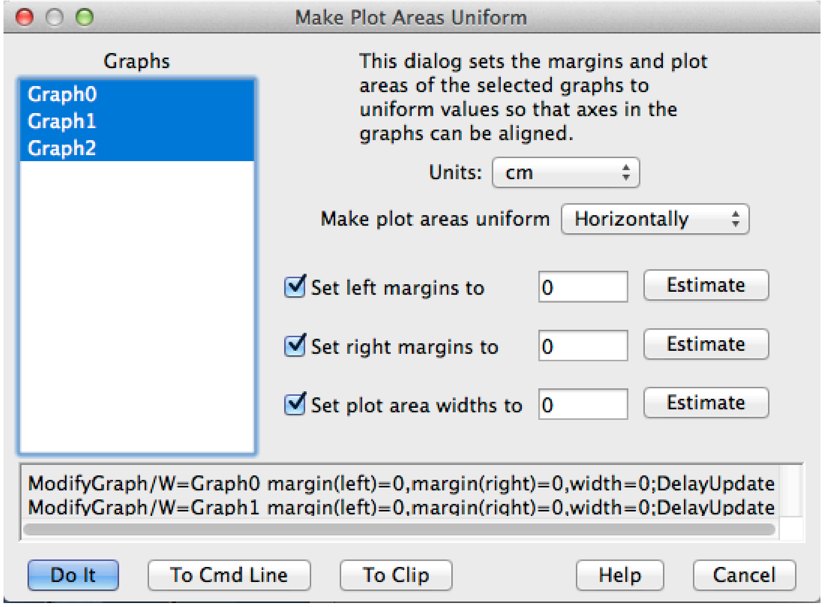
Set Vertical Positions of Layout Objects

Drag the graph objects to their approximate desired positions on the page. You can drag an object vertically without affecting its horizontal position by pressing Shift while dragging. You must press Shift after clicking the object - otherwise the Shift-click will deselect it. Once you have set the approximate position, fine tune the vertical positions using the arrow keys to nudge the selected object.

Set Graph Plot Areas and Margins

At this point, your axes would be aligned except for one subtle thing. The width of text (e.g., tick mark labels) in the left margin of each graph can be different for each graph. For example, if one graph has left axis tick mark labels in the range of 0.0 to 1.0 and another graph has labels in the range 10,000 to 20,000, Igor would leave more room in the left margin of the second graph. The solution to this problem is to set the graph margins, as well as the width of the plot areas, of each graph to the same specific value.

To do this, select all of the graph objects and then choose Make Plot Areas Uniform from the Layout menu. This invokes the following dialog:



Make Plot Areas Uniform

Graphs

Graph0
Graph1
Graph2

This dialog sets the margins and plot areas of the selected graphs to uniform values so that axes in the graphs can be aligned.

Units: cm

Make plot areas uniform: Horizontally

☑ Set left margins to 0

☑ Set right margins to 0

☑ Set plot area widths to 0

```
ModifyGraph/W=Graph0 margin(left)=0,margin(right)=0,width=0;DelayUpdate
ModifyGraph/W=Graph1 margin(left)=0,margin(right)=0,width=0;DelayUpdate
```

Because we are stacking graphs vertically, we want their horizontal margins and plot areas to be the same, which is why we have selected Horizontally from the pop-up menu. The three checkboxes are selected because we want to set both the left and right margins as well as the plot area width.

Now click each of the three Estimate buttons. When you click the Estimate button next to the Set Left Margins To checkbox, Igor sets the corresponding edit box to the largest left margin of all of the graphs selected in the list. Igor does a similar thing for the other two Estimate buttons. As a result, after clicking the three buttons, you should have reasonable values. Click Do It.

Now examine the stacked graph objects. It is possible that you may want to go back into the Make Plot Areas Uniform dialog to manually tweak one or more of the settings.

After doing these steps, the horizontal plot areas in the stacked graphs will be perfectly aligned. This does not, however, guarantee that the left axes will line up. The reason for this is the graphs' axis standoff settings. The axis standoff setting, if enabled, moves the left axis to the left of the plot area to prevent the displayed traces from colliding with the axis. If the graphs have different sized markers, for example, it will offset the left axis of each graph by a different amount. Thus, although the plot areas are perfectly-aligned horizontally, the left axes are not aligned. The solution for this is to use the Modify Axis dialog (Graph menu) to turn axis standoff off for each graph.

Copying and Pasting Layout Objects

This section discusses copying objects from the layout layer of a page layout and pasting them into the same or another page layout. Most users will not need to do this.

Copying Objects from the Layout Layer

You can copy objects to the clipboard by selecting them with the arrow tool or enclosing them with the marquee tool and then choosing Copy from the Edit menu. You can also choose Copy from the pop-up menu that appears when you click inside the marquee.

When you copy an object to the clipboard, it is copied in two formats:

- As an Igor object in a format used internally by Igor
- As a picture that can be understood by other applications

Although you can do a copy for the purposes of exporting to another application, this is not the best way. See **Exporting Page Layouts** on page II-498 for a discussion of exporting graphics to another application. This section deals with copying objects for the purposes of pasting them in the same or another layout. Since it is easy to append graphs and tables to a layout using the pop-up menus in the tool palette, the main utility of this is for copying annotations or pictures from one layout to another.

Copying as an Igor Object Only

There are times when a straightforward copy operation is not desirable. Imagine that you have some graph objects in a layout and you want to put the same objects in another layout. You could copy the graph objects and paste them into the other layout. However, if the graphs are very complex, it could take a lot of time and memory to copy them to the clipboard as a picture. If your purpose is not to export to another application, there is really no need to copy as a picture. If you press Option (*Macintosh*) or Alt (*Windows*) while choosing Copy, then Igor will do the copy only as Igor objects, not as a picture. You can now paste the copied graphs in the other layout.

Pasting Objects into the Layout Layer

This section discusses pasting Igor objects that you have copied from the same or a different page layout. For pasting a new picture that you have generated with another application, see **Inserting a Picture in the Layout Layer** on page II-496.

To paste layout objects that you have copied to the clipboard from the same Igor experiment, just choose Paste from the Edit menu.

When you copy a graph, table, Gizmo or picture layout object from a layout to the clipboard, it is copied as a picture and as an Igor object in an internal Igor format. The Igor format includes the name by which Igor knows the layout object. If you later paste into a layout, Igor will use this name to determine what object should be added to the layout. It normally does not paste the picture representation of the object. In other words, the Igor format of the object that is copied to the clipboard refers to a graph, table, Gizmo or picture by its name.

In rare cases, you may actually want to paste as a picture, not as an Igor object. You might plan to change the graph but want a representation of it as it is now in the layout. To do this, press Option (*Macintosh*) or Alt (*Windows*) while choosing Edit→Paste. This creates a new named picture in the current experiment.

Pasting into a Different Experiment

The reference in the clipboard to Igor objects by name doesn't work across Igor experiments. The second experiment may have a different object with the same name or it may have no object with the name stored in the clipboard. The best you can do when pasting from one experiment to another is to paste a *picture* of the object from the first experiment.

You can force Igor to paste the picture representation instead of the Igor object representation as described above, by pressing Option (*Macintosh*) or Alt (*Windows*) while choosing Edit→Paste.

Pasting Color Scale Annotations

For technical reasons, Igor is not able to faithfully paste a color scale annotation that uses a color index wave or that uses the lookup keyword of the ColorScale operation. If you paste such a color scale, Igor will change it to a color table color scale annotation with no lookup.

Page Layout Annotations

The term “annotation” includes textboxes, legends, tags, and color scales. You can create annotations in graphs and in page layouts. Annotations are discussed in detail in Chapter III-2, **Annotations**. This section discusses aspects of annotations that are unique to page layouts.

Annotations in page layouts exist as layout objects in the layout layer, along with graphs, tables, 3D Gizmo plots, and pictures.

In a graph, an annotation can be a textbox, legend, tag, or color scale. A legend shows the plot symbols for the waves in the graph. A tag is connected to a particular point of a particular wave. In a layout, tags are not applicable. You can create textboxes, legends, and color scales.

Annotations are distinct from the simple text elements that you can create in the drawing layers of graphs, layouts and control panels.

Creating a New Annotation

To create a new annotation, choose Add Annotation from the Layout menu or select the annotation tool and click anywhere on the page, except on an existing annotation. These actions invoke the Add Annotations dialog.

The many options in this dialog are explained in Chapter III-2, **Annotations**.

Modifying an Existing Annotation

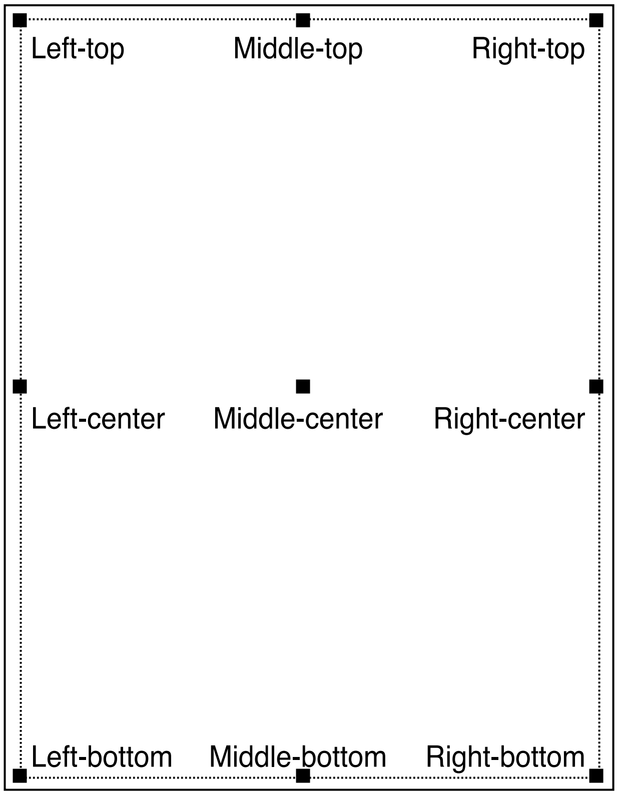
If an annotation is selected when you pull down the Layout menu, you will see a Modify Annotation item instead of the Add Annotation item. Use this to modify the text or style of the selected annotation. You can also invoke the Modify Annotation dialog by clicking the annotation while the annotation tool is selected. Double-clicking an annotation while the arrow tool is selected brings up the Modify Object dialog, not the Modify Annotation dialog.

Positioning an Annotation

An annotation is positioned relative to an anchor point on the edge of the printable part of the page. The distance from the anchor point to the textbox is determined by the X and Y offsets expressed in percent of the width and height of the page inside the margins. The X and Y offsets are automatically set for you when you drag a textbox around the page. You can also set them using the Position tab of the Modify Annotation dialog but this is usually not as easy as just dragging.

Positioning Annotations Programmatically

This diagram shows the anchor points:



Using the top-left anchor, a (0, 0) XY offset would put a tag in the top-left corner of the page:

```
Textbox/A=LT/X=0/Y=0 "Test 1"
```

An XY offset of (50, 50) would put a tag in the middle of the page.

```
Textbox/A=LT/X=50/Y=50 "Test 2"
```

Using the middle-center anchor, a (0, 0) XY offset would put a tag in the middle of the page:

```
Textbox/A=MC/X=0/Y=0 "Test 3"
```

An XY offset of (-50, 50) would put a tag in the top-left corner of the page.

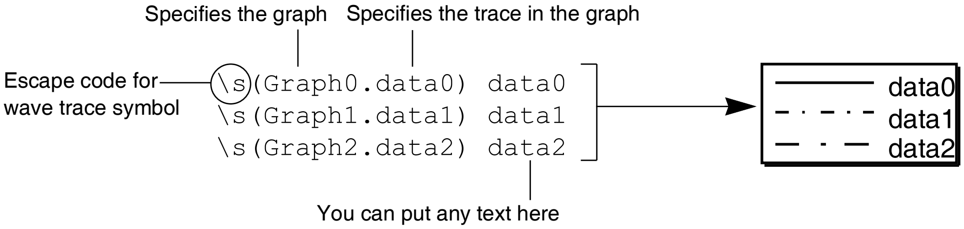
```
Textbox/A=MC/X=-50/Y=50 "Test 4"
```

For most purposes, the left-top anchor is the easiest to use and is sufficient.

The anchor sets not only the reference point on the page but also the reference point on the annotation. For example, if the anchor is right-top then the XY offset sets the position of the right-top corner of the annotation, relative to the right-top corner of the page. For this reason, if you want several textboxes to be right-aligned, you would want to use a right-top, right-center or right-bottom anchor.

Legends in the Layout Layer

When you invoke the Add Annotations dialog and choose Legend, Igor automatically sets the annotation's text to produce a legend containing a symbol for each wave in each graph object in the layout. This diagram illustrates the legend text generated by the dialog:



```
\s(Graph0.data0) data0
\s(Graph1.data1) data1
\s(Graph2.data2) data2
```

Specifies the graph
Specifies the trace in the graph
Escape code for wave trace symbol
You can put any text here
data0
data1
data2

Igor generates the lines of the legend text starting with the bottom graph object in the layout and working toward the top. You can edit the text to remove symbols that you don’t want or to change what appears after the symbol.

If you change the symbol for a trace referenced in the legend, Igor automatically updates the layout legend. If you append or remove waves to the graphs represented in the layout, Igor updates the layout legend. Updating happens when you activate the layout unless you have turned the layout’s DelayUpdate setting off, in which case it happens immediately.

You can freeze a legend by converting it to a textbox. This stops Igor from automatically updating it when waves are added to or removed from graphs. To do this, select the annotation tool and click in the legend. In the resulting Modify Annotation dialog, change the pop-up menu in the top-left corner from Legend to Textbox. You can also do this using the following command:

```
Textbox/C/N=text0    // convert legend named text0 into a textbox
```

Instead of specifying the name of the trace for a legend symbol, you can specify the trace number. For example, "\s(Graph0.#0)" displays the legend for trace number 0 of Graph0.

Default Font

By default, annotations use the default font chosen in the Default Font dialog via the Misc menu. You can override the default font using the Font pop-up menu in the Add Annotation dialog.

Page Layout Pictures

You can insert a picture that you have created in another application, for example a drawing program or equation editor, into the layout layer or into a drawing layer. If the picture has some relation to other drawing elements, you should use the drawing layer. If it has some relation to other layout objects, you should use the layout layer. The use of drawing layers is discussed under **Pasting a Picture Into a Drawing Layer** on page III-73. This section discusses pictures in the layout layer.

Inserting a Picture in the Layout Layer

All pictures displayed in the layout layer reside in the picture gallery which you can see by choosing Misc→Pictures. If you paste a picture from the clipboard into the layout layer, Igor automatically adds it to the picture gallery. If the picture is in a file on disk, you must first load it into the picture gallery. Then you can place it in the layout layer.

See **Pictures** on page III-509 for information on supported picture formats.

Resetting a Picture’s Size

If you expand or shrink a picture in the layout layer, you can reset it to its default size by pressing Option (*Macintosh*) or Alt (*Windows*) and double-clicking it with the arrow tool.

Page Layout Subwindows

The subwindow is a power-user feature. It is described in detail in Chapter III-4, **Embedding and Subwindows** and can not be effectively used without a careful reading of that chapter. In this section we discuss subwindows as they apply to page layouts.

You can create three kinds of subwindows in a page layout window: graphs, tables, and 3D Gizmo plots. To add a subwindow to a layout:

1. Activate the layout layer by clicking the layout icon.
2. Select the marquee tool (dashed-line rectangle).
3. Drag out a marquee.
4. Click inside the marquee and choose one of the following:

- New Graph Here
- New Category Plot Here
- New Contour Plot Here
- New Image Plot Here
- New Table Here
- New 3D Plot Here

You can also create a subwindow by right-clicking (*Windows*) or Control-clicking (*Macintosh*) while in drawing mode and choosing an item from the New submenu.

You can convert a layout object to an embedded subwindow by right-clicking (*Windows*) or Control-clicking (*Macintosh*) while in layout mode and choosing Convert To Embedded. Note that a graph containing a control panel or controls cannot be converted into an embedded graph, even though a graph object with controls or control panels can be added to a layout. Such a graph object does not display the controls or control panels, however.

You can convert a subwindow to a standalone window and layout object object by right-clicking (*Windows*) or Control-clicking (*Macintosh*) while in layout mode and choosing Convert To Window And Object. In a graph window, you must click in the graph background, away from any traces or axes.

Page Layout Drawing

Like graphs and control panels, you can add drawing elements to page layouts. Drawing in general is discussed under Chapter III-3, **Drawing**. This section discusses drawing issues specific to page layouts.

You enter drawing mode by clicking the second icon from the top in the tool palette, as explained under **Activating the Current Drawing Layer** on page II-480. Once in drawing mode, you can select a specific drawing layer using the drawing layer tool, as explained under **Changing the Current Drawing Layer** on page II-480.

Page Layout Slide Shows

A layout slide show is a full-screen display of the pages in a layout, suitable for a presentation to a group. You start a slide shows by clicking the button at the bottom/right corner of the layout page sorter, or using the **LayoutSlideShow** operation.

Using the Slide Show Settings dialog, which you can invoke via the Layout menu, you can control various aspects of the slide show, including:

- How pages are scaled to fit the screen
- How multiple monitors are used
- The time to wait before showing the next slide

Exporting Page Layouts

You can export a layout to another application through the clipboard or by creating a file. To export via the clipboard, use the Export Graphics item in the Edit menu. To export via a file, use the Save Graphics item in the File menu.

If you want to export a section of the page, use the marquee tool to specify the section first. To do this, the layout icon in the top-left corner of the layout window must be selected.

If you don't use the marquee, Igor exports the entire page, or the part of the page that has layout objects or drawing elements in it. The Crop to Page Contents, in the Export Graphics and Save Graphics dialogs, controls this.

The process of exporting graphics from a layout is very similar to exporting graphics from a graph. You can find the details under Chapter III-5, **Exporting Graphics (Macintosh)** and Chapter III-6, **Exporting Graphics (Windows)**. Those chapters describe the various export methods and how to select the method that will give you the best results.

Page Layout Preferences

Page layout preferences allow you to control what happens when you create a new layout or add new objects to the layout layer of an existing layout. To set preferences, create a layout and set it up to your taste. We call this your *prototype* layout. Then choose Capture Layout Prefs from the Layout menu.

Preferences are normally in effect only for *manual* operations, not for programmed operations in Igor procedures. This is discussed in more detail in Chapter III-18, **Preferences**.

When you initially install Igor, all preferences are set to the factory defaults. The dialog indicates which preferences you have changed.

The "Window Position and Size" preference affects the creation of new layouts only.

The Object Properties preference affects the creation of new objects in the layout layer. To capture this, add an object to the layout layer and use the Modify Objects dialog to set its properties. Then select the object and choose Capture Layout Prefs. Select the Object Properties checkbox and click Capture Prefs.

The page size and margins preference affects what happens when you create a new layout, not when you recreate a layout using a recreation macro.

Page Layout Style Macros

The purpose of a layout style macro is to allow you to create a number of layouts with the same stylistic properties. Using the Window Control dialog, you can instruct Igor to automatically generate a style macro from a prototype layout. You can then apply the macro to other layouts.

Igor can generate style macros for graphs, tables and page layouts. However, their usefulness is mainly for graphs. See **Graph Style Macros** on page II-350. The principles explained there apply to layout style macros also.

Page Layout Shortcuts

Action	Shortcut (*Macintosh*)	Shortcut (*Windows*)
Change the layout magnification	Click the magnification readout in the lower-left corner of the layout window.	Click the magnification readout in the lower-left corner of the layout window.
Modify layout object properties	Select the arrow tool in Layout mode and double-click the object.	Select the arrow tool in Layout mode and double-click the object.
Edit an existing annotation	Select the annotation tool in the Layout mode and click in the annotation.	Select the annotation tool in the Layout mode and click in the annotation.
Bring up a graph or table window	Select corresponding object in the layout layer and then double-click the name of the object in the info panel.	Select corresponding object in the layout layer and then double-click the name of the object in the info panel.
Auto-size a picture or annotation object to 100%	Select arrow tool in Layout mode, press Option and double-click the picture or annotation object.	Select arrow tool in Layout mode, press Alt and double-click the picture or annotation object.
Auto-size a table object to an integral number of rows and columns	Select arrow tool in Layout mode, press Option and double-click the table object.	Select arrow tool in Layout mode, press Alt and double-click the table object.
Constrain the resizing direction or dragging an object	Press Shift while resizing or dragging the object. You must press Shift after clicking the object - otherwise the Shift-click will deselect it.	Press Shift while resizing or dragging the object. You must press Shift after clicking the object - otherwise the Shift-click will deselect it.
Copy, cut, or clear multiple layout objects	Use the arrow tool or marquee tool to select the objects, then choose copy, cut or clear from the Edit menu.	Use the arrow tool or marquee tool to select the objects, then choose copy, cut or clear from the Edit menu.
Export a subset of the layout via the clipboard	Using the marquee tool, select a page area, then choose Export Graphics from the Edit menu.	Using the marquee tool, select a page area, then choose Export Graphics from the Edit menu.
Export a subset of the layout via the a graphics file	Using the marquee tool, select a page area and then choose Save Graphics from the File menu.	Using the marquee tool, select a page area and then choose Save Graphics from the File menu.
Drawing tool shortcuts	See Chapter III-3, **Drawing**.	See Chapter III-3, **Drawing**.

Chapter III-1

Notebooks

Overview

A notebook is a window in which you can store text and graphics, very much like a word processor document. Typical uses for a notebook are:

- Keeping a log of your work.
- Generating a report.
- Examining or editing a text file created by Igor or another program.
- Documenting an Igor experiment.

A notebook can also be used as a worksheet in which you execute Igor commands and store text output from them.

Plain and Formatted Notebooks

There are two types of notebooks:

- Plain notebooks.
- Formatted notebooks.

Formatted notebooks can store text and graphics and are useful for reports. Plain notebooks can store text only. They are good for examining data files and other text files where line-wrapping and fancy formatting is not appropriate.

This table lists the properties of each type of notebook.

Property	Plain	Formatted
Can contain graphics	No	Yes
Allows multiple paragraph formats (margins, tabs, alignment, line spacing)	No	Yes
Allows multiple text formats (fonts, text styles, text sizes, text colors)	No	Yes
Does line wrapping	No	Yes
Has rulers	No	Yes
Has headers and footers	Yes	Yes
File name extension	.txt	.ifn
Can be opened by most other programs	Yes	No
Can be exported to word processors via Rich Text file	Yes	Yes

Plain text files can be opened by many programs, including virtually all word processors, spreadsheets and databases. The Igor formatted notebook file format is a proprietary WaveMetrics format that other applications can not open. However, you can save a formatted notebook as a Rich Text file, which is a file format that many word processors can open.

Igor does not store settings (font, size, style, etc.) for plain text files. When you open a file as a plain text notebook, these settings are determined by preferences. You can capture preferences by choosing Notebook→Capture Notebook Prefs.

Notebook Text Encodings

Igor uses UTF-8, a form of Unicode, internally. Prior to Igor7, Igor used non-Unicode text encodings such as MacRoman, Windows-1252 and Shift JIS.

All new notebook files should use UTF-8 text encoding. When you create a new notebook using Windows→New→Notebook, Igor automatically uses UTF-8. Also, the NewNotebook operation defaults to UTF-8.

Igor must convert from the old text encodings to Unicode when opening old files. It is not always possible to get this conversion right. You may get incorrect characters or receive errors when opening files containing non-ASCII text.

For a discussion of these issues, see **Text Encodings** on page III-459, **Plain Text File Text Encodings** on page III-466, and **Formatted Text Notebook File Text Encodings** on page III-472.

Creating a New Notebook File

To create a new notebook, choose Windows→New→Notebook. This displays the New Notebook dialog.

The New Notebook dialog creates a new notebook *window*. The notebook *file* is not created until you save the notebook window or save the experiment.

Normally you should store a notebook as part of the Igor experiment in which you use it. This happens automatically when you save the current experiment unless you do an explicit Save Notebook As before saving the experiment. Save Notebook As stores a notebook separate from the experiment. This is appropriate if you plan to use the notebook in multiple experiments.

Note: There is a risk in sharing notebook files among experiments. If you copy the experiment to another computer and forget to also copy the shared files, the experiment will not work on the other computer. See **References to Files and Folders** on page II-24 for more explanation.

If you do create a shared notebook file then you are responsible for copying the shared file when you copy an experiment that relies on it.

Opening an Existing File as a Notebook

You can create a notebook window by opening an existing file. This might be a notebook that you created in another Igor experiment or a plain text file created in another program. To do this, choose File→Open File→Notebook.

Opening a File for Momentary Use

You might want to open a text file momentarily to examine or edit it. For example, you might read a Read Me file or edit a data file before importing data. In this case, you would open the file as a notebook, do your reading or editing and then kill the notebook. Thus the file would not remain connected to the current experiment.

Sharing a Notebook File Among Experiments

On the other hand, you might want to share a notebook among multiple experiments. For example, you might have one notebook in which you keep a running log of all of your observations. In this case, you could save the experiment with the notebook open. Igor would then save a reference to the shared notebook file in the experiment file. When you later open the experiment, Igor would reopen the notebook file.

As noted above, there is a risk in sharing notebook files among experiments. You might want to “adopt” the opened notebook. See **References to Files and Folders** on page II-24 for more explanation.

Saving All Standalone Notebook Files

When a notebook window is active, you can save all modified standalone notebook files at once by choosing File→Save All Standalone Notebook Files. This saves only standalone notebook files. It does not save packed notebook files, or notebook windows that were just created and never saved to disk; these are saved when you save the experiment.

Autosaving Standalone Notebook Files

Igor can automatically save modified standalone notebook files. See **Autosave** on page II-36 for details.

Notebooks as Worksheets

Normally you enter commands in Igor's command line and press Return or Enter to execute them. You can also enter and execute commands in a notebook window. Some people may find using a notebook as a worksheet more convenient than using Igor's command line.

You can also execute commands from procedure windows and from help windows. The former is sometimes handy during debugging of Igor procedures. The latter provides a quick way for you to execute commands while doing a guided tour or to try example commands that are commonly presented in help files. The techniques described in the next paragraphs for executing commands from a notebook also apply to procedure and help windows.

To execute a command from a notebook, enter the command in a notebook, or select existing text, and press Control-Enter (*Macintosh*) or Ctrl-Enter (*Windows*). You can also select text already in the notebook and press Control-Enter. You can also right-click selected text and choose Execute Selection from the resulting pop-up menu.

When you press Control-Enter, Igor transfers text from the notebook to the command line and starts execution. Igor stores both the command and any text output that it generates in the notebook and also in the history area of the command window. If you don't want to keep the command output in the notebook, just undo it.

Command output is never sent to a procedure window or help window.

Command output is not sent to the notebook if it is open for read only, or if you clicked the write-protect icon, or if you disabled it by unchecking the Copy Command Output to the Notebook checkbox in the Command Window section of the Miscellaneous Settings dialog.

If you don't want to store the commands or the output in the history area, you can disable this using the Command Window section of the Miscellaneous Settings dialog. However, if command output to the notebook is disabled, the command and output are sent to the history area even if you have disabled it.

Showing, Hiding and Killing Notebook Windows

Notebook files can be opened (added to the current experiment), hidden, and killed (removed from the experiment).

When you click the close button of a notebook window, Igor presents the Close Notebook Window dialog to find out what you want to do. You can save and then kill the notebook, kill it without saving, or hide it.

If you just want to hide the window, you can press Shift while clicking the close button. This skips the dialog and just hides the window.

Killing a notebook window closes the window and removes it from the current experiment but does *not* delete the notebook file with which the window was associated. If you want to delete the file, do this on the desktop.

The Close item of the Windows menu and the keyboard shortcut, Command-W (*Macintosh*) or Ctrl+W (*Windows*), behave the same as the close button, as indicated in these tables.

Macintosh:

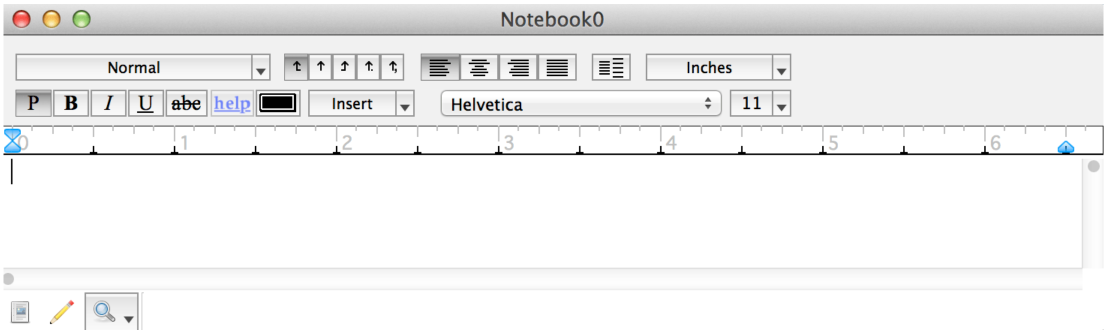
Action	Modifier Key	Result
Click close button, choose Close or press Command-W	None	Displays dialog
Click close button, choose Close or press Command-W	Shift	Hides window

Windows:

Action	Modifier Key	Result
Click close button, choose Close or press Ctrl+W	None	Displays dialog
Click close button, choose Close or press Ctrl+W	Shift	Hides window

Parts of a Notebook

This illustration shows the parts of a formatted notebook window. A plain notebook window has the same parts except for the ruler.



Ruler Bar

Rulers defined paragraph formatting, including font, text size, text style, indents, tabs, and spacing.

You can use the ruler bar to apply a ruler to the selected paragraphs, to modify a ruler, or to apply changes to the selected text without changing the current ruler.

In a formatted text notebook, you can show and hide the ruler bar using the Notebook menu. You can not show the ruler bar in a plain text notebook.

You can create as many rulers as you want in a formatted text notebook. A plain text notebook has just one ruler.

Document Info Icon

The icon in the bottom/left corner of the notebook is the document info icon. When you click it, Igor displays information about the notebook and its associated file, if any.

Write-Protect Icon

Notebooks (as well as procedure windows) have a write-enable/write-protect icon which appears in the lower-left corner of the window and resembles a pencil. If you click this icon, Igor Pro will draw a line through the pencil, indicating that the notebook is write-protected. The main purpose of this is to prevent accidental manual alteration of shared procedure files, but you can also use it to prevent accidental manual alteration of notebooks.

Note that write-protect is not the same as read-only. Write-protect prevents manual modifications while read-only prevents all modifications. See **Notebook Read/Write Properties** on page III-10 for details.

Magnifier Icon

You can magnify procedure text to make it more readable. See **Text Magnification** on page II-53 for details.

Notebook Properties

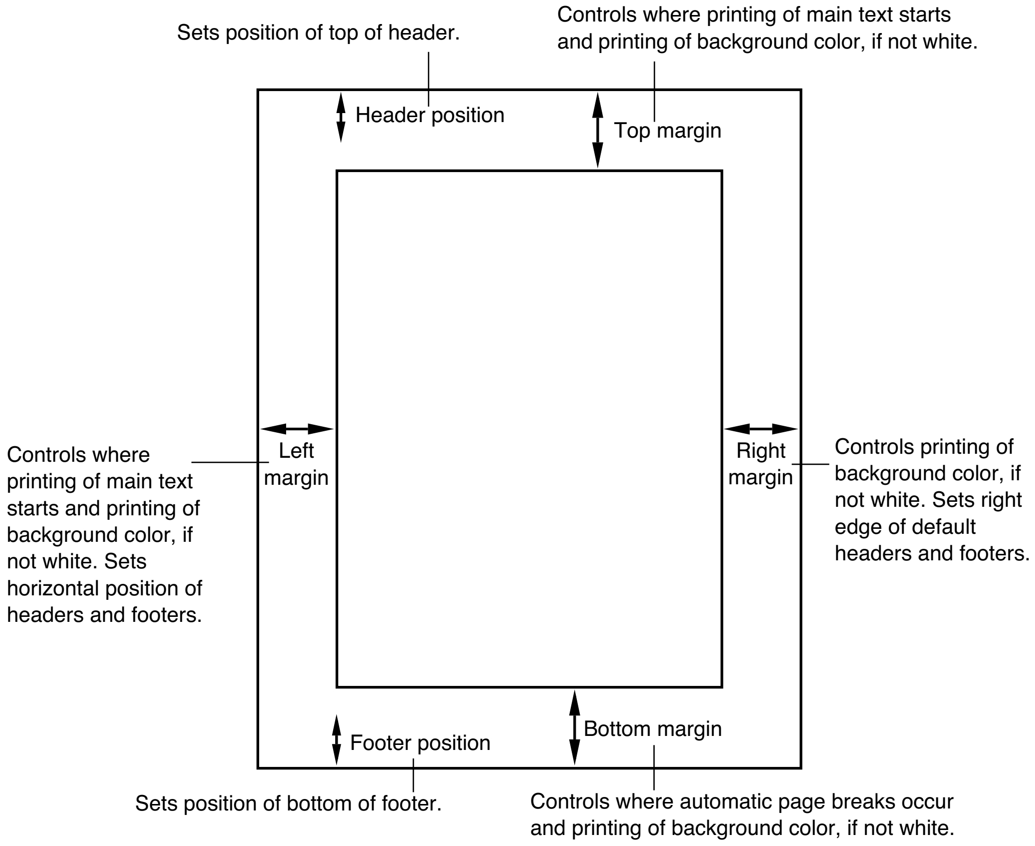
Everything in a notebook that you can control falls into one of four categories, as shown in this table.

Category	Settings
Document properties	Page margins, background color, default tab stops, headers and footers.
Paragraph properties	Paragraph margins and indents, tab stops, line alignment, line spacing, default text format.
Character properties	Font, text size, text style, text color, vertical offset.
Read/write properties	Read-only, write-protect and changeableByCommandOnly.

Notebook Document Properties

To set document properties, choose Notebook→Document Settings. These are properties that apply to the notebook as a whole, such as page margins, headers, footers, background color, and default tab stops.

The next illustration shows the effects of the page margins and header and footer position settings. In addition, these settings affect the Rich Text format file which you can use to export a notebook to a word processor.



Sets position of top of header.
Controls where printing of main text starts and printing of background color, if not white.
Header position
Top margin
Controls where printing of main text starts and printing of background color, if not white. Sets horizontal position of headers and footers.
Left margin
Right margin
Controls printing of background color, if not white. Sets right edge of default headers and footers.
Footer position
Bottom margin
Sets position of bottom of footer.
Controls where automatic page breaks occur and printing of background color, if not white.

The notebook page margins override margins set via the Page Setup dialog and the PrintSettings operation margins keyword.

Notebook Default Tabs

The default tab width setting controls the location of all tab stops in plain text notebooks and of all tab stops after the last explicit tab stop in formatted notebooks. You set this using the Document Settings dialog in the Notebook menu or using the Notebook operation defaultTab or defaultTab2 keywords.

Three modes are available: points, spaces, and mixed. In points mode, you specify the default tab width for all paragraphs in units of points. In the Document Settings dialog, you can enter this setting in inches, centimeters, or points, but it is always stored as points. Prior to Igor Pro 9.00, this was the only mode available.

In spaces mode, you specify the default tab width for all paragraphs in units of spaces.

In mixed mode, you specify the default tab width for paragraphs controlled by proportional fonts in units of points and for paragraphs controlled by monospace fonts in units of spaces.

Specifying default tabs in spaces is mostly of use for indentation and alignment of comments in notebooks that show Igor code such as Igor help files.

For formatted notebooks, the space character unit used in spaces mode and in mixed mode for monospace fonts is the width of a space character in the ruler font for a given paragraph. For plain text notebooks, it is the width of a space character in the notebook font.

In a formatted notebook, the ruler displays explicit tab stops and default tab stops. You can adjust default tab stops by dragging one of them. This sets either the default tab width in points or in spaces, depending on the units used for default tabs by the current paragraph. Default tabs in points are relative to the position of zero on the ruler. Default tabs in spaces are relative to the ruler's left margin.

When you create a new notebook window, Igor applies your preferred default tab width settings. There are separate preferences for plain text notebooks and formatted text notebooks. You can set preferences for a given type of notebook by first using the Document Settings dialog to apply the desired settings to a window of that type and then choosing Notebook→Capture Notebook Prefs as explained under **Notebook Preferences** on page III-30.

Igor stores document settings separately for each formatted text notebook file. In Igor Pro 9.00 and later, it stores the default tab width mode, width in points, and width in spaces settings. Older versions of Igor support only default tabs specified in points and ignore the other settings.

Igor does not store document settings for plain text notebook files, so your preferred default tab width settings for plain text notebooks apply to all plain text notebook files subsequently opened.

Notebook Paragraph Properties

A set of paragraph properties is called a “ruler”. In some word processors, this is called a “style”. The purpose of rulers is to make it easy to keep the formatting of a notebook consistent. This is described in more detail under **Working with Rulers** on page III-11.

Formatted Notebook Paragraph Properties

The paragraph properties for a formatted notebook are all under your control and can be different for each paragraph. A new formatted notebook has one ruler, called the Normal ruler. You can control the properties of the Normal ruler and you can define additional rulers.

The ruler font, ruler text size, ruler text style and ruler text color can be set using the pop-up menu on the left side of the ruler. They set the *default* text format for paragraphs governed by the ruler. You can use the Notebook menu to override these default properties. The Notebook menu permits you to hide or show the ruler in a formatted notebook.

The paragraph properties for formatted notebooks are:

Paragraph Property	Description
First-line indent	Horizontal position of the first line of the paragraph.
Left margin	Horizontal position of the paragraph after the first line.
Right margin	Horizontal position of the right side of the paragraph.

Paragraph Property	Description
Line alignment	Left, center, right or full.
Space before	Extra vertical space to put before the paragraph.
Min line space	Minimum height of each line in the paragraph.
Space after	Extra vertical space to put after the paragraph.
Tab stops	Left, center, right, decimal-aligned or comma-aligned tab stops.
Ruler font	The default font to use for the paragraph.
Ruler text size	Default text size to use for the paragraph.
Ruler text style	Default text style to use for the paragraph.
Ruler text color	Default text color to use for the paragraph.

Plain Notebook Paragraph Properties

For each plain notebook, there is one set of paragraph properties that govern all paragraphs. Many of the items are fixed — you can't adjust them.

Paragraph Property	Comment
First-line indent	Fixed at zero.
Left margin	Fixed at zero.
Right margin	Fixed at infinity.
Line alignment	Fixed as left-aligned.
Space before	Fixed at zero.
Min line space	Fixed at zero.
Space after	Fixed at zero.
Tab stops	None.
Font	Set using Notebook menu.
Text size	Set using Notebook menu.
Text style	Set using Notebook menu.
Text color	Set using Notebook menu.

There is only one font, text size, text style and text color for the entire document which you can set using the Notebook menu.

Although you can not set paragraph tab stops in a plain notebook, you *can* set and use the notebook's default tab stops, which affect the entire notebook.

Notebook Character Properties

The character properties are font, text size, text style, text color and vertical offset. The vertical offset is used mainly to implement superscript and subscript. A specific collection of character properties is called a "text format". You can set the text format using the Notebook menu. The Set Text Format dialog allows you to inspect and set all of the character properties.

Plain Notebook Text Formats

A plain notebook has one text format which applies to all of the text in the notebook. You can set it, using the Notebook menu, except for the vertical offset which is always zero.

Igor does not store settings (font, size, style, etc.) for a plain text files. When you open a file as a plain text notebook, these settings are determined by preferences. You can capture preferences by choosing Notebook→Capture Notebook Prefs.

Formatted Notebook Text Formats

By default, the text format for the text in a paragraph is determined by the ruler font, ruler text size, ruler text style, and ruler color of the ruler governing the paragraph. You can change these properties using the ruler pop-up menu in the ruler bar.

You can override the default text format for the selected text by applying specific formatting using the Notebook menu or the font, size, style, and color icons in the ruler bar.

You can set the text format of the selected text to the ruler default by choosing Notebook→Set Text Format to Ruler Default or by clicking the Default button in the ruler bar.

You should use the ruler to set the basic text format and use overrides for highlighting or other effects. For example, you might override the ruler text format to underline a short stretch of text or to switch to italic.

If you make a selection from the font, size, style, or color submenus of the ruler pop-up menu in the ruler bar, you redefine the current ruler, and all text governed by the ruler is updated.

If you make a selection from the font, size, style, or color submenus of the Notebook menu in the main menu bar, you override the text format for the selected text, and only the selected text is updated. This is also what happens if you use the font, size, style, and color icons in the ruler bar.

Text Sizes

The Text Size submenu in the Notebook menu contains an Other item. This leads to the Set Text Size dialog in which you can specify which sizes should appear in the Text Size submenu.

The text sizes in your Text Size menu are stored in the Igor preferences file so that the menu will include your preferred sizes each time you run Igor.

Vertical Offset

The vertical offset property is available only in formatted notebooks and is used mainly to implement superscript and subscript, as described in the next section.

Vertical offset is also useful for aligning a picture with text within a paragraph. For example, you might want to align the bottom of the picture with the baseline of the text.

The easiest way to do this is to use Control-Up Arrow and Control-Down Arrow key combinations (*Macintosh*) or Alt+Up Arrow and Alt+Down Arrow key combinations (*Windows*), which tweak the vertical offset by one point at a time.

You can set the vertical offset by choosing Notebook→Set Text Format which displays the Set Text Format dialog.

Superscript and Subscript

The last four items in the Text Size submenu of the Notebook menu have to do with superscript and subscript. Igor implements superscript and subscript by setting the text size and the vertical offset of the selected text to achieve the desired effect. They are not character properties but rather are effects accomplished using character properties.

The following table illustrates the use and effects of each of these items.

Action	Effect on Character Properties	Result
Type “XYZ”.		XYZ
Highlight “Y” and then choose Superscript.	Reduces text size and sets vertical offset for “Y”.	$X^{Y}Z$
Highlight “Z” and then choose Superscript.	Sets text size and vertical offset for “Z” to make it superscript relative to “Y”.	$X^{Y^{Z}}$
Highlight “Z” and then choose In Line.	Sets text size and vertical offset for “Z” to be same as for “Y”.	X^{YZ}
Highlight “YZ” and then choose Normal.	Sets text size for “YZ” same as “X” and sets vertical offset to zero.	XYZ

Help Links in Formatted Notebooks

You can format text as a help link by selecting the text and clicking the Help button in the ruler. Usually you do this while editing a help file.

Clicking text in a notebook that is formatted as a help link goes to the specified help topic. This allows you to easily link to help topics from a documentation notebook. The help link text must reference a topic or subtopic in a help file; the target can not be in a notebook.

Since simply clicking a help link in a notebook activates the link, to edit a help link you need to do one of the following:

- Use the arrow keys instead of simply clicking in the help link
- Press the command key (*Macintosh*) or Ctrl key (*Windows*) while clicking in the help link
- Select at least one character instead of simply clicking in the help link

Notebook Read/Write Properties

There are three properties that control whether a notebook can be modified.

Read-only

The read-only property is set if you open the file for read-only by executing **OpenNotebook**/R. It is also set if you open a file for which you do not have read/write permission.

When the read-only property is set, a lock icon appears in the bottom/left corner of the notebook window and you can not modify the notebook manually or via commands.

The read-only property can not be changed after the notebook is opened.

Use read-only if you want no modifications to be made to the notebook.

Write-protect

You can set the write-protect property to on or off by clicking the pencil icon in the bottom/left corner of the notebook window or using the **Notebook** operation with the writeProtect keyword.

The write-protect property is intended to give the user a way to prevent inadvertent manual modifications to the notebook. The user can turn the property on or off at will.

The write-protect property does not affect commands such as **Notebook** and **NotebookAction**. Even if write-protect is on, they can still modify the notebook.

Use write-protect if you want to avoid inadvertent manual modifications to the notebook but want the user to be able to take full control.

Changeable By Command Only

You can control the changeableByCommandOnly property using **NewNotebook**/OPTS=8 or using the **Notebook** operation with the changeableByCommandOnly keyword.

This property is intended to allow programmers to control whether the user can manually modify the notebook or not. Its main purpose is to allow a programmer to create a notebook subwindow in a control panel for displaying status messages and other information that is not intended to be modified by the user. There is no way to manually change this property - it can be changed by command only.

When the changeableByCommandOnly property is on, a lock icon appears in the bottom/left corner of the notebook window.

Use changeableByCommandOnly if you want no manual modifications to be made to the notebook but want it to be modifiable via commands.

The changeableByCommandOnly property is intended for programmatic use only and is not saved to disk.

For further information on notebook subwindows, see **Notebooks as Subwindows in Control Panels** on page III-91.

Working with Rulers

A ruler is a set of paragraph properties that you can apply to paragraphs in a formatted notebook. Using rulers, you can make sure that paragraphs that you *want* to have the same formatting *do* have the same formatting. Also, you can redefine the format of a ruler and all paragraphs governed by that ruler will be automatically updated.

In a simple notebook, you might use just the one built-in ruler, called Normal. In a fancier notebook, where you are concerned with presentation, you might use several rulers.

The pop-up menu on the left side of the ruler shows which ruler governs the first currently selected paragraph. You can use this pop-up menu to:

- Apply an existing ruler to the selected paragraphs
- Create a new ruler
- Redefine an existing ruler
- Find where a ruler is used
- Rename a ruler
- Remove a ruler from the document

Defining a New Ruler

To create a new ruler, choose Define New Ruler from the Ruler pop-up menu. This displays the Define New Ruler dialog.

Enter a name for the ruler. Ruler names must follow rules for standard (not liberal) Igor names. They may be up to 31 bytes in length, must start with a letter and may contain letters, numbers and the underscore character.

Use the icons in the dialog’s ruler bar to set the font, text size, text style, and color for the new ruler.

Click OK to create the new ruler.

In a sophisticated word processor, a ruler can be based on another ruler so that changing the first ruler automatically changes the second. Igor rulers do not have this capability.

Redefining a Ruler

When you redefine a ruler, all paragraphs governed by the ruler are automatically updated. There are three principal ways to redefine a ruler:

- Use the Redefine Ruler dialog.
- Use the Ruler Font, Ruler Text Size, Ruler Text Style or Ruler Text Color pop-up menu items.
- Use the Redefine Ruler from Selection item in the Ruler pop-up menu.
- Press the Command key (Macintosh) or Ctrl key (Windows) while using a margin, indent, tab, alignment, or spacing control in the ruler bar.

To invoke the Redefine Ruler dialog, choose Redefine Ruler from the Ruler pop-up menu.

Another handy way to redefine an existing ruler (e.g. Normal) is to adjust it, creating a derived ruler (e.g. Normal+). Then choose Redefine Ruler from Selection from the Ruler pop-up menu. This redefines the explicitly named ruler (Normal) to match the current ruler (Normal+).

Creating a Derived Ruler

You can adjust a ruler using its icons. When you do this, you create a *derived* ruler. A derived ruler is usually a minor variation of an explicitly created ruler.

If you redefine the Normal ruler, the Normal+ ruler is *not* automatically redefined. This is a limitation in Igor’s implementation of rulers compared to a word-processor program.

Finding Where a Ruler Is Used

You can find the next or previous paragraph governed by a particular ruler. To do this press Option (*Macintosh*) or Alt (*Windows*) while selecting the name of the ruler from the Ruler pop-up menu. To search backwards, press Shift-Option (*Macintosh*) or Shift+Alt (*Windows*) while selecting the ruler. If there is no next or previous use of the ruler, Igor will emit a beep.

Removing a Ruler

Rulers that you no longer need clutter up the Ruler pop-up menu. You can remove them from the document by choosing Remove Ruler from the Ruler pop-up menu.

You might want to know if a particular ruler is used in the document. The only way to do this is to search for the ruler. See **Finding Where a Ruler Is Used** on page III-12.

Transferring Rulers Between Notebooks

The only way to transfer a ruler from one notebook to another is by copying text from the first notebook and pasting it in the second. Rulers needed for the text are also copied and pasted. If a ruler that exists in the source notebook also exists in the destination, the destination ruler takes precedence.

If you expect to create a lot of notebooks that share the same rulers then you should create a template document with the common rulers. See **Notebook Template Files** on page III-30 for details.

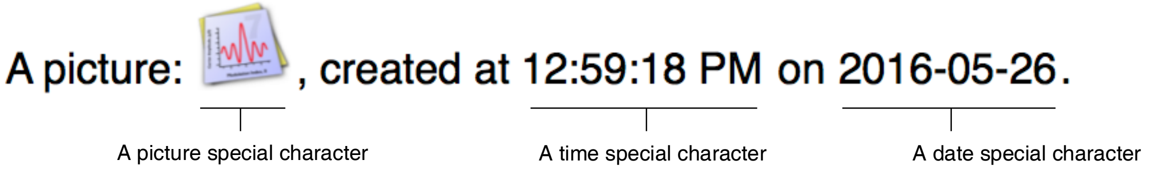
Special Characters

Aside from regular text characters, there are some special things that you can put into a paragraph in a formatted notebook. This table lists of all of the types of special characters and where they can be used.

Special Character Type	Where It Can Be Used
Picture	Main body text, headers and footers.
Igor-object picture (from graph, table, layout)	Main body text, headers and footers.
The date	Main body text, headers and footers.
The time	Main body text, headers and footers.
The name of the experiment file	Main body text, headers and footers.
Notebook window title	Headers and footers only.
Current page number	Headers and footers only.
Total number of pages	Headers and footers only.
Actions	Main body text only.

The main way in which a special character differs from a normal character is that it is not simply a text character. Another significant difference is that some special characters are dynamic, meaning that Igor can update them automatically. Other special characters, while not dynamic, are linked to Igor graphs, tables or page layouts (see **Using Igor-Object Pictures** on page III-18).

This example shows three kinds of special characters:



A picture: , created at 12:59:18 PM on 2016-05-26.

A picture special character

A time special character

A date special character

The time and date look like normal text but they are not. If you click any part of them, the entire time or date is selected. They act like a single character.

An action is a special character which, when clicked, runs Igor commands. See **Notebook Action Special Characters** on page III-14 for details.

Except for pictures, which are pasted, special characters are inserted using the Special submenu in the Notebook menu or using the Insert pop-up menu in the ruler area of a formatted notebook.

Inserting Pictures

You can insert pictures, including Igor-object pictures, by merely doing a paste. You can also insert pictures using Edit→Insert File or using the Notebook insertPicture operation.

When you insert a picture, the contents of the picture file are copied into the notebook. No link to the picture file is created.

If you use a platform-independent picture format, such as PNG (recommended), JPEG, TIFF, PDF, or SVG, then the picture is displayed correctly on all platforms. If you use a platform-specific picture format, such as Enhanced Metafile on Windows, the picture is displayed as a gray box if viewed on the other platform. On Windows, PDF is displayed correctly in Igor Pro 9.00 or later; older versions displayed PDF as a gray box.

Saving Pictures

You can save a picture in a formatted text notebook as a standalone picture file. Select one picture and one picture only. Then choose File→Save Graphics. You can also save a picture using the Notebook savePicture operation.

Special Character Names

Each special character has a name. For most types, the name is automatically assigned by Igor when the special character is created. However for action special characters you specify the name through the Special→New Action dialog. When you click a special character, you will see the name in the notebook status area. Special character names must be unique within a particular notebook.

The special character name is used only for specialized applications and usually you can ignore it. You can use the name with the Notebook findSpecialCharacter operation to select special characters. You can get a list of special character names from the **SpecialCharacterList** function (see page V-895) and get information using the **SpecialCharacterInfo** function (see page V-893).

When you copy a graph, table, layout, or Gizmo plot and paste it into a notebook, an Igor-object picture is created (see **Using Igor-Object Pictures** on page III-18). The Igor-object picture, like any notebook picture, is a special character and thus has a special character name, which, whenever possible, is the same as the source window name. However, this may not always possible such as when, for example, you paste Graph0 twice into a notebook, the first special character will be named *Graph0* and the second *Graph0_1*.

The Special Submenu

Using the Special submenu of the Notebook menu you can:

- Frame or scale pictures
- Insert special characters
- Control updating of special characters
- Convert a picture to cross-platform PNG format
- Specify an action character that executes commands

Scaling Pictures

You can scale a picture by choosing Notebook→Special→Scale or by using the Notebook command line operation. There is currently no way to scale a picture using the mouse.

Updating Special Characters

The window title, page number and total number of pages are dynamic characters—Igor automatically updates them when you print a notebook. These are useful for headers and footers. All other kinds of special characters are not dynamic but Igor makes it easy for you to update them if you need to, using the Update Selection Now or Update All Now items in the Special menu.

To prevent inadvertent updating, Igor disables these items until you enable updating, using the Enable Updating item in the Special menu. This enables updating for the active notebook.

If you are using a notebook as a form for generating reports, you will probably want to enable updating. However, if you are using it as a log of what you have done, you will want to leave updating in the disabled state.

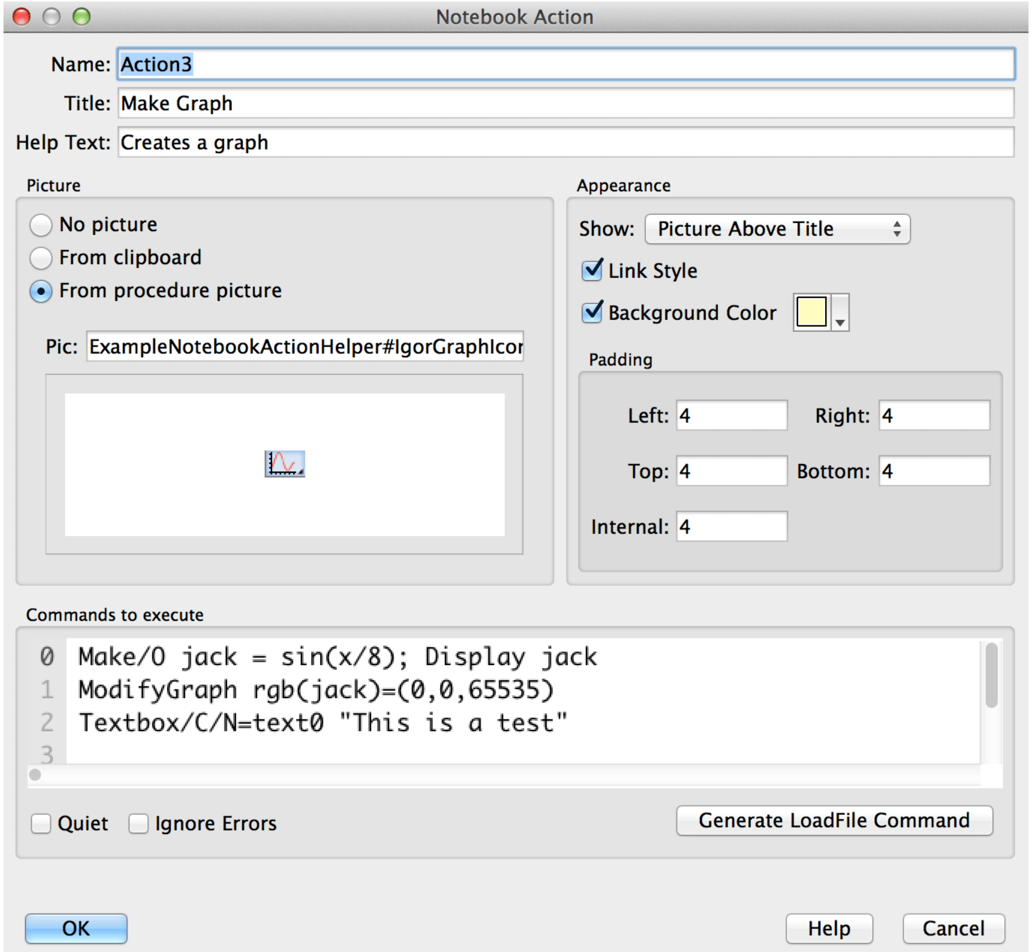
Notebook Action Special Characters

An action is a special character that runs commands when clicked. Use actions to create interactive notebooks, which can be used for demonstrations or tutorials. Help files are formatted notebook files so actions can also be used in help files.

You create actions in a formatted text notebook. You can invoke actions from formatted text notebooks or from help files.

For a demonstration of notebook actions, see the Notebook Actions Demo experiment.

To create an action use the **NotebookAction** operation (see page V-711) or choose Notebook→Special→New Action to invoke the Notebook Action dialog:



Name: Action3

Title: Make Graph

Help Text: Creates a graph

○ No picture
○ From clipboard
● From procedure picture

Pic: ExampleNotebookActionHelper#IgorGraphIcor

Show: Picture Above Title

☑ Link Style

☑ Background Color

Left: 4 Right: 4

Top: 4 Bottom: 4

Internal: 4

```
Make/O jack = sin(x/8); Display jack
ModifyGraph rgb(jack)=(0,0,65535)
Textbox/C/N=text0 "This is a test"
```

☐ Quiet ☐ Ignore Errors

Each action has a name that is unique within the notebook.

The title is the text that appears in the notebook. The text formatting of the notebook governs the default text formatting of the title.

If the Link Style checkbox is selected, the title is displayed like an HTML link — blue and underlined. This style overrides the color and underline formatting applied to the action through the Notebook menu.

The help text is a tip that appears when the cursor is over an action, if tips are enabled in the Help section of the Miscellaneous Settings dialog.

An action can have an associated picture that is displayed instead of or in addition to the title. There are two ways to specify a picture. You can paste one into the dialog using the Paste button or you can reference a Proc Picture stored in a procedure file. The latter source may be useful for advanced programmers (see **Proc Pictures** on page IV-56 for details).

For most purposes it is better to use a picture rather than a Proc Picture. One exception is if you have to use the same picture many times in the notebook, in which case you can save disk space and memory by using a Proc Picture.

If you designate a Proc Picture using a module name (e.g., `MyProcPictures#MyPicture`), then the Proc Picture must be declared static.

If you specify both a Proc Picture and a regular picture, the regular picture is displayed. If you specify no regular picture and your Proc Picture name is incorrect or the procedure file that supplies the Proc Picture is not open or not compiled, `"???"` is displayed in place of the picture.

In order for a picture to display correctly on both Macintosh and Windows, it must be in a cross-platform format such as PNG. You can convert a picture to PNG by clicking the Convert To PNG button. This affects the regular picture only.

Pictures and Proc Picture in actions are drawn transparently. The background color shows through white parts of the picture unless the picture explicitly erases the background.

The action can display one of six things as determined by the Show popup menu:

- The title
- The picture
- The picture below the title
- The picture above the title
- The picture to the left of the title
- The picture to the right of the title

If there is no picture and you choose one of the picture modes, just the title is displayed.

You can add padding to any external side of the action content (title or picture). The Internal Padding value sets the space between the picture and the title when both are displayed. All padding values are in points.

If you enable the background color, the rectangle enclosing the action content is painted with the specified color.

You can enter any number of commands to be executed in the Commands area. When you click the action, Igor sends each line in the Commands area to the Operation Queue, as if you called the Execute/P operation, and the commands are executed.

In addition to regular commands, you can enter special operation queue commands like INSERTINCLUDE, COMPILEPROCEDURES, and LOADFILE. These are explained under **Operation Queue** on page IV-278.

For sophisticated applications, the commands you enter can call functions that you define in a companion “helper procedure file” (see **Notebook Action Helper Procedure Files** on page III-17).

If the Quiet checkbox is selected, commands are not sent to the history area after execution.

If the Ignore Errors checkbox is selected then command execution errors are not reported via error dialogs.

The Generate LoadFile Command button displays an Open File dialog and then generates an Execute/P command to load the file into Igor. This is useful for generating a command to load a demo experiment, for example. This button inserts the newly-generated command at the selection point in the command area so, if you want the command to replace any pre-existing commands, delete any text in the command area before clicking the button. If the selected file is inside the Igor Pro Folder or any subdirectory, the generated path will be relative to the Igor Pro Folder. Otherwise it will be absolute.

Creating a Hyperlink Action

You can use a notebook action to create a hyperlink that displays a web page by calling the **BrowseURL** operation from the action's command.

Modifying Action Special Characters

You can modify an existing action by Control-clicking (*Macintosh*) or right-clicking (*Windows*) on it and choosing Modify Action from the pop-up menu, or by selecting the action special character, and nothing else, and then choosing Notebook→Special→Modify Action.

If you have opened a notebook as a help file and want to modify an action, you must close the help file (press Option or Alt and click the close button) and reopen it as a notebook (choose File→Open

File→Notebook). After editing the action, save the changes, close the notebook, and reopen it as a help file (choose File→Open File→Help File).

Modifying the Action Frame

If the notebook action has a picture, you can frame the action by choosing a frame style from the Notebook→Special→Frame submenu.

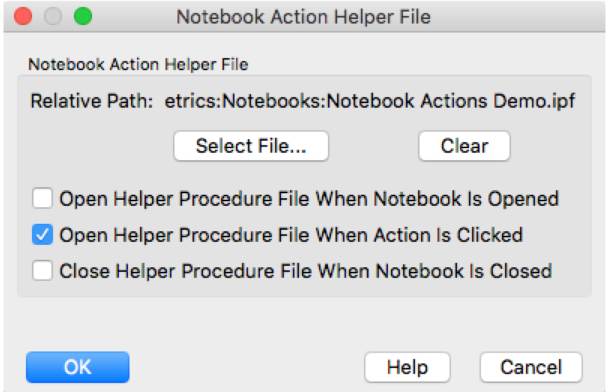
Modifying the Action Picture Scaling

If the notebook action has a picture, you can scale the picture by choosing an item from the Notebook→Special→Scale submenu.

Notebook Action Helper Procedure Files

In some instances you may want an action to call procedures in an Igor procedure file. The notebook action helper procedure file feature provides a convenient way to associate a notebook or help file with a procedure file.

Each formatted notebook (and consequently each help file) can designate only one procedure file as an action helper procedure file. Before choosing the helper file you must save the notebook as a standalone file on disk. Then choose Notebook→Special→Action Helper.



Notebook Action Helper File

Notebook Action Helper File

Relative Path: etrics:Notebooks:Notebook Actions Demo.ipf

□ Open Helper Procedure File When Notebook Is Opened

☑ Open Helper Procedure File When Action Is Clicked

□ Close Helper Procedure File When Notebook Is Closed

Click the File button to choose the helper procedure file for the notebook.

For most cases we recommend that you name your action helper procedure file with the same name as the notebook but with the .ipf extension. This indicates that the files are closely associated.

The helper file will usually be located in the same directory as the notebook file. Less frequently, it will be in a subdirectory or in a parent directory. It must be located on the same volume as the notebook file because Igor finds the helper using a relative path, starting from the notebook directory. If the notebook file is moved, the helper procedure file must be moved with it so that Igor will be able to find the helper using the relative path.

If Open Helper Procedure File When Notebook Is Opened is selected, the helper procedure file is opened along with the notebook. This checkbox can usually be left deselected. However, if you use Proc Pictures stored in the helper file, you should select it so that the pictures can be correctly rendered when the notebook is opened.

If Open Helper Procedure File When Action Is Clicked is selected, then, when you click an action, the procedure file loads, compiles, and executes automatically. This should normally be selected.

In both of these situations, the procedure file loads as a “global” procedure file, which means that it is not part of the current experiment and is not closed when creating a new experiment.

If Close Helper procedure File When Notebook Is Closed is selected and you kill a notebook or help file that has opened a helper file, the helper file is also killed. This should normally be selected.

To avoid unanticipated name conflicts between procedures in your helper file and elsewhere, it is a good idea to declare the procedures static (see **Static Functions** on page IV-105). In order to call such private routines you also need to assign a module name to the procedure file and use the module name when invoking the routines (see **Regular Modules** on page IV-236). For an example see the Notebook Actions Demo experiment.

Using Igor-Object Pictures

You create a picture from an Igor graph, table, page layout or Gizmo plot by choosing Edit→Export Graphics to copy a picture to the clipboard. For graphs, layouts, and Gizmo plots, you can also choose Edit→Copy. When you do this, Igor puts on the clipboard information about the window from which the picture was generated. When you paste into a notebook, Igor stores the window information with the picture. We call this kind of picture an “Igor-object” picture.

The Igor-object information contains the name of the window from which the picture was generated, the date/time at which it was generated, the size of the picture and the export mode used to create the picture. Igor uses this information to automatically update the picture when you request it.

Because of backward compatibility issues, this feature works only if the name of the window is 31 bytes or less.

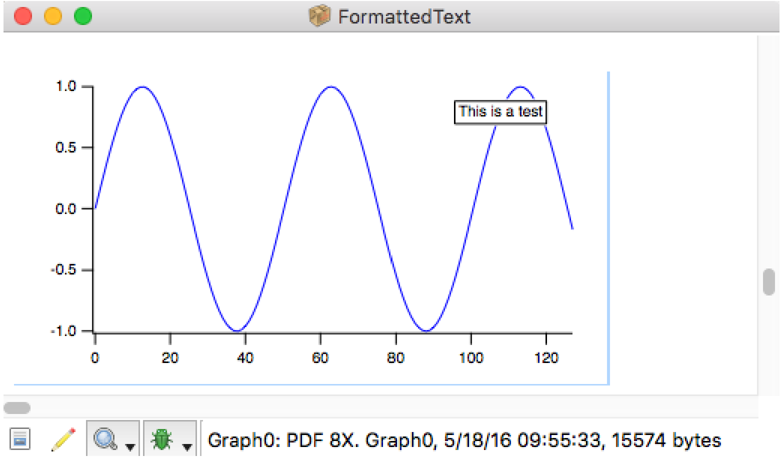
Igor can not link Igor-object pictures to a window in a different Igor experiment.

For good picture quality that works across platforms, we recommend that you use a high-resolution PNG format.

Updating Igor-Object Pictures

Before updating Igor object pictures, you must enable updating using the Notebook→Special→Enable Updating menu item. This is a per-notebook setting.

When you click an Igor-object picture, Igor displays the name of the object from which the picture was generated and the time at which it was generated in the notebook’s status area.



Graph0: PDF 8X. Graph0, 5/18/16 09:55:33, 15574 bytes

The first Graph0 shown in the status area is the name of the picture special character and the second Graph0 is the name of the source graph for the picture. There is no requirement that these be the same but they usually will be.

If you change the Igor graph, table, layout or Gizmo plot, you can update the associated picture by selecting it and choosing Update Selection Now from the Notebook→Special menu or by right-clicking and choosing Update Selection from the contextual menu. You can update all Igor-object pictures as well as any other special characters in the notebook by clicking anywhere so that nothing is selected and then choosing Update All Now from the Notebook→Special menu.

An Igor object picture can be updated even if it was created on another platform using a platform-dependent format. For example, you can create an EMF Igor object picture on Windows and paste it into a notebook. If you open the notebook on Macintosh, the EMF will display as a gray box because EMF is a Windows-specific format. However, if you right-click the EMF picture and choose Update Selection, Igor will regenerate it using a Macintosh format.

An Igor-object picture never updates unless you do so. Thus you can keep pictures of a given object taken over time to record the history of that object.

The Size of the Picture

The size of the picture is determined when you initially paste it into the notebook. If you update the picture, it will stay the same size, even if you have changed the size of the graph window from which the picture is derived. Normally, this is the desired behavior. If you want to change the size of the picture in the notebook, you need to repaste a new picture over the old one.

Activating The Igor-Object Window

You can activate the window associated with an Igor-object picture by double-clicking the Igor object picture in the notebook. If the window exists it is activated. If it does not exist but the associated window recreation macro does exist, Igor runs the window recreation macro.

Breaking the Link Between the Object and the Picture

Lets say you create a picture from a graph and paste it into a notebook. Now you kill the graph. When you click the picture, Igor displays a question mark after the name of the graph in the notebook's status area to indicate that it can't find the object from which the picture was generated. Igor can not update this picture. If you recreate the graph or create a new graph with the same name, this reestablishes the link between the graph and the picture.

If you change the name of a graph, this breaks the link between the graph and the picture. To reestablish it, you need to create a new picture from the graph and paste it into the layout.

Compatibility Issues

A Windows format picture, when updated on Macintosh, is converted to a Macintosh format, and vice versa.

Igor does not recognized Igor-object pictures created by Igor versions before 6.10.

If you save a notebook containing a Gizmo picture and open it in Igor6 version 6.37 or before, you will get errors in Igor6. If you open it in Igor6 version 6.38 or later, it will display correctly.

Cross-Platform Pictures

If you want to create a notebook that contains pictures that display correctly on both Macintosh and Windows, you can use the PDF or PNG (Portable Network Graphics) format. If some pictures are already in JPEG or TIFF format, these too will display correctly on either platform.

PDF pictures are displayed correctly on Windows in Igor Pro 9.00 or later. In earlier versions on Windows, PDF pictures are displayed as gray boxes.

You can convert other types of pictures to PNG using the Convert to PNG item in the Special submenu of the Notebook menu.

Page Breaks

When you print a notebook, Igor automatically goes to the next page when it runs out of room on the current page. This is an automatic page break.

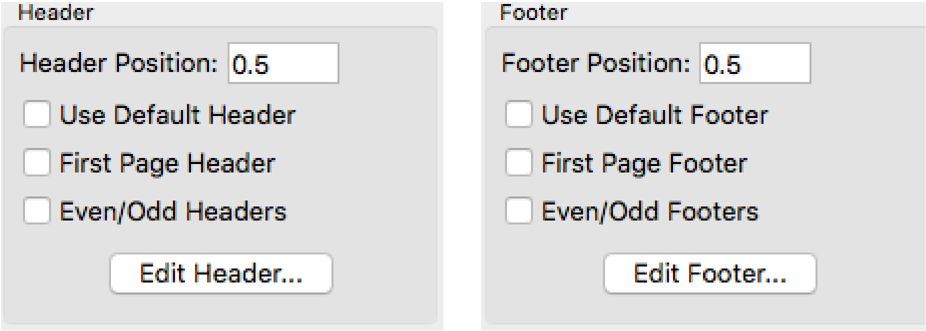
In a formatted notebook, you can insert a *manual* page break using the Insert Page Break item in the Edit menu. Igor displays a manual page break as a dashed line across the notebook window. You can't insert a manual page break into a plain notebook.

There is no way to see where Igor will put automatic page breaks other than by printing the document or using the Print Preview feature.

Headers and Footers

Both formatted and plain notebooks can have headers or footers.

You create headers and footers using the Document Settings dialog.



Header

Header Position: 0.5

□ Use Default Header

□ First Page Header

□ Even/Odd Headers

Footer

Footer Position: 0.5

□ Use Default Footer

□ First Page Footer

□ Even/Odd Footers

The header position is specified as a distance from the top of the paper. The footer position is specified as a distance from the bottom of the paper. The units are your preferred units as specified in the Miscellaneous section of the Miscellaneous Settings dialog.

For most uses, the default header or default footer will be sufficient. The default header consists of the date, window title and page number. The other options are intended for use in fancy reports.

Clicking Edit Header or Edit Footer displays a subdialog in which you can enter text as well as special characters.

The Page Number and Number of Pages special characters are displayed on the screen as # characters but are printed using the actual page number and number of pages in the document. The Date, Time and Window Title special characters are automatically updated when the document is printed.

Header and footer settings are saved in formatted notebook files but not in plain text notebook files. Consequently, settings for plain text notebook files revert to preferred settings, as set by the Capture Notebook Prefs dialog, when you open a file as a plain text notebook.

Printing Notebooks

To print an entire notebook, click so that no text is selected and then choose File→Print Notebook Window.

To print part of a notebook, select the section that you want to print and then choose File→Print Notebook Selection.

Import and Export Via Rich Text Format Files

The Rich Text Format (RTF) is a file format created by Microsoft Corporation for exchanging formatted text documents between programs. Microsoft also calls it the Interchange format. Many word processors can import and export RTF.

You can save an Igor plain or formatted notebook as an RTF file and you can open an RTF file as an Igor formatted notebook. You may find it useful to collect text and pictures in a notebook and to later transfer it to your word processor for final editing.

An RTF file is a plain text file that contains RTF codes. An RTF file starts with "\rtf". Other codes define the text, pictures, document formats, paragraph formats, and text formats and other aspects of the file.

When Igor writes an RTF file from a notebook, it must generate a complex sequence of codes. When it reads an RTF file, it must interpret a complex sequence of codes. The RTF format is very complicated, has evolved and allows some flexibility. As a result, each program writes and interprets RTF codes somewhat differently. Because of this and because of the different feature sets of different programs, RTF translation is sometimes imperfect and requires that you do manual touchup.

Saving an RTF File

To create an RTF file, choose Save Notebook As from the File menu. Select Rich Text Format from the Save File dialog's file type pop-up menu, and complete the save.

The original notebook file, if any, is not affected by saving as RTF, and the notebook retains its connection to the original file.

Opening an RTF File

When Igor opens a plain text file as a notebook, it looks for the "\rtf" code that identifies the file as an RTF file. If it sees this code, it displays a dialog asking if you want to convert the rich text codes into an Igor formatted notebook.

If you answer Yes, Igor creates a new, formatted notebook. It then interprets the RTF codes and sets the properties and contents of the new notebook accordingly. When the conversion is finished, you sometimes need to fix up some parts of the document that were imperfectly translated.

If you answer No, Igor opens the RTF file as a plain text file. Use this to inspect the RTF codes and, if you are so inclined, to tinker with them.

Exporting a Notebook as HTML

Igor can export a notebook in HTML format. HTML is the format used for Web pages. For a demo of this feature, choose File→Example Experiments→Feature Demos→Web Page Demo.

This feature is intended for two kinds of uses. First, you can export a simple Igor notebook in a form suitable for immediate publishing on the Web. This might be useful, for example, to automatically update a Web page or to programmatically generate a series of Web pages.

Second, you can export an elaborate Igor notebook as HTML, use an HTML editor to improve its formatting or tweak it by hand, and then publish it on the Web. It is unlikely that you could use Igor alone to create an elaborately formatted Web page because there is a considerable mismatch between the feature set of HTML and the feature set of Igor notebooks. For example, the main technique for creating columns in a notebook is the use of tabs. But tabs mean nothing in HTML, which uses tables for this purpose.

Because of this mismatch between notebooks and HTML, and so your Web page works with a wide variety of Web browsers, we recommend that you keep the formatting of notebooks which you intend to write as HTML files as simple as possible. For example, tabs and indentation are not preserved when Igor exports HTML files, and you can't rely on Web browsers to display specific fonts and font sizes. If you restrict yourself to plain text and pictures, you will achieve a high degree of browser compatibility.

There are two ways to export an Igor notebook as an HTML file:

- Choose File→Save Notebook As
- Using the `SaveNotebook/S=5` operation

The **SaveNotebook** operation (see page V-823) includes a /H flag which gives you some control over the features of the HTML file:

- The file's character encoding
- Whether or not paragraph formatting (e.g., alignment) is exported
- Whether or not character formatting (e.g., fonts, font sizes) is exported
- The format used for graphics

When you choose File→Save Notebook As, Igor uses the following default parameters:

- Character encoding: UTF-8 (see **HTML Text Encoding** on page III-23)
- Paragraph formatting is not exported
- Character formatting is not exported
- Pictures are exported in the PNG (Portable Network Graphics) format

By default, paragraph and character formatting is not exported because this formatting is often not supported by some Web browsers, is at cross-purposes with Web browser behavior (e.g., paragraph space-before and space-after), or is customarily left in the hands of the Web viewer (e.g., fonts and font sizes).

For creating simple Web pages that work with a majority of Web browsers, this is all you need to know about Igor's HTML export feature. To use advanced formatting, to use non-Roman characters, to use different graphics formats, and to cope with diverse Web browser behavior, you need to know more. Unfortunately, this can get quite technical.

HTML Standards

Igor's HTML export routine writes HTML files that conform to the HTML 4.01 specification, which is available from:

```
http://www.w3.org/TR/1999/PR-html40-19990824
```

It writes style information that conforms to the CSS1 (Cascading Style Sheet - Level 1) specification, which is available from:

```
http://www.w3.org/TR/1999/REC-CSS1-19990111
```

HTML Horizontal Paragraph Formatting

Tabs mean nothing in HTML. A tab behaves like a single space character. Consequently, you can not rely on tabs for notebooks that are intended to be written as HTML files. HTML has good support for tables, which make tabs unnecessary. However, Igor notebooks don't support tables. Consequently, there is no simple way to create an HTML file from an Igor notebook that relies on tabs for horizontal formatting.

HTML files are often optimized for viewing on screen in windows of varying widths. When you make the window wider or narrower, the browser automatically expands and contracts the width of the text. Consequently, the roles played by the left margin and right margin in notebooks are unnecessary in HTML files. When Igor writes an HTML file, it ignores the left and right paragraph margin properties.

HTML Vertical Paragraph Formatting

The behavior of HTML browsers with regard to the vertical spacing of paragraphs makes it difficult to control vertical formatting. For historical reasons, browsers typically add a blank line after each paragraph (<P>) element and they ignore empty paragraph elements. Although it is possible to partially override this behavior, this only leads to more problems.

In an Igor notebook, you would usually use the space-before and space-after paragraph properties in place of blank lines to get paragraph spacing that is less than one line. However, because of the aforementioned browser behavior, the space-before and space-after would add to the space that the browser already adds and you would get more than one line's space when you wanted less. Consequently, Igor ignores the space-before and space-after properties when writing HTML files.

The minimum line height property is written as the CSS1 line-height property, which does not serve exactly the same purpose. This will work correctly so long as the minimum line height that you specify is greater than or equal to the natural line height of the text.

HTML Character Formatting

In an Igor notebook, you might use different fonts, font sizes, and font styles to enhance your presentation. An HTML file is likely to be viewed on a wide range of computer systems and it is likely that your enhancements would be incorrectly rendered or would be a hindrance to the reader. Consequently, it is customary to leave these things to the person viewing the Web page.

If you use the **SaveNotebook** operation (see page V-823) and enable exporting font styles, only the bold, underline and italic styles are supported.

In notebooks, the vertical offset character property is used to create subscripts and superscripts. When writing HTML, Igor uses the CSS vertical-align property to represent the notebook's vertical offset. The HTML property and the Igor notebook property are not a good match. Also, some browsers do not support the vertical-align property. Consequently, subscripts and superscripts in notebooks may not be properly rendered in HTML. In this case, the only workaround is to use a picture instead of using the notebook subscript and superscript.

HTML Pictures

If the notebook contains one or more pictures, Igor writes PNG or JPEG picture files to a “media” folder. For example, if the notebook contains two pictures and you save it as “Test.htm”, Igor writes the file Test.htm and creates a folder named TestMedia. It stores in the TestMedia folder two picture files: Picture0.png (or .jpg) and Picture1.png (or .jpg). The names of the picture files are always of the form Picture<N> where N is a sequential number starting from 0. If the folder already exists when Igor starts to store pictures in it, Igor deletes all files in the folder whose names start with “Picture”, since these files are most likely left over from a previous attempt to create the HTML file.

When you choose Save Notebook As from the File menu, Igor always uses the PNG format for pictures. If you want to use the JPEG format, you must execute a **SaveNotebook** operation (see page V-823) from the command line, using the /S=5 flag to specify HTML and the /H flag to specify the graphics format.

PNG is a lossless format that is excellent for storing web graphics and is supported by virtually all recent web browsers. JPEG is a lossy format commonly used for web graphics. We recommend that you use PNG.

HTML does not support Igor's double, triple, or shadow picture frames. Consequently, when writing HTML, all types of notebook frames are rendered as HTML thin frames.

HTML Text Encoding

By default, Igor uses UTF-8 text encoding when you save a notebook as HTML. For historical reasons, the SaveNotebook operation /H flag allows you to specify other text encodings. However, there is no reason to use anything other than UTF-8.

Embedding HTML Code

If you are knowledgeable about HTML, you may want to access the power of HTML without completely giving up the convenience of having Igor generate HTML code for you. You can do this by embedding HTML code in your notebook, which you achieve by simply using a ruler named HTMLCode.

Normally, Igor translates the contents of the notebook into HTML code. However, when Igor encounters a paragraph whose ruler is named HTMLCode, it writes the contents of the paragraph directly into the HTML file. Here is a simple example:

Living things are generally classified into 5 kingdoms:

```
<OL>
<LI>Monera
<LI>Protista
<LI>Fungi
```

```
<LI>Plantae
<LI>Animalia
</OL>
```

In this example, the gray lines are governed by the HTMLCode ruler. Igor writes the text in these line directly to the HTML file. This example produces a numbered list, called an “ordered list”, which is announced using the HTML “OL” tag.

By convention, we make the ruler font color for the HTMLCode ruler gray. This allows us to distinguish at a glance the HTML code from the normal notebook text. The use of the color gray is merely a convention. It is the fact that the ruler is named HTMLCode that makes Igor write the contents of these paragraphs directly to the HTML file.

Here is an example that shows how to create a simple table:

```
<TABLE border="1" summary="Example of creating a table in HTML.">
<CAPTION><EM>A Simple Table</EM></CAPTION>
<TR><TH><TH>Col 1<TH>Col 2<TH>Col 3
<TR><TH>Row 1<TD>10<TD>20<TD>30
<TR><TH>Row 2<TD>40<TD>50<TD>60
</TABLE>
```

Here is an example that includes a link:

```
<P>Visit the <A HREF="http://www.wavemetrics.com/">WaveMetrics</A> web site</P>
```

Finding Notebook Text

You can find text in a notebook using the *find bar*. Choose Edit→Find or press Command-F (*Macintosh*) or Ctrl+F (*Windows*) to display it. The find bar allows you to set search parameters and search forward and backward.

On Macintosh, you can search for other occurrences of a string with minimal use of the mouse as follows:

1. Select the first occurrence of the string you want to find.
2. Press Command-E (Edit→Use Selection for Find).
3. Press Command-G (Edit→Find Same) to find subsequent occurrences.
4. Press Shift-Command-G (Edit→Find Same) to find previous occurrences.

On Windows you can search for other occurrences of a string with minimal use of the mouse as follows:

1. Select the first occurrence of the string you want to find.
2. Press Command-H (Edit→Find Selection) to find the next occurrence.
3. Press Command-G (Edit→Find Same) to find subsequent occurrences.
4. Press Shift-Command-G (Edit→Find Same) to find the previous occurrences.

You can also perform a Find on multiple help, procedure and notebook windows at one time. See **Finding Text in Multiple Windows** on page II-53.

Replacing Notebook Text

You can replace text in a notebook using the *find bar*. Choose Edit→Replace or press Command-R (*Macintosh*) or Ctrl+R (*Windows*) to display the bar in replace mode.

Another method for finding and replacing text consists of these steps:

1. Copy the replacement text to the clipboard.
2. Do a find to find the first occurrence of the text to be replaced.
3. Press Command-V (*Macintosh*) or Ctrl+V (*Windows*) to paste.

4. Press Command-G (*Macintosh*) or Ctrl+G (*Windows*) to find the next occurrence.

Notebook Names, Titles and File Names

This table explains the distinction between a notebook's name, its title and the name of the file in which it is saved.

Item	What It Is For	How It Is Set
Notebook name	Used to identify a notebook from an Igor command.	Igor automatically gives new notebooks names of the form Notebook0. You can change it using the Window Control dialog or using the DoWindow/C operation.
Notebook title	For visually identifying the window. The title appears in the title bar at the top of the window and in the Other Windows submenu of the Windows menu.	Initially, Igor sets the title to the concatenation of the notebook name and the file name. You can change it using the Window Control dialog or using the DoWindow/T operation.
File name	This is the name of the file in which the notebook is stored.	You enter this in the New Notebook dialog. Change it on the desktop.

Igor automatically opens notebooks that are part of an Igor experiment when you open the experiment. If you change a notebook's file name outside of the experiment, Igor will be unable to automatically open it and will ask for your help when you open the experiment.

A notebook file stored inside a packed experiment file does not exist separately from the experiment file, so there is no way or reason to change the notebook's file name.

Notebook Info Dialog

You can get general information on a notebook by selecting the Info item in the Notebook menu or by clicking the icon in the bottom/left corner of the notebook. This displays the File Information dialog.

The File Information dialog shows you whether the notebook has been saved and if so whether it is stored in a packed experiment file, in an unpacked experiment folder or in a stand-alone file.

Programming Notebooks

Advanced users may want to write Igor procedures to automatically log results or generate reports using a notebook. The operations that you would use are briefly described here.

Operation	What It Does
NewNotebook	Creates a new notebook window.
OpenNotebook	Opens an existing file as a notebook.
SaveNotebook	Saves an existing notebook to disk as a stand-alone file or packed into the experiment file.
PrintNotebook	Prints all of a notebook or just the selected text.
Notebook	Provides control of the contents and all of the properties of a notebook except for headers and footers. Also sets the selection and to search for text or graphics.
NotebookAction	Creates or modifies notebook action special characters.

Operation	What It Does
GetSelection	Retrieves the selected text.
SpecialCharacterList	Returns a list of the names of special characters in the notebook.
SpecialCharacterInfo	Returns information about a specific special character.
KillWindow	Kills a notebook.

There is currently no way to set headers and footers from Igor procedures. A workaround is to create a stationery (*Macintosh*) or template (*Windows*) notebook file with the headers and footers that you want and to open this instead of creating a new notebook.

In addition, the **SpecialCharacterList** function (see page V-895) and **SpecialCharacterInfo** function (see page V-893) may be of use.

The Notebook Demo #1 experiment, in the Examples:Feature Demos folder, provides a simple illustration of generating a report notebook using Igor procedures.

See **Notebooks as Subwindows in Control Panels** on page III-91 for information on using a notebook as a user-interface element.

Some example procedures follow.

Logging Text

This example shows how to add an entry to a log. Since the notebook is being used as a log, new material is always added at the end.

```
// Function AppendToLog(nb, str, stampDateTime)
// Appends the string to the named notebook.
// If stampDateTime is nonzero, appends date/time before the string.
Function AppendToLog(nb, str, stampDateTime)
   String nb              // name of the notebook to log to
   String str             // the string to log
   Variable stampDateTime // nonzero if we want to include stamp

   Variable now
   String stamp

   Notebook $nb selection={endOfFile, endOfFile}
   if (stampDateTime)
      now = datetime
      stamp = Secs2Date(now,0) + ", " + Secs2Time(now,0) + "\r"
      Notebook $nb text=stamp
   endif
   Notebook $nb text= str+"\r"
End
```

You can test this function with the following commands:

```
NewNotebook/F=1/N=Log1 as "A Test"
AppendToLog("Log1", "Test #1\r", 1)
AppendToLog("Log1", "Test #2\r", 1)
```

The **sprintf** operation (see page V-902) is useful for generating the string to be logged.

Inserting Graphics

There are two kinds of graphics that you can insert into a notebook under control of a procedure:

- A picture generated from a graph, table, layout or Gizmo plot (an “Igor-object” picture).
- A copy of a named picture stored in the current experiment’s picture gallery.

The command

```
Notebook Notebook0 picture={Graph0(0,0,360,144), -1, 0}
```

creates a new picture of the named graph and inserts it into the notebook. The numeric parameters allow you to control the size of the picture, the type of picture and whether the picture is black and white or color. This creates an anonymous (unnamed) picture. It has no name and does not appear in the Pictures dialog. However, it is an Igor-object picture with embedded information that allows Igor to recognize that it was generated from Graph0.

The command

```
Notebook Notebook0 picture={PICT_0, 1, 0}
```

makes a *copy* of the named picture, PICT_0, stored in the experiment's picture gallery, and inserts the copy into the notebook as an anonymous picture. The inserted anonymous picture is no longer associated with the named picture from which it sprang.

See **Pictures** on page III-509 for more information on pictures.

Updating a Report Form

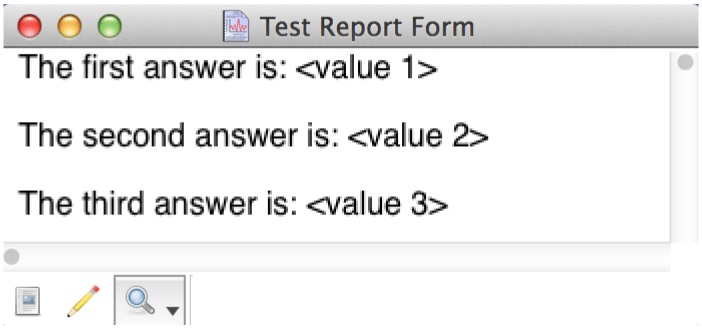
In this example, we assume that we have a notebook that contains a form with specific values to be filled in. These could be the results of a curve fit, for example. This procedure opens the notebook, fills in the values, prints the notebook and then kills it.

```
// DoReport(value1, value2, value3)
// Opens a notebook file with the name "Test Report Form",
// searches for and replaces "<value 1>", "<value 2>" and "<value3>".
// Then prints the notebook and kills it.
// "<value 1>", "<value 2>" and "<value 3>" must appear in the form
// notebook, in that order.
// This procedure assumes that the file is in the Igor folder.
Function DoReport(value1, value2, value3)
   String value1, value2, value3

   OpenNotebook/P=IgorUserFiles/N=trf "Test Report Form.ifn"
   Notebook trf, findText={"<value 1>", 1}, text=value1
   Notebook trf, findText={"<value 2>", 1}, text=value2
   Notebook trf, findText={"<value 3>", 1}, text=value3

   PrintNotebook/S=0 trf
   KillWindow trf
End
```

To try this function, enter it in the Procedure window. Then create a formatted notebook that contains "<value 1>", "<value 2>" and "<value 3>" and save it in the Igor User Files folder using the file name "Test Report Form.ifn". The notebook should look like this:



The first answer is: <value 1>

The second answer is: <value 2>

The third answer is: <value 3>

Now kill the notebook and execute the following command:

```
DoReport("123", "456", "789")
```

This will print the form using the specified values.

Updating Igor-Object Pictures

The following command updates all pictures in the notebook made from Igor graphs, tables, layouts or Gizmo plots from the current experiment.

```
Notebook Notebook0 specialUpdate=0
```

More precisely, it will update all dynamic special characters, including date and time characters as well as Igor-object pictures.

This next fragment shows how to update just one particular Igor-object picture.

```
String nb = "Notebook0"
Notebook $nb selection={startOfFile, startOfFile}
Notebook $nb findPicture={"Graph0", 1}
if (V_Flag)
   Notebook $nb specialUpdate=1
else
   Beep              // can't find Graph0
endif
```

Igor will normally refuse to update special characters unless updating is enabled, via the Enable Updating dialog (Notebook menu). You can override this and force Igor to do the update by using 3 instead of 1 for the specialUpdate parameter.

Retrieving Notebook Text

Since you can retrieve text from a notebook, it is possible to use a notebook as an input mechanism for a procedure. To illustrate this, here is a procedure that tags each point of a wave in the top graph with a string read from the specified notebook. The do-loop in this example shows how to pick out each paragraph from the start to the end of the notebook.

```
#pragma rtGlobals=1  // Make V_Flag and S_Selection be local variables.

// TagPointsFromNotebook(nb, wave)
// nb is the name of an open notebook.
// wave is the name of a wave in the top graph.
// TagPointsFromNotebook reads each line of the notebook and uses it
// to tag the corresponding point of the wave.
Function TagPointsFromNotebook(nb, wave)
   String nb         // name of notebook
   String wave       // name of the wave to tag

   String name       // name of current tag
   String text       // text for current tag
   Variable p

   p = 0
   do
      // move to current paragraph
      Notebook $nb selection={(p, 0), (p, 0)}
      if (V_Flag)          // no more lines in file?
         break
      endif

      // select all characters in paragraph up to trailing CR
      Notebook $nb selection={startOfParagraph, endOfChars}

      GetSelection notebook, $nb, 2    // Get the selected text
      text = S_Selection      // S_Selection is set by GetSelection
      if (strlen(text) > 0)   // skip if this line is empty
         name = "tag" + num2istr(p)
         Tag/C/N=$name/F=0/L=0/X=0/Y=8 $wave, pnt2x($wave, p), text
      endif
      p += 1
   while (p < numpnts($wave)) // break if we hit the end of the wave
End
```

More Notebook Programming Examples

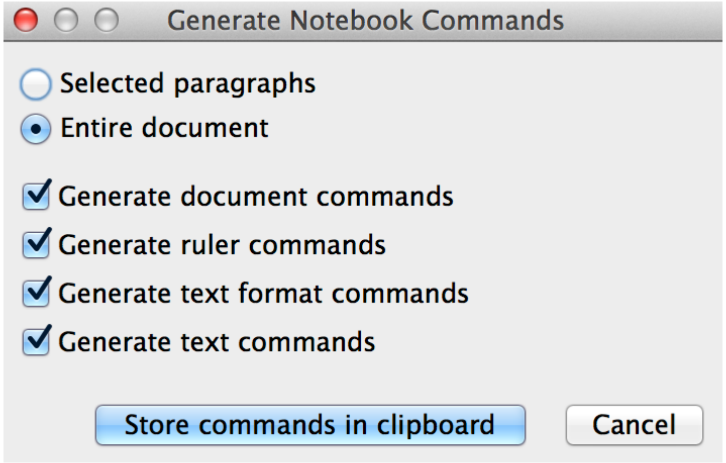
For examples using notebook action special characters, see the Notebook Actions Demo example experiment.

These example experiments illustrate notebook programming:

```
Igor Pro Folder:Examples:Feature Demos:Notebook Actions Demo.pxp
Igor Pro Folder:Examples:Testing:Notebook Operations Test.pxp
Igor Pro Folder:Examples:Testing:Notebook Picture Tests.pxp
Igor Pro Folder:Examples:Feature Demos 2:Notebook in Panel.pxp
```

Generate Notebook Commands Dialog

The Generate Notebook Commands dialog automatically generates the commands required to reproduce a notebook or a section of a notebook. This is intended to make programming a notebook easier. To use it, start by manually creating the notebook that you want to later create automatically from an Igor procedure. Then choose Generate Commands from the Notebook menu to display the corresponding dialog:



Generate Notebook Commands
○ Selected paragraphs
● Entire document
☑ Generate document commands
☑ Generate ruler commands
☑ Generate text format commands
☑ Generate text commands
Store commands in clipboard
Cancel

After clicking Store Commands in Clipboard, open the procedure window and paste the commands into a procedure.

For a very simple formatted notebook, the commands generated look like this:

```
String nb = "Notebook2"
NewNotebook/N=$nb/F=1/V=1/W=(5,40,563,359)
Notebook $nb defaultTab=36,pageMargins={54,54,54,54}
Notebook $nb showRuler=0,rulerUnits=1,updating={1,60}
Notebook $nb newRuler=Normal,justification=0,margins={0,0,504}
Notebook $nb spacing={0,0,0},tabs={}
Notebook $nb rulerDefaults={"Helvetica",10,0,(0,0,0)}
Notebook $nb ruler=Normal,text="This is a test."
```

To make it easier for you to modify the commands, Igor uses the string variable nb instead of repeating the literal name of the notebook in each command.

If the notebook contains an Igor-object picture, you will see a command that looks like

```
Notebook $nb picture={Graph0(0,0,360,144), 0, 1}
```

However, if the notebook contains a picture that is not associated with an Igor object, you will see a command that looks like

```
Notebook $nb picture={putGraphicNameHere, 1, 0}
```

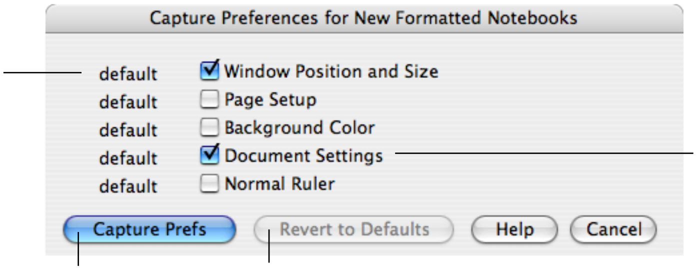
You will need to replace “putGraphicNameHere” with the name of a picture. Use the Pictures dialog, via the Misc menu, to see what named pictures are stored in the current experiment or to add a named picture. See **Pictures** on page III-509 for more information.

There is a shortcut that generates commands without going through the dialog. Select some text in the notebook, press Option (*Macintosh*) or Alt (*Windows*) and choose Copy from the Edit menu. This generates commands for the selected text and text formats. Press the Shift-Option (*Macintosh*) or Shift+Alt (*Windows*) to also generate document and ruler commands.

Notebook Preferences

The notebook preferences affect the creation of *new* notebooks. There is one set of preferences for plain notebooks and another set of preferences for formatted notebooks.

To set notebook preferences, set the attributes of any notebook of the desired type (plain or formatted) and then use the Capture Notebook Prefs item in the Notebook menu.



Capture Preferences for New Formatted Notebooks

default ☑ Window Position and Size
default □ Page Setup
default □ Background Color
default ☑ Document Settings
default □ Normal Ruler

“default” indicates that this preference was never changed from the factory default or was changed and then reverted.

This includes whether or not the ruler is initially showing as well as all settings in the Document Settings dialog.

Click to capture preferences for the selected

Click to revert to factory defaults for the selected items.

To determine what the preference settings are you must create a new notebook and examine its settings.

Notebook windows each have their own Page Setup values. New notebook windows will have their own copy of the captured Page Setup values.

Preferences are stored in the Igor Preferences file. See Chapter III-18, **Preferences**, for further information on preferences.

Notebook Template Files

A template notebook provides a way to customize the initial contents of a new notebook. When you open a template notebook, Igor opens it normally but leaves it untitled and disassociates it from the template notebook file. This leaves you with a new notebook based on your prototype. When you save the untitled notebook, Igor creates a new notebook file.

Template notebooks have ".ift" as the file name extension instead of ".ifn".

To make a template notebook, start by creating a prototype formatted text notebook with whatever contents you would like in a new notebook.

Choose File→Save Notebook As, choose IGOR Formatted Notebook Template from the file type pop-up menu, and save the template notebook.

You can convert an existing formatted text notebook file into a template file by changing the extension from ".ifn" to ".ift".

The Macintosh Finder’s file info window has a Stationery Pad checkbox. Checking it turns a file into a stationery pad. When you double-click a stationery pad file, Mac OS X creates a copy of the file and opens the copy. For most uses, the template technique is more convenient.

Notebook Shortcuts

To view text window keyboard navigation shortcuts, see **Text Window Navigation** on page II-51.

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To revisit a previously-viewed location	Press Cmd-Option-Left Arrow (Go Back) or Cmd-Option-Right Arrow (Go Forward).	Press Alt+Left Arrow (Go Back) or Alt+Right Arrow (Go Forward).
To get a contextual menu of commonly-used actions	Press Control and click in the body of the notebook window.	Right-click the body of the notebook window.
To execute commands in a notebook window	Select the commands or click in the line containing the commands and press Control-Return or Control-Enter.	Select the commands or click in the line containing the commands and press Ctrl+Enter.
To display the Find dialog	Press Command-F.	Press Ctrl+F.
To find the same text again	Press Command-G.	Press Ctrl+G.
To find again but in the reverse direction	Press Command-Shift-G.	Press Ctrl+Shift+G.
To find selected text	Press Command-E and Command-G.	Press Ctrl+H.
To find the selected text but in the reverse direction	Press Command-E and Command-Shift-G.	Press Ctrl+Shift+H.
To select a word	Double-click.	Double-click.
To select an entire line	Triple-click.	Triple-click.
To change a named ruler without using the Redefine Ruler dialog	Press Command while adjusting the icons in the ruler.	Press Ctrl while adjusting the icons in the ruler.
To find the next occurrence of a ruler	Press Option while selecting a ruler from the pop-up menu.	Press Alt while selecting a ruler from the pop-up menu.
To find the previous occurrence of a ruler	Press Shift-Option while selecting a ruler from the pop-up menu.	Press Shift+Alt while selecting a ruler from the pop-up menu.
To get miscellaneous information on notebook	Click the document icon in the bottom-left corner of the window.	Click the document icon in the bottom-left corner of the window.
To generate Notebook commands that will recreate the selected text	Press Option and choose Copy from the Edit menu. This puts the commands in the Clipboard for text and text formats.	Press Alt and choose Copy from the Edit menu. This puts the commands in the Clipboard for text and text formats.
	Press Option-Shift while copying to also generate document and ruler commands.	Press Alt+Shift while copying to also generate document and ruler commands.
To nudge a picture by one point up or down	Select the picture and press Control-Up Arrow or Control-Down Arrow.	Select the picture and press Alt+Up Arrow or Alt+Down Arrow.
To save all modified standalone procedure files	When a procedure window is active, choose File→Save All Standalone Procedure Files.	When a procedure window is active, choose File→Save All Standalone Procedure Files.

Chapter

III-2

Annotations

Overview

Annotations are custom objects that add information to a graph, page layout or Gizmo plot.

Most annotations contain text that you might use to describe the contents of a graph, point out a feature of a wave, identify the axis that applies to a wave, or create a legend. An annotation can also contain color scales showing the data range associated with colors in contour and image plots.

There are four types of annotation: textboxes, legends, color scales, and tags.

A textbox contains one or more lines of text which optionally may be surrounded by a frame, rotated, colorized and aligned.

A legend is similar to a textbox except that it contains trace symbols for one or more waves in a graph. Legends are automatically updated when waves are added to or removed from the graph, or when a wave's appearance is modified.

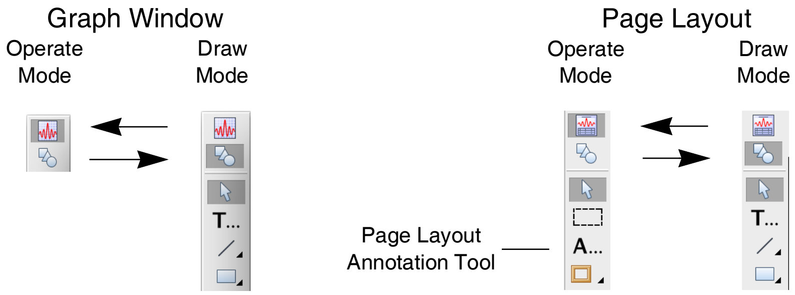
A tag is also similar to a textbox except that it is attached to a point of a trace or image and can contain dynamically updated text describing that point. Tags can be added to graphs, but not to page layouts or Gizmo plots. In contour plots, Igor automatically generates tags to label the contour lines.

A color scale contains a color bar with an axis that spans the range of colors associated with the data. Color scales are automatically updated when the associated data changes. A color scale can also be completely disassociated from any data by directly specifying a named color table and an explicit numeric range for the axis.

Annotations Quick Start

To Do This	Do This
To add an annotation to a graph	Choose Add Annotation from the Graph menu.
To add an annotation to a page layout	Choose Add Annotation from the Layout menu or click with the annotation ("A") tool.
To add an annotation to a Gizmo plot	Choose Add Annotation from the Gizmo menu.
To modify an annotation in a graph or Gizmo plot	Double-click the annotation. This invokes the Modify Annotation dialog.
To modify an annotation in a page layout	Single-click the annotation with the annotation tool. This invokes the Modify Annotation dialog.
To change the annotation type	Use the Annotation pop-up menu in the Modify Annotation dialog, or use the proper Tag, TextBox, ColorScale, or Legend operation.
To move an existing annotation	Click in the annotation and drag it to the new position. If the annotation is frozen, this won't work — double-click it and make it moveable in the Annotation Position tab. To change a tag's attachment point, press Option (*Macintosh*) or Alt (*Windows*) and drag the tag text to the new attachment point on the wave. This works whether or not the tag is frozen.
To duplicate an existing annotation	Double-click the annotation, then click the Duplicate Textbox button in upper-right corner of the Modify Annotation dialog. If the annotation is a tag, the button is titled Duplicate Tag, etc.
To delete an annotation	Double-click the annotation, then click the Delete button in the Modify Annotation dialog. A tag can be deleted by dragging its attachment point off the graph.

When manipulating annotations with the mouse, be sure that the graph or page layout are in the “operate” mode; *not* the “drawing” mode. The tool palette indicates which mode the window is in:



The Annotation Dialog

You can use the annotation dialog to create new annotations or modify existing annotations. The annotation dialog seems complex but comprises only a few major functions:

- A pop-up menu to choose the annotation type.
- A Name setting.
- Tabs that group related Annotations settings.
- A Preview box to show what the annotation will look like or to display commands.
- The normal Igor dialog buttons.

Modifying Annotations

If an annotation is already in a graph or Gizmo plot, you can modify it by double-clicking it while in the “operate” mode. This invokesModify Annotation dialog.

In a page layout, to modify an annotation, you must first select the Annotation (“**A**”) tool in layout mode. Then single-click the annotation to invoke the Modify Annotation dialog.

Annotation Text Content

You enter text into the Annotation text entry area in the Text tab.

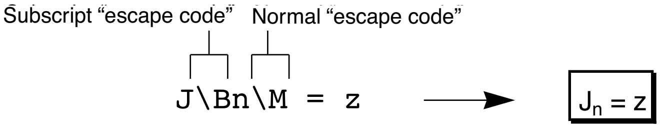
The annotation text may contain both plain text and “escape code” text which produces special effects such as superscript, font, font size and style, alignment, text color and so on. The text can contain multiple lines. At any point when entering plain text, you can choose a special effect from a pop-up menu within the Insert group, and Igor will insert the corresponding escape code. Igor wizards can type them in directly.

As you type annotation text, the Preview box shows what the resulting annotation will look like. You can not enter text in the Preview box.

Annotation Text Escape Codes

An escape code consists of a backslash character followed by one or more characters. It represents the special effect you selected. The effects of the escape code persist until overridden by a following escape code. The escape codes are cryptic but you can see their effects in the Preview box.

In the adjacent example, the subscript escape code “\B” begins a subscript and is not displayed in the annotation; the “n” that follows is plain text displayed as a subscript. The normal escape code “\M” overrides the subscript mode so that the plain text “= z” that follows has the original size and Y position (vertical offset) used for the “J”.



The section **Annotation Escape Codes** on page III-53 provides detailed documentation for the escape codes.

Font Escape Codes

Choosing an item from the Font pop-up menu inserts a code that changes the font for subsequent characters in the annotation. The checked font is the font currently in effect at the current insertion point in the annotation text entry area.

If you don't choose a font, Igor uses the default font or the graph font for annotations in graphs. You can set the default font using the Default Font item in the Misc menu, and the graph font using the Modify Graph item in the Graph menu. The Font pop-up menu also has a "Recall font" item. This item is used in elaborate annotations and is described under **Text Info Variable Escape Codes** on page III-55.

Font Size Escape Codes

Choosing an item from the Font Size pop-up menu inserts a code that changes the font size for subsequent characters in the annotation. The checked font size is the size currently in effect at the current insertion point in the annotation text entry area.

To insert a size not shown, choose any shown size, and edit the escape code to contain the desired font size. Annotation font sizes may be 03 to 99 points; two digits are required after the "`\Z`" escape code.

If you specify no font size escape code for annotations in graphs, Igor chooses a font size appropriate to the size of the graph unless you've specified a graph font size in the Modify Graph dialog. The default font size for annotations in page layouts is 10 points. The Font Size pop-up menu contains a "Recall size" item. This item is used in elaborate annotations and is described under **Text Info Variable Escape Codes** on page III-55.

Relative Font Size Escape Codes

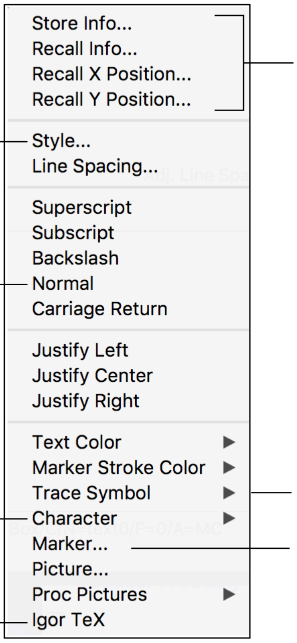
Choosing an item from the Rel. Font Size pop-up menu inserts a code that changes the relative font size for subsequent characters in the annotation. Use values larger than 100 to increase the font size, and values smaller than 100 to decrease the font size.

To insert a size not shown, choose any shown relative size, and edit the escape code to contain the desired relative font size. Annotation relative font sizes may be 001 to 999 (1% to 999%). Three digits are required after the "\Zr" escape code.

Don't use, say, 50% followed by 200% and expect to get exactly the original font size back; rounding inaccuracies will prevent success (because font sizes are handled as only integers). For example, if you start with 15 point text and use `\Zr050` (50%) the result is 7 point text. 200% of 7 points is only 14 point text. Instead, use the Normal "\M" escape code, or an absolute font size or a recalled font size, to return to a known font size.

Special Escape Codes

Choosing an item from the Special pop-up menu inserts an escape code that makes subsequent characters superscript, subscript or normal, affects the style, position or color of subsequent text, or inserts the symbol with which a wave is plotted in a graph.



Text Info Variables.

Bold, Italic, etc.

Return to starting font size and no offset from baseline.

Symbol that a trace is plotted with in a graph.

Insert symbols from a character map.

Choose a marker symbol independent of any traces.

Insert a TeX formula template.

The first four items, Store Info, Recall Info, Recall X Position, and Recall Y Position are used to make elaborate annotations and are described under **Text Info Variable Escape Codes** on page III-55.

The Style item invokes a subdialog that you use to change the style (bold, italic, etc.) for the annotation at the current insertion point in the annotation text entry area. This subdialog has a Recall Style checkbox that is used in elaborate annotations with text info variables.

The Superscript and Subscript items insert an escape code that makes subsequent characters superscript or subscript. Use the Normal item to return the text to the original text size and Y position.

The Backslash item inserts a code to insert a backslash that prints, rather than one which introduces an escape code. Igor does this by inserting two backslashes, which is an escape code that represents a backslash.

The Normal item inserts a code to return to the original font size and baseline. More precisely, Normal sets the font size and baseline to the values stored in text info variable 0 (see **Text Info Variable Escape Codes** on page III-55). The font and style are not affected.

The Justify items insert codes to align the current and following lines.

The Color item inserts a code to color the following text. The initial text color and the annotation background color are set in the Frame Tab.

The Wave Symbol item inserts a code that prints the symbol (line, marker, etc.) used to display the wave trace in the graph. This code is inserted automatically in a legend. You can use this menu item to manually insert a symbol into a tag, textbox, or color scale. For graph annotations, the submenu lists all the trace name instances in the top graph. For layout annotations, all the trace name instances in all graphs in the layout are listed.

The Character item presents a table from which you can select text and special characters to add to the annotation.

The Marker item inserts a code to draw a marker symbol. These symbols are independent of any traces in the graph.

Dynamic Escape Codes for Tags

The Dynamic pop-up menu inserts escape codes that apply only to tags. These codes insert information about the wave or point in the wave to which the tag is attached. This information automatically updates whenever the wave or the attachment point changes.

Dynamic Item	**Effect**
Wave name	Displays the name of the wave to which the tag is attached.
Trace name and instance	Same as wave name but appends an instance number (e.g., #1) if there is more than one trace in the graph associated with a given wave name.
Attach point number	Displays the number of the tag attachment point.
Attach point X value	Displays the X value of the tag attachment point.
Attach point Y value	Displays the Y value of the tag attachment point.
Attach point Z value	Displays the Z value of the tag attachment point. Available only for contour traces, waterfall plots, or image plots.
Attach X offset value	Displays the trace's X offset.
Attach Y offset value	Displays the trace's Y offset.

See also **TagVal and TagWaveRef Functions** on page III-38. These functions provide the same information as the Dynamic pop-up menu items but with greater flexibility.

Other Dynamic Escape Codes

You can enter the dynamic text escape sequence which inserts dynamically evaluated text into any kind of annotation using the escape code sequence:

\{*dynamicText*}

where *dynamicText* may contain numeric and string expressions. This technique is explained under **Dynamic Text Escape Codes** on page III-56.

TagVal and TagWaveRef Functions

If the annotation is a tag, you can use the functions **TagVal** (page V-1022) and **TagWaveRef** (page V-1023) to display information about the data point to which the tag is attached. For example, the following displays the Y value of the tag's data point:

```
\{"%g", TagVal(2)}
```

This is identical in effect to the "\0Y" escape code which you can insert by choosing the "Attach point Y value" item from the Dynamic pop-up menu. The benefit of using the TagVal function is that you can use a formatting technique other than %g. For example:

```
\{"%5.2f",TagVal(2)}
```

TagVal is capable of returning all of the information that you can access via the Dynamic menu escape codes. Use it when you want to control the numeric format of the text.

The TagWaveRef function returns a reference to the wave to which the tag is attached. You can use this reference just as you would use the name of the wave itself. For example, given a graph displaying a wave named wave0, the following tag text displays the average value of the wave:

```
\{"%g",mean(wave0)}
```

This is fine, but if you move the tag to another wave it will still show the average value of wave0. Using TagWaveRef, you can make this show the average value of whichever wave is tagged:

```
\{"%g",mean(TagWaveRef())}
```

The TagVal and TagWaveRef functions work only while Igor is in the process of evaluating the annotation text, so you should use them only in annotation dynamic text or in a function called from annotation dynamic text.

Annotation Tabs

The Text Tab's Annotation text area actually has two functions which are controlled by the pop-up menu at its top-left corner. If you choose Set Tabs from this pop-up menu, Igor shows the tab stops for the annotation.

By default, an annotation has 10 tab stops spaced 1/2 inch apart. You can change the tab stops by dragging them along the ruler. You can remove a tab stop by dragging it down off the ruler. You can add a tab by dragging it from the tab storage area at the left onto the ruler.

Igor supports a maximum of 10 tab stops per annotation and they are always left-aligned tabs. There is only one set of tab stops per annotation and they affect the entire annotation.

General Annotation Properties

Most annotation properties are common to all kinds of annotations.

Annotation Name

You can assign a name to the annotation with the Name item. In the Modify Annotation dialog, this is the Rename item. The name is used to identify the annotation in a Tag, TextBox, ColorScale, or Legend operation. Annotation names must be unique in a given window. See **Programming with Annotations** on page III-52 for more information.

Annotation Frame

In the Frame Tab, the Frame and Border pop-up menus allow you to frame the annotation with a box or shadow box, to underline the textbox, or to have no frame at all. The line size of the frames and the shadow are set by the Thickness and Shadow values.

By default, framed annotations also have a 1-point "halo" that surrounds them to separate them from their surroundings. The halo takes on the color of the annotation's background color. You can change the width of this halo to a value between 0 and 10 points by setting the desired thickness in the Halo box in the Frame tab. A fractional value such as 0.5 is permitted.

Specifying a negative value for Halo allows the halo thickness to be overridden by the global variable V_TBBufZone in the root data folder. If the variable doesn't exist, the absolute value of the entered value is used. The default halo value is -1. You can override the default halo by setting the V_TBBufZone global in a IgorStartOrNewHook hook function. See the example in **User-Defined Hook Functions** on page IV-280.

Annotation Color

The Frame tab contains most of the annotation's color settings.

Use the Foreground Color pop-up menu to set the initial text color. You can change the color of the text from the initial foreground color by inserting a color escape code using the Special pop-up menu in the Text tab.

Use the Background pop-up menu to set the background mode and color:

Background Color Mode	**Effect**
Opaque	The annotation background covers objects behind. You choose the background color from a pop-up menu.
Transparent	Objects behind the annotation show through.

Graph color	The background is opaque and is the same color as the graph background color. This is not available for annotations added to page layout windows.
Window color	The background is opaque and is the same color as the window background color.
Opaque	The annotation background covers objects behind. You choose the background color from a pop-up menu.
Transparent	Objects behind the annotation show through.

Annotation Positioning

You can rotate the annotation into the four principal orientations with the in the Position tab's Rotation pop-up menu. You can also enter an arbitrary rotation angle in integral degrees. Tags attached to contour traces and color scales have specialized rotation settings; see **Modifying Contour Labels** on page II-378 and **ColorScale Size and Orientation** on page III-48.

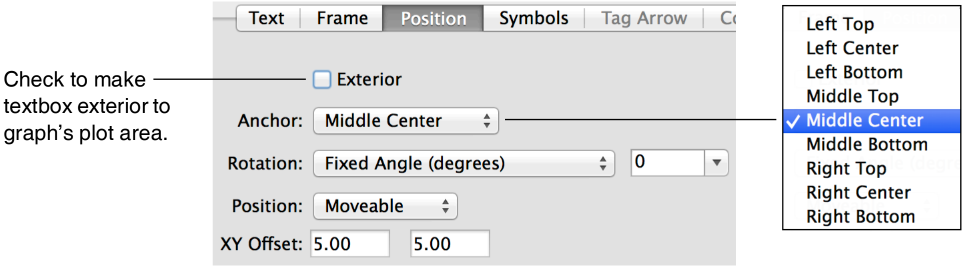
You can position an annotation anywhere in a window by dragging it and in many cases this is all you need to know. However, if you attend to a few extra details you can make the annotation go to the correct position even if you resize the window or print the window at a different size.

This is particularly important when a graph is placed into a page layout window, where the size of the placed graph usually differs from the size of the graph window.

Annotations are positioned using X and Y offsets from “anchor points”. The meaning of these offsets and anchors depends on the type of annotation and whether the window is a graph, layout or Gizmo plot. Tags, for instance, are positioned with offsets expressed as a percentage of the horizontal and vertical sizes of the graph. See **Tag Positioning** on page III-46.

Textbox, Legend, and Color Scale Positioning in a Graph

A textbox, legend, and color scale are positioned identically, so this description will use “textbox” to refer to all of them. A textbox in a graph can be “interior” or “exterior” to the graph’s plot area. You choose this positioning option with the Exterior checkbox:



☐ Exterior

Anchor: Middle Center

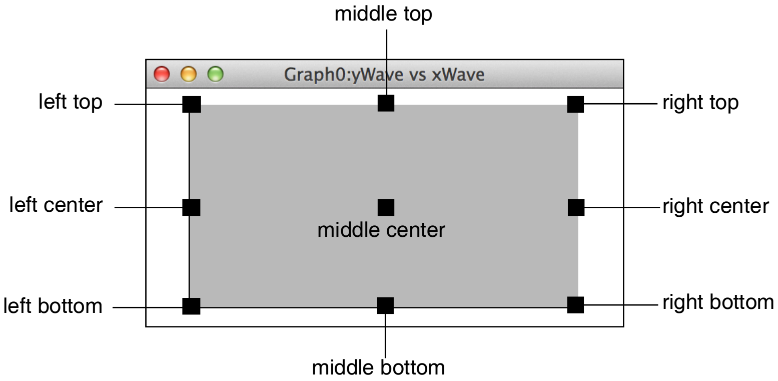
Rotation: Fixed Angle (degrees) 0

Position: Moveable

XY Offset: 5.00 5.00

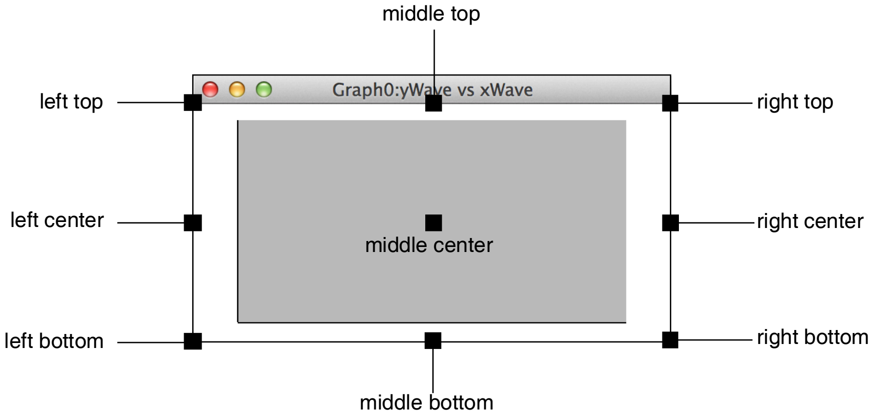
The Anchor pop-up menu specifies the precise location of the reference point on the plot area or graph window edges. It also specifies the location *on the textbox* which Igor considers to be the “position” of the textbox.

An interior textbox is positioned relative to a reference point on the edge of a graph’s plot area. (The plot area is the central rectangle in a graph window where traces are plotted. The standard left, right, bottom, and top axes surround this rectangle.)



Anchor Points for Interior Textboxes

An exterior textbox is positioned relative to a reference point on the edge of the window and the textbox is normally outside the plot area.



Anchor Points for Exterior Textboxes

The purpose of the exterior textbox is to allow you to place a textbox away from the plot area of the graph. For example, you may want it to be above the top axis of a graph or to the right of the right axis. Igor tries to keep exterior textboxes away from the graph by pushing the graph away from the textbox.

The direction in which it pushes the graph is determined by the textbox's anchor. If, for example, the textbox is anchored to the top then Igor pushes the graph down, away from the textbox. If the anchor is middle-center, Igor does not attempt to push the graph away from the textbox. So, an exterior textbox anchored to the middle-center behaves like an interior textbox.

If you specify a margin, using the Modify Graph dialog, this overrides the effect of the exterior textbox, and the exterior textbox will not push the graph.

The XY Offset in the Position Tab gives the horizontal and vertical offset from the anchor to the textbox as a percentage of the horizontal and vertical sizes of the graph's plot area for interior textboxes or the window sizes for exterior textboxes.

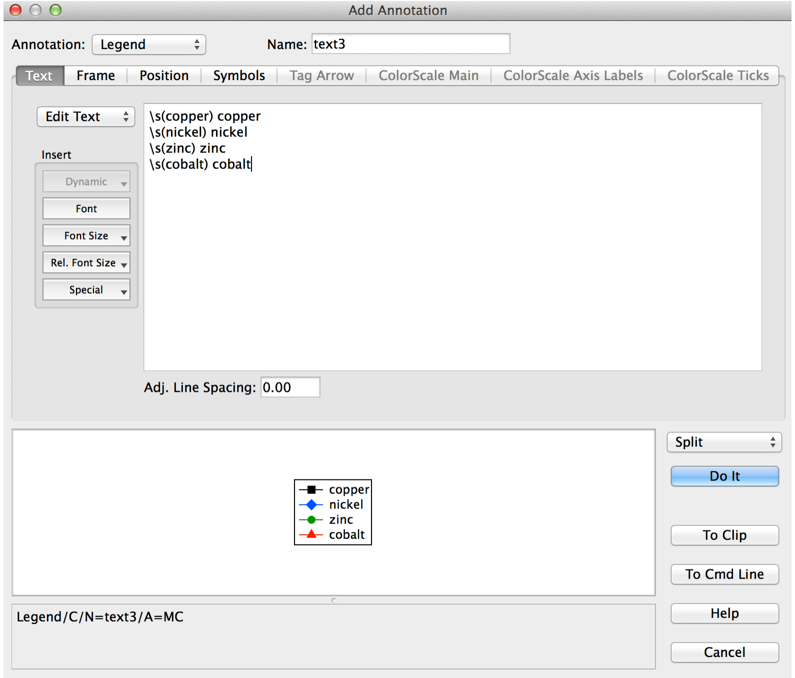
The Position pop-up menu allows you to set the position to moveable or frozen. "Frozen" means that the position of the textbox so that it moved with the mouse. This is useful if you are using the textbox to label an axis tick mark and don't want to accidentally move it.

Textbox and Legend Positioning in a Page Layout

Annotations in a page layout window are positioned relative to an anchor point on the edge of the printable part of the page. The distance from the anchor point to the textbox is determined by the X and Y offsets which are in percent of the printable page. Annotations in a page layout can not be “frozen” as they can in a graph.

Legends

A legend is very similar to a textbox. It shows the symbol for some or all of the traces in a graph or page layout. To make a legend, choose Add Annotation from the Graph or Layout menu.



Add Annotation

Annotation: Legend

Name: text3

```
\s(copper) copper
\s(nickel) nickel
\s(zinc) zinc
\s(cobalt) cobalt
```

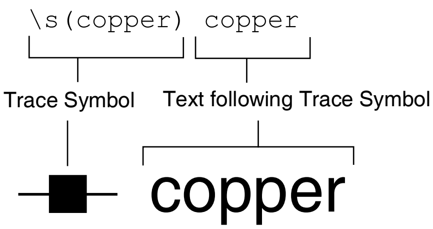
Adj. Line Spacing: 0.00

```
Legend/C/N=text3/A=MC
```

The pop-up menu at the top left of the dialog sets the type of the annotation: TextBox, Tag, Legend or ColorScale. If you choose Legend *when there is no text in the text entry area*, Igor automatically generates the text needed for a “standard legend”. To keep the standard legend, just click Do It. However, you can also modify the legend text as you can for any type of annotation.

Legend Text

The legend text consists of an escape sequence to specify the trace whose symbol you want in the legend plus plain text. In this example dialog above, `\s(copper)` is the escape sequence that inserts the trace symbol (a line and a filled square marker) for the trace whose name is copper. This escape sequence is followed by a space and the name of the wave. The part after the escape sequences is plain text that you can edit as needed.



Instead of specifying the name of the trace for a legend symbol, you can specify the trace number. For example, "`\s(#0)`" displays the legend for trace number 0.

There are only two differences between a legend and a textbox. First, text for a legend is automatically generated when you choose Legend from the pop-up menu while there is no text in the text entry area. Second, if you append or remove a wave from the graph or rename a wave, the legend is automatically updated by adding or removing trace symbols. Neither of these two actions occur for a textbox, tag or color scale.

See **Trace Names** on page II-282 for details on trace names.

Symbol Conditions at a Point

You can create a legend symbol that shows the conditions at a specific point of a trace by appending the point number in brackets to the trace name. For example \s(copper[3]). This feature is useful when a trace uses f(z) mode or when a single point on a trace has been customized.

Freezing the Legend Text

Occasionally you may not want the legend to update automatically when you append waves to the graph. You can freeze the legend text by converting the annotation to a textbox. To create a non-updating legend, invoke the Add Annotation dialog. Choose Legend from the pop-up menu to get Igor to create the legend text, then choose TextBox from the pop-up menu. Now you have converted the legend to a textbox so it will not be automatically updated.

Marker Size

A trace symbol includes a marker if the trace is drawn with one.

Normally the size of the marker drawn in the annotation is based on the font size in effect when the marker is drawn. When you set the font size before the trace symbol escape code, both the marker and following text are adjusted in proportion. You can also change the font size after the trace symbol, which sets the size of the following text without affecting the marker size.

The second method for setting the size of a marker is to choose “Same as on Graph” from the Marker Size pop-up menu in the Symbols Tab. Then the marker size matches the size of the corresponding marker in the graph, regardless of the size of the annotation’s text font.

Trace Symbol Centering

Some trace symbols are vertically centered relative to either the text that precedes or the text that follows the trace symbol escape code, and other symbols are drawn with their bottom at the baseline.

Among the trace styles whose symbols are centered are lines between points, dots, markers, lines and markers, and cityscape. Among the trace styles whose symbols are drawn from the baseline are lines from zero, histogram bars, fill to zero, and sticks and markers.

Trace Symbol Width

The trace symbol width is the width in which all trace symbols in a given legend are drawn. This width is controlled by the font size of the text preceding the trace symbol, or it is set explicitly to a given number of points using the Symbol Width value in the Symbols Tab.

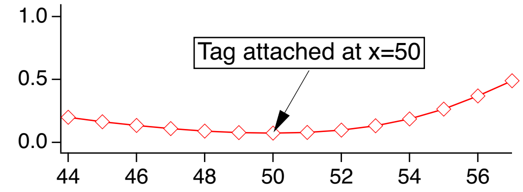
You can widen or narrow the overall symbol size by entering a nonzero width value for Symbol Width. If you use large markers with small text, you may find it necessary to reduce the trace symbol width using this setting. For some line styles that have long dash/gap patterns, you will want to enter an explicit value large enough to show the pattern.

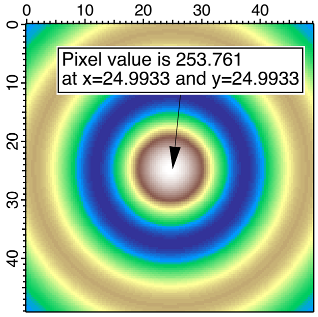
Symbol With Color as f(z)

If you create a graph that uses color as f(z) you may want to create a legend. See **Color as f(z) Legend Example** on page II-301 for a discussion of how to do this.

Tags

A tag is like a textbox but with several added capabilities. A tag is attached to a particular point on a particular trace, image, or waterfall plot in a graph:





Tags can not be added to page layouts or Gizmo plots. However, a graph containing a tag can be added to a page layout.

Igor automatically generates tags to label contour plots.

Tag Text

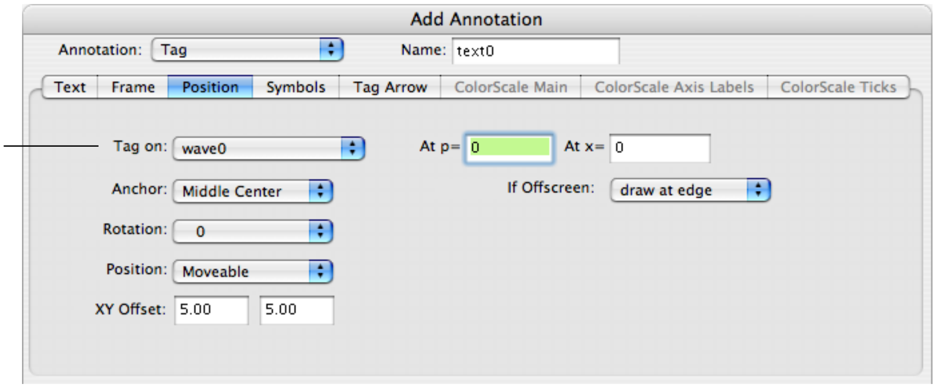
Text in a tag can contain anything a textbox or legend can handle, and more.

The Dynamic pop-up menu of the Text Tab inserts escape codes that apply only to tags. These codes insert information about the wave the tag is attached to, or about the point in the wave to which the tag is attached. This information is “dynamically” updated whenever the wave or the attachment point changes. See **Dynamic Escape Codes for Tags** on page III-38.

The TagVal and TagWaveRef functions are also useful when creating a tag with dynamic text. See **TagVal and TagWaveRef Functions** on page III-38.

Tag Wave and Attachment Point

You specify which wave the tag is attached to in the Position Tab, by choosing a wave from the “Tag on” pop-up menu.



Add Annotation

Annotation: Tag
Name: text0

Tag on: wave0
At p= 0
At x= 0
Anchor: Middle Center
If Offscreen: draw at edge
Rotation: 0
Position: Moveable
XY Offset: 5.00 5.00

Choose which trace or image the tag is attached to

You specify which point the tag is attached to by entering the point number in the “At p=” entry or an X value in the “At x=” entry. The X value is in terms of the X scaling of the wave to which you are attaching the tag. This is not necessarily the same as the X axis position of the point if the wave is displayed in XY mode. It is the X value of the Y wave point to which the tag is attached. If this distinction mystifies you, see **Waveform Model of Data** on page II-62.

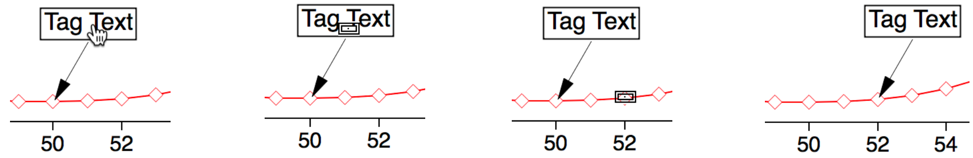
The attachment point of a tag in a (2D) image or waterfall plot is treated a bit differently than for 1D waves. In images it is the sequential point number linearly indexed into the matrix array. The dialog converts this point number, entered as the “At p=” setting, into the X and Y values, and vice versa.

Since it is the point number that determines the actual attachment point, because of rounding, the tag is not necessarily attached exactly at the entered “At x=” and “At y=” values.

As described in the next section, you can position the tag manually by dragging.

Changing a Tag’s Attachment Point

Once a tag is on a graph you can attach it to a different point by pressing Option (*Macintosh*) or Alt (*Windows*), clicking in the tag, and dragging the special tag cursor ▭ to the new attachment point on the trace. You must drag the tag cursor to the point on the trace to which you want to attach the tag, not to the position on the screen where you want the tag text to appear. The dot in the center of the tag cursor shows where the tag will be attached.

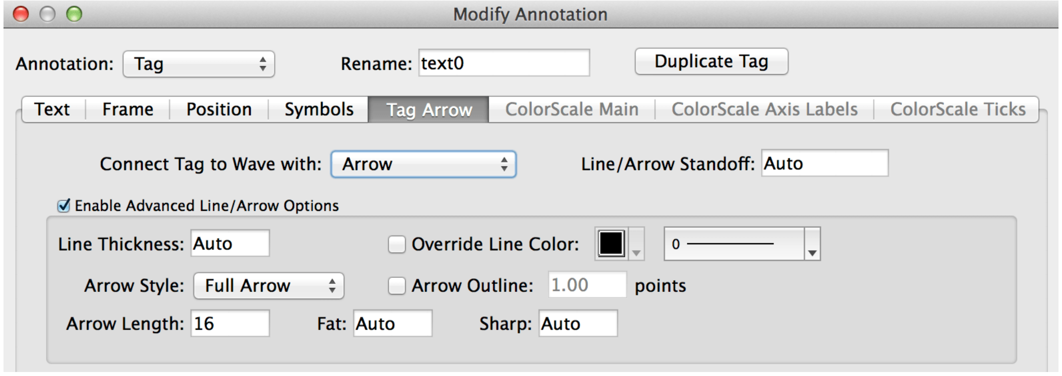


1. Move cursor over tag text
2. Press Option or Alt
3. Drag to new attach point
4. Tag attaches to new point

If you drag the tag cursor off the graph, the tag is deleted from the graph.

Tag Arrows

You can indicate a tag’s attachment point with an arrow or line drawn from the tag’s anchor point using the “Connect Tag to Wave with” pop-up menu in the Tag Arrows tab.



Modify Annotation

Annotation: Tag   Rename: text0   Duplicate Tag

Text | Frame | Position | Symbols | Tag Arrow | ColorScale Main | ColorScale Axis Labels | ColorScale Ticks

Connect Tag to Wave with: Arrow   Line/Arrow Standoff: Auto

☑ Enable Advanced Line/Arrow Options

Line Thickness: Auto   ☐ Override Line Color: ■   0 ————

Arrow Style: Full Arrow   ☐ Arrow Outline: 1.00 points

Arrow Length: 16   Fat: Auto   Sharp: Auto

You can adjust how close the arrow or line comes to the data point by setting the Line/Arrow Standoff distance in units of points.

The Advanced Line/Arrow options give you added control of the line and arrow characteristics.

A Line Thickness value of 0 corresponds to the default line thickness of 0.5 points. Otherwise, enter a value up to 10.0 points. To make the line disappear, select No Line from the “Connect Tag to Wave with” popup menu.

The line color is normally set by the annotation frame color (in the Frame tab). You can override this by checking the Override Line Color checkbox and choosing a color from the popup menu.

Change the attachment line’s style from the default solid line using the line style popup menu.

If “Connect Tag to Wave with” popup is set to Arrow, you can control the appearance of the arrowhead using the remaining controls. Options include full or half arrowhead, filled or outlined arrowhead, arrow length, fatness, and sharpness.

The Arrow Length setting is in units of points with 0 or Auto giving the default length.

The Sharp setting is a small value between -1.0 and 1.0. 0 or Auto gives the default sharpness.

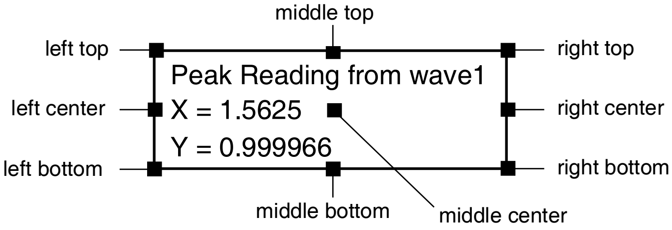
The Fat option specifies the width-to-length ratio. 0 or Auto gives the default ratio of 0.5. Larger numbers result in fatter arrows. If the number is small (say, 0.1), the arrow may seem to disappear unless the arrow length is made longer. Printed arrows can appear narrower than screen-displayed arrows.

Tag Line and Arrow Standoff

You can specify how close to bring the line or arrow to that trace with the Line/Arrow Standoff setting. You can enter an explicit distance in points. If you enter Auto or 0, Igor varies the distance according to the output device resolution and graph size. Use a value of 1 to bring the line as near to the trace as possible. When the wave is graphed with markers, you might prefer to set the standoff to a value larger than the marker size so that the line or arrow does not intersect the marker.

Tag Anchor Point

A tag has an anchor point that is on the tag itself. If there is an arrow or line, it is drawn from the anchor point on the tag to the attachment point on the trace. The anchor setting also determines the precise spot on the tag which represents the position of the tag.



The line is always drawn behind the tag so that if the anchor point is middle center the line doesn't interfere with the text.

Tag Positioning

The position of a tag is determined by the position of the point to which it is attached and by the XY Offset settings in the Position tab. The XY Offset gives the horizontal and vertical distance from the attachment point to the tag's anchor in percentage of the horizontal and vertical sizes of the graph's plot area.

Once a tag is on a graph you can change its XY offset and therefore its position by merely dragging it. You can prevent the tag from being dragged by choosing "frozen" in the Position pop-up menu in the Position Tab. Igor freezes tags when it creates them for contour labels.

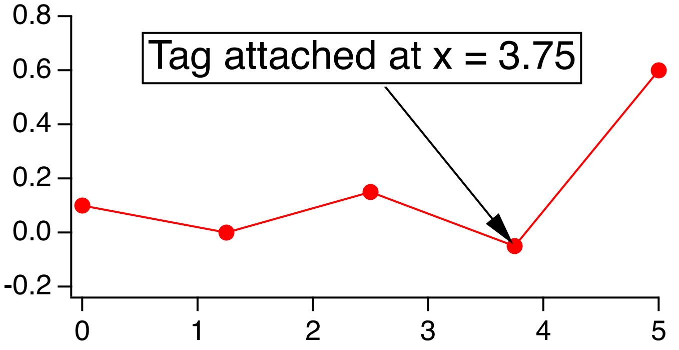
The interior/exterior setting used with textboxes does not apply to tags.

Tags Attached to Offscreen Points

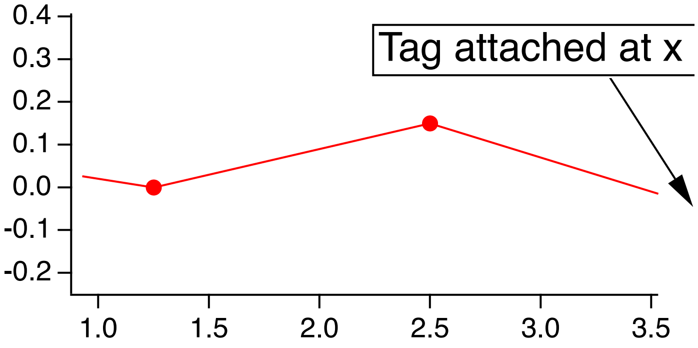
When only a portion of a wave is shown in a graph, it is possible that the attachment point of a tag isn't shown in the graph; it is "off screen" or "out-of-range".

This usually occurs because the graph has been manually expanded or the axes are not autoscaled. Igor draws the attachment line toward the offscreen attachment point.

In this example graph, the attachment point at x=3.75 falls within the range of displayed X axis values:



If we zoom the graph's X range to exclude the x=3.75 attachment point, the tag attachment point is offscreen but the tag is still drawn:



You can suppress the drawing of a tag whose attachment point is offscreen by choosing “hide the tag” from the If Offscreen pop-up menu in the Position Tab.

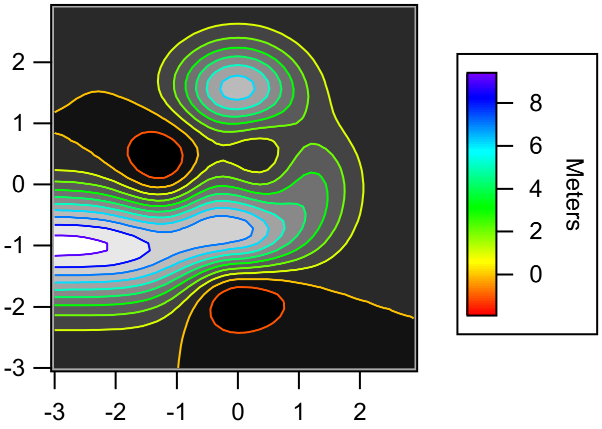
If you want to see or modify a tag that is hidden, autoscale the graph so that it is no longer hidden.

Contour Labels Are Tags

Igor uses specialized tags to create the numerical labels for contour plots. The specialization adds a "tangent" feature to automatically orient the tag along the path of the contour lines. See **Contour Labels** on page II-377 for details.

Color Scales

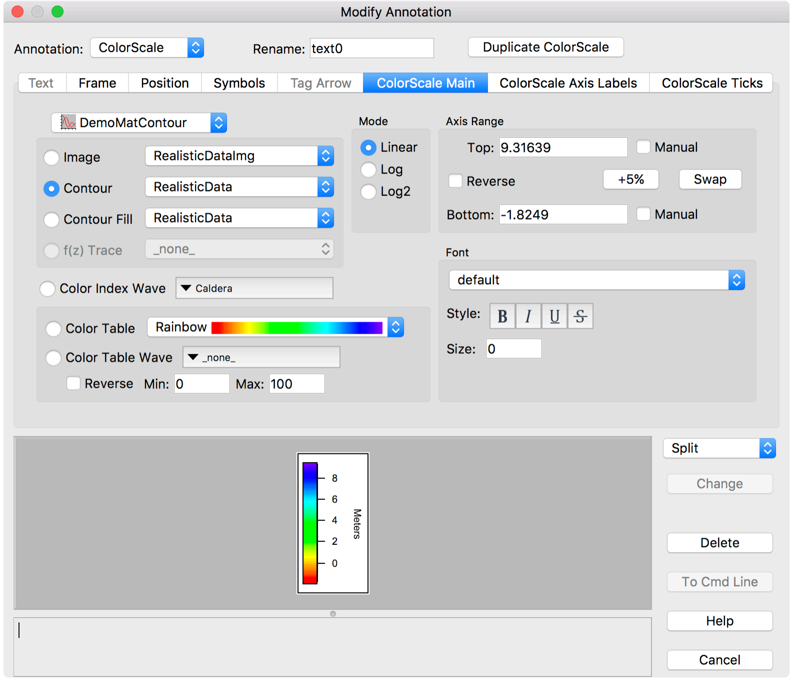
A color scale annotation summarizes the range of data using a color bar and one or more axes.



You create and modify color scales using the **ColorScale** operation which you can invoke via the Add Annotation and Modify Annotation dialogs.

ColorScale Main Tab

A color scale is associated with an f(z) trace, image plot, contour plot in a graph, the first surface object in a Gizmo plot, or with any color index wave or color table. This association can be changed in the ColorScale Main tab.



Modify Annotation

Annotation: ColorScale   Rename: text0

DemoMatContour

○ Image RealisticDataImg

● Contour RealisticData

○ Contour Fill RealisticData

○ f(z) Trace _none_

○ Color Index Wave Caldera

○ Color Table Rainbow

○ Color Table Wave _none_

□ Reverse Min: 0 Max: 100

Mode: ● Linear ○ Log ○ Log2

Axis Range

Top: 9.31639 □ Manual

□ Reverse

Bottom: -1.8249 □ Manual

Font: default

Style: B I U S

Size: 0

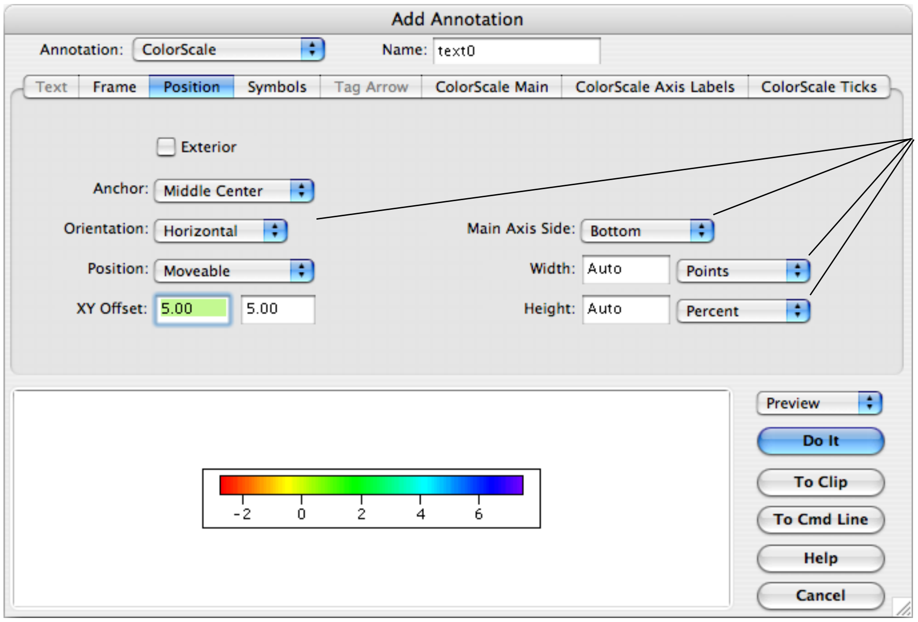
Split

You can infer from the Graph pop-up menu that color scales can be associated with image and contour plots and f(z) traces in a graph other than the graph (or layout) in which the color scale is displayed.

By choosing a graph or Gizmo plot from the pop-up menu, you can create a color scale based on an image, contour plot or f(z) trace in another graph or based on a surface plot in another gizmo window.

ColorScale Size and Orientation

The size and orientation of the color scale is set in the dialog’s Position tab:



Add Annotation

Annotation: ColorScale   Name: text0

□ Exterior

Anchor: Middle Center

Orientation: Horizontal

Position: Moveable

XY Offset: 5.00   5.00

Main Axis Side: Bottom

Width: Auto   Points

Height: Auto   Percent

These settings apply only to ColorScales.

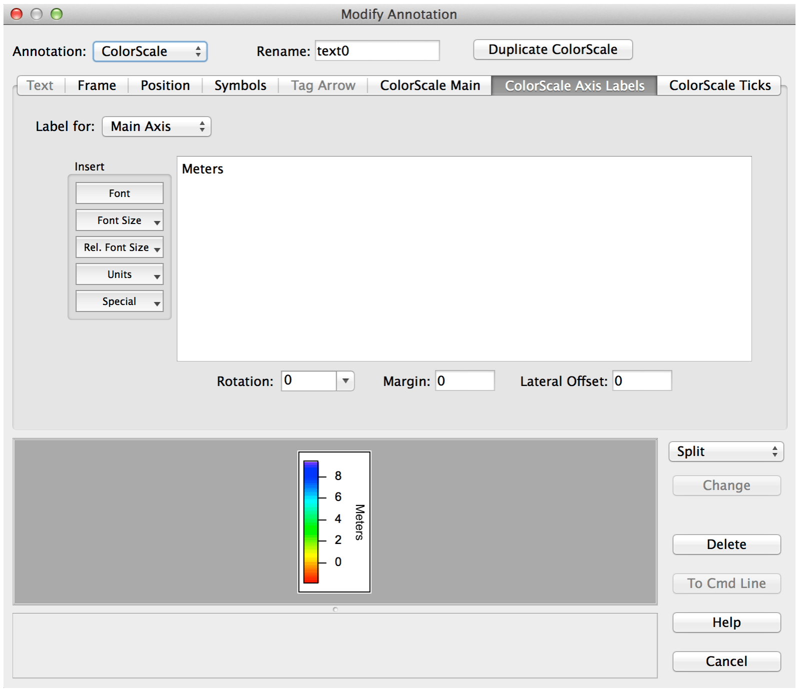
The size of a color scale is indirectly controlled by the size and orientation of the “color bar” inside the annotation, and by the various axis and ticks parameters. The annotation adjusts itself to accommodate the color bar, tick labels, and axis labels.

When set to Auto or 0, the Width and Height settings cause the color scale to auto-size with the window along the color scale’s axis dimension. Horizontal color scales auto-size horizontally but not vertically, and vice versa. The long dimension of the color bar is automatically maintained at 75% of the graph plot area or Gizmo plot dimension. The short dimension is set to 15 points.

You can enter a custom setting for either scale dimension in units of percent or points. Choosing Percent from the menu causes Igor to resize the corresponding dimension in response to graph size changes. Choosing Points fixes the dimension so that it never changes.

ColorScale Axis Labels Tab

You set the axis label for the main axis, and for the second axis if any, in the ColorScale Axis Labels tab:



Annotation: ColorScale

Rename: text0

Label for: Main Axis

Meters

Rotation: 0 Margin: 0 Lateral Offset: 0

The axis label text is limited to one line. This text is the same as is used for text boxes, legends, and tags in the Text tab, but it is truncated to one line when the Annotation pop-up menu is changed to ColorScale.

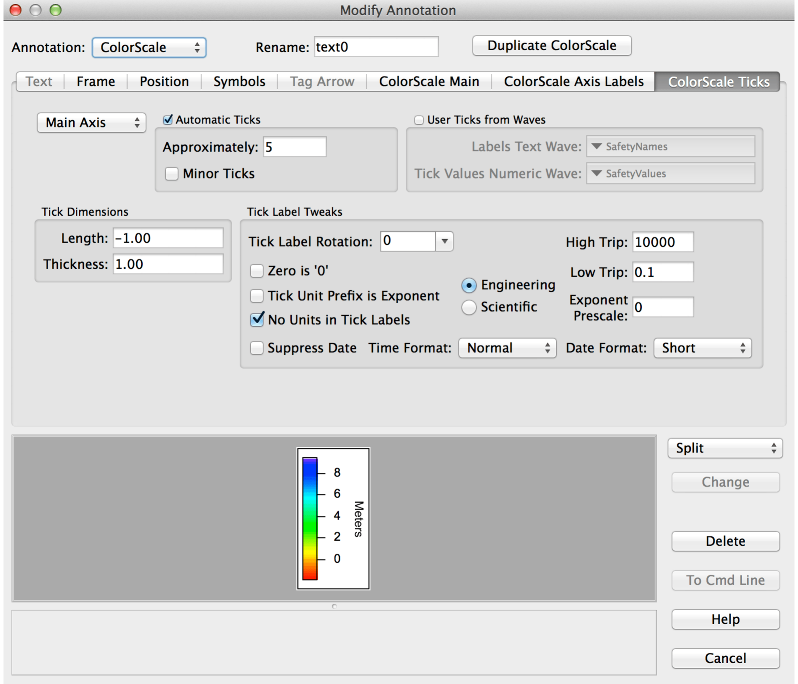
The Units pop-up menu inserts escape codes related to the data units of the item the color scale is associated with. In the case of an image, contour or surface plot, the codes relate to the data units of the image, contour or surface matrix, or of an XYZ contour's Z data wave.

Rotation, Margin, and Lateral Offset adjust the axis label's orientation and position relative to the color axis.

The second axis label is enabled only if the Color Scale Ticks tab has created a second axis through user-supplied tick value and label waves.

ColorScale Ticks Tab

The color scale’s axis ticks settings are similar to those for a graph axis:



Modify Annotation

Annotation: ColorScale   Rename: text0   Duplicate ColorScale

High Trip: 10000
Low Trip: 0.1
Exponent Prescale: 0
□ Suppress Date   Time Format: Normal   Date Format: Short

The main axis tick marks can be automatically computed by checking Automatic Ticks, or you can control tick marks manually by checking User Ticks from Waves. In the latter case, you provide two waves: one numeric wave which specifies the tick mark positions, and one text wave which specifies the corresponding tick mark labels.

You can also specify user-defined tick values and labels to create a second axis. This might be useful, for example, to display a temperature range in Fahrenheit and in Celsius.You do this by choosing Axis 2 from the pop-up menu that normally shows Main Axis. The second axis is drawn on the opposite side of the color bar from the main axis.

The Tick Dimensions settings apply to both axes. A length of -1 means Auto. Otherwise the dimensions are in points. To hide tick marks, set Thickness to 0.

Elaborate Annotations

It is possible to create elaborate annotations with subscripts, superscripts, and math symbols in Igor. Doing so requires entering escape codes. The Add Annotation dialog provides menus for inserting many of the escape codes that you might need.

This is feasible for relatively simple math expressions such as you might use for axis labels or to label graphs. For complex equations, you should use an Igor TeX formula or use a real equation editor and paste a picture representing the equation into an Igor graph or page layout.

Text Info Variables

The **text info variable** is a mechanism that uses escape codes that have a higher degree of “intelligence” than simple changes of font, font size, or style. Using text info variables, you can create quite elaborate annotations if you have the patience to do it. Since you need to know about them only to do fancy things, if you are satisfied with simple annotations, skip the rest of these Text Info Variable sections.

A text info variable saves information about a particular “spot” (text insertion point) in an annotation. Specifically, it saves the font, font size, style (bold, italic, etc.), and horizontal and vertical positions of the spot.

Each annotation has 10 text info variables, numbered 0 through 9. You can embed an escape sequence in an annotation's text to store information about the insertion point in a particular variable. Later, you can embed an escape sequence to recall part or all of that information. In the Label Axis and Add Annotation dialogs, there are items in the Font, Font Size and Special pop-up menus to do this.

See **Text Info Variable Escape Codes** on page III-55 for list of escape sequences.

Text Info Variable Example

To get a feel for this, let's look at a simple example. We want to create a textbox that shows the formula for the chemical compound ethanol: CH_3CH_2OH

To create a textbox showing this formula in 24 point type, we need to enter this, which consists of regular text plus escape codes (shown in red), in the Text tab of the Add Annotations dialog:

```
\Z24\[0CH\B3\MCH\B2\MOH
```

You can enter the escape codes by simply typing them or by making selections from the pop-up menus in the Insert section of the dialog. In this example, the font size escape code, **\Z24**, was generated using the Font Size pop-up menu and the rest of the escape codes were generated using the Special pop-up menu.

Here is what the escape codes mean:

\Z24	Set font size to 24 points.
\[0	Capture the current state as text info variable 0. (Text info variable 0 stores the "normal" state).
\B	Subscript.
\M	Return to normal state (as stored in text info variable 0).
\B	Subscript.
\M	Return to normal state (as stored in text info variable 0).

One way to enter this is to enter the regular text first and then add the escape codes. Here is what the annotation preview would show at each step of this process:

CH3CH2OH	CH3CH2OH
\Z24CH3CH2OH	CH3CH2OH (but in 24 point type)
\Z24**\[0**CH3CH2OH	CH3CH2OH (no visible change)
\Z24\[0CH**\B**3CH2OH	CH$_{3CH2OH}$
\Z24\[0CH\B3**\M**CH2OH	CH$_3$CH2OH
\Z24\[0CH\B3\MCH**\B**2OH	CH$_3$CH$_{2OH}$
\Z24\[0CH\B3\MCH\B2**\M**OH	CH$_3$CH$_2$OH

Programming with Annotations

You can create, modify and delete annotations with the **TextBox**, **Tag**, **Legend**, and **ColorScale** operations. The **AnnotationInfo** function returns information about one existing annotation. The **AnnotationList** returns a list of the names of existing annotations.

Changing Annotation Names

Each annotation has a name which is unique within the window it is in. You supply this name to the TextBox, Tag, Legend, ColorScale, and AnnotationInfo routines to identify the annotation you want to change.

You can rename an annotation by using the /C/N=*oldName*/R=*newName* syntax with the operations. For example:

```
TextBox/C/N=oldTextBoxName/R=newTextBoxName
```

Changing Annotation Types

To change the type of an annotation, apply the corresponding operation to the named annotation. For example, to change a tag or legend into a textbox, use:

```
TextBox/C/N=annotationName
```

Changing Annotation Text

To change the text of an existing annotation, identify the annotation using /N=*annotationName*, and supply the new text. For example, to supply new text for the textbox named text0, use:

```
TextBox/C/N=text0 "This is the new text"
```

To append text to an annotation, use the AppendText operation:

```
AppendText/N=text0 "and this text appears on a new line"
```

You can append text without creating a new line using the /NOCR flag.

Generating Text Programmatically

You can write an Igor procedure to create or update an annotation using text generated from the results of an analysis or calculation. For example, here is a function that creates or updates a textbox in the top graph or layout window. The textbox is named FitResults.

```
Function CreateOrUpdateFitResults(slope, intercept)
   Variable slope, intercept

   String fitText
   sprintf fitText, "Fit results: Slope=%g, Intercept=%g", slope, intercept
   TextBox/C/N=FitResults fitText
End
```

You would call this function, possibly from another function, after executing a CurveFit command that performed a fit to a line, passing coefficients returned by the CurveFit operation.

Deleting Annotations

To programmatically delete an annotation, use:

```
TextBox/K/N=text0
```

Annotation Escape Codes

Annotation escape codes provide formatting control and other features in annotations, including textboxes, tags, legends, and color scales. They can also be used in axis labels, control titles, **SetVariable** values using the styledText keyword, **ListBox** control contents, and with the **DrawUserShape** operation.

Using these escape codes you can control the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects.

General Escape Codes

These escape codes are can be used in any text that supports annotation escape codes:

\B — Subscript.

\F'*fontName*' — Use the specified font (e.g., \F'Helvetica').

\f*dd* — *dd* is a bitwise parameter with each bit controlling one aspect of the font style as follows:

Bit 0:	Bold
Bit 1:	Italic
Bit 2:	Underline
Bit 4:	Strikethrough

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

\JR — Right align text.

\JC — Center align text.

\JL — Left align text.

\K(*r*,*g*,*b*) — Use specified color for text. *r*, *g* and *b* are integers from 0 to 65535.

You can optionally include a fourth alpha parameter which specifies opacity in the range 0 to 65535.

\K also sets the marker fill color for markers added by \W. For setting the marker stroke color, use \k.

\KB(*r*,*g*,*b*) — Use specified color for text background. *r*, *g* and *b* are integers from 0 to 65535.

You can optionally include a fourth alpha parameter which specifies opacity in the range 0 to 65535.

Use \KB0; to turn background color off.

\KB was added in Igor Pro 9.00.

\k(*r*,*g*,*b*) — Use specified color for marker stroke (line color). *r*, *g* and *b* are integers from 0 to 65535. Use before \W*tdd* to change marker stroke color from the default of black (0,0,0).

You can optionally include a fourth alpha parameter which specifies opacity in the range 0 to 65535.

For setting the marker fill color for markers added by \W, use \K.

\L*dtss* — Draws a line from the x position specified in text info variable *d* to the current x position. Uses current text color. Thickness is encoded by digit *t* with values of 4,5,6 and 7 giving 0.25, 0.5, 1.0 and 1.5 pt. Line style is specified by 2 digit number *ss*.

\M — Use normal (main) script (reverts to main line and size).

\$PICT$name=*pictName*$/PICT$

Inserts specified picture. *pictName* can be a ProcPict or the name of a picture as listed in the Misc→Pictures dialog. This is useful for inserting math equations created by another program.

\$WMTEX$ *formula* $/WMTEX$

Inserts a math equation using a subset of LaTeX. See Igor TeX for details.

\S — Superscript.

\sa+*dd* — Adds extra space above line. *dd* is two digits in units of half points (1/144 inch). Can go anywhere in a line.

\sa-*dd* Reduces space above line. *dd* is two digits in units of half points (1/144 inch). Can go anywhere in a line.

\sb+*dd* Adds extra space below line. *dd* is two digits in units of half points (1/144 inch). Can go anywhere in a line.

\sb-*dd* Reduces space below line. *dd* is two digits in units of half points (1/144 inch). Can go anywhere in a line.

\W*tdd* Draws a marker symbol *dd* using current font size and color.

\W*tddd* Draws a marker symbol *ddd* using current font size and color.

The marker outline thickness is specified by the one-digit number *t* with 1, 4, 5, 6, 7 and 8 giving 0.0, 0.25, 0.5, 1.0, 1.25 and 1.5 points. A *t* value of 1, which sets the outline thickness to zero, is useful only for filled markers as it makes unfilled markers disappear.

The marker symbol number is specified by a two-digit number *dd* or a three-digit number *ddd*. New code should use the three-digit marker.

The three-digit syntax was added in Igor Pro 6.30 to support custom markers. This addition causes a two-digit *dd* escape sequence that is directly followed by a digit to be incorrectly interpreted. For example, the sequence:

```
\W718500 m
```

was intended to display marker 18 followed by "500 m". It is now interpreted as a three-digit marker number (185) followed by "00 m". To fix this, change the two-digit marker number to a three-digit marker number by adding a leading zero, like this:

```
\W7018500 m
```

Use \k to set the marker stroke color. Use \K to set the marker fill color.

\x+*dd* Moves the current X position right by 2**dd* percent of the current font max width.

\x-*dd* Moves the current X position left by 2**dd* percent of the current font max width.

\y+*dd* Moves the current Y position up by 2**dd* percent of the current font height.

\y-*dd* Moves the current Y position down by 2**dd* percent of the current font height.

\Z*nn* Use font size *nn*. *nn* must be exactly two digits.

\Zr*nnn* *nnn* is 3 digit percentage by which to change the current font size. *nnn* must be exactly three digits.

Tag Escape Codes

\ON Inserts the name of the wave to which the tag is attached.

\On Inserts the name of the trace and its instance number if greater than 0.

\OP Inserts the point number to which the tag is attached.

\OX Inserts the X value of the point to which the tag is attached.

\OY Inserts the Y value of the point to which the tag is attached.

\OZ Inserts the Z value of the point to which the tag is attached for contour level traces. Inserts NaN for other traces.

Text Info Variable Escape Codes

A text info variable is an internal Igor structure created by Igor. Using the escape codes described in this section, you can manipulate text info variables to create sophisticated annotations. These escape codes are can be used in any text that supports annotation escape codes.

Each annotation is created with 10 text info variables, numbered 0 through 9. Each text info variable is initialized to the default font, font size and style for the graph or page layout hosting the annotation. The X and Y positions are initially undefined.

For background information and an example, see **Text Info Variables** on page III-51.

Here are the supported text info variable escape codes. <digit> means one of 0, 1, 2, ... 9:

\[<digit>	Saves the font, size, style and current X and Y positions in the text info variable.
\]<digit>	Restores all but the X and Y positions from the text info variable.
\X<digit>	Restores the X position from the text info variable.
\Y<digit>	Restores the Y position from the text info variable.
\F]<digit>	Restores the font from the text info variable.
\Z]<digit>	Restores the font size from the text info variable.
\f]<digit>	Restores the style from the text info variable.

Text info variable 0 has a special property. It defines the "main" font size which is restored using the \M escape sequence. \M also sets the Y offset for the baseline to zero. No other text info variable 0 settings (font, style, or offsets) are set by \M.

Dynamic Text Escape Codes

You can enter the dynamic text escape sequence which inserts dynamically evaluated text into any kind of annotation using the escape code sequence:

Dynamic text allows you to create automatically updated annotations. The syntax for inserting dynamic text is:

```
\{dynamicText}
```

dynamicText may contain numeric and string expressions which reference global variables and waves and which invoke user-defined functions. Igor automatically reevaluates *dynamicText* when a global variable or a wave referenced directly in *dynamicText* or indirectly through a function call changes. It also reevaluates *dynamicText* whenever the annotation is updated.

Note: The use of dynamic text creates dependencies that can be fragile and confusing. In most cases, it is better to generate static text programmatically, as described in **Generating Text Programmatically** on page III-53.

Note: You can not reference local variables in *dynamicText* because local variables exist only while a procedure is executing and Igor must reevaluate it at other times.

The numeric and string expressions are evaluated in the context of the root data folder. Use the full data folder path of any non-root objects in the expressions.

dynamicText can take two forms, an easy form for a single numeric expression and a more complex form that provides precise control over the formatting of the result.

The easy form is:

```
\{ numeric-expression }
```

This evaluates the expression and prints with generic ("%g") formatting. For example:

```
TextBox "Two times PI is \\{2*PI}"
```

creates a textbox with this text:

```
Two times PI is 6.28319
```

The use of two backslashes in the TextBox literal string parameter is explained under **Backslashes in Annotation Escape Sequences** on page III-58.

The full form is:

```
\{ formatStr, list-of-numeric-or-string-expressions }
```

formatStr and *list-of-numeric-or-string-expressions* are treated as for the printf operation. For instance, this example has a format string, a numeric expression and a string expression:

```
TextBox "\\{\"Two times PI is %1.2f, and today is %s\", 2*PI, date()}"
```

It produces this result:

```
Two times PI is 6.28, and today is Thu, April 9, 2015
```

You can not use any other annotation escape codes in the format string or numeric or string expressions. They don't work within the \{ ... } context.

Also, the format string and string expressions do not support multiline text. If you need to use multiline text, use the technique described in **Generating Text Programmatically** on page III-53.

As an aid in typing the expressions, Igor considers carriage returns between the braces to be equivalent to spaces. In the Add Annotation dialog, rather than typing:

```
\{"Two times PI is %1.2f, and today is %s",2*PI,date()}
```

you can type:

```
\{
   "Two times PI is %1.2f, and today is %s",
   2*PI,
   date()
}
```

Legend Symbol Escape Codes

You can insert a legend symbol in an annotation.

The syntax for inserting a symbol in a graph is:

\s(*traceName*)

The syntax for inserting a symbol in a page layout is:

\s(*graphName*.*traceName*)

\s is usually used in a legend, in which symbols are created and removed automatically, but can also be used in tags, textboxes, and axis labels where the symbol is updated, but not automatically added or removed. See **Legends** on page III-42.

Axis Label Escape Codes

These escape codes are supported in axis labels and in axis tags:

\c	Inserts the name of the wave that controls the axis. This is the first wave graphed against that axis.
\E	Inserts power of 10 scaling with leading "x". This can be ambiguous and we recommend that you use either \U or \u.
\e	Like \E but inverts the sign of the exponent. This can be ambiguous and we recommend that you use either \U or \u.
\U	Inserts units with automatic prefixes

\u	Inserts power of 10 scaling but without the leading "x" as used by \E. No action if axis is not scaled. Use in front of custom or compound unit strings. Example label: "Field Strength (\\u Volts/Meter)" will produce something like "Field Strength (106 Volts/Meter)".
\u#1	This is a variant of \u that inserts the inverse of \u (e.g., 10-6 instead of 106).
\u#2	Prevents automatic insertion of any units or scaling. Normally, if you set a wave's units and scaling, using the Change Wave Scaling dialog or SetScale operation, and if you do not explicitly specify an axis label, Igor will automatically generate an axis label from the units and scaling. \u#2 provides a way to suppress this behavior when it gets in the way.

Note that escape codes are case sensitive; \u and \U insert different substrings.

Backslashes in Annotation Escape Sequences

An annotation escape code is introduced by a backslash character. Because backslash is itself an escape character in Igor strings, when entering an escape code in a literal string, you need to enter two backslashes to produce one.

For example:

```
TextBox/C/N=text0 "\\Z14Bigger"
```

The Igor command parser converts "\\" to a single backslash. The TextBox operation sees the single backslash and interprets \Z to mean that you want to change the font size.

The next example shows a case where you do not want a double-backslash:

```
TextBox/C/N=text0 "First line\rSecond line"
```

The Igor command parser converts "\r" to a carriage return character. The TextBox operation sees the carriage return character and interprets it to mean that you want to start a new line. There are no annotation escape codes in this example, just a regular escape code, so you must not use a double backslash.

The Add Annotation dialog generates a command to create an annotation. It knows the rules for backslashes. Consequently, if you use the Add Annotation dialog to create an annotation, you can see the correct use of backslashes by observing the command that it generates.

Igor TeX

As of Igor Pro 8, you can use a subset of LaTeX syntax to easily insert math formulas that would otherwise require tedious escape codes or the insertion of a picture generated by another program. LaTeX expressions are delimited by "\\$WMTEX$" and "\\$/WMTEX$" as illustrated here:

```
Display/W=(35,45,339,154)
TextBox/C/N=TeXTest/A=MC "\Z18" + "\\$WMTEX$ \frac{3x}{2} \\$/WMTEX$"
```

which creates

$$\frac{3x}{2}$$

As this example shows, you need double backslashes in the opening and closing escape sequences ("\\$WMTEX$" and "\\$/WMTEX$"). Inside those escape sequences is TeX markup text in which double backslashes are not used ("\frac{3x}{2}").

In the Add Annotation and Modify Annotation dialogs, you can insert the opening and closing escape sequences by choosing the Igor TeX item in the Special pop-up menu. When using the dialogs, do not enter double backslashes as Igor does this for you as necessary.

The example above shows white space after the opening and before the closing escape sequence. Such white space is optional.

You can use local string variables to construct the annotation text. For example:

```
static StrConstant kTeXOpen = "\\$WMTEX$"
static StrConstant kTeXClose = "\\$/WMTEX$"
static StrConstant kTeXFontSize = "\Z18"

Function TeXTest()
   DoWindow/F TexTestGraph
   if (V_Flag == 0)
      Display /N=TexTestGraph /W=(35,45,339,154)
   endif

   String TeXFormula = "\frac{3x}{2}"
   String annotationText = kTeXFontSize + kTeXOpen + TeXFormula + kTeXClose
   TextBox/C/N=TeXTest/A=MC/F=0 annotationText
End
```

For more examples open the Igor TeX Demo experiment by choosing File→Graphing Techniques→Igor TeX Demo.

By default, formulas use an inline style. You can switch to a larger style that is commonly used for formulas on their own line by adding "\displaystyle" at the start of the TeX formula.

Igor Supports a Subset of TeX

Igor does not contain a full LaTeX interpreter. Rather it uses code patterned after Knuth's TeX.web with a subset that supports the most common math syntax that an Igor user is likely to use. Formulas are drawn directly using Igor's normal text and line drawing code — Igor does not first create a picture or .dvi file.

Igor's subset supports LaTeX's \frac but does not support standard TeX's \over and does not support macros. If you discover syntax that Igor does not support but really should, please let us know.

You can use \rm to force letters to be upright (rather than italic.) This is useful in chemical formulas such as ethanol: \rm CH_3CH_2OH

Fonts Used with Igor TeX

For purposes of determining what font is used, each component of a TeX formula is classified as one of these:

- A Greek letter specified by a TeX code like \alpha, \beta, and \gamma
- A math symbol specified by a TeX code like \neg, \prod, \sum, and \int
- Other text (letters, numbers, function names, and anything else other than Greek letters and math symbols as defined above)

By default, Igor uses these fonts for components classified as Greek letters and math symbols:

Macintosh	Hiragino Sans with backups Cambria Math and Symbol
Windows	Symbol with backup Cambria Math

All other text is rendered using the font in effect in the annotation before the TeX formula.

The default Greek and math symbol fonts were chosen based on appearance and support for special characters such as square bracket extensions (used when building a tall square bracket).

You can override these defaults within a given annotation by storing a font name in text info variable 8 for Greek characters and text info variable 9 for math symbols. See **Text Info Variables** on page III-51. You can experiment with different fonts using the Igor TeX Demo experiment.

Although you can use a Greek character such as α (alpha) directly, in order to use the specific font chosen for Greek character display, you should still use the \alpha syntax of TeX.

The fonts used in a formula affect not only the visual appearance of characters but also the font embedding situation when exporting to the graphics formats Igor PDF and EPSF. See **Font Embedding** on page III-99 (*Macintosh*) and **Font Embedding** on page III-105 (*Windows*). When exporting Igor PDF and EPSF with font embedding for standard fonts turned off, you should examine the output carefuly and use full font embedding if problems are found.

Igor TeX Demo

To learn about LaTeX syntax and capabilites, open the Igor TeX Demo experiment by choosing File→Graphing Techniques→Igor TeX Demo.

Igor TeX References

Chapter

III-3

Drawing

Overview

Igor's drawing tools are useful in page layout and graph windows for highlighting material with boxes, circles and arrows and can also be used to create simple diagrams. These drawing tools are object-oriented and optimized for the creation of publication quality graphics.

You can graphically edit a wave's data values when it is displayed in a graph; data points can be deleted, added or modified. You can also create new waves by simply drawing them.

In control panel windows, you can use the drawing tools to create a fancy background for controls.

Like all other aspects of Igor, drawing tools are fully programmable. This allows programmers to create packages of code that add new graph types to Igor's repertoire. Although only programmers can create such packages, everyone can make use of them.

The drawing tools are available only in page layout, graph and control panel windows.

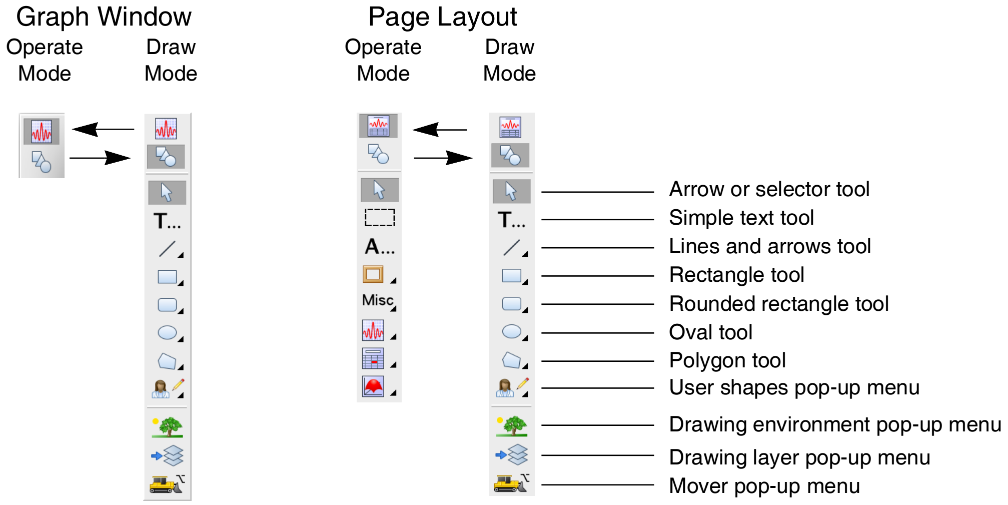
The Tool Palette

To use the drawing tools you first need to invoke the tool palette. In graphs and control panels this is done by the Show Tools menu command in the Graph or Panel menu. This command adds a tool palette along the left edge of the window. The tool palette is always available in page layout windows.

With the exception of Undo, Cut, Copy, Clear, Paste, Select All and Duplicate in the Edit menu, all drawing commands are located in the tool palette.

Once displayed, the tool palette works in two modes:

- **Operate mode:** Click the top (operate) button to enter Operate mode. In this mode, the drawing tool palette is not available, and you interact with the window as normal.
- **Drawing mode:** Click the second (drawing) button to enter Drawing mode. The entire tool palette will then be displayed, and you can add text, arrows, boxes, and other shapes to the window.



The three bottom icons in the tool palette — the Drawing Environment icon (tree and grass), Drawing Layer icon, and the Mover icon (bulldozer) — are pop-up menus. If you press Option (*Macintosh*) or Alt (*Windows*) while clicking the Mover icon, you get a pop-up menu that allows you to retrieve offscreen drawing elements, if any.

The icons above, with the triangle symbol, when clicked, select a mode of operation for creating various shapes using the mouse. If you click them and hold, they present pop-up menus that allow you to invoke dialogs for creating the shapes.

Arrow Tool

Use the arrow tool to select, move and resize one or more drawing objects or user-defined controls.

Selecting, Moving, and Resizing Objects

Click a drawing object once to select it. When selected, small squares called **handles** appear, defining the object's size. You can drag these handles to resize single or multiple objects. By pressing Shift while clicking a handle, an object resize can be constrained to the horizontal, vertical, or diagonal directions depending on how close the cursor is to these directions. By pressing Option (*Macintosh*) or Alt (*Windows*) instead, the resize is constrained to entirely horizontal or entirely vertical, depending on the position of the cursor.

If you click an object and it does not become selected then the object may be in a different drawing layer or it may not in fact be a drawing object at all.

You can select multiple drawing objects by shift clicking additional objects. You can remove an object from a selection by shift clicking a selected object.

You can also select multiple drawing objects by dragging a selection rectangle around a set of drawing objects. Unless you first press Option (*Macintosh*) or Alt (*Windows*), only objects that are completely enclosed by the selection rectangle are included in the selection. With Option (*Macintosh*) or Alt (*Windows*) pressed, objects that are merely touched by the selection rectangle are included. You can append additional objects to a selection by pressing Shift before dragging out a selection rectangle.

You can select all objects in the current layer with the Select All item in the Edit menu.

Rotating Objects

You can rotate draw objects by clicking just beyond a selection's visible resizing handles.

When the mouse is over an invisible rotation handle, the cursor changes shape, indicating that you can rotate the object. Click and drag the invisible rotation handle to rotate it.

Duplicating Objects

You can duplicate selected drawing objects using the Duplicate command found in the Edit menu. If, right after duplicating an object, you reposition the duplicated object and duplicate again then the new object will be offset from the last by the amount you just defined.

Deleting Objects

You can delete selected drawing objects by pressing Delete.

Modifying Objects

Double-clicking a drawing object displays a dialog for that object. You can then change any of the settings available in the dialog. Click the Do it button to apply the changes.

Simple Text Tool

The text tool is usually used to create a single line of simple text with the same font, size, style and rotation. You can also create formatted text using multiple lines and all the escape codes supported by annotations - see **Annotations** on page III-33.

The text tool is the only way to add text to control panel windows.

To create a line of text, click the simple text icon. The cursor will change shape to a text entry vertical line. Then move the cursor to the location in the window where you want the text origin, and click there to invoke the Create Text dialog.

Casual users can ignore the Anchor pop-up menu. It is used mainly by programmers to ensure that text is aligned properly about the numeric origin (X0,Y0). Any rotation is applied first and then the rotated text is aligned relative to the origin as specified by the anchor setting.

To edit or change a text object, double-click the object with the Arrow tool.

Lines and Arrows Tool

You can use the Lines tool to draw lines by clicking at the desired starting point and then dragging to the desired ending point. Press Shift while drawing to constrain the line to be vertical or horizontal.

If you click and hold on the Lines icon, you get a pop-up menu that takes you to a dialog where you can specify the line numerically. You see a similar dialog if you use the arrow tool to double-click a line. It allow you to change the properties of the line.

The dash pattern pop-up palette is the same as the one used for graph traces. You can adjust the dash patterns by use of the Dashed Lines command in the Misc menu.

The arrow fatness parameter is the desired ratio of the width of the arrow head to its length.

The line thickness and arrow length parameters are specified in terms of points and may be fractional.

Line start and end coordinates depend on the chosen coordinate system. See **Drawing Coordinate Systems** on page III-66 for detailed discussion. Programmers should note that the ends of a line are *centered* on the start and end coordinates. This is more obvious when the line is very thick.

Rectangle, Rounded Rectangle, Oval

The Rectangle, Rounded Rectangle, and Oval tools create objects that are defined by an enclosing rectangle. Click and hold on the appropriate icon to invoke a dialog where you can specify the object numerically. You see a similar dialog if you use the arrow tool to double-click the object.

Press Shift while initially dragging out the object to create a square or circle. If you press Shift while resizing the object with the arrow tool, you constrain the object in the horizontal, vertical, or diagonal directions depending on how close the cursor is to one of these directions. Thus, when you Shift-drag along a diagonal the sides are constrained to equal length, but if you Shift-drag along a horizontal or vertical direction, the object is resized along only one of these directions. If instead you hold down Option (*Macintosh*) or Alt (*Windows*), dragging along a diagonal resizes the object proportionally.

The Erase fill mode functions by filling the area with the current background color of the window. The fill background color is used only when a fill pattern other than Solid or Erase is chosen.

An object is always drawn inside the mathematical rectangle defined by its coordinates no matter how thick the lines. This differs from straight lines which are centered on their coordinates.

To adjust the corners of a rounded rectangle, double-click the object and edit the RRect Radius setting in the resulting dialog. Units are in points.

Arcs and Circles

To draw an arc or a circle by center and radius, click and hold on the Oval icon and choose Draw Arc from the resulting pop-up menu. Click and drag to define the center and the radius or start angle. Click again without moving the mouse to create a circle or move and click to define the stop angle for an arc. A variety of click and click-drag methods are supported and experimentation is encouraged.

To edit an arc, click and hold on the Oval icon in the draw tool panel and then choose Edit Arc from the resulting pop-up menu. If necessary, click on an arc to select it. You can then drag the origin, radius, start angle, and stop angle.

To change the appearance of an arc, double click to get to the Modify Arc dialog. Unlike Ovals, Arcs honor the current dash pattern and arrowhead setting in the same way as polygons and Beziers. The center of an arc or circle can be in any coordinate system (see **Drawing Coordinate Systems** on page III-66) but the radius is always in points.

Polygon Tool

The polygon tool creates or edits drawing objects called polygons and, in graphs, it can create or edit waves. For details, see **Drawing Polygons and Bezier Curves** on page III-69.

The User Shapes Tool

This tool creates drawing objects defined by procedure code written by you or another Igor user. For details see the **DrawUserShape** operation and for examples choose File→Example Experiments→Programming→User Draw Shapes.

Drawing Environment Pop-Up Menu

TheDrawing Environment icon allows you to change properties such as line thickness, color, fill pattern, and other visual attributes.

You can change the attributes of existing objects, or you can change the default attributes of objects you are yet to create.

To change the attributes of existing objects, first select them. Then use the Drawing Environment pop-up menu to modify the attributes.

To change the default attributes of objects yet to be created, make sure no objects are selected. Then use the Drawing Environment pop-up menu to change attributes. From that point on, all new objects will have the new attributes, until you change them again.

The items in the menu do not affect all types of objects. The Fill Mode and Fill Color commands affect only enclosed shapes. The Line Dash and Line Arrow commands do not affect rectangles and ovals.

You can invoke the Modify Draw Environment dialog to change multiple attributes by choosing All from the Drawing Environment pop-up menu or by double-clicking an object.

Double-clicking multiple selected objects or groups of object with the selector tool also invokes the Modify Draw Environment dialog. In this case, the properties shown are those of the *first* selected object but if you change a property then all selected objects are affected.

Double-clicking a single drawing object with the selector tool invokes a specific dialog for objects of that type.

Drawing Layer Pop-up Menu

The Drawing Layer pop-up menu selects the active drawing layer. You can create and edit drawing objects in the active drawing layer only. See **Drawing Layers** on page III-68 for details.

Mover Pop-Up Menu

The Mover pop-up menu performs various actions:

- Changing the front-to-back relationship of drawing objects in a given layer
- Aligning drawing objects or controls to each other
- Distributing the space between drawing objects or controls
- Grouping and ungrouping drawing objects
- Retrieving drawing objects or controls that are off screen

Use the Bring to Front, Send to Back, Forward and Backward commands to adjust the drawing order within the current drawing layer.

The Align command adjusts the positions of all the selected drawing objects relative to the first selected object. This works on controls as well as drawing objects.

The Distribute command evens up the horizontal or vertical spacing between selected objects. The original order is maintained. This operation is especially handy when working with buttons or other controls in a user-defined panel. This works on controls as well as drawing objects.

The Retrieve command is used to bring offscreen objects back into the viewable area. You can retrieve an offscreen object by selecting it from the Retrieve submenu of the Mover pop-up menu. Alternatively, if you press Option (*Macintosh*) or Alt (*Windows*) and select an object from the resulting pop-up menu, Igor selects the object and displays the Properties dialog. Use this to set the numeric coordinates for an object to bring it back onscreen. Or you can cancel out of the dialog and then press Delete to remove the object. Retrieve works on controls as well as drawing objects.

The Grid submenu provides options for controlling the grid. See **Drawing Grid** on page III-66 for details.

Drawing Grid

You can display a grid and force objects to snap to the grid, it is visible or not. You do this using the Mover pop-up menu Grid submenu.

The default grid is in inches with 8 subdivisions. The grid origin is the top-left corner of the window or subwindow. Use the **ToolsGrid** to set grid properties. You can independently specify the X and Y grids and set the origin, major grid spacing, and number of subdivisions.

When grid snap is on, you can turn it off temporarily by engaging Caps Lock.

When dragging an object, the corner nearest to where you clicked to start dragging the object is the corner that will be snapped to the grid. You can also snap existing objects to the grid by selecting the Align to Grid from the Mover popup menu.

Set Grid from Selection

If a single object is selected, Set Grid from Selection will set the grid origin at the top left corner of the object. It two objects are selected, the origin will be set to the top left corner of the first object and the major grid spacing will be defined by the distance to the top left corner of the second object. If either the horizontal or vertical separation is small then a uniform (equal X and Y) grid is defined by the larger distance. Otherwise the horizontal and vertical grids are set from the corresponding distances.

Grid Style Function

The Style Function submenu allows you use to create a style function or to run one that you previously created. Style functions are created in the main procedure window with names like *MyGridStyle00*. You can edit these to provide more meaningful names.

Drawing Coordinate Systems

A unique feature of Igor’s drawing tools is the ability to choose different coordinate systems. You can choose different systems on an object-by-object basis and for X and Y independently. This capability is mainly for use in graphs to allow your drawings to adjust to changes in window size or to changes in axis scaling.

You specify the coordinate system using pop-up menus found in the drawing Modify dialogs. The available coordinate systems are:

- Absolute
- Relative
- Plot Relative
- Axis Relative
- Axis

Absolute

In absolute mode, coordinates are measured in points, or **Control Panel Units** for control panels, relative to the top-left corner of the window. Positive x is toward the right and positive y is toward the bottom. In this mode the position and size of objects are unaffected by changes in window size. This is the default and recommended mode in page layouts and control panels.

If you shrink a window, it is possible that some objects will be left behind and may find themselves outside of the window (offscreen). In addition, if you copy an object with absolute coordinates from one window and then paste it in another smaller window it will be placed where the coordinates specify, even if it is offscreen. If you think this has happened, use the Mover pop-up menu to retrieve any offscreen objects or expand the window until the stray objects are visible.

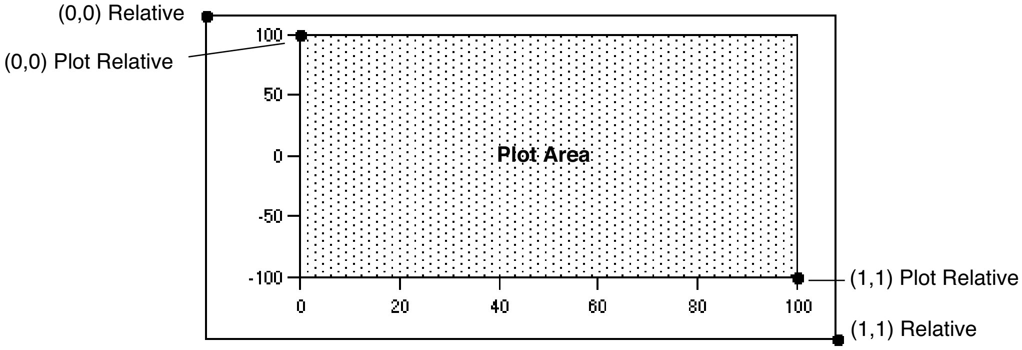
Relative

In this mode, coordinates are measured as fractions of the size of the window. Coordinate values x=0, y=0 represent the top-left corner while x=1,y=1 corresponds to the bottom-right corner. Use this mode if you want your drawing object to remain in the same relative position as you change the window size.

This mode will produce near but not exact WYSIWYG results in graphs. This is because the margins of a graph depend on many factors and only loosely on the window size. This mode gives good results for objects that don't have to be positioned precisely, such as an arrow pointing from near a trace to near an axis. It would not be suitable if you want the arrow to be positioned precisely at a particular data point or at a particular spot on an axis. For that you would use one of the next three coordinate systems.

Plot Relative (Graphs Only)

This system is just like Relative except it is based on the plot rectangle rather than the window rectangle. The plot rectangle is the rectangle enclosed by the default left and bottom axes and their corresponding mirror axes. The coordinates x=0, y=0 represent the top-left corner while x=1,y=1 corresponds to the bottom-right corner. This is the default and recommended mode for graphs.



The Plot Relative system is ideal for objects that should maintain their size and location relative to the axes. A good example is cut marks as used with split axes. In most cases, Plot Relative or Axis Relative is a better choice than the more complex **Axis-Based (Graphs Only)** system discussed below.

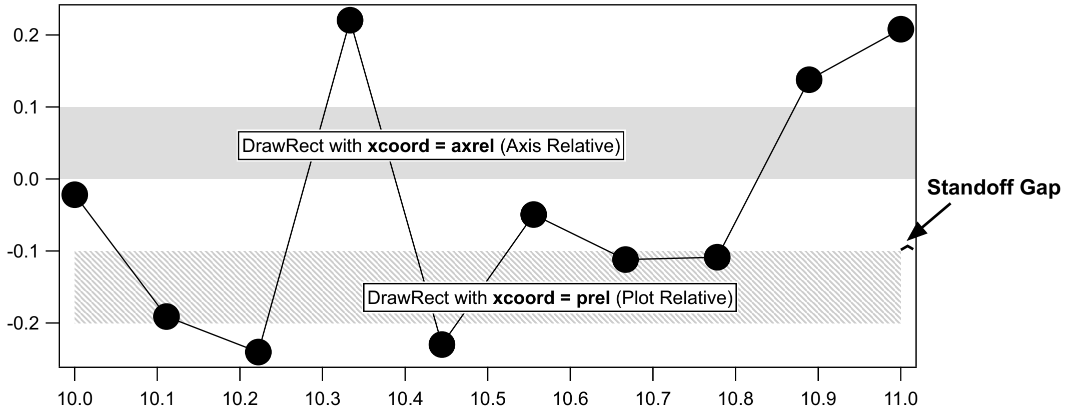
Axis Relative (Graphs Only)

This system is just like Plot Relative except it is based on the plot rectangle expanded by any axis standoff. If there is no axis standoff, the result is the same as using Plot Relative. Axis standoff is described under **Axis Tab** on page II-307.

Axis Relative coordinates require Igor Pro 9.00 or later.

The Axis Relative system is ideal for objects that should maintain their size and location relative to the axes including the standoff areas. A good example is a background highlighting color rectangle that starts or ends at the expanded rectangle's edges, avoiding a standoff gap.

The following graphic shows two rectangles, each with an X range of 0 to 1 but using axis relative mode for the top rectangle and plot relative mode for the bottom rectangle:



Both rectangles use axis-based coordinates, described next, for their Y coordinates.

Axis-Based (Graphs Only)

The pop-up menu for the X coordinate system includes a list of the horizontal axes and the pop-up menu for the Y coordinate includes a list of the vertical axes. When you choose an axis coordinate system, the position on the screen is calculated just as it is for wave data plotted against that axis, with the exception that drawing object coordinates are not limited to the plot area. This mode is ideal when you want an object to stick to a feature in a wave even if you zoom in and out.

Axes are treated as if they extend to infinity in both directions. For this reason along with the fact that axis ranges can be very dynamic, it is very easy to end up with objects that are offscreen. You can use the Mover pop-up menu Retrieve submenu to retrieve objects or, if you press Option (*Macintosh*) or Alt (*Windows*) before clicking the Mover icon, you can edit the numerical coordinates of each offscreen object. You can also end up with objects that are huge or tiny. It is best to have the graph in near final form before using axis-based drawing objects.

Axis-based coordinates are of particular interest to programmers but are also handy for a number of interactive tasks. For example you can easily create a rectangle that shades an exact area of a plot. If you use axis coordinate systems then the rectangle remains correct as the graph is resized and as the axis ranges are changed. You can also create precisely positioned drop lines and scale (calibrator) bars.

Drawing Layers

Layers allow you to control the front-to-back layering of drawing objects relative to other window components. For example, if you want to demarcate a region of interest in a graph, you can draw a shaded rectangle into a layer behind the graph traces. If you drew the same rectangle into a layer above the traces then the traces would be covered up.

Each window type supports a number of separate drawing layers. For example, in graphs, Igor provides three pairs of drawing layers. You can see the layer structure for the current window and change to a different layer by clicking the layer icon. The current layer is indicated by a check mark.

Drawing layers have names. This table shows the names of the layers and which window types support which layers:

Graphs	**Page Layouts**	**Control Panels**
ProgBack	ProgBack	ProgBack
UserBack	UserBack	UserBack
ProgAxes		

UserAxes		
ProgFront	ProgFront	
UserFront	UserFront	
Overlay	Overlay	Overlay

Drawing layers come in pairs named ProgSomething and UserSomething. User layers are provided for interactive drawing while Prog layers are provided for Igor programmers. This usage is just a recommended convention and is not enforced. The purpose of the recommendation is to give Igor procedures free access to the Prog layers. If you were to draw into a Prog layer and then ran a procedure that used that layer then your drawing could be damaged or erased.

The top layer is the Overlay layer. It is provided for programmers who wish to add user-interface drawing elements without disturbing graphic elements. It is not included when printing or exporting graphics. This layer was added in Igor Pro 7.00.

Only drawing objects in the current layer can be selected. If you find you can not select a drawing object then it must be in a different drawing layer. You will have to try the other layers until you find the right one.

To move an object between layers you have to cut, switch layers and then paste.

Drawing Polygons and Bezier Curves

The polygon tool creates or edits drawing objects called polygons and, in graphs, it can create or edit waves. For details, see **Drawing Polygons and Bezier Curves** on page III-69.

A polygon is an open or closed shape with one or more line segments, or edges. Polygons can be filled with a color and pattern and can have arrow heads attached to the start or end.

Although you may create a closed polygon by making the beginning and ending points the same, Igor does not recognize it as a closed shape. You can thus open the Polygon by moving either the beginning or ending points. This is subject to change in a future release.

Creating a New Polygon

You can create a polygon in one of two ways:

- **Segment Mode:** Each click defines a new vertex.
- **Freehand Mode:** Igor adds new vertices as you sweep out a smooth curve.

To create a polygon using segment mode, click the polygon icon once. Then click at the desired location for the beginning of the polygon. As you move the cursor, you create a line segment. A second click anchors the first line segment, and begins the second. You can keep drawing line segments until the polygon is finished.

Pressing the Shift key while dragging constrains movement to angles that are increments of 15 degrees from horizontal or vertical.

Stop drawing by double-clicking to define the last vertex or by clicking at the first vertex. You then automatically enter edit mode, the cursor changes to ⌖ , and vertices are marked with square handles. (For Bezier curves, vertices are called “anchors”.) In edit mode, you can reshape the polygon. To exit edit mode click the arrow tool.

To create a polygon using freehand mode, to edit an existing polygon, or to draw or edit a Bezier curve, click and hold on the polygon icon until the pop-up menu appears. Then choose one of these items:

- **Draw Poly:** Enters the create-segmented-polygon mode in which a click starts a new segmented polygon. This is identical to a single click on the icon.

- **Freehand Poly:** Enters create-freehand-polygon mode in which a click starts a freehand polygon. Click and drag to sweep out a smooth curve as long as you press the mouse button. When you release the mouse button, you automatically enter edit mode, where you can change the shape.
- **Edit Poly:** Enters edit-polygon mode for editing an existing polygon as described in the next section.
- **Draw Bezier:** Enters create-Bezier-polygon mode in which a click starts a Bezier polygon. Click and drag to define anchor and control points. Click on the first point to close the curve.
- **Edit Bezier:** Enters edit-Bezier-polygon mode for editing an existing Bezier polygon as described in the next section. You may need to click on a Bezier curve to select it.

Editing a Polygon

To enter edit mode, click and hold on the polygon icon, and choose Edit Poly from the pop-up menu. Then click the polygon object you want to edit.

While in edit mode you can move, add, and delete vertices, and move line segments:

- **Move a vertex:** Click and drag the vertex to move it and stretch the associated edges.
- **Create a new vertex:** Click between vertices in a line segment.
- **Delete vertices:** Press Option (*Macintosh*) or Alt (*Windows*) and click the vertex you want to delete.
- **Offset pairs of vertices:** Press Command (*Macintosh*) or Ctrl (*Windows*), click a line segment, and drag.

Segmented Polygons

It is possible to separate a polygon into segments by adding coordinate pairs that are NaN. By default, such segments are drawn as if they are separate polygons. If you fill such a polygon with a color having transparency, any overlapping areas will darken because they are painted twice.

If you use SetDrawEnv subpaths=1, the segments are sub paths within a single polygon. The segments are drawn with no line linking the subpaths, but when filled the entire polygon are treated as a single polygon, making it possible to create a polygon with internal holes. The way those holes are filled is affected by the SetDrawEnv fillRule keyword.

The subpaths keyword applies only to polygons created with **DrawPoly** and **DrawBezier**, not to those created manually. You can manually create subpaths by entering Edit Polygon mode, right-clicking a line segment of the polygon, and choosing Break Line.

A side-effect of setting SetDrawEnv subpaths=1 is a change to the way arrows are added to segmented polygons: with SetDrawEnv subpaths=0 (the default), arrows are added to each segment as if they are separate polygons. With subpaths=1, the arrows are added only to the first or last points in the entire polygon.

Editing a Bezier Curve

There are a number of operations you can perform to edit a Bezier curve:

- **Move an anchor point:** Click and drag the anchor point to move it and stretch the associated curves.
- **Move a control point:** Click and drag it. If an anchor point has two control points, this move both.
- **Move only one of two control points associated with an anchor point:** Click the control point, then press Option (*Macintosh*) or Alt (*Windows*), and drag the control point.
- **Move a control point that is directly above an anchor point**: Press Command (*Macintosh*) or Ctrl (*Windows*), click the control point (and anchor), then drag the control point.
- **Create a new anchor point:** Click the curve between anchor points.
- **Delete an anchor point:** Press Option (*Macintosh*) or Alt (*Windows*) and then click the anchor point.
- **Modify an anchor point's control points**: Control-click (Macintosh only) or right-click an anchor to display a contextual menu that sets the lengths and angles of the control points on each side of the anchor.

For example, choosing Make Sharp Corner sets the length of the control points to 0, so they lay directly on top of the anchor, making that point of the Bezier identical to a regular polygon. During editing mode, a "sharp corner" looks like a square marker with a red round marker inside of it.

- **Modify a control point or the "other" control point**: Control-click (*Macintosh only*) or right-click a control point to display a contextual menu that sets the lengths and angles of the clicked control point or the control point on the "other side" of the control point's anchor.

  For example, choosing Make Other Control Point Parallel sets the angle of the other control point so that the Bezier curve is tangent on both sides of the anchor to the angle already defined by the clicked control point.

- **Modify the control points that define the curve between two anchors**: Control-click (*Macintosh only*) or right-click the curve between anchors to display a contextual menu that sets the lengths and angles of the two control points attached to the two anchors that start and end that curve.

  For example, choosing Make 90 Degree Arc sets the angles and lengths of the two control points to draw a 90 degree arc between the two anchor points. In order for this choice to be available, the line between the two anchors must have some curve to it so that the correct orientation of the arc can be chosen.

  Choosing Break Curve to Start Another Bezier replaces the two control points between the anchors with one (NaN,NaN) coordinate pair to draw two separate Beziers curves. See **Segmented Bezier Curves** below for details. Choosing Remove All Bezier Breaks removes all (NaN,NaN) coordinate pairs from the Bezier object.

Pressing the Shift key while dragging a Bezier control handle constrains movement to angles that are increments of 15 degrees from horizontal/vertical.

Pressing the Shift key while dragging while dragging a polygon or Bezier anchor point snaps the anchor location to the nearest of lines through the original anchor location and through the locations of the two neighboring anchor points.

Pressing Shift while dragging constrains movement to horizontal or vertical directions.

Exit edit mode by clicking the arrow tool.

After exiting edit mode, you can use the environment icon to adjust the other attributes of the polygon. You can even add arrows to the start or end of the polygon. Or you can double-click a polygon to invoke the Modify Polygon dialog.

The X0 and Y0 settings determine the location of the first point.

You can change the size of the polygon by modifying the Xscale and Yscale parameters in the dialog. For example, enter 0.5 for both settings to shrink the polygon to half its normal size.

Segmented Bezier Curves

It is possible to separate a Bezier curve into segments by adding coordinate pairs that are NaN. By default, such segments are drawn as if they are separate Bezier curves. If you fill such a curve with a color having transparency, any overlapping areas will darken because they are painted twice.

If you use SetDrawEnv subpaths=1, the segments are treated as subpaths within a single Bezier curve. The segments are drawn with no line linking the subpaths, but when filled the entire curve are treated as a single Bezier curve, making it possible to create a curve with internal holes. The way those holes are filled is affected by the SetDrawEnv fillRule keyword.

The subpaths keyword applies only to polygons created with **DrawPoly** and **DrawBezier**, not to those created manually. You can manually create subpaths by entering Edit Bezier mode, right-clicking the curve, and choosing Break Curve.

A side-effect of setting SetDrawEnv subpaths=1 is a change to the way arrows are added to segmented Bezier curves. With SetDrawEnv subpaths=0 (the default), arrows are added to each segment as if they are separate Bezier curves. With subpaths=1, the arrows are added only to the first or last points in the entire Bezier curve.

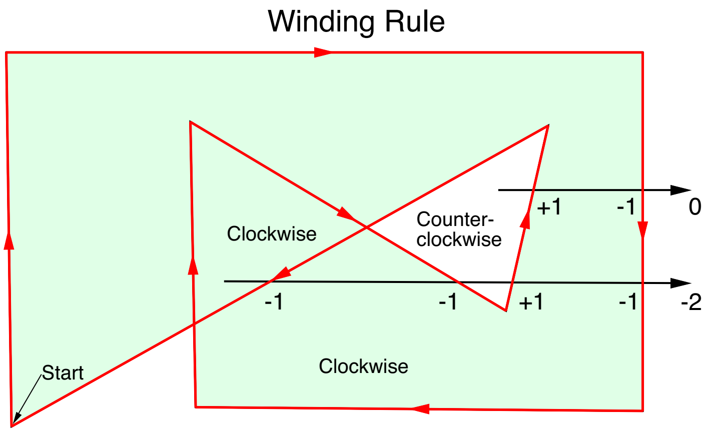
For a demonstration of segmented Bezier curves, execute this in Igor:

```
DisplayHelpTopic "Segmented Bezier Curves"
```

Polygon and Bezier Curve Fill Rules

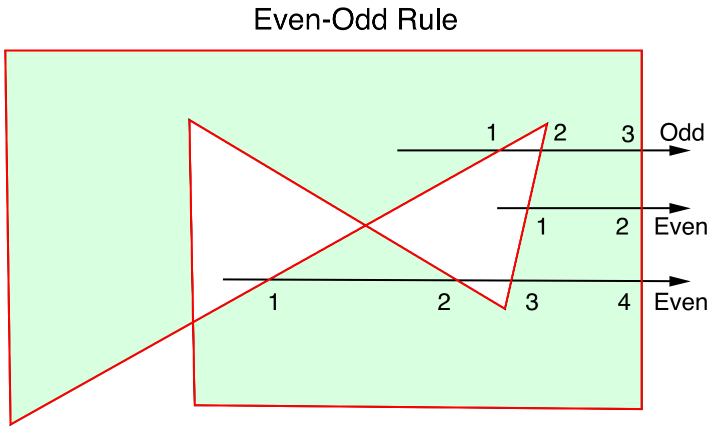
Simple polygons and Bezier curves with no intersecting edges are filled unambiguously - points within the shape are filled with color. But how do you decide what is inside and what is outside if the shape has intersecting edges?

There are two rules in common use: the Even-Odd rule and the Non-Zero Winding rule. Igor uses the Winding rule by default:



Starting at a given point, draw a line to infinity. If an edge is crossed and that edge is drawn from up to down (or clockwise with respect to the start of the line) subtract one. If the edge is drawn from down to up (or counterclockwise), add one. If the result is non-zero, it is inside and should be colored.

You can request the Even-Odd rule using `SetDrawEnv fillRule=1`. The fillRule keyword applies only to polygons and Bezier curves created with **DrawPoly** and **DrawBezier**, not to those created manually. Manually-created polygons and Bezier curves follow the winding rule by default; you can change the rule using the Modify Polygon or Modify Bezier dialogs.



Starting at a given point, draw a line to infinity. Count the number of edges crossed. If the result is an odd number, the point is inside. If it is even, it is outside.

Drawing and Editing Waves

In a graph, you can use the polygon tool to create or edit waves using the same techniques just described for drawing polygons. Click and hold on the polygon tool. Igor displays a pop-up menu containing, in addition to the usual polygon and Bezier commands, the following wave-drawing commands:

```
Draw Wave
Draw Wave Monotonic
Draw Freehand Wave
Draw Freehand Wave Monotonic
Edit Wave
Edit Wave Monotonic
```

The first four commands create and add a pair of waves with names of the form W_XPoly*nn* and W_YPoly*nn* where *nn* are digits chosen to ensure the names are unique. Draw Wave and Draw Freehand Wave work exactly like the corresponding polygon drawing described above. The monotonic variants prevent you from backtracking in the X direction. As with polygons, you enter edit mode when you finish drawing.

You can edit an existing wave, or pair of waves if displayed as an XY pair, by choosing one of the Edit Wave commands and then clicking the wave trace you wish to edit. Again, the monotonic variant prevents backtracking in the X direction. If you edit a wave that is not displayed in XY mode then you can not adjust the X coordinates since they are calculated from point numbers.

You can use the **GraphWaveDraw** and **GraphWaveEdit** operations as described in **Programmatic Drawing** on page III-73 to start wave drawing or editing.

Drawing Exporting and Importing

Copy/Paste Within Igor

You can use the Edit menu to cut, copy, clear and paste drawing objects just as you would expect.

Drawn objects retain all of their Igor properties as long as they are not modified by any other program. If, however, you export an Igor drawing to a program and then copy it back to Igor, the picture will no longer be editable by Igor, even if you made no changes to the picture.

When selected drawing objects are copied to the clipboard and then pasted, they retain their coordinates. However, this can cause the pasted objects to be placed offscreen if the object's coordinates don't fall within the displayed portion of the coordinate systems.

If you find that pasting does not yield what you expected, perhaps it is because some objects were pasted off-screen. You can use the Mover icon to examine or retrieve any of these offscreen objects.

Pasting a Picture Into a Drawing Layer

Pasting a picture from a drawing program may work differently than you expect. Igor does not attempt to take the picture apart to give you access to the component objects. Instead, Igor treats the entire picture as a single object that you can move and resize but not otherwise adjust.

You can change the scale of a pasted picture by either dragging the handles when the object is selected or by double-clicking the object and then setting the x and y scale factors in the resulting dialog.

Programmatic Drawing

All of the drawing capabilities in Igor can be used from Igor procedures. This section describes drawing programming in general terms and provides strategies for use along with example code.

The programmable nature is especially useful in creating new graph types. For example, even though Igor does not support polar plots as a native graph type we were able to create a polar plot package that produces high-quality polar graphs. (To see a demo of the package, choose File→Example Experiments→Graphing Techniques→New Polar Graph Demo.) Nonprogrammers can use the package as-is while programmers can modify the code to suit their purposes or can extract useful code snippets for their own projects.

You can get a quick start on a drawing programming project by first drawing interactively and then asking Igor to create a recreation macro for the window (click the close button and look in the Procedure window). You can then extract useful code snippets for your project. Frequently all you will have to do is replace literal coordinate values with calculated values and you are in business.

Drawing Operations

Here is a list of operations related to drawing.

DrawAction	**DrawArc**	**DrawBezier**	**DrawLine**
DrawOval	**DrawPICT**	**DrawPoly**	**DrawRect**
DrawRRect	**DrawText**	**DrawUserShape**	**GraphNormal**
GraphWaveDraw	**GraphWaveEdit**	**HideTools**	**SetDashPattern**
SetDrawEnv	**SetDrawLayer**	**ShowTools**	**ToolsGrid**

SetDrawLayer Operation

Use **SetDrawLayer** to specify which layer the following drawing commands will affect. If you use the /K flag then the current contents of the given drawing layer are deleted. See **Drawing Programming Strategies** on page III-76 for considerations in the use of SetDrawLayer and the /K flag.

SetDrawEnv Operation

This is the workhorse command of the drawing facility. It is used to specify the characteristics for a single object, to specify the default drawing environment for future objects, and to create groups of objects.

You can issue several SetDrawEnv commands in sequence; their effect is cumulative. By default, the group of SetDrawEnv commands affects only the next drawing command. Drawing commands that follow the first will use the default settings that were in effect before the SetDrawEnv commands were issued. For instance, these SetDrawEnv commands change the font and font size for only the first of the two DrawText commands:

```
SetDrawEnv fname="Courier New"
SetDrawEnv fsize=18     // 18 point Courier New, commands accumulate
DrawText 0,1,"This is in 18 point Courier New"
DrawText 0,0,"Has font and size in use before SetDrawEnv commands"
```

Use the save keyword in the SetDrawEnv specification to make the settings permanent. The usual use of the save keyword is at the end of the last SetDrawEnv command in a series. The permanent settings allow you to draw a number of objects all with the same characteristics without having to reissue SetDrawEnv commands before each object.

To create a grouping of objects, simply bracket a group of drawing commands with SetDrawEnv commands using the gstart and gstop keywords. Grouping is purely a user interface concept. Objects are drawn exactly the same regardless of grouping.

Draw<*object*> Operations

These operations, along with SetDrawEnv, operate differently depending on whether or not drawing objects are selected in the target window. If, for example, a rectangle is selected in the target window and a DrawRect command is executed then the *selected* rectangle is changed. If, on the other hand, no rectangle is selected then *a new* rectangle is created. This behavior exists to support interactive drawing and is not useful to Igor programmers, since there is no programmatic way to select a drawing object. Normally, you will be creating new objects rather than modifying existing objects.

As you can see from the format of the commands, generally all you specify in the commands themselves are the coordinates. Properties such as color and line thickness are specified by SetDrawEnv commands preceding the Draw<*object*> commands. The exception is DrawText where you specify the text to be drawn.

DrawPoly and DrawBezier Operations

The **DrawPoly** operation on page V-176 and **DrawBezier** operation on page V-174 come in the following two types:

- **Literal:** You can specify the vertices or control points with a set of literal numbers. (Polygons and bezier curves created interactively are always of the literal variety.)
- **Wave:** You can use waves to define the vertices or control points.

Because polygons and bezier curves can be of unlimited length, the /A flag allows object definitions to extend over multiple lines.

It is legal to specify a polygon with only a single point. Use this to set up a loop to append vertices to the origin vertex. Note that if you fail to add vertices and leave the polygon with just one vertex then the user will not be able to see or select the polygon.

Literal Versus Wave

As a programmer, you must choose either the literal or the wave polygon type when creating a polygon or bezier curve. This section explains the differences between the two.

The advantage of the literal method is that it does not clutter the experiment with numerous waves that may be distracting to the user. It also has the advantage that all such objects are independent of one another.

With the wave method, objects are not independent. If the user duplicates an object, or runs a window recreation macro several times, then all the objects would be linked via the wave. If the user then edits one of the objects, those edits would affect all of the associated objects; this could also be considered an advantage of the method.

A disadvantage of the literal method is that when Igor creates a recreation macro for a window containing literal method objects then all of the vertices or control points have to be specified in text. This can create huge macros that take a lot of time to create and to run. Because Igor uses the recreation macro technique when saving and restoring experiments, the use of large literal method objects can dramatically lengthen experiment save and restore time.

Wave method objects do not have this disadvantage. One nifty feature of the wave method is that you can read back the vertices or control points after the user has edited the object. Another advantage of the wave method is that you can calculate new vertices or control points at any time and the dependent objects will be automatically updated.

Screen Representation

It is important to note that the value of the first polygon vertex does not determine the location of the first vertex on the screen. The location is specified by the *xOrg*, *yOrg* parameters. Effectively the value of the first vertex is *subtracted* from all the vertices and then the value of the origin is *added* to all vertices. Thus the following commands create the exact same representation on the screen:

```
DrawPoly 120,50,1,1,{0,0,20,40,60,15}
DrawPoly 120,50,1,1,{200,300,220,340,260,315}
```

When programming, the first vertex is usually `0,0`. The *hScaling*, *vScaling* parameters are probably not of any interest to programmers; use 1 for both values.

GraphWaveDraw, GraphWaveEdit, and GraphNormal

These operations relate to graph modes that are only tangentially related to drawing.

- **GraphWaveDraw** puts the graph in a mode where the user can draw a wave using the same user interface as polygon drawing.
- **GraphWaveEdit** allows the user to edit a wave using the same user interface as polygon editing.

- **GraphNormal** puts the user into normal operation mode, and is the equivalent of clicking the top icon in the tool palette.

These operations are provided so a program can allow the user to sketch a region in a graph. The program can then read back what the user did. Unlike the other drawing modes, these wave drawing and edit modes allow user-defined buttons to be active. This is so you can provide a “done” button for the user. The button procedure should call GraphNormal to exit the drawing or edit mode.

The GraphWaveEdit command operates a little differently depending on whether or not you specify a wave with the command. If you do specify a wave then only that wave can be edited by the user. If you let the user choose a wave then he or she can switch to a new trace by clicking it.

Drawing Programming Strategies

There are three distinct ways you can structure your drawing program:

- **Append:** You can append the contents of one or more layers.
- **Replace Layer:** You can replace the contents of the layers.
- **Replace Group**: You can replace the contents of a named group.

The Replace Layer Method

Use this method when you want to maintain a fairly complex drawing completely under program control. For example you may want to extend Igor by adding a new axis type or a new display method or you may want to create a completely new kind of graph. The Polar Graphs package mentioned above utilizes the replace method.

The key to the replace method is the use of the /K flag with the SetDrawLayer command. This “kills” (deletes) the entire contents of the specified layer. After clearing out the layer you must then redraw the entire contents. To do this you will usually have to maintain some sort of data structure to hold all the information required to maintain the drawing.

For example if you are creating an artificial axis package, you will need to maintain user settings similar to those you see in Igor’s modify axis dialog. In many cases setting up a few global variables or waves in a data folder will be sufficient. As an example, see the Drawing Axes procedure file in the WaveMetrics Procedures folder.

The Replace Group Method

With named groups created with the SetDrawEnv gname keyword, you can use DrawAction to delete the group or to set the insertion point for new drawing commands. See the **DrawAction** operation on page V-172 for an example.

The Append Method

Use this method to provide convenience features that automate creation of simple drawings. You add a small drawing, such as a drop line, calibration bar, or shading rectangle, to any existing drawing objects in a given layer when the user runs a procedure or clicks a button. Such drawings are often small and modular — .

Generally, the drawing will be something the user could have done manually and may want to modify. If you need to specify a layer at all it should be a User layer. Often there will be no need to set the drawing layer at all — just use the current layer.

You may, however, need to set the layer for specific circumstances. A shading rectangle is an example of an object that should go in a specific layer, since it must be below the traces of a graph. In this case, if you use the SetDrawLayer operation, then you should set the current layer back with “SetDrawLayer UserTop”.

If you are using the append method, you should avoid using the Prog layers. This is because they are intended for use where the entire layer is to be replaced under program control.

Another consideration is whether or not you should set the default drawing environment. In general you should not but instead leave the uer in control. This varies depending on specific objectives.

Grouping

It is a good idea to use grouping for your drawing. This allows the user to move the entire drawing by merely selecting and dragging it.

Example: Drop Lines

In this example, we show a procedure that adds a line from a particular point on a wave, identified by cursor A, to the bottom axis. The procedure assumes that the graph has left and bottom axes and that cursor A is on a trace. For clarity, error checking is omitted.

```
Menu "Graph"
   "Add Drop Line", AddDropLine()
End

Function AddDropLine()
   Variable includeArrow = 2           // 1=No, 2=Yes
   Prompt includeArrow, "Include arrow head?", popup "No;Yes"
   DoPrompt "Add Drop Line", includeArrow
   includeArrow -= 1                   // 0=No, 1=Yes

   Variable xCursorPosition = hcsr(A)
   Variable yCursorPosition = vcsr(A)

   GetAxis/Q left
   Variable axisYPosition = V_min

   SetDrawEnv xcoord=bottom, ycoord=left
   if (includeArrow)
      SetDrawEnv arrow=1, arrowlen=8, arrowfat=0.5
   else
      SetDrawEnv arrow=0
   endif
   DrawLine xCursorPosition,yCursorPosition,xCursorPosition,axisYPosition
End
```

Drawing Shortcuts

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To temporarily invoke the Arrow tool while in Operate mode	Press Command-Option. You can now select an object and move or resize it. This shortcut works even if the tool palette is not showing.	Press Ctrl+Alt. You can now select an object and move or resize it. This shortcut works even if the tool palette is not showing.
To invoke the dialog to modify a control or drawing object while in Operate mode	Press Command-Option and double-click the control or drawing object. This shortcut works even if the tool palette is not showing. Also, if the palette is showing, the Drawing mode's Arrow tool becomes selected after the dialog is dismissed.	Press Ctrl+Alt and double-click the control or drawing object. This shortcut works even if the tool palette is not showing. Also, if the palette is showing, the Drawing mode's Arrow tool becomes selected after the dialog is dismissed.
To nudge a selected drawing object or control	Use the Arrow keys. Press Shift to nudge faster.	Use the Arrow keys. Press Shift to nudge faster.

Chapter

III-4

Embedding and Subwindows

Overview

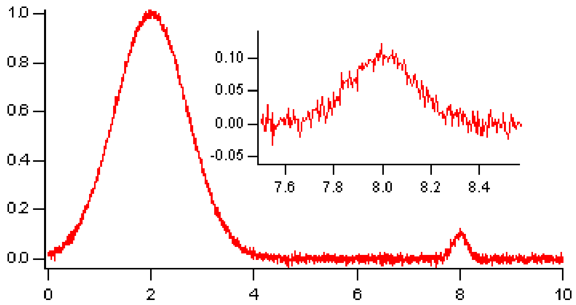
You can embed graphs, tables, Gizmo plots, and control panels into other graphs and control panels.

You can embed graphs, tables, and Gizmo plots into page layouts.

Finally, you can embed notebooks in control panels only.

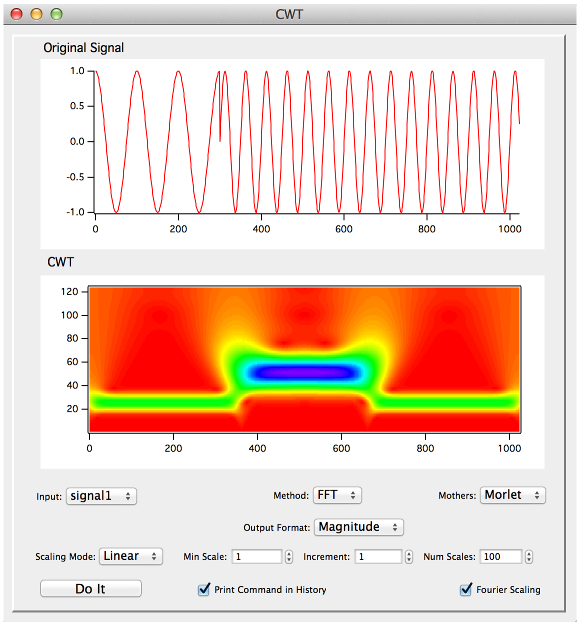
The embedded window is called a *subwindow* and the enclosing window is called the *host*. Subwindows can be nested in a hierarchy of arbitrary depth. The top host window in the hierarchy is known as the *base*.

In this example, the smaller, inset graph is a subwindow:



Although you can create graphs like this by careful positioning of free axes, it is much easier to accomplish using embedding.

In the next example, the two graphs are subwindows embedded in a host panel:



Input: signal1

Method: FFT

Mothers: Morlet

Output Format: Magnitude

Scaling Mode: Linear

Min Scale: 1

Increment: 1

Num Scales: 100

☑ Print Command in History

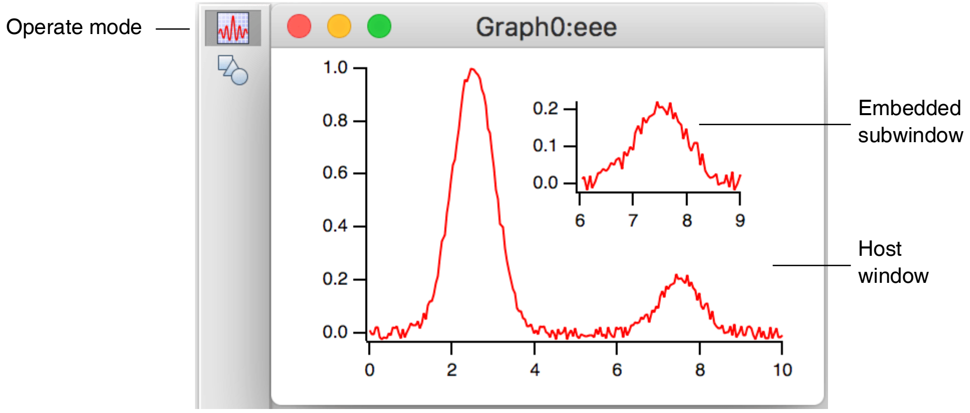
☑ Fourier Scaling

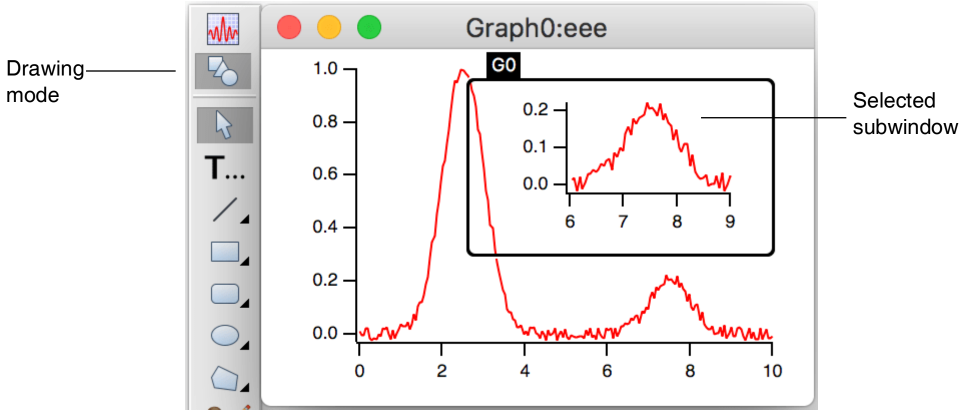
This example is derived from the CWT demo experiment which you can find in the Analysis section of your Examples folder.

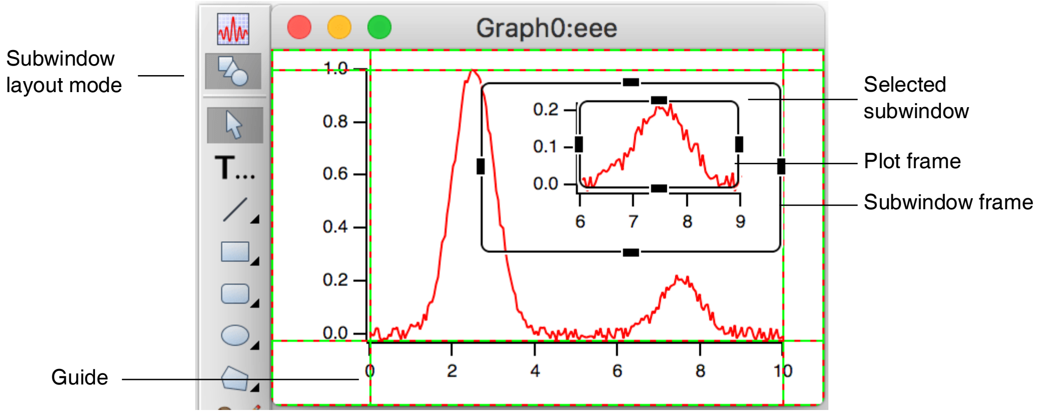
Subwindow Terminology

When a window is inserted into another window it is said to be *embedded*. In some configurations (see **Subwindow Restrictions** on page III-82), an embedded window does not support the same functionality that it has as a standalone window. It is then called a *presentation-only* object. For example, when a table is embedded in a panel, it has scroll bars and data entry features just like a standalone table. But when a table is embedded in a graph or in a page layout, it is a presentation-only object with no scroll bars or other user interface elements.

The following pictures illustrate additional subwindow terminology:







A graph, layout, or control panel window operates in one of three modes:

- Operate mode (also called normal mode)
- Drawing mode
- Subwindow layout mode

When the top icon in the tool palette is selected, the window is in operate mode. This is the mode in which the user normally uses the window or active subwindow.

When the second icon in the tool palette is selected, the window is in drawing mode. In this mode, you can use drawing tools on the window or active subwindow.

If you click the black frame around a subwindow while in edit mode, you enter subwindow layout mode. In this mode, you can position, and resize subwindows, as well as create and adjust guides.

Subwindow Restrictions

The following table summarizes the rules for allowed host and embedded subwindow configurations.

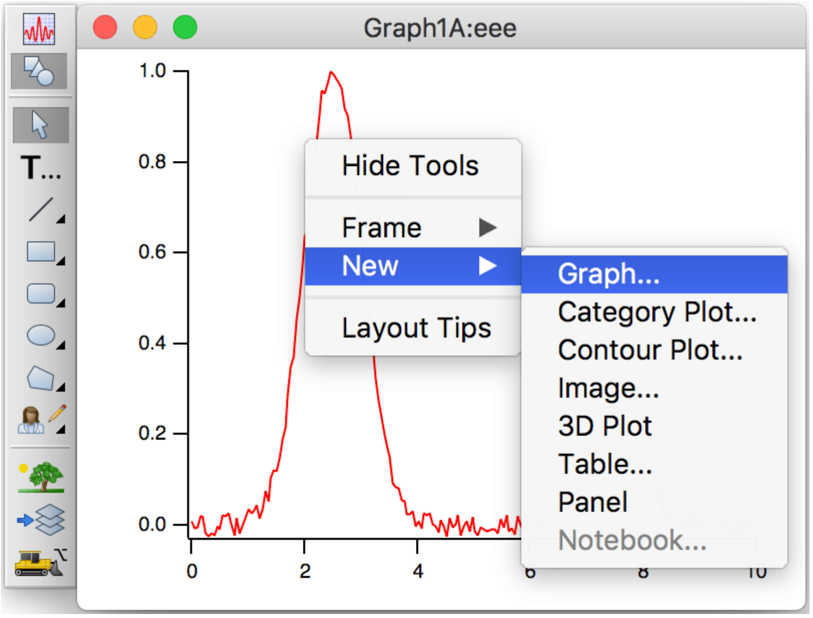
		Host			
		Graph	**Table**	**Panel**	**Layout**
Subwindow	**Graph**	Yes	No	Yes	Yes
	Table	Yes[*]	No	Yes	Yes[*]
	Panel	Yes[†]	No	Yes	No
	Layout	No	No	No	No
	Notebook	No	No	Yes	No
	Gizmo	Yes	No	Yes	No

[*] Tables embedded in graphs or layouts are presentation-only objects. They do not support editing of data.

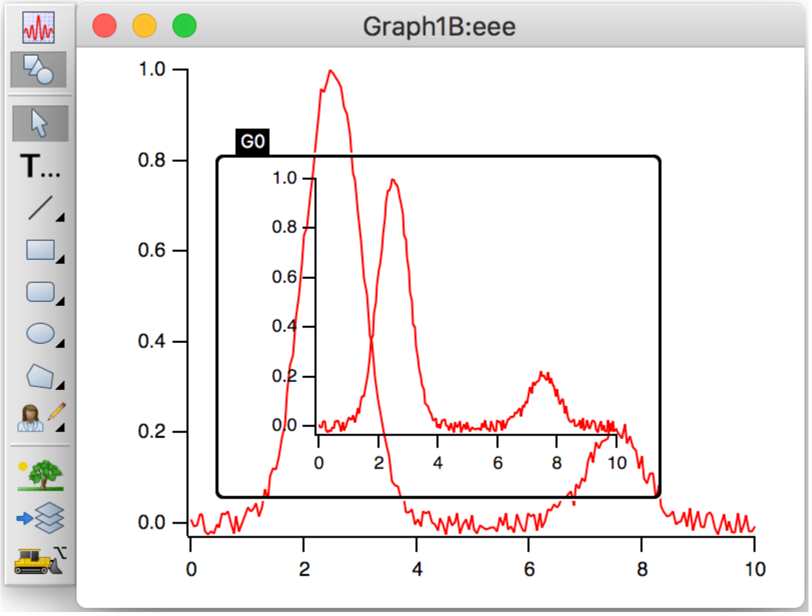
[†] Panels can be embedded in base graphs only.

Creating Subwindows

You can create subwindows either from the command line (see **Subwindow Command Concepts** on page III-92) or interactively using contextual menus. To add a subwindow interactively, show the tool palette of the base window, click the second icon to enter drawing mode, and then right-click (*Windows*) or Control-click (*Macintosh*) in the interior of the window and choose the desired type of subwindow from the New menu:



Igor presents the normal dialog for creating a new window but the result will be a subwindow:



You can position the subwindow by clicking on its heavy frame to enter subwindow layout mode (see **Subwindow Layout Mode and Guides** on page III-85). Finally, click the top icon of the tools to adjust the graphs in operate mode.

Positioning and Guides

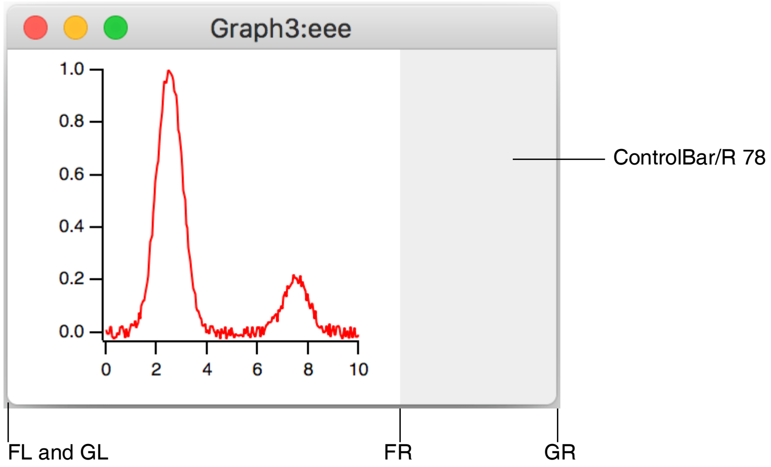
Subwindows can be positioned in their hosts in a wide variety of ways. You can specify the position of a subwindow numerically using either absolute (fixed distance) or relative modes. You can also attach key locations in a subwindow to named guides.

Guides are horizontal or vertical reference locations defined by the immediate host of a subwindow and may be either fixed (built-in) or moveable (user-defined). Built-in guides represent fixed locations of the host such as its frame or the interior plot area of graphs. Built-in guides can not be moved except by moving the object to which the guide refers.

All host windows have built-in guides named *FL*, *FT*, *FR*, and *FB* for Frame Left, Frame Top, Frame Right, and Frame Bottom. Graphs also have the corresponding *PL*, *PR*, *PT*, and *PB* for the interior plot area. In addition, base graphs have built-in guides *GL*, *GR*, *GT*, and *GB* for the graph area.

	Left	**Right**	**Top**	**Bottom**
Host Window Frame	FL	FR	FT	FB
Host Graph Rectangle	GL	GR	GT	GB
Inner Graph Plot Rectangle	PL	PR	PT	PB

The graph area is the total area of the graph window. The frame area is the total area of the graph window excluding the areas occupied by control bars.



User-defined guides can be based on built-in or other user-defined guides. They can be defined as being either a fixed distance from another guide or a relative distance between two guides.

Reference points of a subwindow that can be attached to guides include the outer left, right, top and bottom for all subwindow types and, for graphs only, the interior plot area.

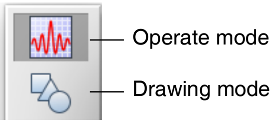
Guides are especially useful when creating stacked graphs. By attaching the plot left (PL) location on each graph to a user-defined guide, all left axes will be lined up and will move in unison when you drag the guide around. This is illustrated in **Layout Mode and Guide Tutorial** on page III-86.

Frames

You can specify a frame style for each subwindow. Frames, if any, are drawn inside the rectangle that defines the location of the subwindow and the normal content is then inset by the frame thickness. Frames can also be specified for base graph and panel windows. This is handy when you want to include a frame when you export or print a graph. You can adjust the frame for a window or subwindow by right-clicking (*Windows*) or Control-clicking (*Macintosh*) in drawing mode.

Subwindow User-Interface Concepts

Each host window has two main modes corresponding to the top two icons in the window’s tool palette. Choose Show Tools from the Graph or Panel menu to show the tool palette. Clicking the top icon selects operate mode and clicking the second icon selects drawing mode.



When using subwindows, there is a third mode: subwindow layout mode (see **Subwindow Layout Mode and Guides** on page III-85).

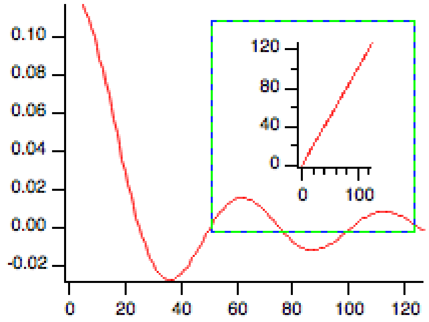
When not using subwindows, a particular window is the *target window* — the default window for command-line commands that do not explicitly specify a window. The addition of subwindows leads to the analogous concept of the *active subwindow*.

You make a subwindow the active subwindow by clicking it. In operate mode the active subwindow is indicated by a green and blue border. In drawing mode it is indicated by a heavy black border with the name of the subwindow shown in the upper left corner.

Panel subwindows are exceptions in that clicking them in operate mode does not make them the active subwindow. You must click them while in drawing mode.

As an example, execute the following:

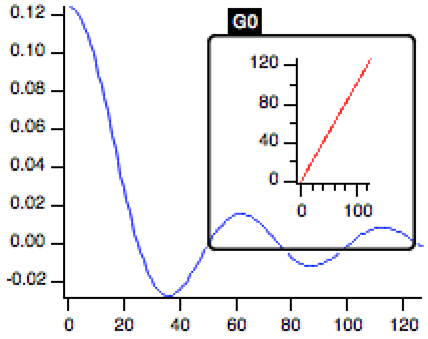
```
Make/O jack=sin(x/8)/x,sam=x
Display jack
Display/W=(0.5,0.14,0.9,0.7)/HOST=# sam
```



Notice the green and blue border around the newly created subwindow:.

This indicates that it is the active subwindow. Now double click on the curve in the host window, outside the subwindow border. Change the color of the trace `jack` to blue and notice that the subwindow is no longer active. Now move the mouse over the subwindow and notice that the cursor changes to the usual shapes corresponding to the parts of the graph that it is hovering over. Drag out a selection rectangle in the plot area of the subwindow and notice that the marquee pop-up menu is available for use on the subwindow and that the subwindow has been activated. Depending on your actions in a window, Igor activates subwindows as appropriate and generally you do not have to be aware of which subwindow is active.

Choose Show Tools from the Graph menu and notice that the tools are provided by the main window. Tools and the cursor information panel are hosted by the base window but apply to the active subwindow, if any.



Click the drawing icon in the tool palette.

Notice the subwindow, which had been indicated as active using the green and blue border, now has a heavy frame.

You are now in a mode where you can use drawing tools on the subwindow. To draw in the main window, click outside the subwindow to make the host window active.

When in operate mode, the main menu bar includes a menu (e.g., Graph) appropriate for the base window. If a subwindow is of the same type as the base window, you can target it by clicking it to make it the active subwindow and using the same main menu bar menu.

To make changes to a subwindow of a different type, you can use a context click to access a menu appropriate for the subwindow.

In drawing mode, the main menu includes a menu appropriate for the active subwindow. For example, if the base window is a graph with an table subwindow, the menu bar shows the Graph menu when in operate mode. When the table subwindow is selected in drawing mode, the main menu bar shows the Table menu.

In drawing mode, you can right-click (*Windows*) or Control-click (*Macintosh*) to get a pop-up menu from which you can choose frame styles and insert new subwindows or delete the active subwindow. Deleting a subwindow is not undoable.

The info panel (see **Info Panel and Cursors** on page II-319) in a graph targets the active subgraph. You can not simultaneously view or move cursors in two different subgraphs.

Subwindow Layout Mode and Guides

To layout one or more subwindows in a host window, enter drawing mode, click the selector (arrow) tool and click in a subwindow. A heavy frame will be drawn with the name of the subwindow in the upper left. Now click on the frame to enter subwindow layout mode. In this mode, the subwindow is drawn with a light frame with handles in the middle of each side. In addition, built-in and user guides are drawn as dashed red and green lines.

In subwindow layout mode, you can move a subwindow dragging its frame and resize it using the handles. If you drag a handle close to a guide, it will snap in place and attach itself to the guide. However, if one or more handles are attached to guides and you drag the subwindow using the frame, all attachments are deleted.

A graph subwindow is drawn using two frames. The inner frame represents the plot area of the graph. Its handles can be attached to guides to allow easy alignment of multiple graph subwindows.

You can create user-defined guides by pressing Alt (*Windows*) or Option (*Macintosh*) and then click-dragging an existing guide. By default, the new guide will be a fixed distance from its parent.

You can convert the new guide to relative mode, where the guide position is specified as a fraction of the distance between two other guides. You do this by right-clicking (*Windows*) or Control-click (*Macintosh*) on the new guide to display a contextual menu and then choosing a partner guide from the "make relative to" submenu.

You can also use the contextual menu to convert a relative guide to fixed or to delete a guide, if it is not in use.

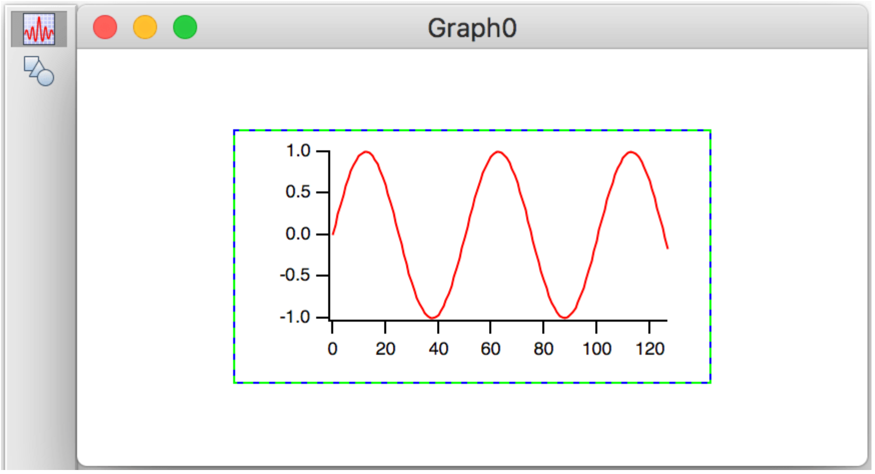
The contextual menu appears only for user-defined guides, not for built-in guides.

Layout Mode and Guide Tutorial

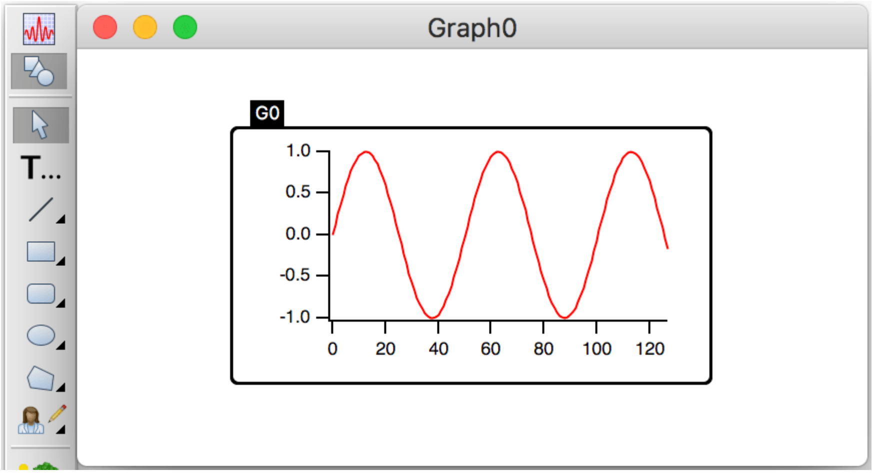
In a new experiment, execute these commands:

```
Make/O jack=sin(x/8),sam=cos(x/8)
Display
Display/HOST=# jack
ShowTools/A
```

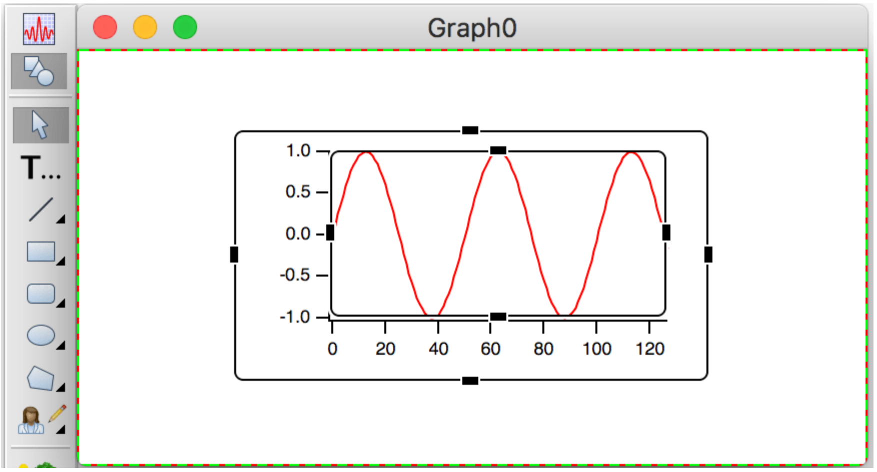
The first `Display` command created an empty graph and the second inserted a subgraph. The graph is in operate mode and it looks like this:



Click the lower icon in the tool palette to enter drawing mode and notice the subwindow is drawn with a black frame with the name of the subwindow (`G0`):

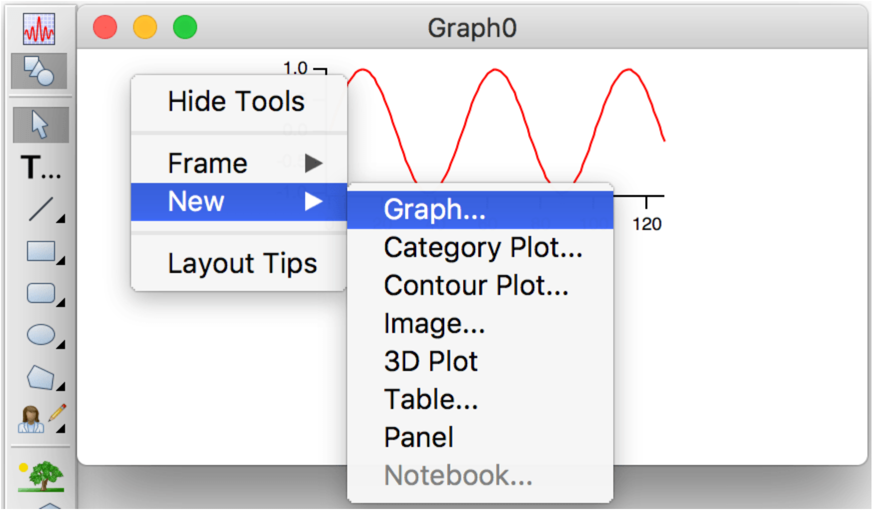


Use the arrow tool to click on the black frame around the subgraph. You are now in subwindow layout mode as indicated by the rectangles with handles on each edge of the subgraph.



Position the mouse over the outer rectangle until the cursor changes to a four-headed arrow. Drag the subwindow up as high as it will go and then drag the bottom handle up to just above the halfway point so that the subgraph is in the upper half of the window.

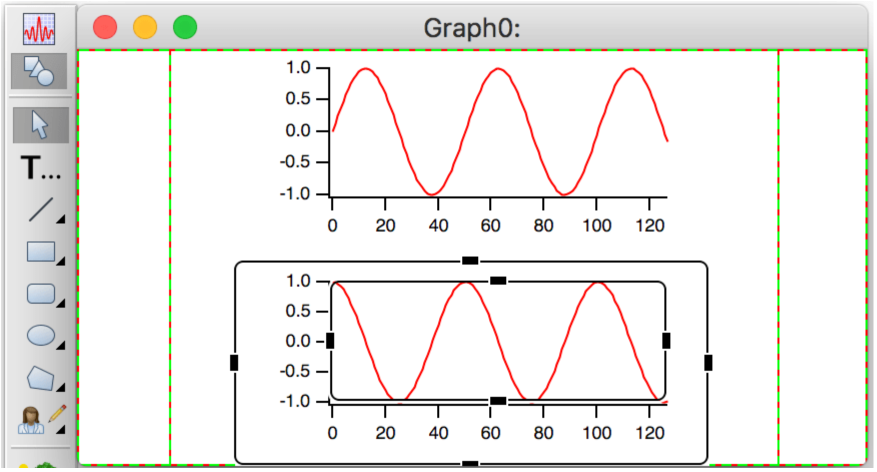
Click outside the subwindow to leave subwindow layout mode and then click again to select the main (empty) graph as the active subwindow. Right-click (*Windows*) or Control-click (*Macintosh*) below the subgraph and choose the New→Graph from the pop-up menu:



Pick sam as the Y wave in the resulting dialog and click Do It. This creates a new subwindow and makes it active. Click on the heavy frame to enter subwindow layout mode for the new subgraph and position it in the lower half of the window.

While still in subwindow layout mode for the second graph, notice the red and green dashed lines around the periphery. These are fixed guides and are properties of the base window. Press Alt (*Windows*) or Option (*Macintosh*) and move the mouse over the left hand dashed line. When you notice the cursor changing to a two headed arrow, click and drag to the right about 3 cm to create a user-defined guide.

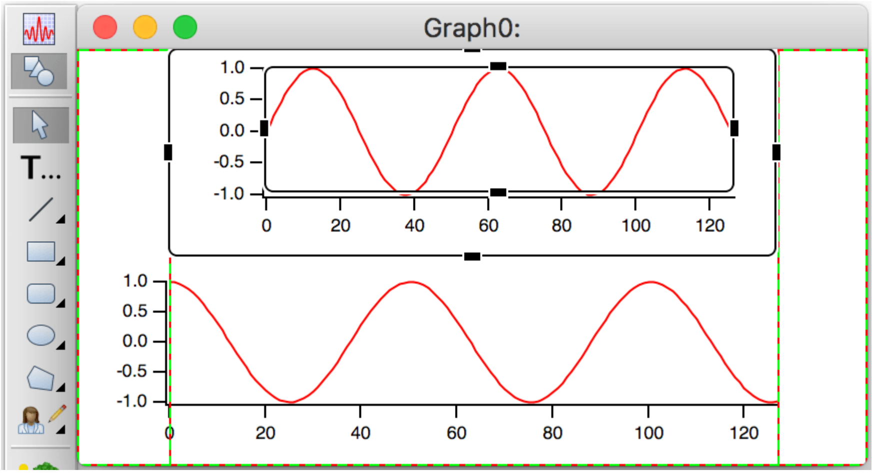
Use the same technique to create another user-defined guide based on the right edge also inset by about 3 cm:



Move the mouse over the new guides and notice the cursor changes to a two headed arrow indicating they can be moved.

While still in subwindow layout mode for the second graph, click in the black handle centered on the left axis and drag the handle over the position of the left user guide. Notice that it snaps into place when it is near the guide. Release the mouse button and use the same technique to connect the right edge of the plot area to the right user guide.

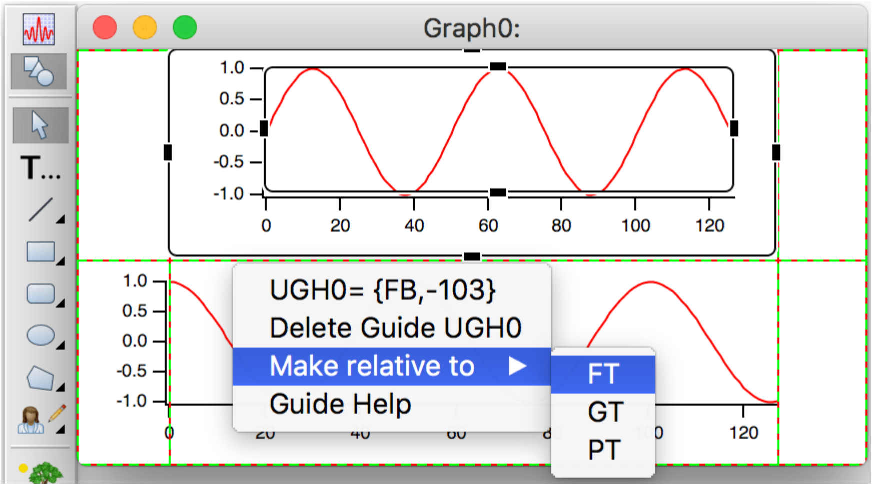
Now place the top subgraph in subwindow layout mode and connect its left and right plot area handles to the user guides:



While still in subwindow layout mode, drag the user guides around and notice that both graphs follow.

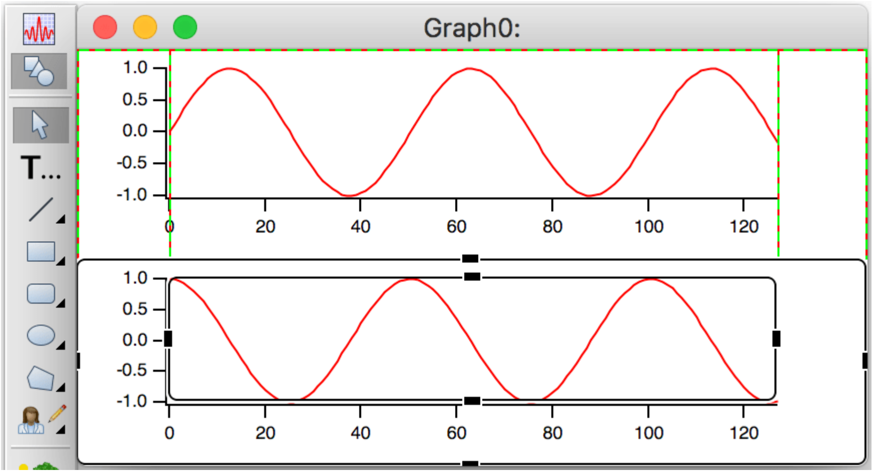
The two guides we created are a fixed distance from another guide (the frame left (FL) and frame right (FR) in this case). We will now create a relative guide.

Press Alt (*Windows*) or Option (*Macintosh*) and move the mouse over the bottom dashed line near the window frame. When you notice the cursor changing to a two headed arrow, click and drag up to about the middle of the graph to create another user-defined guide. Position the mouse over the new guide, right-click (*Windows*) or Control-click (*Macintosh*), and choose Make Relative to→FT from the pop-up menu.



Now, as you resize the window, the guide remains at the same relative distance between the bottom (FB) and the top (FT).

Use the handles to attach the bottom of the top graph to the new guide and then put the bottom graph into subwindow layout mode and attach its top to the guide:



Graph Control Bars and Subpanels

A control bar is a control panel subwindow attached to an edge of a graph.

You can drag out control bar areas from all four sides of a graph window.You do this by entering drawing mode, clicking just inside an outer edge of the window, and dragging toward the center of the window. This creates a subpanel and anchors it to appropriate guides.

Page Layouts and Subwindows

Subwindows in page layouts windows can be a bit confusing because you use two different modes to position conventional graph and table objects versus subwindows. In the normal mode for a page layout (top icon in the tool palette), you can adjust the positioning of conventional layout objects but not subwindows because they are in operate mode.

In operate mode, subwindow graphs act just like conventional graph windows and allow marquee expansion, double clicking on graph elements to bring up dialogs, dragging textboxes and axes and other normal graph behavior. But to adjust the position of subwindows, you have to enter subwindow layout (see **Subwindow Layout Mode and Guides** on page III-85).

Although a bit confusing, the use of subwindows in page layouts is very useful because the page layout is then self-contained and need not refer to other windows.

Here are a few reasons to use the conventional window or object layout method rather than subwindows:

- You can use cursors and buttons in a full graph but not in a subgraph.
- You can place the same graph in multiple layouts.
- You can have a graph window be a different, and more convenient, size than the layout object.

In a page layout, you can insert a graph subwindow or table by first using the marquee tool to specify the desired location and then using the pop-up menu available in the interior of the marquee to choose one of several subwindow types. If you need to reposition the new subwindow, you will need to enter drawing mode and use the selector (arrow) tool of the drawing tool palette, not the layout arrow tool.

You can convert conventional layout graph and table objects to subwindows via the contextual menu for the object. In operate mode (select the top icon in the layout tool palette), Control-click or right-click anywhere on the layout object and choose Convert Graph/Table To Embedded. Portions of a graph that are not allowed in layouts, such as buttons and subpanels, are lost in the conversion.

You can convert a subgraph or subtable to a conventional window and layout object via the contextual menu. In operate mode, Control-click or right-click and choose Convert To Graph/Table and Object. In a graph you must click in an area free of traces or axes, such as in the graph margin, to get the correct popup menu.

Notebooks as Subwindows in Control Panels

You can create a notebook subwindow in a control panel using the NewNotebook operation. A notebook subwindow might be used to present status information to the user or to permit the user to enter multi-line text. Here is an example:

```
NewPanel /W=(150,50,654,684)
NewNotebook /F=1 /N=nb0 /HOST=# /W=(36,36,393,306)
Notebook # text="Hello World!\r"
```

The notebook subwindow can be plain text (/F=0) or formatted text (/F=1).

By default, the notebook ruler is hidden when a notebook subwindow is created. You can change this using the Notebook operation.

The status bar is never shown in a notebook subwindow and there is no way to show it.

To make it easier to use for text input or display, when a formatted text notebook subwindow is first created, and when you resize the width of the subwindow, Igor automatically adjusts the Normal ruler's right indent so that all of the text governed by the Normal ruler fits in the subwindow. This adjustment is done for the Normal ruler only. Other rulers, including Normal+ (variations of Normal) rulers, are not adjusted.

You can programmatically insert text in the notebook using the **Notebook** operation.

If you create a window recreation macro for the control panel, by default the contents of the notebook subwindow are saved in the recreation macro. If you later run the macro to recreate the control panel, the notebook subwindow's contents are restored. This also applies to experiment recreation which automatically uses window recreation macros.

If you do not want the contents of the notebook subwindow to be preserved in the recreation macro, you must disable the autosave property, like this:

```
Notebook Panel0#nb0, autosave=0
```

When you create a window recreation macro while autosave is on, it will contain commands that look something like this:

```
Notebook kwTopWin, zdata="GaqDU%ejN7!Z)ts!+J\\.F^>EB"
Notebook kwTopWin, zdata= "jmRiCVsF?/]21,HG<k,\"@i1,&\\.F^>EB"
Notebook kwTopWin, zdataEnd=1
```

The Notebook zdata command sends to the notebook encoded binary data in an Igor-private format that represents the contents of the notebook when the recreation macro was created. In real life, there would be a number of zdata commands, one after the other, which cumulatively define the contents of the notebook. The notebook accumulates all of the zdata text. The zdataEnd command causes the notebook to decode the binary data and use it to restore the notebook's contents.

When you save an experiment containing a control panel, a window recreation macro is created for you by Igor. When you open the experiment, Igor runs the recreation macro to recreate the control panel. If autosave is off, after saving and reopening the experiment, the notebook will be empty. If autosave is on, the window recreation macro will include zdata and zdataEnd commands that restore the contents of the notebook subwindow.

The encoded binary data includes a checksum. If the Notebook zdata commands have been altered, the checksum will fail and you will receive an error when the Notebook zdataEnd command executes.

For a demonstration of notebook subwindows, choose File→Example Experiments→Feature Demos2→Notebook in Panel.

Subwindow Command Concepts

All operations that create window types that can be subwindows can take a `/HOST=`*hcSpec* flag in order to create a subwindow in a specific host. In addition, operations and functions that can modify or operate on a subwindow can affect a specific subwindow using the `/W=`*hcSpec* flag, for operations, or an *hcSpec* as a string parameter, for functions.

Subwindow Syntax

This table summarizes the command line syntax for identifying a subwindow:

Subwindow Specification	Location
baseName	Base host window
baseName#*sub1*	Absolute path from base host window
#*sub1*	Relative path from the active window or subwindow
#	Active window or subwindow
##	Host of active subwindow

The window path uses the # symbol as a separator between a window name and the name of a subwindow. If you have a panel subwindow named P0 inside a graph subwindow named G0 inside a panel named Panel0, the absolute path to the panel subwindow would be `Panel0#G0#P0`. The relative path from the main panel to the panel subwindow would be `#G0#P0`.

Subwindow Syntax for Page Layouts

For page layout windows, the standard syntax described above applies to subwindows in the currently active page only. To access a subwindow in any page, whether that page is the active page or not, use a page number in square brackets:

Subwindow Specification	Location
LayoutName	Base host window, active page
LayoutName[page]	Base host window, specified page
LayoutName#*sub1*	Absolute path on active page
LayoutName[page]#*sub1*	Absolute path on specified page

Page layout page numbers start at page 1.

This example embeds a graph in page 2 of the layout regardless of what the active page is:

```
NewLayout
LayoutPageAction appendPage         // Create page 2
LayoutPageAction page=1             // Page 1 is now the current page
Make/O wave0 = sin(x/8)
Display/HOST=Layout0[2] wave0       // Add a graph subwindow to page 2
ModifyGraph/W=Layout0[2]#G0 mode=3  // Set markers mode in graph subwindow
```

Subwindow Sizing

When `/HOST` is used in conjunction with **Display**, **NewPanel**, **NewWaterfall**, **NewImage**, **NewGizmo** and **Edit** commands to create a subwindow, the values used with the window size `/W=(`*a*`,`*b*`,`*c*`,`*d*`)` flag can have one of two different meanings. If all the values are less than 1.0, then the values are taken to be fractional relative to the host's frame. If any of the values are greater than 1.0, then they are taken to be fixed locations measured in points relative to the top left corner of the host.

Guides may override the numeric positioning set by `/W`. All operations supporting `/HOST` take the `/FG=(`*`gleft`*`,`*`gtop`*`,`*`gright`*`,`*`gbottom`*`)` flag where the parameters are the names of built-in or user-defined guides. FG stands for frame guide and this flag specifies that the outer frame of the subwindow is attached to the guides. A `*` character in place of a name indicates that the default value should be used.

The inner plot area of a graph subwindow may be attached to guides using the analogous PG flag. Thus a subgraph may need up to three specifications. For example:

```
Display /HOST=# /W=(0,10,400,200) /FG=(FL,*,FR,*) /PG=(PL,*,PR,*)
```

When the subwindow position is fully specified using guides, the /W flag is not needed but it is OK to include it anyway.

Subwindow Operations and Functions

Here are the main operations and functions that are useful in dealing with subwindows:

ChildWindowList(*hostName*)

DefineGuide [/W= *winName*] *newGuideName* = {[*guideName1*, *val*
[, *guideName2*]]} [,…]

KillWindow *winNameStr*

MoveSubwindow [/W=*winName*] *key* = (*values*)[, *key* = (*values*)]…

RenameWindow *oldName*, *newName*

SetActiveSubwindow *subWinName*

Chapter

III-5

Exporting Graphics (Macintosh)

Overview

This chapter discusses exporting graphics from Igor graphs, page layouts, tables, and Gizmo plots to another program on Macintosh. You can export graphics through the clipboard by choosing Edit→Export Graphics, or through a file, by choosing File→Save Graphics.

Igor Pro supports a number of different graphics export formats. You can usually obtain very good results by choosing the appropriate format, which depends on the nature of your graphics and the characteristics of the program to which you are exporting.

Unfortunately, experimentation is sometimes required to find the best export format for your particular circumstances. This section provides the information you need to make an informed choice.

This table shows the available graphic export formats on Macintosh:

Export Format	Export Method	Notes
Quartz PDF	Clipboard, file	Platform-independent and high quality, generated via the operating system.
LowRes PDF	Clipboard, file	Obsolete. Use Quartz PDF or Igor PDF instead.
Igor PDF	Clipboard, file	Platform-independent and high quality. Igor PDF with CMYK color does not support transparency.
EPS (Encapsulated Postscript)	File only	Platform-independent. Supports high resolution. EPS does not support transparency. Useful only when exporting to PostScript-savvy program (e.g., Adobe Illustrator, Tex).
PNG (Portable Network Graphics)	Clipboard, file	Platform-independent bitmap format. Uses lossless compression. Supports high resolution.
JPEG	Clipboard, file	Platform-independent bitmap format. Uses lossy compression. Supports high resolution. PNG is a better choice for scientific graphics.
TIFF	Clipboard, file	Platform-independent bitmap format. Supports high resolution but not compression.
SVG	Clipboard, file	Platform-independent vector graphics format. As of this writing, few Macintosh programs support SVG.

PDF Format

PDF (Portable Document Format) is Adobe's platform-independent vector graphics format that has been adopted by Apple as the standard graphics format for OS X. This is the best format as long as your destination program supports it.

The Quartz PDF format is generated by the operating system while the Igor PDF format uses the Qt application framework. For most graphics they produce similar output, but if you have an issue, it is worth trying both formats to see which is better. If you request CMYK color with the Igor PDF format, older Igor code that does not support transparency is used.

Blurry Images in PDF

When Igor exports an image plot, it exports the image as a single image object when possible. However, some PDF viewers, most notably Apple's, take it upon themselves to blur the pixels. To get around this, you can tell Igor to draw image pixels as individual rectangles using the **ModifyImage** interpolate keyword with a value of -1. You should do this only when necessary as the resulting PDF will be much larger.

Encapsulated PostScript (EPS) Format

Encapsulated PostScript was a widely-used, platform-independent vector graphics format consisting of PostScript commands in plain text form. It usually gives the best quality, but it works only when printed to a PostScript printer or exported to a PostScript-savvy program such as Adobe Illustrator. You should use only PostScript fonts (e.g., Helvetica).

Encapsulated PostScript was a widely-used platform-independent vector graphics format consisting of PostScript commands in plain text form. EPS is largely obsolete but still in use. It usually gives good quality, but it works only when printed to a PostScript printer or exported to a PostScript-savvy program such as Adobe Illustrator. You should use only PostScript fonts such as Helvetica. EPS does not support transparency.

Prior to Igor Pro 7, Igor embedded a screen preview in EPS files. This is no longer done because the preview was not cross-platform and caused problems with many programs.

EPS files normally use the RGB encoding to represent color but you can also use CMYK. See **Exporting Colors** on page III-99 for details.

Igor Pro exports EPS files using PostScript language level 2. This allows much better fill patterns when printing and also allows Adobe Illustrator to properly import Igor's fill patterns. For backwards compatibility with old printers, you can force Igor to use level 1 by specifying /PLL=1 with the SavePICT operation.

If the graph or page layout that you are exporting as EPS contains a non-EPS picture imported from another program, Igor exports the picture as an image incorporated in the output EPS file.

Igor can embed TrueType fonts as outlines. See **Font Embedding** on page III-99 and **Symbols with EPS and Igor PDF** on page III-493 for details.

SVG Format

SVG (Scalable Vector Graphics) is an XML-based platform-independent 2D vector and raster graphics format developed by the World Wide Web Consortium. It is often used for displaying graphics in web pages and is a good choice for other uses if the destination program supports it. However, as of this writing, few Macintosh programs support SVG. Safari supports it but you can not import an SVG file or paste an SVG graphic into Preview.

Platform-Independent Bitmap Formats

PNG (Portable Network Graphics) is a platform-independent bitmap format that uses lossless compression and supports high resolution. It is a superior alternative to JPEG or GIF. Although Igor can export and import PNG images via files and via the clipboard, some programs that allow you to insert PNG files do not allow you to paste PNG images from the clipboard.

JPEG is a lossy image format whose main virtue is that it is accepted by all web browsers. However all modern web browsers support PNG so there is little reason to use JPEG for scientific graphics. Although Igor can export and import JPEG via the clipboard, not all programs can paste JPEGs.

TIFF is an Adobe format often used for digital photographs. Igor's implementation of TIFF export does not use compression. TIFF files normally use the RGB scheme to specify color but you can also use CMYK. See **Exporting Colors** on page III-99 for details. There is no particular reason to use TIFF over PNG unless you are exporting to a program that does not support PNG. Igor can export and import TIFF via files and via the clipboard and most graphics programs can import TIFF.

Choosing a Graphics Format

Because of the wide variety of types of graphics, destination programs, printer capabilities, operating system behaviors and user-priorities, it is not possible to give definitive guidance on choosing an export format. But here is an approach that will work in most situations.

If the destination program accepts PDF or SVG, then they are probably your best choice because of their high-quality vector graphics and platform-independence.

Encapsulated PostScript (EPS) is also a very high quality format which works well if the destination program supports it but it does not support transparency.

If SVG, PDF and EPS are not appropriate, your next choice would be a high-resolution bitmap. The PNG format is preferred because it is platform-independent and is compressed.

Exporting Graphics Via the Clipboard

To export a graphic from the active window via the clipboard, choose Edit→Export Graphics. This displays the Export Graphics dialog.

When you click the OK button, Igor copies the graphics for the active window to the clipboard. You can then switch to another program and do a paste.

When a graph, page layout, or Gizmo plot is active and in operate mode, choosing Edit→Copy copies to the clipboard whatever format was last used in the Export Graphics dialog. For a table, Edit→Copy copies the selected numbers to the clipboard and does not copy graphics.

When a page layout has an object selected or when the marquee is active, choosing Edit→Copy copies an Igor object in a format used internally by Igor along with a PDF and does not use the format from the Export Graphics dialog

Although Igor can export a number of different formats, not all programs can recognize them on the clipboard. You may need to export via a file.

Igor can export PNG images to the clipboard and can then paste them back in. On the Macintosh, the clipboard type is `'PNGf'` but because there is no standard for PNG on the clipboard it is therefore unlikely that other programs can import them except as files.

Exporting Graphics Via a File

To export a graphic from the active window via a file, choose File→Save Graphics. This displays the Save Graphics File dialog.

The controls in the Format area of the dialog change to reflect options appropriate to each export format.

When you click the Do It button, Igor writes the graphic to a file. You can then switch to another program and import the file.

If you select _Use Dialog_ from the Path pop-up menu, Igor presents a Save File dialog in which you can specify the name and location of the saved file.

Exporting a Graphic File for Transfer to a Windows Computer

The best method for transferring Igor graphics to a Windows computer is to transfer the entire Igor experiment file, open it in Igor for Windows, and export the graphic via one of the Windows-compatible methods available in Igor for Windows.

Prior to Igor Pro 9, PDF pictures were not displayed by Igor on Windows. They are nowrendered as high-resolution bitmaps.

Exporting a Section of a Layout

To export a section of a page layout, use the marquee tool to identify the section and then choose Edit→Export Graphics or File→Save Graphics.

If you don’t use the marquee and the Crop to Page Contents checkbox is checked, Igor exports the area of the layout that is in use plus a small margin. If it is unchecked, Igor exports the entire page.

Exporting Colors

The PDF, EPS and TIFF graphics formats normally use the RGB scheme to specify color. Some publications require the use of CMYK instead of RGB, although the best results are obtained if the publisher does the RGB to CMYK conversion using the actual characteristics of the output device. For those publications that insist on CMYK, you can use the SavePICT /C=2 flag

Font Embedding

This section is largely obsolete. It applies only to EPS files and PDF files generated for CMYK colors. Even then you need this information only in unusual circumstances.

You can embed TrueType fonts in EPS files and in PDF files. This means you can print EPS or PDF files on systems lacking the equivalent PostScript fonts. This also helps for publications that require embedded fonts.

Font embedding is done automatically for the Quartz PDF format and you do not need to bother with this section unless you are using EPS or Igor PDF formats.

Font embedding is always on and the only option is to not embed standard fonts. For most purposes, embedding only non-standard fonts is the best choice.

Igor embeds TrueType fonts as synthetic PostScript Type 3 fonts derived from the TrueType font outlines. Only the actual characters used are included in the fonts.

Not all fonts and font styles on your system can be embedded. Some fonts may not allow embedding and others may not be TrueType or may give errors. Be sure to test your EPS files on a local printer or by importing into Adobe Illustrator before sending them to your publisher. You can test your PDF files with Adobe Reader. You can also use the “TrueType Outlines.pxp” example experiment to validate fonts for embedding. Choose Files→Example Experiments→Feature Demos 2→TrueType Outlines.

For EPS, Igor determines if a font is non-standard by attempting to look up the font name in a table described in **PostScript Font Names (OS X)** on page III-100 after doing any font substitution using that table. In addition, if a nonplain font style name is the same as the plain font name, then embedding is done. This means that standard PostScript fonts that do not come in italic versions (such as Symbol), will be embedded for the italic case but not for the plain case.

For PDF, non-standard fonts are those other than the basic fonts guaranteed by the PDF specification to be built-in to any PDF reader. Those fonts are Helvetica and Times in plain, bold, italic and bold-italic forms as well as Symbol and Zapf Dingbats only in plain style. If embedding is not used or if a font can not be embedded, fonts other than those just listed will be rendered as Helvetica and will not give the desired results.

PostScript Font Names (OS X)

When generating PostScript, Igor needs to generate proper PostScript font names. This presents problems under Macintosh OS X. Igor also needs to be able to substitute PostScript fonts for non-PostScript fonts. Here is a list of font names that are translated into the standards:

TrueType Name	PostScript Name
Helvetica	Helvetica
Arial	Helvetica
Helvetica-Narrow	Helvetica-Narrow
Arial Narrow	Helvetica-Narrow
Palatino	Palatino
Book Antiqua	Palatino
Bookman	Bookman
Bookman Old Style	Bookman
Avant Garde	AvantGarde
Century Gothic	AvantGarde
New Century Schlbk	NewCenturySchlbk
Century Schoolbook	NewCenturySchlbk
Courier	Courier
Courier New	Courier
Zapf Chancery	ZapfChancery
Monotype Corsiva	ZapfChancery
Zapf Dingbats	ZapfDingbats
Monotype Sorts	ZapfDingbats
Symbol	Symbol
Times	Times
Times New Roman	Times

Chapter

III-6

Exporting Graphics (Windows)

Overview

This chapter discusses exporting graphics from Igor graphs, page layouts, tables, and Gizmo plots to another program on Windows. You can export graphics through the clipboard by choosing Edit→Export Graphics, or through a file, by choosing File→Save Graphics.

Igor Pro supports a number of different graphics export formats. You can usually obtain very good results by choosing the appropriate format, which depends on the nature of your graphics, your printer and the characteristics of the program to which you are exporting.

Unfortunately, experimentation is sometimes required to find the best export format for your particular circumstances. This section provides the information you need to make an informed choice.

This table shows the available graphic export formats on Windows:

Export Format	Export Method	Notes
EMF (Enhanced Metafile)	Clipboard, file	Windows-specific vector format.
BMP (Bitmap)	Clipboard, file	Windows-specific bitmap format. Does not use compression.
Igor PDF	Clipboard, file	Platform-independent and high quality. Igor PDF with CMYK color does not support transparency.
EPS (Encapsulated Postscript)	File only	Platform-independent except for the screen preview. Supports high resolution. EPS does not support transparency. Useful only when exporting to PostScript-savvy program (e.g., Adobe Illustrator, Tex).
PNG (Portable Network Graphics)	Clipboard, file	Platform-independent bitmap format. Uses lossless compression. Supports high resolution.
JPEG	Clipboard, file	Platform-independent bitmap format. Uses lossy compression. Supports high resolution. PNG is a better choice for scientific graphics.
TIFF	Clipboard, file	Platform-independent bitmap format. Supports high resolution but not compression.
SVG	Clipboard, file	Platform-independent vector graphics format. A good choice if the destination program supports SVG. As of this writing, few Windows programs support SVG.

Metafile Formats

The metafile formats are Windows vector graphics formats that support drawing commands for the individual objects such as lines, rectangles and text that make up a picture. Drawing programs can decompose a metafile into its component parts to allow editing the individual objects. Most word processing programs treat a metafile as a black box and call the operating system to display or print it.

Enhanced Metafile (EMF) is the primary Windows-native graphics format. It comes in two flavors: the older EMF and a newer EMF+. Igor “dual EMF” by default. A dual EMF contains both a plain EMF and an EMF+; applications that don’t support EMF+ will use the plain EMF component. EMF+ is needed if transparency (colors with an alpha channel) is used. You can export using the older EMF format if the destination program does not work well with EMF+ - see **Graphics Technology** on page III-506 for details.

EMF is easy to use because nearly all Windows programs can import it and because it can be copied to the clipboard as well as written to a file. Some programs, notably some older versions of Microsoft Office, require that you choose Paste Special rather than Paste to paste an EMF from the clipboard.

Although drawing programs can decompose an EMF into its component parts to allow editing the individual objects, they often get it wrong due to the complexity of the metafile format. Some applications that decompose an EMF correctly are confused by the dual EMF. For such programs, you need to export a plain EMF by setting the graphics technology to GDI.

BMP Format

BMP is a Windows bitmap format. It is accepted by a wide variety of programs but requires a lot of memory and disk space because it is not compressed. A BMP is also known as a DIB (device-independent bitmap).

If the program to which you are exporting supports PNG then PNG is a better choice.

PDF Format

PDF (Portable Document Format) is Adobe's platform-independent vector graphics format. This is the best format as long as your destination program supports it. It is more widely supported on Macintosh than on Windows.

The Igor PDF format is generated by Igor's own code rather than by the OS. As of Igor Pro 9, Igor PDF supports transparency and does a better job of font embedding. However, if you request CMYK color, the older code is used.

When Igor exports graphics as PDF on Windows, any pictures, including PDF pictures, imported into Igor are exported as bitmap images.

Blurry Images in PDF

When Igor exports an image plot, it exports the image as a single image object when possible. However, some PDF viewers, most notably Apple's, take it upon themselves to blur the pixels. To get around this, you can tell Igor to draw image pixels as individual rectangles using the **ModifyImage** interpolate keyword with a value of -1. You should do this only when necessary as the resulting PDF will be much larger.

Encapsulated PostScript (EPS) Format

Encapsulated PostScript was a widely-used, platform-independent vector graphics format consisting of PostScript commands in plain text form. It usually gives the best quality, but it works only when printed to a PostScript printer or exported to a PostScript-savvy program such as Adobe Illustrator. You should use only PostScript fonts (e.g., Helvetica).

Encapsulated PostScript was a widely-used platform-independent vector graphics format consisting of PostScript commands in plain text form. EPS is largely obsolete but still in use. It usually gives good quality, but it works only when printed to a PostScript printer or exported to a PostScript-savvy program such as Adobe Illustrator. You should use only PostScript fonts such as Helvetica. EPS does not support transparency.

Prior to Igor Pro 7, Igor embedded a screen preview in EPS files. This is no longer done because the preview was not cross-platform and caused problems with many programs.

EPS files normally use the RGB encoding to represent color but you can also use CMYK. See **Exporting Colors** on page III-105 for details.

Igor Pro exports EPS files using PostScript language level 2. This allows much better fill patterns when printing and also allows Adobe Illustrator to properly import Igor’s fill patterns. For backwards compatibility with old printers, you can force Igor to use level 1 by specifying /PLL=1 with the SavePICT operation.

If the graph or page layout that you are exporting as EPS contains a non-EPS picture imported from another program, Igor exports the picture as an image incorporated in the output EPS file.

Igor can embed TrueType fonts as outlines. See **Font Embedding** on page III-105 and **Symbols with EPS and Igor PDF** on page III-493 for details.

SVG Format

SVG (Scalable Vector Graphics) is an XML-based platform-independent 2D vector and raster graphics format developed by the World Wide Web Consortium. It is often used for displaying graphics in web pages and is a good choice for other uses if the destination program supports it. As of this writing, Microsoft Office supports SVG but few other Windows programs support it.

Platform-Independent Bitmap Formats

PNG (Portable Network Graphics) is a platform-independent bitmap format. It uses lossless compression and supports high resolution. It is a superior alternative to JPEG or GIF. Although Igor can export and import PNG images via files and via the clipboard, some programs that allow you to insert PNG files do not allow you to paste PNG images from the clipboard.

JPEG is a lossy format whose main virtue is that it is accepted by all web browsers. However, all modern web browsers support PNG so there is little reason to use JPEG for scientific graphics. Although Igor can export and import JPEG via the clipboard, most Windows programs can not paste JPEGs, but Microsoft Office can.

TIFF is an Adobe format often used for digital photographs. Igor’s implementation of TIFF export does not use compression. TIFF files normally use the RGB scheme to specify color but you can also use CMYK. See **Exporting Colors** on page III-105 for details. There is no particular reason to use TIFF over PNG unless you are exporting to a program that does not support PNG. Igor can export and import TIFF via files and via the clipboard and most graphics programs can import TIFF.

Choosing a Graphics Format

Because of the wide variety of types of graphics, destination programs, printer capabilities, operating system behaviors and user-priorities, it is not possible to give definitive guidance on choosing an export format. But here is an approach that will work in most situations.

PNG is the recommended choice for exporting image plots and Gizmo plots which are inherently bitmaps.

For vector graphics, if the destination program accepts PDF or SVG, then they are probably your best choice because of their high-quality vector graphics and platform-independence.

Encapsulated PostScript (EPS) is also a very high quality format which works well if the destination program supports it, but it does not support transparency.

If PDF, SVG and EPS are not appropriate, your next choice for vector graphics would be a high-resolution bitmap. The PNG format is preferred because it is platform-independent and supports lossless compression.

Exporting Graphics Via the Clipboard

To export a graphic from the active window via the clipboard, choose Edit→Export Graphics. This displays the Export Graphics dialog.

When you click the OK button, Igor copies the graphics for the active window to the clipboard. You can then switch to another program and do a paste.

When a graph, page layout, or Gizmo plot is active and in operate mode, choosing Edit→Copy copies to the clipboard whatever format was last used in the Export Graphics dialog. For a table, Edit→Copy copies the selected numbers to the clipboard and does not copy graphics.

When a page layout has an object selected or when the marquee is active, choosing Edit→Copy copies an Igor object in a format used internally by Igor along with an enhanced metafile and does not use the format from the Export Graphics dialog.

Although Igor can export a number of different formats, not all programs can recognize them on the clipboard. You may need to export via a file.

Exporting Graphics Via a File

To export a graphic from the active window via a file, choose File→Save Graphics. This displays the Save Graphics File.

The controls in the Format area of the dialog change to reflect options appropriate to each export format.

When you click the Do It button, Igor writes a graphics file. You can then switch to another program and import the file.

If you select _Use Dialog_ from the Path pop-up menu, Igor presents a Save File dialog in which you can specify the name and location of the saved file.

Exporting a Section of a Layout

To export a section of a page layout, use the marquee tool to identify the section and then choose Edit→Export Graphics or File→Save Graphics.

If you don’t use the marquee and the Crop to Page Contents checkbox is checked, Igor exports the area of the layout that is in use plus a small margin. If it is unchecked, Igor exports the entire page.

Exporting Colors

The EPS and TIFF graphics formats normally use the RGB scheme to specify color. Some publications require the use of CMYK instead of RGB, although the best results are obtained if the publisher does the RGB to CMYK conversion using the actual characteristics of the output device. For those publications that insist on CMYK, you can use the SavePICT /C=2 flag.

Font Embedding

This section is largely obsolete. It applies only to EPS files and PDF files generated for CMYK colors. Even then you need this info only in unusual circumstances.

You can embed TrueType fonts in EPS files and in PDF Files. This means that you can print EPS or PDF files on systems lacking the equivalent PostScript fonts. This also helps with publications that require embedded fonts.

Font embedding is always on and the only option is to not embed standard fonts. For most purposes, embedding only non-standard fonts is the best choice.

Igor embeds TrueType fonts as synthetic PostScript Type 3 fonts derived from the TrueType font outlines. Only the actual characters used are included in the fonts.

Not all fonts and font styles on your system can be embedded. Some fonts may not allow embedding and others may not be TrueType or may give errors. Be sure to test your EPS files on a local printer or by importing into Adobe Illustrator before sending them to your publisher. You can also use the “TrueType Outlines.pxp” example experiment to validate fonts for embedding. You will find this experiment file in your Igor Pro Folder in the “Examples:Testing:” folder.

For EPS, Igor determines if a font is non-standard by attempting to look up the font name in a table described in **PostScript Font Names** on page III-106 after doing any font substitution using that table. In addition, if a nonplain font style name is the same as the plain font name, then embedding is done. This means that standard PostScript fonts that do not come in italic versions (such as Symbol), will be embedded for the italic case but not for the plain case.

For PDF, non-standard fonts are those other than the basic fonts guaranteed by the PDF specification to be built-in to any PDF reader. Those fonts are Helvetica and TImes in plain, bold, italic, and bold-italic styles as well as plain versions of Symbol and Zapf Dingbats. If embedding is not used or if a font can not be embedded, fonts other than those just listed will be rendered as Helvetica and will not give the desired results.

PostScript Font Names

When generating PostScript, Igor needs to generate proper PostScript font names. This presents problems under Windows. Igor also needs to be able to substitute PostScript fonts for non-PostScript fonts. Here is a list of font names that are translated into the standards:

TrueType Name	PostScript Name
Arial	Helvetica
Arial Narrow	Helvetica-Narrow
Book Antiqua	Palatino
Bookman Old Style	Bookman
Century Gothic	AvantGarde
Century Schoolbook	NewCenturySchlbk
Courier New	Courier
Monotype Corsiva	ZapfChancery
Monotype Sorts	ZapfDingbats
Symbol	Symbol
Times New Roman	Times

Chapter

III-7

Analysis

Overview

Igor Pro is a powerful data analysis environment. The power comes from a synergistic combination of

- An extensive set of basic built-in analysis operations
- A fast and flexible waveform arithmetic capability
- Immediate feedback from graphs and tables
- Extensibility through an interactive programming environment
- Extensibility through external code modules (XOPs and XFUNCs)

Analysis tasks in Igor range from simple experiments using no programming to extensive systems tailored for specific fields. Chapter I-2, **Guided Tour of Igor Pro**, shows examples of the former. WaveMetrics' "Peak Measurement" procedure package is an example of the latter.

This chapter presents some of the basic analysis operations and discusses the more common analyses that can be derived from the basic operations. The end of the chapter shows a number of examples of using Igor's programmability for "number crunching".

Discussion of Igor Pro's more specialized analytic capabilities is in chapters that follow.

See the WaveMetrics procedures, technical notes, and sample experiments that come with Igor Pro for more examples.

Analysis of Multidimensional Waves

Many of the analysis operations in Igor Pro operate on 1D (one-dimensional) data. However, Igor Pro includes the following capabilities for analysis of multidimensional data:

- Multidimensional waveform arithmetic
- Matrix math operations
- The MatrixOp operation
- Multidimensional Fast Fourier Transform
- 2D and 3D image processing operations
- 2D and 3D interpolation operations and functions

Some of these topics are discussed in Chapter II-6, **Multidimensional Waves** and in Chapter III-11, **Image Processing**. The present chapter focuses on analysis of 1D waves.

There are many analysis operations that are designed only for 1D data. Multidimensional waves do not appear in dialogs for these operations. If you invoke them on multidimensional waves from the command line or from an Igor procedure, Igor treats the multidimensional waves as if they were 1D. For example, the Histogram operation treats a 2D wave consisting of *n* rows and *m* columns as if it were a 1D wave with *n***m* rows. In some cases (e.g., WaveStats), the operation will be useful. In other cases, it will make no sense at all.

Waveform Versus XY Data

Igor is highly adapted for dealing with waveform data. In a waveform, data values are uniformly spaced in the X dimension. This is discussed under **Waveform Model of Data** on page II-62.

If your data is uniformly spaced, you can set the spacing using the SetScale operation. This is crucial because most of the built-in analysis operations and functions need to know this to work properly.

If your data is not uniformly spaced, you can represent it using an XY pair of waves. This is discussed under **XY Model of Data** on page II-63. Some of the analysis operations and functions in Igor can *not* handle XY pairs directly. To use these, you must either make a waveform representation of the XY pair or use Igor procedures that build on the built-in routines.

Converting XY Data to a Waveform

Sometimes the best way to analyze XY data is to make a uniformly-spaced waveform representation of it and analyze that instead. Most analysis operations are easier with waveform data. Other operations, such as the FFT, can be done *only* on waveform data. Often your XY data set is nearly uniformly-spaced so a waveform version of it is a very close approximation.

In fact, often XY data imported from other programs has an X wave that is completely unnecessary in Igor because the values in the X wave are actually a simple "series" (values that define a regular intervals, such as 2.2, 2.4, 2.6, 2.8, etc), in which case conversion to a waveform is a simple matter of assigning the correct X scaling to the Y data wave, using **SetScale** (or the Change Wave Scaling dialog):

```
SetScale/P x, xWave[0], xWave[1]-xWave[0], yWave
```

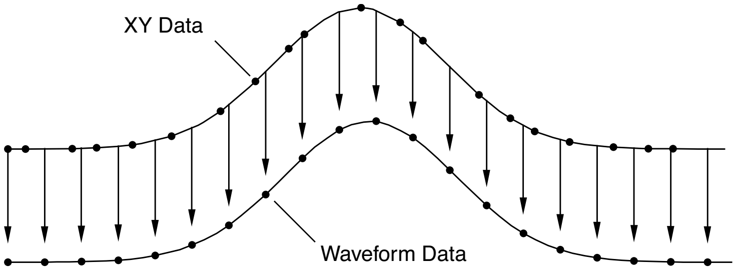
Now the X wave is superfluous and can be discarded:

```
KillWaves/Z xWave
```

The XY Pair to Waveform panel can be used to set the Y wave's X scaling when it detects that the X wave contains series data. See **Using the XY Pair to Waveform Panel** on page III-109.

If your X wave is not a series, then to create a waveform representation of XY data you need to use interpolation. To create a waveform representation of XY data you need to do interpolation. Interpolation creates a waveform from an XY pair by sampling the XY pair at uniform intervals.

The diagram below shows how the XY pair defining the upper curve is interpolated to compute the uniformly-spaced waveform defining the lower curve. Each arrow indicates an interpolated waveform value:



Igor provides three tools for doing this interpolation: The XY Pair to Waveform panel, the built-in **interp** function and the **Interpolate2** operation. To illustrate these tools we need some sample XY data. The following commands make sample data and display it in a graph:

```
Make/N=100 xData = .01*x + gnoise(.01)
Make/N=100 yData = 1.5 + 5*exp(-((xData-.5)/.1)^2)
Display yData vs xData
```

This creates a Gaussian shape. The x wave in our XY pair has some noise in it so the data is not uniformly spaced in the X dimension.

The x data goes roughly from 0 to 1.0 but, because our x data has some noise, it may not be monotonic. This means that, as we go from one point to the next, the x data usually increases but at some points may decrease. We can fix this by sorting the data.

```
Sort xData, xData, yData
```

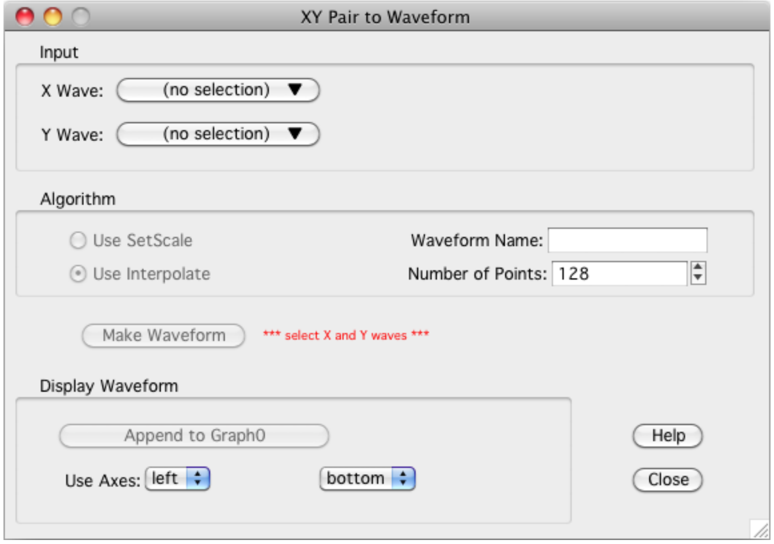
This command uses the xData wave as the sort key and sorts both xData and yData so that xData always increases as we go from one point to the next.

Using the XY Pair to Waveform Panel

The XY Pair to Waveform panel creates a waveform from XY data using the **SetScale** or Interpolate2 operations, based on an automatic analysis of the X wave's data.

The required steps are:

1. Select XY Pair to Waveform from Igor's Data→Packages submenu.
   The panel is displayed:



XY Pair to Waveform

Input

X Wave: (no selection)

Y Wave: (no selection)

Algorithm

○ Use SetScale

● Use Interpolate

Waveform Name:

Number of Points: 128

*** select X and Y waves ***

Display Waveform

Use Axes: left bottom

2. Select the X and Y waves (xData and yData) in the popup menus. When this example's xData wave is analyzed it is found to be "not regularly spaced (slope error avg= 0.52...)", which means that SetScale is not appropriate for converting yData into a waveform.
3. Use Interpolate is selected here, so you need a waveform name for the output. Enter any valid wave name.
4. Set the number of output points. Using a number roughly the same as the length of the input waves is a good first attempt. You can choose a larger number later if the fidelity to the original is insufficient. A good number depends on how uneven the X values are - use more points for more unevenness.
5. Click Make Waveform.
6. To compare the XY representation of the data with the waveform representation, append the waveform to a graph displaying the XY pair. Make that graph the top graph, then click the "Append to <Name of Graph>" button.
7. You can revise the Number of Points and click Make Waveform to overwrite the previously created waveform in-place.

Using the Interp Function

We can use the **interp** function (see page V-458) to create a waveform version of our Gaussian. The required steps are:

1. Make a new wave to contain the waveform representation.
2. Use the **SetScale** operation to define the range of X values in the waveform.
3. Use the interp function to set the data values of the waveform based on the XY data.

Here are the commands:

```
Duplicate yData, wData
SetScale/I x 0, 1, wData
wData = interp(x, xData, yData)
```

To compare the waveform representation to the XY representation, we append the waveform to the graph.

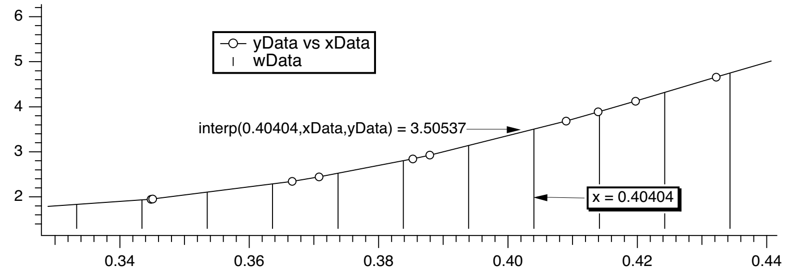
```
AppendToGraph wData
```

Let’s take a closer look at what these commands are doing.

First, we cloned yData and created a new wave, wData. Since we used Duplicate, wData will have the same number of points as yData. We could have made a waveform with a different number of points. To do this, we would use the Make operation instead of Duplicate.

The SetScale operation sets the X scaling of the wData waveform. In this example, we are setting the X values of wData to go from 0 up to and including 1.0. This means that our waveform representation will contain 100 values at uniform intervals in the X dimension from 0 to 1.0.

The last step uses a waveform assignment to set the data values of wData. This assignment evaluates the right-hand expression once for each point in wData. For each evaluation, x takes on a different value from 0 to 1.0. The interp function returns the value of the curve yData versus xData at x. For instance, x=.40404 (point number 40 of wData) falls between two points in the XY curve. The interp function linearly interpolates between those values to estimate a data value of 3.50537:



We can wrap these calculations up into an Igor procedure that can create a waveform version of any XY pair.

```
Function XYToWave1(xWave, yWave, wWaveName, numPoints)
   Wave/D xWave              // X wave in the XY pair
   Wave/D yWave              // Y wave in the XY pair
   String wWaveName          // Name to use for new waveform wave
   Variable numPoints        // Number of points for waveform

   Make/O/N=(numPoints) $wWaveName  // Make waveform.
   Wave wWave= $wWaveName
   WaveStats/Q xWave                // Find range of x coords
   SetScale/I x V_min, V_max, wWave // Set X scaling for wave
   wWave = interp(x, xWave, yWave)  // Do the interpolation
End
```

This function uses the **WaveStats** operation to find the X range of the XY pair. WaveStats creates the variables V_min and V_max (among others). See **Accessing Variables Used by Igor Operations** on page IV-123 for details.

The function makes the assumption that the input waves are already sorted. We left the sort step out because the sorting would be a side-effect and we prefer that procedures not have nonobvious side effects.

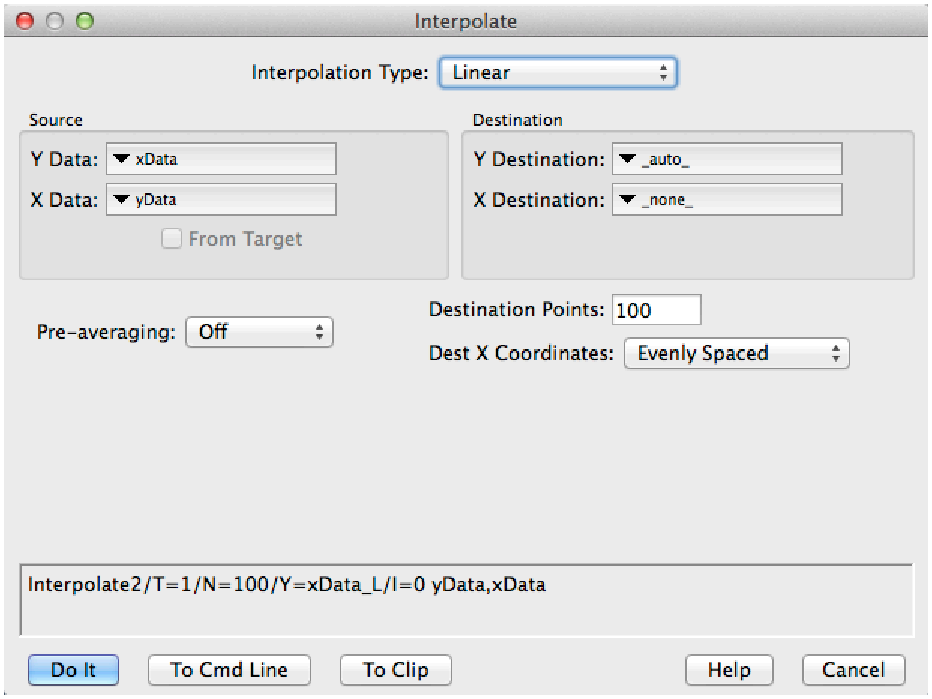
To use the WaveMetrics-supplied XYToWave1 function, include the “XY Pair To Waveform” procedure file. See **The Include Statement** on page IV-166 for instructions on including a procedure file.

If you have blanks (NaNs) in your input data, the interp function will give you blanks in your output waveform as well. The **Interpolate2** operation, discussed in the next section, interpolates across gaps in data and does not produce blanks in the output.

Using the Interpolate2 Operation

The **Interpolate2** operation provides not only linear but also cubic and smoothing spline interpolation. Furthermore, it does not require the input to be sorted and can automatically make the destination waveform and set its X scaling. It also has a dialog that makes it easy to use interactively.

To use it on our sample XY data, choose Analysis→Interpolate and set up the dialog as shown:



```
Interpolate2/T=1/N=100/Y=xData_L/I=0 yData,xData
```

Choosing "_auto_" for Y Destination auto-names the destination wave by appending "_L" to the name of the input "Y data" wave. Choosing "_none_" as the "X destination" creates a waveform from the input XY pair rather than a new XY pair.

Here is a rewrite of the XYToWave1 function that uses the Interpolate2 operation rather than the interp function.

```
Function XYToWave2(xWave, yWave, wWaveName, numPoints)
   Wave xWave                    // X wave in the XY pair
   Wave yWave                    // Y wave in the XY pair
   String wWaveName              // Name to use for new waveform wave
   Variable numPoints            // Number of points for waveform

   Interpolate2/T=1/N=(numPoints)/E=2/Y=$wWaveName xWave, yWave
End
```

Blanks in the input data are ignored.

For details on Interpolate2, see **The Interpolate2 Operation** on page III-115.

Dealing with Missing Values

A missing value is represented in Igor by the value NaN which means "Not a Number". A missing value is also called a "blank", because it appears as a blank cell in a table.

When a NaN is combined arithmetically with any value, the result is NaN. To see this, execute the command:

```
Print 3+NaN, NaN/5, sin(NaN)
```

By definition, a NaN is not equal to anything. Consequently, the condition in this statement:

```
if (myValue == NaN)
```

is always false.

The workaround is to use the **numtype** function:

```
if (NumType(myValue) == 2)          // Is it a NaN?
```

See also **NaNs, INFs and Missing Values** on page II-83 for more about how NaN values.

Some routines deal with missing values by ignoring them. The **CurveFit** operation (see page V-124) is one example. Others may produce unexpected results in the presence of missing values. Examples are the **FFT** operation and the **area** and **mean** functions.

Here are some strategies for dealing with missing values.

Replace the Missing Values With Another Value

You can replace NaNs in a wave with this statement:

```
wave0 = NumType(wave0)==2 ? 0:wave0    // Replace NaNs with zero
```

If you're not familiar with the :? operator, see **Operators** on page IV-6.

For multi-dimensional waves you can replace NaNs using **MatrixOp**. For example:

```
Make/O/N=(3,3) matNaNTest = p + 10*q
Edit matNaNTest
matNaNTest[0][0] = NaN; matNaNTest[1][1] = NaN; matNaNTest[2][2] = NaN
MatrixOp/O matNaNTest=ReplaceNaNs(matNaNTest,0)    // Replace NaNs with 0
```

Remove the Missing Values

For 1D waves you can remove NaNs using **WaveTransform** `zapNaNs`. For example:

```
Make/N=5 NaNTest = p
Edit NaNTest
NaNTest[1] = NaN; NaNTest[4] = NaN
WaveTransform zapNaNs, NaNTest
```

There is no built-in operation to remove NaNs from an XY pair if the NaN appears in either the X or Y wave. You can do this, however, using the RemoveNaNsXY procedure in the "Remove Points" WaveMetrics procedure file which you can access through Help→Windows→WM Procedures Index.

There is no operation to remove NaNs from multi-dimensional waves as this would require removing the entire row and entire column where each NaN appeared.

Work Around Gaps in Data

Many analysis routines can work on a subrange of data. In many cases you can just avoid the regions of data that contain missing values. In other cases you can extract a subset of your data, work with it and then perhaps put the modified data back into the original wave.

Here is an example of extract-modify-replace (even though Smooth properly accounts for NaNs):

```
Make/N=100 data1= sin(P/8)+gnoise(.05); data1[50]= NaN
Display data1
Duplicate/R=[0,49] data1,tmpdata1      // start work on first set
Smooth 5,tmpdata1
data1[0,49]= tmpdata1[P]               // put modified data back
Duplicate/O/R=[51,] data1,tmpdata1     // start work on 2nd set
Smooth 5,tmpdata1
data1[51,]= tmpdata1[P-51]
KillWaves tmpdata1
```

Replace Missing Data with Interpolated Values

You can replace NaN data values prior to performing operations that do not take kindly to NaNs by replacing them with smoothed or interpolated values using the **Smooth** operation (page V-878), the **Loess** operation (page V-515), or **The Interpolate2 Operation**.

Replace Missing Data Using the Interpolate2 Operation

By using the same number of points for the destination as you have source points, you can replace NaNs without modifying the other data.

If you have waveform data, simply duplicate your data and perform linear interpolation using the same number of points as your data. For example, assuming 100 data points:

```
Duplicate data1,data1a
Interpolate/T=1/N=100/Y=data1a data1
```

If you have XY data, the Interpolate2 operation has the ability to include the input x values in the output X wave. For example:

```
Duplicate data1, yData1, xData1
xData1 = x
Display yData1 vs xData1
Interpolate2/T=1/N=100/I/Y=yData1a/X=xData1a xData1,yData1
```

If, after performing an operation on your data, you wish to put the modified data back in the source wave while maintaining the original missing values you can use a wave assignment similar to this:

```
yData1 = (numtype(yData1) == 0) ? yData1 : yData1a
```

This technique can also be applied using interpolated results generated by the **Smooth** operation (page V-878) or the **Loess** operation (page V-515).

Replace Missing Data Using Median Smoothing

You can use the Smooth dialog to replace each NaN with the median of surrounding values.

Select the Median smoothing algorithm, select "NaNs" from the Replace popup, and choose "Median" for the "with:" radio button. Enter the number of surrounding points used to compute the median (an odd number is best).

You can choose to overwrite the NaNs or create a new waveform with the result. The Smooth dialog produces commands like this:

```
Duplicate/O data1,data1_smth;DelayUpdate
Smooth/M=(NaN) 5, data1_smth
```

Interpolation

Igor Pro has a number of interpolation tools that are designed for different applications. We summarize these in the table below.

Data	Operation/Function	Interpolation Method
1D waves	wave assignment, e.g., `val=wave(x)`	Linear
1D waves	**Smooth**	Running median, average, binomial, Savitsky-Golay
1D XY waves	**interp**()	Linear
1D single or XY waves	**The Interpolate2 Operation**	Linear, cubic spline, smoothing spline
1D or 2D single or XY	**Loess**	Locally-weighted regression
Triplet XYZ waves	**ImageInterpolate**	Voronoi
1D X, Y, Z waves	Data→Packages→XYZ to Matrix	Voronoi
1D X, Y, Z waves	**Loess**	Locally-weighted regression
2D waves	**ImageInterpolate**	Bilinear, splines, Kriging, Voronoi

Data	Operation/Function	Interpolation Method
2D waves	**Interp2D**()	Bilinear
2D waves (points on the surface of a sphere)	**SphericalInterpolate**	Voronoi
3D waves	**Interp3D**(), **Interp3DPath**, ImageTransform **extractSurface**	Trilinear
3D scatter data	**Interpolate3D**	Barycentric

All the interpolation methods in this table consist of two common steps. The first step involves the identification of data points that are nearest to the interpolation location and the second step is the computation of the interpolated value using the neighboring values and their relative proximity. You can find the specific details in the documentation of the individual operation or function.

The Interpolate2 Operation

The **Interpolate2** operation performs linear, cubic spline and smoothing cubic spline interpolation on 1D waveform and XY data. The cubic spline interpolation is based on a routine in "Numerical Recipes in C". The smoothing spline is based on "Smoothing by Spline Functions", Christian H. Reinsch, *Numerische Mathematic* 10, 177-183 (1967).

Prior to Igor7, Interpolate2 was implemented as part of the Interpolate XOP. It is now built-in.

The Interpolate XOP also implemented an older operation named Interpolate which used slightly different syntax. If you are using the Interpolate operation, we recommend that you convert to using Interpolate2.

The main use for linear interpolation is to convert an XY pair of waves into a single wave containing Y values at evenly spaced X values so that you can use Igor operations, like **FFT**, which require evenly spaced data.

Cubic spline interpolation is most useful for putting a pleasingly smooth curve through arbitrary XY data. The resulting curve may contain features that have nothing to do with the original data so you should be wary of using the cubic spline for analytic rather than esthetic purposes.

Both linear and cubic spline interpolation are constrained to put the output curve through all of the input points and thus work best with a small number of input points. The smoothing spline does not have this constraint and thus works well with large, noisy data sets.

The Interpolate2 operation has a feature called "pre-averaging" which can be used when you have a large number of input points. Pre-averaging was added to Interpolate2 as a way to put a cubic spline through a large, noisy data set before it supported the smoothing spline. We now recommend that you use the smoothing spline instead of pre-averaging.

The Smooth Curve Through Noise example experiment illustrates spline interpolation. Choose File→Example Experiments→Feature Demos→Smooth Curve Through Noise.

Spline Interpolation Example

Before going into a complete discussion of Interpolate2, let's look at a simple example first.

First, make some sample XY data using the following commands:

```
Make/N=10 xData, yData                          // Make source data
xData = p; yData = 3 + 4*xData + gnoise(2)      // Create sample data
Display yData vs xData                          // Make a graph
Modify mode=2, lsize=3                          // Display source data as dots
```

Now, choose Analysis→Interpolate to invoke the Interpolate dialog.

Set Interpolation Type to Cubic Spline.

Choose yData from the Y Data pop-up menu.

Choose xData from the X Data pop-up menu.

Choose _auto_ from the Y Destination pop-up menu.

Choose _none_ from the X Destination pop-up menu.

Enter 200 in the Destination Points box.

Choose Off from the Pre-averaging pop-up menu.

Choose Evenly Spaced from the Dest X Coords pop-up menu.

Click Natural in the End Points section.

Notice that the dialog has generated the following command:

```
Interpolate2/T=2/N=200/E=2/Y=yData_CS xData, yData
```

This says that Interpolate2 will use yData as the Y source wave, xData as the X source wave and that it will create yData_CS as the destination wave. _CS means "cubic spline".

Click the Do It button to do the interpolation.

Now add the yData_CS destination wave to the graph using the command:

```
AppendToGraph yData_CS; Modify rgb(yData_CS)=(0,0,65535)
```

Now let's try this with a larger number of input data points. Execute:

```
Redimension/N=500 xData, yData
xData = p/50; yData = 10*sin(xData) + gnoise(1.0)      // Create sample data
Modify lsize(yData)=1                                  // Smaller dots
```

Now choose Analysis→Interpolate to invoke the Interpolate dialog. All the settings should be as you left them from the preceding exercise. Click the Do It button.

Notice that the resulting cubic spline attempts to go through all of the input data points. This is usually not what we want.

Now, choose Analysis→Interpolate again and make the following changes:

Choose Smoothing Spline from the Interpolation Type pop-up menu. Notice the command generated now references a wave named yData_SS. This will be the output wave.

Enter 1.0 for the smoothing factor. This is usually a good value to start from.

In the Standard Deviation section, click the Constant radio button and enter 1.0 as the standard deviation value. 1.0 is correct because we know that our data has noise with a standard deviation of 1.0, as a result of the "gnoise(1.0)" term above.

Click the Do It button to do the interpolation. Append the yData_SS destination wave to the graph using the command:

```
AppendToGraph yData_SS; Modify rgb(yData_SS)=(0,0,0)
```

Notice that the smoothing spline adds a pleasing curve through the large, noisy data set. If necessary, enlarge the graph window so you can see this.

You can tweak the smoothing spline using either the smoothing factor parameter or the standard deviation parameter. If you are unsure of the standard deviation of the noise, leave the smoothing factor set to 1.0 and try different standard deviation values. It is usually not too hard to find a reasonable value.

The Interpolate Dialog

Choosing Analysis→Interpolate summons the Interpolate dialog from which you can choose the desired type of interpolation, the source wave or waves, the destination wave or waves, and the number of points in the destination waves. This dialog generates an **Interpolate2** command which you can execute, copy to the clipboard or copy to the command line.

From the Interpolation Type pop-up menu, choose Linear or Cubic Spline or Smoothing Spline. Cubic spline is good for a small input data set. Smoothing spline is good for a large, noisy input data set.

If you choose Cubic Spline, a Pre-averaging pop-up menu appear. The pre-averaging feature is largely no longer needed and is not recommended. Use the smoothing spline instead of the cubic spline with pre-averaging.

If you choose smoothing spline, a Smoothing Factor item and Standard Deviation controls appear. Usually it is best to set the smoothing factor to 1.0 and use the constant mode for setting the standard deviation. You then need to enter an estimate for the standard deviation of the noise in your Y data. Then try different values for the standard deviation until you get a satisfactory smooth spline through your data. See **Smoothing Spline Parameters** on page III-119 for further details.

From the Y Data and X Data pop-up menus, choose the source waves that define the data through which you want to interpolate. If you choose a wave from the X Data pop-up, Interpolate2 uses the XY curve defined by the contents of the Y data wave versus the contents of the X data wave as the source data. If you choose _calculated_ from the X Data pop-up, it uses the X and Y values of the Y data wave as the source data.

If you click the From Target checkbox, the source and destination pop-up menus show only waves in the target graph or table.

The X and Y data waves must have the same number of points. They do not need to have the same data type.

The X and Y source data does not need to be sorted before using Interpolate2. If necessary, Interpolate2 sorts a copy of the input data before doing the interpolation.

NaNs (missing values) and INFs (infinite values) in the source data are ignored. Any point whose X or Y value is NaN or INF is treated as if it did not exist.

Enter the number of points you want in the destination waves in the Destination Points box. 200 points is usually good.

From the Y Destination and X Destination pop-up menus, choose the waves to contain the result of the interpolation. For most cases, choose _auto_ for the Y destination wave and _none_ for the X destination wave. This gives you an output waveform. Other options, useful for less common applications, are described in the following paragraphs.

If you choose _auto_ from the Y Destination pop-up, Interpolate2 puts the Y output data into a wave whose name is derived by adding a suffix to the name of the Y data wave. The suffix is "_L" for linear interpolation, "_CS" for cubic spline interpolation and "_SS" for smoothing spline interpolation. For example, if the Y data wave is called "yData", then the default Y destination wave will be called "yData_L", "yData_CS" or "yData_SS".

If you choose _none_ for the X destination wave, Interpolate2 puts the Y output data in the Y destination wave and sets the X scaling of the Y destination wave to represent the X output data.

If you choose _auto_ from the X Destination pop-up, Interpolate2 puts the X output data into a wave whose name is derived by adding the appropriate suffix to the name of the X data wave. If the X data wave is "xData" then the X destination wave will be "xData_L", "xData_CS" or "xData_SS". If there is no X data wave then the X destination wave name is derived by adding the letter "x" to the name of the Y destination wave. For example, if the Y destination is "yData_CS" then the X destination wave will be "yData_CSx".

For both the X and the Y destination waves, if the wave already exists, Interpolate2 overwrites it. If it does not already exist, Interpolate2 creates it.

The destination waves will be double-precision unless they already exist when Interpolate2 is invoked. In this case, Interpolate2 leaves single-precision destination waves as single-precision. For any other precision, Interpolate2 changes the destination wave to double-precision.

The Dest X Coords pop-up menu gives you control over the X locations at which the interpolation is done. Usually you should choose Evenly Spaced. This generates interpolated values at even intervals over the range of X input values.

The Evenly Spaced Plus Input X Coords setting is the same as Evenly Spaced except that Interpolate2 makes sure that the output X values include all of the input X values. This is usually not necessary. This mode is not available if you choose _none_ for your X destination wave.

The Log Spaced setting makes the output evenly spaced on a log axis. This mode ignores any non-positive values in your input X data. It is not available if you choose _none_ for your X destination wave. See **Interpolating Exponential Data** on page III-118 for an alternative.

The From Dest Wave setting takes the output X values from the X coordinates of the destination wave. The Destination Points setting is ignored. You could use this, for example, to get a spline through a subset of your input data. You must create your destination waves before doing the interpolation for this mode. If your destination is a waveform, use the SetScale operation to define the X values of the waveform. Interpolate2 will calculate its output at these X values. If your destination is an XY pair, set the values of the X destination wave. Interpolate2 will create a sorted version of these values and will then calculate its output at these values. If the X destination wave was originally reverse-sorted, Interpolate2 will reverse the output.

The End Points radio buttons apply only to the cubic spline. They control the destination waves in the first and last intervals of the source wave. Natural forces the second derivative of the spline to zero at the first and last points of the destination waves. Match 1st Derivative forces the slope of the spline to match the straight lines drawn between the first and second input points, and between the last and next-to-last input points. In most cases it doesn't much matter which of these alternatives you use.

Interpolating Exponential Data

It is common to plot data that spans orders of magnitude, such as data arising from exponential processes, versus log axes. To create an interpolated data set from such data, it is often best to interpolate the log of the original data rather than the original data itself.

The Interpolate2 Log Demo experiment demonstrates how to do such interpolation. To open the demo, choose Files→Example Experiments→Feature Demos→Interpolate2 Log Demo.

Smoothing Spline Algorithm

The smoothing spline algorithm is based on "Smoothing by Spline Functions", Christian H. Reinsch, *Numerische Mathematik* 10. It minimizes

$$\int_{x_0}^{x_n} g''(x)^2 \, dx,$$

among all functions g(x) such that

$$\sum_{i=0}^{n} \left(\frac{g(x_i) - y_i}{\sigma_i} \right)^2 \leq S,$$

where $g(x_i)$ is the value of the smooth spline at a given point, y_i is the Y data at that point, σ_i is the standard deviation of that point, and S is the smoothing factor.

Smoothing Spline Parameters

The smoothing spline operation requires a standard deviation parameter and a smoothing factor parameter. The standard deviation parameter should be a good estimate of the standard deviation of the noise in your Y data. The smoothing factor should nominally be close to 1.0, assuming that you have an accurate standard deviation estimate.

Using the Standard Deviation section of the Interpolate2 dialog, you can choose one of three options for the standard deviation parameter: None, Constant, From Wave.

If you choose None, Interpolate2 uses an arbitrary standard deviation estimate of 0.05 times the amplitude of your Y data. You can then play with the smoothing factor parameter until you get a pleasing smooth spline. Start with a smoothing factor of 1.0. This method is not recommended.

If you choose Constant, you can then enter your estimate for the standard deviation of the noise and Interpolate2 uses this value as the standard deviation of each point in your Y data. If your estimate is good, then a smoothing factor around 1.0 will give you a nice smooth curve through your data. If your initial attempt is not quite right, you should leave the smoothing factor at 1.0 and try another estimate for the standard deviation. For most types of data, this is the preferred method.

If you choose From Wave then Interpolate2 expects that each point in the specified wave contains the estimated standard deviation for the corresponding point in the Y data. You should use this method if you have an appropriate wave.

Interpolate2's Pre-averaging Feature

A linear or cubic spline interpolation goes through all of the input data points. If you have a large, noisy data set, this is probably not what you want. Instead, use the smoothing spline.

Before Interpolate2 had a smoothing spline, we recommended that you use the cubic spline to interpolate through a decimated version of your input data. The pre-averaging feature was designed to make this easy.

Because Interpolate2 now supports the smoothing spline, the pre-averaging feature is no longer necessary. However, we still support it for backward compatibility.

When you turn pre-averaging on, Interpolate2 creates a temporary copy of your input data and reduces it by decimation to a smaller number of points, called nodes. Interpolate2 then usually adds nodes at the very start and very end of the data. Finally, it does an interpolation through these nodes.

Identical Or Nearly Identical X Values

This section discusses a degenerate case that is of no concern to most users.

Input data that contains two points with identical X values can cause interpolation algorithms to produce unexpected results. To avoid this, if Interpolate2 encounters two or more input data points with nearly identical X values, it averages them into one value before doing the interpolation. This behavior is separate from the pre-averaging feature. This is done for the cubic and smoothing splines except when the Dest X Coords mode is is Log Spaced or From Dest Wave. It is not done for linear interpolation.

Two points are considered nearly identical in X if the difference in X between them (dx) is less than 0.01 times the nominal dx. The nominal dx is computed as the X span of the input data divided by the number of input data points.

Destination X Coordinates from Destination Wave

This mode, which we call "X From Dest" mode for short, takes effect if you choose From Dest Wave from the Dest X Coords pop-up menu in the Interpolate2 dialog or use the Interpolate2 /I=3 flag. In this mode the number of output points is determined by the destination wave and the /N flag is ignored.

In X From Dest mode, the points at which the interpolation is done are determined by the destination wave. The destination may be a waveform, in which case the interpolation is done at its X values. Alternatively the destination may be an XY pair in which case the interpolation is done at the data values stored in the X destination wave.

Here is an example using a waveform as the destination:

```
Make /O /N=20 wave0                     // Generate source data
SetScale x 0, 2*PI, wave0
wave0 = sin(x) + gnoise(.1)
Display wave0
ModifyGraph mode=3
Make /O /N=1000 dest0                   // Generate dest waveform
SetScale x 0, 2*PI, dest0
AppendToGraph dest0
ModifyGraph rgb(dest0)=(0,0,65535)
Interpolate2 /T=2 /I=3 /Y=dest0 wave0     // Do cubic spline interpolation
```

If your destination is an XY pair, Interpolate2 creates a sorted version of these values and then calculates its output at the X destination wave's values. If the X destination wave was originally reverse-sorted, as determined by examining its first and last values, Interpolate2 reverses the output after doing the interpolation to restore the original ordering.

In X From Dest mode with an XY pair as the destination, the X wave may contain NaNs. In this case, Interpolate2 creates an internal copy of the XY pair, removes the points where the X destination is NaN, does the interpolation, and copies the results to the destination XY pair. During this last step, Interpolate2 restores the NaNs to their original locations in the X destination wave. Here is an example of an XY destination with a NaN in the X destination wave:

```
Make/O xData={1,2,3,4,5}, yData={1,2,3,4,5}           // Generate source data
Display yData vs xData
Make/O xDest={1,2,NaN,4,5}, yDest={0,0,0,0,0}         // Generate dest XY pair
ModifyGraph mode=3,marker=19
AppendToGraph yDest vs xDest
ModifyGraph rgb(yDest)=(0,0,65535)
Interpolate2 /T=1 /I=3 /Y=yDest /X=xDest xData, yData // Do interpolation
```

Differentiation and Integration

The **Differentiate** operation (see page V-158) and **Integrate** operation (see page V-446) provide a number of algorithms for operation on one-dimensional waveform and XY data. These operations can either replace the original data or create a new wave with the results. The easiest way to use these operations is via dialogs available from the Analysis menu.

For most applications, trapezoidal integration and central differences differentiation are appropriate methods. However, when operating on XY data, the different algorithms have different requirements for the number of points in the X wave. If your X wave does not show up in the dialog, try choosing a different algorithm or click the help button to see what the requirements are.

When operating on waveform data, X scaling is taken into account; you can turn this off using the /P flag. You can use the **SetScale** operation (see page V-853) to define the X scaling of your Y data wave.

Although these operations work along just one dimension, they can be targeted to operate along rows or columns of a matrix (or even higher dimensions) using the /DIM flag.

The Integrate operation replaces or creates a wave with the numerical integral. For finding the area under a curve, see **Areas and Means** on page III-120.

Areas and Means

You can compute the area and mean value of a wave in several ways using Igor.

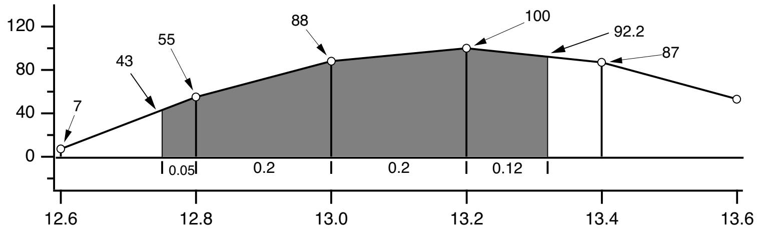
Perhaps the simplest way to compute a mean value is with the Wave Stats dialog in the Analysis menu. The dialog is pictured under **Wave Statistics** on page III-122. You select the wave, type in the X range (or use the current cursor positions), click Do It, and Igor prints several statistical results to the history area. Among them is V_avg, which is the average, or mean value. This is the same value that is returned by the **mean** function (see page V-586), which is faster because it doesn't compute any other statistics. The mean function returns NaN if any data within the specified range is NaN. The **WaveStats** operation, on the other hand, ignores such missing values.

WaveStats and the **mean** function use the same method for computing the mean: find the waveform values within the given X range, sum them together, and divide by the number of values. The X range serves only to select the values to combine. The range is rounded to the nearest point numbers.

If you consider your data to describe discrete values, such as a count of events, then you should use either WaveStats or the mean function to compute the average value. You can most easily compute the total number of events, which is an area of sorts, using the **sum** function (see page V-1007). It can also be done easily by multiplying the WaveStats outputs V_avg and V_npnts.

If your data is a sampled representation of a continuous process such as a sampled audio signal, you should use the **faverage** function to compute the mean, and the area function to compute the area. These two functions use the same linear interpolation scheme as does trapezoidal integration to estimate the waveform values between data points. The X range is *not* rounded to the nearest point. Partial X intervals are included in the calculation through this linear interpolation.

The diagram below shows the calculations each function performs for the data shown. The two values 43 and 92.2 are linear interpolation estimates.



Comparison of area, faverage and mean functions over interval (12.75,13.32)

`WaveStats/R=(12.75,13.32) wave`		
`V_avg`	= (55+88+100+87)/4 = 82.5	
`mean(wave,12.75,13.32)`	= (55+88+100+87)/4 = 82.5	
`area(wave,12.75,13.32)`	= 0.05 · (43+55) / 2	first trapezoid
	+ 0.20 · (55+88) / 2	second trapezoid
	+ 0.20 · (88+100) / 2	third trapezoid
	+ 0.12 · (100+92.2) / 2	fourth trapezoid
	= 47.082	
`faverage(wave,12.75,13.32)`	= area(wave,12.75,13.32) / (13.32-12.75)	
	= 47.082/0.57 = 82.6	

Note that only the area function is affected by the X scaling of the wave. faverage eliminates the effect of X scaling by dividing the area by the same X range that area multiplied by.

One problem with these functions is that they can not be used if the given range of data has missing values (NaNs). See **Dealing with Missing Values** on page III-112 for details.

X Ranges and the Mean, faverage, and area Functions

The X range input for the mean, faverage and area functions are optional. Thus, to include the entire wave you don’t have to specify the range:

```
Make/N=10 wave=2; Edit wave.xy    // X ranges from 0 to 9
Print area(wave)                  // entire X range, and no more
18
```

Sometimes, in programming, it is not convenient to determine whether a range is beyond the ends of a wave. Fortunately, these functions also accept X ranges that go beyond the ends of the wave.

```
Print area(wave, 0, 9)            // entire X range, and no more
18
```

You can use expressions that evaluate to a range beyond the ends of the wave:

```
Print leftx(wave),rightx(wave)
0  10
Print area(wave,leftx(wave),rightx(wave))      // entire X range, and more
18
```

or even an X range of ±×:

```
Print area(wave, -Inf, Inf)  // entire X range of the universe
18
```

Finding the Mean of Segments of a Wave

Under **Analysis Programming** on page III-170 is a function that finds the mean of segments of a wave where you specify the length of the segments. It creates a new wave to contain the means for each segment.

Area for XY Data

To compute the area of a region of data contained in an XY pair of waves, use the **areaXY** function (see page V-41). There is also an XY version of the faverage function; see **faverageXY** on page V-218.

In addition you can use the AreaXYBetweenCursors WaveMetrics procedure file which contains the AreaXYBetweenCursors and AreaXYBetweenCursorsLessBase procedures. For instructions on loading the procedure file, see **WaveMetrics Procedures Folder** on page II-32. Use the **Info Panel and Cursors** to delimit the X range over which to compute the area. AreaXYBetweenCursorsLessBase removes a simple trapezoidal baseline - the straight line between the cursors.

Wave Statistics

The **WaveStats** operation (see page V-1082) computes various descriptive statistics relating to a wave and prints them in the history area of the command window. It also stores the statistics in a series of special variables or in a wave so you can access them from a procedure.

The statistics printed and the corresponding special variables are:

Variable	**Meaning**
V_npnts	Number of points in range excluding points whose value is NaN or INF.
V_numNaNs	Number of NaNs.
V_numINFs	Number of INFs.
V_avg	Average of data values.

Variable	Meaning
V_sum	Sum of data values.
V_sdev	Standard deviation of data values, $\sigma = \sqrt{\frac{1}{V\_npnts - 1}\sum (Y_i - V\_avg)^2}$ “Variance” is V_sdev^2.
V_sem	Standard error of the mean $sem = \frac{\sigma}{\sqrt{V\_npnts}}$
V_rms	RMS (Root Mean Square) of Y values $= \sqrt{\left(\frac{1}{V\_npnts}\sum Y_i^2\right)}$
V_adev	Average deviation $= \frac{1}{V\_npnts} \sum_{i=0}^{V\_npnts-1} \lvert x_i - \bar{x} \rvert$
V_skew	Skewness $= \frac{1}{V\_npnts} \sum_{i=0}^{V\_npnts-1} \left[\frac{x_i - \bar{x}}{\sigma}\right]^3$
V_kurt	Kurtosis $= \frac{1}{V\_npnts} \sum_{i=0}^{V\_npnts-1} \left[\frac{x_i - \bar{x}}{\sigma}\right]^4 - 3$
V_minloc	X location of minimum data value.
V_min	Minimum data value.
V_maxloc	X location of maximum data value.
V_max	Maximum data value.
`V_minRowLoc`	Row containing minimum data value.
`V_maxRowLoc`	Row containing maximum data value.
`V_minColLoc`	Column containing minimum data value (2D or higher waves).
`V_maxColLoc`	Column containing maximum data value (2D or higher waves).
`V_minLayerLoc`	Layer containing minimum data value (3D or higher waves).
`V_maxLayerLoc`	Layer containing maximum data value (3D or higher waves).
`V_minChunkLoc`	Chunk containing minimum v value (4D waves only).
`V_maxChunkLoc`	Chunk containing maximum data value (4D waves only).
`V_startRow`	The unscaled index of the first row included in caculating statistics.
`V_endRow`	The unscaled index of the last row included in caculating statistics.
`V_startCol`	The unscaled index of the first column included in calculating statistics. Set only when /RMD is used.

Variable	Meaning
`V_endCol`	The unscaled index of the last column included in calculating statistics. Set only when /RMD is used.
`V_startLayer`	The unscaled index of the first layer included in calculating statistics. Set only when /RMD is used.
`V_endLayer`	The unscaled index of the last layer included in calculating statistics. Set only when /RMD is used.
`V_startChunk`	The unscaled index of the first chunk included in calculating statistics. Set only when /RMD is used.
`V_endChunk`	The unscaled index of the last chunk included in calculating statistics. Set only when /RMD is used.

To use the WaveStats operation, choose Wave Stats from the Statistics menu.

Igor ignores NaNs and INFs in computing the average, standard deviation, RMS, minimum and maximum. NaNs result from computations that have no defined mathematical meaning. They can also be used to represent missing values. INFs result from mathematical operations that have no finite value.

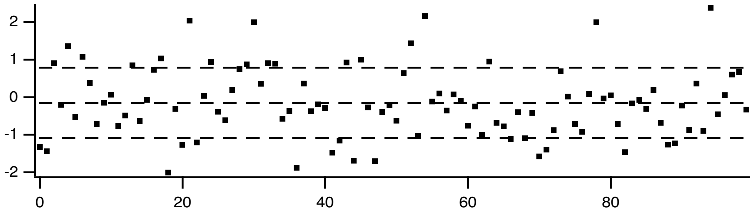
This procedure illustrates the use of WaveStats. It shows the average and standard deviation of a source wave, assumed to be displayed in the top graph. It draws lines to indicate the average and standard deviation.

```
Function ShowAvgStdDev(source)
   Wave source                                        // source waveform

   Variable left=leftx(source),right=rightx(source)   // source X range
   WaveStats/Q source
   SetDrawLayer/K ProgFront
   SetDrawEnv xcoord=bottom,ycoord=left,dash= 7
   DrawLine left, V_avg, right, V_avg                 // show average
   SetDrawEnv xcoord=bottom,ycoord=left,dash= 7
   DrawLine left, V_avg+V_sdev, right, V_avg+V_sdev   // show +std dev
   SetDrawEnv xcoord=bottom,ycoord=left,dash= 7
   DrawLine left, V_avg-V_sdev, right, V_avg-V_sdev   // show -std dev
   SetDrawLayer UserFront
End
```

You could try this function using the following commands.

```
Make/N=100 wave0 = gnoise(1)
Display wave0; ModifyGraph mode(wave0)=2, lsize(wave0)=3
ShowAvgStdDev(wave0)
```



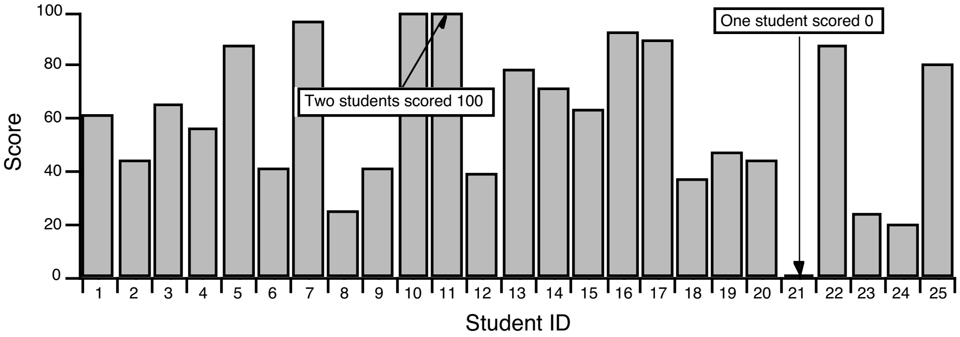
When you use WaveStats with a complex wave, you can choose to compute the same statistics as above for the real, imaginary, magnitude and phase of the wave. By default WaveStats only computes the statistics for the real part of the wave. When computing the statistics for other components, the operation stores the results in a multidimensional wave M_WaveStats.

If you are working with large amounts of data and you are concerned about computation speed you might be able to take advantage of the /M flag that limits the calculation to the first order moments.

If you are working with 2D or 3D waves and you want to compute the statistics for a domain of an arbitrary shape you should use the **ImageStats** operation (see page V-414) with an ROI wave.

Histograms

A histogram totals the number of input values that fall within each of a number of value ranges (or “bins”) usually of equal extent. For example, a histogram is useful for counting how many data values fall in each range of 0-10, 10-20, 20-30, etc. This calculation is often made to show how students performed on a test:



The usual use for a histogram in this case is to figure out how many students fall into certain numerical ranges, usually the ranges associated with grades A, B, C, and D. Suppose the teacher decides to divide the 0-100 range into 4 equal parts, one per grade. The **Histogram** operation (see page V-349) can be used to show how many students get each grade by counting how many students fall in each of the 4 ranges.

We start by creating a wave to hold the histogram output:

```
Make/N=4/D/O studentsWithGrade
```

Next we execute the Histogram command which we generated using the Histogram dialog:

```
Histogram/B={0,25,4} scores,studentsWithGrade
```

The /B flag tells Histogram to create four bins, starting from 0 with a bin width of 25. The first bin counts values from 0 up to but not including 25.

The Histogram operation analyzes the source wave (`scores`), and puts the histogram result into a destination wave (`studentsWithGrade`).

Let’s create a text wave of `grades` to plot `studentsWithGrade` versus a grade letter in a category plot:

```
Make/O/T grades = {"D", "C", "B", "A"}
Display studentsWithGrade vs grades
SetAxis/A/E=1 left
```

Everything *looks* good in the category plot. Let’s double-check that all the students made it into the bins:

```
Print sum(studentsWithGrade)
  23
```

There are two missing students. They are ones who scored 100 on the test. The four bins we defined are actually:

Bin 1:	0 - 24.99999
Bin 2:	25 - 49.99999
Bin 3:	50 - 74.99999
Bin 4:	75 - 99.99999

The problem is that the test scores actually encompass 101 values, not 100. To include the perfect scores in the last bin, we could add a small number such as 0.001 to the bin width:

Bin 1:	0 - 25.00999
Bin 2:	25.001 - 49.00199
Bin 3:	50.002 - 74.00299
Bin 4:	75.003 - 100.0399

The students who scored 25, 50 or 75 would be moved down one grade, however. Perhaps the best solution is to add another bin for perfect scores:

```
Make/O/T grades= {"D", "C", "B", "A", "A+"}
Histogram/B={0,25,5} scores,studentsWithGrade
```

For information on plotting a histogram, see Chapter II-14, **Category Plots** and **Graphing Histogram Results** on page III-127.

This example was intended to point out the care needed when choosing the histogram binning. Our example used “manual binning”.

The Histogram operation provides five ways to set binning. They correspond to the radio buttons in the Histogram dialog:

Bin Mode	What It Does
Manual bins	Sets number of points and X scaling of the destination (output) wave based on parameters that you explicitly specify.
Auto-set bins	Sets X scaling of destination wave to cover the range of values in the **source** wave. Does not change the number of points (bins) in the destination wave. Thus, you must set the number of destination wave points before computing the histogram. When using the Histogram dialog, if you select Make New Wave or Auto from the Output Wave menu, the dialog must be told how many points the new wave should have. It displays the Number of Bins box to let you specify the number.
Set bins from destination wave	Does not change the X scaling or the number of points in the destination wave. Thus, you need to set the X scaling and number of points of the destination wave before computing the histogram. When using the Histogram dialog, the Set from destination wave radio button is only available if you choose Select Existing Wave from the Output Wave menu.
Auto-set bins: 1+log2(N)	Examines the input data and sets the number of bins based on the number of input data points. Sets the bin range the same as if Auto-set bin range were selected.
Auto-set bins: 3.49*Sdev*N^-1/3	Examines the input data and sets the number of bins based on the number of input data points and the standard deviation of the data. Sets the bin range the same as if Auto-set bin range were selected.
Freedman-Diaconis method	Sets the optimal bin width to $binWidth = 2 * \mathrm{IQR} * N^{-1/3}$ where IQR is the interquartile distance (see StatsQuantiles) and the bins are evenly-distributed between the minimum and maximum values. Added in Igor Pro 7.00.

Histogram Caveats

If you use the “Set bins from destination wave” mode, you must create the destination wave, using the **Make** operation, before computing the histogram. You also must set the X scaling of the destination wave, using the **SetScale**.

The Histogram operation does not distinguish between 1D waves and multidimensional waves. If you use a multidimensional wave as the source wave, it will be analyzed as if the wave were one dimensional. This may still be useful - you will get a histogram showing counts of the data values from the source wave as they fall into bins.

If you would like to perform a histogram of 2D or 3D image data, you may want to use the **ImageHistogram** operation (see page V-379), which supports specific features that apply to images only.

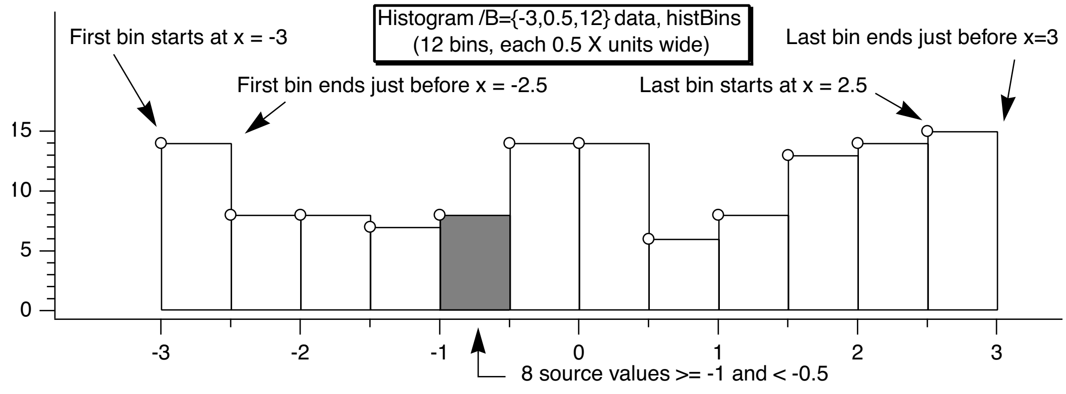
Graphing Histogram Results

Our example above displayed the histogram results as a category plot because the bins corresponded to text values. Often histogram bins are displayed on a numeric axis. In this case you need to know how Igor displays a histogram result.

For example, this histBins destination wave has 12 points (bins), the first bin starting at -3, and each bin is 0.5 wide. The X scaling is shown in the table:

Point	histBins.x	histBins.d
0	-3	14
1	-2.5	8
2	-2	8
3	-1.5	7
4	-1	8
5	-0.5	14
6	0	14
7	0.5	6
8	1	8
9	1.5	13
10	2	14
11	2.5	15

When histBins is graphed in both bars and markers modes, it looks like this:



Note that the markers are positioned at the start of the bars. You can offset the marker trace by half the bin width if you want them to appear in the center of the bin.

Alternatively, you can make a second histogram using the Bin-Centered X Values option. In the Histogram dialog, check the Bin-Centered X Values checkbox.

The Histogram Dialog

To use the Histogram operation, choose Histogram from the Analysis menu.

To use the “Manually set bins” or “Set from destination wave” bin modes, you need to decide the range of data values in the source wave that you want the histogram to cover. You can do this visually by graphing the source wave or you can use the WaveStats operation to find the exact minimum and maximum source values.

The dialog requires that you enter the starting bin value and the bin width. If you know the starting bin value and the ending bin value then you need to do some arithmetic to calculate the bin width.

A line of text at the bottom of the Destination Bins box tells you the first and last values, as well as the width and number of bins. This information can help with trial-and-error settings.

If you use the “Manually set bins” or any of the “Auto-set” modes, Igor will set the X units of the destination wave to be the same as the Y units of the source wave.

If you enable the Accumulate checkbox, Histogram does not clear the destination wave but instead adds counts to the existing values in it. Use this to accumulate results from several histograms in one destination. If you want to do this, don’t use the “Auto-set bins” option since it makes no sense to change bins in mid-stream. Instead, use the “Set from destination wave” mode. To use the Accumulate option, the destination wave must be double-precision or single-precision and real.

The “Bin-Centered X Values” and “Create Square Root(N) Wave” options are useful for curve fitting to a histogram. If you do not use Bin-Centered X Values, any X position parameter in your fit function will be shifted by half a bin width. The Square Root(N) Wave creates a wave that estimates the standard deviation of the histogram data; this is based on the fact that counting data have a Poisson distribution. The wave created by this option does not try to do anything special with bins having zero counts, so if you use the square root(N) wave to weight a curve fit, these zero-count bins will be excluded from the fit. You may need to replace the zeroes with some appropriate value.

The binning modes were added in Igor Pro. In earlier versions of Igor, the accumulate option had *two* effects:

- Did not clear the destination wave.
- Effectively used the “Set bins from destination wave” mode.

To maintain backward compatibility, the Histogram operation still behaves this way if the accumulate (“/A”) flag is used and no bin (“/B”) flag is used. This dialog always generates a bin flag. Thus, the accumulate flag just forces accumulation and has no effect on the binning.

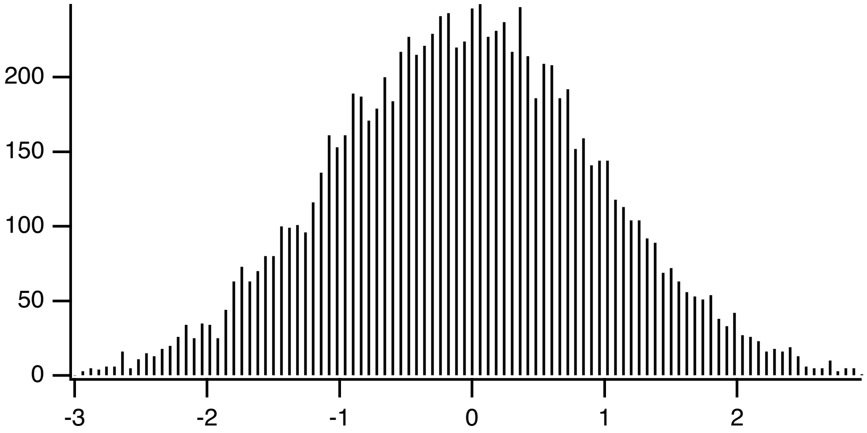
You can use the Histogram operation on multidimensional waves but they are treated as though the data belonged to a single 1D wave. If you are working with 2D or 3D waves you may prefer to use the **ImageHistogram** operation (see page V-379), which computes the histogram of one layer at a time.

Histogram Example

The following commands illustrate a simple test of the histogram operation.

```
SetRandomSeed 0.2                                      // For reproducible randomness
Make/O/N=10000 noise = gnoise(1)                              // Make raw data
Make hist                                                     // Make destination wave
Histogram/B={-3, (3 - -3)/100, 100} noise, hist           // Perform histogram
Display hist; Modify mode(hist)=1
```

These commands produce the following graph:



The raw data has 10,000 samples drawn from a Gaussian distribution having standard deviation of 1.0, and mean of zero. The histogram is made with 100 bins with width of 6/100 = 0.06. The amplitude of the histogram is expected to be:

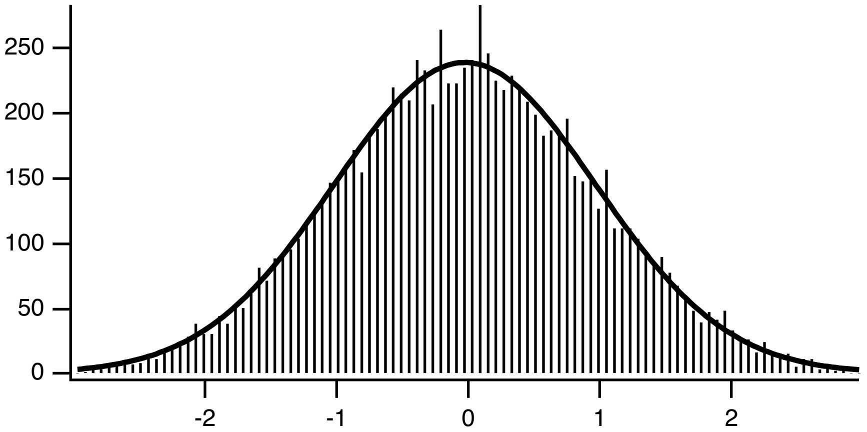
```
A = (N*dx)/sqrt(2*pi)/sigma = (10000*0.06)/sqrt(2*pi)/1 = 239.365
```

The X scaling of the wave hist uses the Histogram default of the left side of the bins.

Curve Fitting to a Histogram

Because the values in the source wave are Gaussian deviates generated by the gnoise function, the histogram should have the familiar Gaussian bell-shape. You can estimate the characteristics of the population the samples were taken from by fitting a Gaussian curve to the data. First try fitting a Gaussian curve to the example histogram:

```
CurveFit gauss hist /D     // Curve fit to histogram
```



The solution from the curve fit is:

```
y0    =  -0.85917 ± 2.74
A     =  238.23 ± 3.07
x0    =  -0.047537 ± 0.0113
width =  1.4337 ± 0.0272
```

Because of the definition of Igor's built-in gauss fit function, we expect the width coefficient to be sqrt(2)*sigma or 1.4142. The coefficients from this fit are within one standard deviation of the expected values, except for peak position x0.

The peak position x0 is shifted approximately half a bin below zero. Since the gnoise() function produces random numbers with mean of zero, we would expect x0 to be close to zero. The shifted value of x0 is a result of Igor's way of storing the X values for histogram bins. Setting the X value to the left edge is good for displaying a bar chart, but bad for curve fitting.

By default, a histogram wave has the X scaling set such that an X value gives the value at the left end of a bin. Usually if you are going to fit a curve to a histogram, you want centered X values. You can change the X scaling to centered values using SetScale. But it is easier to simply use the option to have the Histogram operation produce output with bin-centered X values by adding the /C flag to the Histogram command:

```
Histogram/C/B={-3, (3 - -3)/100, 100} noise, hist  // Perform histogram
CurveFit gauss hist /D                             // Curve fit to histogram
```

The result of the curve fit is the same as before except that x0 is closer to what we expect:

```
y0    =  -0.85917 ± 2.74
A     =  238.23 ± 3.07
x0    =  -0.017537 ± 0.0113
width =  1.4337 ± 0.0272
```

But this shifts the trace showing the histogram by half a bin on the graph. If the trace is displayed using markers or dots, this may be what is desired, but if you have used bars, the display is incorrect.

Another possibility is to make an X wave to go with the histogram data. This X wave would contain X values shifted by half a bin. Use this X wave as input to the curve fit, but don't use it on the graph:

```
Histogram/B={-3, (3 - -3)/100, 100} noise, hist    // Histogram without /C
Duplicate hist, hist_x
hist_x = x + deltax(hist)/2
CurveFit gauss  hist /X=hist_x/D
```

Use this method to graph the original histogram wave without modifying the X scaling, so a graph using bars is correct. It also gives a curve fit that uses the center X values, giving the correct x0. You could also use the Histogram operation twice, once with the /C flag to get bin-centered X values, and once without to get the shifted X scaling appropriate for bars. Both methods have the drawback of creating an extra wave that you must track.

This fit is not statistically correct. Because the histogram represents counts, the values in a histogram should have uncertainties described by a Poisson distribution. The standard deviation of a Poisson distribution is equal to the square root of the mean, which implies that the estimated uncertainty of a histogram bin depends on the magnitude of the value. This in turn implies that the errors are not constant and a curve fit will give a biased solution and possibly poor estimates of the uncertainties of the fit coefficients.

This problem can be solved approximately using a weighting wave. The appropriate weighting wave is generated by the Histogram operation if you add the /N flag or turn on the Create Square Root(N) Wave checkbox in the Histogram dialog.

The next example makes a new data set using gnoise to make gaussian-distributed values, makes a histogram with bin-centered X values and the appropriate weighting wave, and then does two curve fits, one without weighting and one with.

We expect coefficient values from the curve fit to be:

```
y0       =  0
A        =  (1024*deltax(gdata_Hist))/sqrt(2*pi)/1 = 139.863
x0       =  0
width    =  1.4142
```

```
SetRandomSeed 0.5              // For reproducible randomness
Make/O/N=1024 gdata = gnoise(1)
Make/O/N=20 gdata_Hist
Histogram/C/N/B=4 gdata,gdata_Hist
Display gdata_Hist
ModifyGraph mode=3,marker=8
```

```
CurveFit gauss  gdata_Hist /D
CurveFit gauss  gdata_Hist /W=W_SqrtN /I=1 /D
```

Note the addition of "`/W=W_SqrtN /I=1`" addition to the second CurveFit command. This adds the weighting using the weighting wave created by the Histogram operation. Also, /B=4 was used to have the Histogram operation set the number of bins and bin range appropriately for the input data.

The results from the unweighted fit:

```
y0    =  -3.3383 ± 2.98
A     =  133.26 ± 3.51
x0    =  0.024088 ± 0.0252
width =  1.5079 ± 0.0578
```

And from the weighted fit:

```
y0    =  0.33925 ± 0.804
A     =  135.21 ± 5.25
x0    =  0.0038416 ± 0.031
width =  1.3604 ± 0.0405
```

The results are clearly and significantly different. Since we created fake data we know what to expect the results to be; the weighted fit also is closer to our expectation.

There are some possible objections to this weighted fit, that may or may not be important to you.

The weighted fit is only an approximate solution to the fact that the actual errors follow a Poisson distribution. The truly correct way to fit count data is to do a maximum likelihood fit. Igor does not directly support maximum likelihood fitting.

When using the square root approximation of the standard deviation of the Poisson distribution, the fitted model is a better approximation of the actual counts than each individual original data points. But Igor doesn't have a way to replace the weighting based on the current iteration, so the only way to do that is to do the fit, re-compute the weighting wave and do the fit again. Repeat long enough that it doesn't change much any more.

The shape of the Poisson distribution is well-approximated by a Gaussian only for large numbers of counts. In practice, "large" may mean "more than 5 or so". In our example, only five points out on the tails have five or fewer counts, but we started with over 1000 points. You may not be so lucky!

Iterative Weighted Fit

This section is for advanced users only. It provides an example of an iterative fit with corrected weighting wave.

```
Function FitGaussHistogram(Wave histwave, Wave InSqrtNwave)
   // Make a copy so that we don't change the input wave
   Duplicate/FREE InSqrtNwave, sqrtNwave

   // Get a first cut at the correct fit using sqrtNwave provided by Histogram
   CurveFit/Q gauss  histwave /W=sqrtNwave /I=1
   Wave W_coef

   // Save the fit solution for comparison in the loop
   Duplicate/FREE W_coef, lastCoef

   // Compute the length of the initial solution to use in the stopping criterion
   MatrixOp/FREE/O length = sqrt(sum(magSqr(W_coef)))
   Variable initialLength = length[0]

   // Now loop and re-compute the weighting wave for each iteration
   // Do a new fit with the new weighting
   do
```

```
      // New weighting is square root of the expected Y values from the fit
      sqrtNwave = sqrt(Gauss1D(W_coef, pnt2x(histwave, p)))

      // Do a new fit
      CurveFit/Q gauss  histwave /W=sqrtNwave /I=1
      Wave W_coef

      // Compute the length of the difference between this fit and the last
      MatrixOp/FREE/O delta = sqrt(sum(magSqr(W_coef - lastCoef)))

      // Uncomment these lines if you would like to see the progress
      // Print delta
      // Print W_coef

      // Rather arbitrary stopping criterion
      if (delta[0] < 1e-8*initialLength)
         break
      endif

      lastCoef = W_coef
   while(1)

   Wave W_sigma
   Print "y0\t=\t",W_coef[0], "±", W_sigma[0]
   Print "A\t=\t",W_coef[1], "±", W_sigma[1]
   Print "x0\t=\t",W_coef[2], "±", W_sigma[2]
   Print "width\t=\t",W_coef[3], "±", W_sigma[3]
End
```

To try it, paste the code into the procedure window, compile, and execute this on the command line:

```
FitGaussHistogram(gdata_Hist, W_SqrtN)
```

The result is:

```
y0    =  -0.985823 ± 1.22856
A     =  138.462 ± 5.31568
x0    =  -0.00928052 ± 0.0313763
width =  1.45437 ± 0.0521087
```

This result from this example is within one standard deviation of the weighted fit using the weighting wave generated by the histogram.

Computing an “Integrating” Histogram

In a histogram, each bin of the destination wave contains a count of the number of occurrences of values in the source that fell within the bounds of the bin. In an *integrating* histogram, instead of *counting* the occurrences of a value within the bin, we *add* the value itself to the bin. When we’re done, the destination wave contains the sum of all values in the source which fell within the bounds of the bin.

Igor comes with an example experiment called “Integrating Histogram” that illustrates how to do this with a user function. To see the example, choose File→Example Experiments→Analysis→Integrating Histogram.

Sorting

The **Sort** operation (see page V-883) sorts one or more 1D numeric or text waves in ascending or descending order.

The Sort operation is often used to prepare a wave or an XY pair for subsequent analysis. For example, the interp function assumes that the X input wave is monotonic.

There are other sorting-related operations: MakeIndex and IndexSort. These are used in rare cases and are described the section **MakeIndex and IndexSort** on page III-134. The **SortColumns** operation sorts columns of multidimensional waves. Also see the **SortList** function for sorting string lists.

To use the Sort operation, choose Sort from the Analysis menu.

The sort key wave controls the reordering of points. However, the key wave itself is not reordered unless it is also selected as a destination wave in the “Waves to Sort” list.

The number of points in the destination wave or waves must be the same as in the key wave. When you select a wave from the dialog’s Key Wave list, Igor shows only waves with the same number of points in the Waves to Sort list.

The key wave can be a numeric or text wave, but it must not be complex. The destination wave or waves can be text, real or complex except for the MakeIndex operation in which case the destination must be text or real.

The number of destination waves is constrained by the 2500 byte limit in Igor’s command buffer. To sort a very large number of waves, use several Sort commands in succession, being careful not to sort the key wave until the very last.

By default, text sorting is case-insensitive. Use the /C flag with the Sort operation to make it case-sensitive.

Simple Sorting

In the simplest case, you would select a single wave as both the source and the destination. Then Sort would merely sort that wave.

If you want to sort an XY pair such that the X wave is in order, you would select the X wave as the source and both the X and Y waves as the destination.

Sorting to Find the Median Value

The following user-defined function illustrates a simple use of the Sort operation to find the median value of a wave.

```
Function FindMedian(w, x1, x2)// Returns median value of wave w
   Wave w
   Variable x1, x2            // Range of interest

   Variable result

   Duplicate/R=(x1,x2)/FREE w, medianWave // Make a clone of wave
   Sort tempMedianWave, medianWave        // Sort clone
   SetScale/P x 0,1,medianWave
   result = medianWave((numpnts(medianWave)-1)/2)

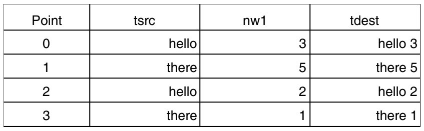
   return result
End
```

It is easier and faster to use the built-in **median** function to find the median value in a wave.

Multiple Sort Keys

If the key wave has two or more identical values, you may want to use a secondary source to determine the order of the corresponding points in the destination. This requires using multiple sort keys. The Sorting dialog does not provide a way to specify multiple sort keys but the Sort operation does. Here is an example demonstrating the difference between sorting by single and by multiple keys. Notice that the sorted wave (`tdest`) is a text wave, and the sort keys are text (`tsrc`) and numeric (`nw1`):

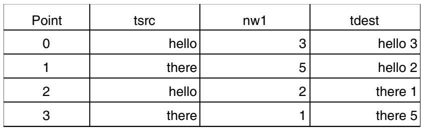
```
Make/O/T tsrc={"hello","there","hello","there"}
Duplicate/O tsrc,tdest
Make nw1= {3,5,2,1}
tdest= tsrc + " " + num2str(nw1)
Edit tsrc,nw1,tdest
```



Point	tsrc	nw1	tdest
0	hello	3	hello 3
1	there	5	there 5
2	hello	2	hello 2
3	there	1	there 1

Single-key text sort:

```
Sort tsrc,tdest             // nw1 not used
```



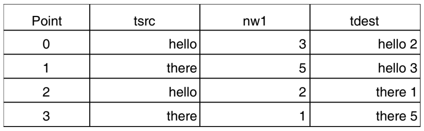
Point	tsrc	nw1	tdest
0	hello	3	hello 3
1	there	5	hello 2
2	hello	2	there 1
3	there	1	there 5

Execute this to scramble tdest again:

```
tdest= tsrc + " " + num2str(nw1)
```

Execute this to see a two key sort (nw1 breaks ties):

```
Sort {tsrc,nw1},tdest
```



Point	tsrc	nw1	tdest
0	hello	3	hello 2
1	there	5	hello 3
2	hello	2	there 1
3	there	1	there 5

The reason that “hello 3” sorts after “hello 2” is because nw1[0] = 3 is greater than nw1[2] = 2.

You can sort by more than two keys by specifying more than two waves inside the braces.

MakeIndex and IndexSort

The MakeIndex and IndexSort operations are infrequently used. You will normally use the Sort operation.

Applications of MakeIndex and IndexSort include:

- Sorting large quantities of data
- Sorting individual waves from a group one at a time
- Accessing data in sorted order without actually rearranging the data
- Restoring data to the original ordering

The MakeIndex operation creates a set of index numbers. IndexSort can then use the index numbers to rearrange data into sorted order. Together they can be used to sort just like the Sort operation but with an extra wave and an extra step.

The advantage is that once you have the index wave you can quickly sort data from a given set of waves at any time. For example, if you have hundreds of waves you can not use the normal sort operation on a single command line. Also, when writing procedures it is sometimes more convenient to loop through a set of waves one at a time than to try to generate a single command line with multiple waves.

You can also use the index values to access data in sorted order without using the IndexSort operation. For example, if you have data and index waves named wave1 and wave1index, you can access the data in sorted order on the right hand side of a wave assignment like so:

```
wave1[wave1index[p]]
```

If you create an index wave, you can undo a sort and restore data to the original order. To do this, simply use the Sort operation with the index wave as the sort key.

Like the Sort operation, the MakeIndex operation can handle multiple sort keys.

The output wave from MakeIndex contains indices which can be used to access the elements of the input wave in sorted order. These indices can be used later with IndexSort to sort the input wave and/or to reorder other waves. For example:

```
Make/O data0 = {1,9,2,3}
Make/O/N=4 index
MakeIndex data0, index
Print index             // Prints 0, 2, 3, 1
```

The output values 0, 2, 3, and 1 mean that, to sort data0, you would access element 0, then element 2, then element 3, then element 1. For example, this prints the values of data0 in order:

```
Print data0[0], data0[2], data0[3], data0[1]
```

You can now apply that sequence of access using IndexSort:

```
IndexSort index, data0
Print data0             // Prints 1, 2, 3, 9
```

You can apply the same reordering to another wave using IndexSort:

```
Make/O data1 = {0,1,2,3}
IndexSort index, data1
Print data1             // Prints 0, 2, 3, 1
```

Decimation

If you have a large data set it may be convenient to deal with a smaller but representative number of points. In particular, if you have a graph with millions of points, it probably takes a long time to draw or print the graph. You can do without many of the data points without altering the graph much. Decimation is one way to accomplish this.

There are at least two ways to decimate data:

1. Keep only every nth data value. For example, keep the first value, discard 9, keep the next, discard 9 more, etc. We call this **Decimation by Omission** (see page III-135).
2. Replace every nth data value with the result of some calculation such as averaging or filtering. We call this **Decimation by Smoothing** (see page III-136).

Decimation by Omission

To decimate by omission, create the smaller output wave and use a simple assignment statement (see **Waveform Arithmetic and Assignments** on page II-74) to set their values. For example, If you are decimating by a factor of 10 (omitting 9 out of every 10 values), create an output wave with 1/10th as many points as the input wave.

For example, make a 1000 point test input waveform:

```
Make/O/N=1000 wave0
SetScale x 0, 5, wave0
wave0 = sin(x) + gnoise(.1)
```

Now, make a 100 point waveform to contain the result of the decimation:

```
Make/O/N=100 decimated
SetScale x 0, 5, decimated    // preserve the x range
decimated = wave0[p*10]       // for(p=0;p<100;p+=1) decimated[p]= wave0[p*10]
```

Decimation by omission can be obtained more easily using the Resample operation and dialog by using an interpolation factor of 1 and a decimation factor of (in this case) 10, and a filter length of 1.

```
Duplicate/O wave0, wave0Resampled
Resample/DOWN=10/N=1 wave0Resampled
```

Decimation by Smoothing

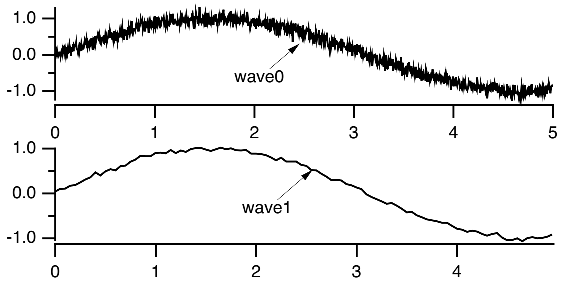
While decimation by omission completely discards some of the data, decimation by smoothing combines all of the data into the decimated result. The smoothing can take many forms: from simple averaging to various kinds of lowpass digital filtering.

The simplest form of smoothing is averaging (sometimes called "boxcar" smoothing). You can decimate by averaging some number of points in your original data set. If you have 1000 points, you can create a 100 point representation by averaging every set of 10 points down to one point. For example, make a 1000 point test waveform:

```
Make/O/N=1000 wave0
SetScale x 0, 5, wave0
wave0 = sin(x) + gnoise(.1)
```

Now, make a 100 point waveform to contain the result of the decimation:

```
Make/O/N=100 wave1
SetScale x 0, 5, wave1
wave1 = mean(wave0, x, x+9*deltax(wave0))
```



Notice that the output wave, wave1, has one tenth as many points as the input wave.

The averaging is done by the waveform assignment

```
wave1 = mean(wave0, x, x+9*deltax(wave0))
```

This evaluates the right-hand expression 100 times, once for each point in wave1. The symbol "x" returns the X value of wave1 at the point being evaluated. The right-hand expression returns the average value of wave0 over the segment that corresponds to the point in wave1 being evaluated.

It is essential that the X values of the output wave span the same range as the X values of the input range. In this simple example, the SetScale commands satisfy this requirement.

Results similar to the example above can be obtained more easily using the **Resample** operation (page V-803) and dialog.

Resample is based on a general sample rate conversion algorithm that optionally interpolates, low-pass filters, and then optionally decimates the data by omission. The lowpass filter can be set to "None" which averages an odd number of values centered around the retained data points. So decimation by a factor of 10 would involve averaging 11 values centered around every 10th point.

The decimation by averaging above can be changed to be 11 values centered around the retained data point instead 10 values from the beginning of the retained data point this way:

```
Make/O/N=100 wave1Centered
SetScale x 0, 5, wave1Centered
wave1Centered = mean(wave0, x-5*deltax(wave0), x+5*deltax(wave0))
```

Each decimated result (each average) is formed from different values than wave1 used, but it isn't any less valid as a representation of the original data.

Using the Resample operation:

```
Duplicate/O wave0, wave2
Resample/DOWN=10/WINF=None/N=11 wave2       // no /UP means no interpolation
```

gives nearly identical results to the wave1Centered = mean(…) computation, the exceptions being only the initial and final values, which are simple end-effect variations.

The /WINF and /N flags of Resample define simple low-pass filtering options for a variety of decimation-by-smoothing choices. The default /WINF=Hanning window gives a smoother result than /WINF=None. See the **WindowFunction** operation (page V-1097) for more about these window options.

See **Multidimensional Decimation** on page II-98 for a discussion of decimating 2D and higher dimension waves.

Miscellaneous Operations

WaveTransform

When working with large amounts of data (many waves or multiple large waves), it is frequently useful to replace various wave assignments with wave operations which execute significantly faster. The **WaveTransform** operation (see page V-1090) is designed to help in these situations. For example, to flip the data in a 1D wave you can execute the following code:

```
Function flipWave(inWave)
   wave inWave

   Variable num=numPnts(inWave)
   Variable n2=num/2
   Variable i,tmp
   num-=1
   Variable j
   for(i=0;i<n2;i+=1)
      tmp=inWave[i]
      j=num-i
      inWave[i]=inWave[j]
      inWave[j]=tmp
   endfor
End
```

You can obtain the same result much faster using the command:

```
WaveTransform/O flip, waveName
```

In addition to “flip”, WaveTransform can also fill a wave with point index or the inverse point index, shift data points, normalize, convert to complex-conjugate, compute the squared magnitude or the phase, etc.

For multi-dimensional waves, use MatrixOp instead of WaveTransform. See **Using MatrixOp** on page III-140 for details.

The Compose Expression Dialog

The Compose Expression item in the Analysis menu brings up the Compose Expression dialog.

This dialog generates a command that sets the value of a wave, variable or string based on a numeric or string expression created by pointing and clicking. Any command that you can generate using the dialog could also be typed directly into the command line.

The command that you generate with the Compose Expression dialog consists of three parts: the destination, the assignment operator and the expression. The command resembles an equation and is of the form:

```
<destination> <assignment-operator> <expression>
```

For example:

```
wave1 = K0 + wave2            // a wave assignment command
K0 += 1.5 * K1                // a variable assigment command
str1 = "Today is" + date()    // a string assignment command
```

Table Selection Item

The Destination Wave pop-up menu contains a “_table selection_” item. When you choose “_table selection_”, Igor assigns the expression to whatever is selected in the table. This could be an entire wave or several entire waves, or it could be a subset of one or more waves.

To use this feature, start by selecting in a table the numeric wave or waves to which you want to assign a value. Next, choose Compose Expression from the Analysis menu. Choose “_table selection_” in the Destination Wave pop-up menu. Next, enter the expression that you want to assign to the waves. Notice the command that Igor has created which is displayed in the command box toward the bottom of the dialog. If you have selected a subset of a wave, Igor will generate a command for that part of the wave only. Finally, click Do It to execute the command.

Create Formula Checkbox

The Create Formula checkbox in the Compose Expression dialog generates a command using the := operator rather than the = operator. The := operator establishes a dependency such that, if a wave or variable on the right hand side of the assignment statement changes, Igor will reassign values to the destination (left hand side). We call the right hand side a formula. Chapter IV-9, **Dependencies**, provides details on dependencies and formulas.

Matrix Math Operations

There are four basic methods for performing matrix calculations: normal wave expressions, the Matrix*XXX* operations, the **MatrixOp** operation, and the **MatrixSparse** operation.

Normal Wave Expressions

You can add matrices to other matrices and scalars using normal wave expressions. You can also multiply matrices by scalars. For example:

```
Make matA={{1,2,3},{4,5,6}}, matB={{7,8,9},{10,11,12}}
matA = matA+0.01*matB
```

gives new values for

```
matA = {{1.07,2.08,3.09},{4.1,5.11,6.12}}
```

Matrix*XXX* Operations

A number of matrix operations are implemented in Igor. Most have names starting with the word “Matrix”. For example, you can multiply a series of matrices using the **MatrixMultiply** operation (page V-548). This operation. The /T flag allows you to specify that a given matrix’s data should be transposed before being used in the multiplication.

Many of Igor’s matrix operations use the LAPACK library. To learn more about LAPACK see:

LAPACK Users’ Guide, 3rd ed., SIAM Publications, Philadelphia, 1999.

or the LAPACK web site:

```
http://www.netlib.org/lapack/lug/lapack_lug.html
```

Unless noted otherwise, LAPACK routines support real and complex, IEEE single-precision and double-precision matrix waves. Most matrix operations create the variable V_flag and set it to zero if the operation is successful. If the flag is set to a negative number it indicates that one of the parameters passed to the LAPACK routines is invalid. If the flag value is positive it usually indicates that one of the rows/columns of the input matrix caused the problem.

MatrixOp Operation

The **MatrixOp** operation (page V-550) improves the execution efficiency and simplifies the syntax of matrix expressions. For example, the command

```
MatrixOp matA = (matD - matB x matC) x matD
```

is equivalent to matrix multiplications and subtraction following standard precedence rules.

See **Using MatrixOp** on page III-140 for details.

MatrixSparse Operation

The **MatrixSparse** operation (page V-580) can improve performance and reduce memory utilization for calculations involving large matrices the elements of which are mostly 0. See **Sparse Matrices** on page III-151 for details.

Matrix Commands

Here are the matrix math operations and functions.

General:

```
MatrixCondition(matrixA)
MatrixConvolve coefMatrix, dataMatrix
MatrixCorr [flags] waveA [, waveB]
MatrixDet(matrixA)
MatrixDot(waveA, waveB)
MatrixFilter [flags] Method  dataMatrix
MatrixGLM [/Z] matrixA, matrixB, waveD
MatrixMultiply matrixA[/T], matrixB[/T] [, additional matrices]
MatrixOp [/O] destwave = expression
MatrixRank(matrixA [, maxConditionNumber])
MatrixTrace(matrixA)
MatrixTranspose [/H] matrix
```

EigenValues, eigenvectors and decompositions:

```
MatrixBalance [flags] srcWave
MatrixEigenV [flags] matrixWave
MatrixFactor [flags] srcWave
MatrixGLM matrixA, matrixB, waveD
MatrixInverse [flags] srcWave
MatrixLUD matrixA
MatrixLUDTD srcMain, srcUpper, srcLower
MatrixReverseBalance [flags] scaleWave, eigenvectorsWave
MatrixSchur [/Z] srcMatrix
MatrixSVD matrixA
```

Linear equations and least squares:

```
MatrixGaussJ matrixA, vectorsB
MatrixLinearSolve [flags] matrixA, matrixB
MatrixLinearSolveTD [/Z] upperW, mainW, lowerW, matrixB
MatrixLLS [flags] matrixA, matrixB
MatrixLUBkSub matrtixL, matrixU, index, vectorB
MatrixSolve method, matrixA, vectorB
MatrixSVBkSub matrixU, vectorW, matrixV, vectorB
```

Sparse matrices:

```
MatrixSparse
```

Using MatrixOp

When performing mathematical calculations your first choice may be to write standard wave assignments such as:

```
wave1 = wave2 + wave3
```

When the expression on the right-hand-side (RHS) is complicated or when the waves are large you can gain a significant performance improvement using MatrixOp (short for "matrix operation"). MatrixOp was originally conceived to perform calculations on 2D waves and was later extended to waves of any dimension.

To use the basic form of **MatrixOp** simply prepend its name to the assignment statement:

```
MatrixOp wave1 = wave2 + wave3
```

Although the two commands appear similar, having the general form:

```
destWave = expression
```

they are different in behavior.

A significant difference is that MatrixOp operates on pure array elements without regard to wave scaling and does not support indexing using x, y, z, t, p, q, r, or s on the RHS.

The wave assignment requires that the destination wave exist at the time of execution but MatrixOp creates its destination wave automatically. In these commands:

```
Make/O wave2 = 1/(p+1), wave3 = 1
MatrixOp/O wave1 = wave2 + wave3
```

MatrixOp creates a single precision (SP) wave named wave1 and stores the result in it.

When MatrixOp creates a destination wave, its data type and dimensions depend on the expression on the RHS. In the preceding example, MatrixOp created wave1 as SP because wave2 and wave3 are SP. The rules that MatrixOp uses to determine the data type and dimensions of the destination are discussed below under **MatrixOp Data Promotion Policy** on page III-145.

These rules leads to the following difference between MatrixOp and wave assignments:

```
Make/O wave1 = 42       // wave1 is 128 points wave, all points are set to 42

MatrixOp/O wave1 = 42   // wave1 is now 1 point wave set to 42
```

Assignment statements evaluate the RHS and store the result in a point-by-point manner. Because of this, you sometimes get unexpected results if the destination wave appears on the RHS. In this example, `WaveMin(wave2)` changes during the evaluation of the assignment statement:

```
wave2 = wave2 - WaveMin(wave2)
```

By contrast, MatrixOp evaluates the RHS for all points in the destination before storing anything in the destination wave. Consequently this command behaves as expected:

```
MatrixOp/O wave2 = wave2 - minVal(wave2)
```

Another important difference appears when the RHS involves complex numbers. If you try, for example,

```
Make/O/C cwave2
Make/O wave1, wave3
wave1 = cwave2 + wave3
```

you get an error, "Complex wave used in real expression".

By contrast, MatrixOp creates the destination as complex so this command works without error:

```
MatrixOp/O wave1 = cwave2 + wave3
```

In this example the RHS mixes real and complex waves, something MatrixOp handles without problems.

In addition to the standard math operators, MatrixOp supports a list of functions that can be applied to operands on the RHS. Examples are `abs`, `sin`, `cos`, `mean`, `minVal` and `maxVal`. There are many more described in the **MatrixOp** reference documentation and listed below under **MatrixOp Functions by Category** on page III-149.

MatrixOp Data Tokens

A MatrixOp command has the general form:

```
MatrixOp [flags] destWave = expression
```

The expression on the RHS is a combination of data tokens with MatrixOp operators and MatrixOp functions. A data token is one of the following:

- A literal number
- A numeric constant declared with the Constant keyword
- A numeric local variable
- A numeric global variable
- A numeric wave
- A numeric wave layer
- The result from a MatrixOp function

You can not call a user-defined function or external function from *expression*.

This function illustrates each type of data token:

```
Constant kConstant = 234
Function Demo()
   // Literal number
   MatrixOp/O dest = 123

   // Constant
   MatrixOp/O dest = kConstant

   // Local Variable
   Variable localVariable = 345
   MatrixOp/O dest = localVariable

   // Global Variable
   Variable/G root:gVar = 456
   NVAR globalVariable = root:gVar
   MatrixOp/O dest = globalVariable

   // Wave
   Make/O/N=(3,3) mat = p + 10*q
   MatrixOp/O tMat = mat^t

   // Wave layer
   Make/O/N=(3,3,3) w3D = p + 10*q + 100*r
   MatrixOp/O layer1 = w3D[][][1]

   // Output from a MatrixOp function
   MatrixOp/O invMat = inv(mat)
End
```

MatrixOp Wave Data Tokens

MatrixOp uses only the numeric data and the dimensions of waves. All other properties, in particular wave scaling, are ignored. If wave scaling is important in your application, follow MatrixOp with **CopyScales** or **SetScale** or use a wave assignment statement instead of MatrixOp.

From the command line you can reference a wave in *expression* using the simple wave name, the partial data folder path to the wave or the full data folder path to a wave. In a user-defined function you can reference a wave using a simple wave name or a wave reference variable pointing to an existing wave. We call all of these methods of referencing waves “wave references”.

A wave data token consists of a wave reference optionally qualified by indices that identify a subset of the wave. For example:

```
Function Demo()
   // Creates automatic wave reference for w3D
   Make/O/N=(3,4,5) w3D = p + 10*q + 100*r

   MatrixOp/O dest = w3D            // dest is a 3D wave
   MatrixOp/O dest = w3D[0][1][2]   // dest is a 1D wave with 1 point
   MatrixOp/O dest = w3D[0][1][]    // dest is a 2D wave with 1 layer
End
```

MatrixOp supports only two kinds of subsets of waves:

- A subset that evaluates to a scalar (a single value)
- A subset that evaluates to one or more layers (2D arrays)

Subsets that evaluate to a row (`w3D[1][][2]`) or a column (`w3D[][1][2]`) are not supported.

Scalars: The following expressions evaluate to scalars:

`wave1d[a]` — *a* is a literal number or a local variable. MatrixOp clips the index *a* to the valid range for *wave1d*. The expression evaluates to a scalar equal to the referenced wave element.

`wave2d[a][b]` — *a* and *b* are literal numbers or local variables. MatrixOp clips the indices to the valid range of the corresponding dimensions. The expression evaluates to a scalar equal to the referenced wave element.

`wave3d[a][b][c]` — *a*, *b* and *c* are literal numbers or local variables. MatrixOp clips the indices to the valid range of the corresponding dimensions. The expression evaluates to a scalar equal to the referenced wave element.

Layers: The following evaluate to one or more 2D layers:

`wave3d[][][a]` — Layer *a* from the 3D wave is treated as a 2D matrix. The first and second bracket pairs must be empty. MatrixOp clips *a* to the valid range of layers. The result is a 2D wave.

`wave3d[][][a,b]` — *expression* is evaluated for all layers between layer *a* and layer *b*. MatrixOp clips *a* and *b* to the valid range of layers. The result is a 3D wave.

`wave3d[][][a,b,c]` — *expression* is evaluated for layers starting with layer *a* and increasing to layer *b* incrementing by *c*. Layers are clipped to the valid range and *c* must be a positive integer. The result is a 3D wave.

You can use waves of any dimensions as parameters to MatrixOp functions. For example:

```
Make/O/N=128 wave1d = x
MatrixOp/O outWave = exp(wave1d)
```

MatrixOp does not support expressions that include the same 3D wave on both sides of the equation:

```
MatrixOp/O wave3D = wave3D + 3   // Not allowed
```

Instead use:

```
MatrixOp/O newWave3D = wave3D + 3
```

You can use any combination of data types for operands. In particular, you can mix real and complex types in *expression*. MatrixOp determines data types of inputs and the appropriate output data type at runtime without regard to any type declaration such as Wave/C.

MatrixOp functions can create certain types of 2D data tokens. Such tokens are used on the RHS of the assignment. The const and zeroMat functions create matrices of specified dimensions containing fixed values. The identity function creates identity matrixes and triDiag creates a tridiagonal matrix from 1D input waves. The **rowRepeat** and colRepeat functions also construct matrices from 1D waves. The setRow, setCol and setOffDiag functions transfer data from 1D waves to elements of 2D waves.

MatrixOp and Wave Dimensions

MatrixOp was designed to optimize operations on 2D arrays (matrices) but it also supports other wave dimensions in various expressions. However it does not support zero point waves.

A 1D wave is treated as a matrix with one column. 3D and 4D waves are treated as arrays of layers so their assignments are processed on a layer-by-layer basis. For example:

```
Make/O/N=(4,5) wave2 = q
Make/O/N=(4,5,6) wave3 = r
MatrixOp/O wave1 = wave2 * wave3       // 2D multiplies 3D one layer at a time
```

wave1 winds up as a 3D wave of dimensions (4,5,6). Each layer of wave1 contains the contents of the corresponding layer of wave3 multiplied on an element-by-element basis by the contents of wave2.

Exceptions for layer-by-layer processing are special MatrixOp functions such as beam and transposeVol.

Some binary operators have dimensional restrictions for their wave operands. For example, matrix multiplication (wave2 x wave3) requires that the number of columns in wave2 be equal to the number of rows in wave3. Regular multiplication (wave2*wave3) requires that the number of rows and the columns of the two be equal. For example,

```
Make/O/N=(4,6) wave2
Make/O/N=(3,8) wave3
MatrixOp/O wave1 = wave2 * wave3       // Error: "Matrix Dimensions Mismatch"
```

The exception to this rule is when the righthand operand is a single wave element:

```
MatrixOp/O wave1 = wave2 * wave3[2][3] // Equivalent to scalar multiplication
```

Some MatrixOp functions operate on each column of the matrix and result in a 1 row by N column wave which may be confusing when used elsewhere in Igor. If what you need is an N row 1D wave you can redimension the wave or simply include a transpose operator in the MatrixOp command:

```
Make/O/N=(4,6) wave2=gnoise(4)
MatrixOp/O wave1=sumCols(wave2)^t      // wave1 is a 1D wave with 6 rows
```

MatrixOp Operators

MatrixOp defines 8 binary operators and two postfix operators which are available for use in the RHS expression. The operators are listed in the Operators section of the reference documentation for **MatrixOp** on page V-550.

MatrixOp does not support operator combinations such as +=.

The basic operators, +, -, *, and /, operate in much the same way as they would in a regular wave assignment with one exception: when the - or / operation involves a matrix and a scalar, it is only supported if the matrix is the first operand and the scalar is the second. For example:

```
Make/O wave2 = 1
Variable var1 = 7
MatrixOp/O wave1 = wave2 - var1  // OK: Subtract var1 to each point in wave2
```

```
MatrixOp/O wave1 = var1 - wave2  // Error: Can't subtract a matrix from a scalar
MatrixOp/O wave1 = var1 / wave2  // Error: Can't divide a scalar by a matrix
```

Division of a scalar by a matrix can be accomplished using the reciprocal function as in:

```
MatrixOp/O wave1 = scalar * rec(wave2)
```

The dot operator . is used to compute the generalized dot product:

```
MatrixOp/O wave1 = wave2 . wave3    // Spaces around '.' are optional
```

The x operator designates matrix-matrix multiplication.

```
MatrixOp/O wave1 = wave2 x wave3    // Spaces around 'x' are required!
```

The logical operators && and `||` are restricted to real-valued data tokens and produce unsigned byte numeric tokens with the value 0 or 1.

The two postfix operators ^t (matrix transpose) and ^h (Hermitian transpose) operate on the first token to their left:

```
MatrixOp/O wave1 = wave2^t + wave3
```

Tthe transpose operation has higher precedence and therefore executes before the addition.

The left token may be a compound token as in:

```
MatrixOp/O wave1 = sumCols(wave2)^t
```

MatrixOp supports the ^ character only in the two postfix operators ^t and ^h. For exponentiation use the *powR* and `powC` functions.

MatrixOp Multiplication and Scaling

MatrixOp provides a number of multiplication and scaling capabilities. They include matrix-scalar multiplication:

```
MatrixOp/O wave1 = wave2 * scalar   // Equivalent to a wave assignment
```

and wave-wave multiplication:

```
MatrixOp wave1 = wave2 * wave3      // Also includes layer-by-layer support
```

and matrix-matrix multiplication:

```
MatrixOp wave1 = wave2 x wave3
```

The latter is equivalent to the **MatrixMultiply** operation with the convenience of allowing you to write and execute complicated compound expressions in one line.

MatrixOp adds two specialized scaling functions that are frequently used. The `scaleCols` function multiplies each column by a different scalar and the `scale` function scales its input to a specified range.

MatrixOp Data Rearrangement and Extraction

MatrixOp is often used to rearrange data in a matrix or to extract a subset of the data for further calculation. You can extract an element or a layer from a wave using square-bracket indexing:

```
// Extract scalar from point a of the wave
MatrixOp destWave = wave1d[a]

// Extract scalar from element a,b of the wave
MatrixOp destWave = wave2d[a][b]

// Extract scalar from element a,b,c of the wave
MatrixOp destWave = wave3d[a][b][c]
```

```
// Extract layer a from the 3D wave
MatrixOp destWave = wave3d[][][a]
```

You can also extract layers from a 3D wave starting with layer a and increasing the layer number up to layer b using increments c:

```
MatrixOp destWave = wave3d[][][a,b,c]
```

a, b and c must be scalars. Layers are clipped to the valid range and c must be a positive integer.

If you need to loop over rows, columns, layers or chunks it is often useful to extract the relevant data using the MatrixOp functions `row`, `col`, `layer` and `chunk`. You can extract matrix diagonals using `getDiag`. You can use `subRange` to extract more than one row or more than one column.

The **Rotate** operation works on 1D waves. MatrixOp extends this to higher dimensions with the functions: `rotateRows`, `rotateCols`, `rotateLayers`, and `rotateChunks`.

MatrixOp `transposeVol` is similar to **ImageTransform** `transposeVol` but it supports complex data types.

The MatrixOp `redimension` function is designed to convert 1D waves into 2D arrays but it can also extract data from higher-dimensional waves.

MatrixOp Data Promotion Policy

MatrixOp chooses the data type of the destination wave based on the data types and operations used in the expression on the RHS. Here are some examples:

```
Make/O/B/U wave2, wave3             // Create two unsigned byte waves

MatrixOp/O wave1 = wave2            // wave1 is unsigned byte

MatrixOp/O wave1 = wave2 + wave3    // wave1 is unsigned word (16 bit)

MatrixOp/O wave1 = wave2 * wave3    // wave1 is unsigned word (16 bit)

MatrixOp/O wave1 = wave2 / wave3    // wave1 is SP

MatrixOp/O wave1 = magsqr(wave2)    // wave1 is SP
```

The examples show the destination wave's data type changing to represent the range of possible results of the operation. MatrixOp does not inspect the data in the waves to determine if the promotion is required for the specific waves.

Igor variables are usually treated as double precision data tokens. MatrixOp applies special rules for variables that contain integers. Here is an example:

```
Make/O/B/U wave2                    // Create unsigned byte wave
Variable vv = 2.1                   // Variable containing DP value
MatrixOp/O wave1 = wave2*vv         // wave1 is DP
```

Now change the variable to store various integers:

```
vv = 2
MatrixOp/O wave1 = wave2*vv         // wave1 is unsigned word (16 bit)
vv = 257
MatrixOp/O wave1 = wave2*vv         // wave1 is unsigned integer (32 bit)
vv = 65538

MatrixOp/O wave1 = wave2*vv         // wave1 is DP
```

These examples show that MatrixOp represents the variable `vv` as a token with a data type that fits it contents. If the variable does not contain an integer value the token is treated as DP.

MatrixOp is convenient for complex math calculations because it automatically creates real or complex destination waves as appropriate. For example:

```
Make/O/C wave2, wave3                        // SP complex
Make/O wave4                                 // SP real
MatrixOp/O wave1 = wave2 * wave3 * wave4     // wave1 is SP complex
MatrixOp/O wave1 = abs(wave2*wave3) * wave4  // wave1 is SP real
```

An exception to the complex policy is the `sqrt` function which returns NaN when its input is real and negative.

If you want to restrict data type promotion you can use the /NPRM flag:

```
Make/O/B/U wave2, wave3
MatrixOp/O wave1 = wave2 * wave3    // wave1 is unsigned word (16 bit).
```

A number of MatrixOp functions convert integer tokens to SP prior to processing and are not affected by the /NPRM flag. These include all the trigonometric functions, `chirp` and `chirpZ`, `fft`, `ifft`, normalization functions, `sqrt`, `log`, `exp` and forward/backward substitutions.

MatrixOp Compound Expressions

You can use compound expressions with most MatrixOp functions that operate on regular data tokens. In a compound expression you pass the result from one MatrixOp operator or function as the input to another. For example:

```
MatrixOp/O wave1 = sum(abs(wave2-wave3))
```

This is particularly convenient for transformations and filtering:

```
MatrixOp/O wave1 = IFFT(FFT(wave1,2)*filterWave,3)
```

Some MatrixOp functions, such as `beam` and `transposeVol`, do not support compound expressions because they require input that has more than two-dimensions while compound expressions are evaluated on a layer by layer basis:

```
Make/O/N=(10,20,30) wave3
MatrixOp/O wave1 = beam(wave3+wave3,5,5)  // Error: Bad MatrixOp token
MatrixOp/O wave1 = beam(wave3,5+1,5)      // Compound expression allowed here
```

MatrixOp Quaternion Data Tokens

A quaternion {w,x,y,z} consists of an amplitude w and three vector components x, y, and z where:

w = a, x = bi, y = cj, z = dk

a, b, c and d are real numbers. i, j, and k are the fundamental quaternion units, analogous to i in complex numbers.

Quaternions are often used to represent rotation in 3D graphics. Igor Pro 8 added support for quaternions via MatrixOp functions.

Quaternion arithmetic has its own rules. For example, multiplication is not commutative (ij is not equal to ji).

You can do quaternion arithmetic with MatrixOp by creating and then manipulating quaternion tokens. For example:

```
Function QuaternionMultiplicationDemo()
   // Create waves containing the w, x, y, and z values of quaternions
   Make/FREE wR = {1, 0, 0, 0}
   Make/FREE wI = {0, 1, 0, 0}
   Make/FREE wJ = {0, 0, 1, 0}
   Make/FREE wK = {0, 0, 0, 1}

   MatrixOp/O rW = quat(wR) * quat(wI)     // rW is the result wave
   Printf "1i = {%g,%g,%g,%g} (i)\r", rW[0], rW[1], rW[2], rW[3]

   MatrixOp/O rW = quat(wI) * quat(wI)
   Printf "ii = {%g,%g,%g,%g} (-1)\r", rW[0], rW[1], rW[2], rW[3]

   MatrixOp/O rW = quat(wI) * quat(wJ)
   Printf "ij = {%g,%g,%g,%g} (k)\r", rW[0], rW[1], rW[2], rW[3]

   MatrixOp/O rW = quat(wJ) * quat(wI)
   Printf "ji = {%g,%g,%g,%g} (-k)\r", rW[0], rW[1], rW[2], rW[3]
End
```

In this example, wR, wI, wJ and wK are waves containing the w, x, y, and z values of quaternions. rW is the result wave from MatrixOp. quat(wR), quat(wI) and quat(wJ) are MatrixOp quaternion tokens. They exist only during the execution of a MatrixOp command. MatrixOp uses quaternion arithmetic to evaluate expressions containing quaternion tokens. After the righthand side has been evaluated, MatrixOp stores the result in a wave. Functions that return quaternion coordinates, such as quat and matrixToQuat, return a 4-element wave containing the w, x, y and z values.

You can also create a quaternion token from a scalar or from a wave containing x, y, and z values:

```
Function QuaternionTokenDemo()
   Make/FREE wI = {0, 1, 0, 0}       // w, x, y, z
   Make/FREE wXYZ = {1, 0, 0}        // x, y, z

   MatrixOp/O rW = quat(wI) * quat(wXYZ)
   Printf "ii = {%g,%g,%g,%g} (-1)\r", rW[0], rW[1], rW[2], rW[3]

   MatrixOp/O rW = quat(wI) * quat(wXYZ) * quat(3)
   Printf "3ii = {%g,%g,%g,%g} (-3)\r", rW[0], rW[1], rW[2], rW[3]
End
```

quat(wXYZ) converts the wave containing x, y, and z to a pure imaginary quaternion whose w component is 0. wXZY can be a 3x1 wave as in this example or it can be a 1x3 wave; both produce the same quaternion token.

quat(3) converts the scalar value 3 to a real quaternion whose x, y and z components are 0.

The input to quat must be real, not complex.

The quat function does not normalize the quaternion. It is normalized when it is used as an input to another MatrixOp quaternion operation.

MatrixOp supports the following quaternion functions:

quat, quatToMatrix, quatToAxis, axisToQuat, quatToEuler, and slerp

These are documented in the reference documenation for MatrixOp.

This example shows how to use quatToEuler to generale Euler angles from a quaternion:

```
Function QuaternionEulerDemo()
   Make/FREE wI = {0, 1, 0, 0}
   MatrixOp/O rW = quatToEuler(quat(wI), 123)
   Printf "Euler angles = {%g,%g,%g}\r", rW[0], rW[1], rW[2]
End
```

MatrixOp Multithreading

Common CPUs are capable of running multiple threads. Some calculations are well suited to run in parallel. There are a several ways to take advantage of multithreading using MatrixOp:

- User-created preemptive threads

  MatrixOp is thread-safe so you can call it from preemptive threads. See **ThreadSafe Functions and Multitasking** on page IV-329 for details.
- Layer threads

  If you are evaluating expressions that involve multiple layers you can use the /NTHR flag to run each layer calculation in a separate thread. When you account for thread overhead it makes sense to use /NTHR when the per-layer calculations are on the order of 1 million CPU cycles or more.
- Internal multithreading of operations or functions

  Some MatrixOp functions are automatically multithreaded for SP and DP data. These include matrix-matrix multiplication, trigonometric functions, `hypot`, `sqrt`, `erf`, `erfc`, `inverseErf`, and `inverseErfc`. The **MultiThreadingControl** operation provides fine-tuning of automatic multithreading but you normally do not need to tinker with it.

MatrixOp Performance

In most situations MatrixOp is faster than a wave assignment statement or **FastOp**. However, for small waves the extra overhead may make it slower.

MatrixOp works fastest on floating point data types. For maximum speed, convert integer waves to single-precision floating point before calling MatrixOp.

Some MatrixOp expressions are evaluated with automatic multithreading. See **MatrixOp Multithreading** on page III-148 for details.

MatrixOp Optimization Examples

The section shows examples of using MatrixOp to improve performance.

- Replace matrix manipulation code with MatrixOp calls. For example, replace this:

```
Make/O/N=(vecSize,vecSize) identityMatrix = p==q ? 1 : 0
MatrixMultiply matB, matC
identityMatrix -= M_Product
MatrixMultiply identityMatrix, matD
MatrixInverse M_Product
Rename M_Inverse, matA
```

  with:

```
MatrixOp matA = Inv((Identity(vecSize) - matB x matC) x matD)
```

- Replace waveform assignment statements with MatrixOp calls. For example, replace this:

```
Duplicate/O wave2,wave1
wave1 = wave2*2
```

  with:

```
MatrixOp/O wave1 = wave2*2
```

- Factor and compute only once any repeated sub-expressions. For example, replace this:

```
MatrixOp/O wave1 = var1*wave2*wave3
MatrixOp/O wave4 = var2*wave2*wave3
```

  with:

```
MatrixOp/O/FREE tmp = wave2*wave3   // Compute the product only once
MatrixOp/O wave1 = var1*tmp
MatrixOp/O wave4 = var2*tmp
```

- Replace instances of the ?: conditional operator in wave assignments with MatrixOp calls. For example, replace this:

  ```
  wave1 = wave1[p]==0 ? NaN : wave1[p]
  ```

  with:

  ```
  MatrixOp/O wave1 = setNaNs(wave1,equal(wave1,0))
  ```

MatrixOp Functions by Category

This section lists the MatrixOp functions by category to help you select the appropriate function.

Sparse Matrices

Some applications require manipulation of large matrices the elements of which are mostly 0. In these applications, the use of sparse matrices can improve performance and reduce memory utilization.

Igor supports sparse matrices through the **MatrixSparse** operation which was added in Igor Pro 9.00. It uses the Intel Math Kernel Library Sparse BLAS routines and employs the libraries terminology and conventions.

Sparse Matrix Concepts

In this section we discuss some basic sparse matrix concepts as they apply to Igor. For a general primer on sparse matrices, see <https://en.wikipedia.org/wiki/Sparse_matrix>.

A normal matrix in Igor is a 2D wave in which each element of the matrix is stored in memory in a regular pattern of rows and columns. In the context of sparse matrices, we use the term "dense matrix" to refer to a normal matrix.

A sparse matrix in Igor is represented by a set of three 1D waves which define the non-zero elements of the matrix. Igor supports three formats, described below, for sparse matrix representation. The formats are called COO (coordinate format), CSC (compressed column format), and CSR (compressed row format). In the following sections, we use the term "sparse matrix" to mean a matrix defined by three 1D waves according to one of these formats.

You can create a sparse matrix equivalent to a dense matrix using the MatrixSparse TOCOO, TOCSR, and TOCSC conversion operations. Alternatively you can create it directly by creating three 1D waves and storing the appropriate values in them. You can create a dense matrix equivalent to a sparse matrix using TODENSE conversion operation.

MatrixSparse supports a number of math operations such as ADD (add two sparse matrices), MV (multiply a sparse matrix by a vector), SMSM (multiply two sparse matrices), and TRSV (solve a system of linear equations).

Sparse matrix operations work on single-precision and double-precision real and complex data. They do not support INFs or NaNs.

Sparse Matrix Formats

A sparse matrix in Igor is represented by a set of three 1D waves which define the non-zero elements of the matrix. Igor supports three sparse matrix storage formats named COO (coordinate format), CSR (compressed row format), and CSC (compressed column format).

MatrixSparse uses the CSR format except for operations that convert between formats.

For the purpose of illustrating these formats, we will use the example dense matrix from the Wikipedia sparse matrix web page:

```
0   0   0   0
5   8   0   0
0   0   3   0
0   6   0   0
```

The term nnz is short for "number of non-zero values" and appears below and in the documentation for MatrixSparse. In this example, nnz = 4.

COO Sparse Matrix Storage Format

"COO" is the shorthand name for "coordinate format". It is conceptually the simplest format and stores each non-zero matrix value along with the corresponding zero-based row and column indices.

In Igor terminology, COO format uses the following three waves:

W_COOValues stores each non-zero value in the matrix.

W_COORows stores the zero-based row index for each non-zero value in the matrix.

W_COOColumns stores the zero-based column index for each non-zero value in the matrix.

Our example matrix is represented in COO format like this:

```
W_COOValues:    5   8   3   6
W_COORows:      1   1   2   3
W_COOColumns:   0   1   2   1
```

These values can be read vertically as a set of ordered triplets: (5,1,0), (8,1,1), (3,2,2), and (6,3,1). The last of these tells us that the value 6 is the value of row 3, column 1.

The wave names W_COOValues, W_COORows, and W_COOColumns are used by MatrixSparse when it creates an output sparse matrix in COO format. When you specify an input sparse matrix, you can use any wave names.

CSR Sparse Matrix Storage Format

"CSR" is the shorthand name for "compressed sparse row". It is widely used because it is more efficient in terms of memory use and computational speed than COO.

MatrixSparse uses the CSR format except for operations that convert between formats.

In CSR format, the three 1D waves store the non-zero values, the zero-based column indices, and a "pointer" vector which is used to determine in which row each value appears.

In Igor terminology, CSR format uses the following three waves:

W_CSRValues stores each non-zero value in the matrix.

W_CSRColumns stores the zero-based column index for each non-zero value in the matrix.

W_CSRPointerB stores indices into W_CSRValues which are used to determine in which row a particular value appears.

Our example matrix is represented in CSR format like this:

```
W_CSRValues:    5   8   3   6
W_CSRColumns:   0   1   2   1
W_CSRPointerB:  0   0   2   3   4
```

Unlike the case of COO format, these values can not be read vertically as a set of ordered triplets. CSR is a bit more complicated.

The first two of these waves can be read as ordered pairs: (5,0), (8,1), (3,2), and (6,1). Each ordered pair specifies a value (e.g., 6) and a column (e.g., 1) but does not tell us in which row the value appears.

The third wave, W_CSRPointerB, is used to determine in which row a given value appears. It contains one index for each row in the represented matrix plus an additional index which is nnz, the number of non-zero values in the matrix. W_CSRPointerB[i] is the zero-based index in W_CSRValues of the first non-zero value in row i.

In this example, we can interpret the values of W_CSRPointerB as follows:

```
W_CSRPointerB[0] = 0    // First value for row 0 is at index 0 in W_CSRValues *
W_CSRPointerB[1] = 0    // First value for row 1 is at index 0 in W_CSRValues
W_CSRPointerB[2] = 2    // First value for row 2 is at index 2 in W_CSRValues
W_CSRPointerB[3] = 3    // First value for row 3 is at index 3 in W_CSRValues
W_CSRPointerB[4] = 4    // Number of non-zero values in W_CSRValues is 4
```

* There are no non-zero values in row 0 so W_CSRPointerB[0] is the same as W_CSRPointerB[1].

When you specify a sparse matrix in CSR format to the MatrixSparse operation, the last element of W_CSRPointerB, specifying nnz, is optional and you can omit it.

The wave names W_CSRValues, W_CSRColumns, and W_CSRPointerB are used by MatrixSparse when it creates an output sparse matrix in CSR format. When you specify an input sparse matrix, you can use any wave names.

CSC Sparse Matrix Storage Format

"CSC" is the shorthand name for "compressed sparse column". It is more efficient in terms of memory use and computational speed than COO.

In CSC format, the three 1D waves store the non-zero values, the zero-based row indices, and a "pointer" vector which is used to determine in which column each value is to be stored.

In Igor terminology, CSC format uses the following three waves:

W_CSCValues stores each non-zero value in the matrix.

W_CSCRows stores the zero-based row indices for each non-zero value in the matrix.

W_CSCPointerB stores indices into W_CSCValues which are used to determine in which column a particular value appears.

The W_CSCPointerB wave works in CSC in a manner analogous to how W_CSRPointerB in CSR.

When you specify a sparse matrix in CSC format to the MatrixSparse operation, the last element of W_CSCPointerB, specifying nnz, is optional and you can omit it.

The wave names W_CSCValues, W_CSCRows, and W_CSCPointerB are used by MatrixSparse when it creates an output sparse matrix in CSC format. When you specify an input sparse matrix, you can use any wave names.

Sparse Matrix Example

To help you get a feel for how the MatrixSparse operation works, here is a simple example showing multiplication of a sparse matrix by a vector using the MatrixSparse MV operation.

```
Function DemoSparseMatrixMV()
   // Define Wikipedia example sparse matrix in CSR format
   Make/FREE/D values = {5, 8, 3, 6}   // Double-precision floating point
   Make/FREE/L columns = {0, 1, 2, 1}  // 64-bit signed integer
   Make/FREE/L ptrB = {0, 0, 2, 3, 4}  // 64-bit signed integer

   // Create a vector
   Make/FREE/D vector = {1, 1, 1, 1}   // Double-precision floating point

   // Multiply the sparse matrix by the vector
   MatrixSparse rowsA=4, colsA=4, csrA={values,columns,ptrB}, vectorX=vector,
            operation=MV

   // Create wave references for output sparse matrix
   WAVE W_MV      // Output from MV

   Print          // Prints W_MV[0]= {0,13,3,6}
End
```

The three Make commands at the start define a sparse matrix in CSR format using free waves. The values wave must be single-precision or double-precision floating point, real or complex, without INFs or NaNs. The waves containing indices, columns and ptrB in this case, must be 64-bit signed integer.

The next Make statement creates a vector which must have the same data type as the values wave.

The sparse input matrix is defined by the rowsA, colsA, and csrA keywords.

The input vector is specified by the vectorX keyword.

The operation keyword specifies the operation to be performed, MV in this case.

The output in this case is a wave named W_MV created in the current directory. It is a vector with the same data type as the values wave.

Different MatrixSparse operations require different inputs and create different outputs.

List of MatrixSparse Operations

Here are the operations supported by MatrixSparse.

Operation	What It Does
ADD	Adds two sparse matrices producing a sparse output matrix. See **MatrixSparse ADD** on page III-157 for details.
MM	Computes the product of a sparse matrix and a dense matrix producing a dense output matrix. See **MatrixSparse MM** on page III-157 for details.
MV	Computes the product of a sparse matrix and a vector producing a sparse output matrix. See **MatrixSparse MV** on page III-158 for details.
SMSM	Computes the product of two sparse matrices producing a sparse output matrix. See **MatrixSparse SMSM** on page III-158 for details.
TOCOO	Produces a sparse output matrix in COO format equivalent to the input matrix which may be in dense, CSC, or CSR format. See **MatrixSparse TOCOO** on page III-159 for details.
TOCSC	Produces a sparse output matrix in CSC format equivalent to the input matrix which may be in dense, COO, or CSR format. See **MatrixSparse TOCSC** on page III-159 for details.
TOCSR	Produces a sparse output matrix in CSR format equivalent to the input matrix which may be in dense, COO, or CSC format. See **MatrixSparse TOCSR** on page III-160 for details.
TODENSE	Produces a dense output matrix equivalent to the sparse input matrix which may be in COO, CSC, or CSR format. See **MatrixSparse TODENSE** on page III-160 for details.
TRSV	Solves a system of linear equations for a triangular sparse input matrix. See **MatrixSparse TRSV** on page III-161 for details.

MatrixSparse Inputs

Inputs to the MatrixSparse operation are documented and can be understood in terms of the following conceptual matrix, vector, and scalar inputs:

Sparse matrix A is defined by the rowsA and colsA keywords and by one of the cooA, csrA or cscA keywords. In this command, from the DemoSparseMatrixMV example above, the keywords specifying sparse matrix A are highlighted in red:

```
MatrixSparse rowsA=4, colsA=4, csrA={values,columns,ptrB}, vectorX=vector, operation=MV
```

Sparse matrix A is used in all MatrixSparse operations that take one or more sparse matrix inputs. MatrixSparse math operations (ADD, MV, MM, SMSM, TRSV) require that input sparse matrices be in CSR format.

Sparse matrix G is defined by the rowsG and colsG keywords and by one of the cooG, csrG or cscG keywords. Sparse matrix G is used only in MatrixSparse operations that take two sparse matrix inputs (ADD and SMSM). These operations require that input sparse matrices be in CSR format.

Matrix B is defined by the matrixB keyword and is used in MatrixSparse operations that take one or more dense matrix inputs (currently just the MM operation).

Matrix C is defined by the matrixC keyword and is used in MatrixSparse operations that take two dense matrix inputs (currently just the MM operation).

Vector X is defined by the vectorX keyword and is used in MatrixSparse operations that take one or more vector inputs (currently the MM and TRSV operations).

Vector Y is defined by the vectorY keyword and is used in MatrixSparse operations that take two vector inputs (currently just the MV operation).

Alpha and ***alphai*** are defined by the alpha and alphai keywords and are used in all MatrixSparse operations that take one or more scalar inputs (currently the MM, MV, and TRSV operations). Alphai is used only when operating on complex data.

Beta and ***betai*** are defined by the beta and betai keywords and are used in MatrixSparse operations that take two scalar inputs(currently the MM and MV operations). Betai is used only when operating on complex data.

MatrixSparse Operation Data Type

The operation data type is the data type required for all data waves participating in the MatrixSparse command. Here "data waves" means the values wave in the representation of a sparse matrix and the matrix wave representing a dense matrix.

If a given MatrixSparse command takes sparse matrix A as an input then the values wave (the first wave specified by the cooA, cscA, or csrA keywords) determines the operation data type. If the command does not take sparse matrix A then the matrix B wave (specified by the matrixB keyword) determines the operation data type.

If there are multiple input data waves, such as for the ADD operation which adds two sparse matrices, the data type of all input data waves must be the same.

The operation data type must be single-precision or double-precision floating point and can be real or complex. MatrixSparse does not support waves containing NaNs or INFs.

Output waves are created using the operation data type.

MatrixSparse math operations (ADD, MV, MM, SMSM, TRSV) require that input sparse matrices be in CSR format. The math operations that return sparse matrices (ADD, SMSM) create output sparse matrices in CSR format.

The conversion operations (TOCOO, TOCSC, TOCSR, TODENSE) accept inputs in COO, CSC, CSR, or dense formats.

MatrixSparse Index Data Type

Index waves, containing row or column indices or indices into values waves (i.e., pointer waves), must be signed 64-bit integer waves which are typically created using Make/L.

MatrixSparse Transformations

You can optionally tell MatrixSparse to operate on a transformed version of an input sparse matrix. The available transformations are named T for transpose, H for Hermitian, and N for no transformation (default).

The opA keyword tells MatrixSparse to operate on a transformed version of sparse matrix A. For example this command:

```
MatrixSparse rowsA=4, colsA=4, csrA={values,columns,ptrB}, opA=T,
            vectorX=vector, operation=MV
```

operates on a transposed version of sparse matrix A.

The opG keyword tells MatrixSparse to operate on a transformed version of sparse matrix G.

Optional Sparse Matrix Information

The MatrixSparse sparseMatrixType keyword allows you to provide optional information characterizing the sparse matrix inputs. If you know the characteristics of a sparse matrix input, you can use sparseMatrixType to pass this information to MatrixSparse. This can improve performance.

The syntax of the sparseMatrixType keyword is:

```
sparseMatrixType={smType,smMode,smDiag}
```

All of the parameters are keywords.

smType: GENERAL, SYMMETRIC, HERMITIAN, TRIANGULAR, DIAGONAL, BLOCK_TRIANGULAR, or BLOCK_DIAGONAL.

smMode: LOWER or UPPER.

smDiag: DIAG or NON_DIAG.

MatrixSparse Operations

This section documents each of the operations supported by **MatrixSparse**. It is assumed that you have read and understood the background material presented under **Sparse Matrices** on page III-151.

The following sections use these abbreviations:

Symbol	Stands For	Specified By Keywords
smA	Sparse matrix A	rowsA, colsA, csrA (1)
smG	Sparse matrix G	rowsG, colsG, csrG (1)
dmB	Dense matrix B	matrixB
dmC	Dense matrix C	matrixC
vX	Vector X	vectorX
vY	Vector Y	vectorY
alpha	Scalar value alpha	alpha and, for complex input, alphai

Symbol	Stands For	Specified By Keywords
beta	Scalar value beta	beta and, for complex input, betai
smOut	Output sparse matrix	N/A (2)

(1) For the matrix format conversion operations TOCOO, TOCSC, TOCSR, and TODENSE, you can also use the cooA and cscA keywords to specify the input sparse matrix in COO or CSC format. For all other operations you must use csrA and csrG to specify the input matrices in CSR format.

(2) The output sparse matrix, smOut, is represented in CSR format by waves W_CSRValues, W_CSRColumns, and W_CSRPointerB.

MatrixSparse ADD

ADD computes the sum of sparse matrices A and G which must be in CSR format. Symbolically:

```
smOut = smA + smG
```

Inputs: Sparse matrix A and sparse matrix G, both in CSR format.

Output: A sparse matrix in CSR format represented by W_CSRValues, W_CSRColumns, and W_CSRPointerB.

MatrixSparse ADD Example

```
Function DemoMatrixSparseADD()
   // Create smA in CSR format
   Make/FREE/D/N=(11) valuesA = {1,25,26,44,16,22,28,5,11,36,42}
   Make/FREE/L/N=(11) columnsA = {0,4,4,7,2,3,4,0,1,5,6}
   Make/FREE/L/N=(6) ptrBA = {0,2,4,4,7,9}

   // Create smG in CSR format
   Make/FREE/D/N=(3) valuesG ={1,2,3}
   Make/FREE/L/N=(3) columnsG ={0,1,2}
   Make/FREE/L/N=(4) ptrBG = {0,1,2,3,3,3,3,3,3}

   // Compute smA + smG
   MatrixSparse rowsA=6, colsA=8, csrA={valuesA,columnsA,ptrBA}, rowsG=6,
            colsG=8, csrG={valuesG,columnsG,ptrBG}, operation=ADD
   WAVE W_CSRValues, W_CSRColumns, W_CSRPointerB   // Outputs from ADD

   // Print the 1D waves representing the output CSR sparse matrix
   Print W_CSRValues
   Print W_CSRColumns
   Print W_CSRPointerB
End
```

MatrixSparse MM

MM computes the product of a sparse matrix and a dense matrix. Symbolically:

```
M_MMOut = alpha*smA*dmB + beta*dmC
```

Inputs: alpha, sparse matrix A in CSR format, dense matrix B, and optionally beta and dense matrix C.

If you leave beta with its default value of 0 by omitting the beta keyword, the beta*dmC term is not computed and you do not need to specify the dmC input.

Output: Dense matrix M_MMOut.

MatrixSparse MM Example

```
Function DemoMatrixSparseMM()
   // Define sparse matrix in CSR format
   Make/FREE/D values = {5, 8, 3, 6}
   Make/FREE/L columns = {0, 1, 2, 1}
   Make/FREE/L ptrB = {0, 0, 2, 3, 4}

   // Create a dense matrix
   Make/FREE/D matrix = { {1,0,0,0}, {0,1,0,0}, {0,0,1,0}, {0,0,0,1} }

   // Multiply the sparse matrix by the dense matrix
   MatrixSparse rowsA=4, colsA=4, csrA={values,columns,ptrB}, matrixB=matrix,
            operation=MM

   // Create wave reference for output dense matrix
   WAVE M_MMOut         // Output from MV

   Print M_MMOut
End
```

MatrixSparse MV

MV computes the product of a sparse matrix which must be in CSR format and a vector producing an output vector. Symbolically:

```
W_MV = alpha*smA*vX + beta*vY
```

Inputs: alpha, sparse matrix A in CSR format, vector X, and optionally beta and vector Y.

If you leave beta with its default value of 0 by omitting the beta keyword, the beta*vY term is not computed and you do not need to specify the vY input.

Output: Vector W_MV.

MatrixSparse MV Example

```
Function DemoMatrixSparseMV()
   // Define sparse matrix in CSR format
   Make/FREE/D values = {5, 8, 3, 6}
   Make/FREE/L columns = {0, 1, 2, 1}
   Make/FREE/L ptrB = {0, 0, 2, 3, 4}

   // Create a vector
   Make/FREE/D vector = {1, 1, 1, 1}

   // Multiply the sparse matrix by the vector
   MatrixSparse rowsA=4, colsA=4, csrA={values,columns,ptrB}, vectorX=vector,
            operation=MV

   // Create wave reference for output vector
   WAVE W_MV      // Output from MV

   Print W_MV
End
```

MatrixSparse SMSM

SMSM computes the product of a two sparse matrices. Symbolically:

```
smOut = smA * smG
```

Inputs: Sparse matrix A in CSR format, sparse matrix G in CSR format.

Output: A sparse matrix in CSR format represented by W_CSRValues, W_CSRColumns, and W_CSRPointerB.

MatrixSparse SMSM Example

```
Function DemoMatrixSparseSMSM()
   // Create sparse matrix A in CSR format
   Make/FREE/D/N=(11) valuesA = {1,25,26,44,16,22,28,5,11,36,42}
   Make/FREE/L/N=(11) columnsA = {0,4,4,7,2,3,4,0,1,5,6}
   Make/FREE/L/N=(6) ptrBA = {0,2,4,4,7,9}

   // Create sparse matrix G in CSR format
   Make/FREE/D/N=(8) valuesG = {1,10,26,6,14,38,15,23}
   Make/FREE/L/N=(8) columnsG = {0,1,3,0,1,4,1,2}
   Make/FREE/L/N=(8) ptrBG = {0,1,3,3,3,3,6,8}

   // Compute product MatrixA x MatrixG
   MatrixSparse rowsA=6, colsA=8, csrA={valuesA,columnsA,ptrBA}, rowsG=8,
            colsG=5, csrG={valuesG,columnsG,ptrBG}, operation=SMSM
   WAVE W_CSRValues, W_CSRColumns, W_CSRPointerB   // Outputs from SMSM

   // Print the 1D waves representing the output CSR sparse matrix
   Print W_CSRValues
   Print W_CSRColumns
   Print W_CSRPointerB
End
```

MatrixSparse TOCOO

TOCOO produces a sparse output matrix in COO format equivalent to the input matrix which may be in dense, CSC, or CSR format.

Inputs: A dense matrix specified by the matrixB keyword or a sparse matrix specified by the cscA or csrA keywords.

Output: A sparse matrix in COO format represented by W_COOValues, W_COORows, and W_COOColumns.

MatrixSparse TOCOO Example

```
Function DemoMatrixSparseTOCOO()
   // Create the Wikipedia example 4x4 matrix in CSR format
   Make/FREE/D values = {5, 8, 3, 6}
   Make/FREE/L columns = {0, 1, 2, 1}
   Make/FREE/L ptrB = {0, 0, 2, 3, 4}

   // Create a sparse matrix in COO format from the CSR matrix
   MatrixSparse rowsA=4, colsA=4, csrA={values,columns,ptrB}, operation=TOCOO
   WAVE W_COOValues, W_COORows, W_COOColumns    // Outputs from TOCOO

   // Print the 1D waves representing the COO sparse matrix
   Print W_COOValues
   Print W_COORows
   Print W_COOColumns
End
```

MatrixSparse TOCSC

TOCSC produces a sparse output matrix in CSC format equivalent to the input matrix which may be in dense, COO, or CSR format.

Inputs: A dense matrix specified by the matrixB keyword or a sparse matrix specified by the cooA or csrA keywords.

Output: A sparse matrix in CSC format represented by W_CSCValues, W_CSCRows, and W_CSCPointerB.

MatrixSparse TOCSC Example

```
Function DemoMatrixSparseTOCSC()
   // Create the Wikipedia example 4x4 matrix in dense format
   Make/FREE/D/N=(4,4) dense
   dense[0][0] = {0,5,0,0}
   dense[0][1] = {0,8,0,6}
   dense[0][2] = {0,0,3,0}
   dense[0][3] = {0,0,0,0}

   // Create a sparse matrix in CSC format from the dense matrix
   // MatrixSparse requires rowsA and colsA even though they are not used here
   MatrixSparse rowsA=4, colsA=4, matrixB=dense, operation=TOCSC
   WAVE W_CSCValues, W_CSCRows, W_CSCPointerB      // Outputs from TOCSC

   // Print the 1D waves representing the CSC sparse matrix
   Print W_CSCValues
   Print W_CSCRows
   Print W_CSCPointerB
End
```

MatrixSparse TOCSR

TOCSR produces a sparse output matrix in CSR format equivalent to the input matrix which may be in dense, COO, or CSC format.

Inputs: A dense matrix specified by the matrixB keyword or a sparse matrix specified by the cooA or cscA keywords.

Output: A sparse matrix in CSR format represented by W_CSRValues, W_CSRColumns, and W_CSRPointerB.

MatrixSparse TOCSR Example

```
Function DemoMatrixSparseTOCSR()
   // Create the Wikipedia example 4x4 matrix in dense format
   Make/FREE/D/N=(4,4) dense
   dense[0][0] = {0,5,0,0}
   dense[0][1] = {0,8,0,6}
   dense[0][2] = {0,0,3,0}
   dense[0][3] = {0,0,0,0}

   // Create a sparse matrix in CSR format from the dense matrix
   // MatrixSparse requires rowsA and colsA even though they are not used here
   MatrixSparse rowsA=4, colsA=4, matrixB=dense, operation=TOCSR
   WAVE W_CSRValues, W_CSRColumns, W_CSRPointerB   // Outputs from TOCSR

   // Print the 1D waves representing the CSR sparse matrix
   Print W_CSRValues
   Print W_CSRColumns
   Print W_CSRPointerB
End
```

MatrixSparse TODENSE

TODENSE produces a dense output matrix equivalent to the sparse input matrix which may be in COO, CSC, or CSR format.

Inputs: A sparse matrix specified by the cooA, cscA, or csrA keywords.

Output: Dense output matrix M_cooToDense, M_cscToDense, or M_csrToDense.

MatrixSparse TODENSE Example

```
Function DemoMatrixSparseTODENSE()
   // Create the Wikipedia example 4x4 matrix in COO format
   Make/FREE/D values = {5, 8, 3, 6}
   Make/FREE/L rows = {1, 1, 2, 3}
   Make/FREE/L columns = {0, 1, 2, 1}

   // Create a dense matrix from the sparse matrix
   MatrixSparse rowsA=4, colsA=4, cooA={values,rows,columns}, operation=TODENSE
   WAVE M_cooToDense          // Output from TODENSE

   // Print the dense output matrix
   Print M_cooToDense
End
```

MatrixSparse TRSV

TRSV solves a system of linear equations for the triangular sparse matrix A. Symbolically it solves for output matrix M_TRSVOut where:

```
smA*M_TRSVOut = alpha*vX
```

Inputs: Sparse matrix A in CSR format, alpha, vector X.

Output: Dense matrix M_TRSVOut.

MatrixSparse TRSV Example

```
// This is based on the example in the Row Reduction section
// of the Wikipedia page
// https://en.wikipedia.org/wiki/System_of_linear_equations
// The system of equations is:
//    x + 3y - 2z = 5
//    3x + 5y + 6z = 7
//    2x + 47 + 3z = 8
// This gives the following augmented matrix:
//    1  3  -2 5
//    3  5  6  7
//    2  4  3  8
// The solution is: x=-15, y=8, z=2
// Because the MatrixSparse TRSV operation requires a triangularized coefficient
// matrix, we start with the upper-triangular version of the augmented matrix
// obtained using Gauss-Jordan elimination:
//    1  3  -2 5
//    0  1  -3 2
//    0  0  1  2
// We create an equivalent sparse matrix using MatrixSparse TOCSR.
// We then create the corresponding solution vector {5, 5, 2}.
// We then call MatrixSparse TRSV an obtain the solution set {-15, 8, 2}
Function DemoMatrixSparseTRSV()
   // Create dense upper-triangular matrix representing coefficients
   Make/FREE/D/N=(3,3) utMat
   utMat[0][0] = {1, 0, 0}       // Column 0
   utMat[0][1] = {3, 1, 0}       // Column 1
   utMat[0][2] = {-2, -3, 1}     // Column 2

   // Create sparse version of upper triangular matrix in CSR format
   MatrixSparse rowsA=3, colsA=3, matrixB=utMat, operation=TOCSR
   WAVE values = W_CSRValues
   WAVE columns = W_CSRColumns
   WAVE ptrB = W_CSRPointerB
   // Create solution vector
   Make/FREE/D/N=(3) vector = {5,2,2}

   // Solve system of linear equations
   // Adding sparseMatrixType={TRIANGULAR,UPPER,NON_DIAG} may improve speed
   MatrixSparse rowsA=3, colsA=3, csrA={values,columns,ptrB}, vectorX=vector,
         operation=TRSV
   WAVE M_TRSVOut       // Output from TRSV

   Print M_TRSVOut      // Should be {-15, 8, 2}
End
```

Clustering

The following operations perform cluster analysis of various kinds:

FastGaussTransform, **FPClustering**, **ImageThreshold**, **KMeans**, **HCluster**

For hierarchical clustering, see the next section.

Hierarchical Clustering

Hierarchical clustering builds a hierarchy of clusters which provides the information needed to create a cluster dendrogram. You can perform hierarchical clustering using the **HCluster** operation added in Igor Pro 9.00. HCluster, based on code developed by Daniel Müllner, uses an agglomerative hierarchical clustering algorithm.

You provide as input either a square dissimilarity matrix or a matrix in which rows represent vectors in some data space as the input wave. A dissimilarity matrix contains values measuring the degree of difference between every pair of vectors in the original data set. It is common to use "distance" instead of "dissimilarity" because for most purposes Euclidean distance is used to measure dissimilarity. We use "dissimilarity" below.

HCluster creates one or two output waves, depending on the output type that you request. The output waves are a square dissimilarity matrix wave and a dendrogram wave. The format of the dendrogram wave is discussed below under **Dendrogram Wave Format**.

Agglomerative hierarchical clustering proceeds by iteratively finding the pair of nodes that have the minimum dissimilarity amongst all pairs. The node pair with the smallest value of dissimilarity is joined into a single replacement node. A node can represent a single original data vector or a set of vectors that have already been joined into a cluster. This process is repeated until all original data vectors are represented by a single cluster. The output dendrogram wave describes a tree identifying the nodes that were combined and the dissimilarity between those nodes. This description is sufficient for drawing a dendrogram illustrating the clusters.

If the input wave is a dissimilarity matrix, then those dissimilarities are used to form pair-wise nodes in a dendrogram expressing the degree of dissimilarity between pairs of nodes in the tree.

If the input wave is a matrix of raw data vectors, the HCluster operation can be used to either create a dissimilarity matrix or to create a dendrogram directly, without outputting a dissimilarity matrix. It is also possible to get both the dissimilarity matrix and the dendrogram wave from a single call. If you don't need the dissimilarity matrix output, in certain cases vector data can be processed using an algorithm that minimizes memory use.

There are two types of dissimilarity that HCluster need to calculate:

- The dissimilarity between two input vectors
  We call this a "vector dissimilarity" calculation.
  You specify how to calculate vector dissimilarity using the HCluster /DISS flag.

The most common method for calculating vector dissimilarity is the Euclidean metric, the familiar square root of the summed squared differences of the vector elements. See **HCluster Vector Dissimilarity Calculation Methods** on page III-163 for a description of the vector dissimilarity metrics offered by the HCluster operation.

If you use /ITYP=DMatrix, you can prepare your own dissimilarity matrix using whatever method you wish for measuring the dissimilarity between vectors. Your dissimilarity metric must return a positive number. Identical vectors, such as comparing a vector with itself, have a dissimilarity of zero.

- The dissimilarity between a vector and a previously-determined cluster or between two previously-determined clusters

  We call this a "linkage" calculation.

  You specify how to calculate linkage using the HCluster /LINK flag.

  See **HCluster Linkage Calculation Methods** on page III-166 dfor a description of the linkage calculation methods offered by the HCluster operation. The linkage method that you choose can have a very strong effect on the resulting dendrogram.

HCluster Vector Dissimilarity Calculation Methods

You use the HCluster /DISS=dm flag to specify the dissimilarity metric between two data vectors. Our definitions of dissimilarity follows Python scipy.spatial.distance.pdist.

The following values are supported for the *dm* keyword. If you omit /DISS, HCluster defaults to the Euclidean method.

***dm* = Euclidean**

This is the usual way to measure the dissimilarity between two vectors, the two-norm or L_2 norm. It is simply the Euclidean distance. This is the default.

$$d(u,v) = \|u - v\|_2 = \sqrt{\sum_j (u_j - v_j)^2}$$

***dm* = SquaredEuclidean**

Just like Euclidean, but omits taking the square root. May be needed to reproduce some results from R or Python. Results in the same clustering as Euclidean, but exaggerates larger differences.

$$d(u,v) = \sum_j (u_j - v_j)^2$$

***dm* = SEuclidean**

Standardized Euclidean. Euclidean distance in which the dimensions are scaled by V_j, which is usually the variance of the j-th element of all the vectors.

$$d(u,v) = \sqrt{\sum_j (u_j - v_j)^2 / V_j}$$

Specify a wave giving the V_j vector using the /VARW flag.

***dm* = Cityblock**

Manhattan distance or L_1 norm.

$$d(u,v) = \sum_j |u_j - v_j|$$

Cityblock gives the same value of 2 for vectors (0,2), (2,0), and (1,1). Euclidean distance gives a smaller value, sqrt(2), for the vector (1,1). This can affect the resulting clusters.

dm **= Chebychev**

Supremum or L_∞ norm.

$$d(u,v) = \max_j |u_j - v_j|$$

dm **= Minkowski**

The L_p norm.

$$d(u,v) = \left(\sum_j |u_j - v_j|^p \right)^{1/p}$$

The value of p is specified using the HCluster /P flag.

p = 1 makes Minkowski equivalent to Cityblock.

p = 2 makes Minkowski equivalent to Euclidean.

p = Inf makes Minkowski equivalent to Chebychev.

dm **= Cosine**

$$d(u,v) = 1 - \frac{\langle u, v \rangle}{\|u\| \cdot \|v\|} = 1 - \frac{\sum_j u_j v_j}{\sqrt{\sum_j u_j^2 \cdot \sum_j v_j^2}}$$

dm **= Canberra**

$$d(u,v) = \sum_j \frac{|u_j - v_j|}{|u_j| + |v_j|}$$

Terms in which uj = vj = 0 contribute 0 to the sum.

dm **= BrayCurtis**

$$d(u,v) = \sum_j \frac{|u_j - v_j|}{|u_j + v_j|}$$

Terms in which uj = vj = 0 contribute 0 to the sum.

In the following, the notation |{...}| indicates the count of true boolean values.

dm **= Hamming**

$$d(u,v) = |\{j | u_j \neq v_j\}|$$

Hamming is actually intended to be used with binary data, but the definition will test a "1" and "2" as being different. See Matching below, which tests each vector element for u_j != 0. For data that is all ones or zeroes, Hamming and Matching give the same results.

dm **= Jaccard**

Like Hamming, Jaccard is intended for boolean data, but tests for "not equal".

$$d(u,v) = \frac{|\{j|u_j \neq v_j\}|}{|\{j|u_j \neq 0 \; or \; v_j \neq 0\}|}$$

HCluster Vector Dissimilarity Calculation Methods for Boolean Data

The remaining metrics are for boolean data. Any data is accepted and each value is converted to a boolean value by testing for u_j != 0.

The following definitions are used:

$$a = |\{j \mid u_j \wedge v_j\}|$$

$$b = |\{j \mid u_j \wedge (\neg v_j)\}|$$

$$c = |\{j \mid (\neg u_j) \wedge v_j\}|$$

$$d = |\{j \mid (\neg u_j) \wedge (\neg v_j)\}|$$

D is the vector length, $D = a + b + c + d$.

***dm* = Yule**

$$d\left(u,v\right) = \frac{2bc}{ad + bc}$$

***dm* = Dice**

$$d\left(u,v\right) = \frac{b + c}{2a + b + c} \;,\; d\left(0,0\right) = 0$$

***dm* = RogersTanimoto**

$$d\left(u,v\right) = \frac{2\left(b + c\right)}{b + c + D}$$

***dm* = RusselRao**

$$d\left(u,v\right) = \frac{b + c + d}{D}$$

***dm* = SokalSneath**

$$d\left(u,v\right) = \frac{2(b + c)}{a + 2(b + c)} \;,\; d(0,0) = 0$$

***dm* = Kulsinski**

$$d\left(u,v\right) = \frac{1}{2} \cdot \left(\frac{b}{a + b} + \frac{c}{a + c}\right)$$

***dm* = Matching**

This metric is the same as Hamming, if Hamming is given only boolean data, that is, only ones and zeroes.

$$d\left(u,v\right)=\frac{b+c}{D}$$

HCluster Linkage Calculation Methods

You use the HCluster /LINK=*linkMethod* flag to specify the method used to determine the dissimilarity between nodes in the dendrogram that represent more than one data vector. This is also referred to as the "linkage" method. Our definitions of node dissimilarity follows Python scipy.cluster.hierarchy.linkage.

linkMethod is a keyword identifying the method to use. Each of these keywords, described below, selects a method for measuring the dissimilarity between two clusters, *A* and *B*, with individual dissimilarities *a* and *b*. The symbol | A | denotes the number of elements in a cluster. It is not always possible to give an expression in this form.

Alternately, dissimilarity between a new node and other nodes in the tree can be computed from the dissimilarities of the two nodes being combined. That is, if nodes I and J are combined to form K, then it is possible to compute the dissimilarity from K to any other node L in terms of I and J.

Each of the following linkage method descriptions includes two equations. The first describes the method for computing dissimilarity between nodes given the dissimilarities of each of the component dissimilarities. The second describes the method for computing the dissimilarity to another node from a node that combines I and J.

The following values are supported for *linkMethod* keyword. If you omit /LINK, HCluster defaults to the average method.

***linkMethod* = single**

This is the default dissimilarity metric.

$$d(A,B)=\min_{a\in A,b\in B}d(a,b)$$

That is, the dissimilarity is the dissimilarity between the two nearest elements of each cluster. Also called Nearest Point algorithm.

$$d(K,L)=min(d(I,L),d(J,L))$$

***linkMethod* = complete**

$$d(A,B)=\max_{a\in A,b\in B}d(a,b)$$

Also called Farthest Point algorithm.

$$d(K,L)=max(d(I,L),d(J,L))$$

***linkMethod* = average**

$$d(A,B)=\frac{1}{|A|\,|B|}\sum_{a\in A,b\in B}d(a,b)$$

That is, the average of all the pairwise dissimilarities between points in each cluster.

$$d(K,L) = \frac{|I| \cdot d(I,L) + |J| \cdot d(J,L)}{|I| + |J|}$$

***linkMethod* = weighted**

There is no general expression for the dissimilarity between clusters as it depends on the order in which the clusters are merged. At each step, new dissimilarities are computed as:

$$d(K,L) = \frac{d(I,L) + d(J,L)}{2}$$

***linkMethod* = centroid**

This method is suitable only for use with the Euclidean dissimilarity metric.

$$d(A,B) = \|\vec{c}_A - \vec{c}_B\|$$

where $\vec{c}$ c indicates the centroid of a cluster.

$$d(K,L) = \sqrt{\frac{|I| \cdot d(I,L)^2 + |J| \cdot d(J,L)^2}{|I| + |J|} - \frac{|I| \cdot |J| \cdot d(I,J)^2}{(|I| + |J|)^2}}$$

***linkMethod* = median**

This method is suitable only for use with the Euclidean dissimilarity metric.

assigns d(K,L) like the centroid method. When two clusters *I* and *J* are combined into a new cluster *K*, the average of centroids *i* and *j* give the new centroid *k*. Or,

$$d(K,L) = \sqrt{\frac{d(I,L)^2}{2} + \frac{d(J,L)^2}{2} - \frac{d(I,J)^2}{4}}$$

***linkMethod* = ward**

This method is suitable only for use with the Euclidean dissimilarity metric.

$$d(A,B) = \sqrt{\frac{2\,|A|\,|B|}{|A| + |B|}} \cdot \|\vec{c}_A - \vec{c}_B\|$$

The Ward variance minimization algorithm

$$d(K,L) = \sqrt{\frac{(|I| + |L|) \cdot d(I,L)^2 + (|J| + |L|) \cdot d(J,L)^2 - |L| \cdot d(I,J)^2}{|I| + |J| + |L|}}$$

Dendrogram Wave Format

The HCluster operation optionally produces a dendrogram output wave that can be used to create a dendrogram plot. This section describes the format of the dendrogram output wave.

The dendrogram wave contains all the information about the node pairs that are combined by HCluster, and the dissimilarity between the nodes. It also has a list of the indices into the original data in the order in which, for instance, labels should be drawn to avoid node connector lines that cross. The wave has four columns and N rows, where N is the number of original data vectors.

Column 0 and Column 1 contain the node numbers that are combined to form the node represented by a given row in the dendrogram wave. If a node number is negative, it represents the row in the original vector data. If a node number is positive, it represents the row number within the dendrogram wave of a combined node. Since negative numbers cannot represent zero-based indices, the row numbers are 1-based. If the value in column 0 or 1 is A, then the zero-based row number is abs(A)-1.

Column 2 contains the dissimilarity value between the nodes represented by columns 0 and 1. If you are drawing a dendrogram tree, a tie bar should be drawn in a location proportional to this dissimilarity.

Column 3 contains ordering information for the original data. This allows you to draw lines that don't cross. Labels for vector rows should also use this ordering. These numbers are zero-based indices into the original data. If you have a text wave with labels for each of the rows in your vector data, you can use this column to access the correct label for a given row in the dendrogram. If you include a false-color image (heat map) of the dissimilarity matrix or the vector data, the rows of the heat map data should be re-ordered based on column 3.

A data set with N vector rows has N-1 dissimilarity values. The information for column 3 has N values, one for each of the vector rows, so column 0 and column 1 contain NaN in row N to show that those cells are not used. The last row in column 2 has zero, which is a nonsense dissimilarity value. Only column 3 has useful data in the last row.

Dendrogram Example

Create a matrix wave containing fake data representing XY pairs with the X values in column 0 of the matrix and the Y values in column 1:

```
Make/N=(10,2)/O vectors
vectors[0][0]= {6.04379,-1.40976,5.32518,-0.140695,1.94087,0.971393,5.29093,-
                0.953138,5.58752,4.16877}
vectors[0][1]= {6.2448,-0.914027,4.36285,1.45288,-
                1.21538,1.21118,5.86274,1.37278,4.43314,4.40538}
```

Each row in vectors, that is, each XY pair, is one input vector to HCluster.

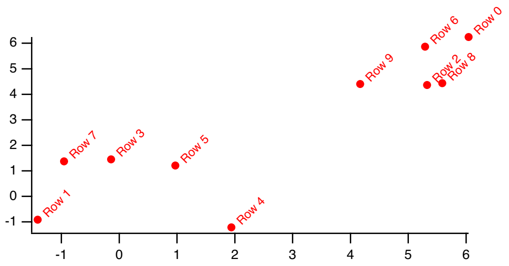
Create a text wave with labels for each of the vector rows:

```
Make/N=10/T/O labels
labels[0]= {"Row0","Row1","Row2","Row3","Row4","Row5","Row6","Row7","Row8","Row9"}
```

Make a graph of the XY pairs:

```
Display vectors[*][1] vs vectors[*][0]       // For displaying markers
AppendToGraph vectors[*][1] vs vectors[*][0] // For displaying labels
ModifyGraph margin(top)=27
ModifyGraph mode=3
ModifyGraph marker(vectors)=19
ModifyGraph textMarker(vectors#1)={labels,"default",0,45,5,15.00,12.00}
```

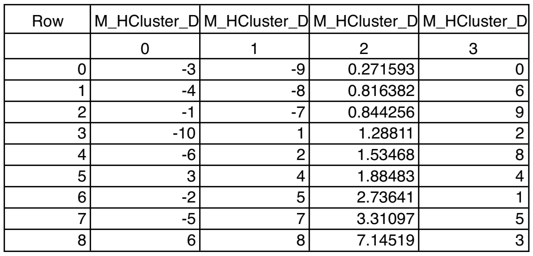
Since this is fake data, we have manipulated it so that there are two clear clusters. We used text markers to show which vector row each XY pair represents:



Invoke HCluster to analyze the vectors and create a dendrogram output wave:

```
HCluster/OTYP=Both vectors
```

The resulting dendrogram wave, with the default name M_HCluster_Dendrogram, has these contents:

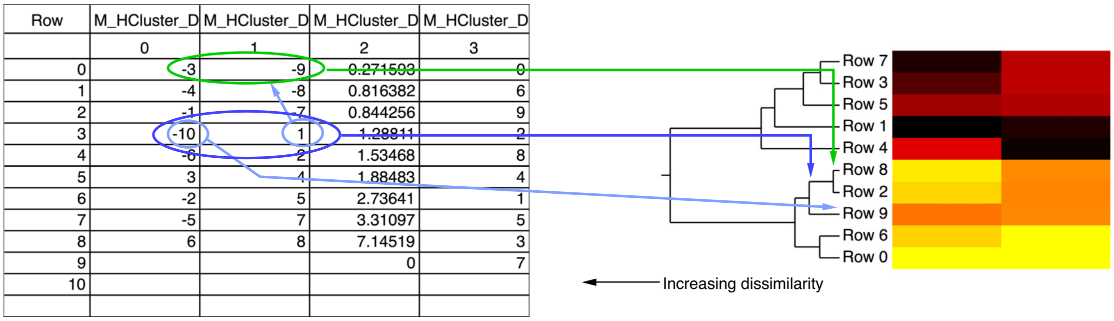


Row	M_HCluster_D	M_HCluster_D	M_HCluster_D	M_HCluster_D
	0	1	2	3
0	-3	-9	0.271593	0
1	-4	-8	0.816382	6
2	-1	-7	0.844256	9
3	-10	1	1.28811	2
4	-6	2	1.53468	8
5	3	4	1.88483	4
6	-2	5	2.73641	1
7	-5	7	3.31097	5
8	6	8	7.14519	3

The first row represents the smallest dissimilarity (0.2716). The first two columns indicate that a node has been formed by combining original vector rows 2 and 8 (that is abs(-3)-1 and abs(-9)-1). If we are drawing a dendrogram, we would position rows 2 and 8 at a position 4 and 5 up from the bottom (or down from the top). We see that from the fact that column 3 has row 2 and row 8 listed in those positions. We would draw a tie line between 2 and 8 at a position on the dendrogram proportional to a distance of 0.2716.

The first three rows have negative numbers in columns 0 and 1, showing that they all combine nodes representing the original vectors. If we have text labels for the rows, these nodes would all tie directly to those labels.

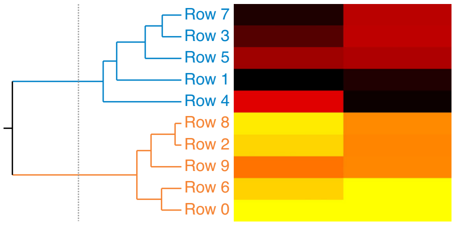
Row 3 lists nodes -10 and 1, indicating that it combines an original vector row 9 with the already combined node from row 0 of the dendrogram wave. The relationships between a dendrogram with a heat map of the original vector data, and the dendrogram wave is illustrated here:



Row	M_HCluster_D	M_HCluster_D	M_HCluster_D	M_HCluster_D
	0	1	2	3
0	-3	-9	0.271593	0
1	-4	-8	0.816382	6
2	-1	-7	0.844256	9
3	-10	1	1.28811	2
4	-6	2	1.53468	8
5	3	4	1.88483	4
6	-2	5	2.73641	1
7	-5	7	3.31097	5
8	6	8	7.14519	3
9			0	7
10				

Here we have ordered the vector rows from bottom to top following the ordering given in column 3 of the dendrogram wave. Rows 2 and 8 are tied together with the tie line least distant from the labels. Then Rows 3 and 7 and Rows 0 and 6 are each a bit more distant. Row 3 of the dendrogram wave indicates the tie between the label "Row 9" and the combined node from Row 2 and Row 8.

The two clusters are clearly indicated by the large distance between the most extreme tie line and the next most distant tie line. We might add a "cut line" in that space, and group the two clusters. To show it more clearly, we could color the two clusters differently, possibly like this:



We created this dendrogram with heat map using the Hierarchical Clustering package which you can access by choosing Analysis→Packages→Hierarchical Clustering.

Analysis Programming

This section contains data analysis programming examples. There are many more examples in the WaveMetrics Procedures, Igor Technical Notes, and Examples folders.

Passing Waves to User Functions and Macros

As you look through various examples you will notice two different ways to pass a wave to a function: using a Wave parameter or using a String parameter.

Using a Wave Parameter	Using a String Parameter

`Function Test1(w)`
`   Wave w`
	`Function Test2(wn)`
	`   String wn`

Usable in functions, not in macros.	Usable in functions and macros.
w is a “formal” name. Use it just as if it were the name of an actual wave.	Use the $ operator to convert from a string to wave name.

The string method is used in macros and in user functions for passing the name of a wave that may not yet exist but will be created by the called procedure. The wave parameter method is used in user functions when the wave will always exist before the function is called. For details, see **Accessing Waves in Functions** on page IV-82.

Returning Created Waves from User Functions

A function can return a wave as the function result. For example:

```
Function Test()
   Wave w = CreateNoiseWave(5, "theNoiseWave")
   WaveStats w
   Display w as "Noise Wave"
End

Function/WAVE CreateNoiseWave(noiseValue, destWaveName)
   Variable noiseValue
   String destWaveName

   Make/O $destWaveName = gnoise(noiseValue)
   Wave w = $destWaveName
   return w
End
```

If the returned wave is intended for temporary use, you can create it as a free wave:

```
Function Test()
   Wave w = CreateFreeNoiseWave(5)// w is a free wave
   WaveStats w
   // w is killed when the function exist
End

Function/WAVE CreateFreeNoiseWave(noiseValue)
   Variable noiseValue

   Make/O/FREE aWave = gnoise(noiseValue)
   return aWave
End
```

To return multiple waves, you can return a "wave reference wave". See **Wave Reference Waves** on page IV-77 for details.

Writing Functions that Process Waves

The user function is a powerful, general-purpose analysis tool. You can do practically any kind of analysis. However, complex analyses require programming skill and patience.

It is useful to think about an analysis function in terms of its input parameters, its return value and any side effects it may have. By return value, we mean the value that the function directly returns. For example, a function might return a mean or an area or some other characteristic of the input. By side effects, we mean changes that the function makes to any objects. For example, a function might change the values in a wave or create a new wave.

This table shows some of the common types of analysis functions. Examples follow.

Input Parameters	Return Value	Side Effects	Example Function
A source wave	A number	None	WaveSum
A source wave	Not used	The source wave is modified	RemoveOutliers
A source wave	Wave reference	A new destination wave is created	LogRatio
A source wave and a destination wave	Not used	The destination wave is modified	
An array of wave references	A number	None	WavesMax
An array of wave references	Wave reference	A new wave is created	WavesAverage

The following example functions are intended to show you the general form for some common analysis function types. We have tried to make the examples useful while keeping them simple.

WaveSum Example

Input:	Source wave
Return value:	Number
Side effects:	None

```
// WaveSum(w)
// Returns the sum of the entire wave, just like Igor’s sum function.
Function WaveSum(w)
   Wave w

   Variable i, n=numpnts(w), total=0
   for(i=0;i<n;i+=1)
      total += w[i]
   endfor

   return total
End
```

To use this, you would execute something like

```
Print "The sum of wave0 is:", WaveSum(wave0)
```

RemoveOutliers Example

Input:	Source wave
Return value:	Number
Side effects:	Source wave is modified

Often a user function used for number-crunching needs to loop through each point in an input wave. The following example illustrates this.

```
// RemoveOutliers(theWave, minVal, maxVal)
// Removes all points in the wave below minVal or above maxVal.
// Returns the number of points removed.
Function RemoveOutliers(theWave, minVal, maxVal)
   Wave theWave
   Variable minVal, maxVal

   Variable i, numPoints, numOutliers
   Variable val
   numOutliers = 0
   numPoints = numpnts(theWave)        // number of times to loop

   for (i = 0; i < numPoints; i += 1)
      val = theWave[i]
      if ((val < minVal) || (val > maxVal))  // is this an outlier?
         numOutliers += 1
      else                                   // if not an outlier
         theWave[i - numOutliers] = val      // copy to input wave
      endif
   endfor

   // Truncate the wave
   DeletePoints numPoints-numOutliers, numOutliers, theWave
   return numOutliers
End
```

To test this function, try the following commands.

```
Make/O/N=10 wave0= gnoise(1); Edit wave0
Print RemoveOutliers(wave0, -1, 1), "points removed"
```

RemoveOutliers uses the for loop to iterate through each point in the input wave. It uses the built-in numpnts function to find the number of iterations required and a local variable as the loop index. This is a very common practice.

The line "`if ((val < minVal) || (val > maxVal))`" decides whether a particular point is an outlier. `||` is the logical OR operator. It operates on the logical expressions "`(val < minVal)`" and "`(val > maxVal)`". This is discussed in detail under **Bitwise and Logical Operators** on page IV-41.

To use the WaveMetrics-supplied RemoveOutliers function, include the Remove Points.ipf procedure file:

```
#include <Remove Points>
```

See **The Include Statement** on page IV-166 for instructions on including a procedure file.

LogRatio Example

Input:	Source waves
Return value:	Wave reference
Side effects:	Output wave created

```
// LogRatio(source1, source2, outputWaveName)
// Creates a new wave that is the log of the ratio of input waves.
// Returns a reference to the output wave.
Function/WAVE LogRatio(source1, source2, outputWaveName)
   Wave source1, source2
   String outputWaveName

   Duplicate/O source1, $outputWaveName
   WAVE wOut = $outputWaveName
   wOut = log(source1/source2)
   return wOut
End
```

To call this from a function, you would execute something like:

```
Wave wRatio = LogRatio(wave0, wave1, "ratio")
Display wRatio
```

The LogRatio function illustrates how to treat input and output waves. Input waves must exist before the function is called and therefore are passed as wave reference parameters. The output wave may or may not already exist when the function is called. If it does not yet exist, it is not possible to create a wave reference for it. Therefore we pass to the function the desired name for the output wave using a string parameter. The function creates or overwrites a wave with that name in the current data folder and returns a reference to the output wave.

WavesMax Example

Input:	Array of wave references
Return value:	Number
Side effects:	None

```
// WavesMax(waves)
// Returns the maximum value in waves in the waves array.
Function WavesMax(waves)
   Wave/WAVE waves

   Variable theMax = -INF

   Variable numWaves = numpnts(waves)
   Variable i
   for(i=0; i<numWaves; i+=1)
      Wave w = waves[i]
      Variable tmp = WaveMax(w)
      theMax = max(tmp, theMax)
   endfor

   return theMax
End
```

This function illustrates how you might call WavesMax from another function:

```
Function DemoWavesMax()
   Make/FREE/N=10 w0 = p
   Make/FREE/N=10 w1 = p + 1

   Make/FREE/WAVE waves = {w0, w1}

   Variable theMax = WavesMax(waves)

   Printf "The maximum value is %g\r", theMax
End
```

WavesAverage Example

Input:	An array of wave references
Return value:	Wave reference
Side effects:	Creates output wave

```
// WavesAverage(waves, outputWaveName)
// Returns a reference to a new wave, each point of which contains the
// average of the corresponding points of a number of source waves.
// waves is assumed to contain at least one wave reference and
// all waves referenced by waves are expected to have the same
// number of points.
Function/WAVE WavesAverage(waves, outputWaveName)
   Wave/WAVE waves         // A wave containing wave references
   String outputWaveName
   // Make output wave based on the first source wave
   Wave first = waves[0]
   Duplicate/O first, $outputWaveName
   Wave wOut = $outputWaveName
   wOut = 0

   Variable numWaves = numpnts(waves)
   Variable i
   for(i=0; i<numWaves; i+=1)
      Wave source = waves[i]
      wOut += source          // Add source to output
   endfor

   wOut /= numWaves           // Divide by number of waves

   return wOut
End
```

This function shows how you might call WavesAverage from another function:

```
Function DemoWavesAverage()
   Make/FREE/N=10 w0 = p
   Make/FREE/N=10 w1 = p + 1

   Make/FREE/WAVE waves = {w0, w1}

   Wave wAverage = WavesAverage(waves, "averageOfWaves")
   Display wAverage
End
```

Finding the Mean of Segments of a Wave

An Igor user who considers each of his waves to consist of a number of segments with some number of points in each segment asked us how he could find the mean of each of these segments. We wrote the FindSegmentMeans function to do this.

```
Function/WAVE FindSegmentMeans(source, n)
   Wave source
   Variable n

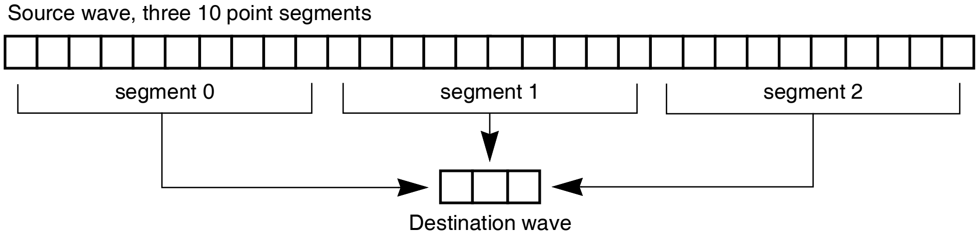
   String dest                    // name of destination wave
   Variable segment, numSegments
   Variable startX, endX, lastX

   dest = NameOfWave(source)+"_m"  // derive name of dest from source
   numSegments = trunc(numpnts(source) / n)
   if (numSegments < 1)
      DoAlert 0, "Destination must have at least one point"
      return $""                     // Null wave reference
   endif

   Make/O/N=(numSegments) $dest
   WAVE destw = $dest
   for (segment = 0; segment < numSegments; segment += 1)
      startX = pnt2x(source, segment*n)      // start X for segment
      endX = pnt2x(source, (segment+1)*n - 1)// end X for segment
      destw[segment] = mean(source, startX, endX)
   endfor

   return destw
End
```

This diagram illustrates a source wave with three ten-point segments and a destination wave that will contain the mean of each of the source segments. The FindSegmentMeans function makes the destination wave.



To test FindSegmentMeans, try the following commands.

```
Make/N=100 wave0=p+1; Edit wave0
FindSegmentMeans(wave0,10)
Append wave0_m
```

The loop index is the variable "segment". It is the segment number that we are currently working on, and also the number of the point in the destination wave to set.

Using the segment variable, we can compute the range of points in the source wave to work on for the current iteration: segment*n up to (segment+1)*n - 1. Since the mean function takes arguments in terms of a wave's X values, we use the pnt2x function to convert from a point number to an X value.

If it is guaranteed that the number of points in the source wave is an integral multiple of the number of points in a segment, then the function can be speeded up and simplified by using a waveform assignment statement in place of the loop. Here is the statement.

```
destw = mean(source, pnt2x(source,p*n), pnt2x(source,(p+1)*n-1))
```

The variable p, which Igor automatically increments as it evaluates successive points in the destination wave, takes on the role of the segment variable used in the loop. Also, the startX, endX and lastX variables are no longer needed.

Using the example shown in the diagram, p would take on the values 0, 1 and 2 as Igor worked on the destination wave. n would have the value 10.

Working with Mismatched Data

Occasionally, you may find yourself with several sets of data each sampled at a slightly different rate or covering a different range of the independent variable (usually time). If all you want to do is create a graph showing the relationship between the data sets then there is no problem.

However, if you want to subtract one from another or do other arithmetic operations then you will need to either:

- Create representations of the data that have matching X values. Although each case is unique, usually you will want to use the **Interpolate2** operation (see **Using the Interpolate2 Operation** on page III-111) or the interp function (see **Using the Interp Function** on page III-110) to create data sets with common X values. You can also use the **Resample** to create a wave to match another.
- Properly set each wave's X scaling, and perform the waveform arithmetic using X scaling values and Igor's automatic linear interpolation. See **Mismatched Waves** on page II-83.

The WaveMetrics procedure file Wave Arithmetic Panel uses these techniques to perform a variety of operations on data in waves. You can access the panel by choosing Packages→Wave Arithmetic from the Analysis menu. This will open the procedure file and display the control panel. Click the help button in the panel to learn how to use it.

Chapter

III-8

Curve Fitting

Overview

Igor Pro’s curve fitting capability is one of its strongest analysis features. Here are some of the highlights:

- Linear and general nonlinear curve fitting.
- Fit by ordinary least squares, or by least orthogonal distance for errors-in-variables models.
- Fit to implicit models.
- Built-in functions for common fits.
- Automatic initial guesses for built-in functions.
- Fitting to user-defined functions of any complexity.
- Fitting to functions of any number of independent variables, either gridded data or multicolumn data.
- Fitting to a sum of fit functions.
- Fitting to a subset of a waveform or XY pair.
- Produces estimates of error.
- Supports weighting.

The idea of curve fitting is to find a mathematical model that fits your data. We assume that you have theoretical reasons for picking a function of a certain form. The curve fit finds the specific coefficients which make that function match your data as closely as possible.

You cannot use curve fitting to find which of thousands of functions fit a data set.

People also use curve fitting to merely show a smooth curve through their data. This sometimes works but you should also consider using smoothing or interpolation, which are described in Chapter III-7, **Analysis**.

You can fit to three kinds of functions:

- Built-in functions.
- User-defined functions.
- External functions (XFUNCs).

The built-in fitting functions are line, polynomial, sine, exponential, double-exponential, Gaussian, Lorentzian, Hill equation, sigmoid, lognormal, log, Gauss2D (two-dimensional Gaussian peak) and Poly2D (two-dimensional polynomial).

You create a user-defined function by entering the function in the New Fit Function dialog. Very complicated functions may have to be entered in the Procedure window.

External functions, XFUNCs, are written in C or C++. To create an XFUNC, you need the optional Igor XOP Toolkit and a C/C++ compiler. You don’t need the toolkit to *use* an XFUNC that you get from WaveMetrics or from another user.

Curve fitting works with equations of the form $y = f(x_1, x_2, \ldots, x_n)$; although you can fit functions of any number of independent variables (the x_n’s) most cases involve just one. For more details on multivariate fitting, see **Fitting to a Multivariate Function** on page III-200.

You can also fit to implicit functions; these have the form$f(x_1, x_2, \ldots, x_n) = 0$. See **Fitting Implicit Functions** on page III-242.

You can do curve fits with linear constraints (see **Fitting with Constraints** on page III-227).

Curve Fitting Terminology

Built-in fits are performed by the CurveFit operation. User-defined fits are performed by the FuncFit or FuncFitMD operation. We use the term “curve fit operation” to stand for CurveFit, FuncFit, or FuncFitMD, whichever is appropriate.

Fitting to an external function works the same as fitting to a user-defined function (with some caveats concerning the Curve Fitting dialog — see **Fitting to an External Function (XFUNC)** on page III-194).

If you use the Curve Fitting dialog, you don't really need to know much about the distinction between built-in and user-defined functions. You may need to know a bit about the distinction between external functions and other types. This will be discussed later.

We use the term "coefficients" for the numbers that the curve fit is to find. We use the term "parameters" to talk about the values that you pass to operations and functions.

Overview of Curve Fitting

In curve fitting we have raw data and a function with unknown coefficients. We want to find values for the coefficients such that the function matches the raw data as well as possible. The "best" values of the coefficients are the ones that minimize the value of Chi-square. Chi-square is defined as:

$$\sum_i \left(\frac{y - y_i}{\sigma_i}\right)^2$$

where y is a fitted value for a given point, y_i is the measured data value for the point and σ_i is an estimate of the standard deviation for y_i.

The simplest case is fitting to a straight line: $y = ax + b$. Suppose we have a theoretical reason to believe that our data should fall on a straight line. We want to find the coefficients a and b that best match our data.

For a straight line or polynomial function, we can find the best-fit coefficients in one step. This is noniterative curve fitting, which uses the singular value decomposition algorithm for polynomial fits.

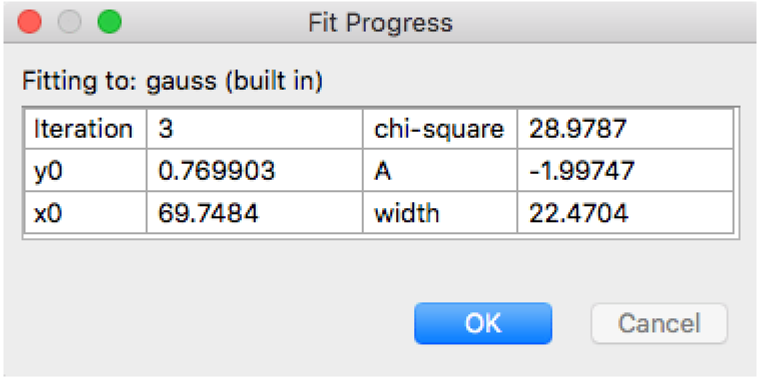
Iterative Fitting

For the other built-in fitting functions and for user-defined functions, the operation is iterative as the fit tries various values for the unknown coefficients. For each try, it computes chi-square searching for the coefficient values that yield the minimum value of chi-square.

The Levenberg-Marquardt algorithm is used to search for the coefficient values that minimize chi-square. This is a form of nonlinear, least-squares fitting.

As the fit proceeds and better values are found, the chi-square value decreases. The fit is finished when the rate at which chi-square decreases is small enough.

During an iterative curve fit, you will see the Curve Fit progress window. This shows you the function being fit, the updated values of the coefficients, the value of chi-square, and the number of passes.



Fitting to: gauss (built in)

Iteration	3	chi-square	28.9787
y0	0.769903	A	-1.99747
x0	69.7484	width	22.4704

Normally you will let the fit proceed until completion when the Quit button is disabled and the OK button is enabled. When you click OK, the results of the fit are written in the history area.

If the fit has gone far enough and you are satisfied, you can click the Quit button, which finishes the iteration currently under way and then puts the results in the history area as if the fit had completed on its own.

Sometimes you can see that the fit is not working, e.g., when chi-square is not decreasing or when some of the coefficients take on very large nonsense values. You can abort it by pressing the **User Abort Key Combinations**, which discards the results of the fit. You will need to adjust the fitting coefficients and try again.

Initial Guesses

The Levenberg-Marquardt algorithm is used to search for the minimum value of chi-square. Chi-square defines a surface in a multidimensional error space. The search process involves starting with an initial guess at the coefficient values. Starting from the initial guesses, the fit searches for the minimum value by travelling down hill from the starting point on the chi-square surface.

We want to find the deepest valley in the chi-square surface. This is a point on the surface where the coefficient values of the fitting function minimize, in the least-squares sense, the difference between the experimental data and fit data. Some fitting functions may have only one valley. In this case, when the bottom of the valley is found, the best fit has been found. Some functions, however, may have multiple valleys, places where the fit is better than surrounding values, but it may not be the best fit possible.

When the fit finds the bottom of a valley it concludes that the fit is complete even though there may be a deeper valley elsewhere on the surface. Which valley is found first depends on the initial guesses.

For built-in fitting functions, you can automatically set the initial guesses. If this produces unsatisfactory results, you can try manual guesses. For fitting to user-defined functions you must supply manual guesses.

Termination Criteria

A curve fit will terminate after 40 passes in searching for the best fit, but will quit if 9 passes in a row produce no decrease in chi-square. This can happen if the initial guesses are so good that the fit starts at the minimum chi-square. It can also happen if the initial guesses are way off or if the function does not fit the data at all.

You can change the 40-pass limit. See the discussion of V_FitMaxIters under **Special Variables for Curve Fitting** on page III-232. Usually needing more than 40 passes is a sign of trouble with the fit. See **Identifiability Problems** on page III-226.

Unless you know a great deal about the fitting function and the data, it is unwise to assume that a solution is a good one. In almost all cases you will want to see a graph of the solution to compare the solution with the data. You may also want to look at a graph of the residuals, the differences between the fitted model and the data. Igor makes it easy to do both in most cases.

Errors in Curve Fitting

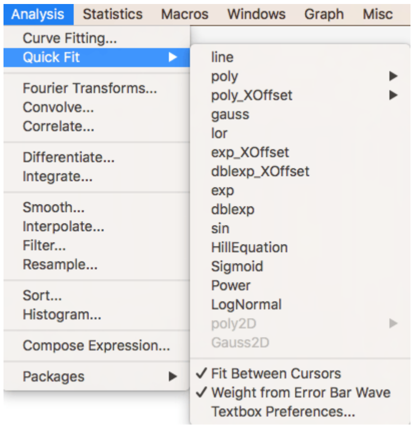
In certain cases you may encounter a situation in which it is not possible to decide where to go next in searching for the minimum chi-square. This results in a “singular matrix” error. This is discussed under **Singularities in Curve Fitting** on page III-265. **Curve Fitting Troubleshooting** on page III-266 can help you find the solution to the problem.

Data for Curve Fitting

You must have measured values of both the dependent variable (usually called “y”) and the independent variables (usually called “x” especially if there is just one). These are sometimes called the “response variable” and “explanatory variables.” You can do a curve fit to waveform data or to XY data. That is, you can fit data contained in a single wave, with the data values in the wave representing the Y data and the wave’s X scaling representing equally-spaced X data. Or you can fit data from two (or more) waves in which the data values in one wave represent the Y values and the data values in another wave represent the X data. In this case, the data do not need to be equally spaced. In fact, the X data can be in random order.

You can read more about waveform and XY data in Chapter II-5, **Waves**.

Curve Fitting Using the Quick Fit Menu



The Quick Fit menu is the easiest, fastest way to do a curve fit.

The Quick Fit menu gives you quick access to curve fits using the built-in fitting functions. The data to be fit are determined by examining the top graph; if a single trace is found, the graphed data is fit to the selected fitting function. If the graph contains more than one trace a dialog is presented to allow you to select which trace should be fit.

The graph contextual menu also gives access to the Quick Fit menu. If you Control-click (*Macintosh*) or right-click (*Windows*) on a trace in a graph, you will see a Quick Fit item at the bottom of the resulting contextual menu. When you access the Quick Fit menu this way, it automatically fits to the trace you clicked on. This gives you a way to avoid the dialog that Quick Fit uses to select the correct trace when there is more than one trace on a graph.

When you use the Quick Fit menu, a command is generated to perform the fit and automatically add the model curve to the graph. By default, if the graph cursors are present, only the data between the cursors is fit. You can do the fit to the entire data set by selecting the Fit Between Cursors item in the Quick Fit menu in order to uncheck the item. When unchecked, fits are done disregarding the graph cursors.

If the trace you are fitting has error bars and the data for the error bars come from a wave, Quick Fit will use the wave as a weighting wave for the fit. Note that this assumes that your error bars represent one standard deviation. If your error wave represents more than one standard deviation, or if it represents a confidence interval, you should not use it for weighting. You can select the Weight from Error Bar Wave item to unmark it, preventing Igor from using the error bar wave for weighting.

By default, a report of curve fit results is printed to the history. If you select Textbox Preferences, the Curve Fit Textbox Preferences dialog is displayed. It allows you to specify that a textbox be added to your graph containing most of the information that is printed in the history. You can select various components of the information by selecting items in the Dialog.

In the screen capture above, the poly2D and Gauss2D fit functions are not available because the top graph does not contain a contour plot or image plot, in which case the fitting functions would be available.

For a discussion of the built-in fit functions, see **Built-in Curve Fitting Functions** on page III-206.

Limitations of the Quick Fit Menu

The Quick Fit menu does not give you access to the full range of curve fitting options available to you. It does not give you access to user-defined fitting functions, automatic residual calculation, masking, or confidence interval analysis. A Quick Fit always uses automatic guesses; if the automatic guesses don't work, you must use the Curve Fitting dialog to enter manual guesses.

If your graph displays an image that uses auxiliary X and Y waves to set the image pixel sizes, Quick Fit will not be able to do the fit. This is because these waves for an image plot have an extra point that makes them unsuitable for fitting. A contour plot uses X and Y waves that set the centers of the data, and these can be used for fitting. Quick Fit will do the right thing with such a contour plot.

Using the Curve Fitting Dialog

If you want options that are not available via the Quick Fit menu, the next easiest way to do a fit is to choose Curve Fitting from the Analysis menu. This displays the Curve Fitting dialog, which presents an interface for selecting a fitting function and data waves, and for setting various curve fitting options. You can use the dialog to enter initial guesses if necessary. The Curve Fitting dialog can also be used to create a new user-defined fitting function.

Most curve fits can be accomplished using the Curve Fitting dialog. If you need to do many fits using the same fit function fitting to numerous data sets you will probably want to write a procedure in Igor's programming language to do the job.

The facility for creating a user-defined fitting function using the Curve Fitting dialog will handle most common cases, but is probably not the best way to create a very complex fitting function. In such cases, you will need to write a fitting function in a procedure window. This is described later under **User-Defined Fitting Functions** on page III-250.

Some very complicated user-defined fitting functions may not work well with the Curve Fitting dialog. In some cases, you may need to write the fitting function in the Procedure window, and then use the dialog to set up and execute the fit. In other cases it may be necessary to enter the operation manually using either a user procedure or by typing on the command line. These cases should be quite rare.

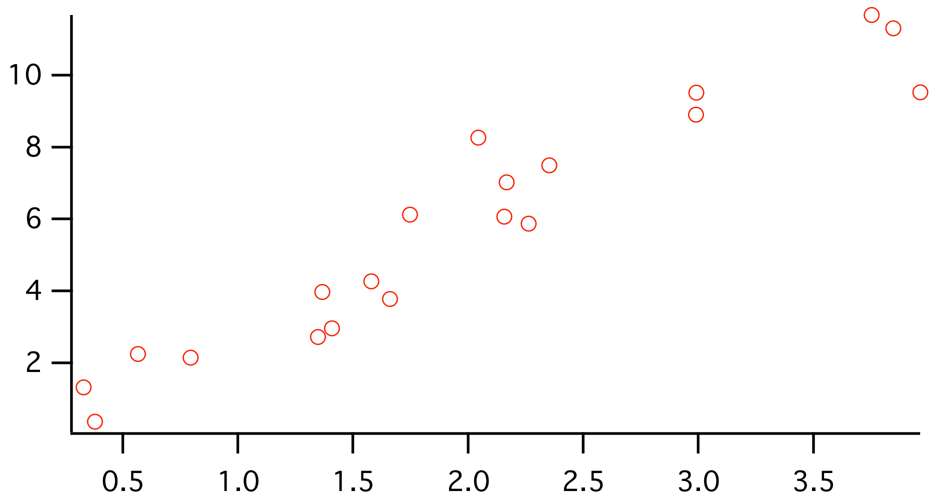
A Simple Case — Fitting to a Built-In Function: Line Fit

To get started, we will cover fitting to a simple built-in fit: a line fit. You may have a theoretical reason to believe that your data should be described by the function $y = ax + b$. You may simply have an empirical observation that the data appear to fall along a line and you now want to characterize this line. It's better if you have a theoretical justification, but we're not all that lucky.

The Curve Fitting dialog is organized into four tabs. Each tab contains controls for some aspect of the fitting operation. Simple fits to built-in functions using default options will require only the Function and Data tab.

We will go through the steps necessary to fit a line to data displayed in a graph. Other built-in functions work much the same way.

You might have data displayed in a graph like this:



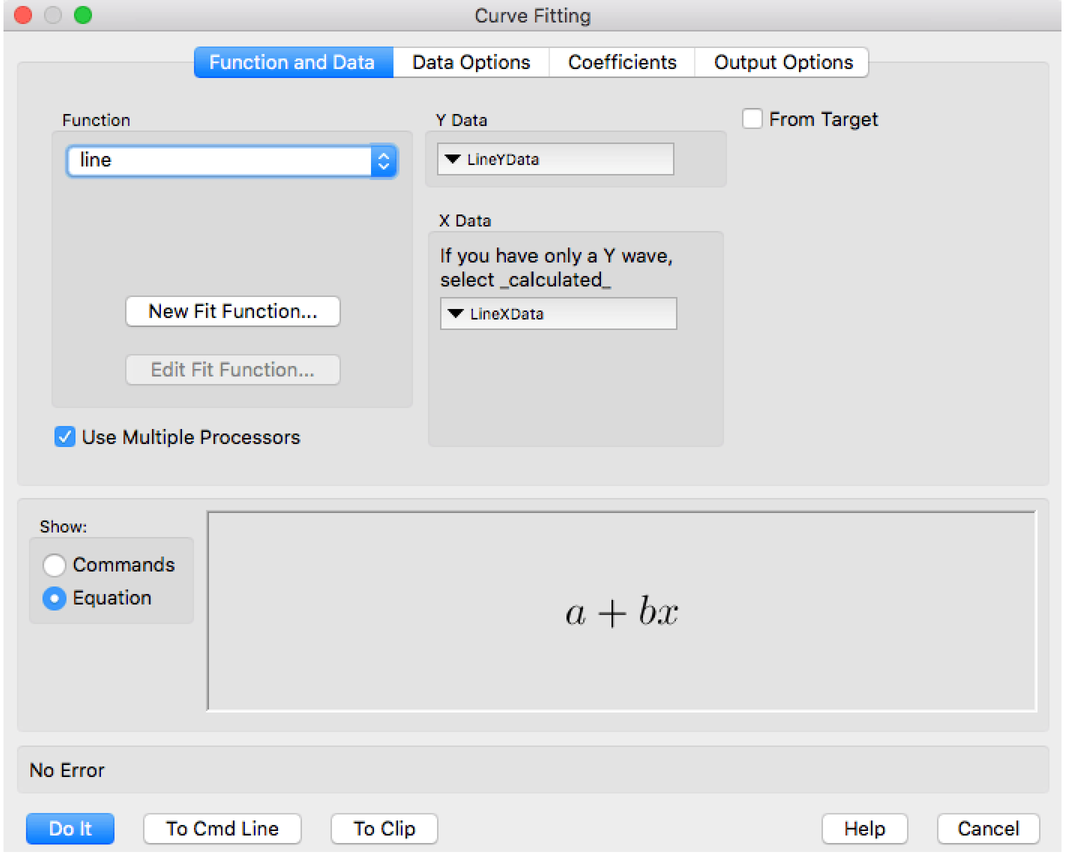
Now you wish to find the best-fitting line for this data. The following commands will make a graph like this one. The SetRandomSeed command is used so that the "random" scatter produced by the enoise function will be the same as shown above. If you would like to perform the actions yourself as you read the manual, you can make the data shown here and the graph by typing these commands on the command line:

```
Make/N=20/D LineYData, LineXData
SetRandomSeed 0.5   // So the example always makes the same "random" numbers
LineXData = enoise(2)+2             // enoise makes random numbers
LineYData = LineXData*3+gnoise(1)   // so does gnoise
Display LineYData vs LineXData
ModifyGraph mode=3,marker=8
```

The first line makes two waves to receive our “data”. The second line sets the seed for Igor's pseudo-random number generators, resulting in reproducible noise. The third line fills the X wave with uniformly-distributed random numbers in the range of zero to four. The fourth line fills the Y wave with data that falls on a line having a slope of three and passing through the origin, with some normally-distributed noise added. The final two lines make the graph and set the display to markers mode with open circles as the marker.

Choosing the Function and Data

You display the Curve Fitting dialog by choosing Curve Fitting from the Analysis menu. If you have not used the dialog yet, it looks like this, with the Function and Data tab showing:



Function: line

Y Data: LineYData

☐ From Target

X Data

If you have only a Y wave, select _calculated_

LineXData

☑ Use Multiple Processors

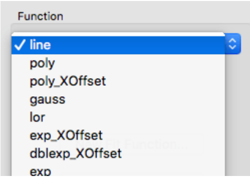
Show:

○ Commands

● Equation

$$a + bx$$

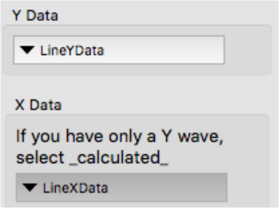
No Error



The first step in doing a curve fit is to choose a fit function. We are doing a simple line fit, so pop up the Function menu and choose “line”.

Select the Y data from the Y Data menu. If you have waveform data, be sure that the X data menu has “_Calculated_” selected.

If you have separate X and Y data waves, you must select the X wave in the X Data menu. Only waves having the same number of data points as the Y wave are shown in this menu. A mismatch in the number of points is usually the problem if you don’t see your X wave in the menu.



Y Data: LineYData

X Data

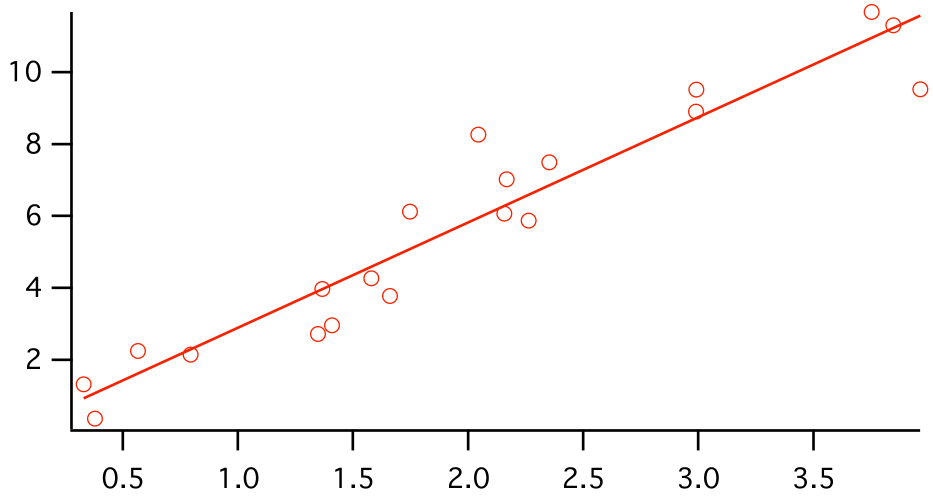
If you have only a Y wave, select _calculated_

LineXData

For the line fit example, we select LineYData from the Y Data menu, and LineX-Data from the X Data menu.

If you have a large number of waves in your experiment, it may be easier if you select the From Target checkbox. When it is selected only waves from the top graph or table are shown in the Y and X wave menus, and an attempt is made to select wave pairs used by a trace on the graph.

At this point, everything is set up to do the fit. For this simple case it is not necessary to visit the other tabs in the dialog. When you click Do It, the fit proceeds. The line fit example graph winds up looking like this:



In addition to the model line shown on the graph, various kinds of information appears in the history area:

```
•CurveFit line LineYData /X=LineXData /D
   fit_LineYData= W_coef[0]+W_coef[1]*x
   W_coef={-0.037971,2.9298}
   V_chisq= 18.25; V_npnts= 20; V_numNaNs= 0; V_numINFs= 0;
   V_startRow= 0;V_endRow= 19;V_q= 1;V_Rab= -0.879789;
   V_Pr= 0.956769;V_r2= 0.915408;
   W_sigma={0.474,0.21}
   Coefficient values ± one standard deviation
      a    =-0.037971 ± 0.474
      b    =2.9298 ± 0.21
```

Command line generated by the dialog.

This line can be copied and used to reevaluate the model curve.

Fit coefficients as a wave.

Standard deviations of the Fit coefficients as a wave.

Coefficient values in a list using the names shown in the dialog.

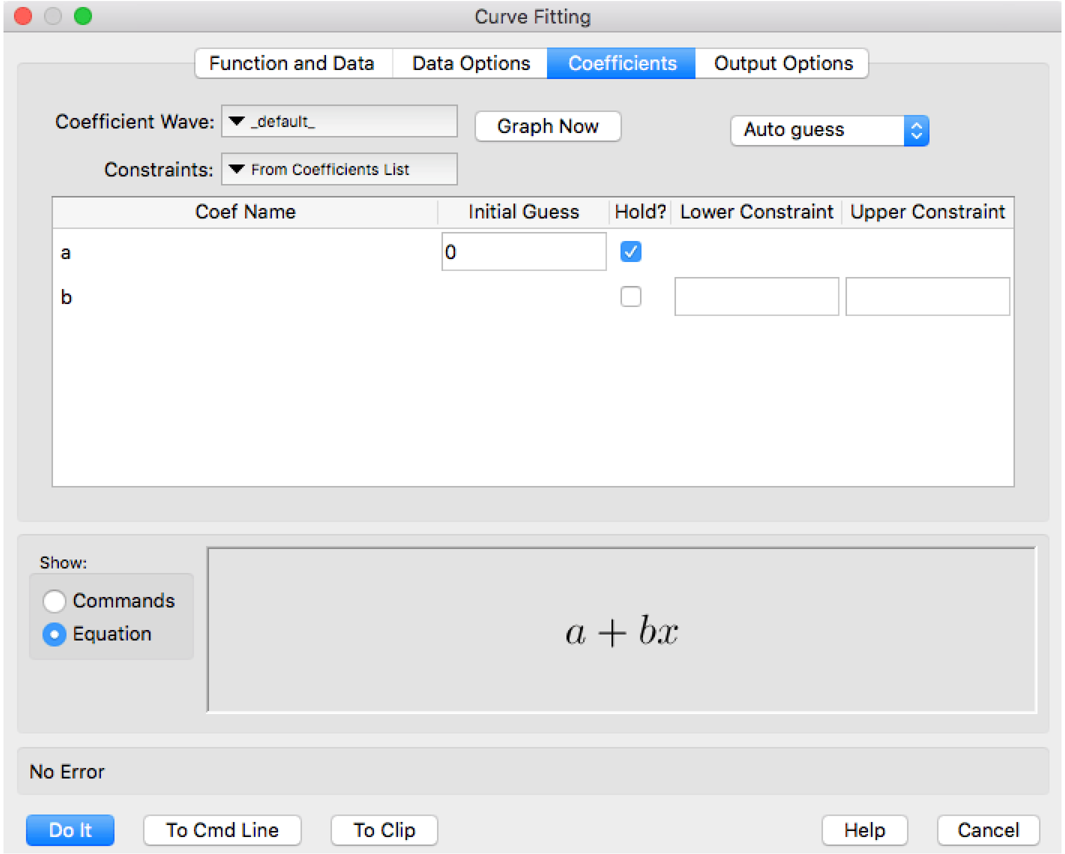
Two Useful Additions: Holding a Coefficient and Generating Residuals

Well, you've done the fit and looked at the graph and you decide that you have reason to believe that the line should go through the origin. Because of the scatter in the measured Y values, the fit line misses the origin. The solution is to do the fit again, but with the Y intercept coefficient held at a value of zero.

You might also want to display the residuals as a visual check of the fit.

Bring up the dialog again. The dialog remembers the settings you used last time, so the line fit function is already chosen in the Function menu, and your data waves are selected in the Y Data and X Data menus.

Select the Coefficients tab. Each of the coefficients has a row in the Coefficients list:



Coefficient Wave: _default_

Constraints: From Coefficients List

Auto guess

Coef Name	Initial Guess	Hold?	Lower Constraint	Upper Constraint
a	0	☑		
b		□		

Show:

○ Commands

● Equation

$$a + bx$$

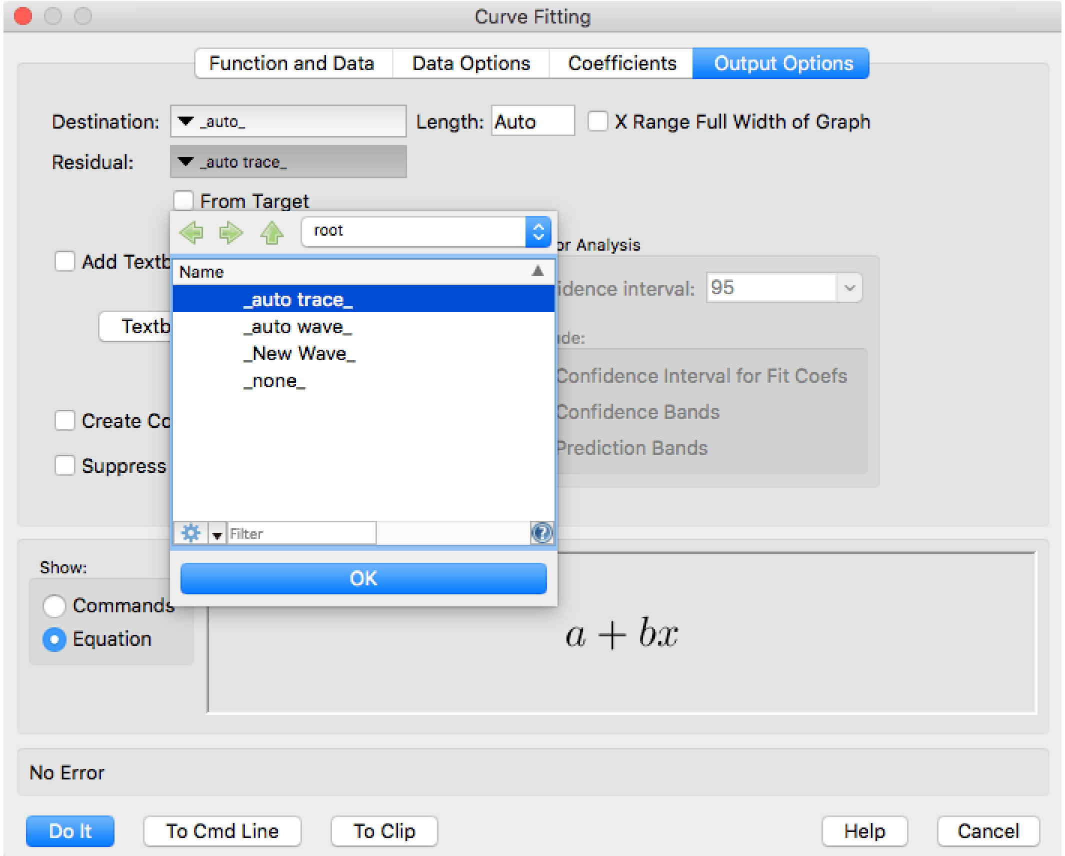
No Error

Click the checkbox in the column labeled “Hold?” to hold the value of that coefficient.

To specify a coefficient value, fill in the corresponding box in the Initial Guess column. Until you select the Hold box the initial guess box is not available because built-in fits don’t require initial guesses.

To fill in a value, click in the box. You can now type a value. When you have finished, press Enter (*Windows*) or Return (*Macintosh*) to exit editing mode for that box.

Now we want to calculate the fit residuals and add them to the graph. Click the Output Options tab and choose _auto trace_ from the Residual menu:



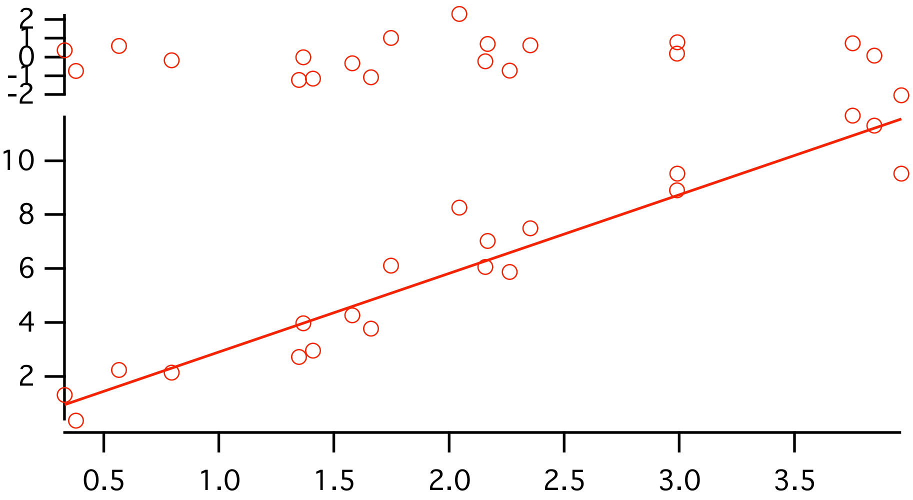
Destination: _auto_
Length: Auto
☐ X Range Full Width of Graph
Residual: _auto trace_
☐ From Target
Confidence interval: 95
○ Commands
● Equation

$a + bx$

No Error

There are a number of options for the residual. We chose _auto trace_ to calculate the residual and add it to the graph. You may not always want the residuals added to your graph; choose _auto wave_ to automatically calculate the residuals but *not* display them on your graph. Both _auto trace_ and _auto wave_ create a wave with the same name as your Y wave with “Res_” prefixed to the name. Choosing _New Wave_ generates commands to make a new wave with your choice of name to fill with residuals. It is not added to your graph.

Now when we click Do It, the fit is recalculated with *a* held at zero so that the line passes through the origin. Residuals are calculated and added to the graph:



Note that the line on the graph doesn't cross the vertical axis at zero, because the horizontal axis doesn't extend to zero.

Holding *a* at zero, the result of the fit printed in the history is:

The /H flag shows that one or more coefficients are held.

```
•K0 = 0;
•CurveFit/H="10" line LineYData /X=LineXData /D /R
   fit_LineYData= W_coef[0]+W_coef[1]*x
   Res_LineYData= LineYData[p] - (W_coef[0]+W_coef[1]*LineXData[p])
   W_coef={0,2.915}
   V_chisq= 18.2565; V_npnts= 20; V_numNaNs= 0; V_numINFs= 0;
   V_startRow= 0; V_endRow= 19; V_q= 1; V_Rab= 0; V_Pr= 0.956769;
   V_r2= 0.906186;
   W_sigma={0,0.0971}
   Coefficient values ± one standard deviation
      a    =   0 ± 0
      b    =   2.915 ± 0.0971
```

a is zero because it was held.

Automatic Guesses Didn't Work

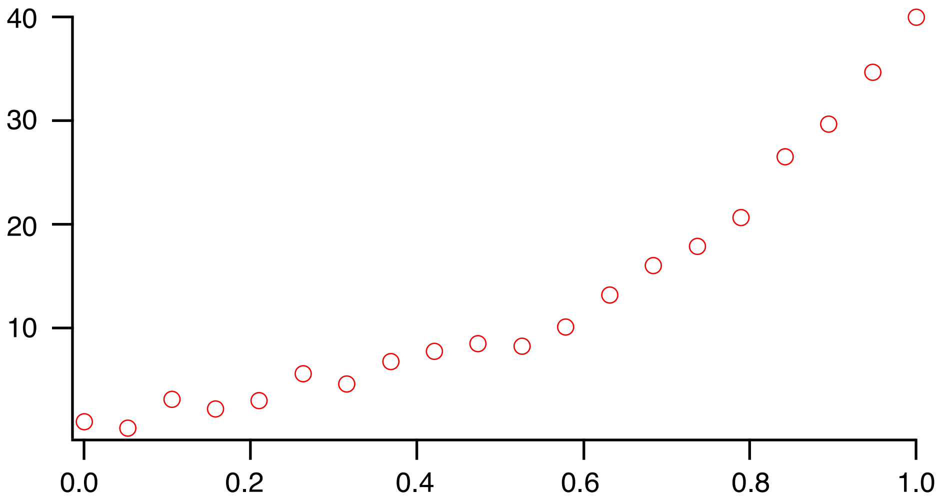
Most built-in fits will work just like the line fit. You simply choose a function from the Function menu, choose your data wave (or waves if you have both X and Y waves) and select output options on the Output Options tab. For built-in fits you don't need the Coefficients tab unless you want to hold a coefficient.

In a few cases, however, automatic guesses don't work. Then you must use the Coefficient tab to set your own initial guesses. One important case in which this is true is if you are trying to fit a growing exponential, $y = ae^{bx}$, where *b* is positive.

Here are commands to create an example for this section. Once again, you may wish to enter these commands on the command line to follow along:

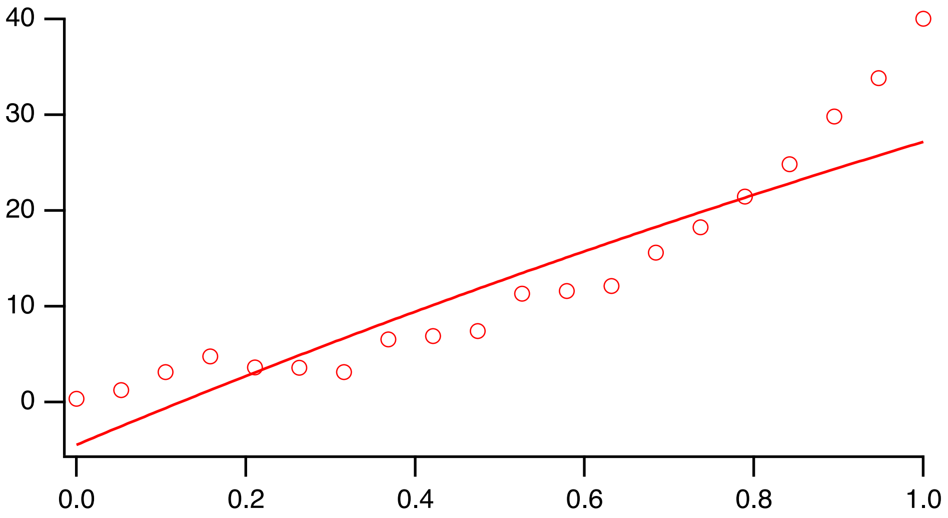
```
Make/N=20 RisingExponential
SetScale/I x 0,1,RisingExponential
SetRandomSeed 0.5
RisingExponential = 2*exp(3*x)+gnoise(1)
Display RisingExponential
ModifyGraph mode=3,marker=8
```

These commands make a 20-point wave, set its X scaling to cover the range from 0 to 1, fill it with exponential values plus a bit of noise, and make a graph:



The first-cut trial to fitting an exponential function is to select exp from the Function menu and the RisingExponential wave in the Y Data menu (if you are continuing from the previous section, you may need to go to the Coefficients tab and un-hold the y0 coefficient, and to the Output Options tab and de-select _auto trace_ in the Residual menu). Automatic guesses assume that the exponential is well described by a negative coefficient in the exponential, so the fit doesn't work:

```
•CurveFit exp RisingExponential /D
   Fit converged properly
   fit_RisingExponential= W_coef[0]+W_coef[1]*exp(-W_coef[2]*x)
   W_coef={108.87,-113.32,0.32737}
   V_chisq= 423.845;V_npnts= 20;V_numNaNs= 0;V_numINFs= 0;
   V_startRow= 0;V_endRow= 19;
   W_sigma={255,252,0.863}
   Coefficient values ± one standard deviation
      y0    =108.87 ± 255
      A     =-113.32 ± 252
      invTau=0.32737 ± 0.863
```



In addition to the fact that the graphed fit curve doesn't follow the data points, the estimated uncertainty for the fit coefficients is unreasonably large.

The solution is to provide your own initial guesses. Click the Coefficients tab and choose Manual Guesses in the menu in the upper-right.

The Initial Guesses column in the Coefficients list is now available for you to type your own initial guesses, including a *negative* value for invTau. In this case, we might enter the following initial guesses:

```
y0       0
A        2
invTau-  3
```

In response, Igor generates some extra commands for setting the initial guesses and this time the fit works correctly:

```
•K0 = 0; K1 = 2; K2 = -3;
•CurveFit/G exp RisingExponential /D
   Fit converged properly
   fit_RisingExponential= W_coef[0]+W_coef[1]*exp(-W_coef[2]*x)
   W_coef={-0.81174,2.2996,-2.8742}
   V_chisq= 15.6292;V_npnts= 20;V_numNaNs= 0;V_numINFs= 0;
   V_startRow= 0;V_endRow= 19;
   W_sigma={0.798,0.41,0.171}
   Coefficient values ± one standard deviation
      y0    =-0.81174 ± 0.798
      A     =2.2996 ± 0.41
      invTau=-2.8742 ± 0.171
```

It may well be that finding a set of initial guesses from scratch is difficult. Automatic guesses might be a good starting point which will provide adequate initial guesses when modified. For this the dialog provides the Only Guess mode.

When Only Guess is selected, click Do It to create the automatic initial guesses, and then stop without trying to do the fit. Now, when you bring up the Curve Fitting dialog again, you can choose the coefficient wave created by the auto guess (W_coef if you chose _default_ in the Coefficient Wave menu). Choosing this wave will set the initial guesses to the automatic guess values. Now choose Manual Guesses and modify the initial guesses. The Graph Now button may help you find good initial guesses (see **Coefficients Tab for a User-Defined Function** on page III-192).

Fits with Constants

A few of the built-in fit functions include constants that are not varied during the fit. They enter only to provide, for instance, a constant X offset to improve numerical stability. One such built-in fit function is the exp_XOffset fit function. It fits this equation:

$$y_0 + A\exp\left(\frac{x-x_0}{\tau}\right)$$

Here, y0, A and tau are fit coefficients - they are varied during iterative fitting, and their final values are the solution to the fit. On the other hand, x0 is a constant - it is not varied, rather you give it any value you wish as part of the fit setup. In the case of the exp_XOffset fit function, if you do not set it yourself, it will be set by default to the minimum X value in your input data. For fits to data far from the origin, this improves numerical stability. Naturally, it affects the value of A in the final solution.

In the Curve Fitting dialog, when you select a built-in fit function that uses a constant, an additional edit box appears below the fit function menu where you can set the value of the constant. Setting it to the default value Auto causes Igor to set the constant to some reasonable value based on your input data.

When you do a fit using a built-in fit function that uses a constant, the output includes the wave W_fitConstants. Each element of this wave holds the value of one constant for the equation. At present, the wave will have just one element because there are no built-in fit functions that use more than one constant.

See **Built-in Curve Fitting Functions** on page III-206 for details on the constants used with specific fit functions.

Fitting to a User-Defined Function

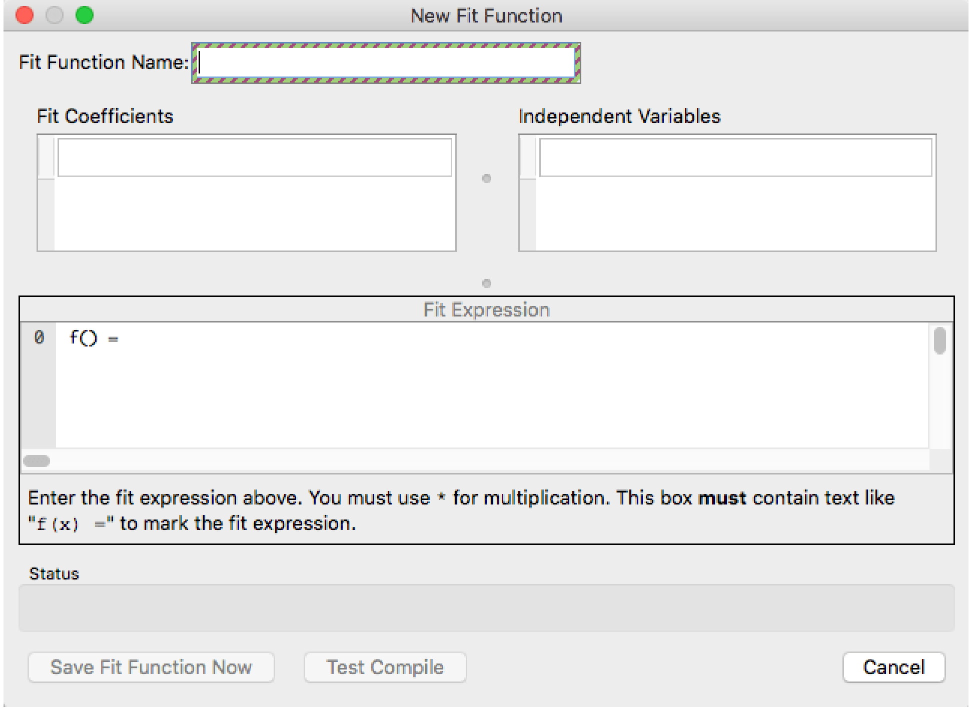
Fitting to a user-defined function is much like fitting to a built-in function, with two main differences:

- You must define the fitting function.
- You must supply initial guesses.

To illustrate the creation of a user-defined fit function, we will create a function to fit a log function: $y = C_1 + C_2\ln(x)$.

Creating the Function

To create a user-defined fitting function, click the New Fit Function button in the Function and Data tab of the Curve Fitting Dialog. The New Fit Function dialog is displayed:



```
0  f() =
```

Enter the fit expression above. You must use * for multiplication. This box **must** contain text like "f(x) =" to mark the fit expression.

You must fill in a name for your function, fill in the Fit Coefficients list with names for the coefficients, fill in the Independent Variables list with names for independent variables, and then enter a fit expression in the Fit Expression window.

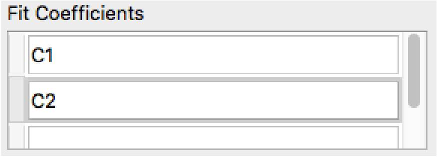
The function name must conform to nonliberal naming rules. That means it must start with a letter, contain only letters, numbers or underscore characters, and it must be 255 or fewer bytes in length (see **Object Names** on page III-501). It must not be the same as the name of another object like a built-in function, user procedure, or wave name.

For the example log function, we enter "LogFit":

Fit Function Name: LogFit

Press Tab to move to the first entry in the Fit Coefficient list. There is always one blank entry in the list where you can add a new coefficient name; since we haven't entered anything yet, there is only one blank entry.

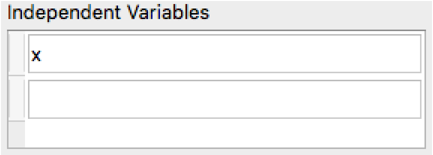
Each time you enter a name, press Return (*Macintosh*) or Enter (*Windows*). Igor accepts that name and makes a new blank entry where you can enter the next name. We enter C1 and C2 as the names:



C1

C2

Click in the first blank entry in the Independent Variables list. Most fit functions will require just a single independent variable. We choose to name our independent variable x:

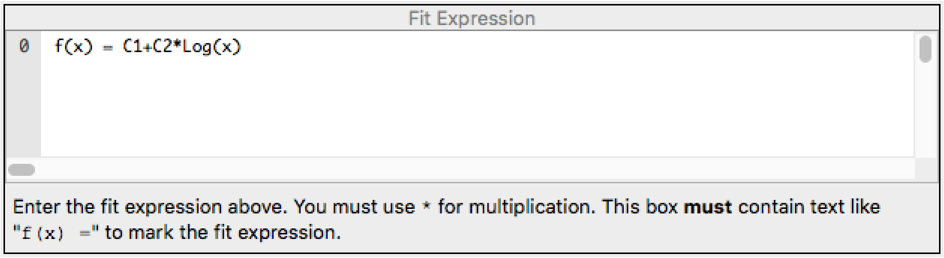


x

It is now time to enter the fit expression. You will notice that when you have entered a name in the Independent Variables list, some text is entered in the expression window. The return value of the fit function (the Y value in most cases) is marked with something like "f(x) = ". If you had entered "temperature" as the independent variable, it would say "f(temperature) = ".

This "f() = " text is required; otherwise the return value of the function will be unknown.

The fit expression is not an algebraic expression. It must be entered in the same form as a command on the command line. If you need help constructing a legal expression, you may wish to read **Assignment Statements** on page IV-4. The expression you need to type is simply the right-hand side of an assignment statement. The log expression in our example will look like this:



```
f(x) = C1+C2*Log(x)
```

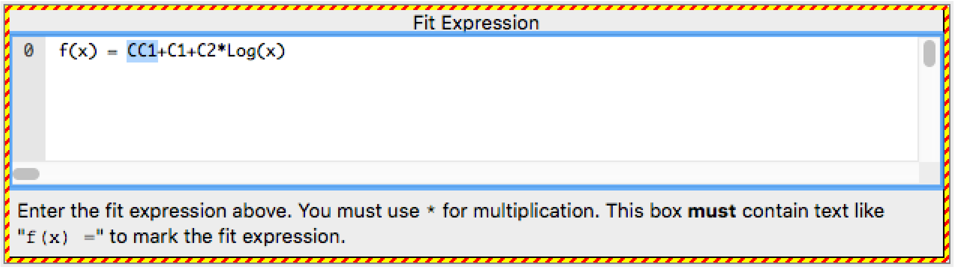
Enter the fit expression above. You must use * for multiplication. This box **must** contain text like "f(x) =" to mark the fit expression.

Multiplication requires an explicit *.

The dialog will check the fit expression for simple errors. For instance, it will not make the Save Fit Function Now button available if any of the coefficients or independent variables are missing from the expression.

The dialog cannot check for correct expression syntax. If all the easily-checked items are correct, the Save Fit Function Now and Test Compile buttons are made available. Clicking either of them will enter a new function in the Procedure window and attempt to compile procedures. If you click the Save Fit Function Now button and compilation is successful, you are returned to the Curve Fitting dialog with the new function chosen in the Function menu.

If compile errors occur, the compiler's error message is displayed in the status box, and the offending part of your expression is highlighted. A common error might be to misspell a coefficient name somewhere in your expression. For instance, if you had typed CC1 instead of C1 somewhere you might see something like this:



```
f(x) = CC1+C1+C2*Log(x)
```

Enter the fit expression above. You must use * for multiplication. This box **must** contain text like "f(x) =" to mark the fit expression.

Note that C1 appears in the expression. Otherwise, the dialog would show that C1 is missing.

When everything is ready to go, click the Save Fit Function Now button to construct a function in the Procedure window. It includes comments in the function code that identify various kinds of information for the dialog. Our example function looks like this:

```
Function LogFit(w,x) : FitFunc
    WAVE w
    Variable x

    //CurveFitDialog/ These comments were created by the Curve Fitting dialog. Altering them will
    //CurveFitDialog/ make the function less convenient to work with in the Curve Fitting dialog.
    //CurveFitDialog/ Equation:
    //CurveFitDialog/ f(x) = C1+C2*log(x)
    //CurveFitDialog/ End of Equation
    //CurveFitDialog/ Independent Variables 1
    //CurveFitDialog/ x
    //CurveFitDialog/ Coefficients 2
    //CurveFitDialog/ w[0] = C1
    //CurveFitDialog/ w[1] = C2

    return w[0]+w[1]*log(x)
End
```

You shouldn't have to deal with the code in the Procedure window unless your function is so complex that the dialog simply can't handle it. You can look at **User-Defined Fitting Functions** on page III-250 for details on how to write a fitting function in the Procedure window.

Having entered the fit expression correctly, click the Save Fit Function Now button, which returns you to the main Curve Fitting dialog. The Function menu will now have LogFit chosen as the fitting function.

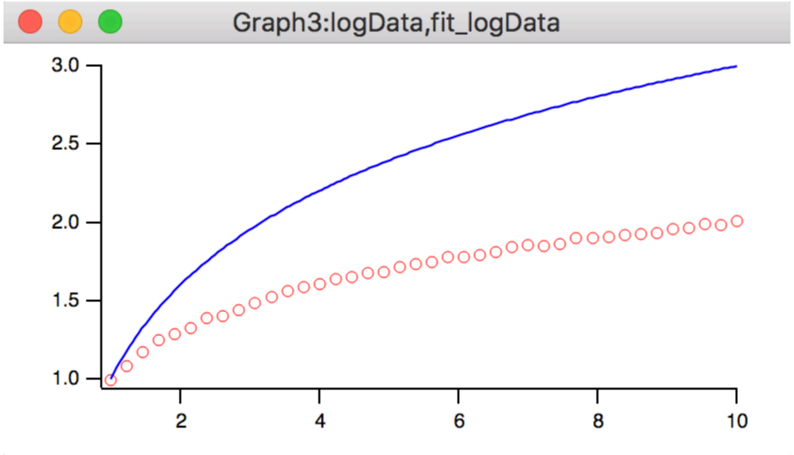
Coefficients Tab for a User-Defined Function

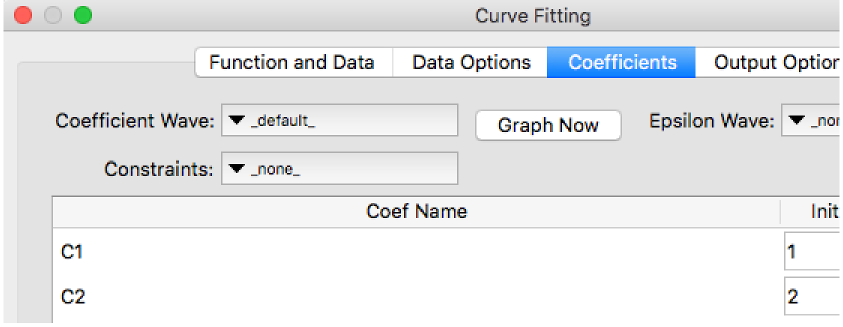
To fit a user-defined function, you will need to enter initial guesses in the Coefficients tab.

Having created a user-defined fitting function (or simply having selected a preexisting one) you will find that the error message window at the bottom of the dialog now states: "You have selected a user-defined fit function so you must enter an initial guess for every fit coefficient. Go to the Coefficients Tab to do this."

When you have selected a user-defined fitting function, the Initial Guess column of the Coefficients List is available. You must enter a number in each row. Some functions may be difficult to fit; in such a case the initial guess may have to be pretty close to the final solution.

To help you find good initial guesses, the Coefficients tab includes the Graph Now button. This button will add a trace to the top graph showing your fitting function using the initial guesses you have entered. For instance:





Coefficient Wave: _default_

Constraints: _none_

Epsilon Wave: _nor

Coef Name	Init
C1	1
C2	2

You can change the values in the initial guess column and click the Graph Now button as many times as you wish. The trace will be updated with the changes each time.

The Graph Now button works as describe in **The Destination Wave** on page III-196, with one exception: if you selected _none_ in the Destination pop-up menu of the Output Options tab, the Graph Now button works as if you selected _auto_. The Graph Now button honors your choices for destination wave style, and it makes a new wave if you selected _New Wave_. Unless you change the destination wave settings before clicking Do It, the wave set by Graph Now will be overwritten by the fit.

On the Coefficients tab you have the option of selecting an “epsilon” wave. An epsilon wave contains one epsilon value for each point in your coefficients wave. By default the Epsilon menu is set to _none_ indicating that the epsilon values are set to the default values.

Each epsilon value is used to calculate partial derivatives with respect to the fit coefficients. The partial derivatives are used to determine the search direction for coefficients that give the smallest chi-square.

In most cases the epsilon values are not critical. However, you can supply your own if you have reason to believe that the default epsilon values are not providing acceptable partial derivatives (sometimes a singular matrix error can be avoided by using custom epsilon values). To specify epsilon values, either select a pre-existing wave from the Epsilon Wave menu, or select _New Wave_. Only waves having a number of points equal to the number of fit coefficients are shown in the menu. Either choice causes the Epsilon column to be shown in the Coefficients list, where you can enter values for epsilon.

If you select a wave from the Epsilon menu, the values in that wave are entered in the list. If you select _New Wave_, the dialog generates commands to create an epsilon wave and fill it with the values in the Epsilon column.

For more information about the epsilon wave and what it does, see **The Epsilon Wave** on page III-267.

Making a User-Defined Function Always Available

Note that, because the fitting function is created in the Procedure window, it is stored as part of the experiment file. That means that it will be available for fitting while you are working on the experiment in which it was created, but will not be available when you work on other experiment files.

You can make the fit function available whenever you start up Igor Pro. Make a new procedure window using the Procedure item under New in the Windows menu. Find the fit function in the Procedure window, select all the text from `Function` through `End` and choose Cut from the Edit menu. Paste the code into your new procedure window. Finally, choose Save Procedure Window from the File menu and save in"Igor Pro User Files/Igor Procedures" (see **Igor Pro User Files** on page II-31 for details). The next time you start Igor Pro you will find that the function is available in all your experiments.

Removing a User-Defined Fitting Function

To remove a user-defined fitting function that you don't want any more, choose Procedure Window from the Windows menu. Find the function in the Procedure window (you can use Find from the Edit menu and search for the name of your function). Select all of the function definition text from the word "`Function`" through the word "`End`" and delete the text.

If you have followed the directions in the section above for making the function always available, find the procedure file in "Igor Pro User Files/Igor Procedures", remove it from the folder, and then restart.

User-Defined Fitting Function Details

The New Fit Function dialog is the easiest way to enter a user-defined fit function. But if your fit expression is very long, or it requires multiple lines with local variables or conditionals, the dialog can be cumbersome. Certain special situations may call for a format that is not supported by the dialog.

For a complete discussion of user-defined fit function formats and the uses for different formats, see **User-Defined Fitting Functions** on page III-250.

Fitting to an External Function (XFUNC)

An external function, or XFUNC, is a function provided via an Igor extension or plug-in. A programmer uses the XOP Toolkit to build an XFUNC. You don't need the toolkit to use one. An XFUNC must be installed before it can be used. See **Igor Extensions** on page III-511.

An XFUNC can speed up curve fitting greatly if your fitting function requires a great deal of computation. The speed of fitting is usually dominated by other kinds of overhead and the effort of writing an XFUNC is not justified.

Fitting to an external function is just like fitting to a user-defined function, except that the Curve Fitting dialog has no way to find out how many fit coefficients are required. When you switch to the Coefficients tab, you will see an alert telling you of that fact. The solution to this problem is to select a coefficient wave with the correct number of points. You must create the wave before entering the Curve Fitting dialog.

When you select a coefficient wave the contents of the wave are used to build the Coefficients list. The wave values are entered in the Initial Guess column. If you change an initial guess, the dialog will generate the commands necessary to enter the new values in the wave.

The Coefficient Wave menu normally shows only those waves whose length is the same as the number of fit coefficients required by the fitting function. When you choose an XFUNC for fitting, the menu shows all waves. You have to know which one to select. We suggest using a wave name that identifies what the wave is for.

Igor doesn't know about coefficient names for an XFUNC. Coefficient names will be derived from the name of the coefficient wave you select. That is, if your coefficient wave is called "coefs", the coefficient names will be "coefs_0", "coefs_1", etc.

Of course, implementing your function in C or C++ is more time-consuming and requires both the XOP Toolkit from WaveMetrics, and a software development environment. See **Creating Igor Extensions** on page IV-208 for details on using the XOP Toolkit to create your own external function.

The Coefficient Wave

When you fit to a user-defined function, your initial guesses are transmitted to the curve fitting operation via a coefficient wave. The coefficients that result from the fit are output in a coefficient wave no matter what kind of function you select. For the most part, the Curve Fitting dialog hides this from you.

When you create a user-defined function, the dialog creates a function that takes a wave as the input containing the fit coefficients. But through special comments in the function code, the dialog gives names to each of the coefficients. A built-in function has names for the coefficients stored internally. Using these names, the dialog is able to hide from you some of the complexities of using a coefficient wave.

In the history printout following a curve fit, the coefficient values are reported both in the form of a wave assignment, using the actual coefficients wave, and as a list using the coefficient names. For instance, here is the printout from the example user-defined fit earlier (**Fitting to a User-Defined Function** on page III-190):

```
•FuncFit LogFit W_coef logData /D
  Fit converged properly
  fit_logData= LogFit(W_coef,x)
  W_coef={1.0041,0.99922}         ———————— Fit Coefficient values as a wave assignment.
  V_chisq= 0.00282525; V_npnts= 30; V_numNaNs= 0; V_numINFs= 0;
  W_sigma={0.00491,0.00679}       ——————— Fit Coefficient sigmas as a wave assignment.
  Coefficient values ± one standard deviation
   C1 =  1.0041± 0.491     | Fit Coefficient values and sigmas in a list using the coefficient names.
   C2 =  0.99922± 0.679    |
```

The wave assignment version can be copied to the command line and executed, or it can be used as a command in a user procedure. The list version is easier to read.

You control how to handle the coefficients wave using the Coefficient Wave menu on the Coefficients tab. Here are the options.

Default

When _default_ is chosen it creates a wave called W_coef. For built-in fits this wave is used only for output. For user-defined fits it is also input. The dialog generates commands to put your initial guesses into the wave before the fit starts.

Explicit Wave

The Coefficient Wave menu lists any wave whose length matches the number of fit coefficients. If you select one of these waves, it is used for input and output from any fit.

When you choose a wave from the menu the data in the wave is used to fill in the Initial Guess column in the Coefficients list. This can be used as a convenient way to enter initial guesses. If you choose an explicit wave and then edit the initial guesses, the dialog generates commands to change the values in the selected coefficient wave before the fit starts. To avoid altering the contents of the wave, after selecting a wave with the initial guesses you want, you can choose _default_ or _New Wave_. The initial guesses will be put into the new or default coefficients wave.

New Wave

A variation on the explicit coefficients wave is _New Wave_. This works just like an explicit wave except that the dialog generates commands to make the wave before the fit starts, so you don't have to remember to make it before entering the dialog. The wave is filled in with the values from the Initial Guess column.

The _New Wave_ option is convenient if you are doing a number of fits and you want to save the fit coefficients from each fit. If you use _default_ the results of a fit will overwrite the results from any previous fit.

Errors

Estimates of fitting errors (the estimated standard deviation of the fit coefficients) are automatically stored in a wave named W_sigma. There is no user choice for this output.

The Destination Wave

When performing a curve fit, it will calculate the model curve corresponding to the fit coefficients. As with most results, the model curve is stored as an array of numbers in a wave. This wave is the “destination wave”.

The main purpose of the destination wave is to show what the fit function looks like with various coefficients during the fit operation and with the final fit coefficients when the operation is finished. You can choose no destination wave, an explicit destination wave or you can use the auto-trace feature.

You choose the destination wave option on the Output Options tab of the dialog. Here are the options.

No Destination

You would choose no destination wave if you don’t want graphic feedback during the fitting process and you don’t need to graphically compare your raw data to the fitting function. This might be the case if you are batch fitting a large number of data sets. Choose _none_ in the Destination menu.

Auto-Trace

In most cases, auto-trace is recommended; choose _auto_ from the Destination menu. When you choose this, it automatically creates a new wave, sets its X scaling appropriately, and appends it to the top graph if the Y data wave is displayed in it. The name of the new wave is generated by prepending “fit_” to the name of the Y data wave. If a wave of that name already exists, it is overwritten. If the name exceeds the 255 character maximum for a wave, the name is truncated.

The number of points in the destination wave depends on the number of independent variables. For the most common case of a univariate fit, the default is 200 points. The rest of this discussion assumes you are fitting univariate data.

If you want to fit more than one function to the same raw data using auto-trace, you should rename the auto-trace wave after the fit so that it will not be overwritten by a subsequent fit. You can rename it using the Rename item in the Data menu or by executing a Rename command directly from the command line. You may also want to save the W_coef and W_sigma waves using the same technique.

Usually the auto-trace wave is set up as a waveform even if you are fitting to XY data. The X scaling of the auto-trace wave is set to spread the 200 points evenly over the X range of the raw data. When preferences are on, the auto-trace wave appended to the graph has the preferred line style (color, size, etc.) *except* that the line mode is always set to “lines between points”, which is best suited to showing the curve fitting results.

Evenly-spaced data are not well suited to displaying a curve on a logarithmic axis. If your data are displayed using a log axis, the fit will create an XY pair of waves. The X wave will be named by prepending “fitX_” to the name of the Y data wave. This X wave is filled with exponentially-spaced X values spread out over the X range of the fit data. Of course, if you subsequently change the axis to a linear axis, the point spacing will not look right.

With _auto_ chosen in the Destination menu, the dialog displays a box labelled Length. Use this to change the number of points in the destination wave. You can set this to any number greater than 3. The more points, the smoother the curve (up to a point). More points will also take longer to draw so the fit will be slower.

Explicit Destination

You can specify an explicit destination wave rather than using auto-trace. Use this if you want a model value at the X location of each of your input data points.

An explicit destination wave must have the same number of points as the Y data wave, so you should create it using the Duplicate operation. The Destination menu shows only waves that have the same number of points as the selected Y Data wave.

The explicit destination wave is not automatically appended to the top graph. Therefore, before executing the curve fit operation, you would normally execute commands like:

```
Duplicate/O yData, yDataFit
AppendToGraph yDataFit vs xData
```

If you are fitting waveform data rather than XY data, you would omit "vs xData" from the AppendToGraph command.

New Wave

As a convenience, the Curve Fitting dialog can create a destination wave for you if you choose _New Wave_ from the Destination menu. It does this by generating a Duplicate command to duplicate your Y data wave and then uses it just like any other explicit destination wave. The new wave is not automatically appended to your graph, so you will have to do that yourself after the fit is completed.

Fitting a Subset of the Data

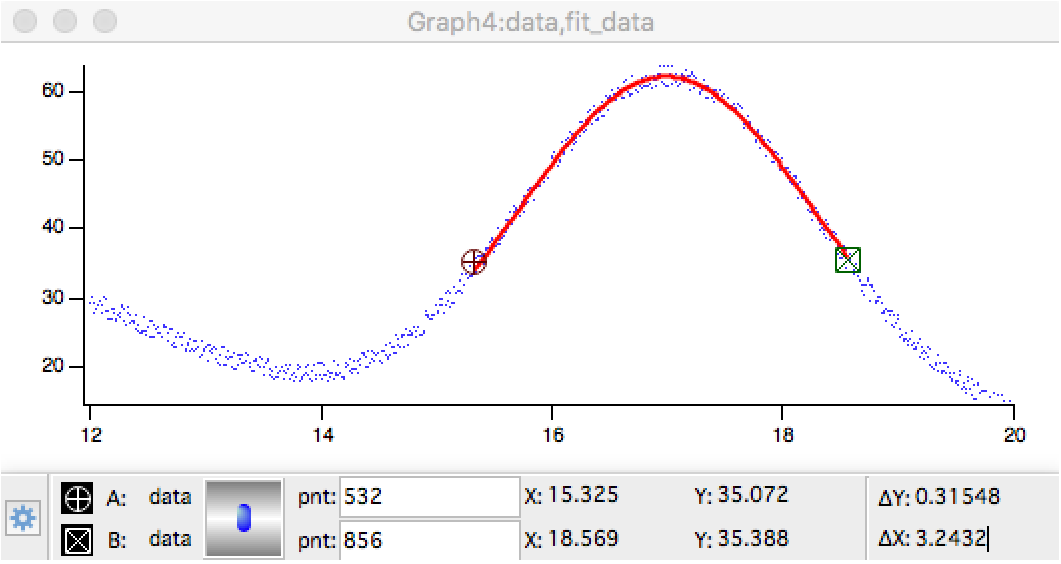
A common problem is that you don't want to include all of the points in your data set in a curve fit. There are two methods for restricting a fit to a subset of points. You will find these options on the Data Options tab of the Curve Fitting dialog.

Selecting a Range to Fit

You can select a contiguous range of points in the Range box. The values that you use to specify the range for a curve fit are in terms of point or row numbers of the Y data wave. Note that if you are fitting to an XY pair of waves and your X values are in random order, you will not be selecting a contiguous range as it appears on a graph.

To simplify selecting the range, you can use graph cursors to select the start and end of the range. To use cursors, display your raw data in a graph. Display the info panel in the graph by selecting ShowInfo from the Graph menu. Drag the cursors onto your raw data. Then use the Cursors button in the Curve Fitting dialog to generate a command to fit the cursor range.

Here is what a graph might look like after a fit over a subrange of a data set:



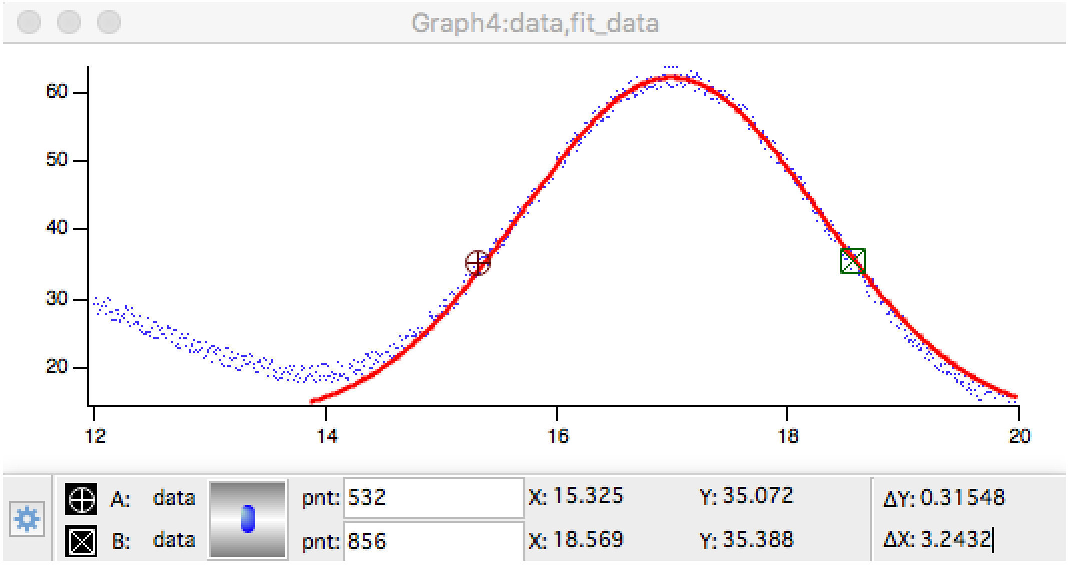
A: data pnt: 532 X: 15.325 Y: 35.072 ΔY: 0.31548
B: data pnt: 856 X: 18.569 Y: 35.388 ΔX: 3.2432

In this example, we used auto-trace for the destination. Notice that the trace appears over the selected range only. If we want to show the destination over a wider range, we need to change the destination wave's X scaling. These commands change the destination wave to show more points over a wider range:

```
Redimension/N=500 fit_data              // change to 500 points
SetScale x 13, 20, fit_data             // set domain from 13 to 20
fit_data= W_coef[0]+W_coef[1]/((x-W_coef[2])^2+W_coef[3])
```

The last line was copied from the history area, where it was displayed after the fit.

This produces the following graph:



A: data pnt: 532 X: 15.325 Y: 35.072 ΔY: 0.31548
B: data pnt: 856 X: 18.569 Y: 35.388 ΔX: 3.2432

If you use an explicit destination wave rather than auto-trace, it is helpful to set the destination wave to blanks (NaN) before performing the fit. As the fit progresses, it will store new values only in the destination wave range that corresponds to the range being fit. Also, it stores into the destination wave only at points where the source wave is not NaN or INF. If you don't preset the destination wave to blanks, you will wind up with a combination of new and old data in the destination wave.

These commands illustrate presetting the destination wave and then performing a curve fit to a range of an XY pair.

```
Duplicate/O yData, yDataFit          // make destination
yDataFit = NaN                       // preset to blank (NaN)
AppendToGraph yDataFit vs xData
CurveFit lor yData(xcsr(A),xcsr(B)) /D=yDataFit
```

Another way to make the fit curve cover a wider range is to select the checkbox labelled X Range Full Width of Graph. You will find the checkbox on the Output Options tab of the Curve Fitting dialog.

Using a Mask Wave

Sometimes the points you want to exclude are not contiguous. This might be the case if you are fitting to a data set with occasional bad points. Or, in spectroscopic data you may want to fit regions of baseline and exclude points that are part of a spectroscopic peak. You can achieve the desired result using a mask wave.

The mask wave must have the same number of points as the Y Data wave. You fill in the mask wave with a NaN (Not-a-Number, blank cell) or zero corresponding to data points to exclude and nonzero for data points you want to include. You must create the mask wave before bringing up the Curve Fitting dialog. You may want to edit the mask wave in a table.

Enter a NaN in a table by typing "NaN" and pressing Return or Enter. Having entered on NaN, you can copy it to the clipboard to paste into other cells.

You can also use a wave assignment on the command line. If your data set has a bad data point at point 4, a suitable command to set point four in the mask wave would be:

```
BadPointMask[4] = NaN
```

When you have a suitable mask wave, you choose it from the Data Mask menu on the Data Options tab.

You can use a mask with NaN points to suppress display of the masked points in a graph if you select the mask wave as an f(z) wave in the Modify Trace Appearance dialog. You could also use the same wave with the ModifyGraph mask keyword.

Weighting

You may provide a weighting wave if you want to assign greater or lesser importance to certain data points. You would do so for one of two reasons:

- To get a better, more accurate fit.
- To get more accurate error estimates for the fit coefficients.

The weighting wave is used in the calculation of chi-square. chi-square is defined as

$$\sum_i \left(\frac{y - y_i}{w_i}\right)^2$$

where y is a fitted value for a given point, y_i is the original data value for the point and w_i is the standard error for the point. The weighting wave provides the $\mathrm{w_i}$ values. The values in the weighting wave can be either $1/\sigma_\mathrm{i}$ or simply σ_i, where σ_i is the standard deviation for each data value. If necessary, Igor takes the inverse of the weighting value before using it to perform the weighting.

You specify the wave containing your weighting values by choosing it from the Weighting menu in the Data Options tab. In addition you must specify whether your wave has standard deviations or inverse standard deviations in it. You do this by selecting one of the buttons below the menu:

- Standard Deviations
- 1/Standard Deviations

Usually you would use standard deviations. Inverse standard deviations are permitted for historical reasons.

There are several ways in which you might obtain values for σ_i. For example, you might have *a priori* knowledge about the measurement process. If your data points are average values derived from repeated measurements, then the appropriate weight value is the standard error. That is the standard deviation of the repeated measurements divided by $\mathrm{N}^{1/2}$. This assumes that your measurement errors are normally distributed with zero mean.

If your data are the result of counting, such as a histogram or a multichannel detector, the appropriate weighting is $(\sqrt{y})$. This formula, however, makes infinite weighting for zero values, which isn't correct and will eliminate those points from the fit. It is common to substitute a value of 1 for the weights for zero points.

You can use a value of zero to completely exclude a given point from the fit process, but it is better to use a data mask wave for this purpose.

If you do not provide a weighting wave, then unity weights are used in the fit and the covariance matrix is normalized based on the assumption that the fit function is a good description of the data. The reported errors for the coefficients are calculated as the square root of the diagonal elements of the covariance matrix and therefore the normalization process will provide valid error estimates only if all the data points have roughly equal errors and if the fit function is, in fact, appropriate to the data.

If you do provide a weighting wave then the covariance matrix is not normalized and the accuracy of the reported coefficient errors rests on the accuracy of your weighting values. For this reason you should not use arbitrary values for the weights.

Proportional Weighting

In some cases, it is desirable to use weighting but you know only proportional weights, not absolute measurement errors. In this case, you can use weighting and after the fit is done, calculate reduced chi-square. The reduced chi-square can be used to adjust the reported error estimates for the fit coefficients. When you do this, the resulting reduced chi-square cannot be used to test goodness of fit.

For example, a data set having Gaussian errors that are proportional to X:

```
Make data = exp(-x/10) + gnoise((x+1)/1000)
Display data
```

Prepare a weighting wave that has weights proportional to X, but are not equal to the true measurement errors:

```
Duplicate data, data_wt
data_wt = x+1        // Right proportionality with X, but 1000 times too big
```

The fit has pretty meaningless coefficient errors because the weights provided were proportional to the true measurement errors, but 1000 times too big:

```
CurveFit/NTHR=0 exp data /W=data_wt /I=1 /D
Fit converged properly
fit_data= W_coef[0]+W_coef[1]*exp(-W_coef[2]*x)
W_coef={0.0044805,0.99578,0.10063}
V_chisq= 0.000117533;V_npnts= 128;V_numNaNs= 0;V_numINFs= 0;
V_startRow= 0;V_endRow= 127;
W_sigma={5.78,5.74,1.15}
Coefficient values ± one standard deviation
   y0    =0.0044805 ± 5.78
   A     =0.99578 ± 5.74
   invTau=0.10063 ± 1.15
```

So now we compute reduced errors based on reduced chi-square:

```
Variable reducedChiSquare = V_chisq/(V_npnts - numpnts(W_coef))
Duplicate W_sigma, reducedSigma
reducedSigma = W_sigma*sqrt(reducedChiSquare)
```

The resulting errors are more reasonable:

```
Print reducedSigma
reducedSigma[0]= {0.00560293,0.0055649,0.00111907}
```

Note that, as with any non-linear fitting, Gaussian statistics like this are not really applicable. The results should be used with caution.

Fitting to a Multivariate Function

A multivariate function is a function having more than one independent variable. This might arise if you have measured data over some two-dimensional area. You might measure surface temperature at a variety of locations, resulting in temperature as a function of both X and Y. It might also arise if you are trying to find dependencies of a process output on the various inputs, perhaps initial concentrations of reagents, plus temperature and pressure. Such a case might have a large number of independent variables.

Fitting a multivariate function is pretty much like fitting to a function with a single independent variable. This discussion assumes that you have already read the instructions above for fitting a univariate function.

You can create a new multivariate user-defined function by clicking the New Fit Function button. In the Independent Variables list, you would enter more than one variable name. You can use as many independent variables as you wish (within generous limits set by the length of a line in the procedure window).

A univariate function usually is written as $y = f(x)$, and the Curve Fitting dialog reflects this in using “Y Data” and “X Data” to label the menus where you select the input data.

Multivariate data isn’t so convenient. Functions intended to fit spatial data are often written as $z = f(x,y)$; volumetric data may be $g = f(x,y,z)$. Functions of a large number of independent variables are often written as $y = f(x_1,x_2,\ldots)$. To avoid confusion, we just keep the Y Data and X Data labels and use them to mean dependent variable and independent variables.

The principle difference between univariate and multivariate functions is in the selection of input data. If you have four or fewer independent variables, you can use a multidimensional wave to hold the Y values. This would be appropriate for data measured on a spatial grid, or any other data measured at regularly-spaced intervals in each of the independent variables. We refer to data in a multidimensional wave as “gridded data.”

Alternately, you can use a 1D wave to hold the Y values. The independent variables can then be in N 1D waves, one wave for each independent variable, or a single N-column matrix wave. The X wave or waves must have the same number of rows as the Y wave.

Selecting a Multivariate Function

When the Curve Fitting dialog is first used, multivariate functions are not listed in the Function menu. The first thing you must do is to turn on the listing of multivariate functions. You do this by choosing Show Multivariate Functions from the Function menu. This makes two built-in multivariate functions, poly2D and Gauss2D, as well as suitable user-defined functions, appear in the menu.

The Show Multivariate Functions setting is saved in the preferences. Unless you turn it off again, you never need select it again.

Now you can select your multivariate function from the menu.

Selecting Fit Data for a Multivariate Function

When you have selected a multivariate function, the Y Data menu is filled with 1D waves and any multidimensional waves that match the number of independent variables required by the fit function.

Selecting X Data for a 1D Y Data Wave

If your Y data are in a 1D wave, you must select an X wave for each independent variable. There is no way to store X scaling data in the Y wave for more than one independent variable, so there is no _calculated_ item.

With a 1D wave selected in the Y Data menu, the X Data menu lists both 1D waves and 2D waves with N columns for a function with N independent variables.

As you select X waves, the wave names are transferred to a list below the menu. When you have selected the right number of waves the X Data menu is disabled. The order in which you select the X waves is important. The first selected wave gives values for the first independent variable, etc.

If you need to remove an X Data wave from the list, simply click the wave name and press Backspace (*Windows*) or Delete (*Macintosh*). To change the order of X Data waves, select one or more waves in the list and drag them into the proper order.

Selecting X Data for Gridded Y Data

When you select a multidimensional Y wave, the independent variable values can come from the dimension scaling of the Y wave or from 1D waves containing values for the associated dimensions of the Y wave. That is, if you have a 2D matrix Y wave, you could select a wave to give values for the X dimension and a wave to give values for the Y dimension. The Independent Variable menus list only waves that match the given dimension of the Y wave.s

Fitting a Subrange of the Data for a Multivariate Function

Selecting a subrange of data for a 1D Y wave is just like selecting a subrange for a univariate function. Simply enter point numbers in the Start and End range boxes in the Data Options tab.

If you are fitting gridded Y data, the Data Options tab displays eight boxes to set start and end ranges for each dimension of a multidimensional wave. Enter row, column, layer or chunk numbers in these boxes:

If your Y wave is a matrix wave displayed in a graph as an image, you can use the cursors to select a subset of the data. With the graph as the target window, clicking the Cursors button will enter text in the range boxes to do this.

Using cursors with a contour plot is not straightforward, and the dialog does not support it.

You can also select data subranges using a data mask wave (see **Using a Mask Wave** on page III-198). The data mask wave must have the same number of points and dimensions as the Y Data wave.

Model Results for Multivariate Fitting

As with fitting to a function of one independent variable, Igor creates waves containing the model output and residuals automatically. This is done if you choose _auto_ for the destination and _auto trace_ for the residual on the Output Options tab. There are some differences in detail, however.

By default, the model curve for a univariate fit is a smooth curve having 200 points to display the model fit. This depends on being able to sensibly interpolate between successive values of the independent variable. Multicolumn independent variables, on the other hand, probably don't have successive values of all the independent variables in sequential order, so it is not possible to do this. Consequently, it calculates a model point for each point in the dependent variable data wave. If the data wave is displayed as a simple 1D trace in the top graph window, the fit results will be appended to the graph.

Residuals are always calculated on a point-for-point basis, so calculating residuals for a multicolumn multivariate fit is just like a univariate fit.

Displaying results of fitting to a multidimensional wave is more problematic. If the dependent variable has three or more dimensions, it is not easy to display the results. The model and residual waves will be created and the results calculated but not displayed. You can make a variety of 3D plots using Gizmo: just choose the appropriate plot type from the Windows→New→3D Plots menu.

Fits to a 2D matrix wave are displayed on the top graph if the Y Data wave is displayed there as either an image or a contour. The model results are plotted as a contour regardless of whether the data are displayed as an image or a contour. Model results contoured on top of data displayed as an image can be a very powerful visualization technique.

Residuals are displayed in the same manner as the data in a separate, automatically-created graph window. The window size will be the same as the window displaying the data.

Time Required to Update the Display

Because contours and images can take quite a while to redraw, the time to update the display at every iteration may cause fits to contour or image data to be very slow. To suppress the updates, click the Suppress Screen Updates checkbox on the Output Options tab.

Multivariate Fitting Examples

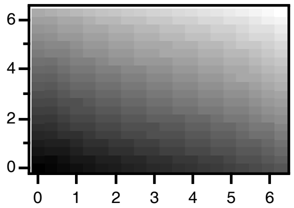
Here are two examples of fitting to a multivariate function — the first uses the built-in poly2D function to fit a plane to a gridded dataset to remove a planar trend from the data. The second defines a simplified 2D gaussian function and uses it to define the location of a peak in XY space using random XYZ data.

Example One — Remove Planar Trend Using Poly2D

Here is an example in which a matrix is filled with a two-dimensional sinusoid with a planar trend that overwhelms the sinusoid. The example shows how you might fit a plane to the data to remove the trend. First, make the data matrix, fill it with values, and display the matrix as an image:

```
Make/O/N=(20,20) MatrixWave
SetScale/I x 0,2*pi,MatrixWave
SetScale/I y 0,2*pi,MatrixWave
MatrixWave = sin(x) + sin(y) + 5*x + 10*y
Display;AppendImage MatrixWave
```

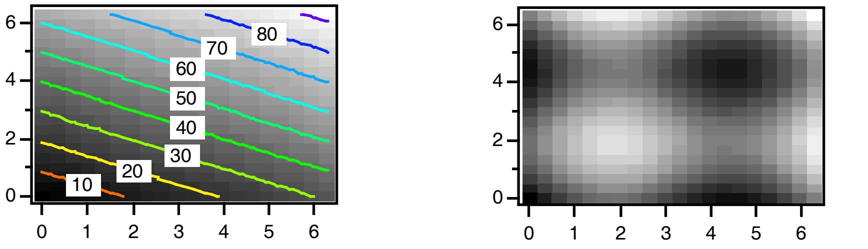
These commands make a graph displaying an image like the one that follows. Note the gradient from the lower left to the upper right:



We are ready to do the fit.

1. Choose Curve Fitting from the Analysis menu to bring up the Curve Fitting dialog.
2. If you have not already done so, choose Show Multivariate Functions from the Function menu.
3. Choose Poly2D from the Function menu.
4. Make sure the 2D Polynomial Order is set to 1.
5. Choose MatrixWave from the Y Data menu.
6. Click the Output Options tab.
7. Choose _auto trace_ from the Residual menu.
8. Click Do It.

The result is the original graph with a contour plot showing the fit to the data, and a new graph of the residuals, showing the sinusoidal signal left over from the fit:



Original graph

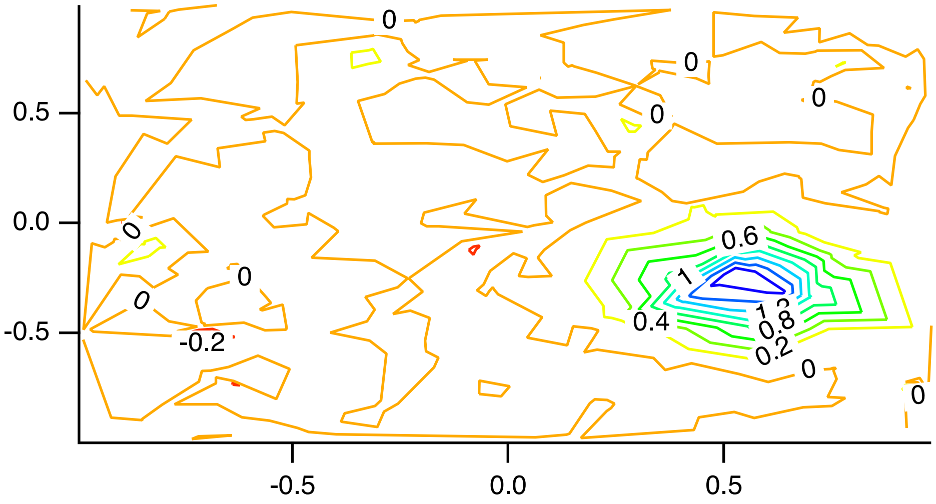
Residual graph showing sinusoidal signal

Similarly, you can use the ImageRemoveBackground operation, which provides a one-step operation to do the same fit. With an image plot as the top window, you will find Remove Background in the Image menu.

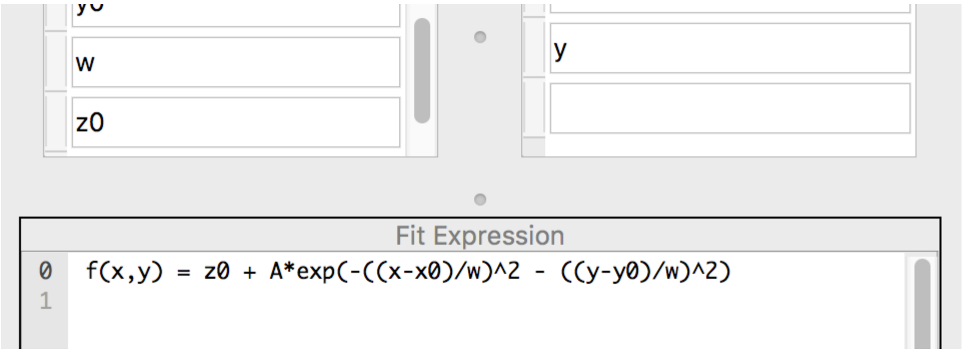
Example Two — User-Defined Simplified 2D Gaussian Fit

In this example, we have data defining a spot which we wish to fit with a 2D Gaussian to find the center of the spot. For some reason this data is in the form of XYZ triplets with random X and Y coordinates. These commands will generate the example data:

```
Make/N=300 SpotXData, SpotYData, SpotZData
SetRandomSeed 0.5
SpotXData = enoise(1)
SpotYData = enoise(1)
// make a gaussian centered at {0.55, -0.3}
SpotZData = 2*exp(-((SpotXData-.55)/.2)^2 -((SpotYData+.3)/.2)^2)+gnoise(.1)
Display; AppendXYZContour SpotZData vs {SpotXData,SpotYData}
```



Now bring up the Curve Fitting dialog and click the New Fit Function button so that you can enter your user-defined fit function. We have reason to believe that the spot is circular so the gaussian can use the same width in the X and Y directions, and there is no need for the cross-correlation term. Thus, the new function has a z0 coefficient for the baseline offset, A for amplitude, x0 and y0 for the X and Y location and w for width. Here is what it looks like in the New Fit Function dialog:



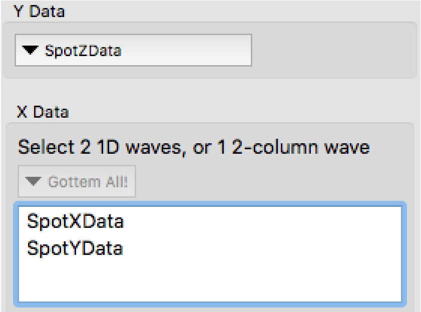
```
f(x,y) = z0 + A*exp(-((x-x0)/w)^2 - ((y-y0)/w)^2)
```

Click Save Fit Function Now to save the function in the Procedure window and return to the Curve Fitting dialog. The new function is selected in the Function menu automatically.

To perform the fit choose:

1. SpotZData in the Y Data menu.
2. SpotXData in the X Data menu.
3. SpotYData in the X Data menu.

At this point, the data selection area of the Function and Data tab looks like this:



Y Data

SpotZData

X Data

Select 2 1D waves, or 1 2-column wave

SpotXData
SpotYData

4. Click the Coefficients tab (the error box at the bottom shows that we must enter initial guesses).
5. Enter initial guesses: we set z0 to 0, A to 2, x0 to 0.5, y0 to -0.3, and width to 0.5.
6. For our problem, residuals and destination aren't really important since we just want to know the coordinates of the spot center. We click Do It and get this in history:

```
FuncFit SimpleGaussian W_coef SpotZData /X={SpotXData,SpotYData} /D
  Fit converged properly
  fit_SpotZData= SimpleGaussian(W_coef,x,y)
  Res_SpotZData= SpotZData[p] - SimpleGaussian(W_coef,SpotXData[p],SpotYData[p])
  W_coef={1.9797,0.54673,-0.2977,0.19962,-0.0067009}
  V_chisq= 3.06428;V_npnts= 300;V_numNaNs= 0;V_numINFs= 0;
  V_startRow= 0;V_endRow= 299;
  W_sigma={0.065,0.00559,0.00553,0.00529,0.00622}
  Coefficient values ± one standard deviation
   A  =1.9797 ± 0.065
   x0 =0.54673 ± 0.00559
   y0 =-0.2977 ± 0.00553
   w  =0.19962 ± 0.00529
   z0 =-0.0067009 ± 0.00622
```

The output shows that the fit has determined that the center of the spot is {0.54697, -0.30557}.

Problems with the Curve Fitting Dialog

Occasionally you may find that things don't work the way you expect when using the Curve Fitting dialog. Common problems are:

- You can't find your user-defined function in the Function menu.

  This usually happens for one of two reasons: either your function is a multivariate function or it is an old-style function. The problem is solved by choosing Show Multivariate Functions or Show Old-Style Functions from the Function menu on the Function and Data tab.

  If you find that choosing Show Old-Style Functions makes your fit function appear, you may want to consider clicking the Edit Fit Function button, which makes the Edit Fit Function dialog appear. Part of the initialization for the dialog involves revising your fit function to make it conform to current standards. While you're there you can give your fit coefficients mnemonic names.

- You get a message that "Igor can't determine the number of coefficients…".

  This happens when you click the Coefficients tab when you are using an external function or a user-defined function that is so complicated that the dialog can't parse the function code to determine how many coefficients are required.

  The only way to get around this is to choose an explicit coefficient wave (**The Coefficient Wave** on page III-195). The dialog will then use the number of points in the coefficient wave to determine the number of coefficients.

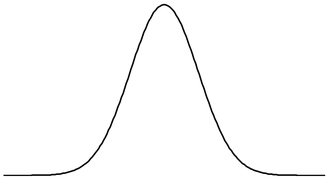
Built-in Curve Fitting Functions

For the most part you will get good results using automatic guesses. A few require additional input beyond what is summarized in the preceding sections. This section contains notes on the fitting functions that give a bit more detail where it may be helpful.

gauss

Fits a Gaussian peak.

$$y_0 + A\exp\left[-\left(\frac{x - x_0}{width}\right)^2\right]$$

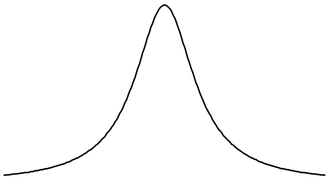


Note that the width parameter is sqrt(2) times the standard deviation of the peak. This is different from the w_i parameter in the Gauss function, which is simply the standard deviation.

lor

Fits a Lorentzian peak.

$$y_0 + \frac{A}{(x - x_0)^2 + B}$$



Voigt

Fits a Voigt peak, a convolution of a Lorentzian and a Gaussian peak. By changing the ratio of the widths of the Lorentzian and Gaussian peak components the shape can grade between a Lorentzian shape and a Gaussian shape.

$$y_0 + \frac{2Area}{W_G}\sqrt{\frac{\ln(2)}{\pi}} \bullet Voigt\left[\frac{2\sqrt{\ln(2)}}{W_G}(x - x_0), Shape \bullet 2\sqrt{\ln(2)}\right]$$

The Voigt function is a normalized Voigt peak shape function. It is the same as the built-in function **VoigtFunc**.

The premultiplier and arguments to the Voigt function result in a peak shape in which fit coefficients are:

Area	The area under the peak excluding the vertical offset
y0	The vertical offset
WG	The Gaussian full width at half maximum (FWHM)
Shape	The ratio of the Lorentzian and Gaussian components, W_L/W_G

There is no analytic expression to compute the height of a Voigt peak.

The FWHM of the Voigt peak can be approximated as

$$W_V = \frac{W_L}{2} + \sqrt{\frac{W_L^2}{4} + W_G^2}$$

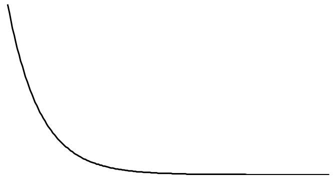
where W_L = Shape * W_G.

Fitting peaks with extreme values of Shape is not recommended as it suffers from numerical instability. Fit the end-point shapes Lor (Shape → ∞) or Gauss (Shape = 0) instead.

exp_XOffset

Fits a decaying exponential.

$$y_0 + A\exp\left(\frac{x-x_0}{\tau}\right)$$



In this equation, x_0 is a constant, not a fit coefficient. During generation of automatic guesses, x_0 will be set to the first X value in your fit data. This eliminates problems caused by floating-point roundoff.

You can set the value of x_0 using the /K flag with the CurveFit operation, but it is recommended that you accept the automatic value. Setting x_0 to a value far from the initial X value in your input data is guaranteed to cause problems.

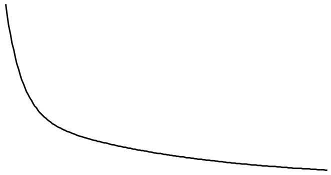
Note: The fit coefficient τ is the inverse of the equivalent coefficient in the exp function. It is actually the decay constant, not the inverse decay constant.

Automatic guesses don't work for growing exponentials (negative τ). To fit a negative value of τ, use Manual Guess on the Coefficients tab, or CurveFit/G on the command line.

dblexp_XOffset

Fits a sum of two decaying exponentials.

$$y_0 + A_1\exp\left(\frac{x-x_0}{\tau_1}\right) + A_2\exp\left(\frac{x-x_0}{\tau_2}\right)$$

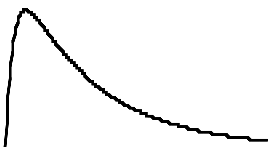


In this equation, x_0 is a constant, not a fit coefficient. During generation of automatic guesses, x_0 wall be set to the smallest X value in your fit data. This eliminates problems caused by floating-point roundoff.

You can set the value of x_0 using the /K flag with the CurveFit operation, but it is recommended that you accept the automatic value. Setting x_0 to a value far from the initial X value in your input data is guaranteed to cause problems.

Note: The fit coefficients τ_1 and τ_2 are the inverse of the equivalent coefficients in the dblexp function. They are actual decay constants, not inverse decay constants.

See the notes for **exp_XOffset** on page III-207 for growing exponentials. You will also need to use manual guesses if the amplitudes have opposite signs:



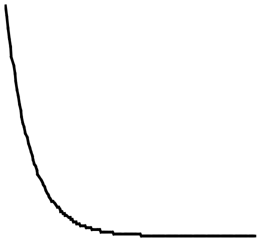
See also the dblexp_peak fit function described below.

If the two decay constants (τ_1 and τ_2) are not quite distinct you may not get accurate results.

exp

Fits a decaying exponential. Similar to exp_XOffset, but not as robust. Included for backward compatibility; in new work you should use exp_Xoffset.

$$y_0 + A\exp(-Bx)$$



Note that offsetting your data in the X direction will cause changes in *A*. Use exp_XOffset for a result that is independent of X position.

Note: The fit coefficient *B* is the inverse decay constant.

Automatic guesses don't work for growing exponentials (negative *B*). To fit a negative value of *B*, use Manual Guess on the Coefficients tab, or CurveFit/G on the command line.

Floating-point arithmetic overflows will cause problems when fitting exponentials with large X offsets. This problem often arises when fitting decays in time as times are often large. The best solution is to use the exp_XOffset fit function. Otherwise, to fit such data, the X values must be offset back toward zero.

You could simply change your input X values, but it is usually best to work on a copy. Use the Duplicate command on the command line, or the Duplicate Waves item in the Data menu to copy your data.

For an XY pair, execute these commands on the command line (these commands assume that you have made a duplicate wave called `myXWave_copy`):

```
Variable xoffset = myXWave_copy[0]
myWave_copy[0] -= xoffset
```

Note that these commands assume that you are fitting data from the beginning of the wave. If you are fitting a subset, replace `[0]` with the point number of the first point you are fitting. If you are using graph cursors to select the points, substitute `[pcsr(A)]`. This assumes that the round cursor (cursor A) marks the beginning of the data.

If you are fitting to waveform data (you selected _calculated_ in the X Data menu) then you need to set the x0 part of the wave scaling to offset the data. If you are fitting the entire wave, simply use the Change Wave Scaling dialog from the Data menu to set the x0 part of the scaling to zero. If you are fitting a subset selected by graph cursors, it is easier to change the scaling on the command line:

```
SetScale/P x leftx(myWave_copy)-xcsr(A), deltax(myWave_copy), myWave_copy
```

This command assumes that you have used the round cursor (cursor A) to mark the beginning of the data.

Subtracting an X offset will change the amplitude coefficient in the fit. Often the only coefficient of interest is the decay constant (invTau) and the change in the amplitude can be ignored. If that is not the case, you can calculate the correct amplitude after the fit is done:

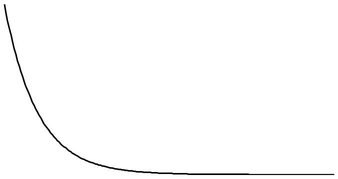
```
W_coef[1] = W_coef[1]*exp(W_coef[2]*xoffset)
```

If you are fitting waveform data, the value of xoffset would be `-leftx(myWave_copy)`.

dblexp

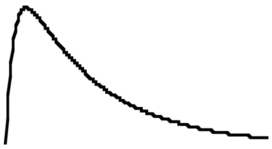
Fits a sum of decaying exponentials. Similar to dblexp_XOffset, but suffers from floating-point roundoff problems if the data do not start quite close to x=0. Included for backward compatibility; in new work you should use exp_Xoffset.

$$y_0 + A_1\exp(-B_1x) + A_2\exp(-B_2x)$$



Note that offsetting your data in the X direction will cause changes in A_1 and A_2. Use dblexp_XOffset for a result that is independent of X position.

Note: The fit coefficients B_1 and B_2 are inverse decay constants.



See the notes for exp for growing exponentials. You will also need to use manual guesses if the amplitudes have opposite signs:

See also the dblexp_peak fit function described below.

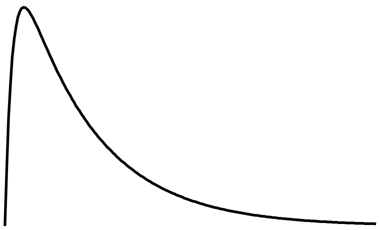
If the two decay constants (B_1 and B_2) are not quite distinct you may not get accurate results.

Fitting data with a large X offset will have the same sort of troubles as when fitting with exp. The best solution is to use the dblexp_XOffset fit function; you can also solve the problem using a procedure similar to the one outlined for **exp** on page III-207.

dblexp_peak

Fits the sum of two exponential terms of opposite sign, making a peak.

$$y_0 + A \cdot \left\{ -exp\left[\frac{-(x-x_0)}{tau_1}\right] + exp\left[\frac{-(x-x_0)}{tau_2}\right]\right\}$$



The location of the peak is given by

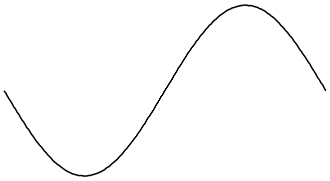
$$X_{peak} = \frac{tau_1\ tau_2\ ln\left(\frac{tau_1}{tau_2}\right)}{tau_1 - tau_2} + x_0$$

If you need individual control of the amplitudes of the two terms, use the dblexp_XOffset function. In that case, you will need to use manual guesses.

sin

Fits a sinusoid.

$$(y_0 + A\sin(fx + \phi))$$



phi is in radians. To convert to degrees, multiply by 180/Pi.

A sinusoidal fit takes an additional parameter that sets the approximate frequency of the sinusoid. This is entered in terms of the approximate number of data points per cycle. When you choose `sin` from the Function menu, a box appears where you enter the expected number of points per cycle.

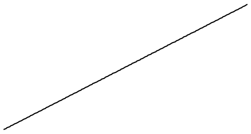
If you enter a number less than 6, the default value will be 7. It may be necessary to try various values to get good results. You may want to simply use manual guesses.

The nature of the sin function makes it impossible for a curve fit to distinguish phases that are different by 2π. It is probably easier to subtract 2nπ than to try to get the fit to fall in the desired range.

line

Fit a straight line through the data.

$$(a + bx)$$



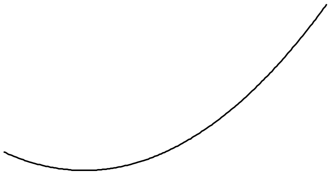
Never requires manual guesses.

If you want to fit a line through the origin, in the Coefficients tab select the Hold box for coefficient *a* and set the Initial Guess value to zero.

poly n

Fits a polynomial with n terms, or order n-1.

$$(K_0 + K_1 x + K_2 x^2 + \ldots)$$



A polynomial fit takes an additional parameter that sets the number of polynomial terms. When you choose `poly` from the Function menu, a box appears where you enter that value.

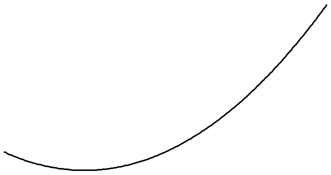
The minimum value of n is 1 corresponding to taking the mean of the Y value. Most Igor users won't need anything less than 3, a quadratic polynomial.

A polynomial fit never requires manual guesses.

poly_XOffset n

Fits a polynomial with n terms, or order n-1. The constant x_0 is not an adjustable fit coefficient; it allows you to place the polynomial anywhere along the X axis. This would be particularly useful for situations in which the X values are large, for instance when dealing with date/time data.

$$(K_0 + K_1(x - x_0) + K_2(x - x_0)^2 + \ldots)$$



The poly_XOffset fit function takes additional parameters that set the number of polynomial terms and the value of x_0. When you select poly_XOffset from the Function menu, boxes appear where you enter these values.

The minimum value of n is 1 corresponding to taking the mean of the Y value. Most Igor users won't need anything less than 3, a quadratic polynomial.

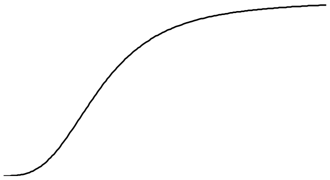
When Set Constant X0 is set to Auto, x_0 is set to the minimum X value found in the data you are fitting. You can set x_0 to any value you wish. Values far from the X values in your data set will cause numerical problems.

A polynomial fit never requires manual guesses.

HillEquation

Fits Hill’s Equation, a sigmoidal function.

$$base + \frac{(max - base)}{1 + \left(\frac{x_{1/2}}{x}\right)^{rate}}$$



The coefficient *base* sets the y value at small X, *max* sets the y value at large X, *rate* sets the rise rate and $x_{1/2}$ sets the X value at which Y is at (*base* + *max*)/2.

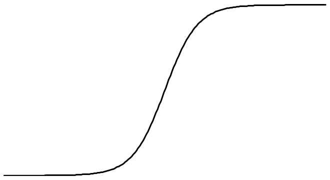
Note that X values must be greater than 0. Including a data point at $X \leq 0$ will result in a singular matrix error and the message, "The fitting function returned NaN for at least one X value."

You can reverse the values of *base* and *max* to fit a falling sigmoid.

sigmoid

Fits a sigmoidal function with a different shape than Hill's equation.

$$base + \frac{max}{1 + \exp\left(\frac{x_0 - x}{rate}\right)}$$

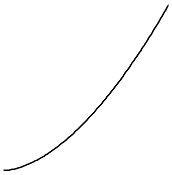


The coefficient *base* sets the Y value at small X. The Y value at large X is *base*+*max*. x0 sets the X value at which Y is at (*base*+*max*/2) and *rate* sets the rise rate. Smaller *rate* causes a faster rise, specifically, the slope at x=x0 is *max*/(4**rate*).

power

Fits a power law.

$$(y_0 + Ax^{pow})$$



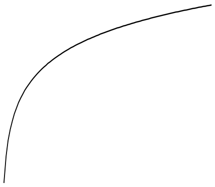
May be difficult to fit, requiring good initial guesses, especially for *pow* > 1 or *pow* close to zero.

Note that X values must be greater than 0. Including a data point at $X \leq 0$ will result in a singular matrix error and the message, "The fitting function returned NaN for at least one X value."

log

Fits a logarithmic curve.

$$a + b\log(x)$$



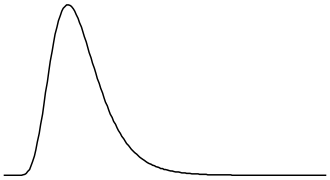
log is very forgiving of bad initial guesses. It was added in Igor Pro 9.00.

X values must be greater than 0. Including a data point with X<=0 results in a singular matrix error and the message "The fitting function returned NaN for at least one X value."

lognormal

Fits a lognormal peak shape. This function is gaussian when plotted on a log X axis.

$$y_0 + A\exp\left[-\left(\frac{\ln(x/x_0)}{width}\right)^2\right]$$



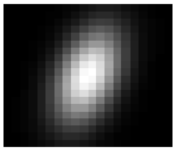
Coefficient y_0 sets the baseline, *A* sets the amplitude, x_0 sets the peak position in X and *width* sets the peak width.

Note that X values must be greater than 0. Including a data point at $X \leq 0$ will cause a singular matrix error and the message, “The fitting function returned NaN for at least one X value.”

gauss2D

Fits a Gaussian peak in two dimensions.

$$z_0 + A\exp\left[\frac{-1}{2(1-cor^2)}\left(\left(\frac{x-x_0}{xwidth}\right)^2 + \left(\frac{y-y_0}{ywidth}\right)^2 - \frac{2cor(x-x_0)(y-y_0)}{xwidth \cdot ywidth}\right)\right]$$



Coefficient *cor* is the cross-correlation term; it must be between -1 and 1 (the small illustration was done with *cor* equal to 0.5). A constraint automatically enforces this range. If you know that a value of zero for this term is appropriate, you can hold this coefficient. Holding *cor* at zero usually speeds up the fit quite a bit.

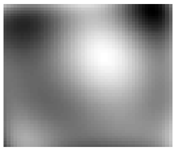
In contrast with the gauss fit function, xWidth and yWidth are standard deviations of the peak.

Note that the Gauss function lacks the cross-correlation parameter *cor*.

poly2D n

Fits a polynomial of order n in two dimensions.

$$(C_0 + C_1x + C_2y + C_3x^2 + C_4xy + C_5y^2 + \ldots)$$



A poly2D fit takes an additional parameter that specifies the order of the polynomial. When you choose poly2D from the Function menu, a box appears where you enter that value.

The minimum value is 1, corresponding to a first-order polynomial, a plane. The coefficient wave for poly2D has the constant term (C_0) in point zero, and following points contain groups of increasing order. There are two first-order terms, C_1*x and C_2*y, then three second-order terms, etc. The total number of terms is (N+1)(N+2)/2, where N is the order.

Poly2d never requires manual guesses.

Inputs and Outputs for Built-In Fits

There are a number of variables and waves that provide various kinds of input and output to a curve fit. Usually you will use the Curve Fitting dialog and the dialog will make it clear what you need, and detailed descriptions are available in various places in this chapter. For a quick introduction, here is a table that lists the waves and variables used for fitting to a built-in function.

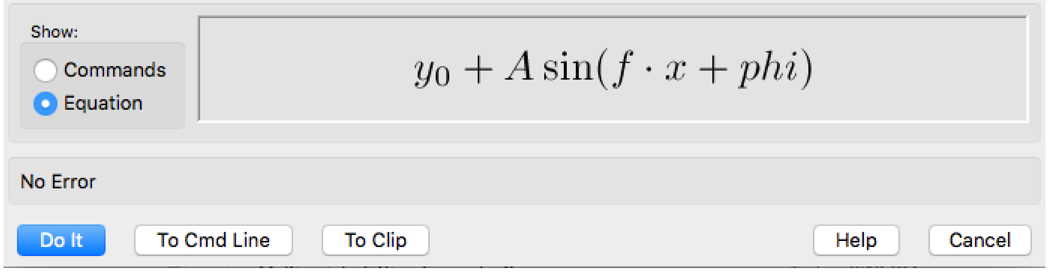
Wave or Variable	Type	What It Is Used For
Dependent variable data wave	Input	Contains measured values of the dependent variable of the curve to fit. Often referred to as “Y data”.
Independent variable data wave	Input	Contains measured values of the independent variable of the curve to fit. Often referred to as “X data”.
Destination wave	Optional output	For graphical feedback during and after the fit. The destination wave continually updates during the fit to show the fit function evaluated with the current coefficients.
Residual wave	Optional output	Difference between the data and the model.
Weighting wave	Optional input	Used to control how much individual Y data points contribute to the search for the output coefficients.
System variables K0, K1, K2 …	Input and output	*Built-in fit functions only.* Optionally takes initial guesses from the system variables and updates them at the end of the fit.
Coefficients wave By default, W_coef.	Input and Output	Takes initial guesses from the coefficients wave, updates it during the fit and leaves final coefficients in it. See the reference for CurveFit and FuncFit for additional options.
Epsilon wave	Optional input	*User-defined fit functions only.* Used by the curve fitting algorithm to calculate partial derivatives with respect to the coefficients.
W_sigma	Output	Creates this wave and stores the estimates of error for the coefficients in it.
W_fitConstants	Output	Created when you do a fit using a built-in fit function containing a constant. Igor creates this wave and stores the values of any constants used by the fit equation. For details, see **Fits with Constants** on page III-189. For notes on constants used in specific fit functions, see **Built-in Curve Fitting Functions** on page III-206.
V_<xxx>	Input	There are a number of special variables, such as V_FitOptions, that you can set to tweak the behavior of the curve fitting algorithms.
V_<xxx>	Output	Creates and sets a number of variables such as V_chisq and V_npnts. These contain various statistics found by the curve fit.
M_Covar	Output	Optionally creates a matrix wave containing the “covariance matrix”. It can be used to generate advanced statistics.
Other waves	Optional input and output	User-supplied or automatically generated waves for displaying confidence and prediction bands, and for specifying constraints on coefficient values.

Curve Fitting Dialog Tabs

This section describes the controls on each tab and on the main pane of the Curve Fitting dialog.

Global Controls

The controls at the bottom of the dialog are always available:



Show:

○ Commands

● Equation

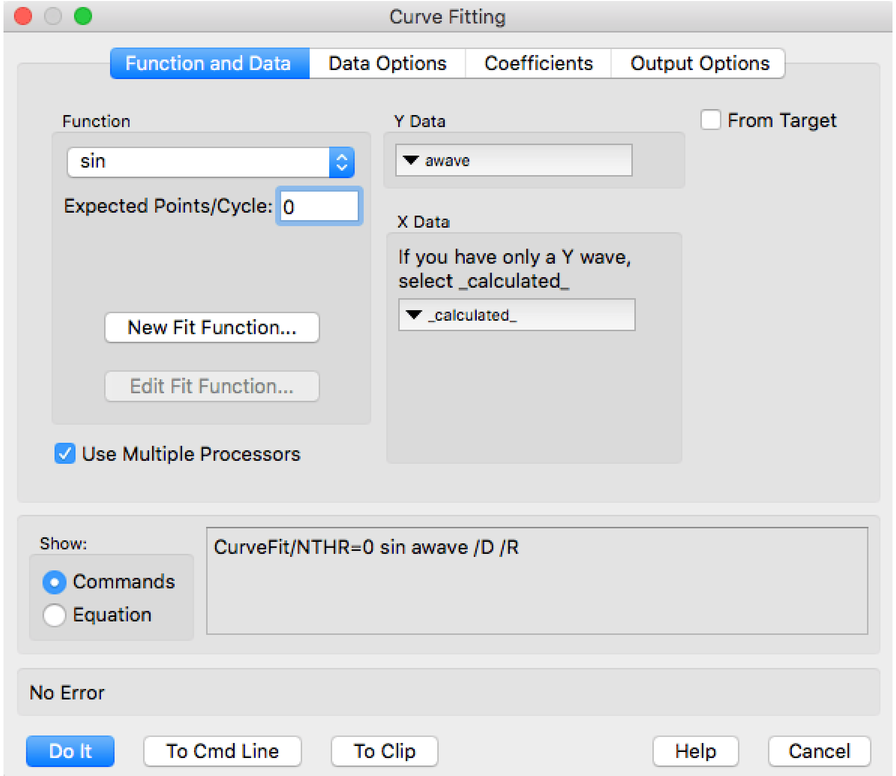
$$y_0 + A\sin(f \cdot x + phi)$$

No Error

If you click the Commands radio button, Igor displays the commands generated by the dialog instead of the equation.

Function and Data Tab

The Function and Data tab has a variety of appearances depending on the function chosen in the Function menu. Here is what it looks like when the built-in sin function is chosen:



Function: sin

Expected Points/Cycle: 0

Y Data: awave

□ From Target

X Data

If you have only a Y wave, select _calculated_

calculated

☑ Use Multiple Processors

Show:

● Commands

○ Equation

```
CurveFit/NTHR=0 sin awave /D /R
```

No Error

Function menu: The main purpose is to choose a function to fit.

The menu also has two items that control what functions are displayed in the menu.

Choose Show Multivariate functions to include functions of more than one independent variable.

Choose Show Old-Style Functions to display functions that lack the FitFunc keyword. See **User-Defined Fitting Functions** on page III-250 for details on the FitFunc keyword. You may need to choose this item if you have fitting functions from a version of Igor Pro older than version 4.

Some of the fit functions require additional information that is collected by customized items that appear when you select the function.

Polynomial Terms: Appears when you choose the poly function to fit a polynomial. Note that the number of terms is one greater than the degree — set this to three for a quadratic polynomial.

Set Constant X0: Appears when you select the exp_XOffset , dblexp_XOffset or poly_XOffset function. X0 is a constant subtracted from the X values to move the X range for fitting closer to zero. This eliminates numerical problems that arise when evaluating exponentials over X ranges even moderately far from zero. Setting X0 to Auto causes it to be set to the minimum X value in your input data. Setting to a number overrides this default behavior.

Expected Points/Cycle: Appears when you choose the sin function. Use it to set the approximate number of data points in one cycle of the sin function. Helps the automatic initial guess come up with good guesses. If it is set to less than four, Igor will use the default of seven.

2D Polynomial Order: Appears when you choose the Poly2D function to fit a two-dimensional polynomial (a multivariate function — only appears in the menu when you have chosen Show Multivariate Functions). Sets the *order* of the polynomial, not the number of terms. Because a given order includes a term for X and a term for Y plus cross terms, the number of terms is (N+1)(N+2)/2 where N is the order.

New Fit Function: Click this button to bring up a dialog in which you can define your own fitting function.

Edit Fit Function: This button is available when you have chosen a user-defined function from the Function menu. Brings up a dialog in which you can edit your user-defined function.

Y Data: Select a wave containing the dependent variable data to fit. When a multivariate function is chosen in the Function menu, the Y Data menu shows1D waves and waves with dimensions matching the number of independent variables used by the function.

X Data: This area changes depending on the function and Y Data wave chosen.

With a **univariate function**, just the X data menu is shown. Choose _calculated_ if you have just a Y wave; the X values will come from the Y wave's X scaling. The X Data menu shows only waves with the same number of points as the Y wave.

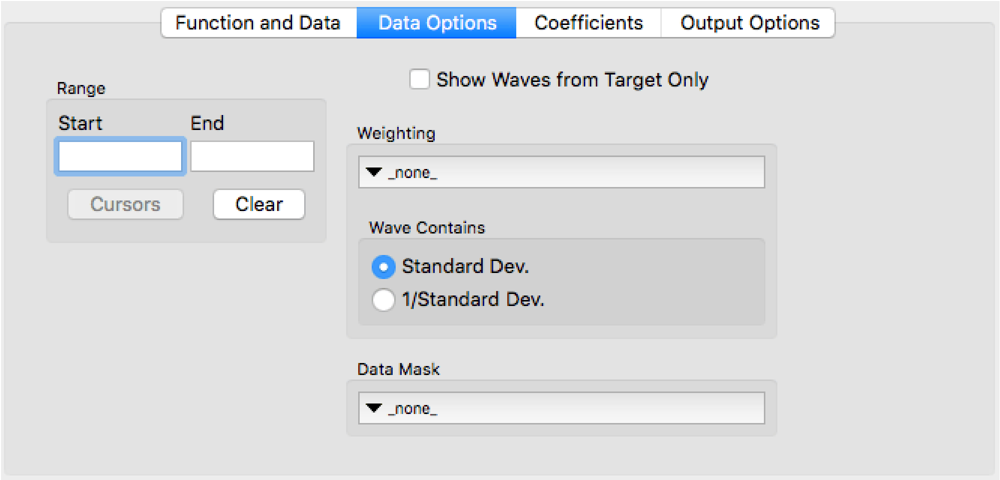
When a **multivariate function** and a **1D Y wave** are selected, it adds a list box below the X wave menu. You must select one X wave for each independent variable used by the fit function, or a single multicolumn wave with the correct number of columns. As you select X waves, they are added to the list. The order of waves in the list is important — it determines which is identified with each of the function's independent variables.

Remove waves from the list by highlighting a wave and pressing Delete (*Macintosh*) or Backspace (*Windows*).

With a **multivariate function** and a **multidimensional Y wave** selected, it displays four independent variable wave menus, one for each dimension that a wave can have. Each menu displays waves of length matching the corresponding dimension of the Y Data wave. Choose "_calculated_" if the independent variable values will come from the Y wave's dimension scaling.

From Target: When From Target is selected, the Y Data and X Data menus show only waves that are displayed in the top table or graph. Makes it easier to find waves in the menus when you are working on an experiment with many waves. When you click the From Target checkbox, it will attempt to select appropriate waves for the X and Y data.

Data Options Tab



Range: Enter point numbers for starting and ending points when fitting to a subset of the Y data.

Historical Note: These boxes used to require X values, they now require point numbers.

Cursors: Available when the top window is a graph displaying the Y data and the graph has the graph cursors on the Y data trace. Click this button to enter text in the Start and End range boxes that will restrict fitting to the data between the graph cursors.

Note: If the data use both a Y wave and an X wave, and the X values are in random order, you won't get the expected result.

Clear: Click this button to remove text from the Start and End range boxes.

The **range** box changes if you have selected a multivariate function and multidimensional Y wave. The dialog presents Start and End range boxes for each dimension of the Y wave.

Weighting: select a wave that contains weighting values. Only waves that match the Y wave in number of points and dimensions are shown in this menu. See **Weighting** on page III-199 for details.

Wave Contains: select Standard Deviation if the weighting wave contains values of standard deviation for each Y data point. A larger value decreases the influence of a point on the fit.

Select 1/Standard Deviation if your weighting wave contains values of the reciprocal of the standard deviation. A larger value increases the influence of the point on the fit.

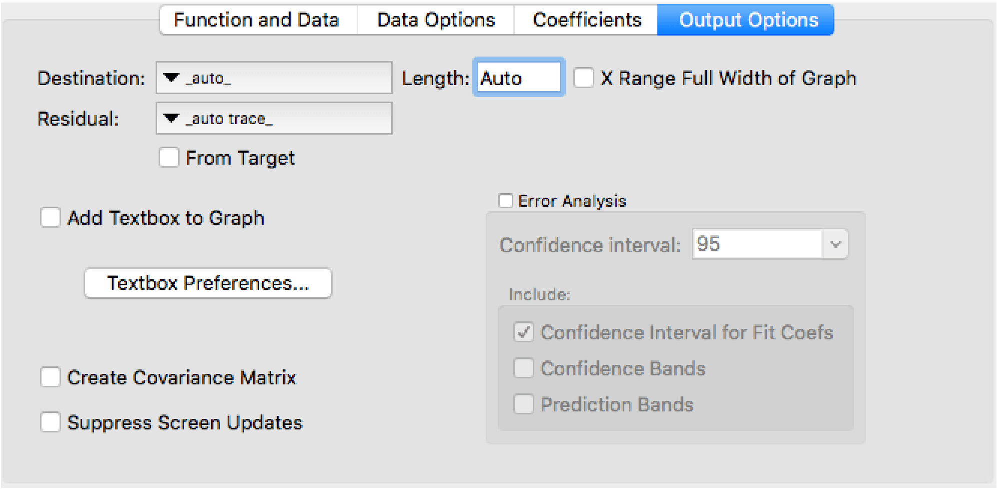
Data Mask: select a wave that contains ones and zeroes or NaN's indicating which Y Data points should be included in the fit. Only waves that match the Y wave in number of points and dimensions are shown in this menu. A one indicates a data point that should be included, a zero or NaN (Not a Number or blank in a table) indicates a point that should be excluded.

Coefficients Tab

The coefficients tab is quite complex. It is completely explained in the various sections on how to do a fit. See **Two Useful Additions: Holding a Coefficient and Generating Residuals** on page III-184, **Automatic Guesses Didn't Work** on page III-187, **Coefficients Tab for a User-Defined Function** on page III-192, and **The Coefficient Wave** on page III-195.

Output Options Tab

The output options tab has settings that control the reporting and display of fit results:



Destination: _auto_ Length: Auto □ X Range Full Width of Graph

Residual: _auto trace_

□ From Target

□ Add Textbox to Graph

□ Error Analysis

Confidence interval: 95

Include:

☑ Confidence Interval for Fit Coefs

□ Confidence Bands

□ Prediction Bands

□ Create Covariance Matrix

□ Suppress Screen Updates

Destination: Select a wave to receive model values from the fit, or select _auto_ to have Igor create an evenly-spaced auto-destination wave for the model values. Updated on each iteration so you can follow the fit progress by the graph display. See **The Destination Wave** on page III-196 for details on the Destination menu, the Length box shown above and on the New Wave box that isn't shown above.

X Range Full Width of Graph: If you have restricted the range of the fit using graph cursors, the auto destination wave will cover only the range selected. Select this checkbox to make the auto destination cover the full width of the graph.

Residual: Select a wave to receive calculated values of residuals, or the differences between the model and the data. See **Computing Residuals** on page III-217 for details on residuals and on the various selections you can make from this menu.

Error Analysis: Selects various kinds of statistical error analysis. See **Confidence Bands and Coefficient Confidence Intervals** on page III-223 for details.

Add Textbox to Graph: When selected, a textbox with information about the fit will be added to the graph containing the Y data. Click the **Textbox Preferences** button to display a dialog in which you can select various bits of information to be included in the text box.

Create Covariance Matrix: When this is selected, the dialog generates the command to create a covariance matrix for the fit. See **Covariance Matrix** on page III-226 for details on the covariance matrix.

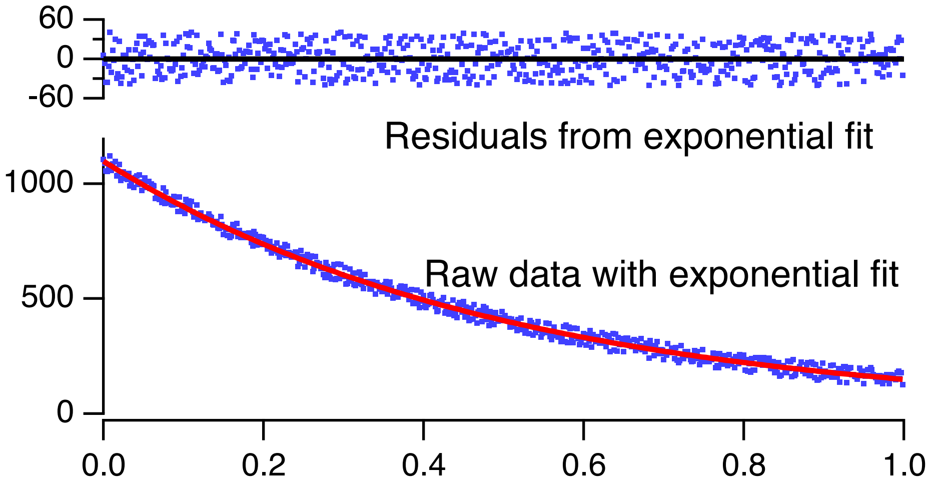
Suppress Screen Updates: When this is selected, graphs and tables are not updated while the fit progresses. This can greatly speed up the fitting process, especially if the fit involves a contour or image plot, but reduces the feedback you get during the fit.

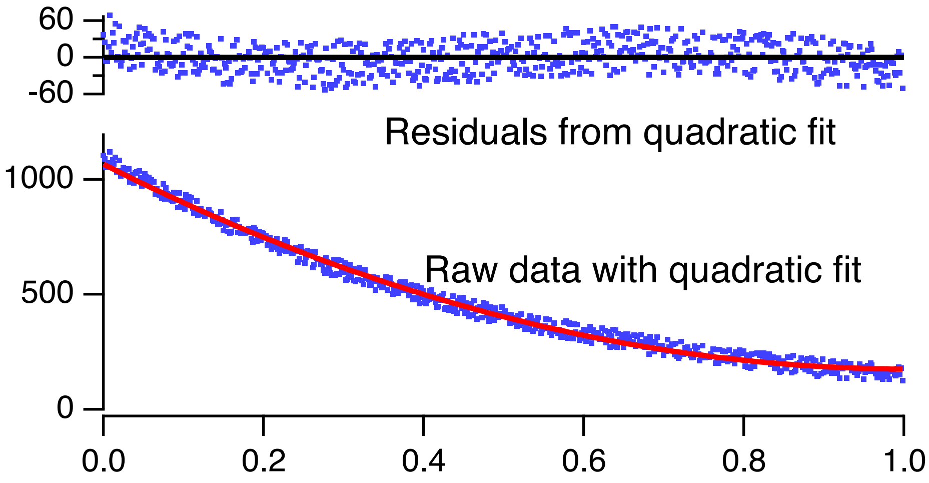
Computing Residuals

A residual is what is left when you subtract your fitting function model from your raw data.

Ideally, your raw data is equal to some known function plus random noise. If you subtract the function from your data, what's left should be noise. If this is not the case, then the function doesn't properly fit your raw data.

The graphs below illustrate some exponential raw data fitted to an exponential function and to a quadratic (3 term polynomial). The residuals from the exponential fit are random whereas the residuals from the quadratic display a trend overlaid on the random scatter. This indicates that the quadratic is not a good fit for the data.





The easiest way to make a graph such as these is to let it proceed automatically using the Residual pop-up menu in the Output Options tab of the Curve Fitting dialog. The graphs above were made this way with some minor tweaks to improve the display.

The residuals are recalculated at every iteration of a fit. If the residuals are displayed on a graph, you can watch the residuals change as the fit proceeds.

In addition to providing an easy way to compute residuals and add the residual plot to a graph, it prints the wave assignment used to create the residuals into the history area as part of the curve fitting process. For instance, this is the result of a line fit to waveform data:

```
•CurveFit line LineYData /X=LineXData /D /R
   fit_LineYData= W_coef[0]+W_coef[1]*x
   Res_LineYData= LineYData[p] - (W_coef[0]+W_coef[1]*LineXData[p])
   W_coef={-0.037971,2.9298}
   V_chisq= 18.25;V_npnts= 20;V_numNaNs= 0;V_numINFs= 0;
   V_startRow= 0;V_endRow= 19;V_q= 1;V_Rab= -0.879789;
   V_Pr= 0.956769;V_r2= 0.915408;
   W_sigma={0.474,0.21}
   Coefficient values ± one standard deviation
      a  =-0.037971 ± 0.474
      b  =2.9298 ± 0.21
```

In this case, a wave called “LineYData” was fit with a straight line model. _auto trace_ was selected for both the destination (/D flag) and the residual (/R flag), so the waves fit_LineYData and Res_LineYData were created. The third line above gives the equation for calculating the residuals. You can copy this line if you wish to recalculate the residuals at a later time. You can edit the line if you want to calculate the residuals in a different way. See **Calculating Residuals After the Fit** on page III-220.

Residuals Using Auto Trace

If you choose _auto trace_ from the Residual menu, it will automatically create a wave for residual values and, if the Y data are displayed in the top graph, it will append the residual wave to the graph.

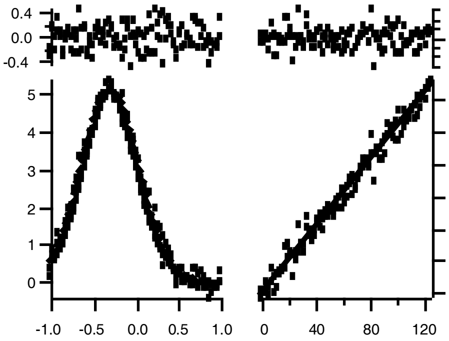
The automatically-created residual wave is named by prepending “Res_” to the name of the Y data wave. If the resulting name is too long, it will be truncated. If a wave with that name already exists, it will be reused, overwriting the values already in the wave. If a wave does not exist already, the newly-created wave is automatically filled with NaN. The residual wave is made with the same number of points as the data wave, with one residual value calculated for each data point.

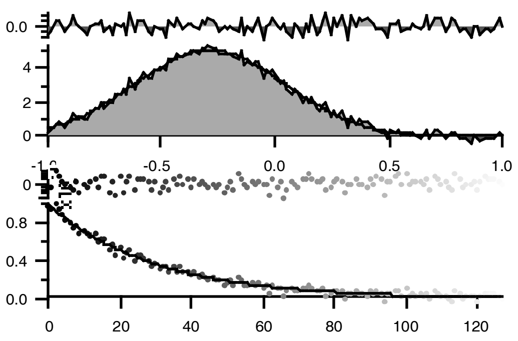
Residual values are stored only for data points that actually participate in fitting. That is, if you fit to a subrange of the data, or use a mask wave to eliminate some points from fitting, residuals are stored only for the data used in fitting and the other points are not disturbed. This allows you to use the auto-residual option to build up the residuals from a piece-wise fit, where parts of the data are fit in succession. It also means that sometimes Igor will leave behind stale values. To prevent that, pre-fill your residual wave with a value of your choice.

If you fit the same data again, the same residual wave will be used. Thus, to preserve a previous result, you must rename the residual wave. This can be done using the Rename item in the Data menu, or the Rename command on the command line.

Residuals are displayed on a stacked graph like those above. This is done by shortening the axis used to display the Y data, and positioning a new free axis above the axis used for the Y data. The residual plot occupies the space made by shortening the data axis. The axis that Igor creates is given a name derived from the axis used to display the Y data, either “Res_Left” or “Res_Right” if the Y data are displayed on the standard axes. If the data axis is a named free axis, the automatically-generated axis is given a name created by prepending “Res_” to the name of the data axis.

Igor tries hard to make the appended residual plot look nice by copying the formatting of the Y data trace and making the residual trace identical so that you can identify which residual trace goes with a given Y data trace. The axis formatting for the residual axis is copied from the vertical axis used for the data trace, and the residual axis is positioned directly above the data axis. Any other vertical axes that might be in the way are also shortened to make room. Here are two examples of graphs that have been modified by the auto-trace residuals:





It is likely that the automatic formatting won’t be quite what you want, but it will probably be close enough that you can use the Modify Axis and Modify Trace Appearance dialogs to tweak the formatting. For details see Chapter II-13, **Graphs**, especially the sections **Creating Graphs with Multiple Axes** on page II-324 and **Creating Stacked Plots** on page II-324.

Removing the Residual Auto Trace

When an auto-trace residual plot is added to a graph, it modifies the axis used to plot the original Y data. If you remove the auto-trace residual from the graph, the residual axis is removed and in most cases the Y data axis is restored to its previous state.

In some complicated graphs the restoration of the data axis isn't done correctly. To restore the graph, double-click the Y data axis to bring up the Modify Axes dialog and select the Axis tab. You will find two settings labeled "Draw between … and … % of normal". Typically, the correct settings will be 0 and 100.

Residuals Using Auto Wave

Because the changes to the graph formatting are substantial, you may want the automatic residual wave created and filled in but not appended to the graph. To accomplish this, simply choose _Auto Wave_ from the Residual pop-up menu in the Curve Fitting dialog. Once the wave is made by the curve fitting process, you can append it to a graph, or use it in any other way you wish.

Residuals Using an Explicit Residual Wave

You can choose a wave from the Residual pop-up menu and that wave will be filled with residual values. In this case, it does not append the wave to the top graph. You can use this technique to make graphs with the formatting completely under your own control, or to use the residuals for some other purpose.

Only waves having the same number of points as the Y data wave are listed in the menu. If you don't want to let the dialog create the wave, you would first create a suitable wave by duplicating the Y data wave using the Duplicate Waves item in the Data menu, or using the Duplicate command:

```
Duplicate yData, residuals_poly3
```

It is often a good idea to set the wave to NaN, especially when fitting to a subrange of the data:

```
residuals_poly3=NaN
```

After the wave is duplicated, it would typically be appended to a graph or table before it is used in curve fitting.

Explicit Residual Wave Using New Wave

The easiest way to make an explicit residual wave is to let the Curve Fitting dialog do it for you. You do this by choosing _New Wave_ in the Residual menu. A box appears allowing you to enter a name for the new wave. The dialog will then generate the required commands to make the wave before the curve fit starts. The wave made this way will not be added to a graph. You will need to do that yourself after the fit is finished.

Calculating Residuals After the Fit

You may wish to avoid the overhead of calculating residuals during the fitting process. This section describes ways to calculate the residuals after a curve fit without depending on automatic wave creation.

Graphs similar to the ones at the top of this section can be made by appending a residuals wave using a free left axis. Then, under the Axis tab of the Modify Axes dialog, the distance for the free axis was set to zero and the axis was set to draw between 80 and 100% of normal. The normal left axis was set to draw between 0 and 70% and axis standoff was turned off for both left and bottom axes.

Here are representative commands used to accomplish this.

```
// Make sample data
Make/N=500 xData, yData
xData = x/500 + gnoise(1/1000)
yData = 100 + 1000*exp(-.005*x) + gnoise(20)

// Do exponential fit with auto-trace
CurveFit exp yData /X=xData /D
Rename fit_yData, fit_yData_exp

// Calculate exponential residuals using interpolation in
// the auto trace wave to get model values
```

```
Duplicate yData, residuals_exp
residuals_exp = yData - fit_yData_exp(xData)

// Do polynomial fit with auto-trace
CurveFit poly 3, yData /X=xData /D
Rename fit_yData fit_yData_poly3

// Find polynomial residuals
Duplicate yData, residuals_poly3
residuals_poly3 = yData - fit_yData_poly3(xData)
```

Calculating model values by interpolating in the auto trace wave may not be sufficiently accurate. Instead, you can calculate the exact value using the actual fitting expression. When the fit finishes, it prints the equation for the fit in the history. With a little bit of editing you can create a wave assignment for calculating residuals. Here are the assignments from the history for the above fits:

```
fit_yData= poly(W_coef,x)
fit_yData= W_coef[0]+W_coef[1]*exp(-W_coef[2]*x)
```

We can convert these into residuals calculations like this:

```
residuals_poly3 = yData - poly(W_coef,xData)
residuals_exp = yData - (W_coef[0]+W_coef[1]*exp(-W_coef[2]*xData))
```

Note that we replaced “x” with “xData” because we have tabulated x values. If we had been fitting equally spaced data then we would not have had a wave of tabulated x values and would have left the “x” alone.

This technique for calculating residuals can also be used if you create and use an explicit destination wave. In this case the residuals are simply the difference between the data and the destination wave. For example, we could have done the exp fit and residual calculations as follows:

```
Duplicate yData, yDataExpFit,residuals_exp
// explicit destination wave using /D=wave
CurveFit exp yData /X=xData /D=yDataExpFit
residuals_exp = yData - yDataExpFit
```

Coefficient of Determination or R-Squared

When you do a line fit, y = a + bx, Igor prints a variety of statistics, including "r-squared", also known as the "coefficient of determination". The value of r-squared is stored in the automatically-created variable V_r2.

The literature on regression shows differences of opinion on the interpretation of r-squared. Because it is commonly reported, Igor provides the value.

There are two ways to compute r-squared that reflect slightly different interpretations:

$$r^2 = 1 - \frac{SS_{res}}{SS_{tot}} \qquad (1)$$

$$r^2 = \frac{SS_{reg}}{SS_{tot}} \qquad (2)$$

where

$$SS_{tot} = \sum_{i=1}^{n} (y_i - \overline{y})^2 \qquad \text{(3 - total sum of squares)}$$

$$SS_{res} = \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 \qquad \text{(4 - residual sum of squares)}$$

$$SS_{reg} = \sum_{i=1}^{n} (\hat{y}_i - \bar{y})^2 \qquad \text{(5 - regression sum of squares)}$$

Here, y_i is the i-th Y data point, $\hat{y}_i$ is i-th predicted or model Y value, and $\bar{y}_i$ is the average of the Y data. When you do a line fit, the fit line is guaranteed to pass through the data average, and you can be sure that

SStot = SSres + SSreg (6)

Consequently, equations (1) and (2) are equivalent, with equation (2) emphasizing the interpretation of r-squared as "explained variance". That is, it is the fraction of the data variance that is "explained" or accounted for by the fit line. The r-squared value reported by Igor generally agrees with values from Excel and other applications.

Igor also reports the Pearson correlation coeffient via the automatically-created variable V_Pr. In the case of a line fit, V_Pr^2 = V_r2.

R-Squared and Fits Through the Origin

The situation changes if you fit a line that is constrained to pass through the origin, that is, you set the value of the fit coefficient a to zero and hold it. This is usually done when common sense or theory demands that the quantity of interest must be zero at X=0.

There is no consensus on the correct way to compute something like r-squared for a line fit through the origin. Such a fit does not, in general, pass through the average data value, and equation (6) does not hold, so equations (1) and (2) do not give the same value.

We prefer the interpretation of r-squared as "explained variance" so we use equation (2) for fits through the origin. This has some consequences. One is that Igor's r-squared will not necessarily agree with other applications, notably Excel. Another is that it is guaranteed to be smaller, some would say, "less good", than a line fit to the same data that is not constrained to pass through the origin.

A more surprising consequence is that it is possible for r-squared to be larger than 1. This has a simple interpretation: your fit line has larger variance than the data! Quite possibly a fit through the origin is simply not justified for your data.

Given the lack of consensus and uncertain interpretation of r-squared for a fit through the origin, we cannot recommend citing it, or using it as any sort of indication of goodness of fit, for such fits.

Estimates of Error

Igor automatically calculates the estimated error (standard deviation) for each of the coefficients in a curve fit. When you perform a curve fit, it creates a wave called W_sigma. Each point of W_sigma is set to the estimated error of the corresponding coefficients in the fit. The estimated errors are also indicated in the history area, along with the other results from the fit. If you don’t provide a weighting wave, the sigma values are estimated from the residuals. This implicitly assumes that the errors are normally distributed with zero mean and constant variance and that the fit function is a good description of the data.

The coefficients and their sigma values are estimates (usually remarkably good estimates) of what you would get if you performed the same fit an infinite number of times on the same underlying data (but with different noise each time) and then calculated the mean and standard deviation for each coefficient.

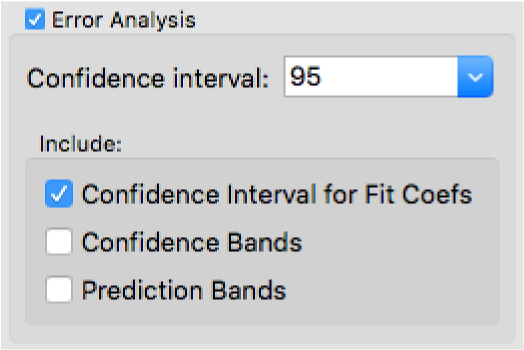
Confidence Bands and Coefficient Confidence Intervals

You can graphically display the uncertainty of a model fit to data by adding confidence bands or prediction bands to your graph. These are curves that show the region within which your model or measured data are expected to fall with a certain level of probability. A confidence band shows the region within which the model is expected to fall while a prediction band shows the region within which random samples from that model plus random errors are expected to fall.

You can also calculate a confidence interval for the fit coefficients. A confidence interval estimates the interval within which the real coefficient will fall with a certain probability.

Note: Confidence and prediction bands are not available for multivariate curve fits.

You control the display of confidence and prediction bands and the calculation of coefficient confidence intervals using the Error Analysis section of the Output Options tab of the Curve Fitting dialog:



☑ Error Analysis

Confidence interval: 95

Include:

☑ Confidence Interval for Fit Coefs

☐ Confidence Bands

☐ Prediction Bands

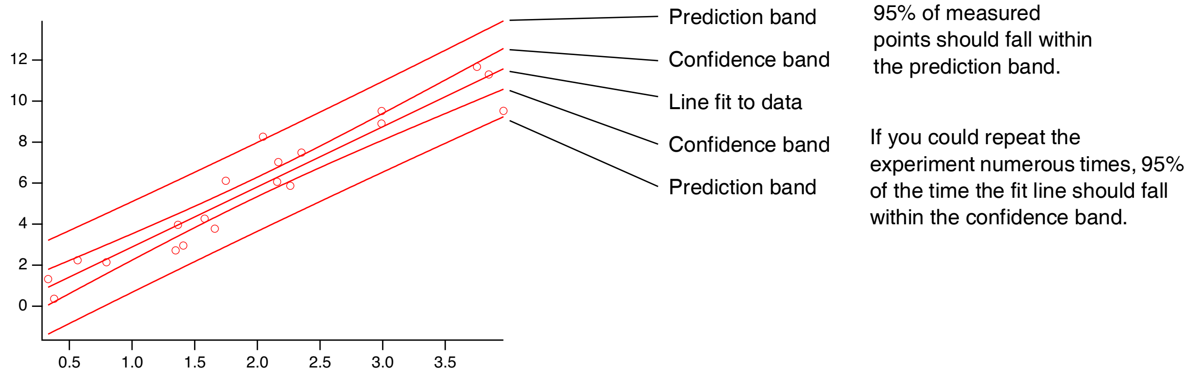
Using the line fit example at the beginning of this chapter (see **A Simple Case — Fitting to a Built-In Function: Line Fit** on page III-182), we set the confidence level to 95% and selected all three error analysis options to generate this output and graph:

Dialog has added the /F with parameters to select error analysis options.

```
•CurveFit line LineYData /X=LineXData /D /F={0.950000, 7}
   fit_LineYData= W_coef[0]+W_coef[1]*x
   W_coef={-0.037971,2.9298}
   V_chisq= 18.25; V_npnts= 20; V_numNaNs= 0; V_numINFs= 0;
   V_startRow= 0; V_endRow= 19; V_q= 1; V_Rab= -0.879789;
   V_Pr= 0.956769;V_r2= 0.915408;
   W_sigma={0.474,0.21}
   Fit coefficient confidence intervals at 95.00% confidence level:
   W_ParamConfidenceInterval={0.995,0.441,0.95}
   Coefficient values ± 95.00% Confidence Interval
      a   =   -0.037971 ± 0.995
      b   =   2.9298 ± 0.441
```

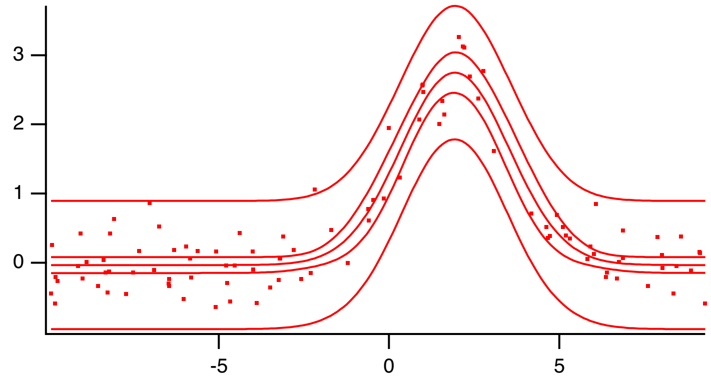
When confidence intervals are available they are listed here instead of the standard deviation.

Coefficient confidence intervals are stored in the wave W_ParamConfidenceInterval. Note that the last point in the wave contains the confidence level used in the calculation.



You can do this with nonlinear functions also, but be aware that it is only an approximation for nonlinear functions:

```
Make/O/N=100 GDataX, GDataY                       // waves for data
GDataX = enoise(10)                               // Random X values
GDataY = 3*exp(-((GDataX-2)/2)^2) + gnoise(0.3)  // Gaussian plus noise
Display GDataY vs GDataX                          // graph the data
ModifyGraph mode=2,lsize=2                        // as dots
CurveFit Gauss GDataY /X=GDataX /D/F={.99, 3}
```



The dialog supports only automatically-generated waves for confidence bands. The CurveFit and FuncFit operations support several other options including an error bar-style display. See **CurveFit** on page V-124 for details.

Calculating Confidence Intervals After the Fit

You can use the values from the W_sigma wave to calculate a confidence interval for the fit coefficients after the fit is finished. Use the StudentT function to do this. The following information was printed into the history following a curve fit:

```
  Fit converged properly
  fit_junk= f(coeffs,x)
  coeffs={4.3039,1.9014}
  V_chisq= 101695; V_npnts= 128; V_numNaNs= 0; V_numINFs= 0;
  W_sigma={4.99,0.0679}
```

To calculate the 95 per cent confidence interval for fit coefficients and deposit the values into another wave, you could execute the following lines:

```
Duplicate W_sigma, ConfInterval
ConfInterval = W_sigma[p]*StudentT(0.95, V_npnts-numpnts(coeffs))
```

Naturally, you could simply type “126” instead of “V_npnts-numpnts(coeffs)”, but as written the line will work unaltered for any fit. When we did this following the fit in the example, these were the results:

```
ConfInterval = {9.86734,0.134469}
```

Clearly, coeffs[0] is not significantly different from zero.

Confidence Band Waves

New waves containing values required to display confidence and prediction bands are created by the curve fit if you have selected these options. The number of waves and the names depend on which options are selected and the style of display. For a contour band, such as shown above, there are two waves: one for the upper contour and one for the lower contour. Only one wave is required to display error bars. For details, see the **CurveFit** operation on page V-124.

Some Statistics

Calculation of the confidence and prediction bands involve some statistical assumptions. First, of course, the measurement errors are assumed to be normally distributed. Departures from normality usually have to be fairly substantial to cause real problems.

If you don’t supply a weighting wave, the distribution of errors is estimated from the residuals. In making this estimate, the distribution is assumed to be not only normal, but also uniform with mean of zero. That is, the error distribution is centered on the model and the standard deviation of the errors is the same for all values of the independent variable. The assumption of zero mean requires that the model be correct; that is, it assumes that the measured data truly represent the model plus random normal errors.

Some data sets are not well characterized by the assumption that the errors are uniform. In that case, you should specify the error distribution by supplying a weighting wave (see **Weighting** on page III-199). If you do this, your error estimates are used for determining the uncertainties in the fit coefficients, and, therefore, also in calculating the confidence band.

The confidence band relies only on the model coefficients and the estimated uncertainties in the coefficients, and will always be calculated taking into account error estimates provided by a weighting wave. The prediction band, on the other hand, also depends on the distribution of measurement errors at each point. These errors are not taken into account, however, and only the uniform measurement error estimated from the residuals are used.
