The calculation of the confidence and prediction bands is based on an estimate of the variance of a predicted model value:

$$V(\hat{Y}) = a^T C a$$
$$a = \delta F / \delta p|_x$$

Here, $\hat{Y}$ is the predicted value of the model at a given value of the independent variable X, $\boldsymbol{a}$ is the vector of partial derivatives of the model with respect to the coefficients evaluated at the given value of the independent variable, and $\boldsymbol{C}$ is the covariance matrix. Often you see the $\boldsymbol{a}^T\boldsymbol{Ca}$ term multiplied by σ^2, the sample variance, but this is included in the covariance matrix. The confidence interval and prediction interval are calculated as:

$$CI = t(n-p,\, 1-\alpha/2)[V(\hat{Y})]^{1/2} \text{ and } PI = t(n-p, 1-\alpha/2)[\sigma^2 + V(\hat{Y})]^{1/2}.$$

The quantities calculated by these equations are the magnitudes of the intervals. These are the values used for error bars. These values are added to the model values ($\hat{Y}$) to generate the waves used to display the bands as contours. The function $t(n-p,\, 1-\alpha/2)$ is the point on a Student’s t distribution having probability $1-\alpha/2$, and σ^2 is the sample variance. In the calculation of the prediction interval, the value used for σ^2 is the uniform value estimated from the residuals. This is not correct if you have supplied a weighting wave with nonuniform values because there is no information on the correct values of the sample variance for arbitrary values of the independent variable. You can calculate the correct prediction interval using the **StudentT** function. You will need a value of the derivatives of your fitting function with respect to the fitting coefficients. You can either differentiate your function and write another function to provide derivatives, or you can use a numerical approximation. Igor uses a numerical approximation.

Confidence Bands and Nonlinear Functions

Strictly speaking, the discussion and equations above are only correct for functions that are linear in the fitting coefficients. In that case, the vector **a** is simply a vector of the basis functions. For a polynomial fit, that means 1, x, x^2, etc. When the fitting function is nonlinear, the equation results from an approximation that uses only the linear term of a Taylor expansion. Thus, the confidence bands and prediction bands are only approximate. It is impossible to say how bad the approximation is, as it depends heavily on the function.

Covariance Matrix

If you select the Create Covariance Matrix checkbox in the Output Options tab of the Curve Fitting dialog, it generates a covariance matrix for the curve fitting coefficients. This is available for all of the fits except the straight-line fit. Instead, a straight-line fit generates the special output variable V_rab giving the coefficient of correlation between the slope and Y intercept.

By default (if you are using the Curve Fitting dialog) it generates a matrix wave having N rows and columns, where N is the number of coefficients. The name of the wave is M_Covar. This wave can be used in matrix operations. If you are using the CurveFit, FuncFit or FuncFitMD operations from the command line or in a user procedure, use the /M=2 flag to generate a matrix wave.

Originally, curve fits created one 1D wave for each fit coefficient. The waves taken all together made up the covariance matrix. For compatibility with previous versions, the /M=1 flag still produces multiple 1D waves with names W_Covar*n*. Please don’t do this on purpose.

The diagonal elements of the matrix, M_Covar[i][i], are the variances for parameter i. The variance is the square of sigma, the standard deviation of the estimated error for that parameter.

The covariance matrix is described in detail in *Numerical Recipes in C*, edition 2, page 685 and section 15.5. Also see the discussion under **Weighting** on page III-199.

Correlation Matrix

Use the following commands to calculate a correlation matrix from the covariance matrix produced during a curve fit:

```
Duplicate M_Covar, CorMat  // You can use any name instead of CorMat
CorMat = M_Covar[p][q]/sqrt(M_Covar[p][p]*M_Covar[q][q])
```

A correlation matrix is a normalized form of the covariance matrix. Each element shows the correlation between two fit coefficients as a number between -1 and 1. The correlation between two coefficients is perfect if the corresponding element is 1, it is a perfect inverse correlation if the element is -1, and there is no correlation if it is 0.

Curve fits in which an element of the correlation matrix is very close to 1 or -1 may signal “identifiability” problems. That is, the fit doesn’t distinguish between two of the parameters very well, and so the fit isn’t very well constrained. Sometimes a fit can be rewritten with new parameters that are combinations of the old ones to get around this problem.

Identifiability Problems

In addition to off-diagonal elements of the correlation matrix that are near 1 or -1, symptoms of identifiability problems include fits that require a large number of iterations to converge, or fits in which the estimated coefficient errors (W_sigma wave) are unreasonably large.

The phrase "identifiability problems" describes a situation in which two or more of the fit coefficients trade off in a way that makes it nearly impossible to solve for the values of both at once. They are correlated in a way that if you adjust one coefficient, you can find a value of the other that makes a fit that is nearly as good.

When the correlation is too strong, the fitting algorithm doesn't know where to go and therefore wanders around in a coefficient space in which a broad range of values all seem about as good. That is, broad regions in chi-square space provide very little variation in chi-square. The usual result is apparent convergence but with large estimated values in W_sigma, or a singular matrix error.

The error estimates are based on the curvature of the chi-square surface around the solution point. A flat-bottomed chi-square surface, such as results from having many solutions that are nearly as good, results in large errors. The flat bottom of the chi-square surface also results in small derivatives with respect to the coefficients that don't give a good indication of where the fit should go next, so iterations wander around, giving rise to fits that require many iterations to converge.

If you see a fit with unreasonably large error estimates, or that take many iterations to converge, compute the correlation matrix and look for off-diagonal values near 1 or -1. In our experience, values about 0.9 are probably OK. Values near 0.99 are suspicious but can be acceptable. Values around 0.999 are almost certainly an indication of problems.

Unfortunately, there is little you can do about identifiability problems. It is a mathematical characteristic of your fitting function. Sometimes a model has regions in coefficient space where two coefficients have similar effects on a fit, and expanding the range of the independent variable can alleviate the problem. Occasionally some feature controlled by a coefficient might be very narrow and you can fix the problem with higher sampling density.

Fitting with Constraints

It is sometimes desirable to restrict values of the coefficients to a fitting function. Sometimes fitting functions may allow coefficient values that, while fine mathematically, are not physically reasonable. At other times, some ranges of coefficient values may cause mathematical problems such as singularities in the function values, or function values that are so large that they overflow the computer representation. In such cases it is often desirable to apply constraints to keep the solution out of the problem areas. It could be that the final solution doesn’t involve any active constraints, but the constraints prevent termination of the fit on an error caused by wandering into bad regions on the way to the solution.

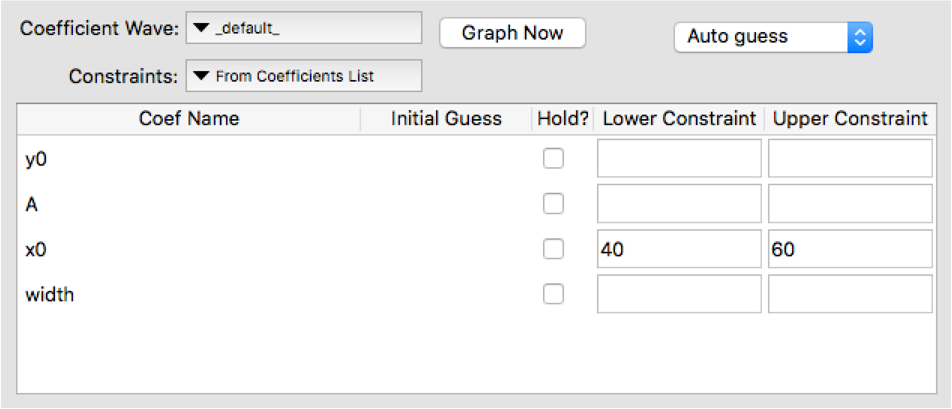
Curve fitting supports constraints on the values of any linear combination of the fit coefficients. The Curve Fitting dialog supports constraints on the value of individual coefficients.

The algorithm used to apply constraints is quite forgiving. Your initial guesses do not have to be within the constraint region (that is, initial guesses can violate the constraints). In most cases, it will simply move the parameters onto a boundary of the constraint region and proceed with the fit. Constraints can even be contradictory (“infeasible” in curve fitting jargon) so long as the violations aren’t too severe, and the fit will simply “split the difference” to give you coefficients that are a compromise amongst the infeasible constraints.

Constraints are not available for the built-in line, poly and poly2D fit functions. To apply constraints to these fit functions you must create a user-defined fit function.

Constraints Using the Curve Fitting Dialog

The Coefficients Tab of the Curve Fitting dialog includes a menu to enable fitting with constraints. When you select the checkbox, the constraints section of the Coefficients list becomes available:



Coefficient Wave: _default_

Constraints: From Coefficients List

Coef Name	Initial Guess	Hold?	Lower Constraint	Upper Constraint
y0		□		
A		□		
x0		□	40	60
width		□		

Filling in a value in the Lower Constraint column causes the dialog to generate a command to constrain the corresponding coefficient to values greater than the value you enter. Filling in a value in the Upper Constraint column constrains the corresponding coefficient to values less than the value you enter. A box that is left empty does not generate any constraint.

The figure above was made with the gauss function chosen. The following commands are generated by the dialog:

```
Make/O/T/N=2 T_Constraints
T_Constraints[0] = {"K2 > 40","K2 < 60"}
CurveFit gauss aa /D /C=T_Constraints
```

A Make command to make a text wave to contain constraint expressions.

A wave assignment to put constraint expressions into the wave.

/C parameter added to CurveFit command line to request a constrained fit.

More complicated constraints are possible, but cannot be entered in the Curve Fitting dialog. This requires that you make a constraints wave before you enter the dialog. Then choose the wave from the Constraints menu. See the following sections to learn how to construct the constraints wave.

Complex Constraints Using a Constraints Wave

You can constrain the values of linear combinations of coefficients, but the Curve Fitting dialog provides support only for simple constraints. You can construct an appropriate text wave with constraints before entering the Curve Fitting dialog. Select the wave from the Constraints menu in the Coefficients tab. You can also use the CurveFit or FuncFit commands on the command line with a constraints wave.

Each element of the text wave holds one constraint expression. Using a text wave makes it easy to edit the expressions in a table. Otherwise, you must use a command line like the second line in the example shown above.

Constraint Expressions

Constraint expressions can be arbitrarily complex, and can involve any or all of the fit coefficients. Each expression must have an inequality symbol (“<”, “<=”, “>”, or “>=”). In the expressions the symbol Kn (K0, K1, etc.) is used to represent the nth fitting coefficient. This is like the Kn system variables, but they are merely symbolic place holders in constraint expressions. Expressions can involve sums of any combination of the Kn’s and factors that multiply or divide the Kn’s. Factors may be arbitrarily complex, even nonlinear, as long as they do not involve any of the Kn’s. The Kn’s cannot be used in a call to a function, and cannot be involved in a nonlinear expression. Here are some legal constraint expressions:

```
K0 > 5
K1+K2 < numVar^2+2       // numVar is a global numeric variable
K0/5 < 2*K1
(numVar+3)*K3 > K1+K2/(numVar-2)
log(numVar)*K3 > 5       // nonlinear factor doesn’t involve K3
```

These are not legal:

```
K0*K1 > 5          // K0*K1 is nonlinear
1/K1 < 4           // This is nonlinear: division by K1
ln(K0) < 1         // K0 not allowed as parameter to a function
```

When constraint expressions are parsed, the factors that multiply or divide the Kn's are extracted as literal strings and evaluated separately. Thus, if you have <expression>*K0 or K0/<expression>, <expression> must be executable on its own.

You cannot use a text wave with constraint expressions for fitting from a threadsafe function. You must use the method described in **Constraint Matrix and Vector** on page III-230.

Equality Constraint

You may wish to constrain the value of a fit coefficient to be equal to a particular value. The constraint algorithm does not have a provision for equality constraints. One way to fake this is to use two constraints that require a coefficient to be both greater than and less than a value. For instance, "K1 > 5" and "K1 < 5" will require K1 to be equal to 5.

If it is a single parameter that is to be held equal to a value, this isn't the best method. You are much better off holding a parameter. In the Curve Fitting dialog, simply select the Hold box in the Coefficients list on the Coefficients tab and enter a value in the Initial Guess column. If you are using a command line to do the fit,

```
FuncFit/H="01"…
```

will hold K1 at a particular value. Note that you have to set that value before starting the fit.

Example Fit with Constraints

The examples here are available in the Curve Fitting help file where they can be conveniently executed directly from the help window.

This example fits to a sum of two exponentials, while constraining the sum of the exponential amplitudes to be less than some limit that might be imposed by theoretical knowledge. We use the command line because the constraint is too complicated to enter into the Curve Fitting dialog.

First, make the data and graph it:

```
Make/O/N=50 expData= 3*exp(-0.2*x) + 3*exp(-0.03*x) + gnoise(.1)
Display expData
ModifyGraph mode=3,marker=8
```

Do a fit without constraints:

```
CurveFit dblExp expData /D/R
```

The following command makes a text wave with a single element containing the string "K1 + K3 < 5" which implements a restriction on the sum of the individual exponential amplitudes.

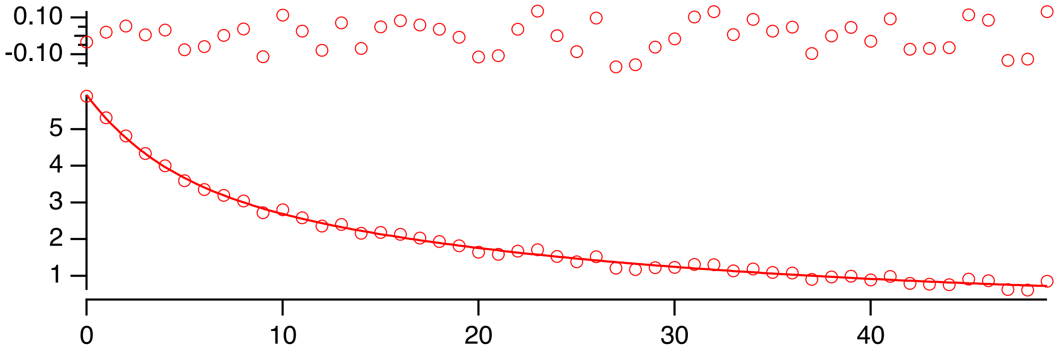
```
Make/O/T CTextWave={"K1 + K3 < 5"}
```

The wave is made using commands so that it could be written into this help file. It may be easier to use the Make Waves item from the Data menu to make the wave, and then display the wave in a table to edit the expressions. Make sure you make Text wave. Do not leave any blank lines in the wave.

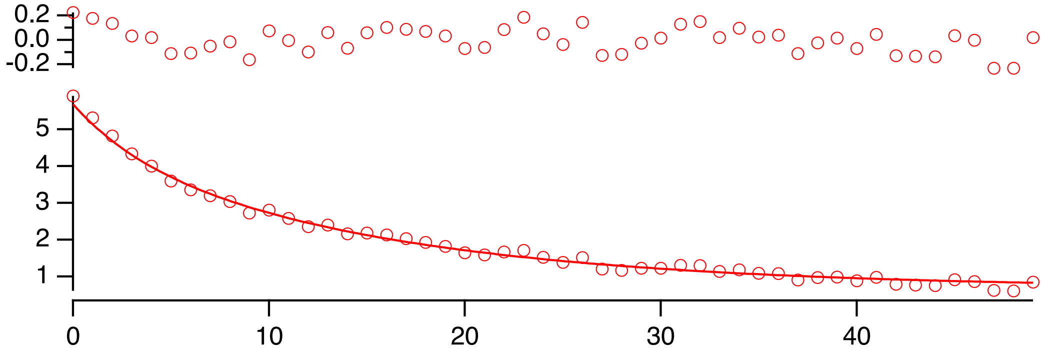
Now do the fit again with constraints:

```
CurveFit dblExp expData /D/R/C=CTextWave
```

In this case, the difference is slight; in the graph of the fit with constraints, notice that the fit line is slightly lower at the left end and slightly higher at the right end than in the standard curve fit, and that difference is reflected in the residual values at the ends:



Standard Curve Fit



Curve Fit with Constraints

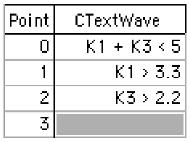
The output from a curve fit with constraints includes these lines reporting on the fact that constraints were used, and that the constraint was active in the solution:

```
  --Curve fit with constraints--
     Active Constraint: Desired:  K1+K3<5  Achieved:  K1+K3=5
```

In most cases you will see a message similar to this one. If you have conflicting constraints, it is likely that one or more constraints will be violated. In that case, you will get a report of that fact. The following commands add two more constraints to the example. The new constraints require values for the individual amplitudes that sum to a number greater than 5, while still requiring that the sum be less than 5 (so these are “infeasible constraints”):

```
Make/O/T CTextWave={"K1 + K3 < 5", "K1 > 3.3", "K3 > 2.2"}
CurveFit dblExp expData /D/R/C=CTextWave
```

In most cases, you would have added the new constraints by editing the constraint wave in a table.



Point	CTextWave
0	K1 + K3 < 5
1	K1 > 3.3
2	K3 > 2.2
3	

The curve fit report shows that all three constraints were violated to achieve a solution:

```
--Curve fit with constraints--
   Constraint VIOLATED:  Desired:  K1>3.3  Achieved:  K1=3.06604
   Constraint VIOLATED:  Desired:  K3>2.2  Achieved:  K3=1.93381
```

Constraint Matrix and Vector

When you do a constrained fit, it parses the constraint expressions and builds a matrix and a vector that describe the constraints.

Each constraint expression is parsed to form a simple expression like $C_0K_0 + C_1K_1 + \ldots \le D$, where the K_i’s are the fit coefficients, and the C_i’s and D are constants. The constraints can be expressed as the matrix operation **CK** ≤ **D**, where **C** is a matrix of constants, **K** is the fit coefficient vector, and **D** is a vector of limits. The matrix has dimensions N by M where N is the number of constraint expressions and M is the number of fit coefficients. In most cases, almost all the elements of the matrix are zeroes. In the previous example, the **C** matrix and **D** vector are:

C matrix					**D vector**
0	1	0	1	0	5
0	-1	0	0	0	-3.3
0	0	0	-1	0	-2.2

This is the form used internally by the curve-fitting code. If you wish, you can build a matrix wave and one-dimensional wave containing the *C* and *D* constants. Instead of using /C=*textwave* to request a fit with constraints, use `/C={matrix, 1Dwave}`.

In general, it is confusing and error-prone to create the right waves for a given set of constraints. However, it is not allowed to use the textwave method for curve fitting from a threadsafe function (see **Constraints and ThreadSafe Functions** on page III-250). Fortunately, Igor can create the necessary waves when it parses the expressions in a text wave.

You can create waves containing the **C** matrix and **D** vector using the /C flag (note that this flag goes right after the CurveFit command name, not at the end). If you have executed the examples above, you can now execute the following commands to build the waves and display them in a table:

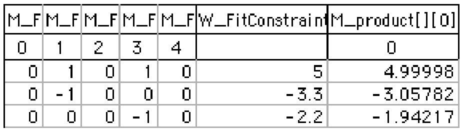
```
CurveFit/C dblExp expData /D/R/C=CTextWave
Edit M_FitConstraint, W_FitConstraint
```

The **C** matrix is named M_FitConstraint and the **D** vector is named W_FitConstraint (by convention, matrix names start with “M_”, and 1D wave names start with “W_”).

In addition to their usefulness for specifying constraints in a threadsafe function, you can use these waves later to check the constraints. The following commands multiply the generated fit coefficient wave (W_coefs) by the constraint matrix and appends the result to the table made previously:

```
MatrixMultiply M_FitConstraint, W_coef
AppendToTable M_Product
```

The result of the MatrixMultiply operation is the matrix wave M_Product. Note that the values of M_Product[1] and M_Product[2] are larger than the corresponding values in W_FitConstraint because the constraints were infeasible and resulted in constraint violations.



M_F	M_F	M_F	M_F	M_F	W_FitConstraint	M_product[][0]
0	1	2	3	4		0
0	1	0	1	0	5	4.99998
0	-1	0	0	0	-3.3	-3.05782
0	0	0	-1	0	-2.2	-1.94217

Constrained Curve Fitting Pitfalls

Bad Values on the Constraint Boundary

The most likely problem with constrained curve fitting is a value on a constraint boundary that produces a singular matrix error during the curve fit. For instance, it would be reasonable in many applications to require a pre-exponential multiplier to be positive, in this case K1>0:

$$y = K_0 + K_1 e^{K_2 x}$$

It would be natural to write a constraint expression “$K_1 > 0$”, but this can lead to problems. If some iteration tries a negative value of K_1, the constraints will set K_1 to be exactly zero. But when K1 is zero, the function has no dependence on K_2 and a singular matrix error results. The solution is to use a constraint that requires K_1 to be greater than some small positive number: “$K_1 > 0.1$”, for instance. The value of the limit must be tailored to your application. If you expect the constraint to be inactive when the solution is found, and the fit reports that the constraint was active, you can decrease the limit and do the fit again.

Severe Constraint Conflict

Although the method used for applying the constraints can find a solution even when constraints conflict with each other (are infeasible), it is possible to have a conflict that is so bad that the method fails. This will result in a singular matrix error.

Constraint Region is a Poor Fit

It is possible that the region of coefficient space allowed by the constraints is such a bad fit to the data that a singular matrix error results.

Initial Guesses Far Outside the Constraint Region

Usually if the initial guesses for a fit lie outside the region allowed by the constraints, the fit coefficients will shift into the constraint region on the first iteration. It is possible, however, for initial guesses to be so far from the constraint region that the solution to the constraints fails. This will cause the usual singular matrix error.

Constraints Conflict with a Held Parameter

You cannot hold a parameter and apply a constraint to the same parameter. Thus, this is not allowed:

```
Make/T CWave="K1 > 5"
FuncFit/H="01" myFunc, myCoefs, myData /C=CWave
```

NaNs and INFs in Curve Fits

Curve fits ignore NaNs and INFs in the input data. This is a convenient way to eliminate individual data values from a fit. A better way is to use a data mask wave (see **Using a Mask Wave** on page III-198).

Special Variables for Curve Fitting

There are a number of special variables used for curve fitting input (to provide additional control of the fit) and for output (to provide additional statistics). Knowledgeable users can use the input variables to tweak the fitting process. However, this is usually not needed. Some output variables help users knowledgeable in statistics to evaluate the quality of a curve fit.

To use an input variable interactively, create it from the command line using the Variable operation before performing the fit.

Most of the output variables are automatically created by the CurveFit or FuncFit operations. Some, as indicated below, are not automatically created; you must create them yourself if you want the information they provide.

If you are fitting using a procedure, both the input and output variables can be local or global. It is best to make them local. See **Accessing Variables Used by Igor Operations** on page IV-123 for information on how to use local variables. In procedures, output-only variables are always as local variables.

If you perform a curve fit interactively via the command line or via the Curve Fitting dialog, the variables will be global. If you use multiple data folders (described in Chapter II-8, **Data Folders**), you need to remember that input and output variables are searched for or created in the current data folder.

The following table lists all of the input and output special variables. Some variables are discussed in more detail in sections following the table.

Variable	I/O	Meaning
V_FitOptions	Input	Miscellaneous options for curve fit.
V_FitTol	Input	Normally, an iterative fit terminates when the fractional decrease of chi-square from one iteration to the next is less than 0.001. If you create a global variable named V_FitTol and set it to a value between 1E-10 and 0.1 then that value will be used as the termination tolerance. Values outside that range will have no effect.
V_tol	Input	(poly fit only) The "singular value threshold". See **Special Considerations for Polynomial Fits** on page III-265.
V_chisq	Output	A measure of the goodness of fit. It has absolute meaning only if you've specified a weighting wave containing the reciprocal of the standard error for each data point.
V_q	Output	(line fit only) A measure of the believability of chi-square. Valid only if you specified a weighting wave.
V_siga, V_sigb	Output	(line fit only) The probable uncertainties of the intercept (K0 = a) and slope (K1 = b) coefficients for a straight-line fit (to y = a + bx).
V_Rab	Output	(line fit only) The coefficient of correlation between the uncertainty in a (the intercept, K0) and the uncertainty in b (the slope, K1).
V_Pr	Output	(line fit only) The linear correlation coefficient r (also called Pearson's r). Values of +1 or -1 indicate complete correlation while values near zero indicate no correlation.
V_r2	Output	(line fit only) The coefficient of determination, usually called simply "r-squared". See **Coefficient of Determination or R-Squared** on page III-221 for details.
V_npnts	Output	The number of points that were fitted. If you specified a weighting wave then points whose weighting was zero are not included in this count. Also not included are points whose values are NaN or INF.
V_nterms	Output	The number of coefficients in the fit.
V_nheld	Output	The number of coefficients held constant during the fit.
V_numNaNs	Output	The number of NaN values in the fit data. NaNs are ignored during a curve fit.
V_numINFs	Output	The number of INF values in the fit data. INFs are ignored during a curve fit.
V_FitError	Input/ Output	Used from a procedure to attempt to recover from errors during the fit.
V_FitQuitReason	Output	Provides additional information about why a nonlinear fit stopped iterating. You must create this variable; it is not automatically created.
V_FitIterStart	Output	Use of V_FitIterStart is obsolete; use all-at-once fit functions instead. See **All-At-Once Fitting Functions** on page III-256 for details. Set to 1 when an iteration starts. Identifies when the user-defined fitting function is called for the first time for a particular iteration. You must create this variable; it is not automatically created.

Variable	I/O	Meaning
V_FitMaxIters	Input	Controls the maximum number of passes without convergence before stopping the fit. By default this is 40. You can set V_FitMaxIters to any value greater than 0. If V_FitMaxIters is less than 1 the default value of 40 is used.
V_FitNumIters	Output	Number of iterations. You must create this variable; it is not automatically created.
S_Info	Output	Keyword-value pairs giving certain kinds of information about the fit. You must create this variable; it is not automatically created.

V_FitOptions

There are a number of options that you can invoke for the fitting process by creating a variable named V_FitOptions and setting various bits in it. Set V_FitOptions to 1 to set Bit 0, to 2 to set Bit 1, etc.

Bit 0: Controls X Scaling of Auto-Trace Wave

If V_FitOptions exists and has bit 0 set (`Variable V_fitOptions=1`) and if the Y data wave is on the top graph then the X scaling of the auto-trace destination wave is set to match the appropriate x axis on the graph. This is useful when you want to extrapolate the curve outside the range of x data being fit.

A better way to do this is with the /X flag (not parameter- this flag goes immediately after the CurveFit or FuncFit operation and before the fit function name). See **CurveFit** for details.

Bit 1: Robust Fitting

You can get a form of robust fitting where the sum of the absolute deviations is minimized rather than the squares of the deviations, which tends to deemphasize outlier values. To do this, create V_FitOptions and set bit 1 (`Variable V_fitOptions=2`).

Warning 1: No attempt to adjust the results returned for the estimated errors or for the correlation matrix has been made. You are on your own.

Warning 2: Don’t set this bit and then forget about it.

Warning 3: Setting Bit 1 has no effect on line, poly or poly2D fits.

Bit 2: Suppresses Curve Fit Window

Normally, an iterative fit puts up an informative window while the fit is in progress. If you don’t want this window to appear, create V_FitOptions and set bit 2 (`Variable V_fitOptions=4`). This may speed things up a bit if you are performing batch fitting on a large number of data sets.

A better way to do this is via the /W=2 flag. See **CurveFit** for details.

Bit 3: Save Iterates

It is sometimes useful to know the path taken by a curve fit getting to a solution (or failing to). To save his information, create V_FitOptions and set bit 3 (`Variable V_FitOptions=8`). This creates a matrix wave called M_iterates, which contains the values of the fit coefficients at each iteration. The matrix has a row for each iteration and a column for each fit coefficient. The last column contains the value of chi square for each iteration.

Bit 4: Suppress Screen Updates

Works just like setting the /N=1 flag. See **CurveFit** for details.

Added in Igor Pro 7.00.

Bit 5: Errors Only

When set, just like setting /O flag (Guess only) but for FuncFit also computes the W_sigma wave and optionally the covariance matrix (/M flag) for your set of coefficients. There is the possibility that setting this bit can generate a singular matrix error.

Added in Igor Pro 7.00.

V_chisq

V_chisq is a measure of the goodness of fit. It has absolute meaning only if you've specified a weighting wave. See the discussion in the section **Weighting** on page III-199.

V_q

V_q (straight-line fit only) is a measure of the believability of chi-square. It is valid only if you specified a weighting wave. It represents the quantity q which is computed as follows:

```
q = gammq((N-2)/2, chisq/2)
```

where gammq is the incomplete gamma function 1-P(a,x) and N is number of points. A q of 0.1 or higher indicates that the goodness of fit is believable. A q of 0.001 indicates that the goodness of fit may be believable. A q of less than 0.001 indicates systematic errors in your data or that you are fitting to the wrong function.

V_FitError and V_FitQuitReason

When an error occurs during a curve fit, it normally causes any running user-defined procedure to abort.

This makes it impossible for you to write a procedure that attempts to recover from errors. However, you can prevent an abort in the case of certain types of errors that arise from unpredictable mathematical circumstances. Do this creating a variable named V_FitError and setting it to zero before performing a fit. If an error occurs during the fit, it will set bit 0 of V_FitError. Certain errors will also cause other bits to be set in V_FitError:

Error	Bit Set
Any error	0
Singular matrix	1
Out of memory	2
Function returned NaN or INF	3
Fit function requested stop	4
Reentrant curve fitting	5

Reentrant curve fitting means that somehow a second curve fit started execution when there was already one running. That could happen if your user-defined fit function tried to do a curve fit, or if a button action procedure that does a fit responded too soon to another click.

There is more than one reason for a fit to stop iterating without an error. To obtain more information about the reason that a nonlinear fit stopped iterating, create a variable named V_FitQuitReason. After the fit, V_FitQuitReason is zero if the fit terminated normally, 1 if the iteration limit was reached, 2 if the user stopped the fit, or 3 if the limit of passes without decreasing chi-square was reached.

Other types of errors, such as missing waves or too few data points for the fit, are likely to be programmer errors. V_FitError does not catch those errors, but you can still prevent an abort if you wish, using the special function **AbortOnRTE** and Igor's **try-catch-endtry** construct. Here is an example function that attempts to do a curve fit to a data set that may contain nothing but NaNs:

```
Function PreventCurveFitAbort()
   Make/O test = NaN
   try
      CurveFit/N/Q line, test; AbortOnRTE
   catch
      if (V_AbortCode == -4)
         Print "Error during curve fit:"
         Variable cfError = GetRTError(1)    // 1 to clear the error
         Print GetErrMessage(cfError,3)
      endif
   endtry
End
```

If you run this function, the output is:

```
  Error during curve fit:
  You must have at least as many data points as fit parameters.
```

No error alert is presented because of the call to **GetRTError**. The error is reported to the user by getting the error message using **GetRTErrMessage** and then printing the message to the history area.

V_FitIterStart

V_FitIterStart provides a way for a user-defined function to know when the fitting routines are about to start a new iteration. The original, obsolete purpose of this is to allow for possible efficient computation of user-defined fit functions that involve convolution. Such functions should now use all-at-once fit functions. See **All-At-Once Fitting Functions** on page III-256 for details.

S_Info

If you create a string variable in a function that calls CurveFit or Funcfit, Igor will fill it with keyword-value pairs giving information about the fit:

Keyword	Information Following Keyword
DATE	The date of the fit.
TIME	The time of day of the fit.
FUNCTION	The name of the fitting function.
AUTODESTWAVE	If you used the /D parameter flag to request an autodestination wave, this keyword gives the name of the wave.
YDATA	The name of the Y data wave.
XDATA	A comma-separated list of X data waves, or "_calculated_" if there were no X waves. In most cases there is just one X wave.

Use **StringByKey** to get the information from the string. You should set keySepStr to "=" and listSepStr to ";".

Errors in Variables: Orthogonal Distance Regression

When you fit a model to data, it is usually assumed that all errors are in the dependent variable, and that independent variables are known perfectly (that is, X is set perfectly and Y is measured with error). This assumption is often not far from true, and as long as the errors in the dependent variable are much larger than those for the independent variable, it will not usually cause much difference to the curve fit.

When the errors are normally distributed with zero mean and constant variance, and the model is exact, then the standard least-squares fit gives the maximum-likelihood solution. This is the technique described earlier (see **Overview of Curve Fitting** on page III-179).

In some cases, however, the errors in both dependent and independent variables may be comparable. This situation has a variety of names including errors in variables, measurement error models or random regressor models. An example of a model that can result in similar errors in dependent and independent variables is fitting the track of an object along a surface; the variables involved would be measurements of cartesian coordinates of the object's location at various instants in time. Presumably the measurement errors would be similar because both involve spatial measurement.

Fitting such data using standard or ordinary least squares can lead to bias in the solution. To solve this problem, we offer Orthogonal Distance Regression (ODR). Rather than minimizing the sum of squared errors in the dependent variable, ODR minimizes the orthogonal distance from the data to the fitted curve by adjusting both the model coefficients and an adjustment to the values of the independent variable. This is also sometimes called "total least squares" or "reduced major axis" (RMA) fitting

For ODR curve fitting, Igor Pro uses a modified version of the freely available ODRPACK95. The CurveFit, FuncFit, and FuncFitMD operations can all do ODR fitting using the /ODR flag (see the documentation for the **CurveFit** operation on page V-124 for details on the /ODR flag, and the **Curve Fitting References** on page III-267 for information about the ODRPACK95 implementation of ODR fitting). Our version of ODRPACK95 has been modified to make it threadsafe and to do some automatic multithreading during single fits.

ODR Fitting is Threadsafe

As of Igor Pro 8.00, ODR fitting is threadsafe. You can perform an ODR fit from a threadsafe user-defined function and you can do multiple ODR fits simultaneously using Igor's preemptive threads.

Weighting Waves for ODR Fitting

Just as with ordinary least-squares fitting, you can provide a weighting wave to indicate the expected magnitude of errors for ODR fitting. But in ODR fitting, there are errors in both the dependent and independent variables, so ODR fits accept weighting waves for both. You use the /XW flag to specify weighting waves for the independent variable.

If you do not supply a weighting wave, it is assumed the errors have a variance of 1.0. This may be acceptable if the errors in the dependent and independent variables truly have similar magnitudes. But if the dependent and independent variables are of very different magnitudes, the chances are good that the errors are also of very different magnitudes, and weighting is essential for a proper fit. Unlike the case for ordinary least squares, where there is only a single weighting wave, ODR fitting depends on both the magnitude of the weights as well as the relative magnitudes of the X and Y weights.

ODR Initial Guesses

An ordinary least squares fit that is linear in the coefficients can be solved directly. No initial guess is required. The built-in line, poly, and poly2D curve fit functions are linear in the coefficients and do not require initial guesses.

An ordinary least-squares fit to a function that is nonlinear in the coefficients is an iterative process that requires a starting point. That means that you must provide an initial guess for the fit coefficients. The accuracy required of your initial guess depends greatly on the function you are fitting and the quality of your data. The built-in fit functions also attempt to calculate a good set of initial guesses, but for user-defined fits you must supply your own initial guesses.

An ODR fit introduces a nonlinearity into the fitting equations that requires iterative fitting and initial guesses even for fit functions that have linear fit coefficients. In the case of line, poly, and poly2D fit functions, ODR fitting uses an ordinary least squares fit to get an initial guess. For nonlinear built-in fit functions, the same initial guesses are used regardless of fitting method.

Because the independent variable is adjusted during the fit, an initial guess is also required for the adjustments to the independent variable. The initial guess is transmitted via one or more waves (one for each independent variable) specified with the /XR flag. The X residual wave is also an output- see the **ODR Fit Results** on page III-238.

In the absence of the /XR flag, initial guesses for the adjustments to the independent variable values are set to zero. This is usually appropriate; in areas where the fitting function is largely vertical, you may need nonzero guesses to fit successfully. One example of such a situation would be the region near a singularity.

Holding Independent Variable Adjustments

In some cases you may have reason to believe that you know some input values of the independent variables are exact (or nearly so) and should not be adjusted. To specify which values should not be adjusted, you supply X hold waves, one for each independent variable, via the /XHLD flag. These waves should be filled with zeroes corresponding to values that should be adjusted, or ones for values that should be held.

This is similar to the /H flag to hold fit coefficients at a set value during fitting. However, in the case of ODR fitting and the independent variable values, holds are specified by a wave instead of a string of ones and zeroes. This was done because of the potential for huge numbers of ones and zeroes being required. To save memory, you can use a byte wave for the holds. In the Make Waves dialog, you select Byte 8 Bit from the Type menu. Use the /B flag with the **Make** operation on page V-526.

ODR Fit Results

An ordinary least-squares fit adjusts the fit coefficients and calculates model values for the dependent variable. You can optionally have the fit calculate the residuals — the differences between the model and the dependent variable data.

ODR fitting adjusts both the fit coefficients and the independent variable values when seeking the least orthogonal distance fit. In addition to the residuals in the dependent variable, it can calculate and return to you a wave or waves containing the residuals in the independent variables, as well as a wave containing the adjusted values of the independent variable.

Residuals in the independent variable are returned via waves specified by the /XR flag. Note that the contents of these waves are inputs for initial guesses at the adjustments to the independent variables, so you must be careful — in most cases you will want to set the waves to zero before fitting.

The adjusted independent variable values are placed into waves you specify via the /XD flag.

Note that if you ask for an auto-destination wave (/D flag; see**The Destination Wave** on page III-196) the result is a wave containing model values at a set of evenly-spaced values of the independent variables. This wave will also be generated in response to the /D flag for ODR fitting.

You can also specify a specific wave to receive the model values (/D=*wave*). The values are calculated at the values of the independent variables that you supply as input to the fit. In the case of ODR fitting, to make a graph of the model, the appropriate X wave would be the output from the /XD flag, not the input X values.

Constraints and ODR Fitting

When fitting with the ordinary least-squares method (/ODR=0) you can provide a text wave containing constraint expressions that will keep the fit coefficients within bounds. These expressions can be used to apply simple bound constraints (keeping the value of a fit coefficient greater than or less than some value) or to apply bounds on linear combinations of the fit coefficients (constrain $a+b>1$, for instance).

When fitting using ODR (/ODR=1 or more) only simple bound constraints are supported.

Error Estimates from ODR Fitting

In a curve fit, the output includes an estimate of the errors in the fit coefficients. These estimates are computed from the linearized quadratic approximation to the chi-square surface at the solution. For a linear fit (line, poly, and poly2D fit functions) done by ordinary least squares, the chi-square surface is actually quadratic and the estimates are exact if the measurement errors are normally distributed with zero mean and constant variance. If the fitting function is nonlinear in the fit coefficients, then the error estimates are an approximation. The quality of the approximation will depend on the nature of the nonlinearity.

In an ODR fit, even when the fitting function is linear in the coefficients, the fitting equations themselves introduce a nonlinearity. Consequently, the error estimates from an ODR fit are always an approximation. See the **Curve Fitting References** on page III-267 for detailed information.

ODR Fitting Examples

A simple example: a line fit with no weighting. If you run these commands, the call to SetRandomSeed will make your “measurement error” (provided by **gnoise** function on page V-323) the same as the example shown here:

```
SetRandomSeed 0.5       // so that the "random" data will always be the same...
Make/N=10 YLineData, YLineXData
YLineXData = p+gnoise(1)      // gnoise simulates error in X values
YLineData = p+gnoise(1)       // gnoise simulates error in Y values
// make a nice graph with errors bars showing standard deviation errors
Display YLineData vs YLineXData
ModifyGraph mode=3,marker=8
ErrorBars YLineData XY,const=1,const=1
```

Now we’re ready to perform a line fit to the data. First, a standard curve fit:

```
CurveFit line, YLineData/X=YLineXData/D
```

This command results in the following history report:

```
fit_YLineData= W_coef[0]+W_coef[1]*x
W_coef={1.3711,0.78289}
V_chisq= 15.413; V_npnts= 10; V_numNaNs= 0; V_numINFs= 0;
V_startRow= 0; V_endRow= 9; V_q= 1; V_Rab= -0.797202; V_Pr= 0.889708;
V_r2= 0.791581;
W_sigma={0.727,0.142}
Coefficient values ± one standard deviation
    a = 1.3711 ± 0.727
    b = 0.78289 ± 0.142
```

Next, we will use /ODR=2 to request orthogonal distance fitting:

```
CurveFit/ODR=2 line, YLineData/X=YLineXData/D
```

which gives this result:

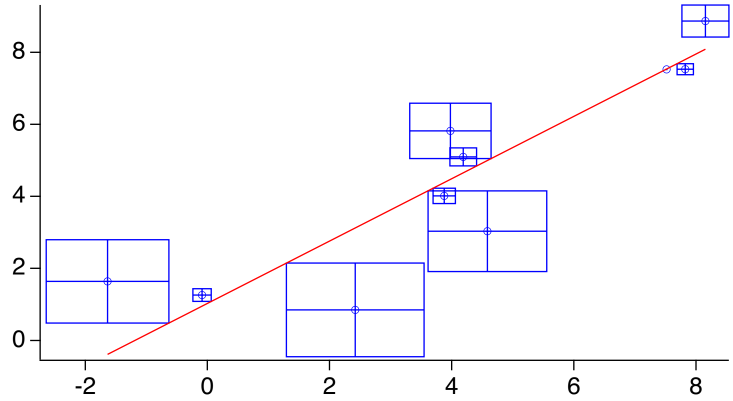
```
Fit converged properly
fit_YLineData= W_coef[0]+W_coef[1]*x
W_coef={1.0311,0.86618}
V_chisq= 9.18468; V_npnts= 10; V_numNaNs= 0; V_numINFs= 0;
V_startRow= 0; V_endRow= 9;
W_sigma={0.753,0.148}
Coefficient values ± one standard deviation
    a   = 1.0311 ± 0.753
    b   = 0.86618 ± 0.148
```

Add output of the X adjustments and Y residuals:

```
Duplicate/O YLineData, YLineDataXRes, YLineDataYRes
CurveFit/ODR=2 line, YLineData/X=YLineXData/D/XR=YLineDataXRes/R=YLineDataYRes
```

And a graph that uses error bars to show the residuals:

```
Display YLineData vs YLineXData
ModifyGraph mode=3,marker=8
AppendToGraph fit_YLineData
ModifyGraph rgb(YLineData)=(0,0,65535)
ErrorBars YLineData BOX,wave=(YLineDataXRes,YLineDataXRes),
wave=(YLineDataYRes,YLineDataYRes)
```



The boxes on this graph do not show error estimates, they show the residuals from the fit. That is, the differences between the data and the fit model. Because this is an ODR fit, there are residuals in both X and Y; error bars are the most convenient way to show this. Note that one corner of each box touches the model line.

In the next example, we do an exponential fit in which the Y values and errors are small compared to the X values and errors. The curve fit history report has been edited to include just the output of the solution. First, fake data and a graph:

```
SetRandomSeed 0.5   // so that the "random" data will always be the same…
Make/D/O/N=20 expYdata, expXdata
expYdata = 1e-6*exp(-p/2)+gnoise(1e-7)
expXdata = p+gnoise(1)
display expYdata vs expXdata
ModifyGraph mode=3,marker=8
```

A regular exponential fit:

```
CurveFit exp, expYdata/X=expXdata/D

Coefficient values ± one standard deviation
    y0        =-1.0805e-08 ± 4.04e-08
    A         =7.0438e-07 ± 9.37e-08
    invTau    =0.38692 ± 0.116
```

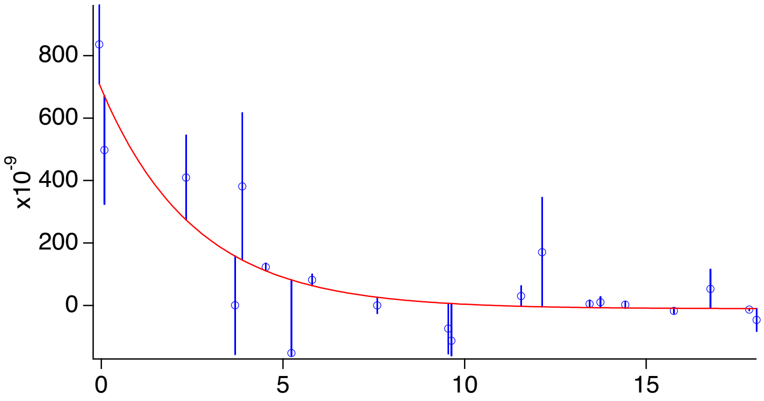
An ODR fit with no weighting, with X and Y residuals:

```
Duplicate/O expYdata, expYdataResY, expYdataResX
expYdataResY=0
expYdataResX=0
CurveFit/ODR=2 exp, expYdata/X=expXdata/D/R=expYdataResY/XR=expYdataResX

Coefficient values ± one standard deviation
    y0     =-1.0541e-08 ± 4.03e-08
    A      =7.0443e-07 ± 9.37e-08
    invTau =0.38832 ± 0.116
```

And a graph:

```
Display /W=(137,197,532,405) expYdata vs expXdata
AppendToGraph fit_expYdata
ModifyGraph mode(expYdata)=3
ModifyGraph marker(expYdata)=8
ModifyGraph lSize(expYdata)=2
ModifyGraph rgb(expYdata)=(0,0,65535)
ErrorBars expYdata
BOX,wave=(expYdataResX,expYdataResX),wave=(expYdataResY,expYdataResY)
```

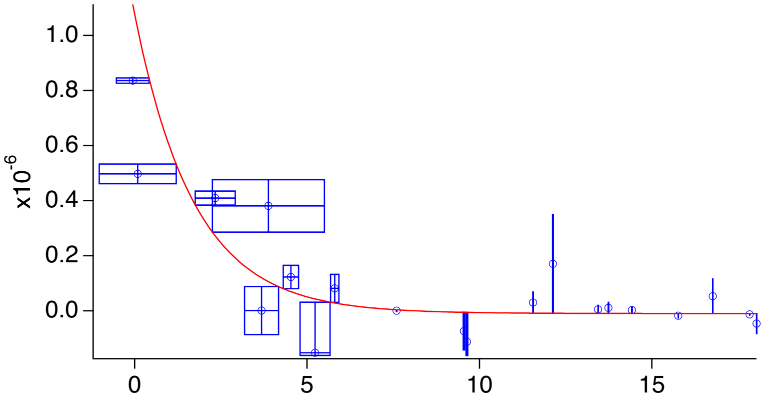


Because the Y values are very small compared to the X values, and we didn't use weighting to reflect smaller errors in Y, the residual boxes are tall and skinny. If the vertical graph scale were the same as the horizontal scale, the boxes would be approximately square. The data line would be very nearly a horizonal line. One way to understand this is to remember that the ODR method is essentially geometric. In this example, the vertical scale on the graph has been expanded very greatly, but the ODR method works in an unexpanded scale where the perpendicular lines to the fit curve are very nearly exactly vertical.

Now we can add appropriate weighting. It's easy to decide on the correct weighting since we added "measurement error" using gnoise():

```
Duplicate/O expYdata, expYdataWY
expYdataWY=1e-7
Duplicate/O expYdata, expYdataWX
expYdataWX=1
// Caution: Next command wrapped to fit on page.
CurveFit/ODR=2 exp, expYdata/X=expXdata/D/R=expYdataResY/XR =expYdataResX/W=expYdataWY
/XW=expYdataWX/I=1

Coefficient values ± one standard deviation
    y0     =-9.8498e-09 ± 3e-08
    A      =1.0859e-06 ± 5.39e-07
    invTau =0.57731 ± 0.248
```



One way to think about the weighting waves for ODR fitting is that they provide geometric scaling. In this example, the vertical dimension is about 10^7 times smaller than the horizontal dimension. When the vertical dimension is scaled by the weighting waves, the dimensions are similar and the perpendicular distances from the fit curve to the data points are no longer merely vertical.

Fitting Implicit Functions

Occasionally you may need to fit data to a model that doesn't have a form that can be expressed as y=f(x). An example would be fitting a circle or ellipse using an equation like

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

Because this equation can't be expressed as y=f(x), you can't write a standard user-defined fitting function for it.

This problem is related to the errors in variables problem in which data has measurement errors in both the dependent and independent variables. You have two inputs, or independent variables (x and y), both with (probably) similar measurement errors. It differs from errors in variables fitting in that the function output is zero instead of being a dependent variable.

The ODRPACK95 package also supports fitting to implicit functions, which you can do with the /ODR=3 flag. You create a fitting function with multiple independent variables (in the case of the ellipse above, two for x and y). The fitting process will attempt to find x and y residuals and fit coefficients to minimize the distance from the data to the zero contour of the function.

It may be a good idea at this point to read the section about errors in variables fitting; see **Errors in Variables: Orthogonal Distance Regression** on page III-236; much of it applies also to implicit fits.

There are a few differences between regular fitting and implicit fitting. For implicit fits, there is no autodestination, and the report printed in the history does not include the wave assignment showing how to get values of the fitted model (doing that is actually not at all easy).

Because of the details of the way ODRPACK95 operates, when you do an implicit fit, the curve fit progress window does not update, and it appears that the fit takes just one iteration. That is because all the action takes place inside the call to ODRPACK95.

The fit function must be written to return zero when the function solution is found. So if you have an equation of the form f(x_i) = 0, you are ready to go; you simply create a fit function that implements f(x_i). If it is in the form f(x_i) = constant, you must move the constant to the other side of the equation: f(x_i)-constant = 0. If it is a form like f(x_i) = g(x_i), you must write your fitting function to return f(x_i) - g(x_i).

Example: Fit to an Ellipse

In this example we will show how to fit an equation like the one above. In the example the center of the ellipse will be allowed to be at nonzero x_0, y_0.

First, we must define a fitting function. The function includes special comments to get mnemonic names for the fit coefficients (see **The New Fit Function Dialog Adds Special Comments** on page III-253). To try the example, you will need to copy this function and paste it into the Procedure window:

```
Function FitEllipse(w,x,y) : FitFunc
	Wave w
	Variable x
	Variable y

	//CurveFitDialog/
	//CurveFitDialog/ Coefficients 4
	//CurveFitDialog/ w[0] = a
	//CurveFitDialog/ w[1] = b
	//CurveFitDialog/ w[2] = x0
	//CurveFitDialog/ w[3] = y0

	return ((x-w[2])/w[0])^2 + ((y-w[3])/w[1])^2 - 1
End
```

An implicit fit seeks adjustments to the input data and fit coefficients that cause the fit function to return zero. To implement the ellipse function above, it is necessary to subtract 1.0 to account for "= 1" on the right in the equation above.

The hard part of creating an example is creating fake data that falls on an ellipse. We will use the standard parametric equations to do the job (y = a*cos(theta), x=b*sin(theta)). So far, we will not add “measurement error” to the data so that you can see the ellipse clearly on a graph:

```
Make/N=20 theta,ellipseY,ellipseX
theta = 2*pi*p/20
ellipseY = 2*cos(theta)+2
ellipseX=3*sin(theta)+1
```

A graph of the data (you could use the Windows→New Graph menu, and then the Modify Trace Appearance dialog):

```
Display ellipseY vs ellipseX
ModifyGraph mode=3,marker=8
ModifyGraph width={perUnit,72,bottom},height={perUnit,72,left}
```

The last command line sets the width and height modes of the graph so that the ellipse is shown in its true aspect ratio. Now add some “measurement error” to the data:

```
SetRandomSeed 0.5       // so that the "random" data will always be the same…
ellipseY += gnoise(.3)
ellipseX += gnoise(.3)
```

Now you can see why we didn’t do that before — it’s a pretty lousy ellipse!

Now, finally, do the fit. That requires making a coefficient wave and filling it with the initial guesses, and making a pair of waves to receive estimated values of X and Y at the fit:

```
Duplicate ellipseY, ellipseYFit, ellipseXFit
Make/D/O ellipseCoefs={3,2,1,2}                  // a, b, x0, y0
FuncFit/ODR=3 FitEllipse, ellipseCoefs /X={ellipseX, ellipseY} /XD={ellipseXFit,ellipseYFit}
```

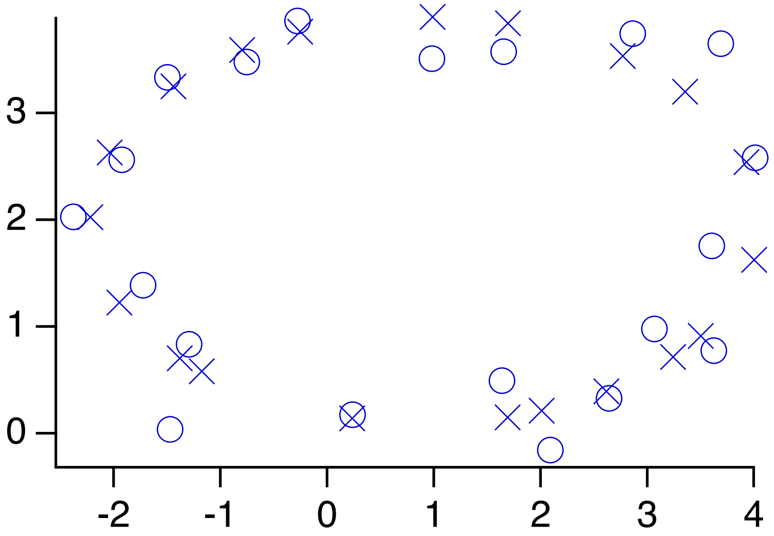
The call to the FuncFit operation has no Y wave specified (it would ordinarily go right after the coefficient wave, ellipseCoefs) because this is an implicit fit.

The results:

```
Fit converged properly
  ellipseCoefs={3.1398,1.9045,0.92088,1.9971}
  V_chisq= 1.74088; V_npnts= 20; V_numNaNs= 0; V_numINFs= 0;
  W_sigma={0.158,0.118,0.128,0.0906}
  Coefficient values ± one standard deviation
   a  =3.1398 ± 0.158
   b  =1.9045 ± 0.118
   x0 =0.92088 ± 0.128
   y0 =1.9971 ± 0.0906
```

And add the destination waves (the ones specified with the /XD flag) to the graph:

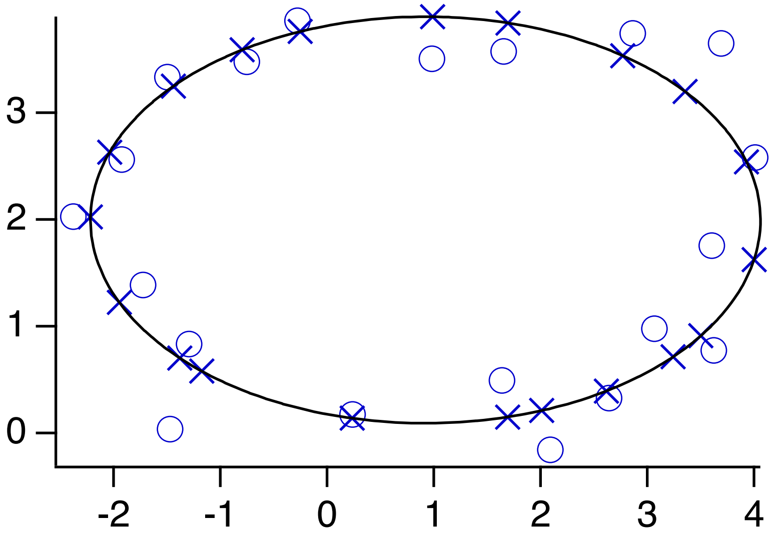
```
AppendToGraph ellipseYFit vs ellipseXFit
ModifyGraph mode=3,marker(ellipseYFit)=1
ModifyGraph rgb=(1,4,52428)
```



It is difficult to compute the model representing the solution, as it requires finding roots of the implicit function. A quick way to add a smooth model curve to a graph is to fill a matrix with values of the fit function at a range of X and Y and then add a contour plot of the matrix to your graph. Then modify the contour plot to show only the zero contour.

Here are commands to add a contour of the example function to the graph above:

```
Make/N=(100,100) ellipseContour
SetScale/I x -3,4.5,ellipseContour
SetScale/I y -.2, 5, ellipseContour
ellipseContour = FitEllipse(ellipseCoefs, x, y)
AppendMatrixContour ellipseContour
ModifyContour ellipseContour labels=0,autoLevels={*,*,0},moreLevels=0,moreLevels={0}
ModifyContour ellipseContour rgbLines=(0,0,0)
```



Fitting Sums of Fit Functions

Sometimes the appropriate model is a combination, typically a sum, of simpler models. It might be a sum of exponential decay functions, or a sum of several different peaks at various locations. Peak fitting can include a baseline function implemented as a separate user-defined fit function. With standard curve fitting, you have to write a user-defined function that implements the sum.

Instead, you can use an alternate syntax for the FuncFit operation to fit to a list of fit functions that are summed automatically. The results for each fit function are returned via separate coefficient waves, making it easy to keep the results of each term in the sum separate. The syntax is described in the **FuncFit** operation on page V-273.

The sum-of-fit-functions feature can mix any kind of fit function — built-in, or any of the variants described in **User-Defined Fitting Functions** on page III-250. However, even if you use only built-in fit functions you must provide initial guesses because our initial-guess generating code cannot discern how the various features of the data are partitioned amongst the list of fit functions.

Linear Dependency: A Major Issue

When you fit a list of fit functions you must be careful not to introduce linear dependencies between the coefficients of the list of functions. The most likely such dependency will arise from a constant Y offset used with all of the built-in fit functions, and commonly included in user functions. This Y offset accounts for any offset error that is common when making real-world measurements. For instance, the equation for the built-in exp function is:

$$y_0 + A\exp(-Bx)$$

If you sum two terms, you get two y_0's (primes used for the second copy of the function):

$$y_0 + A\exp(-Bx) + y_0' + A'\exp(-B'x)$$

As long as B and B' are distinct, the two exponential terms will not be a problem. But y_0 and y'_0 are linearly dependent — they cannot be distinguished mathematically. If you increase one and decrease the other the same amount, the result is exactly the same. This is sure to cause a singular matrix error when you try to do the fit.

The solution is to hold one of the y_0 coefficients. Because each fit function in the list has its own coefficient wave, and you can specify a hold string for each function, this is easy (see **Example: Summed Exponentials** on page III-246).

There are many ways to introduce linear dependence. They are not always so easy to spot!

Constraints Applied to Sums of Fit Functions

The sums of fit functions feature does not include a keyword for specifying constraints on a function-by-function basis. But you can use the normal constraint specifications - you just have to translate the constraint expressions to take account of the list of functions. (If you are interested in using constraints, but don't know about the syntax for constraints, see **Fitting with Constraints** on page III-227.)

Constraint expressions use K*n* to designate fit coefficients where *n* is simply the sequential number of the fit coefficient within the list of coefficients. n starts with zero. In order to reference fit coefficients for a fit function in a list of summed fit functions, you must account for all the fit coefficients in all the fit functions in the list before the fit function you are trying to constrain. For example, this is part of a command that will fit a sum of three exponential terms:

```
FuncFit {{exp,expTerm1},{exp,expTerm2,hold="1"},{exp,expTerm3,hold="1"}} ...
```

In order to constrain coefficients of the second exponential term, you must know first that the built-in exp fit function has three fit coefficients. Here is the equation of the exp fit function:

```
f(x) = y0 + A*exp(-x*invTau)
```

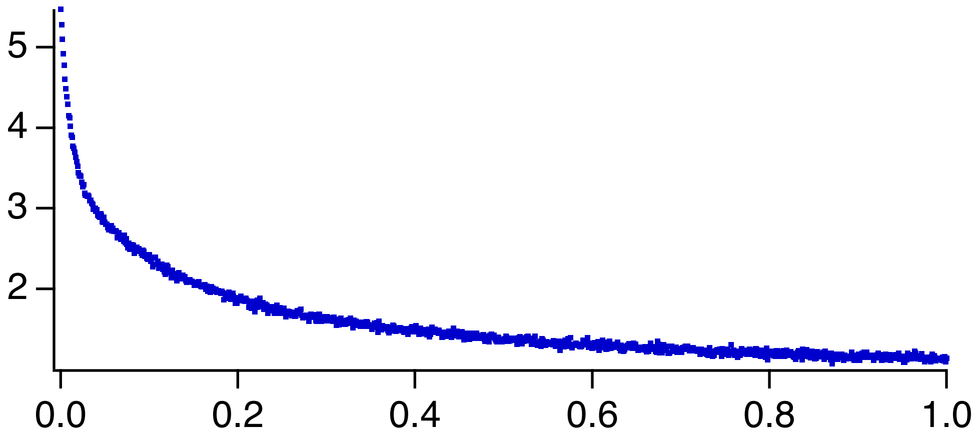
The vertical offset (y0) of the first summed exp term is represented in a constraint expression as "K0", the amplitude as "K1", and invTau as "K2". Constraint expressions for the second exp term continue the count starting with "K3" for y0 (but see the section **Linear Dependency: A Major Issue** on page III-245 and note that you are not allowed to hold and constrain a fit coefficient simultaneously), and use "K4" for the amplitude and "K5" for invTau.

Example: Summed Exponentials

This example fits a sum of three exponentials using the built-in exp fit function. For real work, we recommend the exp_XOffset function; it handles data that's not at X=0 better, and the decay constant fit coefficient is actually the decay constant. The exp fit function gives you the inverse of the decay constant.

First, make some fake data and graph it:

```
Make/D/N=1000 expSumData
SetScale/I x 0,1,expSumData
expSumData = 1 + exp(-x/0.5) + 1.5*exp(-x/.1) + 2*exp(-x/.01)+gnoise(.03)
Display expSumData
ModifyGraph mode=2,rgb=(1,4,52428)
```



The fake data was purposely made with a Y offset of 1.0 in order to illustrate how to handle the vertical offset terms in the fit function.

Next, we need to make a coefficient wave for each of the fit functions. In spite of the linear dependence between the vertical offset in each copy of the function, you must include all the fit coefficients in the coefficient waves. Otherwise when the function is evaluated the fit won't have all the needed information.

```
Make/D/O expTerm1 = {1, 1, 2}
Make/D/O expTerm2 = {0, 1.5, 10}
Make/D/O expTerm3 = {0, 2, 100}
```

Each of these lines makes one coefficient wave with three elements. The first element is y_0, the second is amplitude, and the third is the inverse of the decay constant. Since the data is fake, we have a pretty good idea of the initial guesses!

To reflect the baseline offset of 1.0, the y_0 coefficient for *only* the first exponential coefficient wave was set to 1. If y_0 were set to 1.0 for all three, the offset would be 3.0.

Now we can do the fit. A FuncFit command with a list of fit functions and coefficient waves can be pretty long:

```
FuncFit {{exp, expTerm1},{exp, expTerm2, hold="1"},{exp, expTerm3, hold="1"}}
expSumData/D
```

The entire list of functions is enclosed in braces and each fit function specification in the list is enclosed in braces as well. At a minimum you must provide a fit function and a coefficient wave for each function in the list, as was done here for the first exponential term.

The specification for each function can also contain various keywords; the second and third terms here contain the *hold* keyword in order to include a hold string. The string used will cause the fit to hold the y_0 coefficient for the second and third terms at zero. That prevents problems caused by linear dependence between the three fit functions. Since the coefficient waves for the second and third terms set their respective y_0 to zero, this puts all the vertical offset into the one coefficient for the first term.

In this example the hold strings are literal quoted strings. They can be any string expression but see below for restrictions if you use a function list contained in a string:

```
String holdStr = "1"
FuncFit {{exp,expTerm1},{exp,expTerm2,hold=holdStr},
            {exp,expTerm3,hold="1"}} expSumData/D     // All on one line
```

The history report for a sum of fit functions is enhanced to show all the functions:

```
Fit converged properly
fit_expSumData= Sum of Functions(,x)
expTerm1={1.027,1.045,2.2288}
expTerm2={0,1.4446,10.416}
expTerm3={0,2.0156,102.28}
V_chisq= 0.864844; V_npnts= 1000; V_numNaNs= 0; V_numINFs= 0;
V_startRow= 0; V_endRow= 999; V_startCol= 0; V_endCol= 0;
V_startLayer= 0; V_endLayer= 0; V_startChunk= 0; V_endChunk= 0;
W_sigma={0.0184,0.0484,0.185,0,0.052,0.495,0,0.0239,2.34}
For function 1: exp:
Coefficient values ± one standard deviation
   y0       = 1.027 ± 0.0184
   A        = 1.045 ± 0.0484
   invTau   = 2.2288 ± 0.185
For function 2: exp:
Coefficient values ± one standard deviation
   y0       = 0 ± 0
   A        = 1.4446 ± 0.052
   invTau   = 10.416 ± 0.495
For function 3: exp:
Coefficient values ± one standard deviation
   y0       = 0 ± 0
   A        = 2.0156 ± 0.0239
   invTau   = 102.28 ± 2.34
```

Example: Function List in a String

The list of functions in the FuncFit command in the first example is moderately long, but it could be much longer. If you wanted to sum 20 peak functions and a baseline function, the list could easily exceed the limit of 2500 bytes in a command line.

Fortunately, you can build the function specification in a string variable and use the string keyword. Doing this on the command line for the first example looks like this:

```
String myFunctions="{exp, expTerm1}"
myFunctions+="{exp, expTerm2, hold=\"1\"}"
myFunctions+="{exp, expTerm3, hold=\"1\"}"
FuncFit {string = myFunctions} expSumData/D
```

These commands build the list of functions one function specification at a time. The second and third lines use the += assignment operator to add additional functions to the list. Each function specification includes its pair of braces.

Notice the treatment of the hold strings — in order to include quotation marks in a quoted string expression, you must escape the quotation marks. Otherwise the command line parser thinks that the first quote around the hold string is the closing quote.

The function list string is parsed at run-time outside the context in which FuncFit is running. Consequently, you cannot reference local variables in a user-defined function. The hold string may be either a quoted literal string, as shown here, or it can be a reference to a global variable, including the full data folder path:

```
String/G root:myDataFolder:holdStr="1"
String myFunctions="{exp, expTerm1}"
myFunctions+="{exp, expTerm2, hold=root:myDataFolder:holdStr}"
myFunctions+="{exp, expTerm3, hold=root:myDataFolder:holdStr}"
FuncFit {string = myFunctions} expSumData/D
```

Fitting with Complex-Valued Functions

Prior to Igor Pro 9.00, to fit complex-valued functions to complex-valued data required writing a real-valued fit function that used a special organization of the data to pack real and imaginary parts into a single real-valued wave. Now Igor supports fitting to complex-valued fitting functions directly.

The basic requirement for fitting complex-valued functions is to write a fit function that returns a complex result. Igor supports the traditional format for a user-defined fit function (see **Format of a Basic Fitting Function** on page III-251) and all-at-once format (**All-At-Once Fitting Functions** on page III-256), but the return type of a basic fit function or the Y wave in an all-at-once fit function must be complex. Complex fitting functions are not supported by structure fit functions or by the sum-of-fit-functions format.

No Dialog Support for Complex Fitting

The Curve Fitting dialog does not allow you to select complex waves, or fit functions that return complex values. It may be possible to use a real-valued function and waves to set up a fit in the dialog, then click the To Cmd Line button to copy the generated command to the command line where you can edit the command. It's probably easier to read the reference documentation for the **FitFunc** operation and simply compose a command.

Complex Basic Fitting Function

The basic format for a complex-valued function looks like this:

```
Function/C F(Wave w, Variable xx) : FitFunc
   <body of function>
   <return statement>
End
```

The /C in "Function/C" tells Igor that the function returns a complex value. As shown above, the function takes a real-valued coefficient wave and a real-valued independent variable. If your particular function needs the coefficient wave and/or independent variable to be complex-valued, add /C to the parameter declaration:

```
Function/C F(Wave/C w, Variable/C xx) : FitFunc
   <body of function>
   <return statement>
End
```

We show here both the coefficient wave and the independent variable being complex; either one or both can be complex.

If you specify a complex independent variable, then you must supply a complex-valued X wave. Since Igor's wave scaling cannot be complex, if your fitting function requires a complex independent variable then you must have a separate X wave as input to the **FitFunc** operation.

Complex Basic Multivariate Fitting Function

As with normal real-valued fitting functions, you can write multivariate fitting functions that return complex values:

```
Function/C F(Wave w, Variable x1, Variable x2) : FitFunc
   <body of function>
   <return statement>
End
```

As before, the coefficient wave can be either real or complex, and the independent variables can be real or complex. The independent variables must be either all real-valued or all complex-valued.

Complex All-At-Once Fitting Function

In certain cases, a fit function may need to produce all model values at one time. You can write an all-at-once fitting functions that implement complex-valued functions:

```
Function AAOFitFunc(Wave pw, Wave/C yw, Wave xw) : FitFunc
   yw = <expression involving pw and xw>
End
```

Unlike the basic format, the function does not return a complex value and is not declared with Function/C. Instead, the all-at-once fit function returns the complex model values to Igor via the yw wave which you must declare as complex using /C.

As with the basic format, you can make the coefficient wave pw complex or real, and you can make the independent variable wave xw complex or real, as long as the type matches the waves you pass to the FuncFit operation.

All-at-once fitting functions can be multivariate functions, too, by adding more x input waves. As with the basic format, independent variable inputs must be all either real or complex.

Other Waves

A variety of other waves may be used during a fit: weighting, masking, epsilon, and residuals waves, and a destination wave to receive the model values of the fit solution. All of these waves must be complex or real depending on the nature of the fitting function.

Weighting applied to the dependent variable values must always be complex because a complex fitting function by definition returns complex dependent variable values. Residual and destination waves must be complex for the same reason.

If you use an epsilon wave, it must match your coefficient wave.

Mask waves must be real; they select data points, and cannot select just the real or imaginary part of your input data.

If you are fitting with errors in both dependent and independent variables, the X weighting waves must match the type of your independent variable inputs.

Curve Fitting with Multiple Processors

If you are using a computer with multiple processors, you no doubt want to take advantage of them. Curve fitting can take advantage of multiple processors in two ways:

- Automatic multithreading
- Programmed multithreading

Curve Fitting with Automatic Multithreading

If you use the built-in fit functions or thread-safe user-defined fit functions in the basic or all-at-once formats, Igor automatically uses multiple processors if your data set is “large enough”. The number of points required to be large enough is set by the **MultiThreadingControl** operation.

There are two keywords used by MultiThreadingControl for curve fitting. The `CurveFit1` keyword controls automatic multithreading with built-in and basic format user-defined fit functions. The `CurveFitAllAtOnce` keyword controls automatic multithreading with user-defined fit functions in the all-at-once format. The appropriate setting of these limits depends on the complexity of the fitting function and the nature of your problem. It can be best determined only by experimentation.

The automatic multithreading added in Igor7 makes the CurveFit /NTHR flag obsolete. The automatic multithreading is more effective than the threading available in Igor6.

Automatic multithreading when doing ODR fits (see **Errors in Variables: Orthogonal Distance Regression** on page III-236) is most effective with fit functions having large numbers of fit coefficients and with user-defined fit functions that are expensive to compute. Surprisingly, it may be more effective with fewer input data points.

If you use the ThreadSafe keyword with your user-defined fit function and Igor's automatic multithreading is enabled for your fit, your function must not access waves or global variables. Therefore your function must not use WAVE, NVAR, or SVAR declarations.

Curve Fitting with Programmed Multithreading

The CurveFit, FuncFit, and FuncFitMD operations are threadsafe. Consequently another way to use multiple processors is to do more than one curve fit simultaneously, with each fit using a different processor. This requires threadsafe programming, as described under **ThreadSafe Functions and Multitasking** on page IV-329, and requires at least intermediate-level Igor programming skills.

The fitting function can be either a built-in fit function or a threadsafe user-defined fit function.

For an example, choose File→Example Experiments→Curve Fitting→MultipleFitsInThreads.

Constraints and ThreadSafe Functions

The usual way to specify constraints to a curve fit is via expressions in a text wave (see **Fitting with Constraints** on page III-227). As part of the process of parsing these expressions and getting ready to use them in a curve fit involves evaluating part of the expressions. That, in turn, requires sending them to Igor's command-line interpreter, in a process very similar to the way the **Execute** operation works. Unfortunately, this is not threadsafe.

Instead, you must use the method described in **Constraint Matrix and Vector** on page III-230. Unfortunately, it is hard to understand, inconvenient to set up, and easy to make mistakes. The best way to do it is to set up your constraint expressions using the normal text wave method (see **Constraint Expressions** on page III-228) and use the /C flag with a trial fit. Igor will generate the matrix and vector required.

In most cases, the basic expressions will not change from one fit to another, just the limits of the constraints will change. If that is the case, you can use the matrix provided by Igor, and alter the numbers in the vector to change the constraint limits.

User-Defined Fitting Functions

When you use the New Fit Function dialog to create a user-defined function, the dialog uses the information you enter to create code for your function in the Procedure window. Using the New Fit Function dialog is the easiest way to create a user-defined fitting function, but it is possible also to write the function directly in the Procedure window.

Certain kinds of complexities will *require* that you write the function yourself. It may be that the easiest way to create such a function is to create a skeleton of the function using the dialog, and then modify it by editing in the procedure window.

This section describes the format of user-defined fitting functions so that you can understand the output of the New Fit Function dialog, and so that you can write one yourself.

You can use a variety of formats for user-defined fit functions tailored to different situations, and involving varying degrees of complexity to write and use. The following section describes the simplest format, which is also the format created by the New Fit Function dialog.

User-Defined Fitting Function Formats

You can use three formats for user-defined fitting functions: the Basic format discussed above, the All-At-Once format, and Structure Fit Functions, which use a structure as the only input parameter. Additionally, Structure Fit Functions come in basic and all-at-once variants. Each of these formats address particular situations.

The basic format (see **Format of a Basic Fitting Function** on page III-251) was the original format. It returns just one model value at a time.

The all-at-once format (see **All-At-Once Fitting Functions** on page III-256) addresses problems in which the operations involved, such as convolution, integration, or FFT, naturally calculate all the model values at once. Because of reduced function-call overhead, it is somewhat faster than the basic format for large data sets.

The structure-based format (see **Structure Fit Functions** on page III-261) uses a structure as the only function parameter, allowing arbitrary information to be transmitted to the function during fitting. This makes it very flexible, but also makes it necessary that FuncFit be called from a user-defined function.

Basic Fit Function	All-At-Once Function	Structure Function
Can be selected, created, and edited within the Curve Fitting dialog.	Can be selected, but *not* created or edited, within the Curve Fitting dialog.	Cannot be used from the Curve Fitting dialog.
With appropriate comments, mnemonic coefficient names.	No mnemonic coefficient names.	Must be used with FuncFit called from a user-defined function.
Straight-forward programming: one X value, one return value.	Programming requires a good understanding of wave assignment; there are some issues that can be difficult to avoid.	Hardest to program: requires both an understanding of structures and writing a driver function that calls FuncFit.
Not an efficient way to write a fit function that uses convolution, integration, FFT, or any operation that uses all the data values in a single operation.	Most efficient for problems involving operations like convolution, integration, or FFT. Often much faster than the Basic format, even for problems that don't require it.	Very flexible: any arbitrary information can be transmitted to the fit function. More information about the fit progress transmitted via the structure.
See **Format of a Basic Fitting Function** on page III-251.	See **All-At-Once Fitting Functions** on page III-256.	See **Structure Fit Functions** on page III-261.

Format of a Basic Fitting Function

A basic user-defined fitting function has the following form:

```
Function F(w, x) : FitFunc
   WAVE w; Variable x

   <body of function>
   <return statement>
End
```

You can choose a more descriptive name for your function.

The function must have exactly two parameters in the univariate case shown above. The first parameter is the coefficients wave, conventionally called w. The second parameter is the independent variable, conventionally called x. If your function has this form, it will be recognized as a curve fitting function and will allow you to use it with the FuncFit operation.

The FitFunc keyword marks the function as being intended for curve fitting. Functions with the FitFunc keyword that have the correct format are included in the Function menu in the Curve Fitting dialog.

The FitFunc keyword is not required. The FuncFit operation will allow any function that has a wave and a variable as the parameters. In the Curve Fitting dialog you can choose Show Old-Style Functions from the Function menu to display a function that lacks the FitFunc keyword, but you may also see functions that just happen to match the correct format but aren't fitting functions.

Note that the function does not know anything about curve fitting. All it knows is how to compute a return value from its input parameters. The function is called during a curve fit when it needs the value for a certain X and a certain set of fit coefficients.

Here is an example of a user-defined function to fit a log function. This might be useful since log is not one of the functions provided as a built-in fit function.

```
Function LogFit(w,x) : FitFunc
   WAVE w
   Variable x

   return w[0]+w[1]*log(x)
End
```

In this example, two fit coefficients are used. Note that the first is in the zero element of the coefficient wave. You cannot leave out an index of the coefficient wave. Igor uses the size of your coefficient wave to determine how many coefficients need to be fit. Consequently an unused element of the wave results in a singular matrix error.

Intermediate Results for Very Long Expressions

The body of the function is usually fairly simple but can be arbitrarily complex. If necessary, you can use local variables to build up the result, piece-by-piece. You can also call other functions or operations and use loops and conditionals.

If your function has many terms, you might find it convenient to use a local variable to store intermediate results rather than trying to put the entire function on one line. For example, instead of:

```
return w[0] + w[1]*x + w[2]*x^2
```

you could write:

```
Variable val         // local variable to accumulate result value
val = w[0]
val += w[1]*x
val += w[2]*x^2
return val
```

We often get fitting functions from our customers that use extremely long expressions derived by Mathematica. These expressions are hard to read and understand, and highly resistant to debugging and modification. It is well worth some effort to break them down using assignments to intermediate results.

Conditionals

Flow control statements including `if` statements are allowed in fit functions. You could use this to fit a piece-wise function, or to control the return value in the case of a singularity in the function.

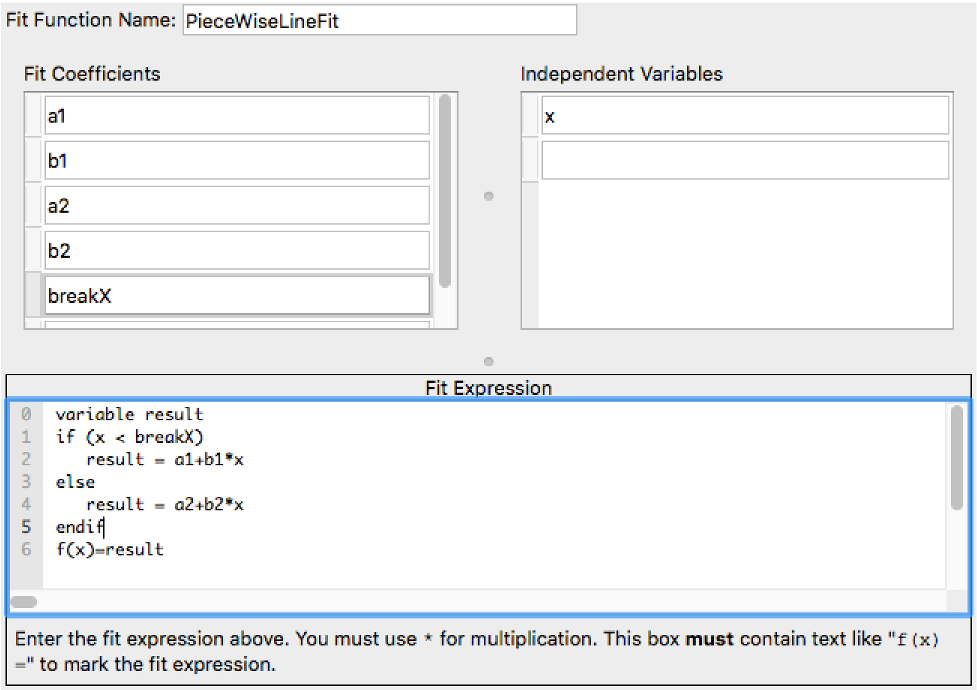
Here is an example of a function that fits two lines to different sections of the data. It uses one of the parameters to decide where to switch from one line to the other:

```
Function PieceWiseLineFit(w,x) : FitFunc
   WAVE w
   Variable x

   Variable result
   if (x < w[4])
      result = w[0]+w[1]*x
   else
      result = w[2]+w[3]*x
```

```
    endif
    return result
End
```

This function can be entered into the New Fit Function dialog. Here is what the dialog looked like when we created the function above:



Fit Function Name: PieceWiseLineFit

Fit Coefficients

- a1
- b1
- a2
- b2
- breakX

Independent Variables

- x

Fit Expression

```
variable result
if (x < breakX)
    result = a1+b1*x
else
    result = a2+b2*x
endif
f(x)=result
```

Enter the fit expression above. You must use * for multiplication. This box **must** contain text like "f(x)=" to mark the fit expression.

The New Fit Function Dialog Adds Special Comments

In the example above of a piece-wise linear fit function, the New Fit Function dialog uses coefficient names instead of indexing a coefficient wave, but there isn't any way to name coefficients in a fit function. The New Fit Function dialog adds special comments to a fit function that contain extra information. For instance, the PieceWiseLineFit function as created by the dialog looks like this:

```
Function PieceWiseLineFit(w,x) : FitFunc
    WAVE w
    Variable x

    //CurveFitDialog/ These comments were created by the Curve Fitting dialog. Alteri
    //CurveFitDialog/ make the function less convenient to work with in the Curve Fit
    //CurveFitDialog/ Equation:
    //CurveFitDialog/ variable result
    //CurveFitDialog/ if (x < breakX)
    //CurveFitDialog/  result = a1+b1*x
    //CurveFitDialog/ else
    //CurveFitDialog/  result = a2+b2*x
    //CurveFitDialog/ endif
    //CurveFitDialog/ f(x) = result
    //CurveFitDialog/ End of Equation
    //CurveFitDialog/ Independent Variables 1
    //CurveFitDialog/ x
    //CurveFitDialog/ Coefficients 5
    //CurveFitDialog/ w[0] = a1
    //CurveFitDialog/ w[1] = b1
    //CurveFitDialog/ w[2] = a2
    //CurveFitDialog/ w[3] = b2
    //CurveFitDialog/ w[4] = breakX
```

Special comments give the Curve Fitting dialog extra information about the fit function.

The function code as it appears in the text window of the New Fit Function dialog.

Independent variable name (or names, for a multivariate function).

Coefficient names.

This prefix in the comment identifies the comment as belonging to the curve fitting dialog.

```
   variable result
   if (x < w[4])
    result = w[0]+w[1]*x
   else
    result = w[2]+w[3]*x
   endif
   return result
End
```

The actual function code.

If you click the Edit Fit Function button, the function code is analyzed to determine the number of coefficients. If the comments that name the coefficients are present, the dialog uses those names. If they are not present, the coefficient wave name is used with the index number appended to it as the coefficient name.

Having mnemonic names for the fit coefficients is very helpful when you look at the curve fit report in the history area. The minimum set of comments required to have names appear in the dialog and in the history is a lead-in comment line, plus the Coefficients comment lines. For instance, the following version of the function above will allow the Curve Fitting dialog and history report to use coefficient names:

```
Function PieceWiseLineFit(w,x) : FitFunc
   WAVE w
   Variable x

   //CurveFitDialog/
   //CurveFitDialog/ Coefficients 5
   //CurveFitDialog/ w[0] = a1
   //CurveFitDialog/ w[1] = b1
   //CurveFitDialog/ w[2] = a2
   //CurveFitDialog/ w[3] = b2
   //CurveFitDialog/ w[4] = breakX

   Variable result
   if (x < w[4])
    result = w[0]+w[1]*x
   else
    result = w[2]+w[3]*x
   endif
   return result
End
```

The blank comment before the line with the number of coefficients on it is required- the parser that looks at these comments needs one lead-in line to throw away. That line can contain anything as long as it includes the lead-in "`//CurveFitDialog/`".

Functions that the Fit Function Dialog Doesn't Handle Well

In the example functions it is quite clear by looking at the function code how many fit coefficients a function requires, because the coefficient wave is indexed with a literal number. The number of coefficients is simply one more than the largest index used in the function.

Occasionally a fit function uses constructions other than a literal number for indexing the coefficient wave. This will make it impossible for the Curve Fitting dialog to figure out how many coefficients are required. In this case, the Coefficients tab can't be constructed until you specify how many coefficients are needed. You do this by choosing a coefficient wave having the right number of points from the Coefficient Wave menu.

You cannot edit such a function by clicking the Edit Fit Function button. You must write and edit the function in the Procedure window.

Here is an example function that can fit an arbitrary number of Gaussian peaks. It uses the length of the coefficient wave to determine how many peaks are to be fit. Consequently, it uses a variable (`cfi`) rather than a literal number to access the coefficients:

```
Function FitManyGaussian(w, x) : FitFunc
   WAVE w
   Variable x

   Variable returnValue = w[0]
```

The first coefficient is a baseline offset.

```
   Variable i
   Variable numPeaks = floor((numpnts(w)-1)/3)
   Variable cfi

   for (i = 0; i < numPeaks; i += 1)
      cfi = 3*i+1
      returnValue += w[cfi]*exp(-((x-w[cfi+1])/w[cfi+2])^2)
   endfor
   return returnValue
End
```

Each peak takes three coefficients: amplitude, x position and width.

Calculate index of amplitude for this peak.

Expression of a single Gaussian peak.

Loop over the peaks, calculating them one at a time.

Each peak is added to the result.

Format of a Multivariate Fitting Function

A multivariate fitting function has the same form as a univariate function, but has more than one independent variable:

```
Function F(w, x1, x2, ...) : FitFunc
   WAVE w;
   Variable x1
   Variable x2
   Variable ...

   <body of function>
   <return statement>
End
```

A function to fit a planar trend to a data set could look like this:

```
Function Plane(w, x1, x2) : FitFunc
   WAVE w
   Variable x1, x2

   return w[0] + w[1]*x1 + w[2]*x2
End
```

There is no limit on the number of independent variables, with the exception that the entire Function declaration line must fit within a single command line of 2500 bytes.

The New Fit Function dialog will add the same comments to a multivariate fit function as it does to a basic fit function. The `Plane()` function above might look like this (we have truncated the first two special comment lines to make them fit):

```
Function Plane(w,x1,x2) : FitFunc
   WAVE w
   Variable x1
   Variable x2

   //CurveFitDialog/ These comments were created by the Curve...
   //CurveFitDialog/ make the function less convenient to work...
   //CurveFitDialog/ Equation:
   //CurveFitDialog/ f(x1,x2) = A + B*x1 + C*x2
   //CurveFitDialog/ End of Equation
   //CurveFitDialog/ Independent Variables 2
   //CurveFitDialog/ x1
   //CurveFitDialog/ x2
   //CurveFitDialog/ Coefficients 3
   //CurveFitDialog/ w[0] = A
   //CurveFitDialog/ w[1] = B
   //CurveFitDialog/ w[2] = C

   return w[0] + w[1]*x1 + w[2]*x2
End
```

All-At-Once Fitting Functions

The scheme of calculating one Y value at a time doesn't work well for some fitting functions. This is true of functions that involve a convolution such as might arise if you are trying to fit a theoretical signal convolved with an instrument response. Fitting to a solution to a differential equation might be another example.

For this case, you can create an "all at once" fit function. Such a function provides you with an X and Y wave. The X wave is input to the function; it contains all the X values for which your function must calculate Y values. The Y wave is for output — you put all your Y values into the Y wave.

Because an all-at-once function is called only once for a given set of fit coefficients, it will be called many fewer times than a basic fit function. Because of the saving in function-call overhead, all-at-once functions can be faster even for problems that don't require an all-at-once function.

Here is the format of an all-at-once fit function:

```
Function myFitFunc(pw, yw, xw) : FitFunc
   WAVE pw, yw, xw

   yw = <expression involving pw and xw>
End
```

Note that there is no return statement because the function result is put into the wave yw. Even if you include a return statement the return value is ignored during a curve fit.

The X wave contains all the X values for your fit, whether you provided an X wave to the curve fit or not. If you did not provide an X wave, xw simply contains equally-spaced values derived from your Y wave's X scaling.

There are some restrictions on all-at-once fitting functions:

1) You can't create or edit an all-at-once function using the Curve Fitting dialog. You must create it by editing in the Procedure window. All-at-once functions are, however, listed in the Function menu in the Curve Fitting dialog.
2) There is no such thing as an "old-style" all-at-once function. It must have the FitFunc keyword.
3) You don't get mnemonic coefficient names.

Here is an example that fits an exponential decay using an all-at-once function. This example is silly — there is no reason to make this an all-at-once function. It is simply an example showing how a real function works without the computational complexities. Here it is, as an all-at-once function:

```
Function allatonce(pw, yw, xw) : FitFunc
   WAVE pw, yw, xw

   // a wave assignment does the work
   yw = pw[0] + pw[1]*exp(-xw/pw[2])
End
```

This is the same function written as a standard user fitting function:

```
Function notallatonce(pw, x) : FitFunc
   WAVE pw
   Variable x

   return pw[0] + pw[1]*exp(-x/pw[2])
End
```

In the all-at-once function, the argument of exp() includes xw, a wave. The basic format uses the input parameter x, which is a variable containing a single value. The use of xw in the all-at-once version of the function uses the implied point number feature of wave assignments (see **Waveform Arithmetic and Assignments** on page II-74).

There are some things to watch out for when creating an all-at-once fitting function:

1. You must not change the yw wave except for assigning values to it. You must not resize it. This will get you into trouble:

```
   Function allatonce(pw, yw, xw) : FitFunc
      WAVE pw, yw, xw

      Redimension/N=2000 yw                  // BAD!
      yw = pw[0] + pw[1]*exp(-xw/pw[2])
   End
```

2. You may not get the same number of points in yw and xw as you have in the waves you provide as the input data. If you fit to a restricted range, if there are NaNs in the input data, or if you use a mask wave to select a subset of the input data, you will get a wave with a reduced number of points. Your fitting function must be written to handle that situation or you must not use those features.
3. It is tricky, but not impossible, to write an all-at-once fitting function that works correctly with the auto-destination feature (that is, _auto_ in the Destination menu, or /D by itself in a FuncFit command).
4. The xw and yw waves are *not* your data waves. They are created by Igor during the execution of CurveFit, FuncFit or FuncFitMD and filled with data from your input waves. They will be destroyed when fitting is finished. For debugging, you can use Duplicate to save a copy of the waves. Altering the contents of the xw wave will have no effect.

The example above uses xw as an argument to the exp function, and it uses the special features of a wave assignment statement to satisfy point 2.

The next example fits a convolution of a Gaussian peak with an exponential decay. It fits a baseline offset, amplitude and width of the Gaussian peak and the decay constant for the exponential. This might model an instrument with an exponentially decaying impulse response to recover the width of an impulsive signal.

```
Function convfunc(pw, yw, xw) : FitFunc
   WAVE pw, yw, xw

   // pw[0] = gaussian baseline offset
   // pw[1] = gaussian amplitude
   // pw[2] = gaussian position
   // pw[3] = gaussian width
   // pw[4] = exponential decay constant of instrument response

   // Make a wave to contain an exponential with decay
   // constant pw[4]. The wave needs enough points to allow
   // any reasonable decay constant to get really close to zero.
   // The scaling is made symmetric about zero to avoid an X
   // offset from Convolve/A
   Variable dT = deltax(yw)
   Make/D/O/N=201 expwave           // Long enough to allow decay to zero
   SetScale/P x -dT*100,dT,expwave

   // Fill expwave with exponential decay
   expwave = (x>=0)*pw[4]*dT*exp(-pw[4]*x)

   // Normalize exponential so that convolution doesn't change
   // the amplitude of the result
   Variable sumexp
   sumexp = sum(expwave)
   expwave /= sumexp

   // Put a Gaussian peak into the output wave
   yw = pw[1]*exp(-((x-pw[2])/pw[3])^2)

   // Convolve with the exponential. NOTE /A.
   Convolve/A expwave, yw

   // Add the vertical offset AFTER the convolution to avoid end effects
   yw += pw[0]
End
```

Some things to be aware of with regard to this function:

1. A wave is created inside the function to store the exponential decay. Making a wave can be a time-consuming operation; it is less convenient for the user of the function, but can save computation time if you make a suitable wave ahead of time and then simply reference it inside the function.
2. The wave containing the exponential decay is passed to the convolve operation. The use of the /A flag prevents the convolve operation from changing the length of the output wave yw. You may wish to read the section on **Convolution** on page III-284.
3. The output wave yw is used as a parameter to the convolve operation. Because the convolve operation assumes that the data are evenly-space, this use of yw means that the function *does not satisfy* points 2) or 3) above. If you use input data to the fit that has missing points or unevenly-spaced X values, this function *will fail*.

You may also find the section **Waveform Arithmetic and Assignments** on page II-74 helpful.

Here is a much more complicated version of the fitting function that solves these problems, and also is more robust in terms of accuracy. The comments in the code explain how the function works.

Note that this function makes at least two different waves using the Make operation, and that we have used Make/D to make the waves double-precision. This can be crucial. To improve performance and reduce clutter in your Igor experiment file, we create the intermediate waves as free waves

```
Function convfunc(pw, yw, xw) : FitFunc
   WAVE pw, yw, xw

   // pw[0] = gaussian baseline offset
   // pw[1] = gaussian amplitude
   // pw[2] = gaussian position
   // pw[3] = gaussian width
   // pw[4] = exponential decay constant of instrument response

   // Make a wave to contain an exponential with decay
   // constant pw[4]. The wave needs enough points to allow
   // any reasonable decay constant to get really close to zero.
   // The scaling is made symmetric about zero to avoid an X
   // offset from Convolve/A.

   // resolutionFactor sets the degree to which the exponential
   // will be over-sampled with regard to the problem's parameters.
   // Increasing this number increases the number of time
   // constants included in the calculation. It also decreases
   // the point spacing relative to the problem's time constants.
   // Increasing will also increase the time required to compute

   Variable resolutionFactor = 10
   // dt contains information on important time constants.
   // We wish to set the point spacing for model calculations
   // much smaller than the exponential time constant or gaussian width.
   // Use absolute values to prevent failures if an iteration strays
   // into unmeaningful but mathematically allowed negative territory.

   Variable absDecayConstant = abs(pw[4])
   Variable absGaussWidth = abs(pw[3])
   Variable dT = min(absDecayConstant/resolutionFactor, absGaussWidth/resolutionFactor)

   // Calculate suitable number points for the exponential. Length
   // of exponential wave is 10 time constants; doubled so
   // exponential can start in the middle; +1 to make it odd so
   // exponential starts at t=0, and t=0 is exactly the middle
```

```
    // point. That is better for the convolution.

    Variable nExpWavePnts = round((10*absDecayConstant)/dT)*2 + 1

    // Important: Make double-precision waves.
    // We make free waves to improve performance and so that
    // the intermediate waves clean themselves up at the end of
    // function execution.

    Make/D/FREE/O/N=(nExpWavePnts) expwave// Double-precision free wave

    // In this version of the function, we make a y output wave
    // ourselves, so that we can control the resolution and
    // accuracy of the calculation. It also will allow us to use
    // a wave assignment later to solve the problem of variable
    // X spacing or missing points.

    Variable nYPnts = max(resolutionFactor*numpnts(yw), nExpWavePnts)
    Make/D/FREE/O/N=(nYPnts) yWave         // Double-precision free wave

    // This wave scaling is set such that the exponential will
    // start at the middle of the wave
    SetScale/P x -dT*(nExpWavePnts/2),dT,expwave

    // Set the wave scaling of the intermediate output wave to have
    // the resolution calculated above, and to start at the first
    // X value.
    SetScale/P x xw[0],dT, yWave

    // Fill expwave with exponential decay, starting with X=0
    expwave = (x>=0)*dT/pw[4]*exp(-x/pw[4])

    // Normalize exponential so that convolution doesn't change
    // the amplitude of the result
    Variable sumexp
    sumexp = sum(expwave)
    expwave /= sumexp

    // Put a Gaussian peak into the intermediate output wave. We use
    // our own wave (yWave) because the convolution requires a wave
    // with even spacing in X, whereas we may get X values input that
    // are not evenly spaced.
    // Also, we do not add the vertical offset here - it will cause problems
    // with the convolution. Before the convolution Igor zero-pads the
    // wave, so the baseline here must be zero. Otherwise there is
    // a step function at the start of the convolution.
    yWave = pw[1]*exp(-((x-pw[2])/pw[3])^2)

    // Now convolve with the exponential. NOTE /A.
    Convolve/A expwave, yWave

    // Move appropriate values corresponding to input X data into
    // the output Y wave. We use a wave assignment involving the
    // input X wave. This will extract the appropriate values from
    // the intermediate wave, interpolating values where the
    // intermediate wave doesn't have a value precisely at an X
    // value that is required by the input X wave. This wave
    // assignment also solves the problem with auto-destination:
    // The function can be called with an X wave that sets any X
    // spacing, so it doesn't matter what X values are required.
    // This is the appropriate place to add the vertical offset.
```

```
   yw = yWave(xw[p]) + pw[0]
End
```

Note that all the waves created in this function are double-precision. If you don't use the /D flag with the Make operation, Igor makes single-precision waves. Curve fitting computations can be very sensitive to floating-point roundoff errors. We have solved many user problems by simply making intermediate waves double precision.

None of the computations involve the wave yw. That was done so that the computations could be done at finer resolution than the resolution of the fitted data. By making a separate wave, it is not necessary to modify yw.

The actual return values are picked out of yWave and stored in yw using the special X-scale-based indexing available for one-dimensional waves in a wave assignment. This allows any arbitrary X values in the xw input wave, so long as the intermediate computations are done over the full X range included in xw.

Multivariate All-At-Once Fitting Functions

A multivariate all-at-once fitting function accepts more than one independent variable. To make one, simply add additional waves after the xw wave:

```
Function MultivariateAllAtOnce(pw, yw, xw1, xw2) : FitFunc
   WAVE pw, yw, xw1, xw2

   yw = <expression involving pw and all the xw waves>
End
```

This example accepts two independent variables, xw1 and xw2. If you have more, add additional X wave parameters.

All the X waves are 1D waves with the same number of points as the Y wave, yw, even if your input data is in the form of a matrix wave. If you use **FuncFitMD** to fit an N row by M column matrix, Igor unrolls the matrix to form a 1D Y wave containing NxM points. This is passed to your function as the Y wave parameter. The X wave parameters are 1D waves containing NxM points with values that repeat for each column.

If you know that the input data fall into a fully-formed matrix wave, you may be able to temporarily re-fold the yw wave into a matrix using the Redimension operation:

```
Function MultivariateAllAtOnce(pw, yw, xw1, xw2) : FitFunc
   WAVE pw, yw, xw1, xw2

   Redimension/N=(rows, columns) yw
   MatrixOP yw = <matrix math expression>
   Redimension/N=(rows*columns) yw

   yw = <expression involving pw and all the xw waves>
End
```

Use this technique with great caution, though. In order to know the appropriate rows and columns for the Redimension command, you must make assumptions about the size of the original data set. If there are missing values (NaNs) in the original input matrix, these values will be missing from the Y wave, resulting in fewer points than you would expect.

If you use this technique, you will not be able to use the auto-destination feature (the /D flag with no destination wave) because the auto-destination wave is pretty much guaranteed to be a different size than you expect.

Similarly to the second example all-at-once function above, you can create an intermediate matrix wave and then use wave assignment to get values from the matrix to assign to the yw wave. It may be tricky to figure out how to extract the correct values from your intermediate matrix.

Structure Fit Functions

Sometimes you may need to transmit extra information to a fitting function. This might include constants that need to be set to reflect conditions in a run, but should not be fit; or a wave containing a look-up table or a measured standard sample that is needed for comparison. Perhaps your fit function is very complex and needs some sort of book-keeping data.

If you use a basic fit function or an all-at-once function, such information must be transmitted via global variables and waves. That, in turn, requires that this global information be looked up inside the fit function. The global data requirement makes it difficult to be flexible: the fit function is tied to certain global variables and waves that must be present for the function to work. In addition to adding complexity and difficulty to management of global information, it adds a possible time-consuming operation: looking up the global information requires examining a list of waves or variables, and comparing the names to the desired name.

Structure fit functions are ideal for such problems because they take a single parameter that is a structure of your own design. The first few members of the structure must conform to certain requirements, but the rest is up to you. You can include any kind of data in the structure. An added bonus is that you can include members in the structure that identify for the fit function which fit coefficient is being perturbed when calculating numerical derivatives, that signal when the fit function is being called to fill in the auto-destination wave, and identify when a new fit iteration is starting. You can pass back a flag to have FuncFit abandon fitting.

To use a structure fit function, you must do three things:

1. Define a structure containing certain standard items at the top.
2. Write a fitting function that uses that structure as its only parameter.
3. Write a wrapper function for FuncFit that creates an instance of your structure, initializes it and invokes FuncFit with the /STRC parameter flag.

You should familiarize yourself with the use of structures before attempting to write a structure fit function (see **Structures in Functions** on page IV-99).

Structure fit functions come in basic and all-at-once variants; the difference is determined by the members at the beginning of the structure. The format for the structure for a basic structure fit function is:

```
Structure myBasicFitStruct
   Wave coefw
   Variable x
   …
EndStructure
```

The name of the structure can be anything you like that conforms to Igor’s naming rules; all that is required is that the first two fields be a wave and a variable. By convention we name the wave coefw and the variable x to match the use of those members. These members of the structure are equivalent to wave and variable parameters required of a basic fit function.

You may wish to use an all-at-once structure fit function for the same reason you might use a regular all-at-once fit function. The same concerns apply to all-at-once structure fit functions; you should read and understand **All-At-Once Fitting Functions** on page III-256 before attempting to write an all-at-once structure fit function.

The structure for an all-at-once structure fit function is:

```
Structure myAllAtOnceFitStruct
   Wave coefw
   Wave yw
   Wave xw
   …
EndStructure
```

The first three members of the structure are equivalent to the pw, yw, and xw parameters required in a regular all-at-once fit function.

A simple example of fitting with a structure fit function follows. More examples are available in the File menu: select appropriate examples from Examples→Curve Fitting.

Basic Structure Fit Function Example

As an example of a basic structure fit function, we will write a fit function that fits an exponential decay using an X offset to compensate for numerical problems that can occur when the X range of an exponential function is small compared to the X values. The X offset must not be a fit coefficient because it is not mathematically distinguishable from the decay amplitude. We will write a structure that carries this constant as a custom member of a structure. This function will duplicate the built-in exp_XOffset function (see **Built-in Curve Fitting Functions** on page III-206).

First, we create fake data by executing these commands:

```
Make/D/O/N=100 expData,expDataX
expDataX = enoise(0.5)+100.5
expData = 1.5+2*exp(-(expDataX-100)/0.2) + gnoise(.05)
Display expData vs expDataX
ModifyGraph mode=3,marker=8
```

Now the code. Copy this code and paste it into your Procedure window:

```
// The structure definition
Structure expFitStruct
   Wave coefw           // required coefficient wave
   Variable x           // required X value input
   Variable x0          // constant
EndStructure

// The fitting function
Function fitExpUsingStruct(s) : FitFunc
   Struct expFitStruct &s

   return s.coefw[0] + s.coefw[1]*exp(-(s.x-s.x0)/s.coefw[2])
End

// The driver function that calls FuncFit:
Function expStructFitDriver(pw, yw, xw, xOff)
   Wave pw     // coefficient wave- pre-load it with initial guess
   Wave yw
   Wave xw
   Variable xOff
   Variable doODR

   // An instance of the structure. We initialize the x0 constant only,
   // Igor (FuncFit) will initialize coefw and x as required.
   STRUCT expFitStruct fs
   fs.x0 = xOff   // set the value of the X offset in the structure

   FuncFit fitExpUsingStruct, pw, yw /X=xw /D /STRC=fs

   // no history report for structure fit functions. We print our own
   // simple report here:
   print pw
   Wave W_sigma
   print W_sigma
End
```

Finally, make a coefficient wave loaded with initial guesses and invoke our driver function:

```
Make/D/O expStructCoefs = {1.5, 2, .2}
expStructFitDriver(expStructCoefs, expData, expDataX, 100)
```

This is a very simple example, intended to show only the most basic aspects of fitting with a structure fit function. An advanced programmer could add a control panel user interface, plus code to automatically calculate initial guesses and provide a default value of the x0 constant.

The WMFitInfoStruct Structure

In addition to the required structure members, you can include a WMFitInfoStruct structure member immediately after the required members. The WMFitInfoStruct structure, if present, will be filled in by FuncFit with information about the progress of fitting, and includes a member allowing you to stop fitting if your fit function detects a problem.

Adding a WMFitInfoStruct member to the structure in the example above:

```
Structure expFitStruct
   Wave coefw                      // Required coefficient wave.
   Variable x                      // Required X value input.
   STRUCT WMFitInfoStruct fi       // Optional WMFitInfoStruct.
   Variable x0                     // Constant.
EndStructure
```

And the members of the WMFitInfoStruct:

WMFitInfoStruct Structure Members

Member	Description
char IterStarted	Nonzero on the first call of an iteration.
char DoingDestWave	Nonzero when called to evaluate the autodestination wave.
char StopNow	Fit function sets this to nonzero to indicate that a problem has occurred and fitting should stop.
Int32 IterNumber	Number of iterations completed.
Int32 ParamPerturbed	Index of the fit coefficient being perturbed for the calculation of numerical derivatives. Set to -1 when evaluating a solution point with no perturbed coefficients.

The IterStarted and ParamPerturbed members may be useful in some obscure cases to short-cut lengthy computations. The DoingDestWave member may be useful in an all-at-once structure fit function.

Multivariate Structure Fit Functions

To fit multivariate functions (those having more than one dimension or independent variable) you simply use an array for the X member of the structure. For instance, for a basic 2D structure fit function:

```
Structure My2DFitStruct
   Wave coefw
   Variable x[2]
   …
EndStructure
```

Or a 2D all-at-once structure fit function:

```
Structure My2DAllAtOnceFitStruct
   Wave coefw
   Wave yw
   Wave xw[2]
   …
EndStructure
```

Curve Fitting Using Commands

A few curve fitting features are not completely supported by the Curve Fitting dialog, such as constraints involving combinations of fit coefficients, or user-defined fit functions involving more complex constructions. Also, you might sometimes want to batch-fit to a number of data sets without interacting with the dialog for each data set. These circumstances will require that you use command lines to do fits.

The easiest way to do this is to use the Curve Fitting dialog to generate command lines that do almost what you want. If you simply want to add a more complex feature, such as a more complicated constraint expression, click the To Cmd Line button, then edit the commands generated by the dialog to add the features you want.

If you are writing a user procedure that does curve fitting, you can click the To Clip button to copy the commands generated by the dialog. Then paste the commands into the Procedure window. Edit them as needed by your application.

Curve fitting is done by three operations — **CurveFit**, **FuncFit**, and **FuncFitMD**. You will find details on these operations in Chapter V-1, **Igor Reference**.

Batch Fitting

If you are doing batch fitting, you probably want to call a curve fitting operation inside a loop. In that case, you probably don't want a history report for every fit- it could possible make a very large amount of text in the history. You probably don't want the progress window during the fits- it slows down the fit and will make a flashing window as it appears and disappears. Finally, you probably don't want graphs and tables updating during the fits, as this can slow down computation considerably.

Here is an example function that will do all of this, plus it checks for an error during the fit. If the use of the $ operator is unfamiliar you will want to consult **Accessing Waves in Functions** on page IV-82**.**

```
Function FitExpToListOfWaves(theList)
   String theList

   Variable i=0
   string aWaveName = ""
   Variable V_fitOptions = 4      // suppress progress window
   Variable V_FitError = 0        // prevent abort on error
   do
      aWaveName = StringFromList(i, theList)
      WAVE/Z aWave = $aWaveName
      if (!WaveExists(aWave))
         break
      endif

      // /N suppresses screen updates during fitting
      // /Q suppresses history output during fitting
      CurveFit/N/Q exp aWave /D/R
      WAVE W_coef

      // save the coefficients
      Duplicate/O W_coef $("cf_"+aWaveName)
      // save errors
      Duplicate/O W_sigma, $("sig_"+aWaveName)
      if (V_FitError != 0)
         // Mark the results as being bad
         WAVE w = $("cf_"+aWaveName)
         w = NaN
         WAVE w = $("sig_"+aWaveName)
         w = NaN
         WAVE w = $("fit_"+aWaveName)
         w = NaN
         WAVE w = $("Res_"+aWaveName)
         w = NaN
         V_FitError = 0
      endif
      i += 1
   while(1)
End
```

This function is very limited. It simply does fits to a number of waves in a list. Igor includes a package that adds a great deal of sophistication to batch fitting, and provides a user interface. For a demonstration, choose File→Example Experiments→Curve Fitting→Batch Curve Fitting Demo.

Curve Fitting Examples

The Igor Pro Folder includes a number of example experiments that demonstrate the capabilities of curve fitting. These examples cover fitting with constraints, multivariate fitting, multipeak fitting, global fitting, fitting a line between cursors, and fitting to a user-defined function. All of these experiments can be found in Igor Pro Folder/Examples/Curve Fitting.

Singularities in Curve Fitting

You may occasionally run across a situation where you see a “singular matrix” error. This means that the system of equations being solved to perform the fit has no unique solution. This generally happens when the fitted curve contains degeneracies, such as if all Y values are equal.

In a fit to a user-defined function, a singular matrix results if one or more of the coefficients has no effect on the function’s return value. Your coefficients wave must have the exact same number of points as the number of coefficients that you actually use in your function or else you must hold constant unused coefficients.

Certain functions may have combinations of coefficients that result in one or more of the coefficients having no effect on the fit. Consider the Gaussian function:

$$K_0 + K_1 \exp((x - K_2)/K_3)^2$$

If K_1 is set to zero, then the following exponential has no effect on the function value. The fit will report which coefficients have no effect. In this example, it will report that K_2 and K_3 have no effect on the fit. However, as this example shows, it is often not the reported coefficients that are at fault.

Special Considerations for Polynomial Fits

Polynomial fits use the singular value decomposition technique. If you encounter singular values and some of the coefficients of the fit have been zeroed, you are probably asking for more terms than can be supported by your data. You should use the smallest number of terms that gives a “reasonable” fit. If your data does not support higher-order terms then you can actually get a poorer fit by including them.

If you really think your data should fit with the number of terms you specified, you can try adjusting the singular value threshold. You do this by creating a special variable called V_tol and setting it to a value smaller than the default value of 1e-10. You might try 1e-15.

Another way to run into trouble during polynomial fitting is to use a range of X values that are very much offset from zero. The solution is to temporarily offset your X values, do the fit and then restore the original X values. This is done for you by the poly_XOffset fit function; see **Built-in Curve Fitting Functions** on page III-206 for details.

Errors Due to X Values with Large Offsets

The single and double exponential fits can be thrown off if you try to fit to a range of X values that are very much offset from zero. In general, any function, which, when extrapolated to zero, returns huge or infinite values, can create problems. The solution is to temporarily offset your x values, perform the fit and then restore the original x values. You may need to perform a bit of algebra to fix up the coefficients.

As an example consider a fit to an exponential where the x values range from 100 to 101. We temporarily offset the x values by 100, perform the fit and then restore the x values by adding 100. When we did the fit, rather than fitting to k0+k1*exp(-k2*x) we really did the fit to c0+c1*exp(-c2*(x-100)). A little rearrangement and we have c0+c1*exp(-c2*x)*exp(c2*100). Comparing these expressions, we see that k0= c0, k1= c1*exp(c2*100) and k2= c2.

A better solution to the problem of fitting exponentials with large X offsets is to use the built-in exp_XOffset and dblexp_XOffset fit functions. These fit functions automatically incorporate the X shifting; see **Built-in Curve Fitting Functions** on page III-206 for details.

The same problem can occur when fitting to high-degree polynomials. In this case, the algebra required to transform the solution coefficients back to unoffset X values is nontrivial. It would be better to simply redefine your problem in terms of offset X value.

Curve Fitting Troubleshooting

If you are getting unsatisfactory results from curve fitting you should try the following before giving up.

Make sure your data is valid. It should not be all one value. It should bear some resemblance to the function that you're trying to fit it to.

If the fit is iterative try different initial guesses. Some fit functions require initial guesses that are very close to the correct solution.

If you are fitting to a user-defined function, check the following:

- Your coefficients wave must have exactly the same number of points as the number of coefficients that you actually use in your function unless you hold constant the unused coefficients.
- Your initial guesses should not be zero unless the expected range is near 1.0 or you have specified an epsilon wave. See **The Epsilon Wave** on page III-267 for details.
- Ensure that your function is working properly. Try plotting it over a representative domain.
- Examine your function to ensure all your coefficients are distinguishable. For example in the fragment (k0+k1)*x, k0 and k1 are indistinguishable. If this situation is detected, the history will contain the message: "Warning: These parameters may be linearly dependent:" followed by a line listing the two parameters that were detected as being indistinguishable.
- Because the derivatives for a user-defined fit function are calculated numerically, if the function depends only weakly on a coefficient, the derivatives may appear to be zero. The solution is to create an epsilon wave and set its values large enough to give a nonzero difference in the function output. See **The Epsilon Wave** on page III-267 for details.
- A variation the previous problem is a function that changes in a step-wise fashion, or is "noisy" because an approximation is used that is good to only a limited precision. Again, create an epsilon wave and set the values large enough to give nonzero differences that are of consistent sign.
- Verify that each of your coefficients has an effect on the function. In some cases, a coefficient may have an effect over a limited range of X values. If your data do not sample that range adequately the fit may not work well, or may give a singular matrix error.
- Make sure that the optimal value of your coefficients is not infinity (it takes a long time to increment to infinity).
- Check to see if your function could possibly return NaN or INF for any value of the coefficients. You might be able to add constraints to prevent this from happening. You will see warnings if a singular matrix error resulted from NaN or INF values returned by the fitting function.
- Use a double-precision coefficient wave. Curve fitting is numerically demanding and usually works best if all computations are done using double precision numbers. Using a single-precision coefficient wave often causes failures due to numeric truncation. Because the **Make** operation defaults to single precision, you must use the /D flag when creating your coefficient wave.
- If you use intermediate waves in your user-defined fit function, make sure they are all double precision. Because the **Make** operation defaults to single precision, you must use the /D flag when creating your coefficient wave.

The Epsilon Wave

Curve fitting uses partial derivatives of your fit function with respect to the fit coefficients in order to find the gradient of the chi-square surface. It then solves a linearized estimate of the chi-square surface to find the next estimate of the solution (the minimum in the chi-square surface).

Since Igor doesn't know the mathematical equation for your fit function, it must approximate derivatives numerically using finite differences. That is, a model value is calculated at the present estimate of the fit coefficients, then each coefficient is perturbed by a small amount, and the derivative is calculated from the difference. This small perturbation, which is different for each coefficient, is called "epsilon".

You can specify the epsilon value for each coefficient by providing an epsilon wave to the **CurveFit** or **FuncFit** operations using the /E flag. If you do not provide an epsilon wave, Igor determines epsilon for each coefficient using these rules:

If your coefficient wave is single precision (which is not recommended),

```
if coef[i] == 0
   eps[i] = 1e-4
else
   eps[i] = 1e-4*coef[i]
```

If your coefficient wave is double precision,

```
if coef[i] == 0
   eps[i] = 1e-10
else
   eps[i] = 1e-10*coef[i]
```

In the Curve Fitting dialog, when you are using a user-defined fitting function, you can select an epsilon wave from the Epsilon Wave menu. When you select _New Wave_, or if you select an existing wave from the menu, Igor adds a column to the Coefficients list where you can edit the epsilon values.

There are a couple of reasons for explicitly setting epsilon. One is if your fit function is insensitive to a coefficient. That is, perturbing the coefficient makes a very small change in the model value. Sometimes the dependence of the model is so small that floating-point truncation results in no change in the model value. You have to set epsilon to a sufficiently large value that the model actually changes when the perturbation is applied.

You also need to set epsilon is when the model is discrete or noisy. This can happen if the model involves a table look-up or a series solution of some sort. In the case of table look-up, epsilon needs to be large enough to make sure that you get two distinct values out of the table.

In the case of a series solution, you have to stop summing terms in the series at some point. If the truncation of the series results in less than full floating-point resolution of the series, you need to make sure epsilon is large enough that the change in the model is larger than the resolution of the series. A series might include something like a numerical solution of an ODE, using the **IntegrateODE** operation. It could also involve **FindRoots** or **Optimize**, each of which gives you an approximate result. Since these operations run faster if you don't demand high precision, there may be a strong incentive to decrease the accuracy of the computation, and that may in turn lead to a need for an epsilon wave.

Curve Fitting References

An explanation of the Levenberg-Marquardt nonlinear least squares optimization can be found in Chapter 14.4 of:

Chapter

III-9

Signal Processing

Overview

Analysis tasks in Igor range from simple experiments using no programming to extensive systems tailored for specific fields. Chapter I-2, **Guided Tour of Igor Pro**, shows examples of the former. WaveMetrics' "Peak Measurement" technical note is an example of the latter.

The Signal Processing chapter covers basic analysis operations with emphasis on signal transformations.

Fourier Transforms

Igor uses the Fast Fourier Transform (FFT) algorithm to compute a Discrete Fourier Transform (DFT). The FFT is usually called from an Igor procedure as one step in a larger process, such as finding the magnitude and phase of a signal. Igor's FFT uses a prime factor decomposition multidimensional algorithm. Prime factor decomposition allows the algorithm to work on nearly any number of data points. Previous versions of Igor were restricted to a power-of-two number of data points.

This section concentrates on the one-dimensional FFT. See **Multidimensional Fourier Transform** on page II-98 for information on multidimensional aspects of the FFT.

You can perform a Fourier transform on a wave by choosing Analysis→Fourier Transforms. This displays the Fourier Transforms dialog.

Select the type of transform by clicking the Forward or Reverse radio button. Select the wave that you want to transform from the Wave list. If you enable the From Target box under the Wave list, only appropriate waves in the target window will appear in the list.

Why Some Waves Aren't Listed

What do we mean by "appropriate" waves?

The data can be either real or complex. If the data are real, the number of data points must be even. This is an artificial limitation that was introduced in order to guarantee that the inverse transform of a forward-transformed wave is equal to the original wave. For multidimensional data, only the number of rows must be even. You can work around some of the restrictions of the inverse FFT with the command line.

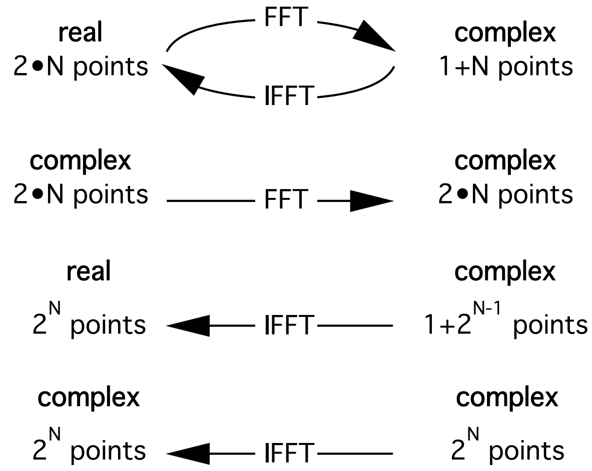
The inverse FFT requires complex data. There are no restrictions on the number of data points. However, for historic and compatibility reasons, certain values for the number of points are treated differently as described in the next sections.

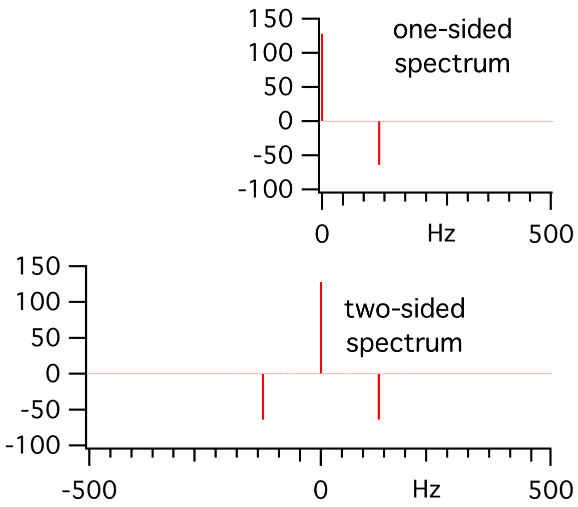
Changes in Wave Type and Number of Points

If the wave is a 1D real wave of N points (N must be even), the FFT operation results in a complex wave consisting of N/2+1 points containing the "one-sided spectrum". The negative spectrum is not computed, since it is identical for real input waves.

If the wave is complex (even if the imaginary part is zero), its data type and number of points are unchanged by the forward FFT. The FFT result is a "two-sided spectrum", which contains both the positive *and* the negative frequency spectra, which are different if the imaginary part of the complex input data is nonzero.

The diagram below shows the two-sided spectrum of 128-point data containing a zero imaginary component.





Magic Number of Points and the IFFT

When performing the inverse FFT, the input is always complex, but the result may be either real or complex.

Because versions of Igor prior to 3.0 only allowed an integral power of two (2^n) to be forward-transformed, Igor could tell from the number of points in the forward-transformed wave what kind of result to create for the inverse transform. To ensure compatibility, Igor versions 3.0 and after continue to treat certain numbers of points as "magical."

If the number of points in the wave is an integral power of two (2^n), then the wave resulting from the IFFT is complex. If the number of points in the wave is one greater than an integral power of two ($1+2^n$), then the wave resulting from the IFFT is real and of length (2^{n+1}).

If the number of points is not one of the two magic values, then the result from the inverse transform is real unless the complex result is selected in the Fourier Transforms dialog.

Changes in X Scaling and Units

The FFT operation changes the X scaling of the transformed wave. If the X-units of the transformed wave are time (s), frequency (Hz), length (m), or reciprocal length (m^{-1}), then the resulting wave units are set to the respective conjugate units. Other units are currently ignored. The X scaling's X_0 value is altered depending on whether the wave is real or complex, but dx is always set the same:

$$\Delta x_{FFT} = \frac{1}{N \cdot \Delta x_{original}} \qquad where,\ N \equiv original\ length\ of\ wave$$

If the original wave is real, then after the FFT its minimum X value (X_0) is zero and its maximum X value is:

$$\begin{aligned} x_{N/2} &= \frac{N}{2} \cdot \Delta x_{FFT} = \frac{N}{2} \cdot \frac{1}{N \cdot \Delta x_{original}} \\ &= \frac{1}{2 \cdot \Delta x_{original}} \\ &= Nyquist\ Frequency \end{aligned}$$

If the original wave is complex, then after the FFT its maximum X value is $X_{N/2}$ - dX_{FFT}, its minimum X value is -$X_{N/2}$, and the X value at point N/2 is zero.

The IFFT operation reverses the change in X scaling caused by the FFT operation except that the X value of point 0 will always be zero.

FFT Amplitude Scaling

Various programs take different approaches to scaling the amplitude of an FFTed waveform. Different scaling methods are appropriate for different analyses and there is no general agreement on how this is done. Igor uses the method described in *Numerical Recipes in C* (see **References** on page III-316) which differs from many other references in this regard.

The DFT equation computed by the FFT for a complex $wave_{orig}$ with N points is:

$$wave_{FFT}[n] = \sum_{k=0}^{N-1} wave_{orig}[k] \cdot e^{2\pi i \cdot kn/N}, \text{ where } i = \sqrt{-1}$$

$wave_{orig}$ and $wave_{FFT}$ refer to the same wave before and after the FFT operation.

The IDFT equation computed by the IFFT for a complex $wave_{FFT}$ with N points is:

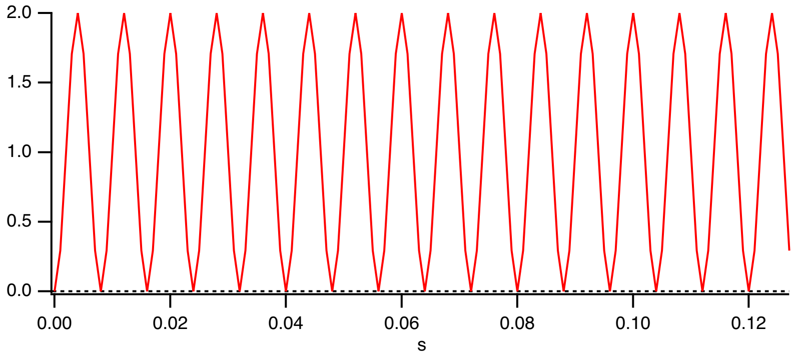
$$wave_{IFT}[n] = \frac{1}{N} \cdot \sum_{k=0}^{N-1} wave_{FFT}[k] \cdot e^{-2\pi i \cdot kn/N}, \text{ where } i = \sqrt{-1}$$

To scale wave_{FFT} to give the same results you would expect from the continuous Fourier Transform, you must divide the spectral values by N, the number of points in $\text{wave}_{\text{orig}}$.

However, for the FFT of a real wave, only the positive spectrum (containing spectra for positive frequencies) is computed. This means that to compare the Fourier and FFT amplitudes, you must account for the identical negative spectra (spectra for negative frequencies) by doubling the positive spectra (but not $\text{wave}_{\text{FFT}}[0]$, which has no negative spectral value).

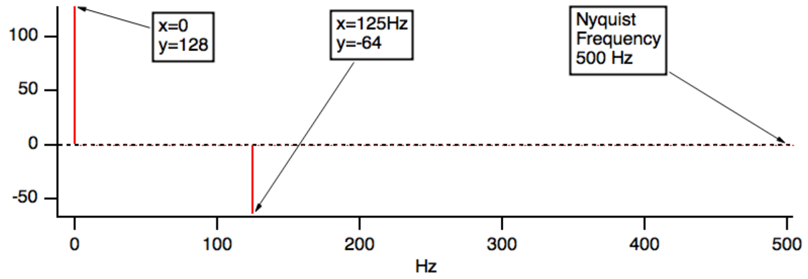
For example, here we compute the one-sided spectrum of a real wave, and compare it to the expected Fourier Transform values:

```
Make/N=128 wave0
SetScale/P x 0,1e-3,"s",wave0 // dx=1ms,Nyquist frequency is 500Hz
wave0= 1 - cos(2*Pi*125*x)    // signal frequency is 125Hz, amp. is -1
Display wave0;ModifyGraph zero(left)=3
```



```
FFT wave0
```

Igor computes the “one-sided” spectrum and updates the graph:



The Fourier Transform would predict a zero-frequency (“DC”) result of 1, which is what we get when we divide the FFT value of 128 by the number of input values which is also 128. In general, the Fourier Transform value at zero frequency is:

$$\textit{Fourier Transform Amplitude}(0) = \frac{1}{N} \cdot real(r2polar(wave_{FFT}(0)))$$

The Fourier Transform would predict a spectral peak at -125Hz of amplitude (-0.5 + i0), and an identical peak in the positive spectrum at +125Hz. The sum of those expected peaks would be (-1+0·i).

(This example is contrived to keep the imaginary part 0; the real part is negative because the input signal contains -cos(…) instead of + cos(…).)

Igor computed only the positive spectrum peak, so we double it to account for the negative frequency peak twin. Dividing the doubled peak of -128 by the number of input values results in (-1+i0), which agrees with the Fourier Transform prediction. In general, the Fourier Transform value at a nonzero frequency f is:

$$\textit{Fourier Transform Amplitude}(f) = \frac{2}{N} \cdot real(r2polar(wave_{FFT}(f)))$$

The only exception to this is the Nyquist frequency value (the last value in the one-sided FFT result), whose value in the one-sided transform is the same as in the two-sided transform (because, unlike all the other frequency values, the two-sided transform computes only one Nyquist frequency value). Therefore:

$$\textit{Fourier Transform Amplitude}(f_{Nyquist}) = \frac{1}{N} \cdot real(r2polar(wave_{FFT}(f_{Nyquist})))$$

The frequency resolution $dX_{FFT} = 1/(N_{original} \cdot dx_{original})$, or 1/(128*1e-3) = 7.8125 Hz. This can be verified by executing:

```
Print deltax(wave0)
```

Which prints into the history area:

```
  7.8125
```

You should be aware that if the input signal *is not* a multiple of the frequency resolution (our example *was* a multiple of 7.8125 Hz) that the energy in the signal will be divided among the two closest frequencies in the FFT result; this is different behavior than the continuous Fourier Transform exhibits.

Phase Polarity

There are two different definitions of the Fourier transform regarding the phase of the result. Igor uses a method that differs in sign from many other references. This is mainly of interest if you are comparing the result of an FFT in Igor to an FFT in another program. You can convert from one method to the other as follows:

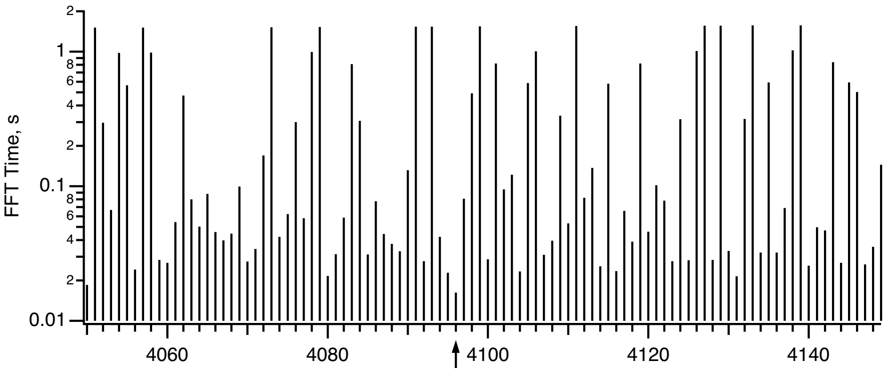
```
FFT wave0; wave0=conj(wave0)  // negate the phase angle by changing
                              // the sign of the imaginary component.
```

Effect of FFT and IFFT on Graphs

Igor displays complex waves in Lines between points mode by default. But, as demonstrated above, if you perform an FFT on a wave that is displayed in a graph and the display mode for that wave is lines between points, then Igor changes its display mode to Sticks to zero. Also, if you perform an IFFT on a wave that is displayed in a graph and the display mode for that wave is Sticks to zero then Igor changes its display mode to Lines between points.

Effect of the Number of Points on the Speed of the FFT

Although the prime factor FFT algorithm does not require that the number of points be a power of two, the speed of the FFT can degrade dramatically when the number of points can not be factored into small prime numbers. The following graph shows the speed of the FFT on a complex vector of varying number of points. Note that the time (speed) axis is log. The results are from a Power Mac 9500/120.



The arrow is at N=4096, a power of two. For that number of points, the FFT time was less than 0.02 seconds while other nearby values exceed one second. The moral of the story is that you should avoid numbers of points that have large prime factors (4078 takes a long time- it has prime factors 2039 and 2). You should endeavor to use a number with small prime factors (4080 is reasonably fast — it has prime factors 2*2*2*2*3*5*17). For best performance, the number of points should be a power of 2, like 4096.

Finding Magnitude and Phase

The FFT operation can create a complex, real, magnitude, magnitude squared, or phase result directly when you choose the desired output type in the Fourier Transforms dialog

If you choose to use the complex wave result of the FFT operation you can compute the magnitude and phase using the **WaveTransform** operation (see page V-1090) (with keywords magnitude, magsqr, and phase), or with various procedures from the WaveMetrics Procedures folder (described in the next section).

If you want to unwrap the phase wave (to eliminate the phase jumps that occur between ±180 degrees), use the Unwrap operation or the Unwrap Waves dialog in the Data menu. See **Unwrap** on page V-1050. In two dimensions you can use **ImageUnwrapPhase** operation (see page V-433).

Magnitude and Phase Using WaveMetrics Procedures

For backward compatibility you can compute FFT magnitude and phase using the WaveMetrics-provided procedures in the “WaveMetrics Procedures:Analysis:DSP (Fourier Etc)” folder.

You can access them using Igor’s “#include” mechanism. See **The Include Statement** on page IV-166 for instructions on including a procedure file.

The WM Procedures Index help file, which you can access from the Help→Help Windows menu, is a good way to find out what routines are available and how to access them.

FTMagPhase Functions

The FTMagPhase functions provide an easy interface to the FFT operation. FTMagPhase has the following features:

- Automatic display of the results.

- Original data is untouched.
- Can display magnitude in decibels.
- Optional phase display in degrees or radians.
- Optional 1D phase unwrapping.
- Resolution enhancement.
- Supports non-power-of-two data with optional windowing.

Use `#include <FTMagPhase>` in your procedure file to access these functions.

FTMagPhaseThreshold Functions

The FTMagPhaseThreshold functions are the same as the FTMagPhase procedures, but with an extra feature:

- Phase values for low-amplitude signals may be ignored.

Use `#include <FTMagPhaseThreshold>` in your procedure file to access these functions.

DFTMagPhase Functions

The DFTMagPhase functions are similar to the FTMagPhase procedures, except that the slower Discrete Fourier Transform is used to perform the calculations:

- User-selectable frequency start and end.
- User-selectable number of frequency bands.

The procedures also include the DFTAtOneFrequency procedure, which computes the amplitude and phase at a single user-selectable frequency.

Use `#include <DFTMagPhase>` in your procedure file to access these functions.

CmplxToMagPhase Functions

The CmplxToMagPhase functions convert a complex wave, presumably the result of an FFT, into separate magnitude and phase waves. It has many of the features of FTMagPhase, but doesn't do the FFT.

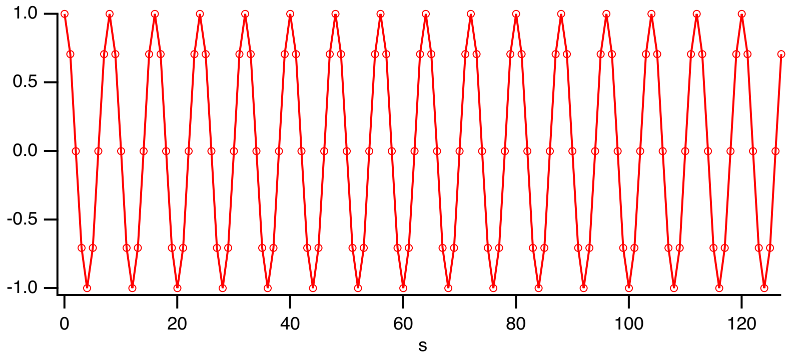
Use `#include <CmplxToMagPhase>` in your procedure file to access these functions.

Spectral Windowing

The FFT computation makes an assumption that the input data repeats over and over. This is important if the initial value and final value of your data are not the same. A simple example of the consequences of this repeating data assumption follows.

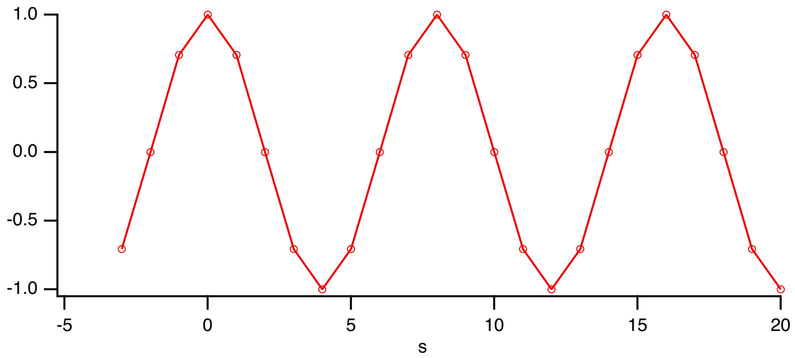
Suppose that your data is a sampled cosine wave containing 16 complete cycles:

```
Make/O/N=128 cosWave=cos(2*pi*p*16/128)
SetScale/P x, 0, 1, "s", cosWave
Display cosWave
ModifyGraph mode=4,marker=8
```



Notice that if you copied the last several points of cosWave to the front, they would match up perfectly with the first several points of cosWave. In fact, let's do that with the **Rotate** operation (see page V-810):

```
Rotate 3,cosWave        // wrap last three values to front of wave
SetAxis bottom,-5,20    // look more closely there
```

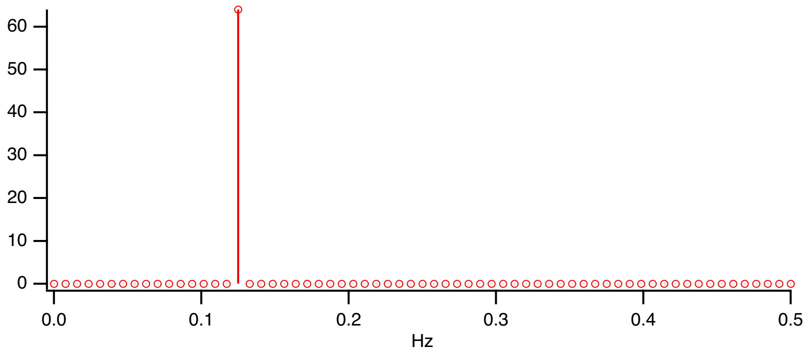


The rotated points appear at x=-3, -2, and -1. This indicates that there is no discontinuity as far as the FFT is concerned.

Because of the absence of discontinuity, the FFT magnitude result matches the ideal expectation:

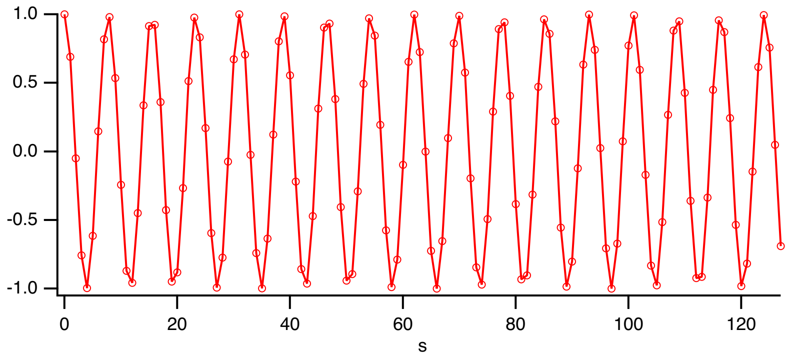
```
Ideal FFT amplitude = cosine amplitude * number of points/2 = 1 * 128 / 2 = 64
```

```
FFT /OUT=3 /DEST=cosWaveF cosWave
Display cosWaveF
ModifyGraph mode=8, marker=8
```



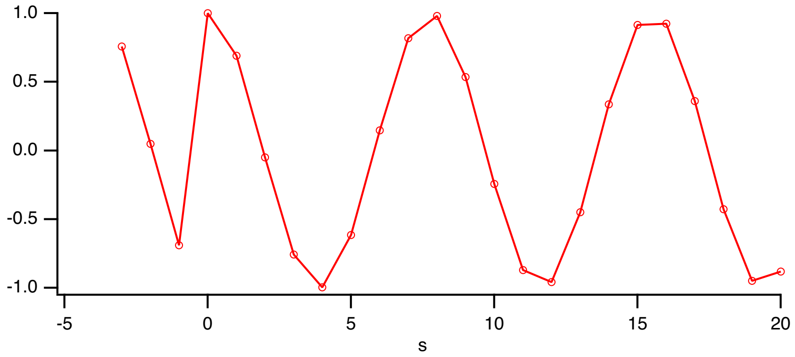
Notice that all other FFT magnitudes are zero. Now let us change the data so that there are 16.5 cosine cycles:

```
Make/O/N=128 cosWave = cos(2*pi*p*16.5/128)
SetScale/P x, 0, 1, "s", cosWave
SetAxis/A
```



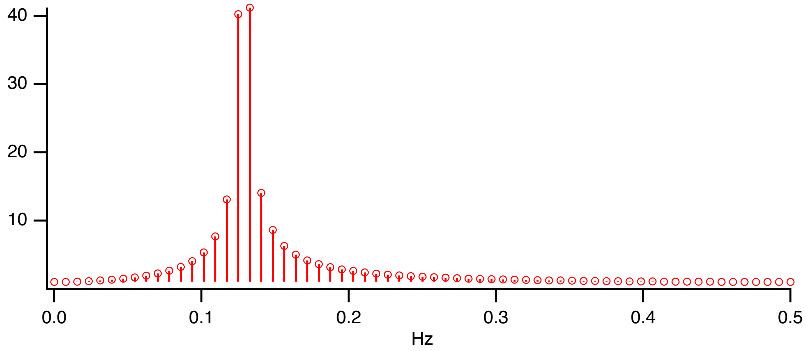
When we rotate this data as before, you can see what the FFT will perceive to be a discontinuity between the point 127 and point 0 of the unrotated data. In this next graph, the original point 127 has been rotated to x= -1 and point 0 is still at x=0.

```
Rotate 3, cosWave
SetAxis bottom, -5, 20
```



When the FFT of this data is computed, the discontinuity causes “leakage” of the main cosine peak into surrounding magnitude values.

```
FFT /OUT=3 /DEST=cosWaveF cosWave
SetAxis/A
```

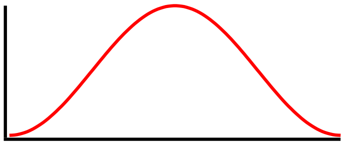


How does all this relate to spectral windowing? Spectral windowing reduces this leakage and gives more accurate FFT results. Specifically, windowing reduces the number of adjacent FFT values affected by leakage. A typical window accomplishes this by smoothly attenuating both ends of the data towards zero.

Hanning Window

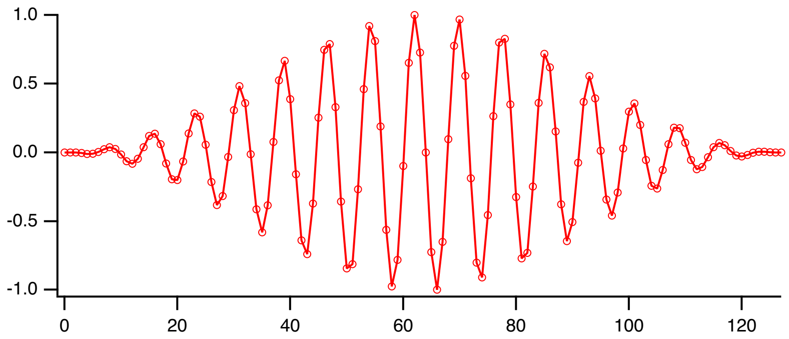
Windowing the data *before* the FFT is computed can reduce the leakage demonstrated above. The Hanning window is a simple raised cosine function defined by the equation:

$$hanning[p] = \frac{1 - \cos\left(\frac{2\pi p}{N-1}\right)}{2}$$



Let us apply the Hanning window to the 16.5 cycle cosine wave data:

```
Make/O/N=128 cosWave=cos(2*pi*p*16.5/128)
Hanning cosWave
Display cosWave
ModifyGraph mode=4, marker=8
```



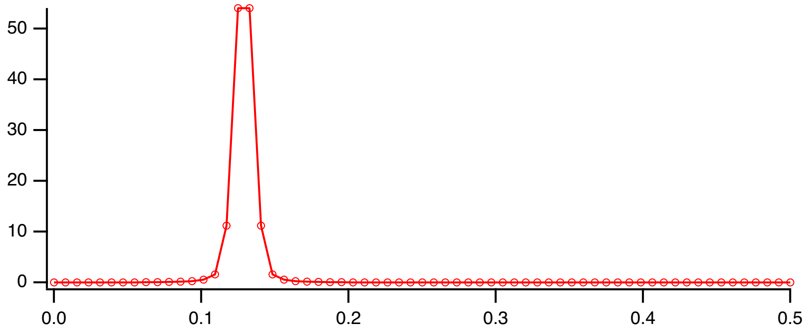
By smoothing the ends of the wave to zero, there is no discontinuity when wrapping around the ends.

In applying a window to the data, energy is lost. Depending on your application you may want to scale the output to account for coherent or incoherent gain. The coherent gain is sometimes expressed in terms of amplitude factor and it is equal to the sum of the coefficients of the window function over the interval. The incoherent gain is a power factor defined as the sum of the squares of the same coefficients. In the case that we are considering the correction factor is just the reciprocal of the coherent gain of the Hanning window

$$coherent\ gain \equiv \int_0^1 \frac{1-\cos(2\pi x / N)}{2} dx = 0.5$$

so we can multiply the FFT amplitudes by 2 to correct for them:

```
cosWave *= 2                              // Account for coherent gain
FFT /OUT=3 /DEST=cosWaveH cosWave
Display cosWaveH
ModifyGraph mode=4, marker=8
```



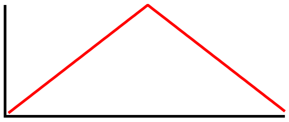
Note that frequency values in the neighborhood of the peak are less affected by the leakage, and that the amplitude is closer to the ideal of 64.

Other Windows

The Hanning window is not the ultimate window. Other windows that suppress more leakage tend to broaden the peaks. The FFT and WindowFunction operations have the following built-in windows: Hanning, Hamming, Bartlett, Blackman, Cosa(x), KaiserBessel, Parzen, Riemann, and Poisson.

You can create other windows by writing a user-defined function or by executing a simple wave assignment statement such as this one which applies a triangle window:

```
data *= 1-abs(2*p/numpnts(data)-1)
```



Use point indexing to avoid X scaling complications. You can determine the effect a window has by applying it to a perfect cosine wave, preferably a cosine wave at 1/4 of the sampling frequency (half the Nyquist frequency).

Other windows are provided in the WaveMetrics-supplied “DSP Window Functions” procedure file.

Multidimensional Windowing

When performing FFTs on images, artifacts are often produced because of the sharp boundaries of the image. As is the case for 1D waves, windowing of the image can help yield better results from the FFT.

To window images, you will need to use the ImageWindow operation, which implements the Hanning, Hamming, Bartlett, Blackman, and Kaiser windowing filters. See the **ImageWindow** operation on page V-435 for further details. For a windowing example, see **Correlations** on page III-362.

Power Spectra

Periodogram

The periodogram of a signal s(t) is an estimate of the power spectrum given by

$$P(f) = \frac{|F(f)|^2}{N},$$

where F(f) is the Fourier transform of s(t) computed by a Discrete Fourier Transform (DFT) and N is the normalization (usually the number of data points).

You can compute the periodogram using the FFT but it is easier to use the DSPPeriodogram operation, which has the same built-in window functions but you can also select your own normalization to suppress the DC term or to have the results expressed in dB as:

20log10(F/F0)

or

10log10(P/P0)

where P0 is either the maximum value of P or a user-specified reference value.

DSPPeriodogram can also compute the cross-power spectrum, which is the product of the Fourier transform of the first signal with the complex conjugate of the Fourier transform of the second signal:

$$P(f) = \frac{F(f)G^*(f)}{N}$$

where F(f) and G(f) are the DFTs of the two waves.

Power Spectral Density Functions

The PowerSpectralDensity routine supplied in the “Power Spectral Density” procedure file computes Power Spectral Density by averaging power spectra of segments of the input data. This is an early procedure file that does not take advantage of the new built-in features of the FFT or DSPPeriodogram operations. The procedure is still supported for backwards compatibility.

The PowerSpectralDensity functions take a long data wave on input and calculate the power spectral density function. These procedures have the following features:

- Automatic display of the results.
- Original data is untouched.
- Pop-up list of windowing functions.
- User setable segment length.

Use `#include <Power Spectral Density>` in your procedure file to access these functions. See **The Include Statement** on page IV-166 for instructions on including a procedure file.

PSD Demo Experiment

The PSD Demo experiment (in the Examples:Analysis: folder) uses the PowerSpectralDensity procedure and explains how it works in great detail, including justification for the scaling applied to the result.

Hilbert Transform

The Hilbert transform of a function f(x) is defined by

$$F_H(x) = \frac{1}{\pi}\int_{-\infty}^{\infty}\frac{f(t)}{t-x}dt .$$

The integral is evaluated as a Cauchy principal value. For numerical computation it is customary to express the integral as the convolution

$$F_H(x) = \left(\frac{-1}{\pi x}\right) \otimes f(x) .$$

Noting that the Fourier transform of (-1/πx) is i*sgn(x), we can evaluate the Hilbert transform using the convolution theorem of Fourier transforms. The **HilbertTransform** operation (see page V-348) is a convenient shortcut. In the next example we compute the Hilbert transform of a cosine function that gives us a sine function:

```
Make/N=512 cosWave=cos(2*pi*x*20/512)
HilbertTransform/Dest=hCosWave cosWave
Display cosWave,hCosWave
ModifyGraph rgb(hCosWave)=(0,0,65535)
```

Time Frequency Analysis

When you compute the Fourier spectrum of a signal you dispose of all the phase information contained in the Fourier transform. You can find out which frequencies a signal contains but you do not know when these frequencies appear in the signal. For example, consider the signal

$$f(t) = \begin{cases} \sin(2\pi f_1 t) & 0 \le t < t_1 \\ \sin(2\pi f_2 t) & t_1 \le t < t_2 \end{cases} .$$

The spectral representation of f(t) remains essentially unchanged if we interchange the two frequencies f_1 and f_2. In other words, the Fourier spectrum is not the best analysis tool for signals whose spectra fluctuate in time. One solution to this problem is the so-called “short time Fourier Transform”, in which you can compute the Fourier spectra using a sliding temporal window. By adjusting the width of the window you can determine the time resolution of the resulting spectra.

Two alternative tools are the Wigner transform and the Continuous Wavelet Transform (CWT).

Wigner Transform

The Wigner transform (also known as the Wigner Distribution Function or WDF) maps a 1D time signal U(*t*) into a 2D time-frequency representation. Conceptually, the WDF is analogous to a musical score where the time axis is horizontal and the frequencies (notes) are plotted on a vertical axis. The WDF is defined by the equation

$$W(t, \nu) = \int_{-\infty}^{\infty} dx U(t+x/2)U^*(t-x/2)e^{-i2\pi x\nu}$$

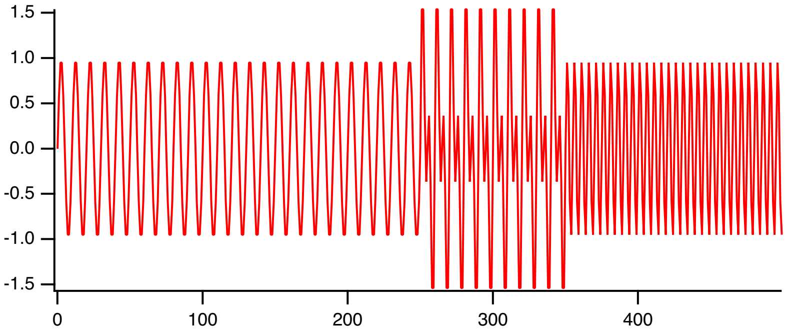
Note that the WDF W(*t*,ν) is real (this can be seen from the fact that it is a Fourier transform of an Hermitian quantity). The WDF is also a 2D Fourier transform of the Ambiguity function.

The localized spectrum can be derived from the WDF by integrating it over a finite area dtdn. Using Gaussian weight functions in both *t* and *n*, and choosing the minimum uncertainty condition dtdn=1, we obtain an estimate for the local spectrum

$$\hat{W}(t, \nu;\delta t) \propto \left|\int U(t')\exp\left[-2\pi\left(\frac{t-t'}{\delta t}\right)^2\right]\exp(-i2\pi\nu t')dt'\right|^2$$

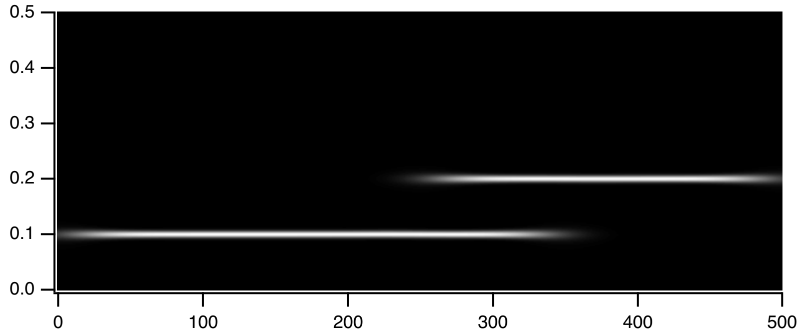
For an application of the **WignerTransform** operation (see page V-1095), consider the two-frequency signal:

```
Make/N=500 signal
signal[0,350]=sin(2*pi*x*50/500)
signal[250,]+=sin(2*pi*x*100/500)
WignerTransform /GAUS=100 signal
DSPPeriodogram signal          // Spectrum for comparison
Display signal
```

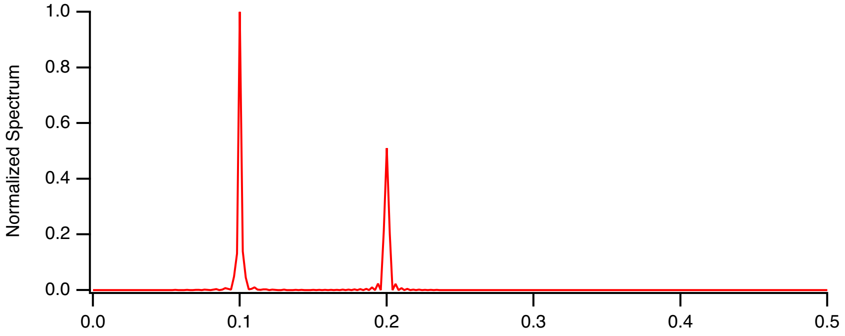


The signal used in this example consists of two “pure” frequencies that have small amount of temporal overlap:

```
Display; AppendImage M_Wigner
```



The temporal dependence is clearly seen in the Wigner transform. Note that the horizontal (time) transitions are not sharp. This is mostly due to the application of the minimum uncertainty relation dtdn=1 but it is also due to computational edge effects. By comparison, the spectrum of the signal while clearly showing the presence of two frequencies it provides no indication of the temporal variation of the signal's frequency content. Furthermore, the different power in the two frequencies may be attributed to either a different duration or a different amplitude.



Continuous Wavelet Transform

The Continuous Wavelet Transform (CWT) is a time-frequency representation of signals that graphically has a superficial similarity to the Wigner transform.

A wavelet transform is a convolution of a signal s(t) with a set of functions which are generated by translations and dilations of a main function. The main function is known as the mother wavelet and the translated or dilated functions are called wavelets. Mathematically, the CWT is given by

$$W(a, b) = \frac{1}{\sqrt{a}}\int s(t)\psi\left(\frac{t-b}{a}\right)dt .$$

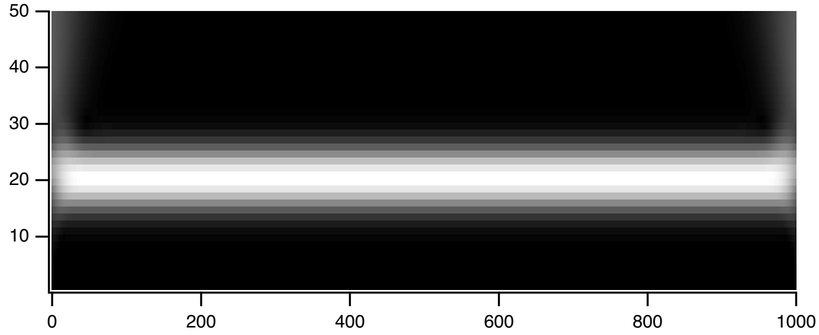
Here b is the time translation and a is the dilation of the wavelet.

From a computational point of view it is natural to use the FFT to compute the convolution which suggests that the results are dependent on proper sampling of s(t).

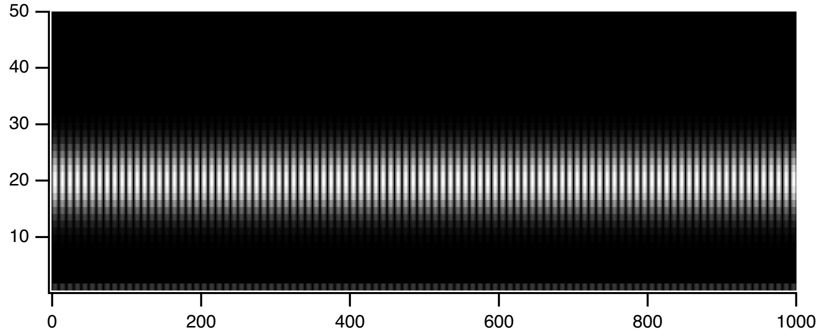
When the mother wavelet is complex, the CWT is also a complex valued function. Otherwise the CWT is real. The squared magnitude of the CWT $|W(a, b)|^2$ is equivalent to the power spectrum so that a typical display (image) of the CWT is a representation of the power spectrum as a function of time offset b. One should note however that the precise form of the CWT depends on the choice of mother wavelet y and therefore the extent of the equivalency between the squared magnitude of the CWT and the power spectrum is application dependent.

The **CWT** operation (see page V-137) is implemented using both the FFT and the direct sum approach. You can use either one to get a representation of the effective wavelet using a delta function as an input. When comparing two CWT results you should always check that both use exactly the same definition of the wavelet function, same normalization and same computation method. For example,

```
Make/N=1000 signal=sin(2*pi*x*50/1000)
CWT/OUT=4/SMP2=1/R2={1,1,40}/WBI1=Morlet/WPR1=5/FSCL signal
Rename M_CWT, M_CWT1
Display as "Morlet FFT"; AppendImage M_CWT1
```

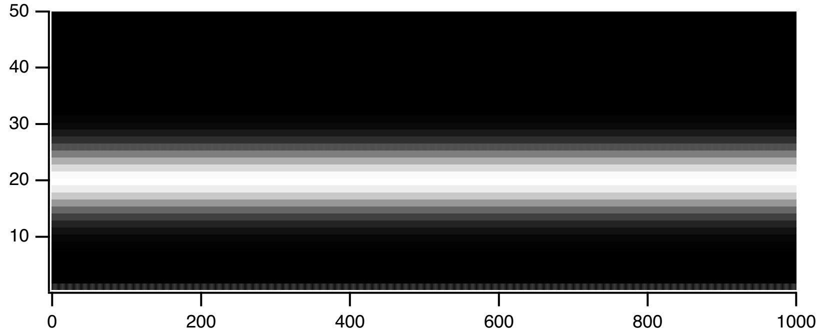


```
CWT /M=1/OUT=4/SMP2=1/R2={1,1,40}/WBI1=Morlet/FSCL /ENDM=2 signal
Rename M_CWT, M_CWT2
Display as "Morlet Direct Sum"; AppendImage M_CWT2
```



Using the complex Morlet wavelet in the direct sum method (/M=1) and displaying the squared magnitude we get:

```
CWT /M=1/OUT=4/SMP2=1/R2={1,1,40}/WBI1=MorletC/FSCL /ENDM=2 signal
Rename M_CWT, M_CWT3
Display as "Complex Morlet Direct Sum"; AppendImage M_CWT3
```



It is apparent that the last image has essentially the same results as the one generated using the FFT approach but in this case the edge effects are completely absent.

Discrete Wavelet Transform

The DWT is similar to the Fourier transform in that it is a decomposition of a signal in terms of a basis set of functions. In Fourier transforms the basis set consists of sines and cosines and the expansion has a single parameter. In wavelet transform the expansion has two parameters and the functions (wavelets) are generated from a single “mother” wavelet using dilation and offsets corresponding to the two parameters.

$$f(t) = \sum_a \sum_b c_{ab} \psi_{ab}(t),$$

where the two-parameter expansion coefficients are given by

$$c_{ab} = \int f(t) \psi_{ab}(t) dt$$

and the wavelets obey the condition

$$\psi_{ab}(t) = 2^{\frac{a}{2}} \Psi(2^a t - b).$$

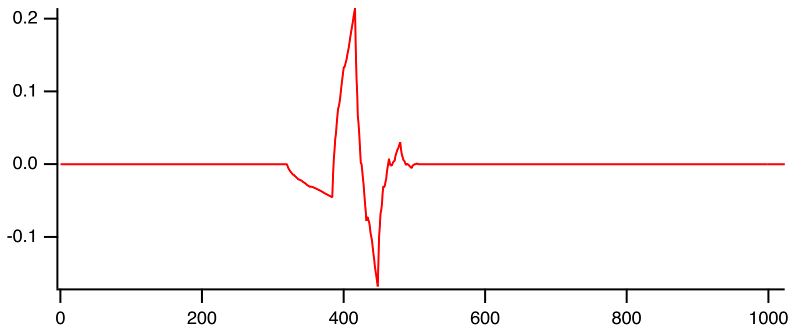
Here Ψ is the mother wavelet, *a* is the dilation parameter and *b* is the offset parameter.

The two parameter representation can complicate things quickly as one goes from 1D signal to higher dimensions. In addition, because the number of coefficients in each scale varies as a power of 2, the DWT of a 1D signal is not conveniently represented as a 2D image (as is the case with the CWT). It is therefore customary to “pack” the results of the transform so that they have the same dimensionality of the input. For example, if the input is a 1D wave of 128 (=27) points, there are 7-1=6 significant scales arranged as follows:

Scale	Storage Location
1	64-127
2	32-63
3	16-31
4	8-15
5	4-7
6	2-3

An interesting consequence of the definition of the DWT is that you can find out the shape of the wavelet by transforming a suitable form of a delta function. For example:

```
Make/N=1024 delta=0
delta[22]=1
DWT/I delta
Display W_DWT     // Daubechies 4 coefficient wavelet
```



Convolution

You can use convolution to compute the response of a linear system to an input signal. The linear system is defined by its impulse response. The convolution of the input signal and the impulse response is the output signal response. Convolution is also the time-domain equivalent of filtering in the frequency domain.

Smoothing is also a form of convolution – see **Smoothing** on page III-292.

The **FilterFIR** implements convolution in the time domain – see **Digital Filtering** on page III-299.

Igor implements general convolution with the **Convolve** operation. To use the Convolve operation, choose Analysis→Convolve.

The built-in Convolve operation computes the convolution of two waves named "source" and "destination" and overwrites the destination wave with the results. The operation can also convolve a single source wave with multiple destination waves (overwriting the corresponding destination wave with the results in each case). The Convolve dialog allows for more flexibility by preduplicating the second waves into new destination waves.

If the source wave is real-valued, each destination wave must be real-valued and if source wave is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; the calculations are performed in the higher precision.

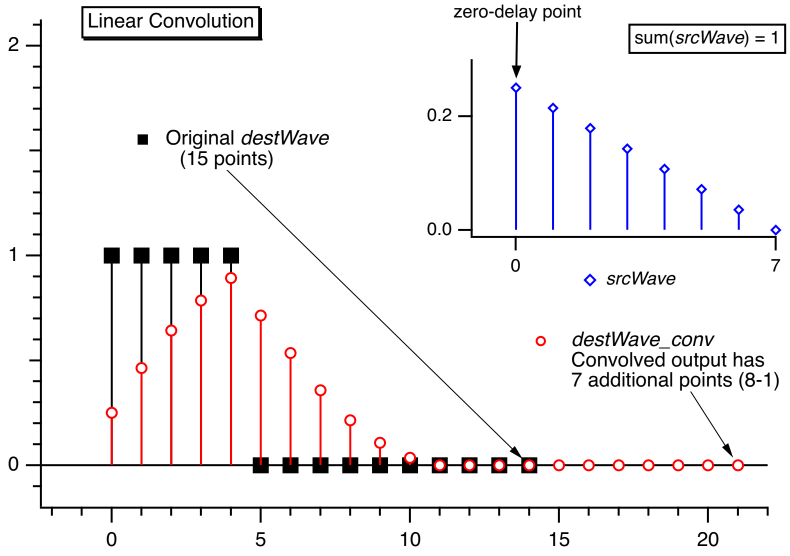
Convolve combines neighboring points before and after the point being convolved, and at the ends of the waves not enough neighboring points exist. This is a general problem in any convolution operation; the smoothing operations use the End Effect pop-up to determine what to do. The Convolve dialog presents three algorithms in the Algorithm group to deal with these missing points.

The Linear algorithm is similar to the Smooth operation's Zero end effect method; zeros are substituted for the values of missing neighboring points.

The Circular algorithm is similar to the Wrap end effect method; this algorithm is appropriate for data which is assumed to endlessly repeat.

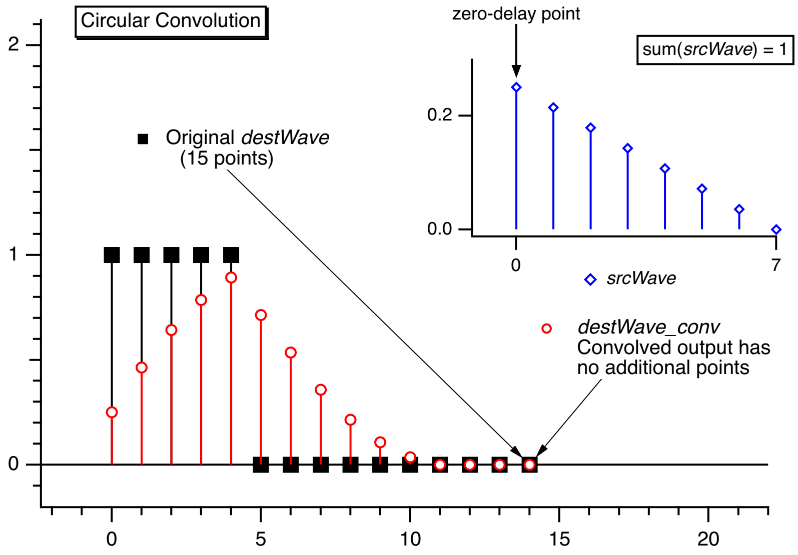
The acausal algorithm is a special case of Linear which eliminates the time delay that Linear introduces.

Depending on the algorithm chosen, the number of points in the destination waves may increase by the number of points in the source wave, less one. For linear and acausal convolution, the destination wave is first zero-padded by one less than the number of points in the source wave. This prevents the "wrap-around" effect that occurs in circular convolution. The zero-padded points are removed after acausal convolution, and retained after linear convolution.

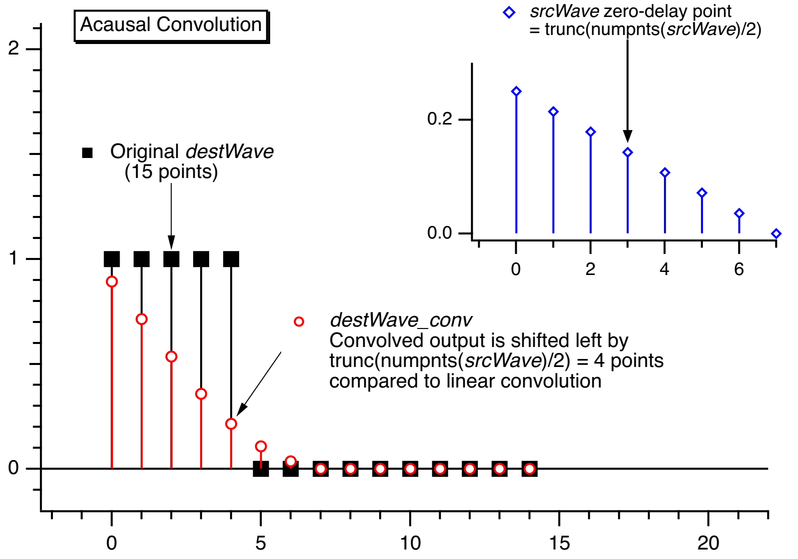


Use linear convolution when the source wave contains an impulse response (or filter coefficients) where the first point of *srcWave* corresponds to no delay ($t = 0$).

Use Circular convolution for the case where the data in the source wave and the destination waves are considered to endlessly repeat (or "wrap around" from the end back to the start), which means no zero padding is needed.

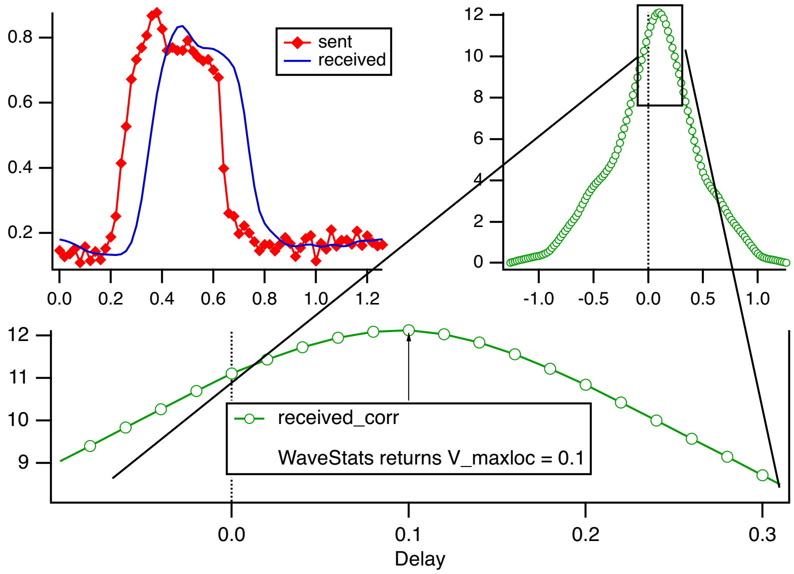


Use acausal convolution when the source wave contains an impulse response where the middle point of the source wave corresponds to no delay (*t* = 0).



Correlation

You can use correlation to compare the similarity of two sets of data. Correlation computes a measure of similarity of two input signals as they are shifted by one another. The correlation result reaches a maximum at the time when the two signals match best. If the two signals are identical, this maximum is reached at *t* = 0 (no delay). If the two signals have similar shapes but one is delayed in time and possibly has noise added to it then correlation is a good method to measure that delay.



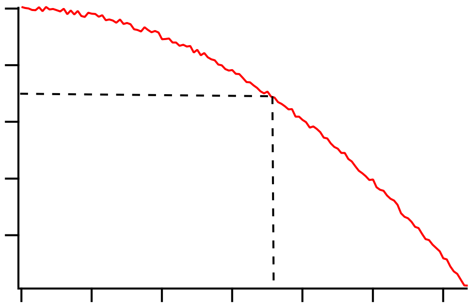
Igor implements correlation with the **Correlate** operation (see page V-107). The Correlate dialog in the Analysis menu works similarly to the Convolve dialog. The source wave may also be a destination wave, in which case afterward it will contain the “auto-correlation” of the wave. If the source and destination are different, this is called “cross-correlation”.

The same considerations about combining differing types of source and destination waves applies to correlation as to convolution. Correlation must also deal with end effects, and these are dealt with by the circular and linear correlation algorithm selections. See **Convolution** on page III-284.

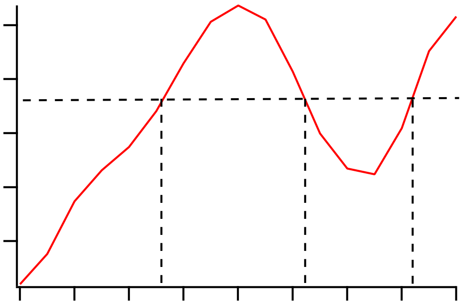
Level Detection

Level detection is the process of locating the X coordinate at which your data passes through or reaches a given Y value. This is sometimes called “inverse interpolation”. Stated another way, level detection answers the question: “given a Y level, what is the corresponding X value?” Igor provides two kinds of answers to that question.

One answer assumes your Y data is a list of unique Y values that increases or decreases monotonically. In this case there is only one X value that corresponds to a Y value. Since search position and direction don’t matter, a binary search is most appropriate. For this kind of data, use the BinarySearch or BinarySearchInterp functions.



The other answer assumes that your Y data varies irregularly, as it would with acquired data. In this case, there may be multiple X values that cross the Y level; the X value returned depends on where the search starts and the search direction through the data. The FindLevel, FindLevels, EdgeStats, and PulseStats operations deal with this kind of data.



A related, but different question is “given a function y = f(x), find x where y is zero (or some other value)”. This question is answered by the FindRoots operation. See **Finding Function Roots** on page III-338, and the **FindRoots** operation on page V-248.

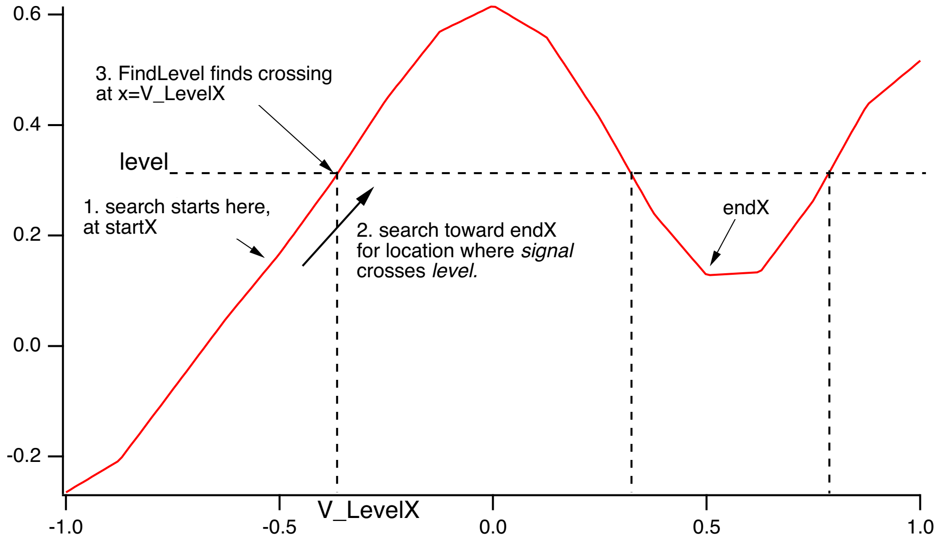
The following sections pertain to detecting level crossings in data that varies irregularly. The operations discussed are not designed to detect peaks; see **Peak Measurement** on page III-290.

Finding a Level in Waveform Data

You can use the **FindLevel** operation (see page V-242) to find a single level crossing, or the **FindLevels** operation (see page V-244) to find multiple level crossings in waveform data. Both of these operations can optionally smooth the waves they search to reduce the effects of noise. A subrange of the data can be searched, by either ascending or descending X values, depending on the *startX* and *endX* values you supply to the operation’s /R flag.

FindLevel locates the first level crossing encountered in the search range, starting at *startX* and proceeding toward *endX* until a level crossing is found. The search is performed sequentially. The outputs of FindLevel are two special numeric variables: V_Flag and V_LevelX. V_Flag indicates the success or failure of the search (0 is success), and V_LevelX contains the X coordinate of the level crossing.

For example, given the following data:



the command:

```
FindLevel/R=(-0.5,0.5) signal,0.30
```

prints this level crossing information into the history area:

```
V_Flag=0; V_LevelX=-0.37497; V_rising=1;
```

Finding a Level in XY Data

You can find a level crossing in XY data by searching the Y wave and then figuring out where in the X wave that X value can be found. This requires that the values in the X wave be sorted in ascending or descending order. To ensure this, the command:

```
Sort xWave,xWave,yWave
```

sorts the waves so that the values in xWave are ascending, and the XY correspondence is preserved.

The following procedure finds the X location where a Y level is crossed within an X range, and stores the result in the output variable V_LevelX:

```
Function FindLevelXY()

   String swy,swx                // strings contain the NAMES of waves
   Variable startX=-inf,endX=inf // startX,endX correspond to VALUEs in wx, not any X
scaling
   Variable level
   // Put up a dialog to get info from user
   Prompt swy,"Y Wave",popup WaveList("*",";","")
   Prompt swx,"X Wave",popup WaveList("*",";","")
   Prompt startX, "starting X value"
   Prompt endX, "ending X value"
   Prompt level, "level to find"
   DoPrompt "Find Level XY", swy,swx,startX, endX, level

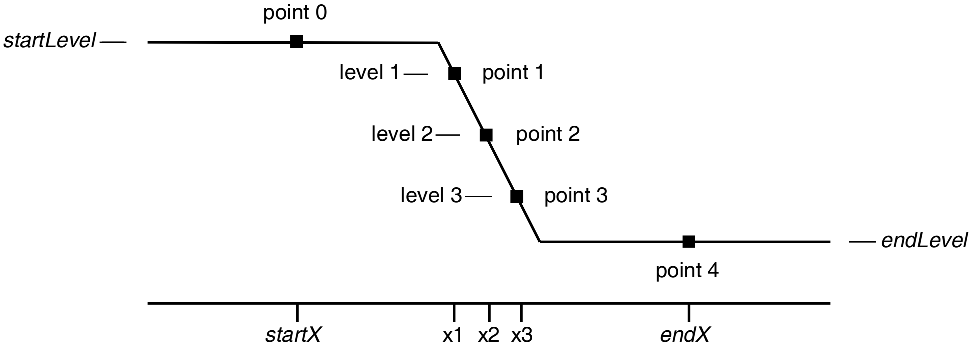
   WAVE wx = $swx
   WAVE wy = $swy

   // Here's where the interesting stuff begins
   Variable startP,endP                  //compute point range covering startX,endX
   startP=BinarySearch(wx,startX)
   endP=BinarySearch(wx,endX)
   FindLevel/Q/R=[startP,endP] wy,level          // search Y wave, assume success
   Variable p1,m
   p1=x2pnt(wy,V_LevelX-deltaX(wy)/2)            //x2pnt rounds; circumvent it
   // Linearly interpolate between two points in wx
   // that bracket V_levelX in wy
   m=(V_LevelX-pnt2x(wy,p1))/(pnt2x(wy,p1+1)-pnt2x(wy,p1))  // slope
   V_LevelX=wx[p1] + m * (wx[p1+1] -wx[p1] )      //point-slope equation
End
```

This function does not handle a level crossing that isn’t found; all that is missing is a test of V_Flag after searching the Y wave with FindLevel.

Edge Statistics

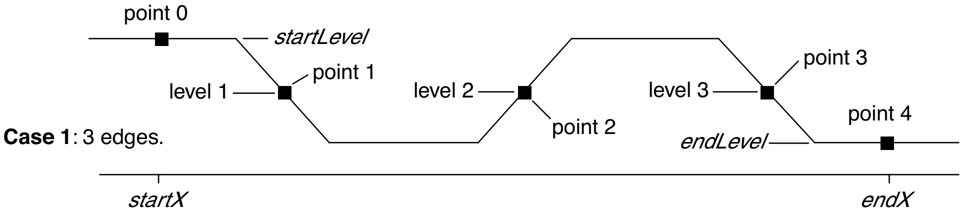
The **EdgeStats** operation (see page V-190) produces simple statistics (measurements, really) on a region of a wave that is expected to contain a single edge as shown below. If more than one edge exists, EdgeStats works on the first edge it finds. The edge statistics are stored in special variables which are described in the EdgeStats reference. The statistics are edge levels, X or point positions of various found “points”, and the distances between them. These found points are actually the locations of level crossings, and are usually located between actual waveform points (they are interpolation locations).



EdgeStats is based on the same principles as FindLevel. EdgeStats does not work on an XY pair. See **Converting XY Data to a Waveform** on page III-109.

Pulse Statistics

The **PulseStats** operation (see page V-783) produces simple statistics (measurements) on a region of a wave that is expected to contain three edges as shown below. If more than three edges exist, PulseStats works on the first three edges it finds. PulseStats handles two other cases in which there are only one or two edges. The pulse statistics are stored in special variables which are described in the PulseStats reference.



PulseStats is based on the same principles as EdgeStats. PulseStats does not work on an XY pair. See **Converting XY Data to a Waveform** on page III-109.

Peak Measurement

The building block for peak measurement is the FindPeak operation. You can use it to build your own peak measurement procedures or you can use procedures provided by WaveMetrics.

Our Multipeak Fitting package provides a powerful GUI and programming interface for curve fitting to peak data. It can fit a number of peak shapes and baseline functions. A demo experiment provides an introduction - choose File→Example Experiments→Curve Fitting→Multipeak Fit Demo.

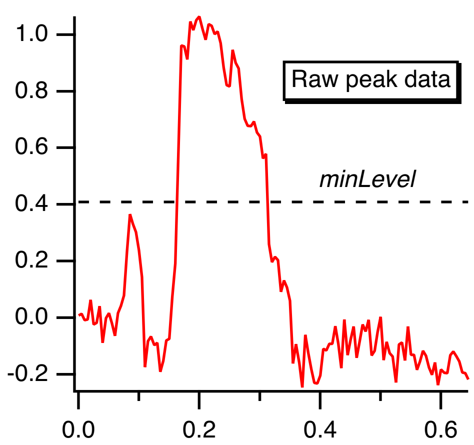
We have created several peak finding and peak fitting Technical Notes. They are described in a summary Igor Technical Note, TN020s-Choosing a Right One.ifn in the Technical Notes folder. There is also an example experiment, called Multi-peak Fit, that does fitting to multiple Gaussian, Lorentzian and Voigt peaks. Multi-peak Fit is less comprehensive but easier to use than Tech Note 20.

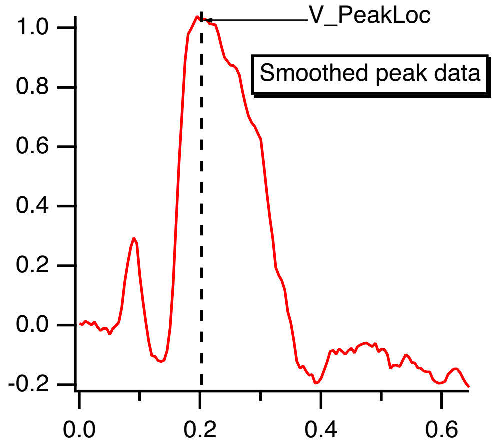
The **FindPeak** operation (see page V-247) searches a wave for a minimum or maximum by analyzing the smoothed first and second derivatives of the wave. The smoothing and differentiation is done on a copy of the input wave (so that the input wave is not modified). The peak maximum is detected at the smoothed first derivative zero-crossing, where the smoothed second derivative is negative. The position of the minimum or maximum is returned in the special variable V_PeakLoc. This and other special variables set by FindPeak are described in the operation reference.

The following describes the process that FindPeak goes through when it executes a command like this:

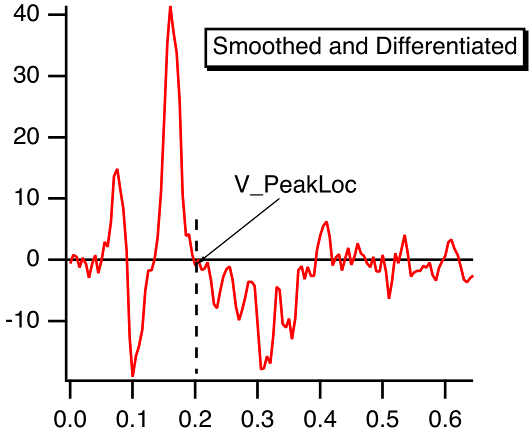
```
FindPeak/M=0.5/B=5 peakData   // 5 point smoothing, min level = 0.5
```

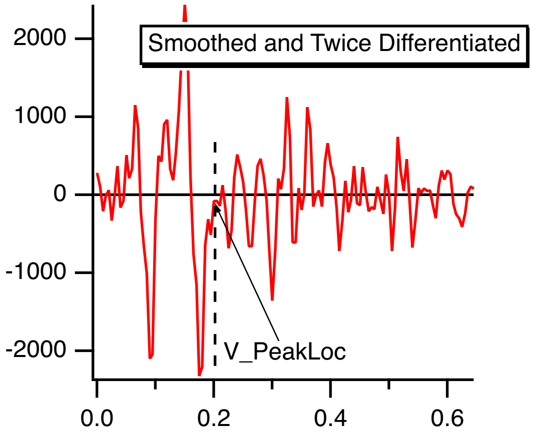
The box smoothing is performed first:





Then two central-difference differentiations are performed to find the first and second derivatives:

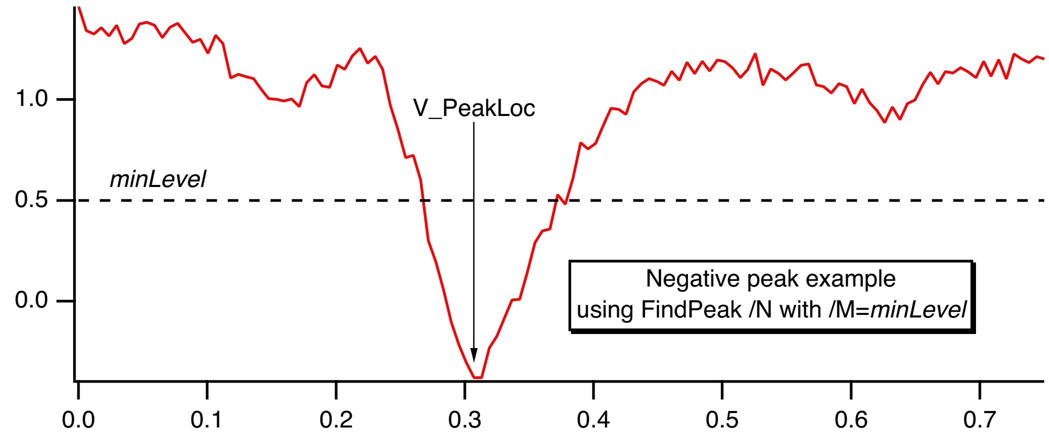




If you use the /M=*minLevel* flag, FindPeak ignores peaks that are lower than *minLevel* (i.e., the Y value of a found peak must exceed *minLevel*). The *minLevel* value is compared to the *smoothed* data, so peaks that appear to be large enough in the raw data may not be found if they are very near *minLevel*. If /N is also specified (search for minimum or "negative peak"), FindPeak ignores peaks whose amplitude is greater than *minLevel* (i.e., the Y value of a found peak will be *less* than *minLevel*). For negative peaks, the peak minimum is at the smoothed first derivative zero-crossing, where the smoothed second derivative is positive.

This command shows an example of finding a negative peak:

```
FindPeak/N/M=0.5/B=5 negPeakData    // 5 point smoothing, max level=0.5
```

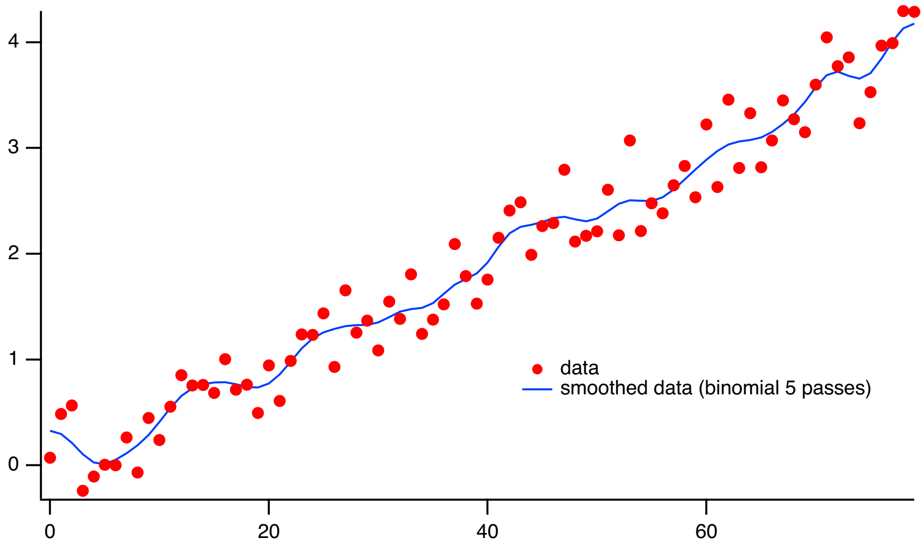


To find multiple peaks, write a procedure that calls FindPeak from within a loop. After a peak is found, restrict the range of the search with /R so that the just-found peak is excluded, and search again. Exit the loop when V_Flag indicates a peak wasn't found.

The FindPeak operation does not work on an XY pair. See **Converting XY Data to a Waveform** on page III-109.

Smoothing

Smoothing is a specialized filtering operation used to reduce the variability of data. It is sometimes used to reduce noise.



This section discusses smoothing 1-dimensional waveform data with the **Smooth**, **FilterFIR**, and **Loess** operations. Also see the **FilterIIR** and **Resample** operations.

Smoothing XY data can also be handled by the **Loess** operation and the Median.ipf procedure file (see **Median Smoothing** on page III-296).

The **MatrixFilter**, **MatrixConvolve**, and **ImageFilter** operations smooth image and 3D data.

Igor has several built-in 1D smoothing algorithms. In addition, you can supply your own smoothing coefficients.

Choose Analysis→Smooth to see the Smoothing dialog.

Depending on the smoothing algorithm chosen, there may be additional parameters to specify in the dialog.

Built-in Smoothing Algorithms

Igor has numerous built-in smoothing algorithms for 1-dimensional waveforms, and one that works with the **XY Model of Data** on page II-63:

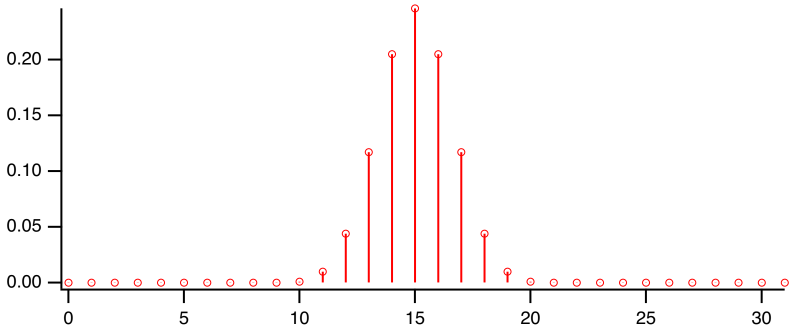
Algorithm	Operation	Data
Binomial	**Smooth**	1D waveform
Savitzky-Golay	**Smooth**/S	1D waveform
Box (Average)	**Smooth**/B	1D waveform
Custom Smoothing	**FilterFIR**	1D waveform
Median	**Smooth**/M	1D waveform
Percentile, Min, Max	**Smooth**/M/MPCT	1D waveform
Loess	**Loess**	1D waveform, XY 1D waves, false-color images*, matrix surfaces*, and multivariate data*.

* The Loess operation supports these data formats, but the Smooth dialog does not provide an interface to select them.

The first four algorithms precompute or apply one set of smoothing coefficients according to the smoothing parameters, and then replaces each data wave with the convolution of the wave with the coefficients.

You can determine what coefficients have been computed by smoothing a wave containing an impulse. For instance:

```
Make/O/N=32 wave0=0; wave0[15]=1; Smooth 5,wave0    // Smooth an impulse
Display wave0; ModifyGraph mode=8,marker=8          // Observe coefficients
```



Compute the FFT of the coefficients with magnitude output to view the frequency response. See **Finding Magnitude and Phase** on page III-274.

The last two algorithms (the **Smooth**/M and **Loess** operations) are not based on creating a fixed set of smoothing coefficients and convolution, so this technique is not applicable.

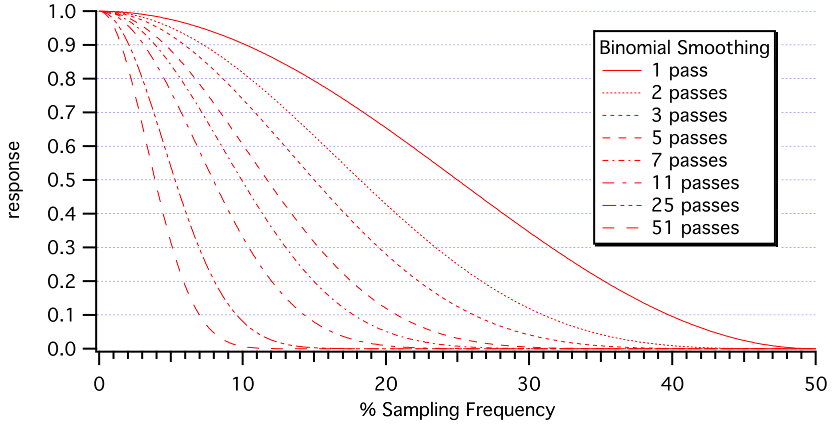
Smoothing Demo

For a demo of various smoothing techniques, choose Files→Example Experiments→Feature Demos→Smooth Curve Through Noise.

Binomial Smoothing

The Binomial smoothing operation is a Gaussian filter. It convolves your data with normalized coefficients derived from Pascal's triangle at a level equal to the Smoothing parameter. The algorithm is derived from an article by Marchand and Marmet (1983).

This graph shows the frequency response of the binomial smoothing algorithm expressed as a percentage of the sampling frequency. For example, if your data is sampled at 1000 Hz and you use 5 passes, the signal at 200 Hz (20% of the sampling frequency) will be approximately 0.1.



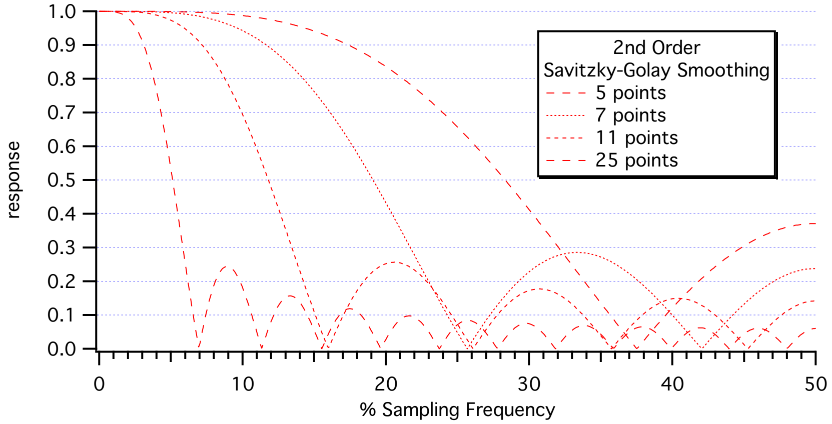
Savitzky-Golay Smoothing

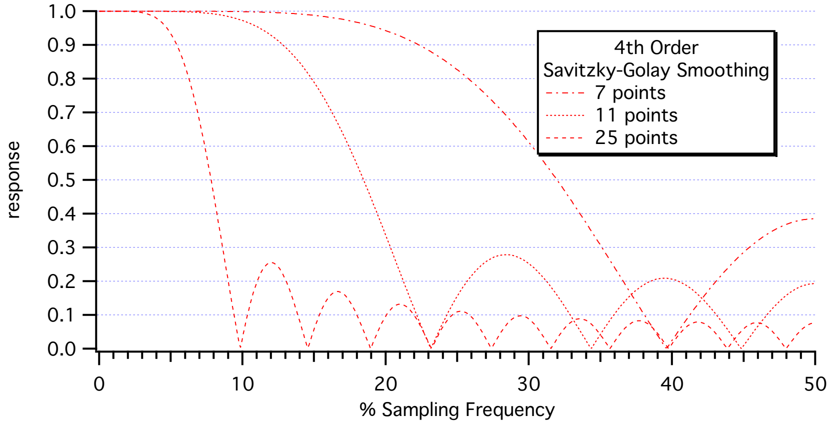
Savitzky-Golay smoothing uses a different set of precomputed coefficients popular in the field of chemistry. It is a type of Least Squares Polynomial smoothing. The amount of smoothing is controlled by two parameters: the polynomial order and the number of points used to compute each smoothed output value. This algorithm was first proposed by A. Savitzky and M.J.E. Golay in 1964. The coefficients were subsequently corrected by others in 1972 and 1978; Igor uses the corrected coefficients.

The maximum Points value is 32767; the minimum is either 5 (2nd order) or 7 (4th order). Note that 2nd and 3rd order coefficients are the same, so we list only the 2nd order choice. Similarly, 4th and 5th order coefficients are identical.

Even though Savitzky-Golay smoothing has been widely used, there are advantages to the binomial smoothing as described by Marchand and Marmet in their article.

The following graphs show the frequency response of the Savitzky-Golay algorithm for 2nd order and 4th order smoothing. The large responses in the higher frequencies show why binomial smoothing is often a better choice.

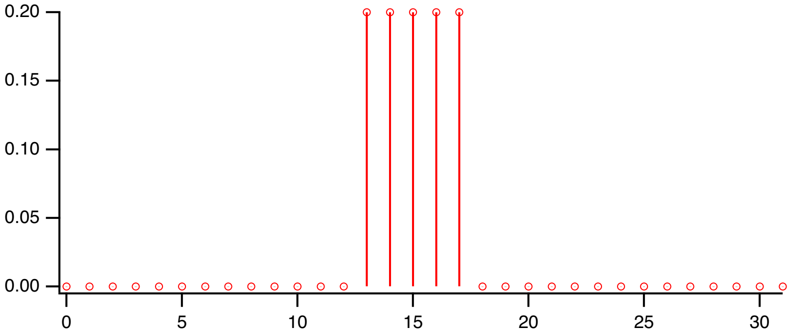




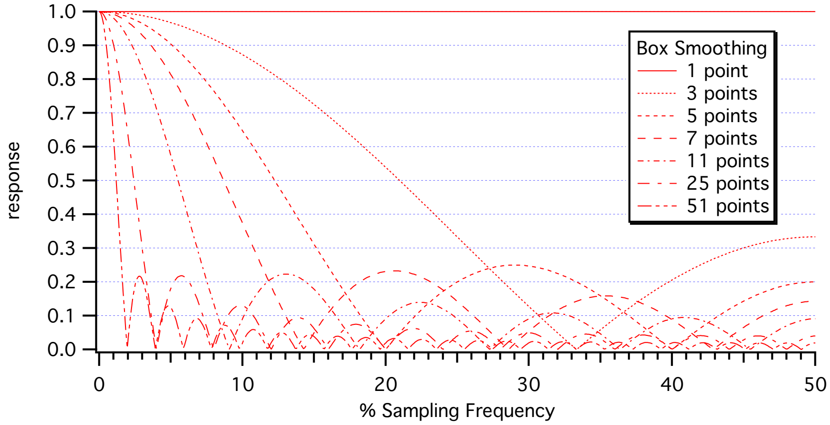
Box Smoothing

Box smoothing is similar to a moving average, except that an equal number of points before *and after* the smoothed value are averaged together with the smoothed value. The Points parameter is the total number of values averaged together. It must be an odd value, since it includes the points before, the center point, and the points after. For instance, a value of 5 averages two points before and after the center point, and the center point itself:

```
Make/O/N=32 wave0=0; wave0[15]=1; Smooth/B 5,wave0     //Smooth impulse
Display wave0; ModifyGraph mode=8,marker=8             // Observe coefficients
```



The following graph shows the frequency response of the box smoothing algorithm.



Median Smoothing

Median smoothing does not use convolution with a set of coefficients. Instead, for each point it computes the median of the values over the specified range of neighboring values centered about the point. NaN values in the waveform data are allowed and are excluded from the median calculations.

For simple XY data median smoothing, include the Median.ipf procedure file:

```
#include <Median>
```

and use the Analysis→Packages→Median XY Smoothing menu item. Currently this procedure file does not handle NaNs in the data and only implements method 1 as described below.

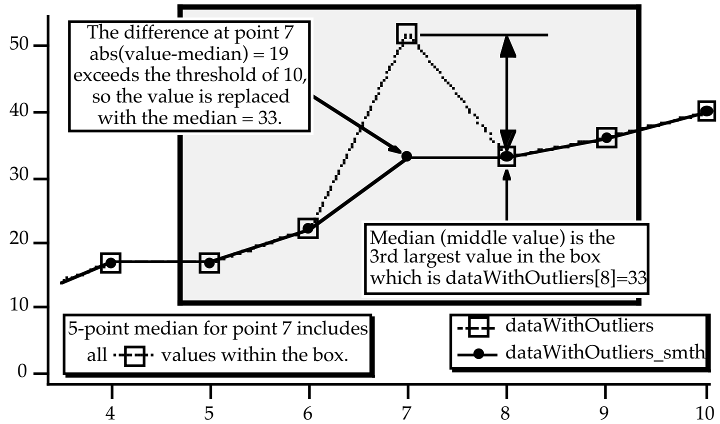
For image (2D matrix) median smoothing, use the **MatrixFilter** or **ImageFilter** operation with the median method. ImageFilter can smooth 3D matrix data.

There are several ways to use median smoothing (Smooth/M) on 1D waveform data:

1. Replace all values with the median of neighboring values.
2. Replace each value with the median if the value itself is NaN. See **Replace Missing Data Using Median Smoothing** on page III-114.
3. Replace each value with the median if the value differs from the median by a the specified threshold amount.
4. Instead of replacing the value with the computed median, replace it with a specified number, including 0, NaN, +inf, or -inf.

Median smoothing can be used to replace “outliers” in data. Outliers are data that seem “out of line” from the other data. One measure of this “out of line” is excessive deviation from the median of neighboring values. The Threshold parameter defines what is considered “excessive deviation”.

```
// Example uses integer wave to simplify checking the results
Make/O/N=20/I dataWithOutliers= 4*p+gnoise(1.5)      // simple line with noise
dataWithOutliers[7] *=2                              // make an outlier at point 7
Display dataWithOutliers
Duplicate/O dataWithOutliers,dataWithOutliers_smth
Smooth/M=10 5, dataWithOutliers_smth                 // threshold=10, 5 point median
AppendToGraph  dataWithOutliers_smth
```



The difference at point 7 abs(value-median) = 19 exceeds the threshold of 10, so the value is replaced with the median = 33.

Median (middle value) is the 3rd largest value in the box which is dataWithOutliers[8]=33

5-point median for point 7 includes all ·-□-· values within the box.

Percentile, Min, and Max Smoothing

Median smoothing is actually a specialization of Percentile smoothing, as are Min and Max.

Percentile smoothing returns the smallest value in the smoothing window that is greater than the smallest percentile % of the values:

Percentile	Type	Description
0	Min	The smoothed value is the minimum value in the smoothing window. 0 is the minimum value for percentile.
50	Median	The smoothed value is the median of the values in the smoothing window.
100	Max	The smoothed value is the maximum value in the smoothing window. 100 is the maximum value for percentile.

As an example, assume that percentile = 25, the number of points in the smoothing window is 7, and for one input point the values in the window after sorting are:

```
{0, 1, 8, 9, 10, 11, 30}
```

The 25th percentile is found by computing the rank R:

```
R = (percentile /100)*(num +1)
```

In this example, R evaluates to 2 so the second item in the sorted list, 1 in this example, is the percentile value for the input point.

The percentile algorithm uses an interpolated rank to compute the value of percentiles other than 0 and 100. See the **Smooth** operation for details.

Loess Smoothing

The Loess operation smooths data using locally-weighted regression smoothing. This algorithm is sometimes classified as a “nonparametric regression” procedure.

The regression can be constant, linear, or quadratic. A robust option that ignores outliers is available. In addition, for small data sets Loess can generate confidence intervals.

See the **Loess** operation on page V-515 help for a discussion of the basic and robust algorithms, examples, and references.

This implementation works with waveforms, XY pairs of waves, false-color images, matrix surfaces, and multivariate data (one dependent data wave with multiple independent variable data waves). Loess discards NaN input values.

The Smooth Dialog, however, provides an interface for only waveforms and XY pairs of waves (see **XY Model of Data** on page II-63), and does not provide an interface for confidence intervals or other less common options.

Here’s an example from the Loess operation help of interpolating (smoothing) an XY pair and creating an interpolated 1D waveform (Y vs. X scaling). **Note**: the Make commands below are wrapped to fit the page:

```
// 3.  1-D Y vs X wave data interpolated to waveform (Y vs X scaling)
//     with 99% confidence interval outputs (cp and cm)
// NOx = f(EquivRatio)
// Y wave
Make/O/D NOx = {4.818, 2.849, 3.275, 4.691, 4.255, 5.064, 2.118, 4.602, 2.286, 0.97,
3.965, 5.344, 3.834, 1.99, 5.199, 5.283, 3.752, 0.537, 1.64, 5.055, 4.937, 1.561};

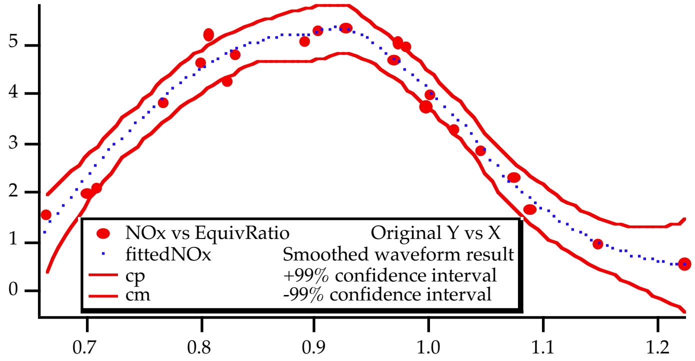
// X wave (Note that the X wave is not sorted)
Make/O/D EquivRatio = {0.831, 1.045, 1.021, 0.97, 0.825, 0.891, 0.71, 0.801,  1.074,
1.148, 1, 0.928, 0.767, 0.701, 0.807, 0.902,   0.997, 1.224, 1.089, 0.973, 0.98, 0.665};

// Graph the input data
Display NOx vs EquivRatio; ModifyGraph mode=3,marker=19

// Interpolate to dense waveform over X range
Make/O/D/N=100 fittedNOx
WaveStats/Q EquivRatio
```

```
SetScale/I x, V_Min, V_max, "", fittedNOx
Loess/CONF={0.99,cp,cm}/DEST=fittedNOx/DFCT/SMTH=(2/3) srcWave=NOx,factors={EquivRatio}

// Display the fit (smoothed results) and confidence intervals
AppendtoGraph fittedNOx, cp,cm
ModifyGraph rgb(fittedNOx)=(0,0,65535)
ModifyGraph mode(fittedNOx)=2,lsize(fittedNOx)=2
Legend
```



Loess is memory intensive, especially when generating confidence intervals. Read the **Memory Details** section of the **Loess** operation (see page V-515) if you use confidence intervals.

Custom Smoothing Coefficients

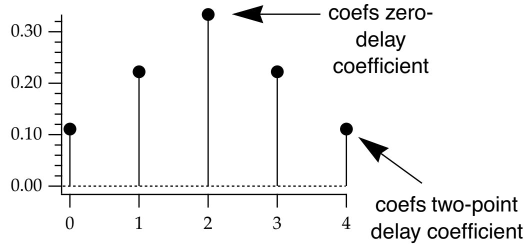
You can smooth data with your own set of smoothing coefficients by selecting the Custom Coefs algorithm. Use this option when you have low-pass filter (smoothing) coefficients created by another program or by the Igor Filter Design Laboratory.

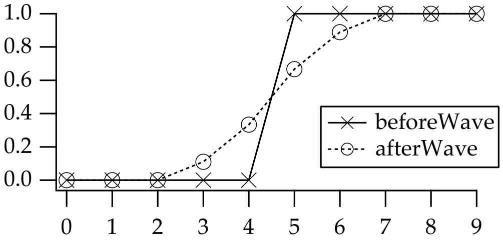
Choose the wave that contains your coefficients from the pop-up menu that appears. Igor will convolve these coefficients with the input wave using the **FilterFIR** operation (see page V-230). You should use FilterFIR when convolving a short wave with a much longer one. Use the **Convolve** operation (see page V-101) when convolving two waves with similar number of points; it's faster.

All the values in the coefficients wave are used. FilterFIR presumes that the middle point of the coefficient wave corresponds to the delay = 0 point. This is usually the case when the coefficient wave contains the two-sided impulse response of a filter, which has an odd number of points. (For a coefficient wave with an even number of points, the "middle" point is `numpnts(coefs)/2-1`, but this introduces a usually unwanted delay in the smoothed data).

In the following example, the coefs wave smooths the data by a simple 7 point Bartlett (triangle) window (omitting the first and last Bartlett window values which are 0):

```
// This example shows a unit step signal smoothed
//   by a 7-point Bartlett window
Make/O/N=10 beforeWave = (p>=5)         // unit step at p == 5
Make/O coefs={1/3,2/3,1,2/3,1/3}        // 7 point Bartlett window
WaveStats/Q coefs
coefs/= V_Sum
Duplicate/O beforeWave,afterWave
FilterFIR/E=3/COEF=coefs afterWave
Display beforeWave,afterWave
```





End Effects

The first four smoothing algorithms compute the output value for a given point using the point's neighbors. Each algorithm combines an equal number of neighboring points before and after the point being smoothed. At the start or end of a wave some points will not have enough neighbors, so a method for fabricating neighbor values must be implemented.

You choose how to fabricate those values with the End Effect pop-up menu in the Smoothing dialog. In the descriptions that follow, i is a small positive integer, and wave[n] is the last value in the wave to be smoothed.

The Bounce method uses wave[i] in place of the missing wave[-i] values and wave[n-i] in place of the missing wave[n+i] values. This works best if the data is assumed to be symmetrical about both the start and the end of the wave. If you don't specify the end effect method, Bounce is used.

The Wrap method uses wave[n-i] in place of the missing wave[-i] values and vice-versa. This works best if the wave is assumed to endlessly repeat.

The Zero method uses 0 for any missing value. This works best if the wave starts and ends with zero.

The Repeat method uses wave[0] in place of the missing wave[-i] values and wave[n] in place of the missing wave[n+i] values. This works best for data representing a single event.

When in doubt, use Repeat.

Digital Filtering

Digital filters are used to emphasize or de-emphasize frequencies present in waveforms. For example, low-pass filters preserve low frequencies and reject high frequencies.

Applying a filter to an input waveform results in a "response" output waveform.

Igor can design and apply Finite Impulse Response (FIR) and Infinite Impulse Response (IIR) digital filters.

Other forms of digital filtering exist in Igor, signficantly the various Smoothing operations (see **Smoothing** on page III-292), which includes Savitzky-Golay, Loess, median, and moving-average smoothing.

Using the **Convolve** operation directly is another way to perform digital filtering, but that requires more knowledge than using the Filter Design and Application Dialog discussed below.

The Igor Filter Design Laboratory (IFDL) package can also be used to design and apply digital filters. IFDL is documented in the "Igor Filter Design Laboratory" help file.

Sampling Frequency and Design Frequency Bands

The XY Model of Data is not used in digital filtering. Use the Waveform Model of Data, and set the sampling frequency using **SetScale** or the Change Wave Scaling dialog.

For example, a waveform sampled at 44.1KHz (the sample rate of music on a compact disc) should have its X scaling set by a command such as:

```
SetScale/P x, 0, 1/44100, "s", musicWave
```

Typically filters are designed by specifying frequency "bands" that define a range of frequencies and the desired response amplitude (gain) and phase in that band.

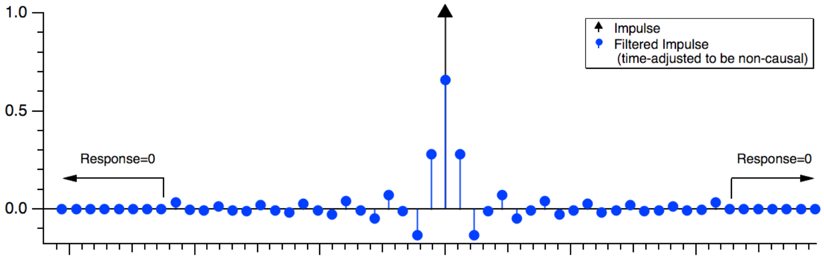
The range of frequencies that are possible range from 0 to one-half the sampling frequency of the signal, which is called the "Nyquist frequency". In the example of musicWave, the Nyquist frequency is 22,050 Hz, so filter designs for that waveform define frequency bands that end no higher than 22,050 Hz.

Filter Design Output

The result of a filter design is a set of filter "coefficients" that are used to implement the filtering. The coefficient values and format depend on the filter design type, number of bands, band frequencies, and other parameters that define the filter response. The formats for FIR and IIR designs are quite different.

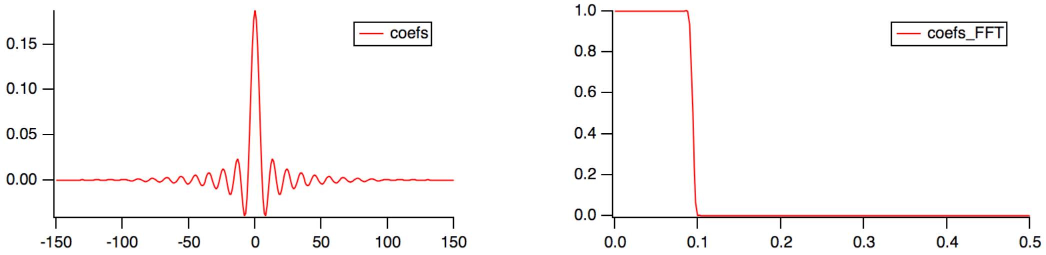
FIR Filters

Finite Impulse Response (FIR) means that the filter's time-domain response to an impulse ("spike") is zero after a finite amount of time:



An FIR filter is a finite length, evenly-spaced time series of impulses with varying amplitudes that is convolved with an input signal to produce a filtered output signal.

The impulse response amplitudes are termed "weighting factors" or "coefficients". They are identical to the filter's response to a unit impulse. You can observe an FIR filter's frequency response by simply computing the FFT of the coefficients. If you set the X scaling of the coefficients to match the sampling frequency of the data it will be applied to, the FFT result's frequency range will be scaled to the data's Nyquist frequency. For default X scaling, the frequency range will be 0 to 0.5 Hz:

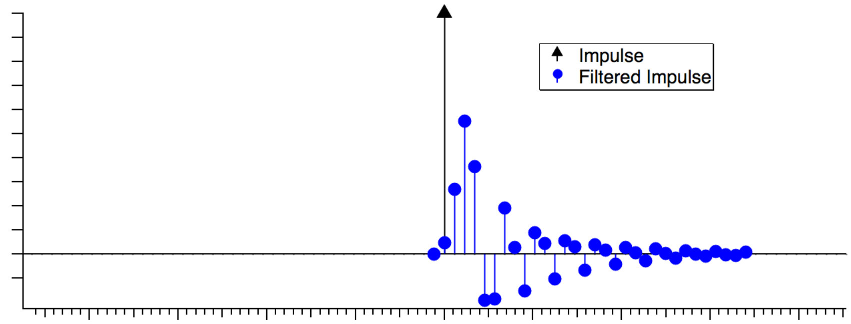


FIR filters are valued for their completely linear phase (constant delay for all frequencies), but they generally need many more coefficients than IIR filters do to achieve similar frequency responses. Consequently, electronic digital realizations of FIR filters are usually more expensive than the corresponding IIR filter.

You supply FIR coefficients to the **FilterFIR** operation along with the input waveform to compute the filtered output waveform.

IIR Filters

The response of an Infinite Impulse Response (IIR) filter continues indefinitely, as it does for analog electronic filters that employ inductors and capacitors:



An IIR filter is a set of coefficients or weights a0, a1, a2,… and b0, b1, b2… whose values and use depend on the digital implementation topology. Unlike the FIR filter, these coefficients are not the same as the filter's response to a unit impulse. See the “IIR Filter Design” topic in the “Igor Filter Design Laboratory” help file for further explanation.

IIR filters can realize quite sophisticated frequency responses with very few coefficients. The drawbacks are non-linear phase, potential for numerical instability (oscillation) when realized using limited-precision arithmetic, and the indirect design methodology (frequency transformations of conventional analog filter methods).

Igor uses two IIR implementations:

- Direct Form I (DF I)
- Cascaded Bi-Quad Direct Form II (DF II)

The IIR coefficients are represented in three forms:

- DF I
- DF II
- "zeros and poles" form

The zeros and poles form is discussed under “IIR Analog Prototype Design Graph” in the “Igor Filter Design Laboratory” help file.

You supply IIR coefficients to the FilterIIR operation along with the input waveform to compute the filtered output waveform. The format of IIR design coefficients depends on the implementation, as you can see in tables showing coefficients for Direct Form 1, Cascaded Bi-Quad Direct Form II, and pole-zero implementations of the same filter design.

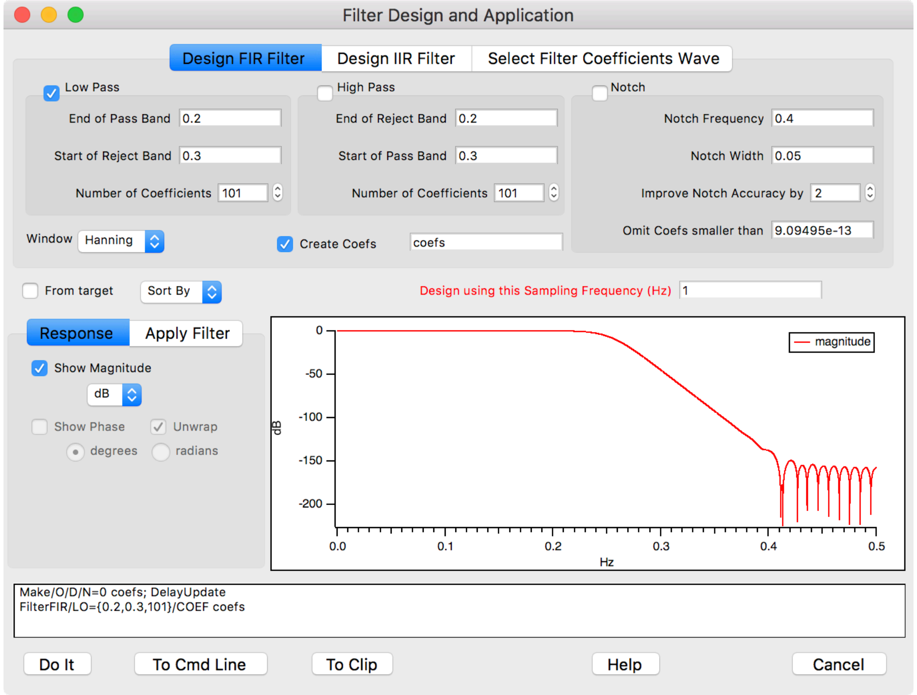
Filter Design and Application Dialog

The Filter Design and Application dialog provides a simple user-interface for designing and applying a digital filter. Choose Analysis→Filter to display it:



Filter Design and Application

☑ Low Pass
End of Pass Band 0.2
Start of Reject Band 0.3
Number of Coefficients 101

□ High Pass
End of Reject Band 0.2
Start of Pass Band 0.3
Number of Coefficients 101

□ Notch
Notch Frequency 0.4
Notch Width 0.05
Improve Notch Accuracy by 2
Omit Coefs smaller than 9.09495e-13

Window Hanning

☑ Create Coefs coefs

□ From target Sort By

Design using this Sampling Frequency (Hz) 1

☑ Show Magnitude dB
□ Show Phase ☑ Unwrap
● degrees ○ radians

```
Make/O/D/N=0 coefs; DelayUpdate
FilterFIR/LO={0.2,0.3,101}/COEF coefs
```

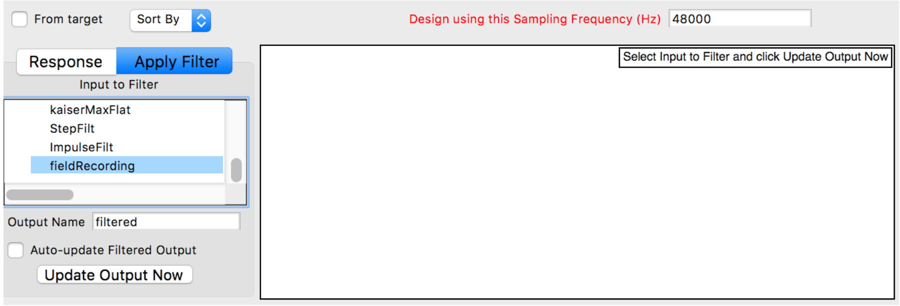
This dialog allows you to design a subset of the Igor Filter Design Laboratory's filters. It is simpler and the filters are sufficient for most purposes.

Initially the Design FIR Filter tab is shown with a simple Low Pass filter pre-selected. "Design using this Sampling Frequency (Hz)" is set to 1 and the frequencies shown are in the default range of 0 to 0.5 Hz because the default design sampling frequency is 1 Hz.

To start the filter design, either:

- Manually enter the sampling frequency or
- Click Apply Filter and select a wave to be filtered whose sampling frequency is properly set as described above

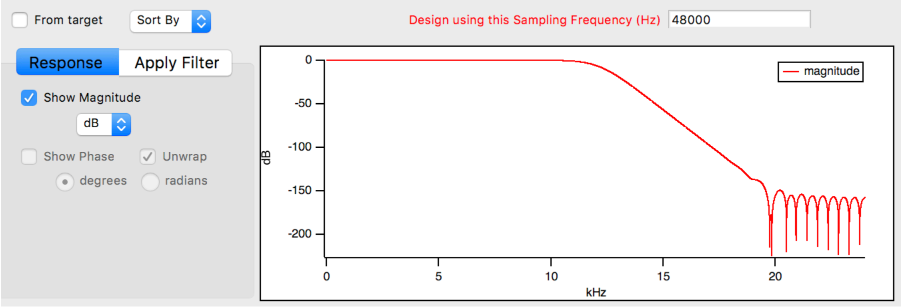
This fieldRecording wave was sampled at 48000 Hz:



Design using this Sampling Frequency (Hz) 48000

Output Name filtered

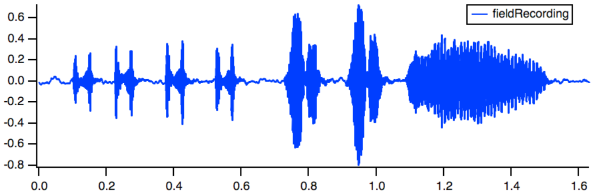
Switch back to the Response tab to show the default Low Pass filter using the entered sampling frequency. The frequency range is now 0-24000 Hz:



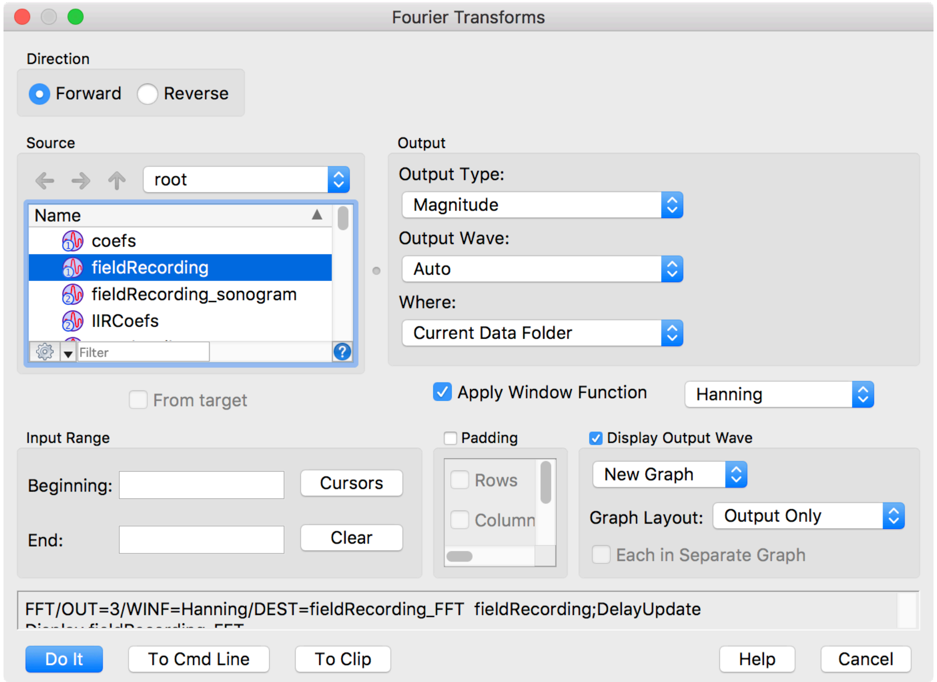
Design using this Sampling Frequency (Hz) 48000

You can use any combination of one low pass band, one high pass band, and one notch to pass or reject frequency components of the sampled data wave. By using both low pass and high pass bands you can create **Band Pass and Band Stop Filters**.

Before we apply a filter to fieldRecording, let's graph the original waveform:



It is also helpful if you know the frequency content of the input wave before filtering. Use the Analysis→Transforms→Fourier dialog:



Direction: ● Forward ○ Reverse

End:

□ Padding

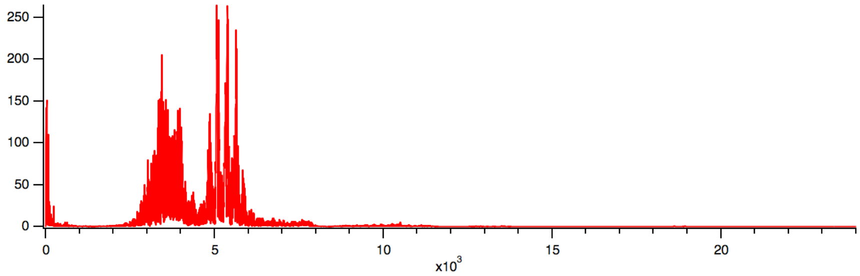
☑ Display Output Wave: New Graph

Graph Layout: Output Only

□ Each in Separate Graph

```
FFT/OUT=3/WINF=Hanning/DEST=fieldRecording_FFT  fieldRecording;DelayUpdate
```

This signal has two interesting bands of frequencies: 0 to 4.5KHz and 4.5 to about 10KHz.



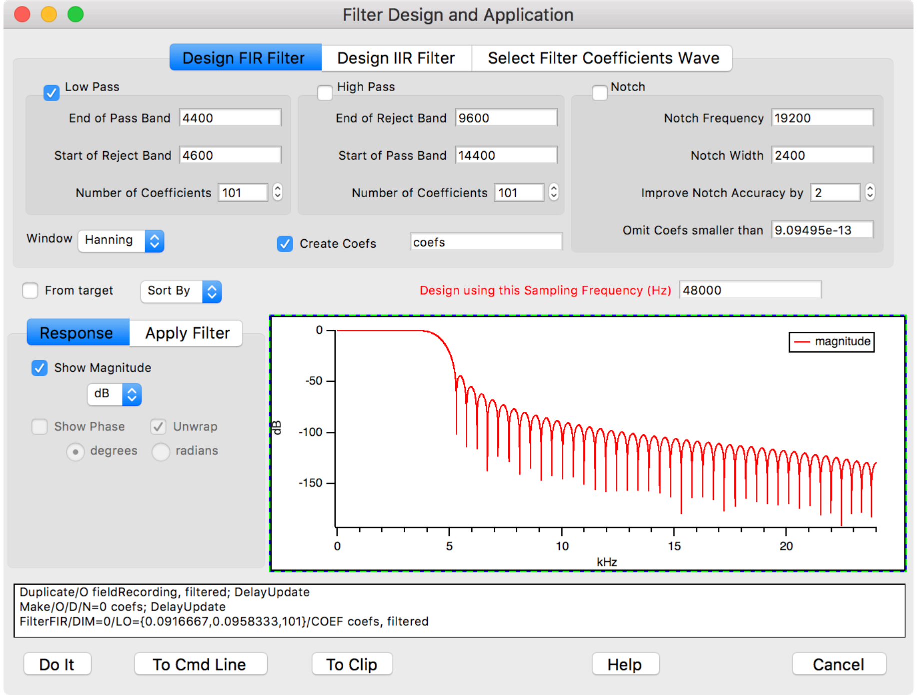
For illustrative purposes, let's walk through designing two filters that isolate each band, a low pass filter and a high pass filter.

Example: Low Pass FIR Filter

A low pass filter can be designed to keep the signal frequencies below 4.5KHz and reject higher frequencies.

An infinitely sharp cutoff between those frequencies isn't practical – it takes an infinite number of coefficients – so we specify two frequencies over which the transition from pass band to reject band happens. The smaller this transition band is, the more coefficients are needed to get a useful rejection of the higher frequencies.

Let's choose a 200 Hz transition width (4400 to 4600 Hz) and look at the frequency response with a reasonable number of coefficients (the default of 101):



☑ Low Pass
End of Pass Band 4400
Start of Reject Band 4600
Number of Coefficients 101

□ High Pass
End of Reject Band 9600
Start of Pass Band 14400
Number of Coefficients 101

□ Notch
Notch Frequency 19200
Notch Width 2400
Improve Notch Accuracy by 2
Omit Coefs smaller than 9.09495e-13

Window Hanning
☑ Create Coefs coefs
□ From target
Design using this Sampling Frequency (Hz) 48000

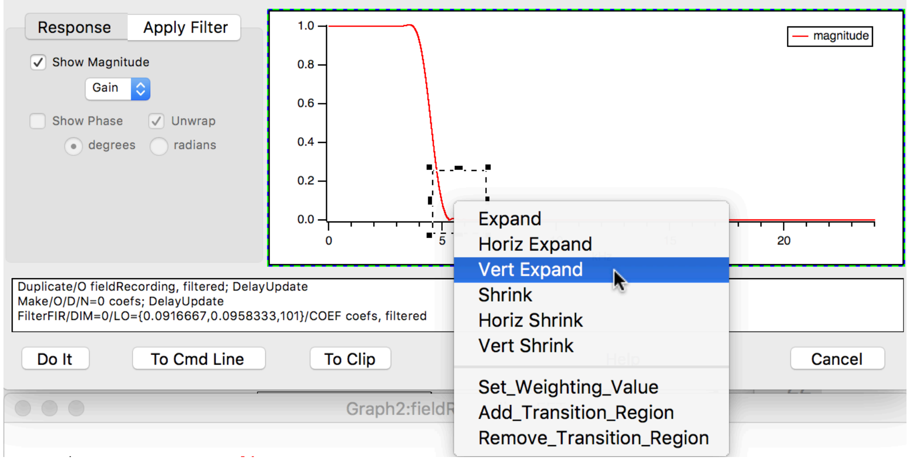
☑ Show Magnitude dB
□ Show Phase ☑ Unwrap ● degrees ○ radians

```
Duplicate/O fieldRecording, filtered; DelayUpdate
Make/O/D/N=0 coefs; DelayUpdate
FilterFIR/DIM=0/LO={0.0916667,0.0958333,101}/COEF coefs, filtered
```

What does dB mean?

dB, an abbreviation for "decibel", is a logarithmic unit used to express the ratio of one value to another. In filtering it is the ratio of the output amplitude to the input amplitude at a given frequency. 0 dB means no change in ratio and is the response of a filter in the pass band.

dB is computed as 20 * log(ratio) where ratio is output amplitude divided by input amplitude. So -100dB means a ratio of 10^{-5} or 0.00001. You can see this by switching the response from dB to Gain and expanding the range vertically quite a lot:



☑ Show Magnitude Gain
□ Show Phase ☑ Unwrap ● degrees ○ radians

```
Duplicate/O fieldRecording, filtered; DelayUpdate
Make/O/D/N=0 coefs; DelayUpdate

Choosing FIR Band Frequencies

You can avoid reducing the amplitude of frequencies near the end of the pass band by increasing the End of Pass Band frequency. A larger number of cofficients may be needed.

Choosing Number of Coefficients for FIR Designs

You can obtain a steeper transition from the pass band to the reject band by increasing the number of coefficients.

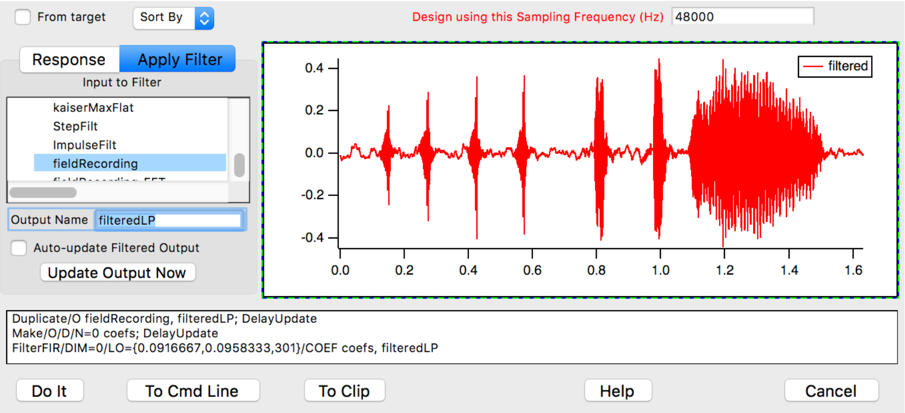
For an FIR filter, use an odd number of coefficients so that the the filtered output waveform is not delayed by a one-half sample.

Applying an FIR Filter to Data

Click the Apply Filter tab to see the result of applying the designed filter to a waveform.

Select the input wave in the Input to Filter listbox and click either Auto-update Filtered Output checkbox or the Update Output Now button. This updates a preview of the filtered result:



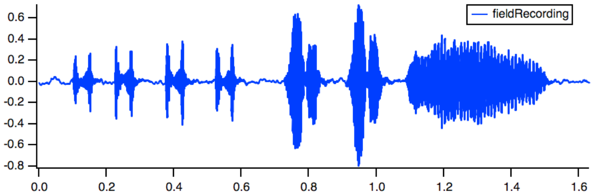
Design using this Sampling Frequency (Hz) 48000

Output Name filteredLP

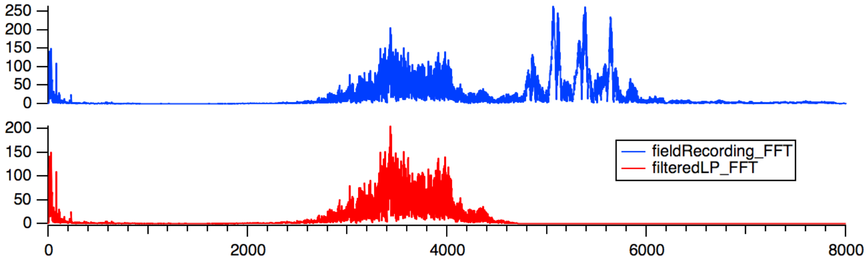
```
Duplicate/O fieldRecording, filteredLP; DelayUpdate
Make/O/D/N=0 coefs; DelayUpdate
FilterFIR/DIM=0/LO={0.0916667,0.0958333,301}/COEF coefs, filteredLP
```

Click Do It to create a final output wave in the current data folder. You can set the name of the final output wave in the Output Name field. Here we used "filteredLP".

For comparision, here is the unfiltered fieldRecording:



The preview in the dialog shows that the higher-frequency elements are removed in the filtered output. An FFT of the filteredLP result verifies the change:



Applying an FIR Filter to Other Data

You can reuse a filter if you keep a copy of the design's output coefficients. For example:

```
Duplicate/O coefs, savedFIRfilter // Keep a copy of the filter design
```

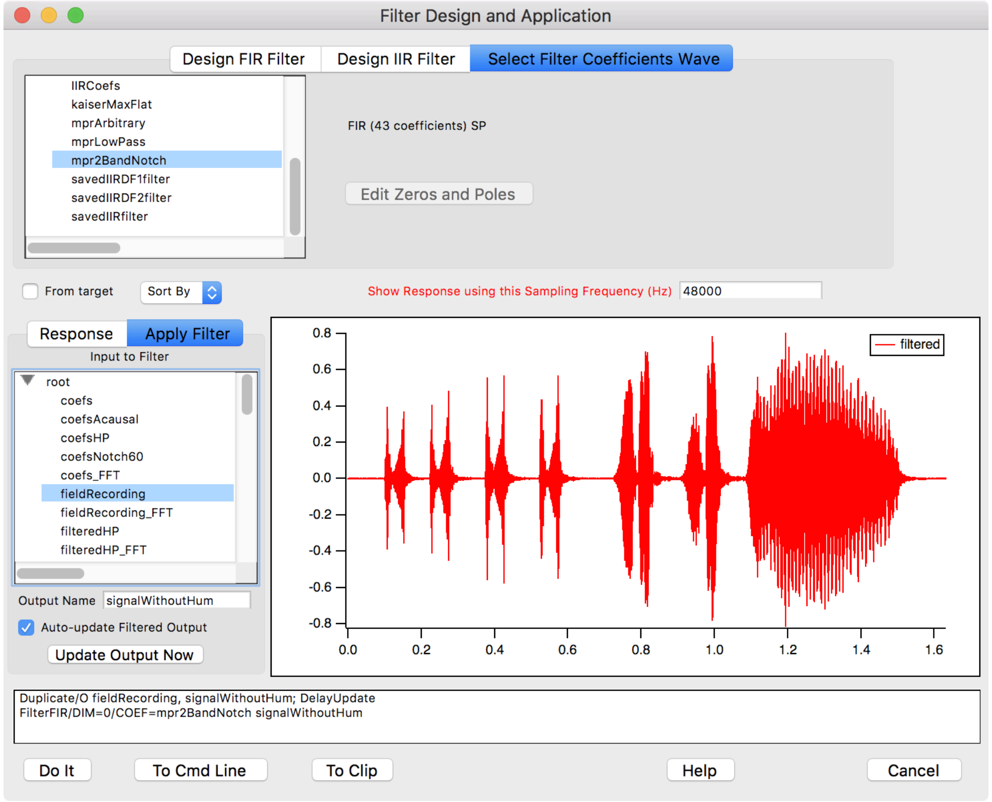
You can apply the saved FIR filter to other data using the FilterFIR operation directly or using the **Select Filter Coefficients Wave** tab of the Filter dialog. Using the **FilterFIR** operation:

```
Duplicate/O otherData, otherDataFiltered
FilterFIR /DIM=0 /COEF=savedFIRfilter otherDataFiltered
```

Select Filter Coefficients Wave

This section shows how to apply a saved FIR or IIR filter to other data using the Filter Design and Application Dialog dialog.

1. Select the saved filter design wave in the Select Filter Coefficients Wave tab of the dialog.
2. Select the wave to be filtered from the Apply Filter tab below.



FIR (43 coefficients) SP

Show Response using this Sampling Frequency (Hz) 48000

Output Name signalWithoutHum

☑ Auto-update Filtered Output

```
Duplicate/O fieldRecording, signalWithoutHum; DelayUpdate
FilterFIR/DIM=0/COEF=mpr2BandNotch signalWithoutHum
```

Example: High Pass FIR Filter

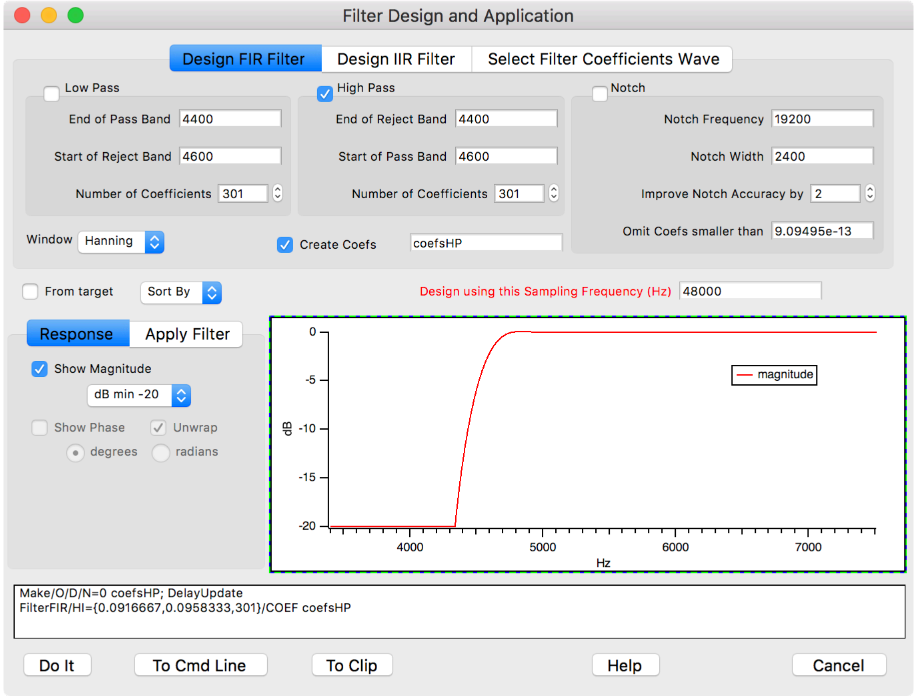
Next we design a high pass filter that preserves only the signal components that were removed by the low pass filter.

Choose Analysis→Filter and set "Design using this Sampling Frequency (Hz)" to 48000.

Uncheck Low Pass, check High Pass, and leave uncheck Notch.

Choosing High Pass FIR Band Frequencies

Set the End of Reject Band to 4400 and set Start of Pass Band to 4600 to define the same transition band as the low pass filter that we created above. Use 301 terms to get a steep transition between rejecting low frequencies and passing high frequencies:



Filter Design and Application

```

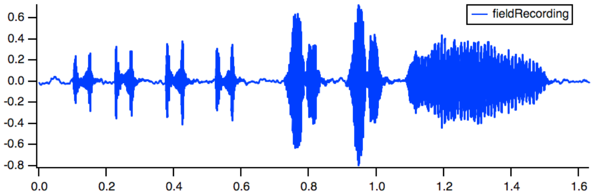
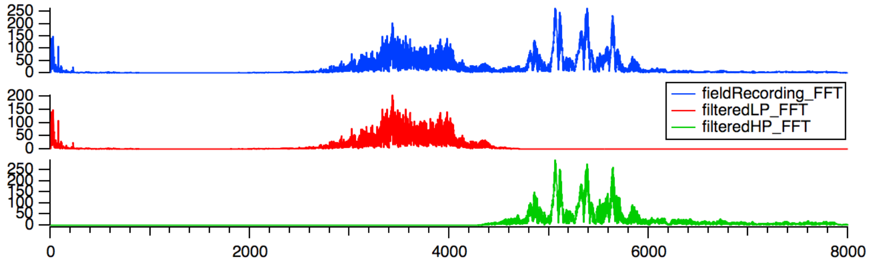
For comparision, here is the unfiltered fieldRecording:



The preview in the dialog shows that the lower-frequency elements are removed in the filtered output.

Click Do It to create the filteredHP result of high pass filtering the fieldRecording waveform.

An FFT of the filteredHP result verifies the change:



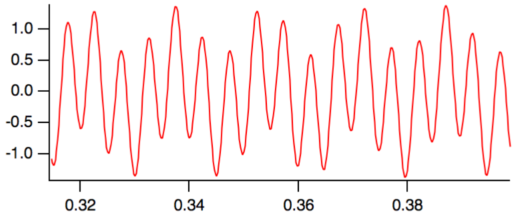
Another way to evaluate the filtering result is to use the PlaySound operation on the original and filtered waveforms:

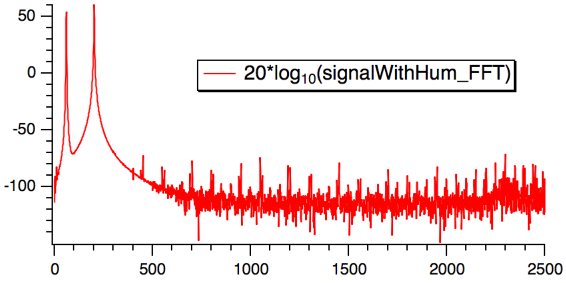
```
PlaySound fieldRecording
PlaySound filteredLP
PlaySound filteredHP
```

Example: Notch FIR Filter

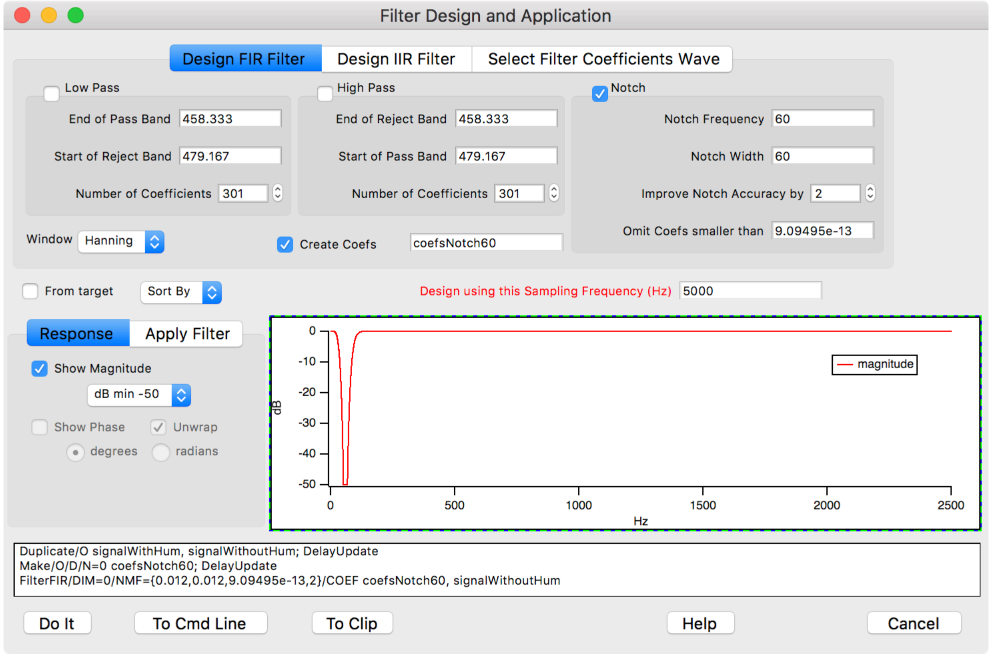
A notch filter is usually employed to reject a very narrow range of frequencies that interfere with the desired signal. Removing the interference of 50 or 60 Hz power signals from phsyiological waveforms is one such use case.

Here is a synthesized waveform with a 5000 Hz sampling frequency, a 200 Hz signal, and 60 Hz interference. The graph on the right shows it's spectral content:





Check the Notch checkbox and uncheck the Low Pass and High Pass checkboxes to create a notch-only filter.



□ Low Pass

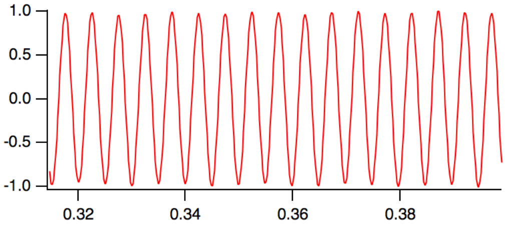
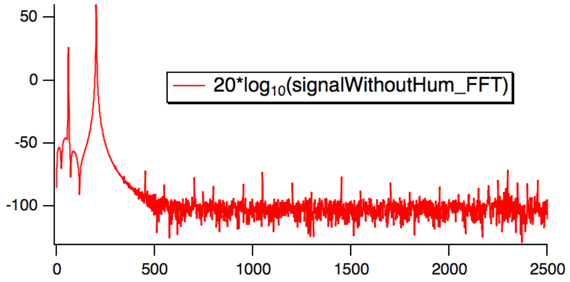
FilterFIR/DIM=0/NMF={0.012,0.012,9.09495e-13,2}/COEF coefsNotch60, signalWithoutHum
```

The FilterFIR operation uses high-precision calculations to get a deep notch at the selected frequency, preferring to adjust the frequency to get deeper notches. The Improve Notch Accuracy value (nMult in the **FilterFIR** documentation) indirectly sets the number of coefficients used to implement the notch.

Here is the result of this filter design:





The frequency response on the right does not look all that different but the filtered signal on the left has much less of the interfering 60 Hz signal.

Other FIR Designs using IFDL

The FIR filters created using the Filter Design and Application dialog are simple filters created by applying a "window" shape - such as the Hanning **WindowFunction** - to truncated sin(x)/x kernels.

The filters are functional but require a lot of coefficients to get high performance (steep filter transition bands, good rejection of unwanted frequencies). Often these aren't important shortcomings, but if the designed filter is intended for actual electronic implementation, those extra coefficients get expensive.

High-performance FIR filters using far fewer coefficients can be computed by using the Igor Filter Design Laboratory package. It optimizes both filter response and the number of filter coefficients using the Remez Exchange algorithm as described in the seminal paper by [McClellan], Parks, and Rabiner. See the **Remez** operation for additional references. See the “Igor Filter Design Laboratory” help file for details.

IIR Designs

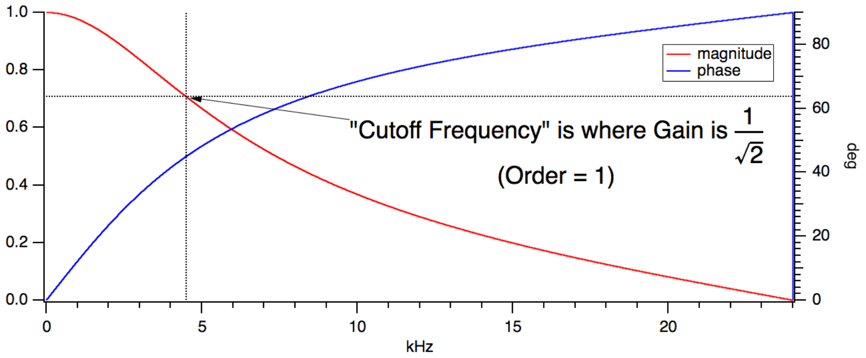
The IIR filters created using the Filter Design and Application dialog are based on tranforms of analog Butterworth filters, a standard smooth-response filter of the electrical and mechanical engineering worlds. See **IIR Filters** on page III-300 for details.

Use the Igor Filter Design Laboratory to design IIR filters based on transforms of analog Bessel and Chebyshev filters. See the “Igor Filter Design Laboratory”help file for details.

Like the **IIR Filters**, the easily-designed IIR filters are specified in terms of filter type (low pass, high pass, notch) and design frequencies.

Choosing IIR Band Frequencies

Unlike FIR Design, the IIR Design uses a single cutoff frequency to define pass and reject bands. You can think of the cutoff frequency as the frequency where the response begins to "cut off" (reject) frequency components of the signal. "Begins" is chosen to be at the -3 dB point of the response, the so-called "half-power" amplitude, where the gain is 1/sqrt(2) = 0.707107:

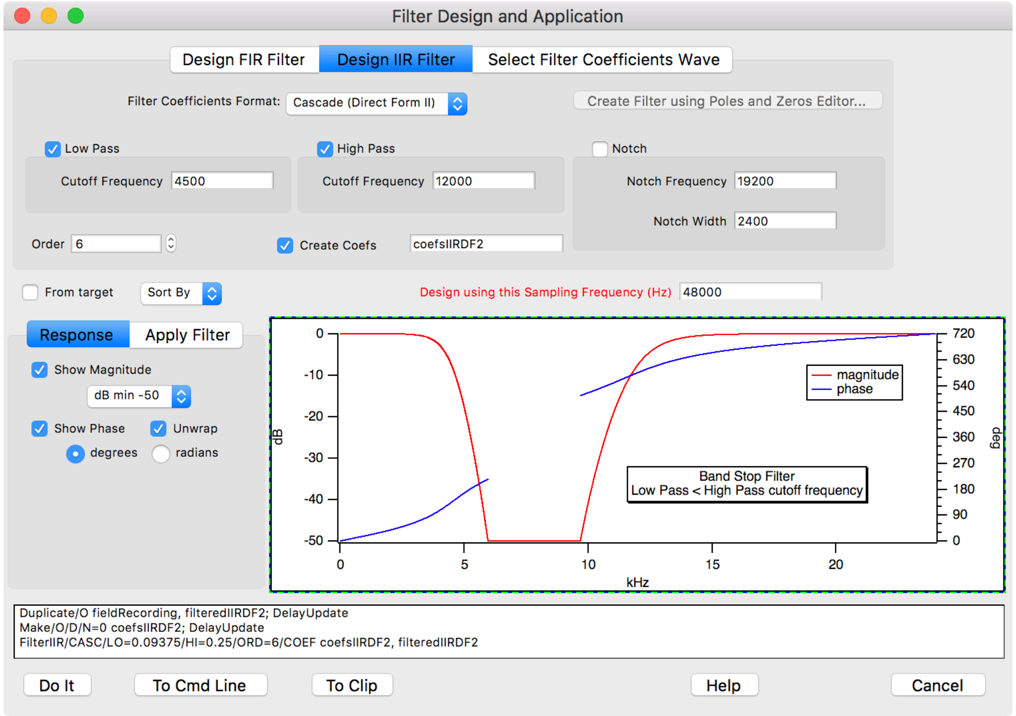


Band Pass and Band Stop Filters

A filter that passes or rejects a range of frequencies that do not include 0 or the Nyquist frequency is called a band pass or band stop filter. Such filters are useful only for preserving or rejecting a narrow range of frequencies. A notch filter is a kind of band stop filter that has its own special implementation.

Band pass and band stop filters both use the Low Pass and High Pass settings of the dialog. The difference is which cutoff frequency is lower than the other.

If the low pass cutoff frequency is less than high pass cutoff frequency, the result is a band stop filter:



Filter Coefficients Format: Cascade (Direct Form II)

☑ Low Pass Cutoff Frequency 4500

☑ High Pass Cutoff Frequency 12000

□ Notch Notch Frequency 19200 Notch Width 2400

Order 6

☑ Create Coefs coefsIIRDF2

□ From target

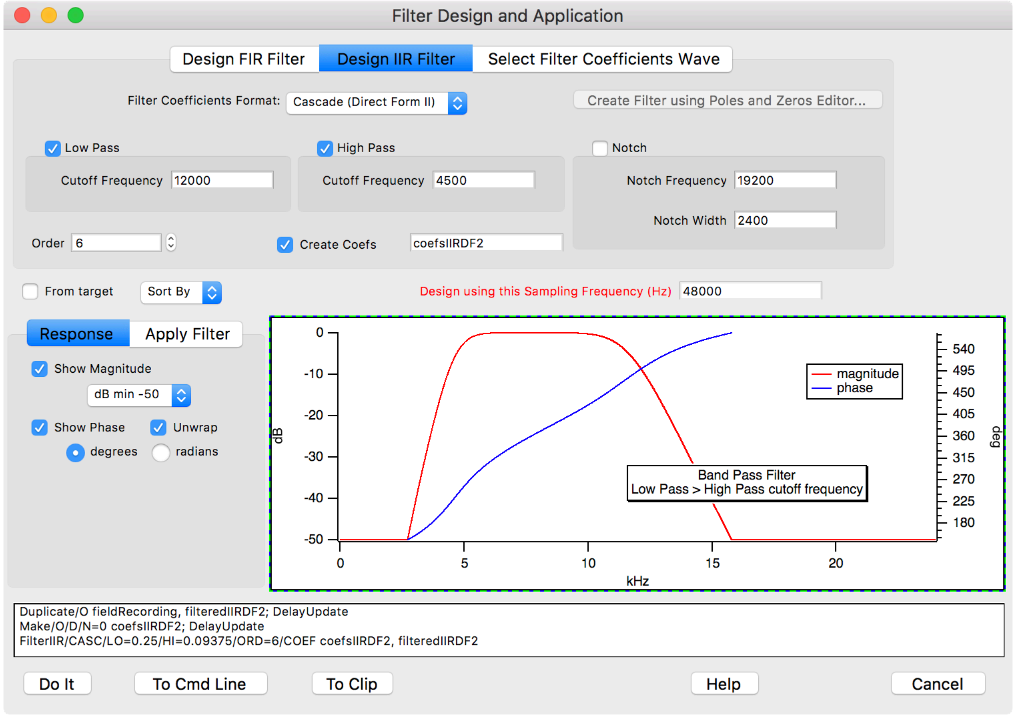
Design using this Sampling Frequency (Hz) 48000

☑ Show Magnitude dB min -50

☑ Show Phase ☑ Unwrap ● degrees ○ radians

```
Duplicate/O fieldRecording, filteredIIRDF2; DelayUpdate
Make/O/D/N=0 coefsIIRDF2; DelayUpdate
FilterIIR/CASC/LO=0.09375/HI=0.25/ORD=6/COEF coefsIIRDF2, filteredIIRDF2
```

If the high pass cutoff frequency is less than low pass cutoff frequency, the result is a band pass filter:



Filter Coefficients Format: Cascade (Direct Form II)

☑ Low Pass Cutoff Frequency 12000

☑ High Pass Cutoff Frequency 4500

□ Notch Notch Frequency 19200 Notch Width 2400

Order 6

☑ Create Coefs coefsIIRDF2

□ From target

Design using this Sampling Frequency (Hz) 48000

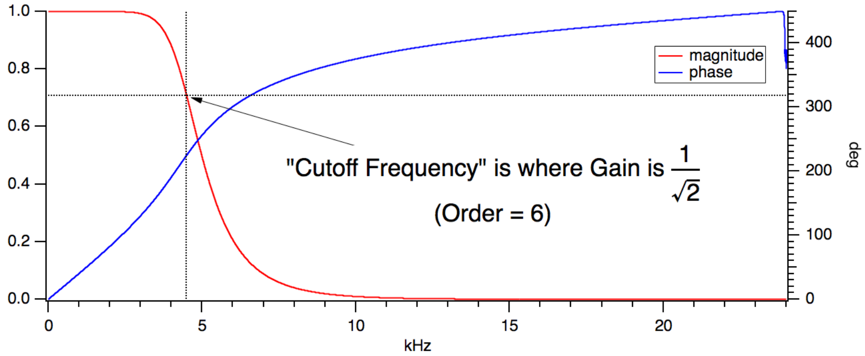
☑ Show Magnitude dB min -50

☑ Show Phase ☑ Unwrap ● degrees ○ radians

```
Duplicate/O fieldRecording, filteredIIRDF2; DelayUpdate
Make/O/D/N=0 coefsIIRDF2; DelayUpdate
FilterIIR/CASC/LO=0.25/HI=0.09375/ORD=6/COEF coefsIIRDF2, filteredIIRDF2
```

Choosing Order for IIR Designs

Instead of adjusting the number of coefficients to alter the performance of the filtering, IIR designs use a filter "order". Essentially, each order represents another layer of recursive filtering. A higher-order filter has steeper band transitions, more phase shift, and can be numerically less stable. Increasing the order from 1 to 6 creates a much steeper transition:



"Cutoff Frequency" is where Gain is $\frac{1}{\sqrt{2}}$

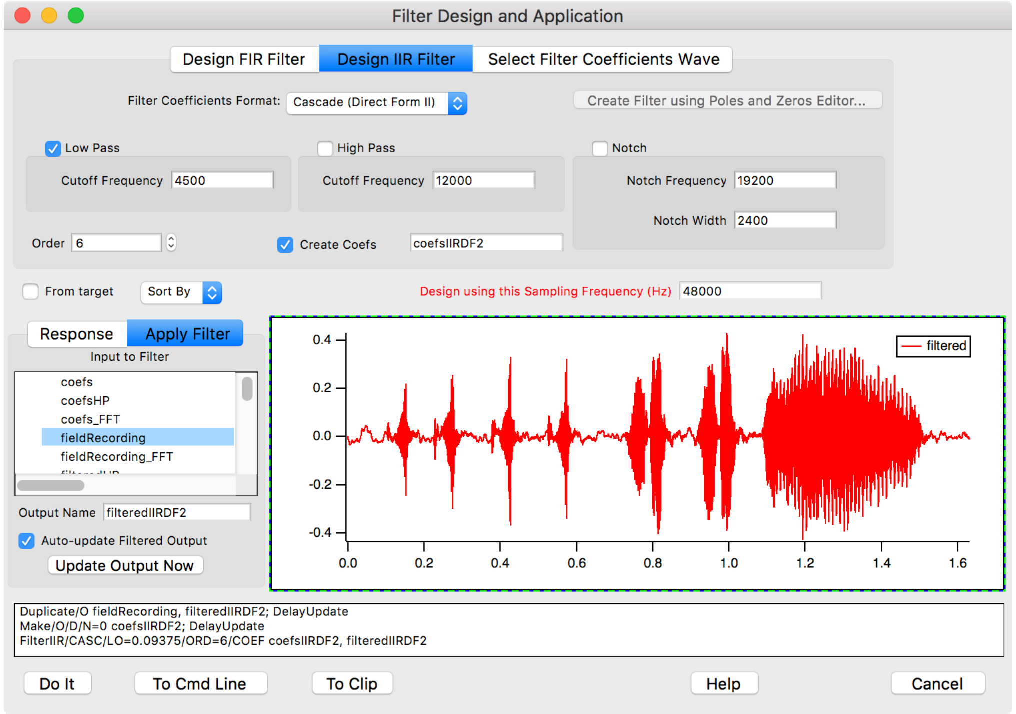
(Order = 6)

Applying an IIR Filter to Data

Click the Apply Filter tab to see the result of applying the designed filter to a waveform.

Select the input wave in the Input to Filter listbox and click either Auto-update Filtered Output checkbox or the Update Output Now button. This updates a preview of the filtered result.

Click Do It to create a final output wave in the current data folder. You can set the name of the final output wave in the Output Name field. Here we used filteredIIRDF2:



Filter Coefficients Format: Cascade (Direct Form II)

☑ Low Pass
Cutoff Frequency 4500

□ High Pass
Cutoff Frequency 12000

□ Notch
Notch Frequency 19200
Notch Width 2400

Order 6

☑ Create Coefs coefsIIRDF2

□ From target

Design using this Sampling Frequency (Hz) 48000

Output Name filteredIIRDF2

☑ Auto-update Filtered Output

```
Duplicate/O fieldRecording, filteredIIRDF2; DelayUpdate
Make/O/D/N=0 coefsIIRDF2; DelayUpdate
FilterIIR/CASC/LO=0.09375/ORD=6/COEF coefsIIRDF2, filteredIIRDF2
```

Evaluating a Digital Filter

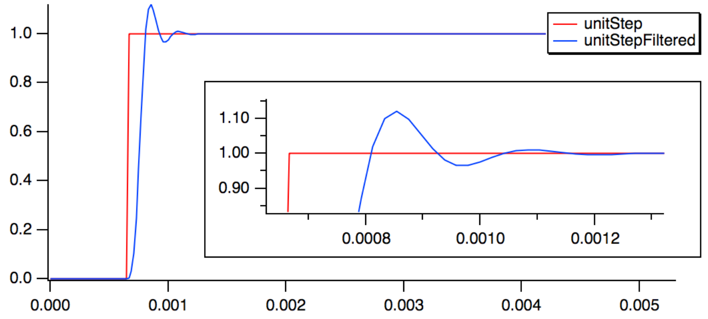
The graph in the Response tab of the Filter Design and Application dialog is the most direct way to evaluate what the filter will do to an input waveform.

You can also graph the original data and filtered data for a detailed visual comparision.

A useful technique, borrowed from electrical engineering, is to see how the filter responds to an ideal "unit step" waveform:

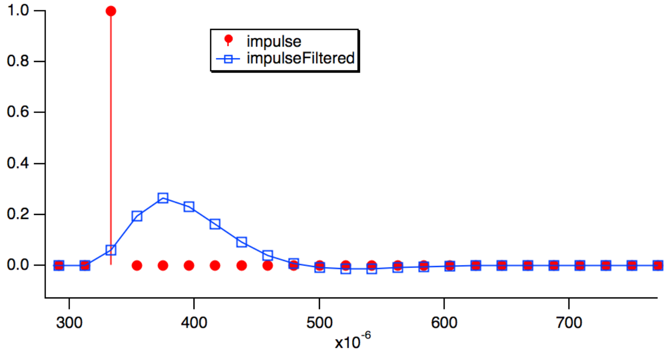
```
Make/O/N=256 unitStep = p >= 32      // Unit step wave for causal IIR filters
CopyScales/P yourData, unitStep      // Same sampling frequency as your data
```

```
Duplicate/O unitStep, unitStepFiltered
FilterIIR/DIM=0/COEF=savedIIRDF1filter unitStepFiltered
Display unitStep, unitStepFiltered
```

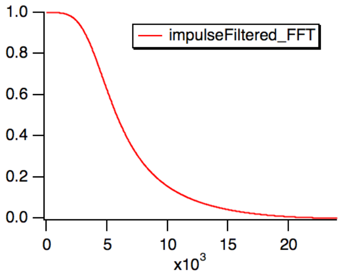


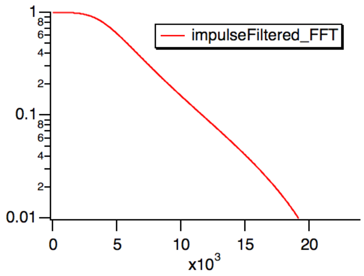
The next example shows how the filter responds to an ideal "unit impulse" waveform and display it's FFT magnitude, as the Filter Design and Application dialog does:

```
Make/O/N=2048 impulse = p == 16     // Unit step wave for causal IIR filters
CopyScales/P yourData, impulse
Duplicate/O impulse, impulseFiltered
FilterIIR/CASC/DIM=0/COEF=savedIIRDF2filter impulseFiltered // DF II 
implementation needs /CASC
Display impulse, impulseFiltered
```



```
FFT/MAG/DEST=impulseFiltered_FFT impulseFiltered   // Magnitude of response
Display impulseFiltered_FFT
Display impulseFiltered_FFT      // A logarithmic axis has the same shape
ModifyGraph log(left)=1          // as computing 20*log(response)
```





Applying an IIR Filter to Other Data

You can reuse a filter if you keep a copy of the design's output coefficients. For example:

```
Duplicate/O coefs, savedIIRfilter // Keep a copy of the filter design.
```

You can apply the saved IIR filter to other data using the **FilterIIR** operation:

```
Duplicate/O otherData, otherDataFiltered
FilterIIR/DIM=0/COEF=savedIIRfilter otherDataFiltered
```

You can also apply the saved IIR filter to other data using the **Select Filter Coefficients Wave** tab of the Filter dialog.

Rotate Operation

The **Rotate** operation (see page V-810) rotates the data values of the selected waves by a specified number of points. Choose Data→Rotate Waves to display the Rotate dialog.

Think of the data values of a wave as a column of numbers. If the specified number of points is positive the points in the wave are rotated downward. If the specified number of points is negative the points in the wave are rotated upward. Values that are rotated off one end of the column wrap to the other end.

The rotate operation shifts the X scaling of the rotated wave so that, except for the points which wrap around, the X value of a given point is not changed by the rotation. To observe this, display the X scaling and data values of the wave in a table and notice the effect of Rotate on the X values.

This change in X scaling may or may not be what you want. It is usually not what you want if you are rotating an XY pair. In this case, you should undo the X scaling change using the SetScale operation:

```
SetScale/P x,0,1,"",waveName     // replace waveName with name of your wave
```

Also see the example of rotation in **Spectral Windowing** on page III-275.

For multi-dimensional wave rotation, see the **MatrixOp** rotateRows, rotateCols, rotateLayers, and rotateChunks functions.

Unwrap Operation

The **Unwrap** operation (see page V-1050) scans through each specified wave trying to undo the effect of a modulus operation. For example, if you perform an FFT on a wave, the result is a complex wave in rectangular coordinates. You can create a real wave which contains the phase of the result of the FFT with the command:

```
wave2 = imag(r2polar(wave1))
```

However the rectangular-to-polar conversion leaves the phase information modulo 2π. You can restore the continuous phase information with the command:

```
Unwrap 2*Pi, wave2
```

The Unwrap operation is designed for 1D waves only. Unwrapping 2D data is considerably more difficult. See the **ImageUnwrapPhase** operation on page V-433 for more information

Choose Analysis→Unwrap to display the Unwrap Waves dialog.

Analysis of Functions

Operations that Work on Functions

Some Igor operations work on functions rather than data in waves. These operations take as input one or more functions that you define in the Procedure window. The result is some calculation based on function values produced when Igor evaluates your function.

Because the operations evaluate a function, they work on continuous data. That is, the functions are not restricted to data values that you provide from measurements. They can be evaluated at any input values. Of course, a computer works with discrete digital numbers, so even a “continuous” function is broken into discrete values. Usually these discrete values are so close together that they are continuous for practical purposes. Occasionally, however, the discrete nature of computer computations causes problems.

The following operations use functions as inputs:

- **IntegrateODE** computes numerical solutions to ordinary differential equations. The differential equations are defined as user functions. The IntegrateODE operation is described under **Solving Differential Equations** on page III-322.
- **FindRoots** computes solutions to f(x)=a, where a is a constant (often zero). The input x may represent a vector of x values. A special form of FindRoots computes roots of polynomials. The FindRoots operation is described in the section **Finding Function Roots** on page III-338.
- **Optimize** finds minima or maxima of a function, which may have one or more input variables. The Optimize operation is described in the section **Finding Minima and Maxima of Functions** on page III-343.
- **Integrate1D** integrates a function between two specified limits. Despite its name, it can also be used for integrating in two or more dimensions. See **Integrating a User Function** on page III-336.

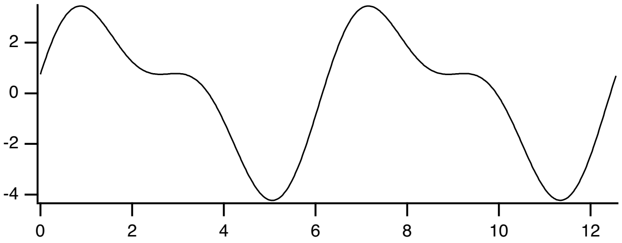
Function Plotting

Function plotting is very easy in Igor, assuming that you understand what a waveform is (see **Waveform Model of Data** on page II-62) and how X scaling works. Here are the steps to plot a function.

1. Decide how many data points you want to plot.
2. Make a wave with that many points.
3. Use the SetScale operation to set the wave’s X scaling. This defines the domain over which you are going to plot the function.
4. Display the wave in a graph.
5. Execute a waveform assignment statement to set the data values of the wave.

Here is an example.

```
Make/O/N=500 wave0
SetScale/I x, 0, 4*PI, wave0      // plot function from x=0 to x=4π
Display wave0
wave0 = 3*sin(x) + 1.5*sin(2*x + PI/6)
```



To evaluate the function over a different domain, you need to reexecute the SetScale command with different parameters. This redefines “x” for the wave. Then you need to reexecute the waveform assignment statement. For example,

```
SetScale/I x, 0, 2*PI, wave0      // plot function from x=0 to x=2π
wave0 = 3*sin(x) + 1.5*sin(2*x + PI/6)
```

Reexecuting commands is easy, using the shortcuts shown in **History Area** on page II-9.

Function Plotting Using Dependencies

If you get tired of reexecuting the waveform assignment statement each time you change the domain, you can use a dependency to cause Igor to automatically reexecute it. To do this, use := instead of =.

```
wave0 := 3*sin(x) + 1.5*sin(2*x + PI/6)
```

See Chapter IV-9, **Dependencies**, for details.

You have made `wave0` depend on “X”. The SetScale operation changes the meaning of “X” for the wave. Now when you do a SetScale on `wave0`, Igor will automatically reexecute the assignment.

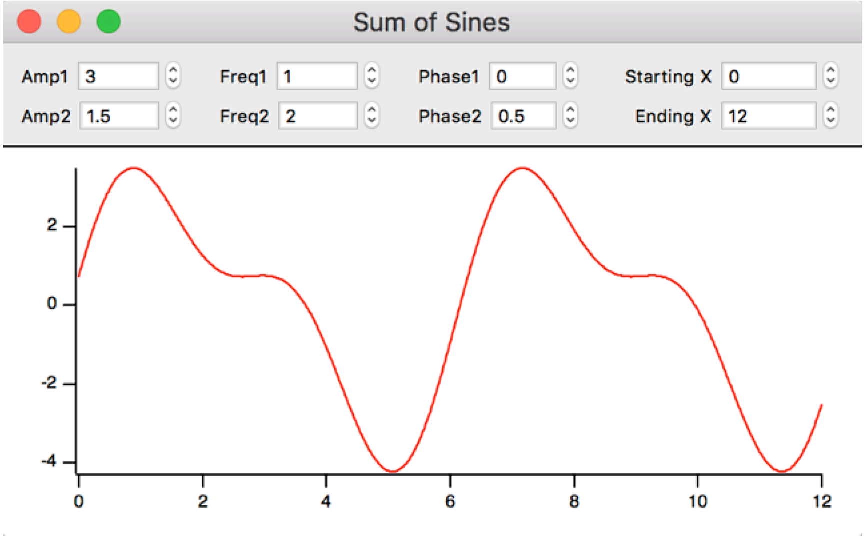
You can take this further by using global variables instead of literal numbers in the right-hand expression. For example:

```
Variable/G amp1=3, amp2=1.5, freq1=1, freq2=2, phase1=0, phase2=PI/6
wave0 := amp1*sin(freq1*x + phase1) + amp2*sin(freq2*x + phase2)
```

Now, wave0 depends on these global variables. If you change them, Igor will automatically reexecute the assignment.

Function Plotting Using Controls

For a slick presentation of function plotting, you can put controls in the graph to set the values of the global variables. When you change the value in the control, the global variable changes, which reexecutes the assignment. This changes the wave, which updates the graph. Here is what the graph would look like.



We’ve added two additional global variables and connected them to the Starting X and Ending X controls. This allows us to set the domain. These controls are both linked to an action procedure that does a SetScale on the wave.

Controls are explained in detail in Chapter III-14, **Controls and Control Panels**.

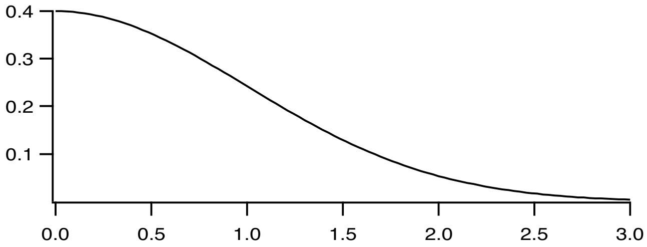
Plotting a User-Defined Function

In the preceding example we used the built-in sin function in the right-hand expression. We can also use a user-defined function. Here is an example using a very simple function — the normal probability distribution function.

```
Function NormalProb(x)
   Variable x

   // the constant is 1/sqrt(2*pi) evaluated in double-precision
   return     0.398942280401433*exp(-(0.5*x^2))
End

Make/N=100 wave0; SetScale/I x, 0, 3, wave0; wave0 = NormalProb(x)
Display wave0
```



Note that, although we are using the NormalProb function to fill a wave, the NormalProb function itself has nothing to do with waves. It merely takes an input and returns a single output. We could also test the NormalProb function at a single point by executing

```
Print NormalProb(0)
```

This would print the output of the function in the history area.

It is the act of using the `NormalProb` function in a wave assignment statement that fills the wave with data values. As it executes the wave assignment, Igor calls the NormalProb function over and over again, 100 times in this case, passing it a different parameter each time and storing the output from the `NormalProb` function in successive points of the destination wave.

For more information on Wave Assignments, see **Waveform Arithmetic and Assignments** on page II-74. You may also find it helpful to read Chapter IV-1, **Working with Commands**.

WaveMetrics provides a procedure package that provides a convenient user interface to graph mathematical expressions. To use it, choose Analysis→Packages→Function Grapher. This displays a graph with controls to create and display a function. Click the Help button in the graph to learn how to use it.

Solving Differential Equations

Numerical solutions to initial-value problems involving ordinary differential equations can be calculated using the **IntegrateODE** operation (see page V-452). You provide a user-defined function that implements a system of differential equations. The solution to your differential equations are calculated by marching the solution forward or backward from the initial conditions in a series of steps or increments in the independent variable.

Terminology

Referring to the independent variable and the dependent variables is very cumbersome, so we refer to these as X and Y[*i*]. Of course, X may represent distance or time or anything else.

A system of differential equations will be written in terms of derivatives of the Y[*i*]s, or dy[*i*]/dx.

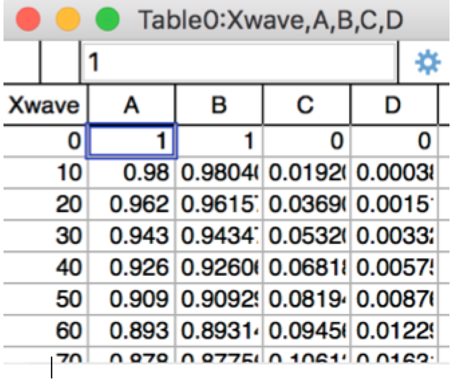
ODE Inputs

You provide to IntegrateODE a function to calculate the derivatives or right-hand-sides of your system of differential equations.

You also provide one output wave for each equation in the system to receive the solution. The solution waves will have a row for each output point you want.

You specify the independent variable either by setting the X scaling of the output waves, by specifying x0 and deltax using the /X={x0,deltax} flag, or by providing an explicit X wave using the /X=*xWave* flag.

For a system of four equations (fourth-order system), if you provide an X wave to specify where you want values, you might have this situation:



Xwave	A	B	C	D
0	1	1	0	0
10	0.98	0.9804	0.0192	0.0003
20	0.962	0.9615	0.0369	0.0015
30	0.943	0.9434	0.0532	0.0033
40	0.926	0.9260	0.0681	0.0057
50	0.909	0.9092	0.0819	0.0087
60	0.893	0.8931	0.0945	0.0122
70	0.878	0.8775	0.1061	0.0163

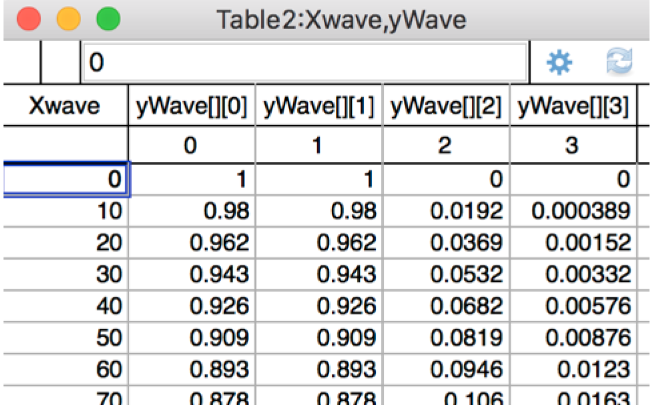
X wave, four Y waves (A, B, C, and D).

First row contains initial conditions.

Subsequent rows receive solution values.

X wave specifies where to report solutions.
In free-run mode, X wave receives X values for solution rows.

Instead of multiple 1D output waves, you can provide a single 2D output wave:



Xwave	yWave[][0]	yWave[][1]	yWave[][2]	yWave[][3]
	0	1	2	3
0	1	1	0	0
10	0.98	0.98	0.0192	0.000389
20	0.962	0.962	0.0369	0.00152
30	0.943	0.943	0.0532	0.00332
40	0.926	0.926	0.0682	0.00576
50	0.909	0.909	0.0819	0.00876
60	0.893	0.893	0.0946	0.0123
70	0.878	0.878	0.106	0.0163

Igor calculates a solution value for each element of the Y (output) waves.

Before executing IntegrateODE, you must load the initial conditions (the initial Y[*i*] values) into the first row of the Y waves. Igor then calculates the solution starting from those values. The first solution value is stored in the second element of the Y waves.

If you use the /R flag with IntegrateODE to start the integration at a point other than the beginning of the Y wave, the initial conditions must be in the first row specified by the /R flag. See **Stopping and Restarting IntegrateODE** on page III-334.

ODE Outputs

The algorithms Igor uses to integrate your ODE systems use adaptive step-size control. That is, the algorithms advance the solution by the largest increment in X that result in errors at least as small as you require. If the solution is changing rapidly, or the solution has some other difficulty, the step sizes may get very small.

IntegrateODE has two schemes for returning solution results to you: you can specify X values where you need solution values, or you can let the solution “free run”.

In the first mode, results are returned to you at values of x corresponding to the X scaling of your Y waves, or at X values that you provide via an X wave or by providing X0 and deltaX and letting Igor calculate the X values. The actual calculation may require X increments smaller than those you ask for. Igor returns results only at the X values you ask for.

In free-run mode, IntegrateODE returns solution values for every step taken by the integration algorithm. In some cases, this may give you extremely small steps. Free-run mode returns to you not only the Y[*i*] values from the solution, but also values of x[*i*]. Free-run mode can be useful in that, to some degree, it will return results closely spaced when the solution is changing rapidly and with larger spacing when the solution is changing slowly.

The Derivative Function

You must provide a user-defined function to calculate derivatives corresponding to the equations you want to solve. All equations are solved as systems of first-order equations. Higher-order equations must be transformed to multiple first-order equations (an example is shown later).

The derivative function has this form:

```
Function D(pw, xx, yw, dydx)
   Wave pw           // parameter wave (input)
   Variable xx       // x value at which to calculate derivatives
   Wave yw           // wave containing y[i] (input)
   Wave dydx         // wave to receive dy[i]/dx (output)

   dydx[0] = <expression for one derivative>
   dydx[1] = <expression for next derivative>
   <etc.>

   return 0
End
```

Note the return statement at the end of the function. The function result should normally be 0. If it is 1, IntegrateODE will stop. If the return statement is omitted, the function returns NaN which IntegrateODE treats the same as 0. But it is best to explicitly return 0.

Because the function may produce a large number of outputs, the outputs are returned via a wave in the parameter list.

The parameter wave is simply a wave containing possible adjustable constants. Using a wave for these makes it convenient to change the constants and try a new integration. It also will make it more convenient to do a curve fit to a differential equation. You must create the parameter wave before invoking IntegrateODE. The contents of the parameter wave are of no concern to IntegrateODE and are not touched. In fact, you can change the contents of the parameter wave inside your function and those changes will be permanent.

Other inputs are the value of x at which the derivatives are to be evaluated, and a wave (yw in this example) containing current values of the y[*i*]’s. The value of X is determined when it calls your function, and the waves yw and dydx are both created and passed to your function when Igor needs new values for the derivatives. Both the input Y wave and the output dydx wave have as many elements as the number of derivative equations in your system of ODEs.

The values in the yw wave correspond to a row of the table in the example above. That is:

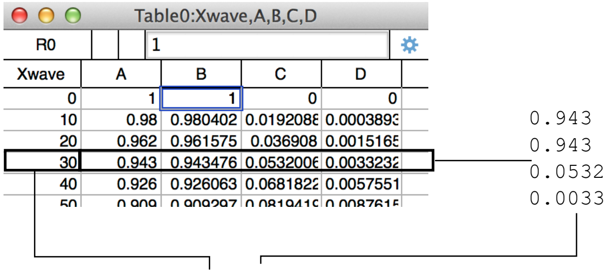


Table0:Xwave,A,B,C,D

R0 | 1

Xwave	A	B	C	D
0	1	1	0	0
10	0.98	0.980402	0.0192088	0.0003893
20	0.962	0.961575	0.036908	0.0015165
30	0.943	0.943476	0.0532006	0.0033232
40	0.926	0.926063	0.0681822	0.0057551
50	0.909	0.909297	0.0819419	0.0087615

```
Function D(pw, xx, yw, dydx)
    Wave pw     // parameter wave (input)
    Variable xx // x value at which to calculate derivatives
    Wave yw     // wave containing y[i] (input)
    Wave dydx   // wave to receive dy[i]/dx (output)

    dydx[0] = <expression for one derivative>
    dydx[1] = <expression for next derivative>
    <etc.>

    return 0
End
```

The wave yw contains the present value, or estimated value, of Y[*i*] at X =xx. You may need this value to calculate the derivatives.

Your derivative function is called many times during the course of a solution, and it will be called at values of X that do not correspond to X values in the final solution. The reason for this is two-fold: First, the solution method steps from one value of X to another using estimates of the derivatives at several intermediate X values. Second, the spacing between X values that you want may be larger than can be calculated accurately, and Igor may need to find the solution at intermediate values. These intermediate values are not reported to you unless you call the **IntegrateODE** operation (see page V-452) in free-run mode.

Because the derivative function is called at intermediate X values, the yw wave is not the same wave as the Y wave you create and pass to IntegrateODE. Note that one row of your Y wave, or one value from each Y wave, corresponds to the elements of the one-dimensional yw wave that is passed in to your derivative function. While the illustration implies that values from your Y wave are passed to the derivative function, in fact the values in the yw wave passed into the derivative function correspond to whatever Y values the integrator needs at the moment. The correspondence to your Y wave or waves is only conceptual.

You should be aware that, with the exception of the parameter wave (`pw` above) the waves are not waves that exist in your Igor experiment. Do not try to resize them with InsertPoints/DeletePoints and don't do anything to them with the Redimension operation. The yw wave is input-only; altering it will not change anything. The dydx wave is output-only; the only thing you should do with it is to assign appropriate derivative (right-hand-side) values.

Some examples are presented in the following sections.

A First-Order Equation

Let's say you want a numerical solution to a simple first-order differential equation:

$$\frac{dy}{dx} = -ay$$

First you need to create a function that calculates the derivative. Enter the following in the procedure window:

```
Function FirstOrder(pw, xx, yw, dydx)
   Wave pw        // pw[0] contains the value of the constant a
   Variable xx    // not actually used in this example
   Wave yw        // has just one element- there is just one equation
   Wave dydx      // has just one element- there is just one equation
```

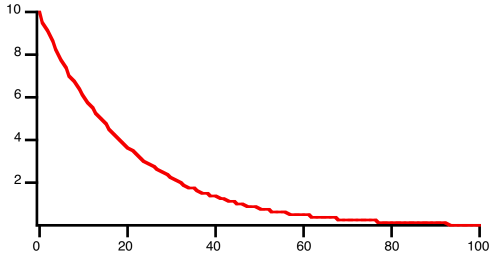
```
    // There's only one equation, so only one expression here.
    // The constant a in the equation is passed in pw[0]
    dydx[0] = -pw[0]*yw[0]

    return 0
End
```

Paste the function into the procedure window and then execute these commands:

```
Make/D/O/N=101 YY     // wave to receive results
YY[0] = 10            // initial condition- y0=10
Display YY            // make a graph
Make/D/O PP={0.05}    // set constant a to 0.05
IntegrateODE FirstOrder, PP, YY
```

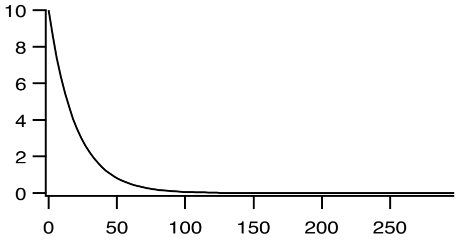
This results in the following graph with the expected exponential decay:



The IntegrateODE command shown in the example is the simplest you can use. It names the derivative function, `FirstOrder`, a parameter wave, `PP`, and a results wave, `YY`.

Because the IntegrateODE command does not explicitly set the X values, the output results are calculated according to the X scaling of the results wave `YY`. You can change the spacing of the X values by changing the X scaling of `YY`:

```
SetScale/P x 0,3,YY         // now the results will be at an x interval of 3
IntegrateODE FirstOrder, PP, YY
```



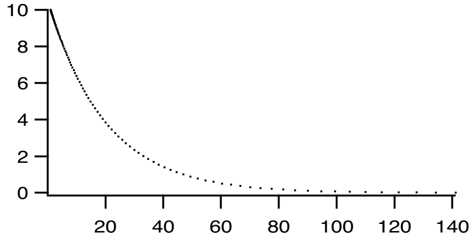
The same thing can be achieved by using your specified x0 and deltax with the /X flag:

```
IntegrateODE/X={0,3} FirstOrder, PP, YY
```

We presume that you have your own reasons for using the /X={x0, deltax} form. Note that when you do this, it doesn't use the X scaling of your Y wave. If you graph the Y wave the values on the X axis may not match the X values used during the calculation.

Finally, you don't have to use a constant spacing in X if you provide an X wave. You might want to do this to get closely-spaced values only where the solution changes rapidly. For instance:

```
Make/D/O/N=101 XX     // same length as YY
XX = exp(p/20)        // X values get farther apart as X increases
Display YY vs XX      // make an XY graph
ModifyGraph mode=2    // plot with dots so you can see the points
IntegrateODE/X=XX FirstOrder, PP, YY
```



Note that throughout these examples the initial value of YY has remained at 10.

A System of Coupled First-Order Equations

While many interesting systems are described by simple (possibly nonlinear) first-order equations, more interesting behavior results from systems of coupled equations.

The next example comes from chemical kinetics. Suppose you mix two substances A and B together in a solution and they react to form intermediate phase C. Over time C transforms into final product D:

$$A+B \underset{k_2}{\overset{k_1}{\rightleftarrows}} C \qquad\qquad C \underset{k_3}{\rightarrow} D$$

Here, k_1, k_2, and k_3 are rate constants for the reactions. The concentrations of the substances might be given by the following coupled differential equations:

$$\frac{dA}{dt} = \frac{dB}{dt} = -k_1 \cdot A \cdot B + k_2 \cdot C \qquad \frac{dC}{dt} = k_1 \cdot A \cdot B - k_2 \cdot C - k_3 \cdot C \qquad \frac{dD}{dt} = k_3 \cdot C$$

To solve these equations, first we need a derivative function:

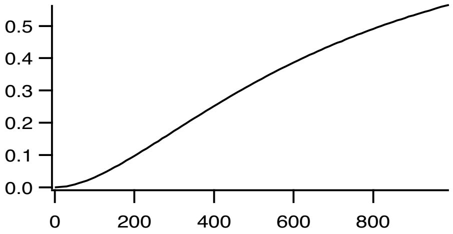
```
Function ChemKinetic(pw, tt, yw, dydt)
   Wave pw           // pw[0] = k1, pw[1] = k2, pw[2] = k3
   Variable tt       // time value at which to calculate derivatives
   Wave yw           // yw[0]-yw[3] containing concentrations of A,B,C,D
   Wave dydt         // wave to receive dA/dt, dB/dt etc. (output)
   dydt[0] = -pw[0]*yw[0]*yw[1] + pw[1]*yw[2]
   dydt[1] = dydt[0]  // first two equations are the same
   dydt[2] = pw[0]*yw[0]*yw[1] - pw[1]*yw[2] - pw[2]*yw[2]
   dydt[3] = pw[2]*yw[2]

   return 0
End
```

We think that it is easiest to keep track of the results using a single multicolumn Y wave. These commands make a four-column Y wave and use dimension labels to keep track of which column corresponds to which substance:

```
Make/D/O/N=(100,4) ChemKin
SetScale/P x 0,10,ChemKin  // calculate concentrations every 10 s
SetDimLabel 1,0,A,ChemKin  // set dimension labels to substance names
SetDimLabel 1,1,B,ChemKin  // this can be done in a table if you make
SetDimLabel 1,2,C,ChemKin  // the table using edit ChemKin.ld
SetDimLabel 1,3,D,ChemKin
ChemKin[0][%A] = 1         // initial conditions: concentration of A
ChemKin[0][%B] = 1         // and B is 1, C and D is 0
ChemKin[0][%C] = 0         // note indexing using dimension labels
ChemKin[0][%D] = 0
Make/D/O KK={0.002,0.0001,0.004}    // rate constants
```

```
Display ChemKin[][%D]    // graph concentration of the product
                         // Note graph made with subrange of wave
IntegrateODE/M=1 ChemKinetic, KK, ChemKin
```



Note that the waves yw and dydt in the derivative function have four elements corresponding to the four equations in the system of ODEs. At a given value of X (or t) yw[0] and dydt[0] correspond to the first equation, yw[1] and dydt[1] to the second, etc.

Note also that we have used the /M=1 flag to request the Bulirsch-Stoer integration method. For well-behaved systems, it is likely to be the fastest method, taking the largest steps in the solution.

Optimizing the Derivative Function

The Igor compiler does no optimization of your code. Because IntegrateODE may call your function thousands (or millions!) of times, efficient code can significantly reduce the time it takes to calculate the solution. For instance, the `ChemKinetic` example function above was written to parallel the chemical equations to make the example clearer. There are three terms that appear multiple times. As written, these terms are calculated again from scratch each time they are encountered. You can save some computation time by precalculating these terms as in the following example:

```
Function ChemKinetic2(pw, tt, yw, dydt)
   Wave pw        // pw[0] = k1, pw[1] = k2, pw[2] = k3
   Variable tt    // time value at which to calculate derivatives
   Wave yw        // yw[0]-yw[3] containing concentrations of A,B,C,D
   Wave dydt      // wave to receive dA/dt, dB/dt etc. (output)

   // Calculate common subexpressions
   Variable t1mt2 = pw[0]*yw[0]*yw[1] - pw[1]*yw[2]
   Variable t3 = pw[2]*yw[2]

   dydt[0] =  -t1mt2
   dydt[1] = dydt[0]          // first two equations are the same
   dydt[2] = t1mt2 - t3
   dydt[3] = t3

   return 0
End
```

These changes reduced the time to compute the solution by about 13 per cent. Your mileage may vary. Larger functions with subexpression repeated many times are prime candidates for this kind of optimization.

Note also that IntegrateODE updates the display every time 10 result values are calculated. Screen updates can be very time-consuming, so IntegrateODE provides the /U flag to control how often the screen is updated. For timing this example we used /U=1000000 which effectively turned off screen updating.

Higher Order Equations

Not all differential equations (in fact, not many) are expressed as systems of coupled first-order equations, but IntegrateODE can only handle such systems. Fortunately, it is always possible to make substitutions to transform an Nth-order differential equation into N first-order coupled equations.

You need one equation for each order. Here is the equation for a forced, damped harmonic oscillator (using y for the displacement rather than x to avoid confusion with the independent variable, which is t in this case):

$$\frac{d^2y}{dt^2} + 2\lambda\frac{dy}{dt} + \omega^2 y = F(t)$$

If we define a new variable *v* (which happens to be velocity in this case):

$$v = \frac{dy}{dt}$$

Then

$$\frac{d^2y}{dt^2} = \frac{dv}{dt}$$

Substituting into the original equation gives us two coupled first-order equations:

$$\frac{dv}{dt} = -2\lambda v - \omega^2 y + F(t)$$

$$\frac{dy}{dt} = v$$

Of course, a real implementation of these equations will have to provide something for F(t). A derivative function to implement these equations might look like this:

```
Function Harmonic(pw, tt, yy, dydt)
   Wave pw      // pw[0]=damping, pw[1]=undamped frequency
                // pw[2]=Forcing amplitude, pw[3]=Forcing frequency
   Variable tt
   Wave yy      // yy[0] = velocity, yy[1] = displacement
   Wave dydt

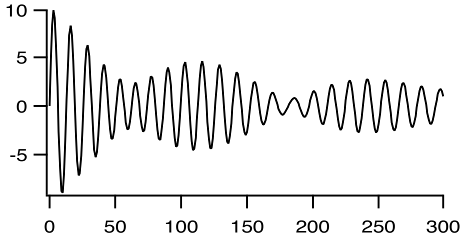
   // simple sinusoidal forcing
   Variable Force = pw[2]*sin(pw[3]*tt)

   dydt[0] = -2*pw[0]*yy[0] - pw[1]*pw[1]*yy[1]+Force
   dydt[1] = yy[0]

   return 0
End
```

And the commands to integrate the equations:

```
Make/D/O/N=(300,2) HarmonicOsc
SetDimLabel 1,0,Velocity,HarmonicOsc
SetDimLabel 1,1,Displacement,HarmonicOsc
HarmonicOsc[0][%Velocity] = 5          // initial velocity
HarmonicOsc[0][%Displacement] = 0      // initial displacement
Make/D/O HarmPW={.01,.5,.1,.45}        // damping, freq, forcing amp and freq
Display HarmonicOsc[][%Displacement]
IntegrateODE Harmonic, HarmPW, HarmonicOsc
```



Free-Run Mode

Most of the examples shown so far use the Y wave's X scaling to set the X values where a solution is desired. In the section **A First-Order Equation** on page III-325, examples are also shown in which the /X flag is used to specify the sequence of X values, either by setting X0 and deltaX or by supplying a wave filled with X values.

These methods have the advantage that you have complete control over the X values where the solution is reported to you. They also are completely deterministic — you know before running IntegrateODE exactly how many points will be calculated and how big your waves need to be.

They also have the potential drawback that you may force IntegrateODE to use smaller X increments than required. If your ODE system is expensive to calculate, this may exact a considerable cost in computation time.

IntegrateODE also offers a "free-run" mode in which the solution is allowed to proceed using whatever X increments are required to achieve the requested accuracy limit. This mode has two possible advantages — it will use the minimum number of solution steps required and it may also produce a higher density of points in areas where the solution changes rapidly (but watch out for stiff systems, see page III-331).

Free-run mode has the disadvantage that in certain cases the solution may require miniscule steps to tip toe through difficult terrain, inundating you with huge numbers of points that you don't really need. You also don't know ahead of time how many points will be required to cover a certain range in X.

To illustrate the use of free-run mode, we will return to the example used in the section **A First-Order Equation** on page III-325. (Make sure the FirstOrder function is compiled in the procedure window.) Because we don't know how many points will be produced, we will make the waves large:

```
Make/D/O/N=1000 FreeRunY      // wave to receive results
FreeRunY = NaN
FreeRunY[0] = 10              // initial condition- y0=10
```

Free-run mode requires that you supply an X wave. Unlike the previous use of an X wave, in free-run mode the X wave is filled by IntegrateODE with the X values at which solution values have been calculated. Like the Y waves, you must provide an initial value in the first row of the X wave. As before, it must have the same number of rows as the Y waves:

```
Make/O/D/N=1000 FreeRunX      // same length as YY
FreeRunX = NaN                // prevent display of extra points
FreeRunX[0] = 0               // initial value of X
```

In free-run mode, only the points that are required are altered. Thus, if you have some preexisting wave contents, they will be seen on a graph. We prevent the resulting confusion by filling the X wave with NaN's (Not a Number, or blanks). Igor graphs do not display points that have NaN values.

Make a graph:

```
Display FreeRunY vs FreeRunX      // make an XY graph
ModifyGraph mode=3, marker=19     // plot with dots to show the points
```

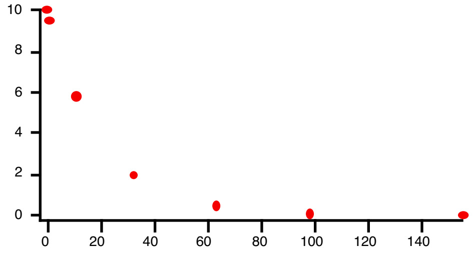
Make the parameter wave and set the value of the equation's lone coefficient:

```
Make/D/O PP={0.05}      // set constant a to 0.05
```

And finally do the integration in free-run mode. The /XRUN flag specifies a suggested first step size and the maximum X value. When the solution passes the maximum X value (100 in this case) or when your waves are filled, IntegrateODE will stop.

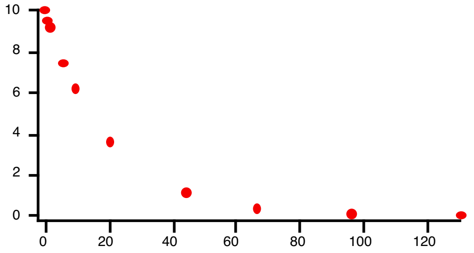
```
FreeRunX = NaN;FreeRunX[0] = 0
IntegrateODE/M=1/X=FreeRunX/XRUN={1,100} FirstOrder, PP, FreeRunY
```

In the earlier example, we (rather arbitrarily) chose 100 steps to make a reasonably smooth plot. In this case, it took 6 steps to cover the same X range, and the steps are closest together at the beginning where the exponential decay is most rapid:



Asking for more accuracy will cause smaller steps to be taken (9 when we executed the following command):

```
FreeRunX = NaN;FreeRunX[0] = 0
IntegrateODE/M=1/X=FreeRunX/XRUN={1,100}/E=1e-14 FirstOrder, PP, FreeRunY
```



After IntegrateODE has finished, you can use Redimension and the V_ODETotalSteps variable to adjust the size of the waves to just the points actually calculated:

```
Redimension/N=(V_ODETotalSteps+1) FreeRunY, FreeRunX
```

Note that we added 1 to V_ODETotalSteps to account for the initial value in row zero.

Stiff Systems

Some systems of differential equations involve components having very different time (or decay) constants. This can create what is called a “stiff” system; even though the short time constant decays rapidly and contributes negligibly to the solution after a very short time, ordinary solution methods (/M = 0, 1, and 2) are unstable because of the presence of the short time-constant component. IntegrateODE offers the Backward Differentiation Formula method (BDF, flag /M=3) to handle stiff systems.

A rather artificial example is the system (see “Numerical Recipes in C”, edition 2, page 734; see **References** on page III-349)

```
du/dt = 998u + 1998v
dv/dt = -999u - 1999v
```

Here is the derivative function that implements this system:

```
Function StiffODE(pw, tt, yy, dydt)
   Wave pw      // not actually used because the coefficients
                // are hard-coded to give a stiff system
   Variable tt
   Wave yy
   Wave dydt

   dydt[0] = 998*yy[0] + 1998*yy[1]
   dydt[1] = -999*yy[0] - 1999*yy[1]

   return 0
End
```

Commands to set up the wave required and to make a suitable graph:

```
Make/D/O/N=(3000,2) StiffSystemY
Make/O/N=0 dummy              // dummy coefficient wave
StiffSystemY = 0
StiffSystemY[0][0] = 1        // initial condition for u component
make/D/O/N=3000 StiffSystemX
Display StiffSystemY[][0] vs StiffSystemX
AppendToGraph/L=vComponentAxis StiffSystemY[][1] vs StiffSystemX

// make a nice-looking graph with dots to show where the solution points are
ModifyGraph axisEnab(left)={0,0.48},axisEnab(vComponentAxis)={0.52,1}
DelayUpdate
ModifyGraph freePos(vComponentAxis)={0,kwFraction}
ModifyGraph mode=2,lsize=2,rgb=(0,0,65535)
```

These commands solve this system using the Bulirsch-Stoer method using free run mode to minimize the number of solution steps computed:

```
StiffSystemX = nan      // hide unused solution points
StiffSystemX[0] = 0     // initial X value
IntegrateODE/M=1/X=StiffSystemX/XRUN={1e-6, 2} StiffODE, dummy, StiffSystemY
Print "Required ",V_ODETotalSteps, " steps to solve using Bulirsch-Stoer"
```

which results in this message in the history area:

```
  Required   401 steps to solve using Bulirsch-Stoer
```

These commands solve this system using the BDF method:

```
StiffSystemX = nan   // hide unused solution points
StiffSystemX[0] = 0  // initial X value
IntegrateODE/M=3/X=StiffSystemX/XRUN={1e-6, 2} StiffODE, dummy, StiffSystemY
Print "Required ",V_ODETotalSteps, " steps to solve using BDF"
```

This results in this message in the history area:

```
  Required   133 steps to solve using BDF
```

The difference between 401 steps and 133 is significant! Be aware, however, that the BDF method is not the most efficient for nonstiff problems.

Error Monitoring

To achieve the fastest possible solution to your differential equations, Igor uses algorithms with adaptive step sizing. As each step is calculated, an estimate of the truncation error is also calculated and compared to a criterion that you specify. If the error is too large, a smaller step size is used. If the error is small compared to what you asked for, a larger step size is used for the next step.

Igor monitors the errors by scaling the error by some (hopefully meaningful) number and comparing to an error level.

The Runge-Kutta and Bulirsch-Stoers methods (IntegrateODE flag /M=0 or /M=1) estimates the errors for each of your differential equations and the largest is used for the adjustments:

$$Max\left(\frac{Error_i}{Scale_i}\right) < eps$$

The Adams-Moulton and BDF methods (IntegrateODE flag /M=2 or /M=3) estimate the errors and use the root mean square of the error vector:

$$\left[\frac{1}{N}\sum\left(\frac{Error_i}{Scale_i}\right)^2\right]^{1/2} < eps\,.$$

Igor sets *eps* to 10^{-6} by default. If you want a different error level, use the /E=*eps* flag to set a different value of *eps*. Using the harmonic oscillator example, we now set a more relaxed error criterion than the default:

```
IntegrateODE/E=1e-3 Harmonic, HarmPW, HarmonicOsc
```

The error scaling can be composed of several parts, each optional:

$$Scale_i = h\cdot(C_i + y_i + dy_i/dx)$$

By default Igor uses constant scaling, setting *h*=1 and C_i=1, and does not use the y_i and dy_i/dx terms making $Scale_i$ = 1. In that case, *eps* represents an absolute error level: the error in the calculated values should be less than *eps*. An absolute error specification is often acceptable, but it may not be appropriate if the output values are of very different magnitudes.

You can provide your own customized values for C_i using the /S=*scaleWave* flag. You must first create a wave having one point for each differential equation. Fill it with your desired scaling values, and add the /S flag to the IntegrateODE operation:

```
Make/O/D errScale={1,5}
IntegrateODE/S=errScale Harmonic, HarmPW, HarmonicOsc
```

Typically, the constant values should be selected to be near the maximum values for each component of your system of equations.

Finally, you can control what Igor includes in $Scale_i$ using the /F=*errMethod* flag. The argument to /F is a bitwise value with a bit for each component of the equation above:

errMethod	**What It Does**
1	Add a constant C_i from *scaleWave* (or 1's if no *scaleWave*).
2	Add the current value of y_i's, the calculated result.
4	Add the current value of the derivatives, dy_i/dx.
8	Multiply by *h*, the current step size

Use *errMethod* = 2 if you want the errors to be a fraction of the current value of Y. That might be appropriate for solutions that asymptotically approach zero when you need smaller errors as the solution approaches zero.

The Scale numbers can never equal zero, and usually it isn't appropriate for $Scale_i$ to get very small. Thus, it isn't usually a good idea to use *errMethod* = 2 with solutions that pass through zero. A good way to avoid this problem can be to add the values of the derivatives (*errMethod* = (2+4)), or to add a small constant:

```
Make/D errScale=1e-6
IntegrateODE/S=errScale/F=(2+1) …
```

Finally, in some cases you need the much more stringent requirement that the errors be less than some global value. Since the solutions are the result of adding up myriad sequential solutions, any truncation error has the potential to add up catastrophically if the errors happen to be all of the same sign. If you are using Runge-Kutta and Bulirsch-Stoers methods (IntegrateODE flag /M=0 or /M=1), you can achieve global error limits by setting bit 3 of *errMethod* (/F=8) to multiply the error by the current step size (h in the equation above). If you are using Adams-Moulton and BDF methods (IntegrateODE flag /M=2 or /M=3) bit 3 does nothing; in that case, a conservative value of *eps* would be needed.

Higher accuracy will make the solvers use smaller steps, requiring more computation time. The trade-off for smaller step size is computation time. If you get too greedy, the step size can get so small that the X increments are smaller than the computer's digital resolution. If this happens Igor will stop the calculation and complain.

Solution Methods

Igor makes four solution methods available, Runge-Kutta-Fehlberg, Bulirsch-Stoers with Richardson extrapolation, Adams-Moulton and Backward Differentiation Formula.

Runge-Kutta-Fehlberg is a robust method capable of surviving solutions or derivatives that aren't smooth, or even have discontinuous derivatives. Bulirsch-Stoers, for well-behaved systems, will take larger steps than Runge-Kutta-Fehlberg, so it may be considerably faster. Step size for a given problem is larger so you get greater accuracy. Of course, if you ask for values closer together than the achievable step size, you get no advantage from this.

Details of these methods can be found in the second edition of *Numerical Recipes*(see **References** on page III-349).

The Adams-Moulton and Backward Differentiation Formula (BDF) methods are adapted from the CVODE package developed at Lawrence Livermore National Laboratory. In our very limited experience, for well-behaved nonstiff systems the Bulirsch-Stoers method is much more efficient than either the Runge-Kutta-Fehlberg method or the Adams-Moulton method, in that it requires significantly fewer steps for a given problem.

As shown above, stiff systems benefit greatly by the use of the BDF method. However, for nonstiff methods, it is not as efficient as the other methods.

See **IntegrateODE** on page V-452 for references on these methods.

Interrupting IntegrateODE

Numerical solutions to differential equations can require considerable computation and, therefore, time. If you find that a solution is taking too long you can abort the operation by clicking the Abort button in the status bar. You may need to press and hold to make sure IntegrateODE notices.

When you abort an integration, IntegrateODE returns whatever results have been calculated. If those results are useful, you can restart the calculation from that point, using the last calculated result row as the initial conditions. Use the /R=(*startX*) flag to specify where you want to start.

For Igor programmers, the V_ODEStepCompleted variable will be set to the last result. It is probably a good idea to restart a step or two before that:

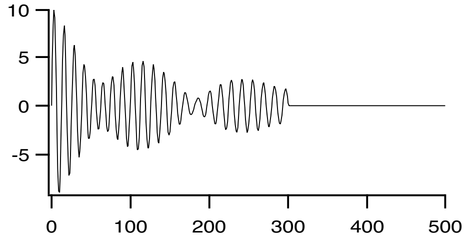
```
IntegrateODE/R=(V_ODEStepCompleted-1) …
```

Stopping and Restarting IntegrateODE

Any result can be used as initial conditions for a new solution. Thus, you can use the /R flag to calculate just a part of the solution, then finish later using the /R flag to pick up where you left off. For instance, using the harmonic oscillator example:

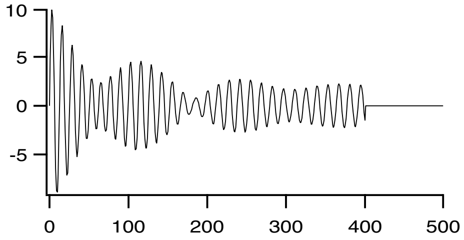
```
Make/D/O/N=(500,2) HarmonicOsc = 0
SetDimLabel 1,0,Velocity,HarmonicOsc
SetDimLabel 1,1,Displacement,HarmonicOsc
HarmonicOsc[0][%Velocity] = 5           // initial velocity
HarmonicOsc[0][%Displacement] = 0       // initial displacement
Make/D/O HarmPW={.01,.5,.1,.45}      // damping, freq, forcing amp and freq
Display HarmonicOsc[][%Displacement]

IntegrateODE/M=1/R=[,300] Harmonic, HarmPW, HarmonicOsc
```



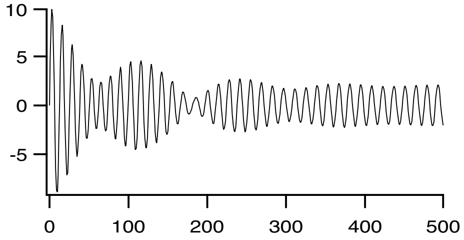
The calculation has been done for points 0-300. Note the comma in /R=[,300], which sets 300 as the end point, not the start point. Now you can restart at 300 and continue to the 400th point:

```
IntegrateODE/M=1/R=[300,400] Harmonic, HarmPW, HarmonicOsc
```



or finish the entire 500 points. Perhaps you need to start from an earlier point:

```
IntegrateODE/M=1/R=[350] Harmonic, HarmPW, HarmonicOsc
```



Stopping IntegrateODE on a Condition

Sometimes it is useful to be able to stop the calculation based on output values from the integration, rather than stopping when a certain value of the independent variable is reached. For instance, a common way to simulate a neuron firing is to solve the relevant system of equations until the output reaches a certain value. At that point, the solution should be stopped and the initial conditions reset to values appropriate to the triggered condition. Then the calculation can be re-started from that point.

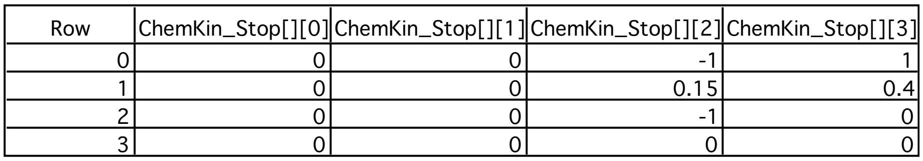
The ability to stop and re-start the calculation is a general solution to the problem of discontinuities in the system you are solving. Integrate the system up to the point of the discontinuity, stop and re-start using a derivative function that reflects the system after the discontinuity.

There are two ways to stop the integration depending on the solution values.

The first way is to use the /STOP={*stopWave*, *mode*} flag, supplying a *stopWave* containing stopping conditions. *StopWave* must have one column for each equation in your system. Each column can specify stopping on a value of the solution for the equation corresponding to the column, or stopping on a value of the derivative corresponding to that equation, or both. Each row has different significance:

Row	Meaning
0	Stop flag for solution value 0: Ignore condition on solution for this equation 1: Stop when solution value is greater than the value in row 1 -1: Stop when solution value is less than the value in row 1
1	Value of solution at which to stop
2	Stop flag for derivative 0: Ignore condition on derivative for this equation 1: Stop when derivative value is greater than the value in row 3 -1: Stop when derivative value is less than the value in row 3
3	Value of derivative at which to stop

In the chemical kinetics example above (see **A System of Coupled First-Order Equations** on page III-327) the system has four equations so you need a stop wave with four columns. This wave:



Row	ChemKin_Stop[][0]	ChemKin_Stop[][1]	ChemKin_Stop[][2]	ChemKin_Stop[][3]
0	0	0	-1	1
1	0	0	0.15	0.4
2	0	0	-1	0
3	0	0	0	0

will stop the integration when the concentration of species C (column 2) is less than 0.15, or when the concentration of species D (column 3) is greater than 0.4, or when the derivative of the concentration of species C is less than zero.

When you have multiple stopping criteria, as in this example, you can specify either OR stopping mode or AND stopping mode using the mode parameter of the /STOP flag. If *mode* is 0, OR mode is applied — any of the conditions with a non-zero flag will stop the integration. If *mode* is 1, AND mode is applied — all conditions with a non-zero flag must be satisfied in order for the integration to be stopped.

The second way to stop the integration is by returning a value of 1 from the derivative function. You can apply any condition you like in the function so it is possible to make much more complex stopping conditions this way than using the /STOP flag. However, the derivative function is called for a many intermediate points during a single step, some of which aren't necessarily even on the eventual solution trajectory. That means that you could be applying your stopping criterion to values that are not meaningful to the final solution. That may be particularly true at a time when the internal step size is contracting — the derivative function may be called for points beyond the eventual solution point as the solver tries a step size that doesn't succeed.

Integrating a User Function

You can use the Integrate1D function to numerically integrate a user function. For example, if you want to evaluate the integral

$$I(a, b) = \int_a^b \exp[-x^3 \sin(2\pi/x^2)]dx,$$

you need to start by defining the user function

```
Function userFunc(v)
   Variable v
   return exp(-v^3*sin(2*pi/v^2))
End
```

The Integrate1D function supports three integration methods: Trapezoidal, Romberg and Gaussian Quadrature.

```
Printf "%.10f\r" Integrate1D(userfunc,0.1,0.5,0)      // default trapezoidal
0.3990547412
Printf "%.10f\r" Integrate1D(userfunc,0.1,0.5,1)      // Romberg
0.3996269165
Printf "%.10f\r" Integrate1D(userfunc,0.1,0.5,2,100)  // Gaussian Q.
0.3990546953
```

For comparison, you can also execute:

```
Make/O/N=1000 tmp
Setscale/I x,.1,.5,"" tmp
tmp=userfunc(x)
Printf "%.10f\r" area(tmp,-inf,inf)
0.3990545084
```

Integrate1D can also handle complex valued functions. For example, if you want to evaluate the integral

$$I(a,b) = \int_a^b \exp\{ix\sin x\}dx'$$

a possible user function could be

```
Function/C cUserFunc(v)
   Variable v
   Variable/C arg=cmplx(0,v*sin(v))
   return exp(arg)
End
```

Note that the user function is declared with a /C flag and that Integrate1D must be assigned to a complex number in order for it to accept a complex user function.

```
Variable/C complexResult=Integrate1D(cUserFunc,0.1,0.2,1)
print complexResult
(0.0999693,0.00232272)
```

Also note that if you just try to print the result without using a complex variable as shown above, you need to use the /C flag with print:

```
Print/C Integrate1D(cUserFunc,0.1,0.2,1)
```

in order to force the function to integrate a complex valued expression.

You can also evaluate multidimensional integrals with the help of Integrate1D. The trick is in recognizing the fact that the user function can itself return a 1D integral of another function which in turn can return a 1D integral of a third function and so on. Here is an example of integrating a 2D function: $f(x,y) = 2x + 3y + xy$.

```
Function do2dIntegration(xmin,xmax,ymin,ymax)
   Variable xmin,xmax,ymin,ymax
   Variable/G globalXmin=xmin
   Variable/G globalXmax=xmax
   Variable/G globalY
   return Integrate1D(userFunction2,ymin,ymax,1)
End

Function userFunction1(inX)
   Variable inX
   NVAR globalY=globalY
   return (3*inX+2*globalY+inX*globalY)
End
```

```
Function userFunction2(inY)
   Variable inY
   NVAR globalY=globalY
   globalY=inY
   NVAR globalXmin=globalXmin
   NVAR globalXmax=globalXmax
   return Integrate1D(userFunction1,globalXmin,globalXmax,1)
End
```

Finding Function Roots

The **FindRoots** operation finds roots or zeros of a nonlinear function, a system of nonlinear functions, or of a polynomial with real coefficients.

Here we discuss how the operation works, and give some examples. The discussion falls naturally into three sections:

- Polynomial roots
- Roots of 1D nonlinear functions
- Roots of systems of multidimensional nonlinear functions

Igor's FindRoots operation finds function zeroes. Naturally, you can find other solutions as well. If you have a function f(x) and you want to find the X values that result in f(x) = 1, you would find roots of the function g(x) = f(x)-1. The FindRoots operation provides the /Z flag to make this more convenient.

A related problem is to find places in a curve defined by data points where the data pass through zero or another value. In this case, you don't have an analytical expression of the function. For this, use either the **FindLevel** operation (see page V-242) or the **FindLevels** operation (see page V-244); applications of these operations are discussed under **Level Detection** on page III-287.

Roots of Polynomials with Real Coefficients

The FindRoots operation can find all the complex roots of a polynomial with real coefficients. As an example, we will find the roots of

$x^4 -3.75x^2 - 1.25x + 1.5$

We just happen to know that this polynomial can be factored as (x+1)(x-2)(x+1.5)(x-0.5) so we already know what the roots are. But let's use Igor to do the work.

First, we need to make a wave with the polynomial coefficients. The wave must have N+1 points, where N is the degree of the polynomial. Point zero is the coefficient for the constant term, the last point is the coefficient for the highest-order term:

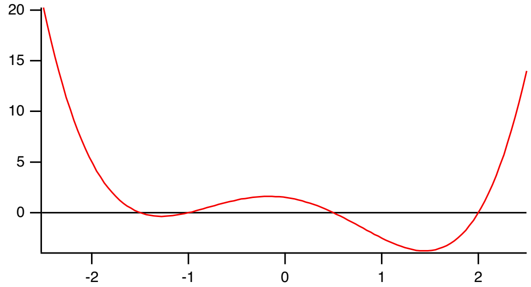
```
Make/D/O PolyCoefs = {1.5, -1.25, -3.75, 0, 1}
```

This wave can be used with the **poly** function to generate polynomial values. For instance:

```
Make/D/O PWave               // a wave with 128 points
SetScale/I x -2.5,2.5,PWave  // give it an X range of (-2.5, 2.5)
PWave = Poly(PolyCoefs, x)   // fill it with polynomial values

Display PWave                // and make a graph of it
ModifyGraph zero(left)=1     // add a zero line to show the roots
```

These commands make the following graph:



Now use FindRoots to find the roots:

```
FindRoots/P=PolyCoefs    // roots are now in W_polyRoots
Print W_polyRoots
```

This prints:

```
W_polyRoots[0] = {cmplx(0.5,0), cmplx(-1,0), cmplx(-1.5,0), cmplx(2,0)}
```

Note that the imaginary part of the roots are zero, because this polynomial was constructed from real factors. In general, this won't be the case.

The FindRoots operation uses the Jenkins-Traub algorithm for finding roots of polynomials:

Jenkins, M.A., "Algorithm 493, Zeros of a Real Polynomial", *ACM Transactions on Mathematical Software, 1,* 178-189, 1975, used by permission of ACM (1998).

Roots of a 1D Nonlinear Function

Unlike the case with polynomials, there is no general method for finding all the roots of a nonlinear function. Igor searches for a root of the function using Brent's method, and, depending on circumstances will find one or two roots in one shot.

You must write a user-defined function to define the function whose roots you want to find. Igor calls your function with values of X in the process of searching for a root. The format of the function is as follows:

```
Function myFunc(w,x)
   Wave w
   Variable x

   return <an arithmetic expression>
End
```

The wave *w* is a coefficient wave — it specifies constant coefficients that you may need to include in the function. It provides a convenient way to alter the coefficients so that you can find roots of members of a function family without having to edit your function code every time. Igor does not alter the values in w.

As an example we will find roots of the function y = a+b*sinc(c*(x-x0)). Here is a user-defined function to implement this:

```
Function mySinc(w, x)
   Wave w
   Variable x

   return w[0]+w[1]*sinc(w[2]*(x-w[3]))
End
```

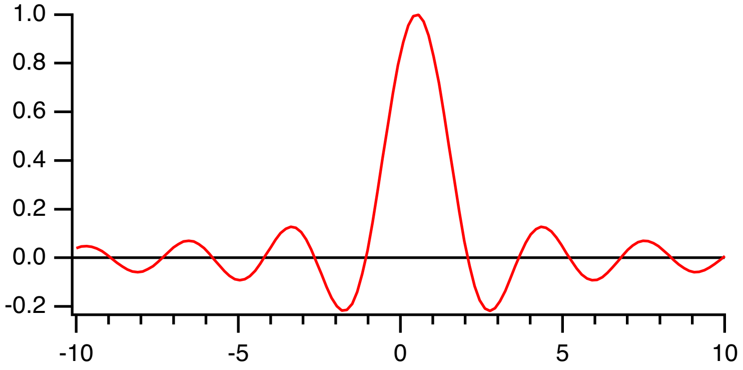
Enter this code into the Procedure window and then close the window.

Make a graph of the function:

```
Make/D/O SincCoefs={0, 1, 2, .5}     // a sinc function offset by 0.5
Make/D/O SincWave                    // a wave with 128 points
```

```
SetScale/I x -10,10,SincWave          // give it an X range of (-2, 2)
SincWave = mySinc(SincCoefs, x)       // fill it with function values

Display SincWave                      // and make a graph of it
ModifyGraph zero(left)=1              // add a zero line to show the roots
ModifyGraph minor(bottom)=1           // add minor ticks to the graph
```



Now we're ready to find roots.

The algorithm for finding roots requires that the roots first be bracketed, that is, you need to know two X values that are on either side of the root (that is, that give Y values of opposite sign). Making a graph of the function as we did here is a good way to figure out bracketing values. For instance, inspection of the graph above shows that there is a root between x=1 and x=3. The FindRoots command line to find a root in this range is

```
FindRoots/L=1/H=3 mySinc, SincCoefs
```

The /L flag sets the lower bracket and the /H flag sets the upper bracket. Igor then finds the root between these values, and prints the results in the history:

```
Possible root found at 2.0708
Y value there is -1.46076e-09
```

Igor reports to you both the root (in this case 2.0708) and the Y value at the root, which should be very close to zero (in this case it is -1.46x10^{-9}). Some pathological functions can fool Igor into thinking it has found a root when it hasn't. The Y value at the supposed root should identify if this has happened.

The bracketing values don't actually have to be at points of opposite sign. If the bracket encloses an extreme point, Igor will find it and then find two roots. Thus, you might use this command:

```
FindRoots/L=0/H=5 mySinc, SincCoefs
```

The Y values at X=0 and X=5 are both positive. Igor finds the minimum point at about X=2.7 and then uses that with the original bracketing values as the starting points for finding two roots. The result, printed in the history:

```
Looking for two roots...

Results for first root:
Possible root found at 2.0708
Y value there is -2.99484e-11

Results for second root:
Possible root found at 3.64159
Y value there is 3.43031e-11
```

Finally, it isn't always necessary to provide bracketing values. If the /L and /H flags are absent, Igor assigns them the values 0 and 1. In this case, there is no root between X=0 and X=1, and there is no extreme point. So Igor searches outward in a series of expanding jumps looking for values that will bracket a root (that is, for X values having Y values of opposite sign). Thus, in this case, the following simple command works:

```
FindRoots mySinc, SincCoefs
```

Igor finds the first of the roots we found previously:

```
Possible root found at 2.0708
Y value there is 2.748e-13
```

You may have noticed by now that FindRoots is reporting Y values that are merely small instead of zero. It isn't usually possible to find exact roots with a computer. And asking for very high accuracy requires more iterations of the search algorithm. If function evaluation is time-consuming and you don't need much accuracy, you may not want to find the root with high accuracy. Consequently, you can use the /T flag to alter the acceptable accuracy:

```
FindRoots/T=1e-3 mySinc, SincCoefs     // low accuracy
Possible root found at 2.07088
   Y value there is -5.5659e-05
Print/D V_root, V_YatRoot
   2.07088376061435  -5.56589998578327e-05

FindRoots/T=1e-15 mySinc, SincCoefs    // high accuracy
Possible root found at 2.0708
   Y value there is 0
Print/D V_root, V_YatRoot
   2.0707963267949  0
```

This also illustrates another point: the results of FindRoots are stored in variables. We used these variables in this case to print the results to higher accuracy than the six digits used by the report printed by FindRoots.

Roots of a System of Multidimensional Nonlinear Functions

Finding roots of a system of multidimensional nonlinear functions works very similarly to finding roots of a 1D nonlinear function. You provide user-defined functions that define your functions. These functions have nearly the same form as a 1D function, but they have a parameter for each independent variable. For instance, if you are going to find roots of a pair of 2D functions, the functions will look like this:

```
Function myFunc1(w, x1, x2)
   Wave w
   Variable x1, x2

   return <an arithmetic expression>
End

Function myFunc2(w, x1, x2)
   Wave w
   Variable x1, x2

   return <an arithmetic expression>
End
```

These function look just like the 1D function mySinc we wrote in the previous section, but they have two input X variables, one for each dimension. The number of functions must match the number of dimensions.

We will use the functions

```
f1= w[0]*sin((x-3)/w[1])*cos(y/w[2])
```

and

```
f2 = w[0]*cos(x/w[1])*tan((y+5)/w[2])
```

Enter this code into your procedure window:

```
Function myf1(w, xx, yy)
   Wave w
   Variable xx,yy
   return w[0]*sin(xx/w[1])*cos(yy/w[2])
End

Function myf2(w, xx, yy)
   Wave w
   Variable xx,yy

   return w[0]*cos(xx/w[1])*tan(yy/w[2])
End
```

Before starting, let’s make a contour plot to see what we’re up against. Here are some commands to make a convenient one:

```
Make/D/O params2D={1,5,4}           // nice set of parameters for both f1 and f2
Make/D/O/N=(50,50) f1Wave, f2Wave   // matrix waves for contouring
SetScale/I x -20,20,f1Wave, f2Wave  // nice range of X values
SetScale/I y -20,20,f1Wave, f2Wave  // and Y values
f1Wave = myf1(params2D, x, y)       // fill f1Wave with values from f1(x,y)
f2Wave = myf2(params2D, x, y)       // fill f2Wave with values from f2(x,y)
Display /W=(5,42,399,396)           // graph window for contour plot
AppendMatrixContour f1Wave
AppendMatrixContour f2Wave
ModifyContour f2Wave labels=0       // suppress contour labels
ModifyContour f1Wave labels=0
ModifyContour f1Wave rgbLines=(65535,0,0)    // make f1 red
ModifyContour f2Wave rgbLines=(0,0,65535)    // make f2 blue
ModifyGraph lsize('f2Wave=0')=2              // make zero contours heavy
ModifyGraph lsize('f1Wave=0')=2
```

Places where the zero contours for the two functions cross are the roots we are looking for. In the contour plot you can see several, for instance the points (0,0) and (7.8, 6.4) are approximate roots.

The algorithm that searches for roots needs a starting point. You can specify this in the FindRoots command with the /X flag, or if you don’t use /X, Igor starts by default at the origin, $X_n = 0$. You must also specify both functions and a coefficient wave for each function. In this case we will use the same coefficient wave for each. The functions and coefficient waves are specified in pairs. Since we are looking for roots of two 2D functions, we have two function-wave pairs:

```
FindRoots myf1,params2D, myf2,params2D
```

Igor finds a root at the origin, and prints the results. The X,Y coordinates of the root are stored in the wave W_Root:

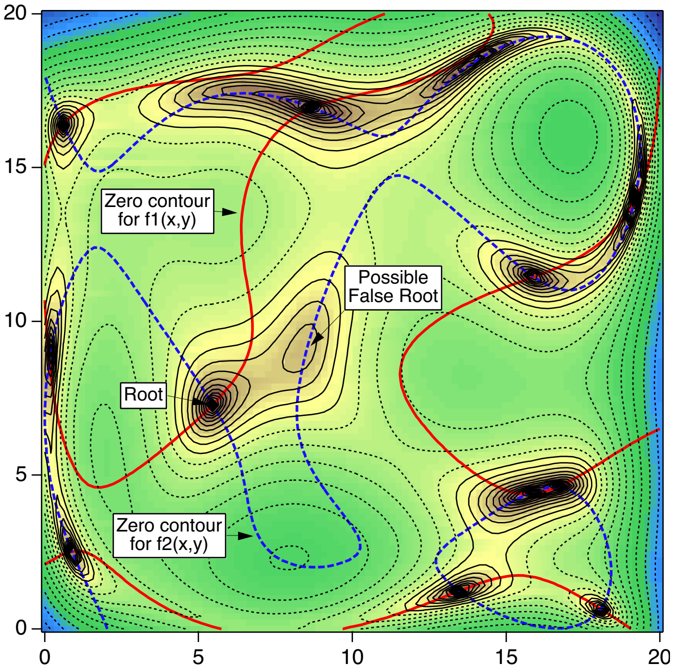
```
   Root found after 4 function evaluations.
W_Root={0,0}
   Function values at root:
W_YatRoot={0,0}
```

The wave W_YatRoot holds the values of each of the functions evaluated at the root.

If that’s not the root you want to find, use /X to specify a different starting point:

```
   FindRoots/X={7.7,6.3} myf1,params2D, myf2,params2D
   Root found after 47 function evaluations.
W_Root={-1.10261e-14,12.5664}
   Function values at root:
W_YatRoot={2.20522e-15,-1.89882e-15}
```

Caveats for Multidimensional Root Finding



Finding roots of multidimensional nonlinear functions is not straightforward. There is no general, foolproof way to do it. The method Igor uses is to search for minima in the sum of the squares of the functions. Since the squared values must be positive, the only places where this sum can be zero is at points where all the functions are zero at the same time. That point is a root, and it is also a minimum in the summed squares of the functions.

To find the zero points, Igor searches for local minima by travelling downhill from the starting point. Unfortunately, a local minimum doesn't have to be a root, it just has to be someplace where the sum of squares of the functions is less than surrounding points.

The adjacent graph shows how this can happen.

The two heavy lines are the zero contours for two functions (they happen to be fifth-order 2D polynomials). Where these zero contours cross are the roots for the system of the two functions.

The thin lines are contours of $f1(x,y)^2+f2(x,y)^2$, with dotted lines for high values; minima are surrounded by thin, solid contours. You can see that every intersection between the heavy zero contours is surrounded by thin contours showing that these are minima in the sum of the squared functions. One such point is labeled “Root”.

There is at least one point, labelled “False Root”, where there is a minimum but the zero contours don’t cross. That is not a root, but FindRoots may find it anyway. For instance, a real root:

```
FindRoots /x={3,6} MyPoly2d, nn1coefs, MyPoly2d, nn2coefs
   Root found after 11 function evaluations.
   W_Root={5.4623,7.28975}
   Function values at root:
   W_YatRoot={-4.15845e-13,1.08297e-12}
```

This point is the point marked “Root”. However:

```
FindRoots/x={9,10} MyPoly2d, nn1coefs, MyPoly2d, nn2coefs
   Root found after 52 function evaluations.
   W_Root={8.38701,9.10129}
   Function values at root:
   W_YatRoot={0.0686792,0.0129881}
```

You can see from the values in W_YatRoot that this is not a root. This point is marked “False root” on the figure above.

The polynomials used in this example have too many coefficients to be conveniently shown here. To see this example and others in action, try out the demo experiment. It is called “MD Root Finder Demo” and you will find it in your Igor Pro 7 folder, in the Examples:Analysis: folder.

Finding Minima and Maxima of Functions

The **Optimize** operation finds extreme values (maxima or minima) of a nonlinear function.

Here we discuss how the operation works, and give some examples. The discussion falls naturally into two sections:

- Extrema of 1D nonlinear functions
- Extrema of multidimensional nonlinear functions

A related problem is to find peaks or troughs in a curve defined by data points. In this case, you don't have an analytical expression of the function. To do this with one dimensional data, use the **FindPeak** operation (see page V-247).

Extreme Points of a 1D Nonlinear Function

The Optimize operation finds local maxima or minima of functions. That is, if a function has some X value where the nearby Y values are all higher than at that X value, it is deemed to be a minimum. Finding the point where a functions value is lower or higher than any other point anywhere is a much more difficult problem that is not addressed by the Optimize operation.

You must write a user-defined function to define the function for which the extreme points are calculated. Igor will call your function with values of X in the process of searching for a root. The format of the function is as follows:

```
Function myFunc(w,x)
   Wave w
   Variable x

   return f(x)          // an expression...
End
```

The wave w is a coefficient wave — it specifies constant coefficients that you may need to include in the function. It provides a convenient way to alter the coefficients so that you can find extreme points of members of a function family without having to edit your function code every time. Igor does not alter the values in *w*.

Although the coefficient wave must be present in the Function declaration, it does not have to be referenced in the function body. This may save computation time, arriving at the solution faster. You will have to create a dummy wave to list in the FindRoots command.

As an example we will find extreme points of the equation

```
y = a+b*sinc(c*(x-x0))
```

A suitable user-defined function might look like this:

```
Function mySinc(w, x)
   Wave w
   Variable x

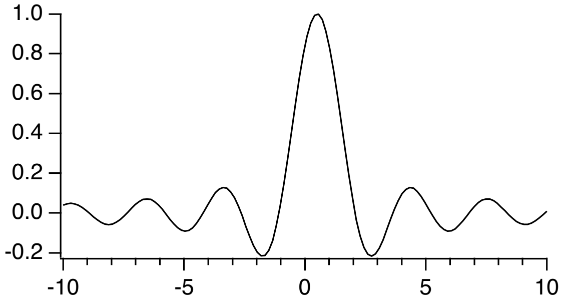
   return w[0]+w[1]*sinc(w[2]*(x-w[3]))
End
```

Enter this code into the Procedure window and then close the window.

Make a graph of the function:

```
Make/D/O SincCoefs={0, 1, 2, .5} // a sinc function offset by 0.5
Make/D/O SincWave                // a wave with 128 points
SetScale/I x -10,10,SincWave     // give it an X range of [-10, 10]
SincWave = mySinc(SincCoefs, x)  // fill it with function values

Display SincWave                 // and make a graph of it
ModifyGraph minor(bottom)=1      // add minor ticks to the graph
```



Now we're ready to find extreme points.

The algorithm for finding extreme points requires that the extreme points first be bracketed, that is, you need to know two X values that are on either side of the extreme point (that is, two points that have a lower or higher point between). Making a graph of the function as we did here is a good way to figure out bracketing values. For instance, inspection of the graph above shows that there is a minimum between x=1 and x=4. The Optimize command line to find a minimum in this range is

```
Optimize/L=1/H=4 mySinc, SincCoefs
```

The /L flag sets the lower bracket and the /H flag sets the upper bracket. Igor then finds the minimum between these values, and prints the results in the history:

```
Optimize probably found a minimum. Optimize stopped because
the Optimize operation found a minimum within the specified tolerance.
Current best solution: 2.7467
Function value at solution: -0.217234
 13 iterations, 14 function calls
V_minloc = 2.7467, V_min = -0.217234, V_OptNumIters = 13, V_OptNumFunctionCalls = 14
```

Igor reports to you both the X value that minimizes the function (in this case 2.7467) and the Y value at the minimum.

The bracketing values don't necessarily have to bracket the solution. Igor first tries to find the desired extremum between the bracketing values. If it fails, the bracketing interval is expanded searching for a suitable bracketing interval. If you don't use /L and /H, Igor sets the bracketing interval to [0,1]. In the case of the mySinc function, that doesn't include a minimum. Here is what happens in that case:

```
Optimize mySinc, SincCoefs
```

```
Optimize probably found a minimum. Optimize stopped because
the Optimize operation found a minimum within the specified tolerance.
Current best solution: 2.74671
Function value at solution: -0.217234
 16 iterations, 47 function calls
V_minloc = 2.74671, V_min = -0.217234, V_OptNumIters = 16, V_OptNumFunctionCalls = 47
```

Note that Igor found the same minimum that it found before.

The mySinc function makes it easy to find bracketing values because of the oscillatory nature of the function. Other functions may be more difficult if they contain just one extreme point, or if they have local extreme points but are unbounded elsewhere. Even in an easy case like mySinc, you can't be sure which extreme point Igor will find, so it is always better to supply a good bracket if you possibly can.

You may wish to find maximum points instead of minima. Use the /A flag to specify this:

```
Optimize/A/L=0/H=2 mySinc, SincCoefs
```

```
Optimize probably found a maximum. Optimize stopped because
the Optimize operation found a maximum within the specified tolerance.
Current best solution: 0.499999
Function value at solution: 1
 16 iterations, 17 function calls
V_maxloc = 0.499999, V_max = 1, V_OptNumIters = 16, V_OptNumFunctionCalls = 17
```

The results of the Optimize operation are stored in variables. Note that the report that Optimize prints in the history includes only six digits of the values. You can print the results to greater precision using the printf operation and the variables:

```
Printf "The max is at %.15g. The Y value there is %.15g\r", V_maxloc, V_max
```

yields this in the history:

```
The max is at 0.499999480759779. The Y value there is 0.99999999999982
```

Extrema of Multidimensional Nonlinear Functions

Finding extreme points of multidimensional nonlinear functions works very similarly to finding extreme points of a 1D nonlinear function. You provide a user-defined function having almost the same format as for 1D functions. A 2D function will look like this:

```
Function myFunc1(w, x1, x2)
   Wave w
   Variable x1, x2

   return f1(x1, x2)        // an expression...
End
```

This function looks just like the 1D function mySinc we wrote in the previous section, but it has two input X variables, one for each dimension.

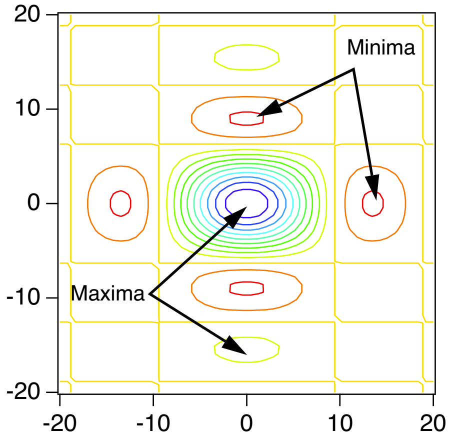
We will make a 2D function based on the sinc function. Copy this code into your procedure window:

```
Function Sinc2D(w, xx, yy)
   Wave w
   Variable xx,yy

   return w[0]*sinc(xx/w[1])*sinc(yy/w[2])
End
```

Before starting, let’s make a contour plot to see what we’re up against. Here are some commands to make a convenient one:

```
Make/D/O params2D={1,3,2}         // nice set of parameters
Make/D/O/N=(50,50) Sinc2DWave     // matrix wave for contouring
SetScale/I x -20,20,Sinc2DWave    // nice range of X values for these functions
SetScale/I y -20,20,Sinc2DWave    // and Y values
Sinc2DWave = Sinc2D(params2D, x, y) // fill f1Wave with values from f1(x,y)
Display /W=(5,42,399,396)         // graph window for contour plot
AppendMatrixContour Sinc2DWave
ModifyContour Sinc2DWave labels=0// suppress contour labels to reduce clutter
```



The algorithm that searches for extreme points needs a starting guess which you provide using the /X flag. Here is a command to find a minimum point:

```
Optimize/X={1,5} Sinc2D,params2D
```

This command results in the following report in the history:

```
Optimize probably found a minimum. Optimize stopped because
the gradient is nearly zero.
Current best solution:
   W_Extremum={-0.000147116,8.98677}
Function gradient:
   W_OptGradient={-4.65661e-08,1.11923e-08}
Function value at solution: -0.217234
11 iterations, 36 function calls
V_min = -0.217234, V_OptTermCode = 1, V_OptNumIters = 11, V_OptNumFunctionCalls = 36
```

Note that the minimum is reported via a wave called W_extremum. Had you specified a wave using the /X flag, that wave would have been used instead. Another wave, W_OptGradient, receives the function gradient at the solution point.

There are quite a few options available to modify the workings of the Optimize operation. See **Optimize** operation on page V-725 for details, including references to reading material.

Stopping Tolerances

The Optimize operation stops refining the solution when certain criteria are met. The most desirable result is that it stops because the function gradient is very close to zero, since that is (almost) diagnostic of an extreme point. The algorithm also will take very small steps near an extreme point, so this is also a stopping criterion. You can set the values for the stopping criteria using the /T={*gradTol*, *stepTol*} flag.

Optimize stops when these conditions are met:

$$\max_{1 \le i \le n} \left\{ |g_i| \cdot \frac{max(|x_i|, typX_i)}{max(|f|, funcSize)} \right\} \le gradTol$$

or

$$\max_{1 \le i \le n} \left\{ \frac{|\Delta x_i|}{max(x_i, typX_i)} \right\} \le stepTol$$

Note that these conditions use values of the gradient (g_i) and step size (Δx_i) that are scaled by a measure of the magnitude of values encountered in the problem. In these equations, x_i is the value of a component of the solution and *f* is the value of the function at the solution; $typX_i$ is a "typical" value of the X component that is set by you using the /R flag and *f* is a typical function value magnitude which you set using the /Y flag. The values of $typX_i$ and *f* are one if the /R and /F flags are not present.

The default values for *gradTol* and *stepTol* are {8.53618x10^{-6}, 7.28664x10^{-11}}. These are the values recommended by Dennis and Schnabel (see the references in **Optimize** operation on page V-725) for well-behaved functions when the function values have full double precision resolution. These values are (6.022x10^{-16})$^{1/3}$ and (6.022x10^{-16})$^{2/3}$ as suggested by Dennis and Schnabel (see the references in **Optimize** operation on page V-725), where 6.022x10^{-16} is the smallest double precision floating point number that, when added to 1, is different from 1. Usually the default is pretty good.

Due to floating point truncation errors, it is possible to set *gradTol* and *stepTol* to values that can never be achieved. In that case you may get a message about "no solution was found that is better than the last iteration".

Problems with Multidimensional Optimization

Finding minima of multidimensional functions is by no means foolproof. The methods used by the Optimize operation are "globally convergent" which means that under suitable circumstances Optimize will be able to find some extreme point from just about any starting guess.

If the gradient of your function is zero, or very nearly so at the starting guess, Optimize has no information on which way to go to find an extreme point. Note that the Sinc2D function has a maximum exactly at (0,0). Here is what happens if you try to find a minimum starting at the origin:

```
Optimize/X={0,0} Sinc2D,params2D
```

```
==== The Optimize operation failed to find a minimum. ====
Optimize stopped because
The function gradient at your starting guess is too near zero, suggesting that
it is a critical point.
A different starting guess usually solves this problem.
Current best solution:
   W_Extremum={0,0}
Function gradient:
   W_OptGradient={0,0}
Function value at solution: 1
0 iterations, 3 function calls
V_min = 1, V_OptTermCode = 6, V_OptNumIters = 0, V_OptNumFunctionCalls = 3
```

In this example the function gradient is zero at the origin because there is a function maximum there. A gradient of zero could also be a minimum or a saddle point.

The algorithms used by the Optimize operation assume that your function is smooth, that is, that the first and second derivatives are continuous. Optimize may work with functions that violate this assumption, but it is not guaranteed.

Although Optimize tends to look downhill to the nearest minimum (or uphill to the nearest maximum), it is not guaranteed to find any particular minimum, especially if your starting guess is near a point where the gradient is small. Sometimes using a different method (/M=(*stepMethod*, *hessianMethod*) will result in a different answer. You can limit the maximum step size to keep progress more or less local (/S=*maxStep*). If you set the maximum step size too small, however, Optimize may stop early because the maximum step size is exceeded too many times. Here is an example using the Sinc2D function. If the starting guess is near the origin, the gradient is small and the solution shoots off into the hinterlands (only a portion of the history report is shown):

```
Optimize/X={1,1} Sinc2D,params2D
   W_Extremum={-61.1192,298.438}
Function gradient:
   W_OptGradient={-1.04095e-08,-1.19703e-08}
```

Use /S to limit the step size, and find a minimum nearer to the starting guess:

```
Optimize/X={1,1}/S=10 Sinc2D,params2D
   W_Extremum={-0.00014911,8.9868}
Function gradient:
   W_OptGradient={9.31323e-09,5.92775e-08}
```

But if the maximum step is too small, it doesn't work:

```
Optimize/X={1,1}/S=1 Sinc2D,params2D
```

```
==== The Optimize operation failed to find a minimum. ====
Optimize stopped because
the maximum step size was exceeded in five consecutive iterations.
This can happen if the function is unbounded (there is no minimum),
or the function approaches the minimum asymptotically. It may also be that the
maximum step size (1) is too small.
```

Another way to get a solution near by is to set the initial trust region to a small value. This works if you select double dogleg or More Hebdon as the step selection method. It does not apply to the default line search method. Here is an example (note that the double dogleg method is selected using /M={1,0}):

```
Optimize/X={1,1}/M={1,0}/F=1 Sinc2D,params2D
   W_Extremum={-0.000619834,8.9872}
Function gradient:
   W_OptGradient={1.09896e-07,2.9017e-08}
```

Chapter

III-11

Image Processing

Overview

Image processing is a broad term describing most operations that you can apply to image data which may be in the form of a 2D, 3D or 4D waves. Image processing may sometimes provide the appropriate analysis tools even if the data have nothing to do with imaging. In Chapter II-16, **Image Plots**, we described operations relating to the display of images. Here we concentrate on transformations, analysis operations and special utility tools that are available for working with images.

You can use the IP Tutorial experiment (inside the Learning Aids folder in your Igor Pro 7 folder) in parallel with this chapter. The experiment contains, in addition to some introductory material, the sample images and most of the commands that appear in this chapter. To execute the commands you can select them in the Image Processing help file and press Control-Enter.

For a listing of all image analysis operations, see **Image Analysis** on page V-4.

Image Transforms

The two basic classes of image transforms are color transforms and grayscale/value transforms. Color transforms involve conversion of color information from one color space to another, conversions from color images to grayscale, and representing grayscale images with false color. Grayscale value transforms include, for example, pixel level mapping, mathematical and morphological operations.

Color Transforms

There are many standard file formats for color images. When a color image is stored as a 2D wave, it has an associated or implied colormap and the RGB value of every pixel is obtained by mapping values in the 2D wave into the colormap.

When the image is a 3D wave, each image plane corresponds to an individual red, green, or blue color component. If the image wave is of type unsigned byte (/B/U), values in each plane are in the range [0,255]. Otherwise, the range of values is [0,65535].

There are two other types of 3D image waves. The first consists of 4 layers corresponding to RGBA where the 'A' represents the alpha (transparency) channel. The second contains more than three planes in which case the planes are grayscale images that can be displayed using the command:

```
ModifyImage imageName plane=n
```

Multiple color images can be stored in a single 4D wave where each chunk corresponds to a separate RGB image.

You can find most of the tools for converting between different types of images in the **ImageTransform** operation. For example, you can convert a 2D image wave that has a colormap to a 3D RGB image wave. Here we create a 3-layer 3D wave named M_RGBOut from the 2D image named 'Red Rock' using RGB values from the colormap wave named 'Red RockCMap':

```
ImageTransform /C='Red RockCMap' cmap2rgb 'Red Rock'
NewImage M_RGBOut          // Resulting 3D wave is M_RGBOut
```

Note: The images in the IP Tutorial experiment are not stored in the root data folder, so many of the commands in the tutorial experiment include data folder paths. Here the data folder paths have been removed for easier reading. If you want to execute the commands you see here, use the commands in the “IP Tutorial Help” window. See Chapter II-8, **Data Folders**, for more information about data folders.

In many situations it is necessary to dispose of color information and convert the image into grayscale. This usually happens when the original color image is to be processed or analyzed using grayscale operations. Here is an example using the RGB image which we have just generated:

```
ImageTransform rgb2gray M_RGBOut
NewImage M_RGB2Gray           // Display the grayscale image
```

The conversion to gray is based on the YIQ standard where the gray output wave corresponds to the Y channel:

```
gray=0.299*red+0.587*green+0.114*blue.
```

If you wish to use a different set of transformation constants say {c_i}, you can perform the conversion on the command line:

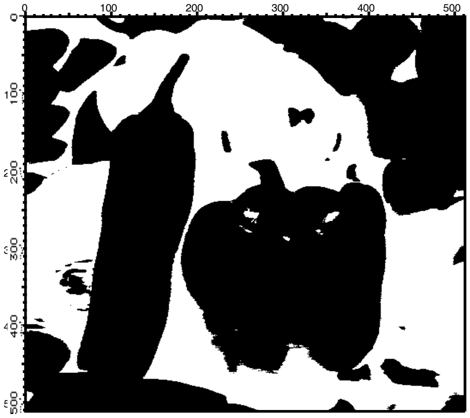
```
gray2DWave=c1*image[p][q][0]+c2*image[p][q][1]+c3*image[p][q][2]
```

For large images this operation may be slow. A more efficient approach is:

```
Make/O/N=3 scaleWave={c1,c2,c3}
ImageTransform/D=scaleWave scalePlanes image // Creates M_ScaledPlanes
ImageTransform sumPlanes M_ScaledPlanes
```

In some applications it is desirable to extract information from the color of regions in the image. We therefore convert the image from RGB to the HSL color space and then perform operations on the first plane (hue) of the resulting 3D wave. In the following example we convert the RGB image wave peppers into HSL, extract the hue plane and produce a binary image in which the red hues are nonzero.

```
ImageTransform /U rgb2hsl peppers// Note the /U for unsigned short result
MatrixOp/O RedPlane=greater(5000,M_RGB2HSL[][][0])+greater(M_RGB2HSL[][][0],60000)
NewImage RedPlane         // Here white corresponds to red hues in the source
```



As you can see, the resulting image is binary, with white pixels corresponding to regions where the original image was predominantly red. The binary image can be used to discriminate between red and other hue regions. The second command line above converts hue values that range from 0 to 65535 to 1 if the color is in the "reddish" range, or zero if it is outside that range. The selection of values below 5000 is due to the fact that red hues appear on both sides of 0° (or 360°) of the hue circle.

Hue based image segmentation is also supported through the **ImageTransform** operation (see page V-417) using the **hslSegment**, **matchPlanes** or **selectColor** keywords. The same operation also supports color space conversions from RGB to CIE XYZ (D65 based) and from XYZ to RGB. See also **Handling Color** on page III-379 and **HSL Segmentation** on page III-374.

Grayscale or Value Transforms

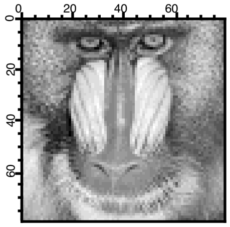
This class of transforms applies only to 2D waves or to individual layers of higher dimensional waves. They are called "grayscale" because 2D waves by themselves do not contain color information. We divide grayscale transforms into level mappings and mathematical operations.

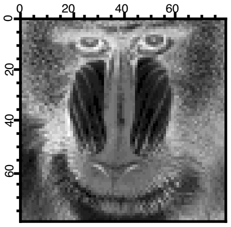
Explicit Lookup Tables

Here is an example of using an explicit lookup table (LUT) to create the negative of an image the hard way:

```
Make/B/U/O/N=256 negativeLookup=255-x     // Create the lookup table
Duplicate/O baboon negativeBaboon
negativeBaboon=negativeLookup[negativeBaboon]// The lookup transformation
```

```
NewImage baboon
NewImage negativeBaboon
```





In this example the negativeBaboon image is a derived wave displayed with standard linear LUT. You can also obtain the same result using the original baboon image but displaying it with a negative LUT:

```
NewImage baboon
Make/N=256 negativeLookup=1-x/255   // Negative slope LUT from 1 to 0
ModifyImage baboon lookup=negativeLookup
```

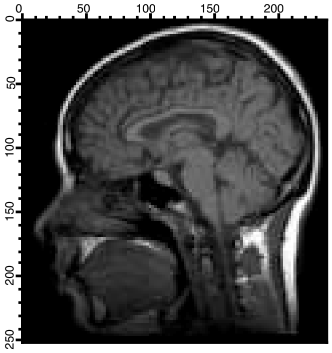
If you are willing to modify the original data you can execute:

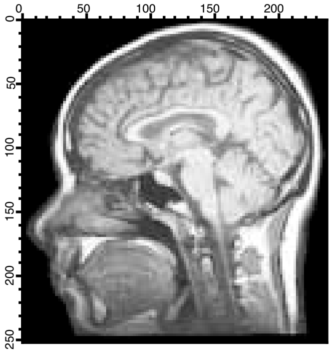
```
ImageTransform invert baboon
```

Histogram Equalization

Histogram equalization maps the values of a grayscale image so that the resulting values utilize the entire available range of intensities:

```
NewImage MRI
ImageHistModification MRI
NewImage M_ImageHistEq
```





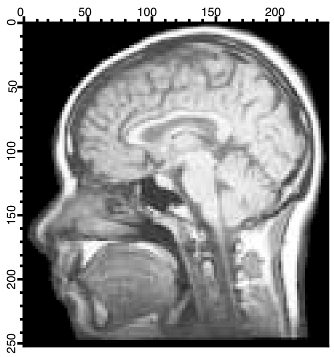
Adaptive Histogram Equalization

The **ImageHistModification** operation calculates a lookup table based on the cumulative histogram of the whole source image. The lookup table is then applied the output image. In cases where there are significant spatial variations in the histogram, a more local approach may be needed, i.e., perform the histogram equalization independently for different parts of the image and then combine the regional results by matching them across region boundaries. This is commonly referred to as "Adaptive Histogram Equalization".

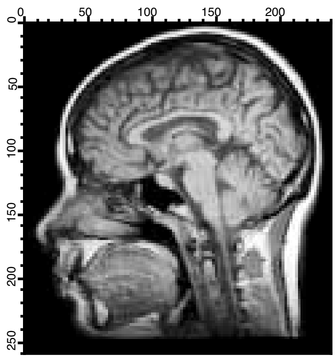
```
ImageHistModification MRI
Duplicate/O M_ImageHistEq, globalHist
NewImage globalHist
ImageTransform/N={2,7} padImage MRI // To make the image divisible
ImageHistModification/A/C=10/H=2/V=2 M_paddedImage
NewImage M_ImageHistEq
```

The original image is 238 by 253 pixels. Because the number of rows and columns must be divisible by the number of equalization intervals, we first padded the image using the ImageTransform **padImage**. The result is an image that is 240 by 260. If you do not find the resulting adaptive histogram sufficiently different from the global histogram equalization, you can increase the number of vertical and horizontal regions that are processed:

```
ImageHistModification/A/C=100/H=20/V=20 M_paddedImage
```



Global



Adaptive

You can now compare the global and adaptive histogram results. Note that the adaptive histogram performed better (increased contrast) over most of the image. The increase in the clipping value (/C flag) gave rise to a minor artifact around the boundary of the head.

Threshold

The threshold operation is an important member of the level mapping class. It converts a grayscale image into a binary image. A binary image in Igor is usually stored as a wave of type unsigned byte. While this may appear to be wasteful, it has advantages in terms of both speed and in allowing you to use some bits of each byte for other purposes (e.g., bits can be turned on or off for binary masking). The threshold operation, in addition to producing the binary thresholded image, can also provide a correlation value which is a measure of the threshold quality.

You can use the **ImageThreshold** operation (see page V-415) either by providing a specific threshold value or by allowing the operation to determine the threshold value for you. There are various methods for automatic threshold determination:

Iterated: Iteration over threshold levels to maximize correlation with the original image.

Bimodal: Attempts to fit a bimodal distribution to the image histogram. The threshold level is chosen between the two modal peaks.

Adaptive: Calculates a threshold for every pixel based on the last 8 pixels on the same scan line. It usually gives rise to drag lines in the direction of the scan lines. You can compensate for this artifact as we show in an example below.

Fuzzy Entropy: Considers the image as a fuzzy set of background and object pixels where every pixel may belong to a set with some probability. The algorithm obtains a threshold value by minimizing the fuzziness which is calculated using Shannon’s Entropy function.

Fuzzy Means: Minimizes a fuzziness measure that is based on the product of the probability that the pixel belongs in the object and the probability that the pixel belongs to the background.

Histogram Clusters: Determines an ideal threshold by histograming the data and representing the image as a set of clusters that is iteratively reduced until there are two clusters left. The threshold value is then set to the highest level of the lower cluster. This method is based on a paper by A.Z. Arifin and A. Asano (see reference below) but modified for handling images with relatively flat histograms. If the image histogram results in less than two clusters, it is impossible to determine a threshold using this method and the threshold value is set to NaN.

Variance: Determines the ideal threshold value by maximizing the total variance between the "object" and "background". See http://en.wikipedia.org/wiki/Otsu’s_method.

Each of the thresholding methods has its advantages and disadvantages. It is sometimes useful to try all the methods before you decide which method applies best to a particular class of images. The following example illustrates the different thresholding methods for an image of light gray blobs on a dark gray background (the “blobs” image in the IP Tutorial).

Threshold Examples

This section shows results using various methods for automatic threshold determination.

The commands shown were executed in the demo experiment that you can open by choosing File→Example Experiments→Tutorials→Image Processing Tutorial.

```
// User defined method

```

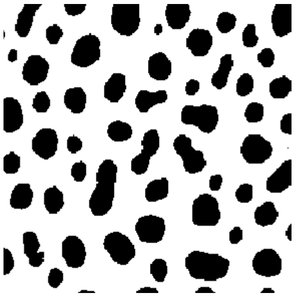
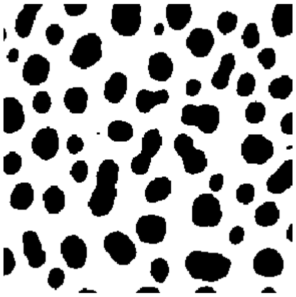
Arifin and Asano



Otsu



In the these examples, you can add the /C flag to each ImageThreshold command and remove the /Q flag to get some feedback about the quality of the threshold; the correlation coefficient will be printed to the history.

It is easy to determine visually that, for this data, the adaptive and the bimodal algorithms performed rather poorly.

You can improve the results of the adaptive algorithm by running the adaptive threshold also on the transpose of the image, so that the operation becomes column based, and then combining the two outputs with a binary AND.

Spatial Transforms

Spatial transforms describe a class of operations that change the position of the data within the wave. These include the operations **ImageTransform** with multiple keywords, **MatrixTranspose**, **ImageRotate**, **ImageInterpolate**, and **ImageRegistration**.

Rotating Images

You can rotate images using the **ImageRotate** operation (see page V-405). There are two issues that are worth noting in connection with image rotations where the rotation angle is not a multiple of 90 degrees. First, the image size is always increased to accommodate all source pixels in the rotated image (no clipping is done). The second issue is that rotated pixels are calculated using bilinear interpolation so the result of N consecutive rotations by 360/N degrees will not, in general, equal the original image. In cases of multiple rotations you should consider keeping a copy of the original image as the same source for all rotations.

Image Registration

In many situations one has two or more images of the same object where the differences between the images have to do with acquisition times, dissimilar acquisition hardware or changes in the shape of the object between exposures. To facilitate comparison between such images it is necessary to register them, i.e., to adjust them so that they match each other. The **ImageRegistration** operation (see page V-398) modifies a test image to match a reference image when the key features are not too different. The algorithm is capable of subpixel resolution but it does not handle very large offsets or large rotations. The algorithm is based on an iterative processing that proceeds from coarse to fine detail. The optimization is performed using a modified Levenberg-Marquardt algorithm and results in an affine transformation for the relative rotation and translation with optional isometric scaling and contrast adjustment. The algorithm is most effective with square images where the center of rotation is not far from the center of the image.

ImageRegistration is based on an algorithm described by Thévenaz and Unser.

Mathematical Transforms

This class of transforms includes standard wave assignments, interpolation and sampling, Fourier, Wavelet, Hough, and Hartley transforms, convolution filters, edge detectors and morphological operators.

Standard Wave Operations

Grayscale image waves are regular 2D Igor waves that can be processed using normal Igor wave assignments (**Waveform Arithmetic and Assignments** on page II-74 and **Multidimensional Wave Assignment** on page II-96). For example, you can perform simple linear operations:

```
Duplicate/O root:images:blobs sample
Redimension/S sample       // create a single precision sample
sample=10+5*sample         // linear operation
NewImage sample            // keep this image displayed
```

Note that the display of the image is invariant for this linear operation.

Nonlinear operations are just as easy:

```
sample=sample^3-sample     // not particularly useful
```

You can add noise and change the background using simple wave assignment:

```
sample=root:images:blobs   // rest to original
sample+=gnoise(20)+x+2*y   // add Gaussian noise and background plane
```

As we have shown in several examples above, it is frequently necessary to create a binary image from your data. For instance, if you want an image that is set to 255 for all pixels in the image wave sample that are between the values of 50 and 250, and set to 0 otherwise, you can use the following one line wave assignment:

```
MatrixOp/O sample=255*greater(sample,50)*greater(250,sample)
```

More Efficient Wave Operations

There are several operations in this category that are designed to improve performance of certain image calculations. For example, you can obtain one plane (layer) from a multiplane image using a wave assignment like:

```
Make/N=(512,512) newImagePlane
newImagePlane[][]=root:Images:peppers[p][q][0]
```

Alternatively, you can execute:

```
ImageTransform/P=0 getPlane root:Images:peppers
```

or

```
MatrixOp/O outWave=root:Images:peppers[][][0]
```

ImageTransform and MatrixOp are much faster for this size of image than the simple wave assignment. See **General Utilities: ImageTransform Operation** on page III-381 and **Using MatrixOp** on page III-140.

Interpolation and Sampling

You can use the **ImageInterpolate** operation (see page V-382) as both an interpolation and sampling tool. In the following example we create an interpolated image from a portion of the MRI image. The resulting image is sampled at four times the original resolution horizontally and twice vertically.

```
NewImage root:images:MRI
ImageInterpolate /S={70,0.25,170,70,0.5,120} bilinear root:images:MRI
NewImage M_InterpolatedImage
```

As the keyword suggests, the interpolation is bilinear. You can use the same operation to sample the image. In the following example we reduce the image size by a factor of 4:

```
NewImage root:images:MRI              // display for comparison
ImageInterpolate /f={0.5,0.5} bilinear root:images:MRI
NewImage M_InterpolatedImage          // the sampled image
```

Note that in reducing the size of certain images, it may be useful to apply a blurring operation first (e.g., MatrixFilter gauss). This becomes important when the image contains thin (smaller than sample size) horizontal or vertical lines.

If the bilinear interpolation does not satisfy your requirements you can use spline interpolations of degrees 2-5. Here is a comparison between the bilinear and spline interpolation of degree 5 used to scale an image:

```
ImageInterpolate /f={1.5,1.5} bilinear MRI
Rename M_InterpolatedImage Bilinear
NewImage Bilinear
ImageInterpolate /f={1.5,1.5}/D=5 spline MRI
NewImage M_InterpolatedImage
```

Another form of sampling is creating a pixelated image. A pixelated image is computed by subdividing the original image into non-overlapping rectangles of nx by ny pixels and computing the average pixel value for each rectangle:

```
ImageInterpolate/PXSZ={5,5}/DEST=pixelatedImage pixelate, MRI
NewImage pixelatedImage
```

Fast Fourier Transform

There are many books on the application of Fourier transforms in imaging so we will only discuss some of the technical aspects of using the **FFT** operation (see page V-222) in Igor.

It is important to keep in mind is that, for historical reasons, the default FFT operation *overwrites* and *modifies* the image wave. You can also specify a destination wave in the FFT operation and your source wave will be preserved. The second issue that you need to remember is that the transformed wave is converted into a complex data type and the number of points in the wave is also changed to accommodate this conversion. The third issue is that when performing the FFT operation on a real wave the result is a one-sided spectrum, i.e., you have to obtain the rest of the spectrum by reflecting and complex-conjugating the result.

A typical application of the FFT in image processing involves transforming a real wave of 2N rows by M columns. The complex result of the FFT is (N+1) rows by M columns. If the original image wave has wave scaling of dx and dy, the new wave scaling is set to 1/(N*dx) and 1/(M*dy) respectively.

The following examples illustrate a number of typical applications of the FFT in imaging.

Calculating Convolutions

To calculate convolutions using the FFT it is necessary that the source wave and the convolution kernel wave have the same dimensions (see **MatrixOp** convolve for an alternative). Consider, for example, smoothing noise via convolution with a Gaussian:

```
// Create and display a noisy image.
Duplicate /O root:images:MRI mri    // an unsigned byte image.
Redimension/s mri                   // convert to single precision.
mri+=gnoise(10)                     // add noise.
NewImage mri
ModifyImage mri ctab= {*,*,Rainbow,0}// show the noise using false color.

// Create the filter wave.
Duplicate/O mri gResponse     // just so that we have the same size wave.
SetScale/I x -1,1,"" gResponse
SetScale/I y -1,1,"" gResponse

// Change the width of the Gaussian below to set the amount of smoothing.
gResponse=exp(-(x^2+y^2)/0.001)

// Calculate the convolution.
Duplicate/O mri processedMri
FFT processedMri                    // Transform the source
FFT gResponse                       // Transform the kernel
processedMri*=gResponse    // (complex) multiplication in frequency space
IFFT processedMri

// Swap the IFFT to properly center the result.
ImageTransform swap processedMri
Newimage processedM
ModifyImage processedMri ctab= {*,*,Rainbow,0}
```

In practice one can perform the convolution with fewer commands. The example above has a number of commands that are designed to make it clearer. Also note that we used the **SetScale** operation (see page V-853) to create the Gaussian filter. This was done to make sure that the Gaussian was created at the center of the filter image, a choice that is compatible with the ImageTransform **swap** operation. This example is also not ideal because one can take advantage of the properties of the Gaussian (the Fourier transform of a Gaussian is also Gaussian) and perform the convolution as follows:

```
// Calculate the convolution.
Duplicate/O mri shortWay
FFT shortWay
shortWay*=cmplx(exp(-(x^2+y^2)/0.01),0)
IFFT shortWay
Newimage shortWay
ModifyImage shortWay ctab={*,*,Rainbow,0}
```

Spatial Frequency Filtering

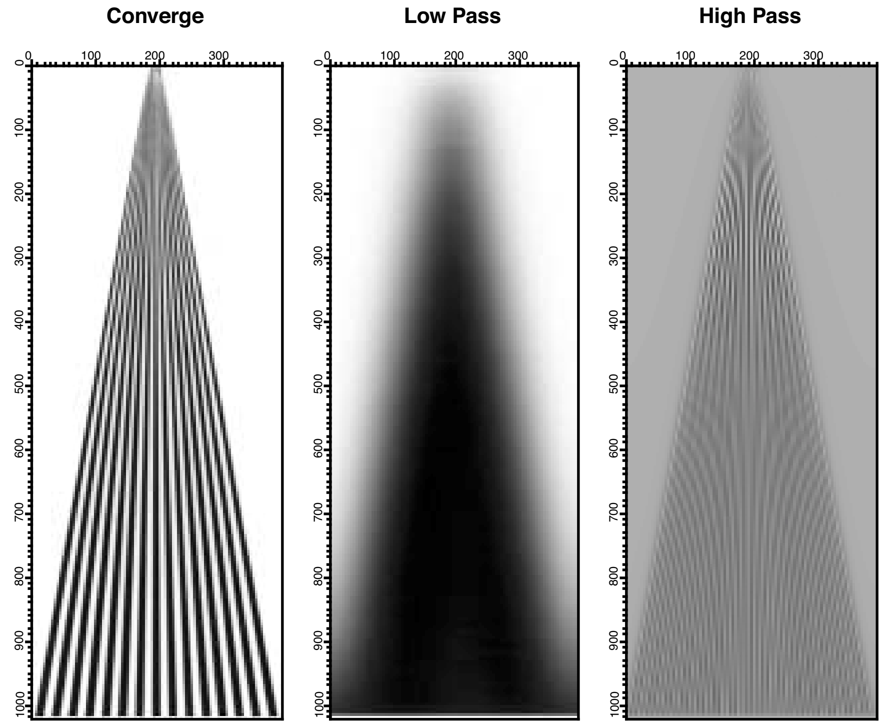
The concept behind spatial frequency filtering is to transform the data into spatial frequency space. Once in frequency domain we can modify the spatial frequency distribution of the image and then inverse-transform to obtain the modified image.

Here is an example of low and high pass filtering. The converge image consists of wide black lines converging to a single point. If you draw a horizontal line profile anywhere below the middle of the image you will get a series of 15 rectangles which will give rise to a broad range of spatial frequencies in the horizontal direction.

```
// Prepare for FFT; we need SP or DP wave.
Duplicate/O root:images:converge converge
Redimension /s converge
FFT converge
Duplicate/O converge lowPass     // new complex wave in freq. domain
lowPass=lowPass*cmplx(exp(-(p)^2/5),0)
```

```
IFFT lowPass
NewImage lowPass                  // nonoptimal lowpass

Duplicate/O converge hiPass
hiPass=hiPass*cmplx(1-1/(1+(p-20)^2/2000),0)
IFFT hiPass
NewImage hiPass                   // nonoptimal highpass
```



Converge

Low Pass

High Pass

We arbitrarily chose the Gaussian form for the low-pass filter. In practical applications it is usually important to select an exact “cutoff” frequency and at the same time choose a filter that is sufficiently smooth so that it does not give rise to undesirable filtering artifacts such as ringing, etc. The high-pass filter that we used above is almost a notch filter that rejects low frequencies. Both filters are essentially one-dimensional filters.

Calculating Derivatives

Using the derivative property of Fourier transform, you can calculate, for example, the x-derivative of an image in the following way:

```
Duplicate/O root:images:mri xDerivative   // retain the original.
Redimension/S xDerivative
FFT xDerivative
xDerivative*=cmplx(0,p)    // neglecting 2pi factor & wave scaling.
IFFT xDerivative
NewImage xDerivative
```

Although this approach may not be appealing in all applications, its advantages are apparent when you need to calculate higher order derivatives. Also note that this approach does not take into account any wave scaling that may be associated with the rows or the columns.

Calculating Integrals or Sums

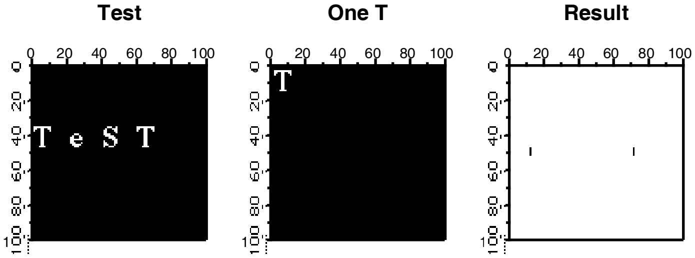
Another useful property of the Fourier transform is that the transform values along the axes correspond to integrals of the image. There is usually no advantage in using the FFT for this purpose. However, if the FFT is calculated anyway for some other purpose, one can make use of this property. A typical situation where this is useful is in calculating correlation coefficient (normalized cross-correlation).

Correlations

The FFT can be used to locate objects of a particular size and shape in a given image. The following example is rather simple in that the test object has the same scale and rotation angle as the ones found in the image.

```
// Test image contains the word Test.
NewImage test                   // We will be looking for the two T's
Duplicate/O root:images:oneT oneT// the object we are looking for
NewImage oneT

Duplicate/O test testf          // because the FFT overwrites
FFT testf
Duplicate/O oneT oneTf
FFT oneTf
testf*=oneTf                    // not a "proper" correlation
IFFT testf
ImageThreshold/O/T=1.25e6 testf  // remove noise (due to overlap with other
characters
NewImage testf          // the results are the correlation spots for the T's
```



When using the FFT it is sometimes necessary to operate on the source image with one of the built-in window functions so that pixel values go smoothly to zero as you approach image boundaries. The **ImageWindow** operation (see page V-435) supports the Hanning, Hamming, Bartlett, Blackman, and Kaiser windows. Normally the **ImageWindow** operation (see page V-435) works directly on an image as in the following example:

```
// The redimension is required for the FFT operation anyway, so you
// might as well perform it here and reduce the quantization of the
// results in the ImageWindow operation.
Redimension/s blobs
ImageWindow /p=0.03 kaiser blobs
NewImage M_WindowedImage
```

To see what the window function looks like:

```
Redimension/S blobs                 // SP or DP waves are necessary
ImageWindow/i/p=0.01 kaiser blobs   // just creates the window data
NewImage M_WindowedImage      // you can also make a surface plot from this.
```

Wavelet Transform

The wavelet transform is used primarily for smoothing, noise reduction and lossy compression. In all cases the procedure we follow is first to transform the image, then perform some operation on the transformed wave and finally calculate the inverse transform.

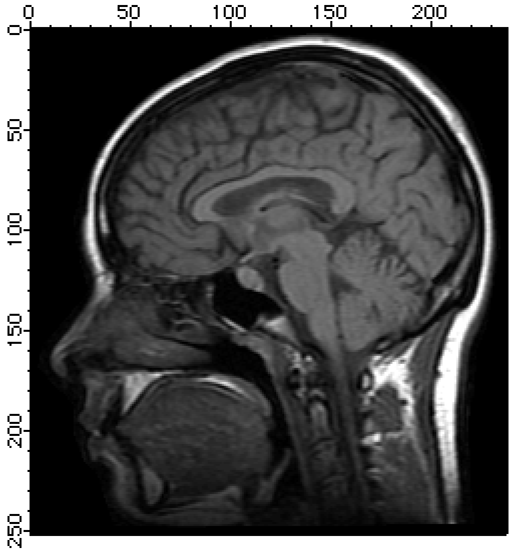
The next example illustrates a wavelet compression procedure. Start by calculating the wavelet transform of the image. Your choice of wavelet and coefficients can significantly affect compression quality. The compressed image is the part of the wave that corresponds to the low order coefficients in the transform (similar to low pass filtering in 2D Fourier transform). In this example we use the **ImageInterpolate** operation (see page V-382) to create a wave from a 64x64 portion of the transform.

```
DWT /N=4/P=1/T=1 root:images:MRI,wvl_MRI     // Wavelet transform
// reduce size by a factor of 16
ImageInterpolate/s={0,1,63,0,1,63} bilinear wvl_MRI
```

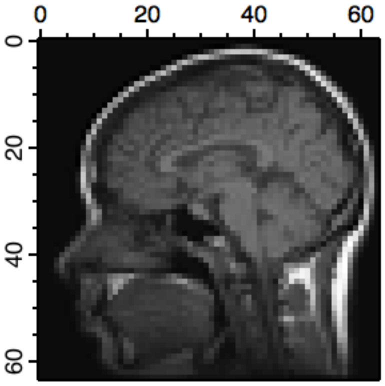
To reconstruct the image and evaluate compression quality, inverse-transform the compressed image and display the result:

```
DWT /I/N=4/P=0/T=1 M_InterpolatedImage,iwvl_compressed
NewImage iwvl_compressed
```

Original



Compressed

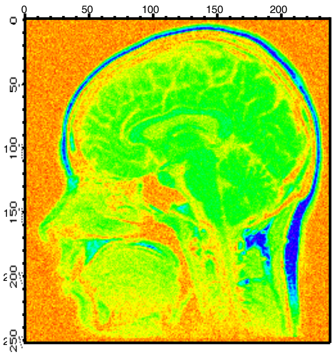


The reconstructed image exhibits a number of compression-related artifacts, but it is worth noting that unlike an FFT based low-pass filter, the advantage of the wavelet transform is that the image contains a fair amount of high spatial frequency content. The factor of 16 mentioned above is not entirely accurate because the original image was stored as a one byte per pixel while the compressed image consists of floating point values (so the true compression ratio is only 4).

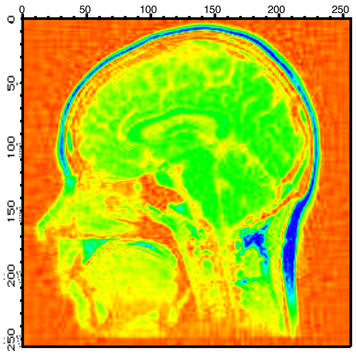
To illustrate the application of the wavelet transform to denoising, we start by adding Gaussian distributed noise with standard deviation 10 to the MRI image:

```
Redimension/S Mri                        // SP so we can add bipolar noise
Mri+=gnoise(10)                          // Gaussian noise added
NewImage Mri
ModifyImage Mri ctab={*,*,Rainbow,0}// false color for better discrimination.
DWT/D/N=20/P=1/T=1/V=0.5 Mri,dMri        // increase /V for more denoising
NewImage dMri                            // display denoised image
ModifyImage dMri ctab={*,*,Rainbow,0}
```

MRI



dMRI



Hough Transform

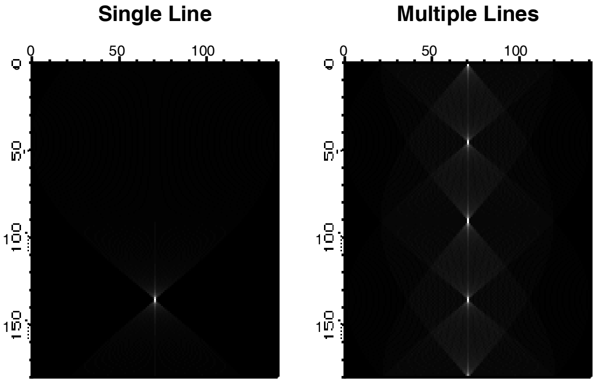
The Hough Transform is a mapping algorithm in which lines in image space map to single points in the transform space. It is most often used for line detection. Specifically, each point in the image space maps to a sinusoidal curve in the transform space. If pixels in the image lie along a line, the sinusoidal curves associated with these pixels all intersect at a single point in the transform space. By counting the number of sinusoids intersecting at each point in the transform space, lines can be detected. Here is an example of an image that consists of one line.

```
Make/O/B/U/N=(100,100) lineImage
lineImage=(p==q ? 255:0)            // single line at 45 degrees
Newimage lineimage
ImageTransform hough lineImage
Newimage M_Hough
```

The Hough transform of a family of lines:

```
lineImage=((p==100-q)|(p==q)|(p==50)|(q==50)) ? 255:0
ImageTransform Hough lineImage
```

The last image shows a series of bright pixels in the center. The first and last points correspond to lines at 0 and 180 degrees. The second point from the top corresponds to the line at 45 degrees and so on.



Fast Hartley Transform

The Hartley transform is similar to the Fourier transform except that it uses only real values. The transform is based on the *cas* kernel defined by:

$$cas(vx) = \cos(vx) + \sin(vx) .$$

The discrete Hartley transform is given by

$$H(u,v) = \frac{1}{MN}\sum_{x=0}^{M-1}\sum_{y=0}^{N-1} f(x,y)\left\{\cos\left(\left[2\pi\left(\frac{ux}{M}-\frac{vy}{N}\right)\right] + \sin\left[2\pi\left(\frac{ux}{M}-\frac{vy}{N}\right)\right]\right)\right\}$$

The Hartley transform has two interesting mathematical properties. First, the inverse transform is identical to the forward transform, and second, the power spectrum is given by the expression:

$$P(f) = \frac{[H(f)]^2 + [H(-f)]^2}{2}$$

The implementation of the Fast Hartley Transform is part of the **ImageTransform** operation (see page V-417). It requires that the source wave is an image whose dimensions are a power of 2.

```
ImageTransform /N={18,3}/O padImage Mri      // make the image 256^2
ImageTransform fht mri
NewImage M_Hartley
```

Convolution Filters

Convolution operators usually refer to a class of 2D kernels that are convolved with an image to produce a desirable effect (simple linear filtering). In some cases it is more efficient to perform convolutions using the FFT (similar to the convolution example above), i.e., transform both the image and the filter waves, multiply the transforms in the frequency domain and then compute the inverse transformation using the IFFT. The FFT approach is more efficient for convolution with kernels that are greater than 13x13 pixels. However, there is a very large number of useful kernels which play an important role in image processing that are 3x3 or 5x5 in size. Because these kernels are so small, it is fairly efficient to implement the corresponding linear filter as direct convolution without using the FFT.

In the following example we implement a low-pass filter with equal spatial frequency response along both axes.

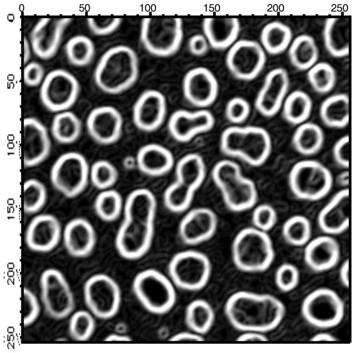
```
Make /O/N=(9,9) sKernel       // first create the convolution kernel
SetScale/I x -4.5,4.5,"", sKernel
SetScale/I y -4.5,4.5,"", sKernel

// Equivalent to rect(2*fx)*rect(2*fy) in the spatial frequency domain.
sKernel=sinc(x/2)*sinc(y/2)

// Remember: MatrixConvolve executes in place; save your image first!
Duplicate/O root:images:MRI mri
Redimension/S mri                          // to avoid integer truncation
MatrixConvolve sKernel mri
NewImage mri
ModifyImage mri ctab= {*,*,Rainbow,0}    // just to see it better
```

The next example illustrates how to perform edge detection using a built-in convolution filter in the **ImageFilter** operation (see page V-372):

```
Duplicate/O root:images:blobs blobs
ImageFilter findEdges blobs
NewImage blobs
```



Other notable examples of image filters are Gauss, Median and Sharpen. You can also apply the same operation to 3D waves. The filters Gauss3D, avg3D, point3D, min3D, max3D and median3Dare the extensions of their 2D counterparts to 3x3x3 voxel neighborhoods. Note that the last three filters are not true *convolution* filters.

Edge Detectors

In many applications it is necessary to detect edges or boundaries of objects that appear in images. The edge detection consists of creating a binary image from a grayscale image where the pixels in the binary image are turned off or on depending on whether they belong to region boundaries or not. In other words, the detected edges are described by an image, not a vector (1D wave). If you need to obtain a wave describing boundaries of regions, you might want to use the **ImageAnalyzeParticles** operation (see page V-363).

Igor supports eight built-in edge detectors (methods) that vary in performance depending on the source image. Some methods require that you provide several parameters which tend to have a significant effect on the quality of the result. In the following examples we illustrate the importance of these choices.

```
// Create and display a simple artificial edge image.
Make/B/U/N=(100,100) edgeImage
edgeImage=(p<50? 50:5)
Newimage edgeImage

// Try a simple Sobel detector using iterated threshold detection.
ImageEdgeDetection/M=1/N Sobel, edgeImage
NewImage M_ImageEdges
ModifyImage M_ImageEdges explicit=0 // to see binary image in color
ModifyImage M_ImageEdges ctab= {*,*,Rainbow,0}
```

This result (the red line) is pretty much what we would expect. Here are other examples that work similarly well:

```
ImageEdgeDetection/M=1/N Kirsch, edgeImage   // same output wave
```

or

```
ImageEdgeDetection/M=1/N Roberts, edgeImage  // same output wave
```

The innocent looking /M=1 flag implies that the operation uses an iterative automatic thresholding. This appears to work well in the examples above, but it fails completely when using the Frei filter:

```
ImageEdgeDetection/M=1/N Frei, edgeImage
```

On the other hand, the bimodal fit thresholding works much better here:

```
ImageEdgeDetection/M=2/N Frei, root:edgeImage
```

The performance of this filter improves dramatically if you add a little noise to the image:

```
edgeImage+=gnoise(1)
ImageEdgeDetection/M=1/N/S=1 Canny, edgeImage
```

Using More Exotic Edge Detectors

The more exotic edge detectors consist of multistep operations that usually involve smoothing and differentiation. Here is an example that illustrates the effect of smoothing:

```
Duplicate/O root:images:blobs blobs
ImageEdgeDetection/M=1/N/S=1 Canny,blobs
Duplicate/O M_ImageEdges smooth1
ImageEdgeDetection/M=1/N/S=2 Canny,blobs
Duplicate/O M_ImageEdges smooth2
ImageEdgeDetection/M=1/N/S=3 Canny,blobs
Duplicate/O M_ImageEdges smooth3
NewImage smooth1
ModifyImage smooth1 explicit=0
NewImage smooth2
ModifyImage smooth2 explicit=0
NewImage smooth3
ModifyImage smooth3 explicit=0
```

As you can see, the third image (smooth3) is indeed much cleaner than the first or the second, however, that result is obtained at the cost of loosing some of the small blobs. The following commands will draw a circle around one of the blobs that is missing in the third image:

```
DoWindow/F Graph0
SetDrawLayer UserFront
SetDrawEnv linefgc= (65280,0,0),fillpat= 0
DrawOval 0.29,0.41,0.35,0.48
DoWindow/F Graph1
SetDrawLayer UserFront
SetDrawEnv linefgc= (65280,0,0),fillpat= 0
```

```
DrawOval 0.29,0.41,0.35,0.48
DoWindow/F Graph2
SetDrawLayer UserFront
SetDrawEnv linefgc= (65280,0,0),fillpat= 0
DrawOval 0.29,0.41,0.35,0.48
```

It is instructive to make a similar set of images using the Marr and Shen detectors.

```
// Note: This will take considerably longer time to execute!
Duplicate/O root:images:blobs blobs
ImageEdgeDetection/M=1/N/S=1 Marr,blobs
Duplicate/O M_ImageEdges smooth1
ImageEdgeDetection/M=1/N/S=2 Marr,blobs
Duplicate/O M_ImageEdges smooth2
ImageEdgeDetection/M=1/N/S=3 Marr,blobs
Duplicate/O M_ImageEdges smooth3
NewImage smooth1
ModifyImage smooth1 explicit=0
NewImage smooth2
ModifyImage smooth2 explicit=0
NewImage smooth3
ModifyImage smooth3 explicit=0
SetDrawLayer UserFront
SetDrawEnv linefgc= (65280,0,0),fillpat= 0
DrawOval 0.29,0.41,0.35,0.48
```

The three images of the calculated edges demonstrate the reduction of noise with the increase in the size of the convolution kernel. It's also worth noting that the blob that disappeared when we used the Canny detector is clearly visible using the Marr detector.

In the following example we use the Shen-Castan detector with various smoothing factors. Note that this edge detection algorithm does not use the standard thresholding (you have to specify the threshold using the /F flag).

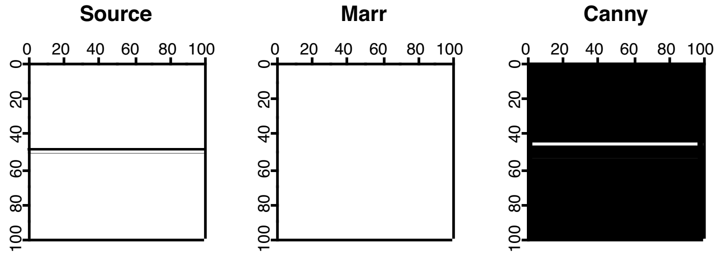
```
Duplicate/O root:images:blobs blobs
ImageEdgeDetection/N/S=0.5 shen,blobs
Duplicate/O M_ImageEdges smooth1
ImageEdgeDetection/N/S=0.75 shen,blobs
Duplicate/O M_ImageEdges smooth2
ImageEdgeDetection/N/S=0.95 shen,blobs
Duplicate/O M_ImageEdges smooth3
NewImage smooth1
ModifyImage smooth1 explicit=0
NewImage smooth2
ModifyImage smooth2 explicit=0
NewImage smooth3
ModifyImage smooth3 explicit=0
SetDrawLayer UserFront
SetDrawEnv linefgc=(65280,0,0),fillpat=0
DrawOval 0.29,0.41,0.35,0.48
```

As you can see in this example, the Shen detector produces a thin, though sometimes broken, boundary. The noise reduction is a trade-off with edge quality.

One of the problems of edge detectors that employ smoothing is that they usually introduce errors when there are two edges that are relatively close to each other. In the following example we construct an artificial image that illustrates this point:

```
Make/B/U/O/N=(100,100) sampleEdge=0
sampleEdge[][49]=255
sampleEdge[][51]=255
NewImage sampleEdge
ImageEdgeDetection/N/S=1 Marr, sampleEdge
Duplicate/O M_ImageEdges s2
```

```
NewImage s2
ImageEdgeDetection/M=1/S=3 Canny, sampleEdge
Duplicate/O M_ImageEdges s3
NewImage s3
```

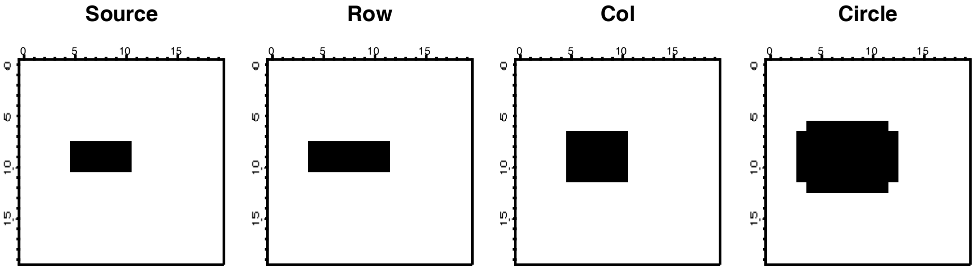


Note that the Marr detector completely misses the edge with the smoothing setting set to 1. Also, the position of the edge moves away from the true edge with increased smoothing in the Canny detector.

Morphological Operations

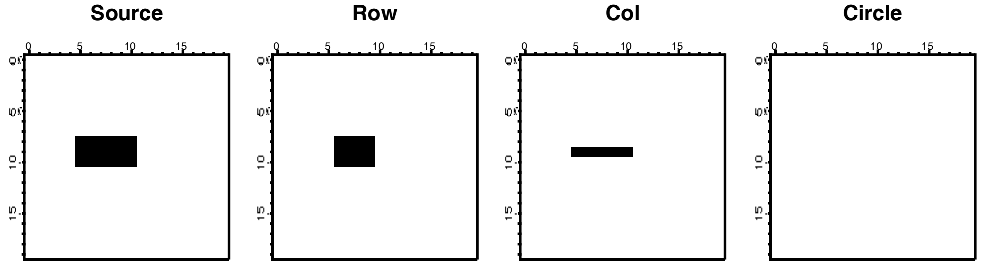
Morphological operators are tools that affect the shape and boundaries of regions in the image. Starting with dilation and erosion, the typical morphological operation involves an image and a structure element. The structure element is normally much smaller in size than the image. Dilation consists of reflecting the structure element about its origin and using it in a manner similar to a convolution mask. This can be seen in the next example:

```
Make/B/U/N=(20,20) source=0
source[5,10][8,10]=255                 // source is a filled rectangle
NewImage source
Imagemorphology /E=2 BinaryDilation source// dilation with 1x3 element
Duplicate M_ImageMorph row
NewImage row                     // display the result of dialation
Imagemorphology /E=3 BinaryDilation source// dilation by 3x1 column
Duplicate M_ImageMorph col
NewImage col                              // display column dilation
Imagemorphology /E=5 BinaryDilation source// dilation by a circle
NewImage M_ImageMorph                     // display circle dilation
```



The result of erosion is the set of pixels x, y such that when the structure element is translated by that amount it is still contained within the set.

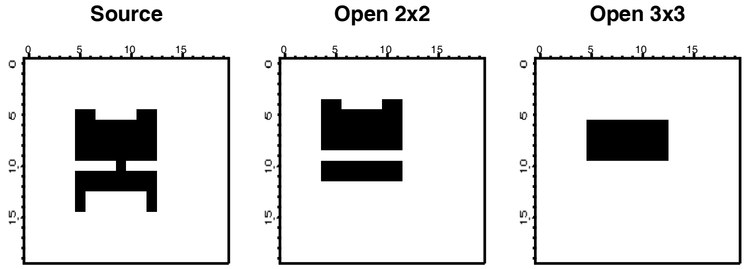
```
Make/B/U/N=(20,20) source=0
source[5,10][8,10]=255                 // source is a filled rectangle
NewImage source
Imagemorphology /E=2 BinaryErosion source// erosion with 1x3 element
Duplicate M_ImageMorph row
NewImage row                           // display the result of erosion
Imagemorphology /E=3 BinaryErosion source// erosion by 3x1 column
Duplicate M_ImageMorph col
NewImage col                           // display column erosion
Imagemorphology /E=5 BinaryErosion source// erosion by a circle
NewImage M_ImageMorph                  // display circle erosion
```



We note first that erosion by a circle erased all source pixels. We get this result because the circle structure element is a 5x5 “circle” and there is no x, y offset such that the circle is completely inside the source. The row and the col images show erosion predominantly in one direction. Again, try to imagine the 1x3 structure element (in the case of the row) sliding over the source pixels to produce the erosion.

The next pair of morphological operations are the opening and closing. Functionally, opening corresponds to an erosion of the source image by some structure element (say E), and then dilating the result using the same structure element E again. In general opening has a smoothing effect that eliminates small (narrow) protrusions as we show in the next example:

```
Make/B/U/N=(20,20) source=0
source[5,12][5,14] = 255
source[6,11][13,14] = 0
source[5,8][10,10] = 0
source[10,12][10,10] = 0
source[7,10][5,5] = 0
NewImage source
ImageMorphology /E=1 opening source // open using 2x2 structure element
Duplicate M_ImageMorph OpenE1
NewImage OpenE1
ImageMorphology /E=4 opening source // open using a 3x3 structure element
NewImage M_ImageMorph
```

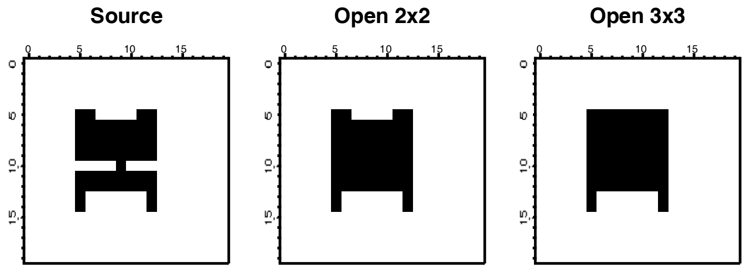


As you can see, the 2x2 structure element removed the thin connection between the top and the bottom regions as well as the two protrusions at the bottom. On the other hand, the two protrusions at the top were large enough to survive the 2x2 structure element. The third image shows the result of the 3x3 structure element which was large enough to eliminate all the protrusions but also the bottom region as well.

The closing operation corresponds to a dilation of the source image followed by an erosion using the same structure element.

```
Make/B/U/N=(20,20) source=0
source[5,12][5,14] = 255
source[6,11][13,14] = 0
source[5,8][10,10] = 0
source[10,12][10,10] = 0
source[7,10][5,5] = 0
NewImage source
ImageMorphology /E=4 closing source // close using 3x3 structure element
Duplicate M_ImageMorph CloseE4
NewImage CloseE4
```

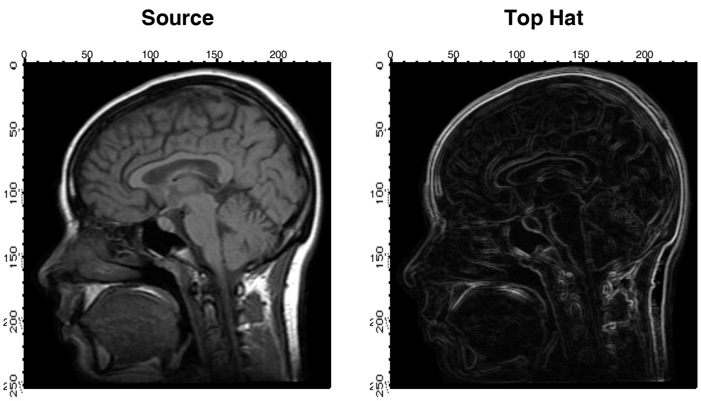
```
ImageMorphology /E=5 closing source // close using 5x5 structure element
NewImage M_ImageMorph
```

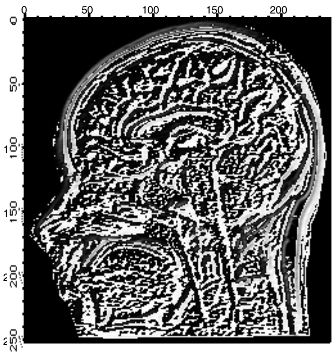


The center image above corresponds to a closing using a 3x3 structure element which appears to be large enough to close the gap between the top and bottom regions but not sufficiently large to fill the gaps between the top and bottom protrusions. The image on the right was created with a 5x5 “circle” structure element, which was evidently large enough to close the gap between the protrusions at the top but not at the bottom.

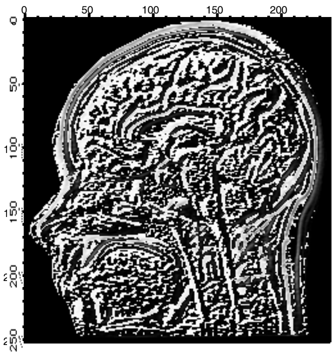
There are various definitions for the Top Hat morphological operation. Igor’s Top Hat calculates the difference between an eroded image and a dilated image. Other interpretations include calculating the difference between the image itself and its closing or opening. In the following example we illustrate some of these variations.

```
Duplicate root:images:mri source
ImageMorphology /E=1 tophat source  // close using 2x2 structure element
Duplicate M_ImageMorph tophat
NewImage tophat
ImageMorphology /E=1 closing source // close using 3x3 structure element
Duplicate M_ImageMorph closing
closing-=source
NewImage closing
ImageMorphology /E=1 opening source // close using 3x3 structure element
Duplicate M_ImageMorph opening
opening=source-opening
NewImage opening
```





Closing

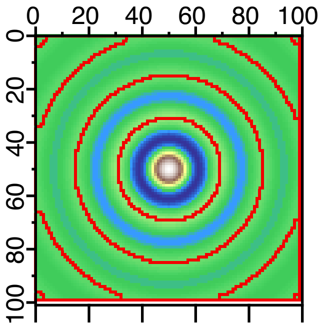


Opening

As you can see from the four images, the built-in Top Hat implementation enhances the boundaries (contours) of regions in the image whereas the opening or closing tophats enhance small grayscale variations.

The watershed operation locates the boundaries of watershed regions as we show below:

```
Make/O/N=(100,100) sample
sample=sinc(sqrt((x-50)^2+(y-50)^2)/2.5)// looks like concentric circles.
ImageTransform/O convert2Gray sample
NewImage sample
ModifyImage sample ctab= {*,*,Terrain,0}// color for better discrimination
ImageMorphology /N/L watershed sample
AppendImage M_ImageMorph
ModifyImage M_ImageMorph explicit=1, eval={0,65000,0,0}
```



Note that omitting the /L flag in the watershed operation may result in spurious watershed lines as the algorithm follows 4-connectivity instead of 8.

Image Analysis

The distinction between image processing and image analysis is rather fine. The pure analysis operations are: ImageStats, line profile, histogram, hsl segmentation and particle analysis.

ImageStats Operation

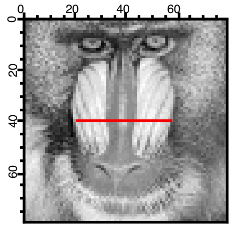
You can obtain global statistics on a wave using the standard **WaveStats** operation (see page V-1082). The **ImageStats** operation (see page V-414) works specifically with 2D and 3D waves. The operation can define a completely arbitrary ROI using a standard ROI wave (see **Working with ROI** on page III-378). A special flag /M=1, speeds up the operation when you only want to know the minimum, maximum and average values in the ROI region, skipping over the additional computation time required to evaluate higher moments. This operation was designed to work in user defined adaptive algorithms.

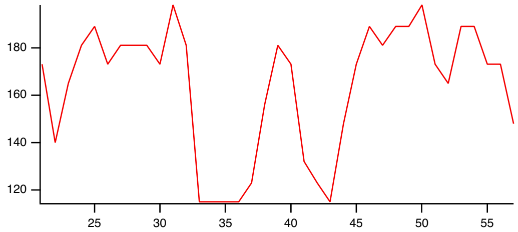
ImageStats can also operate on a specific plane of a 3D wave using the /P flag.

ImageLineProfile Operation

The **ImageLineProfile** operation (see page V-389) is somewhat of a misnomer as it samples the image along a path consisting of an arbitrary number of line segments. To use the operation you first need to create the description of the path using a pair of waves. Here is a simple example:

```
NewImage root:images:baboon    // Display the image that we want to profile
// Create the pair of waves representing a straight line path.
Make/O/N=2 xPoints={21,57}, yPoints={40,40}
AppendToGraph/T yPoints vs xPoints  // display the path on the image
// Calculate the profile.
ImageLineProfile xwave=xPoints, ywave=yPoints, srcwave=root:images:baboon
Display W_ImageLineProfile vs W_LineProfileX // display the profile
```





You can create a more complex path consisting of an arbitrary number of points. In this case you may want to take advantage of the W_LineProfileX and W_LineProfileY waves that the operation creates and plot the profile as a 3D path plot (see “Path Plots” in the Visualization help file). See also the IP Tutorial experiment for more elaborate examples.

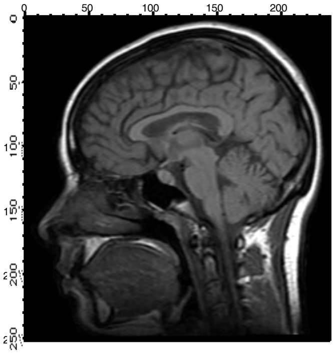
Note: If you are working with 3D waves with more than 3 layers, you can use `ImageLineProfile/P=`*`plane`* to specify the plane for which the profile is computed.

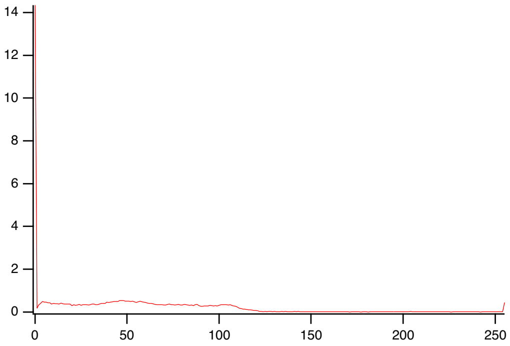
If you are using the line profile to extract a sequential array of data (a row or column) from the wave it is more efficient (about a factor of 3.5 in speed) to extract the data using ImageTransform **getRow** or **getCol**.

Histograms

The histograms is a very important tool in image analysis. For example, the simplest approach to automating the detection of the background in an image is to calculate the histogram and to choose the pixel value which occurs with the highest frequency. Histograms are also very important in determining threshold values and in enhancing image contrast. Here are some examples using image histograms:

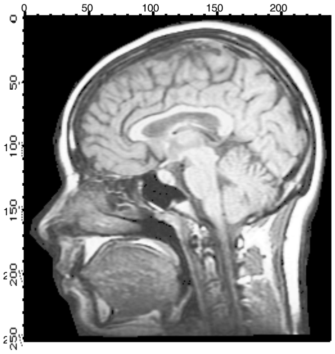
```
NewImage root:images:mri
ImageHistogram root:images:mri
Duplicate W_ImageHist origMriHist
Display /W=(201.6,45.2,411,223.4) origMriHist
```

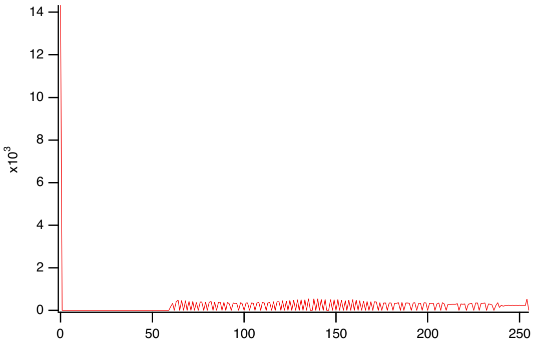




It is obvious from the histogram that the image is rather dark and that the background is most likely zero. The small counts for pixels above 125 suggests that the image is a good candidate for histogram equalization.

```
ImageHistModification root:images:mri
ImageHistogram M_ImageHistEq
NewImage M_ImageHistEq
Display /W=(201.6,45.2,411,223.4) W_ImageHist
```





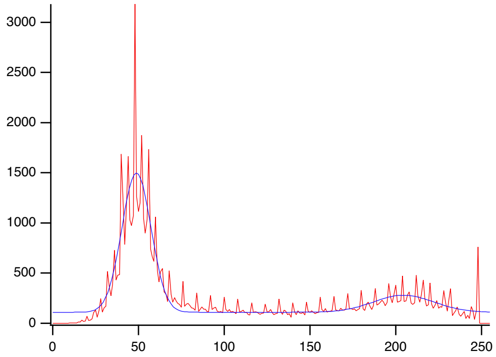
Comparing the two histograms two features stand out: first, there is no change in the dark background because it is only one level (0). Second, the rest of the image which was mostly between the values of 0 and 120 has now been stretched to the range 57-255.

The next example illustrates how you can use the histogram information to determine a threshold value.

```
NewImage root:images:blobs
ImageHistogram root:images:blobs
Display /W=(201.6,45.2,411,223.4) W_ImageHist
```

The resulting histogram is clearly bimodal. Let’s fit it to a pair of Gaussians:

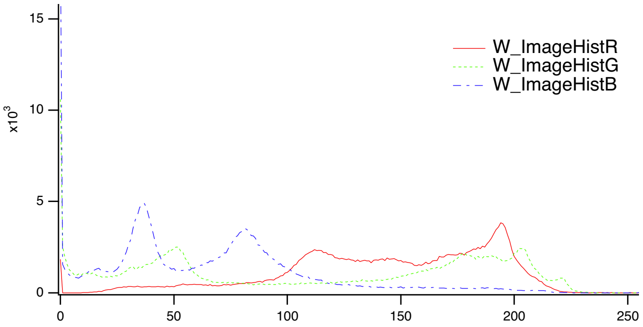
```
// Guess coefficient wave based on the histogram.
Make/O/N=6 coeff={0,3000,50,10,500,210,20}
Funcfit/Q twoGaussians,coeff,W_ImageHist /D
ModifyGraph rgb(fit_W_ImageHist)=(0,0,65000)
```



The curve shown in the graph is the functional fit of the sum of two Gaussians. You can now choose, by visual inspection, an x-value between the two Gaussians — probably somewhere in the range of 100-150. In fact, if you test the same image using the built-in thresholding operations that we have discussed above, you will see that the iterated algorithm chooses the value 125, fuzzy entropy chooses 109, etc.

Histograms of RGB or HSL images result in a separate histogram for each color channel:

```
ImageHistogram root:images:peppers
Display W_ImageHistR,W_ImageHistG,W_ImageHistB
ModifyGraph rgb(W_ImageHistG)=(0,65000,0),rgb(W_ImageHistB)=(0,0,65000)
```



Histograms of 3D waves containing more than 3 layers can be computed by specifying the layer with the /P flag. For example,

```
Make/N=(10,20,30) ddd=gnoise(5)
ImageHistogram/P=10 ddd
Display W_ImageHist
```

Unwrapping Phase

Unwrapping phase in two dimensions is more complicated than in one dimension because the operation's results must be independent of the unwrapping path. The path independence means that any path integral over a closed contour in the unwrapped domain must vanish. In many situations there are points in the domain around which closed contour path integrals do not vanish. Such points are called "residues". The residues are positive if a counter-clockwise path integral is positive. When unwrapping phase in two dimensions, the residues are typically ±1. This suggests that whenever two opposing residues are connected by a line (known as a "branch cut"), any contour integral whose path does not cross the branch cut will vanish. When a positive and negative residues are side by side they combine to a "dipole" which may be removed because a path integral around the dipole also vanishes. It follows that unwrapping can be performed using paths that either do not encircle unbalanced residues or paths that do not cross branch cuts.

The **ImageUnwrapPhase** operation (see page V-433) performs 2D phase unwrapping using either a fast method that ignores possible residues or a slower method which locates residues and attempts to find paths around them. The fast method uses direct integration of the differential phases. It can lead to incorrect results if there are residues in the domain. The slow method first identifies all residues, draws them into an internal bitmap adding branch cuts and then applying repeatedly the algorithm used in ImageSeedFill to obtain the paths around the residues and branch cuts until all pixels have been processed. Sometimes the distribution of residues and branch cuts is such that the domain of the data is covered by several regions, each of which is completely bounded by branch cuts or the data boundary. In this case, the phase is computed independently in each individual region with an offset that is based on the first processed pixel in that region. Note that when you use ImageUnwrapPhase using a method that computes the residues, the operation creates the variables V_numResidues and V_numRegions. You can also obtain a copy of the internal bitmap which could be useful for analyzing the results.

The ImageUnwrapPhase Demo in the Examples:Analysis folder provides a detailed example illustrating different types of residues, branch cuts and resulting unwrapped phase.

HSL Segmentation

When you work with color images you have two analogs to grayscale thresholding. The first is simple thresholding of the luminance of the image. To do this you need to convert the image from RGB to HSL and then perform the thresholding on the luminance plane. The second equivalent of thresholding is HSL segmentation, where the image is subdivided into regions of HSL values that fall within a certain range. In the following example we segment the peppers image to locate regions corresponding to red peppers:

```
NewImage root:images:peppers
ImageTransform/H={330,50}/L={0,255}/S={0,255} root:images:peppers
NewImage M_HueSegment
```

Note that we used /H={330,50}. The apparent flip of the limits is allowed in the case of hue values to cover the single range from hue angle 330 degrees to hue angle 50 degrees.

There are two additional approaches for color segmentation that should be mentioned here. You can use ImageTransform **matchPlanes** operation to segment an image for pixels that satisfy prescribed value ranges in all planes. This operation has the advantage that it can be applied to images in any color space. Another segmentation operation is ImageTransform **selectColor** which is based on RGB color space and a user provided tolerance value. The same concept can be applied with ImageSeedFill to get the effect of a "magic wand" selection.

Particle Analysis

Typical particle analysis consists of three steps. First you need to preprocess the image. This may include noise removal or reduction, possible background adjustments (see **ImageRemoveBackground** operation on page V-403) and thresholding. Once you obtain a binary image, your second step is to invoke the **ImageAnalyzeParticles** operation (see page V-363). The third and final step is making some sense of all the data produced by the ImageAnalyzeParticles operation or "post-processing".

Issues related to the preprocessing have been discussed elsewhere in this chapter. We will assume that we are starting with a preprocessed, clean, binary image which contains some particles.

```
NewImage root:images:blobs                // display the original image

// Step 1:create binary image.
// Note the /I flag to invert the output wave so that particles are marked by 
zero.
ImageThreshold/I/Q/M=1 root:images:blobs  // Note the /I flag!!

// Step 2:Here we are invoking the operation in quiet mode, specifying particles
// of size equal or greater than 2 pixels. We are also asking for particles 
moment
// Information, boundary waves and a particle masking wave.
ImageAnalyzeParticles /Q/A=2/E/W/M=2 stats M_ImageThresh

// Step 3:post processing choices
// Display the detected boundaries on top of the particles
AppendToGraph/T W_BoundaryY vs W_BoundaryX

// If you browse the numerical data:
Edit W_SpotX,W_SpotY,W_circularity,W_rectangularity,W_ImageObjPerimeter
AppendToTable W_xmin,W_xmax,W_ymin,W_ymax,M_Moments,M_RawMoments
```

Note that particles that intersect the boundary of the image may give rise to inaccuracies in particle statistics. It is therefore useful sometimes to remove these particles before performing the analysis.

The raw values generated by ImageAnalyzeParticles operation can be used for further processing.

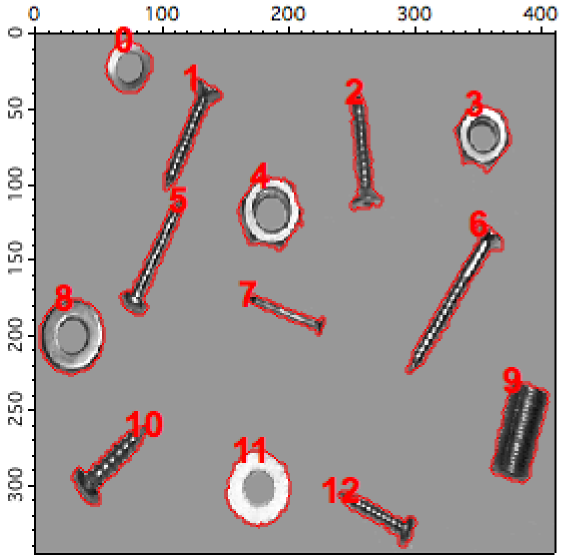
The following example illustrates slightly different pre and post-processing.

```
NewImage screws
// Here we have a synthetic background so the conversion to binary is easy.
screws=screws==163 ? 255:0
ImageMorphology /O/I=2/E=1 binarydilation screws
ImageMorphology /O/I=2/E=1 erosion screws

// Now the particle analysis operation with the option to fill the holes.
ImageAnalyzeParticles/E/W/Q/M=3/A=5/F stats, screws

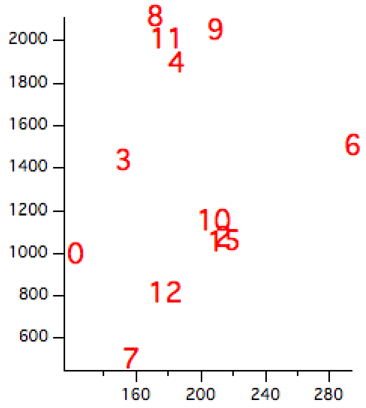
NewImage root:images:screws
AutoPositionWindow/E $WinName(0,1)
// Show the detected boundaries.
AppendToGraph/T W_BoundaryY vs W_BoundaryX
AppendToGraph/T W_SpotY vs W_SpotX
Duplicate/O w_spotx w_index
```

```
w_index=p
ModifyGraph mode(W_SpotY)=3
ModifyGraph textMarker(W_SpotY)={w_index,"default",1,0,5,0.00,0.00}
ModifyGraph msize(W_SpotY)=6
```



Now for some shape classification in which we plot particle area versus perimeter:

```
Display/W=(23.4,299.6,297,511.4) W_ImageObjArea vs W_ImageObjPerimeter
ModifyGraph
mode=3,textMarker(W_ImageObjArea)={w_index,"default",0,0,5,0.00,0.00}
ModifyGraph msize=6
```

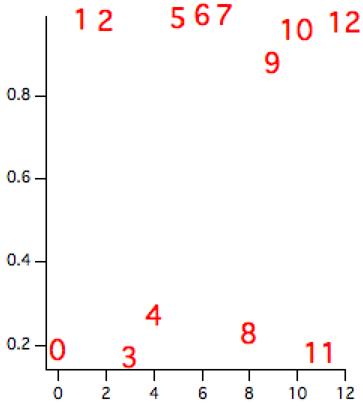


The classification diagram we just created uses two parameters (area and perimeter) that are very sensitive to image noise. We can see that there are two basic classes that can be associated with the roundness of the boundaries but it is difficult to accept the classification of particle 9.

In the following we compute another classification based on the eccentricity of the objects:

```
Make/O/N=(DimSize(M_Moments,0)) ecc
ecc=sqrt(1-M_Moments[p][3]^2/M_Moments[p][2]^2)

Display /W=(23.4,299.6,297,511.4) ecc
ModifyGraph mode=3,textMarker(ecc)={w_index,"default",0,0,5,0.00,0.00}
ModifyGraph msize=6
```



The second classification produces a distinct separation of the screws from the washers and nuts. It also illustrates the importance of selecting the best classification parameters.

You can use the ImageAnalyzeParticles operation also for the purpose of creating masks for particular particles. For example, to create a mask for particle 9 in the example above:

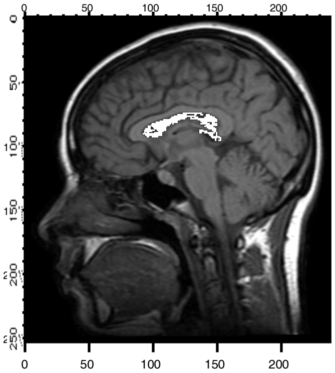
```
ImageAnalyzeParticles /L=(w_spotX[9],w_spotY[9]) mark screws
NewImage M_ParticleMarker
```

You can use this feature of the operation to color different classes of objects using an overlay.

Seed Fill

In some situations you may need to define segments of the image based on a contiguous region of pixels whose values fall within a certain range. The **ImageSeedFill** operation (see page V-409) helps you do just that.

```
NewImage mri
ImageSeedFill/B=64 seedX=132,seedY=77,min=52,max=65,target=255,srcWave=mri
AppendImage M_SeedFill
ModifyImage M_SeedFill explicit=1, eval={255,65535,65535,65535}
```



Here we have used the /B flag to create an overlay image but it can also be used to create an ROI wave for use in further processing. This example represents the simplest use of the operation. In some situations the criteria for a pixel's inclusion in the filled region are not so sharp and the operation may work better if you use the adaptive or fuzzy algorithms. For example (**Note**: the command is wrapped over two lines):

```
ImageSeedFill/B=64/c seedX=144,seedY=83,min=60,max=150,target=255,
srcWave=mri,adaptive=3
```

Note that the min and max values have been relaxed but the adaptive parameter provides alternative continuity criterion.

Other Tools

Igor provides a number of utility operations that help you manage and manipulate image data.

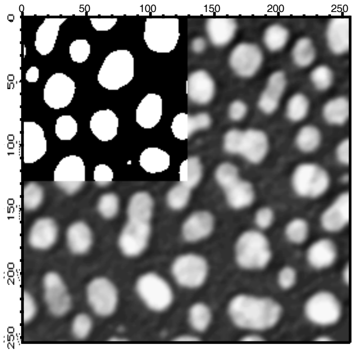
Working with ROI

Many of the image processing operations support a region of interest (ROI). The region of interest is the portion of the image that we want to affect by an operation. Igor supports a completely general ROI, specified as a binary wave (unsigned byte) that has the same dimensions as the image. Set the ROI wave to zero for all pixels within the region of interest and to any other value outside the region of interest. Note that in some situations it is useful to set the ROI pixels to a nonzero value (e.g., if you use the wave as a multiplicative factor in a mathematical operation). You can use ImageTransform with the invert keyword to quickly convert between the two options.

The easiest way to create an ROI wave is directly from the command line. For example, an ROI wave that covers a quarter of the blobs image may be generated as follows:

```
Duplicate root:images:blobs myROI
Redimension/B/U myROI
myROI=64                      // arbitrary nonzero value
myROI[0,128][0,127]=0         // the actual region of interest

// Example of usage:
ImageThreshold/Q/M=1/R=myROI root:images:blobs
NewImage M_ImageThresh
```



If you want to define the ROI using graphical drawing tools you need to open the tools and set the drawing layer to progFront. This can be done with the following instructions:

```
SetDrawLayer progFront
ShowTools/A rect        // selects the rectangle drawing tool first
```

Generating ROI Masks

You can now define the ROI as the area inside all the closed shapes that you draw. When you complete drawing the ROI you need to execute the commands:

```
HideTools/A             // Drawing tools are not needed any more.
// M_ImageThresh is the top image in this example.
ImageGenerateROIMask M_ImageThresh
// The ROI wave has been created; To see it,
NewImage M_ROIMask
```

The Image Processing procedures provide a utility for creating an ROI wave by drawing on a displayed image.

Converting Boundary to a Mask

A third way of generating an ROI mask is using the **ImageBoundaryToMask** operation (see page V-367). This operation takes a pair of waves (y versus x) that contain pixel values and scan-converts them into a mask. When you invoke the operation you also have to specify the rectangular width and height of the output mask.

```
// Create a circle.
Make/N=100 ddx,ddy
ddx=50*(1-sin(2*pi*x/100))
ddy=50*(1-cos(2*pi*x/100))
ImageBoundaryToMask width=100,height=100,xwave=ddx,ywave=ddy
// The result is an image not a curve!
NewImage M_ROIMask
```

Note that the resulting binary wave has the values 0 and 255, which you may need to invert before using them in certain operations.

In many situations the operation ImageBoundaryToMask is followed by ImageSeedFill in order to convert the mask to a filled region. You can obtain the desired mask in one step using the keywords seedX and seedY in ImageBoundaryToMask but you must make sure that the mask created by the boundary waves is a closed domain.

```
ImageBoundaryToMask width=100,height=100,xwave=ddx,ywave=ddy,
seedX=50,seedY=50
ModifyImage M_ROIMask explicit=0
```

Marquee Procedures

A fourth way to create an ROI mask is using the Marquee2Mask procedures. To use this in your own experiment you will have to add the following line to your procedure window:

```
#include <Marquee2Mask>
```

You can now create the ROI mask by selecting one or more rectangular marquees (drag the mouse) in the image. After you select each marquee click inside the marquee and choose MarqueeToMask or Append-MarqueeToMask.

Subimage Selection

You can use an ROI to apply various image processing operations to selected portions of an image. The ROI is a very useful tool especially when the region of interest is either not contiguous or not rectangular. When the region of interest is rectangular, you can usually improve performance by creating a new subimage which consists entirely of the ROI. If you know the coordinates and dimensions of the ROI it is simplest to use the `Duplicate/R` operation. If you want to make an interactive selection you can use the marquee together with CopyImageSubset marquee procedure (after making a marquee selection in the image, click inside the marquee and choose CopyImageSubset).

Handling Color

Most of the image operations are designed to work on grayscale images. If you need to perform an operation on a color image certain aspects become a bit more complicated. In the next example we illustrate how you might sharpen a color image.

```
NewImage root:images:rose
ImageTransform rgb2hsl root:images:rose   // first convert to hsl
ImageTransform/P=2 getPlane M_RGB2HSL
ImageFilter Sharpen M_ImagePlane    // you can also use sharpenmore
ImageTransform /D=M_ImagePlane /P=2 setPlane M_RGB2HSL
ImageTransform hsl2rgb M_RGB2HSL
NewImage M_HSL2RGB
```

Background Removal

There are many approaches to removing the effect of a nonuniform background from an image. If the non uniformity is additive, it is sometimes useful to fit a polynomial to various points which you associate with the background and then subtract the resulting polynomial surface from the whole image. If the nonuniformity is multiplicative, you need to generate an image corresponding to the polynomial surface and use it to scale the original image.

Additive Background

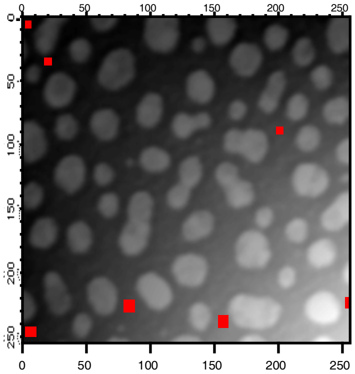
```
Duplicate/O root:images:blobs addBlobs
Redimension/S addBlobs              // convert to single precision
addBlobs+=0.01*x*y                  // add a tilted plane
NewImage addBlobs
```

To use the **ImageRemoveBackground** operation (see page V-403), we need an ROI mask designating regions in the image that represent the background. You can create one using one of the ROI construction methods that we discussed above. For the purposes of this example, we choose the ROI that consists of the 7 rectangles shown in the Degraded Source image below.

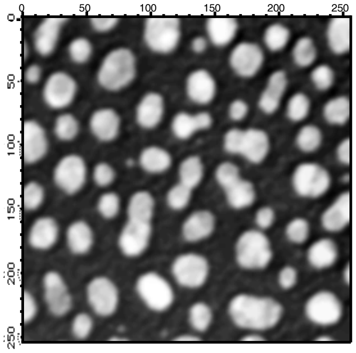
```
// Show the ROI background selection.
AppendImage root:images:addMask
ModifyImage addMask explicit=1, eval={1,65000,0,0}

// Create a corrected image and display it.
ImageRemoveBackground /R=root:images:addMask /w/P=2 addBlobs
NewImage M_RemovedBackground
```

Degraded Source



Background Removed



If the source image contains relatively small particles on a nonuniform background, you may remove the background (for the purpose of particle analysis) by iterating grayscale erosion until the particles are all gone. You are then left with a fairly good representation of the background that can be subtracted from the original image.

Multiplicative Background

This case is much more complicated because the removal of the background requires division of the image by the calculated background (it is assumed here that the system producing the image has an overall gamma of 1). The first complication has to do with the possible presence of zeros in the calculated background. The second complication is that the calculations give us the additional freedom to choose one constant factor to scale the resulting image. There are many approaches for correcting a multiplicative background. The following example shows how an image can be corrected if we assume that the peak values (identified by the ROI mask) would all have the same value in the absence of a background.

```
Duplicate/O root:images:blobs mulBlobs
Redimension/S mulBlobs           // convert to single precision
mulBlobs*=(1+0.005*x*y)
NewImage mulBlobs

// Show us the ROI foreground selection; you can use histogram
// equalization to find fit regions in the dark area.
AppendImage root:images:multMask
ModifyImage multMask explicit=1, eval={1,65000,0,0}

ImageRemoveBackground /R=root:images:multMask/F/w/P=2 mulBlobs
// Normalize the fit.
WaveStats/Q/M=1 M_RemovedBackground

// Renormalize the fit--we can use that one free factor.
```

```
M_RemovedBackground=(M_RemovedBackground-V_min)/(V_max-V_min)
// Remove zeros by replacing with average value.
WaveStats/Q/M=1 M_RemovedBackground
MatrixOp/O M_RemovedBackground=M_RemovedBackground+V_avg*equal(M_RemovedBackground,0)
MatrixOp/O mulBlobs=mulBlobs/M_RemovedBackground   // scaled image.
```

In the example above we have manually created the ROI masks that were needed for the fit. You can automate this process (and actually improve performance) by subdividing the image into a number of smaller rectangles and selecting in each one the highest (or lowest) pixel values. An example of such procedure is provided in connection with the ImageStats operation above.

General Utilities: ImageTransform Operation

As we have seen above, the **ImageTransform** operation (see page V-417) provides a number of image utilities. As a rule, if you are unable to find an appropriate image operation check the options available under ImageTransform. Here are some examples:

When working with RGB or HSL images it is frequently necessary to access one plane at a time. For example, the green plane of the peppers image can be obtained as follows:

```
NewImage root:images:peppers        // display original
Duplicate/O root:images:peppers peppers
ImageTransform /P=1 getPlane peppers
NewImage M_ImagePlane               // display green plane in grayscale
```

The complementary operation can insert a plane into a 3D wave. For example, suppose you wanted to modify the green plane of the peppers image:

```
ImageHistModification/o M_ImagePlane
ImageTransform /p=1 /D=M_ImagePlane setPlane peppers
NewImage peppers                    // display the processed image
```

Some operations are restricted to waves of particular dimensions. For example, if you want to use the Adaptive histogram equalization, the number of horizontal and vertical partitions is restricted by the requirement that the image be an exact multiple of the dimensions of the subregion. The ImageTransform operation provides three image padding options: If you specify a negative number to the changed rows or columns, the corresponding rows and columns are removed from the image. If the numbers are positive, rows and columns are added. By default the added rows and columns contain exactly the same pixel values as the last row and column in the image. If you specify the /W flag the operation duplicates the relevant portion of the image into the new rows and columns. Here are some examples:

```
Duplicate/o root:images:baboon baboon
NewImage baboon
ImageTransform/N={-20,-10} padImage baboon
Rename M_PaddedImage, cropped
NewImage cropped
ImageTransform/N={40,40} padImage baboon
Rename M_PaddedImage, padLastVals
NewImage padLastVals
ImageTransform/W/N={100,100} padImage baboon
NewImage M_PaddedImage
```

Another utility operation is the conversion of any 2D wave into a normalized (0-255) 8-bit image wave. This is accomplished with the ImageTransform operation using the keyword convert2gray. Here is an example:

```
// Create some numerical data
Make/O/N=(50,80) numericalWave=x*sin(x/10)*y*exp(y/100)
ImageTransform convert2gray numericalWave
NewImage M_Image2Gray
```

The conversion to an 8-bit image is required for certain operation. It is also useful sometimes when you want to reduce the size of your image waves.

Chapter

III-12

Statistics

Overview

This chapter describes operations and functions for statistical analysis together with some general guidelines for their use. This is not a statistics tutorial; for that you can consult one of the references at the end of this chapter or the references listed in the documentation of a particular operation or function. The material below assumes that you are familiar with techniques and methods of statistical analysis.

Most statistics operations and functions are named with the prefix "Stats". Naming exceptions include the random noise functions that have traditionally been named based on the distribution they represent.

There are six natural groups of statistics operations and functions. They include:

- Test operations
- Noise functions
- Probability distribution functions (PDFs)
- Cumulative distribution functions (CDFs)
- Inverse cumulative distribution functions
- General purpose statistics operations and functions

Statistics Test Operations

Test operations analyze the input data to examine the validity of a specific hypothesis. The common test involves a computation of some numeric value (also known as "test statistic") which is usually compared with a critical value in order to determine if you should accept or reject the test hypothesis (H_0). Most tests compute a critical value for the given significance *alpha* which has the default value 0.05 or a user-provided value via the /ALPH flag. Some tests directly compute the P value which you can compare to the desired significance value.

Critical values have been traditionally published in tables for various significance levels and tails of distributions. They are by far the most difficult technical aspect in implementing statistical tests. The critical values are usually obtained from the inverse of the CDF for the particular distribution, i.e., from solving the equation

$$cdf(criticalValue) = 1 - alpha,$$

where *alpha* is the significance. In some distributions (e.g., Friedman's) the calculation of the CDF is so computationally intensive that it is impractical (using desktop computers in 2006) to compute for very large parameters. Fortunately, large parameters usually imply that the distributions can be approximated using simpler expressions. Igor's tests provide whenever possible exact critical values as well as the common relevant approximations.

Comparison of critical values with published table values can sometimes be interesting as there does not appear to be a standard for determining the published critical value when the CDF takes a finite number of discrete values (step-like). In this case the CDF attains the value (1-*alpha*) in a vertical transition so one could use the X value for the vertical transition as a critical value or the X value of the subsequent vertical transition. Some tables reflect a "conservative" approach and print the X value of subsequent transitions.

Statistical test operations can print their results to the history area of the command window and save them in a wave in the current data folder. Result waves have a fixed name associated with the operation. Elements in the wave are designated by dimension labels. You can use the /T flag to display the results of the operation in a table with dimension labels. The argument for this flag determines what happens when you kill the table. You can use/Q in all test operations to prevent printing information in the history area and you can use the /Z flag to make sure that the operations do not report errors except by setting the V_Flag variable to -1.

Statistical test operations tend to include several variations of the named test. You can usually choose to execute one or more variations by specifying the appropriate flags. The following table can be used as a guide for identifying the operation associated with a given test name.

Statistical Test Operations by Name

Test Name	Where to find it
Angular Distance	**StatsAngularDistanceTest**
Bartlett's test for variances	**StatsVariancesTest**
BootStrap	**StatsResample**
Brown and Forsythe	**StatsANOVA1Test**
Chi-squared test for means	**StatsChiTest**
Cochran's test	**StatsCochranTest**
Dunn-Holland-Wolfe	**StatsNPMCTest**
Dunnette multicomparison test	**StatsDunnettTest**, **StatsLinearRegression**
Fisher's Exact Test	**StatsContingencyTable**
Fixed Effect Model	**StatsANOVA1Test**
Friedman test on randomized block	**StatsFriedmanTest**
F-test on two distributions	**StatsFTest**
Hodges-Ajne (Batschelet)	**StatsHodgesAjneTest**
Hartigan test for unimodality	**StatsDIPTest**
Hotelling	**StatsCircularTwoSampleTest**, **StatsCircularMeans**
Jackknife	**StatsResample**
Jarque-Bera Test	**StatsJBTest**
Kolmogorov-Smirnov	**StatsKSTest**
Kruskal-Wallis	**StatsKWTest**
Kuiper Test	**StatsCircularMoments**
Levene's test for variances	**StatsVariancesTest**
Linear Correlation Test	**StatsLinearCorrelationTest**
Linear Order Statistic	**StatsCircularMoments**
Mann-Kendall	**StatsKendallTauTest**
Moore test	**StatsCircularTwoSampleTest**, **StatsCircularMeans**
Nonparametric multiple contrasts	**StatsNPMCTest**
Nonparametric angular-angular correlation	**StatsCircularCorrelationTest**
Nonparametric second order circular analysis	**StatsCircularMeans**
Nonparametric serial randomness (nominal)	**StatsNPNominalSRTest**
Parametric angular-angular correlation	**StatsCircularCorrelationTest**
Parametric angular-Linear correlation	**StatsCircularCorrelationTest**
Parametric second order circular analysis	**StatsCircularMeans**
Parametric serial randomness test	**StatsSRTest**
Rayleigh	**StatsCircularMoments**
Repeated Measures	**StatsANOVA2RMTest**

Test Name	Where to find it
Scheffe equality of means	**StatsScheffeTest**
Shapiro-Wilk test for normality	**StatsShapiroWilkTest**
Spearman	**StatsRankCorrelationTest**
Student-Newman-Keuls	**StatsNPMCTest**
Tukey Test	**StatsTukeyTest StatsLinearRegression**, **StatsMultiCorrelationTest**, **StatsNPMCTest**
Two-Factor ANOVA	**StatsANOVA2NRTest**
T-test	**StatsTTest**
Watson’s nonparametric two-sample U2	**StatsWatsonUSquaredTest**, **StatsCircularTwoSampleTest**
Watson-Williams	**StatsWatsonWilliamsTest**
Weighted-rank correlation test	**StatsWRCorrelationTest**
Wheeler-Watson nonparametric test	**StatsWheelerWatsonTest**
Wilcoxon-Mann-Whitney two-sample	**StatsWilcoxonRankTest**
Wilcoxon signed rank	**StatsWilcoxonRankTest**

Statistical Test Operations by Data Format

The following tables group statistical operations and functions according to the format of the input data.

Tests for Single Waves

Analysis Method	Comments
StatsChiTest	Compares with known binned values
StatsCircularMoments	WaveStats for circular data
StatsKendallTauTest	Similar to Spearman's correlation
StatsMedian	Returns the median
StatsNPNominalSRTest	Nonparametric serial randomness test
StatsQuantiles	Computes quantiles and more
StatsResample	Bootstrap analysis
StatsSRTest	Serial randomness test
StatsTrimmedMean	Returns the trimmed mean
StatsTTest	Compares with known mean
Sort	Reorders the data
WaveStats	Basic statistical description
StatsJBTest	Jarque-Bera test for normality
StatsKSTest	Limited scope test for normality
StatsDIPTest	Hartigan test for unimodality
StatsShapiroWilkTest	Shapiro-Wilk test for normality

Tests for Two Waves

Analysis Method	Comments
StatsChiTest	Chi-squared statistic for comparing two distributions
StatsCochranTest	Randomized block or repeated measures test
StatsCircularTwoSampleTest	Second order analysis of angles
StatsDunnettTest	Compares multiple groups to a control
StatsFTest	Computes ratio of variances
StatsFriedmanTest	Nonparametric ANOVA
StatsKendallTauTest	Similar to Spearman's correlation
StatsTTest	Compares the means of two distributions
StatsANOVA1Test	One-way analysis of variances
StatsLinearRegression	Linear regression analysis
StatsLinearCorrelationTest	Linear correlation coefficient and its error
StatsRankCorrelationTest	Computes Spearman's rank correlation
StatsVariancesTest	Compares variances of waves
StatsWilcoxonRankTest	Two-sample or signed rank test
StatsWatsonUSquaredTest	Compares two populations of circular data
StatsWatsonWilliamsTest	Compares mean values of angular distributions
StatsWheelerWatsonTest	Compares two angular distributions

Tests for Multiple or Multidimensional Waves

Analysis Method	Comments
StatsANOVA1Test	One-way analysis of variances
StatsANOVA2Test	Two-factor analysis of variances
StatsANOVA2RMTest	Two-factor repeated measure ANOVA
StatsCochranTest	Randomized block or repeated measures test
StatsContingencyTable	Contingency table analysis
StatsDunnettTest	Comparing multiple groups to a control
StatsFriedmanTest	Nonparametric ANOVA
StatsNPMCTest	Nonparametric multiple comparison tests
StatsScheffeTest	Tests equality of means
StatsTukeyTest	Multiple comparisons based on means
StatsWatsonWilliamsTest	Compares mean values of angular distributions
StatsWheelerWatsonTest	Compares two angular distributions

Noise Functions

The following functions return numbers from a pseudo-random distribution of the specified shapes and parameters. Except for enoise and gnoise where you have an option to select a random number generator, the remaining noise functions use a Mersenne Twister algorithm for the initial uniform pseudo-random distribution. Note that whenever you need repeatable results you should use SetRandomSeed prior to executing any of the noise functions.

The following noise generation functions are available:

binomialNoise

enoise

expNoise

gammaNoise

gnoise

hyperGNoise

logNormalNoise

lorentzianNoise

poissonNoise

StatsPowerNoise

StatsVonMisesNoise

wnoise

Cumulative Distribution Functions

A cumulative distribution function (CDF) is the integral of its respective probability distribution function (PDF). CDFs are usually well behaved functions with values in the range [0,1]. CDFs are important in computing critical values, P values and power of statistical tests.

Many CDFs are computed directly from closed form expressions. Others can be difficult to compute because they involve evaluating a very large number of states, e.g., Friedman or USquared distributions. In these cases you have the following options:

1. Use a built-in table that consists of exact, precomputed values.
2. Compute an approximate CDF based on the prevailing approximation method or using a Monte-Carlo approach.
3. Compute the exact CDF.

Built-in tables are ideal if they cover the range of the parameters that you need. Monte-Carlo methods can be tricky in the sense that repeated application may return small variations in values. Computing the exact CDF may be desirable, but it is often impractical. In most situations the range of parameters that is practical to compute on a desktop machine is already covered in the built-in tables. Larger parameters have not been considered because they take days to compute or because they require 64 bit processors. In addition, most of the approximations tend to improve with increasing size of the parameters.

The functions to calculate values from CDFs are as follows:

StatsBetaCDF

StatsBinomialCDF

StatsCauchyCDF

StatsChiCDF

StatsCMSSDCDF

StatsDExpCDF

StatsErlangCDF

StatsEValueCDF

StatsExpCDF

StatsHyperGCDF

StatsQCDF

StatsWaldCDF

StatsWeibullCDF

Probability Distribution Functions

Probability distribution functions (PDF) are sometimes known as probability densities. In the case of continuous distributions, the area under the curve of the PDF for each interval equals the probability for the random variable to fall within that interval. The PDFs are useful in calculating event probabilities, characteristic functions and moments of a distribution.

The functions to calculate values from PDFs are as follows:

StatsBetaPDF

StatsBinomialPDF

StatsCauchyPDF

StatsChiPDF

StatsDExpPDF

StatsErlangPDF

StatsErrorPDF

StatsEValuePDF

StatsRectangularPDF

StatsStudentPDF

StatsTriangularPDF

StatsVonMisesPDF

StatsWaldPDF

StatsWeibullPDF

Inverse Cumulative Distribution Functions

The inverse cumulative distribution functions return the values at which their respective CDFs attain a given level. This value is typically used as a critical test value. There are very few functions for which the inverse CDF can be written in closed form. In most situations the inverse is computed iteratively from the CDF.

The functions to calculate values from inverse CDFs are as follows:

StatsInvBetaCDF

StatsInvBinomialCDF

StatsInvCauchyCDF

StatsInvChiCDF

StatsInvCMSSDCDF

StatsInvDExpCDF

StatsInvEValueCDF

StatsInvExpCDF

StatsInvFCDF

StatsPermute

Hazard and Survival Functions

Igor does not provide built-in functions to calculate the Survival or Hazard functions. They can be calculated easily from the **Probability Distribution Functions** on page III-391 and **Cumulative Distribution Functions** on page III-390.

In the following, the cumulative distribution functions are denoted by *F*(*x*) and the probability distribution functions are denoted by *p*(*x*).

The Survival Function *S*(*x*) is given by

$$S(x) = 1 - F(x).$$

The Hazard function *h*(*x*) is given by

$$h(x) = \frac{p(x)}{S(x)} = \frac{p(x)}{1 - F(x)}.$$

The cumulative hazard function *H*(*x*) is

$$H(x) = \int_{-\infty}^{x} h(u)\,du,$$

$$H(x) = -\ln\left[1 - F(x)\right].$$

Inverse Survival Function *Z*(*a*) is

$$Z(\alpha) = G(1 - \alpha),$$

where *G*() is the inverse CDF (see **Inverse Cumulative Distribution Functions** on page III-391).

Statistics Procedures

Several procedure files are provided to extend the built-in statistics capability described in this chapter. Some of these procedure files provide user interfaces to the built-in statistics functionality. Others extend the functionality.

In the Analysis menu you will find a Statistics item that brings up a submenu. Selecting any item in the submenu will cause all the statistics-related procedure files to be loaded, making them ready to use. Alternatively, you can load all the statistics procedures by adding the following include statement to the top of your procedure window:

```
#include <AllStatsProcedures>
```

Functionality provided by the statistics procedure files includes the 1D Statistics Report package for automatic analysis of single 1D waves, and the ANOVA Power Calculations Panel, as well as functions to create specialized graphs:

StatsAutoCorrPlot()

StatsBoxPlot()

StatsPlotLag()

StatsProbPlot()

StatsPlotHistogram()

Also included are these convenience functions:

WM_2MeanConfidenceIntervals()

WM_2MeanConfidenceIntervals2()

WM_BernoulliCdf()

WM_BinomialPdf()

WM_CIforPooledMean()

WM_CompareCorrelations()

WM_EstimateMinDetectableDiff()

WM_EstimateReqSampleSize()

WM_EstimateReqSampleSize2()

WM_EstimateSampleSizeForDif()

WM_GetANOVA1Power()

WM_GetGeometricAverage()

WM_GetHarmonicMean()

WM_GetPooledMean()

WM_GetPooledVariance()

WM_MCPointOnRegressionLines()

WM_MeanConfidenceInterval()

WM_OneTailStudentA()

WM_OneTailStudentT()

WM_PlotBiHistogram()

WM_RankForTies()

WM_RankLetterGradesWithTies()

WM_RegressionInversePrediction()

WM_SSEstimatorFunc()

WM_SSEstimatorFunc2()

WM_SSEstimatorFunc3()

WM_VarianceConfidenceInterval()

WM_WilcoxonPairedRanks()

WM_StatsKaplanMeier()

Chapter

III-13

Procedure Windows

Overview

This chapter explains what procedure windows are, how they are created and organized, and how you work with them. It does not cover programming. See Chapter IV-2, **Programming Overview** for an introduction.

A procedure window is where Igor procedures are stored. Igor procedures are the macros, functions and menu definitions that you create or that Igor creates automatically for you.

The content of a procedure window is stored in a procedure file. In the case of a packed Igor experiment, the procedure file is packed into the experiment file.

Types of Procedure Files

There are four types of procedure files:

- The experiment procedure file, displayed in the built-in procedure window
- Global procedure files, displayed in auxiliary procedure windows
- Shared procedure files, displayed in auxiliary procedure windows
- Auxiliary experiment procedure files, displayed in auxiliary procedure windows

The built-in procedure window holds experiment-specific procedures of the currently open experiment. This is the only procedure window that beginning or casual Igor users may need.

All other procedure windows are called **auxiliary** to distinguish them from the built-in procedure window. You create an auxiliary procedure window using Windows→New→Procedure. You can then save it to a standalone file, using File→Save Procedure As, or allow Igor to save it as part of the current experiment.

A global procedure file contains procedures that you might want to use in any experiment. It must be saved as a standalone file in the "Igor Procedures" folder of your **Igor Pro User Files** folder. Procedure files in "Igor Procedures" are automatically opened by Igor at startup and left open until Igor quits. This is the easiest way to make procedures available to multiple experiments.

A shared procedure file contains procedures that you want to use in more than one experiment but that you don't want to be open all of the time. It must be saved as a standalone file. The recommended location is the "User Procedures" folder of your **Igor Pro User Files** folder.

An auxiliary experiment procedure file contains procedures that you want to use in a single experiment but want to keep separate from the built-in procedure window for organizational purposes. In a packed experiment it is saved as a packed file within the experiment file. In an unpacked experiment it is saved as a standalone file in the experiment folder.

Working with the Built-in Procedure Window

Procedures that are specific to the current experiment are usually stored in the built-in procedure window. Also, when Igor automatically generates procedures, it stores them in the built-in procedure window.

To show the built-in procedure window, choose Windows→Procedure Windows→Procedure Window or press Command-M (*Macintosh*) or Ctrl+M (*Windows*). To hide it, click the close button or press Command-W (*Macintosh*) or Ctrl+W (*Windows*).

To create a procedure, just type it into the procedure window.

The contents of the built-in procedure window are automatically stored when you save the current Igor experiment. For unpacked experiments, the contents are stored in a file called “procedure” in the experiment folder. For packed experiments, the contents are stored in the packed experiment file. When you open an experiment Igor loads its procedures back into the built-in procedure window.

Compiling the Procedures

When you modify the text in the procedure window, you will notice that a Compile button appears at the bottom of the window.

Clicking the Compile button scans the procedure window looking for macros, functions and menu definitions. Igor compiles user-defined functions, generating low-level instructions that can be executed quickly.

Igor also compiles the code in the procedure window if you choose Compile from the Macros menu or if you activate any window other than a procedure or help window.

Templates Pop-Up Menu

The Templates pop-up menu lists all of the built-in and external operations and functions in alphabetical order and also lists the common flow control structures.

If you choose an item from the menu, Igor inserts the corresponding template in the procedure window.

If you select, click in, or click after a recognized operation, function or flow-control keyword in the procedure window, two additional items are listed at the top of the menu. The first item inserts a template and the second takes you to help.

In addition to templates, procedure windows also support **Command Completion**.

Procedure Navigation Bar

The procedure navigation bar appears at the top of each procedure window. It consists of a menu and a settings button. The menu provides a quick way to find procedures in the active procedure window.

Certain syntax errors prevent Igor from parsing procedures. In that case, the menu shows no procedures.

You can hide the navigation bar by choosing Misc-Miscellaneous Settings, selecting the Text Editing section, and unchecking the Show Navigation Bar checkbox.

Write-Protect Icon

Procedure windows have a write-enable/write-protect icon which appears in the lower-left corner of the window and resembles a pencil. If you click this icon, Igor Pro displays an icon indicating that the procedure window is write-protected. The main purpose of this is to prevent accidental alteration of shared procedure files.

Igor opens included user procedure files for writing but turns on the write-protect icon so that you will get a warning if you attempt to change them. If you do want to change them, simply click the write-protect icon to turn protection off. You can turn this default write-protection off via the Text Encoding section of the Miscellaneous Settings dialog.

If a procedure file is opened for reading only, you will see a lock icon instead of the pencil icon. A file opened for read-only can not be modified.

WaveMetrics procedures, in the WaveMetrics Procedures folder, are assumed to be the same for all Igor users and should not be modified by users. Therefore, Igor opens included WaveMetrics procedures for reading only.

Magnifier Icon

You can magnify procedure text to make it more readable. See **Text Magnification** on page II-53 for details.

Creating Procedure Windows

There are three ways to create procedures:

- Automatically by Igor

- Manually, when you type in a procedure window
- Semiautomatically, when you use various dialogs

Igor offers to automatically create a **window recreation macro** when you close a target window. A window recreation macro is a procedure that can recreate a graph, table, page layout or control panel window. See **Saving a Window as a Recreation Macro** on page II-47 for details.

You can add procedures by merely typing them in a procedure window.

You can create user-defined controls in a graph or control panel. Each control has an optional **action procedure** that runs when the control is used. You can create a control and its corresponding action procedure using dialogs that you access through the Add Controls submenu in the Graph or Panel menus. These action procedures are initially stored in the built-in procedure window.

You can create user-defined curve fitting functions via the Curve Fitting dialog. These functions are initially stored in the built-in procedure window.

Creating New Procedure Files

You create a new procedure file if you want to write procedures to be used in more than one experiment.

Note: There is a risk in sharing procedure files among experiments. If you copy the experiment to another computer and forget to also copy the shared files, the experiment will not work on the other computer. See **References to Files and Folders** on page II-24 for further details.

If you do create a shared procedure file then you are responsible for copying the shared file when you copy an experiment that relies on it.

To create a new procedure file, choose Windows→New→Procedure. This creates a new procedure *window*. The procedure *file* is not created until you save the procedure window or save the experiment.

You can explicitly save the procedure window by choosing File→Save Procedure As or by closing it and choosing to save it in the resulting dialog. This saves the file as an auxiliary procedure file, separate from the experiment.

If you don’t save the procedure window explicitly, Igor saves it as part of the current experiment the next time you save the experiment.

Opening an Auxiliary Procedure File

You can open a procedure file using the File→Open File→Procedure menu item.

When you open a procedure file, Igor displays it in a new procedure window. The procedures in the window can be used in the current experiment. When you save the current experiment, Igor will save a *reference* to the shared procedure file in the experiment file. When you later open the experiment, Igor will reopen the procedure file.

For procedure files that you use from a large number of experiments, it is better to configure the files as global procedure files. See **Global Procedure Files** on page III-399.

For commonly used auxiliary files, it is better to use the include statement. See **Including a Procedure File** on page III-401.

Showing Procedure Windows

We usually show procedure windows when we are doing programming and hide them for normal use.

To show the built-in procedure window, choose Windows→Procedure Windows→Procedure Window or press Command-M (*Macintosh*) or Ctrl+M (*Windows*). To show auxiliary procedure windows, use the Windows→Procedure Windows submenu.

If you have more than one procedure window, you can cycle to the next procedure window by pressing Command-Option-M (*Macintosh*) or Ctrl+Alt+M (*Windows*). Pressing Command-Shift-Option-M (*Macintosh*) or Ctrl+Shift+Alt+M (*Windows*) hides the active procedure window and shows the next one.

You can also show a procedure window by choosing a menu item added by that window while pressing Option (*Macintosh*) or Alt (*Windows*). This feature works only if the top window is a procedure window.

You can show all procedure windows and hide all procedure windows using the Windows→Show and Windows→Hide submenus.

Hiding and Killing Procedure Windows

The built-in procedure window always exists as part of the current experiment. You can hide it by clicking the close button, pressing Command-W (*Macintosh*) or Ctrl+W (*Windows*) or by choosing Hide from the Windows menu. You can not kill it.

Auxiliary procedure files can be opened (added to the experiment), hidden and killed (removed from the experiment). This leads to a difference in behavior between auxiliary procedure windows and the built-in procedure window.

When you click the close button of an auxiliary procedure file, Igor presents the Close Procedure Window dialog to find out what you want to do.

If you just want to hide the window, you can press Shift while clicking the close button. This skips the dialog and just hides the window.

Killing a procedure window closes the window and removes it from the current experiment but does not delete or otherwise affect the procedure file with which the window was associated. If you have made changes or the procedure was not previously saved, you will be presented with the choice of saving the file before killing the procedure.

The Close item of the Windows menu and the equivalent, Command-W (*Macintosh*) or Ctrl+W (*Windows*), behave the same as the close button.

Saving All Standalone Procedure Files

When a procedure window is active, you can save all modified standalone procedure files at once by choosing File→Save All Standalone Procedure Files. This saves only standalone procedure files. It does not save the built-in procedure window, packed procedure files, or procedure windows that were just created and never saved to disk; these are saved when you save the experiment.

Autosaving Standalone Procedure Files

Igor can automatically save modified standalone procedure files. See **Autosave** on page II-36 for details.

Global Procedure Files

Global procedure files contain procedures that you want to be available in all experiments. They differ from other procedure files in that Igor opens them automatically and never closes them. Configuring a procedure file as a global procedure file is the easiest way to make it widely available.

When Igor starts running, it searches "Igor Pro Folder/Igor Procedures" and "Igor Pro User Files/Igor Procedures" (see **Igor Pro User Files** on page II-31 for details), as well as files and folders referenced by aliases or shortcuts. Igor opens any procedure file that it finds during this search as a global procedure file.

You should save your global procedure files in "Igor Pro User Files/Igor Procedures". You can locate this folder by choosing Help→Show Igor Pro User Files.

Igor opens global procedure files with write-protection on since they presumably contain procedures that you have already debugged and which you don’t want to inadvertently modify. If you *do* want to modify a global procedure file, click the write-protect icon (pencil in lower-left corner of the window). You can turn this default write-protection off via the Text Encoding section of the Miscellaneous Settings dialog.

When you create a new experiment or open an existing one, Igor normally closes any open procedure files, but it leaves global procedure files open. You can explicitly close a global procedure window at any time and then you can manually reopen it. Igor will not automatically reopen it until the next time Igor is launched.

Although its procedures can be used by the current experiment, a global procedure file is not part of the current experiment. Therefore, Igor does not save a global procedure file or a reference to a global procedure file inside an experiment file.

Note: There is a risk in using global procedure files. If you copy an experiment that relies on a global procedure file to another computer and forget to also copy the global procedure file, the experiment will not work on the other computer.

Saving Global Procedure Files

If you modify a global procedure file, Igor will save it when you save the current experiment even though the global procedure file is not part of the current experiment. However, you might want to save the procedure file without saving the experiment. For this, use the File→Save Procedure menu item.

Shared Procedure Files

You may develop procedures that you want to use in several but not all of your experiments. You can facilitate this by creating a shared procedure file. This is a procedure file that you save in its own file, separate from any experiment. Such a file can be opened from any experiment.

There are two ways to open a shared procedure file from an experiment:

- By explicitly opening it, using the File→Open File submenu or by double-clicking it or by drag-and-drop
- By adding an include statement to your experiment procedure window

The include method is preferred and is described in detail under **Including a Procedure File** on page III-401.

When Igor encounters an include statement, it searches for the included file in "Igor Pro Folder/User Procedures" and in "Igor Pro User Files/User Procedures" (see **Igor Pro User Files** on page II-31 for details). The Igor Pro User Files folder is the recommended place for storing user files. You can locate it by choosing Help→Show Igor Pro User Files.

You can store your shared procedure procedure file directly in "Igor Pro User Files/User Procedures" or you can store it elsewhere and put an alias (*Macintosh*) or shortcut (*Windows*) for it in "Igor Pro User Files/User Procedures". If you have many shared procedure files you can put them all in your own folder and put an alias/shortcut for the folder in "Igor Pro User Files/User Procedures".

When you explicitly open a procedure file using the Open File submenu, by double-clicking it, or by drag-and-drop, you are adding it to the current experiment. When you save the experiment, Igor saves a *reference* to the procedure file in the experiment file. When you close the experiment, Igor closes the procedure file. When you later reopen the experiment, Igor reopens the procedure file.

When you use an include statement, the included file is not considered part of the experiment but is still referenced by the experiment. Igor automatically opens the included file when it hits the include statement during procedure compilation.

Note: There is a risk in sharing procedure files among experiments. If you copy the experiment to another computer and forget to also copy the shared files, the experiment will not work on the other computer. See **References to Files and Folders** on page II-24 for more explanation.

Saving Shared Procedure Files

If you modify a shared procedure file, Igor saves it when you save the experiment that is sharing it. However, you might want to save the procedure file without saving the experiment. For this, choose File→Save Procedure.

Including a Procedure File

You can put an include statement in any procedure file. An include statement automatically opens another procedure file. This is the recommended way of accessing files that contain utility routines which you may want to use in several experiments. Using an include statement is preferable to opening a procedure file explicitly because it doesn't rely on the exact location of the file in the file system hierarchy.

Here is a typical include statement:

```
#include <MatrixToXYZ>
```

This automatically opens the MatrixToXYZ.ipf file supplied by WaveMetrics in "Igor ProFolder/WaveMetrics Procedures/Data Manipulation". The angle brackets tell Igor to search the "Igor Pro Folder/WaveMetrics Procedures" hierarchy.

To see what WaveMetrics procedure files are available, choose Help→Help Windows→WM Procedures Index.

You can include your own utility procedure files by using double-quotes instead of the angle-brackets shown above:

```
#include "Your Procedure File"
```

The double-quotes tell Igor to search the "Igor Pro Folder/User Procedures" and "Igor Pro User Files/User Procedures" hierarchies (see **Igor Pro User Files** on page II-31 for details) for the named file. Igor searches those folders and subfolders and files or folders referenced by aliases/shortcuts in those folders.

These are the two main variations on the include statement. For details on less frequently used variations, see **The Include Statement** on page IV-166.

Included procedure files are not considered part of the experiment but are automatically opened by Igor when it compiles the experiment's procedures.

To prevent accidental alteration of an included procedure file, Igor opens it either write-protected (User Procedures) or read-only (WaveMetrics Procedures). See **Write-Protect Icon** on page III-397.

A #include statement must omit the file's ".ipf" extension:

```
#include <Strings as Lists>      // RIGHT

#include <Strings as Lists.ipf>  // WRONG
```

Creating Packages

A package is a set of procedure files, help files and other support files that add significant functionality to Igor.

Igor comes pre-configured with numerous WaveMetrics packages accessed through the Data→Packages, Analysis→Packages, Misc→Packages, Windows→New→Packages and Graph→Packages submenus as well as others.

Intermediate to advanced programmers can create their own packages. See **Packages** on page IV-246 for details.

Invisible Procedure Files

If you create a package of Igor procedures to be used by regular Igor users (as opposed to programmers), you may want to hide the procedures to reduce clutter or to eliminate the possibility that they might inadvertently change them. You can do this by making the procedure files invisible.

Invisible procedure files are omitted from Igor's Procedure Windows submenu which appears in the Windows menu. This keeps them out of the way of regular users.

There are three ways to make a procedure file invisible. In order of difficulty they are:

- Using the #pragma hide compiler directive
- Using an independent module
- Using the operating-system-supplied file visibility property

Invisible Procedure Windows Using #pragma hide

You can make a procedure file invisible by inserting this compiler directive in the file:

#pragma hide=1

This prevents the procedure window from being listed in the Windows→Procedures submenu. Procedures windows that include this compiler directive become invisible on the next compile.

You can make these windows visible during development by executing:

```
SetIgorOption IndependentModuleDev=1
```

and return them to invisible by executing:

```
SetIgorOption IndependentModuleDev=0
```

You must force a compile for this to take effect.

Prior to Igor Pro 6.30 this feature worked for #included procedure files only, not for packed and standalone procedure files.

Invisible Procedure Windows Using Independent Modules

You can also make a set of procedure files invisible by making them an independent module. The independent module technique is more difficult to implement but has additional advantages. For details, see **The IndependentModule Pragma** on page IV-55.

Invisible Procedure Files Using The Files Visibility Property

This section discusses making procedure files invisible by setting the operating-system-supplied file "visible" property.

Note: This is an old technique that is no longer recommended. It may not be supported in future versions of Igor.

When Igor opens a procedure file, it asks the operating system if the file is invisible (*Macintosh*) or hidden (*Windows*). We will use the term "invisible" to mean invisible on Macintosh and hidden on Windows.

If the file is invisible, Igor makes the file inaccessible to the user. Igor checks the invisible property only when it opens the file. It does not pay attention to whether the property is changed while the file is open.

You create Igor procedures using normal visible procedure files, typically all in a folder or hierarchy of folders. When it comes time to ship to the end user, you set the files to be invisible. If you set a file to be invisible, you should also make it read-only.

You can use the **SetFileFolderInfo** operation (see page V-845) to set the visibility and read-only properties of a file:

```
SetFileFolderInfo /INV=1 /RO=1 "<path to file>"
```

The file will be invisible in Igor the next time you open it, typically by opening an experiment or using a #include statement.

On Macintosh, the file disappears from the Finder when you execute the command.

On Windows, merely setting the hidden property is not sufficient to actually hide the file. It is actually hidden only if the Hide Files of These Types radio button in the View Options dialog is turned on. You can access this dialog by opening a folder in the Windows desktop and choosing View→Options from the folder's menu bar. Although the hidden property in Windows does not guarantee that the file will be hidden in the Windows desktop, it does guarantee that it will be hidden from within Igor.

After the files are set to be invisible and read-only, if you want to edit them in Igor, you must close them (typically by closing the open experiment), set the files to be visible and read/write again, and then open them again.

Igor's behavior is changed in the following ways for a procedure file set to invisible:

1. The window will not appear in the Windows→Procedure Windows menu.
2. Procedures in the window will not appear in the contextual pop-up menu in other procedure windows (Control-click on *Macintosh*, right-click on *Windows*).
3. If the user presses Option (*Macintosh*) or Alt (*Windows*) while choosing the name of a procedure from a menu, Igor will do nothing rather than its normal behavior of displaying the procedure window.
4. When cycling through procedure windows using Command-Shift-Option-M (*Macintosh*) or Ctrl+Shift+Alt+M (*Windows*), Igor will omit the procedure window.
5. The Button Control dialog, Pop-Up Menu Control dialog, and other control dialogs will not allow you to edit procedures in the invisible file.
6. The Edit Procedure and Debug buttons will not appear in the Macro Execute Error dialog.
7. If an error occurs in a function in the invisible file and the Debug On Error flag (Procedure menu) is on, the debugger will act as if Debug On Error were off.
8. The debugger won't allow you to step into procedures in the invisible file.
9. The **ProcedureText** and **ProcedureVersion** functions and **DisplayProcedure** will act as if procedures in the invisible file don't exist. The **MacroList** and **FunctionList** functions will, however work as usual.
10. The GetIgorProcedure and SetIgorProcedure XOPSupport routines in the XOP Toolkit will act as if procedures in the invisible file don't exist. The GetIgorProcedureList function will, however work as usual.

Inserting Text Into a Procedure Window

On occasion, you may want to copy text from one procedure file to another. With the procedure window active, choose Edit→Insert File. This displays an Open File dialog in which you can choose a file and then inserts its contents into the procedure window.

Adopting a Procedure File

Adoption is a way for you to copy a procedure file into the current experiment and break the connection to its original file. The reason for doing this is to make the experiment self-contained so that, if you transfer it to another computer or send it to a colleague, all of the files needed to recreate the experiment are stored in the experiment itself.

To adopt a file, open its associated window and choose File→Adopt Window. This item is available only if the active window is a notebook or procedure file that is stored separate from the current experiment and the current experiment has been saved to disk.

If the current experiment is stored in packed form then, when you adopt a file, Igor does a save-as to a temporary file. When you subsequently save the experiment, the contents of the temporary file are stored in the packed experiment file.

If the current experiment is stored in unpacked form then, when you adopt a file, Igor does a save-as to the experiment's home folder. When you subsequently save the experiment, Igor updates the experiment's recreation procedures to open the new file in the home folder instead of the original file. If you adopt a file in an unpacked experiment and then you do not save the experiment, the new file will still exist in the home folder but the experiment's recreation procedures will still refer to the original file. Thus, you should normally save the experiment soon after adopting a file.

Adoption does not cause the original file to be deleted. You can delete it from the desktop if you want.

To "unadopt" a procedure file, choose Save Procedure File As from the File menu.

It is possible to do adopt multiple files at one time. For details see **Adopt All** on page II-25.

Auto-Compiling

If you modify a procedure window and then activate a non-procedure window other than a help window, Igor automatically compiles the procedures.

If you have a lot of procedures and compiling takes a long time, you may want to turn auto-compiling off. You can do this by deselecting the Auto-compile item in the Macros menu. This item appears only when the procedures need to be compiled (you have modified a procedure file or opened a new one). If you uncheck it item, Igor will not auto-compile and compilation will be done only when you click the Compile button or choose Compile from the Macros menu.

Debugging Procedures

Igor includes a symbolic debugger. This is described in **The Debugger** on page IV-212.

Finding Text

To find text in the active window, choose Edit→Find or press Command-F (*Macintosh*) or Ctrl+F (*Windows*). This displays the Find bar. See **Finding Text in the Active Window** on page II-52 for details.

To search multiple windows for text, choose Edit→Find in Multiple Windows. See **Finding Text in Multiple Windows** on page II-53 for details.

On Macintosh, you can search for the next occurrence of a string by selecting the string, pressing Command-E (Use Selection for Find in the Edit menu), and pressing Command-G (Find Same in the Edit menu).

On Windows, you can search for the next occurrence of a string by selecting the string and pressing Ctrl+H (Find Selection in the Edit menu).

After doing a find, you can search for the same text again by pressing Command-G (*Macintosh*) or Ctrl+G (*Windows*) (Find Same in the Edit menu). You can search for the same text but in the reverse direction by pressing Command-Shift-G (*Macintosh*) or Shift+Ctrl+G (*Windows*).

You can search back and forth through a procedure window by repeatedly pressing Command-G and Command-Shift-G (*Macintosh*) or Ctrl+G and Shift-Ctrl+G (*Windows*).

Replacing Text

To replace text in the active window, press Command-R (*Macintosh*) or Ctrl+R (*Windows*). This displays the Find bar in replace mode. See **Find and Replace** on page II-53 for details.

The Search Selected Text Only option is handy for limiting the replacement to a particular procedure.

While replacing text is undoable, the potential for unintended and wide-ranging consequences is such that we recommend saving the file before doing a mass replace so you can revert-to-saved if necessary.

Another method for searching and replacing consists of repeating Command-F or Ctrl-F (Find) followed by Command-V or Ctrl-V (Paste). This has the virtue of allowing you to inspect each occurrence of the target text before replacing it.

Printing Procedure Text

To print the active procedure window, first deselect all text and then choose File→Print Procedure Window.

To print part of the active procedure window, select the text you want to print and choose File→Print Procedure Selection.

Indentation

We use indentation to indicate the structure of a procedure. This is described in **Indentation Conventions** on page IV-26.

To make it easy to use the indentation conventions, Igor maintains indentation when you press Return or Enter in a procedure window. It automatically inserts enough tabs in the new line to have the same indentation as the previous line.

To indent more, as when going into the body of a loop, press Return or Enter and then Tab. To indent less, as when leaving the body of a loop, press Return or Enter and then Delete. When you don’t want to change the level of indentation, just press Return.

Included in the Edit menu for Procedure windows, is the Adjust Indentation item, which adjusts indentation of all selected lines of text to match Igor standards. The Edit menu also contains Indent Left and Indent Right commands that add or remove indentation for all selected lines.

Procedure Window Document Settings

The Document Settings dialog controls settings that affect the procedure window as a whole. You can summon it via the Procedure menu.

Igor does not store document settings for plain text files. When you open a procedure file, these settings are determined by preferences. You can capture preferences by choosing Procedure→Capture Procedure Prefs.

Procedure Window Default Tabs

The default tab width setting controls the location of tabs stops in procedure windows. You set this using the Document Settings dialog in the Procedure menu or using a DefaultTab pragma. In a procedure window the default tab width setting controls the location of all tab stops which affect indentation and alignment of comments.

Igor does not store document settings for procedure files, so your preferred default tab width settings apply to all procedure files subsequently opened unless they include a DefaultTab pragma.

Three modes are available: points, spaces, and mixed. In points mode, you specify the default tab width in units of points. In the Document Settings dialog, you can enter this setting in inches, centimeters, or points, but it is always stored as points. Prior to Igor Pro 9.00, this was the only mode available.

In spaces mode, you specify the default tab width in units of spaces.

In mixed mode, you specify the default tab width for procedure windows controlled by proportional fonts in units of points and for procedure windows controlled by monospace fonts in units of spaces.

Mixed mode is recommended for compatibility with other text editors which typically set default tab widths in units of spaces.

In Igor Pro 9.00 and later, when you create a new procedure window, Igor inserts a DefaultTab pragma statement, like this:

```
#pragma DefaultTab = {3,20,4} // Sets default tab width in Igor Pro 9 or later
```

The DefaultTab pragma is explained in the next section.

The Default Tab Pragma For Procedure Files

In Igor Pro 9.00 and later, you can specify default tab settings by entering a pragma statement in the procedure window, like this:

```
#pragma DefaultTab = {<mode>,<width in points>,<width in spaces>}
```

Older versions of Igor ignore this pragma.

The pragma is applied when the procedure file is compiled. It helps keep aligned comments aligned when you share the procedure file with another Igor user or if you change the font, text size, or magnification of the procedure window.

The DefaultTab pragma, if present, sets the default tab width parameters the same as if you set them in the Document Settings dialog. <mode> is 1 for points mode, 2 for spaces mode, and 3 for mixed mode. Specifying the default tab width in spaces keeps comments in procedure files that you share with others aligned so long as the other users use a proportional font for procedure files. The recommended pragma is:

```
#pragma DefaultTab = {3,20,4} // Sets default tab width in Igor Pro 9 or later
```

When you create a new procedure window, Igor inserts this DefaultTab statement in the new window. It overrides your default tab width preferences and specifies mixed mode (3) with the default tab width for proportional fonts set to 20 points and the default tab width for monospace fonts set to 4 spaces. Most people use a monospace font for procedure windows, in which case the default tab width is 4 spaces. If you share the procedure file with other users, this pragma increases the likelihood that aligned comments will remain aligned.

You can remove or edit the automatically inserted DefaultTab pragma. However, we recommend that you leave it as is.

We also recommend that you manually add this pragma to existing procedure files. You will then need to re-align comments.

Procedure Window Text Format Settings

You can specify the font, text size, style and color using items in the Procedure menu. Since procedure windows are always plain text windows (as opposed to notebooks, which can be formatted text) these text settings are the same for all characters in the window.

Igor does not store text format settings for plain text files. When you open a procedure file, these settings are determined by preferences. You can capture preferences by choosing Procedure→Capture Procedure Prefs.

Syntax Coloring

Procedure windows and the command window colorize comments, literal strings, flow control, and other syntax elements. Colors of various elements can be adjusted in two ways.

The first is from the Miscellaneous Settings dialog. Select the Text Editing category and then select the Color tab.

The second is by executing the following **SetIgorOption** colorize commands::

Command	Effect
`SetIgorOption colorize,doColorize=<1 or 0>`	Turn all colorize on or off
`SetIgorOption colorize,OpsColorized=<1 or 0>`	Turn operation keyword colorization on or off
`SetIgorOption colorize,BIFuncsColorized=<1 or 0>`	Turn function keyword colorization on or off
`SetIgorOption colorize,keywordColor=(`*r*`,`*g*`,`*b*`[,`*a*`])`	Color for language keywords
`SetIgorOption colorize,commentColor=(`*r*`,`*g*`,`*b*`[,`*a*`])`	Color for comments
`SetIgorOption colorize,stringColor=(`*r*`,`*g*`,`*b*`[,`*a*`])`	Color for strings
`SetIgorOption colorize,operationColor=(`*r*`,`*g*`,`*b*`[,`*a*`])`	Color for operation keywords
`SetIgorOption colorize,functionColor=(`*r*`,`*g*`,`*b*`[,`*a*`])`	Color for built-in function keywords
`SetIgorOption colorize,poundColor=(`*r*`,`*g*`,`*b*`[,`*a*`])`	Color for #keywords such as #pragma
`SetIgorOption colorize,UserFuncsColorized=1`	Turn colorizing on for user functions
`SetIgorOption colorize,userFunctionColor=(r,g,b[,`*a*`])`	Color for user-defined functions
`SetIgorOption colorize,SpecialFuncsColorized=1`	Turn colorizing on for special operations (MatrixOP and APMath)
`SetIgorOption colorize,specialFunctionColor=(r,g,b[,a])`	Color for special operations (MatrixOP and APMath)

Values for *r*, *g*, *b*, and the optional alpha range from 0 to 65535. Alpha defaults to 65535 (opaque).

Changes to syntax coloring settings, made via the dialog or via SetIgorOption, are saved to preferences and used for future sessions.

Procedure Window Preferences

The procedure window preferences affect the creation of *new* procedure windows. This includes the creation of auxiliary procedure windows and the initialization of the built-in procedure window that occurs when you create a new experiment.

To set procedure preferences, set the attributes of any procedure window and then choose Procedure→Capture Procedure Prefs.

To determine the current preference settings, you must create a new procedure window and examine its settings.

Preferences are stored in the Igor Preferences file. See Chapter III-18, **Preferences**, for further information on preferences.

Double and Triple-Clicking

Double-clicking a word conventionally selects the entire word. Igor extends this idea a bit. In addition to supporting double-clicking, if you triple-click in a line of text, it selects the entire line. If you drag after triple-clicking, it extends the selection an entire line at a time.

Matching Characters

Igor includes a handy feature to help you check parenthesized expressions. If you double-click a parenthesis, Igor tries to find a matching parenthesis on the same line of text. If it succeeds, it selects all of the text between the parentheses. If it fails, it beeps. Consider the command

```
wave1 = exp(log(x)))
```

If you double-clicked on the first parenthesis, it would select “`log(x)`”. If you double-clicked on the last parenthesis, it would beep because there is no matching parenthesis.

If you double-click in-between adjacent parentheses Igor considers this a click on the outside parenthesis.

Igor does matching if you double-click the following characters:

Left and right parentheses	(xxx)
Left and right brackets	[xxx]
Left and right braces	{xxx}
Plain single quotes	'xxx'
Plain double quotes	"xxx"

Code Comments

The Edit menu for procedures contains two items, Commentize and Decommentize, to help you edit and debug your procedure code when you want to comment out large blocks of code, and later, to remove these comments. Commentize inserts comment symbol at the start of each selected line of text. Decommentize deletes any comment symbols found at beginning of each selected line of text.

Code Marker Comments

You can enter specially-formatted comments in procedure files to mark sections of code and later return to those comments using the Code Markers popup menu in the procedure window's navigation bar.

The navigation bar is visible if Show Navigation Bar is checked in the Editing Behavior tab of the Text Editing section of the Miscellaneous Settings dialog. The Code Markers popup menu appears on the left side of the navigation bar and looks like this this: 📍 .

To get a sense of the purpose of code markers, we will look at the "HDF5 Browser.ipf" procedure file. It is an independent module so you must first execute this:

```
SetIgorOption IndependentModuleDev=1    // Enable editing of independent modules
```

Choose Windows→Procedure Windows→HDF5 Browser.ipf

Click the code markers popup menu and note the list of sections in the file such as "Utility Routines", and "Fill List Routines".

Choose Utility Routines from the popup menu. Igor displays the following line:

```
// *** Utility Routines ***
```

That line contains a code marker comment.

The format of a code marker comment is:

```
// *** <code marker text> ***
```

The code marker text, which appears in the code marker popup menu, is everthing after `"// *** "` and before `" ***"`.

The code marker comment must be flush left with no spaces, tabs, or any other text before `"// *** "`.

You can insert a code marker comment manually or by clicking the code markers popup menu and choosing "Insert Code Marker Comment". You can not insert a code marker comment if the procedure window is write protected or is open for read only.

Aligning Comments

You can align comments introduced by "//" in a procedure window by selecting text and choosing Edit→Align Comments. This aligns subsequent comments with the first comment in the selected text. This feature is available for procedure windows only, not for notebooks.

Aligning comments requires that the procedure window use the spaces mode of defining default tabs. To ensure this, when you choose Edit→Align Comments, Igor adds a DefaultTab pragma to the procedure window if it is not already there. See **The Default Tab Pragma For Procedure Files** on page III-406 for details about this pragma. The DefaultTab pragma is ignored by versions of Igor prior to 9.00 so comments that you align using this technique will not appear aligned in earlier versions.

Aligning comments also requires that the procedure window use a monospace font. It is up to you to make sure that this is the case. The factory default fonts for procedure windows, Monaco on Macintosh and Lucida Console on Windows, are monospace fonts.

When you choose Edit→Align Comments, Igor finds the first selected line containing a comment (introduced by "//"). It then works on each subsequent selected line and attempts to align comments by inserting or removing tabs. During this process, Igor removes spaces that appear between the end of the line's active code and the comment.

Comments that are flush left are left unchanged as they typically appear above function definitions and are already positioned as desired.

By default, other pure comment lines (lines with nothing before the comment symbol except for spaces and tabs) are also left unchanged unless:

- The section consists entirely of pure comment lines
- You press the Option key (*Macintosh*) or Alt key (*Windows*) while choosing Edit→Align Comments to override the default behavior

In some cases, exact alignment is not possible. For example, if the active code of the second selected line extends paste the comment in the first selected line, removing all tabs from the second selected line does not achieve alignment. In such cases, Igor does the best it can.

Procedure File Text Encodings

Igor uses UTF-8, a form of Unicode, internally. Prior to Igor7, Igor used non-Unicode text encodings such as MacRoman, Windows-1252 and Shift JIS.

All new procedure files should use UTF-8 text encoding. When you create a new procedure file using Windows→New→Procedure, Igor automatically uses UTF-8.

Igor must convert from the old text encodings to Unicode when opening old files. It is not always possible to get this conversion right. You may get incorrect characters or receive errors when opening files containing non-ASCII text.

For a discussion of these issues, see **Text Encodings** on page III-459 and **Plain Text File Text Encodings** on page III-466.

Procedure Window Shortcuts

To view text window keyboard navigation shortcuts, see **Text Window Navigation** on page II-51.

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To show the built-in procedure window	Press Command-M.	Press Ctrl+M.
To hide the active procedure file and cycle to the next	Press Command-Shift-Option-M.	Press Ctrl+Shift+Alt+M.
To cycle through the open procedure windows	Press Command-Option-M.	Press Ctrl+Alt+M.
To revisit a previously-viewed location	Press Cmd-Option-Left Arrow (Go Back) or Cmd-Option-Right Arrow (Go Forward).	Press Alt+Left Arrow (Go Back) or Alt+Right Arrow (Go Forward).
To get a contextual menu of commonly-used actions	Press Control and click in the body of the procedure window.	Right-click the body of the procedure window.
To execute commands in a procedure window	Select the commands or click in the line containing the commands and press Control-Return or Control-Enter.	Select the commands or click in the line containing the commands and press Ctrl+Enter.
To insert a template	Type or select the name of an operation, Control-click, and choose Insert Template.	Type or select the name of an operation, right-click, and choose Insert Template.
To get help for a built-in or external operation or function	Type or select the name of an operation, Control-click, and choose Help for <name> or choose Help→Help For <name>.	Type or select the name of an operation, right-click, and choose Help for <name> or choose Help→Help For <name>.
To view the definition of a user-defined function	Type or select the name of an operation, Control-click, and choose Go to <name> or choose Edit→Help For <name>.	Type or select the name of an operation, right-click, and choose Go to <name> or choose Edit→Help For <name>.
To find a procedure in the active procedure window	Click the navigation bar at the top of the procedure window.	Click the navigation bar at the top of the procedure window.
To find the definition of a procedure when you have selected an invocation of it	Control-click the selected invocation and choose “Go to <procedure name>” from the resulting contextual menu.	Right-click the selected invocation and choose “Go to <procedure name>” from the resulting contextual menu.
To find in the procedure window	Press Command-F.	Press Ctrl+F.
To find the same text again	Press Command-G.	Press Ctrl+G.
To find again but in the reverse direction	Press Command-Shift-G.	Press Ctrl+Shift+G.
To find the selected text	Press Command-E and Command-G.	Press Ctrl+H.

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To find the selected text but in the reverse direction	Press Command-E and Command-Shift-G. This shortcut can be changed through the Miscellaneous Settings dialog.	Press Ctrl+Shift+H.
To find a user-defined menu's procedure	Open any procedure window and press Option while selecting a user-defined menu item.	Open any procedure window and press Alt while selecting the user-defined menu item.
To select a word	Double-click.	Double-click.
To select an entire line	Triple-click.	Triple-click.
To save all modified standalone notebook files	When a notebook window is active, choose File→Save All Standalone Notebook Files.	When a notebook window is active, choose File→Save All Standalone Notebook Files.

Chapter

III-14

Controls and Control Panels

Overview

We use the term *controls* for a number of user-programmable objects that can be employed by Igor programmers to create a graphical user interface for Igor users. We call them *controls* even though some of the objects only display values. The term *widgets* is sometimes used by other application programs.

Here is a summary of the types of controls available.

Control Type	**Control Description**
Button	Calls a procedure that the programmer has written.
Chart	Emulates a mechanical chart recorder. Charts can be used to monitor data acquisition processes or to examine a long data record. Programming a chart is quite involved.
CheckBox	Sets an off/on value for use by the programmer's procedures.
CustomControl	Custom control type. Completely specified and modified by the programmer.
GroupBox	An organizational element. Groups controls with a box or line.
ListBox	Lists items for viewing or selecting.
PopupMenu	Used by the user to choose a value for use by the programmer's procedures.
SetVariable	Sets and displays a numeric or string global variable. The user can set the variable by clicking or typing. For numeric variables, the control can include up/down buttons for incrementing/decrementing the value stored in the variable.
Slider	Duplicates the behavior of a mechanical slider. Selects either discrete or continuous values.
TabControl	Selects between groups of controls in complex panels.
TitleBox	An organizational element. Provides explanatory text or message.
ValDisplay	Presents a readout of a numeric expression which usually references a global variable. The readout can be in the form of numeric text or a thermometer bar or both.

The programmer can specify a procedure to be called when the user clicks on or types into a control. This is called the control's *action procedure*. For example, the action procedure for a button may interrogate values in PopupMenu, Checkbox, and SetVariable controls and then perform some action.

Control panels are simple windows that contain these controls. These windows have no other purpose. You can also place controls in graph windows and in panel panes embedded into graphs. Controls are not available in any other window type such as tables, notebooks, or layouts. When used in graphs, controls are not considered part of the *presentation* and thus are **not** included when a graph is printed or exported.

Nonprogrammers will want to skim only the Modes of Operation and Using Controls sections, and skip the remainder of the chapter. Igor programmers should study the entire chapter.

Modes of Operation

With respect to controls, there are two modes of operation: one mode to use the control and another to modify it. To see this, choose Show Tools from the Graph or Panel menu. Two icons will appear in the top-left corner window. When the top icon is selected, you are able to use the controls. When the next icon is selected, the draw tool palette appears below the second icon. To modify the control, select the arrow tool from the draw tool palette.

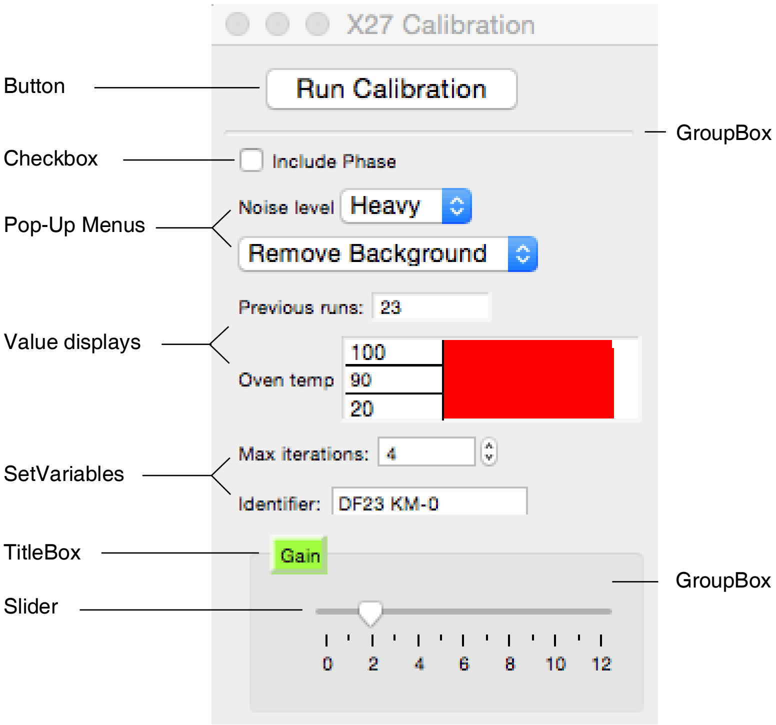
When the top icon is selected or when the icons are hidden, you are in the *use* or *operate* mode. You can momentarily switch to the *modify* or *draw* mode by pressing Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*). Use this to drag or resize a control as well as to double-click it. Double-clicking with the Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*) pressed brings up a dialog that you use to modify the control.

You can also switch to modify mode by choosing an item from the Select Control submenu of the Graph or Panel menu.

Important:To enable the Add Controls submenu in the Graph and Panel menus, you must be in modify mode; either by clicking the second icon or by pressing Command-Option (*Macintosh*) or the Ctrl+Alt (*Windows*) while choosing the Add Controls submenu.

Using Controls

The following panel window illustrates most of the control types.



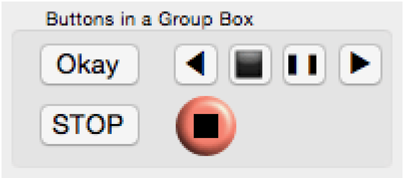
Buttons

When you click a button, it runs whatever procedure the programmer may have specified.

If nothing happens when you click a button, then there is no procedure assigned to the button. If the procedure window(s) haven't been compiled, clicking a button that has an assigned procedure will produce an error dialog.

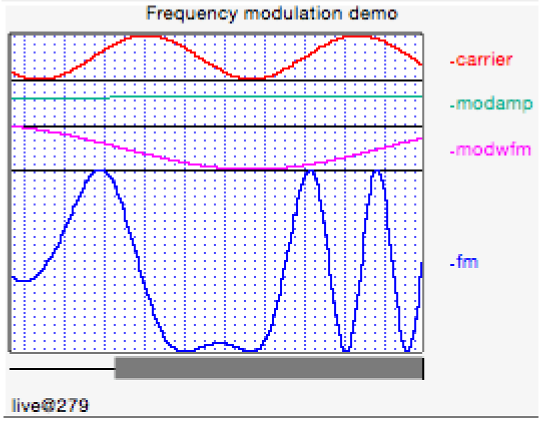
You should choose Compile from the Macros menu to correct this situation. If no error occurs then the button will now be functional.

Buttons usually have a rounded appearance, but a programmer can assign a custom picture so that the button can have nearly any appearance.



Charts

Chart controls can be used to emulate a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. Charts can be used to monitor data acquisition processes or to examine a long data record.

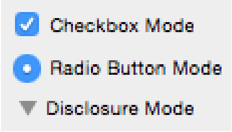


For further discussion of using chart controls, see **Using Chart Recorder Controls** on page IV-317.

Although programming a chart is quite involved, using a chart is actually very easy. See **FIFOs and Charts** on page IV-313 for details.

Checkboxes

Clicking a checkbox changes its selected state and may run a procedure if the programmer specified one. A checkbox may be connected to a global variable. Checkboxes can be configured to look and behave like radio buttons.

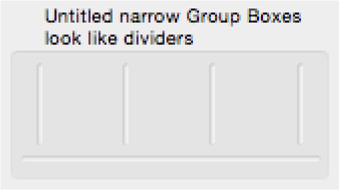


CustomControl

CustomControls are used to create completely new types of controls that are custom-made by the programmer. You can define and control the appearance and all aspects of a custom control's behavior. See **Creating Custom Controls** on page III-424 for examples.

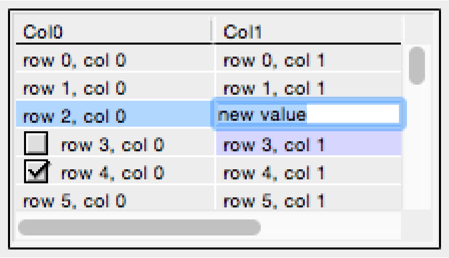
GroupBox

GroupBox controls are organizational or decorative elements. They are used to graphically group sets of controls. They may either draw a box or a separator line and can have optional titles.



ListBox

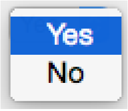
ListBox controls can present a single or multiple column list of items for viewing or selection. ListBoxes can be configured for a variety of selection modes. Items in the list can be made editable and can be configured as checkboxes.



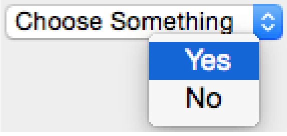
Col0	Col1
row 0, col 0	row 0, col 1
row 1, col 0	row 1, col 1
row 2, col 0	new value
□ row 3, col 0	row 3, col 1
☑ row 4, col 0	row 4, col 1
row 5, col 0	row 5, col 1

Pop-Up Menus

These controls come in two forms: one where the current item is shown in the pop-up menu box:



and another where there is no current item and a title is shown in the box:



The first form is usually used to choose one of many items while the second is used to run one of many commands.

Pop-up menus can also be configured to act like Igor’s color, line style, pattern, or marker pop-up menus. These always show the current item.

SetVariable

SetVariable controls also can take on a number of forms and can display numeric values. Unlike Value Display controls that display the value of an expression, SetVariable controls are connected to individual global variables and can be used to set or change those variables in addition to reading out their current value. SetVariable controls can also be used with global string variables to display or set short one line strings. SetVariable controls are automatically updated whenever their associated variables are changed.

When connected to a numeric variable, these controls can optionally have up or down arrows that increment or decrement the current value of the variable by an amount specified by the programmer. Also, the programmer can set upper and lower limits for the numeric readouts.

New values for both numeric and string variables can be entered by directly typing into the control. If you click the control once you will see a thick border form around the current value.

Frequency 44100

Frequency 44100

You can then edit the readout text using the standard techniques including Cut, Copy, and Paste. If you want to discard changes you have made, press Escape. To accept changes, press Return, Enter, or Tab or click anywhere outside of the control. Tab enters the current value and also takes you to the next control if any. Shift-Tab is similar but takes you to the previous control if any.

If the control is connected to a numeric variable and the text you have entered can not be converted to a number then a beep will be emitted when you try to enter the value and no change will be made to the value of the variable. If the value you are trying to enter exceeds the limits set by the programmer then your value will be replaced by the nearest limit.

When a numeric control is selected for editing, the Up and Down Arrow keys on the keyboard act like the up and down buttons on the control.

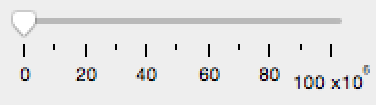
Changing a value in a SetVariable control may run a procedure if the programmer has specified one.

SetVariable Controls and Data Folders

SetVariable controls remember the data folder in which the variable exists, and continue to function properly when the current data folder is different than the controlled variable. See **SetVariable** on page III-417.

The system variables (K0 through K19) belong to no particular data folder (they are available from any data folder), and there is only *one* copy of these variables. If you create a SetVariable controlling K0 while the current data folder is “aFolder”, and another SetVariable controlling K0 while the current data folder is “bFolder”, *they are actually controlling the same K0.*

Sliders



Slider controls can be used to graphically select either discrete or continuous values. When used to select discrete values, a slider is similar to a pop-up menu or a set of radio buttons. Sliders can be live, updating a variable or running a procedure as the user drags the slider, or they can be configured to wait until the user finishes before performing any action.

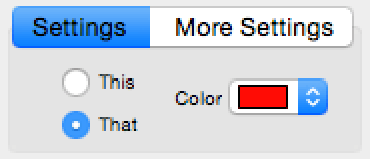
Repeating Sliders

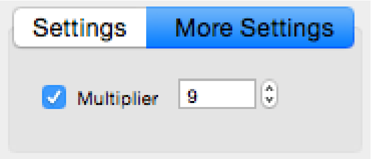
Sliders can be configured to call your action procedure repeatedly while the user is clicking on the thumb. They can be configured to operate at a constant rate or at a rate proportional to the value, and optionally to spring back to a resting value when released. This feature was added in Igor Pro 8.00.

To implement a repeating slider, use the repeat keyword with the **Slider** operation. For a demonstration, see the Slider Repeat Demo demo experiment.

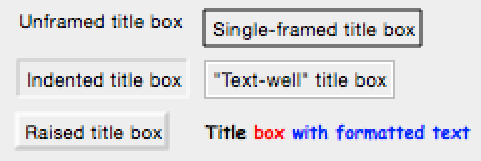
TabControl

TabControls are used to create complex panels containing many more controls than would otherwise fit. When the user clicks on a tab, the programmers procedure runs and hides the previous set of controls while showing the new set.





TitleBox

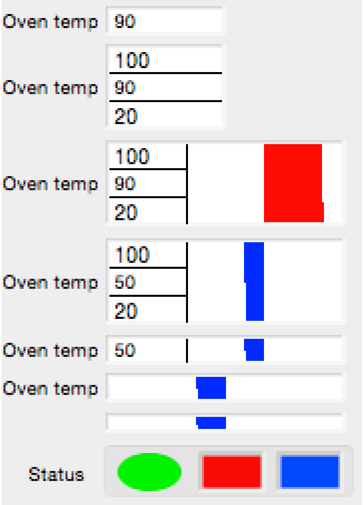


TitleBox controls are mainly decorative elements. They are used provide explanatory text in a control panel. They may also be used to display textual results. The text can be unchanging, or can be the contents of a global string variable. In either case, the user can't inadvertently change the text.

ValDisplays

ValDisplay controls display numeric or string values in a variety of forms ranging from a simple numeric readout to a thermometer bar. Regardless of the form, ValDisplays are just readouts. There is no interaction with the user. They display the current value of whatever expression the programmer specified. Often this will be just the value of a numeric variable, but it can be any numeric expression including calls to user-defined functions and external functions.

Here is a sampling of the forms that ValDisplay controls can assume.



When a thermometer bar is shown, the left edge of the thermometer region represents a low limit set by the programmer while the right edge represents a high limit. The low and high limits appear in some of the above examples. The bar is drawn from a nominal value set by the programmer and will be red if the current value exceeds the nominal value and will be blue if it is less than the nominal value. In the above examples the nominal value is 60. There is no numeric indication of the nominal value. If the nominal value is less than the low limit then the bar will grow from the left to the right. If the nominal value is greater than the high limit then the bar will grow from the right to the left.

If you carefully observe a thermometer bar that is connected to an expression whose value is slowly changing with time you will see that the bar is drawn in a zig-zag fashion. This provides a much finer resolution than if the bar were to be extended or contracted by an entire column of screen pixels at once.

Creating Controls

The ease of creating the various controls varies widely. Anyone capable of writing a simple procedure can create buttons and checkboxes, but creating charts and custom controls requires more expertise. Most controls can be created and modified using dialogs that you invoke via the Add Controls submenu in the Graph or Panel menu.

The Add Controls and Select Control menus are enabled only when the arrow tool in the tool palette is selected. To do this, choose Show Tools from the Graph or Panel menu and then click the second icon from the top in the graph or panel tool palette.

You can temporarily use the arrow tool without the tool palette showing by pressing Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*). While you press these keys, the normally-disabled Add Controls and Select Control submenus are enabled.

When you click a control with the arrow tool, small handles are drawn that allow you to resize the control. Note that some controls can not be resized in this way and some can only be resized in one dimension. You will know this when you try to resize a control and it doesn't budge. You can also use the arrow tool to reposition a control. You can select a control by name with the Select Control submenu in the Graph or Panel menu.

With the arrow tool, you can double-click most controls to get a dialog that modifies or duplicates the control. Charts and CustomControls do not have dialog support.

When you right-click (*Windows*) or Control-click (*Macintosh*) a control, you get a contextual menu that varies depending on the type of control.

You can select multiple controls, mix selections with drawing objects, and perform operations such as move, cut, copy, paste, delete, and align. These operations are undoable. You can't group buttons or use Send to Back as you can with drawing objects.

In panels, when you do a Select All, the selectin includes all controls and drawing objects, but in the case of graphs, only drawing objects are selected. This is because drawing objects in graphs are used for presentation graphics whereas in panels they are used to construct the user interface.

If you want to copy controls from one window to another, simply use the Edit menu to copy and paste. You can also duplicate controls using copy and paste.

When you copy controls to the clipboard, the command and control names are also copied as text. This is handy for programming.

Press Option (*Macintosh*) or Alt (*Windows*) while choosing Edit-Copy to copy the complete commands for creating the copied controls.

If you copy a control from the extreme right side or bottom of a window, it may not be visible when you paste it into a smaller window. Use the smaller window's Retrieve submenu in the Mover tool palette icon to make it visible.

General Command Syntax

All of the control commands use the following general syntax:

```
ControlOperation Name [,keyword[=value] [,keyword[=value]]…]
```

`Name` is the control's name. It must be unique among controls in the window containing the control. If `Name` is not already in use then a new control is created. If a control with the same name already exists then that control is modified, so that multiple commands using the same name result in only one control. This is useful for creating controls that require many keywords.

All keywords are optional. Not all controls accept all keywords, and some controls accept a keyword but do not actually use the value. The value for a keyword with one control can have a different form from the value for the same keyword used with a different type of control. See the specific control operation documentation in Chapter V-1, **Igor Reference** for details.

Some controls utilize a format keyword to set a format string. The format string can be any printf-style format that expects a single numeric value. Think of the output as being the result of the following command:

```
Printf formatString, value_being_displayed
```

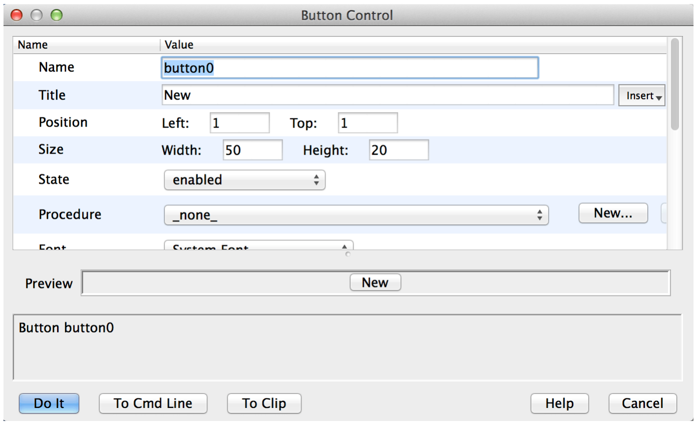
See the **printf** operation on page V-770 for a discussion of printf format strings. The maximum length of the format string is 63 bytes. The format is used only for controls that display numeric values.

All of the clickable controls can optionally call a user-defined function when the user releases the mouse button. We use the term *action procedure* for such a function. Each control passes one or more parameters to the action procedure. The dialogs for each control can create a blank user function with the correct parameters.

Creating Button Controls

The **Button** operation (page V-55) creates or modifies a rounded-edge or custom button with the title text centered in the button. The default font depends on the operating system, but you can change the font, font size, text color and use annotation-like escape codes (see **Annotation Escape Codes** on page III-53). The amount of text does not change the button size, which you can set to what you want.

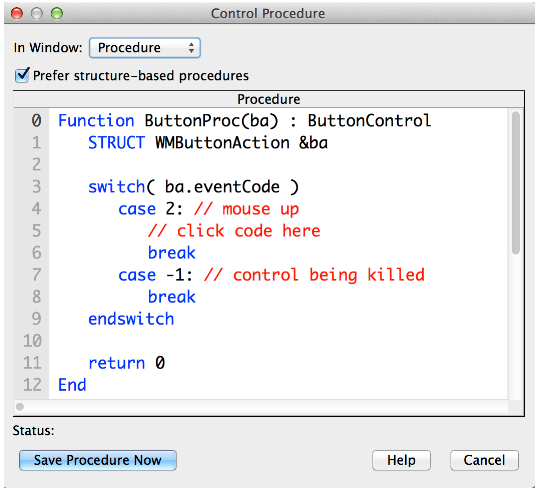
Here we create a simple button that will just emit a beep when pressed. Start by choosing the Add Button menu item in the Graph or Panel menu to invoke the Button Control dialog:



Name	Value
Name	button0
Title	New
Position	Left: 1 Top: 1
Size	Width: 50 Height: 20
State	enabled
Procedure	_none_
Font	System Font

Button button0

Clicking the procedure's New button brings up a dialog containing a procedure template that you can edit, rename, and save. Here we started with the standard ButtonControl template, replaced the default name with `MyBeepProc`, and added the `Beep` command:



In Window: Procedure

☑ Prefer structure-based procedures

```
Function ButtonProc(ba) : ButtonControl
	STRUCT WMButtonAction &ba

	switch( ba.eventCode )
		case 2: // mouse up
			// click code here
			break
		case -1: // control being killed
			break
	endswitch

	return 0
End
```

The controls can work with procedures using two formats: the old procedure format used in Igor 3 and 4, and the "structure-based" format introduced in Igor 5.

Selecting the "Prefer structure-based procedures" checkbox creates new procedure templates using the structure-based format.

The "Prefer structure-based procedures" checkbox is checked by default because structure-based procedures are recommended for all new code. If you uncheck this checkbox before editing the template, Igor switches the template to the old procedure format. Use of the old format is discouraged.

Click Help to get help about the Button operation. In the Details section of the help, you can find information about the WMButtonAction structure.

The fact that you can create the action procedure for a control in a dialog may lead you to believe that the procedure is stored with the button. This is not true. The procedure is actually stored in a procedure window. This way you can use the same action procedure for several controls. The parameters which are passed to a given procedure can be used to differentiate the individual controls.

For more information on using action procedures, see **Control Structures** on page III-437, the **Button** operation (page V-55), and **Using Structures with Windows and Controls** on page IV-103.

Button Example

Here is how to make a button whose title alternates between Start and Stop.

Enter the following in the procedure window:

```
Function MyStartProc()
   Print "Start"
End

Function MyStopProc()
   Print "Stop"
End

Function StartStopButton(ba) : ButtonControl
   STRUCT WMButtonAction &ba

   switch(ba.eventCode)
      case 2:                       // Mouse up
         if (CmpStr(ba.ctrlName,"bStart") == 0)
            Button $ba.ctrlName,title="Stop",rename=bStop
            MyStartProc()
         else
            Button $ba.ctrlName,title="Start",rename=bStart
            MyStopProc()
         endif
         break
   endswitch

   return 0
End
```

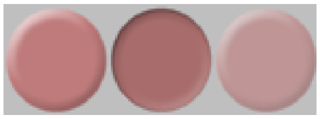
Now execute:

```
NewPanel
Button bStart,size={50,20},proc=StartStopButton,title="Start"
```

Custom Button Control Example

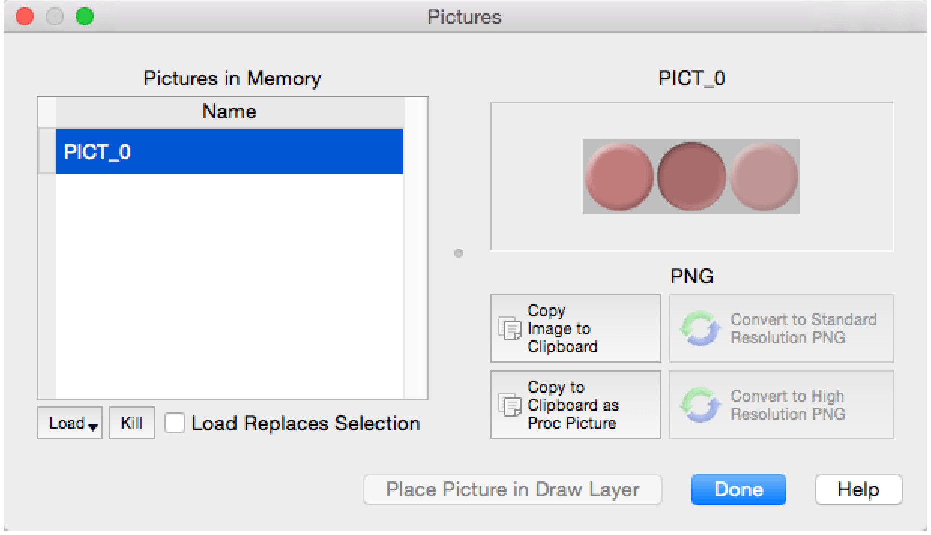
You can create custom buttons by following these steps:

1. Using a graphics-editing program, create a picture that shows the button in its normal (“relaxed”) state, then in the pressed-in state, and then in the disabled state. Each portion of the picture should be the same size:



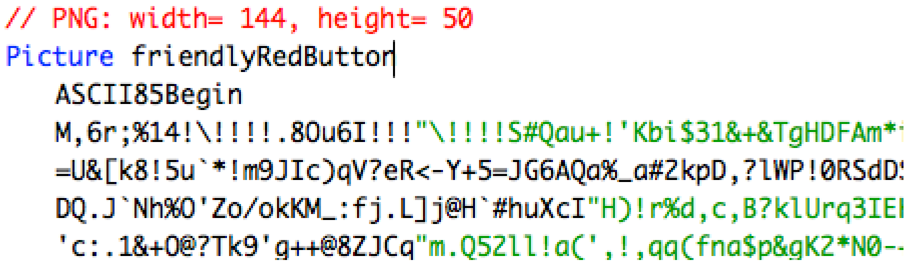
If the button blends into the background it will look better if the buttons are created on the background you will use in the panel. Igor looks at the pixels in the upper left corner, and if they are a light neutral color, Igor omits those pixels when the button is drawn.

2. Copy the picture to the clipboard.
3. Switch to Igor,choose Misc→Pictures, click Load and then From Clipboard.



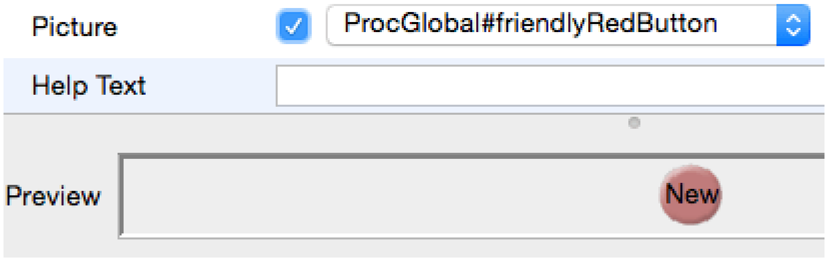
Pictures
Pictures in Memory
Name
PICT_0
Load
Kill
□ Load Replaces Selection
PICT_0
PNG
Copy Image to Clipboard
Convert to Standard Resolution PNG
Copy to Clipboard as Proc Picture
Convert to High Resolution PNG
Place Picture in Draw Layer
Done
Help

4. Click Copy to Clipboard as Proc Picture to create Proc Picture text on the Clipboard.
5. Click Done.
6. Open a procedure window, paste the text, and give a suitable name to the picture:



```
// PNG: width= 144, height= 50
Picture friendlyRedButton
    ASCII85Begin
    M,6r;%14!\!!!!.8Ou6I!!!"\!!!!S#Qau+!'Kbi$31&+&TgHDFAm*
    =U&[k8!5u`*!m9JIc)qV?eR<-Y+5=JG6AQa%_a#2kpD,?lWP!0RSdD
    DQ.J`Nh%O'Zo/okKM_:fj.L]j@H`#huXcI"H)!r%d,c,B?klUrq3IE
    'c:.1&+O@?Tk9'g++@8ZJCq"m.Q52ll!a(',!,qq(fna$p&gK2*N0-
```

7. Activate an existing control panel or create a new one.
8. If the tool palette is not showing, choose Panel→Show Tools.
9. Choose Panel-Add Control→Add Button to display the Button Control dialog.
10. Locate the Picture setting in the dialog, check the checkbox, and select the proc picture from the pop-up menu:



Picture ☑ ProcGlobal#friendlyRedButton

Help Text

11. Locate the Size setting in the dialog and set the appropriate size for the button:

Size Width: 32 Height: 32

Creating Chart Controls

The **Chart** operation creates or modifies a chart control. There is no dialog support for chart controls. You need at least intermediate-level Igor programming skills to create a functional chart control.

For further information, see **FIFOs and Charts** on page IV-313.

Creating Checkbox Controls

The **CheckBox** creates or modifies a checkbox or a radio button.

CheckBox controls automatically size themselves in both height and width. They can optionally be connected to a global variable.

For an example of using checkbox controls as radio buttons, see the reference documentation for the **CheckBox** operation.

The user-defined action procedure that you will need to write for CheckBoxes must have the following form:

```
Function CheckProc(cba) : CheckBoxControl
   STRUCT WMCheckboxAction &cba

   switch(cba.eventCode)
      case 2:             // Mouse up
         Variable checked = cba.checked
         break
      case -1:            // Control being killed
         break
   endswitch

   return 0
End
```

The checked structure member is set to the new checkbox value:; 0 or 1.

You often do not need an action procedure for a checkbox because you can read the state of the checkbox with the **ControlInfo** operation.

You can create custom checkboxes by following steps similar to those for custom buttons (see **Custom Button Control Example** on page III-422), except that the picture has six states side-by-side instead of three. The checkbox states are:

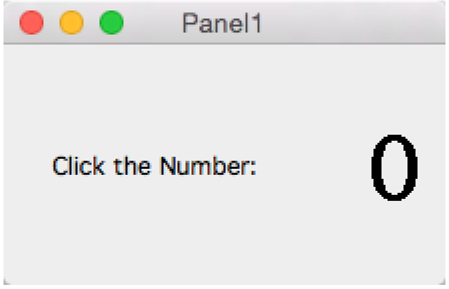
Image Order	Control State
Left	Deselected enabled.
	Deselected enabled and clicked down (about to be selected).
	Deselected disabled.
	Selected enabled.
	Selected enabled and clicked down (about to be deselected).
Right	Selected disabled.

Creating Custom Controls

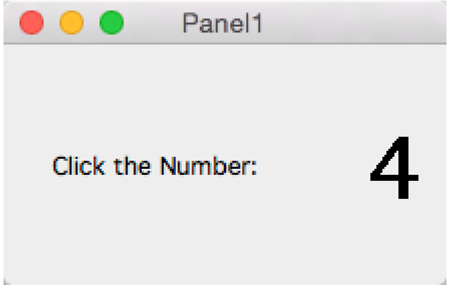
The CustomControl operation creates or modifies a custom control, all aspects of which are completely defined by the programmer. See the **CustomControl** operation on page V-134 for a complete description.

The examples in this section are also available in the Custom Controls demo experiment. Choose File→Example Experiments→Feature Demos 2→Custom Control Demo.

What you can create with a CustomControl can be fairly simple such as this counter that increments when you click on it.



Four clicks later:



The following code implements the counter custom control using the `kCCE_frame` event. In the panel, click on the number to increment the counter; also try clicking and then dragging outside the control.

```
static constant kCCE_mouseup= 2
static constant kCCE_frame= 12

// PNG: width= 280, height= 49
Picture Numbers0to9
	ASCII85Begin
	M,6r;%14!\!!!!.8Ou6I!!!$:!!!!R#Qau+!00#^OT5@]&TgHDFAm*iFE_/6AH5;7DfQssEc39jTBQ
	=U"5QO:5u`*!m@2jnj"La,mA^'a?hQ[Z.[.,Kgd(1o5*(PSO8oS[GX%3u'11dTl)fII/"f-?Jq*no#

	ASCII85End
End

Structure CC_CounterInfo
	Int32 theCount		// current frame of 10 frame sequence of numbers in
EndStructure

Function MyCC_CounterFunc(s)
	STRUCT WMCustomControlAction &s

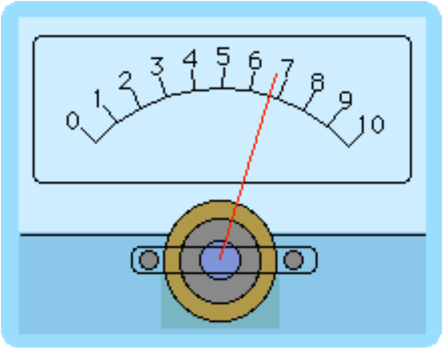
	STRUCT CC_CounterInfo info

	if( s.eventCode==kCCE_frame )
		StructGet/S info,s.userdata
		s.curFrame= mod(info.theCount+(s.curFrame!=0),10)
	elseif( s.eventCode==kCCE_mouseup )
		StructGet/S info,s.userdata
		info.theCount= mod(info.theCount+1,10)
		StructPut/S info,s.userdata	// will be written out to control
	endif

	return 0
End

Window Panel0() : Panel
	PauseUpdate; Silent 1		// building window...
	NewPanel /W=(69,93,271,252)
	CustomControl cc2,pos={82,46},proc=MyCC_CounterFunc,picture=
{ProcGlobal#Numbers0to9,10}
EndMacro
```

You can create even more sophisticated controls, such as this voltage meter control.



Choose File→Example Experiments→Feature Demos 2→Custom Control Demo to try this control and see the code that implements it.

Creating GroupBox Controls

The GroupBox operation creates or modifies a listbox control. See the **GroupBox** operation on page V-334 for a complete description and examples.

Creating ListBox Controls

The **ListBox** operation creates or modifies a listbox control.

We will illustrate listbox creation by example.

1. Create a panel with a listbox control:

   ```
   NewPanel
   ListBox list0 size={200,60}, mode=1
   ```

   The simplest functional listbox needs at least one text wave to contain the list items. Without the text wave, a listbox control has no list items. In this state, the listbox is drawn with a red X over the control.
2. We need a text wave to contain the list items:

   ```
   Make/O/T textWave0 = {"first list item", "second list item", "etc..."}
   ```

3. Choose Panel→Show Tools.

   This puts the panel in edit mode so you can modify controls.
4. Double-click the listbox control to invoke the ListBox Control dialog.
5. For the List Text Wave property, select the wave you created to assign it as the list’s text wave.
6. Click Do It.

   You now have a functional listbox control.
7. Click the operate (top) icon, or choose Panel→Hide Tools, so you can use, rather than edit, the list.

In this example, we created a single-selection list. You can query the selection by calling **ControlInfo** and checking the V_Value output variable.

See the **ListBox** for a complete description and further examples.

Right-clicking (*Windows*) or Control-clicking (*Macintosh*) a listbox shows a contextual menu with commands for editing the list waves and action procedure, and for creating a numeric selection wave, if the control is a multi-selection listbox.

Creating PopupMenu Controls

The **PopupMenu** creates or modifies a pop-up menu control. Pop-up menus are usually used to provide a choice of text items but can also present colors, line styles, patterns, and markers.

The control automatically sizes itself as a function of the title or the currently selected menu item. You can specify the bodyWidth keyword to force the body (non-title portion) of the pop-up menu to be a fixed size. You might do this to get a set of pop-up menus of nicely aligned with equal width. The bodywidth keyword also affects the non-text pop-up menus.

The font and fsize keywords affect only the title of a pop-up menu. The pop-up menu itself uses standard system fonts.

Unlike color, line style, pattern, or marker pop-up menus, text pop-up menu controls can operate in two distinct modes as set by the mode keyword's value.

If the argument to the mode keyword is nonzero then it is considered to be the number of the menu item to be the initial current item *and* displays the current item in the pop-up menu box. This is the *selector mode*. There is often no need for an action procedure since the value of the current item can be read at any time using the **ControlInfo** operation (page V-89).

If mode is zero then the title appears inside the pop-up menu box, hence the name *title-in-box mode*. This mode is generally used to select a command for the action procedure to execute. The current item has no meaning except when the pop-up menu is activated and the selected item is passed to the action procedure.

The menu that pops up when the control is clicked is determined by a string expression that you pass as the argument to the value keyword. For example:

```
PopupMenu name value="Item 1;Item 2;Item 3;"
```

To create the color, line style, pattern or marker pop-up menus, set the string expression to one of these fixed values:

```
"*COLORPOP*"
"*LINESTYLEPOP*"
"*MARKERPOP*"
"*PATTERNPOP*"
```

For text pop-up menus, the string expression must evaluate to a list of items separated by semicolons. This can be a fixed literal string or a dynamically-calculated string. For example:

```
PopupMenu name value="Item 1;Item 2;Item 3;"
PopupMenu name value="_none_;" + WaveList("*",";","")
```

It is possible to apply certain special effects to the menu items, such as disabling an item or marking an item with a check. See **Special Characters in Menu Item Strings** on page IV-133 for details.

The literal text of the string expression is stored with the control rather than the results of the evaluation of the expression. Igor evaluates the expression when the PopupMenu value=<value> command runs and reevaluates it every time the user clicks on the pop-up menu box. This reevaluation ensures that dynamic menus, such as created by the WaveList example above, reflect the conditions at click time rather than the conditions that were in effect when the PopupMenu control was created.

When the user clicks and Igor reevaluates the string expression, the procedure that created the pop-up menu is no longer running. Consequently, its local variables no longer exist, so the string expression can not reference them. To incorporate the value of local variables in the value expression use the **Execute** operation:

```
String str = <code that generates item list>    // str is a local variable
Execute "PopupMenu name value=" + str
```

Igor evaluates the string expression as if it were typed on the command line. You can not know what the current data folder will be when the user clicks the pop-up menu. Consequently, if you want to refer to objects in specific data folders, you must use full paths. For example:

```
PopupMenu name value=#"func(root:DF234:wave0, root:gVar)"
```

Because of click-time reevaluation, the pop-up menu does not automatically update if the value of the string expression changes. Normally this is not a problem, but you can use the **ControlUpdate** operation (page V-94) to force the pop-up menu to update. Here is an example:

```
NewPanel/N=PanelX
String/G gPopupList="First;Second;Third"
PopupMenu oneOfThree value=gPopupList  // pop-up shows “First”
gPopupList="1;2;3"                     // pop-up is unchanged
ControlUpdate/W=PanelX oneOfThree      // pop-up shows “1”
```

If the string expression can not be evaluated at the time the command is compiled, you can defer the evaluation of the expression by enclosing the value this way:

In some cases, the string expression can not be compiled at the time the PopupMenu command is compiled because it references a global object that does not yet exist. In this case, you can prevent a compile-time error by using this special syntax:

```
PopupMenu name value= #"pathToNonExistentGlobalString"
```

If a deferred expression has quotes in it, they need to be escaped with backslashes:

```
PopupMenu name value= #"\"_none_;\"+UserFunc(\"foo\")"
```

The optional user defined action procedure is called after the user makes a selection from the popup menu. Popup menu procedures have the following form:

```
Function PopMenuProc(pa) : PopupMenuControl
   STRUCT WMPopupAction pa

   switch(pa.eventCode)
      case 2:        // Mouse up
         Variable popNum = pa.popNum      // 1-based item number
         String popStr = pa.popStr        // Text of selected item
         break
      case -1:       // Control being killed
         break
   endswitch
End
```

`pa.popNum` is the item number, *starting from one*, and pa.`popStr` is the text of the selected item.

For the color pop-up menus the easiest way to determine the selected color is to use the **ControlInfo**.

Creating SetVariable Controls

The **SetVariable** operation (page V-854) creates or modifies a SetVariable control. SetVariable controls are useful for both viewing and setting values.

SetVariable controls are tied to numeric or string global variables, to a single element of a wave, or to an internal value stored in the control itself. To minimize clutter, you should use internal values in most cases.

When used with numeric variables, Igor draws up and down arrows that the user can use to increment or decrement the value.

You can set the width of the control but the height is determined from the font and font size. The width of the readout area is the width of the control less the width of the title and up/down arrows. However, you can use the bodyWidth keyword to specify a fixed width for the body (nontitle) portion of the control.

For example, executing the commands:

```
Variable/G globalVar=99
SetVariable setvar0 size={120,20},frame=1,font="Helvetica", value=globalVar
```

creates the following SetVariable control:

To associate a SetVariable control with a variable that is not in the current data folder at the time SetVariable runs, you must use a data folder path:

```
Variable/G root:Packages:ImagePack:globalVar=99
SetVariable setvar0 value=root:Packages:ImagePack:globalVar
```

Unlike PopupMenu controls, SetVariable controls remember the current data folder when the SetVariable command executes. Thus an equivalent set of commands is:

```
SetDataFolder root:Packages:ImagePack
Variable/G globalVar=99
SetVariable setvar0 value=globalVar
```

Also see **SetVariable Controls and Data Folders** on page III-417.

You can control the style of the numeric readout via the format keyword. For example, the string "%.2d" will display the value with 2 digits past the decimal point. You should not use the format string to include text in the readout because Igor has to read back the numeric value. You may be able to add suffixes to the readout but prefixes will not work. When used with string variables the format string is not used.

Often it is sufficient to query the value using **ControlInfo** and you there is no need for an action procedure. If you want to do something every time the value is changed, then you need to create an action procedure of the following form:

```
Function SetVarProc(sva) : SetVariableControl
   STRUCT WMSetVariableAction sva

   switch(sva.eventCode)
      case 1:                      // Mouse up
      case 2:                      // Enter key
      case 3:                      // Live update
         Variable dval = sva.dval
         String sval = sva.sval
         break
      break
      case -1:                     // Control being killed
         break
   endswitch

End
```

varName will be the name of the variable being used. If the variable is a string variable then varStr will contain its contents and varNum will be set to the results of an attempt to convert the string to a number. If the variable is numeric then varNum will contain its contents and varStr will be set to the results of a number to string conversion.

If the value is a string, then sva.sval contains the value. If it is numeric, then sva.dval contains the value. sva.isStr is 0 for numeric values and non-zero for string values.

When the user presses and holds in the up or down arrows then the value of the variable will be steadily changed by the increment value but your action procedure will not be called until the user releases the mouse button.

Creating Slider Controls

The **Slider** creates or modifies a slider control.

A slider control is tied to a numeric global variables or to a numeric internal value stored in the control itself. To minimize clutter, you should use internal values in most cases. The value is changed by dragging the “thumb” part of the control.

There are many options for labelling the numeric range such as setting the number of ticks.

You can also provide custom labels in two waves, one numeric and another providing the corresponding text label. For example:

```
NewPanel
Make/O tickNumbers= {0,25,60,100}
Make/O/T tickLabels= {"Off","Slow","Medium","Fast"}
Slider speed,pos={86,28},size={74,73}
Slider speed,limits={0,100,0},value= 40
Slider speed,userTicks={tickNumbers,tickLabels}
```

Often it is sufficient to query the value using **ControlInfo** and you there is no need for an action procedure. If you want to do something every time the value is changed, or to implement a repeating slider, then you need to create an action procedure.

Igor calls the action procedure when the user drags the thumb, when the user clicks the thumb, when the user clicks on either side of the thumb, and when a procedure modifies the slider’s global variable, if any. For a repeating slider, it calls the action procedure periodically while the user clicks the thumb.

See the **Slider** operation on page V-874 and **Repeating Sliders** on page III-418 for further information.

Handling Slider Events

A slider can call your action procedure only when the mouse is released (live mode off) or it can call it each time the slider position changes while the mouse is pressed (live mode on). This section demonstrates how to create both kinds of sliders.

Enter this code in the procedure window of a new experiment. Then execute

```
SliderDemoPanel()
```

in the command line and play with both sliders.

```
Window SliderDemoPanel() : Panel
   PauseUpdate; Silent 1         // building window...
   NewPanel /W=(262,115,665,287)

   TitleBox Title0,pos={46,21},size={139,15},fSize=12,frame=0,fStyle=1
   TitleBox Title0,title="Live Mode Off"
   Slider slider0,pos={197,23},size={150,44},proc=Slider0Proc
   Slider slider0,limits={0,2,0},value=0,live=0,vert=0

   TitleBox Title1,pos={52,114},size={135,15},fSize=12,frame=0,fStyle=1
   TitleBox Title1,title="Live Mode On"
   Slider slider1,pos={197,113},size={150,44},proc=Slider1Proc
   Slider slider1,limits={0,2,0},value=0,live=0,vert=0
EndMacro

Function Slider0Proc(sa) : SliderControl  // Action procedure for slider0
   STRUCT WMSliderAction &sa

   switch(sa.eventCode)
      case -3:       // Control received keyboard focus
      case -2:       // Control lost keyboard focus
      case -1:       // Control being killed
         break
      default:
         if (sa.eventCode & 1) // Value set
            Printf "Value = %g, event code = %d\r", sa.curval, sa.eventCode
         endif
         break
   endswitch

   return 0
```

```
End

Function Slider1Proc(sa) : SliderControl   // Action procedure for slider1
   STRUCT WMSliderAction &sa

   switch(sa.eventCode)
      case -3:       // Control received keyboard focus
      case -2:       // Control lost keyboard focus
      case -1:       // Control being killed
         break
      default:
         if (sa.eventCode & 1)    // Value set
            Printf "Value = %g, event code = %d\r", sa.curval, sa.eventCode
         endif
         if (sa.eventCode & 8)    // Mouse moved or arrow key moved the slider
            Printf "Value = %g, event code = %d\r", sa.curval, sa.eventCode
         endif
         break
   endswitch

   return 0
End
```

Creating TabControl Controls

The **TabControl** creates or modifies a TabControl control. Tabs are used to group controls into visible and hidden groups.

The tabs are numbered. The first tab is tab 0, the second is tab 1, etc.

A default tab control has one tab:

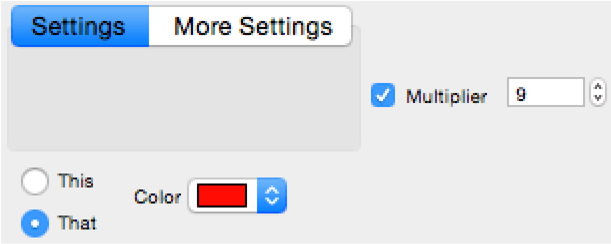
```
NewPanel/W=(150,50,650,400)
TabControl tb, tabLabel(0)="Settings", size={400,250}
```

You add tabs to the control by providing additional tab labels:

```
TabControl tb, tabLabel(1)="More Settings"
```

When you click on a tab, the control’s action procedure receives the number of the clicked-on tab.

The showing and hiding of the controls are accomplished by your action procedure. In this example, the This, That, and Color controls are shown when the Settings tab is clicked, and the Multiplier checkbox is hidden. When the More Settings tab is clicked, the action procedure makes the opposite occur.



The simplest way to create a tabbed user interface is to create an over-sized panel with all the controls visible and outside of the tab control. Place controls in their approximate positions relative to one another. By positioning the controls this way you can more easily modify each control until you are satisfied with them.

Before you put the controls into the tab control, get a list of the non-tab control names:

```
Print ControlNameList("" ,"\r", "!tb")       // all but “tb”
thisCheck
thatCheck
colorPop
multCheck
multVar
```

Determine which controls are to be visible in which tabs:

Tab 0: Settings	Tab 1: More Settings
thisCheck	multCheck
thatCheck	multVar
colorPop	

Write the action procedure for the tab control to show and hide the controls:

```
Function TabProc(tca) : TabControl

   STRUCT WMTabControlAction &tca

   switch (tca.eventCode)
      case 2:                               // Mouse up
         Variable tabNum = tca.tab          // Active tab number
         Variable isTab0 = tabNum==0
         Variable isTab1 = tabNum==1

         ModifyControl thisCheck disable=!isTab0       // Hide if not Tab 0

         ModifyControl thatCheck disable=!isTab0       // Hide if not Tab 0
         ModifyControl colorPop disable=!isTab0        // Hide if not Tab 0

         ModifyControl multCheck disable=!isTab1       // Hide if not Tab 1
         ModifyControl multVar disable=!isTab1         // Hide if not Tab 1
         break
   endswitch

   return 0
End
```

A more elegant method, useful when you have many controls, is to systematically name the controls inside each tab using a prefix or suffix that is unique to that tab, such as tab0_thisCheck, tab0_thatCheck, tab1_multVar. Then use the ModifyControlList operation to show and hide the controls. See the **ModifyControlList** operation for an example.

Assign the action procedure to the tab control:

```
TabControl tb, proc=TabProc
```

Click on the tabs to see whether the showing and hiding is working correctly.

Verify that the action procedure correctly shows and hides controls as you click the tabs. When this works correctly, move the controls into their final positions, inside the tab control.

During this process, the "temporary selection" shortcut comes in handy. While you are in operate mode, pressing Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*) temporarily switchs to select mode, allowing you to select and drag controls.

Save the panel as a recreation macro (Windows→Control→Window Control) to record the final control positions. Rewrite the macro as a function that initially creates the panel:

```
Function CreatePanel()
   KillWindow/Z TabPanel
   NewPanel/N=TabPanel/W=(596,59,874,175) as "Tab Demo Panel"
   TabControl tb,pos={15,19},size={250,80},proc=TabProc
   TabControl tb,tabLabel(0)="Settings"
   TabControl tb,tabLabel(1)="More Settings",value= 0
   CheckBox thisCheck,pos={53,52},size={39,14},title="This"
   CheckBox thisCheck,value= 1,mode=1
   CheckBox thatCheck,pos={53,72},size={39,14},title="That"
   CheckBox thatCheck,value= 0,mode=1
   PopupMenu colorPop,pos={126,60},size={82,20},title="Color"
   PopupMenu colorPop,mode=1,popColor= (65535,0,0)
   PopupMenu colorPop,value= #"\"*COLORPOP*\""
   CheckBox multCheck,pos={50,60},size={16,14},disable=1
   CheckBox multCheck,title="",value= 1
   SetVariable multVar,pos={69,60},size={120,15},disable=1
   SetVariable multVar,title="Multiplier",value=multiplier
End
```

See the **TabControl** operation on page V-1011 for a complete description and examples.

Creating TitleBox Controls

The TitleBox operation creates or modifies a TitleBox control. The control's text can be static or can be tied to a global string variable. See the **TitleBox** operation on page V-1038 for a complete description and examples.

Creating ValDisplay Controls

The **ValDisplay** operation (page V-1060) creates or modifies a value display control.

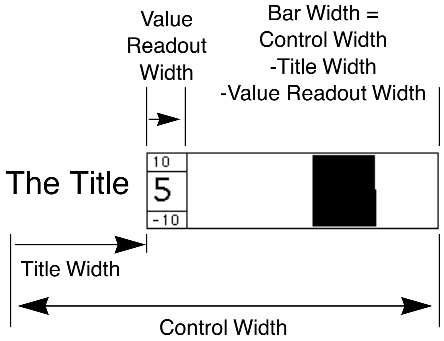
ValDisplay controls are very flexible and multifaceted. They can range from simple numeric readouts to thermometer bars or a hybrid of both. A ValDisplay control is tied to a numeric expression that you provide as an argument to the value keyword. Igor automatically updates the control whenever anything that the numeric expression depends on changes.

ValDisplay controls evaluate their value expression in the context of the root data folder. To reference a data object that is not in the root, you must use a data folder path, such as "root:Folder1:var1".

Here are a few selected keywords extracted from the **ValDisplay** operation on page V-1060:

```
size={width,height}
barmisc={lts, valwidth}
limits={low,high,base}
```

The size and appearance of the ValDisplay control depends primarily on the *valwidth* and size parameters and the width of the title. However, you can use the bodyWidth keyword to specify a fixed width for the body (non-title) portion of the control. Essentially, space for each element is allocated from left to right, with the title receiving first priority. If the control width hasn't all been used by the title, then the value readout width is the smaller of *valwidth* points or what is left. If the control width hasn't been used up, the bar is displayed in the remaining control width:



Here are the various major possible forms of ValDisplay controls. Some of these examples modify previous examples. For instance, the second bar-only example is a modification of the valdisp1 control created by the first bar-only example.

Numeric Readout Only

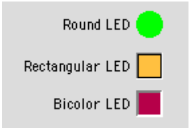
```
// Default readout width (1000) is >= default control width (50)
ValDisplay valdisp0 value=K0
```

LED Display

```
// Create the three LED types
ValDisplay led1,pos={67,17},size={75,20},title="Round LED"
ValDisplay led1,limits={-50,100,0},barmisc={0,0},mode=1
ValDisplay led1,bodyWidth= 20,value= #"K1",zeroColor=(0,65535,0)

ValDisplay led2,pos={38,48},size={104,20},title="Rectangular LED"
ValDisplay led2,frame=5,limits={0,100,0},barmisc={0,0},mode=2
ValDisplay led2,bodyWidth= 20,value= #"K2"
ValDisplay led2,zeroColor= (65535,49157,16385)

ValDisplay led3,pos={60,76},size={82,20},title="Bicolor LED"
ValDisplay led3,limits={-40,100,-100},barmisc={0,0},mode= 2
ValDisplay led3,bodyWidth= 20,value= #"K3"
```



Bar Only

```
// Readout width = 0
ValDisplay valdisp1,frame=1,barmisc={12,0},limits={-10,10,0},value=K0
K0= 5                 // halfway from base of 0 to high limit of 10.
```

The nice thing about a bar-only ValDisplay is that you can make it 5 to 200 points tall whereas with a numeric readout, the height is set by the font sizes of the readout and printed limits.

```
// Set control height= 80
ValDisplay valdisp1, size={50,80}
```

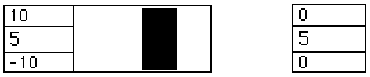
Numeric Readout and Bar

```
// 0 < readout width (50) <  control width (150)
ValDisplay valdisp2 size={150,20},frame=1,limits={-10,10,0}
ValDisplay valdisp2 barmisc={0,50},value=K0  // no limits shown
```

Optional Limits

Whenever the numeric readout is visible, the optional limit values may be displayed too.

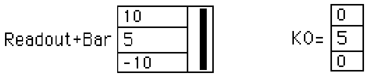
```
// Set limits font size to 10 points. Readout widths unchanged.
ValDisplay valdisp2 barmisc={10,50}
ValDisplay valdisp0 barmisc={10,1000}
```



Optional Title

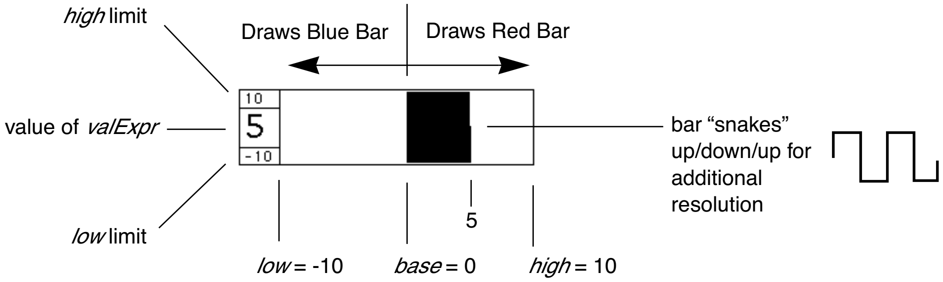
The control title steals horizontal space from the numeric readout and the bar, pushing them to the right. You may need to increase the control width to prevent them from disappearing.

```
// Add titles. Readout widths, control widths unchanged.
ValDisplay valdisp2 title="Readout+Bar"
ValDisplay valdisp0 title="K0="
```



The limits values *low*, *high*, and *base* and the value of *valExpr* control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the *base* value to an ending position determined by the value of *valExpr*, *low* and *high*. *low* corresponds to the left side of the bar, and *high* corresponds to the right. The position that corresponds to the *base* value is linearly interpolated between *low* and *high*.

For example, with *low* = -10, *high*=10, and *base*= 0, a *valExpr* value of 5 will draw from the center of the bar area (0 is centered between -10 and 10) to the right, halfway from the center to the right of the bar area (5 is halfway from 0 to 10):



You can force the control to not draw bars with fractional parts by specifying mode=3.

Killing Controls

You can kill (delete) a control from within a procedure using the **KillControl** operation (page V-468). This might be useful in creating control panels that change their appearance depending on other settings.

You can interactively kill a control by selecting it with the arrow tool or the Select Control submenu and press Delete.

Getting Information About Controls

You can use the **ControlInfo** operation (page V-89) to obtain information about a given control. This is useful to obtain the current state of a checkbox or the current setting of a pop-up menu.

ControlInfo is usually used for control panels that have a Do It button or equivalent. When the user clicks the button, its action procedure calls ControlInfo to query the state of each relevant control and acts accordingly.

ControlInfo is generally not used for the other style of control panel in which the action procedure for each control acts as soon as that control is clicked.

Updating Controls

You can use the **ControlUpdate** operation (page V-94) to cause a given control to redraw with its current value. You would use this in a procedure after changing the value or appearance of a control to display the changes before the normal update occurs.

Help Text for User-Defined Controls

Each control type has a help text property, set using the help keyword, through which you add a help tip. In Igor Pro 9.00 and later, tips are limited to 1970 bytes. Previously they were limited to 255 bytes.

Here is an example:

```
Button button0 title="Beep", help={"This button beeps."}
```

The tip appears when the user moves the mouse over the control, if tooltips are enabled in the Help section of the Miscellaneous Settings dialog.

You can use a limited set of HTML tags for formatting. See **HTML Tags in Tooltips** on page IV-311.

Modifying Controls

The control operations create a new control if the name parameter doesn't match a control already in the window. The operations modify an existing control if the name does match a control in the window, but generate an error if the control kind doesn't match the operation.

For example, if a panel already has a button control named `button0`, you can modify it with another `Button button0` command:

```
Button button0 disable=1            // hide
```

However, if you use a Checkbox instead of Button, you get a "button0 is not a Checkbox" error.

You can use the **ModifyControl** operation (page V-606) and **ModifyControlList** operation (page V-608) to modify a control without needing to know what kind of control it is:

```
ModifyControl button0 disable=1     // hide
```

This is especially handy when used in conjunction with tab controls.

Disabling and Hiding Controls

All controls support the keyword "disable=*d*" where *d* can be:

0:	Normal operation
1:	Hidden
2:	User input disabled
3:	Hidden and user input disabled

Charts and ValDisplays do not change appearance when disable=2 because they are read-only.

SetVariables also have the noedit keyword. This is different from disable=2 mode in that noedit allows user input via the up or down arrows but disable=2 does not.

Control Background Color

The background color of control panel windows and the area at the top of a graph as reserved by the **ControlBar** operation (page V-88) is a shade of gray chosen to match the operating system look. This gray is used when the control bar background color, as set by ModifyGraph cbRGB or ModifyPanel cbRGB, is the default pure white, where the red, green and blue components are all 65535. Any other cbRGB setting, including not quite pure white, is honored. However, some controls or portions of controls are drawn by the operating system and may look out of place if you choose a different background color.

For special purposes, you can specify a background color for an individual control using the labelBack keyword. See the reference help of the individual control types for details.

Control Structures

Control action procedures can take one of two forms: structure-based or an old form that is not recommended. This section assumes that you are using the structure-based form.

The action procedure for a control uses a predefined, built-in structure as a parameter to the function. The procedure has this format:

```
Function ActionProcName(s)
   STRUCT <WMControlTypeActio>& s    // <WMControlTypeActio> is one of the
   …                                 // structures listed below
End
```

The names of the various control structures are:

Control Type	Structure Name
Button	**WMButtonAction**
CheckBox	**WMCheckboxAction**
CustomControl	**WMCustomControlAction**
ListBox	**WMListboxAction**
PopupMenu	**WMPopupAction**
SetVariable	**WMSetVariableAction**
Slider	**WMSliderAction**
TabControl	**WMTabControlAction**

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields in the future. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

You can use the same action procedure for different controls of the same type, for all the buttons in one window, for example. Use the ctrlName field of the structure to identify the control and the win field to identify the window containing the control.

Control Structure Example

This example illustrates the extended event codes available for a button control. The function prints various text messages to the history area of the command window, depending what actions you take while in the button area.

```
Function ControlStructureTest()
   NewPanel
   Button b0,proc= NewButtonProc
End

Structure MyButtonInfo
   Int32 mousedown
   Int32 isLeft
EndStructure

Function NewButtonProc(s)
   STRUCT WMButtonAction &s

   STRUCT MyButtonInfo bi
   Variable biChanged= 0

   StructGet/S bi,s.userdata
   if( s.eventCode==1 )
      bi.mousedown= 1
      bi.isLeft= s.mouseLoc.h < (s.ctrlRect.left+s.ctrlRect.right)/2
      biChanged= 1
   elseif( s.eventCode==2 || s.eventCode==3 )
      bi.mousedown= 0
      biChanged= 1
   elseif( s.eventCode==5 )
      print "Enter button"
   elseif( s.eventCode==6 )
      print "Leave button"
   endif

   if( s.eventCode==4 )             //  mousemoved
      if( bi.mousedown )
         if( bi.isLeft )
            printf "L"
         else
            printf "R"
         endif
      else
         printf "*"
      endif
   endif
   if( biChanged )
      StructPut/S bi,s.userdata     // written out to control
   endif

   return 0
End
```

Control Structure eventMod Field

The eventMod field appears in the built-in structure for each type of control. It is a bitfield defined as follows:

EventMod Bit	Meaning
Bit 0	A mouse button is down.
Bit 1	Shift key is down.
Bit 2	Option (Macintosh) or Alt (Windows) is down.
Bit 3	Command (Macintosh) or Ctrl (Windows) is down.
Bit 4	Contextual menu click occurred.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

Control Structure blockReentry Field

Long ago, on Macintosh version 6 and before, if a control action procedure took a long time to run, it was possible to repeat the action and start the action procedure again before the previous invocation was finished (that's called reentrancy). That is, if a button starts a long computation, like a lengthy curve fit, it was possible to start a new fit before the first was done, if you clicked the button again too soon. To control that, the blockReentry member was added.

In Igor 7 and later, code was added that prevents reentry, so the blockReentry field is obsolete. It is retained for backward compatibility and has no effect.

If you find a case in which reentry is a problem, please contact support@wavemetrics.com with a report. We will need an example that we can use to reproduce the problem.

Control Structure blockReentry Advanced Example

This example further illustrates the use of the blockReentry field. It is of interest only to those who want to experiment with this issue.

The ReentryDemoPanel procedure below creates a panel with two buttons. Each button prints a message in the history area when the action procedure receives the "mouse up" message, then pauses for two seconds, and then prints another message in the history before returning. The pause is a stand-in for a procedure that takes a long time.

The top button does not block reentry so, if you click it twice in quick succession, the action procedure is reentered and you get nested messages in the history area.

The bottom button does block reentry so, if you click it twice in quick succession, the action procedure is not reentered.

Because of architectural differences, reentry of the action procedure occurs on Macintosh only in Igor6 and does not occur at all in Igor7 or later. Because reentry may be affected by internal changes in Igor or by operating system changes, it may reappear as an issue in the future.

```
Function ButtonProc(ba) : ButtonControl
   STRUCT WMButtonAction &ba

   switch( ba.eventCode )
      case 2: // mouse up
         // Block bottom button only
         ba.blockReentry= CmpStr(ba.ctrlName,"Block") == 0
         print "Start button ",ba.ctrlName
         Variable t0= ticks
         do
            DoUpdate
         while(ticks < (t0+120) )
         Print "Finish button",ba.ctrlName
         break
   endswitch

   return 0
End

Window ReentryDemoPanel() : Panel
   PauseUpdate; Silent 1// building window...
   NewPanel /K=1 /W=(322,55,622,255)
   Button NoBlock,pos={25,10},size={150,20},proc=ButtonProc,title="No Block Reentry"
   Button Block,pos={25,50},size={150,20},proc=ButtonProc,title="Block
Reentry"
End
```

User Data for Controls

You can store arbitrary data with a control using the userdata keyword. You can set user data for the following controls: Button, CheckBox, CustomControl, ListBox, PopupMenu, SetVariable, Slider, and TabControl.

Each control has a primary, unnamed user data string that is used by default. You can also store an unlimited number of additional user data strings by specifying a name for each one. The name can be any legal standard Igor name.

You can retrieve information from the default user data using the **ControlInfo** operation (page V-89), which returns such information in the S_UserData string variable. To retrieve any named user data, you must use the **GetUserData** operation (page V-316).

Although there is no size limit to how much user data you can store, it does have to be generated as part of the recreation macro for the window when experiments are saved. Consequently, huge user data strings can slow down experiment saving and loading

User data is intended to replace or reduce the usage of global variables for maintaining state information related to controls.

Control User Data Examples

:Here is a simple example of a button with user data:

```
NewPanel
Button b0, userdata="user data for button b0"
Print GetUserData("","b0","")
```

Here is a more complex example.

Copy the following code into the procedure window of a new experiment and run the `Panel0` macro. Then click the buttons.

```
Structure mystruct
    Int32 nclicks
    double lastTime
EndStructure

Function ButtonProc(ctrlName) : ButtonControl
    String ctrlName

    STRUCT mystruct s1
    String s= GetUserData("", ctrlName,"")
    if( strlen(s) == 0 )
        print "first click"
    else
        StructGet/S s1,s
        // Warning: Next command is wrapped to fit on the page.
        printf "button %s clicked %d time(s), last click = %s\r",ctrlName, s1.nclicks,
Secs2Date(s1.lastTime, 1 )+" "+Secs2Time(s1.lastTime,1)
    endif
    s1.nclicks += 1
    s1.lastTime= datetime
    StructPut/S s1,s
    Button $ctrlName,userdata= s
End

Window Panel0() : Panel
    PauseUpdate; Silent 1           // building window...
    NewPanel /W=(150,50,493,133)
    SetDrawLayer UserBack
    Button b0,pos={12,8},size={50,20},proc=ButtonProc,title="Click"
    Button b1,pos={65,8},size={50,20},proc=ButtonProc,title="Click"
    Button b2,pos={119,8},size={50,20},proc=ButtonProc,title="Click"
    Button b3,pos={172,8},size={50,20},proc=ButtonProc,title="Click"
    Button b4,pos={226,8},size={50,20},proc=ButtonProc,title="Click"
EndMacro
```

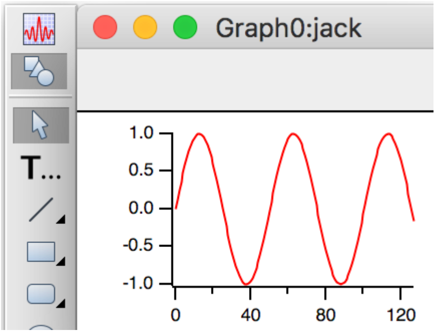
Action Procedures for Multiple Controls

You can use the same action procedure for different controls of the same type, for all the buttons in one window, for example. The name of the control is passed to the action procedure so that it can know which control was clicked. This is usually the name of the control *in the target/active window*, which is what most control operations assume.

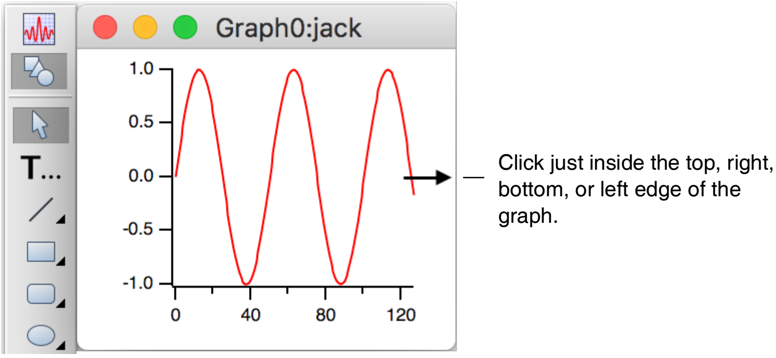
Controls in Graphs

The combination of controls and graphs provides a nice user interface for tinkering with data. You can create such a user interface by embedding controls in a graph or by embedding a graph in a control panel. This section explains the former technique, but the latter technique is usually recommended. See Chapter III-4, **Embedding and Subwindows** for details.

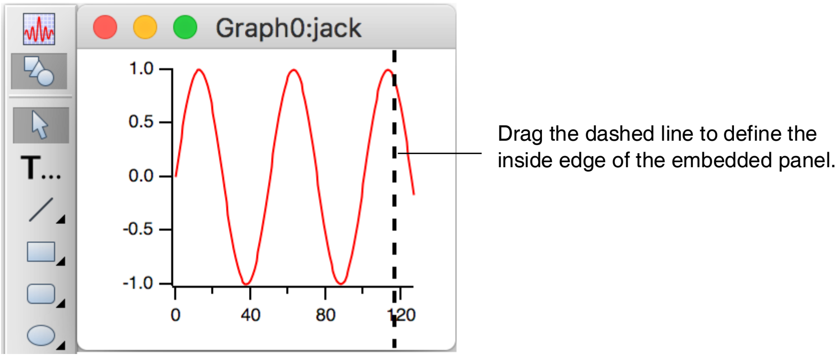
Although controls can be placed anywhere in a graph, you can and should reserve an area just for controls at the edge of a graph window. Controls in graphs operate much more smoothly if they reside in these reserved areas. The **ControlBar** operation (page V-88) or the Control Bar dialog can be used to set the height of a nonembedded control area at the top of the graph.



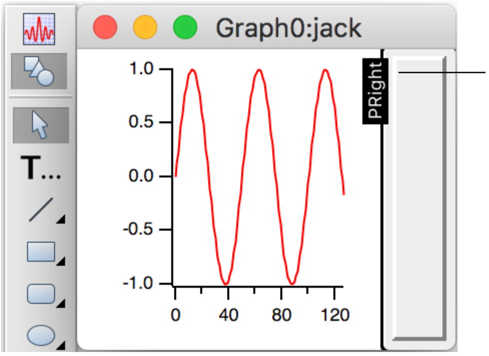
The simplest way to add a panel is to click near the edge of the graph and drag out a control area:



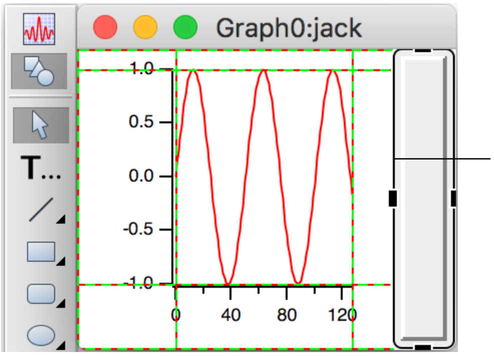
Graph0:jack
T...
1.0
0.5
0.0
-0.5
-1.0
0
40
80
120
Click just inside the top, right, bottom, or left edge of the graph.



Graph0:jack
T...
1.0
0.5
0.0
-0.5
-1.0
0
40
80
120
Drag the dashed line to define the inside edge of the embedded panel.



`PRight` is the name of the resulting embedded panel subwindow. The label disappears in “operate” mode.



Adjust the position of the embedded window by clicking the subwindow frame and dragging its handles. The dashed lines represent the edges of the plot and graph areas, and the subwindow frame snaps and attaches to them.

The background color of a control area or embedded panel can be set by clicking the background to exit any subwindow layout mode, then Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the background, and then selecting a color from the contextual menu’s pop-up color palette. See **Control Background Color** on page III-437 for details.

The contextual menu adjusts the style of the frame around the panel.

You can use the same contextual menu to remove an embedded panel, leaving only the bare control area underneath. Remove the control area by dragging the inside edge back to the outside edge of the graph.

Drawing Limitations

The drawing tools can not be used in bare control areas of a graph. If you want to create a fancy set of controls with drawing tools, you have to embed a panel subwindow into the graph.

Updating Problems

You may occasionally run into certain updating problems when you use controls in graphs. One class of update problems occurs when the action procedure for one control changes a variable used by a ValDisplay control in the same graph and also forces the graph to update while the action procedure is being executed. This short-circuits the normal chain of events and results in the ValDisplay not being updated.

You can force the ValDisplay to update using the **ControlUpdate** operation (page V-94). Another solution is to use a control panel instead of a graph.

The ControlUpdate operation can also solve problems in updating pop-up menus. This is described above under **Creating PopupMenu Controls** on page III-426.

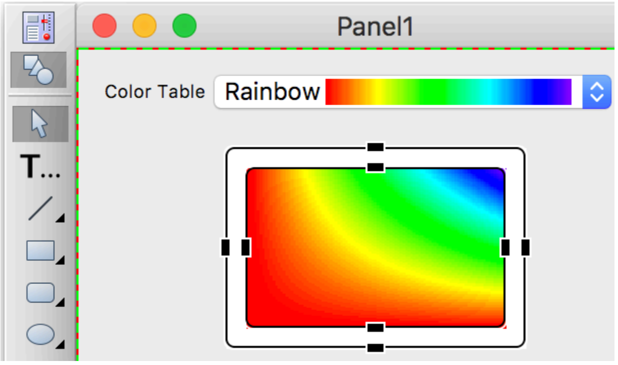
Control Panels

Control panels are windows designed to contain controls. The **NewPanel** creates a control panel.

Drawing tools can be used in panel windows to decorate control panels. Control panels have two drawing layers, UserBack and ProgBack, behind the controls and one layer, Overlay, in front of the controls. See **Drawing Layers** on page III-68 for details.

A panel window's background color can be set by Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the background and then selecting a color from the pop-up color palette. See **Control Background Color** on page III-437 for details.

Embedding into Control Panels



You can embed a graph, table, notebook, or another panel into a control panel window. See Chapter III-4, **Embedding and Subwindows** for details. This technique is cleaner than adding control areas to a graph. It also allows you to embed multiple graphs in one window with controls.

Use the contextual menu while in drawing mode to add an embedded window. Click on the frame of the embedded window to adjust the size and position.

You can use a notebook subwindow in a control panel to display status information or to accept lengthy user input. See **Notebooks as Subwindows in Control Panels** on page III-91 for details.

Exterior Control Panels

Exterior subwindows are panels that act like subwindows but live in their own windows attached to a host window. The host window can be a graph, table, panel or Gizmo plot. The host window and its exterior subwindows move together and, in general, act as a single window. Exterior subwindows have the advantage of not disturbing the host window and, unlike normal subwindows, are not limited in size by the host window.

To create an exterior subwindow panel, use **NewPanel** with the /EXT flag in combination with /HOST.

Floating Control Panels

Floating control panels float above all other windows, except dialogs. To create a floating panel, use **NewPanel** with the /FLT flag.

Control Panel Expansion

In Igor Pro 9.00 and later, you can set an expansion factor for a control panel using the Expansion submenu in the Panel menu or the panel's contextual menu which you summon by right-clicking. You can set it for all control panels using the Panel section of the Miscellaneous Settings dialog. As explained below, setting it for all panels is recommended in most cases.

The factory default control panel expansion factor is 1.0 which means that control panels and their controls are displayed at "normal" size. The normal size depends on the pixel size of your screen and on various complex software factors. It may be too small or too large for your taste. If so, you can use the control panel expansion factor to adjust.

When you change the expansion factor, the size of the panel window and any controls and subwindows in the panel changes accordingly. Additionally, elements drawn in the panel using drawing tools are also expanded.

If normal size is not ideal for you, you will usually want to change the expansion for all control panels, not for just one specific control panel. You can do this by changing the default control panel expansion factor using the Panel section of the Miscellaneous Settings dialog. For most uses, changing the default is recommended over changing the expansion for a specific control panel.

When creating a control panel programmatically, you can set the expansion factor using the NewPanel /EXP=<factor> flag which was added in Igor Pro 9.00. However, for most uses, you should omit /EXP and allow the user's default control panel expansion factor to take effect.

When a control panel is recreated, such as when you open an experiment with a control panel, if the /EXP=<factor> flag is present in the recreation macro, Igor applies the specified expansion factor to the panel. If the /EXP flag is omitted, Igor applies the user's default control panel expansion factor.

When Igor generates a control panel recreation macro, if the control panel uses other than the default expansion as set in the Panel section of the Miscellaneous Settings dialog, Igor uses the NewPanel /EXP flag to specify the desired expansion. If the experiment is opened on a different machine, the specific expansion factor is applied. This overrides the user's default control panel expansion factor. You can avoid overriding the user's preference by using the default control panel expansion rather than setting it for a specific panel.

It is rarely necessary, but you can programmatically set the expansion factor of a control panel window or subwindow using a ModifyPanel command with the expand keyword which was added in Igor Pro 9.00. For main control panel windows, this works the same as setting the expansion using the Expansion submenu. For control panel subwindows, it affects the size of the controls but not the size of the subwindow itself. For the reasons explained above, it is usually best to refrain from programmatically setting the expansion so that the user's default takes effect.

You can add controls to a graph by creating a control bar using the **ControlBar** operation. The default control panel expansion factor affects the size of the control bar in a graph and the sizes of the controls in the control bar.

Control Panel Units

The size and position of a control panel window on screen is set by the NewPanel /W=(*left*,*top*,*right*,*bottom*) flag. The size and position of controls within a control panel are set by the pos={*left*,*top*} and size={*width*,*height*} keywords of control operations like Button and TitleBox.

For historical reasons, the interpretation of these parameters depends on the operating system; see **Control Panel Resolution on Windows** on page III-456 for details.

On Macintosh the parameters are always interpreted as points (1/72 of an inch).

On Windows, they are interpreted as points except if the screen resolution is 96 DPI in which case, for compatibility with existing experiments and procedures, they are interpreted as pixels.

To allow users to control the size of control panels and their contents, Igor Pro 9.00 introduced **Control Panel Expansion** (see page III-443). The rest of this section discusses how control panel expansion affects the interpretation of the NewPanel /W and control operation keyword parameters.

A parameter that is expressed in normal control panel units (points or pixels as described above) to which Igor applies the control panel expansion factor is said to be expressed in *control panel units*.

Interpretation of NewPanel Coordinates

First we consider the NewPanel /W=(*left*,*top*,*right*,*bottom*) flag.

When control panel expansion is other than the factory default 1.0, Igor scales the width (computed as *right-left*) and height (computed as *bottom-top*) of the panel by the expansion factor but does not change the interpretation of left and top.

Consider these examples assuming that the default control panel expansion is 1.0:

```
NewPanel/N=Panel1/W=(100,100,300,200)
NewPanel/N=Panel2/EXP=2/W=(100,100,300,200)
```

The first NewPanel command creates a panel at the specified coordinates which are interpreted as points or pixels as described in the preceding section.

In the second command, the expansion is 2.0 because of the /EXP flag. This does not affect the position of the window as specified by the left and top parameters. It does affect the width and height of the panel as computed by Igor from width=*right-left* and height=*bottom-top*. After computing the width and height, Igor applies the expansion factor. The result is that the top/left corner of Panel2 is the same as Panel1 but Panel2 is twice as wide and twice as tall. We wind up with width=200 and height=100 in both cases but, because of panel expansion, Panel2 is twice as large as Panel1.

The *left*, *top*, *right*, and *bottom* parameters are in normal panel units but NewPanel interprets the internally computed width and height as control panel units (i.e., normal units to which control panel expansion is to be applied).

If you use /I (inches) or /M (centimeters) before /W then the interpretation of the parameters is different. They are converted from inches or centimeters to points and the result is treated as points, as with the Display operation.

Interpretation of Control Operation Coordinates

Now we consider the pos={*left*,*top*} and size={*width*,*height*} keywords of control operations like Button and TitleBox.

All of these parameters are treated as control panel units. This means that they are first treatedas points or pixels as described above and then the expansion factor of the targeted panel, if other than 1.0, is applied.

Consider these examples which use Panel1 and Panel2 from the preceding section:

```
AutopositionWindow /R=Panel1 Panel2       // Make panels side-by-side
Button button0 win=Panel1, pos={100,50}, size={100,20}, title="Button"
Button button0 win=Panel2, pos={100,50}, size={100,20}, title="Button"
```

We created buttons that are one-half the width of the panel and with the top/left corner of the button one-half of the way from the top to the bottom and one-half of the way from the left to the right. We did this using the same parameters in both cases. This gives different results because the Button operation interprets the parameters as being expressed in control panel units.

Interpretation of Drawing Coordinates

When you use drawing tools and drawing operations in control panels, coordinates are interpreted as control panel units the same as for control operations such as Button.

See also **Control Panel Resolution on Windows** on page III-456, **ScreenResolution** on page V-832, **PanelResolution** on page V-732

Control Panel Preferences

Control panel preferences allow you to control what happens when you create a new control panel. To set preferences, create a panel and set it up to your taste. We call this your prototype panel. Then choose Capture Panel Prefs from the Panel menu.

Preferences are normally in effect only for manual operations, not for automatic operations from Igor procedures. This is discussed in more detail in Chapter III-18, **Preferences**.

When you initially install Igor, all preferences are set to the factory defaults. The dialog indicates which preferences you have changed.

The preferences affect the creation of new panels only.

Selecting the Show Tools category checkbox captures whether or not the drawing tools palette is initially shown or hidden when a new panel is created.

See also **Control Panel Expansion** on page III-443.

Controls Shortcuts

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To show or hide a panel's or graph's tool palette	Press Command-T.	Press Ctrl+T.
To move or resize a user-defined control without using the tool palette	Press Command-Option and click the control. With Command-Option still pressed, drag or resize it.	Press Ctrl+Alt and click the control. With Ctrl+Alt still pressed, drag or resize it.
To add a user-defined control without using the tool palette	Press Command-Option and choose from the Panel or Graph menu's Add Control submenu.	Press Ctrl+Alt and choose from the Panel or Graph menu's Add Control submenu.
To modify a user-defined control	Press Command-Option and double-click the control. This displays a dialog for modifying all aspects of the control. If the control is already selected, you don't need to press Command-Option.	Press Ctrl+Alt and double-click the control. This displays a dialog for modifying all aspects of the control. If the control is already selected, you don't need to press Ctrl+Alt.
To edit a user-defined control's action procedure	With the panel in modify mode (tools showing, second icon from the top selected) press the Control key and click the control. This displays a contextual menu with a "Go to <action procedure>" item.	With the panel in modify mode (tools showing, second icon from the top selected) right-click the control. This displays a contextual menu with a "Go to <action procedure>" item.
To create an embedded graph or table in the panel	With the panel in modify mode, press the Control key and click the panel background. Choose the subwindow type from the resulting contextual menu's "New" submenu.	With the panel in modify mode, right-click the panel background. Choose the subwindow type from the resulting contextual menu's "New" submenu.
To change an embedded window's border style	With the panel in modify mode, press the Control key and click the embedded window. Choose the border style from the resulting contextual menu's "Frame" and "Style" submenus.	With the panel in modify mode, right-click the embedded window. Choose the border style from the resulting contextual menu's "Frame" and "Style" submenus.
To remove an embedded window	With the panel in modify mode, press the Control key and click the embedded window. Choose the Delete from the resulting contextual menu.	With the panel in modify mode, right-click the embedded window. Choose the Delete from the resulting contextual menu.
To eliminate a control area at the edge of a graph	In modify mode or while pressing Command-Option, click the inside edge of the control area and drag it to the outside edge of the graph.	In modify mode or while pressing Ctrl+Alt, click the inside edge of the control area and drag it to the outside edge of the graph.
To nudge a user-defined control's position	Select the control and press arrow keys. Press Shift to nudge faster.	Select the control and press arrow keys. Press Shift to nudge faster.

Chapter

III-15

Platform-Related Issues

Platform-Related Issues

Igor Pro runs on Macintosh and Windows. This chapter contains information that is platform-specific and also information for people who use Igor on both platforms.

Windows-Specific Issues

On Windows, the name of the Igor program file must be “Igor64.exe” for the 64-bit version of Igor or “Igor.exe” for the 32-bit version, exactly. If you change the name, Igor extensions will not work because they will be unable to find Igor.

Cross-Platform File Compatibility

Version 3.1 was the first version of Igor Pro that ran on Windows as well as Macintosh.

Crossing Platforms

When crossing from one platform to another, page setups are only partially translated. Igor tries to preserve the page orientation and margins.

When crossing platforms, Igor attempts to do font substitution where necessary. If Igor can not determine an appropriate font it displays the font substitution dialog where you can choose the font.

Platform-specific picture formats are displayed as gray boxes when you attempt to display them on the non-native platform. Windows Metafile, Enhanced Metafile, and Windows bitmap (BMP) pictures are supported on Windows only and appear as gray boxes on Macintosh.

The EPS, PNG, JPEG, TIFF, and SVG formats are platform-independent and are displayed on both platforms.

Prior to Igor Pro 9.00, PDF pictures were supported on Macintosh only and appeared as gray boxes on Windows. Now Igor can display PDF pictures on both platforms.

Transferring Files Using File Transfer Programs

Some transfer programs offer the option of translating file formats as they transfer the program from one computer to another. This translation usually consists of replacing each carriage return character with a carriage return/linefeed pair (Macintosh to Windows) or vice-versa (Windows to Macintosh). This is called a “text mode” transfer, as opposed to a “binary mode” transfer. This translation is appropriate for plain text files only. In Igor, plain text notebooks, procedure files, and Igor Text data files are plain text. All other files are not plain text and will be corrupted if you transfer in text mode. If you get flaky results after transferring a file, transfer it again making sure text mode is off.

If you have a problem opening a binary file after doing a transfer, compare the number of bytes in the file on both computers. If they are not the same, the transfer has corrupted the file.

File Name Extensions, File Types, and Creator Codes

This table shows the file name extension and corresponding Macintosh file type for Igor Pro files:

Extension	File Type	What’s in the File
.pxp	IGsU	Packed experiment file
.pxt	IGsS	Packed experiment template (stationery)
.uxp	IGSU	Unpacked experiment file
.uxt	IGSS	Unpacked experiment template (stationery)
.ifn	WMT0	Igor formatted notebook (last character is zero)

Extension	File Type	What's in the File
.txt	TEXT	Igor plain notebook
.ihf	WMT0	Igor help file
.ibw	IGBW	Igor binary data file

The Macintosh creator code for Igor is 'IGR0' (last character is zero).

Experiments and Paths

An Igor experiment sometimes refers to wave, notebook, or procedure files that are stored separate from the experiment file itself. This is discussed under **References to Files and Folders** on page II-24. In this case, Igor creates a symbolic path that points to the folder containing the referenced file. It writes a **NewPath** command in the experiment file to recreate the symbolic path when the experiment is opened. When you move the experiment to another computer or to another platform, this path may not be valid. However, Igor goes to great lengths to find the folder, if possible.

Igor stores the path to the folder containing the file as a relative path, relative to the experiment file, if possible. This means that Igor will be able to find the folder, even on another computer, if the folder's relative location in the disk hierarchy is the same on both computers. You can minimize problems by using the same disk hierarchy on both computers.

If the folder is not on the same volume as the experiment file, then Igor can not use a relative path and must use an absolute path. Absolute paths cause problems because, although your disk hierarchy may be the same on both computers, often the name of the root volume will be different. For example, on the Macintosh your hard disk may be named "hd" while on Windows it may be named "C:".

If Igor can not locate a folder or file needed to recreate an experiment, it displays a dialog asking you to locate it.

Picture Compatibility

Igor displays pictures in graphs, page layouts, control panels and notebooks. The pictures are stored in the Pictures collection (Misc→Pictures) and in notebooks. Graphs, page layouts and control panels reference pictures stored in the Pictures collection while notebooks store private copies of pictures.

This table shows the graphic formats that Igor can use to store pictures:

Format	How To Create	Notes
PDF	Paste or use Misc→Pictures	Cross-platform high resolution vector format. See **Importing PDF Pictures** on page III-510.
EMF (Enhanced Metafile)	Paste or use Misc→Pictures	Windows only See **Graphics Technology on Windows** on page III-506 for information about different types of EMF pictures.
BMP (bitmap)	Use Misc→Pictures	Windows Only. BMP also called DIB (device-independent bitmap).
PNG (Portable Network Graphics)	Use Misc→Pictures	Cross-platform bitmap format
JPEG	Use Misc→Pictures	Cross-platform bitmap format
TIFF (Tagged Image File Format)	Use Misc→Pictures	Cross-platform bitmap format

Format	How To Create	Notes
EPS (Encapsulated PostScript)	Use Misc→Pictures	High resolution vector format. EPS is largely obsolete. Use PDF instead.
SVG (Scalable Vector Graphics)	Use Misc→Pictures	Cross-platform high resolution vector format.

Formats that are not supported on the current platform are drawn as gray boxes.

Although Igor does not display non-native graphic formats, it does preserve them. For example, you can create an experiment on Windows and paste a Windows metafile into a page layout, graph, or notebook window. If you save the experiment and open it on Macintosh, the Windows metafile is displayed as a gray box. If you now save and open the experiment on Windows again, the Windows metafile is displayed correctly.

Converting to PNG

If you want platform-specific pictures to be displayed correctly on both platforms, you must convert the pictures to PNG. To convert to PNG, use the Pictures dialog (Misc menu) for pictures in graphs and page layouts, or for pictures in notebooks, use the Special submenu in the Notebook menu.

Converting a picture to PNG makes it a bitmap format and may degrade resolution. This is fine for graphics intended to be viewed on the screen but not for graphics intended to be printed at high resolution. You can convert to a high resolution PNG without losing much picture quality.

Page Setup Compatibility

Page setup records store information regarding the size and orientation of the page. Prior to Igor Pro 7, page setups contained platform-depedent and printer-depedent data. This is no longer the case, but as a consequence, only minimal information is stored.

In each experiment file, Igor stores a separate page setup for each page layout, notebook, and procedure window, and stores a single page setup for all graphs and a single page setup for all tables.

File System Issues

This section discusses file system issues that you need to take into account if you use Igor on both Macintosh and Windows.

File and Folder Names

On Windows, the following characters are illegal in file and folder names: backslash (\), forward slash (/), colon (:), asterisk (*), question mark (?), double-quote ("), left angle bracket (<), right angle bracket (>), vertical bar (|). On Macintosh, the only illegal character is colon.

This means, for example, that you can not create a file with a name like “Data 1/23/98” on Windows. You can create a file with this name on Macintosh. If you write an Igor procedure that generates a file name like this, it will run on Macintosh but fail on Windows.

Therefore, if you are concerned about cross-platform compatibility, you must not use any of the Windows illegal characters in a file or folder name, even if you are running on Macintosh. Also, don’t use period except before a file name extension.

File and folder names in Windows can theoretically be up to 255 characters in length. Because of some limitations in Windows and also in Igor, you will encounter errors if you use file names that long. However, both Igor and Windows are capable of dealing with file names up to about 250 characters in length. It is unlikely that you will approach this limit.

An exception to this is that Igor limits names of XOP files to 31 characters, plus the ".xop" extension. Igor will not recognize an XOP file with a longer name.

Paths in Windows are limited to 259 characters in length. Neither Windows nor Igor can deal with a path that exceeds this limit. For example, if you create a directory with a 250 character name and try to create a file with a 15 character name, neither Windows nor Igor will permit this.

This boils down to the following: Feel free to use long file and directory names, but expect to see errors if you use outrageously long names or if you have directories so deeply nested that paths approach the theoretical limit.

Path Separators

The Macintosh HFS file system uses a colon to separate elements in a file path. For example:

```
hd:Igor Pro Folder:Examples:Sample Graphs:Contour Demo.pxp
```

The Windows file system uses a backslash to separate elements in a file path. For example:

```
C:\Igor Pro Folder\Examples\Sample Graphs:Contour Demo.pxp
```

Some Igor operations (e.g., LoadWave) allow you to enter file paths. Igor accepts Macintosh-style or Windows-style paths regardless of the platform on which you are running.

Note: Igor uses the backslash character as an escape character in literal strings. This can cause problems when using Windows-style paths.

For example, the following command creates a textbox with two lines of text. "\r" is an escape code inserts a carriage return character:

```
Textbox "This is line 1.\rThis is line 2."
```

Because Igor interprets a backslash as an escape character, the following command will not execute properly:

```
LoadWave "C:\Data Files\really good data.ibw"
```

Instead of loading a file named "really good data.ibw", Igor would try to load a file named "Data Files<CR>eally good data.ibw", where <CR> represents the carriage return character. This happens because Igor interprets "\r" in literal strings to mean carriage return.

To solve this problem, you must use "\\" instead of "\" in a file path. Igor will correctly execute the following:

```
LoadWave "C:\\Data Files\\really good data.ibw"
```

This works because Igor interprets "\\" as an escape sequence that means "insert a backslash character here".

Another solution to this problem is to use a Macintosh HFS-style path, even on Windows:

```
LoadWave "C:Data Files:really good data.ibw"
```

Igor converts the Macintosh HFS-style path to a Windows-style path before using it. This avoids the backslash issue.

For a complete list of escape sequences, see **Escape Sequences in Strings** on page IV-14.

If you are writing procedures that need to extract sections of file paths or otherwise manipulate file paths, the **ParseFilePath** function on page V-733 may come in handy.

UNC Paths

"UNC" stands for "Universal Naming Convention". This is a Windows convention for identifying resources on a network. One type of network resource is a shared directory. Consequently, when running under Windows, in order to reference a network directory from an Igor command, you need to use a UNC path.

The format of a UNC path that points to a file in a folder on a shared server volume or directory is:

```
    "\\server\share\directory\filename"
```

“server” is the name of the file server and “share” is the name of the top-level shared volume or directory on that server.

Because Igor treats a backslash as an escape character, in order to reference this from an Igor command, you would have to write:

```
"\\\\server\\share\\directory\\filename"
```

As described in the preceding section, you could also use Macintosh HFS path syntax by using a colon in place of two backslashes. However, you can not do this for the “\\server\share” part of the path. Thus, using Macintosh HFS syntax, you would write:

```
"\\\\server\\share:directory:filename"
```

Unix Paths

Unix paths use the forward slash character as a path separator. Igor does not recognize Unix paths. Use Macintosh HFS paths instead.

Keyboard and Mouse Usage

This section describes how keyboard and mouse usage differs on Macintosh versus Windows. It is intended to help Igor users more easily adapt when switching platforms.

There are three main differences between Macintosh and Windows input mechanisms:

1. The Macintosh mouse may have one button and the Windows mouse has two.
2. The Macintosh keyboard has four modifier keys (Shift, Command, Option, Control) while the Windows keyboard has three (Shift, Ctrl, Alt).
3. The Macintosh keyboard has Return and an Enter keys while the Windows keyboard (usually) has two Enter keys.

For the most part, Igor maps between Macintosh and Windows input as follows:

Macintosh	**Windows**
Shift	Shift
Command	Ctrl
Option	Alt
Control	<not mapped>

Macintosh	**Windows**
Return	Enter
Enter	Enter
Control-click	Right-click

In notebooks, procedure windows and help windows, pressing Control-Return or Control-Enter executes the selected text or, if there is no selection, to execute the line of text containing the caret.

Command Window Input

This table compares command window mouse actions:

Action	Macintosh	Windows
Copy history selection to command line	Option-click	Alt+click
Copy history to command and start execution	Command-Option-click	Ctrl+Alt+click
Invoke contextual menu	Control-click	Right-click

Cross-Platform Text and Fonts

Text Encoding Compatibility

Prior to Igor7, Igor used system text encoding. On Macintosh, this was usually MacRoman. On Windows, it was usually Windows-1252. On Japanese systems, it was Shift JIS on both platforms.

As of Igor7, Igor uses UTF-8 text encoding internally on both Macintosh and Windows.

When opening old files, Igor must convert from the file's text encoding to UTF-8 for storage in memory.

Dealing with various text encodings is a complex issue. See **Text Encodings** on page III-459 for details.

Carriage Returns and Linefeeds

The character or character pattern that marks the end of a line of text in a plain text file is called the "line terminator". There are three common line terminators, carriage return (CR, ASCII 13, used on old Macintosh systems), linefeed (LF, ASCII 10, used on Unix) and carriage return plus linefeed (CRLF, used on Windows).

When Igor Pro opens a text file (procedure file, plain text notebook or plain text data file), it accepts CR, LF or CRLF as the line terminator.

If you create a new procedure file or plain text notebook, Igor writes LF on Mac OS and CRLF on Windows. If you open an existing plain text file, edit it and then save it, Igor preserves the original terminator as determined by examining the first line in the file.

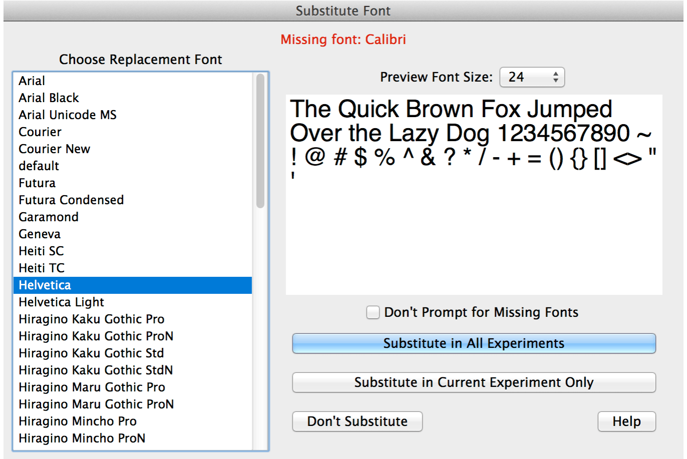
By default, the **FReadLine** operation treats CR, LF, or CRLF as terminators. Use this to write a procedure that can read lines from a text file without caring whether it is a Macintosh, Windows, or Unix file.

Font Substitution

When a font specified in a command or document is not installed, Igor applies font substitution to choose an installed font to use in place of the missing font. Dealing with these missing fonts often occurs when transferring a Windows-originated document to Macintosh or vice versa.

Igor employs two levels of font substitution: user-level editable substitution and built-in uneditable substitution.

The first level is an optional user-level font substitution facility that you will usually encounter for the first time when Igor displays the Substitute Font Dialog while opening an experiment or file. Use the dialog to choose a temporary or permanent replacement for the missing font:



Missing font: Calibri

Preview Font Size: 24

The Quick Brown Fox Jumped Over the Lazy Dog 1234567890 ~ ! @ # $ % ^ & ? * / - + = () {} [] <> " '

The second level is Igor’s built-in substitution table which substitutes between fonts normally installed on various Macintosh and Windows operating systems. For example, it substitutes Arial (a standard Windows font) for Geneva (a standard Macintosh font) if Geneva is not installed (which it usually isn’t on a Windows computer).

The user-level substitutions have priority over the built-in substitutions.

The Substitute Font dialog appears when neither level of font substitution specifies a replacement for the missing font. You can prevent this dialog from appearing by selecting the Don’t Prompt for Missing Fonts checkbox in the Substitute Font dialog.

You can manage font substitutions without waiting for a missing font situation to occur by choosing Misc-Edit Font Substitutions.

The user-level font substitution table is maintained in the “Igor Font Substitutions.txt” text file in Igor’s preferences folder. The file format is:

```
<name of missing font to replace> = <name of font to use instead>
```

one entry per line. For example:

```
Palatino=New Times Roman
```

spaces or tabs are allowed around the equals sign.

When a missing font is replaced, Igor uses the name of the replacement font instead of the name of the font in the command.

The name of the missing font is replaced only in the sense that the altered or created object (window, control, etc.) uses and remembers only the name of the replacement font. Recreation macros, including experiment recreation procedures, use the name of the replacement font when the experiment is saved. The command, however, is unaltered and still contains the name of the missing font.

Cross-Platform Procedure Compatibility

Igor procedures are about 99.5% platform-independent. For the other 0.5%, you need to test which platform you are running on and act accordingly. You can use ifdefs to achieve this. For example:

```
Function Demo()
   #ifdef MACINTOSH
      Print "We are running on Macintosh"
   #else
      #ifdef WINDOWS
         Print "We are running on Windows"
      #else
```

```
         Print "Unknown OS"
      #endif
   #endif
End
```

File Paths

As described under **Path Separators** on page III-451, Igor accepts paths with either colons or backslashes on either platform.

The use of backslashes is complicated by the fact that Igor uses the backslash character as an escape character in literal strings. This is also described in detail under **Path Separators** on page III-451. The simplest solution to this problem is to use a colon to separate path elements, even when you are running on Windows.

If you are writing procedures that need to extract sections of file paths or otherwise manipulate file paths, the **ParseFilePath** function on page V-733 may come in handy.

Igor supports paths up to 2000 bytes but operating system limits may apply. See **File Names and Paths** on page II-21 for details.

File Types and Extensions

On Mac OS 9, all files had a file type property. This property is a four letter code that is stored with the file by the Macintosh file system. For example, plain text files have the file type TEXT. Igor binary wave files have the file type IGBW. The file type property controlled the icon displayed for the file and which programs could open the file.

The file type property is no longer used on Macintosh. On Mac OS X, as well as on Windows, the file type is indicated by the file name extension.

For backward compatibility, some Igor operations and functions, such as **IndexedFile**, still accept Macintosh file types. New code should use extensions instead.

Points Versus Pixels

A pixel is the area taken up by the smallest displayable dot on an output device such as a display screen or a printer. The physical width and height of a pixel depend on the device.

In Igor, most measurements of length are in terms of points. A point is roughly 1/72 of an inch. 72 points make up 1 “logical inch”. Because of hardware differences and system software adjustments, the actual size of a logical inch varies from screen to screen and system to system.

Window Position Coordinates

With one exception, Igor stores and interprets window position coordinates in units of points. For example the command

```
Display/W=(5, 42, 405, 242)
```

specifies the left, top, right, and bottom coordinates of the window in points relative to a reference point which is, roughly speaking, the top/left corner of the menu bar. Other Igor operations that use window position coordinates in points include Edit, Layout, NewNotebook, NewGizmo and MoveWindow.

The exception is the control panel window when running on a standard resolution screen. This is explained under **Control Panel Resolution on Windows** on page III-456.

Most users do not need to worry about the exact meaning of these coordinates. However, for the benefit of programmers, here is a discussion of how Igor interprets them.

On Macintosh, the reference point, (0, 0), is the top/left corner of the menu bar on the main screen. On Windows, the reference point is 20 points above the bottom/left corner of the main Igor menu bar. This difference is designed so that a particular set of coordinates will produce approximately the same effect on both platforms, so that experiments and procedures can be transported from one platform to another.

The coordinates specify the location of the content region, in Macintosh terminology, or the client area, in Windows terminology, of the window. They do not specify the location of the window frame or border.

On Macintosh, a point is always interpreted to be one pixel except on Retina displays where it is two.

On Windows, the correspondence between a point and a pixel can be controlled by the user using system settings. Since Igor stores window positions in units of points, if the user changes the number of pixels per point, the size of Igor windows in pixels will change.

Control Panel Resolution on Windows

In the past, by default, Windows screens ran at 96 DPI (dots-per-inch) resolution. In recent years, high-resolution displays, also called UltraHD displays and 4K displays, have become common.

In Igor6 and before, commands that create control panels and controls use screen pixel units to specify sizes and coordinates. This results in tiny controls on high-resolution displays.

In Igor7 and later, control panels and control sizes and coordinates can be specified in units of points instead of pixels. Since a point is a resolution-independent unit, this results in controls that are the same logical size regardless of the physical resolution of the screen.

By default, panels are drawn using pixels if the screen resolution is 96 DPI but using points for higher-DPI settings. This gives backward compatibility on standard screens and reasonably-sized controls on high-resolution screens.

You can change the way control panel coordinates and control sizes are interpreted using two different methods:

1. Control Panel Expansion (Igor Pro 9.00 and later)

2. You can set control panel expansion using the Expansion submenu in the Panel menu or using the Expansion setting in the Panel section of the Miscellaneous Settings dialog. If you are using Igor Pro 9.00 or later, this method is preferred.

   See the **Control Panel Expansion** on page III-443 for further discussion.

3. SetIgorOption with the PanelResolution keyword.

   This method requires executing commands as described in the next section. It can make panels larger than normal but not smaller. It is not recommended in Igor Pro 9.00 or later.

See also **Control Panel Units** on page III-444.

SetIgorOption PanelResolution

In Igor Pro 9.00 and later we recommend that you use **Control Panel Expansion** instead of SetIgorOption PanelResolution.

You set this option by executing a command of the form:

```
SetIgorOption PanelResolution = <resolution>
```

The <resolution> parameter controls how Igor interprets coordinates and sizes in control panels. It must be one of these values:

0: Coordinates and sizes are treated as points regardless of the screen resolution.

1: Coordinates and sizes are treated as pixels if the screen resolution is 96 DPI, points otherwise. This is the default setting in effect when Igor starts.

72: Coordinates and sizes are treated as pixels regardless of the screen resolution (Igor6 mode).

>96 If <resolution> is greater than 96, panel coordinates and sizes are treated as points regardless of the screen resolution. Larger values make larger panels and controls. For example on a 96 DPI screen `SetIgorOption PanelResolution = 192` makes them twice as large as normal.

This setting is not remembered across Igor sessions.

The resolution for a panel is set when the panel is created so changing the panel resolution does not affect already-existing control panels.

Programmers are encouraged to test their control panels at various resolution settings.

For the most part, Igor6 control panels will work fine in Igor7 and later. However, if you have panels that rearrange their components depending on the window size, you probably have some code that uses the ratio of 72 and ScreenResolution. For example, here is a snippet from the WaveMetrics procedure Axis Slider.ipf:

```
   case "Resize":
      GetWindow kwTopWin,gsize         // Returns points
                                       // Controls are positioned in pixels
      grfName= WinName(0, 1)
      V_left *= ScreenResolution / 72  // Convert points to pixels
      V_right *= ScreenResolution / 72
      Slider WMAxSlSl,size={V_right-V_left-kSliderLMargin,16}
      break
```

To make this work properly at variable resolution, we use the **PanelResolution** function, added in Igor Pro 7.00:

```
   case "Resize":
      GetWindow kwTopWin,gsize         // Returns points
      grfName= WinName(0, 1)
      V_left *= ScreenResolution / PanelResolution(grfName)      // Variable
      V_right *= ScreenResolution / PanelResolution(grfName)     // resolution
      Slider WMAxSlSl,size={V_right-V_left-kSliderLMargin,16}
      break
```

The PanelResolution function, when called with "" as the parameter returns the current global default setting for panel resolution in pixels per inch or, if in Igor6 mode, 72. When called with the name of a control panel or graph, it returns the current resolution of the specified window in pixels per inch.

If you want your procedures to work with Igor6, you should insert this into each procedure file that needs the PanelResolution function:

```
#if Exists("PanelResolution") != 3
Static Function PanelResolution(wName)    // For compatibility with Igor7
   String wName
   return 72
End
#endif
```

To find other examples, use the Help Browser to search procedure files for PanelResolution.

See also **Control Panel Units** on page III-444.

Pictures in Notebooks

If you want to display notebook pictures on both platforms, they must be in one of these cross-platform formats: PDF, PNG, JPEG, TIFF, SVG.

PDF pictures are displayed correctly on Windows in Igor Pro 9.00 or later. In earlier versions on Windows, PDF pictures are displayed as gray boxes.

If you have pictures in other formats and you want them to be viewable on both platforms, you should convert them to PNG.

There are two ways to create a PNG picture in an Igor notebook. You can load it from a file using Misc→Pictures and then place it in a notebook or you can convert a picture that you have pasted into a notebook using Notebook→Special→Convert to PNG.

The Convert to PNG command in the Notebook→Special menu converts the selected picture or pictures into PNG. It skips selected pictures that are already PNG or that are foreign (not native to the platform on which you are running). You can determine the type of a picture in a notebook by clicking in it and looking at the notebook status line.

The Convert to PNG dialog allows you to choose the desired resolution. Usually 4x or 8x is best.

When you create a PNG file from within Igor, from a graph window for example, you can create it at screen resolution or at higher resolution. For good quality when viewed at higher magnifications and when printed, use 4x or 8x.

Chapter

III-16

Text Encodings

Overview

Starting with Igor Pro 7, Igor stores text internally as UTF-8, a Unicode text encoding format. Using Unicode improves Igor's interoperability with other software and gives you easy access to a wide array of characters including Greek, mathematical and special characters.

Previous versions of Igor used non-Unicode text encodings such as MacRoman, Windows-1252, and Shift JIS (Japanese), depending on the operating system you were running. Consequently Igor needs to do text encoding conversions when opening files from earlier versions.

If a file contains accented characters, special symbols, and other non-ASCII text, it is not always possible to get this conversion right. You may see incorrect characters or receive “Unicode conversion errors” or other types of errors.

Text encoding is not an issue with files that contain only ASCII characters as these characters are represented using the same codes in UTF-8 as inn other text encodings.

This chapter provides information that a technically-oriented Igor user can use to understand the conversions and to deal with issues that can arise. To understand these issues, it helps to understand what text encodings are and how they are used in Igor, so we start with an overview.

Text Encoding Overview

A text encoding is a mapping from a set of numbers to a set of characters. The terms "text encoding", "character encoding" and "code page" represent the same thing.

In most commonly-used text encodings, text is stored as an array of bytes. For example, the text "ABC" is stored in memory as three bytes with the numeric values 0x41, 0x42 and 0x43. (The 0x notation means the number is expressed in hexadecimal, also called base 16.)

In the 1960's the ASCII text encoding was defined. It specifies the mapping of 128 numbers, from 0x00 to 0x7F, to characters. ASCII defines mappings for:

- Unaccented letters (A-Z and a-z)
- Numerals (0-9)
- Common punctuation marks (comma, period, dash, question mark ...)
- Other printable characters (space, brackets, slash, backslash, ...)
- Control characters (carriage-return, linefeed, tab, ...)

The "ABC" example above uses the ASCII codes for A, B and C.

Over time, other text encodings were created to permit the representation of characters not supported by ASCII such as:

- Accented western letters
- Asian characters
- Mathematical symbols

Hundreds of text encodings were created for encoding characters used in different languages. Even for a given language, different operating systems often adopted different text encodings.

In ASCII, each character is represented by a 7-bit code which is typically stored in a single 8-bit byte with one bit unused. 7 bits can represent 128 different characters. To represent more characters, other text encodings use 8 bits per character, multiple bytes per character, 16-bit codes or 32-bit codes.

We use the term "byte-oriented text encoding" to distinguish text encodings that represent characters using one byte or multiple bytes per character from those that use 16-bit or 32-bit codes.

The characters represented by the ASCII codes 0x00 to 0x7F are called "ASCII characters" with all other characters called "non-ASCII characters". All byte-oriented text encodings that you are likely to encounter are supersets of ASCII.

Multiple-byte text encodings, such as Shift-JIS and UTF-8, typically use one byte for ASCII characters, and for some frequently-used non-ASCII characters, and two or more bytes for other non-ASCII characters.

In order to properly display and process text, a program must convert any text it reads from outside sources (e.g., files) into whatever text encoding the program uses for internal storage if the source text encoding and the internal text encoding are different.

Since all byte-oriented text encodings that you are likely to encounter are supersets of ASCII, ASCII characters do not require conversion when treated as any byte-oriented text encoding. Non-ASCII characters require conversion and problems arise if the conversion is not done or not done correctly.

Text Encodings Commonly Used in Igor

In Igor the most commonly-used text encodings are:

- MacRoman (Macintosh Western European)
- Windows-1252 (Windows Western European)
- Shift JIS (Japanese)
- UTF-8 (Unicode using a byte-oriented encoding form)

Igor6 and earlier versions of Igor stored text in "system text encoding". For western users this means MacRoman on Macintosh and Windows-1252 on Windows. For Japanese users it means Shift JIS on both platforms.

Igor now uses UTF-8 exclusively.

The system text encoding is determined by the system locale. The system locale determines the text encoding used by non-Unicode programs such as Igor6. It has no effect on Igor7 or later.

On Macintosh you set the system locale through the preferred languages list in the Language & Region preference panel. On Windows you set it through the Region control panel. Most users never have to set the system locale because their systems are initially configured appropriately for them.

Because Igor now uses UTF-8 internally, when it loads a pre-Igor7 file, it must convert the text from system text encoding to UTF-8. If the file contains ASCII text only this conversion is trivial. But if the file contains non-ASCII characters, such as accented letters, Greek letters, math symbols or Japanese characters, issues may arise, as explained in the following sections.

In order to convert text to UTF-8, Igor must know the text encoding of the file from which it is reading the text. This is tricky because plain text files, including computer program source files, data files, and plain text documentation files, usually provide no information that identifies the text encoding they use. As explained below, Igor employs several strategies for determining a file's text encoding so that it can correctly convert the file's text to UTF-8 for internal storage and processing.

Western Text Encodings

MacRoman and Windows-1252 (also called "Windows Latin 1") are used for Western European text and are collectively called "western".

In MacRoman and Windows-1252, the numeric code for each character is stored in a single byte. A byte can represent 256 values, from 0x00 to 0xFF. The 128 values 0x00 through 0x7F represent the same characters as ASCII in both text encodings. The remaining 128 values, from 0x80 to 0xFF, represent different characters in each text encoding. For example the value 0xA5 in MacRoman represents a bullet character while in Windows-1252 it represents a yen symbol.

When Igor6, running on Macintosh, loads an experiment written on Windows, it converts text from Windows-1252 to MacRoman. The opposite occurs if, running on Windows, it loads an experiment written on Macintosh.

When Igor loads an Igor6 experiment written on Macintosh, it converts from MacRoman to UTF-8. If the experiment was written on Windows it converts from Windows-1252 to UTF-8.

Asian Text Encodings

Asian languages have thousands of characters so it is not possible to map one character to one byte as in western text encodings. Consequently various multi-byte text encodings were devised for different Asian languages. Such systems are sometimes called MBCS for "multi-byte character system".

Shift JIS is the predominant MBCS text encoding for Japanese. It uses a single byte for all ASCII characters and some Japanese characters and two bytes for all other Japanese characters.

In Shift JIS, the codes from 0x00 to 0x7F have the same meaning as in ASCII except for 0x5C which represents a backslash in ASCII but a yen symbol in Shift JIS. The codes from 0xA1 to 0xDF represent single-byte katakana characters. The codes from 0x81 to 0x9F and 0xE0 to 0xEF are the first bytes of double-byte characters.

Chinese and Korean text encodings also use MBCS.

Unlike the situation for western text, Macintosh and Windows both use the same, or practically the same, text encodings for Japanese. The same is true for Traditional Chinese and Simplified Chinese.

The MacJapanese and Windows-932 text encodings are variants of Shift JIS. In this documentation, "Shift JIS" and "Japanese" mean "Shift JIS or its variants MacJapanese and Windows-932".

When Igor loads an Igor6 experiment written in Shift JIS it converts text from Shift JIS to UTF-8.

Unicode

The proliferation of text encodings for different languages and even for the same language on different operating systems complicated the exchange and handling of text. This led to the creation of Unicode - a system for representing virtually all characters in all languages with a single text encoding. The first iteration of Unicode was released in the early 1990's. It was based on 16-bit numbers rather than the 8-bit bytes of previous text encodings.

In 1993 Microsoft released Windows NT, one of the first operating systems to use Unicode internally. Mac OS X, developed in the late 1990's and released in 2001, also uses Unicode internally. Most applications at the time still used system text encoding and the operating systems transparently translated between it and Unicode as necessary.

In the mid-1990's the developers of Unicode realized that 16-bits, which can represent 65,536 distinct numbers, were not enough to represent all characters. They extended Unicode so that it can represent over one million characters by using two 16-bit numbers for some characters. However nearly all of the commonly-used characters can still be represented by a single 16-bit number.

Over time most applications migrated to Unicode for internal storage of text. Igor7 was the first version of Igor that uses Unicode internally.

Unicode Character Encoding Schemes

Unicode maps each character to a unique number between 0 and 0x10FFFF (1,114,111 decimal). Each of these numbers is called a "code point".

There are several ways of storing a code point in memory or in a file. Each of them is called a "character encoding scheme". Each character encoding scheme is based on a "code unit" which may be a byte, a 16-bit value or a 32-bit value.

The most straight-forward character encoding scheme is UTF-32. The code unit is a 32-bit value and each code point is directly represented by a single code unit. UTF-32 is not widely used for historical reasons and because it is not memory-efficient.

UTF-16 is a widely-used character encoding scheme in which the code unit is a 16-bit value and each code point is represented by either one or two code units. Nearly all of the commonly-used characters require just one. Both Mac OS X and Windows use UTF-16 internally.

UTF-8 is a widely-used character encoding scheme in which the code unit is a byte and each code point is represented by one, two, three or four code units. The ASCII characters are represented by a single byte using the same code as in ASCII itself. All other characters are represented by two, three or four bytes. UTF-8 is the predominant character encoding scheme on the Worldwide Web and in email. It is the scheme used internally by Igor7 and later.

Problems Caused By Text Encodings

The use of different text encodings on different operating systems, for different languages, and in different versions of Igor requires that Igor convert between text encodings when reading files. In Igor7 and later this means converting from the file's text encoding to UTF-8 which Igor now uses for internal storage. Since ASCII text is the same in UTF-8 as in other byte-oriented text encodings, conversion and the problems it can cause are issues only for files that contain non-ASCII text.

Broadly speaking, when Igor opens an Igor6 file, three types of text encoding-related problems can occur:

- Igor's idea of the file's text encoding might be wrong (text encoding misidentification)
- The file may contain invalid byte sequences for its text encoding (invalid text)
- The file may contain a mixture of text encodings (mixed text encodings)

Text Encoding Misidentification Problems

This problem stems from the fact that it is often unclear what text encoding a given file uses. The clearest example of this is the plain text file - the format used for text data files, Igor procedure files and plain text notebooks. A plain text file usually stores just the text and nothing else. This means that there is often nothing in a plain text file that tells Igor what text encoding the file uses.

The problem is similar for plain text items stored within Igor experiment files. These include:

- wave names, wave units, wave notes, wave dimension labels
- text wave contents
- the experiment recreation procedures stored in an experiment file
- the history area contents
- the built-in procedure window's contents
- packed procedure files
- packed plain text notebook files

Igor Pro 6.30 and later, which we will call Igor6.3x for short, store text encoding information in the experiment file for these items but earlier versions of Igor did not.

The text encoding information stored by Igor6.3x and later is not foolproof. Igor6.3x determines the text encoding for a procedure file or a plain text notebook based on the font used to display it. Usually this is correct but it is not guaranteed as the Igor6 user can change a font at any time.

Waves created pre-Igor6.3x have unknown text encodings for their various items.

Igor6.3x determines the text encoding for wave items when the wave is created based on the text encoding used to enter text into the user interface (e.g., into dialogs). This will be the system text encoding except that in IgorJ (the Japanese version of Igor), it is Japanese regardless of the system text encoding. Usually this produces the correct text encoding but it is not guaranteed as it is possible in Igor6 to make waves using any text encoding. For example, when running IgorJ you can switch the command line to an English font and create a wave whose name contains non-ASCII English characters. This name will therefore use MacRoman on Macintosh and Windows-1252 on Windows but IgorJ63x will record the wave name's text encoding as Shift JIS because that is the user interface text encoding. It is similarly possible to create a Japanese wave name when running an English Igor, causing Igor to record the wave name's text encoding as MacRoman or Windows-1252 even though the wave name is really Japanese.

Igor6.3x sets a wave's text encoding information when the wave is created. If a wave was created prior to Igor6.3x and is opened in Igor6.3x, its text encoding is unknown. Saving the experiment in Igor6.3x does not change this - the wave's text encoding is still unknown. So an Igor6.3x experiment can contain a mix of Igor6.3x waves with known text encodings and pre-Igor6.3x waves with unknown text encodings.

The three main causes of text encoding misidentification are:

- The file is a plain text file which contains no text encoding information
- The file is a pre-Igor6.3x experiment file which contains no text encoding information
- The Igor6.3x assumption that the text encoding can be deduced from the text encoding used to enter text into the user interface was incorrect

In order to convert text to UTF-8, Igor has to know the text encoding used when the text was created. If it gets this wrong then errors or garbled text will result. Some strategies for fixing such problems are described below.

Invalid Text Problems

A file that contains text in a particular text encoding can be damaged, creating sequences of bytes that are illegal in that text encoding.

In Shift JIS, for example, there are rules about how double-byte characters are formed. The first byte must be in a certain range of values and a second byte must be in a different range of values. If, by error, a line break is inserted between the first and second bytes, the resulting text is not valid as Shift JIS.

Damage like this can happen in Igor6 with long Japanese textboxes. When Igor generates a recreation macro for a graph, it generates TextBox commands for textboxes. If the text is long, Igor breaks it up into an initial TextBox command and subsequent AppendText commands. Igor6 is not smart enough to know that it must keep the two bytes of a double-byte Japanese characters together. This problem is asymptomatic in Igor6 because the two bytes of the double-byte character are reassembled when the macro runs. But it causes an error if you load the Igor6 file into Igor7 or later because Igor must convert the entire file to UTF-8 for internal storage before any reassembly occurs.

There are many other ways to damage a Shift JIS file. Similar damage can occur with other multi-byte text encodings such as UTF-8.

When a file contains invalid text but you suspect that it is mostly OK, you can use the Choose Text Encoding dialog to change the text encoding conversion error handling mode. This allows you to open the file despite the invalid text.

Mixed Text Encoding Problems

In Igor6, you can enter text in different text encodings by merely using different fonts. For example:

1. Run Igor6.3x with an English font controlling the built-in procedure window.
2. Create a graph.
3. Create an annotation using a Japanese font and Japanese characters in the graph.
4. Save the graph as a recreation macro.
5. Save the experiment.

Because an English font controls the built-in procedure window, Igor6.3x thinks that the text encoding for the procedure window is western (MacRoman or Windows-1252) and records this information in the experiment.

When Igor7 or later opens this experiment, it must convert the procedure window text to UTF-8. Since the Igor6.3x recorded the file's text encoding as western (MacRoman or Windows-1252), Igor attempts to convert the text from western to UTF-8. You will wind up with gibberish western characters where the Japanese text should be.

In this example Igor mistook Japanese text for western and the result was gibberish. If Igor mistakes western text for Japanese, you can either wind up with gibberish, or you may get an error, or you may see the Unicode replacement character (a white question mark on a black background) where the misidentified text was.

Fortunately this kind of problem is relatively rare. To fix it you need to manually repair the gibberish text.

The Experiment File Text Encoding

Experiments saved by Igor6.3x or later record the "experiment file text encoding". This is the text encoding used by the built-in procedure window at the time the experiment was saved. As explained below, Igor uses the experiment file text encoding as the source text encoding when converting a wave element to UTF-8 if the element's text encoding is unknown.

Prior to version 6.30 Igor did not record the experiment file text encoding so it defaults to unknown when a pre-Igor6.3x experiment is loaded into Igor7 or later. It also defaults to unknown when you first launch Igor and when you create a new experiment.

You can display the experiment file text encoding for the currently open experiment by right-clicking the status bar and choosing Show Experiment Info. Igor will display something like "Unknown / 6.22" or "Mac Roman / 6.36". The first item is the experiment file text encoding while the second is the version of Igor that saved the experiment file. This information is usually of interest only to experts investigating text encoding issues.

You can also see the experiment file text encoding by choosing File→Experiment Info.

The Default Text Encoding

Because it is not always possible for Igor to correctly determine a file's text encoding, it sometimes needs additional information. You supply this information through the Default Text Encoding submenu in the Text Encoding submenu in the Misc menu. Igor uses your selected default text encoding when it can not otherwise determine the text encoding of a file or wave.

You can display the default text encoding for the currently open experiment by right-clicking the status bar and choosing Show Default Text Encoding. Displaying this information in the status bar is usually of interest only to experts investigating text encoding issues.

Igor experiment files record the platform (Macintosh or Windows) on which they were last saved. In Igor6.3x and later, Igor records text encoding information for most of the items stored in an experiment file. Neither platform information nor text encoding information is stored in standalone plain text files. Consequently determining the text encoding of an experiment file is different from determining the text encoding of a standalone file. This makes Igor's handling of text encodings and the meaning of the default text encoding setting more complicated than we would like.

The Default Text Encoding submenu contains the following items:

```
UTF-8
Western
MacRoman
Windows-1252
Japanese
Simplified Chinese
```

```
Traditional Chinese
<Other text encodings>
Override Experiment
```

When you open an experiment, Western means MacRoman if the experiment was last saved on Macintosh and Windows-1252 if it was last saved on Windows. When you open a standalone file, Western means MacRoman if you are running on Macintosh and Windows-1252 if you are running on Windows.

The remaining text encoding items, such as MacRoman, Windows-1252 and Japanese, specify the text encoding to use for conversions to UTF-8 without regard to the platform on which the file was last saved or on which you are currently running.

When opening an experiment saved in Igor6.3x or later, Igor normally uses the text encoding information in the experiment file. As explained above under **Text Encoding Misidentification Problems** on page III-463, occasionally this information will be wrong. The Override Experiment item gives you a way to force Igor to use your selected text encoding even when opening experiments that contain text encoding information.

When Igor first runs it sets the default text encoding to Western or Japanese based on your system locale. This will give the right behavior when opening Igor6 experiments in most cases. Igor stores the default text encoding in preferences so when your launch Igor again it is restored.

For normal operation, leave the default text encoding setting on Western if you use a Western language or on the appropriate Asian language if you use an Asian language and leave Override Experiment unchecked.

Change these only if a problem arises. For example, if you are running an English system but you are opening a file containing Japanese, or if you are running a Japanese system but you are opening a file containing non-ASCII western text, you may get incorrect text or errors. To fix this, change the settings in this menu and reload the file. After loading the problematic file, reset the menu items for normal operation.

Igor sets the Override Experiment setting to unchecked each time Igor is launched since this is less likely to result in undetected erroneous text conversion than if you turned it on and unintentionally left it turned on.

In addition to affecting text encoding conversion during the loading of files, the default text encoding setting is used as follows:

- When you choose New Experiment, it determines the text encoding of the history area and built-in procedure window. This determines the text encoding used for these items when the experiment is saved to disk.
- When you create a new procedure or notebook window, if a text encoding was not explicitly specified, it determines the text encoding used when the file is saved to disk.
- When you insert text into an existing document using Edit→Insert File, it determines the source text encoding for conversion to UTF-8.
- When Igor loads a wave, it determines the source text encoding for conversion to UTF-8 if the source text encoding is not otherwise specified. This will be the case for waves created before Igor6.3x.
- When the help browser searches procedure files, notebook files and help files, it determines the source text encoding for conversion to UTF-8 if it is not otherwise known.

Plain Text File Text Encodings

Plain text files include procedure files, plain text notebook files, the built-in procedure window text and history text. Igor uses UTF-8 when writing new instances of these items.

When reading existing files, Igor must convert text that it reads from plain text files to UTF-8 for storage in memory. In order to do this, it needs to know what text encoding to convert from. Most plain text files contain no indication of their text encoding so it can be tricky to determine the source text encoding. If Igor gets the source text encoding wrong, you will get errors or see incorrect characters in the text.

Starting with Igor6.3x, Igor stores text encoding information for plain text files stored in or accessed by experiment files. Experiment files saved before Igor6.3x do not contain text encoding information. Standalone plain text files not part of an experiment file, such as Igor6 global procedure files, plain text notebook files and data files, also do not contain text encoding information.

Igor looks for the optional byte order mark (see **Byte Order Marks** on page III-471) that some programs write at the start of a Unicode plain text file. If present, the byte order mark unambiguously identifies the file as Unicode and identifies which encoding scheme (UTF-8, UTF-16 or UTF-32) the file uses.

Starting with Igor7, Igor supports a TextEncoding pragma in procedure files that looks like this:

```
#pragma TextEncoding = "<text encoding name>"
```

This is described under **The TextEncoding Pragma** on page IV-55. The TextEncoding pragma allows you to unambiguously specify the text encoding for an Igor procedure file. It is ignored by Igor6.

Starting with Igor9, the text encoding for procedure files defaults to UTF-8.

Igor must deal with a variety of circumstances including:

- Standalone files versus experiment files
- Pre-Igor6.3x experiment files versus experiment files from Igor6.3x and later
- Macintosh versus Windows versus Japanese experiment files
- Procedure files with and without a TextEncoding pragma

Because of these complications there is no simple way for Igor to determine the source text encoding for any given plain text file. To cope with this situation, it employs rules described in the next section.

The status bar of a plain text file's window includes a text encoding button which shows you the "file text encoding" - the text encoding that Igor used to convert the file's text to UTF-8. When the file is saved, Igor converts from UTF-8 back to the file text encoding. You can change the file text encoding by clicking the text encoding button to display the Text Encoding dialog.

Determining the Text Encoding for a Plain Text File

This section describes the rules that Igor uses to determine the source text encoding for a plain text file.

The rules depend on whether Override Experiment (Misc→Default Text Encoding→Override Experiment) is checked.

Override Experiment Unchecked

If Override Experiment is unchecked, Igor tries the following text encodings, one-after-another, until it succeeds (i.e., it is able to convert to UTF-8 without error), in this order:

```
Byte order mark
TextEncoding pragma if present (for procedure files only)
The specified text encoding (described below)
UTF-8 if the text contains non-ASCII characters
The default text encoding
Choose Text Encoding dialog (described below)
```

Note that a conversion can "succeed" without being correct. For example, Japanese can be successfully interpreted as MacRoman or Windows but you will get the wrong characters.

The "specified text encoding" is the explicit text encoding if present (e.g., specified by the /ENCG flag for the OpenNotebook operation) or the item text encoding (e.g., a text encoding stored in an experiment file for its built-in procedure window text).

Starting with Igor Pro 9, during experiment loading, if text is valid as UTF-8, including all ASCII text, it is loaded as UTF-8 regardless of the text encoding stored in the experiment file. The purpose is to transition away from obsolete text encodings.

Also starting with Igor Pro 9, if a plain text file has a UTF-8 byte order mark it is loaded as UTF-8 even if it contains invalid byte sequences. Invalid bytes are displayed using the Unicode replacement character (U+FFFD).

If Igor can not otherwise find a valid text source encoding it displays the Choose Text Encoding dialog. This dialog asks you to choose the text encoding to use for the plain text file being opened.

Override Experiment Checked

If the Misc→Default Text Encoding→Override Experiment menu item is checked then the order changes to this:

```
Byte order mark
TextEncoding pragma if present (for procedure files only)
The default text encoding
The specified text encoding (described below)
UTF-8 if the text contains non-ASCII characters
Choose Text Encoding dialog (described below)
```

In this mode the default text encoding, as set in the Misc→Default Text Encoding submenu, is given a higher priority. This should be used only if the normal mode fails to give the correct results. If you turn Override Experiment on, make sure to select the appropriate default text encoding from the submenu. You should turn Override Experiment on only in emergencies and turn it off for normal use.

Starting with Igor Pro 9, during experiment loading, if text is valid as UTF-8, including all ASCII text, it is loaded as UTF-8 regardless of the Override Experiment setting. The purpose is to transition away from obsolete text encodings.

Potential Problems Determining Plain Text File Text Encodings

The rules listed above have the following potential problems:

TextEncoding pragma (for procedure files only)

The pragma could be wrong. For example, if you set TextEncoding="MacRoman" and then change the file to UTF-8 in an external editor, it will still succeed in Igor but give the wrong characters. This is a programmer error and it is up to you to fix it.

The specified text encoding

There is no specified text encoding for plain text files in a pre-Igor6.3x experiment.

In Igor6.3x and later, Igor includes text encoding information in the experiment restart procedures for each plain text file to be opened. This information is the "specified text encoding".

In Igor6.3x the specified text encoding can be wrong. For example, if the user adds some Japanese characters to a graph annotation, the recreation macro will include Shift-JIS. If the font controlling the procedure window is MacRoman or Windows, the specified text encoding will be MacRoman or Windows and the Japanese characters will show up wrong in Igor7 or later.

UTF-8 if the text contains non-ASCII characters

MacRoman, Windows and ShiftJIS can all masquerade as UTF-8 though this will be rare. By “masquerade” we mean that the non-ASCII bytes in the text are legal as UTF-8 but the text really is encoded using another text encoding.

For a procedure file you can fix this by adding a TextEncoding pragma.

There is currently no fix for plain text notebooks other than setting "Override Experiment" and setting the default text encoding to the correct encoding and reloading or converting the file to UTF-8 with a byte order mark.

The default text encoding

If set to MacRoman or Windows, the default text encoding will always succeed but it might be wrong. For example, Japanese can be successfully interpreted as MacRoman or Windows but you will get the wrong characters.

For a procedure file you can fix this by adding a TextEncoding pragma.

There is currently no fix for plain text notebooks other than setting "Override Experiment" and setting the default text encoding to the correct encoding and reloading or converting the file to UTF-8.

Plain Text Text Encoding Conversion Errors

When Igor opens a plain-text file or an Igor6-compatible experiment file, it must convert plain text to UTF-8. In order to do this, it needs to determine the text encoding of the plain text file or the plain text item within an experiment file.

As the previous section briefly outlined, it is possible that Igor might get this wrong. To illustrate the types of problems that can occur in this situation, we will consider the following scenario:

> In Igor6.x you have created a standalone (not part of an experiment) plain text file on Windows with English as the system locale so the text in the file is encoded as Windows-1252. The file contains some non-ASCII characters. You transfer the file to Macintosh. Your default text encoding, as selected in the Default Text Encoding submenu of the Misc menu, is Western. You open the plain text file as a notebook in Igor.

Since the file is is a plain text file, it contains nothing but plain text; it does not contain information indicating the platform of origin or the text encoding. Consequently Igor uses your selected default text encoding - Western. In the case of a plain text file, Western means "MacRoman when running on Macintosh, Windows-1252 when running on Windows", so Igor uses MacRoman to convert the text to UTF-8. This does not cause an error but gives an incorrect translation of the non-ASCII characters in the file.

Unfortunately, Igor has no way to detect this kind of misidentification error. The conversion completes without error but produces some incorrect characters and there is no way for Igor to know that this has happened. This is an example of a conversion that succeeds but is incorrect.

To get the correct characters you must close the file, choose Windows-1252 from the Default Text Encoding menu, and reopen the file. Now Igor will correctly translate the text to UTF-8. You should restore the default text encoding to its normal value for future use.

An alternative solution is to execute OpenNotebook/ENCG=3. This explicitly tells Igor that the file's text encoding is Windows-1252. Igor's text encoding codes are listed under **Text Encoding Names and Codes** on page III-490.

Now let's change the scenario slightly:

> Instead of your default text encoding being set to Windows-1252, it is set to Japanese. You open the standalone plain text file containing Windows western non-ASCII characters as a notebook on either Macintosh or Windows.

Since the file does not contain any text encoding information, Igor tries to convert the text to UTF-8 using default text encoding, Japanese, as the original text encoding. Two things may happen:

- The conversion may succeed. In this case you will see some seemingly random Japanese characters in your notebook because, although the conversion succeeded, it incorrectly interpreted the text.
- The conversion may fail because the file contains byte patterns that are illegal in the Shift JIS text encoding. In this case Igor will display the Choose Text Encoding dialog and you can choose the

correct text encoding.

The best solution for text encoding issues is to convert the text to valid UTF-8. Once you have successfully opened the file in Igor, you can convert it to UTF-8 by clicking the text encoding button in the status bar. You can convert all open non-UTF-8 text files to UTF-8 using the Convert to UTF-8 dialog; see **Converting to UTF-8** on page III-485 for details.

UTF-8 Procedure Files Containing Invalid UTF-8

Though rare, it is possible to create a UTF-8 procedure file containing invalid UTF-8. This occurs if you use invalid UTF-8 in a window and save the window as a recreation macro. For example:

```
Display/TestGraph
Textbox "\xC5"              // Invalid UTF-8 text in annotation
DoWindow/R TestGraph        // Save graph as recreation macro
```

This creates a TestGraph window macro that recreates the annotation which contains invalid UTF-8. This is a contrived example, but the situation occurs in real life if, for example, you obtain the text for the annotation from a source (e.g., database) that provides non-ASCII text in a text encoding other than UTF-8 and you fail to convert it to UTF-8.

If you now save the experiment to disk, you will have invalid UTF-8 procedure text in the experiment's built-in procedure window and also in the experiment's recreation macros that Igor executes to recreate the graph window when you reopen the experiment.

Prior to Igor Pro 9.00, you would get confusing errors on reopening the experiment. In Igor Pro 9.00 and later, if a procedure file contains a UTF-8 byte order mark or UTF-8 TextEncoding pragma, the file is loaded as UTF-8 even if it contains byte sequences that are not valid UTF-8. The invalid bytes are preserved in the text and are displayed as Unicode replacement characters (U+FFFD). This allows Igor to recreate the experiment as it was, invalid UTF-8 and all.

Some Plain Text Files Must Be Saved as UTF-8

When Igor saves a plain text file, it tries to save using the file's original text encoding. Sometimes this is not possible. For example:

You open a file that contains MacRoman text including non-ASCII characters as an Igor procedure file and Igor converts it to UTF-8 for internal storage. Now you add a Japanese character to the procedure file and save it.

The file can not be saved as MacRoman because MacRoman can not represent Japanese characters. In this event, Igor saves the file in UTF-8 and displays an alert informing you of that fact. If you open this file in Igor6, any non-ASCII characters will be incorrect.

If you tell Igor to save a plain text file in a specific text encoding, for example via `SaveNotebook/ENCG=<textEncoding>`, and if it is not possible to save in that text encoding, Igor returns a text encoding conversion error. You can then explicitly tell Igor to save as UTF-8 using `SaveNotebook/ENCG=1`.

History Text Encoding

When an experiment is saved, Igor saves the history text as plain text.

When you create a new experiment, Igor sets the history area text encoding to your chosen default text encoding. When you save the experiment, Igor tries to save the history text using that text encoding. If the history text contains characters that can not be represented in your default text encoding, Igor then saves the history text as UTF-8 and sets the history area text encoding to UTF-8. If you open this experiment in Igor6, any non-ASCII characters in the history, including the bullet characters used to mark commands, will appear as garbage.

The Shift JIS (Japanese) text encoding does not have a character that maps to the bullet character (U+2022). Consequently, if your default text encoding is Shift JIS, when you save an experiment, Igor will be unable to save the history text as Shift JIS and will save it as UTF-8 instead.

Byte Order Marks

A byte order mark, called a BOM for short, is a special character sometimes used in Unicode plain text files to identify the file as Unicode and to identify the Unicode encoding form used by the file. The BOM, if present, must appear at the beginning of the file.

A FAQ about BOMs can be found at http://www.unicode.org/faq/utf_bom.html#BOM.

Most Unicode plain text files omit the BOM. However, including it has the advantage of unambiguously identifying the file's text encoding.

The BOM is the Unicode "zero width no-break space" character. It's code point is U+FEFF which is represented by the following bytes:

UTF-8	0xEF 0xBB 0xBF
UTF-16 Little Endian	0xFF 0xFE
UTF-16 Big Endian	0xFE 0xFF
UTF-32 Little Endian	0x00 0x00 0xFF 0xFE
UTF-32 Big Endian	0xFE 0xFF 0x00 0x00

If a Unicode file contains a BOM, Igor preserves it when saving the file.

By default Igor writes a BOM when writing a Unicode plain text file and removes the BOM, if present, when reading a plain text file into memory.

When Igor creates a new plain text file, it sets an internal writeBOM flag for that file to true. If the file is later saved to disk as Unicode and if the writeBOM flag is still set, Igor writes the BOM to the file.

When Igor opens a plain text file, it checks to see if the file contains a BOM. If not it clears the file's writeBOM flag. If the file does contain a BOM, Igor sets the writeBOM flag for the file and removes the BOM from the text as loaded into memory. When Igor writes the text back disk, if the writeBOM flag is set, Igor writes the BOM and then the text.

You can see the state of the writeBOM flag using the File Information dialog which you access via the Notebook or Procedure menu. If the file's text encoding is a form of Unicode and the writeBOM flag is set, the Text Encoding section of the File Information dialog will say "with byte order mark".

You can specify the value of the writeBOM flag for a plain text notebook file using **NewNotebook** with the /ENCG flag.

You can set or clear the writeBOM flag for a plain text notebook or procedure file using the Text Encoding dialog accessed via the Notebook or Procedure menu. The Write Byte Order Mark checkbox is visible only if a Unicode text encoding is selected. You can also set the writeBOM flag for a plain text notebook using the **Notebook** operation, writeBOM keyword.

The built-in procedure window is a special case. Its writeBOM flag defaults to false and it is set to false each time you do New Experiment. We make this exception to allow Igor6 to open an experiment whose procedure window text encoding is UTF-8 without generating an error. Igor6 does not know about UTF-8 so non-ASCII characters will be wrong, but at least you will be able to open the experiment.

If you modify a plain text file that is open as a notebook or procedure file using an external editor, Igor reloads the text from the modified file. This sets the internal writeBOM flag for the notebook or procedure file to true if the modified text includes a BOM or false otherwise. This then determines whether Igor writes the BOM if you later save the file. This process of reloading an externally-modified plain text file overwrites the writeBOM flag that you may have set using the Text Encoding dialog or Notebook operation.

BOMs are irrelevant for formatted text notebooks.

The **FReadLine** operation looks for and skips UTF-8 byte order marks and UTF-16 byte order marks if you specify UTF-16 using the /ENCG flag.

Formatted Text Notebook File Text Encodings

Formatted notebook files use an Igor-specific file format. You can open such a file as a formatted notebook or as an Igor help file.

Unlike plain text files, in which all text must be encoded using a single text encoding, Igor6 formatted notebook files can use multiple text encodings in a single file. In Igor6, the text encoding for a given format run is determined by the font controlling that run. For example, a single Igor6 formatted text file can contain western text and Shift JIS (Japanese) text encodings. In fact a single paragraph can contain multiple text encodings.

We use the term MBCS (multi-byte character system) to distinguish these Igor6 formatted text files from formatted text files saved using UTF-8 by Igor7 or later.

Igor now stores text internally (in memory) as UTF-8. Consequently it must convert MBCS text into UTF-8 when opening Igor6 formatted files. When doing this conversion, Igor uses text encoding information written to the file by IP6.3x and later. Pre-IP6.3x formatted text notebook files lack this text encoding information and so may be misinterpreted. If you open a formatted text notebook and you get incorrect characters or text encoding conversion errors, try opening and resaving the file in Igor Pro 6.3x, and then reopen it.

In Igor Pro 8.00 or later, Igor writes new formatted notebooks and formatted notebooks previously written using UTF-8 as UTF-8. It writes in Igor6-compatible MBCS format only when saving a file that was previously written as MBCS and only if all of the file’s characters can be represented in MBCS. If you open a UTF-8 formatted notebook file in Igor6, any non-ASCII characters will appear garbled.

To determine how a particular file is saved, click the page icon in the lower-lefthand corner of a formatted notebook or help window. The resulting File Information dialog will say either "MBCS" or "UTF-8" in the Text Encoding area.

If you open a UTF-8-formatted text notebook in Igor Pro 6.36 or before and then save the notebook, it is marked as an Igor6 notebook using MBCS even though it really contains UTF-8 text. If you subsequently open the notebook in Igor7 or later, all non-ASCII characters will be incorrectly interpreted as MBCS and will be wrong.

If you open a UTF-8-formatted text notebook in Igor Pro 6.37 or a later 6.x version and then save the notebook, it is marked as using UTF-8 text encoding. Igor6 will still display the wrong characters for non-ASCII text, but if you subsequently open the notebook in Igor7 or later, the non-ASCII characters will be correctly interpreted as UTF-8.

Wave Text Encodings

Each wave internally stores several plain text elements. They are:

- wave name
- wave units
- wave note
- wave dimension labels
- text wave content (applies to text waves only)

Each wave stores five settings corresponding to these five plain text elements. The settings record the text encoding used for the corresponding element.

You can inspect the text encodings of the wave elements of a particular wave using the Data Browser. To do so, you must first enable the Text Encoding checkbox in the Info pane of the Data Browser section of the Miscellaneous Settings dialog.

For waves created prior to Igor6.3x, all of the settings are set to 0 which means "unknown". This is because the notion of wave text encodings was added only in Igor Pro 6.30, in anticipation of Igor7 and its use of Unicode as the primary text storage format.

When you make a wave in Igor6.3x the text encoding for each element is set to the system text encoding (typically MacRoman, Windows-1252 or Japanese) except for the text wave content element which is set to "unknown". The reason for treating the text wave content element differntly is because the data may be binary data as explained below under **Text Waves Containing Binary Data** on page III-475.

When you make a wave in Igor7 or later, including when you overwrite an existing wave, the text encoding for each element, including the text wave content element, is set to UTF-8.

These defaults are set when you make or overwrite a wave using Make, Duplicate, LoadWave and any other operation that creates a wave. After creating the wave, you can change them explicitly using **SetWaveTextEncoding**, but only advanced users should do this.

If you overwrite an existing text wave, the text encoding for each element, including the text wave content element, is set to UTF-8, the same as when you first create the wave. However, the wave's text content is not cleared or converted to UTF-8 because it is presumed that you will be completely rewriting the content and, if Igor cleared or converted it on overwriting, it would be a waste of time. If the wave contains non-ASCII text and its previous text content text encoding was not UTF-8, this leaves the wave with invalid text content. This is normally not a problem since you will completely rewrite the text anyway. But if you want to make sure that there is no invalid text, you can clear the wave's text content in the Make/T/O statement. For example:

```
Make/T/O textWave = ""
```

In addition, the text encoding setting for the wave name is set if you rename the wave and the text encoding for the wave note is set if you change the wave note text. However the text encoding for the wave units is not set if you set the units using SetScale, the text encoding for the dimension labels is not set if you set a dimension label using SetDimLabel, and the text encoding for the text content of a text wave is not set if you store text in an element of the wave.

Opening an experiment does not change the text encoding settings for the waves in the experiment. Neither does saving an experiment.

When Igor uses one of these wave elements, it must convert the text from its original text encoding into UTF-8. It uses the rules listed in the next section to determine the original text encoding.

Determining the Text Encoding for Wave Elements

This section describes the rules that Igor uses to determine the source text encoding for a wave element when loading a wave from an Igor binary wave file or from a packed experiment file. You don't need to know these rules. We present them for technically-oriented users who are interested or who need to understand the details to facilitate troubleshooting.

1. If the element's text encoding is set to UTF-8, Igor uses UTF-8 as the source text encoding.

   Igor saves text as UTF-8 if it can not be represented in another text encoding. This rule ensures that Igor correctly loads such text.

2. Otherwise if Override Experiment is turned on, Igor uses the selected default text encoding as the source text encoding.

This provides a way for you to override incorrect text encoding settings when loading an experiment. For example, if you know that an experiment uses Japanese but you get gibberish or Unicode conversion errors when loading it, you can choose Japanese as your default text encoding, select Override Experiment, and reload the experiment. You should restore the default text encoding to its normal value and turn Override Experiment off for future use.

3. Otherwise if the text encoding for the specific element being converted is known, because it was previously set to a value other than "unknown", Igor uses it as the source text encoding.

   This is the effective rule for waves created by Igor6.3x and later.

   This is also the effective rule if you explicitly set a wave's text encoding settings using the **SetWaveTextEncoding** operation.

4. Otherwise if the experiment file text encoding is known, Igor uses it as the source text encoding.

   This rule takes effect for waves created in earlier versions if the experiment was later saved from Igor6.3x or later. Wave text encoding settings would still be unknown but the experiment file text encoding would reflect the text encoding of the experiment's procedure window when it was saved. This will give correct results for most experiments.

5. Otherwise Igor uses the selected default text encoding as the source text encoding.

   This rule takes effect for experiments saved before Igor6.3x in which both the experiment file text encoding and the element-specific text encodings are unknown. This is the effective rule for experiments of this vintage.

Wave Text Encoding Problems

This section describes the problems that may occur when loading a wave from an Igor binary wave file or from a packed experiment file.

If Igor is not able to correctly determine a wave element's text encoding and if the element contains non-ASCII text you may see gibberish text or Igor may generate a text encoding conversion error.

If Igor is not able to correctly determine the text encoding of a wave name you will see gibberish for the name and Igor will be unable to find the wave when it is referenced from procedures such as experiment recreation procedures. This may cause errors when the experiment is loaded.

Igor’s handling of invalid text in tables is described under **Editing Invalid Text** on page II-259.

The **SetWaveTextEncoding** operation allows you to set the text encodings for one or more waves or for all waves in the experiment. This is especially useful for pre-IP6.3x experiments. You can run it in Igor6.3x or later. It is discussed below under **Manually Setting Wave Text Encodings** on page III-477.

If you get text encoding conversion errors when opening an experiment you can try the following:

- Choose a different text encoding from the Default Text Encoding menu and reopen the experiment
- Select Override Experiment in the Default Text Encoding menu so that it is checked and reopen the experiment
- Manually fix the errors after opening the experiment
- Use the **SetWaveTextEncoding** operation to specify the text encodings used by waves
- For pre-IP63x experiments, open the experiment in Igor6.3x, resave it, and reopen it

After attempting to fix a text encoding problem you should restore your default text encoding to the most reasonable setting for your situation and turn Override Experiment off.

If you are unable to solve the problem you can send the experiment to WaveMetrics support with the following information:

- What operating system you are running

- What Igor version you are running
- What incorrect output you are seeing and what you expect to see

LoadWave Text Encodings for Igor Binary Wave Files

The rules that LoadWave uses to determine the source text encoding of an Igor binary wave file are the same as the rules described under **Determining the Text Encoding for Wave Elements** on page III-473. The LoadWave /ENCG flag is ignored when loading an Igor binary wave file.

LoadWave Text Encodings for Plain Text Files

This section describes the rules that the LoadWave operation uses to determine the source text encoding when loading a plain text file. This includes general text, delimited text and Igor text files but not Igor binary wave files.

The rules that LoadWave uses to determine the source text encoding of a plain text file are the same as the rules described under **Determining the Text Encoding for a Plain Text File** on page III-467. The "specified text encoding", which is one of the factors used by the rules, is unknown unless you use the /ENCG flag to tell LoadWave the file's text encoding.

For further details see **LoadWave Text Encoding Issues** on page II-149.

Text Waves Containing Binary Data

You can set a text wave's content text encoding to the special value 255 using **SetWaveTextEncoding**. This marks a text wave as really containing binary data, not text.

Text is data that is represented by numeric codes which map to characters using some recognized text encoding such as MacRoman, Windows-1252, Shift JIS or UTF-8. By contrast, binary data does not follow any recognized text encoding and generally does not map to characters. Whereas text data is typically intended to be readable by humans using a text editor, binary data is intended to be processed only by programs.

You can mark any text wave element as binary but it is normally done only for text wave content because it is rare to store binary data in wave units, wave notes or wave dimension labels.

Igor text waves were designed to store text but are able to store any collection of bytes.

While a numeric wave stores a fixed number of bytes in each element, a text wave has the ability to store a different number of bytes in each point. For example:

```
Make /O /T /N=2 twave0
twave0[0] = "Hello"                  // 5 bytes
twave0[1] = "Goodbye"                // 7 bytes
```

This capability makes a text wave a convenient way to store a collection of binary arrays of different length. For example, you could store the contents of a different downloaded file in each element of a text wave:

```
Make /O /T /N=2 twave0
twave0[0] = FetchURL("http://www.wavemetrics.net/images/tbg.gif")
twave0[1] = FetchURL("http://www.wavemetrics.net/images/mbg.gif")
```

While most text waves contain text data, clever programmers sometimes use text waves to store binary data. Since binary data does not follow any recognized text encoding, it must not be treated as text. For example, you can convert a text wave from Shift JIS to UTF-8 and preserve the meaning of the text; you are merely changing how the characters are encoded. By contrast, if you attempt to convert binary data which you have mistaken for text, you turn your data into garbage.

The **SetWaveTextEncoding** operation can convert text waves from one text encoding to another but you never want to convert binary text waves. SetWaveTextEncoding conveniently skips text waves marked as binary when doing a conversion but it is up to you to mark such waves appropriately. Here is an example that illustrates the utility of marking a text wave as containing binary data:

```
// Mark contents as binary
SetWaveTextEncoding 255, 16, root:MyBinaryTextWave
// Convert contents to UTF-8 skipping binary waves
SetWaveTextEncoding /DF={root:,1} /CONV=1 1, 16
```

The first command marks a particular wave's content (16) as containing binary (255) as opposed to text. The second command converts all text wave text to UTF-8 (1) except that it automatically skips waves marked as binary.

This is fine but it would be tedious to identify and mark each text wave containing binary data. So SetWaveTextEncoding provides a way to do it automatically:

```
// Mark all binary waves as binary
SetWaveTextEncoding /BINA=1 /DF={root:,1} 255, 16
// Convert to UTF-8 skipping binary waves
SetWaveTextEncoding /DF={root:,1} /CONV=1 1, 16
```

The first command goes through each wave in the experiment. If it is a text wave, it examines its contents. If the wave contains control characters (codes less than 0x20) other than carriage-return (0x0D), linefeed (0x0A) and tab (0x09), it marks the wave as containing binary. Then the second command converts all non-binary text waves to UTF-8. These commands can be combined into one:

```
// Mark as binary then convert non-binary to UTF-8
SetWaveTextEncoding /BINA=1 /DF={root:,1} /CONV=1 1, 16
```

NOTE: The heuristic used by the /BINA flag is not foolproof. While most binary data will contain 0x00 bytes or other bytes that flag it as binary, it is possible to have binary data that contains no such bytes. In that case, the first command would fail to mark the text waves as containing binary and the second command would either return an error or clobber the binary data. For this reason, it is imperative that you back up any data before doing text encoding conversions.

PROGRAMMER'S NOTE: If you are a programmer and you create text waves to store binary data, be sure to mark them as binary. For example:

```
Wave/T bw = <path to some text wave used to contain binary data>
SetWaveTextEncoding 255, 16, bw        // Mark text wave as binary
```

Doing this will ensure that your binary data is not "converted" to some text encoding, thereby clobbering it.

Handling Text Waves Containing Binary Data

Usually you use a text wave containing binary data only as a container to be accessed by procedures that understand how to interpret the contents. You normally should not treat it as text. For example, you should not print its contents to the history because this treat the wave's binary contents as text. If you do treat it as text you are likely to get gibberish or a Unicode conversion error.

You can view a text wave marked as binary in a table and you can cut and paste its cells but you can not edit the binary data in the table’s entry line. You can dump the contents of a cell as hex to the history area by pressing Cmd (*Macintosh*) or Ctrl (*Windows*) and double-clicking the cell.

Igor normally does automatic text encoding conversion when fetching data from a text wave or storing data into a text wave. For example:

```
// Make a wave to contain text in UTF-8 text encoding
Make /O /T UTF8 = {"<some Japanese text>"}      // UTF-8 by default

// Make a wave to contain text in Shift JIS text encoding
Make /O /T /N=1 ShiftJIS                        // UTF-8 by default
SetWaveTextEncoding 4, 16, ShiftJIS             // Now Shift JIS
```

```
ShiftJIS = UTF8
```

The last statement triggers a fetch from the wave UTF8 and a store into the wave ShiftJIS. A fetch converts a text wave's data to UTF-8. In this case it is already UTF-8 so no conversion is done. A store converts the data to the text encoding of the destination wave - Shift JIS in this case. You wind up with the same characters in ShiftJIS and in UTF8 but not the same raw bytes because they are governed by different text encodings.

Igor does not do text encoding conversion when fetching from a wave or storing into a wave if the wave is marked as binary. For example:

```
// Make a wave to contain binary data
Make /O /T /N=1 Binary                          // UTF-8 by default
SetWaveTextEncoding 255, 16, Binary             // Now binary
Binary = UTF8
```

The last statement's storing action does not do text encoding conversion because the destination wave is marked as binary. Thus Binary will wind up with the same bytes as in UTF8.

Now consider this:

```
Binary = ShiftJIS
```

Once again the last statement's storing action does not do text encoding conversion because the destination wave is marked as binary. You might think that Binary would wind up with the same bytes as in ShiftJIS but you would be wrong. The reason is that the fecthing action triggered by evaluating the righthand side of the assignment statement converts the Shift JIS text in ShiftJIS to Igor's internal standard, UTF-8. Consequently the same bytes wind up being stored in Binary after each of the two previous statements.

The moral of the story is that, if you want to transfer binary data between text waves, make sure that both waves are marked as binary. It will also work if the source wave is marked as UTF-8 since the fetch conversion does nothing if the source is UTF-8.

Manually Setting Wave Text Encodings

NOTE: Back up your experiment before fiddling with text encoding settings.

With the concepts of wave plain text elements, their text encoding settings, and text waves containing binary data in mind, we can now consider a general approach for setting wave text encodings. This is a task for advanced users only.

As a test case, we will assume that you created an experiment using Igor Pro 6.22 on Windows with English as the system locale. Consequently the experiment contains waves with all text encoding settings set to unknown. You then opened the experiment in Igor Pro 6.30, again on Windows with English as the system locale, and created additional waves. These added waves have text encoding settings set to Windows-1252 except for the text wave content element which is set to unknown. Finally, somewhere along the line, some text waves were created to store binary data, possibly by a package that you use and without your knowledge.

We now open the experiment in Igor7 or later and try to set all of the text encoding settings to correct known values using the SetWaveTextEncoding operation. The magic numbers used in the following commands are detailed below under **Text Encoding Names and Codes** on page III-490 and **SetWaveTextEncoding**.

```
// Mark any text waves containing binary data as such.
// 255 means "binary". 16 means "text wave content".
// /DF={root:,1} means "all waves in all data folders".
// /BINA=1 means "automatically mark text waves containing binary data".
SetWaveTextEncoding /DF={root:,1} /BINA=1 255, 16

// Mark any wave text elements currently set to unknown as Windows-1252.
// 0 means "unknown". 3 means Windows-1252. 31 means "all wave elements".
// /ONLY=0 means apply the command only to wave elements currently marked as
unknown.
SetWaveTextEncoding /DF={root:,1} /ONLY=0 3, 31
```

Now all elements of all waves are set to Windows-1252 except for the content element of text waves containing binary data which are so marked. In other words, there are no unknown text encodings and all elements are correctly marked. Marking all waves correctly ensures that Igor can correctly convert the wave plain text elements to UTF-8 for internal use.

If you were starting from a MacRoman experiment (Macintosh western text), you would use 2 instead of 3. If you were starting from a Japanese experiment (Shift JIS), you would use 4 instead of 3.

NOTE: The heuristic used by the /BINA flag is not foolproof. See **Text Waves Containing Binary Data** on page III-475 for details.

At this point you may want to convert your waves from Windows-1252 to UTF-8. This provides two advantages. First, Igor will not need to convert to UTF-8 when fetching the text waves' contents since the waves will already be UTF-8. Second, you will be able to use a wider repertoire of characters. The disadvantage is that you will get gibberish for non-ASCII characters if you open the experiment in any pre-Igor7 version. Assuming that you do want to convert to UTF-8, you would execute this:

```
// 1 means UTF-8. 31 means "all wave elements".
// /CONV means "convert text encoding". It automatically skips text wave
// content marked as binary.
SetWaveTextEncoding /DF={root:,1} /CONV=1 1, 31
```

Data Folder Name Text Encodings

Igor Pro 7.00 through 7.01 were unable to correctly load non-ASCII data folder names from Igor6 packed experiment files. Starting with version 7.02, in most cases, Igor correctly loads such data folder names.

If Igor mangles a non-ASCII data folder name when loading an Igor6 experiment, try choosing the correct text encoding from the Misc→Text Encoding→Default Text Encoding menu and turn Misc→Text Encoding→Default Text Encoding→Override Experiment on. Remember to restore these settings to their original settings after loading the experiment.

Starting with Igor Pro 7.02, Igor writes non-ASCII data folder names to packed experiment files using the text encoding of the built-in procedure window if possible. This will be Igor6-compatible if that text encoding is MacRoman on Macintosh or Windows-1252 on Windows. Igor Pro 7.00 through 7.01 expect UTF-8 and will therefore misinterpret such data folder names unless the text encoding of the built-in procedure window is UTF-8.

String Variable Text Encodings

Unlike the plain text elements of waves, there is no text encoding setting for string variables. Consequently Igor treats a string variable as if it contains UTF-8 text when printing it to the history area or when displaying it in an annotation or control panel or otherwise treating it as text.

If you have string variables in Igor6 experiments that contain non-ASCII characters, they will be misinterpreted by Igor7 or later. This may cause gibberish text or it may cause a Unicode conversion error. In either case you must manually fix the problem by storing valid UTF-8 text in the string variable.

For a local string variable, you can achieve this by assigning a new value to the string variable or by converting its contents from its original text encoding to UTF-8 using the **ConvertTextEncoding** function.

For a global string variable, you can achieve this by converting its contents from its original text encoding to UTF-8 using the **ConvertGlobalStringTextEncoding** operation. You need to know the original text encoding. It will typically be MacRoman if the Igor6 experiment was created on Macintosh, Windows-1252 if it was created on Windows, or Shift JIS if it was created using a Japanese version of Igor.

ConvertGlobalStringTextEncoding can convert all global string variables in the current experiment at once. Choose Misc→Text Encoding→Convert Global String Text Encoding to generate a ConvertGlobalStringTextEncoding command.

If you don't print or display a string variable or compare it to other text then its text encoding does not matter. For example, if you have a string variable that contains binary data and it is treated by your procedures as binary data, then everything will work out.

String Variable Text Encoding Error Example

This section gives a concrete example of a text encoding error which may help you to understand text encoding issues. As you read the example, keep these thoughts in mind:

- A text wave stores the raw bytes representing its text and an explicit setting that tells Igor the text encoding of the raw bytes. When you access an element of a text wave, Igor converts it to UTF-8 if it is not already stored as UTF-8 and is not marked as binary. During this conversion Igor uses the wave's explicit text encoding setting.
- String variables and other string expressions do not have text encoding settings and are always assumed to contain text encoded as UTF-8.

This example shows how you can create a text encoding problem and how you can avoid it.

```
Function TextEncodingErrorExample()
   // Make a text wave. Its text encoding defaults to UTF-8.
   Make /O/T/N=1 textWave0

   // Create a string variable containing non-ASCII text (the character ¹).
   // Igor converts literal text ("¹ != 3" in this case) to UTF-8
   // and stores it in the string variable.
   String text = "¹ != 3"                    // Stored as UTF-8

   // Convert the string variable contents to MacRoman.
   // Since the string has no text encoding setting, Igor still assumes it
   // contains UTF-8 but we know it really contains MacRoman.
   Variable textEncodingUTF8 = TextEncodingCode("UTF-8")
   Variable textEncodingMacRoman = TextEncodingCode("MacRoman")
   text = ConvertTextEncoding(text,textEncodingUTF8,textEncodingMacRoman,1,0)

   // Store the MacRoman text in the text wave. This creates bad data
   // because Igor assumes you are storing UTF-8 text in a UTF-8 text wave
   // when in fact you are storing MacRoman into a UTF-8 text wave.
   textWave0 = text                          // Store incorrect data

   // Print - an incorrect character will be printed because the wave's
   // text encoding setting is incorrect for the raw data bytes stored in it.
   Print textWave0[0]

   // Here is one way to fix the problem - convert the string variable to UTF-8.
   String textUTF8 = ConvertTextEncoding(text, textEncodingMacRoman,
                                          textEncodingUTF8, 1, 0)
   textWave0 = textUTF8                      // Store correct data

   // Print again - this time it prints correctly because the wave's
   // raw text bytes are consistent with the wave text encoding setting.
   Print textWave0[0]

   // Create the problem again so we can see another way to fix it.
   textWave0 = text                          // Store incorrect data

   // Here is another way to fix the problem - by correcting Igor's idea
   // of what text encoding the wave is using.
   // Tell Igor that the text wave stores text encoded as MacRoman.
   SetWaveTextEncoding textEncodingMacRoman, 16, textWave0

   // Print again - this time it prints correctly because Igor knows
   // that the wave contains MacRoman and so converts from MacRoman
   // to UTF-8 before sending the text to the history.
   Print textWave0[0]
End
```

Text Encoding Programming Issues

Igor6 and earlier versions of Igor stored text in "system text encoding". For western users this means MacRoman on Macintosh and Windows-1252 on Windows. For Japanese users it means Shift JIS on both platforms.

Igor now uses UTF-8, a form of Unicode, exclusively.

If you are an Igor programmer attempting to support Igor6, and if you or your users use non-ASCII text, the introduction of Unicode in Igor7 entails compatibility challenges.

If you fall in this category, we highly recommend that you abandon the idea of supporting Igor6 and later versions with the same procedure files. Instead, freeze your Igor6 code, and do all new development in a new fork. Here are the reasons for not attempting to support Igor6 and later versions with the same code base:

1. You will be unable to use new features without using ifdefs and other workarounds.
2. The use of ifdefs and workarounds will clutter your code and introduce bugs in formerly working Igor6 code.
3. You will have to deal with tricky text encoding issues, as explained in the next section.
4. Eventually Igor6 will be ancient history.

The alternative to supporting both Igor6 and later versions with the same procedure files is to create two versions of your procedures, one version for Igor6 and another for Igor7 and beyond. The benefits of this approach are:

1. You avoid cluttering your Igor6 code or introducing new bugs in it.
2. It will be much easier to write new code and it will be cleaner.
3. Your new code can use the full range of Unicode characters.

The costs of this approach are:

1. If you fix a bug in the Igor6 version of your code, you will have to fix it in the new version also.
2. New features of your code will be unavailable to Igor6 users.

The next section gives a taste of the text encoding issues raised by the use of Unicode starting with Igor7.

Literal Strings in Igor Procedures

Consider this function, which prints a temperature with a degree sign in Igor's history area:

```
Function PrintTemperature(temperature)
   Variable temperature

   // The character after %g is the degree sign
   Printf "The temperature is %g°\r", temperature
End
```

The degree sign is a non-ASCII character. It is encoded as follows:

MacRoman	0xA1
Windows-1252	0xB0
Shift JIS (Japanese)	0x81 0x8B
UTF-8	0xC2 0xB0

To simplify the discussion, we will ignore the issue of Japanese.

If you created the procedure file in Igor6 on Macintosh, it would work correctly in Igor6 on Macintosh but would print the wrong character in Igor6 on Windows. If you opened the procedure file in Igor7 or later with "Western" selected in Misc→Text Encoding→Default Text Encoding, it would work correctly on Macintosh but would print the wrong character on Windows. If you added this to the procedure file:

```
#pragma TextEncoding = "MacRoman"
```

it would work correctly in Igor7 or later on both Macintosh and Windows.

Literal Strings in Igor6/Igor7 Procedures

If you want it to work in Igor6 and Igor7 or later, on Macintosh and Windows, and irrespective of the text encoding of the procedure file and the Misc→Text Encoding→Default Text Encoding setting, you will need to do this:

```
#if IgorVersion() >= 7.00
   static StrConstant kDegreeSignCharacter = "\xC2\xB0"
#else
   #ifdef MACINTOSH
      static StrConstant kDegreeSignCharacter = "\241"
   #else
      static StrConstant kDegreeSignCharacter = "\260"
   #endif
#endif

Function PrintTemperature(temperature)
   Variable temperature

   // The character after %g is the degree sign
   Printf "The temperature is %g%s\r", temperature, kDegreeSignCharacter
End
```

This code uses escape sequences instead of literal characters to keep non-ASCII characters out of the procedure file. This allows it to work regardless of the text encoding of the procedure file in which it appears. For Igor7 or later, it uses the \xXX hexadecimal escape sequence. Igor6 does not support \xXX so it uses octal (\OOO) instead.

The section **Determining the Encodings of a Particular Character** on page III-482 shows how we determined the hex and octal codes.

The reason for making the StrConstants static is that other programmers may include the same code, causing a compile error if a user uses both sets of procedures.

The string constant kDegreeSignCharacter produces the correct string in Igor6 on Macintosh and Windows, and in Igor7 or later on Macintosh and Windows.

This will not print the right character for an Igor6 user using a Japanese font for the history area. Since you can not know the user's history area font, there is no way to cope with that.

If you have code that assumes that degree sign is one byte, you will need to modify it, since it is two bytes in UTF-8.

If the degree sign is the only non-ASCII character that you need to represent in Igor6 and Igor7 or later, this problem is manageable. If not, you will need similar code for other characters. The additional complexity and kludginess will get out of hand. That's why we recommend against supporting Igor6 and Igor7 or later with the same set of procedures.

Literal Strings in Igor7-only Code

If your procedure file requires Igor7 or later, you can write the PrintTemperature function in the obvious way:

```
#pragma TextEncoding = "UTF-8"
#pragma IgorVersion = 7.00

Function PrintTemperature(temperature)
   Variable temperature

   // The character after %g is the degree sign
   Printf "The temperature is %g°\r", temperature
End
```

This will work in Igor7 or later on Macintosh and Windows, and without regard to the user's history font or the Misc→Text Encoding→Default Text Encoding setting.

Unlike the previous approaches, this technique allows you to use any Unicode character, not just the small subset available in MacRoman or Windows-1252.

Determining the Encodings of a Particular Character

This section shows a method for determining how a given character is encoded in MacRoman, Windows-1252, and UTF-8. The commands must be executed in Igor7 or later because they use the ConvertTextEncoding function which does not exist in Igor6.

```
// Print MacRoman code for degree sign as octal - Prints 241
Printf "%03o\r", char2num(ConvertTextEncoding("°", 1, 2, 1, 0)) & 0xFF

// Print Windows-1252 code for degree sign as octal - Prints 260
Printf "%03o\r", char2num(ConvertTextEncoding("°" , 1, 3, 1, 0)) & 0xFF

// Print number of bytes of UTF-8 degree sign character - Prints 2
Printf "%d\r", strlen("°")

// Print first byte of UTF-8 for degree sign as hex - Prints C2
Printf "%02X\r", char2num("°"[0]) & 0xFF

// Print second byte of UTF-8 for degree sign as hex - Prints B0
Printf "%02X\r", char2num("°"[1]) & 0xFF
```

Using the printed information, we created the following Igor6/Igor7 code. It uses a hex escape sequence in Igor7 or later and an octal escape sequence in Igor6 because Igor6 does not support hex escape sequences.

```
#if IgorVersion() >= 7.00
   static StrConstant kDegreeSignCharacter = "\xC2\xB0"
#else
   #ifdef MACINTOSH
      static StrConstant kDegreeSignCharacter = "\241"
   #else
      static StrConstant kDegreeSignCharacter = "\260"
   #endif
#endif

Function PrintTemperature(temperature)
   Variable temperature
   // The character after %g is the degree sign
   Printf "The temperature is %g%s\r", temperature, kDegreeSignCharacter
End
```

This web page is a useful resource for comparing MacRoman and Windows-1252 text encodings:
https://kb.iu.edu/d/aesh

The MacRoman column is labeled "Mac OS" and the Windows-1252 column is labeled "Windows". The Latin1 column is a subset of Windows-1252.

You can see from the table that there are many characters that are available in MacRoman but not in Windows-1252 (e.g., Greek small letter pi) and vice-versa (e.g., multiplication sign). This is one of the reasons for switching to Unicode.

The left column of the table shows UTF-16 character codes. The table does not show UTF-8. You can convert a UTF-16 character code to UTF-8 text in Igor7 or later like this:

```
String piCharacter = "\u03C0"
```

For details on "\u", see **Escape Sequences in Strings** on page IV-14.

Other Text Encodings Issues

This section discusses miscellaneous issues relating to text encodings.

Characters Versus Bytes

In olden times, each character was represented in memory by a single byte. For example, in ASCII, A was represented by 0x41 (0x means hexadecimal) and B was represented by 0x42. Life was simple.

A single byte can represent 256 unique values so it was possible to represent 256 unique characters using a single byte. This was enough for western languages.

There came a time when people wanted to represent Asian text in computers. There are far more than 256 Asian characters, so multi-byte character sets (MBCS), such as Shift JIS, were invented. In MBCS, the ASCII characters are represented by one byte but most Asian characters are represented by two or more bytes. At this point, the equivalence of character and byte was no more and it became important to distinguish the two.

For example, in Igor6, the documentation for strlen said that it returns the number of characters in a string. This was true for western text but not for Asian text. The documentation was changed in Igor7 to say that strlen returns the number of bytes in a string.

In Igor7, Igor was changed to store text internally as UTF-8, a byte-oriented Unicode encoding form. In UTF-8, ASCII characters are represented by the same single-byte codes as in ASCII, thus providing complete backward compatibility for ASCII text. However, all non-ASCII characters, including accented characters, Greek letters, math symbols and special symbols, are represented by multiple bytes. A given character can consist of 1, 2, 3 or 4 bytes. The payback for this complexity is that UTF-8 can represent nearly every character of nearly every language.

In Igor6, this command prints 1 but in Igor7 or later, it prints 2:

```
Print strlen("µ")
```

This distinction is immaterial when you treat a string as a single entity, which is most of the time. For example, this code works correctly regardless of how characters are represented:

```
String units = "µs"
Printf "The units are %s\r", units
```

It is when you tinker with the contents of a string that it makes a difference. This works correctly in Igor6 and incorrectly in Igor7 or later:

```
String units = "µs"
Printf "The unit prefix is %s\r", units[0]
```

This fails in Igor7 or later, and prints a missing character symbol, because the expression "units[0]" returns a single byte, but in UTF-8, "µ" is represented by two bytes. Therefore "units[0]" returns the first byte of a two-byte character and that is an invalid character in UTF-8.

If you are tinkering with the contents of a string, and if the string may contain non-ASCII text, you need to be clear when you want to go byte-by-byte and when you want to go character-by-character. To go byte-by-byte, you merely use sequential indices. At present, there is no built-in support in Igor for going character-by-character. See **Character-by-Character Operations** on page IV-173 for an example of stepping through characters using user-defined functions.

Automatic Text Encoding Detection

Techniques exist for attempting to determine a file's text encoding from the codes it contains. Such techniques are unreliable, especially with the kind of text commonly used in Igor. Consequently Igor does not use them.

Much of Igor plain text is procedure text. Procedure text is mostly ASCII, sometimes with a smattering of non-ASCII characters. The non-ASCII characters may be, for example, MacRoman, Windows-1252, or Japanese.

There is no reliable way to distinguish MacRoman from Windows-1252 or to reliably distinguish a procedure file that contains a smattering of non-ASCII western text from one that contains a smattering of Japanese.

For example, consider an Igor procedure file that contains just one Japanese two-byte character encoded in Shift JIS by the bytes 0x95 and 0x61. This can be interpreted as:

Shift JIS:	CJK UNIFIED IDEOGRAPH-75C5
MacRoman:	LATIN SMALL LETTER I WITH DIERESIS, LOWERCASE LETTER A
Windows-1252:	BULLET, LOWERCASE LETTER A

All three of these interpretations are possible and choosing among them is guesswork so Igor does not attempt to do it.

Shift JIS Backslash Issue

Because Igor now internally process all text as UTF-8, it must convert text that it reads from files that use other encodings. A special issue arises with Japanese text stored in Shift JIS format.

In Shift JIS, the single-byte code 0x5C is hijacked to represent the half-width yen symbol. In ASCII, 0x5C represents the backslash character. When Shift JIS text is converted to UTF-8, Igor's conversion software leaves 0x5C unchanged. Thus its interpretation changes from a half-width yen symbol to a backslash symbol.

In most cases this is the desired behavior because the half-width yen symbol is used in Japanese like the backslash in ASCII - to separate elements of Windows file system paths and to introduce escape sequences in literal strings.

If you are using a half-width yen symbol as a currency symbol then this conversion will be wrong and you will have to manually convert it to a half-width yen symbol by editing the text.

In UTF-8, the half-width yen currency symbol is represented by the code units 0xC2 and 0xA5. It can be entered in a literal text string as "\xC2\xA5".

Converting to UTF-8

In Igor Pro 7 and later, Igor uses UTF-8 text encoding, a form of Unicode, to store text.

Non-Unicode text encodings, including MacRoman, Windows-1252, and Shift JIS, which were used in Igor Pro 6 and before, are antiquated. During the transition from Igor6 to Igor7, backward compatibility with Igor6 was needed so that Igor7 users could share files with Igor6 users. Starting with Igor9, we operate on the premise that compatibility with Igor6 is no longer needed.

Although non-Unicode text encodings are antiquated, Igor can continue to open old files that use them and it is often best to leave those files as they are. Nonetheless, there may be situations where it is beneficial to convert old files to Unicode. For example, if you are exporting data to another program, you may want to convert to UTF-8 for compatibility. This is especially true when exporting as HDF5 because HDF5 has no support for text encodings other than ASCII and UTF-8.

In Igor, text encoding is an issue primarily for three types of objects:

- Waves (for both wave properties and text wave data)
- Text files (plain text notebooks and procedure files)
- String variables

Igor stores text encoding settings for waves and text files. In Igor Pro 9 and later, Igor defaults to UTF-8 for new waves and text files. Igor7 and Igor8 defaulted to UTF-8 for new waves but for new text files it defaulted to the user-specified default text encoding set using the Misc→Text Encoding→Default Text Encoding submenu.

Unlike waves and text files, Igor does not store text encoding settings for string variables. Consequently Igor assumes that a string variable is encoded as UTF-8 when printing it to the history area or when displaying it in an annotation or control panel or otherwise treating it as text. This assumption will be correct for string variables containing only ASCII text and for non-ASCII string variables created by Igor7 or later. It will be incorrect for non-ASCII string variables created by Igor6 or before; these need to be converted to UTF-8 for proper display.

As explained under **Text Encoding Overview** on page III-460, the UTF-8 text encoding includes the ASCII text encoding as a subset. Consequently, converting ASCII to UTF-8 is a trivial operation that does not change the stored bytes. Converting non-ASCII to UTF-8 changes both the number of bytes stored and their values.

To facilitate conversion to UTF-8, Igor9 and later provide the Convert to UTF-8 Text Encoding dialog which you can invoke via the Misc→Text Encoding submenu.

The Convert to UTF-8 Text Encoding Dialog

The Convert to UTF-8 Text Encoding dialog facilitates conversion of waves, global string variables, and text files to UTF-8. The dialog presents four tabs - a Summary tab plus a tab for each type of object that can be converted.

When you click the Convert Waves, Convert Strings, or Convert Text Files buttons, conversions are done on objects in memory only. If you then save the experiments, these objects are written to disk.

Back Up Before Converting to UTF-8

You should back up all data before using the Convert to UTF-8 Text Encoding dialog. Possible problems include:

- Converting objects to UTF-8 that you need to access using Igor Pro 6
- Choosing the wrong source text encoding when converting strings and waves whose text encoding is unknown

- Converting wave text data or strings which contain binary data, not text

Although these problems should be rare, they are possible, so you should back up any data that may be affected before doing conversions.

The Summary Tab

The Summary tab provides an overview of what conversions the other tabs can perform.

The Waves Tab

The Waves tab lists all of the waves in the experiment that use non-UTF-8 text encodings or which appear to contain binary data but are not so marked.

As described under **Wave Text Encodings** on page III-472, each wave has separate text encoding settings for each of five elements: the wave name, the wave units, the wave note, the wave dimension labels, and the wave text content (applies to text waves only). However, for the vast majority of waves, all of these elements will use the same text encoding.

In general, waves created in Igor7 or later use UTF-8 text encoding. Such waves do not need to be converted to UTF-8 and do not appear in the Waves tab unless they appear to contain binary data (details below).

Waves created in Igor6 or before typically use MacRoman, Windows-1252, or Shift JIS (Japanese) text encodings. Such waves can be converted to UTF-8 and do appear in the Waves tab.

A wave element's text encoding may be "Unknown". This is the case for waves written by Igor versions prior to 6.30. If such a wave contains non-ASCII text, to convert it to UTF-8, Igor needs to know what text encoding to convert from. This is controlled by the text encoding pop-up menu to the right of the Convert Waves button. Choose a text encoding from the pop-up menu. Then hover the mouse over the Conversions Required column to see snippets of the wave's non-ASCII text rendered using the text encoding you chose. If the snippets appear incorrect, try choosing a different text encoding from the pop-up menu.

As described under **Text Waves Containing Binary Data** on page III-475, some text waves may be used to contain binary data rather than text. Such waves are created by Igor packages for specialized purposes. Waves that appears to contain binary but are not so marked are included in the list of waves needing conversion. On conversion, Igor marks their text content as binary.

The Waves tab is built on the SetWaveTextEncoding operation. Because it is intended for use by experts or by users instructed by experts, the SetWaveTextEncoding operation does not respect the lock state of waves. That is, it will change waves even if they are locked using SetWaveLock. The Waves tab inherits this behavior and so also does not respect the lock state of waves.

The list in the Waves tab comprises five columns:

Wave: Lists the full data folder path to each wave.

Kind: Indicates if a given wave is a "home" wave, meaning that it is part of the current experiment, or a "shared" wave, meaning that it is stored outside of the current experiment.

A wave that is stored in a packed experiment file or in the experiment folder of an unpacked experiment is a home wave. Otherwise it is a shared wave. A wave that is shared may be used by multiple experiments. See **Home Versus Shared Waves** on page II-87 for background information.

Encoding: Shows the text encoding governing the wave or "Mixed" if the wave uses multiple text encodings. Hover the mouse over "Mixed" to see which wave elements are governed by which text encodings.

Conversions Required: Shows which wave elements contain text that can be converted to UTF-8. Hover the mouse over an item to see a snippet of the non-ASCII text which the wave contains. This column also identifies text waves whose data appears to be binary but which are not yet marked as binary. Before the conversion, the column shows conversions that are required for each wave. After the conversion, it remains unchanged and should be understood as "conversions that were required" rather then "conversions that are required".

Status: After you click the Convert Waves button, this column shows the outcome of the conversion - if the conversion succeeded or if there was an error.

You can double-click a cell to display a modal Data Browser dialog for closer inspection of a wave.

Select one or more cells in the list and click Edit Waves to close the dialog and display a table showing those waves. If you click Edit Waves when no cells are selected in the list, all of the waves are displayed in the table.

Two checkboxes under the list of waves control whether waves requiring non-trivial changes and trivial changes are displayed in the list.

Waves containing non-ASCII text using a text encoding other than UTF-8 are deemed to require a non-trivial change. Also, text waves in which the text data content appears to contain binary data but which are not yet marked as binary are deemed to require a non-trivial change.

Waves containing ASCII text only but which are marked as using a non-UTF-8 text encoding are deemed to require a trivial change. Because the text is ASCII only, and because ASCII text is the same in all text encodings used in Igor waves, no actual text conversion is required. The wave elements just need to be marked as UTF-8.

You may find it convenient to convert the waves requiring trivial changes only first to get them out of the way so that you can focus on those that require non-trivial conversion.

Two checkboxes under the list of waves control whether home waves and shared waves are displayed in the list. Converting shared waves increases the possiblity that the conversion may adversely affect other experiment but this is usually a concern only if you need Igor6 compatibility.

Below the checkboxes, Igor displays an explanation of what waves need conversion.

If no items in the list are selected, clicking the Convert Waves button converts all of the waves in the list. The Status column then indicates if the conversion succeeded or failed.

If items are selected in the list, the Convert Waves button changes to Convert Selected Waves. Clicking the button converts the selected waves only.

After doing a conversion, the Convert Waves button changes to Refresh. Clicking Refresh refreshes the list, showing waves remaining to be converted, if any.

The Strings Tab

The Strings tab lists the global string variables in the experiment and allows you to convert those that need conversion.

As described under **String Variable Text Encodings** on page III-478, unlike waves, there is no text encoding setting for string variables. Consequently Igor treats each string variable as if it contains UTF-8 text when printing it to the history area or when displaying it in an annotation or control panel or otherwise treating it as text.

If a string was created in Igor6 or before and contains non-ASCII characters, treating it as UTF-8 results in incorrect characters being displayed. The Strings tab allows you to fix this by converting such strings to UTF-8.

The following types of strings do not need to be converted:

- Strings containing only ASCII characters
- Strings that are already valid as UTF-8
- Strings that appear contain binary data (typically created by procedure packages)

This leaves non-ASCII, non-binary strings that are not valid as UTF-8 to be converted.

To convert text to UTF-8, Igor needs to know the text encoding in effect when the text was entered. For string variables created in Igor7 and later, this will be UTF-8, and such string variables require no conversion. String variables created in Igor6 or before typically use MacRoman, Windows-1252, or Shift JIS (Japanese) text encodings and require conversion if they contain non-ASCII text.

An experiment may contain a combination of non-UTF-8 strings and UTF-8 strings. This happens if you create non-ASCII strings in Igor6 or before and then create more non-ASCII strings in the same experiment in Igor7 or later.

Since string variables have no text encoding settings, there is no way for Igor to know what text encoding was used to create them. Instead, in the Strings tab of the dialog, Igor uses the text encoding selected in the pop-up menu below the list of strings. When you enter the dialog, the pop-up menu is set to the text encoding governing the experiment, if it is known. As described below, you may need to choose a different text encoding from the pop-up menu.

The list in the Strings tab comprises three columns:

String: Lists the full data folder path to the string variable.

Contents: Shows the contents of the string variable.

The contents of strings that need to be converted are displayed assuming that their text was entered using the text encoding selected in the pop-up menu. If the displayed contents appear incorrect then you probably need to select another text encoding.

Strings that appear to contain binary are not converted and are displayed using hex escape codes for bytes that don't appear in normal ASCII text, such as "\x00" to represent a null byte.

Strings that are already valid as UTF-8, which includes ASCII strings since ASCII is a subset of UTF-8, also do not need to be converted and are displayed as UTF-8.

Status: The Status column displays the following:

Can be converted	The string can be converted to UTF-8 using the text encoding selected in the popup menu. The string will be converted when you click the Convert Strings button if it is selected or if no strings are selected.
Converted to UTF-8	The string was converted to UTF-8 using the text encoding selected in the popup menu. This appears after you click the Convert Strings button.
<An error message>	The string needs to be converted but can not be converted using the text encoding selected in the popup menu.
ASCII	The string is plain ASCII and does not need to be converted.
Valid non-ASCII UTF-8	The string contains non-ASCII text that is valid as UTF-8 and does not need to be converted.
Binary detected	The string appears to contain binary data and will not be converted.

Two checkboxes under the list of strings control whether strings that require conversion or do not require conversion are displayed in the list.

Strings that contain non-ASCII text that is not valid as UTF-8 and which do not appear to contain binary data need to be converted to UTF-8. Such strings appear in the list when the Show Strings That Need to be Converted checkbox is checked.

Strings that that appear to contain binary data, are all ASCII, or contain non-ASCII text that is already valid as UTF-8 do not need to be converted to UTF-8. Such strings appear in the list when the Show Strings That Do Not Need to be Converted checkbox is checked. You may want to display these strings to verify that their contents looks right.

To prevent confusion, it is usually best to examine these two classes of strings separately. Display the strings that do not need conversion only and examine them. When you are satisfied that they are correct, display the strings that need conversion only and proceed.

All string variables are stored as part of the current experiment so there are no "shared" string variables. Consequently, the Home and Shared checkboxes that appear in the Waves and Text Files tabs are not present in the Strings tab.

Inspect the text in the Contents column. If it appears correct, click the Convert Strings button to convert the strings to UTF-8. If it appears incorrect, choose a different text encoding from the pop-up menu and inspect the Contents column again.

Below the checkboxes, Igor displays an explanation of what strings need conversion.

When you click Convert Strings, Igor converts text strings from the selected text encoding to UTF-8. It skips strings that do not need conversion, if they are displayed in the table.

If no items in the list are selected, clicking the Convert Strings button converts all of the strings in the list that need to be converted. If items are selected in the list, the button changes to Convert Selected Strings and clicking it converts the selected strings only and only if they need to be converted. Strings that do not need to be converted are skipped in either case.

The Text Files Tab

The Text Files tab lists all of the text files (plain text notebooks and procedure files) in the experiment that are marked as using a non-UTF-8 text encoding, whether they contain non-ASCII text or not. It also lists "History" if the history area of the command window is marked as using a non-UTF-8 text encoding.

Global procedure files and #included procedure files are not considered part of the current experiment and are not displayed in the list of text files. The programmer responsible for these files should convert them to UTF-8.

The list in the Text Files tab comprises five columns:

Window Title: The title of the notebook or procedure window, or "History" for the history area of the command window.

Window Name: The window name for notebooks. The history area of the command window and procedure windows have no names.

Window Type: The type of window: procedure, notebook, or history.

This column also indicates if the text file is a "home" text file, meaning that it is part of the current experiment, or a "shared" text file, meaning that it is stored outside of the current experiment. See **Home Versus Shared Text Files** on page II-56 for background information.

File Name: The name of the file associated with the window if it has been saved to a standalone file.

Text Encoding: The text encoding currently associated with the window.

Two checkboxes under the list of text files control whether home text files and shared text files are displayed in the list. Converting shared text files increases the possiblity that the conversion may adversely affect other experiment but this is usually a concern only if you need Igor6 compatibility.

If no items in the list are selected, clicking the Convert Text Files button converts all of the files in the list, except for files open for read-only which are skipped. If items are selected in the list, the button changes to Convert Selected Text Files and clicking it converts the selected files only, except for files open for read-only which are skipped.

Unlike read-only files, write-protected files are converted, because write-protect is intended to protect against inadvertent manual editing only.

When a given text file is successfully converted, its entry in the Text Encoding column changes to "UTF-8".

After doing a conversion, the Convert Text Files button changes to Refresh. Clicking Refresh refreshes the list, showing text files remaining to be converted, if any.

Text Encoding Names and Codes

Igor operations and functions such as **ConvertTextEncoding**, **SaveNotebook**, **WaveTextEncoding** and **SetWaveTextEncoding** accept text encoding codes as parameters or return them as results.

The functions **TextEncodingName** and **TextEncodingCode** provide conversion between names and codes. For most Igor programming purpose, you need the code, not the name.

For each text encoding supported by Igor there is one text encoding code. This code may correspond to one or more text encoding names. For example, code 2 is the Macintosh Roman text encoding and corresponds to the text encoding names "macintosh", "MacRoman" and "x-macroman".

Because spelling of text encoding names is inconsistent in practice, Igor recognizes variant spellings such as "Shift JIS", "ShiftJIS", "Shift_JIS" and "Shift-JIS". When comparing text encoding names, Igor ignores all non-alphanumeric characters. It also ignores leading zeros in numbers embedded in text encoding names so that "ISO-8859-1" and "ISO-8859-01" refer to the same text encoding. It uses a case-insensitive comparison.

Some of the entries in the table below are marked NOT SUPPORTED. These are not supported because the ICU (International Components for Unicode) library, which Igor uses for text encoding conversions, does not support it. "Not supported" means that the TextEncodingName and TextEncodingCode functions do not recognize these text encodings and Igor can not convert to them or from them.

Text Encoding Name	**Code**	**Notes**
None	0	Means the text encoding is unknown
UTF-8	1	Unicode UTF-8
macintosh, MacRoman, x-macroman	2	Macintosh Western European
Windows-1252	3	Windows Western European
Shift_JIS	4	Predominant Japanese text encoding
MacJapanese, x-mac-japanese	4	Virtually the same as Shift_JIS
Windows-932	4	Virtually the same as Shift_JIS
EUC-JP	5	Japanese, typically used on Unix
Big5	20	Traditional Chinese
x-mac-chinesetrad	20	Virtually the same as Big5
Windows-950	20	Virtually the same as Big5
EUC-CN	21	Simplified Chinese
x-mac-chinesesimp	21	Simplified Chinese
Windows-936	21	Simplified Chinese
ISO-2022-CN	22	Simplified Chinese
GB18030	23	Official text encoding of the PRC. Encompasses Traditional Chinese and Simplified Chinese. Compatible with Windows-936.
EUC-KR, x-mac-korean	40	Macintosh Korean

Text Encoding Name	Code	Notes
Windows-949, ks_c_5601-1987	41	Windows Korean
ISO-2022-KR	42	Korean text encoding not used on Macintosh or Windows
x-mac-arabic	50	Macintosh Arabic. NOT SUPPORTED.
Windows-1256	51	Windows Arabic
x-mac-hebrew	55	Macintosh Hebrew
Windows-1255	56	Windows Hebrew
x-mac-greek	60	Macintosh Greek
Windows-1253	61	Windows Greek
x-mac-cyrillic	65	Macintosh Cyrillic
Windows-1251	66	Windows Cyrillic
x-mac-thai	70	Macintosh Thai. NOT SUPPORTED.
Windows-874	71	Windows Thai
x-mac-ce	80	Macintosh Central European
Windows-1250	81	Windows Central European
x-mac-turkish	90	Macintosh Turkish
Windows-1254	91	Windows Turkish
UTF-16BE	100	UTF-16, big-endian
UTF-16LE	101	UTF-16, little-endian
UTF-32BE	102	UTF-32, big-endian
UTF-32LE	103	UTF-32, little-endian
ISO-8859-1, Latin1	120	ISO standard western European
Symbol	150	Used by Symbol font
Binary	255	Indicates data is really binary, not text

Binary is not a real text encoding. Rather it marks data stored in a text wave as containing binary rather than text. See **Text Waves Containing Binary Data** on page III-475 for details.

Symbol Font

Igor Pro 6 and before used "system text encoding", typically MacRoman on Macintosh and Windows-1252 on Windows. These text encodings can represent a maximum of 256 characters because each character is represented by a single byte and a single byte can represent only 256 unique values from 0 to 255.

Most Greek letters can not be represented in MacRoman or Windows-1252. Because of that, people resorted to Symbol font when they wanted to display special characters, such as Greek letters. In system text encoding, Symbol font is treated specially. For example, the byte value 0x61 (61 hex, 97 decimal), which is normally interpreted as "small letter a", is interpreted in Symbol font as "Greek small letter alpha".

Thus, in Igor6, to create a textbox that displayed a Greek small letter alpha, you needed to execute this:

```
TextBox "\\F'Symbol'a"
```

Because Igor now uses Unicode, you have at your disposal a wide range of characters of all types without changing fonts. To create a textbox that displays a Greek small letter alpha, you simply execute this:

```
TextBox "α"
```

Also, Symbol font is no longer treated specially. Consequently this:

```
TextBox "\\F'Symbol'a"
```

displays a "small letter a", not a "small Greek letter alpha". This is a departure from Igor6 and creates compatibility issues.

You can copy Symbol font characters to the clipboard as Unicode using the **Symbol Font Characters** table. You can insert Unicode characters by choosing Edit→Characters for commonly-used characters such as Greek letters and math symbols or Edit→Special Characters for other characters. In the Add Annotation dialog and in the Axis Label tab of the Modify Axis dialog, you can click Special and choose a character from the Character submenu.

Symbol Font Backward Compatibility

The use of Unicode greatly simplifies the display of Greek letters and other special characters. But it creates an incompatibility with Igor6. Without special handling, when Igor loads an Igor6 file, Symbol font text meant to display Greek letters would display Roman letters instead. This section explains how Igor deals with this issue to provide backward compatibility.

When loading Igor6-compatible procedure files, which use system text encoding, including the experiment recreation procedures that execute when you open an Igor6-compatible experiment file, Igor attempts to convert incoming Symbol font characters to Unicode. For compatibility with Igor6, the reverse is done on writing procedure files, including experiment recreation procedures, using system text encoding. The conversion is also done for Igor6-compatible formatted notebook files which use system text encoding. This conversion is done using a heuristic that involves scanning for certain patterns and consequently is not, and can not be, perfect.

There may be cases where this attempt at backward compatibility creates problems, for example, if you don't care about Igor6 compatibility. If you want to turn Symbol font compatibility off, you can execute

```
SetIgorOption EnableSymbolToUnicode=0
```

and reload the experiment.

If you encounter Symbol font problems and the information below does not provide the solution, please let us know, and provide the original Igor6 text that caused the problem.

Symbol Font Backward Compatibility Limitations

An important limitation is that, in the original Igor6 experiment, Symbol font specifications in annotations must not include anything other than the Symbol characters. No escape sequences, such as font size specifications, are allowed. For example, Igor will not handle this Igor6 text:

```
TextBox/C/N=text0/F=0/A=MC "\\Z18A\\F'Symbol'\\Bq\\F]0"
```

because the subscript escape code, "\\B", is inside the Symbol font escape sequence and prevents Igor from recognizing this as a Symbol font sequence. As a result, you will see a "q" character instead of the intended small Greek letter theta character.

To enable Igor to recognize this as Symbol text, move the subscript escape code outside the Symbol font escape sequence, like this:

```
TextBox/C/N=text0/F=0/A=MC "\\Z18A\\B\\F'Symbol'q\\F]0"
```

When creating graphics for compatibility with Igor6 or for EPS export, use Unicode characters, like this:

```
TextBox/C/N=text0/F=0/A=MC "\\Z18A\\B\\F'Symbol'θ\\F]0"
```

When Igor writes this out to a procedure file, it will convert the Symbol font sequence into an Igor6-compatible sequence, by replacing the Unicode theta character with "q".

If you don't care about compatibility with Igor6 or EPS export, you don't need to use Symbol font. You can instead write:

```
TextBox/C/N=text0/F=0/A=MC "\\Z18A\\Bθ"
```

On Macintosh, you might still want to specify Symbol font because it provides almost all of the Symbol characters and you may prefer its style compared to other fonts.

Zapf Dingbat Font

Igor deals with Zapf Dingbats font in the same way. Zapf Dingbats was widely available on Macintosh in previous millennium.

Symbol Tips

On Windows, because Igor now uses Unicode, Symbol font does not appear to be useful. Consequently, Igor substitutes another font when Symbol is encountered.

To insert frequently-used symbol characters, such as Greek characters and math symbols, choose Edit→Characters.

In the Add Annotation dialog and in the Axis Label tab of the Modify Axis dialog, you can click Special and choose a character from the Character submenu.

Symbol Font Characters

The “Text Encoding.ihf” help file includes a list of Symbol font characters. To display it, execute:

```
DisplayHelpTopic "Symbol Font Characters"
```

You can copy the characters as Unicode from that section of the help file and paste them into another window.

Symbols with EPS and Igor PDF

Both EPS and PDF include Symbol font as one of their standard supported fonts. When inserting a character from the above list, you can either specify Symbol font or you can use a Unicode font that supports those characters.

In the case of Symbol font, Igor translates the Unicode code point to the corresponding Symbol single byte code (unless you have specified that even standard fonts be embedded) and such characters in the resulting file will be editable in a program such as Adobe Illustrator. The alternative is to specify a font such as Lucida Sans Unicode in which case the characters are embedded using an outline font and will not be editable.

Be sure to specify either Symbol or a font that will be embedded because it is likely that the current default font is one of the EPS or PDF standard supported fonts. These are not Unicode and the result will not be what you expect.

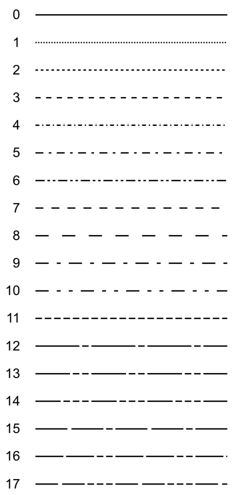
Chapter

III-17

Miscellany

Dashed Lines

You can display traces in graphs, as well as drawn lines, rectangles, ovals, and polygons, using various line styles. This table, generated from the ColorsMarkersLinesPatterns.pxp example experiment, shows Igor’s default line styles:



It is usually not necessary, but you can edit the built-in dashed line styles using the Dashed Lines dialog by choosing Misc→Dashed Lines.

Dashed line 0 (the solid line) cannot be edited. If you need to create a custom dashed line pattern, we recommend that you modify the high numbered dashed lines, leaving the low number ones in their default state. This ensures that the low numbered patterns will be the same for everyone.

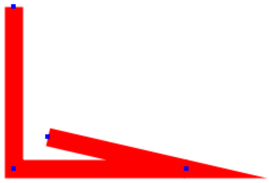
You can also change dashed lines with the **SetDashPattern** operation.

Dashed lines are stored with the experiment, so each experiment can have different dashed lines. You can capture the current dashed lines as the preferred dashed lines for new experiments.

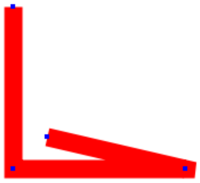
Line Join and End Cap Styles

When graph traces or drawn lines are very wide, you may want to control the appearance of the joins between line segments and the ends of line segments. The ModifyGraph lineJoin keyword provides control of line joins for graph traces in lines-between-points mode. The SetDrawEnv lineJoin keyword provides control for drawn lines.

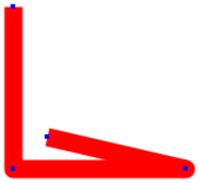
Line joins can have miter, round or bevel styles. For a miter join, you can specify the miter limit to control the length of miters on very acute angles. In these pictures, the blue dots show the position of the ends and join points of the lines:



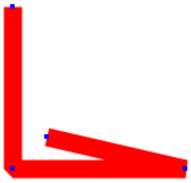
lineJoin={0, 10}
miter, w/ miter limit=10



lineJoin={0, sqrt(2)}
miter, limit=sqrt(2)



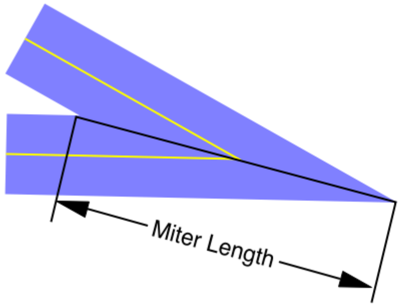
lineJoin={1, 0}
round

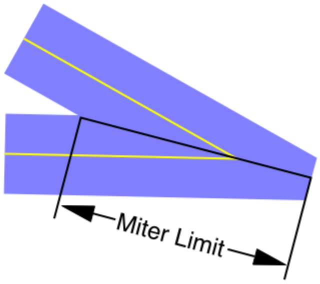


lineJoin={2, 0}
bevel

Miter joins extend the outside edges of the line segments until they intersect. Acute angles may result in very long miters. Round joins draw a circular arc around the join point, and bevel joins truncate the intersection with a bevel at the intersection point.

You can set the miter limit to avoid very long miter extensions:





When the miter limit is sqrt(2), any line join that is more acute than 90 degrees is truncated. Unfortunately, the nature of the truncation depends on the Graphics Technology. Core Graphics (Macintosh), GDI (Windows), PDF and Postscript truncate the miter by reverting to a bevel join; Qt graphics and GDI+ (Windows) truncate the miter by beveling at the miter limit. If you export graphics using a bitmap format such as PNG or JPG, the miter limit is controled by the graphics technology you have chosen (usually Qt graphics) in the Miscellaneous Settings dialog. The second picture above was drawn with Qt graphics as a PNG bitmap; the very acute intersection is truncated at the miter limit.

You can control the way line ends are drawn using ModifyGraph lOptions keyword, or for drawn lines using SetDrawEnv lineCap.

Line caps can be flat, round or square. These pictures show the appearance of each option; the dots show where the geometric end of each line is:

Flat	Round	Square
ModifyGraph lOptions=0	lOptions=1	lOptions=2
SetDrawEnv lineCap=0	lineCap=1	lineCap=2

The end cap style is applied at the end of each segment of a dashed line:

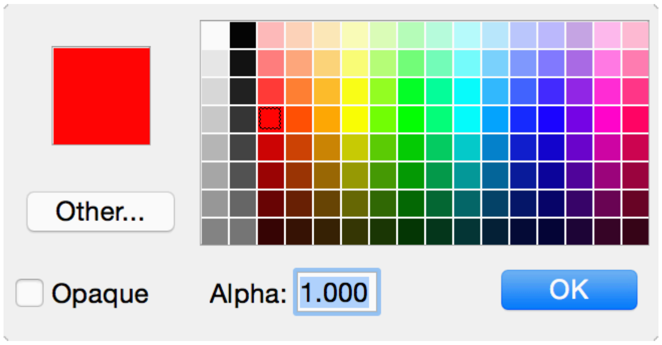
Square end caps extend the square end of the line beyond the geometric end and in Igor are probably not useful.

The Color Environment

Igor has a main color palette that contains colors that you can use for traces in graphs, text, axes, backgrounds and so on. The main color palette appears as a pop-up menu in a number of dialogs, such as the Modify Trace Appearance dialog. This section discusses this palette.

Igor also has color tables and color index waves you can select among when displaying contour plots and images. These are discussed in Chapter II-15, **Contour Plots**, and Chapter II-16, **Image Plots**.

You can select a color from the colors presented in a color palette:



□ Opaque

Alpha: 1.000

You can use the Other button to select colors that are not in the palette. As you use Igor, colors are added to the palette in the Recent Colors area.

The recent colors are remembered by Igor when it quits and restored when it restarts if you have selected the “Save and restore color palette’s recent colors” checkbox in the Miscellaneous Settings dialog’s Color Settings category.

Color Blending

In places where you can supply a color in RGB format, you can optionally provide a fourth parameter called "alpha". Alpha, like the R, G and B values, can range from 65535 (100% opaque) down to 0 (100% transparent). Intermediate values provide translucency. For example:

```
Make jack=sin(x/8),sam=cos(x/6); Display jack, sam
ModifyGraph mode=7,hbFill=2
ModifyGraph rgb(jack)=(65535,32768,32768)
ModifyGraph rgb(sam)=(0,0,65535,40000)       // Translucent
```

Color blending was added in Igor Pro 7.

Color blending does not work on Windows in the old GDI graphics mode explained under **Graphics Technology on Windows** on page III-506.

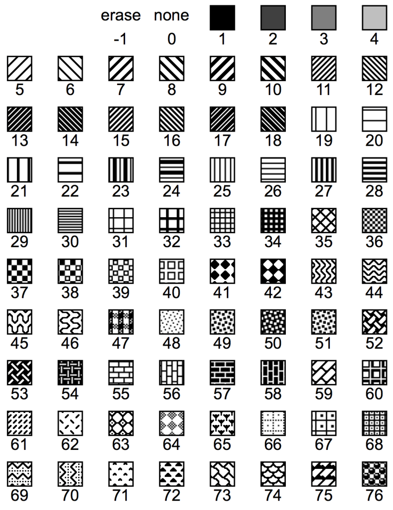
Color blending does not work in graphics exported as EPS. Use PDF instead.

Fill Patterns

Fill patterns can be used in graphs and drawing layers. This table, generated from the ColorsMarkersLinesPatterns.pxp example experiment, shows the available fill patterns.

The fill pattern codes shown below are appropriate for drawing commands. For graph-related commands, such as ModifyGraph hbFill, make the following adjustments:

- Erase is 1 instead of -1
- Add 1 to all pattern codes greater than 0



Gradient Fills

You can specify gradient fills for drawing elements, graph trace fills, and graph window and plot area background fills. A gradient fill is a gradual change of color.

Programmatically you specify gradients using two keywords, gradient and gradientExtra, when calling the ModifyGraph, ModifyLayout or SetDrawEnv operations.

The syntax for the gradient keyword has two forms. The first form provides overall control of the gradient while the second form controls the color details.

The first form for the gradient keyword is:

```
gradient = 0, 1, 2, or 3
```

0 deletes the gradient entirely.

1 turns on an existing gradient or creates a new one with default values.

2 turns off a gradient but keeps the settings.

3 is used in combination with the ModifyLayout operation and signals that a particular page should not display a gradient even when a layout global gradient is set.

The second form for the gradient keyword is:

```
gradient = {type, x0, y0, x1, y1 [,color0 [, color1 ] ]}
```

type is a bitfield.

Bits 0 through 3 specify the gradient mode. 0 is linear, 1 is radial and other values are reserved.

Bits 4 through 7 specify the coordinate mode. 0 is object rect, 1 is window rect.

To construct a type parameter signifying a radial gradient in window rect mode you could write:

```
Variable gradientType = 1 | (1*16)
```

The following commands illustrate the difference between object rect and window rect mode. Execute these commands and then drag the rectangles around:

```
Display /W=(150,50,474,365)
SetDrawLayer UserFront
SetDrawEnv xcoord=abs,ycoord=abs
SetDrawEnv save
SetDrawEnv fillfgc=(16385,16388,65535),fillbgc=(65535,16385,16385)
SetDrawEnv gradient={16, 0, 0, 1, 1}      // Window rect mode
DrawRect 25,38,95,138
SetDrawEnv gradient={1, 0.5, 0.5, 0, 1, (0,65535,0), (65535,0,65535)}
DrawRect 130,150,273,289
ShowTools/A
```

The *x0*, *y0*, *x1*, and *y1* parameters specify normalized locations that define the gradient. (0,0) is the upper left corner of the bounding rectangle while (1,1) is the lower right corner. For a linear gradient, (*x0*, *y0*) defines the start while (*x1*, *y1*) defines the end. Only the slope of the line is used, not the actual extent. For a radial gradient, (*x0*, *y0*) defines the center of a bounding circle while (*x1*, *y1*) is not used at present.

The optional color0 and color1 keywords are specified as (r,g,b) or (r,g,b,a) but use of alpha is not fully supported on all platforms (Quartz PDF on Macintosh for example). When omitted or with a value of (0,0,0) the actual color used is a default for the given circumstance. The default values are specified in the individual operation documentation.

The gradientExtra keyword adds an additional color change point. You can add as many change points as desired.The syntax for the gradientExtra keyword is:

```
gradientExtra = {loc, color}
```

loc is in the range 0.0 to 1.0. Values of exactly 0 or 1 replace the original *color0* or *color1* values as specified by the gradient keyword.

color is specified as (r,g,b) or (r,g,b,a) but use of alpha is not fully supported on all platforms (Quartz PDF on Macintosh for example).

The following operations support the gradient and gradientExtra keywords.

SetDrawEnv

If you specify a gradient it overrides the fill for drawing elements.

If you omit the *color0* parameter or specify (0,0,0,0) then the current pattern background color is used.

If you omit the *color1* parameter or specify (0,0,0,0) then the current foreground color is used.

All gradientExtra keywords must be on the same line as the gradient keyword itself.

ModifyLayout

You can specify gradients for individual pages by combining the gradient and gradientExtra keywords with the /PAGE=*pageNum* flag.

Page numbers start from 1. Use /PAGE=0 to use the currently active page.

/PAGE=-1 causes the operation to modify the layout global gradient which applies to any pages in the targeted page layout for which no explicit gradient has been set.

ModifyGraph (traces)

If you specify a gradient it overrides the fill for traces.

The gradient and gradientExtra keywords apply to all traces unless you specify a trace name like this:

```
gradient(<trace name>) = {...}
gradientExtra(<trace name>) = {...}
```

If you omit the *color0* parameter or specify (0,0,0,0) then the current pattern background color is used.

If you omit the *color1* parameter or specify (0,0,0,0) then the plusRGB color is used.

When the *type* parameter specifies a window rect, the plus and neg areas are used automatically and the *color1* is away from the zero level.

ModifyGraph (colors)

The wbGradient and wbGradientExtra keywords control the window background gradient, if any.

The gbGradient and gbGradientExtra keywords control the graph plot area background gradient, if any.

The "Demo Experiment #1" and "Demo Experiment #2" example experiments demonstrate these gradients. You can turn the on and off using the Macros menu.

Miscellaneous Settings

You can customize many aspects of how Igor works using the Miscellaneous Settings dialog. Choose Misc→Miscellaneous Settings to display the dialog.

Most of the settings are self-explanatory. Many have tooltips that describe what they do.

Object Names

Every Igor object has a name which you give to the object when you create it or which Igor automatically assigns. You use an object's name to refer to it in dialogs, from commands and from Igor procedures. The named objects are:

Waves
Windows
Controls
Symbolic paths
FIFOs
Data folders
Axes
Rulers
Pictures
FIFO channels
Variables (numeric and string)
Annotations
Special characters (in notebooks)
XOPs

In Igor Pro, the rules for naming waves and data folders are not as strict as the rules for naming all other objects, including string and numeric variables, which are required to have standard names. These sections describe the standard and liberal naming rules.

Standard Object Names

Here are the rules for standard object names:

- May be 1 to 255 bytes in length.

  Prior to Igor Pro 8.00, names were limited to 31 bytes. See **Long Object Names** on page III-502 for a discussion of issues related to names longer than 31 bytes.
- Must start with an alphabetic character (A-Z or a-z).
- May include ASCII alphabetic or numeric characters or the underscore character.
- Must not conflict with other names (of operations, functions, etc.).

All names in Igor are case insensitive. wave0 and WAVE0 refer to the same wave.

Characters other than letters and numbers, including spaces and periods, are not allowed. We put this restriction on names so that Igor can identify them unambiguously in commands, including waveform arithmetic expressions.

Liberal Object Names

The rules for liberal names are the same as for standard names except that almost any character can be used in a liberal name. Liberal name rules are allowed for waves and data folders only.

If you are willing to expend extra effort when you use liberal names in commands and waveform arithmetic expressions, you can use wave and data folder names containing almost any character. If you create liberal names then you will need to enclose the names in single (not curly) quotation marks whenever they are used in commands or waveform arithmetic expressions. This is necessary to identify where the name ends. Liberal names have the same rules as standard names except you may use any character except control characters and the following:

```
   "  '  :  ;
```

Here is an example of the creation and use of liberal names:

```
Make 'wave 0';     // 'wave 0' is a liberal name
'wave 0' = p
Display 'wave 0'
```

Note: Providing for liberal names requires extra effort and testing on the part of Igor programmers (see **Programming with Liberal Names** on page IV-168) so you may occasionally experience problems using liberal names with user-defined procedures.

Namespaces

When you refer to an object by name, in a user function for example, each object must be referenced unambiguously. In general, an object must have a unique name so. Sometimes the object type can be inferred from the context, in which case the name can be the same as objects of other types. Objects whose names can be the same are said to be in different namespaces.

Data folders are in their own name space. Therefore the name of a data folder can be the same as the name of any other object, except for another data folder at the same level of the hierarchy.

Waves and variables (numeric and string) are in the same name space and so Igor will not let you create a wave and a variable in a single data folder with the same name.

An annotation is local to the window containing it. Its name must be unique only among annotations in the same window. The same applies for controls and rulers. Data folders, waves, variables, windows, symbolic paths and pictures are global objects, not associated with a particular window.

The names of global objects, except for data folders, are required to be distinct from the names of macros, functions (built-in, external or user-defined) and operations (built-in or external).

Here is a summary of the four global namespaces:

Name Space	Requirements
Data folders	Names must be distinct from other data folders at the same level of the hierarchy.
Waves, variables, windows	Names must be distinct from other waves, variables (numeric and string), windows.
Pictures	Names must be distinct from other pictures.
Symbolic paths	Names must be distinct from other symbolic paths.

Object Name Functions

These functions are useful for programmatically generating object names: **CreateDataObjectName**, **CheckName**, **CleanupName**, **UniqueName**.

Long Object Names

Prior to Igor Pro 8.00, names were limited to 31 bytes. Now names can be up to 255 bytes in length.

The following types of objects support long names in Igor Pro 8.00 or later:

- Data folders
- Waves
- Variables
- Windows
- Axes
- Annotations
- Controls
- Special characters in formatted notebooks
- Symbolic paths
- XOPs, external operations, external functions

In addition, in Igor8, wave dimension labels and procedure names can be up to 255 bytes in length.

The following types of objects are still limited to names of 31 bytes or less:

- Rulers in formatted notebooks

- Global picture names
- Page setup names
- FIFOs
- FIFO channels

If you do not create objects with names longer than 31 bytes, wave and experiment files that you create will be compatible with earlier versions of Igor. However, if you do create objects with long names, older versions of Igor will report errors when opening wave and experiment files containing long names.

NOTE: If you use long names, your wave and experiment files will require Igor Pro 8.00 or later and will return errors when opened by earlier versions of Igor.

You can choose File→Experiment Info to determine if the current experiment uses long object names or has waves with long dimension labels. You can also use the **ExperimentInfo** operation programmatically. These check only wave, variable, data folder, target window, and symbolic path names, and wave dimension labels. They do not check axis, annotation, control, procedure or other names.

If you attempt to save an experiment file that uses long wave, variable, data folder, target window or symbolic path names, or that has waves with long dimension labels, Igor displays a warning dialog telling you that the experiment will require Igor Pro 8.00 or later. The warning dialog is presented only when you save an experiment interactively, not if you save it programmatically using SaveExperiment. You can suppress the dialog by clicking the "Do not show this message again" checkbox.

Global picture names (see **The Picture Gallery** on page III-510) are limited to 31 bytes but names of Proc Pictures (**Proc Pictures** on page IV-56) are not.

Page setup names are used behind the scenes to save a page setup record for each page layout window. The experiment file format limits the name of a page setup record to 31 bytes. If a layout window name exceeds 31 bytes, when you save the experiment, the page setup record for that window is not written to the experiment file. When you reopen the experiment, the layout window receives a default page setup. Since long page layout names are rare and page setups affect printing but not the dimensions of the page (see **Page Layout Page Sizes** on page II-478), this issue will have little impact.

An XOP name is the name of the XOP file without the ".xop" extension. In Igor8, XOP names can be up to 255 bytes. However, if an XOP name exceeds 31 bytes, Igor does not send the SAVESETTINGS message to the XOP. Most XOP names are shorter than 31 bytes and most XOPs do not save experiment settings, so this is not likely to cause a problem.

Long Object Names With Old Igor Versions

If you use long names, your wave and experiment files will require Igor Pro 8.00 or later and will return errors when opened by earlier versions of Igor.

You can choose File→Experiment Info to determine if the current experiment uses long object names or has waves with long dimension labels. You can also use the **ExperimentInfo** operation programmatically.

If you open an experiment file that uses long wave, variable, data folder, window or symbolic path names while running Igor Pro 7.xx, where xx is 01 or later, the old Igor version displays an error dialog explaining that the experiment requires Igor Pro 8.00 or later. This mechanism for informing you that a later version of Igor is required works for long wave, variable, data folder, window and symbolic path names only. It does not work for long axis, annotation, control, special character, procedure or XOP names. For those object types, you will get an error later, when the old version of Igor first encounters the long name.

If you open an experiment file that uses long names of any kind in Igor Pro 7.00 or before, you will get an error such as "name too long" or "incompatible Igor binary version" or some other error.

In Igor Pro 6.38 and Igor Pro 7.01, a bug was fixed that cause Igor to crash if you load a file containing long wave names and the file contains wave reference waves or data folder reference waves. You are very unlikely to have such files.

In Igor Pro 6.38 and Igor Pro 7.01, a bug was fixed that cause Igor to crash if you load a formatted notebook file containing a long special action name and you attempt to modify that special action.

Programming With Long Object Names

If your code must run with Igor7 or before, the best strategy is to avoid using long object names. Attempting to conditionally support long object names will make your code complex and fragile. A better approach is to freeze your Igor7 code and add new features to an Igor8 or later branch.

If you must use conditional programming, you can test whether the running version of Igor supports long object names like this:

```
Variable maxObjectNameLength = 31
if (IgorVersion() >= 8.00)
   maxObjectNameLength = 255
endif
```

The names of functions, constants, variables and other programming entities can be up to 255 bytes, but if you use names longer than 31 bytes, your procedures will require Igor Pro 8.00 or later.

Package names can be up to 255 bytes, but if you use a name longer than 31 bytes, your package will require Igor Pro 8.00 or later.

Long Object Names and XOPs

For most of recorded history, XOPs supported a maximum object name length of 31. Igor now support long object names but pre-existing XOPs continue to work as before. However, if you attempt to use a long object name with a pre-existing XOP, you will get an error. For example:

```
NewPath SymbolicPathWithANameThatExceeds31Bytes, <path>
OldFileLoader /P=SymbolicPathWithANameThatExceeds31Bytes <path>
```

This returns an error because the hypothetical OldFileLoader XOP has not been updated to work with long object names. It continues to work with short object names.

If a pre-existing XOP attempts to retrieve the name of a wave or data folder which has a long name, Igor returns an error to the XOP. If the XOP is properly written, it will generate a "name too long" error and Igor will report the error.

As of XOP Toolkit 8, the XOP Toolkit supports creating XOPs that work with long object names. Supporting long names requires that the XOP programmer modify and recompile the XOP. XOPs compiled to support long object names will require Igor Pro 8 or later. Consequently, many XOPs will not support them.

As of this writing, if the name of the XOP itself, without the ".xop" extension, exceeds 31 bytes in length, the XOP will not be able to save settings using the SAVESETTINGS message or load settings using the LOADSETTINGS message. Consequently it is best to avoid creating an XOP whose name exceeds 31 bytes.

Renaming Objects

You can use Misc→Rename Objects or Data→Rename to rename waves, variables, strings, symbolic paths, and pictures. Both of these invoke the Rename Objects dialog.

Graphs, tables, page layouts, notebooks, control panels, Gizmo windows, and XOP target windows are renamed using the **DoWindow** operation (see page V-168) which you can build using the Window Control dialog (see **The Window Control Dialog** on page II-49).

You can use the Data Browser to rename data folders, waves, and variables. See **The Data Browser** on page II-114.

Object Name Conflicts

In general, Igor does not allow two objects in the same namespace to have the same name. (To see a list of Igor namespaces, see **Namespaces** on page III-502.) The rest of this section discusses some exceptions to this rule and related issues. Most users will not need to know this material.

Object Name Conflicts That Igor Allows

Igor allows you to create name conflicts between waves, variables, and data folders with certain exceptions listed below. For example:

```
Function DemoAllowedNameConflicts()     // Execute this in a new experiment
   Make/O root:test                     // to demonstrate that Igor allows
   Variable/G root:test                 // name conflicts in some cases
   NewDataFolder/O root:test
End
```

This shows that Igor allows you to create a wave and a global variable with the same name and to create a data folder with the same name as a wave or a global variable.

Allowing a wave and a global variable to have the same name is a historical accident that should not have been allowed because waves and variables are in the same namespace, called the "main namespace". This may be disallowed in a future version of Igor.

Allowing a data folder to have the same name as a wave or variable is intended because data folders are in their own namespace.

The following exceptions specify the name conflicts in the main namespace that are not allowed:

1. It is an error to create a variable with the same name as an existing wave from a macro, proc, or from the command line (but it is not an error from a user-defined function as shown above).

2. It is an error to create a wave with the same name as an existing variable from any context (function, macro, proc, or from the command line).

The table below expresses those rules. The left column shows the type of object created first and the top row shows the type of object created second.

F means that Igor returns an error if you attempt to create the objects in a function.

M means that Igor returns an error if you attempt to create the objects in a macro, proc, or from the command line.

--- means Igor returns no error from a function, macro, proc, or from the command line.

	Wave	**Variable**	**Data Folder**
Wave	N/A	M	---
Variable	F, M	N/A	---
Data Folder	---	---	N/A

Object Name Conflicts and HDF5 Files

When saving an experiment in packed or unpacked format, these name conflicts do not cause a problem. If you save and reload the experiment, you get back to where you started.

However, name conflicts do cause problems with HDF5 files, saved via Save Experiment or via the HDF5SaveGroup operation, because HDF5 does not allow a group and a dataset to have the same name.

- If there is a conflict between a wave or variable and a data folder, you get an error when you attempt to save as HDF5.

- If there is a conflict between a wave and a variable, if overwrite is off, you get an error; if overwrite is on, the dataset for the variable overwrites the dataset for the wave so the wave is not saved to the resulting HDF5 file. In Igor Pro 9.00, when writing an HDF5 packed experiment file, Igor turned overwrite on; in Igor Pro 9.01 we changed overwrite to off so that an error will be flagged in this situation.

It is conceptually possible for Igor to handle these conflicts by changing the name of one of the conflicting objects when the file is saved, somehow marking the fact that this change was made, and reversing the process when the file is loaded. When we tried to implement this scheme, we found that it added a significant amount of complexity to already complex code. Adding complexity introduces the possibility of creating new bugs and slowing operations down. Since these name conflicts are rare, the downside of implementing such a workaround outweighed the benefits so we decided to decline to support name conflicts in HDF5 files.

Graphics Technology

As of version 7, Igor Pro is based on the cross-platform Qt framework and, by default, Igor uses Qt for graphics. However, for special purposes, Igor provides access to platform-native graphics.

You should avoid native graphics and stick with Qt graphics if possible because it is the focus for future development. Native graphics is provided mainly for emergency use.

You can select native graphics on a global basis (all windows are affected) in two ways:

1. From the Miscellaneous category of the Miscellaneous Settings dialog (Misc→Miscellaneous Settings menu item).
2. By executing

   ```
   SetIgorOption GraphicsTechnology=n
   ```

   where *n* is interpreted as follows:

n=0	Default (currently Qt)
n=1	Quartz on Macintosh, GDI+ on Windows
n=2	Not used on Macintosh, GDI on Windows
n=3	Qt

   Unlike most other SetIgorOption cases, this change is saved to preferences on disk and applies to future Igor sessions.

In addition to changing the global graphics technology setting, you can change individual windows using

```
SetWindow winName, graphicsTech=n
```

where n is the same as above. *winName* can be kwTopWin or the actual name of a window. Currently this setting is saved for graphs only but that is subject to change.

Over time, it is our intention that Qt graphics will replace the other technologies and the SetIgorOption GraphicsTechnology option may no longer be supported.

Graphics Technology on Windows

In general, you should use the default graphics (GraphicsTechnology=0) which is currently Qt graphics. If you experience problems with graphics, you might try GraphicsTechnology=1 (GDI+) or 2 (GDI). High-resolution displays are supported using Qt graphics only.

On Windows, GraphicsTechnology=1 utilizes the GDI+ interface. This provides support for transparency and other advanced features. Unfortunately, GDI+ is very slow, especially when rendering text.

If speed is an issue, you can try GraphicsTechnology=2 to use the older GDI interface. However, transparency is not honored - colors will be opaque regardless of the alpha value (see **Color Blending** on page III-498 for a discussion of alpha).

In GDI+ mode, EMF export uses a hybrid format, called "dual EMF", that contains both GDI+ and, for compatibility, the older GDI. In GraphicsTechnology=2 mode, only the older GDI-only style is exported. In Qt graphics mode, GDI+ is used for rendering the EMF for export, resulting in the dual EMF format. Some applications don't work well with EMF+ or dual EMF. In that case, try setting GraphicsTechnology=2 (old GDI mode) to export an EMF without the EMF+ component.

Our experience indicates that plain EMF is rendered better by GDI mode. In Qt graphics, the best rendering technology is chosen based on the contents of the picture you are pasting.

Regardless of the selected technology, exporting as EMF on Windows uses native interfaces.

Graphics Technology on Macintosh

On Macintosh, there is only one native format, Core Graphics, also known as Quartz (GraphicsTechnology=1), and it works the same as in Igor Pro 6.3. The native picture format is PDF.

High-resolution screen graphics on Retina displays is supported in Qt graphics technology mode only.

PDF pictures pasted into Igor are also rendered using Quartz. This produces the same picture regardless of the chosen Igor graphics technology, except on a Retina display, in which case the PDF is rendered on-screen at high-resolution only when using Qt graphics.

SVG Graphics

In Qt mode (GraphicsTechnology=3), SVG (Scalable Vector Graphics) is available as an alternative object-based picture format. This can replace EMF and PDF whenever the destination program supports it. In Qt mode, other imported object-based pictures (PDF on Macintosh, EMF on Windows) are rendered as high-resolution bitmap images.

In native graphics modes, imported SVG pictures are rendered as high-resolution bitmap images using Qt graphics.

Regardless of the selected technology, exporting as SVG format is rendered using Qt.

High-Resolution Displays

High-resolution screen graphics is supported in Qt graphics technology mode only.

Macintosh Retina and Windows high-resolution displays, also called Retina, 4K, 5K, Ultra HD, and Quad HD, bring a more pleasing visual experience but also present performance challenges. Depending on the operating system, graphics technology, and your actual data, graph updates can be thousands of times slower. This situation is expected to be temporary as operating systems optimize high-resolution graphics. See the "Graphs and High-Resolution Displays" topic in the release notes for the latest information.

On Windows, prior to Igor Pro 7, control panels were drawn using pixels for coordinates. Now, when the resolution exceeds 96 DPI, those coordinates are taken to be points. This prevents panels from appearing tiny on high-resolution displays. See **Control Panel Resolution on Windows** on page III-456 for more information.

Graphs and High-Resolution Displays

Macintosh Retina and Windows high-resolution displays bring a more pleasing visual experience but also present performance challenges. Previously, one point lines were one pixel wide. Now, on high-resolution displays, such lines are two pixels wide and, depending on the operating system, graphics technology and the actual data, drawing can be thousands of times slower.

Since Igor Pro 8, we now use fast custom code when drawing lines that are two or more pixels wide. However, because the custom code lines are not as pleasing as the system code, it is used only under conditions where the system code is slow, particularly when very long traces are used.

When you need the fastest update speed, you can specify that a trace should use the fast line draw code by using the ModifyGraph live keyword with a value of 2. This will cause even one pixel thick lines to be drawn with the new code. The speed improvement is on the order of a factor of two.

You can use the Live Mode demo experiment to see how different settings affect the speed of graph updates.

Windows High-DPI Recommendations

High-DPI (dots-per-inch) displays have resolutions substantially higher than the Windows standard 96 DPI. These displays sometimes go by the names Retina, 4K, 5K, Ultra HD and Quad HD.

Since the pixels of a high-DPI monitor are typically about one-half the size of pixels on standard monitors, software running on a high-DPI monitor must make adjustments. These adjustments are made by some combination of the operating system and the program itself.

On Macintosh, with its “Retina” high-DPI screens, the operating system handles most resolution issues and there are few problems with Igor on Retina monitors.

On Windows, both the operating system and the Qt framework that Igor uses introduce complexities that sometimes result in less than perfect behavior. This section provides guidance for Windows user to minimize these issues.

To get the best experience when using a high-DPI display, we recommend that you use Windows 10 or later. We do not test or explicitly support high-DPI features on older Windows versions.

If you only have one display, such as a laptop with a high-DPI display, and no external displays are connected, you should not need to make any changes to Igor's default configuration to achieve the correct behavior.

If you have multiple displays with different resolutions, such as a high-resolution laptop display and a standard-resolution external monitor, you may see problems such as text, menus, windows or icons too big or too small. In our experience with Igor8, most or all of these issues are resolved if you make your high-resolution display your main display using the Windows 10 Display control panel.

As an example, here are instructions for configuring a typical mixed-resolution system - a laptop with a built-in high-resolution display and an external standard-resolution monitor:

1. Connect the external standard-resolution monitor.
2. Open the Display settings page. You can do this by right-clicking the Start menu, choosing Settings, clicking System, and selecting Display in the lefthand pane.
3. In the Multiple Displays setting, near the bottom of the pane, select Extend These Displays.
4. Click the Identify link below the diagram of your displays at the top of the pane to confirm which display is which. For these instructions, we assume that display #1 is the high-resolution built-in display and display #2 is a standard-resolution external monitor.
5. Click the box representing the built-in high-resolution display (display #1 for this example).
6. Set Resolution to the recommended value, such as 3840 x 2160.
7. Set Scale and Layout to the recommended value, which may be 200%, 225%, or 250% depending on your hardware.
8. Check the Make This My Main Display checkbox near the bottom of the pane.
9. Close the settings control panel.

10. Reboot your machine twice. To get the best results, you must reboot your machine 2 times after any changes to the display settings.

11. After your machine restarts twice, start Igor. Except for occasional minor glitches, it should work properly.

If the preceding instructions do not give useable results, you may find it necessary to fall back to standard resolution for the high-resolution display. To do this, set Resolution to standard resolution and set Scale and Layout to 100%. Standard resolution is usually half the recommended resolution - for example 1920 x 1080 instead of 3140 x 2160. If you do this, you can make either display the main display.

Pictures

Igor can import pictures from other programs for display in graphs, page layouts and notebooks. It can also export pictures from graphs, page layouts and tables for use in other programs. Exporting is discussed in Chapter III-5, **Exporting Graphics (Macintosh)**, and Chapter III-6, **Exporting Graphics (Windows)**. This section discusses how you can import pictures into Igor, what you can do with them and how Igor stores them.

For information on importing images as data rather than as graphics, see **Loading Image Files** on page II-157.

Importing Pictures

There are three ways to import a picture.

- Pasting from the Clipboard into a graph, layout, or notebook
- Using the Pictures dialog (Misc menu) to import a picture from a file or from the Clipboard
- Using the **LoadPICT** operation (see page V-506) to import a picture from a file or from the Clipboard

Each of these methods, except for pasting into a notebook, creates a *named*, global picture object that you can use in one or more graphs or layouts. Pasting into a notebook creates a picture that is local to the notebook.

This table shows the types of graphics formats from which Igor can import pictures:

Format	Notes
PDF (Portable Document Format)	Macintosh: Supported in native graphics only.
	Windows: Supported in Igor Pro 9.00 and later.
	See **Importing PDF Pictures**.
EMF (Enhanced Metafile)	Supported in Windows native graphics only.
	See **Graphics Technology on Windows** on page III-506 for information about different types of EMF pictures.
BMP (Windows bitmap)	Supported in on Windows only.
	BMP is sometimes called DIB (Device Independent Bitmap).
PNG (Portable Network Graphics)	Lossless cross-platform bitmap format
JPEG	Lossy cross-platform bitmap format
TIFF (Tagged Image File Format)	Lossless cross-platform bitmap format

Format	Notes
EPS (Encapsulated PostScript)	High resolution vector format. Requires PostScript printer. On Windows and on Macintosh in Qt graphics mode, a screen preview is displayed on screen.
SVG (Scalable Vector Graphics)	Cross-platform vector and bitmap format. Always rendered using Qt graphics. In other graphics technology modes, it is drawn into a high-resolution btmap which is then drawn on the screen, exported, or printed.

Formats that are not supported on the current platform are drawn as gray boxes.

See also **Picture Compatibility** on page III-449 for a discussion of Macintosh graphics on Windows and vice-versa.

Importing PDF Pictures

PDF (Portable Document Format) is Adobe's platform-independent vector graphics format. However, not all programs can import PDF.

On Macintosh, Igor has supported importing PDF graphics since Igor Pro 5. PDF pictures are using bitmaps except in Macintosh native graphics mode (see **Graphics Technology** on page III-506).

On Windows, Igor supports importing PDF graphics in Igor Pro 9 or later. PDF pictures are drawn using bitmaps.

The Picture Gallery

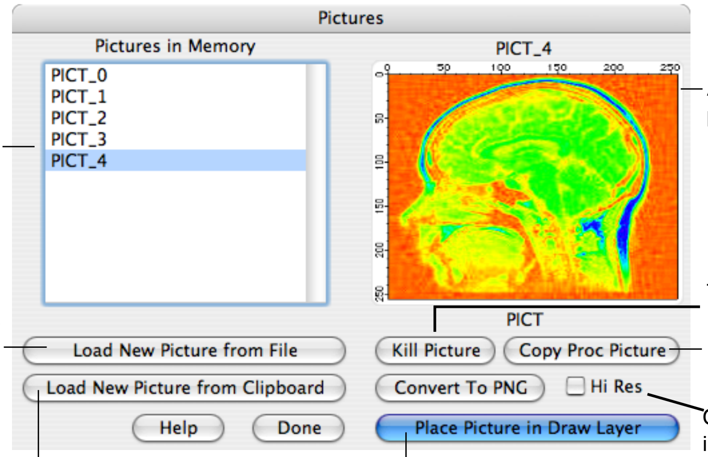
When you create a named picture using one of the techniques listed above, Igor stores it in the current experiment’s **picture gallery**. When you save the experiment, the picture gallery is stored in the experiment file. You can inspect the collection using the Pictures dialog via the Misc menu.

Igor gives names to pictures so they can be referenced from an Igor procedure. For example, if you paste a picture into a layout, Igor assigns it a name of the form “PICT_0” and stores it in the picture gallery. If you then close the layout and ask Igor to create a recreation macro, the macro will reference the picture by name.

You can rename a named picture using the Pictures dialog in the Misc menu, the Rename Objects dialog in the Misc menu, the Rename dialog in the Data menu, or the **RenamePICT** operation (see page V-797). You can kill a named picture using the Pictures dialog or the **KillPICTs** operation (see page V-470).

Pictures Dialog

The Pictures dialog permits you to view the picture gallery, to add pictures, to remove pictures and to place a picture into a graph or page layout. It also can place a copy of a picture into a formatted notebook. To invoke it, choose Pictures from the Misc menu.



Lists the named pictures in the picture gallery. Click to select a picture.

Loads a new picture from a file, usually created in a drawing program.

Loads a new picture that you have copied to the Clipboard, usually from a drawing program.

Click to place the picture in a graph or page layout.

A preview of the selected picture.

Removes the selected picture, from the collection.

Creates an ASCII representation for use in procedures.

Converts the selected picture into a platform-independent PNG format bitmap. Select the box for high resolution

The Kill This Picture button will be dimmed if the selected picture is used in a currently open graph or layout.

Note: Igor determines if a picture is in use by checking to see if it is used in an *open* graph or layout window.

If you kill a graph or layout that contains a picture and create a recreation macro, the recreation macro will *refer* to the picture by name. However, Igor does not check for this. It will consider the picture to be unused and will allow you to kill it. If you later run the recreation macro, an error will occur when the macro attempts to append the picture to the graph or layout. Therefore, don't kill a picture unless you are sure that it is not needed.

NotebookPictures

When you paste a picture into a formatted notebook, you create a notebook picture. These work just like pictures in a word processor document. You can copy and paste them. These pictures will not appear in the Pictures or Rename Objects dialogs.

Igor Extensions

Igor includes a feature that allows a C or C++ programmer to extend its capabilities. An Igor extension is called an "XOP" (short for "external operation"). The term XOP comes from that fact that, originally, adding a command line operation was all that an extension could do. Now extensions can add operations, functions, menus, dialogs and windows.

XOPs come in 32-bit and 64-bit varieties. Because almost all Igor users now run the 64-bit version of Igor, this section focuses on 64-bit XOPs.

WaveMetrics XOPs

The "Igor Pro Folder/Igor Extensions (64-bit)" and "Igor Pro Folder/More Extensions (64-bit)" folders contain XOPs that we developed at WaveMetrics. These add capabilities such as file-loading and instrument control to Igor and also serve as examples of what XOPs can do. These XOPs range from very simple to rather elaborate. Most XOPs come with help files that describe their operation.

The WaveMetrics XOPs are described in the XOP Index help file, accessible through the Help→Help Windows submenu.

Third Party Extensions

A number of Igor users have written XOPs to customize Igor for their particular fields. Some of these are freeware, some are shareware and some are commercial programs. WaveMetrics publicizes third party XOPs through our Web page. User-developed XOPs are available from http://www.igorexchange.com.

See **Creating Igor Extensions** on page IV-208 if you are a programmer interested in writing your own XOPs.

Activating 64-bit Extensions

To activate a 64-bit extension, you put it, or an alias or shortcut pointing to it, in the "Igor Extensions (64-bit)" folder in your "Igor Pro User Files" folder.

For illustration purposes, we show here the steps you need to take to activate Igor's SQL XOP which provides access to databases.

1. In Igor, choose Help->Show Igor Pro User Files to open your "Igor Pro User Files" folder on the desktop.

2. In Igor, choose Help->Show Igor Pro Folder to open your "Igor Pro Folder" on the desktop.

3. Open the "Igor Pro Folder\More Extensions (64-bit)\Utilities" folder on the desktop.

4. Make an alias (*Macintosh*) or shortcut (*Windows*) for "SQL64.xop" and put it in the "Igor Extensions (64-bit)" folder inside your "Igor Pro User Files" folder.

5. Restart Igor64.

If you want to activate an XOP for all users on a given machine, you can put the alias or shortcut in the "Igor Extensions (64-bit)" folder inside your Igor Pro Folder. You may need to run as administrator to do this.

Changes that you make to either "Igor Extensions (64-bit)" folder take effect the next time Igor is launched.

Activating 32-bit Extensions

If you are running the 32-bit version of Igor on Windows, you can activate the 32-bit version of an XOP following the instructions in the preceding section with a few modifications.

Use "Igor Extensions" instead of "Igor Extensions (64-bit)" and "More Extensions" instead of "More Extensions (64-bit)". Activate the 32-bit version of the XOP, for example SQL.xop, instead of SQL64.xop

XOPs on MacOS 10.15 and Later

In MacOS 10.15 (Catalina), Apple added strict security features that prevent downloaded XOPs from running without special security certification ("notarization").

WaveMetrics XOPs that ship with Igor Pro 8.04 or later have the required notarization and so work.

XOPs that you compiled on your own machine are likely to run correctly unless they depend on libraries that are not compatible with Catalina.

Most third-party XOPs that you downloaded will not run on Catalina.

For further information, see https://www.wavemetrics.com/news/igor-pro-macos-1015-catalina and https://www.wavemetrics.com/node/21088 for a workaround.

Memory Management

Igor comes in 32-bit and 64-bit versions called IGOR32 and IGOR64 respectively. IGOR32 is available on Windows only. The only reason to run IGOR32 is if you depend on 32-bit XOPs that have not been ported to 64 bits.

IGOR32 can theoretically address 4GB of virtual address space. For the vast majority of Igor applications, this is more than sufficient. If you must load gigabytes of data into memory at one time, you may run out of memory. This may happen long before you load 4GB of data into memory, because, to allocate a wave for example, you not only need free memory, but the free memory must also be continguous, and memory becomes fragmented over time.

IGOR64 can theoretically address about a billion gigabytes. However, actual operating systems impose far lower limits. On Windows 10, 64-bit programs can address between 128 GB (home edition) and 512 GB (professional edition). On Mac OS X, 64-bit programs can theoretically address the full 64-bit address space.

If you load more data than fits in physical memory, the system starts using "virtual memory", meaning that it swaps data between physical memory and disk, as needed. This is very slow. Consequently, you should avoid loading more data into memory than can fit in physical memory.

Even if your data fits in physical memory, graphing and manipulating very large waves, such as 10 million, 100 million, or 1 billion points, will be slow.

All of this boils down to the following rules:

1. If you don't need to load gigabytes of data into memory at one time then you don't need to worry about memory management.

2. Run IGOR64 unless you rely on 32-bit XOPs that can not be ported to 64 bits. If you are running on Macintosh and rely on 32-bit XOPs, you must run Igor7.

3. Install enough physical memory to avoid the need for virtual memory swapping.

For further information about very large waves, see **IGOR64 Experiment Files** on page II-35.

Macintosh System Requirements

Igor Pro requires Mac OS X 10.9.0 or later.

Windows System Requirements

Igor Pro requires Windows 7 or later.

Chapter III-18

Preferences

Overview

Preferences affect the creation of *new* graphs, panels, tables, layouts, notebooks, and procedure windows, and the *appending* of traces to graphs and columns to tables. In addition, preferences affect the command window, and default font for graphs.

You can turn preferences off or on using the Misc menu. Normally you will run with preferences on.

Preferences are automatically off while a procedure is running so that the effects of the procedure will be the same for all users. See the **Preferences** operation (see page V-768) for further information.

When preferences are off, factory default values are used for settings such as graph size, position, line style, size and color. When preferences are on, Igor applies your preferred values for these settings.

Preferences differ from *settings*, as set in the Miscellaneous Settings dialog, in that settings generally take effect immediately, while preferences are used when something is created.

Igor Preferences Directory

Igor preferences are stored in a per-user directory. The location of this directory depends on your operating system. You generally don't need to access your Igor preferences directory, but you can open it in the desktop by pressing the Shift key while choosing Help→Show Igor Preferences Folder.

You can also determine the location of your Igor preferences directory by executing this command:

```
Print SpecialDirPath("Preferences", 0, 0, 0)
```

For technical reasons, most of the built-in preferences are stored not in the Igor preferences directory but rather one level up in a file named "Igor Pro 9.ini".

Deleting the preferences directory and the "Igor Pro 9.ini" file effectively reverts all preferences to factory defaults. You should use the Capture Prefs dialogs, described in **Captured Preferences** operation on page III-516, to revert preferences more selectively.

Other information is stored in preferences, such as the screen position of dialogs, a few dialog settings, colors recently selected in the color palette, window stacking and tiling information, page setups, font substitution settings, and dashed line settings.

How to Use Preferences

Preferences are always on when Igor starts up. You can turn preferences off by choosing Preferences Off in the Misc menu.

You can also turn preferences on and off with the **Preferences** operation (see page V-768).

Preferences are set by Capture Preferences dialogs, the Tile or Stack Windows dialog, and some dialogs such as the Dashed Lines dialog.

In general, *preferences are applied only when something new is created* such as a new graph, a new trace in a graph, a new notebook, a new column in a table, and then only if preferences are on.

Preferences are normally in effect only for *manual* ("point-and-click") operation, not for user-programmed operations in Igor procedures. See **Procedures and Preferences** on page IV-203.

Captured Preferences

You set most preference values by capturing the current settings of the active window with the Capture Prefs item in the menu for that window. (The dialog to capture the Command Window preferences is found in the Command/History Settings submenu of the Misc menu.) The dialogs are described in more detail in the chapter that discusses each type of window. For instance, see **Graph Preferences** on page II-348.

Working with Commands

Overview

You can execute commands by typing them into the command line and pressing Return or Enter.

You can also use a notebook for entering commands. See **Notebooks as Worksheets** on page III-4.

You can type commands from scratch but often you will let Igor dialogs formulate and execute commands. You can view a record of what you have done in the history area of the command window and you can easily reenter, edit and reexecute commands stored there. See **Command Window Shortcuts** on page II-13 for details.

Multiple Commands

You can place multiple commands on one line if you separate them with semicolons. For example:

```
wave1= x; wave1= wave2/(wave1+1); Display wave1
```

You don’t need a semicolon after the last command but it doesn’t hurt.

Comments

Comments start with //, which end the executable part of a command line. The comment continues to the end of the line.

Maximum Length of a Command

The total length of the command line can not exceed 2500 bytes.

There is no line continuation character in the command line. However, it is nearly always possible to break a single command up into multiple lines using intermediate variables. For example:

```
Variable a = sin(x-x0)/b + cos(y-y0)/c
```

can be rewritten as:

```
Variable t1 = sin(x-x0)/b
Variable t2 = cos(y-y0)/c
Variable a = t1 + t2
```

Parameters

Every place in a command where Igor expects a numeric parameter you can use a numeric expression. Similarly for a string parameter you can use a string expression. In an operation flag (e.g., /N=<number>), you must parenthesize expressions. See **Expressions as Parameters** on page IV-12 for details.

Liberal Object Names

In general, object names in Igor are limited to a restricted set of characters. Only letters, digits and the underscore character are allowed. Such names are called “standard names”. This restriction is necessary to identify where the name ends when you use it in a command.

For waves and data folders only, you can also use “liberal” names. Liberal names can include almost any character, including spaces and dots (see **Liberal Object Names** on page III-501 for details). However, to define where a liberal name ends, you must quote them using single quotes.

In the following example, the wave names are liberal because they include spaces and therefore they must be quoted:

```
'wave 1' = 'wave 2'      // Right
wave 1 = wave 2          // Wrong - liberal names must be quoted
```

(This syntax applies to the command line and macros only, not to user-defined functions in which you must use **Wave References** to read and write waves.)

Note: Providing for liberal names requires extra effort and testing by Igor programmers (see **Programming with Liberal Names** on page IV-168) so you may occasionally experience problems using liberal names with user-defined procedures.

Commands and Data Folders

Data folders provide a way to keep separate sets of data from interfering with each other. You can examine and create data folders using the Data Browser (Data menu). There is always a root data folder and this is the only data folder that many users will ever need. Advanced users may want to create additional data folders to organize their data.

You can refer to waves and variables either in the current data folder, in a specific data folder or in a data folder whose location is relative to the current data folder:

```
// wave1 is in the current data folder
wave1 = <expression>

// wave1 is in a specific data folder
root:'Background Curves':wave1 = <expression>

// wave1 is in a data folder inside the current data folder
:'Background Curves':wave1 = <expression>
```

(This syntax applies to the command line and macros only, not to user-defined functions in which you must use **Wave References** to read and write waves.)

In the first example, we use an object name by itself (wave1) and Igor looks for the object in the current data folder.

In the second example, we use a full data folder path (root:'Background Curves':) plus an object name. Igor looks for the object in the specified data folder.

In the third example, we use a relative data folder path (:'Background Curves':) plus an object name. Igor looks in the current data folder for a subdata folder named Background Curves and looks for the object within that data folder.

Important: The right-hand side of an assignment statement (described under **Assignment Statements** on page IV-4) is evaluated in the context of the data folder containing the destination object. For example:

```
root:'Background Curves':wave1 = wave2 + var1
```

For this to work, wave2 and var1 must be in the Background Curves data folder.

Examples in the rest of this chapter use object names alone and thus reference data in the current data folder. For more on data folders, see Chapter II-8, **Data Folders**.

Command Tooltips

In procedure windows and the command window, if you hover the mouse cursor over a command, such as an operation or function, Igor displays a tooltip that contains information about the command. If you hover over the name of a built-in structure, such as WMButtonAction, Igor displays the structure definition.

You can turn off this feature by choosing Misc→Miscellaneous Settings, selecting the Text Editing section, selecting the Editor Behavior tab, and unchecking the Show Context-sensitive Tooltips checkbox.

Command Completion

Procedure windows and the command line support automatic command completion.

When you type the first few letters of a command, a popup appears and allows you to quickly select a command. Use the arrow keys to move up and down the list of completion options. Press the Enter key or Tab key to insert the highlighted text in the document.

If you hover the mouse cursor over a completion option or use the arrow keys to change the highlighted option, a tool tip is displayed that shows the template of the selected option.

You can adjust Command completion settings in Completion tab of the Text Editing category of the Miscellaneous Settings dialog. You can separately enable or disable completion in procedure windows and the command line. You can control the delay between the last keypress and the display of the completion options popup and whether an opening parenthesis should be appended when you insert an item that requires parentheses.

Completion is currently not supported for objects such as waves and variables. Support for these types may be added in a future version of Igor.

Command completion is not context sensitive. This means that you will sometimes be offered completion options that do not make sense in the context of the text you are entering. For example, if you type "Display/HID", you might get the following completion options: HideIgorMenus, HideInfo, HideProcedures, HideTools". Those options are not valid as a flag for the Display operation, but the command completion algorithm isn't able to filter them out.

Types of Commands

There are three fundamentally different types of commands that you can execute from the command line:

- assignment statements
- operation commands
- user-defined procedure commands

Here are examples of each:

```
wave1 = sin(2*pi*freq*x)       // assignment statement

Display wave1,wave2 vs xwave   // operation command

MyFunction(1.2,"hello")        // user-defined procedure command
```

As Igor executes commands you have entered, it must determine which of the three basic types of commands you have typed. If a command starts with a wave or variable name then Igor assumes it is an assignment statement. If a command starts with the name of a built-in or external operation then the command is treated as an operation. If a command begins with the name of a user-defined macro, user-defined function or external function then the command is treated accordingly.

Note that built-in functions can only appear in the right-hand side of an assignment statement, or as a parameter to an operation or function. Thus, the command:

```
sin(x)
```

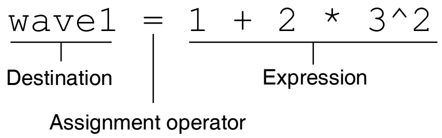
is not allowed and you will see the error, “Expected wave name, variable name, or operation.” On the other hand, these commands are allowed:

```
Print sin(1.567)               // sin is parameter of print operation
wave1 = 5*sin(x)               // sin in right side of assigment
```

If, perhaps due to a misspelling, Igor can not determine what you want to do, it will display an error dialog and the error will be highlighted in the command line.

Assignment Statements

Assignment statement commands start with a wave or variable name. The command assigns a value to all or part of the named object. An assignment statement consists of three parts: a destination, an assignment operator, and an expression. For example:



This assigns 19 to every point in wave1.

The spaces in the above example are not required. You could write:

```
wave1=1+2*3^2
```

See **Waveform Arithmetic and Assignments** on page II-74 for details on wave assignment statements.

In the following examples, str1 is a string variable, created by the String operation, var1 is a numeric variable, created by the Variable operation, and wave1 is a wave, created by the Make operation.

```
str1 = "Today is " + date()                // string assignment

str1 += ", and the time is " + time()      // string concatenation

var1 = strlen(str1)                        // variable assignment

var1 = pnt2x(wave1,numpnts(wave1)/2)       // variable assignment

wave1 = 1.2*exp(-0.2*(x-var1)^2)           // wave assignment

wave1[3] = 5                               // wave assignment

wave1[0,;3]= wave2[p/3] *exp(-0.2*x)       // wave assignment
```

These all operate on objects in the current data folder. To operate on an object in another data folder, you need to use a data folder path:

```
root:'run 1':wave1[3] = 5         // wave assignment
```

(This syntax applies to the command line and macros only, not to user-defined functions in which you must use **Wave References** to read and write waves.)

See Chapter II-8, **Data Folders**, for further details.

If you use liberal wave names (see **Object Names** on page III-501), you must use quotes:

```
'wave 1' = 'wave 2'          // Right

wave 1 = wave 2              // Wrong
```

(This syntax applies to the command line and macros only, not to user-defined functions in which you must use **Wave References** to read and write waves.)

Assignment Operators

The assignment operator determines the way in which the expression is combined with the destination. Igor supports the following assignment operators:

Operator	Assignment Action
=	Destination contents are set to the value of the expression.
+=	Expression is added to the destination.
-=	Expression is subtracted from the destination.
*=	Destination is multiplied by the expression.
/=	Destination is divided by the expression.
:=	Destination is dynamically updated to the value of the expression whenever the value of any part of the expression changes. The := operator is said to establish a “dependency” of the destination on the expression.

For example:

```
wave1 = 10
```

sets each Y value of the wave1 equal to 10, whereas:

```
wave1 += 10
```

adds 10 to each Y value of wave1. This is equivalent to:

```
wave1 = wave1 + 10
```

The assignment operators =, := and += work with string assignment statements but -=, *= and /= do not. For example:

```
String str1; str1 = "Today is "; str1 += date(); Print str1
```

prints something like “Today is Fri, Mar 31, 2000”.

For more information on the := operator, see Chapter IV-9, **Dependencies**.

Operators

Here is a complete list of the operators that Igor supports in the expression part of an assignment statement in order of precedence:

Operator	Effect
`++ --`	Prefix and postfix increment and decrement. Require Igor Pro 7 or later. Available only for local variables in user-defined functions.
`^ << >>`	Exponentiation, bitwise left shift, bitwise right shift. Shifts require Igor Pro 7 or later.
`- ! ~`	Negation, logical complement, bitwise complement.
`* /`	Multiplication, division.
`+ -`	Addition or string concatenation, subtraction.
`== != > < >= <=`	Comparison operators.
`& | %^`	Bitwise AND, bitwise OR, bitwise XOR.
`&& || ? :`	Logical AND, logical OR, conditional operator.
`$`	Substitute following string expression as name.

Comparison operators do not work with NaN parameters because, by definition, NaN compared to anything, even another NaN, is false. Use numtype to test if a value is NaN.

Comparison operators, bitwise AND, bitwise OR, bitwise XOR associate right to left. Therefore a==b>=c means (a==(b>=c)). For example, 2==1>= 0 evaluates to 0, not 1.

All other binary operators associate left to right.

Aside from the precedence of common operators that everyone intuitively knows, it is useful to include parentheses to avoid confusion. You may know the precedence and associativity but someone reading your code may not.

Unary negation changes the sign of its operand. Logical complementation changes nonzero operands to zero and zero operands to 1. Bitwise complementation converts its operand to an unsigned integer by truncation and then changes it to its binary complement.

Exponentiation raises its left-hand operand to a power specified by its right-hand operand. That is, 3^2 is written as 3^2. In an expression a^b, if the result is assigned to a real variable or wave, then a must not be negative if b is not an integer. If the result is used in a complex expression, any combination of negative a, fractional b or complex a or b is allowed.

If the exponent is an integer, Igor evaluates the expression using only multiplication. There is no need to write a^2 as a*a to get efficient evaluation — Igor does the equivalent automatically. If, on the other hand, the exponent is not an integer then the evaluation is performed using logarithms, hence the restriction on negative a in a real expression.

Logical OR (||) and logical AND (&&) determine the truth or falseness of pairs of expressions. The AND operation returns true only when both expressions are true; OR will return true if *either* is true. As in C, true is *any* nonzero value, and false is zero. The operations are undefined for NaNs. These operators are not available in complex expressions.

The logical operators are evaluated from left to right, and an operand will not be evaluated if it is not necessary. For the example:

```
if(MyFunc1() && MyFunc2())
```

when MyFunc1() returns false (zero), then MyFunc2() will not be evaluated because the entire expression is already false. This can produce unexpected consequences when the right-hand expression has side effects, such as creating waves or setting global values.

Bitwise AND (&), OR (|), and XOR (%^) convert their operands to an unsigned integer by truncation and then return their binary AND, OR or exclusive OR.

Bitwise shifts, << and >>, return the lefthand operand shifted by the specified number of bits. They require Igor Pro 7 or later. The lefthand operation is truncated to an integer before shifting.

The conditional operator (? :) is a shorthand form of an if-else-endif expression. In the statement:

```
<expression> ? <TRUE> : <FALSE>
```

the first operand, <expression>, is the test condition; if it is nonzero then Igor evaluates the <TRUE> operand; otherwise <FALSE> is evaluated. Only one operand is evaluated according to the test condition. This is the same as if you had written:

```
if( <expression> )
   <TRUE>
else
   <FALSE>
endif
```

The “:” character in the conditional operator must always be separated from the two adjacent operands with a space. If you omit either space, you will get an error (“No such data folder”) because the expression can also be interpreted as part of a data folder path. To be safe, always separate the operands from the operator symbols with a space.

The operands must be numeric; for strings, use the **SelectString** function. When using complex expressions with the conditional operator, only the real portion is used when the operator evaluates the expression.

The conditional operator can easily cause confusion, so you should exercise caution when using it. For example, it is unclear from simple inspection what Igor may return for

```
1 ? 2 : 3 ? 4 : 5
```

(4 in this case), whereas

```
1 ? 2 : (3 ? 4 : 5)
```

will return 2. Always use parentheses to remove any ambiguity.

The comparison operators return 1 if the result of the comparison is true or 0 if it is false. For example, the == operator returns 1 if its operands are equal or 0 if they are not equal. The != operator returns the opposite. Because comparison operators return the values 1 or 0 they can be used in interesting ways. The assignment:

```
wave1 = sin(x)*(x<=50) + cos(x)*(x>50)
```

sets wave1 so that it is a sine wave below x=50 and a cosine wave above x=50. See also **Example: Comparison Operators and Wave Synthesis** on page II-82.

Note that the double equal sign, ==, is used to mean equality while the single equal sign, =, is used to indicate assignment.

Because of roundoff error, using == to test two numbers for equality may give incorrect results. It is safer to use <= and >= to see if a number falls in a narrow range. For example, imagine that you want to compare a variable to see if it is equal to one-third. The expression:

```
(v1 == 1/3)
```

is subject to failure because of roundoff. It is safer to use something like

```
((v1 > .33332) && (v1 < .33334))
```

If the numbers are integers then the use of == is safe because integers smaller than 2^{53} (approximately 10^{16}) are represented precisely in double-precision floating point numbers.

The previous discussion on operators has assumed numeric operands. The + operator is the only one that works with both numeric *and* string operands. For example, if str1 is a string variable then the assignment statement

```
str1 = "Today is " + "a nice day"
```

assigns the value “Today is a nice day” to str1. The other string operator, $ is discussed in **String Substitution Using $** on page IV-18.

Unless specified otherwise by parentheses, unary negation or complementation are carried out first followed by exponentiation then by multiplication or division followed by addition or subtraction then by comparison operators. The wave assignment:

```
wave1 = ((1 + 2) * 3) ^ 2
```

assigns the value 81 to every point in wave1, but

```
wave1 = 1 + 2 * 3 ^ 2
```

assigns the value 19.

`-a^b` is an exception to this rule and is evaluated as `-(a^b)`.

The precedence of string substitution, substrings, and wave indexing is somewhat complex. When in doubt, use parenthesis to enforce the precedence you want.

Obsolete Operators

As of Igor Pro 4.0, the old bitwise complement (%~), bitwise AND (%&), and bitwise OR (%|) operators have been replaced by new versions that omit the % character from the operator. These old bitwise operators can still be used interchangeably with the new versions but are not recommended for new code.

Operands

In addition to literal numbers like 3.141 or 27, operators can operate on variables and function values. In the assignment statement:

```
var1 = log(3.7) + var2
```

the operator + operates on the function value returned by log and on the variable var2. Functions and function values are discussed later in this chapter.

Numeric Type

In Igor, each numeric destination object (wave or variable) has its own numeric type. The numeric type consists of the numeric precision (e.g., double precision floating point) and the number type (real or complex). Waves can be single or double precision floating point or various sizes of integer but variables are always double precision floating point.

The numeric precision of the destination does not affect the calculations. With the exception of a few operations that are done in place such as the FFT, all calculations are done in double precision.

Although waves can have integer numeric types, wave expressions are always evaluated in double precision floating point. The floating point values are converted to integers by rounding as the final step before storing the value in the wave. If the value to be stored exceeds the range of values that the given integer type can represent, the results are undefined.

Starting with Igor Pro 7, Igor supports integer local variables and 64-bit integer waves. When one of these is the destination of an assignment statement, Igor performs calculations using integer arithmetic. See **Expression Evaluation** on page IV-38 for details.

The number type of the destination determines the initial number type (real or complex) of the assignment expression. This is important because Igor can not deal with "surprise" or "runtime" changes in number type. An example would be taking the square root of a negative number requiring that all following arithmetic be done using complex numbers.

Here are some examples:

```
Variable a, b, c, var1
Variable/C cvar1
Make wave1

var1= a*b
cvar1= c*cmplx(a+1,b-1)
wave1= var1 + real(cvar1)
```

The first expression is evaluated using the real number type. The second expression contains a mixture of two types. The multiplication of c with the result of the cmplx function is evaluated as complex while the arguments to the cmplx function are evaluated as real. The third example is evaluated as real except for the argument to the real function which is evaluated as complex.

Constant Type

You can define named numeric and string constants in Igor procedure files and use them in the body of user-defined functions.

Constants are defined in procedure files using following syntax:

```
Constant <name1> = <literal number> [, <name2> = <literal number>]

StrConstant <name1> = <literal string> [, <name2> = <literal string>]
```

You can use the static prefix to limit the scope to the given source file. For debugging, you can use the Override keyword as with functions.

These declarations can be used in the following ways:

```
Constant kFoo=1,kBar=2
StrConstant ksFoo="hello",ksBar="there"

static Constant kFoo=1,kBar=2
static StrConstant ksFoo="hello",ksBar="there"

Override Constant kFoo=1,kBar=2
Override StrConstant ksFoo="hello",ksBar="there"
```

Programmers may find that using the "k" and "ks" prefixes will make their code easier to read.

Names for numeric and string constants can conflict with all other names. Duplicate constants of a given type are not allowed except for static constants in different files and when used with Override. The only true conflict is with variable names and with certain built-in functions that do not take parameters such as pi. Variable names override constants, but constants override functions such as pi.

Dependency Assignment Statements

You can set up global variables and waves so that they automatically recalculate their contents when other global objects change. See Chapter IV-9, **Dependencies**, for details.

Operation Commands

An operation is a built-in or external routine that performs an action but, unlike a function, does not directly return a value. Here are some examples:

```
Make/N=512 wave1
Display wave1
Smooth 5, wave1
```

Operation commands perform the majority of the work in Igor and are automatically generated and executed as you work with Igor using dialogs.

You can use these dialogs to experiment with operations of interest to you. As you click in a dialog, Igor composes a command. This provides a handy way for you to check the syntax of the operation or to generate a command for use in a user-defined procedure. See Chapter V-1, **Igor Reference**, for a complete list of all built-in operations. Another way to learn their syntax is to use the Igor Help Browser's Command Help tab.

The syntax of operation commands is highly variable but in general consists of the operation name, followed by a list of flags (e.g., `/N=512`), followed by a parameter list. The operation name specifies the main action of the operation and determines the syntax of the rest of the command. The list of flags specifies variations on the default behavior of the operation. If the default behavior of the operation is satisfactory then no flags are required. The parameter list identifies the objects on which the operation is to operate. Some commands take no parameters. For example, in the command:

```
Make/D/N=512 wave1, wave2, wave3
```

the operation name is "`Make`". The list of flags is "`/D/N=512`". The parameter list is "`wave1, wave2, wave3`".

You can use numeric expressions in the parameter list of an operation where Igor expects a numeric parameter, but in an operation flag you need to parenthesize the expression. For example:

```
Variable val = 1.0
Make/N=(val) wave0, wave1
Make/N=(numpnts(wave0)) wave2
```

The most common types of parameters are literal numbers or numeric expressions, literal strings or string expressions, names, and waves. In the example above, wave1 is a name parameter when passed to the Make operation. It is a wave parameter when passed to the Display and Smooth operations. A name parameter can refer to a wave that may or may not already exist whereas a wave parameter must refer to an existing wave.

See **Parameter Lists** on page IV-11 for general information that applies to all commands.

User-Defined Procedure Commands

User-defined procedure commands start with a procedure name and take a list of parameters in parentheses. Here are a few examples:

```
MyFunction1(5.6, wave0, "igneous")
```

Macro and Function Parameters

You can invoke macros, but not functions, with one or more of the input parameters missing. When you do this, Igor displays a dialog to allow you to enter the missing parameters.

You can add similar capabilities to user-defined functions using the **Prompt** (see page V-782) and **DoPrompt** (see page V-167) keywords.

Macros provide very limited programming features so, with rare exceptions, you should program using functions.

Function Commands

A function is a routine that directly returns a numeric or string value. There are three classes of functions available to Igor users:

- Built-in
- External (XFUNCs)
- User-defined

Built-in numeric functions enjoy one advantage over external or user-defined functions: a few come in real and complex number types and Igor automatically picks the appropriate version depending on the current number type in an expression. External and user-defined functions must have different names when different types are needed. Generally, only real user and external functions need be provided.

For example, in the wave assignment:

```
wave1 = enoise(1)
```

if wave1 is real then the function enoise returns a real value. If wave1 is complex then enoise returns a complex value.

You can use a function as a parameter to another function, to an operation, to a macro or in an arithmetic or string expression so long as the data type returned by the function makes sense in the context in which you use it.

User-defined and external functions can also be used as commands by themselves. Use this to write a user function that has some purpose other than calculating a numeric value, such as displaying a graph or making new waves. Built-in functions cannot be used this way. For instance:

```
MyDisplayFunction(wave0)
```

External and user-defined functions can be used just like built-in functions. In addition, numeric functions can be used in curve fitting. See Chapter IV-3, **User-Defined Functions** and **Fitting to a User-Defined Function** on page III-190.

Most functions consist of a function name followed by a left parenthesis followed by a parameter list and followed by a right parenthesis. In the wave assignment shown at the beginning of this section, the function name is `enoise`. The parameter is 1. The parameter is enclosed by parentheses. In this example, the result from the function is assigned to a wave. It can also be assigned to a variable or printed:

```
K0 = enoise(1)
Print enoise(1)
```

User and external functions, but not built-in functions, can be executed on the command line or in other functions or macros without having to assign or print the result. This is useful when the point of the function is not its explicit result but rather its side effects.

Nearly all functions require parentheses even if the parameter list is empty. For example the function date() has no parameters but requires parentheses anyway. There are a few exceptions. For example the function Pi returns π and is used with no parentheses or parameters.

Igor's built-in functions are described in detail in Chapter V-1, **Igor Reference**.

Parameter Lists

Parameter lists are used for operations, functions, and macros and consist of one or more numbers, strings, keywords or names of Igor objects. The parameters in a parameter list must be separated with commas.

Expressions as Parameters

In an operation, function, or macro parameter list which has a numeric parameter you can always use a numeric expression instead of a literal number. A numeric expression is a legal combination of literal numbers, numeric variables, numeric functions, and numeric operators. For example, consider the command

```
SetScale x, 0, 6.283185, "v", wave1
```

which sets the X scaling for wave1. You could also write this as

```
SetScale x, 0, 2*PI, "v", wave1
```

Literal numbers include hexadecimal literals introduced by “0x”. For example:

```
Printf "The largest unsigned 16-bit number is: %d\r", 0xFFFF
```

Parentheses Required for /N=(<expression>)

Many operations accept flags of the form “/A=n” where A is some letter and n is some number. You can use a numeric expression for n but you must parenthesize the expression.

For example, both:

```
Make/N=512 wave1
Make/N=(2^9) wave1
```

are legal but this isn’t:

```
Make/N=2^9 wave1
```

A variable name is a form of numeric expression. Thus, assuming v1 is the name of a variable:

```
Make/N=(v1)
```

is legal, but

```
Make/N=v1
```

is not. This parenthesization is required only when you use a numeric expression in an operation flag.

String Expressions

A string expression can be used where Igor expects a string parameter. A string expression is a legal combination of literal strings, string variables, string functions, UTF-16 literals, and the string operator + which concatenates strings.

A UTF-16 literal represents a Unicode code value and consists of “U+” followed by four hexadecimal digits. For example:

```
Print "This is a bullet character: ‶ + U+2022
```

Setting Bit Parameters

A number of commands require that you specify a bit value to set certain parameters. In these instances you set a certain bit *number* by using a specific bit *value* in the command. The bit value is 2^n, where *n* is the bit number. So, to set bit 0 use a bit value of 1, to set bit 1 use a bit value of 2, etc.

For the example of the TraceNameList function the last parameter is a bit setting. To select normal traces you must set bit 0:

```
TraceNameList("",";",1)
```

and to select contour traces set bit 1:

```
TraceNameList("",";",2)
```

Most importantly, you can set multiple bits at one time by adding the bit values together. Thus, for TraceNameList you can select both normal (bit 0) and contour (bit 1) traces by using:

```
TraceNameList("",";",3)
```

See also **Using Bitwise Operators** on page IV-42.

RGBA Values

This section explains RGBA values used to specify colors in commands other than Gizmo commands. For Gizmo commands, see **Gizmo Color Specification** on page II-428.

In commands, colors are specified as RGBA values in the form (r,g,b[,a]).

r, g, and b specify the amount of red, green and blue in the color as integers from 0 to 65535.

The optional parameter a specifies "alpha" which represents the opacity of the color as an integer from 0 (fully transparent) to 65535 (fully opaque). a defaults to 65535 (fully opaque).

(0,0,0) represents opaque black and (65535,65535,65535) represents opaque white.

For example:

```
ModifyGraph rgb(wave0)=(0,0,0)                  // Opaque black
ModifyGraph rgb(wave0)=(65535,65535,65535)      // Opaque white
ModifyGraph rgb(wave0)=(65535,0,0,30000)        // Translucent red
```

Working With Strings

Igor has a rich repertoire of string handling capabilities. See **Strings** on page V-11 for a complete list of Igor string functions. Many of the techniques described in this section will be of interest only to programmers.

Many Igor operations require *string* parameters. For example, to label a graph axis, you can use the Label operation:

```
Label left, "Volts"
```

Other Igor operations, such as Make, require *names* as parameters:

```
Make wave1
```

Using the string substitution technique, described in **String Substitution Using $** on page IV-18, you can generate a name parameter by making a string containing the name and using the $ operator:

```
String stringContainingName = "wave1"
Make $stringContainingName
```

String Expressions

Wherever Igor requires a string parameter, you can use a string expression. A string expression can be:

- A literal string (`"Today is"`)
- The output of a string function (`date()`)
- An element of a text wave (`textWave0[3]`)
- A UTF-16 literal (`U+2022`)
- Some combination of string expressions (`"Today is" + date()`)

In addition, you can derive a string expression by indexing into another string expression. For example,

```
Print ("Today is" + date())[0,4]
```

prints “Today”.

A string variable can store the result of a string expression. For example:

```
String str1 = "Today is" + date()
```

A string variable can also be part of a string expression, as in:

```
Print "Hello. " + str1
```

Strings in Text Waves

A text wave contains an array of text strings. Each element of the wave can be treated using all of the available string manipulation techniques. In addition, text waves are commonly used to create category axes in bar charts. See **Text Waves** on page II-86 for further information.

String Properties

Strings in Igor can contain up to roughly two billion bytes.

Igor strings are usually used to store text data but you can also use them to store binary data.

When you treat a string as text data, for example if you print it to the history area of the command window or display its contents in an annotation or control, internal Igor routines treat a null byte as meaning “end-of-string”. Consequently, if you treat a binary string as if it were text, you may get unexpected results.

When you treat a string as text, Igor assumes that the text is encoded using the UTF-8 text encoding. For further discussion, see **String Variable Text Encodings** on page III-478.

Unicode Literal Characters

A Unicode literal represents a character using its UTF-16 code value. It consists of “U+” followed by four hexadecimal digits. For example:

```
Print "This is a bullet character: " + U+2022
```

The list of Unicode character codes is maintained at http://www.unicode.org/charts.

Escape Sequences in Strings

Igor treats the backslash character in a special way when reading literal (quoted) strings in a command line. The backslash is used to introduce an “escape sequence”. This just means that the backslash plus the next character or next few characters are treated like a different character — one you could not otherwise include in a quoted string. The escape sequences are:

`\t`	Represents a tab character
`\r`	Represents a return character (CR)
`\n`	Represents a linefeed character (LF)
`\'`	Represents a ' character (single-quote)
`\"`	Represents a " character (double-quote)
`\\`	Represents a \ character (backslash)
`\ddd`	Represents an arbitrary byte code ddd is a 3 digit octal number
`\xdd`	Represents an arbitrary byte code dd is a 2 digit hex number Requires Igor Pro 7.00 or later
`\udddd`	Represents a UTF-16 code point dddd is a 4 digit hex number Requires Igor Pro 7.00 or later
`\Udddddddd`	Represents a UTF-32 code point dddddddd is an 8 digit hex number Requires Igor Pro 7.00 or later

For example, if you have a string variable called “fileName”, you could print it in the history area using:

```
fileName = "Test"
Printf "The file name is \"%s\"\r", fileName
```

which prints

```
The file name is "Test"
```

In the Printf command line, \" embeds a double-quote character in the format string. If you omitted the backslash, the " would end the format string. The \r specifies that you want a carriage return in the format string.

Unicode Escape Sequences in Strings

Igor represents text internally in UTF-8 format. UTF-8 is a byte-oriented encoding format for Unicode. In this section we see how to use the \u, \U and \x escape sequences to represent Unicode characters in literal strings.

The use of UTF-8 and these escape sequences requires Igor Pro 7.00 or later. If you use them, your will get incorrect data or errors in Igor Pro 6.x.

In the first set of examples, we use the hexadecimal code 0041. This is hexadecimal for the Unicode code point representing CAPITAL LETTER A.

```
String str
str = "\x41"        // Specify code point using UTF-8 escape sequence
Print str
str = "\u0041"      // Specify code point using UTF-16 escape sequence
Print str
str = "\U0000041"   // Specify code point using UTF-32 escape sequence
Print str
```

When you use `\xdd`, Igor replaces the escape sequence with the byte specified by dd. Therefore you must specify byte values representing a valid UTF-8 character. 41 is hexadecimal for the UTF-8 encoding for CAPITAL LETTER A. If the code point that you specify is not a valid UTF-16 or UTF-32 code point, Igor replaces the escape sequence with the Unicode replacement character.

When you use `\udddd` or `\Udddddddd`, Igor replaces the escape sequence with the UTF-8 bytes for the corresponding Unicode code point as represented in UTF-16 or UTF-32 format.

Now we specify the characters for "Toyota" in Japanese Kanji:

```
str = "\xE8\xB1\x8A\xE7\x94\xB0"        // UTF-8
Print str
str = "\u8C4A\u7530"                    // UTF-16
Print str
str = "\U00008C4A\U00007530"            // UTF-32
Print str
```

In order to see the correct characters you must be using a font that includes Japanese characters.

\U is mainly of use to enter rare Unicode characters that are not in the Basic Multilingual Plane. Such characters can not be specified with single 16-bit UTF-16. Here is an example:

```
str = "\U00010300"                      // UTF-32 for OLD ITALIC LETTER A
Print str
str = "\xF0\x90\x8C\x80"                // UTF-8 for OLD ITALIC LETTER A
Print str
```

OLD ITALIC LETTER A is located in the Unicode Supplementary Multilingual Plane (plane 1).

Embedded Nulls in Literal Strings

A null in a byte-oriented string is a byte with the value 0.

It is possible to embed an null byte in a string:

```
String test = "A\x00B"                         // OK in Igor Pro 7 or later
Print strlen(text)                                        // Prints 3
Print char2num(test[0]),char2num(test[1]),char2num(test[2]) // Prints 65 0 66
```

Here Igor converts the escape sequence \x00 to a null byte.

You typically have no need to embed a null in an Igor string because strings are usually used to store readable text and null does not represent a readable character. The need might arise, however, if you are using the string to store binary rather than text data. For example, if you need to send a small amount of binary data to an instrument, you can do so using \x escape sequences to represent the data in a literal string.

Although Igor allows you to embed nulls in literal strings, other parts of Igor are not prepared to handle them. For example:

```
Print test           // Prints "A", not "A<null>B"
```

In C null is taken to mean "end-of-string". Because of the use of C strings and C library routines in Igor, many parts of Igor will treat an embedded null as end-of-string. That is why the Print statement above prints just "A".

The bottom line is: You can store binary data, including nulls, in an Igor string but many parts of Igor that expect readable text will treat a null as end-of-string. See **Working With Binary String Data** for further discussion.

String Indexing

Indexing can extract a part of a string. This is done using a string expression followed by one or two numbers in brackets. The numbers are byte positions. Zero is the byte position of the first byte; n-1 is the byte position of the last byte of an n byte string value. For example, assume we create a string variable called s1 and assign a value to it as follows:

```
String s1="hello there"
```

h	e	l	l	o		t	h	e	r	e
0	1	2	3	4	5	6	7	8	9	10

Then,

```
Print s1[0,4]               prints   hello
Print s1[0,0]               prints   h
Print s1[0]                 prints   h
Print s1[1]+s1[2]+s1[3]     prints   ell
Print (s1+" jack")[6,15]    prints   there jack
```

A string indexed with one index, such as s1[p], is a string with one byte in it if p is in range (i.e. 0 ≤ p ≤ n-1). s1[p] is a string with no bytes in it if p is not in range. For example:

```
Print s1[0]                 prints   h
Print s1[-1]                prints   (nothing)
Print s1[10]                prints   e
Print s1[11]                prints   (nothing)
```

A string indexed with two indices, such as s1[p1,p2], contains all of the bytes from s1[p1] to s1[p2]. For example:

```
Print s1[0,10]              prints   hello there
Print s1[-1,11]             prints   hello there
Print s1[-2,-1]             prints   (nothing)
Print s1[11,12]             prints   (nothing)
Print s1[10,0]              prints   (nothing)
```

You can use INF to mean “end of string”:

```
Print s1[10,INF]            prints   (nothing)
```

The indices in these examples are byte positions, not character positions. See **Characters Versus Bytes** on page III-483 for a discussion of this distinction. See **Character-by-Character Operations** on page IV-173 for an example of stepping through characters using user-defined functions.

Because the syntax for string indexing is identical to the syntax for wave indexing, you have to be careful when using text waves. For example:

```
Make/T textWave0 = {"Red", "Green", "Blue"}
```

```
Print textWave0[1]             prints   Green
Print textWave0[1][1]          prints   Green
Print textWave0[1][1][1]       prints   Green
Print textWave0[1][1][1][1]    prints   Green
Print textWave0[1][1][1][1][1] prints   r
```

The first four examples print row 1 of column 0. Since waves may have up to four dimensions, the first four [1]’s act as dimension indices. The column, layer, and chunk indices were out of range and were clipped to a value of 0. Finally in the last example, we ran out of dimensions and got string indexing. Do not count on this behavior because future versions of Igor may support more than four dimensions.

The way to avoid the ambiguity between wave and string indexing is to use parentheses like so:

```
Print (textWave0[1])[1]     prints   r
```

The way to avoid the ambiguity between wave and string indexing is to use parentheses like so:

```
String tmp = textWave0[1]
Print tmp[1]                prints   r
```

String Assignment

You can assign values to string variables using string assignment. We have already seen the simplest case of this, assigning a literal string value to a string variable. You can also assign values to a subrange of a string variable, using string indexing. Once again, assume we create a string variable called s1 and assign a value to it as follows:

```
String s1="hello there"
```

Then,

```
s1[0,4]="hi"; Print s1              prints       hi there
s1[0,4]="greetings"; Print s1       prints       greetings there
s1[0,0]="j"; Print s1               prints       jello there
s1[0]="well "; Print s1             prints       well hello there
s1[100000]=" jack"; Print s1        prints       hello there jack
s1[-100]="well ";print s1           prints       well hello there
```

When the s1[p1,p2]= syntax is used, the right-hand side of the string assignment *replaces* the subrange of the string variable identified by the left-hand side, after p1 and p2 are clipped to 0 to n, where n is the number of bytes in the destination.

When the s1[p]= syntax is used, the right-hand side of the string assignment *is inserted before* the byte identified by p after p is clipped to 0 to n.

The subrange assignment just described for string variables is not supported when a text wave is the destination. To assign a value to a range of a text wave element, you will need to create a temporary string variable. For example:

```
Make/O/T tw = {"Red", "Green", "Blue"}
String stmp= tw[1]
stmp[1,2]="XX"
tw[1]= stmp;
```

```
Print tw[0],tw[1],tw[2]                prints        Red GXXen Blue
```

The indices in these examples are byte positions, not character positions. See **Characters Versus Bytes** on page III-483 for a discussion of this distinction.

String Substitution Using $

Wherever Igor expects the literal *name* of an operand, such as the name of a wave, you can instead provide a string expression preceded by the $ character. The $ operator evaluates the string expression and returns the *value* as a *name*.

For example, the Make operation expects the name of the wave to be created. Assume we want to create a wave named wave0:

```
Make wave0                // OK: wave0 is a literal name.

Make $"wave0"             // OK: $"wave0" evaluates to wave0.

String str = "wave0"
Make str                  // WRONG: This makes a wave named str.
Make $str                 // OK: $str evaluates to wave0.
```

$ is often used when you write a function which receives the name of a wave to be created as a parameter. Here is a trivial example:

```
Function MakeWave(wName)
   String wName       // name of the wave

   Make $wName
End
```

We would invoke this function as follows:

```
MakeWave("wave0")
```

We use $ because we need a wave name but we have a string containing a wave name. If we omitted the $ and wrote:

```
Make wName
```

Igor would make a wave whose name is wName, not on a wave whose name is wave0.

String substitution is capable of converting a string expression to a *single* name. It can not handle multiple names. For example, the following will *not* work:

```
String list = “wave0;wave1;wave2”
Display $list
```

See **Processing Lists of Waves** on page IV-198 for ways to accomplish this.

See **Converting a String into a Reference Using $** on page IV-62 for details on using $ in a user-defined function.

$ Precedence Issues In Commands

There is one case in which string substitution does not work as you might expect. Consider this example:

```
String str1 = "wave1"
wave2 = $str1 + 3
```

(The uses of $ in this section apply to the command line and macros only, not to user-defined functions in which you must use **Wave References** to read and write waves.)

You might expect that this would cause Igor to set wave2 equal to the sum of wave1 and 3. Instead, it generates an “expected string expression” error. The reason is that Igor tries to concatenate str1 and 3 *before* doing the substitution implied by $. The + operator is also used to concatenate two string expressions, and it has higher precedence than the $ operator. Since str1 is a string but 3 is not, Igor cannot do the concatenation.

You can fix this by changing this wave assignment to one of the following:

```
wave2 = 3 + $str1
wave2 = ($str1) + 3
```

Both of these accomplish the desired effect of setting wave2 equal to the sum of wave1 and 3. Similarly,

```
wave2 = $str1 + $str2   // Igor sees "$(str1 + $str2)"
```

generates the same “expected string expression” error. The reason is that Igor is trying to concatenate str1 and $str2. $str2 is a name, not a string. The solution is:

```
wave2 = ($str1) + ($str2)  // sets wave2 to sum of two named waves
```

Another situation arises when using the $ operator and [. The [symbol can be used for either point indexing into a wave, or byte indexing into a string. The commands

```
String wvName = "wave0"
$wvName[1,2] = wave1[p]    // sets two values in wave named "wave0"
```

are interpreted to mean that points 1 and 2 of wave0 are set values from wave1.

If you intended “$wvName[1,2] = wave1” to mean that a wave whose name comes from bytes 1 and 2 of the wvName string (“av”) has all of its values set from wave1, you must use parenthesis:

```
$(wvName[1,2]) = wave1     // sets all values of wave named "av"
```

String Utility Functions

WaveMetrics provides a number of utility functions for dealing with strings. To see a list of the built-in string functions:

1. Open the Igor Help Browser Command Help tab.
2. Open the Advanced Filtering control.
3. Uncheck all checkboxes except for Functions.
4. Choose String from the Functions pop-up menu.

See **Character-by-Character Operations** on page IV-173 for an example of stepping through characters using user-defined functions.

Special Cases

This section documents some techniques that were devised to handle certain specialized situations that arise with respect to Igor’s command language.

Instance Notation

There is a problem that occurs when you have multiple instances of the same wave in a graph or multiple instances of the same object in a layout. For example, assume you want to graph yWave versus xWave0, xWave1, and xWave2. To do this, you need to execute:

```
Display yWave vs xWave0
AppendToGraph yWave vs xWave1
AppendToGraph yWave vs xWave2
```

The result is a graph in which yWave occurs three times. Now, if you try to remove or modify yWave using:

```
RemoveFromGraph yWave
```

or

```
ModifyGraph lsize(yWave)=2
```

Igor will always remove or modify the first instance of yWave.

Instance notation provides a way for you to specify a particular instance of a particular wave. In our example, the command

```
RemoveFromGraph yWave#2
```

will remove instance number 2 of yWave and

```
ModifyGraph lsize(yWave#2)=2
```

will modify instance number 2 of yWave. Instance numbers start from zero so "yWave" is equivalent to "yWave#0". Instance number 2 is the instance of yWave plotted versus xWave2 in our example.

Where necessary to avoid ambiguity, Igor operation dialogs (e.g., Modify Trace Appearance) automatically use instance notation. Operations that accept trace names (e.g., ModifyGraph) or layout object names (e.g., ModifyObject) accept instance notation.

A graph can also display multiple waves with the same name if the waves reside in different datafolders. Instance notation applies to the this case also.

Instance Notation and $

The $ operator can be used with instance notation. The # symbol may be either inside the string operand or may be outside. For example `$"wave0#1"` or `$"wave0"#1`. However, because the # symbol may be inside the string, the string must be parsed by Igor. Consequently, unlike other uses of $, the wave name portion must be surrounded by single quotes if liberal names are used. For example, suppose you have a wave with the liberal name of `'ww#1'` plotted twice. The first instance would be `$"'ww#1'"` and the second `$"'ww#1'#1"` whereas `$"ww#1"` would reference the second instance of the wave ww.

Object Indexing

The ModifyGraph, ModifyTable and ModifyLayout operations, used to modify graphs, tables and page layouts, each support another method of identifying the object to modify. This method, object indexing, is used to generate style macros (see **Graph Style Macros** on page II-350). You may also find it handy in other situations.

Normally, you need to know the name of the object that you want to modify. For example, assume that we have a graph with three traces in it and we want to set the traces' markers from a procedure. We can write:

```
ModifyGraph marker(wave0)=1, marker(wave1)=2, marker(wave2)=3
```

Because it uses the names of particular traces, this command is specific to a particular graph. What do we do if we want to write a command that will set the markers of three traces in *any* graph, regardless of the names of the traces? This is where object indexing comes in.

Using object indexing, we can write:

```
ModifyGraph marker[0]=1, marker[1]=2, marker[2]=3
```

This command sets the markers for the first three traces in a graph, no matter what their names are.

Indexes start from zero. For graphs, the object index refers to traces starting from the first trace placed in the graph. For tables the index refers to columns from left to right. For page layouts, the index refers to objects starting from the first object placed in the layout.

/Z Flag

The ModifyGraph marker command above works fine if you know that there *are* three waves in the graph. It will, however, generate an error if you use it on a graph with fewer than 3 waves. The ModifyGraph operation supports a flag that can be used to handle this:

```
ModifyGraph/Z marker[0]=1, marker[1]=2, marker[2]=3
```

The /Z flag ignores errors if the command tries to modify an object that doesn't exist. The /Z flag works with the SetAxis and Label operations as well as with the ModifyGraph, ModifyTable and ModifyLayout operations. Like object indexing, the /Z flag is primarily of use in creating style macros, which is done automatically, but it may come in handy for other uses.

Chapter

IV-2

Programming Overview

Overview

You can perform powerful data manipulation and analysis interactively using Igor's dialogs and the command line. However, if you want to automate common tasks or create custom data analysis features, then you need to use procedures.

You can write procedures yourself, use procedures supplied by WaveMetrics, or find someone else who has written procedures you can use. Even if you don't write procedures from scratch, it is useful to know enough about Igor programming to be able to understand code written by others.

Programming in Igor entails creating procedures by entering text in a procedure window. After entering a procedure, you can execute it via the command line, by choosing an item from a menu, or using a button in a control panel.

The bulk of the text in a procedure window falls into one of the following categories:

- Pragmas, which send instructions from the programmer to the Igor compiler
- Include statements, which open other procedure files
- Constants, which define symbols used in functions
- Structure definitions, which can be used in functions
- Proc Pictures, which define images used in control panels, graphs, and layouts
- Menu definitions, which add menu items or entire menus to Igor
- Functions — compiled code which is used for nearly all Igor programming
- Macros — interpreted code which, for the most part, is obsolete

Functions are written in Igor's programming language. Like conventional procedural languages such as C or Pascal, Igor's language includes:

- Data storage elements (variables, strings, waves)
- Assignment statements
- Flow control (conditionals and loops)
- Calls to built-in and external operations and functions
- Ability to define and call subroutines

Igor programming is easier than conventional programming because it is much more interactive — you can write a routine and test it right away. It is designed for interactive use within Igor rather than for creating stand-alone programs.

Names in Programming

Functions, constants, variables, structures and all other programming entities have names. Names used in programming must follow the standard Igor naming conventions.

Names can consist of up to 255 characters. Only ASCII characters are allowed. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names in Igor are case insensitive.

Prior to Igor Pro 8.00, names used in programming were limited to 31 bytes. If you use long names, your procedures will require Igor Pro 8.00 or later.

The names of external operations and external functions are an exception. They are limited to 31 bytes.

Organizing Procedures

Procedures can be stored in the built-in Procedure window or in separate auxiliary procedure files. Chapter III-13, **Procedure Windows**, explains how to edit the Procedure window and how to create auxiliary procedure files.

At first you will find it convenient to do all of your Igor programming in the built-in Procedure window. In the long run, however, it will be useful to organize your procedures into categories so that you can easily find and access general-purpose procedures and keep them separate from special-case procedures.

This table shows how we categorize procedures and how we store and access the different categories.

Category	What	Where	How
Experiment Procedures	These are specific to a single Igor experiment. They include procedures you write as well as window recreation macros created automatically when you close a graph, table, layout, control panel, or Gizmo plot.	Usually experiment procedures are stored in the built-in Procedure window. You can optionally create additional procedure windows in a particular experiment but this is usually not needed.	You create an experiment procedure by typing in the built-in Procedure window.
Utility Procedures	These are general-purpose and potentially useful for any Igor experiment. WaveMetrics supplies utility procedures in the WaveMetrics Procedures folder. You can also write your own procedures or get them from colleagues.	WaveMetrics-supplied utility procedure files are stored in the WaveMetrics Procedures folder. Utility procedure files that you or other Igor users create should be stored in your own folder, in the Igor Pro User Files folder (see **Igor Pro User Files** on page II-31 for details) or at another location of your choosing. Place an alias or shortcut for your folder in "Igor Pro User Files/User Procedures".	Use an include statement to use a WaveMetrics or user utility procedure file. Include statements are described in **The Include Statement** on page IV-166.
Global Procedures	These are procedures that you want to be available from all experiments.	Store your global procedure files in "Igor Pro User Files/Igor Procedures" (see **Igor Pro User Files** on page II-31 for details). You can also store them in another folder of your choice and place an alias or shortcut for your folder in "Igor Pro User Files/Igor Procedures".	Igor automatically opens any procedure file in "Igor Pro 7 Folder/Igor Procedures" and "Igor Pro User Files/Igor Procedures" and subfolders or referenced by an alias or shortcut in those folders, and leaves it open in all experiments.

Following this scheme, you will know where to put procedure files that you get from colleagues and where to look for them when you need them.

Utility and global procedures should be general-purpose so that they can be used from any experiment. Thus, they should not rely on specific waves, global variables, global strings, specific windows or any other objects specific to a particular experiment. See **Writing General-Purpose Procedures** on page IV-167 for further guidelines.

After they are debugged and thoroughly tested, you may want to share your procedures with other Igor users via **IgorExchange**.

WaveMetrics Procedure Files

WaveMetrics has created a large number of utility procedure files that you can use as building blocks. These files are stored in the WaveMetrics Procedures folder. They are described in the WM Procedures Index help file, which you can access through the Help→Help Windows menu.

You access WaveMetrics procedure files using include statements. Include statements are explained under **The Include Statement** on page IV-166.

Using the Igor Help Browser, you can search the WaveMetrics Procedures folder to find examples of particular programming techniques.

Macros and Functions

There are two kinds of Igor procedures: **macros** and **functions**. They use similar syntax. The main difference between them is that Igor compiles user functions but interprets macros.

Because functions are compiled, they are dramatically faster than macros. Compilation also allows Igor to detect errors in functions when you write the function, whereas errors in macros are detected only when they are executed.

Functions provide many programming features that are not available in macros.

Macros are a legacy of Igor's early days. With rare exceptions, **all new programming should use functions**, not macros. To simplify the presentation of Igor programming, most discussion of macros is segregated into Chapter IV-4, **Macros**.

Scanning and Compiling Procedures

When you modify text in a procedure window, Igor must process it before you can execute any procedures. There are two parts to the processing: scanning and function compilation. In the scanning step, Igor finds out what procedures exist in the window. In the compilation step, Igor's function compiler converts the function text into low-level instructions for later execution.

For the sake of brevity, we use the term "compile" to mean "scan and compile" except when we are specifically pointing out the distinction between these two steps.

You can *explicitly* compile the procedures using the Compile button in the Procedure window or the Compile item in the Macros menu.

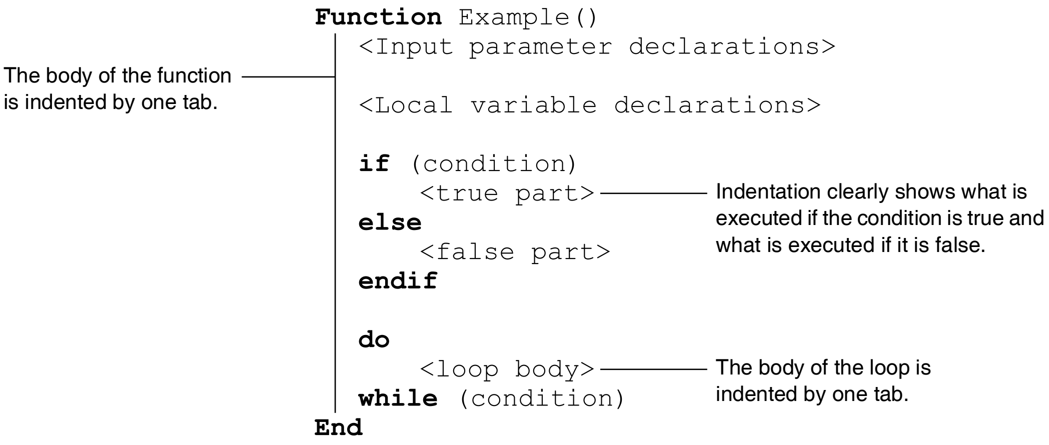
By default, Igor *automatically* compiles the procedure text at appropriate times. For example, if you type in the Procedure window and then hide it by clicking in the close button, Igor will automatically compile.

If you have many procedures that take long to compile, you may want to turn auto-compiling off using the Macros menu.

When Auto-compile is deselected, Igor compiles only when you explicitly request it. Igor will still scan the procedures when it needs to know what macros and functions exist.

Indentation Conventions

We use indentation to indicate the structure of a procedure.



```
Function Example()
    <Input parameter declarations>

    <Local variable declarations>

    if (condition)
        <true part>
    else
        <false part>
    endif

    do
        <loop body>
    while (condition)
End
```

The body of the function is indented by one tab.
Indentation clearly shows what is executed if the condition is true and what is executed if it is false.
The body of the loop is indented by one tab.

The structural keywords, shown in bold here, control the flow of the procedure. The purpose of the indentation is to make the structure of the procedure apparent by showing which lines are within which structural keywords. Matching keywords are at the same level of indentation and all lines within those keywords are indented by one tab.

The Edit menu contains aids for maintaining or adjusting indentation. You can select multiple lines and choose Indent Left or Indent Right. You can have Igor automatically adjust the indentation of a procedure by selecting the whole procedure or a subset and then choosing Adjust Indentation.

Igor does not require that you use indentation but we recommend it for readability.

What’s Next

The next chapter covers the core of Igor programming — writing user-defined functions.

Chapter IV-4, **Macros**, explains macros. Because new programming does not use macros, that chapter is mostly of use for understanding old Igor code.

Chapter IV-5, **User-Defined Menus**, explains user-defined menus. It explains how you can add menu items to existing Igor menus and create entire new menus of your own.

Chapter IV-6, **Interacting with the User**, explains other methods of interacting with the user, including the use of dialogs, control panels, and cursors.

Chapter IV-7, **Programming Techniques**, covers an assortment of programming topics. An especially important one is the use of the include statement, which you use to build procedures on top of existing procedures.

Chapter IV-8, **Debugging**, covers debugging using Igor’s symbolic debugger.

Chapter IV-9, **Dependencies**, covers dependencies — a way to tie a variable or wave to a formula.

Chapter IV-10, **Advanced Topics**, covers advanced topics, such as communicating with other programs, doing FTP transfers, doing data acquisition, and creating a background task.

Chapter

IV-3

User-Defined Functions

Overview

Most of Igor programming consists of writing user-defined functions.

A function has zero or more parameters. You can use local variables to store intermediate results. The function body consists of Igor operations, assignment statements, flow control statements, and calls to other functions.

A function can return a numeric, string, wave reference or data folder reference result. It can also have a side-effect, such as creating a wave or creating a graph.

Before we dive into the technical details, here is an informal look at some simple examples.

```
Function Hypotenuse(side1, side2)
   Variable side1, side2

   Variable hyp
   hyp = sqrt(side1^2 + side2^2)

   return hyp
End
```

The Hypotenuse function takes two numeric parameters and returns a numeric result. “hyp” is a local variable and sqrt is a built-in function. You could test Hypotenuse by pasting it into the built-in Procedure window and executing the following statement in the command line:

```
Print Hypotenuse(3, 4)
```

Now let’s look at a function that deals with text strings.

```
Function/S FirstStr(str1, str2)
   String str1, str2

   String result

   if (CmpStr(str1,str2) < 0)
      result = str1
   else
      result = str2
   endif

   return result
End
```

The FirstStr function takes two string parameters and returns the string that is first in alphabetical order. CmpStr is a built-in function. You could test FirstStr by executing pasting it into the built-in Procedure window the following statement in the command line:

```
Print FirstStr("ABC", "BCD")
```

Now a function that deals with waves.

```
Function CreateRatioOfWaves(w1, w2, nameOfOutputWave)
   WAVE w1, w2
   String nameOfOutputWave

   Duplicate/O w1, $nameOfOutputWave
   WAVE wOut = $nameOfOutputWave
   wOut = w1 / w2
End
```

The CreateRatioOfWaves function takes two wave parameters and a string parameter. The string is the name to use for a new wave, created by duplicating one of the input waves. The “`WAVE wOut`” statement creates a wave reference for use in the following assignment statement. This function has no direct result (no return statement) but has the side-effect of creating a new wave.

Here are some commands to test CreateRatioOfWaves:

```
Make test1 = {1, 2, 3}, test2 = {2, 3, 4}
CreateRatioOfWaves(test1, test2, "ratio")
Edit test1, test2, ratio
```

Function Syntax

The basic syntax of a function is:

```
Function <Name> (<Parameter list> [<Optional Parameters>]) [:<Subtype>]
   <Parameter declarations>

   <Local variable declarations>

   <Body code>

   <Return statement>
End
```

Here is an example:

```
Function Hypotenuse(side1, side2)
   Variable side1, side2            // Parameter declaration

   Variable hyp                     // Local variable declaration

   hyp = sqrt( side1^2 + side2^2 )  // Body code

   return hyp                       // Return statement
End
```

You could test this function from the command line using one of these commands:

```
Print Hypotenuse(3,4)
Variable/G result = Hypotenuse(3,4); Print result
```

As shown above, the function returns a real, numeric result. The Function keyword can be followed by a flag that specifies a different result type.

Flag	Return Value Type
/D	Double precision number (obsolete)
/C	Complex number
/S	String
/WAVE	Wave reference
/DF	Data folder reference

The /D flag is obsolete because all calculations are now performed in double precision. However, it is still permitted.

The Function Name

The names of functions must follow the standard Igor naming conventions. Names can consist of up to 255 characters. Only ASCII characters are allowed. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names must not conflict with the names of other Igor objects, functions or operations. Names in Igor are case insensitive.

Prior to Igor Pro 8.00, function names were limited to 31 bytes. If you use long function names, your procedures will require Igor Pro 8.00 or later.

The Procedure Subtype

You can identify procedures designed for specific purposes by using a subtype. Here is an example:

```
Function ButtonProc(ctrlName) : ButtonControl
   String ctrlName

   Beep
End
```

Here, " : ButtonControl" identifies a function intended to be called when a user-defined button control is clicked. Because of the subtype, this function is added to the menu of procedures that appears in the Button Control dialog. When Igor automatically generates a procedure it generates the appropriate subtype. See **Procedure Subtypes** on page IV-204 for details.

The Parameter List and Parameter Declarations

The parameter list specifies the name for each input parameter. There is no limit on the number of parameters.

All parameters must be declared immediately after the function declaration. In Igor Pro 7 or later you can use inline parameters, described below.

The parameter declaration declares the type of each parameter using one of these keywords:

Variable	Numeric parameter
Variable/C	Complex numeric parameter
String	String parameter
Wave	Wave reference parameter
Wave/C	Complex wave reference parameter
Wave/T	Text wave reference parameter
DFREF	Data folder reference parameter
FUNCREF	Function reference parameter
STRUCT	Structure reference parameter
int	Signed integer parameter- requires Igor7 or later
int64	Signed 64-bit integer parameter - requires Igor7 or later
uint64	Unsigned 32-bit integer parameter - requires Igor7 or later
double	Numeric parameter - requires Igor7 or later
complex	Complex numeric parameter - requires Igor7 or later

`int` is 32 bits in IGOR32 and 64 bits in IGOR64.

`double` is a synonym for `Variable` and `complex` is a synonym for `Variable/C`.

`WAVE/C` tells the Igor compiler that the referenced wave is complex.

`WAVE/T` tells the Igor compiler that the referenced wave is text.

Variable and string parameters are usually passed to a subroutine *by value* but can also be passed by reference. For an explanation of these terms, see **How Parameters Work** on page IV-58.

Integer Parameters

In Igor Pro 7 or later you can use these integer types for parameters and local variables in user-defined functions:

`int`	32-bit integer in IGOR32; 64-bit integer in IGOR64
`int64`	64-bit signed integer
`uint64`	64-bit unsigned integer

`int` is a generic signed integer that you can use for wave indexing or general use. It provides a speed improvement over Variable or double in most cases.

Signed `int64` and unsigned `uint64` are for special purposes where you need explicit access to bits. You can also use them in structures.

Optional Parameters

Following the list of required function input parameters, you can also specify a list of optional input parameters by enclosing the parameter names in brackets. You can supply any number of optional parameter values when calling the function by using the *`ParamName=Value`* syntax. Optional parameters may be of any valid data type. There is no limit on the number of parameters.

All optional parameters must be declared immediately after the function declaration. As with all other variables, optional parameters are initialized to zero. You must use the **ParamIsDefault** function to determine if a particular optional parameter was supplied in the function call.

See **Using Optional Parameters** on page IV-60 for an example.

Inline Parameters

In Igor Pro 7 or later you can declare user-defined functions parameters inline. This means that the parameter types and parameter names are declared in the same statement as the function name:

```
Function Example(Variable a, [ Variable b, double c ])
   Print a,b,c
End
```

or, equivalently:

```
Function Example2(
      Variable a,// The comma is optional
      [
         Variable b,
         double c
      ]
   )
   Print a,b,c
End
```

Local Variable Declarations

The parameter declarations are followed by the local variable declarations if the procedure uses local variables. Local variables exist only during the execution of the procedure. They are declared using one of these keywords:

Variable	Numeric variable
Variable/C	Complex numeric variable
String	String variable
NVAR	Global numeric variable reference
NVAR/C	Global complex numeric variable reference
SVAR	Global variable reference
Wave	Wave reference
Wave/C	Complex wave reference
Wave/T	Text wave reference
DFREF	Data folder reference
FUNCREF	Function reference
STRUCT	Structure
int	Signed integer - requires Igor7 or later
int64	Signed 64-bit integer - requires Igor7 or later
uint64	Unsigned 32-bit integer - requires Igor7 or later
double	Numeric variable - requires Igor7 or later
complex	Complex numeric variable - requires Igor7 or later

`double` is a synonym for `Variable` and `complex` is a synonym for `Variable/C`.

Numeric and string local variables can optionally be initialized. For example:

```
Function Example(p1)
   Variable p1

   // Here are the local variables
   Variable v1, v2
   Variable v3=0
   Variable/C cv1=cmplx(0,0)
   String s1="test", s2="test2"

   <Body code>
End
```

If you do not supply explicit initialization, Igor automatically initializes local numeric variables with the value zero. Local string variables are initialized with a null value such that, if you try to use the string before you store a value in it, Igor reports an error.

Initialization of other local variable types is discussed below. See **Wave References** on page IV-71, **Data Folder References** on page IV-78, **Function References** on page IV-107, and **Structures in Functions** on page IV-99.

The name of a local variable is allowed to conflict with other names in Igor, but they must be unique within the function. If you create a local variable named “sin”, for example, then you will be unable to use Igor’s built-in sin function within the function.

You can declare local variables anywhere in the function after the parameter declarations.

Body Code

This table shows what can appear in body code of a function.

What	Allowed in Functions?	Comment
Assignment statements	Yes	Includes wave, variable and string assignments.
Built-in operations	Yes, with a few exceptions.	See **Operations in Functions** on page IV-111 for exceptions.
Calls to user functions	Yes	
Calls to macros	No	
External functions	Yes	
External operations	Yes, with exceptions.	

Statements are limited to 2500 bytes per line except for assignment statements which, in Igor Pro 7 or later, can be continued on subsequent lines.

Line Continuation

In user-defined functions in Igor Pro 7 or later, you can use arbitrarily long expressions by including a line continuation character at the very end of a line. The line continuation character is backslash. For example:

```
Function Example1(double v1)
   return v1 + \
   2
End
```

Line continuation is supported for any numeric or string expression in a user-defined function. Here is an example using a string expression:

```
Function/S Example2(string s1)
   return s1 + \
      " " + \
      "there"
End
```

Line continuation is supported for numeric and string expressions only. It is not supported on other types of commands. For example, this generates a compile error:

```
Function Example3(double v1)
   Make wave0        \
        wave1
End
```

The Return Statement

A return statement often appears at the end of a function, but it can appear anywhere in the function body. You can also have more than one return statement.

The return statement immediately stops executing the function and returns a value to the calling function. The type of the returned value must agree with the type declared in the function declaration.

If there is no return statement, or if a function ends without hitting a return statement, then the function returns the value NaN (Not a Number) for numeric functions and null for other types of functions. If the calling function attempts to use the null value, Igor reports an error.

Multiple Return Syntax

In Igor Pro 8 or later, you can create a function with multiple return values using this syntax:

```
Function [ <output parameter list> ] <function name> ( <input parameter list> )
```

The square brackets are part of the syntax.

Both the output parameter list and the input parameter list must be specifed using inline syntax (see **Inline Parameters** on page IV-33). The entire function declaration must appear on one line.

You can return all output values using one return statement:

```
return [ <value list> ]
```

For example:

```
Function [ Variable v, String s ] Subroutine( Variable a )
   return [1+a, "hello"]
End

Function CallingRoutine()
   Variable v1
   String s1
   [v1, s1] = Subroutine(10)
   Print v1, s1
End
```

In Igor Pro 9.00 and later, you can declare the return variables in the destination parameter list like this:

```
Function CallingRoutine()
   [Variable v1, String s1] = Subroutine(10)
   Print v1, s1
End
```

You can set the return values individually without using a return statement like this:

```
Function [ Variable v, String s ] Subroutine( Variable a )
   v = 1 + a
   s = "hello"
End
```

The output parameter list can include numeric and string variables as well as structures. Any type that can be used as a pass-by-reference parameter (see **Pass-By-Reference** on page IV-59) can be used in the output parameter list.

Multiple Return Syntax Example

This example illustrates using structure and WAVE references as output parameters:

```
Structure DemoStruct
   Variable num
   String str
EndStructure

Function [STRUCT DemoStruct sOut, WAVE/T wOut] Subroutine(Variable v1)
   STRUCT DemoStruct s
   s.num = 4 + v1
   s.str = "from Subroutine"

   Make/O/T tw = {"text wave point 0","text wave point 1"}

   return [ s, tw ]
End

Function CallingRoutine()
```

```
   STRUCT DemoStruct s
   WAVE/T w
   [ s, w ] = Subroutine(2)
   Print s, w
End
```

Executing CallingRoutine gives:

```
STRUCT DemoStruct
 num: 6
 str: from Subroutine
tw[0]= {"text wave point 0","text wave point 1"}
```

In Igor Pro 9.00 and later, the CallingRoutine can be rewritten to declare the return variables in the destination parameter list:

```
Function CallingRoutine()
   [ STRUCT DemoStruct s, WAVE/T w ] = Subroutine(2)
   Print s, w
End
```

At runtime, WAVE variables declared in the destination list do not perform the usual time consuming lookup (trying to find a wave named w in this case.) They act as if WAVE/ZZ was specified. See **WAVE** on page V-1069 for details.

Using Multiple Return Syntax Variables As Input and Output

Igor initializes local numeric variables to 0, local string variables to NULL, and local WAVE variables to NULL. If you use a local variable as both and input and an output to a function that uses multiple return syntax, you should assign a value to the variable before using it:

```
Function [String str] AppendToString()
   str += "DEF"
End

Function CallingRoutineBad()
   String str                 // Initialized by Igor to NULL
   [str] = AppendToString()   // Error: Attempt to use a NULL string
   Print str
End

Function CallingRoutineGood()
   String str = "ABC"         // Explicitly initialized
   [str] = AppendToString()
   Print str                  // Prints "ABCDEF"
End
```

CallingRoutineBad passes a NULL string to AppendToString which treats it as both an input and an output. AppendToString attempts to append to the NULL string causing an "attempt to use NULL string" error.

Here is a more subtle way to make this mistake:

```
Function CallingRoutineBad()
   [String str] = AppendToString()  // Error: Attempt to use a NULL string
   Print str
End
```

Again, str is NULL and this results in an "attempt to use NULL string" error.

The same principle applies to local numeric variables and to WAVE references. If you are passing them to an MRS function that uses them as both an input and an output, you must initialize them in the calling function.

Expression Evaluation

An expression is a combination of literal values, variable references, wave references, function calls, parentheses and operators. Expressions appear on the right-hand side of assignment statements and as parameters in commands. For example:

```
Variable v = ((123 + someVariable) * someWave[3]) / SomeFunction()
```

In most cases Igor evaluates expressions using double-precision floating point. However, if the destination is an integer type, then Igor uses integer calculations.

Integer Expressions

Prior to Igor Pro 7, all calculations were performed in double-precision floating point. Double-precision can represent integers of up to 53 bits precisely. Integers larger than 53 bits are represented approximately in double-precision.

Igor Pro 7 or later can perform integer calculations instead of floating point. You trigger this by assigning a value to a local variable declared using the integer types int, int64 and uint64. Calculations are done using 32 bits or 64 bits depending on the type of the integer.

When an integer type variable is the destination in an expression in a function, the right-hand side is compiled using integer math. This avoids the limitation of 53 bits for double precision and may also provide a speed advantage. If you use a function such as sin that is inherently floating point, it is calculated as a double and then converted to an integer. You should avoid using anything that causes a double-to-integer conversion when the destination is a 64-bit integer.

This example shows various ways to use integer expressions:

```
Function Example()
   int a = 0x101              // 0x introduces a hexadecimal literal number
   int b = a<<2
   int c = b & 0x400
   printf "a=%x, b=%x, c=%x\r",a, b, c
End
```

This prints

```
a=101, b=404, c=400
```

To set bits in an integer, use the left-shift operator, <<. For example to set bit 60 in a 64-bit integer, use 1<<60. This is the integer equivalent of 2^60, but you can not use ^ because exponentiation is not supported in integer expressions.

To print all the bits in a 64-bit integer, use Printf with the %x or %d conversion specification. You can also use a Print command as long as the compiler can clearly see the number is an integer from the first symbol. For example:

```
Function Example()
   int64 i = 1<<60   // 1152921504606846976 (decimal), 1000000000000000 (hex)
   Printf "i = %0.16X\r", i
   Printf "i = %d\r", i
   Print "i =", i
   Print "i =", 0+i  // First symbol is not an integer variable or wave
End
```

This prints:

```
  i = 1000000000000000
  i = 1152921504606846976
  i = 1152921504606846976
  i = 1.15292e+18
```

Integer Expressions in Wave Assignment Statements

When compiling a wave assignment statement, the right-hand expression is compiled as 64-bit integer if the compiler knows that the destination wave is 64-bit integer. Otherwise, the expression is compiled as double. For example:

```
Function ExpressionCompiledAsInt64()
   Make/O/N=1/L w64
   w64 = 0x7FFFFFFFFFFFFFFF
   Print w64[0]
End
```

0x7FFFFFFFFFFFFFFF is the largest signed 64-bit integer value expressed in hexadecimal. It can not be precisely represented in double precision.

Here the /L flag tells Igor that the wave is signed 64-bit integer. This causes the compiler to compile the right-hand expression using signed 64-bit signed operations. The correct value is assigned to the wave and the correct value is printed.

In the next example, the compiler does not know that the wave is signed 64-bit integer because the /L flag was not used. Consequently the right-hand expression is compiled using double-precision operations. Because 0x7FFFFFFFFFFFFFFF can not be precisely represented in double precision, the value assigned to the wave is incorrect, as is the printed value:

```
Function ExpressionCompiledAsDouble()
   Make/O/N=1/Y=(0x80) w64    // Wave is int64 but Igor does not know it
   w64 = 0x7FFFFFFFFFFFFFFF   // Expression compiled as double
   Print w64[0]
End
```

You can use the /L flag in a wave declaration. For example:

```
Function ExpressionCompiledAsInt64()
   Make/O/N=1Y=(0x80) w64     // Wave is int64 but Igor does not know it
   Wave/L w = w64             // Igor knows that w refers to int64 wave
   w = 0x7FFFFFFFFFFFFFFF     // Expression compiled as int64
   Print w[0]
End
```

This tells Igor that the wave reference by w is signed 64-bit integer, causing the compiler to use signed 64-bit integer to compile the right-hand expression.

If the wave was unsigned 64-bit, we would need to use Wave/L/U.

In summary, to assign values to a 64-bit integer wave, make sure to use the correct flags so that Igor will compile the right-hand expression using 64-bit integer operations.

To view the contents of an integer wave, especially a 64-bit integer wave, display it in a table using an integer or hexadecimal column format or print individual elements on the command line. Print on an entire wave is not yet integer-aware and uses doubles.

Complex Integer Expressions

In Igor Pro 7, you could write wave assignment statements for complex integer waves up to 32 bits. For example:

```
Make/O/I/C complex32BitWave = cmplx(p,p)
```

In Igor Pro 8 or later, you can also write wave assignment statements for 64-bit complex integer waves. For example:

```
Make/O/L/C complex64BitWave = cmplx(p,p)   // This was not supported in Igor7
```

The cmplx function uses double-precision for its argument. This limits the precision of integer arguments to to cmplx to 53 bits. Consequently, when assigning to a 64-bit complex integer wave, values above 2^53 are imprecise.

In the case of 8-, 16- and 32-bit complex integer waves, math is done in double-precision floating point and then converted to integer. This is fine since double-precision supports up to 2^53 precisely. However, for 64-bit complex integers, doubles are not sufficient. Igor uses special routines for 64-bit complex integer addition and subtraction and returns an error for other operations such as multiplication and division. For example:

```
complex64BitWave += cmplx(-p,-p)     // OK
complex64BitWave *= cmplx(1,1)       // Feature not implemented error
```

Conditional Statements in Functions

Igor Pro supports two basic forms of conditional statements: if-else-endif and if-elseif-endif statements. Igor also supports multiway branching with switch and strswitch statements.

If-Else-Endif

The form of the if-else-endif structure is

```
if ( <expression> )
   <true part>
else
   <false part>
endif
```

`<expression>` is a numeric expression that is considered true if it evaluates to any nonzero number and false if it evaluates to zero. The true part and the false part may consist of any number of lines. If the expression evaluates to true, only the true part is executed and the false part is skipped. If the expression evaluates to false, only the false part is executed and the true part is skipped. After the true part or false part code is executed, execution continues with any code immediately following the if-else-endif statement.

The keyword “else” and the false part may be omitted to give a simple conditional:

```
if ( <expression> )
   <true part>
endif
```

Because Igor is line-oriented, you may not put the `if`, `else` and `endif` keywords all on the same line. They must each be in separate lines with no other code.

If-Elseif-Endif

The if-elseif-endif statement provides a means for creating nested if structures. It has the form:

```
if ( <expression1> )
   <true part 1>
elseif ( <expression2> )
   <true part 2>
[else
   <false part>]
endif
```

These statements follow similar rules as for if-else-endif statements. When any expression evaluates as true (nonzero), the code immediately following the expression is executed. If all expressions evaluate as false (zero) and there is an else clause, then the statements following the else keyword are executed. Once any code in a true part or the false part is executed, execution continues with any code immediately following the if-elseif-endif statement.

Comparisons

The relational comparison operators are used in numeric conditional expressions.

Symbol	Meaning	Symbol	Meaning
==	equal	<=	less than or equal
!=	not-equal	>	greater than
<	less than	>=	greater than or equal

These operators return 1 for true and 0 for false.

The comparison operators work with numeric operands only. To do comparisons with string operands, use the **CmpStr** function.

Comparison operators are usually used in conditional structures but can also be used in arithmetic expressions. For example:

```
wave0 = wave0 * (wave0 < 0)
```

This clips all positive values in wave0 to zero.

See also **Example: Comparison Operators and Wave Synthesis** on page II-82.

Operators in Functions

This section discusses operators in the context of user-defined functions. See **Operators** on page IV-6 for a discussion of operators used in the command line and macros as well as functions.

Bitwise and Logical Operators

The bitwise and logical operators are also used in conditional expressions.

Symbol	Meaning
~	Bitwise complement
&	Bitwise AND
|	Bitwise OR
%^	Bitwise exclusive OR
!	Logical NOT
&&	Logical AND
||	Logical OR
<<	Shift left (requires Igor7 or later)
>>	Shift right (requires Igor7 or later)

The precedence of operators is shown in the table under **Operators** on page IV-6. In the absence of parentheses, an operator with higher precedence (higher in the table) is executed before an operator with lower precedence.

Because the precedence of the arithmetic operators is higher than the precedence of the comparison operators, you can write the following without parentheses:

```
if (a+b != c+d)
   Print "a+b is not equal to c+d"
endif
```

Because the precedence of the comparison operators is higher than the precedence of the logical OR operator, you can write the following without parentheses:

```
if (a==b || c==d)
   Print "Either a equals b or c equals d"
endif
```

The same is true of the logical AND operator, &&.

For operators with the same precedence, there is no guaranteed order of execution and you must use parentheses to be sure of what will be executed. For example:

```
if ((a&b) != (c&d))
   Print "a ANDED with b is not equal to c ANDED with d"
endif
```

See **Operators** on page IV-6 for more discussion of operators.

Using Bitwise Operators

The bitwise operators are used to test, set, and clear bits. This makes sense only when you are dealing with integer operands.

Bit Action	Operation
Test	AND operator (&)
Set	OR operator (|)
Clear	Bitwise complement operator (~) followed by the bitwise AND operator (&)
Shift left	<< operator (requires Igor7 or later)
Shift right	>> operator (requires Igor7 or later)

This function illustrates various bit manipulation techniques.

```
Function DemoBitManipulation(vIn)
   Variable vIn

   vIn = trunc(vIn)               // Makes sense with integers only
   Printf "Original value: %d\r", vIn

   Variable vOut

   if ((vIn & 2^3) != 0)          // Test if bit 3 is set
      Print "Bit 3 is set"
   else
      Print "Bit 3 is cleared"
   endif

   vOut = vIn | (2^3)             // Set bit 3
   Printf "Set bit 3: %d\r", vOut

   vOut = vIn & ~(2^3)            // Clear bit 3
   Printf "Clear bit 3: %d\r", vOut

   vOut = vIn << 3                // Shift three bits left
   Printf "Shift three bits left: %d\r", vOut

   vOut = vIn >> 3                // Shift three bits right
   Printf "Shift three bits right: %d\r", vOut
End
```

For a simple demonstration, try this function passing 1 as the parameter.

Bit Shift Operators

Igor Pro 7 or later supports the bit shift operators << and >>. a<<n shifts the bits of the integer a left by n bits. a>>n shifts the bits of the integer a right by n bits.

Normally you should apply bit shift operators to integer values. If you apply a bit shift operator to a floating point value, any fractional part is truncated.

Increment and Decrement Operators

In Igor7 and later, in a user-defined function, you can use these operators on local variables:

++var	Pre-increment
var++	Post-increment
--var	Pre-decrement
var--	Post-decrement

var must be a real local variable.

The pre-increment functions increment the variable and then return its new value. In this example, a is initialized to 0. ++a then increments a to 1 and returns the new value. Consequently 1 is stored in b.

```
Function PreIncrementDemo()
   int a = 0
   int b = ++a
End
```

The post-increment functions return the variable's original value and then increment it. In this example, a is initialized to 0. a++ returns the original value, 0, and then increments a to 1. Consequently 0 is stored in b.

```
Function PostIncrementDemo()
   int a = 0
   int b = a++
End
```

The pre-decrement and post-decrement work the same but decrement the variable rather than incrementing it.

Switch Statements

The switch construct can sometimes be used to simplify complicated flow control. It chooses one of several execution paths depending on a particular value.

Instead of a single form of switch statement, as is the case in C, Igor has two types: *switch* for numeric expressions and *strswitch* for string expressions. The basic syntax of these switch statements is as follows:

```
switch(<numeric expression>)        // numeric switch
   case <literal number or numeric constant>:
      <code>
      [break]
   case <literal number or numeric constant>:
      <code>
      [break]
   . . .
   [default:
      <code>]
endswitch
```

```
strswitch(<string expression>)      // string switch
   case <literal string or string constant>:
      <code>
      [break]
   case <literal string or string constant>:
      <code>
      [break]
   . . .
   [default:
      <code>]
endswitch
```

The switch numeric or string expression is evaluated. In the case of numeric switches, the result is rounded to the nearest integer. Execution proceeds with the code following the matching case label. When none of the case labels match, execution continues at the default label, if it is present, or otherwise the switch exits with no action taken.

All of the case labels must be numeric or string constant expressions and they must all have unique values within the switch statement. The constant expressions can either be literal values or they must be declared using the Constant and StrConstant keywords for numeric and string switches respectively.

Literal numbers used as case labels are required by the compiler to be integers. Numeric constants used as case labels are rounded by the compiler to the nearest integers.

Execution proceeds within each case until a break statement is encountered or the endswitch is reached. The break statement explicitly exits the switch construct. Usually, you should put a break statement at the end of each case. If you omit the break statement, execution continues with the next case label. Do this when you want to execute a single action for more than one switch value.

The following examples illustrate how switch constructs can be used in Igor:

```
Constant kThree=3
StrConstant ksHow="how"

Function NumericSwitch(a)
   Variable a

   switch(a)                     // numeric switch
      case 1:
         print "a is 1"
         break
      case 2:
         print "a is 2"
         break
      case kThree:
      case 4:
         print "a is 3 or 4"
         break
      default:
         print "a is none of those"
         break
   endswitch
End

Function StringSwitch(a)
   String a

   strswitch(a)                  // string switch
      case "hello":
         print "a is hello"
         break
      case ksHow:
         print "a is how"
         break
      case "are":
      case "you":
         print "a is are or you"
         break
      default:
         print "a is none of those"
         break
   endswitch
End
```

Loops

Igor implements two basic types of looping structures: do-while and for loops.

The do-while loop iterates through the loop code and tests an exit condition at the end of each iteration.

The for loop is more complex. The beginning of a for loop includes expressions for initializing and updating variables as well as testing the loop's exit condition at the start of each iteration.

Do-While Loop

The form of the do-while loop structure is:

```
do
   <loop body>
while(<expression>)
```

This loop runs until the expression evaluates to zero or until a break statement is executed.

This example will always execute the body of the loop at least once, like the do-while loop in C.

```
Function Test(lim)
   Variable lim      // We use this parameter as the loop limit.

   Variable sum=0
   Variable i=0      // We use i as the loop variable.
   do
      sum += i       // This is the body; equivalent to sum=sum+i.
      i += 1         // Increment the loop variable.
   while(i < lim)
   return sum
End
```

Nested Do-While Loops

A nested loop is a loop within a loop. Here is an example:

```
Function NestedLoopTest(numOuterLoops, numInnerLoops)
   Variable numOuterLoops, numInnerLoops

   Variable i, j

   i = 0
   do
      j = 0
      do
         <inner loop body>
         j += 1
      while (j < numInnerLoops)
      i += 1
   while (i < numOuterLoops)
End
```

While Loop

This fragment will execute the body of the loop zero or more times, like the while loop in C.

```
do
   if (i > lim)
      break        // This breaks out of the loop.
   endif
   <loop body>
   i += 1
while(1)           // This would loop forever without the break.
...                // Execution continues here after the break.
```

In this example, the loop increment is 1 but it can be any value.

For Loop

The basic syntax of a for loop is:

```
for(<initialize loop variable>; <continuation test>; <update loop variable>)
   <loop body>
endfor
```

Here is a simple example:

```
Function Example1()
   Variable i

   for(i=0; i<5; i+=1)
      print i
   endfor
End
```

The beginning of a for loop consists of three semicolon-separated expressions. The first is usually an assignment statement that initializes one or more variables. The second is a conditional expression used to determine if the loop should be terminated — if true, nonzero, the loop is executed; if false, zero, the loop terminates. The third expression usually updates one or more loop variables.

When a for loop executes, the initialization expression is evaluated only once at the beginning. Then, for each iteration of the loop, the continuation test is evaluated at the start of every iteration, terminating the loop if needed. The third expression is evaluated at the end of the iteration and usually increments the loop variable.

All three expressions in a for statement are optional and can be omitted independent of the others; only the two semicolons are required. The expressions can consist of multiple assignments, which must be separated by commas.

In addition to the continuation test expression, for loops may also be terminated by break or return statements within the body of the loop.

A continue statement executed within the loop skips the remaining body code and execution continues with the loop's update expression.

Here is a more complex example:

```
Function Example2()
   Variable i,j

   for(i=0,j=10; ;i+=1,j*=2)
      if (i == 2)
         continue
      endif
      Print i,j
      if (i == 5)
         break
      endif
   endfor
End
```

Range-Based For Loop

A range-based for loop iterates over all elements of a wave. The basic syntax is:

```
for(<type> varName : <wave expression>)
   <loop body>
endfor
```

The range-based for loop feature was added in Igor Pro 9.00.

During each iteration of the loop, the specified loop variable contains the value of the corresponding wave element. For example:

```
Function Example1()
   Make/O/T/N=(2,2) tw = "p=" + num2str(p) + ",q=" + num2str(q)
   for (String s : tw)
      Print s
   endfor
End
```

Executing Example1 prints this:

```
p=0,q=0
p=1,q=0
p=0,q=1
p=1,q=1
```

You can omit the loop variable type if the loop variable was defined earlier in the function. You can also omit it if the wave expression is a wave reference defined earlier in the function either explicitly or automatically as in Example1. The for statement in Example1 could be written like this:

```
for (s : tw)      // Omit "String" because the tw is a know wave reference
```

Here is an example in which the wave expression is not a wave reference so the loop variable type is required:

```
Function Example2()
   for (String s : ListToTextWave(IndependentModuleList(";"),";"))
      Print s
   endfor
End
```

Example2 could be rewritten like this:

```
Function Example3()
   WAVE/T tw = ListToTextWave(IndependentModuleList(";"),";")
   for (s : tw)
      Print s
   endfor
End
```

A range-based for loop iterates over all elements of the wave, regardless of its dimensionality. For a multidimensional wave, it iterates in column-major order. For a 2D wave, this means that it iterates over all rows of column 0, then all rows of column 1, and so on for each column.

If the wave is numeric, the type of the loop variable does not need to be an exact match for the wave type. For example, the loop variable can be double even if the wave is an integer wave.

If the wave is a text wave, the loop variable must be a string. If the wave is a data folder reference wave, the loop variable must be a DFREF. If the wave is a wave reference wave, the loop variable must be a WAVE.

The next example illustrates looping over all elements of a wave reference wave:

```
Function WaveWaveExample()
   Make/O wave0 = {0,1,2}
   Make/O/T textWave0 = {"A","B","C"}
   Make/WAVE/FREE ww = {wave0,textWave0}      // Make a wave reference wave
   for (WAVE w : ww)
      String name = NameOfWave(w)
      int dataType = WaveType(w)
      Printf "Name=%s, dataType=%d\r", name, dataType
   endfor
End
```

In this example, the loop variable is a wave reference named w. It holds a reference to a numeric wave (wave0) on the first iteration and to a text wave (textWave0) on the second.

Break Statement

A break statement terminates execution of do-while loops, for loops, and switch statements. The break statement continues execution with the statement after the *enclosing* loop's while, endfor, or endswitch statement. A nested do-while loop example demonstrates this:

```
   …
   Variable i=0, j

   do                // Starts outer loop.
      if (i > numOuterLoops)
         break       // Break #1, exits from outer loop.
      endif
      j = 0
      do             // Start inner loop.
         if (j > numInnerLoops)
            break    // Break #2, exits from inner loop only.
         endif
         j += 1
      while (1)      // Ends inner loop.
      …              // Execution continues here from break #2.
      i += 1
   while (1)         // Ends outer loop.
   …                 // Execution continues here from break #1.
```

Continue Statement

The continue statement can be used in do-while and for loops to short-circuit the loop and return execution back to the top of the loop. When Igor encounters a continue statement during execution, none of the code following the continue statement is executed during that iteration.

Flow Control for Aborts

Igor Pro includes a specialized flow control construct and keywords that you can use to test for and respond to abort conditions. The AbortOnRTE and AbortOnValue keywords can be used to trigger aborts, and the try-catch-endtry construct can be used to control program execution when an abort occurs. You can also trigger an abort by pressing the **User Abort Key Combinations** or by clicking the Abort button in the status bar.

These are advanced techniques. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

AbortOnRTE Keyword

The AbortOnRTE (abort on runtime error) keyword can be used to raise an abort whenever a runtime error occurs. Use AbortOnRTE immediately after a command or sequence of commands for which you wish to catch a runtime error.

See **AbortOnRTE** on page V-18 for further details. For a usage example see **Simple try-catch-endtry Example** on page IV-49.

AbortOnValue Keyword

The AbortOnValue keyword can be used to abort function execution when a specified abort condition is satisfied. When AbortOnValue triggers an abort, it can also return a numeric abort code that you can use to characterize the cause.

See **AbortOnValue** on page V-19 for further details. For a usage example see **Simple try-catch-endtry Example** on page IV-49.

try-catch-endtry Flow Control

The try-catch-endtry flow control construct has the following syntax:

```
try
   <code>
catch
   <code to handle abort>
endtry
```

The try-catch-endtry flow control construct can be used to catch and respond to abnormal conditions in user functions. Code within the try and catch keywords tests for abnormal conditions and calls Abort, AbortOnRTE or AbortOnValue if appropriate. An abort also occurs if the user clicks the Abort button in the status bar or presses the **User Abort Key Combinations**.

When an abort occurs, execution immediately jumps to the first statement after the catch keyword. This catch code handles the abnormal condition, and execution then falls through to the first statement after endtry.

If no abort occurs, then the code between catch and endtry is skipped, and execution then falls through to the first statement after endtry.

When an abort occurs within the try-catch area, Igor stores a numeric code in the V_AbortCode variable. The catch code can use V_AbortCode to determine what caused the abort.

See **try-catch-endtry** on page V-1047 for further details.

Simple try-catch-endtry Example

We start with a simple example that illustrates the most common try-catch use. It catches and handles a runtime error.

```
Function DemoTryCatch0(name)
   String name              // Name to use for a new wave

   try
      Make $name            // Generates error if name is illegal or in use
      AbortOnRTE            // Abort if an error occurred

      // This code executes if no error occurred
      Printf "The wave '%s' was successfully created\r", name
   catch
      // This code executes if an error occurred in the try block
      Variable err = GetRTError(1)      // Get error code and clear error
      String errMessage = GetErrMessage(err, 3)
      Printf "While executing Make, the following error occurred: %s\r", errMessage
   endtry
End
```

Copy the code to the Procedure window of a new experiment and then execute:

```
DemoTryCatch0("wave0")
```

Since wave0 does not exist in a new experiment, DemoTryCatch0 creates it.

Now execute the same command again. This time the call to Make generates a runtime error because wave0 already exists. The call to AbortOnRTE generates an abort, because of the error generated by Make. The abort causes the catch code to run. It reports the error to the user and clears it to allow execution to continue.

Without the clearing of the runtime error, via the GetRTError call, the error would cause procedure execution to halt and Igor would report the error to the user via an error dialog.

Complex try-catch-endtry Example

The following example demonstrates how aborting flow control works. Copy the code to the Procedure window and execute the `DemoTryCatch1` function with 0 to 6 as input parameters. When you execute `DemoTryCatch1(6)`, the function loops until you click the Abort button at the right end of the status bar.

```
Function DemoTryCatch1(a)
   Variable a

   Print "A"
   try
      Print "B1"
      AbortOnValue  a==1 || a==2,33
      Print "B2"
      DemoTryCatch2(a)
      Print "B3"
      try
         Print "C1"
         if( a==4 || a==5 )
            Make $""; AbortOnRTE
         endif
         Print "C2"
      catch
         Print "D1"
         // will be runtime error so pass along to outer catch
         AbortOnValue a==5, V_AbortCode
         Print "D2"
      endtry
      Print "B4"
      if( a==6 )
         do
         while(1)
      endif
      Print "B5"
   catch
      Print "Abort code= ", V_AbortCode
      if( V_AbortCode == -4 )
         Print "Runtime error= ", GetRTError(1)
      endif
      if( a==1 )
         Abort "Aborting again"
      endif
      Print "E"
   endtry
   Print "F"
End
```

```
Function DemoTryCatch2(b)
   Variable b

   Print "DemoTryCatch2 A"
   AbortOnValue b==3,99
   Print "DemoTryCatch2 B"
End
```

User Abort Key Combinations

You can abort procedure execution by clicking the Abort button in the status bar or by pressing the following user abort key combinations:

Command-dot	Macintosh only
Ctrl+Break	Windows only
Shift+Escape	All platforms

Constants

You can define named numeric and string constants in Igor procedure files and use them in the body of user-defined functions.

Constants are defined in procedure files using following syntax:

```
Constant <name1> = <literal number> [, <name2> = <literal number>]
StrConstant <name1> = <literal string> [, <name2> = <literal string>]
```

For example:

```
Constant kIgorStartYear=1989, kIgorEndYear=2099
StrConstant ksPlatformMac="Macintosh", ksPlatformWin="Windows"

Function Test1()
   Variable v1 = kIgorStartYear
   String s1 = ksPlatformMac
   Print v1, s1
End
```

We suggest that you use the “k” prefix for numeric constants and the “ks” prefix for string constants. This makes it immediately clear that a particular keyword is a constant.

Constants declared like this are public and can be used in any function in any procedure file. A typical use would be to define constants in a utility procedure file that could be used from other procedure files as parameters to the utility routines. Be sure to use precise names to avoid conflicts with public constants declared in other procedure files.

If you are defining constants for use in a single procedure file, for example to improve readability or make the procedures more maintainable, you should use the `static` keyword (see **Static** on page V-906 for details) to limit the scope to the given procedure file.

```
static Constant kStart=1989, kEnd=2099
static StrConstant ksMac="Macintosh", ksWin="Windows"
```

Names for numeric and string constants are allowed to conflict with all other names. Duplicate constants of a given type are not allowed, except for static constants in different files and when used with the override keyword. The only true conflict is with variable names and with certain built-in functions that do not take parameters such as pi. Variable names, including local variable names, waves, NVARs, and SVARs, override constants, but constants override functions such as pi.

Pragmas

A pragma is a statement in a procedure file that sets a compiler mode or passes other information from the programmer to Igor. The form of a pragma statement is:

```
#pragma keyword [= parameter]
```

The pragma statement must be flush against the left margin of the procedure window, with no indentation.

Igor ignores unknown pragmas such as pragmas introduced in later versions of the program.

Currently, Igor supports the following pragmas:

```
#pragma rtGlobals = value
#pragma version = versionNumber
#pragma IgorVersion = versionNumber
#pragma hide = value
#pragma ModuleName = name
#pragma IndependentModule = name
#pragma TextEncoding = textEncodingNameStr // Igor Pro 7.00
#pragma DefaultTab = {mode, widthInPoints, widthInSpaces} // Igor Pro 9.00
```

The effect of a pragma statement lasts until the end of the procedure file that contains it.

The rtGlobals Pragma

The rtGlobals pragma controls aspects of the Igor compiler and runtime error checking in user-defined functions.

Prior to Igor Pro 3, to access a global (wave or variable) from a user-defined function, the global had to already exist. Igor Pro 3 introduced "runtime lookup of globals" under which the Igor compiler did not require globals to exist at compile time but rather connected references, declared with WAVE, NVAR and SVAR statements, to globals at runtime. Igor Pro 6.20 introduced stricter compilation of wave references and runtime checking of wave index bounds.

You enable and disable these behaviors using an rtGlobals pragma. For example:

```
#pragma rtGlobals = 3   // Strict wave reference mode, runtime bounds checking
```

A given rtGlobals pragma governs just the procedure file in which it appears. The pragma must be flush left in the procedure file and is typically put at the top of the file.

The rtGlobals pragma is defined as follows:

#pragma rtGlobals=0 Specifies the old, pre-Igor Pro 3 behavior.

This is no longer supported and acts like rtGlobals=1.

#pragma rtGlobals=1 Turns on runtime lookup of globals.

This is the default setting if there is no rtGlobals pragma in a given procedure file.

#pragma rtGlobals=2 Forces old experiments out of compatibility mode. This is superceded by rtGlobals=3. It is described under **Legacy Code Issues** on page IV-113.

#pragma rtGlobals=3 Turns on runtime lookup of globals, strict wave references and runtime checking of wave index bounds. Requires Igor Pro 6.2 or later.

rtGlobals=3 is recommended.

Under strict wave references (rtGlobals=3), you must create a wave reference for any use of a wave. Without strict wave references (rtGlobals=1), you do not need to create a wave reference unless the wave is used in an assignment statement. For example:

```
Function Test()
   jack = 0       // Error under rtGlobals=1 and under rtGlobals=3
   Display jack   // OK under rtGlobals=1, error under rtGlobals=3

   Wave jack      // jack is now a wave reference rather than a bare name
   Display jack   // OK under rtGlobals=1 and under rtGlobals=3
End
```

Even with rtGlobals=3, this compiles without error:

```
Function Test()
   // Make creates an automatic wave reference when used with a simple name
   Make jack
   Display jack   // OK under rtGlobals=1 and rtGlobals=3
End
```

See **Automatic Creation of WAVE References** on page IV-72 for details.

Under runtime wave index checking (rtGlobals=3), Igor reports an error if a wave index is out-of-bounds:

```
Function Test()
   Make/O/N=5 jack = 0  // Creates automatic wave reference

   jack[4] = 123        // OK
   jack[5] = 234        // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.

   Variable index = 5
   jack[index] = 234    // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.

   // Create and use a dimension label for point 4 of jack
   SetDimLabel 0,4,four,jack
   jack[%four] = 234    // OK

   // Use a non-existent dimension label.
   jack[%three] = 345   // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.
   // Under rtGlobals=1, this statement writes to point 0 of jack.
End
```

In Igor Pro 9.00 and later, Igor does runtime wave type checking which reports an error if a wave's type does not match the wave reference's type. In this example, we assign a numeric wave to a text wave reference:

```
#pragma rtGlobals=3
Function DemoRuntimeWaveTypeCheck()
   // WRONG: Assigning a numeric wave to a text wave reference
   WAVE/T tw = NewFreeWave(4,3)

   // Error is detected when the incorrect wave reference is used:
   // "An attempt was made to treat a numeric wave as if it were a text wave"
   String str = tw[0]
End
```

You can disable runtime wave type checking by executing:

```
SetIgorOption ReportWaveTypeMismatch = 0  // Turn runtime type checking off
```

You can ignore it for a specific line of code using GetRTError on the same line as the error:

```
String str = w[0]; int err = GetRTError(1)
```

See also: **Runtime Lookup of Globals** on page IV-65
Automatic Creation of WAVE References on page IV-72
Automatic Creation of WAVE, NVAR and SVAR References on page IV-70
Legacy Code Issues on page IV-113

The version Pragma

The version pragma sets the version of the procedure file. It is optional and is of interest mostly if you are the developer of a package used by a widespread group of users.

For details on the version pragma, see **Procedure File Version Information** on page IV-166.

The IgorVersion Pragma

The IgorVersion pragma is also optional and of interest to developers of packages. It gives you a way to prevent procedures from compiling under versions of Igor Pro older than the specified version number.

For example, the statement:

```
#pragma IgorVersion = 7.00
```

tells Igor that the procedure file requires Igor Pro 7.00 or later.

The hide Pragma

The hide pragma allows you to make a procedure file invisible.

For details on the hide pragma, see **Invisible Procedure Files** on page III-402.

The ModuleName Pragma

The ModuleName pragma gives you the ability to use static functions and proc pictures in a global context, such as in the action procedure of a control or on the command line. Using this pragma entails a two step process: define a name for the procedure file, and then use a special syntax to access objects in the named procedure file.

To define a module name for a procedure file use the format:

```
#pragma ModuleName = name
```

This statement associates the specified module name with the procedure file in which the statement appears.

You can then use objects from the named procedure file by preceding the object name with the name of the module and the # character. For example:

```
#pragma ModuleName = MyModule

Static Function Test(a)
   Variable a

   return a+100
End
```

Then, on the command line or from another procedure file, you can execute:

```
Print MyModule#Test(3)
```

Choose a distinctive module name so that it does not clash with module names used by other programmers. WaveMetrics uses module names with a `WM_` prefix, so you must not use such names.

For further discussion see **Regular Modules** on page IV-236.

The IndependentModule Pragma

The IndependentModule pragma is a way for you to designate groups of one or more procedure files to be compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows your control panels, menus, and procedures to continue to work regardless of user programming errors.

A file is designated as an independent module using

```
#pragma IndependentModule=imName
```

This is similar to `#pragma ModuleName=modName` (see **The ModuleName Pragma** on page IV-54) and, just as in the case of calling static functions in a procedure with #pragma ModuleName, calling nonstatic function in an IndependentModule from outside the module requires the use of *imName#functionName*() syntax.

To call any function, static or not, defined in an independent module from outside that module, you must qualify the call with the independent module name:

```
MyIndependentModule#Test()
```

For further discussion see **Independent Modules** on page IV-238.

The rtFunctionErrors Pragma

Normally, when an error occurs in a built-in function, the built-in function does not post an error but rather returns 0, NaN, or an empty string as the function result. For example, by default, the str2num built-in function in this user-defined function returns NaN but does not post an error:

```
Function Test()
   Variable val = str2num("abc")     // Returns NaN
   Print val
End
```

As a debugging aid, you can force Igor to post an error that occurs in a built-in function called from a user-defined function by adding this statement to the procedure file:

```
#pragma rtFunctionErrors = 1
```

Now, if you run the Test function, Igor displays an error dialog telling you that the str2num function expects a number.

The rtFunctionErrors pragma works for most errors in built-in functions called from user-defined functions, but not in all.

The rtFunctionErrors pragma was added in Igor Pro 7.00. Earlier versions of Igor ignore it.

The TextEncoding Pragma

The TextEncoding pragma provides a way for a programmer to mark an Igor procedure file as using a particular text encoding. This pragma was added in Igor Pro 7.00 and is ignored by earlier versions.

Here is an example:

```
#pragma TextEncoding = "UTF-8"
```

This pragma tells Igor7 or later that the procedure file is encoded using UTF-8, a form of Unicode. All new procedure files should use UTF-8.

Like all pragmas, the TextEncoding pragma must be flush against the left margin of the procedure file. It is an error to have more than one TextEncoding pragma in a given procedure file. The TextEncoding pragma can appear anywhere in the file and affects the whole file. By convention it is placed near the top of the file.

If your procedure file uses only ASCII characters then all versions of Igor on all platforms will interpret it correctly and there is no need for a TextEncoding pragma.

If your procedure file uses non-ASCII characters then we recommend that you add a TextEncoding pragma as this will allow Igor to reliably interpret it regardless of the user's operating system, system locale and default text encoding setting.

If the procedure file is to be used in Igor7 and later only then you should use the UTF-8 text encoding, like this:

```
#pragma TextEncoding = "UTF-8"
```

This allows you to use any Unicode character in the file.

The following text encodings are not supported for procedure files:

```
UTF-16LE, UTF-16BE, UTF32-LE, UTF32-BE
```

If you attempt to use these in a procedure file Igor will report an error.

Igor automatically adds a TextEncoding pragma under some circumstances.

It adds a TextEncoding pragma if you set the text encoding of a procedure file by clicking the Text Encoding button at the bottom of the window or by choosing Procedure→Text Encoding.

It adds a TextEncoding pragma if it displays the Choose Text Encoding dialog when you open a procedure file because it is unable to convert the text to UTF-8 without your help.

It is possible for the TextEncoding pragma to be in conflict with the text encoding used to open the file. For example, imagine that you open a file containing

```
#pragma TextEncoding = "Windows-1252"
```

and then you change "Windows-1252" to "UTF-8" by editing the file. You have now created a conflict where the text encoding used to open the file was one thing but the TextEncoding pragma is another. To resolve this conflict, Igor displays the Resolve Text Encoding Conflict dialog. In the dialog you can choose to make the file's text encoding match the TextEncoding pragma or to make the TextEncoding pragma match the file's text encoding. You can also cancel the dialog and manually edit the TextEncoding pragma.

For background information, see **Text Encodings** on page III-459.

The DefaultTab Pragma

The DefaultTab pragma allows you to set the width of a procedure file's default tabs to facilitate aligning comments in the file. It was added in Igor Pro 9.00 and is ignored by earlier versions of Igor. See **The Default Tab Pragma For Procedure Files** on page III-406 for details.

Unknown Pragmas

Igor ignores pragmas that it does not know about. This allows newer versions of Igor to use new pragmas while older versions ignore them. The downside of this change is that, if you misspell a pragma keyword, Igor will not warn you about it.

Proc Pictures

Proc pictures are binary PNG or JPEG images encoded as printable ASCII text in procedure files. They are intended for programmers who need to display pictures as part of the user interface for a procedure package. They can be used with the **DrawPICT** operation and with the picture keyword of the **Button**, **CheckBox**, and **CustomControl** operations.

The syntax for defining and using a proc picture is illustrated in the following example:

```
// PNG: width= 56, height= 44
Picture MyGlobalPicture
   ASCII85Begin
   M,6r;%14!\!!!!.8Ou6I!!!!Y!!!!M#Qau+!5G;q_uKc;&TgHDFAm*iFE_/6AH5;7DfQssEc39jTBQ
   =U!7FG,5u`*!m?g0PK.mR"U!k63rtBW)]$T)Q*!=Sa1TCDV*V+l:Lh^NW!fu1>;(.<VU1bs4L8&@Q_
   <4e(%"^F50:Jg6);j!CQdUA[dh6]%[OkHSC,ht+Q7ZO#.6U,IgfSZ!R1g':oO_iLF.GQ@RF[/*G98D
   bjE.g?NCte(pX-($m^\_FhhfL`D9uO6Qi5c[r4849Fc7+*)*O[tY(6<rkm^)/KLIc]VdDEbF-n5&Am
   2^hbTu:U#8ies_W<LGkp_LEU1bs4L8&?fqRJ[h#sVSSz8OZBBY!QNJ
   ASCII85End
End

Function Demo()
   NewPanel
   DrawPict 0,0,1,1,ProcGlobal#MyGlobalPicture
End
```

The ASCII text in the `MyGlobalPicture` procedure between the `ASCII85Begin` and `ASCII85End` is similar to output from the Unix `btoa` command, but with the header and trailer removed.

You can create proc pictures in Igor Pro from normal, global pictures using the Pictures dialog (Misc menu) which shows the experiment's picture gallery. Select a picture in the dialog and click the Copy Proc Picture button to place the text on the dlipboard. Then paste it in your procedure file. If the existing picture is not a JPEG or PNG, it is converted to PNG.

Proc pictures can be either global or local in scope. Global pictures can be used in all procedure files. Local pictures can be used only within the procedure file in which they are defined. Proc pictures are global by default and the picture name must be unique for all open procedure files.

Proc pictures can be defined in global procedure files (not in a regular module or independent module), in regular modules (see **Regular Modules** on page IV-236), or independent modules (see **Independent Modules** on page IV-238).

Proc Pictures in Global Procedure Files

Here is an example of a proc picture in a global procedure file:

```
Picture MyGlobalPicture
   ASCII85Begin
   ...
   ASCII85End
End
```

To draw a proc picture defined in a global procedure file you must qualify the picture name with the ProcGlobal keyword:

```
DrawPICT 0,0,1,1,ProcGlobal#MyGlobalPicture
```

A proc picture defined in a global procedure file can be used in any procedure file using the qualified name.

Proc Pictures in Regular Modules

Here is an example of a proc picture in a regular module:

```
#pragma ModuleName = MyRegularModule

static Picture MyRegularPicture
   ASCII85Begin
   ...
   ASCII85End
End
```

Notice the use of the static keyword. The puts the picture name in the namespace of the regular module.

To draw a proc picture defined in a regular module you must qualify the picture name with the name of the regular module:

```
DrawPICT 0,0,1,1,MyRegularModule#MyRegularPicture
```

A proc picture defined in a regular module is usually intended to be used in that module only but can also be used from a global procedure file using the qualified name. It can not be used from an independent module.

Proc Pictures in Independent Modules

Here is an example of a proc picture in an independent module:

```
#pragma IndependentModule = MyIndependentModule

Picture MyIndependentPicture
   ASCII85Begin
   ...
   ASCII85End
End
```

The static keyword is not used but the the picture name is still in the namespace of the independent module.

To draw a proc picture defined in an independent module you must qualify the picture name with the name of the independent module:

```
DrawPICT 0,0,1,1,MyIndependentModule#MyIndependentPicture
```

A proc picture defined in an independent module is usually intended to be used in that module only but can also be used from any procedure file using the qualified name.

How Parameters Work

There are two ways of passing parameters from a routine to a subroutine:

- Pass-by-value
- Pass-by-reference

“Pass-by-value” means that the routine passes the *value* of an expression to the subroutine. “Pass-by-reference” means that the routine passes *access to a variable* to the subroutine. The important difference is that, in pass-by-reference, the subroutine can change the original variable in the calling routine.

Like C++, Igor allows either method for numeric and string variables. You should use pass-by-value in most cases and reserve pass-by-reference for those situations in which you need multiple return values.

Example of Pass-By-Value

```
Function Routine()
   Variable v = 4321
   String s = "Hello"

   Subroutine(v, s)
End

Function Subroutine(v, s)
   Variable v
   String s

   Print v, s

   // These lines have NO EFFECT on the calling routine.
   v = 1234
   s = "Goodbye"
End
```

Note that v and s are *local variables* in Routine. In Subroutine, they are *parameters* which act very much like local variables. The names “v” and “s” are local to the respective functions. The v in Subroutine is not the same variable as the v in Routine although it initially has the same value.

The last two lines of Subroutine set the value of the local variables v and s. They have no effect on the value of the variables v and s in the calling Routine. What is passed to Subroutine is the numeric value 4321 and the string value “Hello”.

Pass-By-Reference

You can specify that a parameter to a function is to be passed by reference rather than by value. In this way, the function called can change the value of the parameter and update it in the calling function. This is much like using pointers to arguments in C++. This technique is needed and appropriate only when you need to return more than one value from a function.

Functions with pass-by-reference parameters can only be called from other functions — not from the command line.

Only numeric variables (declared by Variable, double, int, int64, uint64 or complex), string variables, structures, DFREF, and WAVE variables can be passed by reference. Structures are always passed by reference. Pass by reference DFREF and WAVE variables were added in Igor Pro 8.00.

The variable or string being passed must be a local variable and can not be a global variable. To designate a variable or string parameter for pass-by-reference, simply prepend an ampersand symbol before the name in the parameter declaration:

```
Function Subroutine(num1,num2,str1)
   Variable &num1, num2
   String &str1

   num1= 12+num2
   str1= "The number is"
End
```

and then call the function with the name of a local variable in the reference slot:

```
Function Routine()
   Variable num= 1000
   String str= "hello"
   Subroutine(num,2,str)
   Print str, num
End
```

When executed, Routine prints “The number is 14” rather than “hello 1000”, which would be the case if pass-by-reference were not used.

A pass-by-reference parameter can be passed to another function that expects a reference:

```
Function SubSubroutine(b)
   Variable &b
   b= 123
End

Function Subroutine(a)
   Variable &a
   SubSubroutine(a)
End

Function Routine()
   Variable num
   Subroutine(num)
   print num
End
```

You can not pass NVARs, SVARS, or FUNCREFs by reference to a function. You can use a structure containing fields of these types to achieve the same end.

How Waves Are Passed

Here is an example of a function “passing a wave” to a subroutine.

```
Function Routine()
   Make/O wave0 = x
   Subroutine(wave0)
End

Function Subroutine(w)
   WAVE w

   w = 1234    // This line DOES AFFECT the wave referred to by w.
End
```

We are really not passing a wave to Subroutine, but rather we are passing a reference to a wave. The parameter `w` is the wave reference.

Waves are global objects that exist independent of functions. The subroutine can use the wave reference to modify the contents of the wave. Using the terminology of “pass-by-value” and “pass-by-reference”, the wave reference is passed by value, but this has the effect of “passing the wave” by reference.

In Igor Pro 8.00 or later, you can specify that a WAVE reference variable itself be passed by reference. This allows you to change the WAVE reference variable so that it references a different wave. For example:

```
Function Routine()
   Make/O wave0 = {1, 2, 3}
   WAVE w = wave0
   Print "Original:", w
   Subroutine(w)
   Print "New:", w
End

Function Subroutine(WAVE& ww)
   Make/O wave1 = {5, 6}
   WAVE ww = wave1// Changes w variable in Routine to reference wave1
End
```

Executing Routine prints:

```
Original:
wave0[0]= {1,2,3}
  New:
wave1[0]= {5,6}
```

Using Optional Parameters

Following is an example of a function with two optional input parameters:

```
Function OptionalParameterDemo(a,b, [c,d])
   Variable a,b,c,d           // c and d are optional parameters

   // Determine if the optional parameters were supplied
   if( ParamIsDefault(c) && ParamIsDefault(d) )
      Print "Missing optional parameters c and d."
   endif

   Print a,b,c,d
End
```

Executing on the command line with none of the optional inputs:

```
OptionalParameterDemo(8,6)
  Missing optional parameters c and d.
  8  6  0  0
```

Executing with an optional parameter as an input:

```
OptionalParameterDemo(8,6, c=66)
  8  6  66  0
```

Note that the optional parameter is explicitly defined in the function call using the *ParamName=Value* syntax. All optional parameters must come after any required function parameters.

Local Versus Global Variables

Numeric and string variables can be **local** or **global**. “Local” means that the variable can be accessed only from within the procedure in which it was created. “Global” means that the variable can be accessed from the command line or from within any procedure. The following table shows the characteristics of local and global variables:

Local Variables	Global Variables
Are part of a procedure.	Are part of the data folder hierarchy of an Igor experiment.
Created using Variable or String within a procedure.	Created using Variable or String or Variable/G or String/G from the command line or within a procedure.
Used to store temporary results while the procedure is executing.	Used to store values that are saved from one procedure invocation to the next.
Cease to exist when the procedure ends.	Exist until you use KillVariables, KillStrings, or KillDataFolder.
Can be accessed only from within the procedure in which they were created.	Can be accessed from the command line or from within any procedure.

Local variables are private to the function in which they are declared and cease to exist when the function exits. Global variables are public and persistent — they exist until you explicitly delete them.

If you write a function whose main purpose is to display a dialog to solicit input from the user, you may want to store the user’s choices in global variables and use them to initialize the dialog the next time the user invokes it. This is an example of saving values from one invocation of a function to the next.

If you write a set of functions that loads, displays and analyzes experimentally acquired data, you may want to use global variables to store values that describe the conditions under which the data was acquired and to store the results from the analyses. These are examples of data accessed by many procedures.

With rare exceptions, you should not use global variables to pass information to procedures or from one procedure to another. Instead, use parameters. Using global variables for these purposes creates a web of hidden dependencies which makes understanding, reusing, and debugging procedures difficult.

Local Variables Used by Igor Operations

When invoked from a function, many Igor’s operations return results via local variables. For example, the WaveStats operation creates a number of local variables with names such as V_avg, V_sigma, etc. The following function illustrates this point.

```
Function PrintWaveAverage(w)
   WAVE w

   WaveStats/Q w
   Print V_avg
End
```

When the Igor compiler compiles the WaveStats operation, it creates various local variables, V_avg among them. When the WaveStats operation runs, it stores results in these local variables.

In addition to creating local variables, a few operations, such as CurveFit and FuncFit, check for the existence of specific local variables to provide optional behavior. For example:

```
Function ExpFitWithMaxIterations(w, maxIterations)
   WAVE w
   Variable maxIterations

   Variable V_FitMaxIters = maxIterations

   CurveFit exp w
End
```

The CurveFit operation looks for a local variable named V_FitMaxIters, which sets the maximum number of iterations before the operation gives up.

The documentation for each operation lists the special variables that it creates or looks for.

Converting a String into a Reference Using $

The $ operator converts a string expression into an object reference. The referenced object is usually a wave but can also be a global numeric or global string variable, a window, a symbolic path or a function. This is a common and important technique.

We often use a *string* to pass the *name* of a wave to a procedure or to algorithmically generate the name of a wave. Then we use the $ operator to convert the string into a wave reference so that we can operate on the wave.

The following trivial example shows why we need to use the $ operator:

```
Function MakeAWave(str)
   String str

   Make $str
End
```

Executing

```
MakeAWave("wave0")
```

creates a wave named wave0.

Here we use $ to convert the contents of the string parameter str into a name. The function creates a wave whose name is stored in the str string parameter.

If we omitted the $ operator, we would have

```
Make str
```

This would create a wave named str, not a wave whos name is specified by the contents of str.

As shown in the following example, $ can create references to global numeric and string variables as well as to waves.

```
Function Test(vStr, sStr, wStr)
   String vStr, sStr, wStr

   NVAR v = $vStr        // v is local name for global numeric var
   v += 1
   SVAR s = $sStr        // s is local name for global string var
   s  += "Hello"
   WAVE w = $wStr        // w is local name for global wave
   w += 1
End

Variable/G gVar = 0; String/G gStr = ""; Make/O/N=5 gWave = p
Test("gVar", "gStr", "gWave")
```

The NVAR, SVAR and WAVE references are necessary in functions so that the compiler can identify the kind of object. This is explained under **Accessing Global Variables and Waves** on page IV-65.

Using $ to Refer to a Window

A number of Igor operations modify or create windows, and optionally take the name of a window. You need to use a string variable if the window name is not determined until run time but must convert the string into a name using $.

For instance, this function creates a graph using a name specified by the calling function:

```
Function DisplayXY(xWave, yWave, graphNameStr)
   Wave xWave, yWave
   String graphNameStr     // Contains name to use for the new graph

   Display /N=$graphNameStr yWave vs xWave
End
```

The $ operator in /N=$graphNameStr converts the contents of the string graphNameStr into a graph name as required by the Display operation /N flag. If you forget $, the command would be:

```
Display /N=graphNameStr yWave vs xWave
```

This would create a graph literally named graphNameStr.

Using $ In a Data Folder Path

$ can also be used to convert a string to a name in a data folder path. This is used when one of many data folders must be selected algorithmically.

Assume you have a string variable named dfName that tells you in which data folder a wave should be created. You can write:

```
Make/O root:$(dfName):wave0
```

The parentheses are necessary because the $ operator has low precedence.

Using $ Examples

This function illustrates various uses of $ in user-defined functions:

```
Function Demo()
    String s = "wave0"        // A string containing a name

   // Make requires a name, not a string
   Make/O $s

   // A wave declaration requires a name on the righthand side, not a string
   WAVE w = $s                // w is a wave reference

   // Display requires a wave reference
   Display w

   // ModifyGraph requires a trace name, not a string or a wave reference
   ModifyGraph mode($s) = 0

   AppendToGraph w            // Add another trace showing wave0

   // #1 is "instance notation" to distinguish multiple traces from same wave
   String t = "wave0#1"

   // ModifyGraph requires a trace name, not a string or a wave reference
   ModifyGraph mode($t) = 3
End
```

Compile Time Versus Runtime

Because Igor user-defined functions are compiled, errors can occur during compilation (“compile time”) or when a function executes (“runtime”). It helps in programming if you have a clear understanding of what these terms mean.

Compile time is when Igor analyzes the text of all functions and produces low-level instructions that can be executed quickly later. This happens when you modify a procedure window and then:

- Choose Compile from the Macros menu.
- Click the Compile button at the bottom of a procedure window.
- Activate a window other than a procedure or help window.

Runtime is when Igor actually executes a function’s low-level instructions. This happens when:

- You invoke the function from the command line.
- The function is invoked from another procedure.
- Igor updates a dependency which calls the function.
- You use a button or other control that calls the function.

Conditions that exist at compile time are different from those at runtime. For example, a function can reference a global variable. The global does not need to exist at compile time, but it does need to exist at runtime. This issue is discussed in detail in the following sections.

Here is an example illustrating the distinction between compile time and runtime:

```
Function Example(w)
   WAVE w

   w = sin(x)
   FFT w
   w = r2polar(w)
End
```

The declaration “`WAVE w`” specifies that w is expected to be a real wave. This is correct until the FFT executes and thus the first wave assignment produces the correct result. After the FFT is executed at runtime, however, the wave becomes complex. The Igor compiler does not know this and so it compiled the second wave assignment on the assumption that w is real. A compile-time error will be generated complaining that r2polar is not available for this number type — i.e., real. To provide Igor with the information that the wave is complex after the FFT you need to rewrite the function like this:

```
Function Example(w)
   WAVE w

   w= sin(x)
   FFT w
   WAVE/C wc = w
   wc = r2polar(wc)
End
```

A statement like “`WAVE/C wc = w`” has the compile-time behavior of creating a symbol, wc, and specifying that it refers to a complex wave. It has the runtime behavior of making wc refer to a specific wave. The runtime behavior can not occur at compile time because the wave may not exist at compile time.

Accessing Global Variables and Waves

Global numeric variables, global string variables and waves can be referenced from any function. A function can refer to a global that does not exist at compile-time. For the Igor compiler to know what type of global you are trying to reference, you need to declare references to globals.

Consider the following function:

```
Function BadExample()
   gStr1 = "The answer is:"
   gNum1 = 1.234
   wave0 = 0
End
```

The compiler can not compile this because it doesn't know what gStr1, gNum1 and wave0 are. We need to specify that they are references to a global string variable, a global numeric variable and a wave, respectively:

```
Function GoodExample1()
   SVAR gStr1 = root:gStr1
   NVAR gNum1 = root:gNum1
   WAVE wave0 = root:wave0

   gStr1 = "The answer is:"
   gNum1 = 1.234
   wave0 = 0
End
```

The SVAR statement specifies two important things for the compiler: first, that gStr1 is a global string variable; second, that gStr1 refers to a global string variable named gStr1 in the root data folder. Similarly, the NVAR statement identifies gNum1 and the WAVE statement identifies wave0. With this knowledge, the compiler can compile the function.

The technique illustrated here is called "runtime lookup of globals" because the compiler compiles code that associates the symbols gStr1, gNum1 and wave0 with specific global variables at runtime.

Runtime Lookup of Globals

The syntax for runtime lookup of globals is:

```
NVAR <local name1>[= <path to var1>][, <loc name2>[= <path to var2>]]…
SVAR <local name1>[= <path to str1>][, <loc name2>[= <path to str2>]]…
WAVE <local name1>[= <path to wave1>][, <loc name2>[= <path to wave2>]]…
```

NVAR creates a reference to a global numeric variable.

SVAR creates a reference to a global string variable.

WAVE creates a reference to a wave.

At compile time, these statements identify the referenced objects. At runtime, the connection is made between the local name and the actual object. Consequently, the object must exist when these statements are executed.

<local name> is the name by which the global variable, string or wave is to be known within the user function. It does not need to be the same as the name of the global variable. The example function could be rewritten as follows:

```
Function GoodExample2()
   SVAR str1 = root:gStr1      // str1 is the local name.
   NVAR num1 = root:gNum1      // num1 is the local name.
   WAVE w = root:wave0         // w is the local name.

   str1 = "The answer is:"
   num1 = 1.234
   w = 0
End
```

If you use a local name that is the same as the global name, and if you want to refer to a global in the current data folder, you can omit the <path to …> part of the declaration:

```
Function GoodExample3()
   SVAR gStr1           // Refers to gStr1 in current data folder.
   NVAR gNum1           // Refers to gNum1 in current data folder.
   WAVE wave0           // Refers to wave0 in current data folder.

   gStr1 = "The answer is:"
   gNum1 = 1.234
   wave0 = 0
End
```

GoodExample3 accesses globals in the current data folder while GoodExample2 accesses globals in a specific data folder.

If you use <path to …>, it may be a simple name (gStr1) or it may include a full or partial path to the name.

The following are valid examples, referencing a global numeric variable named gAvg:

```
   NVAR gAvg= gAvg
   NVAR avg= gAvg
   NVAR gAvg
   NVAR avg= root:Packages:MyPackage:gAvg
   NVAR avg= :SubDataFolder:gAvg
   NVAR avg= $"gAvg"
   NVAR avg= $("g"+ "Avg")
   NVAR avg= ::$"gAvg"
```

As illustrated above, the local name can be the same as the name of the global object and the lookup expression can be either a literal name or can be computed at runtime using $<string expression>.

If your function creates a global variable and you want to create a reference to it, put the NVAR statement after the code that creates the global. The same applies to SVARs and, as explained next, to WAVEs.

Put WAVE Declaration After Wave Is Created

A wave declaration serves two purposes. At compile time, it tells Igor the local name and type of the wave. At runtime, it connects the local name to a specific wave. In order for the runtime purpose to work, you must put wave declaration after the wave is created.

```
Function BadExample()
   String path = "root:Packages:MyPackage:wave0"
   Wave w = $path          // WRONG: Wave does not yet exist.
   Make $path
   w = p                   // w is not connected to any wave.
End

Function GoodExample()
   String path = "root:Packages:MyPackage:wave0"
   Make $path
   Wave w = $path          // RIGHT
   w = p
End
```

Both of these functions will successfully compile. BadExample will fail at runtime because w is not associated with a wave, because the wave does not exist when the "Wave w = $path" statement executes.

This rule also applies to NVAR and SVAR declarations.

Runtime Lookup Failure

At runtime, it is possible that a NVAR, SVAR or WAVE statement may fail. For example,

```
NVAR v1 = var1
```

will fail if var1 does not exist in the current data folder when the statement is executed. You can use the NVAR_Exists, SVAR_Exists, and WaveExists functions to test if a given global reference is valid:

```
Function Test()
   NVAR/Z v1 = var1
   if (NVAR_Exists(v1))
      <use v1>
   endif
End
```

The /Z flag is necessary to prevent an error if the NVAR statement fails. You can also use it with SVAR and WAVE.

A common cause for failure is putting a WAVE statement in the wrong place. For example:

```
Function BadExample()
   WAVE w = resultWave
   <Call a function that creates a wave named resultWave>
   Display w
End
```

This function will compile successfully but will fail at runtime. The reason is that the `WAVE w = resultWave` statement has the runtime behavior of associating the local name w with a particular wave. But that wave does not exist until the following statement is executed. The function should be rewritten as:

```
Function GoodExample()
   <Call a function that creates a wave named resultWave>
   WAVE w = resultWave
   Display w
End
```

Runtime Lookup Failure and the Debugger

You can break whenever a runtime lookup fails using the symbolic debugger (described in Chapter IV-8, **Debugging**). It is a good idea to do this, because it lets you know about runtime lookup failures at the moment they occur.

Sometimes you may create a WAVE, NVAR or SVAR reference knowing that the referenced global may not exist at runtime. Here is a trivial example:

```
Function Test()
   WAVE w = testWave
   if (WaveExists(testWave))
      Printf "testWave had %d points.\r", numpnts(testWave)
   endif
End
```

If you enable the debugger's WAVE checking and if you execute the function when testWave does not exist, the debugger will break and flag that the WAVE reference failed. But you wrote the function to handle this situation, so the debugger break is not helpful in this case.

The solution is to rewrite the function using WAVE/Z instead of just WAVE. The /Z flag specifies that you know that the runtime lookup may fail and that you don't want to break if it does. You can use NVAR/Z and SVAR/Z in a similar fashion.

Accessing Complex Global Variables and Waves

You must specify if a global numeric variable or a wave is complex using the /C flag:

```
   NVAR/C gc1 = gc1
   WAVE/C gcw1 = gcw1
```

Accessing Text Waves

Text waves must be accessed using the /T flag:

```
   WAVE/T tw= MyTextWave
```

Accessing Global Variables and Waves Using Liberal Names

There are two ways to initialize a reference an Igor object: using a literal name or path or using a string variable. For example:

```
Wave w = root:MyDataFolder:MyWave               // Using literal path
String path = "root:MyDataFolder:MyWave"
Wave w = $path                                  // Using string variable
```

Things get more complicated when you use a liberal name rather than a standard name. A standard name starts with a letter and includes letters, digits and the underscore character. A liberal name includes other characters such as spaces or punctuation.

In general, you must quote liberal names using single quotes so that Igor can determine where the name starts and where it ends. For example:

```
Wave w = root:'My Data Folder':'My Wave'        // Using literal path
String path = "root:'My Data Folder':'My Wave'"
Wave w = $path                                  // Using string variable
```

However, there is an exception to the quoting requirement. The rule is:

> You must quote a literal liberal name and you must quote a liberal path stored in a string variable but you must not quote a simple literal liberal name stored in a string variable.

The following functions illustrate this rule:

```
// Literal liberal name must be quoted
Function DemoLiteralLiberalNames()
   NewDataFolder/O root:'My Data Folder'

   Make/O root:'My Data Folder':'My Wave' // Literal name must be quoted

   SetDataFolder root:'My Data Folder'    // Literal name must be quoted

   Wave w = 'My Wave'                     // Literal name must be quoted
   w = 123

   SetDataFolder root:
End

// String liberal PATH must be quoted
Function DemoStringLiberalPaths()
   String path = "root:'My Data Folder'"
   NewDataFolder/O $path

   path = "root:'My Data Folder':'My Wave'"  // String path must be quoted
   Make/O $path

   Wave w = $path
   w = 123

   SetDataFolder root:
End

// String liberal NAME must NOT be quoted
Function DemoStringLiberalNames()
   SetDataFolder root:

   String dfName = "My Data Folder"       // String name must NOT be quoted
   NewDataFolder/O $dfName

   String wName = "My Wave"               // String name must NOT be quoted
   Make/O root:$(dfName):$wName

   Wave w = root:$(dfName):$wName         // String name must NOT be quoted
   w = 123

   SetDataFolder root:
End
```

The last example illustrates another subtlety. This command would generate an error at compile time:

```
Make/O root:$dfName:$wName        // ERROR
```

because Igor would intepret it as:

```
Make/O root:$(dfName:$wName)      // ERROR
```

To avoid this, you must use parentheses like this:

```
Make/O root:$(dfName):$wName      // OK
```

Runtime Lookup Example

In this example, a function named Routine calls another function named Subroutine and needs to access a number of result values created by Subroutine. To make it easy to clean up the temporary result globals, Subroutine creates them in a new data folder. Routine uses the results created by Subroutine and then deletes the temporary data folder.

```
Function Subroutine(w)
   WAVE w

   NewDataFolder/O/S SubroutineResults    // Results go here

   WaveStats/Q w              // WaveStats creates local variables
   Variable/G gAvg = V_avg    // Return the V_avg result in global gAvg
   Variable/G gMin = V_min
   String/G gWName = NameOfWave(w)

   SetDataFolder ::           // Back to original data folder
End

Function Routine()
   Make aWave= {1,2,3,4}
   Subroutine(aWave)

   DFREF dfr = :SubroutineResults

   NVAR theAvg = dfr:gAvg                    // theAvg is local name
   NVAR theMin = dfr:gMin
   SVAR theName = dfr:gWName
   Print theAvg, theMin, theName
   KillDataFolder SubroutineResults          // We are done with results
End
```

Note that the NVAR statement must appear *after* the call to the procedure (Subroutine in this case) that creates the global variable. This is because NVAR has both a compile-time and a runtime behavior. At compile time, it creates a local variable that Igor can compile (theAvg in this case). At runtime, it actually looks up and creates a link to the global (variable gAvg stored in data folder SubroutineResults in this case).

Often a function needs to access a large number of global variables stored in a data folder. In such cases, you can write more compact code using the ability of NVAR, SVAR and WAVE to access multiple objects in one statement:

```
Function Routine2()
   Make aWave= {1,2,3,4}
   Subroutine(aWave)

   DFREF dfr = :SubroutineResults

   NVAR theAvg=dfr:gAvg, theMin=dfr:gMin     // Access two variables
   SVAR theName = dfr:gWName
   Print theAvg, theMin, theName

   KillDataFolder SubroutineResults          // We are done with results
End
```

Automatic Creation of WAVE, NVAR and SVAR References

The Igor compiler sometimes automatically creates WAVE, NVAR and SVAR references. For example:

```
Function Example1()
   Make/O wave0
   wave0 = p

   Variable/G gVar1
   gVar1= 1

   String/G gStr1
   gStr1= "hello"
End
```

In this example, we did not use WAVE, NVAR or SVAR references and yet we were still able to compile assignment statements referencing waves and global variables. This is a feature of *Make*, `Variable/G` and `String/G` that automatically create local references for simple object names.

Simple object names are names which are known at compile time for objects which will be created in the current data folder at runtime. `Make`, `Variable/G` and `String/G` do not create references if you use $ expression, a partial data folder path or a full data folder path to specify the object unless you include the /N flag, discussed next.

Explicit Creation of NVAR and SVAR References

If you create a global variable in a user-defined function using a path or a $ expression, you can explicitly create an NVAR or SVAR reference like this:

```
Function Example2()
   String path

   Variable/G root:gVar2A = 2
   NVAR gVar2A = root:gVar2A        // Create NVAR gVar2A

   path = "root:gVar2B"
   Variable/G $path = 2
   NVAR gVar2B = $path              // Create NVAR gVar2B

   String/G root:gStr2A = "Two A"
   SVAR gStr2A = root:gStr2A        // Create SVAR gStr2A

   path = "root:gStr2B"
   String/G $path = "Two B"
   SVAR gStr2B = $path              // Create SVAR gStr2B
End
```

In Igor Pro 8.00 or later, you can combine the creation of the reference with the creation of the variable by using the /N flag with **Variable** or **String**:

```
Function Example3()
   String path

   Variable/G root:gVar3A/N=gVar3A = 3

   path = "root:gVar3B"
   Variable/G $path/N=gVar3B = 3

   String/G root:gStr3A/N=gStr3A = "Three A"

   path = "root:gStr3B"
   String/G $path/N=gStr3B = "Three B"
End
```

Wave References

A wave reference is a value that identifies a particular wave. Wave references are used in commands that operate on waves, including assignment statements and calls to operations and functions that take wave reference parameters.

Wave reference variables hold wave references. They can be created as local variables, passed as parameters and returned as function results.

Here is a simple example:

```
Function Test(wIn)
   Wave wIn          // Reference to the input wave received as parameter

   String newName = NameOfWave(wIn) + "_out" // Compute output wave name

   Duplicate/O wIn, $newName                 // Create output wave

   Wave wOut = $newName       // Create wave reference for output wave
   wOut += 1                  // Use wave reference in assignment statement
End
```

This function might be called from the command line or from another function like this:

```
Make/O/N=5 wave0 = p
Test(wave0)                   // Pass wave reference to Test function
```

A Wave statement declares a wave reference variable. It has both a compile-time and a runtime effect.

At compile time, it tells Igor what type of object the declared name references. In the example above, it tells Igor that wOut references a wave as opposed to a numeric variable, a string variable, a window or some other type of object. The Igor compiler allows wOut to be used in a waveform assignment statement (wOut += 1) because it knows that wOut references a wave.

The compiler also needs to know if the wave is real, complex or text. Use Wave/C to create a complex wave reference and Wave/T to create a text wave reference. Wave by itself creates a real wave reference.

At runtime the Wave statement stores a reference to a specific wave in the wave reference variable (wOut in this example). The referenced wave must already exist when the wave statement executes. Otherwise Igor stores a NULL reference in the wave reference variable and you get an error when you attempt to use it. We put the `Wave wOut = $newName` statement *after* the Duplicate operation to insure that the wave exists when the Wave statement is executed. Putting the Wave statement before the command that creates the wave is a common error.

Automatic Creation of WAVE References

The Igor compiler sometimes automatically creates WAVE references. For example:

```
Function Example1()
   Make wave1
   wave1 = x^2
End
```

In this example, we did not declare a wave reference, and yet Igor was still able to compile an assignment statement referring to a wave. This is a feature of the **Make** operation (see page V-526) which automatically creates local references for simple object names. The **Duplicate** operation (see page V-185) and many other operations that create output waves also automatically create local wave references for simple object names.

Simple object names are names which are known at compile time for objects which will be created in the current data folder at runtime. Make and Duplicate do not create references if you use $<name>, a partial data folder path, or a full data folder path to specify the object.

In the case of Make and Duplicate with simple object names, the type of the automatically created wave reference is determined by flags. Make/C and Duplicate/C create complex wave references. Make/T and Duplicate/T create text wave references. Make and Duplicate without type flags create real wave references. See **WAVE Reference Types** on page IV-73 and **WAVE Reference Type Flags** on page IV-74 for a complete list of type flags and further details.

Most built-in operations that create output waves (often called "destination" waves) also automatically create wave references. For example, if you write:

```
DWT srcWave, destWave
```

it is as if you wrote:

```
DWT srcWave, destWave
WAVE destWave
```

After the discrete wavelet transform executes, you can reference `destWave` without an explicit wave reference.

Standalone WAVE Reference Statements

In cases where Igor does not automatically create a wave reference, because the output wave is not specified using a simple object name, you need to explicitly create a wave reference if you want to access the wave in an assignment statement.

You can create an explicit standalone wave reference using a statement following the command that created the output wave. In this example, the name of the output wave is specified as a parameter and therefore we can not use a simple object name when calling Make:

```
Function Example2(nameForOutputWave)
   String nameForOutputWave   // String contains the name of the wave to make

   Make $nameForOutputWave          // Make a wave
   Wave w = $nameForOutputWave      // Make a wave reference
   w = x^2
End
```

If you make a text wave or a complex wave, you need to tell the Igor compiler about that by using Wave/T or Wave/C. The compiler needs to know the type of the wave in order to properly compile the assignment statement.

Inline WAVE Reference Statements

You can create a wave reference variable using `/WAVE=<name>` in the command that creates the output wave. For example:

```
Function Example3(nameForOutputWave)
   String nameForOutputWave

   Make $nameForOutputWave/WAVE=w   // Make a wave and a wave reference
   w = x^2
End
```

Here `/WAVE=w` is an inline wave reference statement. It does the same thing as the standalone wave reference in the preceding section.

Here are some more examples of inline wave declarations:

```
Function Example4()
   String name = "wave1"
   Duplicate/O wave0, $name/WAVE=wave1
   Differentiate wave0 /D=$name/WAVE=wave1
End
```

When using an inline wave reference statement, you do not need to, and in fact can not, specify the type of the wave using `WAVE/T` or `WAVE/C`. Just use `WAVE` by itself regardless of the type of the output wave. The Igor compiler automatically creates the right kind of wave reference. For example:

```
Function Example5()
   Make real1, $"real2"/WAVE=r2     // real1, real2 and r2 are real
   Make/C cplx1, $"cplx2"/WAVE=c2   // cplx1, cplx2 and c2 are complex
   Make/T text1, $"text2"/WAVE=t2   // text1, text2 and t2 are text
End
```

Inline wave reference statements are accepted by those operations which automatically create a wave reference for a simple object name.

Inline wave references are not allowed after a simple object name.

Inline wave references are allowed on the command line but do nothing.

WAVE Reference Types

When wave references are created at compile time, they are created with a specific numeric type or are defined as text. The compiler then uses this type when compiling expressions based on the WAVE reference or when trying to match two instances of the same name. For example:

```
Make rWave           // Creates single-precision real wave reference

Make/C cWave         // Creates single-precision complex wave reference

Make/L int64Wave     // Creates signed 64-bit integer wave reference

Make/L/U int64Wave   // Creates unsigned 64-bit integer wave reference

Make/T tWave         // Creates text wave reference
```

These types then define what kind of right-hand side expression Igor compiles:

```
rWave = expression      // Compiles real expression as double precision

cWave = expression      // Compiles complex expression as double precision
```

```
int64Wave = expression  // Compiles signed 64-bit integer expression

uint64Wave = expression // Compiles unsigned 64-bit integer expression

tWave = expression      // Compiles text expression
```

See also **Integer Expressions in Wave Assignment Statements** on page IV-39.

The compiler is sometimes picky about the congruence between two declarations of wave reference variables of the same name. For example:

```
WAVE aWave
if (!WaveExists(aWave))
   Make/D aWave
endif
```

This generates a compile error complaining about inconsistent types for a wave reference. Because Make automatically creates a wave reference, this is equivalent to:

```
WAVE aWave
if (!WaveExists(aWave))
   Make/D aWave
   WAVE/D aWave
endif
```

This creates two wave references with the same name but different types. To fix this, change the explicit wave reference declaration to:

```
WAVE/D aWave
```

WAVE Reference Type Flags

The **WAVE** reference (see page V-1069) along with certain operations such as Duplicate can accept the following flags identifying the type of WAVE reference:

/B	8-bit signed integer destination waves, unsigned with /U.
/C	Complex destination waves.
/D	Double precision destination waves.
/I	32-bit signed integer destination waves, unsigned with /U.
/L	64-bit signed integer destination waves, unsigned with /U. Requires Igor Pro 7.00 or later.
/S	Single precision destination waves.
/T	Text destination waves.
/U	Unsigned destination waves.
/W	16-bit signed integer destination waves, unsigned with /U.
/DF	Wave holds data folder references.
/WAVE	Wave holds wave references.

These are the same flags used by the **Make**. In the case of WAVE declarations and Duplicate, they do not affect the actual wave but rather tell Igor what kind of wave is expected at runtime. The compiler uses this information to determine what kind of code to compile if the wave is used as the destination of a wave assignment statement later in the function. For example:

```
Function DupIt(wv)
   WAVE/C wv                  // complex wave
   Duplicate/O/C wv,dupWv      // dupWv is complex
   dupWv[0]=cmplx(5.0,1.0)     // no error, because dupWv known complex
   . . .
End
```

If Duplicate did not have the /C flag, you would get a “function not available for this number type” message when compiling the assignment of `dupWv` to the result of the `cmplx` function.

Problems with Automatic Creation of WAVE References

Operations that change a wave's type or which can create output waves of more than one type, such as **FFT**, **IFFT** and **WignerTransform** present special issues.

In some cases, the wave reference automatically created by an operation might be of the wrong type. For example, the FFT operation automatically creates a complex wave reference for the destination wave, so if you write:

```
FFT/DEST=destWave srcWave
```

it is as if you wrote:

```
FFT/DEST=destWave srcWave
WAVE/C destWave
```

However, if a real wave reference for the same name already exists, FFT/DEST does not create a new wave reference. For example:

```
Wave destWave                 // Real wave reference
. . .
FFT /DEST=destWave srcWave    // FFT does not create wave reference
                              // because it already exists.
```

In this case, you would need to create a complex wave reference using a different name, like this:

```
Wave/C cDestWave = destWave
```

The output of the FFT operation can sometimes be real, not complex. For example:

```
FFT/DEST=destWave/OUT=2 srcWave
```

The /OUT=2 flag creates a real destination wave. Thus the complex wave reference automatically created by the FFT operation is wrong and can not be used to subsequently access the destination wave. In this case, you must explicitly create a real wave reference, like this:

```
FFT/DEST=destWave/OUT=2 srcWave
WAVE realDestWave = destWave
```

Note that you can not write:

```
FFT/DEST=destWave/OUT=2 srcWave
WAVE destWave
```

because the FFT operation has already created a complex wave reference named `destWave`, so the compiler will generate an error. You must use a different name for the real wave reference.

The **IFFT** has a similar problem but in reverse. IFFT automatically creates a real wave reference for the destination wave. In some cases, the actual destination wave will be complex and you will need to create an explicit wave reference in order to access it.

WAVE Reference Is Needed to Pass a Wave By Name

As of Igor Pro 6.3, new procedure windows are created with this pragma statement:

```
#pragma rtGlobals=3 // Use modern global access method and strict wave access.
```

The strict wave access mode causes a compile error if you pass a literal wave name as a parameter to an operation or function. Instead you must pass a wave reference.

With rtGlobals=3, this function has errors on both lines:

```
Function Test()
   Display jack                          // Error: Expected wave reference
   Variable tmp = mean(jack,0,100)       // Error: Expected wave reference
End
```

The proper way to do this is to create a wave reference, like this:

```
Function Test()
   WAVE jack
   Display jack                          // OK
   Variable tmp = mean(jack,0,100)       // OK
End
```

The purpose of the strict wave access mode is to detect inadvertent name mistakes. This applies to simple names only, not to full or partial paths. Even with rtGlobals=3, it is OK to use a full or partial path where a wave reference is expected:

```
Function Test()
   Display :jack                         // OK
   Variable tmp = mean(root:jack,0,100)  // OK
End
```

If you have old code that is impractical to fix, you can revert to using rtGlobals=1 or rtGlobals=2.

Wave Reference Function Results

Advanced programmers can create functions that return wave references using Function/WAVE:

```
Function/WAVE Test(wIn) // /WAVE flag says function returns wave reference
   Wave wIn    // Reference to the input wave received as parameter

   String newName = NameOfWave(wIn) + "_out" // Compute output wave name

   Duplicate/O wIn, $newName                 // Create output wave

   Wave wOut = $newName       // Create wave reference for output wave
   wOut += 1                  // Use wave reference in assignment statement

   return wOut                // Return wave reference
End
```

This function might be called from another function like this:

```
Make/O/N=5 wave0 = p
Wave wOut = Test(wave0)
Display wave0, wOut
```

This technique is useful when a subroutine creates a free wave for temporary use:

```
Function Subroutine()
   Make/FREE tempWave = <expression>
   return tempWave
End

Function Routine()
   Wave tempWave = Subroutine()
   <Use tempWave>
End
```

When Routine returns, tempWave is automatically killed because all references to it have gone out of scope.

Wave Reference Waves

You can create waves that contain wave references using the Make /WAVE flag. You can use a wave reference wave as a list of waves for further processing and in multithreaded wave assignment using the **MultiThread** keyword.

Wave reference waves are recommended for advanced programmers only.

Note: Wave reference waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only.

Here is an example:

```
Make/O wave0, wave1, wave2              // Make some waves
Make/O/WAVE wr                          // Make a wave reference wave
wr[0]=wave0; wr[1]=wave1; wr[2]=wave2   // Assign values
```

The wave reference wave wr could now be used, for example, to pass a list of waves to a function that performs display or analysis operations.

Make/WAVE without any assignment creates a wave containing null wave references. Similarly, inserting points or redimensioning to a larger size initializes the new points to null. Deleting points or redimensioning to a smaller size deletes any free waves if the deleted points contained the only reference to them.

To determine if a given wave is a type that stores wave references, use the **WaveType** function with the optional selector = 1.

In the next example, a subroutine supplies a list of references to waves to be graphed by the main routine. A wave reference wave is used to store the list of wave references.

```
Function MainRoutine()
   Make/O/WAVE/N=5 wr        // Will contain references to other waves
   wr= Subroutine(p)         // Fill w with references

   WAVE w= wr[0]             // Get reference to first wave
   Display w                 // and display in a graph

   Variable i
   for(i=1;i<5;i+=1)
      WAVE w= wr[i]          // Get reference to next wave
      AppendToGraph w        // and append to graph
   endfor
End

Function/WAVE Subroutine(i)
   Variable i

   String name = "wave"+num2str(i)

   // Create a wave with a computed name and also a wave reference to it
   Make/O $name/WAVE=w = sin(x/(8+i))

   return w       // Return the wave reference to the calling routine
End
```

As another example, here is a function that returns a wave reference wave containing references to all of the Y waves in a graph:

```
Function/WAVE GetListOfYWavesInGraph(graphName)
   String graphName          // Must contain the name of a graph

   // If graphName is not valid, return NULL wave
   if (strlen(graphName)==0 || WinType(graphName)!=1)
      return $""
   endif

   // Make a wave to contain wave references
   Make /FREE /WAVE /N=0 listWave

   Variable index = 0
   do
      // Get wave reference for next Y wave in graph
      WAVE/Z w = WaveRefIndexed(graphName,index,1)
      if (WaveExists(w) == 0)
         break                // No more waves
      endif

      // Add wave reference to list
      InsertPoints index, 1, listWave
      listWave[index] = w

      index += 1
   while(1)                   // Loop till break above

   return listWave
End
```

The returned wave reference wave is a free wave. See **Free Waves** on page IV-91 for details.

For an example using a wave reference wave for multiprocessing, see **Wave Reference MultiThread Example** on page IV-327.

Data Folder References

The data folder reference is a lightweight object that refers to a data folder, analogous to the wave reference which refers to a wave. You can think of a data folder reference as an identification number that Igor uses to identify a particular data folder.

Data folder reference variables (DFREFs) hold data folder references. They can be created as local variables, passed as parameters and returned as function results.

The most common use for a data folder reference is to save and restore the current data folder during the execution of a function:

```
Function Test()
   DFREF saveDFR = GetDataFolderDFR()  // Get reference to current data folder

   NewDataFolder/O/S MyNewDataFolder   // Create a new data folder
   . . .                               // Do some work in it

   SetDataFolder saveDFR               // Restore current data folder
End
```

Data folder references can be used in commands where Igor accepts a data folder path. For example, this function shows three equivalent methods of accessing waves in a specific data folder:

```
Function Test()
   // Method 1: Using paths
   Display root:Packages:'My Package':yWave vs root:Packages:'My Package':xWave

   // Method 2: Using the current data folder
   DFREF dfSave = GetDataFolderDFR()// Save the current data folder
   SetDataFolder root:Packages:'My Package'
   Display yWave vs xWave
   SetDataFolder dfSave            // Restore current data folder

   // Method 3: Using data folder references
   DFREF dfr = root:Packages:'My Package'
   Display dfr:yWave vs dfr:xWave
End
```

Using data folder references instead of data folder paths can streamline programs that make heavy use of data folders.

Using Data Folder References

In an advanced application, the programmer often defines a set of named data objects (waves, numeric variables and string variables) that the application acts on. These objects exist in a data folder. If there is just one instance of the set, it is possible to hard-code data folder paths to the objects. Often, however, there will be a multiplicity of such sets, for example, one set per graph or one set per channel in a data acquisition application. In such applications, procedures must be written to act on the set of data objects in a data folder specified at runtime.

One way to specify a data folder at runtime is to create a path to the data folder in a string variable. While this works, you wind up with code that does a lot of concatenation of data folder paths and data object names. Using data folder references, such code can be streamlined.

You create a data folder reference variable with a DFREF statement. For example, assume your application defines a set of data with a wave named wave0, a numeric variable named num0 and a string named str0 and that we have one data folder containing such a set for each graph. You can access your objects like this:

```
Function DoSomething(graphName)
   String graphName
   DFREF dfr = root:Packages:MyApplication:$graphName
   WAVE w0 = dfr:wave0
   NVAR n0 = dfr:num0
   SVAR s0 = dfr:str0
   . . .
End
```

Igor accepts a data folder reference in any command in which a data folder path would be accepted. For example:

```
Function Test()
   Display root:MyDataFolder:wave0  // OK

   DFREF dfr = root:MyDataFolder
   Display dfr:wave0                // OK

   String path = "root:MyDataFolder:wave0"
   Display $path                    // OK. $ converts string to path.

   path = "root:MyDataFolder"
   DFREF dfr = $path                // OK. $ converts string to path.
   Display dfr:wave0                // OK

   String currentDFPath
   currentDFPath = GetDataFolder(1) // OK
   DFREF dfr = GetDataFolder(1)     // ERROR: GetDataFolder returns a string
                                    // not a path.

   DFREF dfr = GetDataFolderDFR()   // OK
End
```

The /SDFR Flag

You can also use the /SDFR (source data folder reference) flag in a WAVE, NVAR or SVAR statement. The utility of /SDFR is illustrated by this example which shows three different ways to reference multiple waves in the same data folder:

```
Function Test()
   // Assume a data folder exists at root:Run1

   // Use explicit paths
   Wave wave0=root:Run1:wave0, wave1=root:Run1:wave1, wave2=root:Run1:wave2

   // Use a data folder reference
   DFREF dfr = root:Run1
   Wave wave0=dfr:wave0, wave1=dfr:wave1, wave2=dfr:wave2

   // Use the /SDFR flag
   DFREF dfr = root:Run1
   Wave/SDFR=dfr wave0, wave1, wave2
End
```

Igor Pro 8 and Igor Pro 9 handle invalid data folder references in /SDFR=*dfr* flags differently when /Z is included. Igor Pro 8 incorrectly flags an error on the /SDFR statement despite the /Z. Igor Pro 9 correctly suppresses the error on the /SDFR statement because of /Z.

If you use WAVE/Z, NVAR/Z, or SVAR/Z, this means you want to handle errors yourself so you should follow it with a WaveExists, NVAR_Exists, or SVAR_Exists test.

The DFREF Type

In functions, you can define data folder reference variables using the DFREF declaration:

```
DFREF localname [= <DataFolderRef or path>] [<more defs]
```

You can then use the data folder reference in those places where you can use a data folder path. For example:

```
DFREF dfr = root:df1
Display dfr:wave1             // Equivalent to Display root:df1:wave1
```

The syntax is limited to a single name after the data folder reference, so this is not legal:

```
Display dfr:subfolder:wave1   // Illegal
```

You can use DFREF to define input parameters for user-defined functions. For example:

```
Function Test(df)
   DFREF df
   Display df:wave1
End
```

You can also use DFREF to define fields in structures. However, you can not directly use a DFREF structure field in those places where Igor is expecting a path and object name. So, instead of:

```
Display s.dfr:wave1              // Illegal
```

you would need to write:

```
DFREF dftmp = s.dfr
Display dftmp:wave1              // OK
```

You can use a DFREF structure field where just a path is expected. For example:

```
SetDataFolder s.dfr              // OK
```

Built-in DFREF Functions

Some built-in functions take string data folder paths as parameters or return them as results. Those functions can not take or return data folder references. Here are equivalent DFREF versions that take or return data folder references:

```
   CountObjectsDFR(dfr, type)

   GetDataFolderDFR()

   GetIndexedObjNameDFR(dfr, type, index)

   GetWavesDataFolderDFR(wave)
```

These additional data folder reference functions are available:

```
   DataFolderRefChanges(dfr, changeType)

   DataFolderRefStatus(dfr)

   NewFreeDataFolder()

   DataFolderRefsEqual(dfr1, dfr2)
```

Just as operations that take a data folder path accept a data folder reference, these DFREF functions can also accept a data folder path:

```
Function Test()
   DFREF dfr = root:MyDataFolder
   Print CountObjectsDFR(dfr,1)                  // OK
   Print CountObjectsDFR(root:MyDataFolder,1)    // OK
End
```

Checking Data Folder Reference Validity

The **DataFolderRefStatus** function returns zero if the data folder reference is invalid. You should use it to test any DFREF variables that might not be valid, for example, when you assign a value to a data folder reference and you are not sure that the referenced data folder exists:

```
Function Test()
   DFREF dfr = root:MyDataFolder    // MyDataFolder may or may not exist
   if (DataFolderRefStatus(dfr) != 0)
      . . .
   endif
End
```

For historical reasons, an invalid DFREF variable will often act like root.

Data Folder Reference Function Results

A user-defined function can return a data folder reference. This might be used for a subroutine that returns a set of new objects to the calling routine. The set can be returned in a new data folder and the subroutine can return a reference it.

For example:

```
Function/DF Subroutine(newDFName)
   String newDFName
   NewDataFolder/O $newDFName
   DFREF dfr = $newDFName
   Make/O dfr:wave0, dfr:wave1
   return dfr
End
```

```
Function/DF MainRoutine()
   DFREF dfr = Subroutine("MyDataFolder")
   Display dfr:wave0, dfr:wave1
End
```

Data Folder Reference Waves

You can create waves that contain data folder references using the **Make** /DF flag. You can use a data folder reference wave as a list of data folders for further processing and in multithreaded wave assignment using the MultiThread keyword.

Data folder reference waves are recommended for advanced programmers only.

Note: Data folder reference waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only.

Make/DF without any assignment creates a wave containing null data folder references. Similarly, inserting points or redimensioning to a larger size initializes the new points to null. Deleting points or redimensioning to a smaller size deletes any free data folders if the wave contained the only reference to them.

To determine if a given wave is a type that stores data folder references, use the **WaveType** function with the optional selector = 1.

For an example using a data folder reference wave for multiprocessing, see **Data Folder Reference MultiThread Example** on page IV-325.

Accessing Waves in Functions

To access a wave in a user-defined function, we need to create, one way or another, a wave reference. The section **Accessing Global Variables and Waves** on page IV-65 explained how to access a wave using a WAVE reference. This section introduces several additional techniques.

We can create the wave reference by:

- Declaring a wave parameter
- Using $<string expression>
- Using a literal wave name
- Using a wave reference function

Each of these techniques is illustrated in the following sections.

Each example shows a function and commands that call the function. The function itself illustrates how to deal with the wave within the function. The commands show how to pass enough information to the function so that it can access the wave. Other examples can be found in **Writing Functions that Process Waves** on page III-171.

Wave Reference Passed as Parameter

This is the simplest method. The function might be called from the command line or from another function.

```
Function Test(w)
   WAVE w                  // Wave reference passed as a parameter

   w += 1                  // Use in assignment statement
   Print mean(w)           // Pass as function parameter
   WaveStats w             // Pass as operation parameter
   AnotherFunction(w)      // Pass as user function parameter
End

Make/O/N=5 wave0 = p
Test(wave0)
Test($"wave0")
String wName = "wave0"; Test($wName)
```

In the first call to Test, the wave reference is a literal wave name. In the second call, we create the wave reference using $<literal string>. In the third call, we create the wave reference using $<string variable>. $<literal string> and $<string variable> are specific cases of the general case $<string expression>.

If the function expected to receive a reference to a text wave, we would declare the parameter using:

```
   WAVE/T w
```

If the function expected to be receive a reference to a complex wave, we would declare the parameter using:

```
   WAVE/C w
```

If you need to return a large number of values to the calling routine, it is sometimes convenient to use a parameter wave as an output mechanism. The following example illustrates this technique:

```
Function MyWaveStats(inputWave, outputWave)
   WAVE inputWave
   WAVE outputWave

   WaveStats/Q inputWave

   outputWave[0] = V_npnts
   outputWave[1] = V_avg
   outputWave[2] = V_sdev
End

Function Test()
   Make/O testwave= gnoise(1)

   Make/O/N=20 tempResultWave
   MyWaveStats(testwave, tempResultWave)
   Variable npnts = tempResultWave[0]
   Variable avg = tempResultWave[1]
   Variable sdev = tempResultWave[2]
   KillWaves tempResultWave

   Printf "Points: %g; Avg: %g; SDev: %g\r", npnts, avg, sdev
End
```

If the calling function needs the returned values only temporarily, it is better to return a free wave as the function result. See **Wave Reference Function Results** on page IV-76.

Wave Accessed Via String Passed as Parameter

This technique is of most use when the wave might not exist when the function is called. It is appropriate for functions that create waves.

```
Function Test(wName)
   String wName            // String containing a name for wave

   Make/O/N=5 $wName
   WAVE w = $wName         // Create a wave reference
   Print NameOfWave(w)
End

Test("wave0")
```

This example creates wave0 if it does not yet exist or overwrites it if it does exist. If we knew that the wave had to already exist, we could and should use the wave parameter technique shown in the preceding section. In this case, since the wave may not yet exist, we can not use a wave parameter.

Notice that we create a wave reference immediately after making the wave. Once we do this, we can use the wave reference in all of the ways shown in the preceding section. We can not create the wave reference before making the wave because a wave reference must refer to an existing wave.

The following example demonstrates that $wName and the wave reference w can refer to a wave that is not in the current data folder.

```
NewDataFolder root:Folder1
Test("root:Folder1:wave0")
```

Wave Accessed Via String Calculated in Function

This technique is used when creating multiple waves in a function or when algorithmically selecting a wave or a set of waves to be processed.

```
Function Test(baseName, startIndex, endIndex)
   String baseName
   Variable startIndex, endIndex

   Variable index = startIndex
   do
      String name = baseName + num2istr(index)
      WAVE w = $name
      Variable avg = mean(w)
      Printf "Wave: %s; average: %g\r", NameOfWave(w), avg
      index += 1
   while (index <= endIndex)
End

Make/O/N=5 wave0=gnoise(1), wave1=gnoise(1), wave2=gnoise(1)
Test("wave", 0, 2)
```

We need to use this method because we want the function to operate on any number of waves. If the function were to operate on a small, fixed number of waves, we could use the wave parameter method.

As in the preceding section, we create the wave reference using $<string expression>.

Wave Accessed Via Literal Wave Name

In data acquisition or analysis projects, you often need to write procedures that deal with runs of identically-structured data. Each run is stored in its own data folder and contains waves with the same names. In this kind of situation, you can write a set of functions that use literal wave names specific for your data structure.

```
Function CreateRatio()
   WAVE dataA, dataB
   Duplicate dataA, ratioAB
   WAVE ratioAB
   ratioAB = dataA / dataB
End

Make/O/N=5 dataA = 1 + p, dataB = 2 + p
CreateRatio()
```

The CreateRatio function assumes the structure and naming of the data. The function is hard-wired to this naming scheme and assumes that the current data folder contains the appropriate data.

We don't need explicit wave reference variables because Make and Duplicate creat automatic wave reference for simple wave names, as explained under **Automatic Creation of WAVE References** on page IV-72.

Wave Accessed Via Wave Reference Function

A wave reference function is a built-in Igor function or user-defined function that returns a reference to a wave. Wave reference functions are typically used on the right-hand side of a WAVE statement. For example:

```
WAVE w = WaveRefIndexedDFR(:,i)  // ith wave in current data folder
```

A common use for a wave reference function is to get access to waves displayed in a graph, using the TraceNameToWaveRef function. Here is an example.

```
Function PrintAverageOfDisplayedWaves()
   String list, traceName

   list = TraceNameList("",";",1)   // List of traces in top graph
   Variable index = 0
   do
      traceName = StringFromList(index, list)   // Next trace name
      if (strlen(traceName) == 0)
         break                                  // No more traces
      endif
      WAVE w = TraceNameToWaveRef("", traceName)// Get wave ref
      Variable avg = mean(w)
      Printf "Wave: %s; average: %g\r", NameOfWave(w), avg
      index += 1
   while (1)              // loop till break above
End

Make/O/N=5 wave0=gnoise(1), wave1=gnoise(1), wave2=gnoise(1)
Display wave0, wave1, wave2
PrintAverageOfDisplayedWaves()
```

See **Wave Reference Waves** on page IV-77 for an example using WaveRefIndexed to return a list of all of the Y waves in a graph.

There are other built-in wave reference functions (see **Wave Reference Functions** on page IV-197), but **WaveRefIndexed**, **WaveRefIndexedDFR** and **TraceNameToWaveRef** are the most used.

See **Wave Reference Function Results** on page IV-76 for details on user-defined functions that return wave references.

Destination Wave Parameters

Many operations create waves. Examples are Make, Duplicate and Differentiate. Such operations take "destination wave" parameters. A destination wave parameter can be:

A simple name	`Differentiate fred /D=jack`
A path	`Differentiate fred /D=root:FolderA:jack`

$ followed by a string expression	`String str = "root:FolderA:jack"`
	`Differentiate fred /D=$str`

A wave reference to an existing wave	`Wave w = jack`
	`Differentiate fred /D=w`

The wave reference works only in a user-defined function. The other techniques work in functions, in macros and from the command line.

Using the first three techniques, the destination wave may or may not already exist. It is created if it does not exist and overwritten if it does exist.

In the last technique, the destination wave parameter is a wave reference. This technique works properly only if the referenced wave already exists. Otherwise the destination wave is a wave with the name of the wave reference itself (w in this case) in the current data folder. This situation is further explained below under **Destination Wave Reference Issues** on page IV-86.

Wave Reference as Destination Wave

Here are the rules for wave references when used as destination waves:

1. If a simple name (not a wave reference) is passed as the destination wave parameter, the destination wave is a wave of that name in the current data folder whether it exists or not.
2. If a path or $ followed by a string containing a path is passed as the destination wave parameter, the destination wave is specified by the path whether the specified wave exists or not.
3. If a wave reference is passed as the destination wave parameter, the destination wave is the referenced wave if it exists. See **Destination Wave Reference Issues** on page IV-86 for what happens if it does not exist.

Exceptions To Destination Wave Rules

The Make operation is an exception in regard to wave references. The following statements make a wave named w in the current data folder whether root:FolderA:jack exists or not:

```
Wave/Z w = root:FolderA:jack
Make/O w
```

Prior to Igor Pro 6.20, many operations behaved like Make in this regard. In Igor Pro 6.20 and later, most operations behave like Differentiate.

Updating of Destination Wave References

When a simple name is provided as the destination wave parameter in a user-defined function, Igor automatically creates a wave reference variable of that name at compile time if one does not already exist. This is an implicit automatic wave reference variable.

When a wave reference variable exists, whether implicit or explicit, during the execution of the command, the operation stores a reference to the destination wave in that wave reference variable. You can use the wave reference to access the destination wave in subsequent commands.

Similarly, when the destination is specified using a wave reference field in a structure, the operation updates the field to refer to the destination wave.

Inline Wave References With Destination Waves

When the destination wave is specified using a path or a string containing a path, you can use an inline wave reference to create a reference to the destination wave. For example:

```
String dest = "root:FolderA:jack"
Differentiate input /D=$dest/WAVE=wDest
Display wDest
```

Here the Igor compiler creates a wave reference named wDest. The Differentiate operation stores a reference to the destination wave (root:FolderA:jack in this case) in wDest which can then be used to access the destination wave in subsequent commands.

Inline wave references do not determine which wave is the destination wave but merely provide a wave reference pointing to the destination wave when the command finishes.

Destination Wave Reference Issues

You will get unexpected behavior when a wave reference variable refers to a wave with a different name or in a different data folder and the referenced wave does not exist. For example, if the referenced wave does not exist:

```
Wave/Z w = jack
Differentiate fred /D=w    // Creates a wave named w in current data folder

Wave/Z w = root:FolderA:jack
Differentiate fred /D=w    // Creates a wave named w in current data folder

Wave/Z jack = root:FolderA:jack
Differentiate fred /D=jack // Creates a wave named jack in current data folder

STRUCT MyStruct s          // Contains wave ref field w
Differentiate fred /D=s.w  // Creates a wave named w in current data folder
```

In a situation like this, you should add a test using WaveExists to verify that the destination wave is valid and throw an error if not or otherwise handle the situation. For example:

```
Wave/Z w = root:FolderA:jack
if (!WaveExists(w))
   Abort "Destination wave does not exist"
endif
Differentiate fred /D=w
```

As noted above, when you use a simple name as a destination wave, the Igor compiler automatically creates a wave reference. If the automatically-created wave reference conflicts with a pre-existing wave reference, the compiler generates an error. For example, this function generates an "inconsistent type for wave reference error":

```
Function InconsistentTypeError()
   Wave/C w                   // Explicit complex wave reference
   Differentiate fred /D=w    // Implicit real wave reference
End
```

Another consideration involves loops. Suppose in a loop you have code like this:

```
SetDataFolder <something depending on loop index>
Duplicate/O srcWave, jack
```

You may think you are creating a wave named jack in each data folder but, because the contents of the automatically-created wave refrence variable jack is non-null after the first iteration, you will simply be overwriting the same wave over and over. To fix this, use

```
Duplicate/O srcWave,jack
WaveClear jack
```

or

```
Duplicate/O srcWave,$"jack"/WAVE=jack
```

This creates a wave named jack in the current data folder and stores a reference to it in a wave reference variable also named jack.

Changes in Destination Wave Behavior

Igor's handling of destination wave references was improved for Igor Pro 6.20. Previously some operations treated wave references as simple names, did not set the wave reference to refer to the destination wave on output, and exhibited other non-standard behavior.

Programming With Trace Names

A trace is the graphical representation of a 1D wave or a subset of a multi-dimensional wave. Each trace in a given graph has a unique name within that graph.

The name of a trace is, by default, the same as the name of the wave that it represents, but this is not always the case. For example, if you display the same wave twice in a given graph, the two trace names will be unique. Also, for programming convenience, an Igor programmer can create a trace whose name has no relation to the represented wave.

Trace names are used when changing traces in graphs, when accessing waves associated with traces in graphs, and when getting information about traces in graphs. See **Trace Names** on page II-282 for a general discussion.

These operations take trace name parameters:

ModifyGraph (traces), **ErrorBars**, **RemoveFromGraph**, **ReplaceWave**, **ReorderTraces**, **GraphWaveEdit**

Tag, **TextBox**, **Label**, **Legend**

These operations return trace names:

GetLastUserMenuInfo

These functions take trace name parameters:

GetUserData, **TraceInfo**, **TraceNameToWaveRef**, **XWaveRefFromTrace**

These functions return trace names:

TraceNameList, **CsrInfo**, **CsrWave**, **TraceFromPixel**

Trace Name Parameters

A trace name is not the same as a wave. An example may clarify this subtle point:

```
Function Test()
   Wave w = root:FolderA:wave0
   Display w
   ModifyGraph rgb(w) = (65535,0,0)          // WRONG
End
```

This is wrong because ModifyGraph is looking for the name of a trace in a graph and w is not the name of a trace in a graph. The name of the trace in this case is wave0. The function should be written like this:

```
Function Test()
   Wave w = root:FolderA:wave0
   Display w
   ModifyGraph rgb(wave0) = (65535,0,0)      // CORRECT
End
```

In the next example, the wave is passed to the function as a parameter so the name of the trace is not so obvious:

```
Function Test(w)
   Wave w
   Display w
   ModifyGraph rgb(w) = (65535,0,0)          // WRONG
End
```

This is wrong for the same reason as the first example: w is not the name of the trace. The function should be written like this:

```
Function Test(w)
   Wave w
   Display w

   String name = NameOfWave(w)
   ModifyGraph rgb($name) = (65535,0,0)      // CORRECT
End
```

Trace User Data

For advanced procedures that manage traces in graphs, you can attach user data to a trace using the userData keyword of the ModifyGraph operation. You can retrieve the user data using the GetUserData function.

User-defined Trace Names

As of Igor Pro 6.20, you can provide user-defined names for traces using /TN=<name> with **Display** and **AppendToGraph**. For example:

```
Make/O jack=sin(x/8)
NewDataFolder/O foo; Make/O :foo:jack=sin(x/9)
NewDataFolder/O bar; Make/O :bar:jack=sin(x/10)
Display jack/TN='jack in root', :foo:jack/TN='jack in foo'
AppendToGraph :bar:jack/TN='jack in bar'
ModifyGraph mode('jack in bar')=7,hbFill('jack in bar')=6
ModifyGraph rgb('jack in bar')=(0,0,65535)
```

As of Igor Pro 9.00, you can change the name of an existing trace using ModifyGraph with the traceName keyword.

Trace Name Programming Example

This example illustrates applying some kind of process to each trace in a graph. It appends a smoothed version of each trace to the graph. To try it, copy the code below into the procedure window of a new experiment and execute these commands one-at-a-time:

```
SetupForSmoothWavesDemo()
AppendSmoothedWavesToGraph("", 5)       // Less smoothing
AppendSmoothedWavesToGraph("", 15)      // More smoothing

Function SetupForSmoothWavesDemo()
   Variable numTraces = 3

   Display /W=(35,44,775,522)           // Create graph

   Variable i
   for(i=0; i<numTraces; i+=1)
      String xName, yName
      sprintf xName, "xWave%d", i
      sprintf yName, "yWave%d", i
      Make /O /N=100 $xName = p + 20*i
      Wave xW = $xName
      Make /O /N=100 $yName = p + gnoise(5)
      Wave yW = $yName
      AppendToGraph yW vs xW
   endfor
End

Function CopyTraceOffsets(graphName, sourceTraceName, destTraceName)
   String graphName              // Name of graph or "" for top graph
   String sourceTraceName        // Name of source trace
   String destTraceName          // Name of dest trace

   // info will be "" if no offsets or something like "offset(x)={10,20}"
   String info = TraceInfo(graphName, sourceTraceName, 0)

   String offsetStr = StringByKey("offset(x)", info, "=")   // e.g., "{10,20}"
   Variable xOffset=0, yOffset=0
   if (strlen(offsetStr) > 0)
      sscanf offsetStr, "{%g,%g}", xOffset, yOffset
   endif
   ModifyGraph offset($destTraceName) = {xOffset, yOffset}
End

Function AppendSmoothedWavesToGraph(graphName, numSmoothingPasses)
   String graphName              // Name of graph or "" for top graph
   Variable numSmoothingPasses   // Parameter to Smooth operation, e.g., 15

   // Get list of all traces in graph
   String traceList = TraceNameList(graphName, ";", 3)
   Variable numTraces = ItemsInList(traceList)
   Variable traceIndex

   // Remove traces representing smoothed waves previously added
   for(traceIndex=0; traceIndex<numTraces; traceIndex+=1)
      String traceName = StringFromList(traceIndex, traceList)
      if (StringMatch(traceName, "*_sm"))
         traceList = RemoveFromList(traceName, traceList)
         numTraces -= 1
         traceIndex -= 1
      endif
   endfor

   // Create smoothed versions of the traces
   for(traceIndex=0; traceIndex<numTraces; traceIndex+=1)
      traceName = StringFromList(traceIndex, traceList)

      Variable isXYTrace = 0

      Wave yW = TraceNameToWaveRef(graphName, traceName)
      DFREF dfr = $GetWavesDataFolder(yW, 1)
      String ySmoothedName = NameOfWave(yW) + "_sm"
      // Create smoothed wave in data folder containing Y wave
      Duplicate /O yW, dfr:$ySmoothedName
      Wave yWSmoothed = dfr:$ySmoothedName
      Smooth numSmoothingPasses, yWSmoothed

      Wave/Z xW = XWaveRefFromTrace(graphName, traceName)
      if (WaveExists(xW))        // It is an XY pair?
         isXYTrace = 1
      endif

      // Append smoothed wave to graph if it is not already in it
      CheckDisplayed /W=$graphName yWSmoothed
      if (V_flag == 0)           // Not yet already in graph?
         if (isXYTrace)
            AppendToGraph yWSmoothed vs xW
         else
            AppendToGraph yWSmoothed
         endif
         ModifyGraph /W=$graphName rgb($ySmoothedName) = (0, 0, 65535)
      endif

      // Copy trace offsets from input trace to smoothed trace
      CopyTraceOffsets(graphName, traceName, ySmoothedName)
   endfor
End
```

Free Waves

Free waves are waves that are not part of any data folder hierarchy. They are used mainly for temporary storage in a user function. They are somewhat faster to create than global waves, and when used as temporary storage in a user function, they are automatically killed the end of the function.

Free waves are recommended for advanced programmers only.

A wave that is stored in no data folder is called a “free” wave to distinguish it from a “global” wave which is stored in the root data folder or its descendants and from a “local” wave which is stored in a free data folder or its descendants.

Note: Free waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only. The only way to save a free wave in an experiment file is by storing a wave reference in a wave reference wave.

You most commonly create free waves using the **NewFreeWave** function, or the **Make**/FREE and **Duplicate**/FREE operations. There are some other operations that can optionally make their output waves free waves. By default free waves are given the name '_free_' but NewFreeWave and Make/FREE allow you to specify other names - see **Free Wave Names** (see page IV-95) for details.

Here is an example:

```
Function ReverseWave(w)
   Wave w

   Variable lastPoint = numpnts(w) - 1
   if (lastPoint > 0)
      // This creates a free wave named _free_ and an automatic
      // wave reference named wTemp which refers to the free wave
      Duplicate /FREE w, wTemp

      w = wTemp[lastPoint-p]
   endif
End
```

In this example, wTemp is a free wave. As such, it is not contained in any data folder and therefore can not conflict with any other wave.

As explained below under **Free Wave Lifetime** on page IV-92, a free wave is automatically killed when there are no more references to it. In this example that happens when the function ends and the local wave reference variable wTemp goes out of scope.

You can access a free wave only using the wave reference returned by NewFreeWave, Make/FREE or Duplicate/FREE.

Free waves can not be used in situations where global persistence is required such as in graphs, tables and controls. In other words, you should use free waves for computation purposes only.

For a discussion of multithreaded assignment statements, see **Automatic Parallel Processing with MultiThread** on page IV-323. For an example using free waves, see **Wave Reference MultiThread Example** on page IV-327.

Free Wave Created When Free Data Folder Is Deleted

A wave stored in a free data folder or one of its descendants is called a local wave. This is in contrast to free waves which are stored in no data folder and to global waves which are stored in the main data folder hierarchy (in the root data folder or one of its descendants).

Local waves, like free waves, can not be used in situations where global persistence is required such as in graphs, tables and controls.

A local wave becomes a free wave if the parent data folder is killed while other references to the wave exist, as shown in thus example:

```
Function/WAVE Test()
   DFREF dfSav= GetDataFolderDFR()

   // Create a free data folder. It persists because it is the current
   // data folder (i.e., there is a reference to it in Igor itself).
   SetDataFolder NewFreeDataFolder()

   Make jack={1,2,3}    // jack is not a free wave at this point.
   // This also creates an automatic wave reference named jack.

   // The free data folder created above is killed because there
   // are no more references to it.
   SetDataFolder dfSav

   // The free data folder is now gone but jack persists
   // because of the wave reference to it and is now a free wave.

   return jack
End
```

In this example, jack was created as a local wave, not as a free wave, and consequently has the name jack, not _free_. When a local wave's data folder is killed, but the wave lives on due to a remaining wave reference, the wave retains the name it had when it was a local wave. See **Free Wave Names** (see page IV-95) for details.

Free Wave Created For User Function Input Parameter

If a user function takes a wave reference as in input parameter, you can create and pass a short free wave using a list of values as illustrated here:

```
Function Test(w)
   WAVE/D w
   Print w
End
```

You can invoke this function like this:

```
Test({1,2,3})
```

Igor automatically creates a free wave and passes it to Test. The free wave is automatically deleted when Test returns.

The data type of the free wave is determined by the type of the function's wave parameter. In this case the free wave is created as double-precision floating point because the wave parameter is defined using the /D flag. If /D were omitted, the free wave would be single-precision floating point. Wave/C/D would give a double-precision complex free wave. Wave/T would give a text free wave.

This list of values syntax is allowed only for user-defined functions because only they have code to test for and delete free waves upon exit.

Free Wave Lifetime

A free wave is automatically deleted when the last reference to it disappears.

Wave references can be stored in:

1. Wave reference variables in user-defined functions
2. Wave reference fields in structures
3. Elements of a wave reference wave (created by Make/WAVE)

The first case is the most common.

A wave reference disappears when:

1. The wave reference variable containing it is explicitly cleared using WaveClear.
2. The wave reference variable containing it is reassigned to refer to another wave.
3. The wave reference variable containing it goes out-of-scope and ceases to exist when the function in which it was created returns.
4. The wave reference wave element containing it is deleted or the wave reference wave is killed.

When there are no more references to a free wave, Igor automatically deletes it. This example illustrates the first three of these scenarios:

```
Function TestFreeWaveDeletion1()
   Wave w = NewFreeWave(2,3)  // Create a free wave with 3 points
   WaveClear w                // w no longer refers to the free wave
   // There are no more references to the free wave so it is deleted

   Wave w = NewFreeWave(2,3)  // Create a free wave with 3 points
   Wave w = root:wave0        // w no longer refers to the free wave
   // There are no more references to the free wave so it is deleted

   Wave w = NewFreeWave(2,3)  // Create a free wave with 3 points
End   // Wave reference w ceases to exist so the free wave is deleted
```

In the preceding example we used NewFreeWave which creates a free wave named '_free_' that is not part of any data folder. Next we will use Make/FREE instead of NewFreeWave. When reading this example, keep in mind that "Make jack" creates an automatic wave reference variable named jack:

```
Function TestFreeWaveDeletion2()
   Make /D /N=3 /FREE jack    // Create a free DP wave with 3 points
   // Make created an automatic wave reference named jack

   Make /D /N=5 /FREE jack    // Create a free DP wave with 5 points
   // Make created an automatic wave reference named jack
   // which refers to the 5-point jack.
   // There are now no references to 3-point jack so it is automatically deleted.

End   // Wave reference jack ceases to exist so free wave jack is deleted
```

In the next example, a subroutine returns a reference to a free wave to the calling routine:

```
Function/WAVE Subroutine1()
   Make /D /N=3 /FREE jack=p  // Create a free DP wave with 3 points
   return jack                // Return reference to calling routine
End

Function MainRoutine1()
   WAVE w= Subroutine1()   // Wave reference w references the free wave jack
   Print w
End   // Wave reference w ceases to exist so free wave jack is deleted
```

In the next example, the wave jack starts as an object in a free data folder (see **Free Data Folders** on page IV-96). It is not free because it is part of a data folder hierarchy even though the data folder is free. We call such a wave a local wave. When the free data folder is deleted, jack becomes a free wave.

When reading this example, keep in mind that the free data folder is automatically deleted when there are no more references to it. Originally, it survives because it is the current data folder and therefore is referenced by Igor internally. When it is no longer the current data folder, there are no more references to it and it is automatically deleted:

```
Function/WAVE Subroutine2()
   DFREF dfSav= GetDataFolderDFR()

   // Create free data folder and set as current data folder
   SetDataFolder NewFreeDataFolder()

   // Create wave jack and an automatic wave reference to it
   Make jack={1,2,3}    // jack is not free - it is an object in a data folder

   SetDataFolder dfSav  // Change the current data folder
   // There are now no references to the free data folder so it is deleted
   // but wave jack remains because there is a reference to it.
   // jack is now a free wave.

   return jack          // Return reference to free wave to calling routine
End

Function MainRoutine2()
   WAVE w= Subroutine2()   // Wave reference w references free wave jack
   Print w
End   // Wave reference w ceases to exist so free wave jack is deleted
```

Not shown in this section is the case of a free wave that persists because a reference to it is stored in a wave reference wave. That situation is illustrated by the **Automatic Parallel Processing with MultiThread** on page IV-323 example.

Free Wave Leaks

A leak occurs when an object is created and is never released. Leaks waste memory. Igor uses wave reference counting to prevent leaks but in the case of free waves there are special considerations.

A free wave must be stored in a wave reference variable in order to be automatically released because Igor does the releasing when a wave reference variable goes out of scope.

To avoid the possibility of leaks, when you call a function that returns a free wave, always store the function result in a wave reference variable.

The following example results in two memory leaks:

```
Function/WAVE GenerateFree()
   return NewFreeWave(2,3)
End

Function Leaks()
   Duplicate/O GenerateFree(),dummy             // This leaks
   Variable maxVal = WaveMax(generateFree())    // So does this
End
```

Both lines leak because the free wave returned by GenerateFree is not stored in any wave reference variable. By contrast, this function does not leak:

```
Function NoLeaks()
   Wave w = GenerateFree()              // w references the free wave
   Duplicate/O w,dummy
   Variable maxVal = WaveMax(w)         // WaveMax is a built-in function
   // The free wave is released when w goes out of scope
End
```

In the Leaks function, there would be no leak if you replaced the call to WaveMax with a call to a user-defined function. This is because Igor automatically creates a wave reference variable when you pass a wave to a user-defined function. Because this distinction is subtle, it is best to always store a free wave in your own explicit wave reference variable.

To a discussion of leak detection and investigation techniques, see **Detecting Wave Leaks** on page IV-206.

Free Wave Names

By default, the name of a free wave is _free_. If you use free waves in programming, you may find that the lack of specific names makes debugging difficult. If you break into the debugger, you see a lot of waves named _free_ and you can't tell which is used for what purpose.

In Igor Pro 9.00 and later, you can override the default and provide specific names for free waves using **Make**/FREE=1 and **NewFreeWave**. This improves debuggability and also helps in investigating leaks using the **WaveTracking** operation.

This example shows how to use Make/FREE=1 to specify the name of a free wave:

```
Function FreeWaveName1()
   // Creates a wave reference named tempw, wave name is _free_
   Make/FREE tempw
   Print NameOfWave(tempw)       // Prints _free_

   // Creates a wave reference named tempw, wave name is also tempw
   Make/FREE=1 tempw2
   Print NameOfWave(tempw2)      // Prints tempw2
End
```

You can also give a name to a free wave using the optional name string input to NewFreeWave:

```
Function FreeWaveName2()
   // Creates a wave reference named tempw, wave name is _free_
   Wave tempw = NewFreeWave(4,2)
   Print NameOfWave(tempw)       // Prints _free_

   // Creates a wave reference named tempw, wave name is myFreeWave
   Wave tempw = NewFreeWave(4,2,"myFreeWave")
   Print NameOfWave(tempw)       // Prints myFreeWave
End
```

Igor does not use the name of a free wave but in user procedure code there could be an assumption that free waves are named '_free_'. In that rare case, specifying the name of a free wave could expose a bug. The fix is to use WaveType to determine if a wave is free instead of the wave name.

Even if you didn't give a name to a free wave explicitly, there are tricky ways for a free wave to have a name other than '_free_'. One such way is to create a wave inside a free data folder, and then kill the free data folder:

```
Function/WAVE WaveInFreeDF()
   DFREF saveDF = GetDataFolderDFR()
   DFREF freeDF = NewFreeDataFolder()
   SetDataFolder freeDF    // Free data folder is current data folder
   Make jack               // Wave in free data folder
   SetDataFolder saveDF    // Free data folder is no longer current data folder
   return jack
   // At this point the free data folder is killed because freeDF
   // goes out of scope and consequently jack becomes a free wave
End

Function Tricky()
   Wave w = WaveInFreeDF()
   Print NameOfWave(w)     // Prints jack
   Print WaveType(w, 3)    // Prints 1 meaning free wave
End
```

Another way is to call an Igor operation that creates an output wave inside a free data folder. This happens if you set a free data folder as the current data folder and then call an operation, such as ColorTab2Wave, that creates an output wave in the current data folder.

Converting a Free Wave to a Global Wave

You can use **MoveWave** to move a free wave into a global data folder, in which case it ceases to be free. If the wave was created by NewFreeWave its name will be '_free_'. You can use MoveWave to provide it with a more descriptive name.

Here is an example illustrating Make/FREE:

```
Function Test()
   Make/FREE/N=(50,50) w
   SetScale x,-5,8,w
   SetScale y,-7,12,w
   w= exp(-(x^2+y^2))
   NewImage w
   if( GetRTError(1) != 0 )
      Print "Can't use a free wave here"
   endif
   MoveWave w,root:wasFree
   NewImage w
End
```

Note that MoveWave requires that the new wave name, wasFree in this case, be unique within the destination data folder.

To determine if a given wave is free or global, use the **WaveType** function with the optional selector = 2.

Free Data Folders

Free data folders are data folders that are not part of any data folder hierarchy. Their principal use is in multithreaded wave assignment using the MultiThread keyword in a function. They can also be used for temporary storage within functions.

Free data folders are recommended for advanced programmers only.

A wave that is stored in a free data folder or its descendants is called a “local” wave to distinguish it from a “global” wave which is stored in the root data folder or its descendants and from a “free” wave which is stored in no data folder.

Note: Free data folders are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only.

You create a free data folder using the NewFreeDataFolder function. You access it using the data folder reference returned by that function.

After using SetDataFolder with a free data folder, be sure to restore it to the previous value, like this:

```
Function Test()
   DFREF dfrSave = GetDataFolderDFR()

   SetDataFolder NewFreeDataFolder()   // Create new free data folder.

   . . .

   SetDataFolder dfrSave
End
```

This is good programming practice in general but is especially important when using free data folders.

Free data folders can not be used in situations where global persistence is required such as in graphs, tables and controls. In other words, you should use objects in free data folders for short-term computation purposes only.

For a discussion of multithreaded assignment statements, see **Automatic Parallel Processing with MultiThread** on page IV-323. For an example using free data folders, see **Data Folder Reference MultiThread Example** on page IV-325.

Free Data Folder Lifetime

A free data folder is automatically deleted when the last reference to it disappears.

Data folder references can be stored in:

1. Data folder reference variables in user-defined functions
2. Data folder reference fields in structures
3. Elements of a data folder reference wave (created with Make/DF)
4. Igor's internal current data folder reference variable

A data folder reference disappears when:

1. The data folder reference variable containing it is explicitly cleared using KillDataFolder.
2. The data folder reference variable containing it is reassigned to refer to another data folder.
3. The data folder reference variable containing it goes out-of-scope and ceases to exist when the function in which it was created returns.
4. The data folder reference wave element containing it is deleted or the data folder reference wave is killed.
5. The current data folder is changed which causes Igor's internal current data folder reference variable to refer to another data folder.

When there are no more references to a free data folder, Igor automatically deletes it.

In this example, a free data folder reference variable is cleared by KillDataFolder:

```
Function Test1()
   DFREF dfr= NewFreeDataFolder()      // Create new free data folder.
   // The free data folder exists because dfr references it.
   . . .
   KillDataFolder dfr   // dfr no longer refers to the free data folder
End
```

KillDataFolder kills the free data folder only if the given DFREF variable contains the last reference to it.

In the next example, the free data folder is automatically deleted when the DFREF that references it is changed to reference another data folder:

```
Function Test2()
   DFREF dfr= NewFreeDataFolder()      // Create new free data folder.
   // The free data folder exists because dfr references it.
   . . .
   DFREF dfr= root:
   // The free data folder is deleted since there are no references to it.
End
```

In the next example, a free data folder is created and a reference is stored in a local data folder reference variable. When the function ends, the DFREF ceases to exist and the free data folder is automatically deleted:

```
Function Test3()
   DFREF dfr= NewFreeDataFolder()      // Create new free data folder.
   // The free data folder exists because dfr references it.
   . . .
End   // The free data folder is deleted because dfr no longer exists.
```

The fourth case, where a data folder reference is stored in a data folder reference wave, is discussed under **Data Folder Reference Waves** on page IV-82.

In the next example, the free data folder is referenced by Igor's internal current data folder reference variable because it is the current data folder. When the current data folder is changed, there are no more references to the free data folder and it is automatically deleted:

```
Function Test4()
   SetDataFolder NewFreeDataFolder()   // Create new free data folder.
   // The free data folder persists because it is the current data folder
   // and therefore is referenced by Igor's internal
   // current data folder reference variable.
   . . .

   // Change Igor's internal current data folder reference
   SetDataFolder root:
   // The free data folder is deleted since there are no references to it.
End
```

Free Data Folder Objects Lifetime

Next we consider what happens to objects in a free data folder when the free data folder is deleted. In this event, numeric and string variables in the free data folder are unconditionally automatically deleted. A wave is automatically deleted if there are no wave references to it. If there is a wave reference to it, the wave survives and becomes a free wave. Free waves are waves that exists outside of any data folder as explained under **Free Waves** on page IV-91.

For example:

```
Function Test()
   SetDataFolder NewFreeDataFolder()   // Create new free data folder.
   // The free data folder exists because it is the current data folder.

   Make jack      // Make a wave and an automatic wave reference

   . . .

   SetDataFolder root:
   // The free data folder is deleted since there are no references to it.
   // Because there is a reference to the wave jack, it persists
   // and becomes a free wave.

   . . .

End   // The wave reference to jack ceases to exist so jack is deleted
```

When this function ends, the reference to the wave jack ceases to exist, there are no references to jack, and it is automatically deleted.

Next we look at a slight variation. In the following example, Make does not create an automatic wave reference because of the use of $, and we do not create an explicit wave reference:

```
Function Test()
   SetDataFolder NewFreeDataFolder()   // Create new free data folder.
   // The free data folder exists because it is the current data folder.

   Make $"jack"         // Make a wave but no wave reference
   // jack persists because the current data folder references it.
   . . .

   SetDataFolder root:
   // The free data folder is deleted since there are no references to it.
   // jack is also deleted because there are no more references to it.

   . . .

End
```

Converting a Free Data Folder to a Global Data Folder

You can use **MoveDataFolder** to move a free data folder into the global hierarchy. The data folder and all of its contents then become global. The name of a free data folder created by NewFreeDataFolder is 'freeroot'. You should rename it after moving to a global context. For example:

```
Function Test()
   DFREF saveDF = GetDataFolderDFR()
   DFREF dfr = NewFreeDataFolder()      // Create free data folder
   SetDataFolder dfr                    // Set as current data folder
   Make jack=sin(x/8)                   // Create some data in it
   SetDataFolder saveDF                 // Restore original current data folder
   MoveDataFolder dfr, root:            // Free DF becomes root:freeroot
   RenameDataFolder root:freeroot,TestDF  // Rename with a proper name
   Display root:TestDF:jack
End
```

Note that MoveDataFolder requires that the data folder name, freeroot in this case, be unique within the destination data folder.

Structures in Functions

You can define structures in procedure files and use them in functions. Structures can be used only in user-defined functions as local variables and their behavior is defined almost entirely at compile time. Runtime or interactive definition and use of structures is not currently supported; for this purpose, use Data Folders (see Chapter II-8, **Data Folders**), the **StringByKey** function (see page V-997), or the **NumberByKey** function (see page V-714).

Use of structures is an advanced technique. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

Simple Structure Example

Before we get into the details, here is a quick example showing how to define and use a structure.

```
Structure DemoStruct
   double dval
   int32 ival
   char str[100]
EndStructure

Function Subroutine(s)
   STRUCT DemoStruct &s       // Structure parameter

   Printf "dval=%g; ival=%d; str=\"%s\"\r", s.dval, s.ival, s.str
End

Function Routine()
   STRUCT DemoStruct s        // Local structure instance
   s.dval = 1.234
   s.ival = 4321
   s.str = "Hello"
   Subroutine(s)
End
```

As this example shows, you define a structure type using the Structure keyword in a procedure file. You define a local structure variable using the STRUCT keyword in a user-defined function. And you pass a structure from one user-defined function to another as a pass-by-reference parameter, as indicated by the use of & in the subroutine parameter declaration.

Defining Structures

Structures are defined in a procedure file with the following syntax:

```
Structure structureName
   memType memName [arraySize] [, memName [arraySize]]
   …
EndStructure
```

Structure member types (*memType*) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, DFREF, FUNCREF, or STRUCT.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

Igor Member Type	C Equivalent	Byte Size	Note
char	signed char	1	
uchar	unsigned char	1	
int16	16-bit int	2	
uint16	unsigned 16-bit int	2	
int32	32-bit int	4	
uint32	unsigned 32-bit int	4	
int64	64-bit int	8	Igor7 or later
uint64	unsigned 64-bit int	8	Igor7 or later
float	float	4	
double	double	8	

The Variable and double types are identical although Variable can be also specified as complex using the /C flag.

The optional *arraySize* must be specified using an expression involving literal numbers or locally-defined constants enclosed in brackets. The value must be between 1 and 400 for all but STRUCT where the upper limit is 100. The upper limit is a consequence of how memory is allocated on the stack frame.

Structures are two-byte aligned. This means that if an odd number of bytes has been allocated and then a nonchar field is defined, an extra byte of padding is inserted in front of the new field. This is mainly of concern only when reading and writing structures from and to disk files.

The Structure keyword can be preceded with the **Static** keyword (see page V-906) to make the definition apply only to the current procedure window. Without the Static designation, structures defined in one procedure window may be used in any other.

Structure Initialization

When a user-defined function that declares a structure is called, the structure fields are automatically initialized. Numeric fields are initialized to zero. String, WAVE, NVAR, SVAR, DFREF, and FUNCREF fields are initialized to null.

You can further initialize numeric and string fields using normal assignment statements.

You can further initialize WAVE, NVAR, SVAR, DFREF, and FUNCREF fields using the same syntax as used for the corresponding non-structure variables. See **Runtime Lookup of Globals** on page IV-65 and **Function References** on page IV-107.

You can also use the **StructFill** operation to automatically initialize NVAR, SVAR, and WAVE fields.

Using Structures

To use ("instantiate") a structure in a function, you must allocate a STRUCT variable using:

```
STRUCT sName name
```

where *sName* is the name of an existing structure and *name* is the local structure variable name.

To access a member of a structure, specify the STRUCT variable name followed by a "." and the member name:

```
STRUCT Point pt
pt.v= 100
```

When a member is defined as an array:

```
Structure mystruct
   Variable var1
   Variable var2[10]
   …
EndStructure
```

you must specify `[index]` to use a given element in the array:

```
STRUCT mystruct ms
ms.var2[n]= 22
```

Structure and field names must be literal and can not use `$str` notation.

The *index* value can be a variable calculated at runtime or a literal number.

If the field is itself a STRUCT, continue to append "." and field names as needed.

You can define an array of structures as a field in a structure:

```
Structure mystruct
   STRUCT Point pt[100]    // Allowed as a sub-structure
EndStructure
```

However, you can not define an array of structures as a local variable in a function:

```
STRUCT Point pt[100]       // Not allowed as a function local variable
```

Structures can be passed to functions **only** by reference, which allows them to be both input and output parameters (see **Pass-By-Reference** on page IV-59). The syntax is:

```
STRUCT sName  &varName
```

In a user function you define the input parameter:

```
Function myFunc(s)
   STRUCT mystruct &s
   …
End
```

Char and uchar arrays can be treated as zero-terminated strings by leaving off the brackets. Because the Igor compiler knows the size, the entire array can be used with no zero termination. Like normal string variables, concatenation using += is allowed but substring assignment using `[p1,p2]= subStr` is not supported.

Structures, including substructures, can be copied using simple assignment from one structure to the other. The source and destination structures must defined using the same structure name.

The **Print** operation can print individual elements of a structure or can print a summary of the entire STRUCT variable.

Structure Example

Here is a contrived example using structures. Try executing `foo(2)`:

```
Constant kCaSize = 5

Structure substruct
   Variable v1
   Variable v2
EndStructure

Structure mystruct
   Variable var1
   Variable var2[10]
   String s1
   WAVE fred
   NVAR globVar1
   SVAR globStr1
   FUNCREF myDefaultFunc afunc
   STRUCT substruct ss1[3]
   char ca[kCaSize+1]
EndStructure

Function foo(n)
   Variable n

   Make/O/N=20 fred
   Variable/G globVar1 = 111
   String/G aGlobStr="a global string var"

   STRUCT mystruct ms
   ms.var1 = 11
   ms.var2[n] = 22
   ms.s1 = "string s1"
   WAVE ms.fred     // could have =name if want other than waves named fred
   NVAR ms.globVar1
   SVAR ms.globStr1 = aGlobStr
   FUNCREF myDefaultFunc ms.afunc = anotherfunc
   ms.ss1[n].v1 = ms.var1/2
   ms.ss1[0] = ms.ss1[n]
   ms.ca = "0123456789"
   bar(ms,n)
   Print ms.var1,ms.var2[n],ms.s1,ms.globVar1,ms.globStr1,ms.ss1[n].v1
   Print ms.ss 1[n].v2,ms.ca,ms.afunc()
   Print "a whole wave",ms.fred
   Print "the whole ms struct:",ms

   STRUCT substruct ss
   ss = ms.ss1[n]
   Print "copy of substruct",ss
End

Function bar(s,n)
   STRUCT mystruct &s
   Variable n

   s.ss1[n].v2 = 99
   s.fred = sin(x)
   Display s.fred
End

Function myDefaultFunc()
   return 1
End

Function anotherfunc()
   return 2
End
```

Note the use of WAVE, NVAR, SVAR and FUNCREF in the function foo. These keywords are required both in the structure definition and again in the function, when the structure members are initialized.

Built-In Structures

Igor includes a few special purpose, predefined structures for use with certain operations. Some of those structures use these predefined general purpose structures:

```
Structure Rect
   Int16 top,left,bottom,right
EndStructure

Structure Point
   Int16 v,h
EndStructure

Structure RGBColor
   UInt16 red, green, blue
EndStructure
```

A number of operations use built-in structures that the Igor programmer can use. See the command reference information for details about these structures and their members.

Operation	Structure Name
Button	**WMButtonAction**
CheckBox	**WMCheckboxAction**
CustomControl	**WMCustomControlAction**
ListBox	**WMListboxAction**
ModifyFreeAxis	**WMAxisHookStruct**
PopupMenu	**WMPopupAction**
SetVariable	**WMSetVariableAction**
SetWindow	**WMWinHookStruct**
SetWindow	**WMTooltipHookStruct**
Slider	**WMSliderAction**
TabControl	**WMTabControlAction**

Applications of Structures

Structures are useful for reading and writing disk files. The **FBinRead** and the **FBinWrite** understand structure variables and read or write the entire structure from or to a disk file. The individual fields of the structure are byte-swapped if you use the /B flag.

Structures can be used in complex programming projects to reduce the dependency on global objects and to simplify passing data to and getting data from functions. For example, a base function might allocate a local structure variable and then pass that variable on to a large set of lower level routines. Because structure variables are passed by reference, data written into the structure by lower level routines is available to the higher level. Without structures, you would have to pass a large number of individual parameters or use global variables and data folders.

Using Structures with Windows and Controls

Action procedures for controls and window hook functions take parameters that use predefined structure types. These are listed under **Built-In Structures** on page IV-103.

Advanced programmers should also be aware of userdata that can be associated with windows using the **SetWindow** operation (see page V-865). Userdata is binary data that persists with individual windows; it is suitable for storing structures. Storing structures in a window's userdata is very handy in eliminating the need for global variables and reduces the bookkeeping needed to synchronize those globals with the window's life cycle. Userdata is also available for use with controls. See the **ControlInfo**, **GetWindow**, **GetUserData**, and **SetWindow** operations.

Here is an example illustrating built-in and user-defined structures along with userdata in a control. Put the following in the procedure window of a new experiment and run the Panel0 macro. Then click on the buttons. Note that the buttons remember their state even if the experiment is saved and reloaded. To fully understand this example, examine the definition of WMButtonAction in the **Button** operation (see page V-55).

```
#pragma rtGlobals=1        // Use modern global access method.

Structure mystruct
    Int32 nclicks
    double lastTime
EndStructure

Function ButtonProc(bStruct) : ButtonControl
    STRUCT WMButtonAction &bStruct

    if( bStruct.eventCode != 1 )
        return 0         // we only handle mouse down
    endif

    STRUCT mystruct s1
    if( strlen(bStruct.userdata) == 0 )
        Print "first click"
    else
        StructGet/S s1,bStruct.userdata
        String ctime= Secs2Date(s1.lastTime, 1 )+" "+Secs2Time(s1.lastTime,1)
    // Warning: Next command is wrapped to fit on the page.
        Printf "button %s clicked %d time(s), last click =
%s\r",bStruct.ctrlName,s1.nclicks,ctime
    endif
    s1.nclicks += 1
    s1.lastTime= datetime
    StructPut/S s1,bStruct.userdata
    return 0
End

Window Panel0() : Panel
    PauseUpdate; Silent 1         // building window…
    NewPanel /W=(150,50,493,133)
    SetDrawLayer UserBack
    Button b0,pos={12,8},size={50,20},proc=ButtonProc,title="Click"
    Button b1,pos={65,8},size={50,20},proc=ButtonProc,title="Click"
    Button b2,pos={119,8},size={50,20},proc=ButtonProc,title="Click"
    Button b3,pos={172,8},size={50,20},proc=ButtonProc,title="Click"
    Button b4,pos={226,8},size={50,20},proc=ButtonProc,title="Click"
EndMacro
```

Limitations of Structures

Although structures can reduce the need for global variables, they do not eliminate them altogether. A structure variable, like all local variables in functions, disappears when its host function returns. In order to maintain state information, you need to store and retrieve structure information using global variables. You can do this using a global variable for each field or, with certain restrictions, you can store entire structure variables in a single global using the **StructPut** operation (see page V-1004) and the **StructGet** operation (see page V-1003).

As of Igor Pro 5.03, a structure can be passed to an external operation or function. See the Igor XOP Toolkit manual for details.

Using StructFill, StructPut, and StructGet

Igor Pro 8 provides the new convenience operation StructFill, which reads in NVAR, SVAR and WAVE fields, along with relaxed limitations for the StructPut and StructGet operations. The following example illustrates these operations.

```
Structure t
   SVAR gStructData
   WAVE myData
   double someResults
EndStructure

Function AnalyzeThis(DFREF df)
   STRUCT t t
   StructFill/AC=1/SDFR=df t
   if( V_Error )
      print "no data"
      return -1
   endif
   if( strlen(t.gStructData) != 0 )       // this may have been autocreated
      StructGet/S t,t.gStructData
      print "previous result:", t.someResults
   else
      print "no previous result"
   endif
   t.someResults= mean(t.myData)
   print "current result:", t.someResults
   StructPut/S t,t.gStructData
   return 0
End

Function Demo()
   NewDataFolder/O/S root:data1
   Make/O myData= gnoise(1)
   SetDataFolder root:

   AnalyzeThis(root:data1)
   myData= gnoise(2)
   AnalyzeThis(root:data1)
End
```

Running Demo() then prints this:

```
  no previous result
  current result:  -0.0675801
  previous result:  -0.0675801
  current result:  -0.00269252
```

Static Functions

You can create functions that are local to the procedure file in which they appear by inserting the keyword *Static* in front of *Function* (see **Static** on page V-906 for usage details). The main reason for using this technique is to minimize the possibility of your function names conflicting with other names, thereby making the use of common intuitive names practical.

Functions normally have global scope and are available in any part of an Igor experiment, but the static keyword limits the scope of the function to its procedure file and hides it from all other procedure files. Static functions can only be used in the file in which they are defined. They can not be called from the command line and they cannot be accessed from macros.

Because static functions cannot be executed from the command line, you will have write a public test function to test them.

You can break this rule and access a static function using a module name; see **Regular Modules** on page IV-236.

Non-static functions (functions without the static keyword) are sometimes called “public” functions.

ThreadSafe Functions

A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads.

ThreadSafe user functions provide support for multiprocessing and can be used for preemptive multitasking background tasks.

Note: Writing a multitasking program is for expert programmers only. Intermediate programmers can write thread-safe curve-fitting functions and multithreaded assignment statements; see **Automatic Parallel Processing with MultiThread** on page IV-323. Beginning programmers should gain experience with regular programming before using multitasking.

You create thread safe functions by inserting the keyword `ThreadSafe` in front of `Function`. For example:

```
ThreadSafe Function myadd(a,b)
   Variable a,b

   return a+b
End
```

Only a subset of Igor's built-in functions and operations can be used in a threadsafe function. Generally, numeric or utility functions can be used but those that access windows can not. To determine if a routine is ThreadSafe, use the Command Help tab of the Help Browser.

Although file operations are listed as threadsafe, they have certain limitations when running in a threadsafe function. If a file load hits a condition that normally would need user assistance, the load is aborted. No printing to history is done.

Threadsafe functions can call other threadsafe functions but may not call non-threadsafe functions. Non-threadsafe functions can call threadsafe functions.

When threadsafe functions execute in the main thread, they have normal access to data folders, waves, and variables. But when running in a preemptive thread, threadsafe functions use their own private data folders, waves, and variables.

When a thread is started, waves can be passed to the function as input parameters. Such waves are flagged as being in use by the thread, which prevents any changes to the size of the wave. When all threads under a given main thread are finished, the waves return to normal. You can pass data folders between the main thread and preemptive threads but such data folders are never shared.

See **ThreadSafe Functions and Multitasking** on page IV-329 for a discussion of programming with preemptive multitasking threads.

Function Overrides

In some very rare cases, you may need to temporarily change an existing function. When that function is part of a package provided by someone else, or by WaveMetrics, it may be undesirable or difficult to edit the original function. By using the keyword "Override" in front of "Function" you can define a new function that will be used in place of another function of the same name that is defined in a *different and later* procedure file.

Although it is difficult to determine the order in which procedure files are compiled, the main procedure window is always first. Therefore, always define override functions in the main procedure file.

Although you can override static functions, you may run into a few difficulties. If there are multiple files with the same static function name, your override will affect all of them, and if the different functions have different parameters then you will get a link error.

Here is an example of the Override keyword. In this example, start with a new experiment and create a new procedure window. Insert the following in the new window (not the main procedure window).

```
Function foo()
   print "this is foo"
```

```
End

Function Test()
   foo()
End
```

Now, on the command line, execute Test(). You will see “this is foo” in the history.

Open the main procedure window and insert the following:

```
Override Function foo()
   print "this is an override version of foo"
End
```

Now execute Test() again. You will see the “this is an override version of foo” in the history.

Function References

Function references provide a way to pass a function to a function. This is a technique for advanced programmers. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

To specify that an input parameter to a function is a function reference, use the following syntax:

```
Function Example(f)
   FUNCREF myprotofunc f
   . . .
End
```

This specifies that the input parameter f is a function reference and that a function named myprotofunc specifies the kind of function that is legal to pass. The calling function passes a reference to a function as the f parameter. The called function can use f just as it would use the prototype function.

If a valid function is not passed then the prototype function is called instead. The prototype function can either be a default function or it can contain error handling code that makes it obvious that a proper function was not passed.

Here is the syntax for creating function reference variables in the body of a function:

```
FUNCREF protoFunc f = funcName
FUNCREF protoFunc f = $"str"
FUNCREF protoFunc f = <FuncRef>
```

As shown, the right hand side can take either a literal function name, a $ expression that evaluates to a function name at runtime, or it can take another FUNCREF variable.

FUNCREF variables can refer to external functions as well as user-defined functions. However, the prototype function must be a user-defined function and it must not be static.

Although you can store a reference to a static function in a FUNCREF variable, you can not then use that variable with Igor operations that take a function as an input. FuncFit is an example of such an operation.

Following are some example functions and FUNCREFs that illustrate several concepts:

```
Function myprotofunc(a)
   Variable a

   print "in myprotofunc with a= ",a
End

Function foo1(var1)
   Variable var1
   print "in foo1 with a= ",var1
End

Function foo2(a)
   Variable a

   print "in foo2 with a= ",a
End

Function foo3(a)
   Variable a

   print "in foo3 with a= ",a
End

Function badfoo(a,b)
   Variable a,b

   print "in badfoo with a= ",a
End

Function bar(a,b,fin)
   Variable a,b
   FUNCREF myprotofunc fin

   if( a==1 )
      FUNCREF myprotofunc f= foo1
   elseif( a==2 )
      FUNCREF myprotofunc f= $"foo2"
   elseif( a==3 )
      FUNCREF myprotofunc f= fin
   endif
   f(b)
End
```

For the above functions, the following table shows the results for various invocations of the bar function executed on the command line:

Command	Result
`bar(1,33,foo3)`	`in foo1 with a= 33`
`bar(2,44,foo3)`	`in foo2 with a= 44`
`bar(3,55,foo3)`	`in foo3 with a= 55`
`bar(4,55,foo3)`	`in myprotofunc with a= 55`

Executing `bar(3,55,badfoo)` generates a syntax error dialog that highlights “badfoo” in the command. This error results because the format of the badfoo function does not match the format of the prototype function, myprotofunc.

Conditional Compilation

Compiler directives can be used to conditionally include or exclude blocks of code. This is especially useful when an XOP may or may not be available. It is also convenient for supporting different versions of Igor with the same code and for testing and debugging code.

For example, to enable a block of procedure code depending on the presence or absence of an XOP, use

```
#if Exists("nameOfAnXopRoutine")
   <code using XOP routines>
#endif
```

To conditionally compile based on the version of Igor, use:

```
#if IgorVersion() < 7.00
   <code for Igor6 or before>
#else
   <code for Igor7 or later>
#endif
```

Conditional Compilation Directives

The conditional compiler directives are modeled after the C/C++ language. Unlike other #keyword directives, these may be indented. For defining symbols, the directives are:

```
#define symbol
```

```
#undef symbol
```

For conditional compilation, the directives are:

```
#ifdef symbol
```

```
#ifndef symbol
```

```
#if expression
```

```
#elif expression
```

```
#else
```

```
#endif
```

Expressions are ordinary Igor expressions, but cannot involve any user-defined objects. They evaluate to TRUE if the absolute value is > 0.5.

Conditionals must be either completely outside or completely inside function definitions; they cannot straddle a function definition. Conditionals cannot be used within macros but the **defined** function can.

Nesting depth is limited to 16 levels. Trailing text other than a comment is illegal.

Conditional Compilation Symbols

#define is used purely for defining symbols (there is nothing like C's preprocessor) and the only use of a symbol is with #if, #ifdef, #ifndef and the defined function.

The defined function allows you to test if a symbol was defined using #define:

```
#if defined(symbol)
```

Symbols exist only in the file where they are defined; the only exception is for symbols defined in the main procedure window, which are available to all other procedure files except independent modules. In addition, you can define global symbols that are available in all procedure windows (including independent modules) using:

```
SetIgorOption poundDefine=symb
```

This adds one symbol to a global list. You can query the global list using:

```
SetIgorOption poundDefine=symb?
```

This sets V_flag to 1 if symb exists or 0 otherwise. To remove a symbol from the global list use:

```
SetIgorOption poundUndefine=symb
```

For non-independent module procedure windows, a symbol is defined if it exists in the global list *or* in the main procedure window's list *or* in the given procedure window.

For independent module procedure windows, a symbol is defined if it exists in the global list *or* in the given procedure window; it does not use the main procedure window list.

A symbol defined in a global list is not undefined by a #undef in a procedure window.

Predefined Global Symbols

These global symbols are predefined if appropriate and available in all procedure windows:

Symbol	Automatically Predefined If
MACINTOSH	The Igor application is a Macintosh application.
WINDOWS	The Igor application is a Windows application.
IGOR64	The Igor application is a 64-bit application.

Conditional Compilation Examples

```
#define MYSYMBOL

#ifdef MYSYMBOL

Function foo()
   Print "This is foo when MYSYMBOL is defined"
End

#else

Function foo()
   Print "This is foo when MYSYMBOL is NOT defined"
End

#endif   // MYSYMBOL

// This works in Igor Pro 6.10 or later
#if IgorVersion() >= 7.00
   <code for Igor7 or later>
#else
   <code for Igor6 or before>
#endif

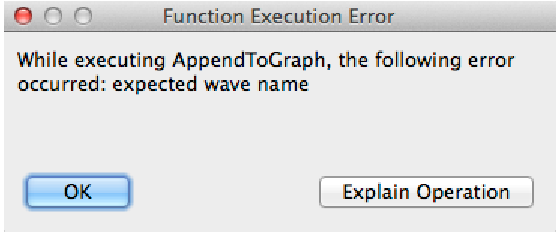
// This works in Igor Pro 6.20 or later
#if defined(MACINTOSH)
   <conditionally compiled code here>
#endif
```

Function Errors

During function compilation, Igor checks and reports syntactic errors and errors in parameter declarations. The normal course of action is to edit the offending function and try to compile again.

Runtime errors in functions are not reported on the spot. Instead, Igor saves information about the error and function execution continues. Igor presents an error dialog only after the last function ceases execution and Igor returns to the idle state. If multiple runtime errors occur, only the first is reported.

When a runtime error occurs, after function execution ends, Igor presents an error dialog:



While executing AppendToGraph, the following error occurred: expected wave name

In this example, we tried to pass to the AppendToGraph function a reference to a wave that did not exist. To find the source of the error, you should use Igor's debugger and set it to break on error (see **Debugging on Error** on page IV-213 for details).

Runtime Errors From Built-in Functions

Normally, when an error occurs in a built-in function, the built-in function does not post an error but instead returns 0, NaN or an empty string as the function result. As a debugging aid, you can use the rtFunctionErrors pragma to force Igor to post an error. See **The rtFunctionErrors Pragma** on page IV-55 for details.

Custom Error Handling

Normally when an error occurs, Igor aborts function execution.

Sophisticated programmers may want to detect and deal with runtime errors on their own. See **Flow Control for Aborts** on page IV-48 for details and examples.

Coercion in Functions

The term "coercion" means the conversion of a value from one numeric precision or numeric type to another. Consider this example:

```
Function foo(awave)
   WAVE/C awave

   Variable/C var1

   var1 = awave[2]*cmplx(2,3)
   return real(var1)
End
```

The parameter declaration specifies that awave is complex. You can pass any kind of wave you like but it will be coerced into complex before use. For example, if you pass a real valued integer wave the value at point index 2 will be converted to double precision and zero will be used for the imaginary part.

Operations in Functions

You can call most operations from user-defined functions. To provide this capability, WaveMetrics had to create special code for each operation. Some operations weren't worth the trouble or could cause problems. If an operation can't be invoked from a function, an error message is displayed when the function is compiled. The operations that can't be called from a function are:

```
AppendToLayout      Layout       Modify              OpenProc
PrintGraphs         Quit         RemoveFromLayout
Stack               Tile
```

If you need to invoke one of these operations from a user-defined function, use the Execute operation. See **The Execute Operation** on page IV-201.

While Modify can not be called from a function, ModifyGraph, ModifyTable and ModifyLayout can.

You can use the **NewLayout** instead of Layout, the **AppendLayoutObject** instead of AppendToLayout, and the **RemoveLayoutObjects** instead of RemoveFromLayout.

External operations implemented by very old XOPs also can not be called directly from user-defined functions. Again, the solution is to use the Execute operation.

Updates During Function Execution

An update is an action that Igor performs which consists of:

- Reexecuting formulas for dependent objects whose antecedents have changed (see Chapter IV-9, **Dependencies**)
- Redrawing graphs, tables and Gizmo plots which display waves that have changed
- Redrawing page layouts containing graphs, tables, Gizmo plots, or annotations that have changed
- Redrawing windows that have been uncovered

When no procedure is executing, Igor continually checks whether an update is needed and does an update if necessary.

When a user-defined function is executing, Igor does no automatic updates at all. You can force an update by calling the **DoUpdate** operation (see page V-168). Call DoUpdate if you don’t want to wait for the next automatic update which will occur when function execution finishes.

Aborting Functions

There are two ways to prematurely stop procedure execution: a user abort or a programmed abort. Both stop execution of all procedures, no matter how deeply nested.

You can abort function execution by pressing the **User Abort Key Combinations** or by clicking the Abort button in the status bar. You may need to press the keys down for a while because Igor looks at the keyboard periodically and if you don’t press the keys long enough, Igor will not see them.

A user abort does not directly return. Instead it sets a flag that stops loops from looping and then returns using the normal calling chain. For this reason some code will still be executed after an abort but execution should stop quickly. This behavior releases any temporary memory allocations made during execution.

A **programmed abort** occurs during procedure execution according to conditions set by the programmer.

The simplest programmed abort occurs when the **Abort** operation (see page V-18) is executed. Here is an example:

```
if (numCells > 10)
   Abort "Too many cells! Quitting."
endif
// code here doesn't execute if numCells > 10
```

Other programmed aborts can be triggered using the AbortOnRTE and AbortOnValue flow control keywords. The try-catch-endtry flow control construct can be used for catching and testing for aborts. See **Flow Control for Aborts** on page IV-48 for more details.

If your code uses Igor pre-emptive threads that can run for a long time, you should detect aborts and make your threads quit. See **Aborting Threads** on page IV-337 for details.

Igor Pro 7 Programming Extensions

The following programming features were added in Igor Pro 7. They bring Igor programming closer to the C language. If you use these features, your procedures will not compile in Igor Pro 6.

Double and Complex Variable Types

You can use `double` and `complex` in functions as aliases for `Variable` and `Variable/C`:

```
Function foo()
   double d = 4
   complex c = cmplx(2,3)
   Print d,c
End
```

Integer Variable Types

In Igor Pro 7 or later you can use the integer types `int`, `int64` and `uint64` for parameters and local variables in user-defined functions. You can also use `int64` and `uint64` in structures. See **Integer Parameters** on page IV-33 for details.

Integer Expressions in User-Defined Functions

Prior to Igor Pro 7, all calculations were performed in double-precision floating point. In Igor Pro 7 or later, Igor uses integer calculations when the destination is an integer type. See **Expression Evaluation** on page IV-38 for details.

Inline Parameters in User-Defined Functions

In Igor Pro 7 or later you can declare user-defined functions parameters inline. See **Inline Parameters** on page IV-33 for details.

Line Continuation in User-Defined Functions

In user-defined functions in Igor Pro 7 or later, you can use arbitrarily long expressions by including a line continuation character at the very end of a line. See **Line Continuation** on page IV-35 for details.

Bit Shift Operators in User-Defined Functions

Igor Pro 7 or later supports the bit shift operators << and >> on local variables. See **Bit Shift Operators** on page IV-43 for details.

Increment and Decrement Operators in User-Defined Functions

In a user-defined function in Igor Pro 7 or later, you can use increment and decrement operators on local variables. See **Increment and Decrement Operators** on page IV-43 for details.

Legacy Code Issues

This section discusses changes that have occurred in Igor programming over the years. If you are writing new code, you don’t need to be concerned with these issues. If you are working with existing code, you may run into some of them.

If you are just starting to learn Igor programming, you have enough to think about already, so it is a good idea to skip this section. Once you are comfortable with the modern techniques described above, come back and learn about these antiquated techniques.

Old-Style Comments and Compatibility Mode

In Igor Pro 1.00 through 3.00, the comment symbol was the vertical bar (|). Starting with Igor Pro 4.00 vertical bar is used as the bitwise OR operator (see Operators) and the comment symbol is //.

In the unlikely event that you encounter an ancient procedure file that used vertical bar as the comment symbol, you need to replace the vertical bars with //.

From Igor Pro 4.00 through Igor Pro 6.37, there was a compatibility mode that told Igor to accept vertical bar as a comment symbol:

```
Silent 100        // Enter compatibility mode
```

Support for this compatibility mode was removed in Igor Pro 7.00.

Text After Flow Control

Prior to Igor Pro 4, Igor ignored any extraneous text after a flow control statement. Such text was an error, but Igor did not detect it.

Igor now checks for extra text after flow control statements. When found, a dialog is presented asking the user if such text should be considered an error or not. The answer lasts for the life of the Igor session.

Because previous versions of Igor ignored this extra text, it may be common for existing procedure files to have this problem. The text may in many cases simply be a typographic error such as an extra closing parenthesis:

```
if( a==1 ))
```

In other cases, the programmer may have thought they were creating an elseif construct:

```
else if( a==2 )
```

even though the “if(a==2)” part was simply ignored. In some cases this may represent a bug in the programmer’s code but most of the time it is asymptomatic.

Global Variables Used by Igor Operations

The section **Local Variables Used by Igor Operations** on page IV-61 explains that certain Igor operations create and set certain special local variables. Very old procedure code expects such variables to be created as global variables and must be rewritten.

Also explained in **Local Variables Used by Igor Operations** on page IV-61 is the fact that some operations, such as CurveFit, look for certain special local variables which modify the behavior of the operations. For historic reasons, operations that look for special variables will look for global variables in the current data folder if the local variable is not found. This behavior is unfortunate and may be removed from Igor some day. New programming should use local variables for this purpose.

Direct Reference to Globals

The section **Accessing Global Variables and Waves** on page IV-65 explains how to access globals from a procedure file. Very old procedure files may attempt to reference globals directly, without using WAVE, NVAR, or SVAR statements. This section explains how to update such procedures.

Here are the steps for converting a procedure file to use the runtime lookup method for accessing globals:

1. Insert the #pragma rtGlobals=3 statement, with no indentation, at or near the top of the procedure in the file.
2. Click the Compile button to compile the procedures.
3. If the procedures use a direct references to access a global, Igor will display an error dialog indicating the line on which the error occurred. Add an NVAR, SVAR or WAVE reference.
4. If you encountered an error in step 3, fix it and return to step 2.

Chapter

IV-4

Macros

Overview

When we first created Igor, some time in the last millennium, it supported automation through macros. The idea of the macro was to allow users to collect commands into conveniently callable routines. Igor interpreted and executed each command in a macro as if it were entered in the command line.

WaveMetrics soon realized the need for a faster, more robust technology that would support full-blown programming. This led to the addition of user-defined functions. Because functions are compiled, they execute much more quickly. Also, compilation allows Igor to catch syntactic errors sooner. Functions have a richer set of flow control capabilities and support many other programming refinements.

Over time, the role of macros has diminished in favor of functions. With rare exceptions, new programming should be done using user-defined functions.

Macros are still supported and there are still a few uses in which they are preferred. When you close a graph, table, page layout, Gizmo plot, or control panel, Igor offers to automatically create a window recreation macro which you can later run to recreate the window. You can also ask Igor to automatically create a window style macro using the Window Control dialog. The vast majority of programming, however, should be done using functions.

The syntax and behavior of macros are similar to the syntax and behavior of functions, but the differences can be a source of confusion for someone first learning Igor programming. If you are just starting, you can safely defer reading the rest of this chapter until you need to know more about macros, if that time ever comes.

Comparing Macros and Functions

Like functions, macros are created by entering text in procedure windows. Each macro has a name, a parameter list, parameter declarations, and a body. Unlike functions, a macro has no return value.

Macros and functions use similar syntax. Here is an example of each. To follow along, open the Procedure window (Windows menu) and type in the macro and function definitions.

```
Macro MacSayHello(name)
   String name

   Print "Hello "+name
End

Function FuncSayHello(name)
   String name

   Print "Hello "+name
End
```

Now click in the command window to bring it to the front.

If you execute the following on the command line

```
MacSayHello("John"); FuncSayHello("Sue")
```

you will see the following output printed in the history area:

```
Hello John
Hello Sue
```

This example may lead you to believe that macros and functions are nearly identical. In fact, there are a lot of differences. The most important differences are:

- Macros automatically appear in the Macros menu. Functions must be explicitly added to a menu, if desired, using a menu definition.
- Most errors in functions are detected when procedures are compiled. Most errors in macros are detected when the macro is executed.

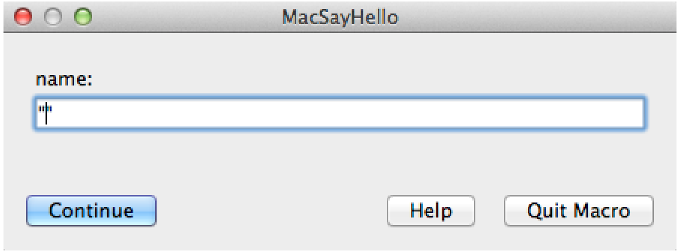
- Functions run a lot faster than macros.
- Functions support wave parameters, for loops, switches, structures, multithreading, and many other features not available in macros.
- Functions have a richer syntax.

If you look in the Macros menu, you will see MacSayHello but not FuncSayHello.

If you execute `FuncSayHello()` on the command line you will see an error dialog. This is because you must supply a parameter. You can execute, for example:

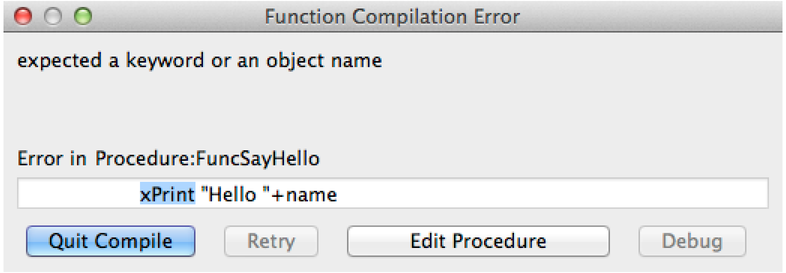
```
FuncSayHello("Sam")
```

On the other hand, if you run MacSayHello from the Macros menu or if you execute `MacSayHello()` on the command line, you will see a dialog that you use to enter the name before continuing:



This is called the “missing parameter dialog”. It is described under **The Missing Parameter Dialog** on page IV-121. Functions can display a similar dialog, called a simple input dialog, with a bit of additional programming.

Now try this: In both procedures, change “Print” to “xPrint”. Then click in the command window. You will see an error dialog complaining about the xPrint in the function:



expected a keyword or an object name

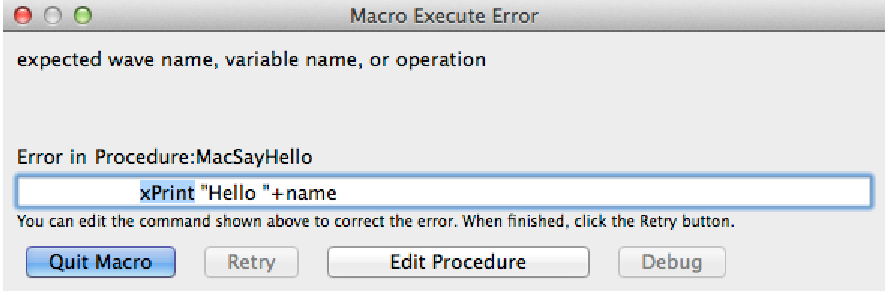
Error in Procedure:FuncSayHello

```
xPrint "Hello "+name
```

Click the Edit Procedure button and change “xPrint” back to “Print” in the function but not in the macro. Then click in the command window.

Notice that no error was reported once you fixed the error in the function. This is because only functions are compiled and thus only functions have their syntax completely checked at compile time. Macros are interpreted and most errors are found only when the line in the procedure window in which they occur is executed.

To see this, run the macro by executing “`MacSayHello("Sam")`” on the command line. Igor displays an error dialog:



expected wave name, variable name, or operation

Error in Procedure:MacSayHello

```
xPrint "Hello "+name
```

You can edit the command shown above to correct the error. When finished, click the Retry button.

Notice the outline around the line containing the error. This outline means you can edit the erroneous command. If you change “xPrint” to “Print” in this dialog, the Retry button becomes enabled. If you click Retry, Igor continues execution of the macro. When the macro finishes, take a look at the Procedure window. You will notice that the correction you made in the dialog was put in the procedure window and your “broken” macro is now fixed.

Macro Syntax

Here is the basic syntax for macros.

```
<Defining keyword> <Name> ( <Input parameter list> ) [:<Subtype>]
   <Input parameter declarations>

   <Local variable declarations>

   <Body code>
End
```

The Defining Keyword

<Defining keyword> is one of the following:

Defining Keyword	Creates Macro In
Window	Windows menu
Macro	Macros menu
Proc	—

The Window keyword is used by Igor when it automatically creates a window recreation macro. Except in rare cases, you will not write window recreation macros but instead will let Igor create them automatically.

The Procedure Name

The names of macros must follow the standard Igor naming conventions. Names can consist of up to 255 characters. Only ASCII characters are allowed. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names must not conflict with the names of other Igor objects, functions or operations. Names in Igor are case insensitive.

Prior to Igor Pro 8.00, macro names were limited to 31 bytes. If you use long macro names, your procedures will require Igor Pro 8.00 or later.

The Procedure Subtype

You can identify procedures designed for specific purposes by using a subtype. Here is an example:

```
Proc ButtonProc(ctrlName) : ButtonControl
   String ctrlName

   Beep
End
```

Here, “ : ButtonControl” identifies a macro intended to be called when a user-defined button control is clicked. Because of the subtype, this macro is added to the menu of procedures that appears in the Button Control dialog. When Igor automatically generates a procedure it generates the appropriate subtype. See **Procedure Subtypes** on page IV-204 for details.

The Parameter List and Parameter Declarations

The parameter list specifies the name for each input parameter. Macros have a limit of 10 parameters.

The parameter declaration must declare the type of each parameter using the keywords `Variable` or `String`. If a parameter is a complex number, it must be declared `Variable/C`.

Note: There should be no blank lines or other commands until after all the input parameters are defined. There should be one blank line after the parameter declarations, before the rest of the procedure. Igor will report errors if these conditions are not met.

Variable and string parameters in macros are always passed to a subroutine by value.

When macros are invoked with some or all of their input parameters missing, Igor displays a missing parameter dialog to allow the user to enter those parameters. In the past this has been a reason to use macros. However, as of Igor Pro 4, functions can present a similar dialog to fetch input from the user, as explained under **The Simple Input Dialog** on page IV-144.

Local Variable Declarations

The input parameter declarations are followed by the local variable declarations if the macro uses local variables. Local variables exist only during the execution of the macro. They can be numeric or string and are declared using the `Variable` or `String` keywords. They can optionally be initialized. Here is an example:

```
Macro Example(p1)
   Variable p1

   // Here are the local variables
   Variable v1, v2
   Variable v3=0
   Variable/C cv1=cmplx(0,0)
   String s1="test", s2="test2"

   <Body code>
End
```

If you do not supply explicit initialization, Igor automatically initializes local numeric variables with the value zero and local string variables with the value "".

The name of a local variable is allowed to conflict with other names in Igor although they must be unique within the macro. Clearly if you create a local variable named “sin” then you will be unable to use Igor’s built-in sin function within the macro.

You can declare a local variable in any part of a macro with one exception. If you place a variable declaration inside a loop in a macro then the declaration will be executed multiple times and Igor will generate an error since local variable names must be unique.

Body Code

The local variable declarations are followed by the body code. This table shows what can appear in body code of a macro.

What	Allowed in Macros?	Comments
Assignment statements	Yes	Includes wave, variable and string assignments.
Built-in operations	Yes	
External operations	Yes	
External functions	Yes	
Calls to user functions	Yes	
Calls to macros	Yes	
if-else-endif	Yes	
if-elseif-endif	No	
switch-case-endswitch	No	
strswitch-case-endswitch	No	
try-catch-endtry	No	
structures	No	
do-while	Yes	
for-endfor	No	
Comments	Yes	Comments start with //.
break	Yes	Used in loop statements.
continue	No	
default	No	
return	Yes, but with no return value.	

Conditional Statements in Macros

The conditional if-else-endif statement is allowed in macros. It works the same as in functions. See **If-Else-Endif** on page IV-40.

Loops in Macros

The do-while loop is supported in macros. It works the same as in functions. See **Do-While Loop** on page IV-45.

Return Statement in Macros

The return keyword immediately stops executing the current macro. If it was called by another macro, control returns to the calling macro.

A macro has no return value so return is used just to prematurely quit the macro. Most macros will have no return statement.

Invoking Macros

There are several ways to invoke a macro:

- From the command line

- From the Macros, Windows or user-defined menus
- From another macro
- From a button or other user control

The menu in which a macro appears, if any, is determined by the macro's type and subtype.

This table shows how a macro's type determines the menu that Igor puts it in.

Macro Type	Defining Keyword	Menu
Macro	`Macro`	Macros menu
Window Macro	`Window`	Windows menu
Proc	`Proc`	—

If a macro has a subtype, it may appear in a different menu. This is described under **Procedure Subtypes** on page IV-204. You can put macros in other menus as described in Chapter IV-5, **User-Defined Menus**.

You can not directly invoke a macro from a user function. You can invoke it indirectly, using the **Execute** operation (see page V-204).

Using $ in Macros

As shown in the following example, the $ operator can create references to global numeric and string variables as well as to waves.

```
Macro MacroTest(vStr, sStr, wStr)
   String vStr, sStr, wStr

   $vStr += 1
   $sStr += "Hello"
   $wStr += 1
End

Variable/G gVar = 0; String/G gStr = ""; Make/O/N=5 gWave = p
MacroTest("gVar", "gStr", "gWave")
```

See **String Substitution Using $** on page IV-18 for additional examples using $.

Waves as Parameters in Macros

The only way to pass a wave to a macro is to pass the name of the wave in a string parameter. You then use the $ operator to convert the string into a wave reference. For example:

```
Macro PrintWaveStdDev(w)
   String w

   WaveStats/Q $w
   Print V_sdev
End

Make/O/N=100 test=gnoise(1)
Print NamedWaveStdDev("test")
```

The Missing Parameter Dialog

When a macro that is declared to take a set of input parameters is executed with some or all of the parameters missing, it displays a dialog in which the user can enter the missing values. For example:

```
Macro MacCalcDiag(x,y)
   Variable x=10
   Prompt x, "Enter X component: "      // Set prompt for y param
   Variable y=20
   Prompt y, "Enter Y component: "      // Set prompt for x param

   Print "diagonal=",sqrt(x^2+y^2)
End
```

If invoked from the command line or from another macro with parameters missing, like this:

```
MacCalcDiag()
```

Igor displays the Missing Parameter dialog in which the parameter values can be specified.

The Prompt statements are optional. If they are omitted, the variable name is used as the prompt text.

There must be a blank line after the set of input parameter and prompt declarations and there must not be any blank lines within the set.

The missing parameter dialog supports the creation of pop-up menus as described under **Pop-Up Menus in Simple Dialogs** on page IV-145. One difference is that in a missing parameter dialog, the menu item list can be continued using as many lines as you need. For example:

```
Prompt color, "Select Color", popup "red;green;blue;"
"yellow;purple"
```

Macro Errors

Igor can find errors in macros at two times:

- When it scans the macros
- When it executes the macros

After you modify procedure text, scanning occurs when you activate a non-procedure window, click the Compile button or choose Compile from the Macros menu. At this point, Igor is just looking for the names of procedures. The only errors that it detects are name conflicts and ill-formed names. If it finds such an error, it displays a dialog that you use to fix it.

Igor detects other errors when the macro executes. Execution errors may be recoverable or non-recoverable. If a recoverable error occurs, Igor puts up a dialog in which you can edit the erroneous line.

You can fix the error and retry or quit macro execution.

If the error is non-recoverable, you get a similar dialog except that you can’t fix the error and retry. This happens with errors in the parameter declarations and errors related to if-else-endif and do-while structures.

The Silent Option

Normally Igor displays each line of a macro in the command line as it executes the line. This gives you some idea of what is going on. However it also slows macro execution down considerably. You can prevent Igor from showing macro lines as they are executed by using the `Silent 1` command.

You can use `Silent 1` from the command line. It is more common to use it from within a macro. The effect of the `Silent` command ends at the end of the macro in which it occurs. Many macros contain the following line:

```
Silent 1; PauseUpdate
```

The Slow Option

You can observe the lines in a macro as they execute in the command line. However, for debugging purposes, they often whiz by too quickly. The `Slow` operation slows the lines down. It takes a parameter which controls how much the lines are slowed down. Typically, you would execute something like “`Slow 10`” from the command line and then “`Slow 0`” when you are finished debugging.

You can also use the `Slow` operation from within a macro. You must explicitly invoke “`Slow 0`” to revert to normal behavior. It does not automatically revert at the end of the macro from which it was invoked.

We never use this feature. Instead, we generally use print statements for debugging or we use the Igor symbolic debugger, described in Chapter IV-8, **Debugging**.

Accessing Variables Used by Igor Operations

A number of Igor’s operations return results via variables. For example, the WaveStats operation creates a number of variables with names such as V_avg, V_sigma, etc.

When you invoke these operations from the command line, they create global variables in the current data folder.

When you invoke them from a user-defined function, they create local variables.

When you invoke them from a macro, they create local variables unless a global variable already exists. If both a global variable and a local variable exist, Igor uses the local variable.

In addition to creating variables, a few operations, such as CurveFit and FuncFit, check for the existence of specific variables to provide optional behavior. The operations look first for a local variable with a specific name. If the local variable is not found, they then look for a global variable.

Updates During Macro Execution

An update is an action that Igor performs. It consists of:

- Reexecuting assignments for dependent objects whose antecedents have changed (see Chapter IV-9, **Dependencies**);
- Redrawing graphs and tables which display waves that have changed;
- Redrawing page layouts containing graphs, tables, or annotations that have changed;
- Redrawing windows that have been uncovered.

When no procedure is executing, Igor continually checks whether an update is needed and does an update if necessary.

During macro execution, Igor checks if an update is needed after executing each line. You can suspend checking using the PauseUpdate operation. This is useful when you want an update to occur when a macro finishes but not during the course of the macro’s execution.

PauseUpdate has effect only inside a macro. Here is how it is used.

```
Window Graph0() : Graph
   PauseUpdate; Silent 1
   Display /W=(5,42,400,250) w0,w1,w2
   ModifyGraph gFont="Helvetica"
   ModifyGraph rgb(w0)=(0,0,0),rgb(w1)=(0,65535,0),rgb(w2)=(0,0,0)
   <more modifies here...>
End
```

Without the PauseUpdate, Igor would do an update after each modify operation. This would take a long time.

At the end of the macro, Igor automatically reverts the state of update-checking to what it was when this macro was invoked. You can use the ResumeUpdate operation if you want to resume updates before the macro ends or you can call DoUpdate to force an update to occur at a particular point in the program flow. Such explicit updating is rarely needed.

Aborting Macros

There are two ways to prematurely stop macro execution: a user abort or a programmed abort. Both stop execution of all macros, no matter how deeply nested.

You can abort macro execution by pressing the **User Abort Key Combinations** or by clicking the Abort button in the status bar. You may need to press the keys down for a while because Igor looks at the keyboard periodically and if you don't press the keys long enough, Igor will not see them.

A user abort does not directly return. Instead it sets a flag that stops loops from looping and then returns using the normal calling chain. For this reason some code will still be executed after an abort but execution should stop quickly. This behavior releases any temporary memory allocations made during execution.

A **programmed abort** occurs when the Abort operation is executed. Here is an example:

```
if (numCells > 10)
   Abort "Too many cells! Quitting."
endif
// code here doesn't execute if numCells > 10
```

Converting Macros to Functions

If you have old Igor procedures written as macros, as you have occasion to revisit them, you can consider converting them to functions. In most cases, this is a good idea. An exception is if the macros are so complex that there would be a substantial risk of introducing bugs. In this case, it is better to leave things as they are.

If you decide to do the conversion, here is a checklist that you can use in the process.

1. Back up the old version of the procedures.
2. Change the defining keyword from Macro or Proc to Function.
3. If the macro contained Prompt statements, then it was used to generate a missing parameter dialog. Change it to generate a simple input dialog as follows:
   a. Remove the parameters from the parameter list. The old parameter declarations now become local variable declarations.
   b. Make sure that the local variable for each prompt statement is initialized to some value.
   c. Add a DoPrompt statement after all of the Prompt statements.
   d. Add a test on V_Flag after the DoPrompt statement to see if the user canceled.
4. Look for statements that access global variables or strings and create NVAR and SVAR references for them.
5. Look for any waves used in assignment statements and create WAVE references for them.
6. Compile procedures. If you get an error, fix it and repeat step 6.

Chapter

IV-5

User-Defined Menus

Overview

You can add your own menu items to many Igor menus by writing a menu definition in a procedure window. A simple menu definition looks like this:

```
Menu "Macros"
   "Load Data File/1"
   "Do Analysis/2"
   "Print Report"
End
```

This adds three items to the Macros menu. If you choose Load Data File or press Command-1 (*Macintosh*) or Ctrl+1 (*Windows*), Igor executes the procedure LoadDataFile which, presumably, you have written in a procedure window. The command executed when you select a particular item is derived from the text of the item. This is an *implicit* specification of the item's execution text.

You can also *explicitly* specify the execution text:

```
Menu "Macros"
   "Load Data File/1", Beep; LoadWave/G
   "Do Analysis/2"
   "Print Report"
End
```

Now if you choose Load Data File, Igor will execute "`Beep; LoadWave/G`".

When you choose a user menu item, Igor checks to see if there is execution text for that item. If there is, Igor executes it. If not, Igor makes a procedure name from the menu item string. It does this by removing any characters that are not legal characters in a procedure name. Then it executes the procedure. For example, choosing an item that says

```
"Set Sampling Rate..."
```

executes the SetSamplingRate procedure.

If a procedure window is the top window and if Option (*Macintosh*) or Alt (*Windows*) is pressed when you choose a menu item, Igor tries to find the procedure in the window, rather than executing it.

A menu definition can add submenus as well as regular menu items.

```
Menu "Macros"
   Submenu "Load Data File"
      "Text File"
      "Binary File"
   End

   Submenu "Do Analysis"
      "Method A"
      "Method B"
   End

   "Print Report"
End
```

This adds three items to the Macros menu, two submenus and one regular item. You can nest submenus to any depth.

Menu Definition Syntax

The syntax for a menu definition is:

```
Menu <Menu title string> [,<menu options>]
   [<Menu help strings>]
   <Menu item string> [,<menu item flags>] [,<execution text>]
   [<Item help strings>]
   …
   Submenu <Submenu title string>
      [<Submenu help strings>]
      <Submenu item string> [,<execution text>]
      [<Item help strings>]
      …
   End
End
```

<Menu title string> is the title of the menu to which you want to add items. Often this will be Macros but you can also add items to Analysis, Misc and many other built-in Igor menus, including some submenus and the graph marquee and layout marquee menus. If <Menu title string> is not the title of a built-in menu then Igor creates a new main menu on the menu bar.

<Menu options> are optional comma-separated keywords that change the behavior of the menu. The allowed keywords are dynamic, hideable, and contextualmenu. For usage, see **Dynamic Menu Items** (see page IV-129), **HideIgorMenus** (see page V-346), and **PopupContextualMenu** (see page V-756) respectively.

<Menu help strings> specifies the help for the menu title. This is optional. As of Igor7, menu help is not supported and the menu help specification, if present, is ignored.

<Menu item string> is the text to appear for a single menu item, a semicolon-separated string list to define **Multiple Menu Items** (see page IV-131), or **Specialized Menu Item Definitions** (see page IV-132) such as a color, line style, or font menu.

<Menu item flags> are optional flags that modify the behavior of the menu item. The only flag currently supported is /Q, which prevents Igor from storing the executed command in the history area. This is useful for menu commands that are executed over and over through a keyboard shortcut. This feature was introduced in Igor Pro 5. Using it will cause errors in earlier versions of Igor. Menus defined with the contextualmenu keyword implicitly set all the menu item flags in the entire menu to /Q; it doesn't matter whether /Q is explicitly set or not, the executed command is not stored in the history area.

<Execution text> is an Igor command to execute for the menu item. If omitted, Igor makes a procedure name from the menu item string and executes that procedure. Use "" to prevent command execution (useful only with PopupContextualMenu/N).

<Item help strings> specifies the help for the menu item. This is optional. As of Igor7, menu help is not supported and the menu item help specification, if present, is ignored.

The Submenu keyword introduces a submenu with <Submenu title string> as its title. The submenu continues until the next End keyword.

<Submenu item string> acts just like <Menu item string>.

Built-in Menus That Can Be Extended

The titles of the built-in menus that you can extend using user-defined menus are listed below.

These menu titles must appear in double quotes when used in a menu definition.

Use these menu titles to identify the menu to which you want to append items even if you are working with a version of Igor translated into a language other than English.

All other Igor menus, including menus added by XOPs, can not accept user-defined items.

Main Menu Bar Menus That You Can Extend

You can extend the following main menu bar menus using user-defined menus:

- Add Controls
- Analysis
- Append to Graph
- Control
- Data
- Edit
- File
- Gizmo
- Graph
- Help
- Layout
- Load Waves
- Macros
- Misc
- Statistics
- New
- Notebook
- Open File
- Panel
- Procedure
- Save Waves
- Table

Contexual Menus That You Can Extend

Contextual menus are also called pop-up menus. You can extend the following contextual menus using user-defined menus:

- AllTracesPopup
- GraphMarquee
- DataBrowserObjectsPopup
- GraphPopup
- LayoutMarquee
- TablePopup
- TracePopup
- WindowBrowserWindowsPopup

See **Marquee Menus** on page IV-137, **Trace Menus** on page IV-137, **TablePopup Menu**, **DataBrowserObjectsPopup Menu** on page IV-138, and xxx for more information about these items.

Hiding User-Defined Menu Extensions

The **HideIgorMenus** operation (see page V-346) and the **ShowIgorMenus** operation (see page V-869) hide or show most of the built-in main menus (but not the Marquee and Popup menus). User-defined menus that add items to built-in menus are normally not hidden or shown by these operations. When a built-in menu is hidden, the user-defined menu items create a user-defined menu with only user-defined items. For example, this user-defined menu:

```
Menu "Table"
   "Append Columns to Table...", DoIgorMenu "Table", "Append Columns to Table"
End
```

will create a Table menu with only one item in it after the HideIgorMenus "Table" command is executed.

To have your user-defined menu items hidden along with the built-in menu items, add the hideable keyword after the Menu definition:

```
Menu "Table", hideable
   "Append Columns to Table...", DoIgorMenu "Table", "Append Columns to Table"
End
```

Adding a New Main Menu

You can add an entirely new menu to the main menu bar by using a menu title that is not used by Igor. For example:

```
Menu "Test"
   "Load Data File"
   "Do Analysis"
   "Print Report"
End
```

Dynamic Menu Items

In the examples shown so far all of the user-defined menu items are static. Once defined, they never change. This is sufficient for the vast majority of cases and is by far the easiest way to define menu items.

Igor also provides support for dynamic user-defined menu items. A dynamic menu item changes depending on circumstances. The item might be enabled under some circumstances and disabled under others. It might be checked or deselected. Its text may toggle between two states (e.g. “Show Tools” and “Hide Tools”).

Because dynamic menus are much more difficult to program than static menus and also slow down Igor’s response to a menu-click, we recommend that you keep your use of dynamic menus to a minimum. The effort you expend to make your menu items dynamic may not be worth the time you spend to do it.

For a menu item to be dynamic, you must define it using a string expression instead of the literal strings used so far. Here is an example.

```
Function DoAnalysis()
   Print "Analysis Done"
End

Function ToggleTurboMode()
   Variable prevMode = NumVarOrDefault("root:gTurboMode", 0)
   Variable/G root:gTurboMode = !prevMode
End

Function/S MacrosMenuItem(itemNumber)
   Variable itemNumber

   Variable turbo = NumVarOrDefault("root:gTurboMode", 0)

   if (itemNumber == 1)
      if (strlen(WaveList("*", ";", ""))==0) // any waves exist?
         return "(Do Analysis"   // disabled state
      else
         return "Do Analysis"    // enabled state
      endif
   endif

   if (itemNumber == 2)
      if (turbo)
         return "!"+num2char(18)+"Turbo"  // Turbo with a check
      else
         return "Turbo"
      endif
   endif
End

Menu "Macros", dynamic
   MacrosMenuItem(1)
   MacrosMenuItem(2), /Q, ToggleTurboMode()
End
```

In this example, the text for the menu item is computed by the MacrosMenuItem function. It computes text for item 1 and for item 2 of the menu. Item 1 can be enabled or disabled. Item 2 can be checked or unchecked.

The dynamic keyword specifies that the menu definition contains a string expression that needs to be reevaluated each time the menu item is drawn. This rebuilds the user-defined menu each time the user clicks in the menu bar. Under the current implementation, it rebuilds *all* user menus each time the user clicks in the menu bar if *any* user-defined menu is declared dynamic. If you use a large number of user-defined items, the time to rebuild the menu items may be noticeable.

There is another technique for making menu items change. You define a menu item using a string expression rather than a literal string but you do not declare the menu dynamic. Instead, you call the BuildMenu operation whenever you need the menu item to be rebuilt. Here is an example:

```
Function ToggleItem1()
   String item1Str = StrVarOrDefault("root:MacrosItem1Str","On")
   if (CmpStr(item1Str,"On") == 0)      // Item is now "On"?
      String/G root:MacrosItem1Str = "Off"
   else
      String/G root:MacrosItem1Str = "On"
   endif
   BuildMenu "Macros"
End

Menu "Macros"
   StrVarOrDefault("root:MacrosItem1Str","On"), /Q, ToggleItem1()
End
```

Here, the menu item is controlled by the global string variable MacrosItem1Str. When the user chooses the menu item, the ToggleItem1 function runs. This function changes the MacrosItem1Str string and then calls BuildMenu, which rebuilds the user-defined menu the next time the user clicks in the menu bar. Under the current implementation, it rebuilds *all* user-defined menus if BuildMenu is called for *any* user-defined menu.

Optional Menu Items

A dynamic user-defined menu item *disappears* from the menu if the menu item string expression evaluates to ""; the remainder of the menu definition line is then ignored. This makes possible a variable number of items in a user-defined menu list. This example adds a menu listing the names of up to 8 waves in the current data folder. If the current data folder contains less than 8 waves, then only those that exist are shown in the menu:

```
Menu "Waves", dynamic
   WaveName("",0,4), DoSomething($WaveName("",0,4))
   WaveName("",1,4), DoSomething($WaveName("",1,4))
   WaveName("",2,4), DoSomething($WaveName("",2,4))
   WaveName("",3,4), DoSomething($WaveName("",3,4))
   WaveName("",4,4), DoSomething($WaveName("",4,4))
   WaveName("",5,4), DoSomething($WaveName("",5,4))
   WaveName("",6,4), DoSomething($WaveName("",6,4))
   WaveName("",7,4), DoSomething($WaveName("",7,4))
End

Function DoSomething(w)
   Wave/Z w

   if( WaveExists(w) )
      Print "DoSomething: wave's name is "+NameOfWave(w)
   endif
End
```

This works because WaveName returns "" if the indexed wave doesn’t exist.

Note that each potential item must have a menu definition line that either appears or disappears.

Multiple Menu Items

A menu item string that contains a semicolon-separated “string list” (see **StringFromList** on page V-998) generates a menu item for each item in the list. For example:

```
Menu "Multi-Menu"
   "first item;second item;", DoItem()
End
```

Multi-Menu is a two-item menu. When either item is selected the DoItem procedure is called.

This begs the question: How does the DoItem procedure know which item was selected? The answer is that DoItem must call the **GetLastUserMenuInfo** operation (see page V-306) and examine the appropriate returned variables, usually V_value (the selected item’s one-based item number) or S_Value (the selected item’s text).

The string list can be dynamic, too. The above "Waves" example can be rewritten to handle an arbitrary number of waves using this definition:

```
Menu "Waves", dynamic
   WaveList("*",";",""), DoItem()
End

Function DoItem()
   GetLastUserMenuInfo           // Sets S_value, V_value, etc.
   WAVE/Z w= $S_value
   if( WaveExists(w) )
      Print "The wave's name is "+NameOfWave(w)
   endif
End
```

Consolidating Menu Items Into a Submenu

It is common to have many utility procedure files open at the same time. Each procedure file could add menu items which would clutter Igor’s menus. When you create a utility procedure file that adds multiple menu items, it is usually a good idea to consolidate all of the menu items into one submenu. Here is an example.

Let’s say we have a procedure file full of utilities for doing frequency-domain data analysis and that it contains the following:

```
Function ParzenDialog()
   …
End

Function WelchDialog()
   …
End

Function KaiserDialog()
   …
End
```

We can consolidate all of the menu items into a single submenu in the Analysis menu:

```
Menu "Analysis"
   Submenu "Windows"
      "Parzen…", ParzenDialog()
      "Welch…", WelchDialog()
      "Kaiser…", KaiserDialog()
   End
End
```

Specialized Menu Item Definitions

A menu item string that contains certain special values adds a specialized menu such as a color menu.

Only one specialized menu item string is allowed in each menu or submenu, it must be the first item, and it must be the only item.

Menu Item String	Result
"*CHARACTER*	"Character menu, no character is initially selected, font is Geneva, font size is 12.
"*CHARACTER*(Arial)	Character menu shown using Arial font at default size.
"*CHARACTER*(Arial,36)	"Character menu of Arial font in 36 point size.
"*CHARACTER*(,36)	"Character menu of Geneva font in 36 point size.
"*CHARACTER*(Arial,36,m)	"Character menu of Arial font in 36 point size, initial character is m.
"*COLORTABLEPOP*	"Color table menu, initial table is Grays.
"*COLORTABLEPOP*(YellowHot)	"Color table menu, initial table is YellowHot. See **CTabList** on page V-118 for a list of color tables.
"*COLORTABLEPOP*(YellowHot,1)	"Color table menu with the colors drawn reversed.
"*COLORPOP*	"Color menu, initial color is black.
"*COLORPOP*(0,65535,0)	"Color menu, initial color is green.
"*COLORPOP*(0,65535,0,49151)	"Color menu, initial color is green at 75% opacity.
"*FONT*	"Font menu, no font is initially selected, does not include “default” as a font choice.
"*FONT*(Arial)	"Font menu, Arial is initially selected.
"*FONT*(Arial,default)	"Font menu with Arial initially selected and including “default” as a font choice.
"*LINESTYLEPOP*	"Line style menu, no line style is initially selected.
"*LINESTYLEPOP*(3)	"Line style menu, initial line style is style=3 (coarse dashed line).
"*MARKERPOP*	"Marker menu, no marker is initially selected.
"*MARKERPOP*(8)	"Marker menu, initial marker is 8 (empty circle).
"*PATTERNPOP*	"Pattern menu, no pattern is initially selected.
"*PATTERNPOP*(1)	"Pattern menu, initial pattern is 1 (SW-NE light diagonal).

To retrieve the selected color, line style, etc., the execution text must be a procedure that calls the **GetLastUserMenuInfo** operation (see page V-306). Here’s an example of a color submenu implementation:

```
Menu "Main", dynamic
   "First Item", /Q, Print "First Item"
   Submenu "Color"
      CurrentColor(), /Q, SetSelectedColor() // Must be first submenu item
      // No items allowed here
   End
End

Function InitializeColors()
   NVAR/Z red= root:red
   if(!NVAR_Exists(red))
      Variable/G root:red=65535, root:green=0, root:blue=1, root:alpha=65535
   endif
End

Function/S CurrentColor()
   InitializeColors()
   NVAR red = root:red
   NVAR green = root:green
   NVAR blue = root:blue
   NVAR alpha = root:alpha
   String menuText
   sprintf menuText, "*COLORPOP*(%d,%d,%d,%d)", red, green, blue, alpha
   return menuText
End

Function SetSelectedColor()
   GetLastUserMenuInfo// Sets V_Red, V_Green, V_Blue, V_Alpha, S_value, V_value
   NVAR red = root:red
   NVAR green = root:green
   NVAR blue = root:blue
   NVAR alpha = root:alpha
   red = V_Red
   green = V_Green
   blue = V_Blue
   alpha = V_Alpha

   Make/O/N=(2,2,4) root:colorSpot
   Wave colorSpot = root:colorSpot
   colorSpot[][][0] = V_Red
   colorSpot[][][1] = V_Green
   colorSpot[][][2] = V_Blue
   colorSpot[][][3] = V_Alpha

   CheckDisplayed/A colorSpot
   if (V_Flag == 0)
      NewImage colorSpot
   endif
End
```

Special Characters in Menu Item Strings

You can control some aspects of a menu item using special characters. These special characters are based on the behavior of the Macintosh menu manager and are only partially supported on Windows (see **Special Menu Characters on Windows** on page IV-134). They affect user-defined menus in the main menu bar. On Macintosh, but not on Windows, they also affect user-defined pop-up menus in control panels, graphs and simple input dialogs.

By default, special character interpretation is enabled in user-defined menu bar menus and is disabled in user-defined control panel, graph and simple input dialog pop-up menus. This is almost always what you would want. In some cases, you might want to override the default behavior. This is discussed under **Enabling and Disabling Special Character Interpretation** on page IV-135.

This table shows the special characters and their effect if special character interpretation is enabled. See **Special Menu Characters on Windows** on page IV-134 for Windows-specific considerations.

Character	Behavior
/	Creates a keyboard shortcut for the menu item.
	The character after the slash defines the item's keyboard shortcut. For example, `"Low Pass/1"` makes the item "Low Pass" with a keyboard shortcut for Command-1 (*Macintosh*) or Ctrl-1 (*Windows*). You can also use function keys. To avoid conflicts with Igor, use the numeric keys and the function keys only. See **Keyboard Shortcuts** on page IV-136 and **Function Keys** on page IV-136 for further details.
	Keyboard shortcuts are not supported in the graph marquee and layout marquee menus.
-	Creates a divider between menu items.
	If a hyphen (minus sign) is the first character in the item then the item will be a disabled divider. This can be a problem when trying to put negative numbers in a menu. Use a leading space character to prevent this. The string "(-" also disables the corresponding divider.
(	Disables the menu item.
	If the first character of the item text is a left parenthesis then the item will be disabled.
!	Adds a mark to the menu item.
	If an exclamation point appears in the item, any character after the exclamation point adds a checkmark to the left of the menu item. For example:
	`"Low Pass!*"`
	makes an item "Low Pass" with an checkmark to the left.
	For compatibility with Igor6, use:
	`"Low Pass!" + num2char(18)`
;	Separates one menu item from the next.
	Example: `"Item 1;Item 2"`

Whereas it is standard practice to use a semicolon to separate items in a pop-up menu in a control panel, graph or simple input dialog, you should avoid using the semicolon in user-defined main-menu-bar menus. It is clearer if you use one item per line. It is also necessary in some cases (see **Menu Definition Syntax** on page IV-126).

If special character interpretation is disabled, these characters will appear in the menu item instead of having their special effect. The semicolon character is treated as a separator of menu items even if special character interpretation is disabled.

Special Menu Characters on Windows

On Windows, these characters are treated as special in menu bar menus but not in pop-up menus in graphs, control panels, and simple input dialogs. The following table shows which special characters are supported.

Character	Meaning
/	Defines accelerator
-	Divider
(	Disables item
!	Adds mark to item
;	Separates items

In general, Windows does not allow using Ctrl+<punctuation> as an accelerator. Therefore, in the following example, the accelerator will not do anything:

```
Menu "Macros"
   "Test/["       // "/[" will not work on Windows.
End
```

On Windows, you can designate a character in a menu item as a mnemonic keystroke by preceding the character with an ampersand:

```
Menu "Macros"
   "&Test", Print "This is a test"
End
```

This designates “T” as the mnemonic keystroke for Test. To invoke this menu item, press Alt and release it, press the “M” key to highlight the Macros menu, and press the “T” key to invoke the Test item. If you hold the Alt key pressed while pressing the “M” and “T” keys and if the active window is a procedure window, Igor will not execute the item’s command but rather will bring up the procedure window and display the menu definition. This is a programmer’s shortcut.

Note: The mnemonic keystroke is not supported on Macintosh. For this reason, if you care about cross-platform compatibility, you should not use ampersands in your menu items.

On Macintosh, if you include a single ampersand in a menu item, it does not appear in the menu item. If you use a double ampersand, it appears as a single ampersand.

Enabling and Disabling Special Character Interpretation

The interpretation of special characters in menu items can sometimes get in the way. For example, you may want a menu item to say “m/s” or “A<B”. With special character interpretation enabled, the first of these would become “m” with “s” as the keyboard shortcut and the second would become “A” in a bold typeface.

Igor provides WaveMetrics-defined escape sequences that allow you to override the default state of special character interpretation. These escape sequences are case sensitive and must appear at the very start of the menu item:

Escape Code	Effect	Example
`"\\M0"`	Turns special character interpretation off.	`"\\M0m/s"`
`"\\M1"`	Turns special character interpretation on.	`"\\M1m/s"`

The most common use for this will be in a user-defined menu bar menu in which the default state is on and you want to display a special character in the menu item text itself. That is what you can do with the “`\\M0`” escape sequence.

Another possible use on Macintosh is to create a disabled menu item in a control panel, graph or simple input dialog pop-up menu. The default state of special character interpretation in pop-up menus is off. To disable the item, you either need to turn it on, using “\\M1” or to use the technique described in the next paragraph.

What if we want to include a special character in the menu item itself *and* have a keyboard shortcut for that item? The first desire requires that we turn special character interpretation off and the second requires that we turn it on. The WaveMetrics-defined escape sequence can be extended to handle this. For example:

```
"\\M0:/1:m/s"
```

The initial “\\M0” turns normal special character interpretation off. The first colon specifies that one or more special characters are coming. The /1 makes Command-1 (*Macintosh*) or Ctrl+1 (*Windows*) the keyboard shortcut for this item. The second colon marks the end of the menu commands and starts the regular menu text which is displayed in the menu without special character interpretation. The final result is as shown above.

Any of the special characters can appear between the first colon and the second. For example:

```
Menu "Macros"
   "\\M0:/1:(Cmd-1 on Macintosh, Ctrl+1 on Windows)"
   "\\M0:(:(Disabled item)"
   "\\M0:!*:(Checked)"
   "\\M0:/2!*:(Cmd-2 on Macintosh, Ctrl+2 on Windows and checked)"
End
```

The \\M escape code affects just the menu item currently being defined. In the following example, special character interpretation is enabled for the first item but not for the second:

```
"\\M1(First item;(Second item"
```

To enable special character interpretation for both items, we need to write:

```
"\\M1(First item;\\M1(Second item"
```

Keyboard Shortcuts

A keyboard shortcut is a set of one or more keys which invoke a menu item. In a menu item string, a keyboard shortcut is introduced by the / special character. For example:

```
Menu "Macros"
   "Test/1"       // The keyboard shortcut is Cmd-1 (Macintosh)
End               // or Ctrl+1 (Windows).
```

All of the plain alphabetic keyboard shortcuts (/A through /Z) are used by Igor.

Numeric keyboard shortcuts (/0 through /9) are available for use in user menu definitions as are Function Keys, described below.

You can define a numeric keyboard shortcut that includes one or more modifier keys. The modifier keys are:

Macintosh:	Shift (S), Option (O), Control (L)
Windows:	Shift (S), Alt (O), Meta (L) (Meta is often called the “Windows key”.

For example:

```
Menu "Macros"
   "Test/1"       // Cmd-1, Ctrl+1
   "Test/S1"      // Shift-Cmd-1, Ctrl+Shift+1.
   "Test/O1"      // Option-Cmd-1, Ctrl+Alt+1
   "Test/OS1"     // Option-Shift-Cmd-1, Ctrl+Shift+Alt+1
End
```

Function Keys

Most keyboards have function keys labeled F1 through F12. In Igor, you can treat a function key as a keyboard shortcut that invokes a menu item.

Note: Mac OS X reserves nearly all function keys for itself. In order to use function keys for an application, you must check a checkbox in the Keyboard control panel. Even then the OS will intercept some function keys.

Note: On Windows, Igor uses F1 for help-related operations. F1 will not work as a keyboard shortcut on Windows. Also, the Windows OS reserves Ctrl-F4 and Ctrl-F6 for closing and reordering windows. On some systems, F12 is reserved for debugging.

Here is a simple function key example:

```
Menu "Macros"
   "Test/F5"      // The keyboard shortcut is F5.
End
```

As with other keyboard shortcuts, you can specify that one or more modifier keys must be pressed along with the function key. By including the “C” modifier character, you can specify that Command (*Macintosh*) or Ctrl (*Windows*) must also be pressed:

```
Menu "Macros"
   // Function keys without modifiers
   "Test/F5"      // F5

   // Function keys with Shift and/or Option/Alt modifiers
   "Test/SF5"     // Shift-F5 (Macintosh), Shift+F5 (Windows)
   "Test/OF5"     // Option-F5, Alt+F5
   "Test/SOF5"    // Shift-Option-F5, Shift+Alt+F5

   // Function keys with Command (Macintosh) or Ctrl (Windows) modifiers
   "Test/CF5"     // Cmd-F5, Ctrl+F5
   "Test/SCF5"    // Shift-Cmd-F5, Shift-Ctrl-F5
   "Test/OCF5"    // Option-Cmd-F5, Alt-Ctrl-F5
   "Test/OSCF5"   // Option-Shift-Cmd-F5, Alt-Shift-Ctrl-F5

   // Function keys with Ctrl (Macintosh) or Meta (Windows) modifiers
   "Test/LOSCF5"  // Control-Option-Shift-Cmd-F5, Meta+Alt+Shift+Ctrl+F5
End
```

Although some keyboards have function keys labeled F13 and higher, they do not behave consistently and are not supported.

Marquee Menus

Igor has two menus called “marquee menus”. In graphs and page layouts you create a marquee when you drag diagonally. Igor displays a dashed-line box indicating the area of the graph or layout that you have selected. If you click inside the marquee, you get a marquee menu.

You can add your own menu items to a marquee menu by creating a GraphMarquee or LayoutMarquee menu definition. For example:

```
Menu "GraphMarquee"
   "Print Marquee Coordinates", GetMarquee bottom; Print V_left, V_right
End
```

The use of keyboard shortcuts is not supported in marquee menus.

See **Marquee Menu as Input Device** on page IV-163 for details.

Trace Menus

Igor has two “trace” menus named “TracePopup” and “AllTracesPopup”. When you control-click or right-click in a graph on a trace you get the TracesPopup menu. If you press Shift while clicking, you get the AllTracesPopup (standard menu items in that menu operated on all the traces in the graph). You can append menu items to these menus with Menu “TracePopup” and Menu “AllTracesPopup” definitions.

For example, this code adds an Identify Trace item to the TracePopup contextual menu but not to the AllTracesPopup menu:

```
Menu "TracePopup"
   "Identify Trace", /Q, IdentifyTrace()
End

Function IdentifyTrace()
   GetLastUserMenuInfo
   Print S_graphName, S_traceName
End
```

GraphPopup Menu

Igor has a contextual menu named "GraphPopup". When you control-click or right-click in a graph away from any trace while in operate mode, you get the GraphPopup menu. You can append menu items to this menu with a GraphPopup menu definition.

For example, the following code adds an "Identify Graph" item to the GraphPopup contextual menu:

```
Menu "GraphPopup"
   "Identify Graph", /Q, IdentifyGraph()
End

Function IdentifyGraph()
   Print WinName(0,1)
End
```

TablePopup Menu

Igor Pro 9.00 and later have a contextual menu named "TablePopup". When you right-click in a table, Igor displays the TablePopup menu. You can append menu items to this menu with a TablePopup menu definition.

For example, the following code adds a "Print Path To Wave" item to the TablePopup contextual menu:

```
Menu "TablePopup", dynamic
   ContextualTableMenuItem(), /Q, PrintPathToSelWave()
End

Function/S ContextualTableMenuItem()
   GetLastUserMenuInfo
   WAVE/Z selWave = $S_firstColumnPath
   if (WaveExists(selWave))
      return "Print Path To Wave"
   endif

   // Here if the user clicked the Point column or an unused column
   return ""         // No menu item is added
End

Function PrintPathToSelWave()
   GetLastUserMenuInfo
   WAVE/Z selWave = $S_firstColumnPath
   if (WaveExists(selWave))
      Print GetWavesDataFolder(selWave,2)
   endif
End
```

DataBrowserObjectsPopup Menu

Igor Pro 9.00 and later have a contextual menu named "DataBrowserObjectsPopup". When you right click the list of objects in the Data Browser, Igor displays the DataBrowserObjectsPopup menu.

You can append menu items to this menu with a DataBrowserObjectsPopup menu definition. If necessary, you can use **GetLastUserMenuInfo** to get information about which menu was selected by the user and **GetBrowserSelection** to determine which objects, if any, are currently selected in the Data Browser.

For example, the following code adds a menu item to the DataBrowserObjectsPopup contextual menu if two numeric waves are selected. The text of the menu item is different depending on whether or not the shift key is pressed when the menu is shown.

```
Menu "DataBrowserObjectsPopup", dynamic
   // This menu item is displayed if the shift key is not pressed
   Display1vs2MenuItemString(0), /Q, DisplayWave1vsWave2(0)

   // This menu item is displayed if the shift key is pressed
   Display1vs2MenuItemString(1), /Q, DisplayWave1vsWave2(1)
End

// If at least two items are selected in the Data Browser object list and the
// first two selected items are numeric waves, this function returns the first
// selected wave via w1 and the second selected wave via w1 unless reverse
// is non-zero in which case the waves are reversed.
// The function result is 1 if the first two selected objects are numeric waves
// and 0 otherwise.
static Function GetWave1AndWave2(WAVE/Z &w1, WAVE/Z &w2, int reverse)
   if (strlen(GetBrowserSelection(-1)) == 0)
      return 0       // Data Browser is not open
   endif

   WAVE/Z w1 = $(GetBrowserSelection(reverse ? 1 : 0))// May be null
   WAVE/Z w2 = $(GetBrowserSelection(reverse ? 0 : 1))// May be null

   if (!WaveExists(w1) || !WaveExists(w2))
      return 0       // Fewer than two waves are selected
   endif

   if (WaveType(w1,1)!=1 || WaveType(w2,1)!=1)
      return 0       // Waves are not numeric
   endif

   return 1
End

Function/S Display1vs2MenuItemString(reverse)
   int reverse    // True (1) if caller wants the reverse menu item string

   int shiftKeyPressed = GetKeyState(0) & 4  // User is asking for reverse?
   if (shiftKeyPressed && !reverse)
      // User is asking for reverse so hide unreversed menu item
      return ""
   endif
   if (!shiftKeyPressed && reverse)
      // User is not asking for reverse so hide reversed menu item
      return ""
   endif

   WAVE/Z w1, w2
   int twoNumericWavesSelected = GetWave1AndWave2(w1, w2, reverse)
   if (!twoNumericWavesSelected)
      return ""
   endif

   String menuText
   sprintf menuText, "Display %s vs %s", NameOfWave(w1), NameOfWave(w2)
   return menuText
End

// If reverse is false, execute Display w1 vs w2
// If reverse is true, execute Display w2 vs w1
Function DisplayWave1vsWave2(int reverse)
   WAVE/Z w1, w2
   int twoNumericWavesSelected = GetWave1AndWave2(w1, w2, reverse)
   if (twoNumericWavesSelected)
      Display w1 vs w2
   endif
End
```

WindowBrowserWindowsPopup Menu

Igor Pro 9.00 and later have a contextual menu named "WindowBrowserWindowsPopup". When you right click the list of windows in the Window Browser, Igor displays the WindowBrowserWindowsPopup menu.

You can add items to this menu with a WindowBrowserWindowsPopup menu definition. If necessary, you can use **GetLastUserMenuInfo** to get information about which menu was selected by the user and **GetWindowBrowserSelection** to determine which windows, if any, are currently selected in the Window Browser.

For example, the following code adds a menu item to the WindowBrowserWindowsPopup contextual menu if the Window Browser has one graph window selected. The text of the menu item is different depending on whether or not a modifier key is pressed when the menu is shown. Clicking on the menu item copies the selected graph to the clipboard as either PNG or SVG format, depending on whether or not a modifier key was pressed.

```
Menu "WindowBrowserWindowsPopup", dynamic
   // If a single graph is selected in the Window Browser, if the shift
   // key is pressed, this adds "Copy <graph> as SVG".
   // If a single graph is selected in the Window Browser, if the shift
   // key is not pressed, this adds "Copy <graph> as PNG".
   // Otherwise it adds no menu items.
   CopySelectedGraphToClipMenuString(0),/Q,CopySelectedGraphToClip(0)
   CopySelectedGraphToClipMenuString(1),/Q,CopySelectedGraphToClip(1)
End

// If the Window Browser is open, and exactly one item is selected, and that
// item is a graph, the name of the graph is returned. Otherwise an empty string
// is returned.
Function/S GetSingleSelectedGraphName()
   Variable dummy

   // GetWindowBrowserSelection generates an error if the Window Browser is not
   // open. If the Debugger's Stop on Error setting is enabled, the error causes
   // the debugger to break on this statement. Calling GetRTError(1) on the same
   // line clears the error and prevents the debugger from breaking here.
   String selectedList = GetWindowBrowserSelection(0); dummy = GetRTError(1)

   if (ItemsInList(selectedList,";") == 1)
      String name = StringFromList(0, selectedList, ";")
      if (WinType(name) == 1)
         return name          // It is a graph
      endif
   endif

   return ""                  // Nothing selected or not a graph
End

// If doSVG is false and the shift key is not key pressed, return
// "Copy Graph as PNG". If doSVG is true and the shift key is pressed,
// return "Copy Graph as SVG".
Function/S CopySelectedGraphToClipMenuString(Variable doSVG)
   int shiftKeyPressed = (GetKeyState(0) & 4) != 0
   if (doSVG && !shiftKeyPressed)
      return ""   // Caller wants SVG menu item but shift key is not pressed
   endif
   if (!doSVG && shiftKeyPressed)
      return ""   // Caller wants PNG menu item but shift key is pressed
   endif

   String selectedGraphName = GetSingleSelectedGraphName()
   if (strlen(selectedGraphName) == 0)
      return ""   // The selection is other than a single graph window
   endif

   String format = "PNG"
   if (doSVG)
      format = "SVG"
   endif
   String menuText = ""
   sprintf menuText, "Copy %s as %s", selectedGraphName, format
   return menuText
End

// If doSVG is true, copy the graph as SVG. Otherwise copy it as PNG.
Function CopySelectedGraphToClip(Variable doSVG)
   String selectedGraphName = GetSingleSelectedGraphName()
   if (strlen(selectedGraphName) > 0)
      Variable formatCode = -5   // PNG
      if (doSVG)
         formatCode = -9         // SVG
      endif
      SavePict/E=(formatCode)/WIN=$(selectedGraphName) as "Clipboard"
   endif
End
```

Popup Contextual Menus

You can create a custom pop-up contextual menu to respond to a control-click or right-click. For an example, see **Creating a Contextual Menu** on page IV-162.

Chapter

IV-6

Interacting with the User

Overview

The following sections describe the various programming techniques available for getting input from and for interacting with a user during the execution of your procedures. These techniques include:

- The simple input dialog
- Control panels
- Cursors
- Marquee menus

The simple input dialog provides a bare bones but functional user interfaces with just a little programming. In situations where more elegance is required, control panels provide a better solution.

Modal and Modeless User Interface Techniques

Before the rise of the graphical user interface, computer programs worked something like this:

1. The program prompts the user for input.
2. The user enters the input.
3. The program does some processing.
4. Return to step 1.

In this model, the program is in charge and the user must respond with specific input at specific points of program execution. This is called a “modal” user interface because the program has one mode in which it will only accept specific input and another mode in which it will only do processing.

The Macintosh changed all this with the idea of event-driven programming. In this model, the computer waits for an event such as a mouse click or a key press and then acts on that event. The user is in charge and the program responds. This is called a “modeless” user interface because the program will accept any user action at any time.

You can use both techniques in Igor. Your program can put up a modal dialog asking for input and then do its processing or you can use control panels to build a sophisticated modeless event-driven system.

Event-driven programming is quite a bit more work than dialog-driven programming. You have to be able to handle user actions in any order rather than progressing through a predefined sequence of steps. In real life, a combination of these two methods is often used.

The Simple Input Dialog

The simple input dialog is a way by which a function can get input from the user in a modal fashion. It is very simple to program and is also simple in appearance.

A simple input dialog is presented to the user when a DoPrompt statement is executed in a function. Parameters to DoPrompt specify the title for the dialog and a list of local variables. For each variable, you must include a Prompt statement that provides the text label for the variable.

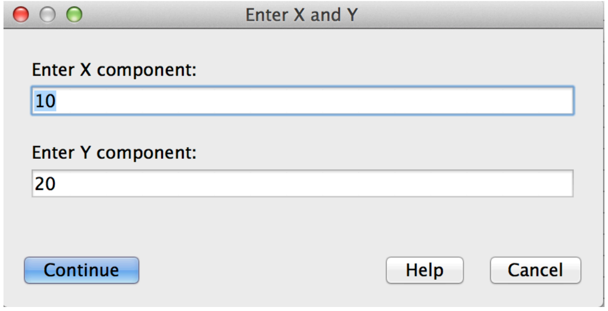
Generally, the simple input dialog is used in conjunction with routines that run when the user chooses an item from a menu. This is illustrated in the following example which you can type into the procedure window of a new experiment:

```
Menu "Macros"
   "Calculate Diagonal...", CalcDiagDialog()
End

Function CalcDiagDialog()
   Variable x=10,y=20
   Prompt x, "Enter X component: "  // Set prompt for x param
   Prompt y, "Enter Y component: "  // Set prompt for y param
   DoPrompt "Enter X and Y", x, y
   if (V_Flag)
      return -1                     // User canceled
   endif

   Print "Diagonal=",sqrt(x^2+y^2)
End
```

If you run the CalcDiagDialog function, you see the following dialog:



Enter X and Y

Enter X component: 10

Enter Y component: 20

If the user presses Continue without changing the default values, “Diagonal= 22.3607” is printed in the history area of the command window. If the user presses Cancel, nothing is printed because DoPrompt sets the V_Flag variable to 1 in this case.

The simple input dialog allows for up to 10 numeric or string variables. When more than 5 items are used, the dialog uses two columns and you may have to limit the length of your Prompt text.

The simple input dialog is unique in that you can enter not only literal numbers or strings but also numeric expressions or string expressions. Any literal strings that you enter must be quoted.

If the user presses the Help button, Igor searches for a help topic with a name derived from the dialog title. If such a help topic is not found, then generic help about the simple input dialog is presented. In both cases, the input dialog remains until the user presses either Continue or Cancel.

Pop-Up Menus in Simple Dialogs

The simple input dialog supports pop-up menus as well as text items. The pop-up menus can contain an arbitrary list of items such as a list of wave names. To use a pop-up menu in place of the normal text entry item in the dialog, you use the following syntax in the prompt declaration:

```
Prompt <variable name>, <title string>, popup <menu item list>
```

The popup keyword indicates that you want a pop-up menu instead of the normal text entry item. The menu list specifies the items in the pop-up menu separated by semicolons. For example:

```
Prompt color, "Select Color", popup "red;green;blue;"
```

If the menu item list is too long to fit on one line, you can compose the list in a string variable like so:

```
String stmp= "red;green;blue;"
stmp += "yellow;purple"
Prompt color, "Select Color", popup stmp
```

The pop-up menu items support the same special characters as the user-defined menu definition (see **Special Characters in Menu Item Strings** on page IV-133) except that items in pop-up menus are limited to 50 characters, keyboard shortcuts are not supported, and special characters are disabled by default.

You can use pop-up menus with both numeric and string parameters. When used with numeric parameters the number of the item chosen is placed in the variable. Numbering starts from one. When used with string parameters the text of the chosen item is placed in the string variable.

There are a number of functions, such as the **WaveList** function (see page V-1075) and the **TraceNameList** function (see page V-1044), that are useful in creating pop-up menus.

To obtain a menu item list of all waves in the current data folder, use:

```
WaveList("*", ";", "")
```

To obtain a menu item list of all waves in the current data folder whose names end in “_X”, use:

```
WaveList("*_X", ";", "")
```

To obtain a menu item list of all traces in the top graph, use:

```
TraceNameList("", ";", 1)
```

For a list of all contours in the top graph, use ContourNameList. For a list of all images, use ImageNameList. For a list of waves in a table, use WaveList.

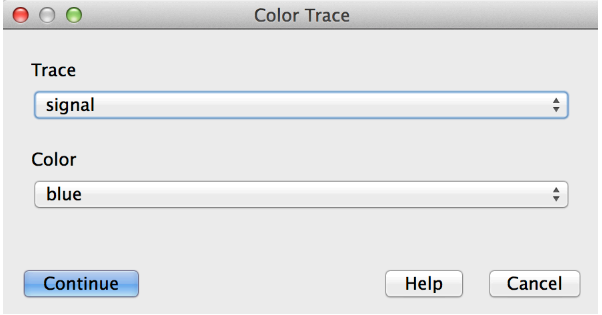
This next example creates two pop-up menus in the simple input dialog.

```
Menu "Macros"
   "Color Trace...", ColorTraceDialog()
End

Function ColorTraceDialog()
   String traceName
   Variable color=3
   Prompt traceName,"Trace",popup,TraceNameList("",";",1)
   Prompt color,"Color",popup,"red;green;blue"
   DoPrompt "Color Trace",traceName,color
   if( V_Flag )
      return 0          // user canceled
   endif

   if (color == 1)
      ModifyGraph rgb($traceName)=(65000, 0, 0)
   elseif(color == 2)
      ModifyGraph rgb($traceName)=(0, 65000, 0)
   elseif(color == 3)
      ModifyGraph rgb($traceName)=(0, 0, 65000)
   endif
End
```

If you choose Color Trace from the Macros menu, Igor displays the simple input dialog with two pop-up menus. The first menu contains a list of all traces in the target window which is assumed to be a graph. The second menu contains the items red, green and blue with blue (item number 3) initially chosen.



Color Trace

Trace: signal

Color: blue

After you choose the desired trace and color from the pop-up menus and click the Continue button, the function continues execution. The string parameter traceName will contain the name of the trace chosen from the first pop-up menu. The numeric parameter color will have a value of 1, 2 or 3, corresponding to red, green and blue.

In the preceding example, we needed a trace name to pass to the ModifyGraph operation. In another common situation, we need a wave reference to operate on. For example:

```
Menu "Macros"
   "Smooth Wave In Graph...",SmoothWaveInGraphDialog()
End

Function SmoothWaveInGraphDialog()
   String traceName
   Prompt traceName,"Wave",popup,TraceNameList("",";",1)
   DoPrompt "Smooth Wave In Graph",traceName

   WAVE w = TraceNameToWaveRef("", traceName)
   Smooth 5, w
End
```

The traceName parameter alone is not sufficient to specify which wave we want to smooth because it does not identify in which data folder the wave resides. The TraceNameToWaveRef function returns a wave reference which solves this problem.

Saving Parameters for Reuse

It is possible to write a procedure that presents a simple input dialog with default values for the parameters saved from the last time it was invoked. To accomplish this, we use global variables to store the values between calls to the procedure. Here is an example that saves one numeric and one string variable.

```
Function TestDialog()
   String saveDF = GetDataFolder(1)
   NewDataFolder/O/S root:Packages
   NewDataFolder/O/S :TestDialog

   Variable num = NumVarOrDefault("gNum", 42)
   Prompt num, "Enter a number"
   String str = StrVarOrDefault("gStr", "Hello")
   Prompt str, "Enter a string"
   DoPrompt "test",num,str

   Variable/G gNum = num      // Save for next time
   String/G gStr = str

   // Put function body here
   Print num,str

   SetDataFolder saveDF
End
```

This example illustrates the NumVarOrDefault and StrVarOrDefault functions. These functions return the value of a global variable or a default value if the global variable does not exist. 42 is the default value for gNum. NumVarOrDefault returns 42 if gNum does not exist. If gNum does exist, it returns the value of gNum. Similarly, “Hello” is the default value for gStr. StrVarOrDefault returns “Hello” if gStr does not exist. If gStr does exist, it returns the value of gStr.

Multiple Simple Input Dialogs

Prompt statements can be located anywhere within the body of a function and they do not need to be grouped together, although it will aid code readability if associated Prompt and DoPrompt code is kept together. Functions may contain multiple DoPrompt statements, and Prompt statements can be reused or redefined.

The following example illustrates multiple simple input dialogs and prompt reuse:

```
Function Example()
   Variable a= 123
   Variable/C ca= cmplx(3,4)
   String s

   Prompt a,"Enter a value"
   Prompt ca,"Enter complex value"
   Prompt s,"Enter a string", popup "red;green;blue"
   DoPrompt "Enter Values",a,s,ca
   if(V_Flag)
      Abort "The user pressed Cancel"
   endif

   Print "a= ",a,"s= ",s,"ca=",ca

   Prompt a,"Enter a again please"
   Prompt s,"Type a string"
   DoPrompt "Enter Values Again", a,s

   if(V_Flag)
      Abort "The user pressed Cancel"
   endif

   Print "Now a=",a," and s=",s
End
```

When this function is executed, it produces two simple input dialogs, one after the other after the user clicks Continue.

Help For Simple Input Dialogs

You can create, for each simple input dialog, custom help that appears when the user clicks the Help button. You do so by providing a custom help file with topics that correspond to the titles of your dialogs as specified in the DoPrompt commands.

If there is no exactly matching help topic or subtopic for a given dialog title, Igor munges the presumptive topic by replacing underscore characters with spaces and inserting spaces before capital letters in the interior of the topic. For example, if the dialog title is “ReallyCoolFunction”, and there is no matching help topic or subtopic, Igor looks for a help topic or subtopic named “Really Cool Function”.

See **Creating Your Own Help File** on page IV-255 for information on creating custom help files.

Displaying an Open File Dialog

You can display an Open File dialog to allow the user to choose a file to be used with a subsequent command. For example, the user can choose a file which you will then use in a **LoadWave** command. The Open File dialog is displayed using an **Open**/D/R command. Here is an example:

```
Function/S DoOpenFileDialog()
   Variable refNum
   String message = "Select a file"
   String outputPath
   String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
   fileFilters += "All Files:.*;"

   Open /D /R /F=fileFilters /M=message refNum
   outputPath = S_fileName

   return outputPath    // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays an Open File dialog. If the user chooses a file and clicks the Open button, the Open operation returns the full path to the file in the S_fileName output string variable. If the user cancels, Open sets S_fileName to "".

The /M flag is used to set the prompt message. As of OS X 10.11, Apple no longer shows the prompt message in the Open File dialog. It continues to work on Windows.

The /F flag is used to control the file filter which determines what kinds of files the user can select. This is explained further under **Open File Dialog File Filters**.

Displaying a Multi-Selection Open File Dialog

You can display an Open File dialog to allow the user to choose multiple files to be used with subsequent commands. The multi-selection Open File dialog is displayed using an **Open**/D/R/MULT=1 command. The list of files selected is returned via S_fileName in the form of a carriage-return-delimited list of full paths.

Here is an example:

```
Function/S DoOpenMultiFileDialog()
   Variable refNum
   String message = "Select one or more files"
   String outputPaths
   String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
   fileFilters += "All Files:.*;"

   Open /D /R /MULT=1 /F=fileFilters /M=message refNum
   outputPaths = S_fileName

   if (strlen(outputPaths) == 0)
      Print "Cancelled"
   else
      Variable numFilesSelected = ItemsInList(outputPaths, "\r")
      Variable i
      for(i=0; i<numFilesSelected; i+=1)
         String path = StringFromList(i, outputPaths, "\r")
         Printf "%d: %s\r", i, path
      endfor
   endif

   return outputPaths   // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays an Open File dialog. Because /MULT=1 was used, if the user chooses one or more files and clicks the Open button, the Open operation returns the list of full paths to files in the S_fileName output string variable. If the user cancels, Open sets S_fileName to "".

The list of full paths is delimited with a carriage return character, represented by "\r" in the example above. We use carriage return as the delimiter because the customary delimiter, semicolon, is a legal character in a Macintosh file name.

The /M flag is used to set the prompt message. As of OS X 10.11, Apple no longer shows the prompt message in the Open File dialog. It continues to work on Windows.

The /F flag is used to control the file filter which determines what kinds of files the user can select. This is explained further under **Open File Dialog File Filters**.

Open File Dialog File Filters

The **Open** operation displays the open file dialog if you use the /D/R flags or if the file to be opened is not fully specified using the pathName and fileNameStr parameters. The Open File dialog includes a file filter menu that allows the user to choose the type of file to be opened. By default this menus contain "Plain Text Files" and "All Files". You can use the /T and /F flags to override the default filter behavior.

The /T flag uses obsolescent Macintosh file types or file name extensions consisting of a dot plus three characters. The /F flag, added in Igor Pro 6.10, supports file name extensions only (not Macintosh file types) and extensions can be from one to 31 characters. Procedures written for Igor Pro 6.10 or later should use the /F flag in most cases but can use /T or both /T and /F. Procedures that must run with Igor Pro 6.0x and earlier must use the /T flag.

Using the /T=typeStr flag, you specify acceptable Macintosh-style file types represented by four-character codes (e.g., "TEXT") or acceptable three-character file name extensions (e.g., ".txt"). The pattern "????" means "any type of file" and is represented by "All Files" in the filter menu.

typeStr may contain multiple file types or extensions (e.g., "TEXTEPSF????" or ".txt.eps????"). Each file type or extension must be exactly four characters in length. Consequently the /T flag can accommodate only three-character file name extensions. Each file type or extension creates one entry in the Open File dialog filter menu.

If you use the /T flag, the Open operation automatically adds a filter for All Files ("????") if you do not add one explicitly.

Igor maps Macintosh file types to extensions. For example, if you specify /T="TEXT", you can open files with the extension ".txt" as well as any file whose Macintosh file type property is 'TEXT'. Igor does similar mappings for other extensions. See **File Types and Extensions** on page III-455 for details.

Using the /F=fileFilterStr flag, you specify a filter menu string plus acceptable file name extensions for each filter. fileFilterStr specifies one or more filters in a semicolon-separated list. For example, this specifies three filters:

```
String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
fileFilters += "HTML Files (*.htm,*.html):.htm,.html;"
fileFilters += "All Files:.*;"
Open /F=fileFilters . . .
```

Each file filter consists of a filter menu string (e.g., "Data Files") followed by a colon, followed by one or more file name extensions (e.g., ".txt,.dat,.csv") followed by a semicolon. The syntax is rigid - no extra characters are allowed and the semicolons shown above are required. In this example the filter menu would contain "Data Files" and would accept any file with a ".txt", ".dat", or ".csv" extension. ".*" creates a filter that accepts any file.

If you use the /F flag, it is up to you to add a filter for All Files as shown above. It is recommended that you do this.

Displaying a Save File Dialog

You can display a Save File dialog to allow the user to choose a file to be created or overwritten by a subsequent command. For example, the user can choose a file which you will then create or overwrite via a Save command. The Save File dialog is displayed using an **Open**/D command. Here is an example:

```
Function/S DoSaveFileDialog()
   Variable refNum
   String message = "Save a file"
   String outputPath
   String fileFilters = "Data Files (*.txt):.txt;"
   fileFilters += "All Files:.*;"

   Open /D /F=fileFilters /M=message refNum
   outputPath = S_fileName

   return outputPath    // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays a Save File dialog. If the user chooses a file and clicks the Save button, the Open operation returns the full path to the file in the S_fileName output string variable. If the user cancels, Open sets S_fileName to "".

The /M flag is used to set the prompt message. As of OS X 10.11, Apple no longer shows the prompt message in the Save File dialog. It continues to work on Windows.

The /F flag is used to control the file filter which determines what kinds of files the user can create. This is explained further under **Save File Dialog File Filters**.

Save File Dialog File Filters

The Save File dialog includes a file filter menu that allows the user to choose the type of file to be saved. By default this menus contain "Plain Text File" and, on Windows only, "All Files". You can use the /T and /F flags to override the default filter behavior.

The /T and /F flags work as explained under Open File Dialog File Filters. Using the /F flag for a Save File dialog, you would typically specify just one filter plus All Files, like this:

String fileFilters = "Data File (*.dat):.dat;"

fileFilters += "All Files:.*;"

Open /F=fileFilters . . .

The file filter chosen in the Save File dialog determines the extension for the file being saved. For example, if the "Plain Text Files" filter is selected, the ".txt" extension is added if you don't explicitly enter it in the File Name edit box. However if you select the "All Files" filter then no extension is automatically added and the final file name is whatever you enter in the File Name edit box. You should include the "All Files" filter if you want the user to be able to specify a file name with any extension. If you want to force the file name extension to an extension of your choice rather than the user's, omit the "All Files" filter.

Using Open in a Utility Routine

To be as general and useful as possible, a utility routine that acts on a file should have a pathName parameter and a fileName parameter, like this:

```
Function ShowFileInfo(pathName, fileName)
   String pathName   // Name of symbolic path or "" for dialog.
   String fileName   // File name or "" for dialog.

   <Show file info here>
End
```

This provides flexibility to the calling function. The caller can supply a valid symbolic path name and a simple leaf name in fileName, a valid symbolic path name and a partial path in fileName, or a full path in fileName in which case pathName is irrelevant.

If pathName and fileName fully specify the file of interest, you want to just open the file and perform the requested action. However, if pathName and fileName do not fully specify the file of interest, you want to display an Open File dialog so the user can choose the file. This is accomplished by using the **Open** operation's /D=2 flag.

With /D=2, if pathName and fileName fully specify the file, the Open operation merely sets the S_fileName output string variable to the full path to the file. If pathName and fileName do not fully specify the file, Open displays an Open File dialog and then sets the S_fileName output string variable to the full path to the file. If the user cancels the Open File dialog, Open sets S_fileName to "". In all cases, Open/D=2 just sets S_fileName and does not actually open the file.

If pathName and fileName specify an alias (*Macintosh*) or shortcut (*Windows*), Open/D=2 returns the file referenced by the alias or shortcut.

Here is how you would use Open /D=2.

```
Function ShowFileInfo(pathName, fileName)
   String pathName      // Name of symbolic path or "" for dialog.
   String fileName      // File name or "" for dialog.

   Variable refNum

   Open /D=2 /R /P=$pathName refNum as fileName    // Sets S_fileName

   if (strlen(S_fileName) == 0)
      Print "ShowFileInfo was canceled"
   else
      String fullPath = S_fileName
      Print fullPath
      Open /R refNum as fullPath
      FStatus refNum    // Sets S_info
      Print S_info
      Close refNum
   endif
End
```

In this case, we wanted to open the file for reading. To create a file and open it for writing, omit /R from both calls to Open.

Pause For User

The **PauseForUser** operation (see page V-738) allows an advanced programmer to create a more sophisticated semi-modal user interface. When you invoke it from a procedure, Igor suspends procedure execution and the user can interact with graph, table or control panel windows using the mouse or keyboard. Execution continues when the user kills the main window specified in the PauseForUser command.

PauseForUser is fragile because it attempts to create a semi-modal mode which is not supported by the operating system. Before using it, consider using an **Alternative to PauseForUser**.

Uses of PauseForUser

Pausing execution can serve two purposes. First, the programmer can pause function execution so that the user can, for example, adjust cursors in a graph window before continuing with a curve fit. In this application, the programmer creates a control panel with a continue button that the user presses after adjusting the cursors in the target graph. Pressing the continue button kills the host control panel (see example below).

In the second application, the programmer may wish to obtain input from the user in a more sophisticated manner than can be done using DoPrompt commands. This method uses a control panel as the main window with no optional target window. It is similar to the control panel technique shown above, except that it is modal.

Following are some examples of how you can use the **PauseForUser** operation (see page V-738) in your own user functions.

PauseForUser Simple Cursor Example

This example shows how to allow the user to adjust cursors on a graph while a procedure is executing. Most of the work is done by the UserCursorAdjust function. UserCursorAdjust is called by the Demo function which first creates a graph and shows the cursor info panel.

This example illustrates two modes of PauseForUser. When called with autoAbortSecs=0, UserCursorAdjust calls PauseForUser without the /C flag in which case PauseForUser retains control until the user clicks the Continue button.

When called with autoAbortSecs>0, UserCursorAdjust calls PauseForUser/C. This causes PauseForUser to handle any pending events and then return to the calling procedure. The procedure checks the V_flag variable, set by PauseForUser, to determine when the user has finished interacting with the graph. PauseForUser/C, which requires Igor Pro 6.1 or later, is for situations where you want to do something while the user interacts with the graph.

To try this yourself, copy and paste all three routines below into the procedure window of a new experiment and then run the Demo function with a value of 0 and again with a value such as 30.

```
Function UserCursorAdjust(graphName,autoAbortSecs)
   String graphName
   Variable autoAbortSecs

   DoWindow/F $graphName                  // Bring graph to front
   if (V_Flag == 0)                       // Verify that graph exists
      Abort "UserCursorAdjust: No such graph."
      return -1
   endif

   NewPanel /K=2 /W=(187,368,437,531) as "Pause for Cursor"
   DoWindow/C tmp_PauseforCursor          // Set to an unlikely name
   AutoPositionWindow/E/M=1/R=$graphName  // Put panel near the graph

   DrawText 21,20,"Adjust the cursors and then"
   DrawText 21,40,"Click Continue."
   Button button0,pos={80,58},size={92,20},title="Continue"
   Button button0,proc=UserCursorAdjust_ContButtonProc
   Variable didAbort= 0
   if( autoAbortSecs == 0 )
      PauseForUser tmp_PauseforCursor,$graphName
   else
      SetDrawEnv textyjust= 1
      DrawText 162,103,"sec"
      SetVariable sv0,pos={48,97},size={107,15},title="Aborting in "
      SetVariable sv0,limits={-inf,inf,0},value= _NUM:10
      Variable td= 10,newTd
      Variable t0= ticks
      Do
         newTd= autoAbortSecs - round((ticks-t0)/60)
         if( td != newTd )
            td= newTd
            SetVariable sv0,value= _NUM:newTd,win=tmp_PauseforCursor
            if( td <= 10 )
               SetVariable sv0,valueColor= (65535,0,0),win=tmp_PauseforCursor
            endif
         endif
         if( td <= 0 )
            KillWindow tmp_PauseforCursor
            didAbort= 1
            break
         endif

         PauseForUser/C tmp_PauseforCursor,$graphName
      while(V_flag)
   endif
   return didAbort
End

Function UserCursorAdjust_ContButtonProc(ctrlName) : ButtonControl
   String ctrlName

   KillWindow/Z tmp_PauseforCursor           // Kill panel
End

Function Demo(autoAbortSecs)
```

```
   Variable autoAbortSecs

   Make/O jack;SetScale x,-5,5,jack
   jack= exp(-x^2)+gnoise(0.1)
   DoWindow Graph0
   if( V_Flag==0 )
      Display jack
      ShowInfo
   endif

   if (UserCursorAdjust("Graph0",autoAbortSecs) != 0)
      return -1
   endif

   if (strlen(CsrWave(A))>0 && strlen(CsrWave(B))>0)// Cursors are on trace?
      CurveFit gauss,jack[pcsr(A),pcsr(B)] /D
   endif
End
```

Alternative to PauseForUser

In normal non-modal operation, when the user invokes a user-defined function, the function executes, terminates, and returns control to the user. The user is in complete control of what happens next. With PauseForUser, the user-defined function is running the whole time and the user's control is restricted control to what PauseForUser allows.

For example, with PauseForUser, the user can not use the help system, search for text in a notebook, activate another window for copy and paste into a table, use the Data Browser, and so on. The user can do the few things PauseForUser permits.

The alternative to PauseForUser is non-modal operation. To facilitate this in a situation where you might consider using PauseForUser, you need to break the task into two or more steps, each implemented by a separate function, and provide the user with the means to invoke each function as he sees fit. The user initiates the first step which runs to completion. The user is then free to do what he wishes before invoking the second step.

To see the non-modal approach in action, execute this in Igor and follow the instructions for running the example:

```
DisplayHelpTopic "Alternatives to PauseForUser"
```

The main difference between the non-modal alternative approach and the PauseForUser approach is that, in the non-modal case, the user is free to do whatever he wants between step one (creating the graph) and step two (performing the fit).

A hidden difference is that the semi-modal operation of PauseForUser relies on tricky and potentially fragile code inside Igor while the non-modal approach uses Igor in a natural way.

PauseForUser Advanced Cursor Example

Now for something a bit more complex. Here we modify the preceding example to include a Cancel button. For this, we need to return information about which button was pressed. Although we could do this by creating a single global variable in the root data folder, we use a slightly more complex technique using a temporary data folder. This technique is especially useful for more complex panels with multiple output variables because it eliminates name conflict issues. It also allows much easier clean up because we can kill the entire data folder and everything in it with just one operation.

```
Function UserCursorAdjust(graphName)
   String graphName

   DoWindow/F $graphName   // Bring graph to front
   if (V_Flag == 0)        // Verify that graph exists
```

```
      Abort "UserCursorAdjust: No such graph."
      return -1
   endif

   NewDataFolder/O root:tmp_PauseforCursorDF
   Variable/G root:tmp_PauseforCursorDF:canceled= 0

   NewPanel/K=2 /W=(139,341,382,450) as "Pause for Cursor"
   DoWindow/C tmp_PauseforCursor          // Set to an unlikely name
   AutoPositionWindow/E/M=1/R=$graphName  // Put panel near the graph

   DrawText 21,20,"Adjust the cursors and then"
   DrawText 21,40,"Click Continue."
   Button button0,pos={80,58},size={92,20},title="Continue"
   Button button0,proc=UserCursorAdjust_ContButtonProc
   Button button1,pos={80,80},size={92,20}
   Button button1,proc=UserCursorAdjust_CancelBProc,title="Cancel"

   PauseForUser tmp_PauseforCursor,$graphName

   NVAR gCaneled= root:tmp_PauseforCursorDF:canceled
   Variable canceled= gCaneled   // Copy from global to local
                                 // before global is killed
   KillDataFolder root:tmp_PauseforCursorDF

   return canceled
End

Function UserCursorAdjust_ContButtonProc(ctrlName) : ButtonControl
   String ctrlName

   KillWindow/Z tmp_PauseforCursor  // Kill self
End

Function UserCursorAdjust_CancelBProc(ctrlName) : ButtonControl
   String ctrlName

   Variable/G root:tmp_PauseforCursorDF:canceled= 1
   KillWindow/Z tmp_PauseforCursor  // Kill self
End

Function Demo()
   Make/O jack;SetScale x,-5,5,jack
   jack= exp(-x^2)+gnoise(0.1)
   DoWindow Graph0
   if (V_Flag==0)
      Display jack
      ShowInfo
   endif
   Variable rval= UserCursorAdjust("Graph0")
   if (rval == -1)            // Graph name error?
      return -1;
   endif
   if (rval == 1)             // User canceled?
      DoAlert 0,"Canceled"
      return -1;
   endif
   CurveFit gauss,jack[pcsr(A),pcsr(B)] /D
End
```

PauseForUser Control Panel Example

This example illustrates using a control panel as a modal dialog via PauseForUser. This technique is useful when you need a more sophisticated modal user interface than provided by the simple input dialog.

We started by manually creating a control panel. When the panel design was finished, we closed it to create a recreation macro. We then used code copied from the recreation macro in the DoMyInputPanel function and deleted the recreation macro.

```
Function UserGetInputPanel_ContButton(ctrlName) : ButtonControl
   String ctrlName

   KillWindow/Z tmp_GetInputPanel      // Kill self
End

// Call with these variables already created and initialized:
//    root:tmp_PauseForUserDemo:numvar
//    root:tmp_PauseForUserDemo:strvar
Function DoMyInputPanel()
   NewPanel /W=(150,50,358,239)
   DoWindow/C tmp_GetInputPanel        // Set to an unlikely name
   DrawText 33,23,"Enter some data"
   SetVariable setvar0,pos={27,49},size={126,17},limits={-Inf,Inf,1}
   SetVariable setvar0,value= root:tmp_PauseForUserDemo:numvar
   SetVariable setvar1,pos={24,77},size={131,17},limits={-Inf,Inf,1}
   SetVariable setvar1,value= root:tmp_PauseForUserDemo:strvar
   Button button0,pos={52,120},size={92,20}
   Button button0,proc=UserGetInputPanel_ContButton,title="Continue"

   PauseForUser tmp_GetInputPanel
End

Function Demo1()
   NewDataFolder/O root:tmp_PauseForUserDemo
   Variable/G root:tmp_PauseForUserDemo:numvar= 12
   String/G root:tmp_PauseForUserDemo:strvar= "hello"

   DoMyInputPanel()

   NVAR numvar= root:tmp_PauseForUserDemo:numvar
   SVAR strvar= root:tmp_PauseForUserDemo:strvar

   printf "You entered %g and %s\r",numvar,strvar

   KillDataFolder root:tmp_PauseForUserDemo
End
```

Progress Windows

Sometimes when performing a long calculation, you may want to display an indication that the calculation is in progress, perhaps showing how far along it is, and perhaps providing an abort button. As of Igor Pro 6.1, you can use a control panel window for this task using the **DoUpdate** /E and /W flags and the mode=4 setting for **ValDisplay**.

DoUpdate /W=win /E=1 marks the specified window as a progress window that can accept mouse events while user code is executing. The /E flag need be used only once to mark the panel but it does not hurt to use it in every call. This special state of the control panel is automatically cleared when procedure execution finishes and Igor's outer loop again runs.

For a window marked as a progress window, DoUpdate sets V_Flag to 2 if a mouse up happened in a button since the last call. When this occurs, the full path to the subwindow containing the button is stored in S_path and the name of the control is stored in S_name.

Here is a simple example that puts up a progress window with a progress bar and a Stop button. Try each of the four input flag combinations.

```
//    ProgressDemo1(0,0)
//    ProgressDemo1(1,0)
//    ProgressDemo1(0,1)
//    ProgressDemo1(1,1)
Function ProgressDemo1(indefinite, useIgorDraw)
   Variable indefinite
   Variable useIgorDraw// True to use Igor's own draw method rather than native

   NewPanel /N=ProgressPanel /W=(285,111,739,193)
   ValDisplay valdisp0,pos={18,32},size={342,18}
   ValDisplay valdisp0,limits={0,100,0},barmisc={0,0}
   ValDisplay valdisp0,value= _NUM:0
   if( indefinite )
      ValDisplay valdisp0,mode= 4// candy stripe
   else
      ValDisplay valdisp0,mode= 3// bar with no fractional part
   endif
   if( useIgorDraw )
      ValDisplay valdisp0,highColor=(0,65535,0)
   endif
   Button bStop,pos={375,32},size={50,20},title="Stop"
   DoUpdate /W=ProgressPanel /E=1// mark this as our progress window

   Variable i,imax= indefinite ? 10000 : 100
   for(i=0;i<imax;i+=1)
      Variable t0= ticks
      do
      while( ticks < (t0+3) )
      if( indefinite )
         ValDisplay valdisp0,value= _NUM:1,win=ProgressPanel
      else
         ValDisplay valdisp0,value= _NUM:i+1,win=ProgressPanel
      endif
      DoUpdate /W=ProgressPanel
      if( V_Flag == 2 )// we only have one button and that means stop
         break
      endif
   endfor
   KillWindow ProgressPanel
End
```

When performing complex calculations, it is often difficult to insert DoUpdate calls in the code. In this case, you can use a window hook that responds to event #23, spinUpdate. This is called at the same time that the beachball icon in the status bar spins. The hook can then update the window's control state and then call DoUpdate/W on the window. If the window hook returns non-zero, then an abort is performed. If you desire a more controlled quit, you might set a global variable that your calculation code can test

The following example provides an indefinite indicator and an abort button. Note that if the abort button is pressed, the window hook kills the progress window since otherwise the abort would cause the window to remain.

```
// Example: ProgressDemo2(100)
Function ProgressDemo2(nloops)
   Variable nloops

   Variable useIgorDraw=0  // set true for Igor draw method rather than native

   NewPanel/FLT /N=myProgress/W=(285,111,739,193) as "Calculating..."
   ValDisplay valdisp0,pos={18,32},size={342,18}
   ValDisplay valdisp0,limits={0,100,0},barmisc={0,0}
   ValDisplay valdisp0,value= _NUM:0
   ValDisplay valdisp0,mode=4    // candy stripe
   if( useIgorDraw )
      ValDisplay valdisp0,highColor=(0,65535,0)
   endif
   Button bStop,pos={375,32},size={50,20},title="Abort"
   SetActiveSubwindow _endfloat_
   DoUpdate/W=myProgress/E=1     // mark this as our progress window

   SetWindow myProgress,hook(spinner)=MySpinnHook

   Variable t0= ticks,i
   for(i=0;i<nloops;i+=1)
      PerformLongCalc(1e6)
   endfor
   Variable timeperloop= (ticks-t0)/(60*nloops)

   KillWindow myProgress

   print "time per loop=",timeperloop
End

Function MySpinnHook(s)
   STRUCT WMWinHookStruct &s

   if( s.eventCode == 23 )
      ValDisplay valdisp0,value= _NUM:1,win=$s.winName
      DoUpdate/W=$s.winName
      if( V_Flag == 2 )    // we only have one button and that means abort
         KillWindow $s.winName
         return 1
      endif
   endif
   return 0
End

Function PerformLongCalc(nmax)
   Variable nmax

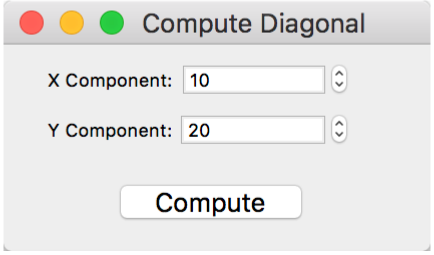
   Variable i,s
   for(i=0;i<nmax;i+=1)
      s+= sin(i/nmax)
   endfor
End
```

Control Panels and Event-Driven Programming

The CalcDiagDialog function shown under **The Simple Input Dialog** on page IV-144 creates a modal dialog. “Modal” means that the function retains complete control until the user clicks Cancel or Continue. The user can not activate another window or choose a menu item until the dialog is dismissed.

This section shows how to implement the same functionality using a control panel as a modeless dialog. “Modeless” means that the user can activate another window or choose a menu item at any time. The modeless window accepts input whenever the user wants to enter it but does not block the user from accessing other windows.

The control panel looks like this:



X Component: 10

Y Component: 20

The code implementing this control panel is given below. Before we look at the code, here is some explanation of the thinking behind it.

The X Component and Y Component controls are SetVariable controls. We attach each SetVariable control to a global variable so that, if we kill and later recreate the panel, the SetVariable control is restored to its previous state. In other words, we use global variables to remember settings across invocations of the panel. To keep the global variables from cluttering the user's space, we bury them in a data folder located at root:Packages:DiagonalControlPanel.

The DisplayDiagonalControlPanel routine creates the data folder and the global variables if they do not already exist. DisplayDiagonalControlPanel creates the control panel or, if it already exists, just brings it to the front.

We added a menu item to the Macros menu so the user can easily invoke DisplayDiagonalControlPanel.

We built the control panel manually using techniques explained in Chapter III-14, **Controls and Control Panels**. Then we closed it so Igor would create a display recreation macro which we named DiagonalControlPanel. We then manually tweaked the macro to attach the SetVariable controls to the desired globals and to set the panel's behavior when the user clicks the close button by adding the /K=1 flag.

Here are the procedures.

```
// Add a menu item to display the control panel.
Menu "Macros"
   "Display Diagonal Control Panel", DisplayDiagonalControlPanel()
End

// This is the display recreation macro, created by Igor
// and then manually tweaked. The parts that were tweaked
// are shown in bold. NOTE: Some lines are wrapped to fit on the page.
Window DiagonalControlPanel() : Panel
   PauseUpdate; Silent 1   // building window...

   NewPanel/W=(162,95,375,198)/K=1 as "Compute Diagonal"

   SetVariable XSetVar,pos={22,11},size={150,15},title="X Component:"
   SetVariable XSetVar,limits={-Inf,Inf,1},value=
               root:Packages:DiagonalControlPanel:gXComponent

   SetVariable YSetVar,pos={22,36},size={150,15},title="Y Component:"
   SetVariable YSetVar,limits={-Inf,Inf,1},value=
               root:Packages:DiagonalControlPanel:gYComponent

   Button ComputeButton,pos={59,69},size={90,20},
                    proc=ComputeDiagonalProc,title="Compute"
EndMacro

// This is the action procedure for the Compute button.
// We created it using the Button dialog.
Function ComputeDiagonalProc(ctrlName) : ButtonControl
   String ctrlName

   DFREF dfr = root:Packages:DiagonalControlPanel
   NVAR gXComponent = dfr:gXComponent
   NVAR gYComponent = dfr:gYComponent
   Variable diagonal
   diagonal = sqrt(gXComponent^2 + gYComponent^2)
   Printf "Diagonal=%g\r", diagonal
End

// This is the top level routine which makes sure that the globals
// and their enclosing data folders exist and then makes sure that
// the control panel is displayed.
Function DisplayDiagonalControlPanel()
   // If the panel is already created, just bring it to the front.
   DoWindow/F DiagonalControlPanel
   if (V_Flag != 0)
      return 0
   endif

   String dfSave = GetDataFolder(1)

   // Create a data folder in Packages to store globals.
   NewDataFolder/O/S root:Packages
   NewDataFolder/O/S root:Packages:DiagonalControlPanel

   // Create global variables used by the control panel.
   Variable xComponent = NumVarOrDefault(":gXComponent", 10)
   Variable/G gXComponent = xComponent
   Variable yComponent = NumVarOrDefault(":gYComponent", 20)
   Variable/G gYComponent = yComponent

   // Create the control panel.
   Execute "DiagonalControlPanel()"

   SetDataFolder dfSave
End
```

To try this example, copy all of the procedures and paste them into the procedure window of a new experiment. Close the procedure window to compile it and then choose Display Diagonal Control Panel from the Macros menu. Next enter values in the text entry items and click the Compute button. Close the control panel and then reopen it using the Display Diagonal Control Panel menu item. Notice that the values that you entered were remembered. Use the Data Browser to inspect the root:Packages:DiagonalControlPanel data folder.

Although this example is very simple, it illustrates the process of creating a control panel that functions as a modeless dialog. There are many more examples of this in the Examples folder. You can access them via the File→Example Experiments submenu.

See Chapter III-14, **Controls and Control Panels**, for more information on building control panels.

Detecting a User Abort

If you have written a user-defined function that takes a long time to execute, you may want to provide a way for the user to abort it. One solution is to display a progress window as discussed under **Progress Windows** on page IV-156.

Here is a simple alternative using the escape key:

```
Function PressEscapeToAbort(phase, title, message)
   Variable phase    // 0: Display control panel with message.
                     // 1: Test if Escape key is pressed.
                     // 2: Close control panel.
   String title      // Title for control panel.
   String message    // Tells user what you are doing.
   if (phase == 0)   // Create panel
      DoWindow/F PressEscapePanel
      if (V_flag == 0)
         NewPanel/K=1 /W=(100,100,350,200)
         DoWindow/C PressEscapePanel
         DoWindow/T PressEscapePanel, title
      endif
      TitleBox Message,pos={7,8},size={69,20},title=message
      String abortStr = "Press escape to abort"
      TitleBox Press,pos={6,59},size={106,20},title=abortStr
      DoUpdate
   endif

   if (phase == 1)   // Test for Escape key
      Variable doAbort = 0
      if (GetKeyState(0) & 32)      // Is Escape key pressed now?
         doAbort = 1
      else
         if (strlen(message) != 0)  // Want to change message?
            TitleBox Message,title=message
            DoUpdate
         endif
      endif
      return doAbort
   endif

   if (phase == 2)   // Kill panel
      KillWindow/Z PressEscapePanel
   endif

   return 0
End

Function Demo()
   // Create panel
   PressEscapeToAbort(0, "Demonstration", "This is a demo")

   Variable startTicks = ticks
   Variable endTicks = startTicks + 10*60
   Variable lastMessageUpdate = startTicks

   do
      String message
      message = ""
      if (ticks>=lastMessageUpdate+60) // Time to update message?
         Variable remaining = (endTicks - ticks) / 60
         sprintf message, "Time remaining: %.1f seconds", remaining
         lastMessageUpdate = ticks
      endif

      if (PressEscapeToAbort(1, "", message))
         Print "Test aborted by Escape key."
         break
      endif
   while(ticks < endTicks)

   PressEscapeToAbort(2, "", "")       // Kill panel.
End
```

Creating a Contextual Menu

You can use the **PopupContextualMenu** operation to create a pop-up menu in response to a contextual click (control-click (*Macintosh*) or right-click). You would do this from a window hook function or from the action procedure for a control in a control panel.

In this example, we create a control panel with a list. When the user right-clicks on the list, Igor sends a mouse-down event to the listbox procedure, TickerListProc in this case. The listbox procedure uses the eventMod field of the WMListboxAction structure to determine if the click is a right-click. If so, it calls HandleTickerListRightClick which calls PopupContextualMenu to display the contextual menu.

```
Menu "Macros"

   "Show Demo Panel", ShowDemoPanel()
End

static Function HandleTickerListRightClick()
   String popupItems = ""
   popupItems += "Refresh;"

   PopupContextualMenu popupItems
   strswitch (S_selection)
      case "Refresh":
         DoAlert 0, "Here is where you would refresh the ticker list."
         break
   endswitch
End

Function TickerListProc(lba) : ListBoxControl
   STRUCT WMListboxAction &lba

   switch (lba.eventCode)
      case 1:                    // Mouse down
         if (lba.eventMod & 0x10)// Right-click?
            HandleTickerListRightClick()
         endif
         break
   endswitch

   return 0
End

Function ShowDemoPanel()
   DoWindow/F DemoPanel
   if (V_flag != 0)
      return 0 // Panel already exists.
   endif

   // Create panel data.
   Make/O/T ticketListWave = {{"AAPL","IBM","MSFT"}, {"90.25","86.40","17.17"}}

   // Create panel.
   NewPanel /N=DemoPanel /W=(321,121,621,321) /K=1
   ListBox TickerList,pos={48,16},size={200,100},fSize=12
   ListBox TickerList,listWave=root:ticketListWave
   ListBox TickerList,mode= 1,selRow= 0, proc=TickerListProc
End
```

Cursors as Input Device

You can use the cursors on a trace in a graph to identify the data to be processed.

The examples shown above using PauseForUser are modal - the user adjusts the cursors in the middle of procedure execution and can do nothing else. This technique is non-modal — the user is expected to adjust the cursors before invoking the procedure.

This function does a straight-line curve fit through the data between cursor A (the round cursor) and cursor B (the square cursor). This example is written to handle both waveform and XY data.

```
Function FitLineBetweenCursors()
   Variable isXY

   // Make sure both cursors are on the same wave.
   WAVE wA = CsrWaveRef(A)
   WAVE wB = CsrWaveRef(B)
   String dfA = GetWavesDataFolder(wA, 2)
   String dfB = GetWavesDataFolder(wB, 2)
   if (CmpStr(dfA, dfB) != 0)
      Abort "Both cursors must be on the same wave."
      return -1
   endif

   // Find the wave that the cursors are on.
   WAVE yWave = CsrWaveRef(A)

   // Decide if this is an XY pair.
   WAVE xWave = CsrXWaveRef(A)
   isXY = WaveExists(xWave)

   if (isXY)
      CurveFit line yWave(xcsr(A),xcsr(B)) /X=xWave /D
   else
      CurveFit line yWave(xcsr(A),xcsr(B)) /D
   endif
End
```

This technique is demonstrated in the **Fit Line Between Cursors** example experiment in the “Examples:Curve Fitting” folder.

Advanced programmers can set things up so that a hook function is called whenever the user adjusts the position of a cursor. For details, see **Cursors — Moving Cursor Calls Function** on page IV-339.

Marquee Menu as Input Device

A marquee is the dashed-line rectangle that you get when you click and drag diagonally in a graph or page layout. It is used for expanding and shrinking the range of axes, for selecting a rectangular section of an image, and for specifying an area of a layout. You can use the marquee as an input device for your procedures. This is a relatively advanced technique.

This menu definition adds a user-defined item to the graph marquee menu:

```
Menu "GraphMarquee"
   "Print Marquee Coordinates", PrintMarqueeCoords()
End
```

To add an item to the layout marquee menu, use LayoutMarquee instead of GraphMarquee.

When the user chooses Print Marquee Coordinates, the following function runs. It prints the coordinates of the marquee in the history area. It assumes that the graph has left and bottom axes.

```
Function PrintMarqueeCoords()
   String format
   GetMarquee/K left, bottom
   format = "flag: %g; left: %g; top: %g; right: %g; bottom: %g\r"
   printf format, V_flag, V_left, V_top, V_right, V_bottom
End
```

The use of the marquee menu as in input device is demonstrated in the **Marquee Demo** and **Delete Points from Wave** example experiments.

Polygon as Input Device

This technique is similar to the marquee technique except that you can identify a nonrectangular area. It is implemented using **FindPointsInPoly** operation (see page V-248).

Chapter

IV-7

Programming Techniques

Overview

This chapter discusses programming techniques and issues that go beyond the basics of the Igor programming language and which all Igor programmers should understand. Techniques for advanced programmers are discussed in Chapter IV-10, **Advanced Topics**.

The Include Statement

The include statement is a compiler directive that you can put in your procedure file to open another procedure file. A typical include statement looks like this:

```
#include <Split Axis>
```

This statement opens the file "Split Axis.ipf" in the WaveMetrics Procedures folder. Once this statement has been compiled, you can call routines from that file. This is the recommended way to access procedure files that contain utility routines.

The # character at the beginning specifies that a compiler directive follows. Compiler directives, except for conditional compilation directives, must start at the far left edge of the procedure window with no leading tabs or spaces. Include statements can appear anywhere in the file but it is conventional to put them near the top.

It is possible to include a file which in turn includes other files. Igor opens all of the included files.

Igor opens included files when it compiles procedures. If you remove an include statement from a procedure file, Igor automatically closes the file on the next compile.

There are four forms of the include statement:

1. Igor searches for the named file in "Igor Pro Folder/WaveMetrics Procedures" and in any subfolders:
   `#include <`*`fileName`*`>`
   Example: `#include <Split Axis>`
2. Igor searches for the named file in "Igor Pro Folder/User Procedures" and "Igor Pro User Files/User Procedures" and in any subfolders:
   `#include "`*`fileName`*`"`
   Example: `#include "Utility Procs"`
3. Igor looks for the file only in the exact location specified:
   `#include "`*`full file path`*`"`
   Example: `#include "Hard Disk:Procedures:Utility Procs"`
4. Igor looks for the file relative to the Igor Pro folder and the Igor Pro User Files folder and the folder containing the procedure file that contains the #include statement:
   `#include "`*`:partial file path`*`"`
   Example: `#include ":Spectroscopy Procedures:Voigt Procs"`

   Igor looks first relative to the Igor Pro Folder. If that fails, it looks relative to the **Igor Pro User Files** folder. If that fails it looks relative to the procedure file containing the #include statement or, if the #include statement is in the built-in procedure window, relative to the experiment file.

   The name of the file being included must end with the standard ".ipf" extension but the extension is not used in the include statement.

Procedure File Version Information

If you create a procedure file to be used by other Igor users, it's a good idea to add version information to the file. You do this by putting a #pragma version statement in the procedure file. For example:

```
#pragma version = 1.10
```

This statement must appear with no indentation and must appear in the first 50 lines of the file. If Igor finds no version pragma, it treats the file as version 1.00.

Igor looks for the version information when the user invokes the File Information dialog from the Procedure menu. If the file has version information, Igor displays the version next to the file name in the dialog.

Igor also looks for version information when it opens an included file. An include statement can require a certain version of the included file using the following syntax:

```
#include <Bivariate Histogram> version>=1.02
```

If the required version of the procedure file is not available, Igor displays a warning to inform the user that the procedure file needs to be updated.

In Igor Pro 9.01 and later, you can programmatically determine the procedure file's version using the **ProcedureVersion** function.

Turning the Included File's Menus Off

Normally an included procedure file's menus and menu items are displayed. However, if you are including a file merely to call one of its procedures, you may not want that file's menu items to appear. To suppress the file's menus and menu items, use:

```
#include <Decimation> menus=0
```

To use both the menus and version options, you must separate them with a comma:

```
#include <Decimation> menus=0, version>=1.1
```

Optionally Including Files

Compilation usually ceases and returns an error if the included file isn't found. On occasion it is advantageous to allow compilation to proceed if an included file isn't present or is the wrong version. Optionally including a procedure file is appropriate only if the file truly isn't needed to make procedures compile or operate.

Use the "optional" keyword to optionally include a procedure file:

```
#include <Decimation> version>=1.1, optional
```

Writing General-Purpose Procedures

Procedures can be placed on a scale ranging from general to specific. Usually, the high-level procedures of a program are specific to the task at hand and call on more general, lower-level procedures. The most general procedures are often called "utility" procedures.

You can achieve a high degree of productivity by building a library of utility procedures that you reuse in different programs. In Igor, you can think of the routines in an experiment's built-in Procedure window as a program. It can call utility routines which should be stored in a separate procedure file so that they are available to multiple experiments.

The files stored in the WaveMetrics Procedures folder contain general-purpose procedures on which your high-level procedures can build. Use the include statement (see **The Include Statement** on page IV-166) to access these and other utility files.

When you write utility routines, you should keep them as general as possible so that they can be reused as much as possible. Here are some guidelines.

- Avoid the use of global variables as inputs or outputs. Using globals hard-wires the routine to specific names which makes it difficult to use and limits its generality.
- If you use globals to store state information between invocations of a routine, package the globals in data folders.

  WaveMetrics packages usually create data folders inside "root:Packages". We use the prefix "WM" for data folder names to avoid conflict with other packages. Follow this lead and should pick your own data folder names so as to minimize the chance of conflict with WaveMetrics packages or with others. See **Managing Package Data** on page IV-249 for details.

- Choose a clear and specific name for your utility routine.

  By choosing a name that says precisely what your utility routine does, you minimize the likelihood of collision with the name of another procedure. You also increase the readability of your program.
- Make functions which are used only internally by your procedures static.

  By making internal functions static (i.e., private), you minimize the likelihood of collision with the name of another procedure.

Programming with Liberal Names

Standard names in Igor can contain letters, numbers and the underscore character only.

It is possible to use wave names and data folder names that contain almost any character. Such names are called “liberal names” (see **Liberal Object Names** on page III-501).

As this section explains, programmers need to use special techniques for their procedures to work with liberal names. Consequently, if you do use liberal names, some existing Igor procedures may break.

Whenever a liberal name is used in a command or expression, the name must be enclosed in single quotes. For example:

```
Make 'Wave 1', wave2, 'miles/hour'
'Wave 1' = wave2 + 'miles/hour'
```

Without the single quotes, Igor has no way to know where a particular name ends. This is a problem whenever Igor parses a command or statement. Igor parses commands at the following times:

- When it compiles a user-defined function.
- When it compiles the right-hand side of an assignment statement, including a formula (:= dependency expression).
- When it interprets a macro.
- When it interprets a command that you enter in the command line or via an Igor Text file.
- When it interprets a command you submit for execution via the Execute operation.
- When it interprets a command that an XOP submits for execution via the XOPCommand or XOPSilentCommand callback routines.

When you use an Igor dialog to generate a command, Igor automatically uses quotes where necessary.

Programmers need to be concerned about liberal names whenever they create a command and then execute it, via an Igor Text file, the Execute operation or the XOPCommand and XOPSilentCommand callback routines, and when creating a formula. In short, when you create something that Igor has to parse, names must be quoted if they are liberal. Names that are not liberal can be quoted or unquoted.

If you have a procedure that builds up a command in a string variable and then executes it via the Execute operation, you must use the PossiblyQuoteName function to provide the quotes if needed.

Here is a trivial example showing the liberal-name unaware and liberal-name aware techniques:

```
Function AddOneToWave(w)
   WAVE w

   String cmd
   String name = NameOfWave(w)

   // Liberal-name unaware - generates error with liberal name
   sprintf cmd, "%s += 1", name
   Execute cmd

   // Liberal-name aware way
   sprintf cmd, "%s += 1", PossiblyQuoteName(name)
   Execute cmd
End
```

Imagine that you pass a wave named *wave 1* to this function. Using the old technique, the Execute operation would see the following text:

```
wave 1 += 1
```

Igor would generate an error because it would try to find an operation, macro, function, wave or variable named *wave*.

Using the new technique, the Execute operation would see the following text:

```
'wave 1' += 1
```

This works correctly because Igor sees 'wave 1' as a single name.

When you pass a string expression containing a simple name to the $ operator, the name must not be quoted because Igor does no parsing:

```
String name = "wave 1"; Display $name                 // Right
String name = "'wave 1'"; Display $name               // Wrong
```

However, when you pass a *path* in a string to $, any liberal names in the path must be quoted:

```
String path = "root:'My Data':'wave 1'"; Display $path// Right
String path = "root:My Data:wave 1"; Display $path    // Wrong
```

For further explanation of liberal name quoting rules, see **Accessing Global Variables and Waves Using Liberal Names** on page IV-68.

Some built-in string functions return a list of waves. WaveList is the most common example. If liberal wave names are used, you will have to be extra careful when using the list of names. For example, you can't just append the list to the name of an operation that takes a list of names and then execute the resulting string. Rather, you will have to extract each name in turn, possibly quote it and then append it to the operation.

For example, the following will work if all wave names are standard but not if any wave names are liberal:

```
Execute "Display " + WaveList("*", ",", "")
```

Now you will need a string function that extracts out each name, possibly quotes it, and creates a new string using the new names separated by commas. The PossiblyQuoteList function in the WaveMetrics procedure file Strings as Lists does this. The preceding command becomes:

```
Execute "Display " + PossiblyQuoteList(WaveList("*", ",", ""), ",")
```

To include the Strings as Lists file in your procedures, see **The Include Statement** on page IV-166.

For details on using liberal names in user-defined functions, see **Accessing Global Variables and Waves Using Liberal Names** on page IV-68.

These functions are useful for programmatically generating object names: **CreateDataObjectName**, **CheckName**, **CleanupName**, **UniqueName**.

Programming with Data Folders

For general information on data folders, including syntax for using data folders in command line operations, see Chapter II-8, **Data Folders**.

Data folders provide a powerful way to organize data and reduce clutter. However, using data folders introduces some complexity in Igor programming. The name of a variable or wave is no longer sufficient to uniquely identify it because the name alone does not indicate in which data folder it resides.

If a procedure is designed to work on the current data folder, then it is the user's responsibility to set the current data folder correctly before running the procedure. When writing such a procedure, you can use

WaveExists, **NVAR_Exists**, and **SVAR_Exists** to check the existence of expected objects and fail gracefully if they do not exist.

Data Folder Applications

There are two main uses for data folders:

- To store globals used by procedures to keep track of their state
- To store runs of data with identical structures

The following sections explore these applications.

Storing Procedure Globals

If you create packages of procedures, for example data acquisition, data analysis, or a specialized plot type, you typically need to store global variables, strings and waves to maintain the state of your package. You should keep all such items in a data folder that you create with a unique name to reduce clutter and avoid conflicts with other packages.

If your package is inherently global in nature, data acquisition for example, create your data folder within a data folder named Packages that you create in the root data folder. If your package is named MyDataAcq, you would store your globals in root:Packages:MyDataAcq. See **Managing Package Data** on page IV-249 for details and examples.

On the other hand, if your package needs to create a group of variables and waves as a result of an operation on a single input wave, it makes sense to create your data folder in the one that holds the input wave (see the **GetWavesDataFolder** function on page V-317). Similarly, if you create a package that takes an entire data folder as input (via a DFREF parameter pointing to the data folder) and needs to create a data folder containing output, it should create the output data folder in the one, or possibly at the same level as the one containing the input.

If your package creates and maintains windows, it should create a master data folder in root:Packages and then create individual data folders within the master that correspond to each instance of a window. For example, a Smith Chart package would create a master data folder as root:Packages:SmithCharts: and then create individual data folders inside the master with names that correspond to the individual graphs.

A package designed to operate on traces within graphs would go one step further and create a data folder for each trace that it has worked on, inside the data folder for the graph. This technique is illustrated by the Smooth Control Panel procedure file. For a demonstration, choose File→Examples→Feature Demos→Smoothing Control Panel.

Storing Runs of Data

If you acquire data using a well-established experimental protocol, your data will have a well-defined structure. Each time you run your protocol, you produce a new data set with the same structure. Storing each data set in its own data folder avoids name conflicts between corresponding items of different data sets. It also simplifies the writing of procedures to analyze and compare data set.

To use a trivial example, your data might have a structure like this:

```
<Run of data>
   String: conditions
   Variable: temperature
   Wave: appliedVoltage
   Wave: luminosity
```

Having defined this structure, you could then write procedures to:

1. Load your data into a data folder
2. Create a graph showing the data from one run
3. Create a graph comparing the data from many runs

Writing these procedures is greatly simplified by the fact that the names of the items in a run are fixed. For example, step 2 could be written as:

```
Function GraphOneRun()  // Graphs data run in the current data folder.
   SVAR conditions
   NVAR temperature
   WAVE appliedVoltage, luminosity

   Display luminosity vs appliedVoltage

   String text
   sprintf text, "Temperature: %g.\rExperimental conditions: %s.",
         temperature, conditions
   Textbox text
End
```

To create a graph, you would first set the current data folder to point to a run of data and then you would invoke the GraphOneRun function.

The Data Folder Tutorial experiment shows in detail how to accomplish the three steps listed above. Choose File→Example Experiments→Tutorials→Data Folder Tutuorial.

Setting and Restoring the Current Data Folder

There are many reasons why you might want to save and restore the current data folder. In this example, we have a function that does a curve fit to a wave passed in as a parameter. The CurveFit operation creates two waves, W_coef and W_sigma, in the current data folder. If you use the /D option, it also creates a destination wave in the current data folder. In this function, we make sure that the W_coef, W_sigma and destination waves are all created in the same data folder as the source wave.

```
Function DoLineFit(w)
   WAVE w

   String saveDF = GetDataFolder(1)
   SetDataFolder GetWavesDataFolder(w,1)
   CurveFit line w /D
   SetDataFolder saveDF
End
```

Many other operations create output waves in the current data folder. Depending on what your goal is, you may want to use the technique shown here to control where the output waves are created.

A function should always save and restore the current data folder unless it is designed explicitly to change the current data folder.

Determining a Function’s Target Data Folder

There are three common methods for determining the data folder that a function works on or in:

1. Passing a wave in the target data folder as a parameter
2. Having the function work on the current data folder
3. Passing a DFREF parameter that points to the target data folder

For functions that operate on a specific wave, method 1 is appropriate.

For functions that operation on a large number of variables within a single data folder, methods 2 or 3 are appropriate. In method 2, the calling routine sets the data folder of interest as the current data folder. In method 3, the called function does this, and restores the original current data folder before it returns.

Clearing a Data Folder

There are times when you might want to clear a data folder before running a procedure, to remove things left over from a preceding run. If the data folder contains no child data folders, you can achieve this with:

```
KillWaves/A/Z; KillVariables/A/Z
```

If the data folder does contain child data folders, you could use the KillDataFolder operation. This operation kills a data folder and its contents, including any child data folders. You could kill the main data folder and then recreate it. A problem with this is that, if the data folder or its children contain a wave that is in use, you will generate an error which will cause your function to abort.

Here is a handy function that kills the contents of a data folder and the contents of its children without killing any data folders and without attempting to kill any waves that may be in use.

```
Function ZapDataInFolderTree(path)
   String path

   String saveDF = GetDataFolder(1)
   SetDataFolder path

   KillWaves/A/Z
   KillVariables/A/Z
   KillStrings/A/Z

   Variable i
   Variable numDataFolders = CountObjects(":", 4)
   for(i=0; i<numDataFolders; i+=1)
      String nextPath = GetIndexedObjName(":", 4, i)
      ZapDataInFolderTree(nextPath)
   endfor

   SetDataFolder saveDF
End
```

Using Strings

This section explains some common ways in which Igor procedures use strings. The most common techniques use built-in functions such as StringFromList and FindListItem. In addition to the built-in functions, there are a number of handy Igor procedure files in the WaveMetrics Procedures:Utilities:String Utilities folder.

Using Strings as Lists

Procedures often need to deal with lists of items. Such lists are usually represented as semicolon-separated text strings. The StringFromList function is used to extract each item, often in a loop. For example:

```
Function Test()
   Make jack,sam,fred,sue
   String list = WaveList("*",";","")
   Print list

   Variable numItems = ItemsInList(list), i
   for(i=0; i<numItems; i+=1)
      Print StringFromList(i,list)      // Print ith item
   endfor
End
```

For lists with a large number of items, using StringFromList as shown above is slow. This is because it must search from the start of the list to the desired item each time it is called. In Igor7 or later, you can iterate quickly using the optional StringFromList offset parameter:

```
Function Test()
   Make jack,sam,fred,sue
   String list = WaveList("*",";","")
   Print list

   Variable numItems = ItemsInList(list), i
   Variable offset = 0
   for(i=0; i<numItems; i+=1)
      String item = StringFromList(0, list, ";", offset) // Get ith item
      Print item
      offset += strlen(item) + 1
   endfor
End
```

See **ListToTextWave** for another fast way to iterate through the items in a large string list.

Using Keyword-Value Packed Strings

A collection of disparate values is often stored in a list of keyword-value pairs. For example, the TraceInfo and AxisInfo functions return such a list. The information in these strings follows this form

```
KEYWORD:value;KEYWORD:value; ...
```

The **keyword** is always upper case and followed by a colon. Then comes the **value** and a semicolon. When parsing such a string, you should avoid reliance on the specific ordering of keywords — the order is likely to change in future releases of Igor.

Two functions will extract information from keyword-value strings. NumberByKey is used when the data is numeric, and StringByKey is used when the information is in the form of text.

Using Strings with Extractable Commands

The **AxisInfo** and **TraceInfo** readback functions provide much of their information in a form that resembles the commands that you use to make the settings in the first place. For example, to set an axis to log mode, you would execute something like this:

```
ModifyGraph log(left)=1
```

If we now look at the characters of the string returned by AxisInfo we see:

```
AXTYPE:left;CWAVE:jack; ... RECREATION:grid(x)=0;log(x)=1 ...
```

To use this information, we need to extract the value following “log(x)=” and then use it in a ModifyGraph command with the extracted value with the desired graph as the target. Here is a user function that sets the log mode of the bottom axis to the same value as the left axis:

```
Function CopyLogMode()
   String info,text
   Variable pos
   info=AxisInfo("","left")
   pos= StrSearch(info,"RECREATION:",0) // skip to start of "RECREATION:"
   pos += strlen("RECREATION:")         // skip "RECREATION:", too
                                        // get text after "log(x)="
   text= StringByKey("log(x)",info[pos,inf],"=",";")

   String cmd = "ModifyGraph log(bottom)=" + text
   Execute cmd
End
```

Character-by-Character Operations

Igor functions like **strlen** and **strsearch**, as well as Igor string indexing (see **String Indexing** on page IV-16), are byte-oriented. That is, strlen returns the number of bytes in a string. Strsearch takes a byte position as a parameter. Expressions like `str[<index>]` return a single byte.

In Igor6, for western languages, each character is represented by a single byte, so the distinction between bytes and characters is insignificant, and byte-by-byte operations are sufficient.

In Igor7 and later, which use the UTF-8 text encoding to represent text in strings, all ASCII characters are represented by one byte but all non-ASCII characters are represented by multiple bytes (see **Text Encodings** on page III-459 for details). Consequently, byte-by-byte operations are insufficient for stepping through characters. Character-by-character operations are needed.

There is no straightforward way to step through text containing non-ASCII characters. In the rare cases where this is necessary, you can use the user-defined functions shown in this section.

The following functions show how to step through UTF-8 text character-by-character rather than byte-by-byte.

```
// NumBytesInUTF8Character(str, byteOffset)
// Returns the number of bytes in the UTF-8 character that starts byteOffset
// bytes from the start of str.
// NOTE: If byteOffset is invalid this routine returns 0.
//       Also, if str is not valid UTF-8 text, this routine return 1.
Function NumBytesInUTF8Character(str, byteOffset)
   String str
   Variable byteOffset

   Variable numBytesInString = strlen(str)
   if (byteOffset<0 || byteOffset>=numBytesInString)
      return 0          // Programmer error
   endif

   Variable firstByte = char2num(str[byteOffset]) & 0x00FF

   if (firstByte < 0x80)
      return 1
   endif

   if (firstByte>=0xC2 && firstByte<=0xDF)
      return 2
   endif

   if (firstByte>=0xE0 && firstByte<=0xEF)
      return 3
   endif

   if (firstByte>=0xF0 && firstByte<=0xF4)
      return 4
   endif

   // If we are here, str is not valid UTF-8.
   // Treat the first byte as a 1-byte character.
   // This prevents infinite loops.
   return 1
End

Function UTF8CharactersInString(str)
   String str

   Variable numCharacters = 0

   Variable length = strlen(str)
   Variable byteOffset = 0
   do
      if (byteOffset >= length)
         break
      endif
      Variable numBytesInCharacter = NumBytesInUTF8Character(str, byteOffset)
      if (numBytesInCharacter <= 0)
         Abort "Bug in CharactersInUTF8String"     // Should not happen
      endif
      numCharacters += 1
      byteOffset += numBytesInCharacter
   while(1)

   return numCharacters
End

Function/S UTF8CharacterAtPosition(str, charPos)
   String str
   Variable charPos

   if (charPos < 0)
      // Print "charPos is invalid"             // For debugging only
      return ""
   endif

   Variable length = strlen(str)
   Variable byteOffset = 0
   do
      if (byteOffset >= length)
         // Print "charPos is out-of-range"     // For debugging only
         return ""
      endif
      if (charPos == 0)
         break
      endif
      Variable numBytesInCharacter = NumBytesInUTF8Character(str, byteOffset)
      byteOffset += numBytesInCharacter
      charPos -= 1
   while(1)

   numBytesInCharacter = NumBytesInUTF8Character(str, byteOffset)
   String result = str[byteOffset, byteOffset+numBytesInCharacter-1]
   return result
End

Function DemoCharacterByCharacter()
   String str = "<string containing non-ASCII text>"

   Variable numCharacters = UTF8CharactersInString(str)
   Variable charPos

   for(charPos=0; charPos<numCharacters; charPos+=1)
      String character = UTF8CharacterAtPosition(str, charPos);
      Printf "CharPos=%d, char=\"%s\"\r", charPos, character
   endfor
End
```

Working With Binary String Data

Although Igor strings were originally conceived to store human-readable text such (e.g., "Hello, World"), advanced users have found them useful as containers for binary data. Such binary data is usually read from binary files, obtained from the Internet (e.g., via **FetchURL** or **URLRequest**), or obtained via data acquisition.

It is sometimes useful to store the bytes contained in a string into a byte wave so commands that work on waves can be used to analyze the contents. One example is determining the frequency of each letter in a piece of text for a linguistic analysis or analysis of DNA/RNA/protein sequences. Another use is to convert the bytes of a downloaded string into a numeric wave. Igor provides the **StringToUnsignedByteWave** and **WaveDataToString** functions to make facilitate such analyses. These functions were added in Igor Pro 9.00.

Examples can be found at https://www.wavemetrics.com/code-snippet/working-binary-string-data-examples.

Regular Expressions

A regular expression is a pattern that is matched against a subject string from left to right. Regular expressions are used to identify lines of text containing a particular pattern and to extracts substrings matching a particular pattern.

A regular expression can contain regular characters that match the same character in the subject and special characters, called "metacharacters", that match any character, a list of specific characters, or otherwise identify patterns.

The regular expression syntax is based on PCRE — the Perl-Compatible Regular Expression Library.

Igor syntax is similar to regular expressions supported by various UNIX and POSIX `egrep(1)` commands.

See **Regular Expressions References** on page IV-194 for details on PCRE.

Regular Expression Operations and Functions

Here are the Igor operations and functions that work with regular expressions:

Grep

The **Grep** operation identifies lines of text that match a pattern.

The subject is each line of a file or each row of a text wave or each line of the text in the clipboard.

Output is stored in a file or in a text wave or in the clipboard.

Grep Example

```
Function DemoGrep()
   Make/T source={"Monday","Tuesday","Wednesday","Thursday","Friday"}
   Make/T/N=0 dest
   Grep/E="sday" source as dest           // Find rows containing "sday"
   Print dest
End
```

The output from Print is:

```
   dest[0]= {"Tuesday","Wednesday","Thursday"}
```

GrepList

The **GrepList** function identifies items that match a pattern in a string containing a delimited list.

The subject is each item in the input list.

The output is a delimited list returned as the function result.

GrepList Example

```
Function DemoGrepList()
   String source = "Monday;Tuesday;Wednesday;Thursday;Friday"
   String dest = GrepList(source, "sday") // Find items containing "sday"
   Print dest
End
```

The output from Print is:

```
   Tuesday;Wednesday;Thursday;
```

GrepString

The **GrepString** function determines if a particular pattern exists in the input string.

The subject is the input string.

The output is 1 if the input string contains the pattern or 0 if not.

GrepString Example

```
Function DemoGrepString()
   String subject = "123.45"
   String regExp = "[0-9]+"             // Match one or more digits
   Print GrepString(subject,regExp)     // True if subject contains digit(s)
End
```

The output from Print is: 1

SplitString

The **Demo** operation identifies subpatterns in the input string.

The subject is the input string.

Output is stored in one or more string output variables.

SplitString Example

```
Function DemoSplitString()
   String subject = "Thursday, May 7, 2009"
   String regExp = "([[:alpha:]]+), ([[:alpha:]]+) ([[:digit:]]+), ([[:digit:]]+)"
   String dayOfWeek, month, dayOfMonth, year
   SplitString /E=(regExp) subject, dayOfWeek, month, dayOfMonth, year
   Print dayOfWeek, month, dayOfMonth, year
End
```

The output from Print is:

```
   Thursday  May  7  2009
```

Basic Regular Expressions

Here is a **Grep** command that uses "Fred" as the regular expression. "Fred" contains no metacharacters so this command identifies lines of text containing the literal string "Fred". It examines each line from the input file, afile.txt. All lines containing the pattern "Fred" are written to the output file, "FredFile.txt":

```
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
```

Character matching is case-sensitive by default. Prepending the Perl 5 modifier (?i) gives a case-insensitive pattern that matches upper and lower-case versions of “Fred”:

```
// Copy lines that contain "Fred", "fred", "FRED", "fREd", etc
Grep/P=myPath/E="(?i)fred" "afile.txt" as "AnyFredFile.txt"
```

To copy lines that do not match the regular expression, use the Grep /E flag with the optional *reverse* parameter set to 1 to reverse the sense of the match:

```
// Copy lines that do NOT contain "Fred", "fred", "fREd", etc
Grep/P=myPath/E={"(?i)fred",1} "afile.txt" as "NotFredFile.txt"
```

Note: Igor doesn't use the Perl opening and closing regular expression delimiter character which is the forward slash. In Perl you would use `"/Fred/"` and `"/(?i)fred/"`.

Regular Expression Metacharacters

The power of regular expressions comes from the ability to include alternatives and repetitions in the pattern. These are encoded in the pattern by the use of “metacharacters”, which do not stand for themselves but instead are interpreted in some special way.

There are two different sets of metacharacters: those that are recognized anywhere in the pattern except within brackets, and those that are recognized in brackets. Outside brackets, the metacharacters are as follows:

`\`	General escape character with several uses
`^`	Match start of string
`$`	Match end of string
`.`	Match any character except newline (by default)
	(To match newline, see **Matching Newlines** on page IV-184)
`[`	Start character class definition (for matching one of a set of characters)
`|`	Start of alternative branch (for matching one or the other of two patterns)
`(`	Start subpattern
`)`	End subpattern
`?`	0 or 1 quantifier (for matching 0 or 1 occurrence of a pattern)
	Also extends the meaning of (
	Also quantifier minimizer
`*`	0 or more quantifier (for matching 0 or more occurrence of a pattern)
`+`	1 or more quantifier (for matching 1 or more occurrence of a pattern)
	Also possessive quantifier
`{`	Start min/max quantifier (for matching a number or range of occurrences)

Character Classes in Regular Expressions

A character class is a set of characters and is used to specify that one character of the set should be matched. Character classes are introduced by a left-bracket and terminated by a right-bracket. For example:

```
[abc]       Matches a or b or c

[A-Z]       Matches any character from A to Z

[A-Za-z]    Matches any character from A to Z or a to z.
```

POSIX character classes specify the characters to be matched symbolically. For example:

```
[[:alpha:]] Matches any alphabetic character (A to Z or a to z).

[[:digit:]] Matches 0 to 9.
```

In a character class the only metacharacters are:

`\`	General escape character
`^`	Negate the class, but only if ^ is the first character
`-`	Indicates character range
`[`	POSIX character class (only if followed by POSIX syntax)

`]`	Terminates the character class

Backslash in Regular Expressions

The backslash character has several uses. First, if it is followed by a nonalphanumeric character, it takes away any special meaning that character may have. This use of backslash as an escape character applies both inside and outside character classes.

For example, the * character normally means "match zero or more of the preceding subpattern". If you want to match a `*` character, you write `\*` in the pattern. This escaping action applies whether or not the following character would otherwise be interpreted as a metacharacter, so it is always safe to precede a nonalphanumeric with backslash to specify that it stands for itself. In particular, if you want to match a backslash, you write `\\`.

Note: Because Igor also has special uses for backslash (see **Escape Sequences in Strings** on page IV-14), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes sends one backslash to, say, the **Grep** command.

For example, to copy lines that contain a backslash followed by a *z* character, the Perl pattern would be `"\\z"`, but the equivalent Igor Grep expression would be `/E="\\\\z"`.

Igor's input string parser converts "`\\`" to "`\`" so, when you write `/E="\\\\z"`, the regular expression engine sees `/E="\\z"`.

This difference is important enough that the PCRE and Igor Patterns (using Grep /E syntax) are both shown below when they differ.

Only ASCII numbers and letters have any special meaning after a backslash. All other characters are treated as literals.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between `\Q` and `\E`. This is different from Perl in that `$` and `@` are handled as literals in `\Q`…`\E` sequences in PCRE, whereas in Perl, `$` and `@` cause variable interpolation. Note the following examples:

Igor Pattern	PCRE Pattern	PCRE Matches	Perl Matches
`\\Qabc$xyz\\E`	`\Qabc$xyz\E`	abc\$xyz	abc followed by the contents of \$xyz
`\\Qabc\\$xyz\\E`	`\Qabc\$xyz\E`	abc\\$xyz	abc\\$xyz
`\\Qabc\\E\\$\\Qxyz\\E`	`\Qabc\E\$\Qxyz\E`	abc\$xyz	abc\$xyz

The `\Q`…`\E` sequence is recognized both inside and outside character classes.

Backslash and Nonprinting Characters

A second use of backslash provides a way of encoding nonprinting characters in patterns in a visible manner. There is no restriction on where nonprinting characters can occur, apart from the binary zero that terminates a pattern, but when a pattern is being prepared by text editing, it is usually easier to use one of the following escape sequences than the binary character it represents:

Igor Pattern	PCRE Pattern	Character Matched
`\\a`	`\a`	Alarm, that is, the BEL character (hex 07)
`\\cx`	`\cx`	“Control-x”, where x is any character
`\\e`	`\e`	Escape (hex 1B)
`\\f`	`\f`	Formfeed (hex 0C)
`\\n`	`\n`	Newline (hex 0A)
`\\r`	`\r`	Carriage return (hex 0D)

Igor Pattern	PCRE Pattern	Character Matched
`\\t`	`\t`	Tab (hex 09)
`\\ddd`	`\ddd`	Character with octal code ddd, or backreference
`\\xhh`	`\xhh`	Character with hex code hh

Backslash and Nonprinting Characters Arcania

The material in this section is arcane and rarely needed. We recommend that you skip it.

The precise effect of `\cx` is if `x` is a lower case letter, it is converted to upper case. Then bit 6 of the character (hex 40) is inverted. Thus `\cz` becomes hex 1A, but `\c{` becomes hex 3B, while `\c;` becomes hex 7B.

After `\x`, from zero to two hexadecimal digits are read (letters can be in upper or lower case). If characters other than hexadecimal digits appear between `\x{` and `}`, or if there is no terminating `}`, this form of escape is not recognized. Instead, the initial `\x` will be interpreted as a basic hexadecimal escape, with no following digits, giving a character whose value is zero.

After `\0` up to two further octal digits are read. In both cases, if there are fewer than two digits, just those that are present are used. Thus the sequence `\0\x\07` specifies two binary zeros followed by a BEL character (code value `7`). Make sure you supply two digits after the initial zero if the pattern character that follows is itself an octal digit.

The handling of a backslash followed by a digit other than 0 is complicated. Outside a character class, PCRE reads it and any following digits as a decimal number. If the number is less than 10, or if there have been at least that many previous capturing left parentheses in the expression, the entire sequence is taken as a back reference. A description of how this works is given later, following the discussion of parenthesized subpatterns.

Inside a character class, or if the decimal number is greater than 9 and there have not been that many capturing subpatterns, PCRE rereads up to three octal digits following the backslash, and generates a single byte from the least significant 8 bits of the value. Any subsequent digits stand for themselves. For example:

Igor Pattern	PCRE Pattern	Character(s) Matched
`\\040`	`\040`	Another way of writing a space
`\\40`	`\40`	A space, provided there are fewer than 40 previous capturing subpatterns
`\\7`	`\7`	Always a back reference
`\\11`	`\11`	Might be a back reference, or another way of writing a tab
`\\011`	`\011`	Always a tab
`\\0113`	`\0113`	A tab followed by the character “3”
`\\113`	`\113`	Might be a back reference, otherwise the character with octal code 113
`\\377`	`\377`	Might be a back reference, otherwise the byte consisting entirely of 1 bits
`\\81`	`\81`	Either a back reference or a binary zero followed by the two characters “8” and “1”

Note that octal values of 100 or greater must not be introduced by a leading zero, because no more than three octal digits are ever read.

All the sequences that define a single byte value can be used both inside and outside character classes. In addition, inside a character class, the sequence `\b` is interpreted as the backspace character (hex 08), and the sequence `\X` is interpreted as the character *X*. Outside a character class, these sequences have different meanings (see **Backslash and Nonprinting Characters** on page IV-179).

Backslash and Generic Character Types

The third use of backslash is for specifying generic character types. The following are always recognized:

Igor Pattern	PCRE Pattern	Character(s) Matched
`\\d`	`\d`	Any decimal digit
`\\D`	`\D`	Any character that is not a decimal digit
`\\s`	`\s`	Any whitespace character
`\\S`	`\S`	Any character that is not a whitespace character
`\\w`	`\w`	Any “word” character
`\\W`	`\W`	Any “nonword” character

Each pair of escape sequences, such as `\d` and `\D`, partitions the complete set of characters into two disjoint sets. Any given character matches one, and only one, of each pair.

These character type sequences can appear both inside and outside character classes. They each match one character of the appropriate type. If the current matching point is at the end of the subject string, all of them fail, since there is no character to match.

The `\s` whitespace characters are HT (9), LF (10), VT (11), FF (12), CR (13), and space (32). In Igor Pro 6 `\s` did not match the VT character (code 11).

A “word” character is an underscore or any character that is a letter or digit.

Backslash and Simple Assertions

The fourth use of backslash is for certain simple assertions. An assertion specifies a condition that has to be met at a particular point in a match without consuming any characters from the subject string. The use of subpatterns for more complicated assertions is described in **Assertions** on page IV-190. The backslashed assertions are:

Igor Pattern	PCRE Pattern	Character(s) Matched
`\\b`	`\b`	At a word boundary
`\\B`	`\B`	Not at a word boundary
`\\A`	`\A`	At start of subject
`\\Z`	`\Z`	At end of subject or before newline at end
`\\z`	`\z`	At end of subject
`\\G`	`\G`	At first matching position in subject

These assertions may not appear in character classes (but note that `\b` has a different meaning, namely the backspace character, inside a character class).

A word boundary is a position in the subject string where the current character and the previous character do not both match `\w` or `\W` (i.e. one matches `\w` and the other matches `\W`), or the start or end of the string if the first or last character matches `\w`, respectively.

While PCRE defines additional simple assertions (`\A`, `\Z`, `\z` and `\G`), they are not any more useful to Igor’s regular expression commands than the `^` and `$` characters.

Circumflex and Dollar

Outside a character class, in the default matching mode, the circumflex character `^` is an assertion that is true only if the current matching point is at the start of the subject string. Inside a character class, circumflex has an entirely different meaning (see **Character Classes and Brackets** on page IV-182).

Circumflex need not be the first character of the pattern if a number of alternatives are involved, but it should be the first thing in each alternative in which it appears if the pattern is ever to match that branch. If all possible alternatives start with a circumflex, that is, if the pattern is constrained to match only at the start of the subject, it is said to be an “anchored” pattern. (There are also other constructs that can cause a pattern to be anchored.)

A dollar character `$` is an assertion that is true only if the current matching point is at the end of the subject string, or immediately before a newline character that is the last character in the string (by default). Dollar need not be the last character of the pattern if a number of alternatives are involved, but it should be the last item in any branch in which it appears. Dollar has no special meaning in a character class.

Dot, Period, or Full Stop

Outside a character class, a dot in the pattern matches any one character in the subject, including a nonprinting character, but not (by default) newline. Dot has no special meaning in a character class.

The match option setting (?s) changes the default behavior of dot so that it matches any character including newline. The setting can appear anywhere before the dot in the pattern. See **Matching Newlines** on page IV-184 for details.

Character Classes and Brackets

An opening bracket introduces a character class which is terminated by a closing bracket. A closing bracket on its own is not special. If a closing bracket is required as a member of the class, it must be the first data character in the class (after an initial circumflex, if present) or escaped with a backslash.

A character class matches a single character in the subject. A matched character must be in the set of characters defined by the class, unless the first character in the class definition is a circumflex, in which case the subject character must not be in the set defined by the class. If a circumflex is actually required as a member of the class, ensure it is not the first character, or escape it with a backslash.

For example, the character class `[aeiou]` matches any English lower case vowel, whereas `[^aeiou]` matches any character that is not an English lower case vowel. Note that a circumflex is just a convenient notation for specifying the characters that are in the class by enumerating those that are not.

When caseless matching is set, using the `(?i)` match option setting, any letters in a class represent both their upper case and lower case versions, so for example, the caseless pattern `(?i)[aeiou]` matches *A* as well as *a*, and the caseless pattern `(?i)[^aeiou]` does not match *A*.

The minus (hyphen) character can be used to specify a range of characters in a character class. For example, `[d-m]` matches any letter between *d* and *m*, inclusive. If a minus character is required in a class, it must be escaped with a backslash or appear in a position where it cannot be interpreted as indicating a range, typically as the first or last character in the class.

To include a right-bracket in a range you must use `\]`. As usual, this would be represented in a literal Igor string as `\\]`.

Though it is rarely needed, you can specify a range using octal numbers, for example `[\000-\037]`.

The character types `\d`, `\D`, `\p`, `\P`, `\s`, `\S`, `\w`, and `\W` may also appear in a character class, and add the characters that they match to the class. For example, `[\dABCDEF]` matches any hexadecimal digit. A circumflex can conveniently be used with the upper case character types to specify a more restricted set of characters than the matching lower case type. For example, the class `[^\W_]` matches any letter or digit, but not underscore. The corresponding **Grep** command would begin with

```
Grep/E="[^\\W_]"…
```

The only metacharacters that are recognized in character classes are backslash, hyphen (only where it can be interpreted as specifying a range), circumflex (only at the start), opening bracket (only when it can be interpreted as introducing a POSIX class name — see **POSIX Character Classes** on page IV-183), and the terminating closing bracket. However, escaping other nonalphanumeric characters does no harm.

POSIX Character Classes

Perl supports the POSIX notation for character classes. This uses names enclosed by `[:` and `:]` within the enclosing brackets. PCRE also supports this notation. For example,

```
[01[:alpha:]%]
```

matches “0”, “1”, any alphabetic character, or “%”.

The supported class names, all of which must appear between `[:` and `:]` inside a character class specification, are

`alnum`	Letters and digits.
`alpha`	Letters.
`ascii`	Character codes 0 - 127.
`blank`	Space or tab only.
`cntrl`	Control characters.
`digit`	Decimal digits (same as `\d`).
`graph`	Printing characters, excluding space. [:graph:] matches all characters with the Unicode L, M, N, P, S, or Cf properties with a few arcane exceptions.
`lower`	Lower case letters.
`print`	Printing characters, including space. [:print:] matches the same characters as [:graph:] plus space characters that are not controls, that is, characters with the Unicode Zs property.
`punct`	Printing characters, excluding letters and digits. [:punct:] matches all characters that have the Unicode P (punctuation) property, plus those characters whose code points are less than 128 that have the S (Symbol) property.
`space`	White space (not quite the same as `\s`).
`upper`	Upper case letters.
`word`	“Word” characters (same as `\w`).
`xdigit`	Hexadecimal digits.

The “space” characters are horizontal tab (`HT-9`), linefeed (`LF-10`), vertical tab (`VT-11`), formfeed (`FF-12`), carriage-return (`CR-13`), and space (`32`).

The class name `word` is a Perl extension, and `blank` is a GNU extension from Perl 5.8. Another Perl extension is negation that is indicated by a `^` character after the colon. For example,

```
[12[:^digit:]]
```

matches “1”, “2”, or any nondigit. PCRE (and Perl) also recognize the POSIX syntax `[.ch.]` and `[=ch=]` where “ch” is a “collating element”, but these are not supported, and an error is given if they are encountered.

Alternation

Vertical bar characters are used to separate alternative patterns. For example, the pattern

```
gilbert|sullivan
```

matches either “gilbert” or “sullivan”. Any number of alternative patterns may be specified, and an empty alternative is permitted (matching the empty string). The matching process tries each alternative in turn, from left to right, and the first one that succeeds is used. If the alternatives are within a subpattern (defined in **Subpatterns** on page IV-186), “succeeds” means matching the rest of the main pattern as well as the alternative in the subpattern.

Match Option Settings

Character matching options can be changed from within the pattern by a sequence of Perl option letters enclosed between `(?` and `)`. The option letters are:

Option	PCRE Name	Characters Matched
i	PCRE_CASELESS	Upper and lower case.
m	PCRE_MULTILINE	^ matches start of string and just after a new line (\n). $ matches end of string and just before a new line. Without (?m), ^ and $ match only the start and end of the entire string.
s	PCRE_DOTALL	. matches all characters including newline. Without (?s), . does not match newlines. See **Matching Newlines** on page IV-184.
U	PCRE_UNGREEDY	Reverses the "greediness" of the quantifiers so that they are not greedy by default, but become greedy if followed by ?.

For example, `(?i)` sets caseless matching.

You can unset these options by preceding the letter with a hyphen: (?-i) turns off caseless matching.

You can combine a setting and unsetting such as `(?i-U)`, which sets PCRE_CASELESS while unsetting PCRE_UNGREEDY.

When an option change occurs at top level (that is, not inside subpattern parentheses), the change applies to the remainder of the pattern that follows. If the change is placed right at the start of a pattern, PCRE extracts it into the global options.

An option change within a subpattern affects only that part of the current pattern that follows it, so

```
(a(?i)b)c
```

matches abc and aBc and no other strings.

Any changes made in one alternative do carry on into subsequent branches within the same subpattern. For example,

```
(a(?i)b|c)
```

matches “ab”, “aB”, “c”, and “C”, even though when matching “C” the first branch is abandoned before the option setting. This is because the effects of option settings happen at compile time.

The other PCRE 5-specific options, such as (?e), (?A), (?D), (?S), (?x) and (?X), are implemented but are not very useful with Igor's regular expression commands.

Matching Newlines

Igor generally uses carriage-return (ASCII code 13) return to indicate a new line in text. This is represented in a literal string by "\r". For example:

```
Print "Hello\rGoodbye"
```

prints two lines of text to the history area.

However, in regular expressions, the newline character is linefeed (ASCII code 10). This is represented in a literal string by "\n". Carriage-return has no special status in regular expressions.

The match option setting `(?s)` changes the default behavior of dot so that it matches any character including newline. The setting can appear anywhere before the dot in the pattern. For example:

```
Function DemoNewline(includeNewline)
   Variable includeNewline

   String subject = "Hello\nGoodbye"   // \n represents newline

   String regExp
   if (includeNewline)
      regExp = "(?s)(.+)"      // One or more of any character
   else
      regExp = "(.+)"          // One or more of any character except newline
   endif

   String result
   SplitString /E=(regExp) subject, result
   Print result
End
```

The output from DemoNewline(0) is:

```
   Hello
```

The output from DemoNewline(1) is:

```
   Hello\nGoodbye
```

Here is a more realistic example:

```
Function DemoDotAll()
   String theString = ExampleHTMLString()

   // This regular expression attempts to extract items from
   // HTML code for an ordered list. It fails because the HTML
   // code contains newlines and, by default, . does not match newlines.
   String regExpFails="<li>(.*?)</li>.*<li>(.*?)</li>"
   String str1, str2
   SplitString/E=regExpFails theString, str1, str2
   Print V_flag, " subpatterns were matched using regExpFails"
   Printf "\"%s\", \"%s\"\r", str1, str2

   // This regular expression works because the "(?s)" match
   // option setting causes . to match newlines.
   String regExpWorks="(?s)<li>(.*?)</li>.*<li>(.*?)</li>"
   SplitString/E=regExpWorks theString, str1, str2
   Print V_flag, " subpatterns were matched using regExpWorks"
   Printf "\"%s\", \"%s\"\r", str1, str2
End
Function/S ExampleHTMLString()   // Returns HTML code containing newlines
   String theString = ""
   theString += "<ol>\n"
   theString += "\t<li>item 1</li>\n"
   theString += "\t<li>item 2</li>\n"
   theString += "<\ol>\n"
   return theString
End
```

```
•DemoDotAll()
  0   subpatterns were matched using regExpFails
  "", ""
  2 subpatterns were matched using regExpWorks
  "item 1", "item 2"
```

Subpatterns

Subpatterns are used to group alternatives, to match a previously-matched pattern again, and to extract match text using **Demo**.

Subpatterns are delimited by parentheses, which can be nested. Turning part of a pattern into a subpattern localizes a set of alternatives. For example, this pattern (which includes two vertical bars signifying alternation):

```
cat(aract|erpillar|)
```

matches one of the words "cat", "cataract", or "caterpillar". Without the parentheses, it would match "cataract", "erpillar" or the empty string.

Named Subpatterns

Specifying subpatterns by number is simple, but it can be very hard to keep track of the numbers in complicated regular expressions. Furthermore, if an expression is modified, the numbers may change. To help with this difficulty, PCRE supports the naming of subpatterns, something that Perl does not provide. The Python syntax (`?P<`*`name`*`>`...) is used. For example:

```
My (?P<catdog>cat|dog) is cooler than your (?P=catdog)
```

Here catdog is the name of the first and only subpattern. `?P<catdog>` names the subpattern and `(?P=catdog)` matches the previous match for that subpattern.

Names consist of alphanumeric characters and underscores, and must be unique within a pattern.

Named capturing parentheses are still allocated numbers as well as names. This has the same effect as the previous example:

```
My (?P<catdog>cat|dog) is cooler than your \\1
```

Repetition

Repetition is specified by quantifiers:

?	0 or 1 quantifier Example: `[abc]?` - Matches 0 or 1 occurrences of a or b or c
*	0 or more quantifier Example: `[abc]*` - Matches 0 or more occurrences of a or b or c
+	1 or more quantifier Example: `[abc]+` - Matches 1 or more occurrences of a or b or c
{n}	n times quantifier Example: `[abc]{3}` - Matches 3 occurrences of a or b or c
{n,m}	n to m times quantifier Example: `[abc]{3,5}` - Matches 3 to 5 occurrences of a or b or c

Quantifiers can follow any of the following items:

- A literal data character
- The . metacharacter
- The \C escape sequence
- An escape such as \d that matches a single character
- A character class

- A back reference (see **Back References** on page IV-189)
- A parenthesized subpattern (unless it is an assertion)

The general repetition quantifier specifies a minimum and maximum number of permitted matches, by giving the two numbers in braces, separated by a comma. The numbers must be less than 65536, and the first must be less than or equal to the second. For example:

```
z{2,4}
```

matches “zz”, “zzz”, or “zzzz”.

If the second number is omitted, but the comma is present, there is no upper limit; if the second number and the comma are both omitted, the quantifier specifies an exact number of required matches. Thus

```
[aeiou]{3,}
```

matches at least 3 successive vowels, but may match many more, while

```
\d{8}
```

matches exactly 8 digits. A left brace that appears in a position where a quantifier is not allowed, or one that does not match the syntax of a quantifier, is taken as a literal character. For example, `{,6}` is not a quantifier, but a literal string of four characters.

Quantifiers apply to characters rather than to individual data units. Thus, for example, \x{100}{2} matches two characters, each of which is represented by a two-byte sequence in a UTF-8 string. Similarly, \X{3} matches three Unicode extended grapheme clusters, each of which may be several data units long (and they may be of different lengths).

The quantifier `{0}` is permitted, causing the expression to behave as if the previous item and the quantifier were not present.

For convenience (and historical compatibility) the three most common quantifiers have single-character abbreviations:

`*`	Equivalent to `{0,}`
`+`	Equivalent to `{1,}`
`?`	Equivalent to `{0,1}`

It is possible to construct infinite loops by following a subpattern that can match no characters with a quantifier that has no upper limit, for example:

```
(a?)*
```

Earlier versions of Perl and PCRE used to give an error at compile time for such patterns. However, because there are cases where this can be useful, such patterns are now accepted, but if any repetition of the subpattern does in fact match no characters, the loop is forcibly broken.

Quantifier Greediness

By default, the quantifiers are “greedy”, that is, they match as much as possible (up to the maximum number of permitted times), without causing the rest of the pattern to fail. The classic example of where this gives problems is in trying to match comments in C programs. These appear between `/*` and `*/` and within the comment, individual `*` and `/` characters may appear. An attempt to match C comments by applying the pattern

```
/\*.*\*/        or    Grep/E="/\\*.*\\*/"
```

to the string

```
/* first comment */  not comment  /* second comment */
```

fails because it matches the entire string owing to the greediness of the `.*` item.

However, if a quantifier is followed by a question mark, it ceases to be greedy, and instead matches the minimum number of times possible, so the pattern

```
/\*.*?\*/        or    Grep/E="/\\*.*?\\*/"
```

does the right thing with the C comments. The meaning of the various quantifiers is not otherwise changed, just the preferred number of matches.

Do not confuse this use of question mark with its use as a quantifier in its own right. Because it has two uses, it can sometimes appear doubled, as in

```
\d??\d           or    Grep/E="\\d??\\d"
```

which matches one digit by preference, but can match two if that is the only way the rest of the pattern matches.

If the PCRE_UNGREEDY option `(?U)` is set, the quantifiers are not greedy by default, but individual ones can be made greedy by following them with a question mark. In other words, it inverts the default behavior.

Quantifiers With Subpatterns

When a parenthesized subpattern is quantified with a minimum repeat count that is greater than 1 or with a limited maximum, more memory is required for the compiled pattern, in proportion to the size of the minimum or maximum.

When a capturing subpattern is repeated, the value captured is the substring that matched the final iteration. For example, after

```
(tweedle[dume]{3}\s*)+   or    Grep/E="(tweedle[dume]{3}\\s*)+"
```

has matched "tweedledum tweedledee" the value of the captured substring is "tweedledee". However, if there are nested capturing subpatterns, the corresponding captured values may have been set in previous iterations. For example, after

```
/(a|(b))+/
```

matches "aba" the value of the second captured substring is "b".

Atomic Grouping and Possessive Quantifiers

With both maximizing and minimizing repetition, failure of what follows normally reevaluates the repeated item to see if a different number of repeats allows the rest of the pattern to match. Sometimes it is useful to prevent this, either to change the nature of the match, or to cause it fail earlier than it otherwise might, when the author of the pattern knows there is no point in carrying on.

Consider, for example, the pattern `\d+foo` when applied to the subject line

```
123456bar
```

After matching all 6 digits and then failing to match "foo", the normal action of the matcher is to try again with only 5 digits matching the `\d+` item, and then with 4, and so on, before ultimately failing. "Atomic grouping" provides the means for specifying that once a subpattern has matched, it is not to be reevaluated in this way.

If we use atomic grouping for the previous example, the matcher would give up immediately on failing to match "foo" the first time. The notation is a kind of special parenthesis, starting with `(?>` as in this example:

```
(?>\d+)foo       or    Grep/E="(?>\\d+)foo"
```

This kind of parenthesis "locks up" the part of the pattern it contains once it has matched, and a failure further into the pattern is prevented from backtracking into it. Backtracking past it to previous items, however, works as normal.

An alternative description is that a subpattern of this type matches the string of characters that an identical standalone pattern would match, if anchored at the current point in the subject string.

Atomic grouping subpatterns are not capturing subpatterns. Simple cases such as the above example can be thought of as a maximizing repeat that must swallow everything it can. So, while both `\d+` and `\d+?`

are prepared to adjust the number of digits they match in order to make the rest of the pattern match, `(?>\d+)` can only match an entire sequence of digits.

Atomic groups in general can of course contain arbitrarily complicated subpatterns, and can be nested. However, when the subpattern for an atomic group is just a single repeated item, as in the example above, a simpler notation, called a “possessive quantifier” can be used. This consists of an additional + character following a quantifier. Using this notation, the previous example can be rewritten as

```
\d++foo         or    Grep/E="\\d++foo"
```

Possessive quantifiers are always greedy; the setting of the PCRE_UNGREEDY option is ignored. They are a convenient notation for the simpler forms of atomic group. However, there is no difference in the meaning or processing of a possessive quantifier and the equivalent atomic group.

The possessive quantifier syntax is an extension to the Perl syntax. It originates in Sun’s Java package.

When a pattern contains an unlimited repeat inside a subpattern that can itself be repeated an unlimited number of times, the use of an atomic group is the only way to avoid some failing matches taking a very long time indeed. The pattern

```
(\D+|<\d+>)*[!?]  or    Grep/E="(\\D+|<\\d+>)*[!?]"
```

matches an unlimited number of substrings that either consist of nondigits, or digits enclosed in <>, followed by either `!` or `?`. When it matches, it runs quickly. However, if it is applied to

```
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
```

it takes a long time before reporting failure. This is because the string can be divided between the internal `\D+` repeat and the external `*` repeat in a large number of ways, and all have to be tried. (The example uses `[!?]` rather than a single character at the end, because both PCRE and Perl have an optimization that allows for fast failure when a single character is used. They remember the last single character that is required for a match, and fail early if it is not present in the string.) If the pattern is changed so that it uses an atomic group, like this:

```
((?>\D+)|<\d+>)*[!?]     or    Grep/E="((?>\\D+)|<\\d+>)*[!?]"
```

sequences of nondigits cannot be broken, and failure happens quickly.

Back References

Outside a character class, a backslash followed by a digit greater than 0 (and possibly further digits) is a back reference to a capturing subpattern earlier (that is, to its left) in the pattern, provided there have been that many previous capturing left parentheses.

However, if the decimal number following the backslash is less than 10, it is always taken as a back reference, and causes an error only if there are not that many capturing left parentheses in the entire pattern. In other words, the parentheses that are referenced need not be to the left of the reference for numbers less than 10. See **Backslash and Nonprinting Characters** on page IV-179 for further details of the handling of digits following a backslash.

A back reference matches whatever actually matched the capturing subpattern in the current subject string, rather than anything matching the subpattern itself (see **Subpatterns as Subroutines** on page IV-194 for a way of doing that). So the pattern

```
(sens|respons)e and \1ibility or /E="(sens|respons)e and \\1ibility"
```

matches “sense and sensibility” and “response and responsibility”, but not “sense and responsibility”. If caseful matching is in force at the time of the back reference, the case of letters is relevant. For example,

```
((?i)rah)\s+\1    or    Grep/E="((?i)rah)\\s+\\1"
```

matches “rah rah” and “RAH RAH”, but not “RAH rah”, even though the original capturing subpattern is matched caselessly.

Back references to named subpatterns use the Python syntax (?P<name>). We could rewrite the above example as follows:

```
(?P<p1>(?i)rah)\s+(?P=p1)   or     Grep/E="(?P<p1>(?i)rah)\\s+(?P=p1)"
```

There may be more than one back reference to the same subpattern. If a subpattern has not actually been used in a particular match, any back references to it always fail. For example, the pattern

```
(a|(bc))\2
```

always fails if it starts to match "a" rather than "bc". Because there may be many capturing parentheses in a pattern, all digits following the backslash are taken as part of a potential back reference number. If the pattern continues with a digit character, some delimiter must be used to terminate the back reference. An empty comment (see **Regular Expression Comments** on page IV-193) can be used.

A back reference that occurs inside the parentheses to which it refers fails when the subpattern is first used, so, for example, (a\1) never matches. However, such references can be useful inside repeated subpatterns. For example, the pattern

```
(a|b\1)+          or     Grep/E="(a|b\\1)+"
```

matches any number of *a*'s and also "aba", "ababbaa" etc. At each iteration of the subpattern, the back reference matches the character string corresponding to the previous iteration. In order for this to work, the pattern must be such that the first iteration does not need to match the back reference. This can be done using alternation, as in the example above, or by a quantifier with a minimum of zero.

Assertions

An assertion is a test on the characters following or preceding the current matching point that does not actually consume any characters. The simple assertions coded as \b, \B, ^ and $ are described in **Backslash and Simple Assertions** on page IV-181.

More complicated assertions are coded as subpatterns. There are two kinds: those that look ahead of the current position in the subject string, and those that look behind it. An assertion subpattern is matched in the normal way, except that it does not cause the current matching position to be changed.

Assertion subpatterns are not capturing subpatterns, and may not be repeated, because it makes no sense to assert the same thing several times. If any kind of assertion contains capturing subpatterns within it, these are counted for the purposes of numbering the capturing subpatterns in the whole pattern. However, substring capturing is carried out only for positive assertions, because it does not make sense for negative assertions.

Lookahead Assertions

Lookahead assertions start with (?= for positive assertions and (?! for negative assertions. For example,

```
\w+(?=;)          or     Grep/E="\\w+(?=;)"
```

matches a word followed by a semicolon, but does not include the semicolon in the match, and

```
foo(?!bar)
```

matches any occurrence of "foo" that is not followed by "bar". Note that the apparently similar pattern

```
(?!foo)bar
```

does not find an occurrence of "bar" that is preceded by something other than "foo"; it finds any occurrence of "bar" whatsoever, because the assertion (?!foo) is always true when the next three characters are "bar". A lookbehind assertion is needed to achieve the other effect.

If you want to force a matching failure at some point in a pattern, the most convenient way to do it is with (?!) because an empty string always matches, so an assertion that requires there not to be an empty string must always fail.

Lookbehind Assertions

Lookbehind assertions start with `(?<=` for positive assertions and `(?<!` for negative assertions. For example,

```
(?<!foo)bar
```

does find an occurrence of "bar" that is not preceded by "foo". The contents of a lookbehind assertion are restricted such that all the strings it matches must have a fixed length. However, if there are several alternatives, they do not all have to have the same fixed length. Thus

```
(?<=bullock|donkey)
```

is permitted, but

```
(?<!dogs?|cats?)
```

causes an error at compile time. Branches that match different length strings are permitted only at the top level of a lookbehind assertion. This is an extension compared with Perl (at least for 5.8), which requires all branches to match the same length of string. An assertion such as

```
(?<=ab(c|de))
```

is not permitted, because its single top-level branch can match two different lengths, but it is acceptable if rewritten to use two top-level branches:

```
(?<=abc|abde)
```

In some cases, the escape sequence \K (see above) can be used instead of a lookbehind assertion to get round the fixed-length restriction.

The implementation of lookbehind assertions is, for each alternative, to temporarily move the current position back by the fixed width and then try to match. If there are insufficient characters before the current position, the match is deemed to fail.

PCRE does not allow the \C escape (which matches a single data unit) to appear in lookbehind assertions, because it makes it impossible to calculate the length of the lookbehind. The \X and \R escapes, which can match different numbers of data units, are also not permitted.

Atomic groups can be used in conjunction with lookbehind assertions to specify efficient matching at the end of the subject string. Consider a simple pattern such as

```
abcd$
```

when applied to a long string that does not match. Because matching proceeds from left to right, PCRE will look for each *a* in the subject and then see if what follows matches the rest of the pattern. If the pattern is specified as

```
^.*abcd$
```

the initial `.*` matches the entire string at first, but when this fails (because there is no following *a*), it backtracks to match all but the last character, then all but the last two characters, and so on. Once again the search for *a* covers the entire string, from right to left, so we are no better off. However, if the pattern is written as

```
^(?>.*)(?<=abcd)
```

or, equivalently, using the possessive quantifier syntax,

```
^.*+(?<=abcd)
```

there can be no backtracking for the `.*` item; it can match only the entire string. The subsequent lookbehind assertion does a single test on the last four characters. If it fails, the match fails immediately. For long strings, this approach makes a significant difference to the processing time.

Using Multiple Assertions

Several assertions (of any sort) may occur in succession. For example,

```
(?<=\d{3})(?<!999)foo    or    Grep/E="(?<=\\d{3})(?<!999)foo"
```

matches “foo” preceded by three digits that are not “999”. Notice that each of the assertions is applied independently at the same point in the subject string. First there is a check that the previous three characters are all digits, and then there is a check that the same three characters are not “999”. This pattern does not match “foo” preceded by six characters, the first of which are digits and the last three of which are not “999”. For example, it doesn’t match “123abcfoo”. A pattern to do that is

```
(?<=\d{3}...)(?<!999)fooor    Grep/E="(?<=\\d{3}...)(?<!999)foo"
```

This time the first assertion looks at the preceding six characters, checking that the first three are digits, and then the second assertion checks that the preceding three characters are not “999”.

Assertions can be nested in any combination. For example,

```
(?<=(?<!foo)bar)baz
```

matches an occurrence of “baz” that is preceded by “bar” which in turn is not preceded by “foo”, while

```
(?<=\d{3}(?!999)...)foo or Grep/E=" (?<=\\d{3}(?!999)...)foo"
```

is another pattern that matches “foo” preceded by three digits and any three characters that are not “999”.

Conditional Subpatterns

It is possible to cause the matching process to obey a subpattern conditionally or to choose between two alternative subpatterns, depending on the result of an assertion, or whether a previous capturing subpattern matched or not. The two possible forms of conditional subpattern are

```
(?(condition)yes-pattern)
(?(condition)yes-pattern|no-pattern)
```

If the condition is satisfied, the yes-pattern is used; otherwise the no-pattern (if present) is used. If there are more than two alternatives in the subpattern, a compile-time error occurs.

There are three kinds of condition. If the text between the parentheses consists of a sequence of digits, the condition is satisfied if the capturing subpattern of that number has previously matched. The number must be greater than zero. Consider the following pattern, which contains nonsignificant white space to make it more readable and to divide it into three parts for ease of discussion:

```
( \( )?    [^()]+    (?(1) \) )
```

The first part matches an optional opening parenthesis, and if that character is present, sets it as the first captured substring. The second part matches one or more characters that are not parentheses. The third part is a conditional subpattern that tests whether the first set of parentheses matched or not. If they did, that is, if subject started with an opening parenthesis, the condition is true, and so the yes-pattern is executed and a closing parenthesis is required. Otherwise, since no-pattern is not present, the subpattern matches nothing. In other words, this pattern matches a sequence of nonparentheses, optionally enclosed in parentheses.

If the condition is the string `(R)`, it is satisfied if a recursive call to the pattern or subpattern has been made. At “top level”, the condition is false. This is a PCRE extension. Recursive patterns are described in the next section.

If the condition is not a sequence of digits or `(R)`, it must be an assertion. This may be a positive or negative lookahead or lookbehind assertion. Consider this pattern, again containing nonsignificant white space, and with the two alternatives on the second line:

```
(?(?=[^a-z]*[a-z])
\d{2}-[a-z]{3}-\d{2}  |  \d{2}-\d{2}-\d{2})
```

The condition is a positive lookahead assertion that matches an optional sequence of nonletters followed by a letter. In other words, it tests for the presence of at least one letter in the subject. If a letter is found, the subject is matched against the first alternative; otherwise it is matched against the second. This pattern matches strings in one of the two forms `dd-aaa-dd` or `dd-dd-dd`, where `aaa` are letters and `dd` are digits.

Regular Expression Comments

The sequence `(?#` marks the start of a comment that continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part in the pattern matching at all.

Recursive Patterns

Consider the problem of matching a string in parentheses, allowing for unlimited nested parentheses. Without the use of recursion, the best that can be done is to use a pattern that matches up to some fixed depth of nesting. It is not possible to handle an arbitrary nesting depth. Perl provides a facility that allows regular expressions to recurse (amongst other things). It does this by interpolating Perl code in the expression at runtime, and the code can refer to the expression itself. A Perl pattern to solve the parentheses problem can be created like this:

```
$re = qr{\( (?: (?>[^()]+) | (?p{$re}) )* \)}x;
```

The `(?p{…})` item interpolates Perl code at runtime, and in this case refers recursively to the pattern in which it appears. Obviously, PCRE cannot support the interpolation of Perl code. Instead, it supports some special syntax for recursion of the entire pattern, and also for individual subpattern recursion.

The special item that consists of `(?` followed by a number greater than zero and a closing parenthesis is a recursive call of the subpattern of the given number, provided that it occurs inside that subpattern. (If not, it is a “subroutine” call, which is described in **Subpatterns as Subroutines** on page IV-194.) The special item `(?R)` is a recursive call of the entire regular expression.

For example, this PCRE pattern solves the nested parentheses problem (additional nonfunction whitespace has been added to separate the expression into parts):

```
\( ( (?>[^()]+) | (?R) )* \)
```

First it matches an opening parenthesis. Then it matches any number of substrings which can either be a sequence of nonparentheses, or a recursive match of the pattern itself (that is a correctly parenthesized substring). Finally there is a closing parenthesis.

If this were part of a larger pattern, you would not want to recurse the entire pattern, so instead you could use this:

```
( \( ( (?>[^()]+) | (?1) )* \))
```

We have put the pattern into parentheses, and caused the recursion to refer to them instead of the whole pattern. In a larger pattern, keeping track of parenthesis numbers can be tricky. It may be more convenient to use named parentheses instead. For this, PCRE uses `(?P>name)`, which is an extension to the Python syntax that PCRE uses for named parentheses (Perl does not provide named parentheses). We could rewrite the above example as follows:

```
(?P<pn> \( ( (?>[^()]+) | (?P>pn) )* \))
```

This particular example pattern contains nested unlimited repeats, and so the use of atomic grouping for matching strings of nonparentheses is important when applying the pattern to strings that do not match. For example, when this pattern is applied to

```
(aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa()
```

it yields “no match” quickly. However, if atomic grouping is not used, the match runs for a very long time indeed because there are so many different ways the + and * repeats can carve up the subject, and all have to be tested before failure can be reported.

At the end of a match, the values set for any capturing subpatterns are those from the outermost level of the recursion at which the subpattern value is set. If you want to obtain intermediate values, a callout function can be used (see **Subpatterns as Subroutines** on page IV-194). If the pattern above is matched against

```
(ab(cd)ef)
```

the value for the capturing parentheses is “ef”, which is the last value taken on at the top level. If additional parentheses are added, giving

```
\(( ( (?>[^()]+) | (?R) )* ) \)
    ↑                       ↑
```

the string they capture is “ab(cd)ef”, the contents of the top level parentheses. If there are more than 15 capturing parentheses in a pattern, PCRE has to obtain extra memory to store data during a recursion, which it does by using pcre_malloc, freeing it via pcre_free afterward. If no memory can be obtained, the match fails with the PCRE_ERROR_NOMEMORY error.

Do not confuse the `(?R)` item with the condition `(R)`, which tests for recursion. Consider this pattern, which matches text in angle brackets, allowing for arbitrary nesting. Only digits are allowed in nested brackets (that is, when recursing), whereas any characters are permitted at the outer level.

```
< (?: (?(R) \d++  | [^<>]*+) | (?R)) * >
```

In this pattern, `(?(R)` is the start of a conditional subpattern, with two different alternatives for the recursive and nonrecursive cases. The `(?R)` item is the actual recursive call.

Subpatterns as Subroutines

If the syntax for a recursive subpattern reference (either by number or by name) is used outside the parentheses to which it refers, it operates like a subroutine in a programming language. An earlier example pointed out that the pattern

```
(sens|respons)e and \1ibility
```

matches “sense and sensibility” and “response and responsibility”, but not “sense and responsibility”. If instead the pattern

```
(sens|respons)e and (?1)ibility
```

is used, it does match “sense and responsibility” as well as the other two strings. Such references must, however, follow the subpattern to which they refer.

Regular Expressions References

The regular expression syntax supported by **Grep**, **GrepString**, **GrepList**, and **Demo** is based on the *PCRE — Perl-Compatible Regular Expression Library* by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.

Visit <`http://pcre.org/`> for more information about the PCRE library. The description of regular expressions above is taken from the PCRE documentation.

A good introductory book on regular expressions is: Forta, Ben, *Regular Expressions in 10 Minutes*, Sams Publishing, 2004.

A good comprehensive book on regular expressions is: Friedl, Jeffrey E. F., *Mastering Regular Expressions*, 2nd ed., 492 pp., O’Reilly Media, 2002.

A good web site is: http://www.regular-expressions.info

Working with Files

Here are the built-in operations that you can use to read from or write to files:

Operation	What It Does
Open	Opens an existing file for reading or writing. Can also create a new file. Can also append to an existing file. Returns a file reference number that you must pass to the other file operations. Use Open/D to present a dialog that allows the user to choose a file without actually opening the file.
fprintf	Writes formatted text to an open file.

Operation	What It Does
wfprintf	Writes wave data as formatted text to an open file.
FGetPos	Gets the position at which the next file read or write will be done.
FSetPos	Sets the position at which the next file read or write will be done.
FStatus	Given a file reference number, returns miscellaneous information about the file.
FBinRead	Reads binary data from a file into an Igor string, variable or wave. This is used mostly to read nonstandard file formats.
FBinWrite	Writes binary data from an Igor string, variable or wave. This is used mostly to write nonstandard file formats.
FReadLine	Reads a line of text from a text file into an Igor string variable. This can be used to parse an arbitrary format text file.
Close	Closes a file opened by the Open operation.

Before working with a file, you must use the Open operation to obtain a file reference number that you use with all the remaining commands. The Open operation creates new files, appends data to an existing file, or reads data from an existing file. There is no facility to deal with the resource fork of a Macintosh file.

Sometimes you may write a procedure that uses the Open operation and the Close operation but, because of an error, the Close operation never gets to execute. You then correct the procedure and want to rerun it. The file will still be open because the Close operation never got a chance to run. In this case, execute:

```
Close/A
```

from the command line to close all open files.

Finding Files

Two functions are provided to help you to determine what files exist in a particular folder:

- **TextFile**
- **IndexedFile**

IndexedFile is a more general version of TextFile.

You can also use the Open operation with the /D flag to present an open dialog.

Other File– and Folder–Related Operations and Functions

Igor Pro also supports a number of operations and functions for file or folder manipulation:

CopyFile	CopyFolder
DeleteFile	DeleteFolder
GetFileFolderInfo	SetFileFolderInfo
MoveFile	MoveFolder
CreateAliasShortcut	
NewPath	PathInfo
ParseFilePath	

Warning: Use caution when writing code that deletes or moves files or folders. These actions are not undoable.

Because the DeleteFolder, CopyFolder and MoveFolder operations have the potential to do a lot of damage if used incorrectly, they require user permission before overwriting or deleting a folder. The user controls the permission process using the Miscellaneous Settings dialog (Misc menu).

Writing to a Text File

You can generate output text files from Igor procedures or from the command line in formats acceptable to other programs. To do this, you need to use the **Open** and **Close** operations and the **fprintf** operation (page V-260) and the **wfprintf** operation (page V-1093).

The following commands illustrate how you could use these operations to create an output text file. Each operation is described in detail in following sections:

```
Function WriteFileDemo(pathName, fileName)
   String pathName   // Name of Igor symbolic path (see Symbolic Paths)
   String fileName   // File name, partial path or full path

   Variable refNum
   Open refNum as "A New File"                // Create and open file
   fprintf refNum, "wave1\twave2\twave3\r"    // Write column headers
   Wave wave1, wave2, wave3
   wfprintf refNum, "" wave1, wave2, wave3    // Write wave data
   Close refNum                               // Close file
End
```

Open and Close Operations

You use the **Open** operation (page V-716) to open a file. For our purposes, the syntax of the Open operation is:

```
Open [/R/A/P=pathName/M=messageStr] variableName [as "filename"]
```

variableName is the name of a numeric variable. The Open operation puts a file reference number in that variable. You use the reference number to access the file after you've opened it.

A file specifications consists of a path (directions for finding a folder) and a file name. In the Open operation, you can specify the path in three ways:

Using a full path as the filename parameter:

```
Open refNum as “hd:Data:Run123.dat”
```

Or using a symbolic path name and a file name:

```
Open/P=DataPath refNum as “Run123.dat”
```

Or using a symbolic path name and a partial path including the file name:

```
Open/P=HDPath refNum as “:Data:Run123.dat”
```

A symbolic path is a short name that refers to a folder on disk. See **Symbolic Paths** on page II-22.

If you do not provide enough information to find the folder and file of interest, Igor displays a dialog which lets you select the file to open. If you supply sufficient information, Igor open the file without displaying the dialog.

To open an existing file for reading, use the /R flag. To append new data to an existing file, use the /A flag. If you omit both of these flags and if the file already exists, you overwrite any data that is in the file.

If you open a file for writing (you don't use /R) then, if there exists a file with the specified name, Igor opens the file and overwrites the existing data in the file. If there is no file with the specified name, Igor creates a new file.

Warning: If you're not careful you can inadvertently lose data using the Open operation by opening for writing without using the /A flag. To avoid this, use the /R (open for read) or /A (append) flags.

Wave Reference Functions

It is common to write a user-defined function that operates on all of the waves in a data folder, on the waves displayed in a graph or table, or on a wave identified by a cursor in a graph. For these purposes, you need to use wave reference functions.

Wave reference functions are built-in Igor functions that return a reference that can be used in a user-defined function. Here is an example that works on the top graph. Cursors are assumed to be placed on a region of a trace in the graph.

```
Function WaveAverageBetweenCursors()
   WAVE/Z w = CsrWaveRef(A)
   if (!WaveExists(w))         // Cursor is not on any wave.
      return NaN
   endif

   Variable xA = xcsr(A)
   Variable xB = xcsr(B)
   Variable avg = mean(w, xA, xB)

   return avg
End
```

CsrWaveRef returns a wave reference that identifies the wave a cursor is on.

An older function, CsrWave, returns the *name* of the wave the cursor is on. It would be tempting to use this to determine the wave the cursor is on, but it would be incorrect. The name of a wave by itself does not uniquely identify a wave because it does not specify the data folder in which the wave resides. For this reason, we usually need to use the wave reference function CsrWaveRef instead of CsrWave.

This example uses a wave reference function to operate on the waves displayed in a graph:

```
Function SmoothWavesInGraph()
   String list = TraceNameList("", ";", 1)
   String traceName
   Variable index = 0
   do
      traceName = StringFromList(index, list)
      if (strlen(traceName) == 0)
         break          // No more traces.
      endif
      WAVE w = TraceNameToWaveRef("", traceName)
      Smooth 5, w
      index += 1
   while(1)
End
```

Use **WaveRefIndexedDFR** to iterate over the waves in a given data folder.

Here are the wave reference functions. See Chapter V-1, **Igor Reference**, for details on each of them.

Function	Comment
CsrWaveRef	Returns a reference to the Y wave to which a cursor is attached.
CsrXWaveRef	Returns a reference to the X wave when a cursor is attached to an XY pair.
WaveRefIndexedDFR	Returns a reference to a wave in the specified data folder.
WaveRefIndexed	Returns a reference to a wave in a graph or table or to a wave in the current data folder.
XWaveRefFromTrace	Returns a reference to an X wave in a graph. Used with the output of TraceNameList.

Function	Comment
ContourNameToWaveRef	Returns a reference to a wave displayed as a contour plot. Used with the output of ContourNameList.
ImageNameToWaveRef	Returns a reference to a wave displayed as an image. Used with the output of ImageNameList.
TraceNameToWaveRef	Returns a reference to a wave displayed as a waveform or as the Y wave of an XY pair in a graph. Used with the output of TraceNameList.
TagWaveRef	Returns a reference to a wave to which a tag is attached in a graph. Used in creating a smart tag.
WaveRefsEqual	Returns the truth two wave references are the same.
WaveRefWaveToList	Returns a semicolon-separated string list containing the full or partial path to the wave referenced by each element of the input wave reference wave.
ListToWaveRefWave	Returns a free wave containing a wave reference for each of the waves in the semicolon-separated input string list.

This simple example illustrates the use of the CsrWaveRef wave reference function:

```
Function/WAVE CursorAWave()
   WAVE/Z w = CsrWaveRef(A)
   return w
End

Function DemoCursorAWave()
   WAVE/Z w = $CursorAWave()
   if (WaveExists(w)==0)
      Print "oops: no wave"
   else
      Printf "Cursor A is on the wave '%s'\r", NameOfWave(w)
   endif
End
```

Processing Lists of Waves

Igor users often want to use a string list of waves in places where Igor is looking for just the name of a single wave. For example, they would like to do this:

```
Display "wave0;wave1;wave2"
```

or, more generally:

```
Function DisplayListOfWaves(list)
   String list                // e.g., "wave0;wave1;wave2"

   Display $list
End
```

Unfortunately, Igor can't handle this. However, there are techniques for achieving the same result.

Graphing a List of Waves

This example illustrates the basic technique for processing a list of waves.

```
Function DisplayWaveList(list)
   String list             // A semicolon-separated list.

   Variable index = 0
   do
      // Get the next wave name
      String name = StringFromList(index, list)
      if (strlen(name) == 0)
```

```
         break                       // Ran out of waves
      endif

      Wave w = $name
      if (index == 0)                // Is this the first wave?
         Display w
      else
         AppendToGraph w
      endif
      index += 1
   while (1)         // Loop until break above
End
```

To make a graph of all of the waves in the current data folder, you could execute

```
DisplayWaveList(WaveList("*", ";", ""))
```

Operating on the Traces in a Graph

In a previous section, we showed an example that operates on the waves displayed in a graph. It used a wave reference function, TraceNameToWaveRef. If you want to write a function that operates on *traces* in a graph, you would *not* use wave reference functions. That's because Igor operations that operate on *traces* expect *trace names*, not wave references. For example:

```
Function GrayOutTracesInGraph()
   String list = TraceNameList("", ";", 1)
   Variable index = 0
   do
      String traceName = StringFromList(index, list)
      if (strlen(traceName) == 0)
         break                       // No more traces.
      endif

      // WRONG: ModifyGraph expects a trace name and w is not a trace name
      WAVE w = TraceNameToWaveRef("", traceName)
      ModifyGraph rgb(w)=(50000,50000,50000)

      // RIGHT
      ModifyGraph rgb($traceName)=(50000,50000,50000)

      index += 1
   while(1)
End
```

Using a Fixed-Length List

In the previous examples, the number of waves in the list was unimportant and all of the waves in the list served the same purpose. In this example, the list has a fixed number of waves and each wave has a different purpose.

```
Function DoLineFit(list)
   String list          // List of waves names: source, weight

   // Pick out the expected wave names

   String sourceStr = StringFromList(0, list)
   Wave source = $sourceStr

   String weightStr = StringFromList(2, list)
   Wave weight = $weightStr

   CurveFit line source /D /W=weight
End
```

You could invoke this function as follows:

```
DoLineFit("wave0;wave1;")
```

For most purposes, it is better to design the function to take wave reference parameters rather than a string list.

Operating on Qualified Waves

This example illustrates how to operate on waves that match a certain criterion. It is broken into two functions - one that creates the list of qualified waves and a second that operates on them. This organization gives us a general purpose routine (ListOfMatrices) that we would not have if we wrote the whole thing as one function.

```
Function/S ListOfMatrices()
   String list = ""
   Variable index=0
   do
      WAVE/Z w=WaveRefIndexedDFR(:,index)     // Get next wave.
      if (WaveExists(w) == 0)
         break                                // No more waves.
      endif
      if (WaveDims(w) == 2)
         // Found matrix. Add to list with separator.
         list += NameOfWave(w) + ";"
      endif
      index += 1
   while(1)             // Loop till break above.
   return list
End

Function ChooseAndDisplayMatrix()
   String theList = ListOfMatrices()

   String theMatrix
   Prompt theMatrix, "Matrix to display:", popup theList
   DoPrompt "Display Matrix", theMatrix
   if (V_Flag != 0)
      return -1
   endif

   WAVE m = $theMatrix
   NewImage m
End
```

In the preceding example, we needed a list of wave names in a string to use in a Prompt statement. More often we want a list of wave references on which to operate. The next example illustrates how to do this using a general purpose routine that returns a list of wave references in a free wave:

```
// Returns a free wave containing wave references
// for each 2D wave in the current data folder
Function/WAVE GetMatrixWavesInCDF()
   Variable numWavesInCDF = CountObjects(":", 1)
   Make/FREE/WAVE/N=(numWavesInCDF) list

   Variable numMatrixWaves = 0
   Variable i
   for(i=0; i<numWavesInCDF; i+=1)
      WAVE w = WaveRefIndexedDFR(:,i)
      Variable numDimensions = WaveDims(w)
      if (numDimensions == 2)
         list[numMatrixWaves] = w
         numMatrixWaves += 1
      endif
   endfor

   Redimension/N=(numMatrixWaves) list
   return list       // Ownership of the wave is passed to the calling routine
End

Function DemoMatrixWaveList()
   Wave/WAVE freeList = GetMatrixWavesInCDF()   // We now own the freeList wave
   Variable numMatrixWaves = numpnts(freeList)
   Printf "Number of matrix waves in current data folder: %d\r", numMatrixWaves

   Variable i
   for(i=0; i<numMatrixWaves; i+=1)
      Wave w = freeList[i]
      String name = NameOfWave(w)
      name = PossiblyQuoteName(name)
      Printf "Wave %d: %s\r", i, name
   endfor

   // freeList is automatically killed when the function returns
End
```

The ExecuteCmdOnList Function

The ExecuteCmdOnList function is implemented by a WaveMetrics procedure file and executes any command for each wave in the list. For example, the following commands do a WaveStats operation on each wave.

```
Make wave0=gnoise(1), wave1=gnoise(10), wave2=gnoise(100)
ExecuteCmdOnList("WaveStats %s", "wave0;wave1;wave2;")
```

The ExecuteCmdOnList function is supplied in the “Execute Cmd On List” procedure file. See **The Include Statement** on page IV-166 for instructions on including a procedure file.

This technique is on the kludgy side. If you can achieve your goal in a more straightforward fashion without heroic efforts, you should use regular programming techniques.

The Execute Operation

Execute is a built-in operation that executes a string expression as if you had typed it into the command line. The main purpose of Execute is to get around the restrictions on calling macros and external operations from user functions.

We try to avoid using Execute because it makes code obscure and difficult to debug. If you can write a procedure without Execute, do it. However, there are some cases where using Execute can save pages of code or achieve something that would otherwise be impossible. For example, the TileWindow operation can not be directly called from a user-defined function and therefore must be called using Execute.

It is a good idea to compose the command to be executed in a local string variable and then pass that string to the Execute operation. Use this to print the string to the history for debugging. For example:

```
Function DemoExecute(list)
   String list    // Semicolon-separated list of names of windows to tile
   list = ReplaceString(";", list, ",")    // We need commas for TileWindows
   list = RemoveEnding(list, ",")          // Remove trailing comma, if any
   String cmd
   sprintf cmd, "TileWindows %s", list
   Print cmd                               // For debugging only
   Execute cmd
End
```

When you use Execute, you must be especially careful in the handling of wave names. See **Programming with Liberal Names** on page IV-168 for details.

When Execute runs, it is as if you typed a command in the command line. Local variables in macros and functions are not accessible. The example in **Calling an External Operation From a User-Defined Function** on page IV-202 shows how to use the sprintf operation to solve this problem.

Using a Macro From a User-Defined Function

A macro can not be called directly from a user function. To do so, we must use Execute. This is a trivial example for which we would normally not resort to Execute but which clearly illustrates the technique.

```
Function Example()
   Make wave0=enoise(1)
   Variable/G V_avg              // Create a global
   Execute "MyMacro(\"wave0\")"  // Invokes MyMacro("wave0")
   return V_avg
End

Macro MyMacro(wv)
   String wv
   WaveStats $wv     // Sets global V_avg and 9 other local vars
End
```

Execute does not supply good error messages. If the macro generates an error, you may get a cryptic message. Therefore, debug the macro *before* you call it with the Execute operation.

Calling an External Operation From a User-Defined Function

Prior to Igor Pro 5, external operations could not be called directly from user-defined functions and had to be called via Execute. Now it is possible to write an external operation so that it can be called directly. However, very old XOPs that have not been updated still need to be called through Execute. This example shows how to do it.

If you attempt to directly use an external operation which does not support it, Igor displays an error dialog telling you to use Execute for that operation.

The external operation in this case is VDTWrite which sends text to the serial port. It is implemented by the VDT XOP (no longer shipped as of Igor7).

```
Function SetupVoltmeter(range)
   Variable range    // .1, .2, .5, 1, 2, 5 or 10 volts

   String voltmeterCmd
   sprintf voltmeterCmd, "DVM volts=%g", range
   String vdtCmd
   sprintf vdtCmd "VDTWrite \"%s\"\r\n", voltmeterCmd
   Execute vdtCmd
End
```

In this case, we are sending the command to a voltmeter that expects something like:

```
DVM volts=.2<CR><LF>
```

to set the voltmeter to the 0.2 volt range.

The parameter that we send to the Execute operation is:

```
VDTWrite "DVM volts=.2\r\n"
```

The backslashes used in the second sprintf call insert two quotation marks, a carriage return, and a linefeed in the command about to be executed.

A newer VDT2 XOP exists which includes external operations that *can* be directly called from user-functions. Thus, new programming should use the VDT2 XOP and will not need to use Execute.

Other Uses of Execute

Execute can also accept as an argument a string variable containing commands that are algorithmically constructed. Here is a simple example:

```
Function Fit(w, fitType)
   WAVE w               // Source wave
   String fitType       // One of the built-in Igor fit types

   String name = NameOfWave(w)
   name = PossiblyQuoteName(name)   // Liberal names need quotes

   String cmd
   sprintf cmd, "CurveFit %s %s", fitType, name
   Execute cmd
End
```

Use this function to do any of the built-in fits on the specified wave. Without using the Execute operation, we would have to write it as follows:

```
Function Fit(w, fitType)
   WAVE w                  // Source wave
   String fitType          // One of the built-in Igor fit types

   strswitch(fitType)
      case "line":
         CurveFit line w
         break

      case "exp":
         CurveFit exp w
         break

      <and so on for each fit type>
   endswitch
End
```

Note the use of sprintf to prepare the string containing the command to be executed. The following would not work because when Execute runs, local variables and parameters are not accessible:

```
Execute "CurveFit fitType name"
```

Deferred Execution Using the Operation Queue

It is sometimes necessary to execute a command after the current function has finished. This is done using the Execute/P operation. For details, see **Operation Queue** on page IV-278.

Procedures and Preferences

As explained under **Preferences** on page III-515, Igor allows you to set many preferences. Most of the preferences control the style of new objects, including new graphs, traces and axes added to graphs, new tables, columns added to tables, and so on.

Preferences are usually used only for manual “point-and-click” operation. We usually don’t want preferences to affect the behavior of procedures. The reason for this is that we want a procedure to do the same thing no matter who runs it. Also, we want it to do the same thing tomorrow as it does today. If we allowed preferences to take effect during procedure execution, a change in preferences could change the effect of a procedure, making it unpredictable.

By default, preferences do not take effect during procedure execution. If you want to override the default behavior, you can use the Preferences operation. From within a procedure, you can execute `Preferences 1` to turn preferences on. This affects the procedure and any subroutines that it calls. It stays in effect until you execute `Preferences 0`.

When a *macro* ends, the state of preferences reverts to what it was when that macro started. If you change the preference setting within a *function*, the preferences state does *not* revert when that function ends. You must turn preferences on, save the old preferences state, execute Igor operations, and then restore the preferences state. For example:

```
Function DisplayWithPreferences(w)
   Wave w

   Variable oldPrefState
   Preferences 1                     // Turn preferences on
   oldPrefState = V_Flag             // Save the old state

   Display w                         // Create graph using preferences

   Preferences oldPrefState          // Restore old prefs state
End
```

Experiment Initialization Procedures

When Igor loads an experiment, it checks to see if there are any commands in the procedure window before the first macro, function or menu declaration. If there are such commands Igor executes them. This provides a way for you to initialize things. These initialization commands can invoke procedures that are declared later in the procedure window.

Also see **BeforeFileOpenHook** on page IV-287 and **IgorStartOrNewHook** on page IV-292 for other initialization methods.

Procedure Subtypes

A procedure subtype identifies the purpose for which a particular procedure is intended and the appropriate menu from which it can be chosen. For example, the Graph subtype puts a procedure in the Graph Macros submenu of the Windows menu.

```
Window Graph0() : Graph
   PauseUpdate; Silent 1      // building window...
   Display/W=(5,42,400,250) wave0,wave1,wave2
   <more commands>
End
```

When Igor automatically creates a procedure, for example when you close and save a graph, it uses the appropriate subtype. When you create a curve fitting function using the Curve Fitting dialog, the dialog automatically uses the FitFunc subtype. You usually don't need to use subtypes for procedures that you write.

This table shows the available subtypes and how they are used.

Subtype	Effect	Available for
Graph	Displayed in Graph Macros submenu.	Macros
GraphStyle	Displayed in Graph Macros submenu and in Style pop-up menu in New Graph dialog.	Macros
GraphMarquee	Displayed in graph marquee. This keyword is no longer recommended. See **Marquee Menu as Input Device** on page IV-163 for details.	Macros and functions
CursorStyle	Displayed in Style Function submenu of cursor pop-up menu in graph info pane.	Functions
DrawUserShape	Marks a function as suitable for drawing a user-defined drawing object. See **DrawUserShape**.	Functions
GridStyle	Displayed in Grid-Style submenu of mover pop-up menu in drawing tool palette.	Functions

Subtype	Effect	Available for
`Table`	Displayed in Table Macros submenu.	Macros
`TableStyle`	Displayed in Table Macros submenu and in Style pop-up menu in New Table dialog.	Macros
`Layout`	Displayed in Layout Macros submenu.	Macros

Memory Considerations

Running out of memory is usually not an issue unless you load gigabytes of data into memory at one time. If this is true in your case, make sure to run IGOR64 (the 64-bit version of Igor) rather than IGOR32 (the 32-bit version). IGOR32 is provided only for users who rely on 32-bit XOPs that have not yet been ported to 64 bits and is available on Windows only.

On most systems, IGOR32 can access 4 GB of virtual memory. The limits for IGOR64 are much higher and depend on your operating system.

If memory becomes fragmented, you may get unexpected out-of-memory errors. This is much more likely in IGOR32 than IGOR64.

See **Memory Management** on page III-512 for further information.

Wave Reference Counting

Igor uses reference counting to determine when a wave is no longer referenced anywhere and memory can be safely deallocated.

Because memory is not deallocated until all references to a given wave are gone, memory may not be freed when you think. Consider the function:

```
Function myfunc()
   Make/N=10E6 bigwave
   // do stuff
   FunctionThatKillsBigwave()
   // do more stuff
End
```

The memory allocated for bigwave is not deallocated until the function returns because Make creates an automatic wave reference variable which, by default, exists until the function returns. To free memory before the function returns, use the **WAVEClear**:

```
Function myfunc()
   Make/N=10E6 bigwave
   // do stuff
   FunctionThatKillsBigwave()
   WAVEClear bigwave
   // do more stuff
End
```

The WAVEClear command takes a list of WAVE reference variables and stores NULL into them. It is the same as:

```
WAVE/Z wavref= $""
```

Detecting Wave Leaks

Igor Pro 9.00 introduced two ways to detect wave leaks: **IgorInfo**(16) and **Wave Tracking**. These are tools for advanced Igor programmers. Wave tracking is discussed in the next section.

IgorInfo(16) is a quick and lightweight way to detect possible wave leaks. Unlike wave tracking, IgorInfo(16) can be used independently by different procedure packages without interference among them.

IgorInfo(16) returns the total number of waves of all kinds in existence at any given time. You can use it like this:

```
Function DetectWaveLeaks()
   int originalNumberOfWaves = str2num(IgorInfo(16))

   <Do a lot of processing that you suspect might leak waves>

   int newNumberOfWaves = str2num(IgorInfo(16))
   int change = newNumberOfWaves - originalNumberOfWaves
   if (change > 0)
      Beep
      Printf "Possible leak: Number of waves changed by %d\r", change
   endif
End
```

IgorInfo(16) may sometimes create false positives. For example, the Igor debugger and the Igor Data Browser sometimes create hidden waves for their internal use. An example is the debugger if you choose Show Waves in Graph from the Local Waves, Strings, and SVARs popup menu. This can cause a discrepancy in the number of waves at the start and end of a function but it is not a real leak as Igor will eventually reuse or kill the wave.

Because of the possibility of false positives, you should consider a discrepancy such as detected by the DetectWaveLeaks function above evidence of a possible leak only. To confirm the leak, rerun the function without the use of the debugger or any other user-interface interactions. If it still appears to be a leak, use Wave Tracking to investigate the cause.

Wave Tracking

The **WaveTracking** operation is a tool for detecting and investigating wave leaks. WaveTracking was introduced in Igor Pro 9.00.

A fast alternative and lightweight alternative to wave tracking is **IgorInfo**(16). For details, see **Detecting Wave Leaks** above.

Igor waves fall into three categories and each category can be tracked separately: global, free, and local.

Global waves are waves stored in the main data folder hierarchy, i.e., in the root data folder or one of its descendants. These are the usual waves that you work with on a regular basis. They are global in the sense that they are persistent (you must explicitly kill them) and are accessible from any context (any function or from the command line) at any time.

Free waves are waves that are not contained in any data folder. You create them in user-defined functions via the **NewFreeWave** function, the **Make**/FREE operation, or other operations that support the /FREE flag. You use a wave reference variable to access a free wave (see **Wave References** on page IV-71). When the last wave reference for a given free wave has gone out of scope or is cleared by **WAVEClear**, Igor automatically kills the wave.

Local waves are waves that are stored in a free data folder or a descendant of a free data folder. They are local in the sense that they are automatically killed and are accessible only if you hold a data folder reference for the containing data folder or its ancestor.

Local waves become free waves when the containing data folder is destroyed if a wave reference still remains. See **Free Wave Lifetime** on page IV-92 and **Free Data Folder Lifetime** on page IV-97.

The topic **Free Wave Leaks** on page IV-94 illustrates how you can permanently leak a free wave. After they are leaked, there is no way to access them, so the only way to recover the memory is to restart Igor. You can use the WaveTracking operation to detect and investigate such leaks.

Sometimes you may have a backlog of global waves that were created for temporary use but not deleted. These waves are stored in memory and on disk when you save an experiment. You can use the WaveTracking operation to identify and clean up the backlog.

The **WaveTracking** operation allows you to keep track of the number of waves created but not killed over a given period of time and to get information on those waves. When Igor starts up, tracking is turned off. You must turn it on, as illustrated below, before you run code that you suspect is causing a problem.

WaveTracking provides two modes. Counter mode tells you the number waves of a given category created minus the number killed since counting started. Tracker mode keeps a list of every wave created but not yet been killed since tracking started. Tracker mode adds to the time it takes to create and kill waves, so counter mode is useful for detecting leaks while tracker mode is useful for investigating leaks once they are detected.

To illustrate, we will use the Leaks function defined here. It demonstrates how free wave leaks can occur and in the process leaks two free waves.

```
Function/WAVE GenerateFree()
   return NewFreeWave(2,3)
End

Function Leaks()
   Duplicate/O GenerateFree(),dummy             // This leaks
   Variable maxVal = WaveMax(GenerateFree())    // So does this
End
```

If you want to follow along with the example, copy these functions to your procedure window and then close it.

First we turn on the free wave counter:

```
WaveTracking/FREE counter
```

Turning wave tracking on resets the counter even if it was already on.

This command demonstrates that no free waves were leaked since counting was turned on:

```
WaveTracking/FREE count; Print V_numWaves
  0
```

Now we run the Leaks function and check the count again:

```
Leaks(); WaveTracking/FREE count; Print V_numWaves
  2
```

After running the Leaks function, there are two free waves that did not exist before. There is no way at this point to get rid of them, but at least now you know about it, and perhaps you can figure out what leaked them.

The counter tracking mode does a simple increment when a wave of a given category is created, and a decrement when a wave is killed. If you kill a wave that was created before the tracking counter was started, the count can go negative.

Naturally the Leaks function is much less complex than typical code. It can be quite difficult to figure out where the leaked waves are created. To help with that, you can use the tracker mode and give your free waves names. If you want to follow along with the example, copy these functions to your procedure window and then close it:

```
Function/WAVE GenerateFreeNamed()
   return NewFreeWave(2,3, "MadeByGenerateFree")
End

Function LeaksNamed()
   Duplicate/O GenerateFreeNamed(),dummy           // This leaks
   Variable maxVal = WaveMax(GenerateFreeNamed())  // So does this
End
```

We now run LeaksNamed with WaveTracking in tracker mode:

```
WaveTracking/FREE tracker
LeaksNamed()
WaveTracking/FREE dump
Since tracking began, 2 free wave(s) have been created and not killed.
Wave 'MadeByGenerateFree'; refcount: 0
Wave 'MadeByGenerateFree'; refcount: 0
```

This time, instead of printing the count of free waves, we used "dump" to get a list of the free waves. The dump keyword prints a list in the history area showing the name of each free wave and its reference count. The names tell you that those were waves made by the GenerateFreeNamed function.

In the example in **Wave Reference MultiThread Example** on page IV-327, a WAVE wave, named ww, is created at the start of the Demo function. ww is filled with free waves by the MultiThread call. At the end of the function, KillWaves is called to kill ww which automatically kills the free waves. If you omitted the KillWaves call at the end, this would create a large leak. You could investigate it using `WaveTracking/FREE tracker` and `WaveTracking/FREE dump`.

Creating Igor Extensions

Igor includes a feature that allows a C or C++ programmer to extend its capabilities. Using Apple's Xcode or Microsoft Visual C++, a programmer can add command line operations and functions to Igor. These are called external operations and external functions. Experienced programmers can also add menu items, dialogs and windows.

A file containing external operations or external functions is called an “XOP file” or “XOP” (pronounced “ex-op”) for short.

Here are some things for which you might want to write an XOP:

- To do number-crunching on waves.
- To import data from a file format that Igor does not support.
- To acquire data directly into Igor waves.
- To communicate with a remote computer, instrument or database.

The main reasons for writing something as an XOP instead of writing it as an Igor procedure are:

- It needs to be blazing fast.
- You already have a lot of C code that you want to reuse.
- You need to call drivers for data acquisition.
- It requires programming techniques that Igor doesn’t support.
- You want to add your own dialogs or windows.

Writing an XOP that does number-crunching is considerably easier than writing a stand-alone program. You don’t need to know anything about Macintosh or Windows APIs.

If you are a C or C++ programmer and would like to extend Igor with your own XOP, you need to purchase the Igor External Operations Toolkit from WaveMetrics. This toolkit contains documentation on writing XOPs as well as the source code for several WaveMetrics sample XOPs. It supplies a large library of routines that enable communication between Igor and the external code. You will also need the a recent version of Xcode, or Microsoft Visual C++.

Chapter IV-8

Debugging

Debugging Procedures

There are two techniques for debugging procedures in Igor:

- Using print statements
- Using the symbolic debugger

For most situations, the symbolic debugger is the most effective tool. In some cases, a strategically placed print statement is sufficient.

Debugging With Print Statements

This technique involves putting print statements at a certain point in a procedure to display debugging messages in Igor's history area. In this example, we use Printf to display the value of parameters to a function and then Print to display the function result.

```
Function Test(w, num, str)
   Wave w
   Variable num
   String str

   Printf "Wave=%s, num=%g, str=%s\r", NameOfWave(w), num, str

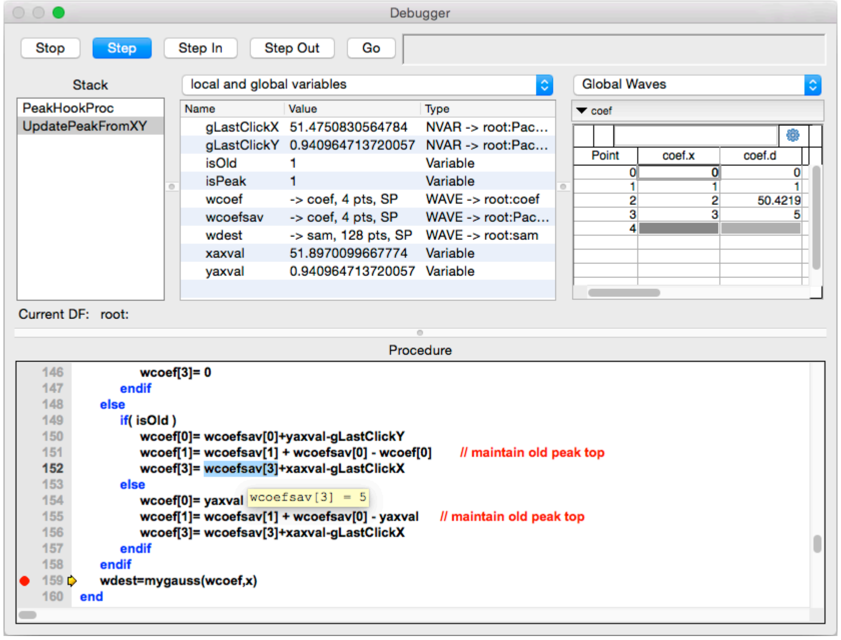
   <body of function>

   Print result
   return result
End
```

See **Creating Formatted Text** on page IV-259 for details on the Printf operation.

The Debugger

When a procedure doesn't produce the results you want, you can use Igor's built-in debugger to observe the execution of macros and user-defined functions while single-stepping through the lines of code.



Stack:
PeakHookProc
UpdatePeakFromXY

Name	Value	Type
gLastClickX	51.4750830564784	NVAR -> root:Pac…
gLastClickY	0.940964713720057	NVAR -> root:Pac…
isOld	1	Variable
isPeak	1	Variable
wcoef	-> coef, 4 pts, SP	WAVE -> root:coef
wcoefsav	-> coef, 4 pts, SP	WAVE -> root:Pac…
wdest	-> sam, 128 pts, SP	WAVE -> root:sam
xaxval	51.8970099667774	Variable
yaxval	0.940964713720057	Variable

Point	coef.x	coef.d
0	0	0
1	1	1
2	2	50.4219
3	3	5
4		

Current DF: root:

```
            wcoef[3]= 0
         endif
      else
         if( isOld )
            wcoef[0]= wcoefsav[0]+yaxval-gLastClickY
            wcoef[1]= wcoefsav[1] + wcoefsav[0] - wcoef[0]      // maintain old peak top
            wcoef[3]= wcoefsav[3]+xaxval-gLastClickX
         else
            wcoef[0]= yaxval
            wcoef[1]= wcoefsav[1] + wcoefsav[0] - yaxval      // maintain old peak top
            wcoef[3]= wcoefsav[3]+xaxval-gLastClickX
         endif
      endif
      wdest=mygauss(wcoef,x)
   end
```

The debugger is normally disabled. Select Enable Debugger in either the Procedure menu or the contextual menu shown by control-clicking (Macintosh) or by right-clicking (Windows) in any procedure window.

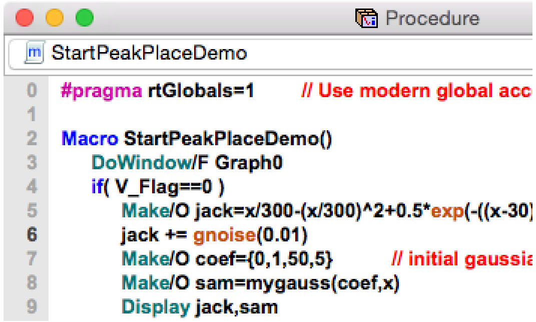
Igor displays the debugger window when one of the following events occurs:

1. A breakpoint that you previously set is hit
2. An error occurs, and you have enabled debugging on that kind of error
3. An error dialog is presented, and you click the Debug button
4. The **Debugger** command is executed

The debugger can not be used with threadsafe code. See **Debugging ThreadSafe Code** on page IV-225 for details.

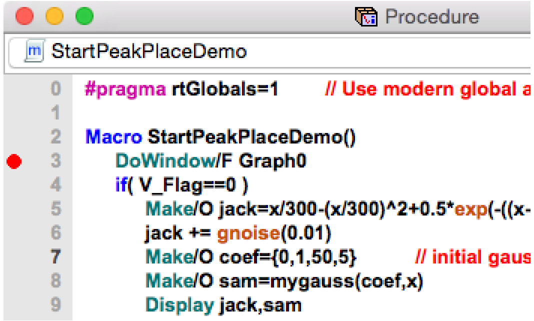
Setting Breakpoints

When you want to observe a particular routine in action, set a breakpoint on the line where you want the debugger to appear. To do this, open the procedure window which contains the routine, and click in the left “breakpoint margin”. The breakpoint margin appears only if the debugger has been enabled. These graphics show the procedure windowwith the debugger disabled (left) and enabled (right):



```
#pragma rtGlobals=1		// Use modern global acc

Macro StartPeakPlaceDemo()
	DoWindow/F Graph0
	if( V_Flag==0 )
		Make/O jack=x/300-(x/300)^2+0.5*exp(-((x-30)
		jack += gnoise(0.01)
		Make/O coef={0,1,50,5}		// initial gaussia
		Make/O sam=mygauss(coef,x)
		Display jack,sam
```



```
#pragma rtGlobals=1		// Use modern global a

Macro StartPeakPlaceDemo()
	DoWindow/F Graph0
	if( V_Flag==0 )
		Make/O jack=x/300-(x/300)^2+0.5*exp(-((x-
		jack += gnoise(0.01)
		Make/O coef={0,1,50,5}		// initial gaus
		Make/O sam=mygauss(coef,x)
		Display jack,sam
```

The red dot denotes a breakpoint that you have set.

When a line of code marked with a breakpoint is about to execute, Igor displays the debugger window.

Click the red dot again to clear the breakpoint. Control-click (*Macintosh*) or right-click (*Windows*) and use the pop-up menu to clear all breakpoints or disable a breakpoint on the currently selected line of the procedure window.

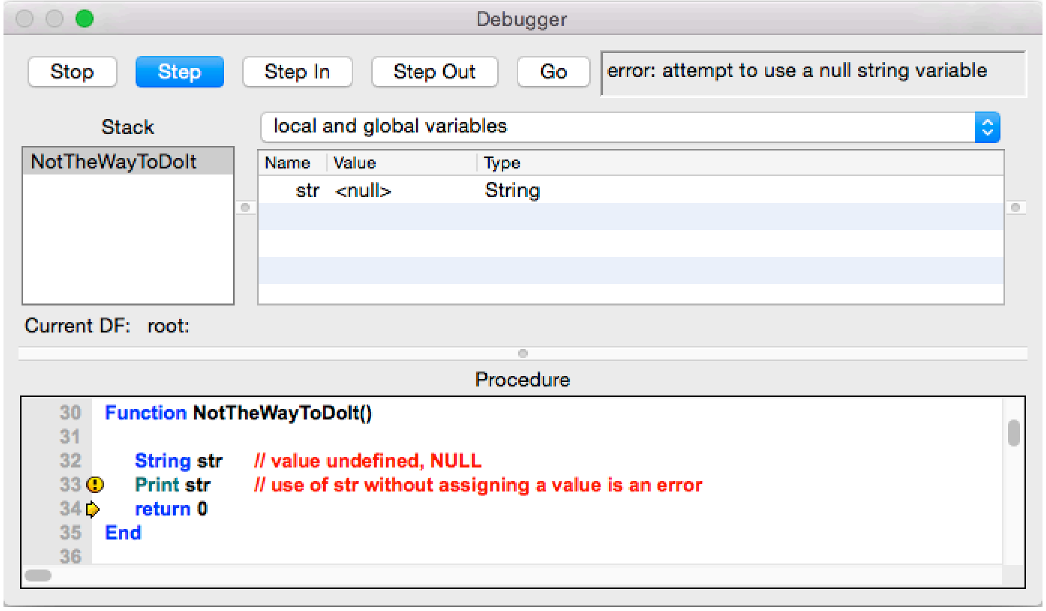
Debugging on Error

You can automatically open the debugger window when an error occurs. There are two categories of errors to choose from:

Debug On Error	Any runtime error except failed NVAR, SVAR, or WAVE references.
NVAR SVAR WAVE Checking	Failed NVAR, SVAR, or WAVE references.

We recommend that Igor programmers turn both of these options on to get timely information about errors.

Use the Procedure or contextual menus to enable or disable both error categories. If the selected error occurs, Igor displays the debugger with an error message in its status area. The error message was generated by the command indicated by a round yellow icon, in this example the Print str command:



error: attempt to use a null string variable

NotTheWayToDoIt

Name	Value	Type
str	<null>	String

Current DF: root:

```
Function NotTheWayToDoIt()

    String str    // value undefined, NULL
    Print str     // use of str without assigning a value is an error
    return 0
End
```

Sometimes you do something that you know may cause an error and you want to handle the error yourself, without breaking into the debugger. One such case is attempting to access a wave or variable that may or may not exist. You want to test its existence without breaking into the debugger.

You can use the /Z flag to prevent the Debug on Error feature from kicking in when an NVAR, SVAR, or WAVE reference fails. For example:

```
WAVE/Z w = <path to possibly missing wave>
if (WaveExists(w))
   <do something with w>
endif
```

In other cases where an error may occur and you want to handle it yourself, you need to temporarily disable the debugger and use **GetRTError** to get and clear the error. For example:

```
Function DemoDisablingDebugger()
   DebuggerOptions              // Sets V_enable to 1 if debugger is enabled
   Variable debuggerEnabled=V_enable
   DebuggerOptions enable=0     // Disable debugger

   String name = ";"            // This is an illegal wave name
   Make/O $name                 // So this will generate and error

   DebuggerOptions enable=debuggerEnabled    // Restore

   Variable err = GetRTError(1)              // Clear error
   if (err != 0)
      Printf "Error %d\r", err
   else
      Print "No error"
   endif
End
```

Debugging on Abort

You can tell Igor to automatically open the debugger window if you interrupt command execution by enabling Debug On Abort. This is useful for stopping code that is taking much longer than expected. It pauses execution and opens the debugger so you can see what is going on.

To enable or disable this feature, choose Procedure→Debug On Abort or right-click in a procedure window and choose Debug On Abort from the pop-up menu.

When Debug On Abort is enabled, the Abort button in the status bar is labeled "Debug", instead of "Abort". Click Debug to enter the debugger after the currently executing line finishes.

When Debug On Abort is disabled, clicking the Abort button stops all command execution and returns Igor to normal interactive operation.

Debug on Abort does not affect programmed aborts using the Abort, AbortOnRTE, or AbortOnValue operations.

Normally clicking the Abort button interrupts whatever command is running. For example, you can abort a wave assignment statement that is taking a long time.

To avoid entering the debugger when a command is half-finished, with Debug on Abort enabled, when you click the Debug button, Igor waits for the current command to finish before breaking into the debugger. If a very length operation or assignment statement is running, you may have to wait a long time for the debugger to activate.

You can interrupt the currently running command and enter the debugger more quickly using the **User Abort Key Combinations** instead of clicking the Debug button. This may enter the debugger at a time when an assignment is only partially finished.

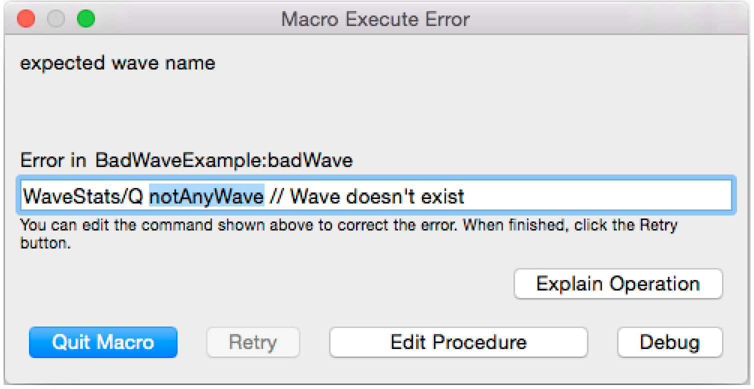
Some Igor code cannot be debugged. This includes thread-safe function code, hidden code, or independent module code (but see **SetIgorOption IndependentModuleDev=1** on page IV-239). If you click the Debug button or use the Abort key combinations while running code that cannot be debugged, code execution is stopped just as if Debug on Abort was not set. For instance, this:

```
ThreadSafe Function Mistake()
   Variable n=1
   do
      // forgot to increment n
   while (n<10)
End
```

cannot be debugged. Clicking Debug or using the Abort key combinations aborts execution. To debug this code, temporarily remove the Threadsafe keyword from the function declaration.

Macro Execute Error: The Debug Button

When the debugger is enabled and an error occurs in a macro, Igor presents an error dialog with, in most cases, a Debug button. Click the Debug button to open the debugger window.



expected wave name

Error in BadWaveExample:badWave

WaveStats/Q notAnyWave // Wave doesn't exist

You can edit the command shown above to correct the error. When finished, click the Retry button.

Errors in macros and procs are reported immediately after they occur.

When an error occurs in a user-defined function, Igor displays an error dialog long after the error actually occurred. The Debug On Error option is for programmers and displays errors in functions when they occur.

Stepping Through Your Code

Single-stepping through code is useful when you are not sure what path it is taking or how variables wound up containing their values.

Begin by enabling the debugger and setting a breakpoint on the line of code you are interested in, or begin when the debugger automatically opens because of an error. Use the buttons at the top of the debugger window to step through your code:

The Stop Button

The Stop button ceases execution of the running function or macro before it completes. This is equivalent to clicking Igor's Abort button while the procedure is running. If you have enabled Debug on Abort, the Stop button still causes execution to cease.

Keyboard shortcuts: Command-period (*Macintosh*), Ctrl+Break (*Windows*)

Pressing Command-period on a Macintosh while the debugger window is showing is equivalent to clicking the *Go* button, not the Stop button.

The Step Button

The Step button executes the next line. If the line contains a call to one or more subroutines, execution continues until the subroutines return or until an error or breakpoint is encountered. Upon return, execution halts until you click a different button.

Keyboard shortcuts: Enter, keypad Enter, or Return

The Step Into Button

The Step Into button executes the next line. If that line contains a call to one or more subroutines, execution halts when the first subroutine is entered. The Stack list of currently executing routines shows the most recently entered routine as the last item in the list.

Keyboard shortcuts: +, =, or keyPad +

The Step Out Button

The Step Out button executes until the current subroutine is exited, or an error or breakpoint is encountered.

Keyboard shortcuts: -, _ (underscore) or keypad -

The Go Button

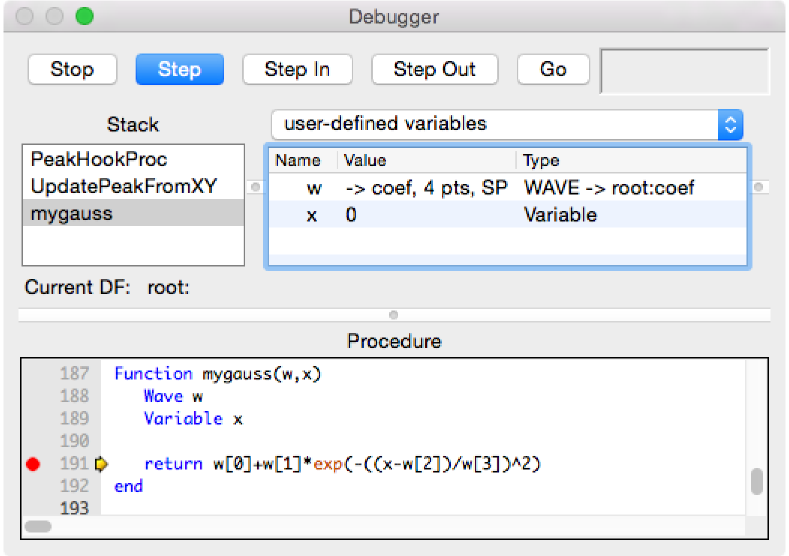
The Go button resumes program execution. The debugger window remains open until execution completes or an error or breakpoint is encountered.

If you press the Option (*Macintosh*) or Alt (*Windows*) key while clicking the Go button, the debugger window is closed until execution completes or an error or breakpoint is encountered.

Keyboard shortcuts: Esc

The Stack and Variables Lists

The Stack List shows the routine that is currently executing and the chain of routines that called it. The top item in the list is the routine that began execution and the bottom item is the routine which is currently executing.



user-defined variables

PeakHookProc
UpdatePeakFromXY
mygauss

Name	Value	Type
w	-> coef, 4 pts, SP	WAVE -> root:coef
x	0	Variable

Current DF: root:

```
Function mygauss(w,x)
	Wave w
	Variable x

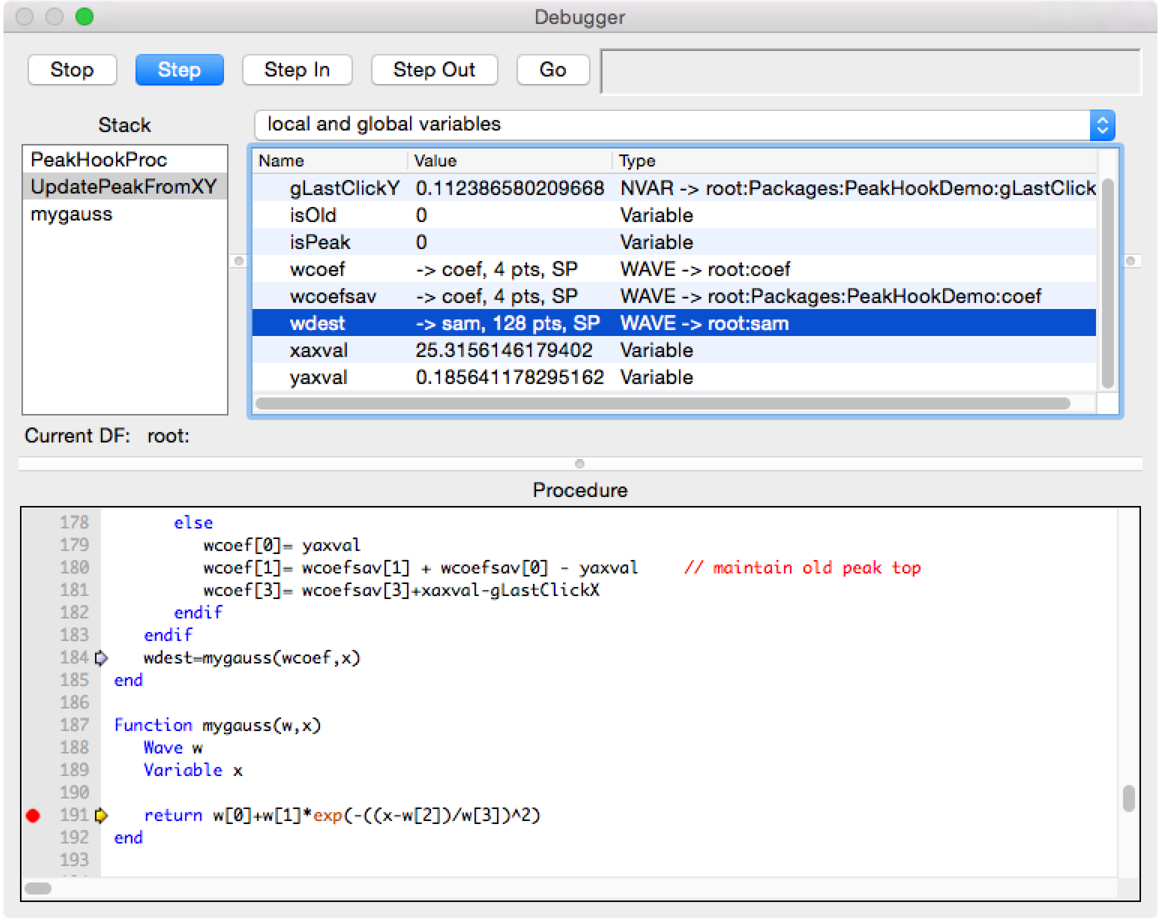
	return w[0]+w[1]*exp(-((x-w[2])/w[3])^2)
end

```

In this example, the routine that started execution is PeakHookProc, which most recently called UpdatePeakFromXY, which then called the currently executing mygauss user function.

The Variables List, to the right of the Stack List, shows that the function parameters w and x have the values coef (a wave) and 0 (a number). The pop-up menu controls which variables are displayed in the list; the example shows only user-defined local variables.

You can examine the variables associated with any routine in the Stack List by simply selecting the routine:



local and global variables

PeakHookProc
UpdatePeakFromXY
mygauss

Name	Value	Type
gLastClickY	0.112386580209668	NVAR -> root:Packages:PeakHookDemo:gLastClick
isOld	0	Variable
isPeak	0	Variable
wcoef	-> coef, 4 pts, SP	WAVE -> root:coef
wcoefsav	-> coef, 4 pts, SP	WAVE -> root:Packages:PeakHookDemo:coef
wdest	-> sam, 128 pts, SP	WAVE -> root:sam
xaxval	25.3156146179402	Variable
yaxval	0.185641178295162	Variable

Current DF: root:

```
		else
			wcoef[0]= yaxval
			wcoef[1]= wcoefsav[1] + wcoefsav[0] - yaxval		// maintain old peak top
			wcoef[3]= wcoefsav[3]+xaxval-gLastClickX
		endif
	endif
	wdest=mygauss(wcoef,x)
end

Function mygauss(w,x)
	Wave w
	Variable x

	return w[0]+w[1]*exp(-((x-w[2])/w[3])^2)
end

```

Here we’ve selected UpdatePeakFromXY, the routine that called mygauss (see the light blue arrow). Notice that the Variables List is showing the variables that are local to UpdatePeakFromXY.

For illustration purposes, the Variables List has been resized by dragging the dividing line, and the pop-up menu has been set to show local and global variables and type information.

The Variables List Columns

The Variables List shows either two or three columns, depending on whether the "show variable types" item in the Variable pop-up menu is checked.

Double-clicking a column's header resizes the column to fit the contents. Double-clicking again resizes the column to a default width.

The first column is the name of the local variable. The name of an NVAR, SVAR, or WAVE reference is a name local to the macro or function that refers to a global object in a data folder.

The second column is the value of the local variable. Double-click the second column to edit numbers in-place, double-click anywhere on the row to "inspect" waves, strings, SVARS, or char arrays in structures in the appropriate Inspector.

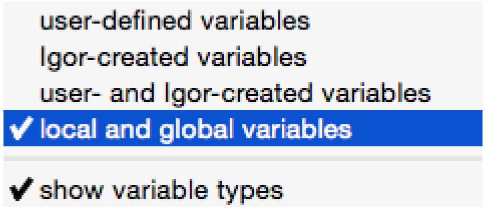
In the case of a wave, the size and precision of the wave are shown here. The "->" characters mean "refers to". In our example wcoef is a local name that refers to a (global) wave named coef, which is one-dimensional, has 4 points, and is single precision.

To determine the value of a particular wave element, use an inspector as described under **Inspecting Waves**.

The optional third column shows what the type of the variable is, whether Variable, String, NVAR, SVAR, WAVE, etc. For global references, the full data folder path to the global is shown.

Variables Pop-Up Menu

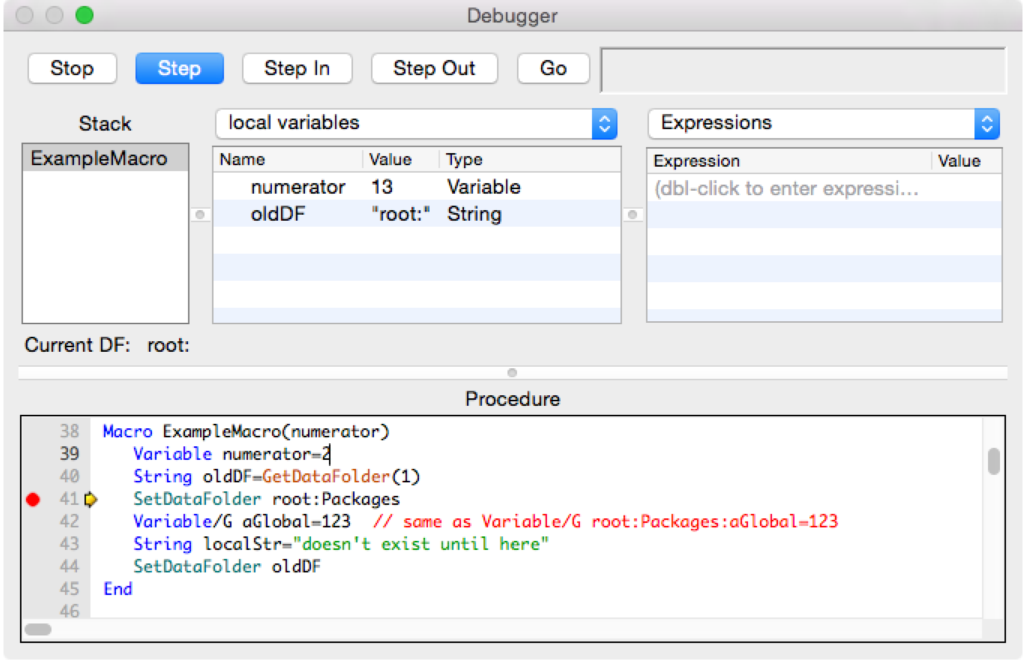
The Variables pop-up menu controls which information is displayed in the Variables List. When debugging a function, it looks like this:



When debugging a macro, proc or window macro, the first two items in the popup menu are unavailable.

Macro Variables

The ExampleMacro below illustrates how variables in Macros, Procs or Window procedures are classified as locals or globals:



Name	Value	Type
numerator	13	Variable
oldDF	"root:"	String

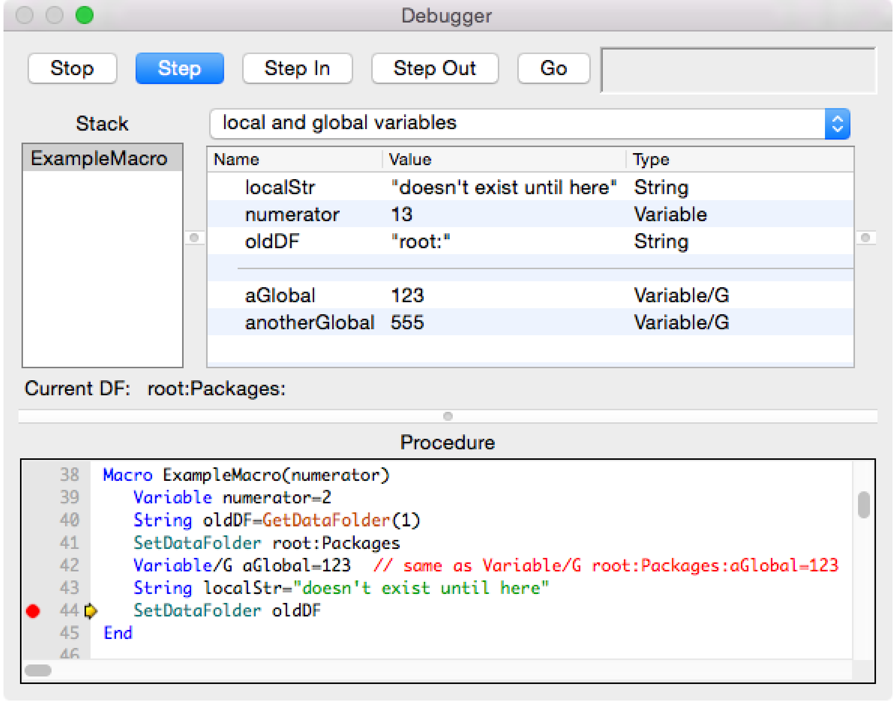
Expression	Value
(dbl-click to enter expressi…	

Current DF: root:

```
Macro ExampleMacro(numerator)
   Variable numerator=2
   String oldDF=GetDataFolder(1)
   SetDataFolder root:Packages
   Variable/G aGlobal=123  // same as Variable/G root:Packages:aGlobal=123
   String localStr="doesn't exist until here"
   SetDataFolder oldDF
End
```

Local variables in macros include all items passed as parameters (numerator in this example) and local variables and local strings (oldDF) whose definitions have been executed, and Igor-created local variables created by operations such as WaveStats after the operation has been executed. Note that localStr isn't listed, because the command has not yet executed.

Global variables in macros include all items in the current data folder, whether they are used in the macro or not. If the data folder changes because of a SetDataFolder operation, the list of global variables also changes. Note that there are no NVAR, SVAR, WAVE or STRUCT references in a macro.



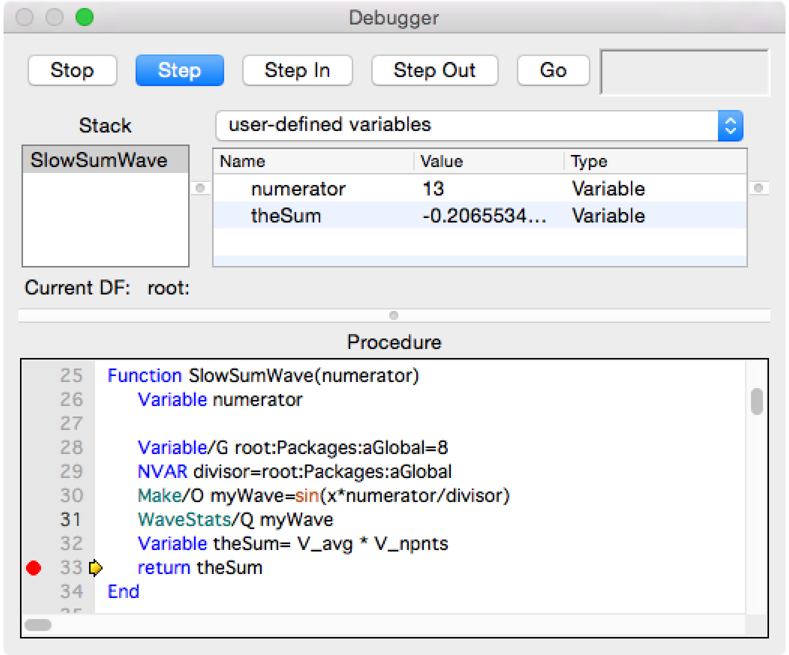
Name	Value	Type
localStr	"doesn't exist until here"	String
numerator	13	Variable
oldDF	"root:"	String
aGlobal	123	Variable/G
anotherGlobal	555	Variable/G

Current DF: root:Packages:

```
Macro ExampleMacro(numerator)
   Variable numerator=2
   String oldDF=GetDataFolder(1)
   SetDataFolder root:Packages
   Variable/G aGlobal=123  // same as Variable/G root:Packages:aGlobal=123
   String localStr="doesn't exist until here"
   SetDataFolder oldDF
End
```

Function Variables

The SlowSumWaveFunction example below illustrates how different kinds of variables in functions are classified:



Name	Value	Type
numerator	13	Variable
theSum	-0.2065534...	Variable

```
Function SlowSumWave(numerator)
    Variable numerator

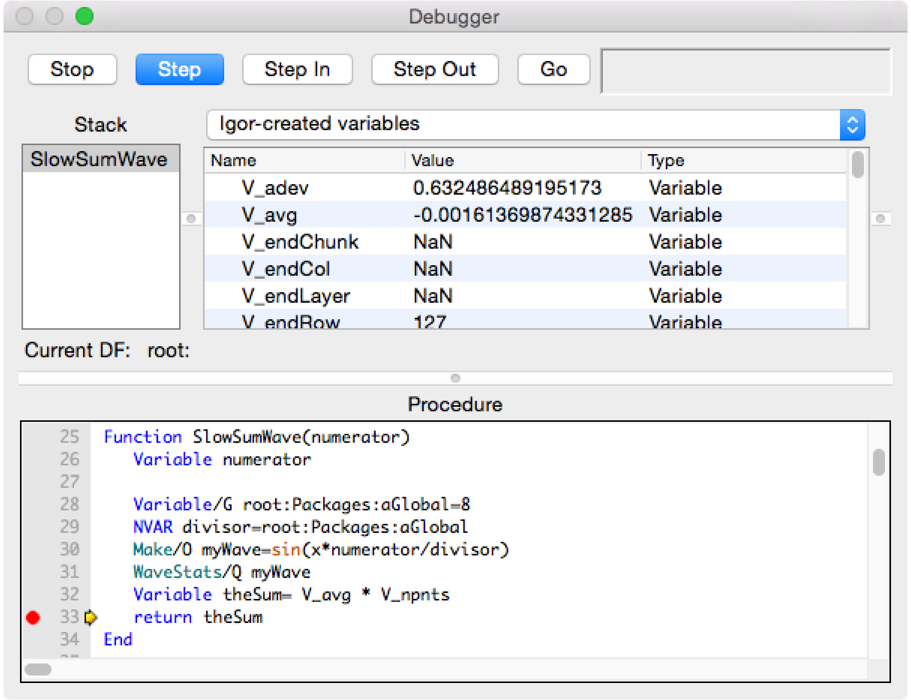
    Variable/G root:Packages:aGlobal=8
    NVAR divisor=root:Packages:aGlobal
    Make/O myWave=sin(x*numerator/divisor)
    WaveStats/Q myWave
    Variable theSum= V_avg * V_npnts
    return theSum
End
```

User-defined variables in functions include all items passed as parameters (numerator in this example) and any local strings and variables.

Local variables exist while a procedure is running, and cease to exist when the procedure returns; they never exist in a data folder like globals do.

NVAR, SVAR, WAVE, Variable/G and String/G references point to global variables, and therefore, aren't listed as user-defined (local) variables.

Use "Igor-created variables" to show local variables that Igor creates for functions when they call an operation or function that returns results in specially-named variables. The **WaveStats** operation (see page V-1082), for example, defines V_adev, V_avg, and other variables to contain the statistics results:



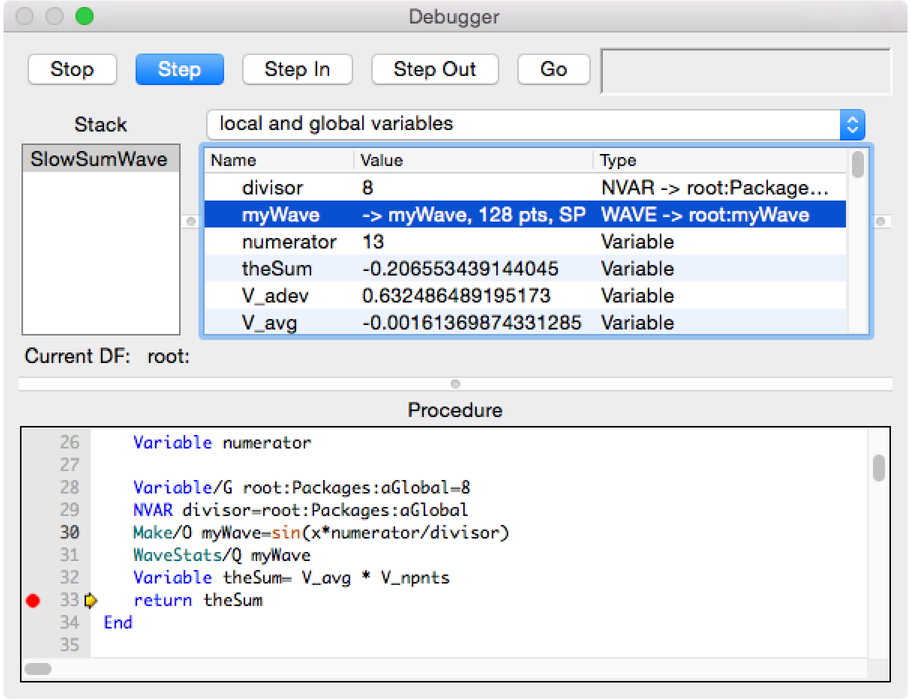
Name	Value	Type
V_adev	0.632486489195173	Variable
V_avg	-0.00161369874331285	Variable
V_endChunk	NaN	Variable
V_endCol	NaN	Variable
V_endLayer	NaN	Variable
V_endRow	127	Variable

```
Function SlowSumWave(numerator)
   Variable numerator

   Variable/G root:Packages:aGlobal=8
   NVAR divisor=root:Packages:aGlobal
   Make/O myWave=sin(x*numerator/divisor)
   WaveStats/Q myWave
   Variable theSum= V_avg * V_npnts
   return theSum
End
```

The “user- and Igor-created” menu item shows both kinds of local variables.

The “local and global variables” item shows user-created local variables, most Igor-created local variables, and references to global variables and waves through NVAR, SVAR, and WAVE references:



Name	Value	Type
divisor	8	NVAR -> root:Package...
myWave	-> myWave, 128 pts, SP	WAVE -> root:myWave
numerator	13	Variable
theSum	-0.206553439144045	Variable
V_adev	0.632486489195173	Variable
V_avg	-0.00161369874331285	Variable

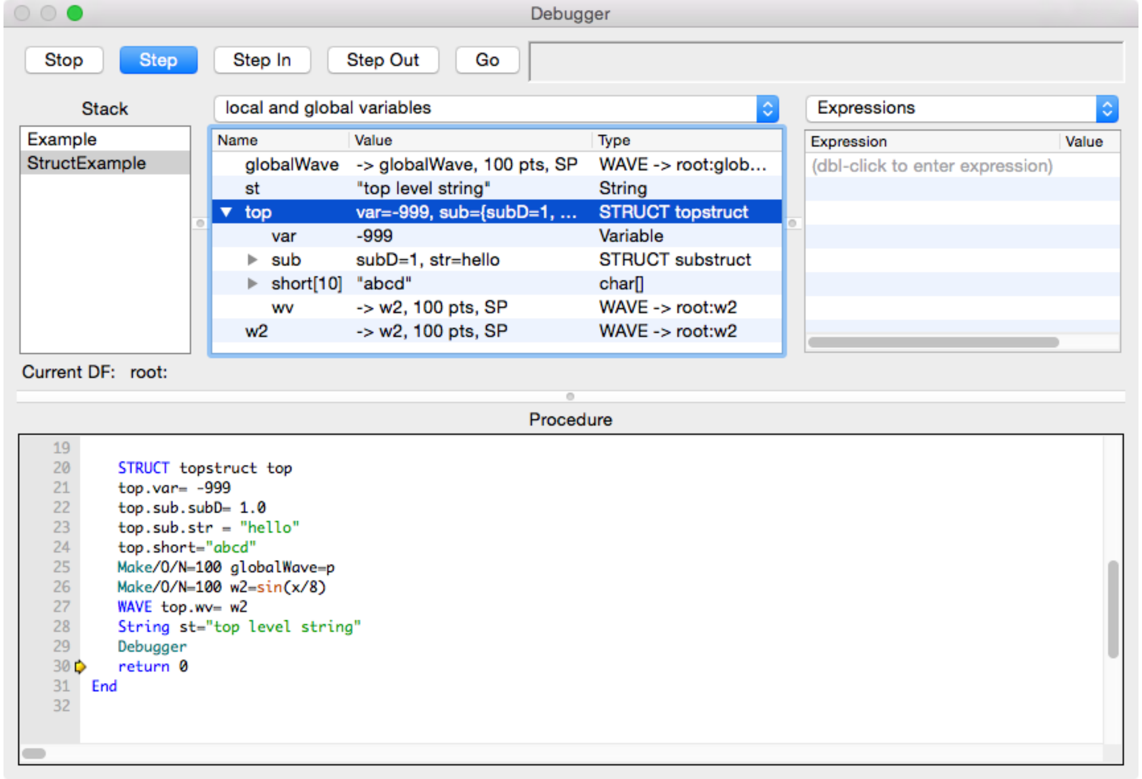
```
   Variable numerator

   Variable/G root:Packages:aGlobal=8
   NVAR divisor=root:Packages:aGlobal
   Make/O myWave=sin(x*numerator/divisor)
   WaveStats/Q myWave
   Variable theSum= V_avg * V_npnts
   return theSum
End

```

Function Structures

The elements of a structure (see **Structures in Functions** on page IV-99) are displayed in tree form in the Variables "list". Click the triangles to expand or collapse a node in the structure, or double-click the row:



Stack
Example
StructExample

Current DF: root:

Name	Value	Type
globalWave	-> globalWave, 100 pts, SP	WAVE -> root:glob…
st	"top level string"	String
▼ top	var=-999, sub={subD=1, …	STRUCT topstruct
var	-999	Variable
▶ sub	subD=1, str=hello	STRUCT substruct
▶ short[10]	"abcd"	char[]
wv	-> w2, 100 pts, SP	WAVE -> root:w2
w2	-> w2, 100 pts, SP	WAVE -> root:w2

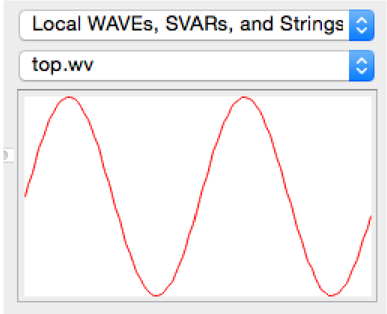
Expression	Value
(dbl-click to enter expression)	

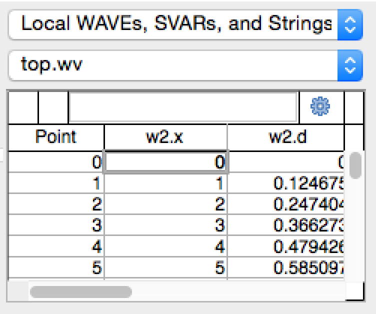
```

	STRUCT topstruct top
	top.var= -999
	top.sub.subD= 1.0
	top.sub.str = "hello"
	top.short="abcd"
	Make/O/N=100 globalWave=p
	Make/O/N=100 w2=sin(x/8)
	WAVE top.wv= w2
	String st="top level string"
	Debugger
	return 0
End

```

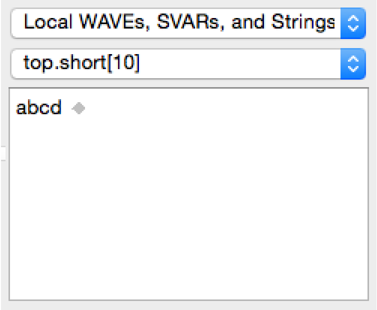
Double-clicking a WAVE element (such as top.wv) will send it to the Wave Inspector (either a table or graph depending on what is checked in the Inspector popup):





Point	w2.x	w2.d
0	0	0
1	1	0.124675
2	2	0.247404
3	3	0.366273
4	4	0.479426
5	5	0.585097

Double-clicking a String element or char array (such as top.short) will send it to the String Inspector:



abcd

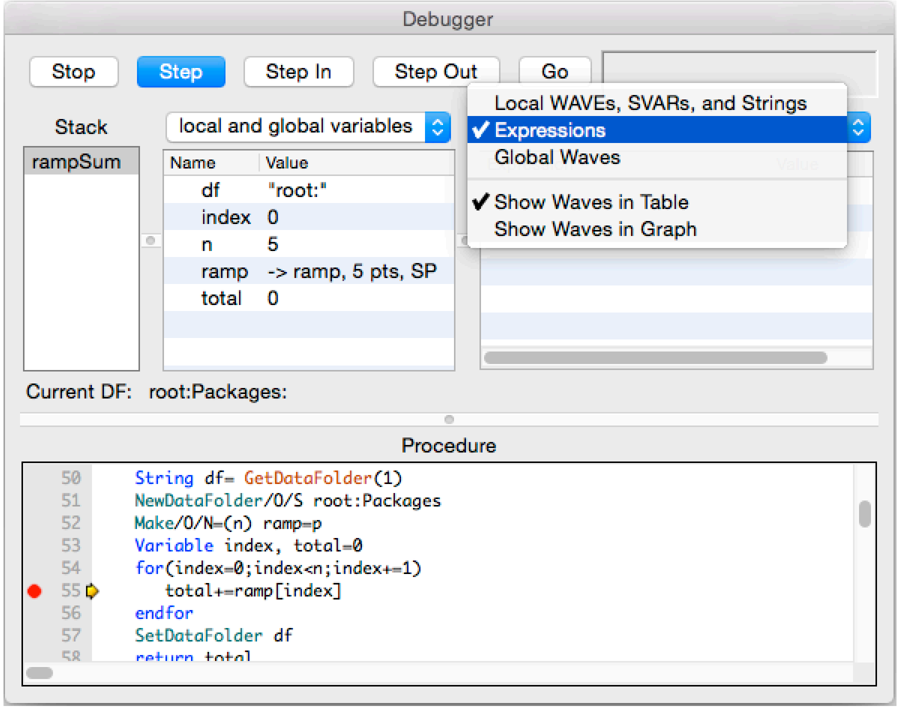
The Current Data Folder

The "Current DF" displays the path to the current data folder. You can select and copy the data folder path. See **Data Folders** on page II-107 for more information about data folders.

Graph, Table, String, and Expressions Inspectors

One of the Wave, String, or Expressions Inspectors is visible to right side of the variables list. This pane is hidden when the divider between the pane and the variables list is dragged all the way to the right. Drag the divider to the left to show the pane. You may need to widen the window to make room.

Use the popup to select the Inspector you want.



Name	Value
df	"root:"
index	0
n	5
ramp	-> ramp, 5 pts, SP
total	0

Current DF: root:Packages:

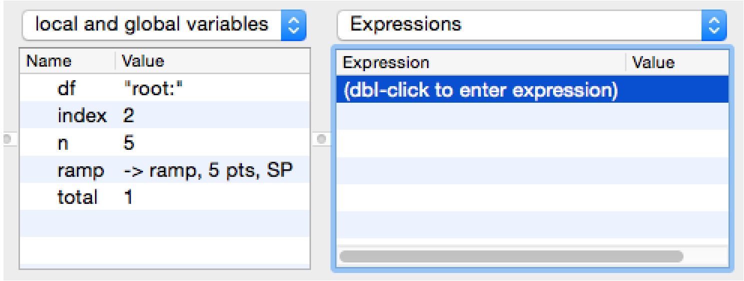
```
	String df= GetDataFolder(1)
	NewDataFolder/O/S root:Packages
	Make/O/N=(n) ramp=p
	Variable index, total=0
	for(index=0;index<n;index+=1)
		total+=ramp[index]
	endfor
	SetDataFolder df
	return total
```

The pop-up menu controls what is shown in the pane:

Pop-up Menu Selection	Pane Contents
Local WAVEs, SVARs, and Strings	A list of these things in the selected function. References to free waves are also listed here, as are elements in a STRUCT that are "inspectable", including char arrays which can be viewed as if they were Strings.
Local Strings	A list of Strings local to the selected function, macro or proc.
Expressions	Numeric or string expressions which are evaluated in the context of the selected function or macro.
Global Waves	A popup wave selector to display any wave in a global data folder. Free waves are not listed here.
Show Waves in Table Show Waves in Graph	Waves will be displayed in a table or graph, depending on which one of these two is checked.

Expressions Inspector

Selecting "Expressions" from the inspector popup shows a list of Expressions and their values:



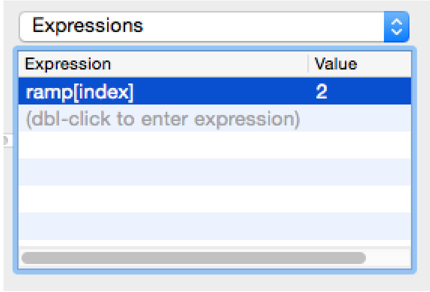
local and global variables

Name	Value
df	"root:"
index	2
n	5
ramp	-> ramp, 5 pts, SP
total	1

Expressions

Expression	Value
(dbl-click to enter expression)	

Replace the "(dbl-click to enter expression)" invitation by clicking it, typing a numeric or string expression, and pressing Return.



Expressions

Expression	Value
ramp[index]	2
(dbl-click to enter expression)	

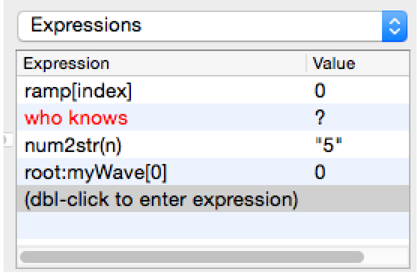
Adding an expression adds a blank row at the end of the list that can be double-clicked to enter another expression. You can edit any of the expressions by double-clicking and typing.

The expression can be removed by selecting it and pressing Delete or Backspace.

The result of the expression is recomputed when stepping through procedures. The expressions are evaluated in the context of the currently selected procedure.

Global expressions are evaluated in the context of the current data folder, though you can specify the data folder explicitly as in the example below.

If an expression is invalid the result is shown as “?” and the expression is changed to red:



Expressions

Expression	Value
ramp[index]	0
who knows	?
num2str(n)	"5"
root:myWave[0]	0
(dbl-click to enter expression)	

The expressions are discarded when a new Igor experiment is opened or when Igor quits.

Inspecting Waves

You can "inspect" (view) the contents of a wave in either a table or a graph. They aren't full-featured tables or graphs, as there are no supporting dialogs for them. You can change their properties using contextual menus.

Select the Wave to be inspected by one of three methods:

1. Choose "Global Waves", and then choose a wave from the popup wave browser.
2. Choose "Local WAVEs, SVARs, and Strings", and then choose a wave from among the objects listed.
3. Double-click any WAVE reference in the Variables list.

Inspecting Waves in a Table

You can edit the values in a wave using the table, just like a regular table. With the contextual menu you can alter the column format, among other things.

Inspecting Waves in a Graph

You can view waves in a Graph. With the contextual menu, you can choose to show or hide the axes and change display modes.

Two-dimensional waves are displayed as an image plot.

Inspecting Strings

Select a String or char array to be inspected by two methods:

1. Choose "Local WAVEs, SVARs, and Strings", and then choose a String, SVAR or char array from among the objects listed.
2. Double-click any String, SVAR or char array in the Variables list.

The Procedure Pane

The procedure pane contains a copy of the procedure window of the routine selected in the Stack List. You can set and clear breakpoints in this pane just as you do in a procedure window, using the breakpoint margin and the Control-click (*Macintosh*) or right-click (*Windows*) menu.

A very useful feature of the debugger is the automatic text expression evaluator that shows the value of a variable or expression under the cursor. The value is displayed as a tool tip. This is often faster than scrolling through the Variables List or entering an expression in the Expressions List to determine the value of a variable, wave, or structure member reference.

The value of a variable can be displayed whether or not the variable name is selected. To evaluate an expression such as "wave[ii]+3", the expression must be selected and the cursor must be over the selection.

The debugger won't evaluate expressions that include calls to user-defined functions; this prevents unintended side effects (a function could overwrite a wave's contents, for example). You can remove this limitation by creating the global variable root:V_debugDangerously and setting it to 1.

After You Find a Bug

Editing in the debugger window is disabled because the code is currently executing. Tracking down the routine after you've exited the debugger is easy if you follow these steps:

1. Scroll the debugger text pane back to the name of the routine you want to modify, and select it.
2. Control-click (Macintosh) or Right-click (Windows) the name, and choose "Go to <routineName>" from the pop-up menu.
3. Exit the debugger by clicking the "Go" button or by pressing Escape.

Now the selected routine will be visible in the top procedure window, where you can edit it.

Debugging ThreadSafe Code

The Igor debugger can not be used with threadsafe functions.

The debugger does not break on breakpoints in threadsafe functions.

The debugger does not allow you to step into a threadsafe function.

These restrictions apply even if you call a threadsafe function from a non-threadsafe function.

The main technique for debugging threadsafe code is the use of print statements. See Debugging With Print Statements.

You can use the debugger on functions marked as threadsafe by temporarily disabling multithreading by executing:

```
SetIgorOption DisableThreadSafe = 1    // Disable multithreading
```

This causes Igor to recompile all procedures and to ignore the Threadsafe and MultiThread keywords. You can then debug procedures using the debugger. When you are finished, re-enable multithreading by executing:

```
SetIgorOption DisableThreadSafe = 0    // Re-enable multithreading
```

Debugger Shortcuts

Action	Shortcut
To enable debugger	Choose Enable Debugger from the Procedure menu or choose Enable Debugger from the procedure window's pop-up menu after Control-clicking (*Macintosh*) or right-clicking (*Windows*).
To automatically enter the debugger when an error occurs	Choose Debug on Error from the Procedure menu or choose Enable Debugger from a procedure window's pop-up menu after Control-clicking (*Macintosh*) or right-clicking (*Windows*).
To set or clear a breakpoint	Click in the left margin of the procedure window or click anywhere on the procedure window line where you want to set or clear the breakpoint and choose Set Breakpoint or Clear Breakpoint from a procedure window's pop-up menu after Control-clicking (*Macintosh*) or right-clicking (*Windows*).
To enable or disable a breakpoint	Shift-click a breakpoint in the left margin of the procedure window. Click anywhere on the procedure window line where you want to enable or disable the breakpoint and choose Enable Breakpoint or Disable Breakpoint procedure window's pop-up menu after Control-clicking (*Macintosh*) or right-clicking (*Windows*).
To execute the next command	On *Macintosh* press Enter, keypad Enter, or Return. For *Windows*, if no button has the focus, press Enter or Return. Otherwise, click the yellow arrow button.
To step into a subroutine	Press the +, =, or keypad + keys, or click the blue descending arrow button.
To step out of a subroutine to the calling routine	Press the -, _ (underscore) or keypad - keys, or click the blue ascending arrow button.
To resume executing normally	Press Escape (Esc), or click the green arrow button.
To cancel execution	Click the red stop sign button.
To edit the value of a macro or function variable	Double-click the second column of the variables list, edit the value, and press Return or Enter.
To set the value of a function's string to null	Double-click the second column of the variables list, type "<null>" (without the quotes), and press Return or Enter.
To view the current value of a macro or function variable	Move the cursor to the procedure text of the variable name and wait. On *Macintosh*, the value appears to the right of the debugger buttons. On *Windows*, the value appears in a tooltip window.

Action	Shortcut
To view the current value of an expression	Select the expression text with the cursor, position the cursor over the selection, and wait. (Expressions involving user-defined functions will not be evaluated unless V_debugDangerously is set to 1.)
To view global values in the current data folder	Choose “local and global variables” from the debugger pop-up menu.
To view type information about variables	Choose “show variable types” from the debugger pop-up menu.
To resize the columns in the variables list	Drag a divider in the list to the left or right.
To show or hide the Waves, Structs, and Expressions pane	Drag the divider on the right side of the Variables list left or right.

Chapter

IV-9

Dependencies

Dependency Formulas

Igor Pro supports “dependent objects”. A dependent object can be a wave, a global numeric variable or a global string variable that has been linked to an expression. The expression to which an object is linked is called the object’s “dependency formula” or “formula” for short.

The value of a dependent object is updated whenever any other global object involved in the formula is modified, even if its value stays the same. We say that the dependent object *depends* on these other global objects *through* the formula.

You might expect that an assignment such as:

```
Variable var0 = 1
Make wave0
wave0 = sin(var0*x/16)
```

meant that wave0 would be updated whenever var0 changed. It doesn’t. Values are computed for wave0 only once, and the relationship between wave0 and var0 is forgotten.

However, if the equal sign in the above assignment is replaced by a colon followed by an equal sign:

```
wave0 := sin(var0*x/16)
```

then Igor *does* create just such a dependency. Now whenever var0 changes, Igor reevaluates the assignment statement and updates wave0. In this example, wave0 is a dependent object. It depends on var0, and “sin(var0*x/16)” is wave0’s dependency formula.

You can also establish a dependency using the SetFormula operation, like this:

```
SetFormula wave0, "sin(var0*x/16)"
```

Wave1 depends on var0 because var0 is a changeable variable. Wave1 *also* depends on the function x which returns the X scaling of the destination wave (wave0). When the X scaling of wave0 changes, the values that the x function returns change, so this dependency assignment is reevaluated. The remaining terms (sin and 16) are not changeable, so wave0 does not depend on them.

From the command line, you can use either a dependency assignment statement or SetFormula to establish a dependency. In a user-defined function, you must use SetFormula.

Like other assignment statements, the data folder context for the right-hand side is that of the destination object. Therefore, in the following example, wave2 and var1 must be in the data folder named foo, var2 must be in root, and var3 must be in root:bar.

```
root:foo:wave0 := wave2*var1 + ::var2 + root:bar:var3
```

Data Folders are described in Chapter II-8, **Data Folders**.

A dependency assignment is often used in conjunction with SetVariable controls and ValDisplay controls.

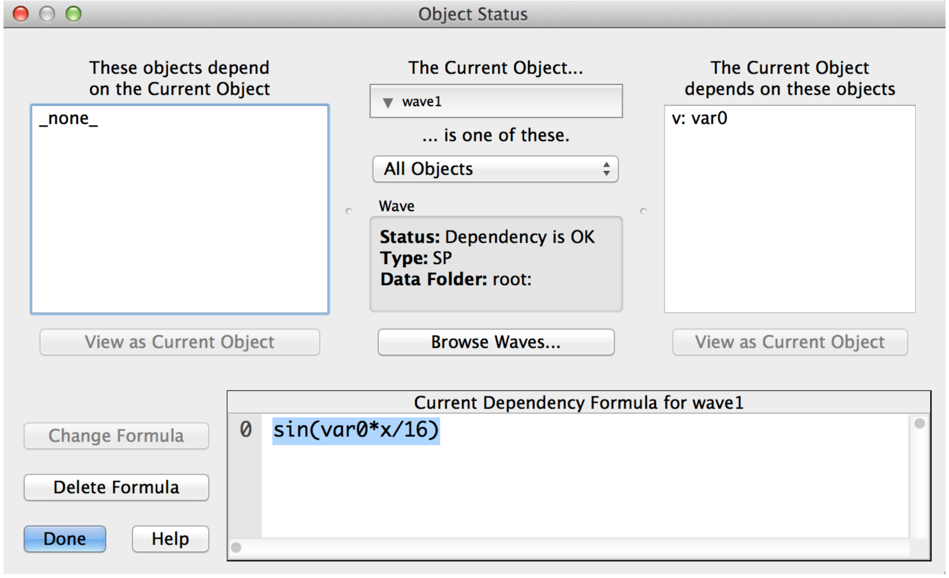
Here’s a simple example. Execute these commands on the command line:

```
Variable/G var0 = 1
Make/O wave0:=sin(var0*x/16)
Display /W=(4,53,399,261) wave0
ControlBar 23
SetVariable setvar0,size={60,15},value=var0
```

Click the SetVariable control’s up and down arrows to adjust var0 and observe that wave0 is automatically updated.

Dependencies and the Object Status Dialog

You can use the Object Status dialog, which you can access via the the Misc menu, to check dependencies. After executing the commands in the preceding section, the dialog looks like this:



Status: Dependency is OK
Type: SP
Data Folder: root:

```
0  sin(var0*x/16)
```

The Status area indicates any dependency status:

- “No dependency” means that the current object does not depend on anything.
- “Dependency is OK” means that the dependency formula successfully updated the current object.
- “Update failed” means that the dependency formula used to compute the current object’s value failed.

An update may fail because there is a syntax error in the formula or one of the objects referenced in the formula does not exist or has been renamed. If the formula includes a call to a user-defined function then the update will fail if the function does not exist or if procedures are not compiled.

If an update fails, then the objects that depend on that update are broken. See **Broken Dependent Objects** on page IV-233 for details.

You can create a new dependency formula with the New Formula button, which appears only if the current object is not the target of a dependency formula.

You can delete a dependency formula using the Delete Formula button.

You can change an existing dependency formula by typing in the Dependency Formula window, and clicking the Change Formula button.

For further details on the Object Status dialog, click the Help button in the dialog.

Numeric and String Variable Dependencies

Dependencies can also be created for global user-defined numeric and string variables. You can not create a dependency that uses a local variable on either side of the dependency assignment statement.

Here is a user-defined function that creates a dependency. The global variable `recalculateThis` is made to depend on the global variable `dependsOnThis`:

```
Function TestRecalculation()
   Variable/G recalculateThis
   Variable/G dependsOnThis = 1

   // Create dependency on global variable
   SetFormula recalculateThis, "dependsOnThis"

   Print recalculateThis       // Prints original value

   dependsOnThis = 2           // Changes something recalculateThis
   DoUpdate                    // Make Igor recalculate formulae

   Print recalculateThis       // Prints updated value
End
```

Running this function prints the following to the history area:

```
•TestRecalculation()
   1
   2
```

The call to DoUpdate is needed because Igor recalculates dependency formulas only when no user-defined functions are running or when DoUpdate is called.

This function uses SetFormula to create the dependency because the := operator is not allowed in user-defined functions.

Wave Dependencies

The assignment statement:

```
dependentWaveName := formula
```

creates a dependency and links the dependency formula to the dependent wave. Whenever any change is made to any object in the formula, the contents of the dependent wave are updated.

The command

```
SetFormula dependentWaveName, "formula"
```

establishes the same dependency.

From the command line, you can use either a dependency assignment statement or SetFormula to establish a dependency. In a user-defined function, you must use SetFormula.

Cascading Dependencies

“Cascading dependencies” refers to the situation that arises when an object depends on a second object, which in turn depends on a third object, etc. When an object changes, all objects that directly depend on that object are updated, *and* objects that depend directly on those updated objects are updated until no more updates are needed.

You can use the Object Status dialog to investigate cascading dependencies.

Deleting a Dependency

A dependency is deleted when the dependent object is assigned a value using the = operator:

```
recalculateThis := dependsOnThis     // Creates a dependency
recalculateThis = 0                  // Deletes the dependency
```

This method of deleting a dependency does not work in user-defined functions. You must use the SetFormula operation.

For example:

```
Execute "recalculateThis = 0"
```

will delete the dependency even in a user-defined function.

You can also delete this dependency using the SetFormula operation.

```
SetFormula recalculateThis, ""
```

Wave dependencies are also deleted by operations that overwrite the values of their wave parameters. Some of these operations are:

```
FFT      Convolve        Correlate   Smooth   GraphWaveEdit
Hanning  Differentiate   Integrate   UnWrap
```

Dependencies can also be deleted using the Object Status dialog.

Broken Dependent Objects

Igor compiles the text of a dependency formula to low-level code and stores both the original text and the low-level code with the dependent object. At various times, Igor may need to recompile the dependency formula text. At that time, a compilation error will occur if:

- The dependency formula contains an error
- An object used in the dependency formula has been deleted, renamed, or moved
- The dependency formula references a user-defined function that is missing
- The dependency formula references a user-defined function and procedures are not compiled

When this happens, the dependent object will no longer update but will retain its last value. We call such an object “broken”.

To inspect broken objects, invoke the Object Status dialog. Choose Broken Objects from the pop-up menu above the status area. If there are any broken objects, they will appear in the Current Object pop-up. Select an object from the Current Object pop-up to inspect it.

When Dependencies are Updated

Dependency updates take place at the same time that graphs are updated. This happens after each line in a macro is executed, or when DoUpdate is called from a macro or user function, or continuously if a macro or function is not running.

Dependency formulas used as input to the SetBackground and ValDisplay operations, and in some other contexts, can alternately be specified as a literal string of characters using the following syntax:

```
#"text_of_the_dependency_expression"
```

Note that what follows the # char must be a literal string — not a string expression.

This sets the dependency formula *without* compiling it or checking it for validity. If you need to set the dependency formula of an object to something that is not currently valid but will be in the future, then use this alternate method.

Programming with Dependencies

You cannot use := to create dependencies in user-defined functions. Instead you must use the **SetFormula** operation (see page V-847).

```
Function TestFunc()
   Variable/G varNum=-666
   Make wave0
   SetFormula wave0, "varNum"    // Equivalent to wave0 := varNum
End
```

Using Operations in Dependency Formulas

The dependency formula must be a single expression — and you can not use operations, such as FFT's, or other command type operations. However, you can invoke user-defined functions which invoke operations. For example:

```
Function MakeDependencyUsingOperation()
   Make/O/N=128 data = p         // A ramp from 0 to 127
   Variable/G power

   SetFormula power, "RMS(data)" // Dependency on function and wave
   Print power

   data = p * 2                  // Changes something power depends
   DoUpdate                      // Make Igor recalc formulae
   Print power
EndMacro

Function RMS(w)
   Wave w

   WaveStats/Q w           // An operation! One output is V_rms
   return V_rms
End
```

When `MakeDependencyUsingOperation` is executed, it prints the following in the history area:

```
•MakeDependencyUsingOperation()
   73.4677
   146.935
```

Dependency Caveats

The extensive use of dependencies can create a confusing tangle that can be difficult to manage. Although you can use the Object Status dialog to explore the dependency hierarchy, you can still become very confused very quickly, especially when the dependencies are highly cascaded. You should use dependencies only where they are needed. Use conventional assignments for the majority of your calculations.

Dependency formulas are generally not recalculated when a user-defined function is running unless you explicitly call the DoUpdate operation. However, they can run at other unpredictable times so you should not make any assumptions as to the timing or the current data folder when they run.

The text of the dependency formula that is saved for a dependent object is the original literal text. The dependency formula needs to be recompiled from time to time, for example when procedures are compiled. Therefore, any objects used in the formula must persist until the formula is deleted.

We recommend that you never use $ expressions in a dependency formula.

Chapter

IV-10

Advanced Topics

This chapter contains material on topics of interest to advanced Igor users.

Procedure Modules

Igor supports grouping procedure files into modules to prevent name conflicts and to isolate procedure packages from other packages. This feature is for intermediate to advance Igor programmers.

There are three types of modules:

- ProcGlobal
- Regular Modules
- Independent Modules

You set a procedure file's module using the **ModuleName** or **IndependentModule** pragmas. A procedure file that does not contain one of these pragmas is in the ProcGlobal module by default.

Igor compiles independent modules separately from other procedures. This allows independent modules to continue to work even if there are errors in other procedure files. Independent module programming is demanding and is intended for use by advance Igor programmers. See **Independent Modules** on page IV-238 for details.

Regular modules provide protection against name conflicts and are easier to work with than independent modules. Regular modules are intended for use by intermediate to advanced Igor programmers who are creating procedure packages. See **Regular Modules** for details.

Regular Modules

Regular modules provide a way to avoid name conflicts between procedure files. Regular modules are distinct from "independent modules" which are discussed in the next section.

Igor's module concept provides a way to group related procedure files and to prevent name conflicts between procedure packages. You specify that a procedure file is part of a regular module using the #pragma ModuleName statement. The statement is allowed in any procedure file but not in the built-in main procedure window.

A procedure file that does not contain a #pragma ModuleName statement (or a #pragma IndependentModule statement) defines public procedure names in the default ProcGlobal module. All functions in the procedure file can be called from any other procedure file in ProcGlobal or in any regular module by simply specifying the name without any name qualifications (explained below).

When you execute a function from the command line or use the **Execute** operation, you are operating in the ProcGlobal context.

Functions are public by default and private if declared using the static keyword. For example

```
// In a procedure file with no #pragma ModuleName or #pragma IndependentModule

static Function Test()           // "static" means private to procedure file
   Print "Test in ProcGlobal"
End

Function TestInProcGlobal()      // Public
   Print "TestInProcGlobal in ProcGlobal"
End
```

Because it is declared static, the Test function is private to its procedure file. Each procedure file can have its own static Test function without causing a name conflict.

The TestInProcGlobal function is public so there can be only one public function with this name in ProcGlobal.

In this example the static Test function is accessible only from the procedure file in which it is defined.

Sometimes you have a need to avoid name conflicts but still want to be able to call functions from other procedure files, from control action procedures or from the command line. This is where a regular module is useful.

You specify that a procedure file is in a regular module using the ModuleName pragma so that even static functions can be called from other procedure files. For example:

```
#pragma ModuleName = ModuleA      // The following procedures are in ModuleA

static Function Test()            // Semi-private
   Print "Test in ModuleA"
End

Function TestModuleA()            // Public
   Print "Test in ModuleA"
End
```

Because it is declared static, this Test function does not conflict with Test functions in other procedure files. But because it is in a regular module (ModuleA), it can be called from other procedure files using a qualified name:

```
ModuleA#Test()                    // Call Test in ModuleA
```

This qualified name syntax overrides the static nature of Test and tells Igor that you want to execute the Test function defined in ModuleA. The only way to access a static function from another procedure file is to put it in a regular module and use a qualified name.

If you are writing a non-trivial set of procedures, it is a good idea to use a module and to declare your functions static, especially if other people will be using your code. This prevents name conflicts with other procedures that you or other programmers write.

Make sure to choose a distinctive module name. Module names must be unique.

Regular Modules in Action Procedures and Hook Functions

Control action procedures and hook functions are called by Igor at certain times. They are executed in the ProcGlobal context, as if they were called from the command line. This means that you must use a qualified name to call a static function as an action procedure or a hook function. For example:

```
#pragma ModuleName = RegularModuleA

static Function ButtonProc(ba) : ButtonControl
   STRUCT WMButtonAction &ba

   switch (ba.eventCode)
      case 2: // mouse up
         Print "Running RegularModuleA#ButtonProc"
         break
   endswitch

   return 0
End

static Function CreatePanel()
   NewPanel /W=(375,148,677,228)
   Button button0,pos={106,23},size={98,20},title="Click Me"
   Button button0,proc=RegularModuleA#ButtonProc
End
```

RegularModuleA is the name we have chosen for the regular module for demonstration purposes. You should choose a more descriptive module name.

The use of a qualified name, RegularModuleA#ButtonProc, allows Igor to find and execute the static ButtonProc function in the RegularModuleA module even though ButtonProc is running in the ProcGlobal context.

To protect the CreatePanel function from name conflicts we also made it static. To create the panel, execute:

```
RegularModuleA#CreatePanel()
```

Regular Modules and User-Defined Menus

Menu item execution text also runs in the ProcGlobal context. If you want to call a routine in a regular module you must use a qualified name.

Continuing the example from the preceding section, here is how you would write a menu definition:

```
#pragma ModuleName = RegularModuleA

Menu "Macros"
   "Create Panel", RegularModuleA#CreatePanel()
End
```

See also **Procedure Modules** on page IV-236, **Independent Modules** below, **Controls and Control Panels** on page III-413, **User-Defined Hook Functions** on page IV-280 and **User-Defined Menus** on page IV-125.

Independent Modules

An independent module is a set of procedure files that are compiled separately from all other procedures. Because it is compiled separately, an independent module can run when other procedures are in an uncompiled state because the user is editing them or because an error occurred in the last compile. This allows the independent module's control panels and menus to continue to work regardless of user programming errors.

Creating an independent module adds complexity and requires a solid understanding of Igor programming. You should use an independent module if it is important that your procedures be runnable at all times. For example, if you have created a data acquisition package that must run regardless of what the user is doing, that would be a good candidate for an independent module.

A file is designated as being part of an independent module using the IndependentModule pragma:

```
#pragma IndependentModule = imName
```

Make sure to use a distinctive name for your independent module.

The IndependentModule pragma is not allowed in the built-in procedure window which is always in the ProcGlobal module.

It is normal for multiple procedure files that are part of the same package to be in the same independent module.

An independent module creates an independent namespace. Function names in an independent module do not conflict with the same names used in other modules. To call an independent module function from the ProcGlobal module or from a regular module the function must be public (non-static) and you must use a qualified name as illustrated in the next section.

An independent module can call only procedures in that independent module.

Independent Modules - A Simple Example

Here is a simple example using an independent module. This code must be in its own procedure file and not in the built-in procedure file:

```
#pragma IndependentModule = IndependentModuleA

static Function Test()              // static means private to file
   Print "Test in IndependentModuleA"
End

// This must be non-static to call from command line (ProcGlobal context)
Function CallTestInIndependentModuleA()
   Test()
End
```

From the command line (the ProcGlobal context):

```
CallTestInIndependentModuleA()                     // Error

IndependentModuleA#CallTestInIndependentModuleA()  // OK

IndependentModuleA#Test()                          // Error
```

The first command does not work because the functions in the independent module are accessible only using a qualified name. The second command does work because it uses a qualified name and because the function is public (non-static). The third command does not work because the function is private (static) and therefore is accessible only from the file in which it is defined. A static function in an independent module is not accessible from outside the procedure file in which it is defined unless it is in an enclosed regular module as described under **Regular Modules Within Independent Modules** on page IV-242.

SetIgorOption IndependentModuleDev=1

By default, the debugger is disabled for independent modules. It can be enabled using:

```
SetIgorOption IndependentModuleDev=1
```

Also by default, independent module procedure windows are not listed in the Windows→Procedure Windows submenu unless you use `SetIgorOption IndependentModuleDev=1`.

When `SetIgorOption IndependentModuleDev=1` is in effect, the Windows→Procedure Windows submenu shows all procedure windows, and those that belong to an independent module are listed with the independent module name in brackets. For example:

```
DemoLoader.ipf [WMDemoLoader]
```

This bracket syntax is used in the **WinList**, **FunctionList**, **DisplayProcedure**, and **ProcedureText** functions and operations.

To get the user experience, as opposed to the programmer experience, return to normal operation by executing:

```
SetIgorOption IndependentModuleDev=0
```

Independent Module Development Tips

Development of an independent module may be easier if it is first done as for normal code. Add the module declaration

```
#pragma IndependentModule = moduleName
```

only after the code has been fully debugged and is working properly.

A procedure file that is designed to be #included should ideally work inside or outside of an independent module. Read the sections on independent modules below to learn what the issues are.

When developing an independent module, you will usually want to execute:

```
SetIgorOption IndependentModuleDev=1
```

Independent Modules and #include

If you #include a procedure file from an independent module, Igor copies the #included file into memory and makes it part of the independent module by inserting a #pragma IndependentModule statement at the start of the copy. If the same file is included several times, there will be several copies, each with a different independent module name.

Warning: Do not edit procedure windows created by #including into an independent module because they are temporary and your changes will not be saved. You would not want to save them anyway because Igor has modified them.

Warning: Do not #include files that already contain a #pragma IndependentModule statement unless the independent module name is the same.

Limitations of Independent Modules

Independent modules are not for every-day programming and are more difficult to create than normal modules because of the following limitations:

1. Macros and Procs are not supported.
2. Button and control dialogs do not list functions in an independent module.
3. Functions in an independent module can not call functions in other modules except through the Execute operation.

Independent Modules in Action Procedures and Hook Functions

Normally you must use a qualified name to invoke a function defined in an independent module from the ProcGlobal context. Control action procedures and hook functions execute in the ProcGlobal context. But, as a convenience and to make #include files more useful, Igor eliminates this requirement when you create controls and specify hook functions from a user-defined function in an independent module.

When you execute an operation that creates a control or specifies a hook function while running in an independent module, Igor examines the specified control action function name or hook function name. If the named function is defined in the same independent module, Igor automatically inserts the independent module name. This means you can write something like:

```
#pragma IndependentModule = IndependentModuleA
Function SetProcAndHook()
   Button b0, proc=ButtonProc
   SetWindow hook(Hook1)=HookFunc
End
```

You don't have to write:

```
#pragma IndependentModule = IndependentModuleA
Function SetProcAndHook()
   Button b0, proc=IndependentModuleA#ButtonProc
   SetWindow hook(Hook1)=IndependentModuleA#HookFunc
End
```

Such independent module name insertion is only done when an operation is called from a function defined in an independent module. It is not done if the operation is executed from the command line or via **Execute**.

The control action function or hook function must be public (non-static) except as described under **Regular Modules Within Independent Modules** on page IV-242.

Here is a working example:

```
#pragma IndependentModule = IndependentModuleA

Function ButtonProc(ba) : ButtonControl   // Must not be static
   STRUCT WMButtonAction &ba

   switch (ba.eventCode)
      case 2: // mouse up
         Print "Running IndependentModuleA#ButtonProc"
         break
   endswitch

   return 0
End

Function CreatePanel()
   NewPanel /W=(375,148,677,228)
   Button button0,pos={106,23},size={98,20},title="Click Me"
   Button button0,proc=ButtonProc
End
```

Independent Modules and User-Defined Menus

Independent modules can contain user-defined menus. When you choose a user-defined menu item, Igor determines if the menu item was defined in an independent module. If so, and if the menu item's execution text starts with a call to a function defined in the independent module, then Igor prepends the independent module name before executing the text. This means that the second and third menu items in the following example both call IndependentModuleA#DoAnalysis:

```
#pragma IndependentModule = IndependentModuleA

Menu "Macros"
   "Load Data File/1", Beep; LoadWave/G
   "Do Analysis/2", DoAnalysis() // Igor automatically prepends IndependentModuleA#
   "Do Analysis/3", IndependentModuleA#DoAnalysis()
End

Function DoAnalysis()
   Print "DoAnalysis in IndependentModuleA"
End
```

This behavior on Igor's part makes it possible to #include a procedure file that creates menu items into an independent module and have the menu items work. However, in many cases you will not want a #included file's menu items to appear. You can suppress them using `menus=0` option in the #include statement. See **Turning the Included File's Menus Off** on page IV-167.

Note: If a procedure file with menu definitions is included into multiple independent modules, the menus are repeatedly defined (see **Independent Modules and #include** on page IV-240). Judicious use of the menus=0 option in the #include statements helps prevent this. See **Turning the Included File's Menus Off** on page IV-167.

When the execution text doesn't start with a user-defined function name, as for the first menu item in this example, Igor executes the text without altering it.

Independent Modules and Popup Menus

In an independent module, implementing a popup menu whose items are determined by a function call at click time requires special care. For example, outside of an independent module, this works:

```
Function/S MyPopMenuList()
   return "Item 1;Item2;"
```

```
End
...
PopupMenu pop0 value=#"MyPopMenuList()"       // Note the quotation marks
```

But inside an independent module you need this:

```
#pragma IndependentModule=MyIM
Function/S MyPopMenuList()
   return "Item 1;Item2;"
End
...
String cmd= GetIndependentModuleName()+"#MyPopMenuList()"
PopupMenu pop0 value=#cmd                     // No enclosing quotation marks
```

GetIndependentModuleName returns the name of the independent module to which the currently-running function belongs or "ProcGlobal" if the currently-running function is not part of an independent module.

You could change the command string to:

```
PopupMenu pop0 value=#"MyIM#MyPopMenuList()"
```

but using GetIndependentModuleName allows you to disable the IndependentModule pragma by commenting it out and have the code still work, which can be useful during development. With the pragma commented out you are running in ProcGlobal context and GetIndependentModuleName returns "ProcGlobal".

When the user clicks the popup menu, Igor generates the menu items by evaluating the text specified by the PopupMenu value keyword as an Igor expression. The expression ("MyIM#MyPopMenuList()" in this case) is evaluated in the ProcGlobal context. In order for Igor to find the function in the independent module, it must be public (non-static), except as describe under **Regular Modules Within Independent Modules** on page IV-242, and you must use a qualified name.

Note that #cmd is not the same as #"cmd". The #cmd form was introduced with Igor Pro 6. The string variable cmd is evaluated when PopupMenu runs which occurs in the context of the independent module. The contents of cmd ("MyIM#MyPopMenuList()" in this case) are stored in the popup menu's internal data structure. When the popup menu is clicked, Igor evaluates the stored text as an Igor expression in the ProcGlobal context. This causes the function MyIM#MyPopMenuList to run.

With the older #"cmd" syntax, the stored text is evaluated only when the popup menu is clicked, not when the PopupMenu operation runs, and this evaluation occurs in the ProcGlobal context. It is too late to capture the independent module in which the text should be evaluated.

Regular Modules Within Independent Modules

It is usually not necessary but you can create a regular module within an independent module. For example:

```
#pragma IndependentModule = IndependentModuleA
#pragma ModuleName = RegularModuleA
Function Test()
   Print "Test in RegularModuleA within IndependentModuleA"
End
```

Here RegularModuleA is a regular module within IndependentModuleA.

To call the function Test from outside of the independent module you must qualify the call like this:

```
IndependentModuleA#RegularModuleA#Test()
```

This illustrates that the independent module establishes its own namespace (IndependentModuleA) which can host one level of sub-namespace (RegularModuleA). By contrast, a regular module creates a namespace within the global namespace (called ProcGlobal) and can not host additional sub-namespaces.

This nesting of modules is useful to prevent name conflicts in a large independent module project comprising multiple procedure files. Otherwise it is not necessary.

Because all procedure files in a given independent module are compiled separately from all other files, function names never conflict with those outside the group and there is little or no need to use the static designation on functions in an independent module. However, if need be, you can call static functions in a regular module inside an independent module from outside the independent module using a triple-qualified name:

```
IndependentModuleName#RegularModuleName#FunctionName()
```

Calling Routines From Other Modules

Code in an independent module can not directly call routines in other modules and usually should not need to. If you must call a routine from another module, you can do it using the **Execute** operation. You must use a qualified name. For example:

```
Execute "ProcGlobal#foo()"
```

To call a function in a regular module, you must prepend ProcGlobal and the regular module name to the function name:

```
Execute "ProcGlobal#MyRegularModule#foo()"
```

Calling a nonstatic function in a different independent modules requires prepending just the other independent module name:

```
Execute "OtherIndependentModule#bar()"
```

Calling static functions in other independent modules requires prepending the independent module name and a regular module name:

```
Execute "OtherIndependentModule#RegularModuleName#staticbar()"
```

Using Execute Within an Independent Module

If you need to call a function in the current independent module using Execute, you can compose the name using the **GetIndependentModuleName** function. For example, outside of an independent module the commands would be:

```
String cmd = "WS_UpdateWaveSelectorWidget(\"Panel0\", \"selectorWidgetName\")"
Execute cmd
```

But inside an independent module the commands are:

```
#pragma IndependentModule=MyIM
String cmd="WS_UpdateWaveSelectorWidget(\"Panel0\", \"selectorWidgetName\")"
cmd = GetIndependentModuleName() + "#" + cmd    // Make qualified name
Execute cmd
```

You could change the command string to:

```
cmd = "MyIM#" + cmd
```

but using GetIndependentModuleName allows you to disable the IndependentModule pragma by commenting it out and have the code still work, which can be useful during development. With the pragma commented out you are running in ProcGlobal context and GetIndependentModuleName returns "ProcGlobal".

Independent Modules and Dependencies

GetIndependentModuleName is also useful for defining dependencies using functions in the current independent module. Dependencies are evaluated in the global procedure context (ProcGlobal). In order for dependencies to evaluate correctly, the dependency must use GetIndependentModuleName to create a formula to pass to the **SetFormula** operation. For example, outside of an independent module, this works:

```
String formula = "foo(root:wave0)"
SetFormula root:aVariable $formula
```

But inside an independent module you need this:

```
#pragma IndependentModule=MyIM
String formula = GetIndependentModuleName() + "#foo(root:wave0)"
SetFormula root:aVariable $formula
```

Independent Modules and Pictures

To allow DrawPICT to use a picture in the picture gallery, you must prepend GalleryGlobal# to the picture name:

```
DrawPICT 0,0,1,1,GalleryGlobal#PICT_0
```

Without GalleryGlobal, only proc pictures can be used in an independent module.

Making Regular Procedures Independent-Module-Compatible

You may want to make an existing set of procedures into an independent module. Alternatively, you may want to make an existing procedure independent-module-compatible so that it can be #included into an independent module. This section outlines the necessary steps.

1. If you are creating an independent module, add the IndependentModule pragma:

   ```
   #pragma IndependentModule=<NameOfIndependentModule>
   ```
2. Change any Macro or Proc procedures to functions.
3. Make Execute commands suitable for running in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Using Execute Within an Independent Module** on page IV-243.
4. Make PopupMenu controls that call a string function to populate the menu work in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Independent Modules and Popup Menus** on page IV-241.
5. Make any dependencies work in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Independent Modules and Dependencies** on page IV-243.

See also **Procedure Modules** on page IV-236, **Regular Modules** on page IV-236, **Controls and Control Panels** on page III-413, **User-Defined Hook Functions** on page IV-280, **User-Defined Menus** on page IV-125, and **GetIndependentModuleName** on page V-303.

Public and Static Functions

The static keyword marks a user-defined function as private to the file in which it is defined. It can be called within that file only, with an exception explained below for "regular modules".

If you are a beginning Igor programmer and you are not familiar with the advanced concepts of Regular Modules and Independent Modules, it is sufficient to think of this like this:

- A static function can be called only from the procedure file in which it is defined.
- A public function can be called from any procedure file.

The rest of this section is for advanced programmers with an understanding of **Regular Modules** and **Independent Modules**.

- A public function defined in the default ProcGlobal module can be called from another file in the ProcGlobal module or from a regular module without using a qualified name.
- A public function defined in a regular module can be called from a procedure file in ProcGlobal or

from a regular module without using a qualified name.

- A public function defined in an independent module can be called from a procedure file in ProcGlobal or from a regular module using a qualified name such as IndependentModuleA#Test.
- A public function defined in an independent module can not be called from another independent module.
- A static function defined in ProcGlobal can be called only from the file in which it is defined.
- A static function defined in a regular module can be called from a procedure file in ProcGlobal or from another regular module using a qualified name such as RegularModuleA#Test.
- A static function defined in a regular module can not be called from an independent module.
- A static function defined in an independent module can be called only from the procedure file in which it is defined.
- An independent module can call only functions defined in that independent module.

Sound

Two operations are provided for playing of sound through the computer speakers:

- PlaySound
- PlaySnd (*Macintosh*)

The **PlaySound** operation takes the sound data from a wave.

The obsolete **PlaySnd** operation gets its data from a Macintosh 'snd ' resource stored in a file.

A number of sound input operations are provided: **SoundInStatus** (page V-888) , **SoundInSet** (page V-887) , **SoundInRecord** (page V-887) , **SoundInStartChart** (page V-888) and **SoundInStopChart** (page V-889) . Several example experiments that use these routines can be found in your Igor Pro Folder in the Examples folder.

The **SoundLoadWave** operation loads various sound file formats into waves and **SoundSaveWave** saves wave data to sound files. These operations replace SndLoadWave, SoundSaveAIFF and SoundSaveWAV from the obsolete SndLoadSaveWave XOP.

Movies

You can create movies, optionally with a soundtrack, and extract frames from movies for analysis.

Playing Movies

Use the PlayMovie operation to play a movie in your default movie viewing program.

Creating Movies

You can create a movie from a graph, page layout, or Gizmo window. To do this, you write a procedure that modifies the window and adds a frame to the movie in a loop. On Windows, you can include audio.

Here are the operations used to create and play a movie:

- **NewMovie**
- **AddMovieFrame**
- **AddMovieAudio**
- **CloseMovie**
- **PlayMovie**
- **PlayMovieAction**

The NewMovie operation creates a movie file and also defines the movie frame rate and optional audio track specifications.

Before calling NewMovie, you need to prepare the first frame of your movie as the target graph, page layout, or Gizmo window.

If you will be using audio you also need to prepare a sound wave. The sound wave can be of any time duration but usually will either be the entire length of the movie or will be the length of one video frame. As of Igor Pro 7, sound is not supported on Macintosh.

After creating the file and the first video frame and optional audio, you use AddMovieFrame to add as many video frames as you wish. You may also add more audio using the AddMovieAudio operation. Finally you use the CloseMovie and PlayMovie operations.

When you write a procedure to generate a movie, you need to call the DoUpdate operation after all modifications to the graph, page layout, or Gizmo window and before calling AddMovieFrame. This allows Igor to process any changes you have made to the window.

In addition to creating a movie from a window, you can also create movies from pictures in the picture gallery (see **Pictures** on page III-509) using the /PICT flag with NewMovie and AddMovieFrame. You can put pictures of Igor graphs, tables, page layouts, and Gizmo plots in the gallery using **SavePICT**.

Extracting Movie Frames

You can extract individual frames from a movie and can control movie playback using **PlayMovieAction**.

Movie Programming Examples

For examples of programming with movies, choose File→Example Experiments→Movies & Audio.

Timing

There are two methods you can use when you want to measure elapsed time:

- The ticks counter using the ticks function
- The microsecond timer using **StartMSTimer** and **StopMSTimer**

Ticks Counter

You can easily measure elapsed time with a precision of 1/60th of a second using the ticks function. It returns the tick count which starts at zero when you first start your computer and is incremented at a rate of approximately 60 Hz rate from then on.

Here is an example of typical use:

```
…
Variable t0
…
t0= ticks
<operations you wish to time>
printf "Elapsed time was %g seconds\r",(ticks-t0)/60
…
```

Microsecond Timer

You can measure elapsed time to microsecond accuracy for durations up to 35 minutes using the microsecond timer. See the **StartMSTimer** function (page V-906) for details and an example.

Packages

A package is a set of files that adds significant functionality to Igor. Packages consist of procedure files and may also include XOPs, help files and other supporting files.

A package usually adds one or more items to Igor's menus that allow the user to interactively load the package, access its functionality, and unload the package.

A package typically provides some level of user-interface, such as a menu item and a control panel, for accessing the added functionality. It may store settings in experiments or in global preferences.

A package is typically loaded into memory and unloaded at the user's request.

Igor comes pre-configured with numerous WaveMetrics packages accessed through the Data→Packages, Analysis→Packages, Misc→Packages, Windows→New→Packages and Graph→Packages submenus as well as others. Take a peek at these submenus to see what packages are supplied with Igor.

Menu items for WaveMetrics packages are added to Igor's menus by the WMMenus.ipf procedure file which is shipped in the Igor Procedures folder. WMMenus.ipf is hidden unless you enable independent module development. See **Independent Modules** on page IV-238.

Creating a Package

This section shows how to create a package through a simple example. The package is called "Sample Package". It adds a Load Sample Package item to the Macros menu. When the user chooses Load Sample Package, the package's procedure file is loaded. This adds two additional items to the Macros menu: Hello From Sample Package and Unload Sample Package.

The package consists of two procedure files stored in a folder in the Igor Pro User Files folder. If you are not familiar with Igor Pro User Files, take a short detour and read **Special Folders** on page II-30 and **Igor Pro User Files** on page II-31.

The sample package is installed as follows:

```
Igor Pro User Files
   Sample Package
      Sample Package Loader.ipf
      Sample Package.ipf
   Igor Procedures
      Alias or shortcut pointing to the "Sample Package Loader.ipf" file
   User Procedures
      Alias or shortcut pointing to the "Sample Package" folder
```

Putting the alias/shortcut for the "Sample Package Loader.ipf" in Igor Procedures causes Igor to load that file at launch time. The file adds the "Load Sample Package" item to the Macros menu. See **Global Procedure Files** on page III-399 for details.

Putting the alias/shortcut for the "Sample Package" folder in User Procedures causes Igor to search that folder when a #include is invoked. See **Shared Procedure Files** on page III-400 for details.

A real package might include other procedure files and a help file in the "Sample Package" folder.

To try this out yourself, follow these steps:

1. Create the "Sample Package" folder in your Igor Pro User Files folder.

   You can locate your Igor Pro User Files folder using the Help menu.

2. Create a new procedure file named "Sample Package Loader.ipf" in the "Sample Package" folder and enter the following contents in the file:

```
Menu "Macros"
   "Load Sample Package", /Q, LoadSamplePackage()
End

Function LoadSamplePackage()
   Execute/P/Q/Z "INSERTINCLUDE \"Sample Package\""
   Execute/P/Q/Z "COMPILEPROCEDURES "// Note the space before final quote
End
```

Save the procedure file.

3. Create a new procedure file named "Sample Package.ipf" in the "Sample Package" folder and enter the following contents in the file:

```
Menu "Macros"
   "Hello From Sample Package", HelloFromSamplePackage()
   "Unload Sample Package", UnloadSamplePackage()
End

Function HelloFromSamplePackage()
   DoAlert /T="Sample Package Wants to Say" 0, "Hello!"
End

Function UnloadSamplePackage()
   Execute /P /Q /Z "DELETEINCLUDE \"Sample Package\""
   Execute /P /Q /Z "COMPILEPROCEDURES "// Note the space before final quote
End
```

   Save the procedure file.

4. In the desktop, make an alias or shortcut for "Sample Package Loader.ipf" file and put it in the Igor Procedures folder in the Igor Pro User Files folder.

   This causes Igor to load the "Sample Package Loader.ipf" file at launch time. This is how the Load Sample Package menu item gets into the Macros menu.

5. In the desktop, make an alias or shortcut for the "Sample Package" folder and put it in the User Procedures folder in the Igor Pro User Files folder.

   This causes Igor to search the "Sample Package" folder when a #include is invoked. This allows Igor to find the "Sample Package.ipf" file when it is #included.

6. Quit and restart Igor so that Igor will load the "Sample Package Loader.ipf" file.

   If you prefer you can just manually make sure that "Sample Package Loader.ipf" is open and "Sample Package.ipf" is closed. This simulates the state of affairs after restarting Igor.

7. Choose Windows→Procedure Windows and verify that Igor has loaded the "Sample Package Loader.ipf" file.

8. Click the Macros menu and verify that the "Load Sample Package" item is present.

9. Choose Macros→Load Sample Package.

   The LoadSamplePackage function runs, adds a #include statement to the built-in procedure window, and forces procedures to be recompiled. This cause Igor to load the "Sample Package.ipf" procedure file which contains the bulk of the package's procedures and adds items to the Macros menu.

10. Click the Macros menu and notice that the "Hello From Sample Package" and "Unload Sample Package" items have been added.

11. Choose Macros→Hello From Sample Package.

    The package displays an alert. A real package would do something more exciting.

12. Choose Macros→Unload Sample Package.

    The UnloadSamplePackage function runs, removes the #include statement from the built-in procedure window, and forces procedures to be recompiled. This cause Igor to unload the "Sample Package.ipf" procedure.

13. Click the Macros menu and notice that the "Hello From Sample Package" and "Unload Sample Package" items have been removed.

Most real packages do not create Unload menu items. Instead they provide an Unload Package button in a control panel or automatically unload when a control panel is closed. Or they might not support unloading.

A real package typically does not include "Package" in its name or in its menu items.

Lightweight Packages

A lightweight package is one that consists of at most a few procedure files and does not create clutter in the current experiment unless it is actually used.

If your package is lightweight you might prefer to dispense with loading and unload it and just keep it loaded all the time. To do this you would organize your files like this:

```
Igor Pro User Files
   Your Package
      Your Package Part 1.ipf
      Your Package Part 2.ipf
   Igor Procedures
      Alias or shortcut pointing to the "Your Package" folder
```

Here both of your package procedure files are global, meaning that Igor loads them at launch time and never unloads them. You do not need procedures for loading and unloading your package.

If you have an ultra-light package, consisting of just a single procedure file, you can dispense with the "Your Package" folder and put the procedure file directly in the Igor Procedures folder.

Managing Package Data

When you create a package of procedures, you need some place to store private data used by the package to keep track of its state. It's important to keep this data separate from the user's data to avoid clutter and to protect your data from inadvertent changes.

Private data should be stored in a data folder named after the package inside a generic data folder named Packages. For example, if your package is named My Package you would store your private data in `root:Packages:My Package`.

There are two general types of private data that you might need to store: overall package data and per-instance data. For example, for a data acquisition package, you may need to store data describing the state of the acquisition as a whole and other data on a per-channel basis.

Creating and Accessing the Package Data Folder

This section demonstrates the recommended way to create and access a package data folder. We use a bottleneck function that returns a **DFREF** for the package data folder. If the package data folder does not yet exist, the bottleneck function creates and initializes it. This way calling functions don't need to worry about whether the package data folder has been created.

First we write a function to create and initialize the package data folder:

```
Function/DF CreatePackageData()     // Called only from GetPackageDFREF
   // Create the package data folder
   NewDataFolder/O root:Packages
   NewDataFolder/O root:Packages:'My Package'

   // Create a data folder reference variable
   DFREF dfr = root:Packages:'My Package'

   // Create and initialize package data
   Variable/G dfr:gVar1 = 1.0
   String/G dfr:gStr1 = “hello”
   Make/O dfr:wave1
   WAVE wave1 = dfr:wave1
   wave1= x^2

   return dfr
End
```

Now we can write the bottleneck function:

```
Function/DF GetPackageDFREF()
   DFREF dfr = root:Packages:'My Package'
   if (DataFolderRefStatus(dfr) != 1)      // Data folder does not exist?
      DFREF dfr = CreatePackageData()      // Create package data folder
   endif
   return dfr
End
```

GetPackageDFREF would be used like this:

```
Function/DF DemoPackageDFREF()
   DFREF dfr = GetPackageDFREF()

   // Read a package variable
   NVAR gVar1 = dfr:gVar1
   Printf "On entry gVar1=%g\r", gVar1

   // Write to a package variable
   gVar1 += 1
   Printf "Now gVar1=%g\r", gVar1
End
```

All functions that access the package data folder should do so through GetPackageDFREF. The calling functions do not need to worry about whether the data folder has been created and initialized because GetPackageDFREF does this for them.

Creating and Accessing the Package Per-Instance Data Folders

Here we extend the technique of the preceding section to handle per-instance data. This example shows how you might handle per-channel data in a data acquisition package. If your package does not use per-instance data then you can skip this section.

First we write a function to create and initialize the per-instance package data folder:

```
Function/DF CreatePackageChannelData(channel)    // Called only from
   Variable channel     // 0 to 3                // GetPackageChannelDFREF

   DFREF dfr = GetPackageDFREF()    // Access main package data folder

   String dfName = "Channel" + num2istr(channel)    // Channel0, Channel1, ...

   // Create the package channel data folder
   NewDataFolder/O dfr:$dfName

   // Create a data folder reference variable
   DFREF channelDFR = dfr:$dfName

   // Initialize per-instance data
   Variable/G channelDFR:gGain = 5.0
   Variable/G channelDFR:gOffset = 0.0

   return channelDFR
End
```

Now we can write the bottleneck function:

```
Function/DF GetPackageChannelDFREF(channel)
   Variable channel     // 0 to 3

   DFREF dfr = GetPackageDFREF()    // Access main package data folder
   String dfName = "Channel" + num2istr(channel)    // Channel0, Channel1, ...
   DFREF channelDFR = dfr:$dfName
   if (DataFolderRefStatus(channelDFR) != 1)     // Data folder does not exist?
      DFREF channelDFR = CreatePackageChannelData(channel)  // Create it
   endif
   return channelDFR
End
```

GetPackageChannelDFREF would be used like this:

```
Function/DF DemoPackageChannelDFREF(channel)
   Variable channel     // 0 to 3

   DFREF channelDFR = GetPackageChannelDFREF(channel)

   // Read a package variables
   NVAR gGain = channelDFR:gGain
   NVAR gOffset = channelDFR:gOffset
   Printf "Channel %d: Gain=%g, offset=%g\r", channel, gGain, gOffset
End
```

All functions that access a package channel data folder should do so through GetPackageChannelDFREF. The calling functions do not need to worry about whether the data folder has been created and initialized because GetPackageChannelDFREF does this for them.

Saving Package Preferences

If you are writing a sophisticated package of Igor procedures you may want to save preferences for your package. For example, if your package creates a control panel that can be opened in any experiment, you may want it to remember its position on screen between invocations. Or you may want to remember various settings in the panel from one invocation to the next.

Such “state” information can be stored either separately in each experiment or it can be stored just once for all experiments in preferences. These two approaches both have their place, depending on circumstances. But, if your package creates a control panel that is intended to be present at all times and used in any experiment, then the preferences approach is usually the best fit.

If you choose the preferences approach, you will store your package preference file in a directory created for your package. Your package directory will be in the Packages directory, inside Igor’s own preferences directory.

The location of Igor’s Packages directory depends on the operating system and the particular user’s configuration. You can find where it is on a particular system by executing:

```
Print SpecialDirPath("Packages", 0, 0, 0)
```

Important:You must choose a very distinctive name for your package because that is the only thing that prevents some other package from overwriting yours. All package names starting with "WM" are reserved for WaveMetrics.

A package name is limited to 255 bytes and must be a legal name for a directory on disk.

If you use a name longer than 31 bytes, your package will require Igor Pro 8.00 or later.

There are two ways to store package preference data:

- In a special-format binary file stored in your package directory
- As Igor waves and variables in an Igor experiment file stored in your package directory

The special-format binary file approach is relatively simple to implement but is not suitable for storing very large amounts of data. In most cases it is not necessary to store very large amounts of data so this is the way to go.

The use of the Igor experiment file supports storing a large amount of preference data but creates a problem of synchronizing your preference data stored in memory and your preference data stored on disk. It also leads to a proliferation of preference data stored in various experiments. You should avoid using this technique if possible.

Saving Package Preferences in a Special-Format Binary File

This approach supports preference data consisting of a collection of numeric and string data. You define a structure encapsulating your package preference data. You use the **LoadPackagePreferences** operation (page V-505) to load your data from disk and the **SavePackagePreferences** operation (page V-825) to save it to disk.

SavePackagePreferences stores data from your package's preferences data structure in memory. LoadPackagePreferences returns that data to you via the same structure.

SavePackagePreferences also creates a directory for your package preferences and stores your data in a file in that directory. Your package directory is located in the Packages directory in Igor's preferences directory. The job of storing the preferences data in the file is handled transparently which, by default, automatically flushes your data to the file when the current experiment is saved or closed and when Igor quits.

You would call LoadPackagePreferences every time you need to access your package preference data and SavePackagePreferences every time you want to change your package preference data. You pass to these operations an instance of a structure that you define.

Here are example functions from the Package Preferences Demo experiment that use the LoadPackagePreferences and SavePackagePreferences operations to implement preferences for a particular package:

```
// NOTE: The package name you choose must be distinctive!
static StrConstant kPackageName = "Acme Data Acquisition"
static StrConstant kPrefsFileName = "PanelPreferences.bin"
static Constant kPrefsVersion = 100
static Constant kPrefsRecordID = 0

Structure AcmeDataAcqPrefs
   uint32version    // Preferences structure version number. 100 means 1.00.
   double panelCoords[4]      // left, top, right, bottom
   uchar phaseLock
   uchar triggerMode
   double ampGain
   uint32 reserved[100]       // Reserved for future use
EndStructure

// DefaultPackagePrefsStruct(prefs)
// Sets prefs structure to default values.
static Function DefaultPackagePrefsStruct(prefs)
   STRUCT AcmeDataAcqPrefs &prefs

   prefs.version = kPrefsVersion

   prefs.panelCoords[0] = 5          // Left
   prefs.panelCoords[1] = 40         // Top
   prefs.panelCoords[2] = 5+190      // Right
   prefs.panelCoords[3] = 40+125     // Bottom
   prefs.phaseLock = 1
   prefs.triggerMode = 1
   prefs.ampGain = 1.0

   Variable i
   for(i=0; i<100; i+=1)
      prefs.reserved[i] = 0
   endfor
End

// SyncPackagePrefsStruct(prefs)
// Syncs package prefs structures to match state of panel.
// Call this only if the panel exists.
static Function SyncPackagePrefsStruct(prefs)
   STRUCT AcmeDataAcqPrefs &prefs

   // Panel does exists. Set prefs to match panel settings.
   prefs.version = kPrefsVersion
```

```
    GetWindow AcmeDataAcqPanel wsize
    // NewPanel uses device coordinates. We therefore need to scale from
    // points (returned by GetWindow) to device units for windows created
    // by NewPanel.
    Variable scale = ScreenResolution / 72
    prefs.panelCoords[0] = V_left * scale
    prefs.panelCoords[1] = V_top * scale
    prefs.panelCoords[2] = V_right * scale
    prefs.panelCoords[3] = V_bottom * scale

    ControlInfo /W=AcmeDataAcqPanel PhaseLock
    prefs.phaseLock = V_Value        // 0=unchecked; 1=checked

    ControlInfo /W=AcmeDataAcqPanel TriggerMode
    prefs.triggerMode = V_Value      // Menu item number starting from on

    ControlInfo /W=AcmeDataAcqPanel AmpGain
    prefs.ampGain = str2num(S_value)  // 1, 2, 5 or 10
End

// InitPackagePrefsStruct(prefs)
// Sets prefs structures to match state of panel or
// to default values if panel does not exist.
static Function InitPackagePrefsStruct(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    DoWindow AcmeDataAcqPanel
    if (V_flag == 0)
        // Panel does not exist. Set prefs struct to default.
        DefaultPackagePrefsStruct(prefs)
    else
        // Panel does exists. Sync prefs struct to match panel state.
        SyncPackagePrefsStruct(prefs)
    endif
End

static Function LoadPackagePrefs(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    // This loads preferences from disk if they exist on disk.
    LoadPackagePreferences kPackageName, kPrefsFileName, kPrefsRecordID, prefs

    // If error or prefs not found or not valid, initialize them.
    if (V_flag!=0 || V_bytesRead==0 || prefs.version!=kPrefsVersion)
        InitPackagePrefsStruct(prefs) // Set from panel if it exists or to default values.
        SavePackagePrefs(prefs)       // Create initial prefs record.
    endif
End

static Function SavePackagePrefs(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    SavePackagePreferences kPackageName, kPrefsFileName, kPrefsRecordID, prefs
End
```

NOTE: The package preferences structure, AcmeDataAcqPrefs in this case, must not use fields of type Variable, String, WAVE, NVAR, SVAR or FUNCREF because these fields refer to data that may not exist when LoadPackagePreferences is called.

The structure can use fields of type char, uchar, int16, uint16, int32, uint32, int64, uint64, float and double as well as fixed-size arrays of these types and substructures with fields of these types.

Use the reserved field to add fields to the structure in a backward-compatible fashion. For example, a subsequent version of the structure might look like this:

```
Structure AcmeDataAcqPrefs
    uint32   // Preferences structure version number. 100 means 1.00.
    double panelCoords[4]       // left, top, right, bottom
    uchar phaseLock
    uchar triggerMode
    double ampGain
```

```
   uint32 triggerDelay
   uint32 reserved[99]        // Reserved for future use
EndStructure
```

Here the triggerDelay field was added and size of the reserved field was reduced to keep the overall size of the structure the same. The AcmeDataAcqLoadPackagePrefs function would also need to be changed to set the default value of the triggerDelay field.

If you need to change the structure such that its size changes or its fields are changed in an incompatible manner then you must change your structure version, which will overwrite old preferences with new preferences.

A functioning example using this technique can be found in:

“Igor Pro Folder:Examples:Programming:Package Preferences Demo.pxp”

In the example above we store just one structure in the preference file. However LoadPackagePreferences and SavePackagePreferences allow storing any number of structures of the same or different types in the preference file. You can store either multiple instances of the same structure or multiple different structures. You must assign a unique nonnegative integer as a record ID for each structure stored and pass this record ID to LoadPackagePreferences and SavePackagePreferences. You could use this feature, for example, to store a different structure for each type of control panel that your package presents. Since all data is cached in memory you should not attempt to store hundreds or thousands of structures.

In almost all cases a particular package will need just one preference file. For the rare cases where this is inconvenient, LoadPackagePreferences and SavePackagePreferences allow each package to create any number of preference files, each with a distinct file name. All of the preference files for a particular package are stored in the same directory, the package’s preferences directory. Each file can store a different set of structure. However, the code that implements this feature is not tuned to handle large numbers of files so you should not use this feature indiscriminately.

Saving Package Preferences in an Experiment File

This approach supports package preference data consisting of waves, numeric variables and string variables. It is more difficult to implement than the special-format binary file approach and is not recommended except for expert programmers and then only if the previously described approach is not suitable.

You use the SaveData operation to store your waves and variables in a packed experiment file in your package directory on disk. You can later use the LoadData operation to load the waves and variables into a new experiment.

You must create your package directory as illustrated by the SavePackagePrefs function below.

The following example functions save and load package preferences. These functions assume that the package preferences consist of all waves and variables at the top level of the package’s data folder. You may need to customize these functions for your situation.

```
// SavePackagePrefs(packageName)
// Saves the top-level waves, numeric variables and string variables
// from the data folder for the named package into a file in the Igor
// preferences hierarchy on disk.
Function SavePackagePrefs(packageName)
   String packageName             // NOTE: Use a distinctive package name.

   // Get path to Packages preferences directory on disk.
   String fullPath = SpecialDirPath("Packages", 0, 0, 0)
   fullPath += packageName

   // Create a directory in the Packages directory for this package
   NewPath/O/C/Q tempPackagePrefsPath, fullPath

   fullPath += ":Preferences.pxp"

   DFREF saveDF = GetDataFolderDFR()
   SetDataFolder root:Packages:$packageName
   SaveData/O/Q fullPath          // Save the preference file
   SetDataFolder saveDF
```

```
    // Kill symbolic path but leave directory on disk.
    KillPath/Z tempPackagePrefsPath
End

// LoadPackagePrefs(packageName)
// Loads the data from the previously-saved package preference file,
// if it exist, into the package's data folder.
// Returns 0 if the preference file existed, -1 if it did not exist.
// In either case, this function creates the package's data folder if it
// does not already exist.
// LoadPackagePrefs does not affect any other data already in the
// package's data folder.
Function LoadPackagePrefs(packageName)
    String packageName              // NOTE: Use a distinctive package name.

    Variable result = -1
    DFREF saveDF = GetDataFolderDFR()

    NewDataFolder/O/S root:Packages     // Ensure root:Packages exists
    NewDataFolder/O/S $packageName      // Ensure package data folder exists

    // Find the disk directory in the Packages directory for this package
    String fullPath = SpecialDirPath("Packages", 0, 0, 0)
    fullPath += packageName
    GetFileFolderInfo/Q/Z fullPath
    if (V_Flag == 0)                    // Disk directory exists?
        fullPath += ":Preferences.pxp"
        GetFileFolderInfo/Q/Z fullPath
        if (V_Flag == 0)                // Preference file exist?
            LoadData/O/R/Q fullPath     // Load the preference file.
            result = 0
        endif
    endif

    SetDataFolder saveDF
    return result
End
```

The hard part of using the experiment file for saving package preferences is not in saving or loading the package preference data but in choosing when to save and load it so that the latest preferences are always used. There is no ideal solution to this problem but here is one strategy:

1. When package preference data is needed (e.g., you are about to create your control panel and need to know the preferred coordinates), check if it exists in memory. If not load it from disk.
2. When the user does a New Experiment or quits Igor, if package preference data exists in memory, save it to disk. This requires that you create an IgorNewExperimentHook function and an IgorQuitHook function.
3. When the user opens an experiment file, if it contains package preference data, delete it and reload from disk. This requires that you create an AfterFileOpenHook function. This is necessary because the package preference data in the just opened experiment is likely to be older than the data in the package preference file.

Creating Your Own Help File

If you are an advanced user, you can create an Igor help file that extends the Igor help system. This is something you might want to do if you write a set of Igor procedures or extensions for use by your colleagues. If your procedures or extensions are generally useful, you might want to make them available to all Igor users. In either case, you can provide documentation in the form of an Igor help file.

Here are the steps for creating an Igor help file.

1. Create a formatted-text notebook.

   A good way to do this is to open the Igor Help File Template provided by WaveMetrics in the More Help Files folder. Alternatively, you can start by duplicating another WaveMetrics-supplied help file and then open it as a notebook using File→Open File→Notebook. Either way, you are starting with a notebook that contains the rulers used to format an Igor help file.
2. Choose Save Notebook As from the File menu to create a new file. Use a “.ihf” extension so that Igor will recognize it as a help file.

3. Enter your help text in the new file.
4. Save and kill the notebook.
5. Open the file as a help file using File→Open File→Help File.

When you open the file as a help file, it needs to be compiled. When Igor compiles a help file, it scans through it to find out where the topics start and end and makes a note of subtopics. When the compilation is finished, it saves the help file which now includes the help compiler information.

Once Igor has successfully compiled the help file, it acts like any other Igor help file. That is, when opened it appears in the Help Windows submenu, its topics will appear in the Help Browser, and you can click links to jump around.

Here are the steps for modifying a help file.

1. If the help file is open, kill it by pressing Option (*Macintosh*) or Alt (*Windows*) and clicking the close button.
2. Open it as a notebook, using File→Open File→Notebook.

   Alternatively, you can press Shift while choosing the file from File→Recent Files. Then, in the resulting dialog, specify that you want to open the file as a formatted notebook.
3. Modify it using normal editing techniques.
4. Choose Save Notebook from the File menu.
5. Click the close button and kill the notebook.
6. Reopen it as a help file using File→Open File→Help File.

   Alternatively, you can press Shift while choosing the file from File→Recent Files. Then, in the resulting dialog, specify that you want to open the file as a help file.

Syntax of a Help File

Igor needs to be able to identify topics, subtopics, related topics declarations, and links in Igor help files. To do this it looks for certain rulers, text patterns and text formats described in **Creating Links** on page IV-257. You can get most of the required text formats by using the appropriate ruler from the Igor Help File Template file.

Igor considers a paragraph to be a help topic declaration if it starts with a bullet character followed by a tab and if the paragraph's ruler is named Topic. By convention, the Topic ruler's font is Geneva on Macintosh or Arial on Windows, its text size is 12 and its text style is bold-underlined. The bullet and tab characters should be plain, not bold or underlined.

The easiest way to create a new topic with the right formatting is to copy an existing topic and then modify it.

Once Igor finds a topic declaration, it scans the body of the topic. The body is all of the text until the next topic declaration, a related-topics declaration, or the end of the file. While scanning, it notes any subtopics.

Igor considers a paragraph to be a subtopic declaration if the name of the ruler governing the paragraph starts with "Subtopic". Thus if the ruler is named Subtopic or Subtopic+ or Subtopic2, the paragraph is a subtopic declaration. By convention, the Subtopic ruler's font is Geneva on Macintosh or Arial on Windows, its text size is 10 and its text style is bold and underlined. Text following the subtopic name that is not bold and underlined is not part of the subtopic name.

The easiest way to create a new subtopic with the right formatting is to copy an existing subtopic and then modify it.

Igor considers a paragraph to be a related-topics declaration if the ruler governing the paragraph is named RelatedTopics and if the paragraph starts with the text pattern "Related Topics:". When Igor sees this pattern it knows that this is the end of the current topic. The related-topics declaration is optional. Prior to Igor Pro 4, Igor displayed a list of related topics in the Igor Help Browser. Igor Pro no longer displays this list. The user can still click the links in the related topics paragraph to jump to the referenced topics.

Igor knows that it has hit the end of the current topic when it finds the related-topics declaration or when it finds a new topic declaration. In either case, it proceeds to compile the next topic. It continues compiling until it hits the end of the file.

When compiling the help file, Igor may encounter syntax that it can't understand. For example, if you have a related-topics declaration paragraph, Igor will expect the next paragraph to be a topic declaration. If it is not, Igor will stop the compilation and display an error dialog. You need to open the file as a notebook, fix the error, save and kill it and then reopen it as a help file.

Another error that is easy to make is to fail to use the plain text format for syntactic elements like bullet-tab, "Related Topics:" or the comma and space between related topics. If you run into a non-obvious compile error in a topic, subtopic or related topics declaration, recreate the declaration by copying from a working help file.

The help files supplied by WaveMetrics contain a large number of rulers to define various types of paragraphs such as topic paragraphs, subtopic paragraphs, related topic paragraphs, topic body paragraphs and so on. The Igor Help File Template contains many but not all of these rulers. If you find that you need to use a ruler that exists in a WaveMetrics help file but not in your help file then copy a paragraph governed by that ruler from the WaveMetrics help file and paste it into your file. This transfers the ruler to your file.

Creating Links

A link is text in an Igor help file that, when clicked, takes the user to some other place in the help. Igor considers any pure blue, underlined text to be a link. Pure blue means that the RGB value is (0, 0, 65535). By convention links use the Geneva font on Macintosh and the Arial font on Windows.

To create a link, select the text in the notebook that you are preparing to be a help file. Then choose Make Help Link from the Notebook menu. This sets the text format for the selected text to pure blue and underlined.

The link text refers to another place in the help using one of these forms:

- The name of a help topic (e.g., Command Window)
- The name of a help subtopic (e.g., History Area)
- A combined topic and subtopic (e.g., Command Window[History Area])

Use the combined form if there is a chance that the help topic or subtopic name by itself may be ambiguous. For example, to refer to the Preferences operation, use Operations[Preferences] rather than Preferences by itself.

When the user double-clicks a link, Igor performs the following search:

1. If the link is a topic name, Igor goes to that topic.
2. If the link is in topic[subtopic] form, Igor goes to that subtopic.
3. If steps 1 and 2 fail, Igor searches for a subtopic with the same name as the link. First, it searches for a subtopic in the current topic. If that fails, it searches for a subtopic in the current help file. If that fails, it searches for a subtopic in all help files.
4. If step 3 fails, Igor searches all help files in the Igor Pro folder. If it finds the topic in a closed help file, it opens and displays it.
5. If step 4 fails, Igor searches all help files in the Igor Pro User Files folder. If it finds the topic in a closed help file, it opens and displays it.
6. If all of the above fail, Igor displays a dialog saying that the required help file is not available.

You can create a link in a help file that will open a Web page or FTP site in the user's Web or FTP browser. You do this by entering the Web or FTP URL in the help file while you are editing it as a notebook. The URL must appear in this format:

```
<http://www.wavemetrics.com>
<ftp://ftp.wavemetrics.com>
```

The URL must include the angle brackets and the "http://", "https://" or "ftp://" protocol specifier. Support for https was added in Igor Pro 7.02.

After entering the URL, select the entire URL, including the angle brackets, and choose Make Help Link from the notebook menu. Once the file is compiled and opened as a help file, clicking the link will open the user's Web or FTP browser and display the specified URL.

For any other kind of URL, such as sftp or mailto, use a notebook action that calls BrowseURL instead of a help link.

It is currently not possible make ordinary text into a Web or FTP link. The text must be an actual URL in the format shown above or you can insert a notebook action which brings up a web page using the **BrowseURL** operation on page V-54. See **Notebook Action Special Characters** on page III-14 for details.

Checking Links

You can tell Igor to check your help links as follows:

1. Open your Igor help file and compile it as a help file if necessary.
2. Activate your help window.
3. Right-click in the body of the help file and choose Check Help Links. Igor will check your links from where you clicked to the end of the file and note any problems by writing diagnostics to the history area of the command window.
4. When Igor finishes checking, if it found bad links, kill the help file and open it as a notebook.
5. Use the diagnostics that Igor wrote in the history to find and fix any link errors.
6. Save the notebook and kill it.
7. Open the notebook as a help file. Igor will compile it.
8. Repeat the check by going back to Step 1 until you have no bad links.

During this process, Igor searches for linked topics and subtopics in open and closed help files and opens any closed help file to which a link refers. If a link is not satisfied by an already open help file, Igor searches closed help files in:

- The Igor Pro Folder and subfolders
- The Igor Pro User Files folder and subfolders
- Files and folders referenced by aliases or shortcuts in one of those folders

You can abort the check by pressing the **User Abort Key Combinations**.

The diagnostic that Igor writes to the history in case of a bad link is in the form:

```
Notebook $nb selection={(33,292), (33,334)} …
```

This is set up so that you can execute it to find the bad link. At this point, you have opened the help file as a notebook. Assuming that it is named Notebook0, execute

```
String/G nb = "Notebook0"
```

Now, you can execute the diagnostic commands to find the bad link and activate the notebook. Fix the bad link and then proceed to the next diagnostic. It is best to do this in reverse order, starting with the last diagnostic and cutting it from the history after fixing the problem.

If you press the Shift key while right-clicking a help window, you can choose Check Help Links in All Open Help Files. Then Igor checks all help links all help files open at that time. While checking a help file, Igor may open a previously unopened help file. Such newly opened help files are not checked. Only those help files open when you chose Check Help Links in All Open Help Files are checked. However, if you repeat the process, help files opened during the previous iteration are checked.

When fixing a bad link, check the following:

- A link is the name of a topic or subtopic in a currently open help file. Check spelling.

- There are no extraneous blue/underlined characters, such as tabs or spaces, before or after the link. (You can not identify the text format of spaces and tabs by looking at them. Check them by selecting them and then using the Set Text Format dialog.)
- There are no duplicate topics. If you specify a link in topic[subtopic] form and there are two topics with the same topic name, Igor may not find the subtopic.

Help for User-Defined Functions

You can provide help for user-defined functions in your package by including a topic similar to the built-in Functions topic in your help file. In Igor Pro 9.00 or later, the user can go to the help for your user-defined function by selecting it in a procedure or notebook window, right-clicking, and choosing Help For <topic name>.

Here is how add help for your user-defined functions:

1. Display the built-in Functions topic.
2. Copy that topic paragraph and the first subtopic to the clipboard.
3. Paste into your help file.
4. Change the topic name to a distinctive name such as My Package Functions.
6. Edit the subtopic to provide help for one of your user-defined function.
7. Add additional subtopics by copying and pasting the original and editing as needed.

Make sure that your package name and user-defined function names are distinctive to avoid collisions with other packages.

The Insert Template For item in the contextual menu gets information from the procedure file and does not depend on help.

Creating Formatted Text

The printf, sprintf, and fprintf operations print formatted text to Igor's history area, to a string variable or to a file respectively. The wfprintf operation prints formatted text based on data in waves to a file.

All of these operations are based on the C printf function which prints the contents of a variable number of string and numeric variables based on the contents of a format string. The format string can contain literal text and conversion specifications. Conversion specifications define how a variable is to be printed.

Here is a simple example:

```
printf "The minimum is %g and the maximum is %g\r", V_min, V_max
```

In this example, the format string is `"The minimum is %g and the maximum is %g\r"` which contains some literal text along with two conversion specifications — both of which are "`%g`"— and an escape code ("`\r`") indicating "carriage-return". If we assume that the Igor variable V_min = .123 and V_max = .567, this would print the following to Igor's history area:

```
The minimum is .123 and the maximum is .567
```

We could print this output to an Igor string variable or to a file instead of to the history using the **sprintf** (see page V-902) or **fprintf** (see page V-260) operations.

Printf Operation

The syntax of the printf operation is:

```
printf format [, parameter [, parameter ]. . .]
```

where *format* is the format string containing literal text or format specifications. The number and type of parameters depends on the number and type of format specifications in the format string. The parameters, if any, can be literal numbers, numeric variables, numeric expressions, literal strings, string variables or string expressions.

The conversion specifications are very flexible and make printf a powerful tool. They can also be quite involved. The simplest specifications are:

Specification	What It Does
%g	Converts a number to text using integer, floating point or exponential notation depending on the number's magnitude.
%e	Converts a number to text using exponential notation.
%f	Converts a number to text using floating point notation.
%d	Converts a number to text using integer notation.
%s	Converts a string to text.

Here are some examples:

```
printf "%g, %g, %g\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3.14159, 6.022e+23, 1.602e-19
```

```
printf "%e, %e, %e\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3.141593e+00, 6.022000e+23, 1.602000e-19
```

```
printf "%f, %f, %f\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3.141593, 602200000000000027200000.000000, 0.000000
```

```
printf "%d, %d, %d\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3, 9223372036854775807, 0
```

```
printf "%s, %s\r", "Hello, world", "The time is " + Time()
```

prints:

```
Hello, world, The time is 11:43:40 AM
```

Note that the output for 6.022e23 when printed using the %d conversion specification is wrong. This is because 6.022e23 is too big a number to represent as an 64-bit integer.

If you want better control of the output format, you need to know more about conversion specifications. It gets quite involved. See the **printf** operation on page V-770.

sprintf Operation

The sprintf operation is very similar to printf except that it prints to a string variable instead of to Igor's history. The syntax of the sprintf operation is:

```
sprintf stringVariable, format [, parameter [, parameter ]. . .]
```

where *stringVariable* is the name of the string variable to print to and the remaining parameters are as for printf. sprintf is useful for generating text to use as prompts in macros, in axis labels and in annotations.

fprintf Operation

The fprintf operation is very similar to printf except that it prints to a file instead of to Igor's history. The syntax of the fprintf operation is:

```
fprintf variable, format [, parameter [, parameter ]. . .]
```

where *variable* is the name of a numeric variable containing the file reference number for the file to print to and the remaining parameters are as for printf. You get the file reference number using the Open operation, described under **Open and Close Operations** on page IV-196.

For debugging purposes, if you specify 1 for the file reference number, Igor prints to the history area instead of to a file, as if you used printf instead of fprintf.

wfprintf Operation

The wfprintf operation is similar to printf except that it prints the contents of one to 100 waves to a file. The syntax of the wfprintf operation is:

```
wfprintf variable, format [/R=(start,end)] wavelist
```

variable is the name of a numeric variable containing the file reference number for the file to print to.

Unlike printf, which rounds, wfprintf converts floating point values to integers by truncating, if you use an integer conversion specification such as “%d”.

Example Using fprintf and wfprintf

Here is an example of a command sequence that creates some waves and put values into them and then writes them to an output file with column headers.

```
Make/N=25 wave1, wave2, wave3
wave1 = 100+x; wave2 = 200+x; wave3 = 300+x
Variable f1
Open f1
fprintf f1, "wave1, wave2, wave3\r"
wfprintf f1, "%g, %g, %g\r" wave1, wave2, wave3
Close f1
```

This generates a comma delimited file. To generate a tab delimited file, use:

```
fprintf f1, "wave1\twave2\twave3\r"
wfprintf f1, "%g\t%g\t%g\r" wave1, wave2, wave3
```

Since tab-delimited is the default format for wfprintf, this last command is equivalent to:

```
wfprintf f1, "" wave1, wave2, wave3
```

Client/Server Overview

An application can interact with other software as a server or as a client.

A server accepts commands and data from a client and returns results to the client.

A client sends commands and data to a server program and receives results from the server.

For the Macintosh, see **Apple Events** on page IV-261 for server information and **AppleScript** on page IV-263 for client capabilities.

For Windows, see **ActiveX Automation** on page IV-265. Igor can play the role of an Automation server but not an Automation client. However it is possible to generate script files that allow Igor to indirectly play the role of client.

Apple Events

This topic is of interest to *Macintosh* programmers. For Windows, see **ActiveX Automation** on page IV-265.

This topic contains information for Igor users who wish to control Igor from other programs (e.g., AppleScript). It also contains information useful to people who are writing their own programs and wish to use Igor Pro as a computing or graphing engine.

There is also a mechanism that allows Igor to act like a controller and initiate Apple event communication with other programs. See **AppleScript** on page IV-263.

Apple Event Capabilities

Igor Pro supports the following Apple events:

Event	Suite	Action
Open Application	Required	Basically a nop; don't use.
Open Document	Required	Loads an experiment.
Print Document	Required	NA; don't use.
Quit Application	Required	Quits.
Close	Core	Acts on experiment, window or PPC port.
Save	Core	Acts on experiment only.
Open	Core	NA; don't use.
Do Script	Misc	Executes commands; can return ASCII results.
Eval Expression	Misc	Same as Do Script; obsolete but included for compatibility.

Apple Events — Basic Scenario

You use the Open Document event to cause Igor to load an experiment with whatever goodies you find useful. You then use the Do Script or Eval Expression events to send commands to Igor for execution and to retrieve results. To get data into Igor you write files and then send commands to Igor to load the data. To get data waves from Igor you do the reverse. To get graphics, you send commands to Igor that cause it to write a graphics file that you can read. You may then close the experiment and start over with a new one. You will not likely use the Save event.

Apple Events — Obtaining Results from Igor

To return information from Igor, you will need to embed special commands in the script you send to Igor for execution. When Igor encounters these commands, it appends results to a packet that is returned to your application after script execution ends. The special commands are variations on the standard Igor commands FBinWrite and fprintf. Both of these commands take a file reference number as a parameter. If the magic value zero is used rather than a real file reference number, then the data that would normally be written to a file is appended to the result packet.

As far as Igor is concerned, there is no difference between the Do Script and Eval Expression events. However, old applications may expect results from Eval Expression and not from Do Script.

To use waves and graphics with Apple events, you will need to write or read the data via standard Igor files. For example, you might include

```
SavePICT /E=-8 /P=MyPath as "Graphics.pdf"
```

in a script that you send to Igor for execution. You could then read the file in your application.

Apple Event Details

This information is intended for programmers familiar with Apple events terminology.

Some of the following events can act on experiments or windows.

To specify an experiment, use object class cDocument (`'docu'`) and specify either formAbsolutePosition with index=1 or formName with name=*name of experiment*.

To specify a window, use object class cWindow ('cwin') and either formAbsolutePosition or formName with name=*title of window*.

Event	Class	Code	Action
Open Application	'aevt'	'oapp'	Basically a nop; don’t use.
Open Document	'aevt'	'odoc'	Loads an experiment. Direct object is assumed to be coercible to a File System Spec record.
Print Document	'aevt'	'pdoc'	NA; don’t use.
Quit Application	'aevt'	'quit'	Quits the program. If the experiment was modified, then Igor attempts to interact with the user to get save/no save directions. If interaction is not allowed, then an error is returned and nothing is done. To prevent errors, send the close event with appropriate save options prior to sending quit.
Close	'core'	'clos'	Acts on an experiment or window. For a window, the save/no save/ask optional parameter (keyAESaveOptions) is allowed and refers to making/replacing a recreation macro. For a document (experiment), keyAESaveOptions is allowed and an additional optional parameter keyAEDestination may be used to specify where to save (must be coercible to a FSS). If this is not given and the experiment is untitled and if an attempt to interact with the user fails then the experiment is not saved and an error (such as errAENoUserInteraction) is returned. Note that if the optional destination is given then the save options are ignored (why give a destination and then say no save?).
Save	'core'	'save'	Acts on experiment only. Takes same optional destination parameters as Close. A save with a destination is the same as a Save as.
Do Script	'misc'	'dosc'	Same as Eval Expression.
Eval Expression	'aevt'	'eval'	Executes commands. Acts just as if commands had been typed into the command line except the individual command lines are preceded by a percent symbol rather than the usual bullet symbol. Also, errors are returned in the error reply parameter of the event rather than putting up a dialog. **Note**: You can suppress history logging by executing the command, “Silent 2”, and you can turn it back on by executing “Silent 3”. Direct parameter must be text and not a file. Text can be of any length. You can return a string containing results by using the fprintf command with a file reference number of zero.

AppleScript

This topic is of interest to *Macintosh* programmers. For Windows, see **ActiveX Automation** on page IV-265.

Igor supports the creation and execution of simple AppleScripts in order to send commands to other programs.

To execute an AppleScript program, you first compose it in a string and then pass it to the ExecuteScriptText operation, which in turn passes the text to Apple's scripting module for compilation and execution. The result, which might be an error message, is placed in a string variable named S_value. Igor does not save the compiled script so every time you call ExecuteScriptText your script will have to be recompiled. See the **ExecuteScriptText** operation on page V-205 for additional details.

The documentation for the **ExecuteScriptText** operation (page V-205) includes an example that shows how to execute a Unix command.

Because there is no easy way to edit a script or to see where errors occur, you should first test your script using Apple's Script Editor application.

You can use "Silent 2" to prevent commands your script sends to Igor from being placed in the history area.

You can send commands to Igor without using the tell keyword.

You should check your quoting carefully. Your text must be quoted both for Igor and for Apple's scripting system. For example,

```
ExecuteScriptText "Do Script \"Print \\\"hello\\\"\""
```

You should compose scripts in string variables one line at a time to improve readability.

If an error occurs that you can't figure out, print the string, copy from the history and paste into a Script Editor for debugging.

If the script returns a text return value, it may be quoted within the S_value string. See the discussion of quoting in the **ExecuteScriptText** documentation for details.

Don't forget to include the carriage return escape code, `\r`, at the end of each line of a multiline script.

The first time you call this routine, it may take an extra long time while the Mac OS loads the scripting modules.

Executing Unix Commands on Mac OS X

On Mac OS X, you can use AppleScript to send a command to the Unix shell. Here is a function that illustrates this:

```
Function/S ExecuteUnixShellCommand(uCommand, printCommandInHistory,
                                        printResultInHistory [, asAdmin])
    String uCommand                     // Unix command to execute
    Variable printCommandInHistory
    Variable printResultInHistory
    Variable asAdmin                    // Optional - defaults to 0

    if (ParamIsDefault(asAdmin))
        asAdmin = 0
    endif

    if (printCommandInHistory)
        Printf "Unix command: %s\r", uCommand
    endif

    String cmd
    sprintf cmd, "do shell script \"%s\"", uCommand
    if (asAdmin)
        cmd += " with administrator privileges"
    endif
    ExecuteScriptText/UNQ/Z cmd // /UNQ removes quotes surrounding reply

    if (printResultInHistory)
        Print S_value
    endif

    return S_value
End
```

You can test the function with this command:

```
ExecuteUnixShellCommand("ls", 1, 1)
```

Life is a bit more complicated if the command that you want to execute contains spaces or other nonstandard Unix command characters. For example, imagine that you want to execute this:

```
ls /System/Library/Image Capture
```

These commands will not work because of the space in the command's file path:

```
String unixCmd = "ls /System/Library/Image Capture"
ExecuteUnixShellCommand(unixCmd, 1, 1)
```

You need to quote the path part of the command so that the UNIX parses:

```
/System/Library/Image Capture
```

as one argument, not two (/System/Library/Image and ./Capture).

There are two ways to do this:

1. Use single-quote characters around the parts of the command where needed:

   ```
   String unixCmd = "ls '/System/Library/Image Capture'"
   ExecuteUnixShellCommand(unixCmd, 1, 1)
   ```

2. Use double-quote characters with the backslashes needed to make it through Igor's parser and AppleScript's parser:

   ```
   String unixCmd = "ls \\\"/System/Library/Image Capture\\\""
   ExecuteUnixShellCommand(unixCmd, 1, 1)
   ```

   Igor's parser converts \\ to \ and \" to ", so AppleScript sees this:

   ```
   "ls \"/System/Library/Image Capture\""
   ```

   AppleScript's parser converts \" to " so Unix sees this:

   ```
   ls "/System/Library/Image Capture"
   ```

ActiveX Automation

ActiveX Automation, often called just Automation, is Microsoft's technology for allowing one program to control another. The program that does the controlling is called the Automation client. The program that is controlled is called the Automation Server. The client initiates things by making calls to the server which carries out the requested actions and returns results.

Automation client programs are most often written in Visual Basic or C#. They can also be written in C++ and other programming languages, and in various scripting languages such as VBScript, JavaScript, Perl, Python and so on.

Igor can play the role of Automation Server. If you want to write an client program to drive Igor, see "Automation Server Overview" in the "Automation Server" help file in "\Igor Pro Folder\Miscellaneous\Windows Automation".

Igor Pro does not directly support playing the role of Automation client. However, it is possible to write an Igor program which generates a script file which can act like an Automation client. For an example, choose File→Example Experiments→Programming→CallMicrosoftWord.

Calling Igor from Scripts

You can call Igor from shell scripts, batch files, Apple Script, and the Macintosh terminal window using an operation-like syntax. You can also use this feature to register an Igor license.

The syntax for calling Igor is:

```
<IGOR> [/I /Q /X /N /Automation]  [pathToFileOrCommands] [pathToFile] ...

<IGOR> [/I /N /Automation]  [pathToFileOrCommands] [pathToFile] ...

<IGOR> [/I /Q /X /Automation] "commands"

<IGOR> /SN=num /KEY="key" /NAME="name" [/ORG="org" /QUIT]
```

where `<IGOR>` is the full path to the Igor executable file.

On Windows, the Igor executable file resides in a folder within the Igor Pro folder. The full path will be something like:

```
"C:\Program Files\WaveMetrics\IgorBinaries_x64\Igor Pro Folder\Igor64.exe"
```

On Macintosh, the Igor application is an "application bundle" and the actual executable file is inside the bundle. The full path will be something like:

```
'/Applications/Igor Pro Folder/Igor64.app/Contents/MacOS/Igor64'
```

In the following discussions, `<IGOR>` means "the full path to the Igor executable file".

Parameters

All parameters are optional. If you omit all parameters, including just the full path to the Igor executable, a new instance of Igor is launched.

The usual parameter is a file for Igor to open. It is recommended that both the path and the path to the file parameter be enclosed in quotes.

You can open multiple files by using a space between one quoted file path and the next.

With the /X flag, only one parameter is allowed and it is interpreted as an Igor command.

Flags

When you specify a flag, you can use a - instead of /. For example, you can write /Q or -Q.

/Automation — This flag is supported on Windows only. The Windows OS uses it when launching Igor Pro as an ActiveX Automation server. It is not intended for use in batch files.

/I — Launches a new instance of Igor if one would otherwise not be launched. See ***Details*** for a discussion of instances.

/KEY="*key*" — Specifies the license activation key when registering a license. For example:

```
/KEY="ABCD-EFGH-IJKL-MNOP-QRST-UVWX-Y"
```

Do not omit the quotes, or it will fail.

/N — Forces the current experiment to be closed without saving if any of the file parameters are an experiment file.

To save a currently open experiment, use:

```
<IGOR> /X "SaveExperiment"
```

/NAME="*name*" — Specifies the name of the licensed user when registering a license. A name is required when registering.

/ORG="*org*" — Specifies the optional name of the licensed organization when registering a license. /ORG is optional and defaults to "".

/Q — Prevents the command from being displayed in Igor's command line as it is executing.

/QUIT — Quits Igor Pro after entering license information when used with /SN, /KEY, and /NAME. Otherwise /QUIT is ignored.

To quit Igor Pro, use:

```
<IGOR> /X "Quit/N"
```

/SN=*num* — Specifies the license serial number when registering a license.

/START=*x* Controls logging of diagnostic information for use in troubleshooting slow startup or crashes during startup. Allowed values for *x* are:

0: Regular startup.

1: Write diagnostic information to "Igor Debug Log.txt" in the Diagnostics folder of the Igor Pro preferences folder.

2: Write diagnostic information to an Igorlogging window.

/START was added in Igor Pro 9.00.

/UNATTENDED Suppresses certain interactions that are inconvenient for unattended operations. An example is the About Autosave dialog that appears when Igor is launched until the user clicks “Do not show this message again”.

/ /UNATTENDED was added in Igor Pro 9.00.

X Executes the commands in the parameter. Only one parameter is allowed with /X. Use semicolons to separate Igor commands within the parameter.

Details

If an existing instance of Igor is running, the command is sent to the existing instance if you omit the /I flag and you include /X, /SN, or a path to a file. Otherwise, a new instance of Igor is launched.

Registering a License

You can register an Igor license using the /SN, /KEY, and /NAME flags. All of these flags must be present to successfully register a license. The optional /ORG parameter defaults to "".

These batch file commands register Igor Pro with the given serial number and license activation key:

```
<IGOR> /SN=1234567 /KEY="ABCD-EFGH-IJKL-MNOP-QRST-UVWX-Y" /NAME="Jack" /ORG="Acme Scientific" /QUIT
```

Network Communication

The following sections contain material related to the network communication and Internet-related capabilities of Igor Pro:

URLs on page IV-267

Safe Handling of Passwords on page IV-270

Network Timeouts and Aborts on page IV-270

Network Connections From Multiple Threads on page IV-271

File Transfer Protocol (FTP) on page IV-272

Hypertext Transfer Protocol (HTTP) on page IV-276

URLs

URLs, or Uniform Resource Locators, are compact strings that represent a resource available via the Internet. The description of the URL standard is described in RFC1738 (http://www.rfc-editor.org/rfc/rfc1738.txt) and updated in RFC3986 (http://www.rfc-editor.org/rfc/rfc3986.txt).

Each URL is composed of several different parts, most of which are optional:

```
<scheme>://<username>:<password>@<host>:<port>/<path>?<query>
```

Some examples of valid URLs are:

```
http://www.example.com
http://www.example.com/afolder?key1=45&key2=66
http://myusername:Passw0rD@www.example.com:8010/index.html
ftp://ftp.wavemetrics.com
```

```
file:///C:\\Data\\Trial1\\control.ibw (on Windows only)
file:///Users/bob/Data/Trial1/control.ibw (on Macintosh only)
```

For most operations and functions that take a *urlStr* parameter, only the scheme and host parts of the URL are required. See the **Supported Network Schemes** section for information on which schemes are supported by which operations and functions, and which port is used by default if it is not provided as part of the URL.

Usernames and Passwords

You can provide a username and password as part of the URL. However authentication credentials may not be supported by all schemes (such as file://). Some operations allow you to provide a username and password by using a flag, such as the /U and /W flags with **FTPDownload** or the /AUTH flag with **URLRequest**.

If a URL contains a username and password in the URL and the authentication flags are also used, the values specified in the flags override values provided in the URL.

If you do not provide a username and password as part of the URL, and you do not use the authentication flags, then no authentication is attempted. An exception to this rule is that the FTP operations will login to the FTP server using "anonymous" as the username and a generic email address as the password.

If either the username or password contains special or reserved characters, those characters must be percent-encoded.

Supported Network Schemes

Different operations and functions support different schemes:

Operation	Supported Schemes	Default Port
FetchURL and **URLRequest**	http	80
	https	443
	ftp	21
	file	Not applicable
FTP operations*	ftp	21

* Includes **FTPUpload**, **FTPDownload**, **FTPDelete**, and **FTPCreateDirectory**.

Percent Encoding

Percent encoding is a way to encode characters in URLs that would otherwise have a special meaning or could be misinterpreted by servers. For example, a space character in a URL is encoded as "%20" using a percent character followed by the hex code for a space in the ASCII character set.

Most URLs contain only the letters A-Z and a-z, the digits 0-9, and a few other characters such as the underscore (_), hyphen (-), period (.), and tilde (~).

A URL may also contain "reserved characters" that may have special meaning depending on the way that they are used. Every URL contains the reserved characters ":" and "/" and may also contain one or more of the following reserved characters: !*'();@&=+$,?#[].

All operations and functions provided by Igor Pro that accept a URL string parameter expect that the URL has already been percent-encoded as necessary.

In most cases you don't need to worry about percent encoding because most URLs don't use reserved characters except for their special meaning. If you need to use a reserved character in a way that differs from the character's special meaning, you must percent-encode the character. You can use the **URLEncode** function for this purpose.

It is important that you not pass your entire URL to URLEncode to be encoded because that URL will not be understood by a server. URLEncode percent-encodes all reserved characters in the string you pass to it, because it cannot distinguish between reserved characters used for their special meaning and reserved characters used outside of their special meaning. Instead, you must pass each piece of the URL through URLEncode so that the final URL uses the correct syntax.

As an example, we'll use URLEncode to properly encode a URL that contains the following parts:

Part Name	Example
Scheme	http
Username	A. MacGyver
Password	yj@!2M
Host	www.example.com
Path	/tape/duct
Query	discount=10%&color=red

Without any percent-encoding, the URL is:

```
http://A. MacGyver:yj@!2M@www.example.com/tape/duct?discount=10%&color=red
```

If this URL were passed to **FetchURL**, the result would be an error because the URL contains several reserved characters that are not intended to be used in their standard way. For example, the "@" character indicates the separation between the username:password information and the start of the host name, but in this case the password itself also contains the "@" character. In addition, the "%" character is typically used to indicate that the next two characters represent a percent-encoded character, but in this example it is also part of the query. Finally, the username contains a space character. The space character is not technically a reserved character, but should be percent-encoded to ensure that it is handled correctly.

The following table shows the values of the parts of the URL that need to be percent-encoded by passing them through the URLEncode function:

Part Name	Encoded Value
Username	A%2E%20MacGyver
Password	yj%40%212M
Host	www.example.com
Path	/tape/duct
Query	discount=10%25&color=red

The properly percent-encoded URL is:

```
http://A%2E%20MacGyver:yj%40%212M@www.example.com/tape/duct?discount=10%25&color=red
```

For keyword-value pairs that make up the query part, each keyword and value must be percent-encoded separately because the "=" character that separates the key from the value and the "&" character that separates the pairs in the list must not be percent-encoded.

For more information on percent-encoding and reserved characters, see http://en.wikipedia.org/wiki/Percent-encoding.

Safe Handling of Passwords

Some operations and functions support the use of a username and password when making a network connection. If you use sensitive passwords you must take certain precautions to prevent them from being accidentally revealed.

1. Always use the /V=0 flag when using a username or password with the /U (username) and /W (password) flags or the /AUTH flag. Otherwise, the debugging information that is printed to the history area will contain those values and anyone who sees the experiment could see them.
2. Do not hard code username or password values into procedures, since anyone with access to the procedure file could read them.
3. Do not store username or password values in global variables. Since global variables are saved with an experiment, if someone else had access to your experiment they could see this information.

Here is an example of how a username and sensitive password can be used in a secure manner:

```
Function SafeLogin()
   String username = ""
   String password = ""
   Prompt username, "Username"
   Prompt password, "Password"
   DoPrompt "Enter username and password", username, password
   if (V_flag == 1)
      // User hit cancel button, so do nothing.
      return 0
   endif

   // Percent-encode in case username and password contain reserved characters.
   String encodedUser = URLEncode(username)
   String encodedPass = URLEncode(password)

   String theURL
   sprintf theURL, "http://%s:%s@www.example.com", encodedUser, encodedPass
   String response = FetchURL(theURL)
   // NOTE: For FTP operations and URLRequest, make sure to use /V=0 so that
   // the username and password are not printed to the history.

   return 0
End
```

Note that the user is prompted to provide the username and password when the function is called and that only local string variables are used to store the username and password. The values in those string variables are not stored once the function is done executing.

Note also that the password is not hidden during entry in the dialog. Igor currently does not provide a way to do this.

Network Timeouts and Aborts

Some network calls may return an error code to Igor if they timeout. Depending on the specific operation or function, there can be a number of causes for a timeout.

If a network connection cannot be made after a period of time it will timeout. The amount of time allowed for a connection to be established is dependent on several factors.

You can always abort a network operation or function by pressing the **User Abort Key Combinations**.

Network Connections From Multiple Threads

All network-related operations and functions are thread-safe, which means that they can be called from multiple preemptive threads at the same time. This capability can be useful when:

- You want to retrieve information from several different URLs as quickly as possible.
- You want to do a long download or other operation in the background to avoid tieing Igor up.

The following example illustrates the first of these cases. It uses **FetchURL** to retrieve a list of the most frequently downloaded books from the Project Gutenberg web site. It then uses FetchURL to download the entire text of the top four books and prints the number of bytes in each.

```
ThreadSafe Function GetThePage(url)
   String url

   String response = FetchURL(url)
   return strlen(response)
End

Function ListGutenbergTopBooks()
   String topBooksURL = "http://www.gutenberg.org/browse/scores/top"
   String baseURL = "http://www.gutenberg.org/files/"

   // Get the contents of the page.
   String response = FetchURL(topBooksURL)
   Variable error = GetRTError(1)
   if (error || numtype(strlen(response)) != 0)
      Print "Error getting the list of most popular books."
      return 0
   endif

   String topBooksHTML = response

   // Remove all line endings.
   topBooksHTML = ReplaceString("\n", topBooksHTML, "")
   topBooksHTML = ReplaceString("\r", topBooksHTML, "")

   // Parse the page to get the section of the page
   // with the list of the most popular books from yesterday.
   // This could break if the format of the web page changes.
   String regExp = "(?i)<h2 id=\"books-last1\">.*?<ol>(.*?)</ol>"
   String topYesterdayHTML = ""
   SplitString/E=regExp topBooksHTML, topYesterdayHTML
   if (V_flag != 1)
      Print "Error parsing the top 100 books section."
      return 0
   endif

   // Replace the line endings.
   topYesterdayHTML = ReplaceString("</li><li>", topYesterdayHTML, "\r")

   // Create a wave to store text info about the top four books.
   Variable numBooksToUse = 4
   Make/O/T/N=(numBooksToUse, 2) topBooksInfo

   Make/O/N=(numBooksToUse) byteCounts

   Variable n
   String bookNumStr
   Variable bookNum
   String titleAuthor
   String thisLine
   Variable pos
   String bookURL = ""
   regExp = "(?i)a href=\".*?(\d+)\">(.+?)</a>"
   for (n=0; n<numBooksToUse; n+=1)
      // For each book we're going to look at, get the
      // partial URL and the title/author text.
      thisLine = StringFromList(n, topYesterdayHTML, "\r")
      SplitString/E=regExp thisLine, bookNumStr, titleAuthor
      if (V_flag != 2)
         Print "Error parsing the URL and title/author information."
         return 0
      endif

      // Remove the (###) stuff at the end of titleAuthor if it's there.
      pos = strsearch(titleAuthor, "(", 0)
      if (pos > 0)
         titleAuthor = titleAuthor[0, pos - 1]
      endif

      bookNum = str2num(bookNumStr)

      // Store the information about the book in the text wave.
      sprintf bookURL, "%s%d/%d.txt", baseURL, bookNum, bookNum
      topBooksInfo[n][0] = bookURL
      topBooksInfo[n][1] = titleAuthor
   endfor

   // Download each book (using multiple threads if possible)
   // and count the number of bytes in each.
   MultiThread byteCounts = GetThePage(topBooksInfo[p][0])

   // Print the results.
   Print "The top four books by download from yesterday are:"
   for (n=0; n<numBooksToUse; n+=1)
      Printf "%s (%d bytes)\r", topBooksInfo[n][1], byteCounts[n]
   endfor
End
```

Here is an example of what the output was when this help file was written:

The top four books by download from yesterday are:

```
Ulysses by James Joyce (1573044 bytes)
Alice's Adventures in Wonderland by Lewis Carroll (167529 bytes)
Piper in the Woods by Philip K. Dick (62214 bytes)
Pride and Prejudice by Jane Austen (704160 bytes)
```

File Transfer Protocol (FTP)

The **FTPDownload**, **FTPUpload**, **FTPDelete**, and **FTPCreateDirectory** operations support simple transfers of files and directories over the Internet.

Since Igor’s SaveNotebook operation can generate HTML files from notebooks, it is possible to write an Igor procedure that downloads data, analyzes it, graphs it, and uploads an HTML file to a directory used by a Web server. You can then use the BrowseURL operation to verify that everything worked as expected. For a demo of some of these features, choose File→Example Experiments→Feature Demos→Web Page Demo.

FTP Limitations

All FTP operations run “synchronously”. This means that, if the operation executes in the main thread, Igor can not do anything else. However, it is possible to perform these operations using an Igor preemptive thread so that they execute in the background and you can continue to use Igor for other purposes. For more information, see **Network Connections From Multiple Threads** on page IV-271.

Igor does not currently provide any way for the user to browse the remote server from within Igor itself.

Igor does not provide any secure way to store passwords. Consequently, you should not use Igor for FTP in situations where tight security is required. See **Safe Handling of Passwords** on page IV-270 for an example of how to securely prompt the user for a password.

Igor does not provide any support for using proxy servers. Proxy servers are security devices that stand between the user and the Internet and permit some traffic while prohibiting other traffic. If your site uses a proxy server, FTP operations may fail. Your network administrator may be able to provide a solution.

Igor does not include operations for listing a server directory or changing its current directory.

Downloading a File

The following function transfers a file from an FTP server to the local hard disk:

```
Function DemoFTPDownload()
   String url = "ftp://ftp.wavemetrics.net/welcome.msg"
   String localFolder = SpecialDirPath("Desktop",0,0,0)
   String localPath = localFolder + "DemoFTPDownloadFile.txt"
   FTPDownload/U="anonymous"/W="password" url, localPath
End
```

The output directory must already exist on the local hard disk. The target file may or may not exist on the local hard disk. If it does not exist, the FTPDownload command creates it. If it does exist, FTPDownload asks if you want to overwrite it. To overwrite it without being asked, use the /O flag.

Warning: If you elect to overwrite it, all previous contents of the local target file are obliterated.

FTPDownload presents a dialog asking you to specify the local file name and location in the following cases:

1. You use the /I (interactive) flag.
2. The parent directory specified by the local path does not exist.
3. The specified local file exists and you do not use the /O (overwrite) flag.

Downloading a Directory

The following function transfers a directory from an FTP server to the local hard disk:

```
Function DemoFTPDownloadDirectory()
   String url = "ftp://ftp.wavemetrics.net/Utilities"
   String localFolder = SpecialDirPath("Desktop",0,0,0)
   String localPath = localFolder + "DemoFTPDownloadDirectory"
   FTPDownload/D/U="anonymous"/W="password" url, localPath
End
```

The /D flag specifies that you are transferring a directory.

The output directory may or may not already exist on the local hard disk. If it does not exist, the FTPDownload command creates it. If it does exist, FTPDownload asks if you want to overwrite it. To overwrite it without being asked, use the /O flag.

Warning: If you elect to overwrite it, all previous contents of the local directory are obliterated.

If the local path that you specify ends with a colon or backslash, FTPDownload presents a dialog asking you to specify the local directory because it is looking for the name of the directory to be created on the local hard disk.

FTPDownload presents a dialog asking you to specify the local directory in the following cases:

1. You use the /I (interactive) flag.
2. The parent directory specified by the local path does not exist.
3. The specified directory (DemoFTPDownloadFolder in the example above) exists and you have not used the /O (overwrite) flag.
4. FTPDownload gets an error when it tries to create the specified directory. This could happen, for example, if you don't have write privileges for the parent directory.

Uploading a File

The following function uploads a file to an FTP server:

```
Function DemoFTPUploadFile()
   String url = "ftp://ftp.wavemetrics.com/pub"
   String localFolder = SpecialDirPath("Desktop",0,0,0)
   String localPath = localFolder + "DemoFTPUploadFile.txt"
   FTPUpload/U="username"/W="password" url, localPath
End
```

To successfully execute this, you need a real user name and a real password.

Note: The /O flag has no effect on the FTPUpload operation when uploading a file. FTPUpload *always* overwrites an existing server file, whether /O is used or not.

Warning: If you overwrite a server file, all previous contents of the file are obliterated.

To overwrite an existing file on the server, you must have permission to delete files on that server. The server administrator determines what permission a particular user has.

FTPUpload presents a dialog asking you to specify the local file in the following cases:

1. You use the /I (interactive) flag.
2. The local parent directory or the local file does not exist.

Uploading a Directory

The following function uploads a directory to an FTP server:

```
Function DemoFTPUploadDirectory()
   String url = "ftp://ftp.wavemetrics.com/pub"
   String localFolder = SpecialDirPath("Desktop",0,0,0)
   String localPath = localFolder + "DemoFTPUploadDirectory"
   FTPUpload/D/U="username"/W="password" url, localPath
End
```

To successfully execute this, you need a real user name and a real password. Also, the server would have to allow uploading directories.

Note: FTPUpload *always* overwrites an existing server directory, whether /O is used or not.

Warning: If you omit /O or specify /O or /O=1, all previous contents of the directory are obliterated.

If you specify /O=2, FTPUpload performs a merge of the directory contents. This means that files and directories in the source overwrite files and directories on the server that have the same name, but files and directories on the server whose names do not conflict with those in the source directory are not modified.

To overwrite an existing directory on the server, you must have permission to delete directories on that server. The server administrator determines what permission a particular user has.

If the local path that you specify ends with a colon or backslash, FTPUpload presents a dialog asking you to specify the local directory because it is looking for the name of the directory to be uploaded.

FTPUpload presents a dialog asking you to specify the local directory in the following cases:

1. You use the /I (interactive) flag.
2. The specified directory or any of its parents do not exist.

If you don’t have permission to remove and to create directories on the server, FTPUpload will fail and return an error.

Creating a Directory

The **FTPCreateDirectory** operation creates a new directory on an FTP server.

If the directory already exists on the server, the operation does nothing. This is not treated as an error, though the V_Flag output variable is set to -1 to indicate that the directory already existed.

If you don't have permission to create directories on the server, FTPCreateDirectory fails and returns an error.

Deleting a Directory

The **FTPDelete** operation with the /D flag deletes a directory on an FTP server.

If you don't have permission to delete directories on the server, or if the specified directory does not exist on the server, FTPDelete fails and returns an error.

FTP Transfer Types

The FTP protocol supports two types of transfers: image and ASCII. Image transfer is appropriate for binary files. ASCII transfer is appropriate for text files.

In an image transfer, also called a binary transfer, the data on the receiving end will be a replica of the data on the sending end. In an ASCII transfer, the receiving FTP agent changes line terminators to match the local convention. On Macintosh and Unix, the conventional line terminator is linefeed (LF, ASCII code 0x0A). On Windows, it is carriage-return plus linefeed (CR+LF, ASCII code 0x0D + ASCII code 0x0A).

If you transfer a text file using an image transfer, the file may not use the local conventional line terminator, but the data remains intact. Igor Pro can display text files that use any of the three conventional line terminators, but some other programs, especially older programs, may display the text incorrectly.

On the other hand, if you transfer a binary file, such as an Igor experiment file, using an ASCII transfer, the file will almost certainly be corrupted. The receiving FTP agent will convert any byte that happens to have the value 0x0D to 0x0A or vice versa. If the local convention calls for CRLF, then a single byte 0x0D will be changed to two bytes, 0x0D0A. In either case, the file will become unusable.

FTP Troubleshooting

FTP involves a lot of hardware and software on both ends and a network in between. This provides ample opportunity for errors.

Here are some tips if you experience errors using the FTP operations.

1. Use an FTP client or web browser to connect to the FTP site. This confirms that your network is operating, the FTP server is operating, and that you are using the correct URL.
2. Use an FTP client or web browser to verify that the user name and password that you are using is correct or that the server allows anonymous FTP access.

   Many web browser accept URLs of the form:

   ```
   ftp://username:password@ftp.example.com
   ```

   However the password is not transferred securely.

3. Use an FTP client or web browser to verify that the directory structure of the FTP server is what you think it is.
4. Using an FTP client or web browser, do the operation that you are attempting to do with Igor. This verifies that you have sufficient permissions on the server.
5. Use /V=7 to tell the Igor operation to display status information in the history area.
6. Try the simplest transfer you can. For example, try to download a single file that you know exists on the server.
7. If you have access to the FTP server, examine the FTP server log for clues.

Hypertext Transfer Protocol (HTTP)

The **FetchURL** function supports simple URL requests over the Internet from web or FTP servers and to local files. For example, you can use FetchURL to get the source code of a web page in text form, and then process the text to extract specific information from the response.

The **URLRequest** operation supports both simple URL requests and more complicated requests such as using the http POST, PUT, and DELETE methods. It also provides experimental support for using a proxy server.

HTTP Limitations

At this time, **FetchURL** and **BrowseURL** routines work with the HTTP protocol.

Currently not supported are features such as using network proxy servers, using the HTTP POST method to submit forms and upload files to a web server, and making secure network connections using the Secure Socket Layer (SSL) protocol.

Downloading a Web Page Via HTTP

This example uses FetchURL to download the contents of the WaveMetrics home page into a string, and then counts the number of times that the string "Igor" occurs in the text of the page.

```
Function DownloadWebPageExample()
   String webPageText = FetchURL("http://www.wavemetrics.com")
   if (numtype(strlen(webPageText)) == 2)
      Print "There was an error while downloading the web page."
   endif
   Variable count, pos
   do
      pos = strsearch(webPageText, "Igor", pos, 2)
      if (pos == -1)
         break    // No more occurrences of "Igor"
      else
         pos += 1
         count += 1
      endif
   while (1)
   Printf "The text \"Igor\" was found %d times on the web page.\r", count
End
```

Downloading a File Via HTTP

This example uses FetchURL to download a file from a web server. Because FetchURL does not support storing the downloaded data into a file directly, we store the data in memory and then use Igor to write that data to a file on disk.

Though the example uses a URL that begins with http://, FetchURL also supports https://, ftp:// and file://. You could use the code below with a different URL to download a file from an FTP server or even to access a local on-disk file.

```
Function DownloadWebFileExample()
   String url = "http://www.wavemetrics.net/IgorManual.zip"

   // Based on the URL, determine what the destination
   // file name should be. This will be the default in the
   // Save As... dialog.
   String urlStrParam = RemoveEnding(url, "/")
   Variable parts = ItemsInList(urlStrParam, "/")
   String destFileNameStr = StringFromList(parts - 1, urlStrParam, "/")
   if (strlen(destFileNameStr) < 1)
      Print "Error: Could not determine the name of the destination file."
      return 0
   endif

   Variable refNum
   Open/D/M="Save File As..."/T="????" refNum as destFileNameStr
   String fullFilePath = S_fileName

   if (strlen(fullFilePath) > 0) // No error and user didn't cancel in dialog.
      // Open the selected file so that it can later be written to.
      Open/Z/T="????" refNum as fullFilePath
      if (V_flag != 0)
         Print "There was an error opening the local destination file."
      else
         String response = FetchURL(url)
         Variable error = GetRTError(1)
         if (error == 0 && numtype(strlen(response)) == 0)
            FBinWrite refNum, response
            Close refNum
            Print "The file was successfully downloaded as " + fullFilePath
         else
            Close refNum
            DeleteFile/Z fullFilePath  // Clean up the empty file.
            Print "There was an error downloading the file."
         endif
      endif
   endif
End
```

Making a Query Via HTTP

Another use for HTTP requests is to get the server's response to a query. Many simple web forms use the HTTP GET method, which both FetchURL and URLRequest support. For example, you can simulate the submission of the basic Google search form using the following code.

```
Function WebQueryExample()
   String keywords
   String baseURL = "http://www.gutenberg.org/ebooks/search/"

   // Prompt the user to enter search keywords.
   Prompt keywords, "Enter search term"
   DoPrompt "Search Gutenberg.org", keywords
   if (V_flag == 1)
      return -1   // User clicked cancel button
   endif

   // Pass the search terms through URLEncode to
   // properly percent-encode them.
   keywords = URLEncode(keywords)

   // Build the full URL.
   String url = ""
   sprintf url, "%s?query=%s", baseURL, keywords

   // Fetch the results.
   String response
   response = FetchURL(url)
   Variable error = GetRTError(1)
   if (error != 0 || numtype(strlen(response)) != 0)
      Print "Error fetching search results."
      return -1
   endif

   // Try to extract the thumbnail image of the first result.
   String regExp = "(?s)<img class=\"cover-thumb\" src=\"(.+?)\".*"
   String firstURL
   SplitString/E=regExp response, firstURL
   firstURL = TrimString(firstURL)
   firstURL = "http:" + firstURL
   if (V_flag == 1)
      BrowseURL firstURL
   else
      Print "Could not extract the first result from the"
      Print "results page. Your search terms might not"
      Print "have given any results, or the format of"
      Print "the results may have changed so that the"
      Print "first result cannot be extracted."
      return -1
   endif

   return 0
End
```

Examples using the POST method can be found in the section ***The HTTP POST Method*** of the documentation for the **URLRequest** operation.

HTTP Troubleshooting

Here are some tips if you experience errors using **FetchURL** or **URLRequest**:

1. Use a web browser to connect to the site. This confirms that your network is operating, the server is operating, and that you are using the correct URL.
2. FetchURL and URLRequest generate an error if it cannot connect to the destination server, which could happen if your computer is not connected to the network or if the target URL contains an invalid host name or port number.

   However if the URL contains an invalid path or if the destination URL requires you to provide a username and password, these operations will likely not generate an error. The reason is these errors typically result in a web page being returned, though not the one you expected. If you need to check that a call to FetchURL returned a valid web page and not an error web page, you must do that in your own code. One possibility would be to try searching the page for key phrases, such as "File Not Found" or "Page Not Found".

   With URLRequest, you can inspect the value of the V_responseCode output variable. For successful HTTP requests, this value will usually be 200. A different value may indicate that there was an error making the request.

Operation Queue

Igor implements an operation queue that supports deferred execution of commands and some special commands for dealing with files, procedures, and experiments.

Igor services the operation queue when no procedures are running and the command line is empty. If the operation queue is not empty, Igor then executes the oldest command in the queue.

You can append a command to the operation queue using

```
Execute/P <command string>
```

The /P flag tells Igor to post the command to operation queue instead of executing it immediately.

You can also specify the /Q (quiet) or /Z (ignore error) flags. See **Execute/P** operation (page V-204) for details about /Q and /Z.

The command string can contain either a special command that is unique to the operation queue or ordinary Igor commands. The special commands are:

INSERTINCLUDE *procedureSpec*

DELETEINCLUDE *procedureSpec*

AUTOCOMPILE ON

AUTOCOMPILE OFF

COMPILEPROCEDURES

NEWEXPERIMENT

LOADFILE *filePath*

LOADFILEINNEWINSTANCE *filePath*

LOADHELPEXAMPLE *filePath*

MERGEEXPERIMENT *filePath*

RELOAD CHANGED PROCS (added in Igor Pro 9.00)

Note: The special operation queue keywords must be all caps and must have exactly one space after the keyword.

INSERTINCLUDE and DELETEINCLUDE insert or delete #include lines in the main procedure window. *procedureSpec* is whatever you would use in a #include statement except for “#include” itself.

AUTOCOMPILE ON and AUTOCOMPILE OFF require Igor Pro 8.03 or later. See **Auto-Compiling** on page III-404 for details.

COMPILEPROCEDURES does just what it says, compiles procedures. You must call it after operations such as INSERTINCLUDE that modify, add, or remove procedure files.

NEWEXPERIMENT closes the current experiment without saving.

LOADFILE opens the file specified by *filePath*. *filePath* is either a full path or a path relative to the Igor Pro Folder. The file can be any file that Igor can open. If the file is an experiment file, execute NEWEXPERIMENT first to avoid displaying a “Do you want to save” dialog. If you want to save the changes in an experiment before loading another, you can use the standard SaveExperiment operation.

LOADFILEINNEWINSTANCE opens the file specified by *filePath* in a new instance of Igor. *filePath* is either a full path or a path relative to the Igor Pro Folder. The file can be any file that Igor can open. LOADFILEINNEWINSTANCE was added in Igor Pro 7.01.

LOADHELPEXAMPLE opens the file specified by *filePath* in a new instance of Igor. It works the same as LOADFILEINNEWINSTANCE and is recommended for **Notebook Action Special Characters** that load example experiments, such as those used throughout Igor’s help files. LOADHELPEXAMPLE was added in Igor Pro 8.00.

MERGEEXPERIMENT merges the experiment file specified by *filePath* into the current experiment. Before using this, make sure you understand the caveats regarding merging experiments. See **Merging Experiments** on page II-19 for details.

RELOAD CHANGED PROCS, added in Igor Pro 9.00, causes Igor to reload procedure windows from their disk files if they have been modified outside of Igor. This is useful if you run a system that modifies procedure files using external software which is part of a system running from Igor. The sequence of events is:

1. Most likely, you use ExecuteScriptText to trigger the external modifications.

2. You use Execute/P "RELOAD CHANGED PROCS " to reload the modified procedures.

3. You use Execute/P "COMPILEPROCEDURES " to compile the modified procedures.

Operation Queue Example

```
Function DemoQueue()
   Execute/P "INSERTINCLUDE <Multipeak Fitting>"
   Execute/P "COMPILEPROCEDURES "
   Execute/P "fStartMultipeakFit2()"
   Execute/P "Sleep 00:00:04"
   Execute/P "NEWEXPERIMENT "
   Execute/P "LOADFILE :Examples:Feature Demos:Live mode.pxp"
   Execute/P "DoWindow/F Graph0"
   Execute/P "StartButton(\"StartButton\")"
End
```

Operation Queue For Loading Packages

One important use of the operation queue is providing easy access to useful procedure packages. The "Igor Pro Folder/Igor Procedures" folder contains a procedure file named “DemoLoader.ipf” that creates the Packages submenus found in various menus. To try it out, choose one of the items from the Analysis→Packages menu.

DemoLoader.ipf is an independent module. To examine it, execute:

```
SetIgorOption IndependentModuleDev=1
```

and then use the Windows→Procedure Windows submenu.

User-Defined Hook Functions

Igor calls specific user-defined functions, called “hook” functions, if they exist, when it performs certain actions. This allows savvy programmers to customize Igor’s behavior.

In some cases the hook function may inform Igor that the action has been completely handled, and that Igor shouldn’t perform the action. For example, you could write a hook function to load data from a certain kind of text file that Igor can not handle directly.

This section discusses general hook functions that do not apply to a particular window. For information on window-specific events, see Window Hook Functions.

There are two ways to get Igor to call your general hook function. The first is by using a predefined function name. For example, if you create a function named AfterFileOpenHook, Igor will automatically call it after opening a file. The second way is to explicitly tell Igor that you want it to call your hook using the **SetIgorHook** operation.

If you use a predefined hook function name, you should make the function static (private to the file containing it) so that other procedure files can use the same predefined name.

Here are the predefined hook functions.

Action	Hook Function Called
Procedures were successfully compiled	**AfterCompiledHook**
A file or experiment was opened	**AfterFileOpenHook**

Action	Hook Function Called
The Windows-only "MDI frame" (main application window) was resized	**AfterMDIFrameSizedHook**
A target window was created	**AfterWindowCreatedHook**
The debugger window is about to open	**BeforeDebuggerOpensHook**
An experiment is about to be saved	**BeforeExperimentSaveHook**
A file or XOP is about to be opened	**BeforeFileOpenHook**
A modification to a procedure window is about to cause procedures to be uncompiled	**BeforeUncompiledHook** (Igor Pro 8.03 or later)
HDF5 dataset for wave is about to be written	**HDF5SaveDataHook** (Igor Pro 9.00 or later)
Igor is about to open a new experiment	**IgorBeforeNewHook**
Igor is about to quit	**IgorBeforeQuitHook**
Igor is building and enabling menus or about to handle a menu selection	**IgorMenuHook**
Igor is about to quit	**IgorQuitHook**
Igor launching or creating a new experiment	**IgorStartOrNewHook**

To create hook functions, you must write functions with the specified names and store them in any procedure file. If you store the procedure file in "Igor Pro User Files/Igor Procedures" (see **Igor Pro User Files** on page II-31 for details), Igor will automatically open the file and compile the functions when it starts up and will execute the IgorStartOrNewHook function if it exists.

To allow for multiple procedure files to define the same predefined hook function, you should declare your hook function static. For example:

```
static Function IgorStartOrNewHook(igorApplicationNameStr)
   String igorApplicationNameStr
```

The use of the static keyword makes the function private to the procedure file containing it and allows other procedure files to have their own static function with the same name.

Igor calls static hook functions after the **SetIgorHook** functions are called. The static hook functions themselves are called in the order in which their procedure file was opened. You should not rely on any execution order among the static hook functions. However, any hook function which returns a nonzero result prevents remaining hook functions from being called and prevents Igor from performing its usual processing of the hook event. In most cases hook functions should exercise caution in returning any value other than 0. For hook functions only, returning a NaN or failing to return a value (which returns a NaN) is considered the same as returning 0.

The following sections describe the individual hook functions in detail.

AfterCompiledHook

`AfterCompiledHook()`

AfterCompiledHook is a user-defined function that Igor calls after the procedure windows have all been compiled successfully.

You can use AfterCompiledHook to initialize global variables or data folders, among other things.

The function result from AfterCompiledHook must be 0. All other values are reserved for future use.

See Also

SetIgorHook, **BeforeUncompiledHook**, **User-Defined Hook Functions** on page IV-280.

AfterFileOpenHook

AfterFileOpenHook(*refNum*, *fileNameStr*, *pathNameStr*, *fileTypeStr*, *fileCreatorStr*, *fileKind*)

AfterFileOpenHook is a user-defined function that Igor calls after it has opened a file because the user dragged it onto the Igor icon or into Igor or double-clicked it.

AfterFileOpenHook is not called when a file is opened via a menu.

Windows system files with .bin, .com, .dll, .exe, and .sys extensions aren't passed to the hook functions.

The parameters contain information about the file, which has already been opened for read-only access.

AfterFileOpenHook's return value is ignored unless *fileKind* is 9. If the returned value is zero, the default action is performed.

Parameters

refNum is the file reference number. You use this number with file I/O operations to read from the file. Igor closes the file when the user-defined function returns, and *refNum* becomes invalid. The file is opened for read-only; if you want to write to it, you must close and reopen it with write access. *refNum* will be -1 for experiment files and XOPs. In this case, Igor has not opened the file for you.

fileNameStr contains the name of the file.

pathNameStr contains the name of the symbolic path. *pathNameStr* is not the value of the path. Use the **PathInfo** operation to determine the path's value.

fileTypeStr contains the Macintosh file type, if applicable. File type codes are obsolete. Use the file name extension to determine if you want to handle the file. You can use **ParseFilePath** to obtain the extension from *fileNameStr*.

fileCreatorStr contains the Macintosh creator code, if applicable. Creator codes are obsolete so ignore this parameter.

fileKind is a number that identifies what kind of file Igor thinks it is. Values for *fileKind* are listed in the next section.

AfterFileOpenHook *fileKind* Parameter

This table describes the AfterFileOpenHook function *fileKind* parameter.

If the user's AfterFileOpenHook function returns 0, Igor performs the default action listed in the table:

Kind of File	*fileKind*	Default Action, if Any
Unknown	0	
Igor Experiment, packed (stationery, too)	1	
Igor Experiment, unpacked (stationery, too)	2	
Igor XOP	3	
Igor Binary Wave File	4	
Igor Text (data and commands)	5	
Text, no numbers detected in first two lines	6	
General Numeric text (no tabs)	7	
Numeric text Tab-Separated-Values	8	
Numeric text Tab-Separated-Values, MIME	9	Display loaded data in a new table and a new graph.
Text, with tabs	10	
Igor Notebook (unformatted or formatted)	11	
Igor Procedure	12	
Igor Help	13	

Details

AfterFileOpenHook's return value is ignored, except when *fileKind* is 9 (Numeric text, Tab-Separated-Values, MIME). If you return a value of 0, Igor executes the default action, which displays the loaded data in a table and a graph. If you return a value of 1, Igor does nothing.

Another way to disable the MIME-TSV default action is define a global variable named V_no_MIME_TSV_Load (in the root data folder) and set its value to 1. In this case any file of *fileKind* = 9 is reassigned a *fileKind* of 8.

The default action for *fileKind* = 9 makes Igor a MIME-TSV document Helper Application for Web browsers such as Netscape or Internet Explorer.

The exact criteria for Igor to consider a file to be of kind 9 are:

- *fileTypeStr* must be "TEXT" or "WMT0" (that's a zero, not an oh).
- Either the first line of the file must begin with a # character, or the name of the file must end with ".tsv" in either lower or upper case.
- The first line must contain one or more column titles. If the line starts with a # character, the first column title must not start with "include", "pragma" or the ! character. Spaces are allowed in the titles, but if two or more title columns are present, they must be separated by one tab character.
- The second line must contain one or more numbers. If two or more numbers, they must be separated by one tab character, and the first line's words must also be separated by tabs.

When the MIME-TSV file contains one column of data, it is graphed as a series of Y values.

Short columns (less than 50 values) are graphed with lines and markers, longer columns with lines only. Preferences are turned on when the graph is made.

Two columns are assumed to be X followed by Y, and are graphed as Y versus X. More columns do not affect the graph, though they are shown in the table.

Example

```
// This hook function prints the first line of opened TEXT files
// into the history area
Function AfterFileOpenHook(refNum,file,pathName,type,creator,kind)
   Variable refNum,kind
   String file,pathName,type,creator
   // Check that the file is open (read only), and of correct type
   if( (refNum >= 0) && (CmpStr(type,"TEXT")==0) )  // also "text", etc.
      String line1
      FReadLine refNum, line1 // Read the line (and carriage return)
      Print line1       // Print line in the history area.
   endif
   return 0             // don't prevent MIME-TSV from displaying
End
```

BeforeFileOpenHook and **SetIgorHook**.

BeforeDebuggerOpensHook

`BeforeDebuggerOpensHook(`*`errorInRoutineStr`*`, `*`stoppedByBreakpoint`*`)`

BeforeDebuggerOpensHook is a user-defined function that Igor calls when the debugger window is about to be opened, whether by hitting a breakpoint or when Debug on Error is enabled.

BeforeDebuggerOpensHook can be used to prevent the debugger window opening for certain error codes or in selected user-defined functions when Debug on Error is enabled. This is a feature for advanced programmers only. Most programmers will not need it.

This hook does not work well for macros or procs, because their runtime errors don't automatically open the debugger, but instead present an error dialog from which the user manually enters the debugger by clicking the Debug button.

Parameters

errorInRoutineStr contains the name of the routine (function or macro) the debugger will be stopping in as a fully-qualified name, comprised of at least "`ModuleName#RoutineName`", suitable for use with FunctionInfo.

If the routine is in a regular module procedure window (see **Regular Modules** on page IV-236), *errorInRoutineStr* will be a triple name such as "`MyIM#MyModule#MyFunction`".

stoppedByBreakpoint is 0 if the debugger is about to be shown because of Debug on Error, or non-zero if the debugger encountered a user-set breakpoint (see **Setting Breakpoints** on page IV-213).

If a breakpoint exists at the line where an error caused the debugger to appear, *stoppedByBreakpoint* will be non-zero, even though the cause was Debug on Error.

Details

If BeforeDebuggerOpensHook returns 0 or NaN (or doesn't return a value), the debugger window is opened normally.

If it returns 1, the debugger window is not shown and program execution continues.

All other return values are reserved for future use.

Example

The following hypothetical example:

1. Prevents breakpoints from bringing up the debugger, unless DEBUGGING is defined.
2. Prints the name of the routine with the error, and the error message.
3. Beeps before the debugger appears.

```
Function ProvokeDebuggerInFunction()
   DebuggerOptions enable=1, debugOnError=1     // Enable debug on error

   ProvokeDebugger()
```

```
End

Function ProvokeDebugger()
   Variable var=0 // Put a breakpoint here.
                  // Without a #define DEBUGGING, the breakpoint is skipped.
   Make/O $""     // Cause an error
   Print "Back from bad Make command in function"
End

static Function BeforeDebuggerOpensHook(pathToErrorFunction,isUserBreakpoint)
   String pathToErrorFunction
   Variable isUserBreakpoint

   #ifndef DEBUGGING
      if( isUserBreakpoint )
         return 1 // Ignore user breakpoints we forgot to clear.
                  // Don't use this during development!
      endif
   #endif

   Print "stackCrawl = ", GetRTStackInfo(0)
   Print "FunctionInfo = ", FunctionInfo(pathToErrorFunction)

   // Don't clear errors unless you're preventing the debugger from appearing
   Variable clearErrors= 0
   Variable rtErr= GetRTError(clearErrors)   // Get the error #

   Variable substitutionOption= exists(pathToErrorFunction)== 3 ? 3 : 2
   String errorMessage= GetErrMessage(rtErr,substitutionOption)

   Beep     // Audible cue that the debugger is showing up!

   Print "Error \""+errorMessage+"\" in "+pathToErrorFunction+""

   return 0 // Return 0 to show the debugger; an unexpected error occurred.
End

•ProvokeDebuggerInFunction()  // Execute this in the command line
  stackCrawl =
      ProvokeDebuggerInFunction;ProvokeDebugger;BeforeDebuggerOpensHook;
  FunctionInfo =
      NAME:ProvokeDebugger;PROCWIN:Procedure;MODULE:;INDEPENDENTMODULE:;...
  Error "Expected name" in ProcGlobal#ProvokeDebugger
  Back from bad Make command in function
```

AfterMDIFrameSizedHook

AfterMDIFrameSizedHook(*param*)

AfterMDIFrameSizedHook is a user-defined function that Igor calls when the Windows-only "MDI frame" (main application window) has been resized.

AfterMDIFrameSizedHook can be used to resize windows to fit the new frame size. See **GetWindow** kwFrame and **MoveWindow**.

Parameters

param is one of the following values:

Size Event	*param*
Normal resize	0
Minimized	1
Maximized	2
Moved	3

Details

This function is not called on Macintosh.

Resizing the MDI frame by the top left corner calls AfterMDIFrameSizedHook twice: first for the move (param = 3) and then for the normal resize (param = 0).

Igor currently ignores the value returned by AfterMDIFrameSizedHook. Return 0 in case Igor uses this value in the future.

See Also

SetWindow, **GetWindow**, **SetIgorHook**, and **User-Defined Hook Functions** on page IV-280.

AfterWindowCreatedHook

`AfterWindowCreatedHook(`*`windowNameStr`*`, `*`winType`*`)`

AfterWindowCreatedHook is a user-defined function that Igor calls when a target window is first created.

AfterWindowCreatedHook can be used to set a window hook on target windows created by the user or by other procedures.

Parameters

windowNameStr contains the name of the created window.

winType is the type of the window, the same value as returned by **WinType**.

Details

“Target windows” are graphs, tables, layout, panels, and notebook windows.

AfterWindowCreatedHook is not called when an Igor experiment is being opened.

Igor ignores the value returned by AfterWindowCreatedHook.

See Also

SetWindow, **SetIgorHook**, and **User-Defined Hook Functions** on page IV-280.

BeforeExperimentSaveHook

`BeforeExperimentSaveHook(`*`refNum`*`, `*`fileNameStr`*`, `*`pathNameStr`*`, `*`fileTypeStr`*`, `*`fileCreatorStr`*`, `*`fileKind`*`)`

BeforeExperimentSaveHook is a user-defined function that Igor calls when an experiment is about to be saved by Igor.

Igor ignores the value returned by BeforeExperimentSaveHook.

Parameters

refNum identifies what is causing the experiment to be saved:

Cause	*refNum*
Save Experiment (File menu or SaveExperiment)	1
Save Experiment As (File menu or SaveExperiment)	2
Save Experiment Copy (File menu or SaveExperiment/C)	3
Autosave Experiment (direct mode)	17 (0x10 + 1)
Autosave Experiment Copy (indirect mode)	19 (0x10 + 3)

Before Igor Pro 9.00, *refNum* was always -1.

fileNameStr contains the name of the file.

pathNameStr contains the name of the symbolic path. *pathNameStr* is not the value of the path. Use the **PathInfo** operation to determine the path's value.

fileTypeStr contains the Macintosh file type, if applicable. File type codes are obsolete. Use the file name extension to determine if you want to handle the file. You can use **ParseFilePath** to obtain the extension from *fileNameStr*

fileCreatorStr contains the Macintosh creator code, if applicable. Creator codes are obsolete so ignore this parameter.

Variable *fileKind* is a number that identifies what kind of file Igor will be saving:

Kind of File	***fileKind***
Igor Experiment, packed*	1
Igor Experiment, unpacked*	2

* Including stationery experiment files.

Details

You can determine the full directory and file path of the experiment by calling the **PathInfo** operation with $*pathNameStr*.

Example

This example prints the full file path of the about-to-be-saved experiment to the history area, and deletes all unused symbolic paths.

```
#pragma rtGlobals=1        // treat S_path as local string variable

Function BeforeExperimentSaveHook(rN,fileName,path,type,creator,kind)
   Variable rN,kind
   String fileName,path,type,creator

   PathInfo $path             // puts path value into (local) S_path
   Printf "Saved \"%s\" experiment\r",S_path+fileName

   KillPath/A/Z               // Delete all unneeded symbolic paths
End
```

See Also

The **SetIgorHook** operation.

BeforeFileOpenHook

BeforeFileOpenHook(*refNum*, *fileNameStr*, *pathNameStr*, *fileTypeStr*, *fileCreatorStr*, *fileKind*)

BeforeFileOpenHook is a user-defined function that Igor calls when a file *is* about to be opened because the user dragged it onto the Igor icon or into Igor or double-clicked it.

BeforeFileOpenHook is not called when a file is opened via a menu.

Windows system files with .bin, .com, .dll, .exe, and .sys extensions aren't passed to the hook functions.

The value returned by BeforeFileOpenHook informs Igor whether the hook function handled the open event and therefore Igor should not perform its default action. In some cases, this return value is ignored, and Igor performs the default action anyway.

Parameters

refNum is the file reference number. You use this number with file I/O operations to read from the file. Igor closes the file when the user-defined function returns, and *refNum* becomes invalid. The file is opened for read-only; if you want to write to it, you must close and reopen it with write access. *refNum* will be -1 for experiment files and XOPs. In this case, Igor has not opened the file for you.

fileNameStr contains the name of the file.

pathNameStr contains the name of the symbolic path. *pathNameStr* is not the value of the path. Use the **PathInfo** operation to determine the path's value.

fileTypeStr contains the Macintosh file type, if applicable. File type codes are obsolete. Use the file name extension to determine if you want to handle the file. You can use **ParseFilePath** to obtain the extension from *fileNameStr*

fileCreatorStr contains the Macintosh creator code, if applicable. Creator codes are obsolete so ignore this parameter.

fileKind is a number that identifies what kind of file Igor thinks it is. Values for *fileKind* are listed in the next section.

BeforeFileOpenHook *fileKind* Parameter

This table describes the BeforeFileOpenHook function *fileKind* parameter.

Kind of File	*fileKind*	Default Action, if Any
Unknown	0	
Igor Experiment, packed *	1	(Hook not called)
Igor Experiment, unpacked*	2	(Hook not called)
Igor XOP	3	
Igor Binary Wave File	4	Data loaded
Igor Text (data and commands)	5	Data loaded, commands executed
Text, no numbers detected in first two lines	6	Opened as unformatted notebook
General Numeric text (no tabs)	7	Data loaded as general text
Numeric text Tab-Separated-Values	8	Data loaded as delimited text
Numeric text Tab-Separated-Values, MIME	9	Display loaded data in a new table and a new graph.
Text, with tabs	10	Opened as unformatted notebook
Igor Notebook (unformatted or formatted)	11	Opened as notebook
Igor Procedure	12	*Always* opened as procedure file
Igor Help	13	*Always* opened as help file

* Including stationery experiment files.

Details

BeforeFileOpenHook must return 1 if Igor is not to take action on the file (it won't be opened), or 0 if Igor is permitted to take action on the file. Igor ignores the return value for *fileKind* values of 3, 12, and 13. The hook function is not called for Igor experiments (*fileKind* values of 1 and 2).

Igor always closes the file when the user-defined function returns, and *refNum* becomes invalid (don't store the value of *refNum* in a global for use by other routines, since the file it refers to has been closed).

Example

This example checks the first line of the file about to be opened to determine whether it has a special, presumably user-specific, format. If it does, then LoadMyFile (another user-defined function) is called to load it. LoadMyFile presumably loads this custom data file, and returns 1 if it succeeded. If it returns 0 then Igor will open it using the Default Action from the above table.

```
Function BeforeFileOpenHook(refNum,fileName,path,type,creator,kind)
   Variable refNum,kind
   String fileName,path,type,creator

   Variable handledOpen=0
   if( CmpStr(type,"TEXT")==0 )              // text files only
      String line1
      FReadLine refNum, line1 // First line (and carriage return)
      if( CmpStr(line1[0,4],"XYZZY") == 0 )  // My special file
```

```
         FSetPos refNum, 0             // rewind to start of file
         handledOpen= LoadMyFile(refNum)  // returns 1 if loaded OK
      endif
   endif
   return handledOpen   // 1 tells Igor not to open the file
End
```

See Also

AfterFileOpenHook, **SetIgorHook**.

BeforeUncompiledHook

`BeforeUncompiledHook(`*`changeCode`*`, `*`procedureWindowTitleStr`*`, `*`textChangeStr`*`)`

BeforeUncompiledHook is a user-defined function that Igor calls before procedures enter the uncompiled state after a change to the procedures.

You can use BeforeUncompiledHook to shut down background tasks or threads before the user functions they depend on go away. You can use **AfterCompiledHook** to restart them.

BeforeUncompiledHook was added in Igor Pro 8.03.

Parameters

changeCode is one of the following values:

Pending Change	*changeCode*	Scenarios
Text deletion	1	Delete/backspace key, cut, saved recreation macro, merge experiment
Text insertion	2	User typing, paste insert, Execute/P "INSERTINCLUDE "
Text replacement	3	User typing, paste over selected text
Open procedure file	4	File→Open Procedure, OpenProc
Close procedure file	5	Procedure close icon click, CloseProc
SetIgorOption poundDefine	6	SetIgorOption poundDefine causes a recompile
SetIgorOption poundUndefine	7	SetIgorOption poundUndefine causes a recompile

procedureWindowTitleStr contains the title of the procedure window whose text is about to change. If the procedure window is in an independent module, the title is followed by

```
[<nameOfIndependentModule>]
```

as described in documentation for the **WinList** function.

The content of *textChangeStr* depends on *changeCode*:

changeCode	*textChangedStr*
1	""
2	Inserted text
3	Replacement text
4	""
5	""
6	*name* defined by SetIgorOption poundDefine=*name*
7	*name* undefined by SetIgorOption poundUndefine=*name*

Details

In most cases your BeforeUncompiledHook function should return 0.

Returning non-zero prevents the pending change to the text from taking effect for changeCode = 1, 2, or 3, though only when procedures are already compiled.

The returned value is ignored for other values of *changeCode*.

BeforeUncompiledHook is not called before a new experiment is opened, before the experiment is reverted, or before Igor quits. Use **IgorBeforeNewHook** and **IgorBeforeQuitHook** for those scenarios.

See Also

User-Defined Hook Functions on page IV-280, **SetIgorHook**, **AfterCompiledHook**, **Operation Queue** on page IV-278.

HDF5SaveDataHook

`HDF5SaveDataHook(`*`s`*`)`

HDF5SaveDataHook is a user-defined function that Igor calls when saving a wave to an HDF5 file. It allows advanced users to control compression of the dataset written for the wave.

HDF5SaveDataHook was added in Igor Pro 9.00.

NOTE: HDF5SaveDataHook is an experimental feature for advanced users only. The feature may be changed or removed. If you find it useful, please let us know, and send your function and an explanation of what purpose it serves.

Parameters

s is an HDF5SaveDataHookStruct.

Details

See **Using HDF5SaveDataHook** on page II-215 for details.

IgorBeforeNewHook

`IgorBeforeNewHook(`*`igorApplicationNameStr`*`)`

IgorBeforeNewHook is a user-defined function that Igor calls before a new experiment is opened in response to the New Experiment, Revert Experiment, or Open Experiment menu items in the File menu.

You can use IgorBeforeNewHook to clean up the current experiment, or to avoid losing unsaved data even if the user chooses to not save the current experiment.

Igor ignores the value returned by IgorBeforeNewHook.

Parameters

igorApplicationNameStr contains the name of the currently running Igor Pro application.

See Also

IgorStartOrNewHook and **SetIgorHook**.

IgorBeforeQuitHook

`IgorBeforeQuitHook(`*`unsavedExp,unsavedNotebooks,unsavedProcedures`*`)`

IgorBeforeQuitHook is a user-defined function that Igor calls just before Igor is about to quit, before any save-related dialogs have been presented.

Parameters

unsavedExp is 0 if the experiment is saved, non-zero if unsaved.

unsavedNotebooks is the count of unsaved notebooks.

unsavedProcedures is the count of unsaved procedures.

The save state of packed procedure and notebook files is part of *unsavedExp*, not *unsavedNotebooks* or *unsavedProcedures*. This applies to adopted procedure and notebook files and new procedure and notebook windows that have never been saved.

Details

IgorBeforeQuitHook should normally return 0. In this case, Igor presents the "Do you want to save" dialog, and if the user approves, proceeds with the quit, which includes calling IgorQuitHook.

If IgorBeforeQuitHook returns 1, then the normal save-and-quit process is aborted and Igor quits immediately. The current experiment, notebooks, and procedures are not saved, no dialogs are presented to the user, and IgorQuitHook is not called.

If IgorBeforeQuitHook returns 2, then the normal save-and-quit process is aborted and Igor does not quit. The current experiment, notebooks, and procedures are not saved, no dialogs are presented to the user, and IgorQuitHook is not called. This return value was first supported in Igor Pro 8.05.

See Also

IgorQuitHook and **SetIgorHook**.

IgorMenuHook

IgorMenuHook(*isSelection*, *menuStr*, *itemStr*, *itemNo*, *activeWindowStr*, *wType*)

IgorMenuHook is a user-defined function that Igor calls just before and just after menu selection, whether by mouse or keyboard.

Parameters

isSelection is 0 before a menu item has been selected and 1 after a menu item has been selected.

When *isSelection* is 1, *menuStr* is the name of the selected menu. It is always in English, regardless of the localization of Igor. When *isSelection* is 0, *menuStr* is "".

When *isSelection* is 1, *itemStr* is the name of the selected menu item. When *isSelection* is 0, *itemStr* is "".

When *isSelection* is 1, *itemNo* is the one-based item number of the selected menu item. When *isSelection* is 0, *itemNo* is 0.

activeWindowStr identifies the active window. See details below.

wType identifies the kind of window that *activeWindowStr* identifies. It returns the same values as the **WinType** function.

activeWindowStr Parameter

activeWindowStr identifies the window to which the menu selection will apply. It can be a window name, window title, or special keyword, as follows:

Window	***activeWindowStr***
Target window	Window name. The target window is that top graph, table, page layout, notebook, control panel, Gizmo plot, or XOP target window.
Command window	`kwCmdHist` (as used with **GetWindow**).
Procedure window	Window title as shown in the window’s title bar. The built-in procedure window is “Procedure”.
XOP non-target window	The window title as shown in the window’s title bar.

See **Window Names and Titles** on page II-45 for a discussion of the distinction.

Details

IgorMenuHook is called with *isSelection* set to 0 after all the menus have been enabled and before a mouse click or keyboard equivalent is handled.

The return value should normally be 0. If the return value is nonzero (1 is usual) then the active window’s hook function (see **SetWindow** operation on page V-865) is not called for the enablemenu event.

IgorMenuHook is called with *isSelection* set to 1 after the menu has been selected and before Igor has acted on the selection.

If the IgorMenuHook function returns 0, Igor proceeds to call the active window’s hook function for the menu event. (If the window hook function exists and returns nonzero, Igor ignores the menu selection. Otherwise Igor handles the menu selection normally.)

If the IgorMenuHook function returns nonzero (1 is recommended), Igor does not call the remaining hook functions and Igor ignores the menu selection.

Example

This example invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for all graphs, preventing Igor from performing the usual Copy.

```
Function IgorMenuHook(isSel, menuStr, itemStr, itemNo, activeWindowStr, wt)
   Variable isSel
   String menuStr, itemStr
   Variable itemNo
   String activeWindowStr
   Variable wt

   Variable handled= 0
   if( Cmpstr(menuStr,"Edit") == 0 && CmpStr(itemStr,"Copy") == 0 )
      if( wt == 1 )                                  // graph
         // DoIgorMenu would cause recursion, so we defer execution
         Execute/P/Q/Z "DoIgorMenu \"Edit\", \"Export Graphics\""
         handled= 1
      endif
   endif

   return handled
End
```

See Also

SetWindow, **Execute**, and **SetIgorHook**.

IgorQuitHook

`IgorQuitHook(`*`igorApplicationNameStr`*`)`

IgorQuitHook is a user-defined function that Igor calls when Igor is about to quit.

The value returned by IgorQuitHook is ignored.

Parameters

igorApplicationNameStr contains the name of the currently running Igor Pro application (including the .exe extension under Windows).

Details

You can determine the full directory and file path of the Igor application by calling the **PathInfo** operation with the Igor path name. See the example in **IgorStartOrNewHook** on page IV-292.

See Also

IgorBeforeQuitHook and **SetIgorHook**.

IgorStartOrNewHook

`IgorStartOrNewHook(`*`igorApplicationNameStr`*`)`

IgorStartOrNewHook is a user-defined function that Igor calls when starting up and when creating a new experiment. It is also called if Igor is launched as a result of double-clicking a saved Igor experiment.

Igor ignores the value returned by IgorStartOrNewHook.

Parameters

igorApplicationNameStr contains the name of the currently running Igor Pro application (including the .exe extension under Windows).

Details

You can determine the full directory and file path of the Igor application by calling the **PathInfo** operation with the Igor path name.

Example

This example prints the full path of Igor application whenever Igor starts up or creates a new experiment:

```
Function IgorStartOrNewHook(igorApplicationNameStr)
   String igorApplicationNameStr

   PathInfo Igor              // puts path value into (local) S_path
   printf "\"%s\" (re)starting\r", S_path + igorApplicationNameStr
End
```

See Also

IgorBeforeNewHook and **SetIgorHook**.

Window User Data

The window user data feature provides a way for packages that create or manage windows to store per-window settings. You can store arbitrary data with a window using the userdata keyword with the **SetWindow**.

Each window has a primary, unnamed user data that is used by default.

You can also store an unlimited number of different user data strings by specifying a name for each different user data string. The name can be any legal Igor name. It should be distinct to prevent clashes between packages.

Packages should use named user data.

You can retrieve information from the default user data using the **GetWindow**. To retrieve named user data, you must use the **GetUserData**.

Here is a simple example of user data using the top window:

```
SetWindow kwTopWin,userdata= "window data"
Print GetUserData("","","")
```

Although there is no size limit to how much user data you can store, it does have to be stored as part of the recreation macro for the window when experiments are saved. Consequently, huge user data can slow down experiment saving and loading.

You can also attach user data to traces in graphs using the userData keyword of the ModifyGraph operation and to controls using the userData keyword of the various control operations.

Window Hook Functions

A window hook function is a user-defined function that receives notifications of events that occur in a specific window. Your window hook function can detect and respond to events of interest. You can then allow Igor to also process the event or inform Igor that you have handled it.

This section discusses window hook functions that apply to a specific window. For information on general events hooks, see **User-Defined Hook Functions** on page IV-280.

To handle window events, you first write a window hook function and then use the **SetWindow** operation to install the hook on a particular window. This example shows how you would detect arrow key events in a particular window. To try it, paste the code below into the procedure window and then execute `DemoWindowHook()`:

```
Function MyWindowHook(s)
   STRUCT WMWinHookStruct &s

   Variable hookResult = 0 // 0 if we do not handle event, 1 if we handle it.

   switch(s.eventCode)
      case 11:            // Keyboard event
         switch (s.keycode)
            case 28:
               Print "Left arrow key pressed."
               hookResult = 1
               break
            case 29:
               Print "Right arrow key pressed."
```

```
                hookResult = 1
                break
            case 30:
                Print "Up arrow key pressed."
                hookResult = 1
                break
            case 31:
                Print "Down arrow key pressed."
                hookResult = 1
                break
            default:
                // The keyText field requires Igor Pro 7 or later
                // See Keyboard Events on page IV-300
                Printf "Key pressed: %s\r", s.keyText
                break
         endswitch
         break
   endswitch

   return hookResult // If non-zero, we handled event and Igor will ignore it.
End

Function DemoWindowHook()
   DoWindow/F DemoGraph    // Does graph exist?
   if (V_flag == 0)
      Display /N=DemoGraph // Create graph
      SetWindow DemoGraph, hook(MyHook)=MyWindowHook  // Install window hook
   endif
End
```

The window hook function receives a WMWinHookStruct structure as a parameter. WMWinHookStruct is a built-in structure that contains all of the information you might need to respond to an event. One of its fields, the eventCode field, specifies what kind of event occurred.

If your hook function returns 1, this tells Igor that you handled the event and Igor does not handle it. If your hook function returns 0, this tells Igor that you did not handle the event, so Igor does handle it.

This example uses a named window hook. In this case the name is MyHook. More than one procedure file can install a hook on a given window. The purpose of the name is to allow a package to install and remove its own hook function without disturbing the hook functions of other packages. Choose a distinct hook function name that is unlikely to conflict with other hook names.

Earlier versions of Igor supported only one unnamed hook function. This meant that only one package could hook any particular window. Unnamed hook functions are still supported for backward compatibility but new code should always use named hook functions.

Window Hooks and Subwindows

Except for the modified event (see **Modified Events** on page IV-299), Igor calls window hook functions for top-level windows only, not for subwindows. If you want to hook a subwindow, you must set the hook on the top-level window. In the hook function, test to see if the subwindow is active. For example, this code, at the start of a window hook function, insures that the hook runs only if a subwindow named G0 is active.

```
GetWindow $s.winName activeSW
String activeSubwindow = S_value
if (CmpStr(activeSubwindow,"G0") != 0)
   return 0
endif
```

Exterior panels (see **Exterior Control Panels** on page III-443) are top-level windows even though they are subwindows. To hook an exterior subwindow, you must install the hook on the exterior panel using subwindow syntax.

Named Window Hook Functions

A named window hook function takes one parameter - a `WMWinHookStruct` structure. This built-in structure provides your function with information about the status of various window events.

The named window hook function has this format:

```
Function MyWindowHook(s)
   STRUCT WMWinHookStruct &s

   Variable hookResult = 0

   switch(s.eventCode)
      case 0:              // Activate
         // Handle activate
         break

      case 1:              // Deactivate
         // Handle deactivate
         break

      // And so on . . .
   endswitch

   return hookResult       // 0 if nothing done, else 1
End
```

If you handle a particular event and you want Igor to ignore it, return 1 from the hook function. However, you cannot make Igor ignore a window kill event - once the kill event is received the window will be killed.

Named Window Hook Events

Here are the events passed to a named window hook function:

eventCode	eventName	Notes
0	"Activate"	
1	"Deactivate"	
2	"Kill"	Returning 1 when you receive this event does not cause Igor to ignore the event. At this point, you cannot prevent the window from being killed. See the killVote event to prevent the window being killed.
3	"Mousedown"	
4	"Mousemoved"	
5	"Mouseup"	
6	"Resize"	
7	"Cursormoved"	See **Cursors — Moving Cursor Calls Function** on page IV-339.
8	"Modified"	A modification to the window has been made. See **Modified Events** on page IV-299.
9	"Enablemenu"	
10	"Menu"	
11	"Keyboard"	See **Keyboard Events** on page IV-300.
12	"moved"	
13	"renamed"	

eventCode	eventName	Notes
14	“subwindowKill”	One of the window’s subwindows is about to be killed.
15	“hide”	The window or one of its subwindows is about to be hidden. See **Window Hook Show and Hide Events** on page IV-304.
16	“show”	The window or one of its subwindows is about to be unhidden. See **Window Hook Show and Hide Events** on page IV-304.
17	“killVote”	Window is about to be killed. Return 2 to prevent the window from being killed, otherwise return 0. **Note**: Don’t delete data structures during this event, use killVote only to decide whether the window kill should actually happen. Delete data structures in the kill event. See **Window Hook Deactivate and Kill Events** on page IV-303.
18	“showTools”	
19	“hideTools”	
20	“showInfo”	
21	“hideInfo”	
22	“mouseWheel”	
23	“spinUpdate”	This event is sent only to windows marked via DoUpdate/E=1 as progress windows. It is sent when Igor spins the beachball cursor. See **Progress Windows** on page IV-156 for details.
24	"tableEntryAccepted"	This event is sent to tables only. It is sent when the user manually accepts text entered in the table entry line, for example by clicking the checkmark button or pressing the Enter or Return keys. It is also sent by a **ModifyTable** `entryMode=1` command. This hook event was added in Igor Pro 8.03.
25	"tableEntryCancelled"	This event is sent to tables only. It is sent when the user cancels text entry, for example by clicking the X button or pressing the Escape key. It is also sent by a **ModifyTable** `entryMode=0` command. This hook event was added in Igor Pro 8.03.
26	"earlyKeyboard"	See **EarlyKeyboard Events** on page IV-302.

WMWinHookStruct

The `WMWinHookStruct` structure has members as described in the following tables:

Base `WMWinHookStruct` Structure Members

Member	Description
`char winName[MAX_PATH_LENGTH+1]`	hcSpec of the affected (sub)window.
`STRUCT Rect winRect`	Local coordinates of the affected (sub)window.
`STRUCT Point mouseLoc`	Mouse location.
`double ticks`	Tick count when event happened.
`Int32 eventCode`	See see **eventCode** table on page IV-295.
`char eventName[255+1]`	Name-equivalent of `eventCode`, see **eventCode** table on page IV-295. Added in Igor 5.03.
`Int32 eventMod`	Bitfield of modifiers. See description for `MODIFIERS:`*`flags`*.

Members of `WMWinHookStruct` Structure Used with `menu` Code

Member	Description
`char menuName[255+1]`	Name of menu (in English) as used by **SetIgorMenuMode**.
`char menuItem[255+1]`	Text of the menu item as used by SetIgorMenuMode

Members of `WMWinHookStruct` Structure Used with `keyboard and earlyKeyboard` Code

Member	Description
`Int32 keycode`	ASCII value of key struck. Function keys are not available but navigation keys are translated to specific values and will be the same on Macintosh and Windows. This field can not represent non-ASCII text such as accented characters. Use keyText instead.
`Int32 specialKeyCode`	See **Keyboard Events** on page IV-300. This field was added in Igor Pro 7.
`char keyText[16]`	UTF-8 representation of key struck. This field was added in Igor Pro 7.
`char focusCtrl[MAX_WIN_PATH+1]`	Used only with **EarlyKeyboard Events**. This field was added in Igor Pro 9.

Members of `WMWinHookStruct` Structure Used with `cursormoved` Code

Member	Description
`char traceName[MAX_OBJ_NAME+1]`	The name of the trace or image to which the moved cursor is attached or which supplies the X (and Y) values. Can be `""` if the cursor is free.
`char cursorName[2]`	Cursor name A through J.
`double pointNumber`	Point number of the trace or the X (row) point number of the image where the cursor is attached. If the cursor is “free”, `pointNumber` is actually the fractional relative *xValue* as used in the **Cursor**/F/P command.
`double yPointNumber`	Valid only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot, or when the cursor is free. If attached to an image, contour, or waterfall plot, `yPointNumber` is the Y (column) point number of the image where the cursor is attached. If the cursor is “free”, `yPointNumber` is actually the fractional relative *yValue* as used in the **Cursor**/F/P command.
`Int32 isFree`	Has value of 1 if the cursor is not attached to anything, or value of 0 if it is attached to a trace, image, contour, or waterfall.

Members of `WMWinHookStruct` Structure Used with `mouseWheel` Code

Member	Description
`double wheelDy`	Vertical lines to scroll. Typically +1 or -1.
`double wheelDx`	Horizontal lines to scroll. Typically +1 or -1. On Windows, horizontal mouse wheel requires Vista.

Members of `WMWinHookStruct` Used with `renamed` Code

Member	Description
`char oldWinName[MAX_OBJ_NAME+1]`	Old name of the window or subwindow. Not the absolute path *hcSpec*, just the name.

User-Modifiable Members of `WMWinHookStruct` Structure

Member	Description
`Int32 doSetCursor`	Set to 1 to change cursor to that specified by `cursorCode`.
`Int32 cursorCode`	See **Setting the Mouse Cursor**.

Mouse Events

Igor sends mouse down and mouse up events with the `eventCode` field of the `WMWinHookStruct` structure set to 3 or 5. With rare exceptions, your hook function should act on the mouse up event. Consider, for instance, a click on a button- the button's action should occur when you release the mouse button.

One exception is for a contextual click, that is, right-click on Windows, or Ctrl-click on Macintosh. On Macintosh, a contextual menu should be displayed on the mouse-down event. On Windows, the contextual menu should be shown on mouse-up, but in Igor confoundingly, the mouse-down is not delivered until the mouse-up has occurred. Thus, displaying a contextual menu on mouse-down on Windows will do the Right Thing.

A mouse click on a table cell causes Igor to send a mouse down event to your hook function before Igor acts on the click, allowing you to block the action by returning a non-zero result. Igor then sends a mouse down event after Igor has acted on the click.

In Igor6, the mouse down event was sent only when the selection was finished, that is, after the mouse up event occurred. If you have existing code that uses the mouse down event to get a table selection, you need to change your code to use the mouse up event.

Modified Events

A modified event is sent when a modification to the window has been made. This is sent to graph and notebook windows only.

As of Igor Pro 9.00, modified events are sent to both top-level graphs and notebooks and also to graph and notebook subwindows. That means that a window hook on a control panel window could receive a modified event for a notebook or graph subwindow in the panel. In that case, the winName member of the WMWinHookStruct structure is set to the subwindow path.

It is an error to try to kill a graph or notebook window or subwindow from the window hook during the modified event.

The modified event is issued in Igor's outer loop when it is idling (i.e., after any processing is finished). This means that, if you modify a graph or notebook programmatically, the modified event is not sent to hook functions until Igor returns to idling.

Most changes to the graph are reported by the modified event, but not all:

Action	**Sends Modified Event**
Dragging axis	Yes
Dragging plot area	Yes
Dragging trace	Sent only after drag ends
Dragging annotation	Yes - see note 1
Adding, removing or changing a control	No
Showing or hiding drawing tools	No - see note 1
Showing or hiding info panel	No - see note 1

1. At present, only in top-level windows, not in graph subwindows.

2. But see events 18, 19, 20, and 21 in **Named Window Hook Events** on page IV-295.

In Igor Pro 9.00 and later, if you modify a notebook from a modified event, this does not cause recursion into your hook function.

If your hook function modifies a graph window, this may trigger another modify event after your function returns from the first. Without something to stop it, this will create a cascade of modified events. Checking for recursion in your hook function does not solve the problem because subsequent hook event calls occur after your hook function has returned.

To break the chain, your hook function needs to modify the graph window only if necessary. For example, assume that your hook function needs to change something when the range of an axis in a graph changes. You need to store the axis range from the last time your function was called using user data (see **GetUserData**). If, in the current call, the axis range has not changed, your function must return without making any changes, thereby breaking the chain.

Keyboard Events

The `WMWinHookStruct` structure has three members used with keyboard and earlyKeyboard events. A fourth member, `focusCtrl`, is used only with earlyKeyboard events, described below.

The `keycode` field works with ASCII characters and some special keys such as keyboard navigation keys.

The `specialKeyCode` fields works with navigation keys, function keys and other special keys. `specialKeyCode` is zero for normal text such as letters, numbers and punctuation.

The `keyText` field works with ASCII characters and non-ASCII characters such as accented characters.

The `specialKeyCode` and `keyText` fields were added in Igor Pro 7. New code that does not need to run with earlier Igor versions should use these new fields instead of the keycode field. See **Keyboard Events Example** on page IV-301 for an example.

Here are the codes for the `specialKeyCode` and `keyCode` fields:

Key	specialKeyCode	keyCode	Note
F1 through F39	1 through 39	Not supported	Function keys
LeftArrow	100	28	
RightArrow	101	29	
UpArrow	102	30	
DownArrow	103	31	
PageUp	104	11	
PageDown	105	12	
Home	106	1	
End	107	4	
Return	200	13	
Enter	201	3	
Tab	202	9	
BackTab	203	Not supported	Tab with Shift pressed
Escape	204	27	
Delete	300	8	Backspace key
ForwardDelete	301	127	
Clear	302	Not supported	
Insert	303	Not supported	
Help	400	Not supported	
Break	401	Not supported	Pause/Break key

Key	specialKeyCode	keyCode	Note
Print	402	Not supported	
SysReq	403	Not supported	

Keyboard Events Example

This example illustrates the use of the various keyboard event fields in the WMWinHookStruct structure. It requires Igor Pro 7 or later.

```
Function KeyboardWindowHook(s)
   STRUCT WMWinHookStruct &s

   Variable hookResult = 0    // 0 if we do not handle event, 1 if we handle it.

   String message = ""

   switch(s.eventCode)
      case 11:                // Keyboard event
         String keyCodeInfo
         sprintf keyCodeInfo, "s.keycode = 0x%04X", s.keycode
         if (strlen(message) > 0)
            message += "\r"
         endif
         message +=keyCodeInfo

         message += "\r"
         String specialKeyCodeInfo
         sprintf specialKeyCodeInfo, "s.specialKeyCode = %d", s.specialKeyCode
         message +=specialKeyCodeInfo
         message += "\r"

         String keyTextInfo
         sprintf keyTextInfo, "s.keyText = \"%s\"", s.keyText
         message +=keyTextInfo

         String text = "\\Z24" + message
         Textbox /C/N=Message/W=KeyboardEventsGraph/A=MT/X=0/Y=15 text

         hookResult = 1    // We handled keystroke
         break
   endswitch

   return hookResult // If non-zero, we handled event and Igor will ignore it.
End

Function DemoKeyboardWindowHook()
   DoWindow/F KeyboardEventsGraph      // Does graph exist?
   if (V_flag == 0)
      // Create graph
      Display /N=KeyboardEventsGraph as "Keyboard Events"

      // Install hook
      SetWindow KeyboardEventsGraph, hook(MyHook)=KeyboardWindowHook

      String text = "\\Z24" + "Press a key"
      Textbox /C/N=Message/W=KeyboardEventsGraph/A=MT/X=0/Y=15 text
   endif
End
```

EarlyKeyboard Events

The earlyKeyboard event was added in Igor Pro 9.00.

The earlyKeyboard event is like the keyboard event but is sent, to graph and control panel windows only, before other components of those windows get the keyboard event. Its purpose is to let you filter key presses in graphs and panels before they reach a control.

The keycode, specialKeyCode, and keyText fields work the same as with the keyboard event.

The earlyKeyboard event sets the focusCtrl field which was added in Igor Pro 9.00.

If the event is earlyKeyboard and the window or its subwindows have a control with keyboard focus, the focusCtrl field is set to the name of the control and the winName field is set to the path of the window or subwindow that contains the control. If you return a non-zero result from the hook function when it receives the earlyKeyboard event, you prevent the control from receiving the keyboard event.

Only graphs and control panels receive earlyKeyboard events. Other window types receive normal keyboard events before any use is made of the keyboard events, making the earlyKeyboard event redundant.

Setting the Mouse Cursor

An advanced programmer can use a named window hook function to change the mouse cursor.

You might want to do this, for example, if your window hook function intercepts mouse events on certain items (e.g., waves) and performs custom actions. By setting a custom mouse cursor you indicate to the user that clicking the items results in different-from-normal actions.

See the Mouse Cursor Control example experiment - in Igor choose File→Example Experiments→Programming→Mouse Cursor Control.

Panel Done Button Example

This example uses a window hook and button action procedure to implement a panel dialog with a Done button such that the panel can't be closed by clicking the panel's close widget, but can be closed by the Done button's action procedure:

```
Proc ShowDialog()
   PauseUpdate; Silent 1         // building window...
   NewPanel/N=Dialog/W=(225,105,525,305) as "Dialog"
   Button done,pos={119,150},size={50,20},title="Done"
   Button done,proc=DialogDoneButtonProc
   TitleBox warning,pos={131,83},size={20,20},title=""
   TitleBox warning,anchor=MC,fColor=(65535,16385,16385)
   SetWindow Dialog hook(dlog)=DialogHook, hookevents=2
EndMacro

Function DialogHook(s)
   STRUCT WMWinHookStruct &s
   Variable statusCode= 0
      strswitch( s.eventName )
      case "killVote":
         TitleBox warning win=$s.winName, title="Press the Done button!"
         Beep
         statusCode=2                  // prevent panel from being killed.
         break
      case "mousemoved":               // to reset the warning
         TitleBox warning win=$s.winName, title=""
         break
   endswitch
   return statusCode
End
```

```
Function DialogDoneButtonProc(ba) : ButtonControl
   STRUCT WMButtonAction &ba
   switch( ba.eventCode )
      case 2:             // mouse up
         // turn off the named window hook
         SetWindow $ba.win hook(dlog)=$""
         // kill the window AFTER this routine returns
         Execute/P/Q/Z "KillWindow " + ba.win
         break
   endswitch
   return 0
End
```

Window Hook Deactivate and Kill Events

The actions caused by these events (eventCode 2, 14, 15, 16 and 17) potentially affect multiple subwindows.

If you kill a subwindow, the root window's hook functions receives a subwindowKill event for that subwindow and any child subwindows.

If you kill a root window, the root window's hook function(s) receives a subwindowKill event for each child subwindow, and then the root window's hook function(s) receive a kill event.

Likewise, hiding and showing windows can result in subwindows being hidden or shown. In each case, the window hook function receives a hide or show event for each affected window or subwindow.

The winName member of WMWinHookStruct will be set to the full subwindow path of the subwindow that is affected.

Events for an exterior subwindow are a special case. See **Hook Functions for Exterior Subwindows** on page IV-305.

The hook functions attached to an exterior subwindow will receive a subwindowKill event if the exterior subwindow is killed as a result of killing the parent window. But it will receive a regular kill event if it is killed directly. Normal subwindows always receive only subwindowKill events.

The kill-related events are sent in this order when a window or subwindow is killed:

1. A killVote event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed.
2. If the window is not a subwindow and wasn't created with /K=1, /K=2 or /K=3, the standard window close dialog appears. If the close is cancelled, the window is not killed, the window will receive an activate event when the dialog is dismissed, and no further events are generated. Otherwise, proceed to step 3.
3. If the window being killed has subwindows, starting from the bottom-most subwindow and working back toward the window being killed:

3a. If the subwindow is a panel, action procedures for controls contained in the subwindow are called with event -1, “control being killed”.

3b. The root window's hook function(s) receive a subwindowKill event for the subwindow. If any hook function returns 1, no further subwindow hook events or control being killed events are sent, but the window killing process continues.

   Steps 3a and 3b are repeated for each subwindow until the window or subwindow being killed is reached.

4. If the killed window is a root window, a kill event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed. This method of preventing a window from closing is to be avoided: use the killVote event or the window-equivalent of `NewPanel/K=2`.

   Prior to Igor 7, you could return 2 when the window hook received a kill event to prevent the killing of the window. This is no longer supported. Use the killVote event instead.

There are several ways to prevent a window being killed. You might want to do this in order to enforce use of a Done or Do It button, or to prevent killing a control panel while some hardware action is taking place.

The best method is to use /K=2 when creating the window (see **Display** or **NewPanel**). Then the only way to kill the window is via the DoWindow/K command, or KillWindow command. In general, you would provide a button that kills the window after checking for any conditions that would prevent it.

The KillVote event is more flexible but harder to use. It gives your code a chance to decide whether or not killing is allowed. This means the user can close and kill the window with the window close box when it is allowed.

Returning 2 for the window kill event is not recommended. If you have old code that uses this method, we strongly recommend changing it to return 2 for the killVote event. New code should never return 2 for the kill event.

As of Igor Pro 7, returning 2 for the window kill event does not prevent the window from being killed. If you have old code that uses this technique, change it to return 2 for the killVote event instead.

Window Hook Show and Hide Events

Igor sends the show event to your hook function when the affected window is about to be shown but is still hidden. Likewise, Igor sends the hide event when the window is about to be hidden but is still visible. Other events, notably resize or move events, may be triggered by showing or hiding a window and may be sent before the change in visibility actually occurs. Here is an example that illustrates this issue:

```
Function MyHookFunction(s)
   STRUCT WMWinHookStruct &s

   strswitch(s.eventName)
      case "resize":
         GetWindow $(s.winName) hide
         if (V_value)
            Print "Resized while hidden"
         else
            Print "Resized while visible"
         endif
         break

      case "moved":
         GetWindow $(s.winName) hide
         if (V_value)
            Print "Moved while hidden"
         else
            Print "Moved while visible"
         endif
         break

      case "hide":
         print "Hide event"
         break

      case "show":
         print "Show event"
         break
   endswitch

   return 0    // Don't interfere with Igor's handling of events
End

Function MakePanelWithHook()
   NewPanel/N=MyPanel/HIDE=1
   SetWindow MyPanel, hook(myHook)=MyHookFunction
End
```

If you run the MakePanelWithHook function on the command line, you see nothing because the panel is hidden. Now select Windows→Other Windows→MyPanel. The following is printed in the history:

```
Show event
Moved while hidden
Resized while hidden
```

The hook function received the Move and Resize events *after* the Show event, but before the window actually became visible.

Hook Functions for Exterior Subwindows

A regular subwindow lives inside a host window and receives events through a hook function attached to its host window.

An exterior subwindow is different because, although it is a subwindow (it is controlled by a host window), unlike a regular subwindow, it has its own actual window and therefore you can attach a hook function directly to it. A hook function attached to the root window does not receive events for an exterior subwindow. To handle events for an exterior subwindow, you must attach a hook function to the exterior subwindow itself. For example:

```
// Make a panel
NewPanel/N=RootPanel

// Make an exterior subwindow attached to RootPanel
NewPanel/HOST=RootPanel/EXT=0

// Attach a hook function to the exterior subwindow
SetWindow RootPanel#P0 hook(myhook)=MyHookFunction
```

Unnamed Window Hook Functions

Unnamed window hook functions are supported for backward compatibility only. New code should use named window hook functions. See **Named Window Hook Functions** on page IV-295.

Each window can have one unnamed hook function. You designate a function as the unnamed window hook function using the **SetWindow** operation with the hook keyword.

The unnamed hook function is called when various window events take place. The reason for the hook function call is stored as an event code in the hook function’s infoStr parameter.

The hook function is not called during experiment creation or load time so as to prevent the hook function from failing because the experiment is not fully recreated.

The hook function has the following syntax:

```
Function procName(infoStr)
   String infoStr
   String event= StringByKey("EVENT",infoStr)
   …
   return statusCode    // 0 if nothing done, else 1
End
```

`infoStr` is a string containing a semicolon-separated list of ***key:value*** pairs:

Key	Value
EVENT	*eventKey* See list of *eventKey* values below.
HCSPEC	Absolute path of the window or subwindow. See **Subwindow Command Concepts** on page III-92.
`MODIFIERS`	Bit flags as follows: Bit 0: Set if mouse button is down. Bit 1: Set if Shift is down. Bit 2: Set if Option (*Macintosh*) or Alt (*Windows*) is down. Bit 3: Set if Command (*Macintosh*) or Ctrl (*Windows*) is down. Bit 4: Contextual menu click: right-click or Control-click (*Macintosh*), or right-click (*Windows*). See **Setting Bit Parameters** on page IV-12 for details about bit settings.
`OLDWINDOW`	Previous name of the window or subwindow (for renamed event). Not the old absolute path *hcSpec*, just the name. WINDOW and HCSPEC contain the new name and new *hcSpec*.
`WINDOW`	Name of the window.

The value accompanying the EVENT keyword is one of the following:

eventKey	Meaning
`activate`	Window has just been activated.
`copy`	Copy menu item has been selected.
`cursormoved`	A graph cursor was moved. This event is sent only if bit 2 of the **SetWindow** operation hookevents flag is set.
`deactivate`	Window has just been deactivated.
`enablemenu`	Menus are being built and enabled.
`hide`	Window or subwindows about to be hidden.
`hideInfo`	The window info panel or window has just been hidden by **HideInfo**.
`hideTools`	The window tool palette or window has just been hidden by **HideTools**.
`kill`	Window is being killed. As of Igor Pro version 7, returning 2 as the hook function result no longer prevents Igor from killing the window. Use the killVote event instead.
`killVote`	Window is about to be killed. Return 2 to prevent that, otherwise return 0. See **Window Hook Deactivate and Kill Events** on page IV-303.
`menu`	A built-in menu item has been selected.
`modified`	A modification to the window has been made. See **Modified Events** on page IV-299.
mousedown	Mouse button was clicked. This event is sent only if bit 0 of the **SetWindow** operation hookevents flag is set.

eventKey	**Meaning**
mousemoved	The mouse moved. This event is sent only if bit 1 of the **SetWindow** operation hookevents flag is set.
mouseup	Mouse button was released. This event is sent only if bit 0 of the **SetWindow** operation hookevents flag is set.
moved	Window has just been moved.
renamed	Window has just been renamed. The previous name is available under the OLDWINDOW key.
resize	Window has just been resized.
show	Window or subwindow is about to be unhidden.
showInfo	The window info panel or window has just been shown by **ShowInfo**.
showTools	The window tool palette or window has just been shown by **ShowTools**.
subwindowKill	One of the window's subwindows is about to be killed.

If mouse events are enabled then the following key:value pairs will also be present in infoStr:

Key	**Value**
MOUSEX	X coordinate in pixels of the mouse.
MOUSEY	Y coordinate in pixels of the mouse.
TICKS	Time event happened.

Note that a mouseup event may or may not correspond to a previous mousedown. If the user clicks in the window, drags out and releases the button then the mouseup event will be missing. If the user clicks in another window, drags into this one and then releases then a mouseup will be sent that had no previous mousedown.

In the case of mousedown or mousemoved messages, a nonzero return value will skip normal processing of the message. This is most useful with mousedown.

The cursormoved event is not reported if Option (*Macintosh*) or Alt (*Windows*) is held down.

If the cursormoved event is enabled then the following key:value pairs will also be present in infoStr:

Key	**Value**
CURSOR	Name of the cursor that moved (A through J).
TNAME	Name of the trace the cursor is attached to (invalid if ISFREE=1).
ISFREE	1 if the cursor is "free" (not attached to a trace), 0 if it is attached to a trace or image.
POINT	Point number of the trace if not a free cursor. If the cursor is attached to an image, value is the row number of the image. If a free cursor, value is the fraction of the plot width, 0 being the left edge of the plot area, and 1 being the right edge.
YPOINT	Column number if the cursor is attached to an image, NaN if attached to a trace. If a free cursor, value is the fraction of the plot height, 0 being the top edge, and 1 being the bottom edge.

When the a menu event is reported then the following key:value pairs will also be present in infoStr:

Key	Value
MENUNAME	Name of menu (in English) as used by **SetIgorMenuMode**.
MENUITEM	Text of menu item as used by **SetIgorMenuMode**.

The enablemenu event does not pass MENUNAME or MENUITEM.

The menu and enablemenu messages are not sent when drawing tools are in use in a graph or layout or when waves are being edited in a graph.

Returning a value of 0 for the enablemenu message is recommended, though the return value is (currently) ignored.

You can use the **SetIgorMenuMode** operation to alter the enable state of Igor's built-in menus in a way you find appropriate for the window. If you do this, usually you will also handle the menu message and perform your idea of an appropriate action.

Note: Dynamic user-defined menus (see **Dynamic Menu Items** on page IV-129) are built and enabled by using string functions in the menu definitions.

Returning a value of 0 for any menu message allows Igor to perform the normal action. Returning any other value (1 is commonly used) tells Igor to skip performing the normal action.

See the user function description with **IgorMenuHook** on page IV-291 for details on the sequence of menu building, enabling, and handling.

Custom Marker Hook Functions

You can define custom marker shapes for use with graph traces. To do this, you must define a custom marker hook function, activate it by calling SetWindow with the markerHook keyword, and set a trace to use it via the ModifyGraph operation marker keyword.

A custom marker hook function takes one parameter - a WMMarkerHookStruct structure. This structure provides your function with information you need to draw a marker.

The function prototype used with a custom marker hook has the format:

```
Function MyMarkerHook(s)
   STRUCT WMMarkerHookStruct &s
   <code to draw marker>
   ...
   return statusCode       // 0 if nothing done, else 1
End
```

Your function can use the DrawXXX operations to draw the marker. The function is called each time the marker is drawn and should not do anything other than drawing the marker. The function should return 1 if it handled the marker or 0 if not.

Because the user-defined function runs during a drawing operation that cannot be interrupted without crashing Igor, the debugger cannot be invoked while it is running. Consequently breakpoints set in the function are ignored. Use **Debugging With Print Statements** on page IV-212 instead.

The marker number range, which you specify via the SetWindow markerHook call, can be any positive integers less than 1000 and can overlap built-in marker numbers.

WMMarkerHookStruct

The WMMarkerHookStruct structure has the following members:

WMMarkerHookStruct Structure Members

Member	Description
`Int32 usage`	0= normal draw, 1= legend draw (others reserved).
`Int32 marker`	Marker number minus start (i.e., starts from zero).
`float x,y`	Location of desired center of marker
`float size`	Half width/height of marker
`Int32 opaque`	1 if marker should be opaque
`float penThick`	Stroke width
`STRUCT RGBColor mrkRGB`	Fill color
`STRUCT RGBColor eraseRGB`	Background color
`STRUCT RGBColor penRG`	Stroke color
`WAVE ywave`	Trace's y wave
`double ywIndex`	Point number; ywave[wyIndex] is the y value where the marker is being drawn.
`char winName[MAX_HostChildSpec+1]`	Full path to window or subwindow
`char traceName[MAX_OBJ_INST+1]`	Full name of trace or "" if no trace

When your marker function is called, the pen thickness and colors of the drawing environment of the target window are already set consistent with the penThick, mrkRGB, eraseRGB and penRGB members.

The winName and traceName members were added in Igor Pro 9.00 to provide access to trace userData. See **Trace User Data** on page IV-89.

Marker Hook Example

Here is an example that draws audiology symbols:

```
Function AudiologyMarkerProc(s)
   STRUCT WMMarkerHookStruct &s

   if( s.marker > 3 )
      return 0
   endif

   Variable size= s.size - s.penThick/2

   if( s.opaque )
      SetDrawEnv linethick=0,fillpat=-1
      DrawRect s.x-size,s.y-size,s.x+size,s.y+size
      SetDrawEnv linethick=s.penThick
   endif
   SetDrawEnv fillpat= 0      // polys are not filled

   if( s.marker == 0 )        // 90 deg U open to the right
      DrawPoly s.x+size,s.y-size,1,1,{size,-size,-size,-size,-size,size,size,size}
   elseif( s.marker == 1 )    // 90 deg U open to the left
      DrawPoly s.x-size,s.y-size,1,1,{-size,-size,size,-size,size,size,-size,size}
   elseif( s.marker == 2 )    // Cap Gamma
      DrawPoly s.x+size,s.y-size,1,1,{size,-size,-size,-size,-size,size}
   elseif( s.marker == 3 )    // Cap Gamma reversed
      DrawPoly s.x-size,s.y-size,1,1,{-size,-size,size,-size,size,size}
   endif
   return 1
End

Window Graph1() : Graph
   PauseUpdate; Silent 1      // building window...
   Make/O/N=10 testw=sin(x)
   Display /W=(35,44,430,252) testw,testw,testw,testw
   ModifyGraph offset(testw#1)={0,-0.2},offset(testw#2)={0,-0.4},
               offset(testw#3)={0,-0.6}
   ModifyGraph mode=3,marker(testw)=100,marker(testw#1)=101,marker(testw#2)=102,
               marker(testw#3)=103
   SetWindow kwTopWin,markerHook={AudiologyMarkerProc,100,103}
EndMacro
```

See also the Custom Markers Demo experiment - in Igor choose File→Example Experiments→Feature Demos 2→Custom Markers Demo.

Tooltip Hook Functions

Igor displays tooltips for traces and images in graphs if you have selected Graph→Show Trace Info Tags and for table data cells if you have selected Table→Show Column Info Tags. You can also set help text for user-defined controls. In Igor Pro 9.00 or later, you can customize those tooltips by creating a tooltip hook function and activating it for a graph or control panel using **SetWindow**.

A tooltip hook function is similar to a window hook function (see **Named Window Hook Functions** on page IV-295). Igor calls the tooltip hook function for a graph when the mouse hovers over a trace or image, and for a table when the mouse hovers over a cell associated with a wave. The tooltip hook function is also called for a graph or control panel when the mouse hovers over a control.

Unlike a window hook function, you can associate a tooltip hook function with either a top-level graph or control panel window or with a control panel subwindow.

A tooltip hook function takes one parameter - a **WMTooltipHookStruct** structure. The structure contains fields describing the trace, image, wave or control for which tooltip help is being requested and fields that allow you to return information to Igor.

When Igor calls a tooltip hook function, the tooltip field or the structure is preset to the text that Igor has composed for the tooltip. The function can alter it, add to it, or replace it completely. If you want to specify the displayed tooltip, set the tooltip field to your desired text and return 1 from the hook function. Otherwise return 0. Other return values are reserved for future use.

Here is a tooltip hook function that generates tool tips for traces in graphs:

```
Function MyGraphTraceTooltipHook(s)
   STRUCT WMTooltipHookStruct &s

   Variable hookResult = 0    // 0 tells Igor to use the standard tooltip

   // traceName is set only for graphs and only if the mouse hovered near a trace
   if (strlen(s.traceName) > 0)
      hookResult = 1          // 1 tells Igor to use our custom tooltip
      WAVE w = s.yWave        // The trace's Y wave
      s.tooltip = GetWavesDataFolder(w, 2)    // Replace Igor's tooltip
      if (WaveDims(w) > 0)
         s.tooltip += "[" + num2str(s.row) + "]"
         if (WaveDims(w) > 1)
            s.tooltip += "[" + num2str(s.column) + "]"
         endif
      endif
   endif

   return hookResult
End
```

Use the SetWindow operation to establish the tooltip hook function for a given window, like this:

```
SetWindow Graph0, tooltipHook(MyTooltipHook) = MyGraphTraceTooltipHook
```

You can clear the tooltip function like this:

```
SetWindow Graph0, tooltipHook(MyTooltipHook) = $""
```

Because the hook function runs during an operation that cannot be interrupted without crashing Igor, the debugger cannot be invoked while it is running. Consequently breakpoints set in the function are ignored. Use **Debugging With Print Statements** on page IV-212 instead.

Tooltip Tracking Rectangle

When your function is called, the WMTooltipHookStruct trackRect field is set to a tracking rectangle in local window coordinates. When the tooltip is displayed, the tooltip system tracks the mouse. If the mouse leaves the tracking rectangle, the tooltip is hidden. If the the mouse enters another area appropriate for display of a tooltip, the hook function is called again.

In a graph, the tracking rectangle is a 20x20 point rectangle around the mouse location. In a table, the tracking rectangle corresponds to the bounds of the table cell under the mouse. If the mouse hovers over a control, the tracking rectangle is the bounding box of the control.

The trackRect field is both an input and an output. You can modify it to change when the tooltip disappears, but this is rarely necessary. You might want to do it if, for instance, you want to define help text for different parts of a control.

HTML Tags in Tooltips

You can control formatting of the tooltip by including certain HTML tags in the text. The subset of tags supported is described here: http://doc.qt.io/qt-5/richtext-html-subset.html

To use HTML tags, start your text with "<html>", end it with "</html>", and set the structure field isHTML to 1.

For example, this code:

```
s.tooltip = "<html><font size=\"+2\">Large</font> and <b>bold</b> text</html>"
s.isHTML=1
```

results in this tooltip: This tooltip has large and bold text

The Tooltip Row, Column, Layer and Chunk Fields

These fields specify the wave element of the wave associated with the graph trace, graph image, or table cell under the mouse. A value of -1 indicates that the dimension is not used.

Tooltip Display Duration

By default, Igor displays a tooltip for 10 seconds or longer for long messages. After that time, the tooltip disappears.

You can adjust the time by setting the WMTooltipHookStruct duration_ms field. When your function is called, that field is set to -1, which selects the default duration. To get an effectively permanent tooltip, set duration_ms to a large number in units of milliseconds. For example, setting duration_ms to 600000 causes the tooltip to be displayed for ten minutes.

Regardless of the duration, Igor hides the tooltip if you click the mouse or move it out of the tracking rectangle.

Data Acquisition

Igor Pro provides a number of facilities to allow working with live data:

- Live mode traces in graphs
- FIFOs and Charts
- Background task
- External operations and external functions
- Controls and control panels
- User-defined functions

Live mode traces in graphs are useful when you acquiring complete waveforms in a single short operation and you want to update a graph many times per second to create an oscilloscope type display. See **Live Graphs and Oscilloscope Displays** on page II-347 for details.

FIFOs and Charts are used when you have a continuous stream of data that you want to capture and, perhaps, monitor. See **FIFOs and Charts** on page IV-313 details.

You can set up a background task that periodically performs data acquisition while allowing you to continue to work with Igor in the foreground. The background operations are *not* done using interrupts and therefore are easily disrupted by foreground operations. Background tasks are useful only for relatively infrequent tasks that can be quickly accomplished and do not cause a cascade of graph updates or other things that take a long time. See **Background Tasks** on page IV-319 for details.

You can create an instrument-like front panel for your data acquisition setup using user-defined controls in a panel window. Refer to Chapter III-14, **Controls and Control Panels**, for details. There are many example experiments that can be found in the Examples folder.

Igor Pro comes with an XOP named VDT2 for communicating with instruments via serial port (RS232), another XOP named NIGPIB2 for communicating via General Purpose Interface Bus (GPIB), and another XOP named VISA for communicating with VISA-compatible instruments. See the Igor Pro Folder:More Extensions:Data Acquisition folder.

Sound I/O can be done using the built-in **SoundInRecord** and **PlaySound** operations.

The **NewCamera**, **GetCamera** and **ModifyCamera** operations support frame grabbing.

WaveMetrics produces the NIDAQ Tools software package for doing data acquisition using National Instruments cards. NIDAQ Tools is built on top of Igor using all of the techniques mentioned in this section. Information about NIDAQ Tools is available via the WaveMetrics Web site <http://www.wavemetrics.com/Products/NIDAQTools/nidaqtools.htm>.

Third parties have created data acquisition packages that use other hardware. Information about these is also available at <http://www.wavemetrics.com/Products/thirdparty/thirdparty.htm>.

If an XOP package is not available for your hardware you can write your own. For this, you will need to purchase the XOP Toolkit product from WaveMetrics. See **Creating Igor Extensions** on page IV-208 for details.

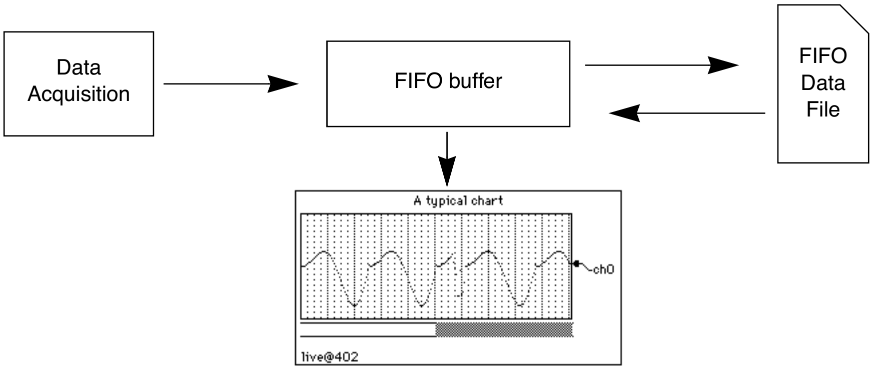
FIFOs and Charts

This section will be of interest principally to programmers writing data acquisition packages.

Most people who use FIFOs and chart recorder controls will do so via packages provided by expert Igor programmers. For information on using, as opposed to programming, chart controls, see **Using Chart Recorder Controls** on page IV-317.

FIFO Overview

A FIFO is an invisible data objects that can act as a First-In-First-Out buffer between a data source and a disk file. Data is placed in a FIFO either via the AddFIFOData operation or via an XOP package designed to interface to a particular piece of hardware. Chart recorder controls provide a graphical view of a portion of the data in a FIFO. When data acquisition is complete a FIFO can operate as a bidirectional buffer to a disk file. This allows the user to review the contents of a file by scrolling the chart "paper" back and forth. FIFOs can be used without a chart but charts have no use without a FIFO to monitor.

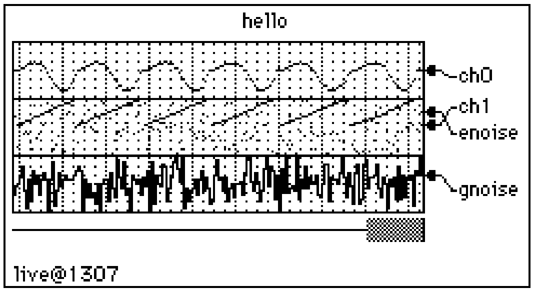


A FIFO can have an arbitrary number of channels each with its own number type, scaling, and units. All channels of a given FIFO share a common "timebase".

Chart Recorder Overview

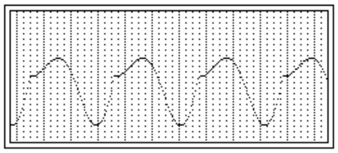
Chart recorder controls can be used to emulate a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. Charts can be used to monitor data acquisition processes or to examine a long data record. Although programming a chart is quite involved, using a chart is very easy.

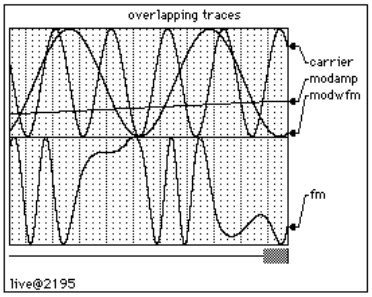
Here is a typical chart recorder control:



The First-In-First-Out (FIFO) buffer is an invisible Igor component that buffers the data coming from data acquisition hardware and software and also writes the data to a file. The data that is streaming through the FIFO can be observed using a chart recorder control. When data acquisition is finished the process can be reversed with data coming back out of the file and into the FIFO where it can be reviewed using the chart. The FIFO file is optional but if missing then all data pushed out the end of the FIFO is lost.

Chart recorder controls can take on quite a number of forms from the simple to the sophisticated:





A given chart recorder control can monitor an arbitrary selection of channels from a single FIFO. Each trace can have its own display gain, color and line style and can either have its own area on the "paper" or can share an area with one or more other traces. There can be multiple chart recorder controls active an one time in one or more panel or graph windows.

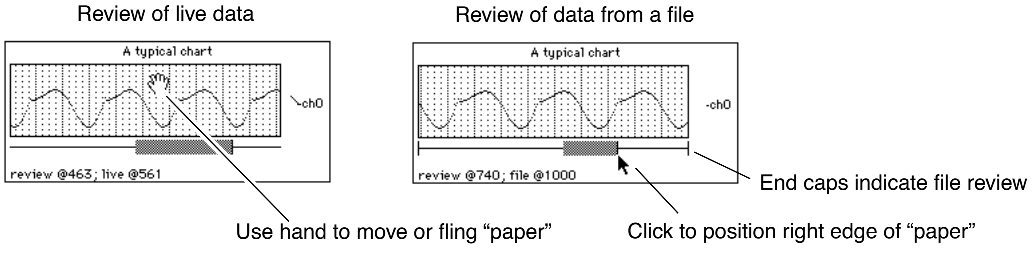
Chart recorders can display an image strip when hooked up to a FIFO channel defined using the optional vectPnts parameter to NewFIFOChan. An example experiment, Image Strip FIFO Demo, is provided to illustrate how to use this feature.

Chart recorders can operate in two modes — live and review. When a chart is in live mode and data acquisition is in progress, the chart "paper" scrolls by from right to left under the influence of the acquisition process. When in review mode, you are in control of the chart. When you position the mouse over the chart area you will see that the cursor turns into a hand. You can move the chart paper right or left by dragging with the hand. If you give the paper a push it will continue scrolling until it hits the end.

You can place the chart in review mode even as data acquisition is in progress by clicking in the paper with the hand cursor. To go back to live mode, give the paper a hard push to the left. When the paper hits the end then the chart will go to into live mode. You can also go back to live mode by clicking anywhere in the margins of the chart.

Depending on the exact details of the data acquisition hardware and software you may run the risk of corrupting the data if you use review mode while acquisition is in progress. The person that created the hardware and software system you are using should have provided guidelines for the use of review mode during acquisition. In general, if the acquisition process is paced by hardware then it should be OK to use review mode.

In the chart recorder graphics above, you may have noticed the line directly under the scrolling paper area. This line represents the current extent of data while the gray bar represents the data that is being shown in the chart. The right edge of the gray bar represents the right edge of the section of data being shown in the chart window. The above example is shown in live mode. Here are two examples shown in review mode:



End caps indicate file review

Use hand to move or fling "paper"

Click to position right edge of "paper"

While data acquisition is in progress, the horizontal line represents the extent of the data in the FIFO's memory. After acquisition is over then the line includes all of the data in the FIFO's output file, if any.

If you are in review mode while data acquisition is taking place, you will notice that the gray bar indicates the view area is moving even though the paper appears to be motionless. This is because the FIFO is moving out from under the chart. Eventually it will reach a position where the chart display can not be valid since the data it wants to display has been flushed off the end of the FIFO. When this happens the view area will go blank. Because it is very time-consuming for Igor to try to keep the chart updated in this situation your data acquisition rate may suffer.

Chart recorder controls sometimes try to auto-configure themselves to match their FIFO. Generally this action is exactly what you want and is unobtrusive. Here are the rules that charts use:

When the FIFO becomes invalid or if it ceases to exist then the chart marks itself as being in auto-configure mode. If the FIFO then becomes valid the chart will read the FIFO information and configure itself to monitor all channels. It tries to set the ppStrip parameter to a value appropriate for the deltaT value of the FIFO. It does so by assuming a desirable update rate of around 10 strips per second. Thus, for example, if deltaT was 1 millisecond then ppStrip would be set to 100. The moral is: deltaT had better be valid or weird values of ppStrip may be created.

Any chart recorder channel configuration commands executed after the FIFO becomes invalid but before the FIFO becomes valid again will prevent auto-configuration from taking place.

Programming with FIFOs

You can create a FIFO by using the NewFIFO operation. When you are done using a FIFO you use the KillFIFO operation. A freshly created FIFO is not useful until either channels are created with the NewFIFOChan operation or until the FIFO is attached to a disk file for review using a variant of the CtrlFIFO operation.

You can obtain information about a FIFO using the FIFOStatus operation and you can extract data from a FIFO using the FIFO2Wave operation. Once a FIFO is set up and ready to accept data, you can insert data using the AddFIFOData operation. Alternately, you can insert data using an XOP package.

Once data is stored in a file you can review the data using a FIFO or extract data using user-defined functions. See the example experiment, “FIFO File Parse”, for sample utility routines.

Here are the operations and functions used in FIFO programming:

NewFIFO **KillFIFO**

NewFIFOChan **CtrlFIFO**

FIFO2Wave **AddFIFOData**

AddFIFOVectData **FIFOStatus**

As with background tasks, FIFOs are considered transient objects — they are not saved and restored as part of an experiment.

A FIFO does not need to be attached to a file to be useful. Note, however, that the oldest data is lost when a FIFO overflows.

A FIFO set up to acquire data does not become valid until the start command is issued. Chart controls will report invalid FIFOs on their status line. FIFO2Wave will give an error if it is invoked on an invalid FIFO. A stopped FIFO remains valid until the first command is issued that could potentially change the FIFO’s setup.

Data in a running FIFO is written to disk when Igor notices that the FIFO is half full or when the AddFIFOData command is issued and the FIFO is full. The amount of time it takes to write data to disk can be quite considerable and at the same time unpredictable. If the computer disk cache size is large then writes to disk will be less frequent but when they do occur they will take a long time. This will matter to you most if you are attempting to take data rapidly using software, perhaps using an Igor background task.

If you are taking data via interrupt transfer to an intermediate buffer of adequate size or if your hardware has an adequate internal buffer then the disk write latency may not be a concern. If dead time due to disk writes is a concern then you may want to decrease the size of the disk cache and you may want to run with a relatively small FIFO. Note that if you change the size of the disk cache you may have to reboot for the change to take effect.

When the stop command is given to a running FIFO then it goes into review mode and remains valid. If the FIFO is attached to a file then the entire contents of the file can be reviewed or be transferred to a wave using the FIFO2Wave command.

The act of attaching a FIFO to an existing file for review using the rfile keyword of the CtrlFIFO command reads in the file contents and sets itself up for review. You should not use the NewFIFOChan command or any of the other CtrlFIFO keywords except size. Here is all that is required to review a preexisting file:

```
Variable refnum
Open/R/P=mypath refnum as "my file"
NewFIFO dave
CtrlFIFO dave,rfile=refnum
```

If any chart controls have been set up to monitor FIFO dave then they will automatically configure themselves to display all the channels of dave using default parameters.

The connection between FIFOs and chart controls relies on Igor’s dependency manager. The dependency manager does not automatically run during function execution — you have to explicitly call it by executing the DoUpdate command.

The dependency manager sends messages to a chart control when:

- A FIFO is created
- A FIFO is killed
- A FIFO becomes valid (start command)
- Data is added to a FIFO

In particular, if inside a user function, you kill a FIFO and then create it again you should call DoUpdate after the kill so that the chart control notices the kill and can get ready for the creation.

FIFO File Format

This section is provided for programmers who want to create FIFO files as input for Igor with their own programs or to analyze data stored in Igor-generated FIFO files. Such applications require familiarity with C programming.

The FIFO file uses C structures named FIFOFileHeader, ChartChunkInfo, ChartChanInfo, and FIFOSplitFileHeader. These are defined in the file NamedFIFO.h which is shipped in "Igor Pro Folder\Miscellaneous\More Documentation". NamedFIFO.h is the primary documentation for the FIFO file format.

The FIFOFileHeader, ChartChunkInfo, and FIFOSplitFileHeader structures contain version fields. These structures may evolve in the future, so your code should check them and fail gracefully if you encounter an unexpected value.

Igor supports integrated FIFO files, in which the header and data are in the same file, and split FIFO files, in which the header and data are in separate files.

An integrated FIFO file consists of a FIFOFileHeader structure followed by a ChartChunkInfo structure and finally by chunks of data until the end of the file. A user-defined function that can parse an integrated FIFO file can be found in the "FIFO File Parse" example experiment.

The split format uses the FIFOSplitFileHeader structure to allow the raw data to reside in its own file rather than having to be in the same file as the header. This facilitates the use of Igor to review large binary files generated by third-party programs.

See the "Wave Review Chart Demo" example experiment for sample code for both the integrated and split FIFO file formats.

Another way to use a FIFO and chart control to review a raw binary file is to use the rdfile keyword with the **CtrlFIFO** command.

```

Using Chart Recorder Controls

The information provided here pertains to using rather than programming a chart recorder control. For information on programming chart controls, see **FIFOs and Charts** on page IV-313.

An Igor chart recorder control works in conjunction with a FIFO to display data as it is acquired or to review data that has previously been acquired.

Chart Reorder Control Basics

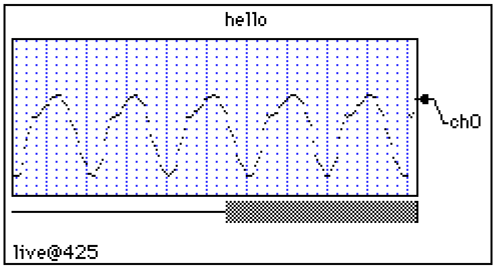
An Igor chart recorder control is neither an analytical tool nor a presentation quality graphic. It is meant only for real time monitoring of incoming data or to review data from a FIFO file. When you want an analytical or presentation quality graph you must transfer the data to a wave and then use a conventional Igor graph.

An Igor chart recorder control emulates a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. It differs from a real chart recorder in that the paper of the latter moves at a constant velocity whereas the “paper” of an Igor chart moves only when data becomes available in the FIFO it is monitoring. If data is placed in the FIFO at a constant rate then the “paper” will scroll by at a constant rate. However, since there can be no guarantee that the data is coming in at a constant rate, we refer to the horizontal axis not in terms of time but rather in terms of data sample number.

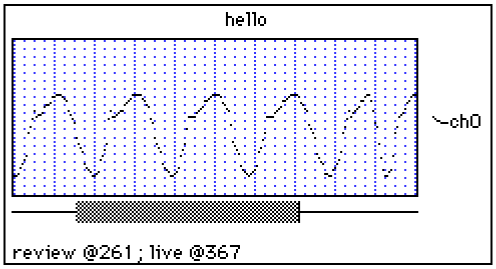
A given chart recorder control can monitor an arbitrary selection of channels from a single FIFO. Each chart trace can have its own display gain, color and line style and can either have its own area on the “paper” or can share an area with one or more other traces. There can be multiple charts active an one time in one or more control panel or graph windows.

Operating a Chart Recorder

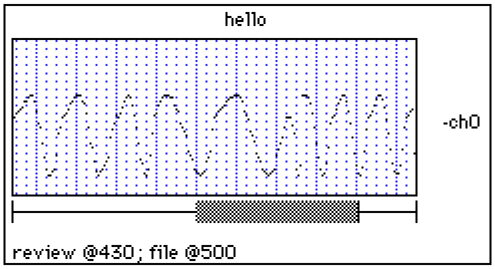
Here is a typical chart recorder while taking data:



And here is the same chart recorder while reviewing data even though data acquisition is still taking place:



And here we are while reviewing data from the file after data acquisition is complete:



Notice the positioning strip just under the chart and above the status line. It consists of a horizontal line and a horizontal, gray bar. The line, called the positioning line, represents the extent of available data. The bar, called the positioning bar, represents the currently displayed region of this data.

While data acquisition is in progress, the available data is the data in the FIFO's memory. After the acquisition is over then the available data includes all of the data in the FIFO's output file, if any. The vertical bars at the ends of the positioning line indicate we are reviewing from a file.

You can instantly jump to any portion of the data by clicking on the positioning line. The spot that you click on indicates the part of the available data that you want to view. After clicking you can drag the "paper" region around.

The chart recorder will be in one of two modes: live mode or review mode. While data acquisition is under way, the chart recorder will display incoming data if it is in live mode. If it is in review mode, you can review previously acquired data.

Clicking on the positioning line or in the positioning bar puts the chart recorder into review mode even if data acquisition is taking place. To exit review mode and go into live mode, simply click anywhere in the chart recorder outside of the "paper" and the positioning strip. Of course, if you are not acquiring data you can not go into live mode.

Another way to go into review mode and navigate is to grab the "paper" with the mouse and fling it to the left or right. It will keep going until it hits the end of available data. The speed at which the "paper" moves depends on how hard you fling it.

If you are in review mode while data acquisition is taking place, you will notice that the positioning bar indicates the view area is moving even though the "paper" appears to be motionless. This is because the FIFO is moving out from under the chart. Eventually it will reach a position where the chart display can not be valid since the data it wants to display has been flushed off the end of the FIFO. When this happens the paper will go blank. Because it is very time consuming for Igor to try to keep the chart updated in this situation, your data acquisition rate may suffer. To get an idea of what kind of data rates can be sustained using an Igor background task, spend some time experimenting with the "FIFO/Chart Overhead" example experiment.

Chart Recorder Control Demos

```

Igor Pro Folder:Examples:Feature Demos:FIFO Chart Overhead.pxp
Igor Pro Folder:Examples:Feature Demos:Wave Review Chart Demo.pxp
Igor Pro Folder:Examples:Imaging:Image Strip FIFO Demo.pxp
```

Background Tasks

Background tasks allow procedures to run periodically "in the background" while you continue to interact normally with Igor. This is useful for data acquisition, simulations and other processes that run indefinitely, over long periods of time, or need to run at regular intervals. Using a background task allows you to continue to interact with Igor while your data acquisition or simulation runs.

Originally Igor supported just one unnamed background task controlled using the **CtrlBackground** operation (page V-118). New code should use the **CtrlNamedBackground** operation (page V-119) to create named background tasks instead, as shown in the following sections. You can run any number of named backgrounds tasks.

In addition to the documentation provided here, the Background Task Demo experiment provides sample code that is designed to be redeployed for other projects. We recommend reading this documentation first and then opening the demo by choosing File→Example Experiments→Programming→Background Task Demo.

Background Task Example #1

You create and control background tasks using the **CtrlNamedBackground** operation. The main parameters of CtrlNamedBackground are the background task name, the name of a procedure to be called periodically, and the period. Here is a simple example:

```
Function TestTask(s)     // This is the function that will be called periodically
   STRUCT WMBackgroundStruct &s

   Printf "Task %s called, ticks=%d\r", s.name, s.curRunTicks
   return 0             // Continue background task
End

Function StartTestTask()
   Variable numTicks = 2 * 60    // Run every two seconds (120 ticks)
   CtrlNamedBackground Test, period=numTicks, proc=TestTask
   CtrlNamedBackground Test, start
End

Function StopTestTask()
   CtrlNamedBackground Test, stop
End
```

You start this background task by calling `StartTestTask()` from the command line or from another procedure. StartTestTask creates a background task named Test, sets the period which is specified in units of ticks (1 tick = 1/60th of a second), and specifies the user-defined function to be called periodically (TestTask in this example).

You stop the Test background task by calling `StopTestTask().`

As shown above, the background procedure takes a **WMBackgroundStruct** parameter. In most cases you won't need to access it.

Background Task Exit Code

The background procedure (TestTask in the example above) returns an exit code to Igor. The code is one of the following values:

0: The background procedure executed normally.

1: The background procedure wants to stop the background task.

2: The background procedure encountered an error and wants to stop the background task.

Normally the background procedure should return 0 and the background task will continue to run. If you return a non-zero value, Igor stops the background task. You can tell Igor to terminate the background task by returning the value 1 from the background function.

If you forget to add a return statement to your background procedure, this acts like a non-zero return value and stops the background task.

Background Task Period

The CtrlNamedBackground operation's period keyword takes an integer parameter expressed in ticks. A tick is approximately 1/60th of a second. Thus the timing of Igor background tasks has a nominal resolution of 1/60th of a second.

You can override the specified period in the background task procedure by writing to the nextRunTicks field of the **WMBackgroundStruct** structure. This is needed only if you want your procedure to run at irregular intervals.

The actual time between calls to the background procedure is not guaranteed. Igor runs the background task from its outer loop, when Igor is doing nothing else. If you do something in Igor that takes a long time, for example performing a lengthy curve fit, running a user-defined function that takes a long time, or saving a large experiment, Igor's outer loop does not run so the background task will not run. If you do something that causes a compilation of Igor procedures to fail, the background task is not called. On Macintosh, the background task is not called while a menu is displayed or while the mouse button is pressed.

If you need your background task to continue running even if you edit other procedures in Igor, you need to make your project an independent module. See **Independent Modules** on page IV-238 for details.

If you need precise timing that can not be interrupted, things get much more complicated. You need to do your data acquisition in an Igor thread running in an independent module or in a thread created by an XOP that you write. See **ThreadSafe Functions and Multitasking** on page IV-329 for details.

The shortest supported period is one tick. The minimum actual period for the background task depends on your hardware and what your background task is doing. If you set the period too low for your background task, interacting with Igor becomes sluggish.

It is very easy to bog your computer down using background tasks. If the background task takes a long time to execute or if it triggers something that takes a long time (like a wave dependency formula or updating a complex graph) then it may appear that the system is hung. It is not, but it may take longer to respond to user actions than you are willing to wait.

Background Task Limitations

The principal limitation of Igor background tasks is that they are stopped while other operations are taking place. Thus, although you can type commands into the command line without disrupting the background task, when you press Return the task is stopped until execution of the command line is finished.

Background tasks do not run if procedures are in an uncompiled state. If you need your background task to continue running even if you edit other procedures in Igor, you need to make your project an independent module. See **Independent Modules** on page IV-238 for details.

On Macintosh, the background task does not run when the mouse button is pressed or when a menu is displayed.

Background Tasks and Errors

If a background task procedure contains a bug, it will typically generate an error each time the procedure runs. Normally an error generates an error dialog. If this happened over and over again, it would prevent you from fixing the bug.

Igor handles such repeated errors as follows: The first time an error occurs during the execution of the background task procedure, Igor displays an error dialog. On subsequent errors, Igor prints an error message in the history. After printing 10 such error messages, Igor stops printing messages. When you click a control, execute a command from the command line or execute a command through a menu item, the process starts over.

If the Igor debugger is enabled and Debug on Error is turned on, Igor will break into the debugger each time an error occurs in the background task procedure. You may have to turn Debug on Error off to give you time to stop the background task. You can do this from within the debugger by right-clicking.

Background Tasks and Dialogs

By default, a background task created by CtrlNamedBackground does not run while a dialog is displayed. You can change this behavior using the CtrlNamedBackground dialogsOK keyword.

If you allow background tasks to run while an Igor dialog is present, you should ensure that your background task does not kill anything that a dialog might depend on. It should not kill waves or variables. It should never directly modify a window (except for a status panel) and especially should never remove something from a window (such as a trace from a graph). Otherwise your background task may kill something that the dialog depends on which will cause a crash.

Background Task Tips

Background tasks should be designed to execute quickly. They do not run in separate threads threads and they hang Igor’s event processing as long as they run. For maximum responsiveness, your task procedure should take no more than a fraction of a second to run even when the period is long. If you have to perform a lengthy computation, let the user know what is going on, perhaps via a message in a status control panel.

Background tasks should never attempt to put up dialogs or directly wait for user input. If you need to get the attention of the user, you should design your system to include a status control panel with an area for messages or some other change in appearance. If you need to wait for the user, you should do so by monitoring global variables set by nonbackground code such as a button procedure in a panel.

Your task procedure should always leave the current data folder unchanged on exit.

Background Task Example #2

Here is an example that uses many of the concepts discussed above. The task prints a message in the history area at one second intervals five times, performs a “lengthy calculation”, and then waits for the user to give the go-ahead for another run.

The task does its own timing and consequently is set to run at the maximum rate (60 times per second). The task procedure, MyBGTask, tests to see if one second has elapsed since the last time it printed a message. In a real application, you might test to see if some external event has occurred.

To try the example, copy the code below to the Procedure window and execute:

```
BGDemo()
```

```
Function BGDemo()
   DoWindow/F BGDemoPanel        // bring panel to front if it exists
   if( V_Flag != 0 )
      return 0                   // panel already exists
   endif

   String dfSav= GetDataFolderDFR()         // so we can leave current DF as we found it
   NewDataFolder/O/S root:Packages
   NewDataFolder/O/S root:Packages:MyDemo  // our variables go here
   // still here if no panel, create globals if needed
   if( NumVarOrDefault("inited",0) == 0 )
      Variable/G inited= 1

      Variable/G lastRunTicks= 0 // value of ticks function last time we ran
      Variable/G runNumber= 0              // incremented each time we run
      // message displayed in panel using SetVariable...
      String/G message="Task paused. Click Start to resume."

      Variable/G running=0                 // when set, we do our thing
   endif

   SetDataFolder dfSav
   NewPanel /W=(150,50,449,163)
   DoWindow/C BGDemoPanel                  // set panel name
   Button StartButton,pos={21,12},size={50,20},proc=BGStartStopProc,title="Start"
   SetVariable msg,pos={21,43},size={300,17},title=" ",frame=0
   SetVariable msg,limits={-Inf,Inf,1},value= root:Packages:MyDemo:message
End

Function MyBGTask(s)
   STRUCT WMBackgroundStruct &s

   NVAR running= root:Packages:MyDemo:running

   if( running == 0 )
      return 0                      // not running -- wait for user
   endif

   NVAR lastRunTicks= root:Packages:MyDemo:lastRunTicks

   if( (lastRunTicks+60) >= ticks )
      return 0                      // not time yet, wait
   endif

   NVAR runNumber= root:Packages:MyDemo:runNumber

   runNumber += 1

   printf "Hello from the background, #%d\r",runNumber

   if( runNumber >= 5 )
      runNumber= 0
      running= 0                    // turn ourself off after five runs

      // run again when user says to
      Button StopButton,win=BGDemoPanel,rename=StartButton,title="Start"

      // Simulate a long calculation after a run
      String/G root:Packages:MyDemo:message="Performing long calculation. Please wait."
      ControlUpdate /W=BGDemoPanel msg
      DoUpdate /W=BGDemoPanel       // Required on Macintosh for control to be redrawn

      Variable t0= ticks
      do
         if (GetKeyState(0) & 32)
            Print "Lengthy process aborted by Escape key"
            break
         endif
      while( ticks < (t0+60*3) )    // delay for 3 seconds

      String/G root:Packages:MyDemo:message="Task paused. Click Start to resume."
   endif

   lastRunTicks= ticks

   return 0
End

Function BGStartStopProc(ctrlName) : ButtonControl
   String ctrlName

   NVAR running= root:Packages:MyDemo:running
   if( CmpStr(ctrlName,"StartButton") == 0 )
      running= 1
      Button $ctrlName,rename=StopButton,title="Stop"
      String/G root:Packages:MyDemo:message=""
      CtrlNamedBackground MyBGTask, proc=MyBGTask, period=1, start
   endif
```

```
    if( CmpStr(ctrlName,"StopButton") == 0 )
        running= 0
        Button $ctrlName,rename=StartButton,title="Start"
        CtrlNamedBackground MyBGTask, stop
        String/G root:Packages:MyDemo:message="Task paused. Press Start to resume."
    endif
End
```

Background Task Example #3

For another example including code that you can easily redeploy for your own project, open the Background Task Demo experiment by choosing File→Example Experiments→Programming→Background Task Demo.

Old Background Task Techniques

Originally Igor supported just one unnamed background task. This is still supported for backward compatibility but new code should use CtrlNamedBackground to create and control named background tasks instead.

The unnamed background task is designated using **SetBackground**, controlled using **CtrlBackground** and killed using **KillBackground**. The **BackgroundInfo** operation returns information about the unnamed background task.

The SetBackground, CtrlBackground, KillBackground and BackgroundInfo operations work only with the unnamed background task. For named background tasks, the CtrlNamedBackground operation provides all necessary functionality.

By default, a background task created by CtrlBackground does not run while a dialog is displayed. You can change this behavior using the CtrlBackground dialogsOK keyword.

Automatic Parallel Processing with TBB

TBB stands for “Threading Building Blocks”. It is an Intel technology that facilitates the use of multiple processors on a given task. The home page for TBB is:

https://www.threadingbuildingblocks.org

Starting with Igor Pro 7, some Igor operations, such as CurveFit, DSPPeriodogram, and ImageProfile, automatically use TBB. To see which operations use TBB, choose Help→Command Help, click Show All, and then check the Automatically Multithreaded Only checkbox.

You don’t need to do anything to take advantage of automatic multithreading with TBB. It happens automatically.

Running on multiple threads reduces the time required for number crunching tasks when the benefit of using multiple processors exceeds the overhead. Operations that use TBB automatically use multiple threads only when the size of the data or the complexity of the problem crosses a certain threshold. Igor is programmed to use a reasonable threshold for each supported operation. You can control the threshold using the **MultiThreadingControl** operation.

Automatic Parallel Processing with MultiThread

Intermediate-level Igor programmers can make use of multiple processors to speed up wave assignment statements in user-defined functions. To do this, simply insert the keyword MultiThread in front of a normal wave assignment. For example, in a function:

```
Make wave1
Variable a=4
MultiThread wave1= sin(x/a)
```

The expression, on the right side of the assignment statement, is compiled as threadsafe even if the host function is not.

Because of the overhead of spawning threads, you should use MultiThread only when the destination has a large number of points or the expression takes a significant amount of time to evaluate. Otherwise, you may see a performance penalty rather than an improvement.

The assignment is, by default, automatically parceled into as many threads as there are processors, each evaluating the right-hand expression for a different output point. You can specify the number of threads that you want to use using MultiThread /NT=(<number of threads>). In most cases, you should omit /NT to get the default behavior.

The MultiThread keyword causes Igor to evaluate the expression for multiple output points simultaneously. Do not make any assumptions as to the order of processing and certainly do not try to use a point from the destination wave other than the current point in the expression. For example, do not do something like this:

```
wave1 = wave1[p+1] - wave1[p-1]  // Result is indeterminate
```

Expressions like give unexpected results even in the absence of threading.

Here is a simple example to try on your own machine:

```
Function TestMultiThread(n)
   Variable n                    // Number of wave points

   Make/O/N=(n) testWave

   // To prime processor data cache so comparison will be valid
   testWave= 0

   Variable t1,t2
   Variable timerRefNum

   // First, non-threaded
   timerRefNum = StartMSTimer
   testWave= sin(x/8)
   t1= StopMSTimer(timerRefNum)

   // Now, automatically threaded
   timerRefNum = StartMSTimer
   MultiThread testWave= sin(x/8)
   t2= StopMSTimer(timerRefNum)

   Variable processors = ThreadProcessorCount
   Print "On a machine with",processors,"cores,MultiThread is", t1/t2,"faster"
End
```

Here is the output on a Mac Pro:

```
•TestMultiThread(100)
  On a machine with  8  cores, MultiThread is  0.059746  faster

•TestMultiThread(10000)
  On a machine with  8  cores, MultiThread is  3.4779  faster

•TestMultiThread(1000000)
  On a machine with  8  cores, MultiThread is  6.72999  faster

•TestMultiThread(10000000)
  On a machine with  8  cores, MultiThread is  8.11069  faster
```

The first result shows that the MultiThread keyword slowed the assignment down. This is because the assignment involved a small number of points and MultiThread has some overhead.

The remaining results illustrate that MultiThread can provide increased speed for assignments involving large waves.

In the last result, the speed improvement factor was greater than the number of processors. This is explained by the fact that, once running, a threadsafe expression has slightly less overhead than a normal expression.

If the right-hand expression involves calling user-defined functions, those functions must be threadsafe (see **ThreadSafe Functions** on page IV-106) and must also follow these rules:

1. Do not do anything to waves that are passed as parameters that might disturb memory. For example, do not change the number of points in the wave or change its data type or kill it or write to a text wave.
2. Do not write to a variable that is passed by reference.
3. Note that any waves or global variables created by the function will disappear when then wave assignment is finished.
4. Each thread has its own private data folder tree. You can not use WAVE, NVAR or SVAR to access objects in the main thread.

Failure to heed rule #1 will likely result in a crash.

Although it is legal to use the MultiThread mechanism in a threadsafe function that is already running in a preemptive thread via **ThreadStart**, it is not recommended and will likely result in a substantial loss of speed.

For an example using MultiThread, open the Mandelbrot demo experiment file by choosing “File→Example Experiments→Programming→MultiThreadMandelbrot”.

Data Folder Reference MultiThread Example

Advanced programmers can use waves containing data folder references and wave references along with MultiThread to perform multithreaded calculations more involved than evaluating an arithmetic expression. Here we use **Free Data Folders** (see page IV-96) to facilitate multithreading.

In this example, we extract each of the planes of a 3D wave, perform a filtering operation on the planes, and then finally assemble the planes into an output 3D wave. The main function, Test, executes a multithreaded assignment statement where the expression includes a call to a subroutine named Worker.

Because MultiThread is used, multiple instances of Worker execute simultaneously on different cores. Each instance runs in its own thread, working on a different plane. Each instance returns one filtered plane in a wave named M_ImagePlane in a thread-specific free data folder. The use of free data folders allows each instance of Worker to work on its own M_ImagePlane wave without creating a name conflict.

When the multithreaded assignment is finished, the main function assembles an output 3D wave.

```
// Extracts a plane from the 3D input wave, filters it, and returns the
// filtered output as M_ImagePlane in a new free data folder
ThreadSafe Function/DF Worker(w3DIn, plane)
   WAVE w3DIn
   Variable plane

   DFREF dfSav= GetDataFolderDFR()

   // Create a free data folder to hold the extracted and filtered plane
   DFREF dfFree= NewFreeDataFolder()
   SetDataFolder dfFree

   // Extract the plane from the input wave into M_ImagePlane.
   // M_ImagePlane is created in the current data folder
   // which is a free data folder.
   ImageTransform/P=(plane) getPlane, w3DIn
   Wave M_ImagePlane             // Created by ImageTransform getPlane

   // Filter the plane
   WAVE wOut= M_ImagePlane
   MatrixFilter/N=21 gauss,wOut

   SetDataFolder dfSav

   // Return a reference to the free data folder containing M_ImagePlane
   return dfFree
End

Function Demo(numPlanes)
   Variable numPlanes

   // Create a 3D wave and fill it with data
   Make/O/N=(200,200,numPlanes) src3D= (p==(2*r))*(q==(2*r))

   // Create a wave to hold data folder references returned by Worker.
   // /DF specifies the data type of the wave as "data folder reference".
   Make/DF/N=(numPlanes) dfw

   Variable timerRefNum = StartMSTimer

   MultiThread dfw= Worker(src3D,p)

   Variable elapsedTime = StopMSTimer(timerRefNum) / 1E6

   Printf "Statement took %g seconds for %d planes\r", elapsedTime, numPlanes

   // At this point, dfw holds data folder references to 50 free
   // data folders created by Worker. Each free data folder holds the
   // extracted and filtered data for one plane of the source 3D wave.

   // Create an output wave named out3D by cloning the first filtered plane
   DFREF df= dfw[0]
   Duplicate/O df:M_ImagePlane, out3D

   // Concatenate the remaining filtered planes onto out3D
   Variable i
   for(i=1; i<numPlanes; i+=1)
      df= dfw[i]     // Get a reference to the next free data folder
      Concatenate {df:M_ImagePlane}, out3D
   endfor

   // Redimension out3D to contain the correct number of planes
   Redimension/N=(-1, -1, numPlanes) out3D

   // Assign values to the remaining planes of out3D
   Variable i
   for(i=1; i<numPlanes; i+=1)
      df= dfw[i]                           // Reference to next free data folder
      WAVE thisPlaneWave = df:M_ImagePlane// Reference to wave in data folder
      out3D[][][i] = thisPlaneWave[p][q]
   endfor

   // dfw holds references to the free data folders. By killing dfw,
   // we kill the last reference to the free data folders which causes
   // them to be automatically deleted. Because there are no remaining
   // references to the various M_ImagePlane waves, they too are
   // automatically deleted.
   KillWaves dfw
End
```

To run the demo, execute:

```
Demo(50)
```

On an eight-core Mac Pro, this took 4.1 seconds without the MultiThread keyword and 0.6 seconds with the MultiThread keyword for a speedup of about 6.8 times.

Wave Reference MultiThread Example

In the preceding example, free data folders were used to hold data processed by threads. Since each free data folder held just a single wave, the example can be simplified by using free waves instead of free data folders. So here we perform the same threaded filtering of planes using free waves.

Because MultiThread is used, multiple instances of Worker execute simultaneously on different cores. Each instance runs in its own thread, working on a different plane. Each instance returns one filtered plane in a free wave named M_ImagePlane. The use of free waves allows each instance of Worker to work on its own M_ImagePlane wave without creating a name conflict.

This version of the example relies on the fact that a wave in a free data folder becomes a free wave when the free data folder is automatically deleted. See **Free Wave Lifetime** on page IV-92 for details.

```
ThreadSafe Function/WAVE Worker(w3DIn, plane)
   WAVE w3DIn
   Variable plane

   DFREF dfSav= GetDataFolderDFR()

   // Create a free data folder and set it as the current data folder
   SetDataFolder NewFreeDataFolder()

   // Extract the plane from the input wave into M_ImagePlane.
   // M_ImagePlane is created in the current data folder
   // which is a free data folder.
   ImageTransform/P=(plane) getPlane, w3DIn
   Wave M_ImagePlane             // Created by ImageTransform getPlane

   // Filter the plane
   WAVE wOut= M_ImagePlane
   MatrixFilter/N=21 gauss,wOut

   // Restore the current data folder
   SetDataFolder dfSav

   // Since the only reference to the free data folder created above
   // was the current data folder, there are now no references it.
   // Therefore, Igor has automatically deleted it.
   // Since there IS a reference to the M_ImagePlane wave in the free
   // data folder, M_ImagePlane is not deleted but becomes a free wave.

   return wOut       // Return a reference to the free M_ImagePlane wave
End

Function Demo(numPlanes)
   Variable numPlanes

   // Create a 3D wave and fill it with data
   Make/O/N=(200,200,numPlanes) srcData= (p==(2*r))*(q==(2*r))
   // Create a wave to hold data folder references returned by Worker.
   // /WAVE specifies the data type of the wave as "wave reference".
   Make/WAVE/N=(numPlanes) ww

   Variable timerRefNum = StartMSTimer

   MultiThread ww= Worker(srcData,p)

   Variable elapsedTime = StopMSTimer(timerRefNum) / 1E6

   Printf "Statement took %g seconds for %d planes\r", elapsedTime, numPlanes

   // At this point, ww holds wave references to 50 M_ImagePlane free waves
   // created by Worker. Each M_ImagePlane holds the extracted and filtered
   // data for one plane of the source 3D wave.

   // Create an output wave named out3D by cloning the first filtered plane
   WAVE w= ww[0]
   Duplicate/O w, out3D

   // Concatenate the remaining filtered planes onto out3D
   Variable i
   for(i=1;i<numPlanes;i+=1)
      WAVE w= ww[i]
      Concatenate {w}, out3D
   endfor

   // Create a 3D output wave by concatenating the filtered planes
   Concatenate/O {ww}, out3D

   // ww holds references to the free waves. By killing ww, we kill
   // the last reference to the free waves which causes them to be
   // automatically deleted.
   KillWaves ww
End
```

To run the demo, execute:

```
Demo(50)
```

Structure Array MultiThread Example

In a preceding example, free data folders were used to hold data processed by threads. A somewhat simpler approach is to use one or more structures to pass input data and to receive output data. The following example uses a single structure for both input and output. An array of these structures stored in a wave ensures that each thread works on its own data. After the calculation, the results are extracted. The net result for this simple example is nothing more than: `dataOutput = sin(p)`.

```
Structure ThreadIOData
   // Input to thread
   double x

   // Output from thread
   double out
EndStructure

Function Demo()
   if (IgorVersion() < 6.36)
      // This example crashes in Igor Pro 6.35 or before
      // because of a bug in StructGet/StructPut
      Abort "Function requires Igor Pro 6.36 or later."
   endif

   STRUCT ThreadIOData ioData

   // Prepare input
   Make/O ioDataArray      // This wave will be redimensioned by StructPut
   Variable i, imax=100
   for(i=0; i<imax; i+=1)
      ioData.x = i                        // Set input data
      StructPut ioData, ioDataArray[i]    // Pack structure into wave column
   endfor

   // Generate output
   Make/O/N=(imax) threadOutput
   MultiThread threadOutput = Worker(ioDataArray, p)

   // Extract output
   Make/O/N=(imax) outputData
   for(i=0; i<imax; i+=1)
      StructGet ioData, ioDataArray[i]
      outputData[i] = ioData.out
   endfor

   KillWaves ioDataArray, threadOutput
End

ThreadSafe Function Worker(w, point)
   WAVE w
   Variable point

   STRUCT ThreadIOData ioData
   StructGet ioData, w[point]       // Extract structure from wave column

   ioData.out = sin(ioData.x)       // Calculate of output data

   StructPut ioData, w[point]       // Pack structure into wave column

   // The return value from the thread worker function is accessible
   // via ThreadReturnValue. It is not used in this example.
   return point
End
```

To run the demo, execute:

```
Demo()
```

ThreadSafe Functions and Multitasking

Igor supports two multitasking techniques that are easy to use:

- **Automatic Parallel Processing with TBB**
- **Automatic Parallel Processing with MultiThread**

This section discusses the third technique, **ThreadSafe Functions**, which expert programmers can use to create complex, preemptive multitasking background tasks.

Preemptive multitasking uses the following functions and operations:

ThreadProcessorCount

ThreadStart

ThreadGroupCreate

ThreadGroupPutDF

ThreadGroupGetDF (deprecated)

ThreadGroupWait

ThreadGroupRelease

ThreadGroupGetDFR

ThreadReturnValue

To run a threadsafe function preemptively, you first create a thread group using **ThreadGroupCreate** and then call **ThreadStart** to start your worker function. Usually you will use the same function for each thread of a group although they can be different.

The worker function must be defined as threadsafe and must return a real or complex numeric result. The return value can be obtained after the function finishes by calling **ThreadReturnValue**.

The worker function can take variable and wave parameters. It can not take pass-by-reference parameters or data folder reference parameters.

Any waves you pass to the worker are accessible to both the main thread and to your preemptive thread. Such waves are marked as being in use by a thread and Igor will refuse to perform any operations that could change the size of the wave.

You can determine if any threads of a group are still running by calling **ThreadGroupWait**. Use zero for the "milliseconds to wait" parameter to just test if all threads are finished. Use a larger value to cause the main thread to sleep until all threads are finished. If you know the maximum time the threads should take, you can use that value and print an error message or take other action if the threads don't finish in time.

When ThreadGroupWait is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling ThreadReturnValue.

Once you are finished with a given thread group, call **ThreadGroupRelease**.

If your threads can run for a long time, you should detect aborts and make your threads quit. See **Aborting Threads** on page IV-337 for details.

The Igor debugger can not be used with threadsafe functions. See **Debugging ThreadSafe Code** on page IV-225 for details.

The hard part of using multithreading is devising a scheme for partitioning your data processing algorithms into threads.

Thread Data Environment

When a thread is started, Igor creates a root data folder for that thread. This root data folder and any data objects that the thread creates in it are private to the thread. This constitutes a separate data hierarchy for each thread.

Data is transferred, when you request it, from the main thread to a preemptive thread and vice-versa using input and output queues. The "currency" of these queues is the data folder, which provides considerable flexibility for passing data to threads and for retrieving results. Each thread group has an input queue to which the main thread may post data and an output queue from which the main thread may retrieve results.

The terms "input" and "output" are relative to the preemptive thread. The main thread posts a data folder to the input queue to send input to the preemptive thread. The preemptive thread retrieves the data folder from the input queue. After processing, the preemptive thread may post a data folder to the output queue. The main thread reads output from the preemptive thread by retrieving the data folder from the output queue.

Use **ThreadGroupPutDF** to post data folders and **ThreadGroupGetDFR** to retrieve them. These are called from both the main thread and from preemptive threads.

ThreadGroupPutDF clips the specified data folder, and everything it contains, out of the source thread's data hierarchy and puts it in the queue. From the standpoint of the source thread, it is as if KillDataFolder had been called. While a data folder resides in a queue, it is not accessible by any thread. See the documentation for **ThreadGroupPutDF** for some warnings about its use.

ThreadGroupGetDFR removes the data folder from the queue and returns it, as a free data folder, to the calling thread. Because it is a free data folder, Igor will automatically delete it when there are no more references to it, for example, when the thread returns.

Except for waves passed to the thread worker function as parameters and the thread worker's return value, the input and output queues are the only way for a thread to share data with the main thread. Examples below illustrate the use of these queues.

Parallel Processing - Group-at-a-Time Method

In this example, we attempt to improve the speed of filling columns of a 2D wave with a sin function. The traditional method is compared with parallel processing. Notice how much more complicated the multi-threaded version, MTFillWave, is compared to the single threaded STFillWave.

```
ThreadSafe Function MyWorkerFunc(w,col)
    WAVE w
    Variable col

    w[][col]= sin(x/(col+1))

    return stopMSTimer(-2)             // Time when we finished
End

Function MTFillWave(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable i,col,nthreads= ThreadProcessorCount
    Variable threadGroupID= ThreadGroupCreate(nthreads)

    for(col=0; col<ncol;)
        for(i=0; i<nthreads; i+=1)
            ThreadStart threadGroupID,i,MyWorkerFunc(dest,col)
            col+=1
            if( col>=ncol )
                break
            endif
        endfor

        do
            Variable threadGroupStatus= ThreadGroupWait(threadGroupID,100)
        while( threadGroupStatus != 0 )
    endfor
    Variable dummy= ThreadGroupRelease(threadGroupID)
End

Function STFillWave(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable col

    for(col= 0;col<ncol;col+=1)
        MyWorkerFunc(dest,col)
    endfor
End

Function ThreadTest(rows)
    Variable rows

    Variable cols=10

    make/o/n=(rows,cols) jack

    Variable i

    for(i=0;i<10;i+=1)        // get any pending pause events out of the way
    endfor
    Variable ttime= stopMSTimer(-2)

    Variable t0= stopMSTimer(-2)
    MTFillWave(jack)
    Variable t1= stopMSTimer(-2)
    STFillWave(jack)
    Variable t2= stopMSTimer(-2)

    ttime= (stopMSTimer(-2) - ttime)*1e-6

    // Times are in microseconds
    printf "ST: %d, MT: %d; ",t2-t1,t1-t0
    printf "speed up factor: %.3g; total time= %.3gs\r",(t2-t1)/(t1-t0),ttime
End
```

The empty loop above is necessary because of periodic pauses in execution when Igor checks for user aborts. If a pause was pending, we want to get it out of the way beforehand to avoid it affecting the first timing test.

After starting Igor Pro, there is initially some extra overhead associated with creating new threads. Consequently, in the test results to follow, the first test is run twice.

Results for Mac Mini 1.66 GHz Core Duo, OS X 10.4.6:

```
•ThreadTest(100)
  ST: 223, MT: 1192; speed up factor: 0.187; total time= 0.00146s
•ThreadTest(100)
  ST: 211, MT: 884; speed up factor: 0.239; total time= 0.0011s
•ThreadTest(1000)
  ST: 1991, MT: 1821; speed up factor: 1.09; total time= 0.00381s
•ThreadTest(10000)
  ST: 19857, MT: 11921; speed up factor: 1.67; total time= 0.0318s
•ThreadTest(100000)
  ST: 199174, MT: 113701; speed up factor: 1.75; total time= 0.313s
•ThreadTest(1000000)
  ST: 2009948, MT: 1146113; speed up factor: 1.75; total time= 3.16s
```

As you can see, when there is sufficient work to be done, the speed up factor approaches the theoretical maximum of 2 for dual processors.

Now on the same computer but booting into Windows XP Pro:

```
•ThreadTest(100)
  ST: 245, MT: 523; speed up factor: 0.468; total time= 0.000776s
•ThreadTest(100)
  ST: 399, MT: 247; speed up factor: 1.61; total time= 0.000655s
•ThreadTest(1000)
  ST: 3526, MT: 1148; speed up factor: 3.07; total time= 0.00468s
•ThreadTest(10000)
  ST: 34830, MT: 10467; speed up factor: 3.33; total time= 0.0453s
•ThreadTest(100000)
  ST: 350253, MT: 99298; speed up factor: 3.53; total time= 0.45s
•ThreadTest(1000000)
  ST: 2837645, MT: 1057275; speed up factor: 2.68; total time= 3.89s
```

So, what is happening here? The speed-up factors for Windows XP are greater than for Mac OS X, but mostly because the ST version is much slower. We do not known why the ST version runs more slowly — the Benchmark 2.01 example experiment shows similar values for OS X vs. XP on this same computer.

Parallel Processing - Thread-at-a-Time Method

In the previous section, we dispatched a group of threads, waited for them to all finish, and then dispatched another group of threads. Using that technique, a slow thread in the group would cause all of the group's threads to wait.

In this section, we dispatch a thread anytime there is a free thread in the group. This technique requires Igor Pro 6.23 or later.

The only thing that changes from the preceding example is that the MTFillWave function is replaced with this MTFillWaveThreadAtATime function:

```
Function MTFillWaveThreadAtATime(dest)
   WAVE dest

   Variable ncol= DimSize(dest,1)
   Variable col,nthreads= ThreadProcessorCount
   Variable threadGroupID= ThreadGroupCreate(nthreads)
   Variable dummy

   for(col=0; col<ncol; col+=1)
      // Get index of a free thread - Requires Igor Pro 6.23 or later
      Variable threadIndex = ThreadGroupWait(threadGroupID,-2) - 1
      if (threadIndex < 0)
         dummy = ThreadGroupWait(threadGroupID, 50)// Let threads run a while
         col -= 1                   // Try again for the same column
         continue                   // No free threads yet
      endif
      ThreadStart threadGroupID, threadIndex, MyWorkerFunc(dest,col)
   endfor

   // Wait for all threads to finish
   do
      Variable threadGroupStatus = ThreadGroupWait(threadGroupID,100)
   while(threadGroupStatus != 0)

   dummy = ThreadGroupRelease(threadGroupID)
End
```

The ThreadGroupWait statement suspends the main thread for a while so that the preemptive threads get more processor time. The parameter 50 is the number of milliseconds to wait. You should tune this for your application.

Input/Output Queues

In this example, data folders containing a data wave and a string variable that specifies the task to be performed are created and posted to the thread group's input queue. The thread worker function waits for an input data folder to become available. It then processes the input and posts an output data folder to the thread group's output queue from which it is retrieved by the main thread.

```
ThreadSafe Function MyWorkerFunc()
   do
      do
         DFREF dfr = ThreadGroupGetDFR(0,1000)// Get free data folder from input queue
         if (DataFolderRefStatus(dfr) == 0)
            if( GetRTError(2) ) // New in 6.20 to allow this distinction:
               Print "worker closing down due to group release"
            else
               Print "worker thread still waiting for input queue"
            endif
         else
            break
         endif
      while(1)

      SVAR todo = dfr:todo
      WAVE jack = dfr:jack

      NewDataFolder/S outDF

      Duplicate jack,outw // WARNING: outw must be cleared. See WAVEClear below
      String/G did= todo
      if( CmpStr(todo,"sin") )
         outw= sin(outw)
      else
         outw= cos(outw)
      endif
      // Clear outw so Duplicate above does not try to use it and to allow
      // ThreadGroupPutDF to succeed.
      WAVEClear outw

      ThreadGroupPutDF 0,:   // Put current data folder in output queue

      KillDataFolder dfr     // We are done with the input data folder
   while(1)

   return 0
End

Function DemoThreadQueue()
   Variable i,ntries= 5,nthreads= 2

   Variable threadGroupID = ThreadGroupCreate(nthreads)

   for(i=0;i<nthreads;i+=1)
      ThreadStart threadGroupID,i,MyWorkerFunc()
   endfor

   for(i=0;i<ntries;i+=1)
      NewDataFolder/S forThread
      String/G todo
      if( mod(i,3) == 0 )
         todo= "sin"
      else
         todo= "cos"
      endif
      Make/N= 5 jack= x + gnoise(0.1)

      WAVEClear jack

      ThreadGroupPutDF threadGroupID,: // Send current data folder to input queue
   endfor

   for(i=0;i<ntries;i+=1)
      do
         // Get results in free data folder
         DFREF dfr= ThreadGroupGetDFR(threadGroupID,1000)
         if ( DatafolderRefStatus(dfr) == 0 )
            Print "Main still waiting for worker thread results."
         else
            break
         endif
      while(1)

      SVAR did = dfr:did
      WAVE outw = dfr:outw

      Print "task= ",did,"results= ",outw

      // The next two statements are not really needed as the same action
      // will happen the next time through the loop or, for the last iteration,
      // when this function returns.
      WAVEClear outw      // Redundant because of the WAVE statement above
      KillDataFolder dfr  // Redundant because dfr refers to a free data folder
   endfor

   // This terminates the MyWorkerFunc by setting an abort flag
   Variable tstatus= ThreadGroupRelease(threadGroupID)
   if( tstatus == -2 )
      Print "Thread would not quit normally, had to force kill it. Restart Igor."
   endif
End
```

Typical output:

```
•DemoThreadQueue()
   task=   sin  results=
outw[0]= {0.994567,0.660904,-0.516692,-0.996884,-0.63106}
   task=   cos  results=
outw[0]= {0.0786631,0.709576,0.873524,0.0586175,-0.718122}
   task=   cos  results=
outw[0]= {-0.23686,0.848603,0.871922,0.0992451,-0.856209}
   task=   sin  results=
outw[0]= {0.999734,0.531563,-0.172071,-0.931296,-0.750942}
   task=   cos  results=
outw[0]= {-0.166893,0.767707,0.925874,0.114511,-0.662994}
   worker closing down due to group release
   worker closing down due to group release
```

Parallel Processing With Large Datasets

In the preceding section we synthesized the input data. In the real-world, your input data would most-likely be in an existing wave and you would have to copy it to a data folder to put into the input queue.

If your input data is very large, for example, a 3D stack of images, copying would require too much memory. In that case, a good choice is to pass the input directly to the thread using parameters to the thread worker function and use the output queue to return output to the main thread.

To do this you can use the **Parallel Processing - Thread-at-a-Time Method** and the output queue to return results.

Preemptive Background Task

In this example, we create a single worker thread that runs while the user does other things. A normal cooperative background task retrieves results from the preemptive thread. Although the background task will sometimes be blocked (as described in **Background Tasks** on page IV-319) the preemptive worker thread will always be running or waiting for data.

Another example of this kind of multitasking can be found in the “Slow Data Acq” demo experiment referenced under **More Multitasking Examples** on page IV-339.

In some cases, it may be possible to run two instances of Igor instead of using a preemptive background task. Running two instances is far simpler, so use that approach if it is feasible.

We put the code for the background tasks in an independent module (see **The IndependentModule Pragma** on page IV-55) so that the user can recompile procedures, which is done automatically when a recreation macro is created, without stopping the background task.

You might use a preemptive background task is when you have lengthy computations but want to continue to do other things, such as creating graphics for publication. Although you can do anything you want while the task runs in the experiment, if you load a different experiment, the thread is killed.

For this example, our “lengthy computation” is simply creating a wave of sine values which is not lengthy at all and consequently there is no reason for using a preemptive thread in this case. To simulate a lengthy computation, the code delays for a few seconds before posting its results.

The named background task checks the output queue every 10 ticks, when it is not blocked, and updates a graph with data retrieved from the queue.

Independent modules can not be defined in the built-in procedure window so paste the following code in a new procedure window:

```
#pragma IndependentModule= PreemptiveExample

ThreadSafe Function MyWorkerFunc()
   do
      DFREF dfr = ThreadGroupGetDFR(0,inf)
      if( DataFolderRefStatus(dfr) == 0 )
         return -1                // Thread is being killed
      endif

      WAVE frequencies = dfr:frequencies    // Array of frequencies to calculate
      Variable i, n= numpnts(frequencies)

      for(i=0;i<n;i+=1)
         NewDataFolder/S resultsDF
         Make jack= sin(frequencies[i]*x)
         Variable t0= ticks
         do
            // waste cpu for a few seconds
         while(ticks < (t0+120))

         // ThreadGroupPutDF requires that no waves in the data folder be referenced
         WAVEClear jack

         ThreadGroupPutDF 0,:              // Send current data folder to input queue
      endfor

      KillDataFolder dfr      // We are done with the input data folder
   while(1)

   return 0
End

Function DisplayResults(s)     // Called from cooperative background task
   STRUCT WMBackgroundStruct &s

   DFREF dfSav= GetDataFolderDFR()

   SetDataFolder root:testdf
   NVAR threadGroupID
   DFREF dfr = ThreadGroupGetDFR(threadGroupID,0) // Get free data folder from queue
   if( DataFolderRefStatus(dfr) != 0 )
      // Make free data folder a regular data folder in root:testdf
      MoveDataFolder dfr, :

   // Give data folder a unique name
      String dfName = UniqueName("Results", 11, 0)
      RenameDataFolder dfr, $dfName

      WAVE jack = dfr:jack       // This is the output from the thread
      AppendToGraph/W=ThreadResultsGraph jack
   endif

   SetDataFolder dfSav
   return 0
End
```

And put this in the main procedure window:

```
Function DemoPreemptiveBackgroundTask()
   DFREF dfSav= GetDataFolderDFR()

   NewDataFolder/O/S root:testdf // thread group ID and result datafolders go here

   Variable/G threadGroupID= ThreadGroupCreate(1)

   ThreadStart threadGroupID,0,PreemptiveExample#MyWorkerFunc()

   // MyWorkerFunc is now running and waiting for input data
   // now, let's give it something to do
   NewDataFolder/S tasks
   Make/N=10 frequencies= 1/(10+p/2+enoise(0.2))// array of frequencies to calculate
   WAVEClear frequencies

   ThreadGroupPutDF threadGroupID,:        // thread is now crunching away

   // Results will be appended to this graph
   Display /N=ThreadResultsGraph as "Thread Results"

   // ...by this named task
   CtrlNamedBackground ThreadResultsTask,period=10,proc=PreemptiveExample#DisplayResults,start

   SetDataFolder dfSav     // restore current df
End

Function PostMoreFreqs()
   NVAR threadGroupID = root:testdf:threadGroupID

   NewDataFolder/S moretasks
   Make/N=50 frequencies= 1/(15+p/2+enoise(0.2))  // array of frequencies to calculate
   WAVEClear frequencies

   ThreadGroupPutDF threadGroupID,:               // thread continues crunching
End
```

Open the Data Browser and then, on the command line, execute:

```
DemoPreemptiveBackgroundTask()
```

After the action stops, send more tasks to the background thread by executing

```
PostMoreFreqs()
```

While this is running, experiment with creating graphs, using dialogs, creating functions, etc. Note that both tasks run indefinitely.

To start over you need to stop the preemptive background task, stop the named background task, kill the graph, and delete the data. This function, which you can paste into the main procedure window, will do it.

```
Function StopDemo()
   NVAR threadGroupID = root:testdf:threadGroupID

   // Stop preemptive thread
   Variable status = ThreadGroupRelease(threadGroupID)

   // Stop named background task
   CtrlNamedBackground ThreadResultsTask, stop

   // Kill graph
   DoWindow /K ThreadResultsGraph

   // Kill data
   KillDataFolder root:testdf
End
```

Aborting Threads

If a procedure abort occurs, via a user abort or a programmed abort (see **Aborting Functions** on page IV-112), we would like all pre-emptive threads to stop running. In most cases, this is not something you need to worry about because the threads, by the nature of what they are doing, are guaranteed to stop in a relatively short period of time. It becomes an issue for threads that can run for arbitrarily long periods of time. In such cases, it is a good idea to handle the abort as explained in this section.

To signal running pre-emptive threads to stop, the thread-coordinating function, running in the main thread, must detect the abort and call ThreadGroupRelease. ThreadGroupRelease signals the pre-emptive threads to quit. For example:

```
// A thread worker function that may take a long time
ThreadSafe Function ThreadWorkerFunc(threadNumber, numWaves, numPoints)
   Variable threadNumber, numWaves, numPoints

   Printf "Thread worker %d starting\r", threadNumber

   try
      int i
      for(i=0; i<numWaves; i+=1)
         Make/FREE/N=(numPoints) junk=gnoise(1) // Busy work to take up time
      endfor
   catch
      // ThreadGroupRelease, called from the main thread,
      // causes this catch block to execute
      Printf "Thread worker %d aborted after %d iterations\r", threadNumber, i
      return -1
   endtry

   Printf "Thread worker %d quitting normally\r", threadNumber
   return 0
End

Function ThreadCoordinatingFunction(numThreads, numWaves, numPoints)
   int numThreads, numWaves, numPoints    // Runs in main thread
   Variable timerRefNum = StartMSTimer
   Variable elapsedTime

   Variable threadGroupID = ThreadGroupCreate(numThreads)

   // Start all threads
   int i
   for(i=0; i<numThreads; i+=1)
      ThreadStart threadGroupID, i, ThreadWorkerFunc(i, numWaves, numPoints)
   endfor

   // Wait for threads to finish or for abort to occur
   Variable threadGroupResult
   try
      do
         Variable threadGroupStatus = ThreadGroupWait(threadGroupID,100)
         DoUpdate // Needed for Printf output from worker to appear in history
      while(threadGroupStatus != 0)
   catch
      // If a user or programmed abort occurs, this executes and stops threads
      elapsedTime = StopMSTimer(timerRefNum) / 1E6       // In seconds
      Printf "Aborted after %g seconds\r", elapsedTime
      DoUpdate // Needed for Printf output from worker to appear in history

      // Signal running threads to stop
      threadGroupResult = ThreadGroupRelease(threadGroupID)
      return -1
   endtry

   // Here if threads ran to normal completion
   threadGroupResult = ThreadGroupRelease(threadGroupID)
   elapsedTime = StopMSTimer(timerRefNum) / 1E6    // In seconds
   Printf "ThreadCoordinatingFunction completed in %g seconds\r", elapsedTime
   return threadGroupResult
End
```

To try this example, execute this from the command line:

```
ThreadCoordinatingFunction(5, 1E3, 1E5)   // Completes in about 25 seconds
```

After about 25 seconds, it completes normally. If you click the Abort button in Igor's status bar, the code in the catch block runs. The ThreadGroupRelease call in the catch block signals running threads to quit. After a short period of time, all threads have quit and the coordinating function returns.

If Igor signals a thread to quit but it fails to do so, Igor forces the thread to quit.

Aborting Threads Gracefully

When an abort occurs, whether initiated by the user (see **User Abort Key Combinations** on page IV-51) or programmatically using the **AbortOnValue**, **AbortOnRTE** or **Abort** operations, Igor sets an internal per-thread abort flag. The abort flag causes Igor to short-circuit loops and subroutine calls so that the function to be aborted finishes quickly.

If a thread worker function needs to run cleanup code in the event of an abort then the it must include a try-catch-endtry block (see **try-catch-endtry Flow Control**). This section explains what you must do to enable the catch code to run without interference.

By default, ThreadGroupRelease attempts to stop running threads by marking them with an unclearable abort flag. "Unclearable" means that, if a thread worker function has a catch block, when the abort flag is set, the catch block is called but the abort is still in effect which interferes with the code in the catch block.

As of Igor Pro 9, you can provide the optional beGraceful flag when calling ThreadGroupRelease. If you specify beGraceful=1, ThreadGroupRelease sets a clearable abort flag. "Clearable" means that, if a thread worker function has a catch block, the abort flag is cleared when the catch block is called. This allows code in the catch block to execute without interference. The catch block must include a return statement so that the thread worker function returns.

The interaction between Igor and threads when an abort occurs is complex. You don't need to understand more that is explained in the preceding paragraphs of this section. Advanced programmers who want to understand the details can find them in the Threads and Aborts example experiment.

More Multitasking Examples

More multitasking examples can be found in the following example experiments:

The Multithreaded LoadWave demo experiment in “Igor Pro Folder/Examples/Programming”.

The Multithreaded Mandelbrot demo experiment in “Igor Pro Folder/Examples/Programming”.

The Multiple Fits in Threads demo experiment in “Igor Pro Folder/Examples/Curve Fitting”.

The Slow Data Acq demo experiment in “Igor Pro Folder/Examples/Programming”.

The Thread-at-a-Time demo experiment in “Igor Pro Folder/Examples/Programming”.

Cursors — Moving Cursor Calls Function

You can write a hook function which Igor calls whenever a cursor is moved.

Graph-Specific Cursor Moved Hook

The preferred way to do this is to use SetWindow to designate a window hook function for a specific graph window (see **Window Hook Functions** on page IV-293). In your window hook function, look for the cursormoved event. Your hook function receives a **WMWinHookStruct** structure containing fields that describe the cursor and its properties.

For a demo of this technique, choose File→Example Experiments→Techniques→Cursor Moved Hook Demo.

Global Cursor Moved Hook

This section describes an old technique in which you create a hook function that is called any time a cursor is moved in any graph. This technique is more difficult to implement and kludgy, so it is no longer recommended.

You can write a hook function named CursorMovedHook. Igor automatically calls it whenever any cursor is moved in any graph, unless Option (*Macintosh*) or Alt (*Windows*) is pressed.

The CursorMovedHook function takes one string argument containing information about the graph, trace or image, and cursor in the following format:

```
GRAPH:graphName;CURSOR:<A - J>;TNAME:traceName; MODIFIERS:modifierNum;
ISFREE:freeNum;POINT:xPointNumber; [YPOINT:yPointNumber;]
```

The *traceName* value is the name of the graph trace or image to which the cursor is attached.

The *modifierNum* value represents the state of some of the keyboard keys summed together:

1 If Command (*Macintosh*) or Ctrl (*Windows*) is pressed.

2 If Control (*Macintosh only*) is pressed.

4 If Shift is pressed.

8 If Caps Lock is pressed.

The Option key (*Macintosh*) or Alt key (*Windows*) is not represented because it prevents the hook from being called.

The YPOINT keyword and value are present only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot or when the cursor is free.

If cursor is free, POINT and YPOINT values are fractional relative positions (see description in **Cursor** operation on page V-121). If TNAME is empty, fields POINT, ISFREE and YPOINT are not present.

This example hook function simply prints the information in the history area:

```
Function CursorMovedHook(info)
   String info
   Print info
End
```

Whenever any cursor on any graph is moved, this CursorMovedHook function will print something like the following in the history area:

```
GRAPH:Graph0;CURSOR:A;TNAME:jack;MODIFIERS:0;ISFREE:0;POINT:6;
```

Cursor Globals

On older technique involving globals named S_CursorAInfo and S_CursorBInfo is no longer recommended. For details, see the “Cursor Globals” subtopic in the Igor6 help files.

Profiling Igor Procedures

You can find bottlenecks in your procedures using profiling.

Profiling is supported by the FunctionProfiling.ipf file. To use it, add this to your procedures:

```
#include <FunctionProfiling
```

Then choose Windows→Procedures→FunctionProfiling.ipf and read the instructions in the file.

Crashes

A crash results from a software bug and prevents a program from continuing to run. Crashes are highly annoying at best and, at worst, can cause you to lose valuable work.

WaveMetrics uses careful programming practices and extensive testing to make Igor as reliable and bug-free as we can. However in Igor as in any complex piece of software it is impossible to exterminate all bugs. Also, crashes can sometimes occur in Igor because of bugs in other software, such as printer drivers, video drivers or system extensions.

We are committed to keeping Igor a solid and reliable program. If you experience a crash, we would like to know about it.

When reporting a crash to WaveMetrics, please start by choosing Help-Contact Support. This provides us with important information such as your Igor version and your OS version.

Please include the following in your report:

- A description of what actions preceded the crash and whether it is reproducible.
- A recipe for reproducing the crash, if possible.
- A crash log (described below), if possible.

In most cases, to fix a crash, we need to be able to reproduce it.

Crash Logs on Mac OS X

When a crash occurs on Mac OS X, most of the time the system is able to generate a crash log. You can usually find it at:

```
/Users/<user>/Library/Logs/DiagnosticReports/Igor Pro_<date>_<machinename>.crash
```

where <user> is your user name.

The /Users/<user>/Library folder is hidden. To reveal the DiagnosticReports folder:

1. Choose Finder->Go to Folder
2. Enter ~/Library/Logs/DiagnosticReports
3. Click Go

Send this log as an attachment when reporting a crash.

Crashes On Windows

When a crash occurs on Windows, Igor attempts to write a crash report that may help WaveMetrics determine and fix the cause of the crash. If Igor is able to write a crash report, it displays a dialog showing the location of the crash report on disk. The location is in your Igor preferences folder and will be something like:

```
C:\Users\<user>\AppData\Roaming\WaveMetrics\Igor Pro 8\Diagnostics\Igor Crash Reports.txt
```

If the "Igor Crash Reports.txt" file already exists when a crash occurs, Igor appends a new report to the existing file.

Igor may also write a minidump file to the same folder. A minidump file, which has a ".dmp" extension, contains additional information about the crash. There will typically be one minidump file for each crash.

When a crash occurs, Igor attempts to open the Diagnostics folder on your desktop to make it easy for you to find the report and minidump files.

Please send the "Igor Crash Reports.txt" file, along with the minidump files related to the current crash, as email attachments to WaveMetrics support. If possible, include instructions for reproducing the crash and any other details that may help us understand what you were doing leading to the crash.

Once the problem has been resolved, if you want to reduce clutter and reclaim disk space, you can delete the Diagnostics folder and its contents. Igor will recreate the folder if necessary.

There may be cases where Igor is not able to write a crash report. This would happen if a library, security software or the operating system has overridden Igor's crash handler for some reason.

Igor Reference

This volume contains detailed information about Igor Pro’s built-in operations, functions, and keywords. They are listed alphabetically after the category sections that follow.

External operations (XOPs) and external functions (XFUNCs) are not covered here. For information about them, use the Command Help tab of the Igor Help Browser.

Built-In Operations by Category

Note: Some operations may appear in more than one category.

Alphabetic Listing of Functions, Operations and Keywords

This section alphabetically lists all built-in functions, operations and keywords. Much of this information is also accessible online in the Command Help tab of the Igor Help Browser.

External operations (XOPs) and external functions (XFUNCs) are not covered here. For information about them, use the Command Help tab of the Igor Help Browser and the XOP help file in the same folder as the XOP file.

Reference Syntax Guide

In the descriptions of functions and operations that follow, italics indicate parameters for which you can supply numeric or string expressions. Non-italic keywords must be entered literally as they appear. Commas, slashes, braces and parentheses in these descriptions are always literals. Brackets surround optional flags or parameters. Ellipses (…) indicate that the preceding element may be repeated a number of times.

Italicized parameters represent values you supply. Italic words ending with "*Name*" are names (wave names, for example), and those ending with "*Str*" are strings. Italic words ending with "*Spec*" (meaning "specification") are usually further defined in the description. If none of these endings are employed, the italic word is a numeric expression, such as a literal number, the name of a variable or function, or some valid combination.

Strings and names are different, but you can use a string where a name is expected using "string substitution": precede a string expression with the $ operator. See **String Substitution Using $** on page IV-18.

A syntax description may span several lines, but the actual command you create must occupy a single line.

Many operations have optional "flags". Flags that accept a value (such as the Make operation's /N=*n* flag) sometimes require additional parentheses. For example:

```
Make/N=1 aNewWave
```

is acceptable because here *n* is the literal "1". To use a numeric expression (anything other than a literal number) for *n*, parentheses are needed:

```
Make/N=(numberOfPoints) aNewWave              // error if no parentheses!
```

For more about using functions, operations and keywords, see Chapter IV-1, **Working with Commands**, Chapter IV-2, **Programming Overview**, and Chapter IV-10, **Advanced Topics**.

#define

```
#define symbol
```

The #define statement is a conditional compilation directive that defines a *symbol* for use only with #ifdef or #ifndef expressions. #undef removes the definition.

Details

The defined *symbol* exists only in the file where it is defined; the only exception is in the main procedure window where the scope covers all other procedures except independent modules. See **Conditional Compilation** on page IV-108 for information on defining a global *symbol*.

#define cannot be combined inline with other conditional compilation directives.

See Also

The #**undef**, #**ifdef**-#**endif**, and #**ifndef**-#**endif** statements.

Conditional Compilation on page IV-108.

#if-#elif-#endif

```
#if expression1
   <TRUE part 1>
#elif expression2
   <TRUE part 2>
[…]
[#else
   <FALSE part>]
#endif
```

In a #if-#elif-#endif conditional compilation statement, when an expression evaluates as TRUE (absolute value > 0.5), then only code corresponding to the TRUE part of that expression is compiled, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then *FALSE part* is compiled when present.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

See Also

Conditional Compilation on page IV-108 for more usage details.

#if-#endif

```
#if expression
   <TRUE part>
[#else
   <FALSE part>]
#endif
```

A #if-#endif conditional compilation statement evaluates *expression*. If *expression* is TRUE (absolute value > 0.5) then the code in *TRUE part* is compiled, or if FALSE (zero) then the optional *FALSE part* is compiled.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

See Also

Conditional Compilation on page IV-108 for more usage details.

#ifdef-#endif

```
#ifdef symbol
   <TRUE part>
[#else
   <FALSE part>]
#endif
```

A #ifdef-#endif conditional compilation statement evaluates *symbol*. When *symbol* is defined the code in *TRUE part* is compiled, or if undefined then the optional *FALSE part* is compiled.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

symbol must be defined before the conditional with #define.

See Also

The #**define** statement and **Conditional Compilation** on page IV-108 for more usage details.

#ifndef-#endif

```
#ifndef symbol
   <TRUE part>
[#else
   <FALSE part>]
#endif
```

An #ifndef-#endif conditional compilation statement evaluates *symbol*. When *symbol* is undefined the code in *TRUE part* is compiled, or if defined then the optional *FALSE part* is compiled.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

symbol must be defined before the conditional with #define.

See Also

The #**define** statement and **Conditional Compilation** on page IV-108 for more usage details.

#include

```
#include "file spec" or <file spec>
```

A #include statement in a procedure file automatically opens another procedure file. You should use #include in any procedure file that you write if it requires that another procedure file be open. A #include statement must always appear flush against the left margin in a procedure window.

Parameters

The ".ipf" extension must be omitted from both "*file spec*" and <*file spec*>.

The <*file spec*> syntax is used to include a WaveMetrics procedure file in "Igor Pro Folder/WaveMetrics Procedures". *file spec* is the name of the procedure file without the extension.

The "*file spec*" syntax is used to include a user procedure file typically in "Igor Pro User Files/User Procedures". If *file spec* is the name of or a partial path to the file, Igor interprets it as relative to the "User Procedures" folder. If *file spec* is a full path then it specifies the exact path to the file without the extension.

See Also

The Include Statement on page IV-166 for usage details.

Igor Pro User Files on page II-31.

#pragma

```
#pragma pragmaName = value
```

#pragma introduces a compiler directive, which is a message to the Igor procedure compiler. A #pragma statement must always appear flush against the left margin in a procedure window.

Igor ignores unknown pragmas such as pragmas introduced in later versions of the program.

Currently Igor supports the following pragmas:

```
#pragma rtGlobals = value
#pragma version = versionNumber
#pragma IgorVersion = versionNumber
#pragma hide = value
#pragma ModuleName = name
#pragma IndependentModule = name
#pragma rtFunctionErrors = value
#pragma TextEncoding = "textEncodingName"  // Igor Pro 7.00
#pragma DefaultTab = {<mode>,<width in points>,<width in spaces>} // Igor Pro 9.00
```

#undef

`#undef` ***`symbol`***

A #undef statement removes a nonglobal *symbol* created previously by #define. See **Conditional Compilation** on page IV-108 for information on undefining a global *symbol.*

See Also

The #**define** statement and **Conditional Compilation** on page IV-108 for more usage details.

Abort

`Abort` `[`***`errorMessageStr`***`]`

The Abort operation aborts procedure execution.

Parameters

The optional *errorMessageStr* is a string expression, which, if present, specifies the message to be displayed in the error alert.

Details

Abort provides a way for a procedure to abort execution when it runs into an error condition.

See Also

Aborting Functions on page IV-112 , **Aborting Macros** on page IV-124, and **Flow Control for Aborts** on page IV-48. The **DoAlert** operation.

AbortOnRTE

`AbortOnRTE`

The AbortOnRTE flow control keyword raises an abort when a runtime error has occurred in a user-defined function.

AbortOnRTE should be used after a command that might give rise to a runtime error.

You can place AbortOnRTE immediately after a command that might give rise to a runtime error that you want to handle instead of allowing Igor to handle it by halting procedure execution. Use a **try-catch-endtry** block to catch the abort, if it occurs.

AbortOnRTE has very low overhead and should not significantly slow program execution.

Details

In terms of programming style, you should consider using AbortOnRTE (preceded by a semicolon) on the same line as the command that may give rise to an abort condition.

When using AbortOnRTE after a related sequence of commands, then it should be placed on its own line.

When used with try-catch-endtry, you should place a call to **GetRTError**(1) in your catch section to clear the runtime error.

Example

Abort if the wave does not exist:

```
WAVE someWave; AbortOnRTE
```

See Also

Flow Control for Aborts on page IV-48 and **AbortOnRTE Keyword** on page IV-49 for further details.

The **try-catch-endtry** flow control statement.

AbortOnValue

`AbortOnValue` ***`abortCondition`*****`,`** ***`abortCode`***

The AbortOnValue flow control keyword will abort function execution when the *abortCondition* is nonzero and it will then return the numeric *abortCode*. No dialog will be displayed when such an abort occurs.

Parameters

abortCondition can be any valid numeric expression using comparison or logical operators.

abortCode is a nonzero numeric value returned to any abort or error handling code by AbortOnValue whenever it causes an abort.

Details

When used with try-catch-endtry, you should place a call to **GetRTError**(1) in your catch section to clear the runtime error.

See Also

Flow Control for Aborts on page IV-48 and **AbortOnValue Keyword** on page IV-49 for further details.

The **AbortOnRTE** keyword and the **try-catch-endtry** flow control statement.

abs

`abs(`***`num`*****`)`**

The abs function returns the absolute value of the real number *num*. To calculate the absolute value of a complex number, use the cabs function.

See Also

The **cabs** function.

acos

`acos(`***`num`*****`)`**

The acos function returns the inverse cosine of *num* in radians in the range [0,π].

In complex expressions, *num* is complex and acos returns a complex value.

See Also

cos

acosh

`acosh(`***`num`*****`)`**

The acosh function returns the inverse hyperbolic cosine of *num*. In complex expressions, *num* is complex and acosh returns a complex value.

AddFIFOData

`AddFIFOData` *`FIFOName`*`,` *`FIFO_channelExpr`* `[,` *`FIFO_channelExpr`*`]`...

The AddFIFOData operation evaluates *FIFO_channelExpr* expressions as double precision floating point and places the resulting values into the named FIFO.

Details

There must be one *FIFO_channelExpr* for each channel in the FIFO.

See Also

FIFOs are used for data acquisition. See **FIFOs and Charts** on page IV-313.

Other operations used with FIFOs: **NewFIFO**, **NewFIFOChan**, **CtrlFIFO**, and **FIFOStatus**.

AddFIFOVectData

`AddFIFOVectData` *`FIFOName`*`,` *`FIFO_channelKeyExpr`* `[,` *`FIFO_channelKeyExpr`*`]`...

The AddFIFOVectData operation is similar to AddFIFOData except the expressions use a keyword to allow either a single numeric value for a normal channel or a wave containing the data for a special image vector channel.

Details

There must be one *FIFO_channelKeyExpr* for each channel in the FIFO.

A *FIFO_channelKeyExpr* may be one of:

```
num = numericExpression
vect = wave
```

For best results, the wave should have the same number of points as used to define the FIFO channel and the same number type. See the **NewFIFOChan** operation.

See Also

FIFOs and Charts on page IV-313.

AddListItem

`AddListItem(`*`itemStr`*`,` *`listStr`* `[,` *`listSepStr`* `[,` *`itemNum`*`]])`

The AddListItem function returns *listStr* after adding *itemStr* to it. *listStr* should contain items separated by *listSepStr*, such as "abc;def;".

Use AddListItem to add an item to a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like **TraceNameList** or **AnnotationList**, or to a line from a delimited text file.

listSepStr and *itemNum* are optional; their defaults are ";" and 0, respectively.

Details

By default *itemStr* is added to the start of the list. Use the optional list index *itemNum* to add *itemStr* at a different location. The returned list will have *itemStr* at the index *itemNum* or at ItemsInList(*returnedListStr*)-1 when *itemNum* equals or exceeds ItemsInList(*listStr*).

itemNum can be any value from -infinity (`-Inf`) to infinity (`Inf`). Values from -infinity to 0 prepend *itemStr* to the list, and values from ItemsInList(*listStr*) to infinity append *itemStr* to the list.

itemStr may be `""`, in which case an empty item (consisting of only a separator) is added.

If *listSepStr* is `""`, then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case an empty string (`""`) is returned).

listStr is treated as if it ends with a *listSepStr* even if it doesn't.

In Igor6, only the first byte of *listSepStr* was used. In Igor7 and later, all bytes are used.

Examples

```
Print AddListItem("hello","kitty;cat;")        // prints "hello;kitty;cat;"
Print AddListItem("z", "b,c,", ",", 1)         // prints "b,z,c,"
Print AddListItem("z", "b,c,", ",", 999)       // prints "b,c,z,"
Print AddListItem("z", "b,c,", ",", Inf)       // prints "b,c,z,"
Print AddListItem("", "b-c-", "-")             // prints "-b-c-"
```

See Also

The **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveFromList**, **RemoveListItem**, **StringFromList**, **StringList**, **TraceNameList**, **VariableList**, and **WaveList** functions.

AddMovieAudio

`AddMovieAudio` ***`soundWave`***

The AddMovieAudio operation adds audio samples to the audio track of the currently open movie.

In Igor Pro 7.00 and later, this operation is not supported on Macintosh.

Parameters

soundWave contains audio samples with an amplitude from -128 to +127 and with the same time scale as the prototype *soundWave* used to open the movie.

Flags

/Z	Suppresses error reporting. If you use /Z, check the V_Flag output variable to see if the operation succeeded.

Details

You can create movies with 16-bit and stereo sound by providing a sound wave in the appropriate format. To specify 16-bit sound, the wave type must be signed 16-bit integer (/W flag in **Make** or **Redimension**). To specify stereo, use a wave with two columns (or any other number of channels as desired).

Output Variables

`V_Flag`	Set to 0 if the operation succeeded or to a non-zero error code. V_Flag is set only if you use the /Z flag.

See Also

Movies on page IV-245, **NewMovie**, **AddMovieFrame**

AddMovieFrame

`AddMovieFrame [/PICT=`*`pictName`*`]`

The AddMovieFrame operation adds the top graph, page layout, Gizmo window, or the specified picture to the currently open movie.

Support for page layout and Gizmo windows was added in Igor Pro 7.00.

When you write a procedure to generate a movie, you need to call the **DoUpdate** operation after all modifications to the target window and before calling AddMovieFrame. This allows Igor to process any changes you have made to the window.

In Igor7 or later, the target window at the time you call NewMovie is remembered and is used by AddMovieFrame even if it is not the target window when you call AddMovieFrame.

If the /PICT flag is provided, then the specified picture from the picture gallery (see **Pictures** on page III-509) is used in place of the target window.

Flags

/Z	Suppresses error reporting. If you use /Z, check the V_Flag output variable to see if the operation succeeded.

Output Variables

`V_Flag`	Set to 0 if the operation succeeded or to a non-zero error code. V_Flag is set only if you use the /Z flag.

See Also

Movies on page IV-245, **NewMovie**, **AddMovieAudio**

AddWavesToBoxPlot

```
AddWavesToBoxPlot [/W=winName /T=traceName /INST=traceInstance] wave [, wave ]
    . . .
```

Adds additional 1D waves to a pre-existing box plot trace created by AppendBoxPlot.

AddWavesToBoxPlot was added in Igor Pro 8.00.

Because a box plot trace may require a number of waves to define each data set in the trace, and because wave names may be quite long, the AddWavesToBoxPlot operation is provided to add waves to a list begun by AppendBoxPlot.

Flags

/T=*traceName*

/INST=*traceInstance* These flags specify the name and instance number of an existing box plot trace to which waves will be added. You can use /T without /INST, in which case a trace with instance number zero will be used. Do not use /INST without /T.

See **Creating Graphs** on page II-277 for information about trace names and trace instance numbers.

In the absence of both /T and /INST, the default is to use the top box plot trace found on the graph. That would be the most recently added box plot trace.

/W=*winName* Appends to the named graph window or subwindow. When omitted, AddWavesToBoxPlot operates on the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

If your original AppendBoxPlot command included an X wave, the total number of waves in the list of box plot data set waves cannot be greater than the number of points in your X wave.

If the box plot trace is defined by a multicolumn wave, you cannot add additional waves using this operation.

See Also

Box Plots on page II-331, **AppendBoxPlot**, **ModifyBoxPlot**

AddWavesToViolinPlot

```
AddWavesToViolinPlot [/W=winName /T=traceName /INST=traceInstance] wave [, wave
    ] . . .
```

Adds additional 1D waves to a pre-existing violin plot trace created by AppendViolinPlot.

AddWavesToViolinPlot was added in Igor Pro 8.00.

Because a violin plot trace may require a number of waves to define each data set in the trace, and because wave names may be quite long, the AddWavesToViolinPlot operation is provided to add waves to a list begun by AppendViolinPlot.

Flags

/T=*traceName*

/INST=*traceInstance*	These flags specify the name and instance number of an existing violin plot trace to which waves will be added. You can use /T without /INST, in which case a trace with instance number zero will be used. Do not use /INST without /T. See **Creating Graphs** on page II-277 for information about trace names and trace instance numbers. In the absence of both /T and /INST, the default is to use the top violin plot trace found on the graph. That would be the most recently added violin plot trace.
/W=*winName*	Appends to the named graph window or subwindow. When omitted, AppendViolinPlot operates on the active window or subwindow. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

If your original AppendViolinPlot command included an X wave, the total number of waves in the violin plot trace cannot be greater than the number of points in your X wave.

If the violin plot trace is defined by a multicolumn wave, you cannot add additional waves using this operation.

See Also

Violin Plots on page II-337, **AppendViolinPlot**, **ModifyViolinPlot**

AdoptFiles

AdoptFiles [***flags***]

The AdoptFiles operation adopts external files and waves into the current experiment.

When the experiment is next saved, the files and waves are saved in the experiment file for a packed experiment or in the experiment folder for an unpacked experiment. References to the external files are eliminated.

AdoptFiles cannot be called from a function except via Execute/P.

Flags

/A	Adopts all external notebooks and user procedure files and all waves in the experiment. WaveMetrics Procedure files are not adopted. /A is equivalent to /NB/UP/DF.
/DF	Adopts all waves saved external to the experiment.
/DF=*dataFolderPathStr*	Adopts all waves saved external to the experiment that are in the specified data folder.
/I	Shows the Adopt All dialog and adopts what the user selects there.
/NB	Adopts all external notebook files.
/UP	Adopts all external user procedure files.

/W=*winTitleOrName*	Adopts the specified notebook or procedure file. /W was added in Igor Pro 7.02.
	winTitleOrName is a name, not a string, so you construct /W like this:
	`/W=$"New Polar Graph.ipf"`
	or:
	`/W=Notebook0`
	When working with independent modules, *winTitleOrName* is a procedure window title followed by a space and, in brackets, an independent module name. See **Independent Modules** on page IV-238 for details.

/WP	Adopts all WaveMetrics Procedure procedure files.

/WV=*wave*	Adopts only the specified wave.

Details

Only files and waves saved external to the current experiment are adopted. See **References to Files and Folders** on page II-24 for a discussion of such standalone files.

The number of objects actually adopted is returned in V_Flag.

To adopt just one wave, use:

```
AdoptFiles/WV=wave
```

To adopt just one notebook or procedure window use AdoptFiles/W=*winTitleOrName*.

Command Line and Macro Examples

```
// Using AdoptFiles from the command line or from a macro
AdoptFiles/I                  // Show the Adopt All dialog.
AdoptFiles/A/WP               // Adopt everything that can be adopted.
AdoptFiles/DF/NB/UP/WP        // Adopt everything that can be adopted.
AdoptFiles/DF=root:subfolder  // Adopt any externally saved waves in root:subfolder.
AdoptFiles/W=$"Proc0.ipf"     // Adopt Proc0.ipf if it is saved externally.
AdoptFiles/WV=GetWavesDataFolder(wave0,2)   // Adopt wave0 if it is saved externally.
```

Function Examples

```
// Using AdoptFiles from a user-defined function - you must use Execute/P
Execute/P "AdoptFiles/A"         // Schedule adoption of all user files and waves
Execute/P "AdoptFiles/WV="+GetWavesDataFolder(w,2)    // Schedule adoption of wave w
```

See Also

Adopt All on page II-25, **Adopting Notebook and Procedure Files** on page II-25, **Avoiding Shared Igor Binary Wave Files** on page II-24, **Operation Queue** on page IV-278.

airyA

`airyA(`*`x`*`[, `*`accuracy`*`])`

The airyA function returns the value of the Airy $Ai(x)$ function:

$$Ai(x) = \frac{1}{\pi}\sqrt{\frac{x}{3}}K_{1/3}\left(\frac{2}{3}x^{3/2}\right),$$

where K is the modified Bessel function.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyAD** and **airyB** functions.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

airyAD

`airyAD(`*`x`*`[, `*`accuracy`*`])`

The airyAD function returns the value of the derivative of the Airy function.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyA** function.

airyB

airyB(*x* [, *accuracy*])

The airyB function returns the value of the Airy $Bi(x)$ function:

$$Bi(x)=\sqrt{\frac{x}{3}}\left[I_{-1/3}\left(\frac{2}{3}x^{3/2}\right)+I_{1/3}\left(\frac{2}{3}x^{3/2}\right)\right],$$

where I is the modified Bessel function.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyBD** and **airyA** functions.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

airyBD

airyBD(*x* [, *accuracy*])

The airyBD function returns the value of the derivative $Bi'(x)$ of the Airy function.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyB** function.

alog

alog(*num*)

The alog function returns 10^{num}.

AnnotationInfo

AnnotationInfo(*winNameStr*, *annotationNameStr* [, *options*])

The AnnotationInfo function returns a string containing a semicolon-separated list of information about the named annotation in the named graph or page layout window or subwindow.

The main purpose of AnnotationInfo is to use a tag or textbox as an input mechanism to a procedure. This is illustrated in the “Tags as Markers Demo” sample experiment, which includes handy utility functions (supplied by AnnotationInfo Procs.ipf).

Parameters

winNameStr can be `""` to refer to the top graph or layout window or subwindow.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

options is an optional parameter that controls the text formatting in the annotation output. The default value is 0.

Omit *options* or use 0 for *options* to escape the returned annotation text, which is appropriate for printing the output to the history or for using the text in an Execute operation.

Use 1 for *options* to not escape the returned annotation text because you intend to extract the text for use in a subsequent command such as Textbox or Tag.

Details

The string contains thirteen pieces of information. The first twelve pieces are prefaced by a keyword and colon and terminated with a semicolon. The last piece is the annotation text, which is prefaced with a keyword and a colon but is not terminated with a semicolon.

Keyword	Information Following Keyword
ABSX	X location, in points, of the anchor point of the annotation. For graphs, this is relative to the top-left corner of the graph window. For layouts, it is relative to the top-left corner of the page.
ABSY	Y location, in points, of the anchor point of the annotation. For graphs, this is relative to the top-left corner of the graph window. For layouts, it is relative to the top-left corner of the page.
ATTACHX	For tags, it is the X value of the wave at the point where the tag is attached, as specified with the Tag operation. For textboxes, color scales, and legends, this will be zero and has no meaning.
AXISX	X location of the anchor point of the annotation. For tags or color scales in graphs, it is in terms of the X axis against which the tagged wave is plotted. For textboxes and legends in graphs, it is in terms of the first X axis. For layouts, this has no meaning and is always zero.
AXISY	Y location of the anchor point of the annotation. For layouts, this has no meaning and is always zero. For tags or color scales in graphs, it is in terms of the Y axis against which the tagged wave is plotted. For textboxes and legends in graphs, it is in terms of the first Y axis.
AXISZ	Z value of the image or contour level trace to which the tag is attached or NaN if the trace is not a contour level trace or the annotation is not a tag.
COLORSCALE	Parameters used in a ColorScale operation to create the annotation.
FLAGS	Flags used in a Tag, Textbox, ColorScale, or Legend operation to create the annotation.
RECT	The outermost corners of the annotation (values are in points): RECT:*left*, *top*, *right*, *bottom*
TEXT	Text that defines the contents of the annotation or the main axis label of a color scale.
TYPE	Annotation type: “Tag”, “TextBox”, “ColorScale”, or “Legend”.
XWAVE	For tags, it is the name of the X wave in the XY pair to which the tag is attached. If the tag is attached to a single wave rather than an XY pair, this will be empty. For textboxes, color scales, and legends, this will be empty and has no meaning.
XWAVEDF	For tags, the full path to the data folder containing the X wave associated with the trace to which the tag is attached. For textboxes, color scales, and legends, this will be empty and has no meaning.
YWAVE	For tags, it is the name of the trace or image to which the tag is attached. See **ModifyGraph (traces)** and **Instance Notation** on page IV-20 for discussions of trace names and instance notation. For color scales, it is the name of the wave displayed in associated the contour plot, image plot, f(z) trace, or the name of the color scale’s cindex wave. For textboxes and legends, this will be empty and has no meaning.
YWAVEDF	Full path to the data folder containing the Y wave or blank if the annotation is not a tag or color scale.

AnnotationList

`AnnotationList(`*`winNameStr`*`)`

The AnnotationList function returns a semicolon-separated list of annotation names from the named graph or page layout window or subwindow.

Parameters

winNameStr can be `""` to refer to the top graph or layout window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

APMath

APMath [*flags*] *destStr* = *Expression*

The APMath operation provides arbitrary precision calculation of basic mathematical expressions. It converts the final result into the assigned string *destStr*, which can then be printed or used to represent a value (at the given precision) in another APMath operation.

Parameters

destStr	Specifies a destination string for the assignment expression. If *destStr* is not an existing variable, it is created by the operation. When executing in a function, *destStr* will be a local variable if it does not already exist.
Expression	Algebraic expression containing constants, local, global, and reference variables or strings, as well as wave elements together with the operators shown below.

APMath Operators

+	Scalar addition	Lowest precedence
-	Scalar subtraction	Lowest precedence
*	Scalar multiplication	Medium precedence
/	Scalar division	Medium precedence
^	Exponentiation	Highest precedence

APMath Functions on Scalar Parameters

The following functions are supported for arbitrary precision math on scalar parameters:

sqrt(*x*)	Square root of *x*.
cbrt(*x*)	Cube root of *x*.
pi	Value of π (without parentheses).
sin(*x*)	Sine of *x*.
cos(*x*)	Cosine of *x*.
tan(*x*)	Tangent of *x*.
asin(*x*)	Inverse sine of *x*.
acos(*x*)	Inverse cosine of *x*.
atan(x)	Inverse tangent of *x*.
atan2(*y*,*x*)	Inverse tangent of *y*/*x*.
log(*x*)	Logarithm of *x*.
log10(*x*)	Logarithm based 10 of *x*.
exp(*x*)	Exponential function e^*x*.
pow(*x*,*n*)	*x* to the power *n* (*n* not necessarily integer).
sinh(*x*)	Hyperbolic sine of *x*.
cosh(*x*)	Hyperbolic cosine of *x*.
tanh(*x*)	Hyperbolic tangent of *x*.
asinh(*x*)	Inverse hyperbolic sine of *x*.
acosh(*x*)	Inverse hyperbolic cosine of *x*.
atanh(*x*)	Inverse hyperbolic tangent of *x*.

`ceil(x)` Smallest integer larger than *x*.

`comp(x,y)` Returns 0 for *x* == *y*, 1 if *x* > *y* and -1 if *y* > *x*.

`factorial(n)` Factorial of integer *n*.

`floor(x)` Greatest integer smaller than *x*.

`gcd(x,y)` Greatest common divisor of *x* and *y*.

`lcd(x,y)` Lowest common denominator of *x* and *y* (given by *x***y*/gcd(*x*,*y*).

`sgn(x)` Sign of *x* or zero if *x* == 0.

`binomial(n,k)` Returns the the binomial function for integers n and k.

`Bernoulli(n)` Returns the Bernoulli number Bn (with Bn(1)=-1/2).

`Stirling2(n,k)` Returns the Stirling number of the second kind.

APMath Functions on Wave Parameters

The following functions are supported for arbitrary precision math on waves.

These restrictions apply to all of these APMath functions on waves:

1. The parameter *w* must be a simple wave reference. It can not be a data folder path to a wave or a $ expression pointing to a wave.
2. The wave can be a real numeric wave or a text wave containing arbitrary precision numbers in string form.
3. Complex waves are not allowed.
4. 64-bit integer waves are not allowed.
5. The functions return an error if the wave contains NaNs or INFs.
6. Multidimensional waves are treated as 1D.

`kurtosis(w)` Returns the kurtosis of the entire wave *w*. See **WaveStats** for a discussion of kurtosis. The kurtosis function was added in Igor Pro 8.00.

`mean(w)` Returns the mean of the entire wave *w*. The mean function was added in Igor Pro 8.00.

`skew(w)` Returns the skewness of the entire wave *w*. See **WaveStats** for a discussion of skewness. The skew function was added in Igor Pro 8.00.

`sum(w)` Returns the sum of the entire wave *w*. The sum function was added in Igor Pro 8.00.

`variance(w)` Returns the variance of the entire wave *w*. See **WaveStats** for a discussion of variance. The variance function was added in Igor Pro 8.00.

Flags

/EX=*exDigits* Specifies the number of extra digits added to the precision digits (/N) for intermediate steps in the calculation.

/N=*numDigits* Specifies the precision of the final result. To add digits to the intermediate computation steps, use /EX.

/V Verbose mode; prints the result in the history in addition to performing the assignment.

/Z No error reporting.

Details

By default, all arbitrary precision math calculations are performed with *numDigits*=50 and *exDigits*=6, which yields a final result using at least 56 decimal places. Because none of the built-in variable types can express numbers with such high accuracy, the arbitrary precision numbers must be stored as strings. The operation automatically converts between strings and constants. It evaluates all of the numerical functions listed above using the specified accuracy. If you need functions that are not supported by this operation, you may have to precompute them and store the results in a local variable.

The operation stores the result in *destStr*, which may or may not exist prior to execution. When you execute the operation from the command line, *destStr* becomes a global string in the current data folder if it does not already exist. If it exists, then the result of the operation overwrites its value (as with any normal string assignment). In a user function, *destStr* can be a local string, an SVAR, or a string passed by reference. If *destStr* is not one of these then the operation creates a local string by that name.

Arbitrary precision math calculations are much slower (by a factor of about 300) than equivalent floating point calculations. Execution time is a function of the number of digits, so you should use the /N flag to limit the evaluation to the minimum number of required digits.

Output Variables

In Igor Pro 8.00 or later, the APMath operation returns information in the following output variables:

`V_Flag`	Set to 0 if the operation succeeds or to a non-zero error code.
`V_Value`	Set to a double-precision representation of the output string.

Examples

Evaluate pi to 50 digits:

```
APMath/V aa = pi
```

Evaluate ratios of large factorials:

```
APMath/V aa = factorial(500)/factorial(499)
```

Evaluate ratios of large exponentials:

```
APMath/V aa = exp(-1000)/exp(-1001)
```

Division of mixed size values:

```
APMath/V aa = 1-sgn(1-(1-0.00000000000000000001234)/(1-0.000000000000000000012345)))
```

you'll get a different result trying to evaluate this using double precision.

Difference between built-in pi and the arbitrary precision pi:

```
Variable/G biPi = pi
APMath/V aa = biPi-pi
```

Precision control:

```
Function test()
   APMath aa = pi                // Assign 50 digit pi to the string aa.
   APMath/V bb = aa              // Create local string bb equal to aa.
   APMath/V bb = aa-pi           // Subtract arb. prec. pi from aa.
                                 // note the default exDigits=6.
   APMath/V/N=50/ex=0 bb = aa-pi // setting exDigits=0.
End
```

Numerical recreation:

```
APMath/V/N=16 aa = 111111111^2
```

The solution for the sum of three cubes problem for the number 42:

```
APMath/V aa = pow((-80538738812075974),3) + pow(80435758145817515,3) +
   pow(12602123297335631,3)
```

Append

`Append`

The Append operation is interpreted as **AppendToGraph**, **AppendToTable**, or **AppendToLayout**, depending on the target window. This does not work when executing a user-defined function. Therefore we now recommend that you use **AppendToGraph**, **AppendToTable**, or **AppendLayoutObject** rather than Append.

AppendBoxPlot

```
AppendBoxPlot [ flags ] wave[, wave, ...] [vs xWave]
```

The AppendBoxPlot operation appends a box plot trace to the target or named graph. A box plot is a way to display a summary of the distribution of data values. Another way to display a summary of data distribution is via a violin plot.

AppendBoxPlot was added in Igor Pro 8.00.

A box plot trace is treated within Igor as a single graph trace, and many of the operations such as removing from a graph or reordering traces work the same with a box plot trace as with any other graph trace.

There is no DisplayBoxPlot operation. Use Display followed by AppendBoxPlot.

Parameters

The data for a single box in a box plot trace comes from either one entire 1D wave or from a single column of a multi-column wave. The number of box plots in the trace is determined by either the number of 1D waves in the list of waves, or by the number of columns in the single multi-column wave. It is not permitted to mix 1D and multi-column waves.

You can list up to 100 individual 1D waves. If you want more boxes than 100 in a box plot trace you must use a multi-column wave or add to the list using the AddWavesToBoxPlot operation.

If you do not provide *xWave*, each box plot is positioned on a numeric axis at X=0, 1, etc. If the data is in a multi-column wave, positioning comes by default from the X scaling of the matrix wave. Providing a numeric *xWave* allows you to position each box plot at an arbitrary position on the X axis. A text *xWave* displays the box plots using a category axis. If you use the /CATL flag with a multi-column wave, the result is a category X axis using the dimension labels as the category labels. See **Category Plots** on page II-355 and **Dimension Labels** on page II-93.

xWave must have at least as many points as you have 1D Y waves or columns in a multi-column wave. Because a list of waves may become too long for the command line, you can use an *xWave* that is longer than the list. Use **AddWavesToBoxPlot** to complete the list.

Flags

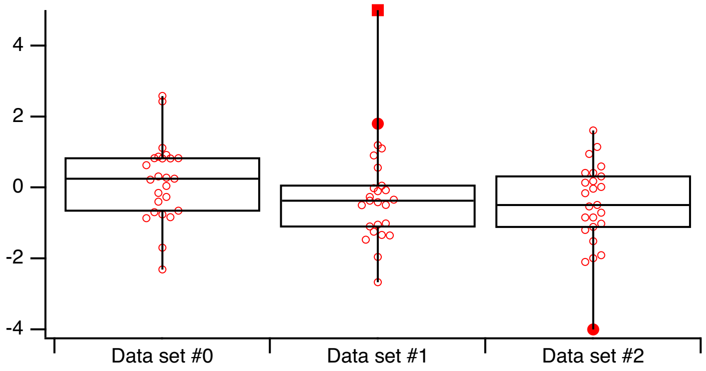
/L/R/B/T	These axis flags are the same as used by **AppendToGraph**.
/CATL[=*doCatLabels*]	Use the column dimension labels to produce box plots on a category axis using the column dimension labels as the category labels. *doCatLabels* is 0 or 1 and /CATL is equivalent to /CATL=1.
/TN=*traceName*	Allows you to provide a custom name for a trace. This is useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-89 for details, except that the /TN flag for AppendBoxPlot comes in the normal position in the command, after the command name.
/VERT[=*doVert*]	Arranges the individual box plots vertically along the Y axis. *doVert* is 0 or 1 and /VERT is equivalent to /VERT=1. /VERT is similar to ModifyGraph SwapXY but on a trace-by-trace basis. To make a box plot with horizontal boxes, use either ModifyGraph SwapXY or AppendBoxPlot/VERT.
/W=*winName*	Appends to the named graph window or subwindow. When omitted, AppendBoxPlot is directed to the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with winName, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Some aspects of the overall appearance of a box plot trace can be set using ModifyGraph. By default, the line color is black and markers for non-outlier data points are hollow circles 0.7 times the size of the normal trace marker. Using the Modify Box Plot dialog or the ModifyBoxPlot operation, you can choose to use trace color, line size, line dash style, marker and marker size as set by ModifyGraph just as for a regular trace. Detailed control of these characteristics for various parts of a box plot trace is provided by **ModifyBoxPlot**. Markers to represent outliers, far outliers, and non-outliers override the marker set by ModifyGraph.

Examples

```
// Demo vertical box plot
Make/O/N=(25,3) multicol                // A three-column wave with 25 rows
SetRandomSeed(.4)
multicol = gnoise(1)                    // Three normally-distributed datasets
multicol[20][1] = 5                     // A "far" outlier
multicol[13][2] = -4                    // An outlier
Make/O/N=3/T labels                     // A text wave to make a category plot
labels = "Dataset #"+num2str(p)         // Labels for the X axis of a category plot
Display; AppendBoxPlot multicol vs labels
```



```
// Demo horizontal box plot
Make/O/N=50 ds1, ds2, ds3, ds4
Make/O/N=4 dsX
ds1 = gnoise(1)
ds2 = gnoise(2)
ds3 = logNormalNoise(0, 1)
ds4 = enoise(2)
dsX = p^2
Display; AppendBoxPlot ds1,ds2,ds3,ds4 vs dsX
ModifyGraph swapXY=1                    // horizontal boxes
ModifyGraph margin(top)=20              // top margin may be too small
```

AppendImage

AppendImage [**/G=*g*/W=*winName***][***axisFlags***] ***matrix*** [**vs** {***xWaveName***, ***yWaveName***}]

The AppendImage operation appends the matrix as an image to the target or named graph. By default the image is plotted versus the left and bottom axes.

Parameters

matrix is either an NxM 2D wave for false color or indexed color images, or it can be a 3D NxMx3 wave containing a layer of data for red, a layer for green and a layer for blue. It can also be a 3D NxMx4 wave with the fourth plane containing alpha values.

If *matrix* contains multiple planes other than three or four or if it contains three or four and multiple chunks, the **ModifyImage** plane keyword can be used to specify the desired subset to display.

If you provide *xWaveName* and *yWaveName*, *xWaveName* provides X coordinate values, and *yWaveName* provides Y coordinate values. This makes an image with uneven pixel sizes. In both cases, you can use * to specify calculated values based on the dimension scaling of *matrix*. See **Details** if you use *xWaveName* or *yWaveName*.

Flags

axisFlags Flags /L, /R, /B, and /T are the same as used by **AppendToGraph**.

/G=*g* Controls the interpretation of three-plane images as direct RGB.

g=1 Suppresses the auto-detection of three or four plane images as direct (RGB) color.

g=0 Same as no /G flag (default).

/W=*winName* Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

When appending an image to a graph each image data point is displayed as a rectangle. You can supply optional X and Y waves to define the coordinates of the rectangle edges. *These waves need to contain one more data point than the X (row) or Y (column) dimension of the matrix*. The waves must also be either strictly increasing or strictly decreasing. See **Image X and Y Coordinates** on page II-388 for details.

For false color, the values in the matrix are linearly mapped into a color table. See the ModifyImage ctab keyword. For indexed color, the values in the matrix are interpreted as Z values to be looked up in a user-supplied 3 column matrix of colors. See the ModifyImage cindex keyword. Direct color NxMx3 waves contain the actual red, green, and blue values for each pixel. NxMx4 waves add an alpha channel. If the number type is unsigned bytes, then the range of intensity ranges from 0 to 255. For all other number types, the intensity ranges from 0 to 65535.

By default, nondirect color matrices are initially displayed as false color using the Grays color table and autoscale mode.

If the matrix is complex, the image is displayed in terms of the magnitude of the Z value, that is, sqrt(real^2 + imag^2).

See Also

Image X and Y Coordinates on page II-388, **Color Blending** on page III-498.

The **NewImage**, **ModifyImage**, and **RemoveImage** operations. For general information on image plots see Chapter II-16, **Image Plots**.

AppendLayoutObject

```
AppendLayoutObject [flags] objectType objectName
```

The AppendLayoutObject operation appends a single object to the top layout or to the layout specified via the /W flag. It targets the active page or the page specified by the /PAGE flag.

Unlike the AppendToLayout operation, AppendLayoutObject can be used in user-defined functions. Therefore, AppendLayoutObject should be used in new programming instead of AppendToLayout.

Parameters

objectType identifies the type of object to be appended. It is one of the following keywords: `graph`, `table`, `picture`, `gizmo`.

objectName is the name of the graph, table, picture or Gizmo window to be appended.

Use a space between *objectType* and *objectName*. A comma is not allowed.

Flags

/D=*fidelity*
Draws layout objects in low fidelity (*fidelity*=0) or high fidelity (*fidelity*=1; default). This affects drawing on the screen only, not exporting or printing. Low fidelity is somewhat faster but less accurate and should be used only for graphs that take a very long time to draw.

/F=*frame*
Specifies the type of frame enclosing the object.

frame =1	Single frame (default).
frame =2	Double frame.
frame =3	Triple frame.
frame =4	Shadow frame.

/T=*trans*
Sets the transparency of the object background to opaque (*trans* =0; default) or transparent (*trans* =1).

For transparency to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. PICTs may have been created transparent or opaque. Opaque PICTs cannot be made transparent.

/R=(*l*, *t*, *r*, *b*)
Sets the size and position of the object. If omitted, the object is placed with a default size and position. *l*, *t*, *r*, and *b* are the left, top, right, and bottom coordinates of the object, respectively. Coordinates are expressed in units of points, relative to the top/left corner of the paper.

/PAGE=*page*
Appends the object to the specified page.

Page numbers start from 1. To target the active page, omit /PAGE or use *page*=0.

The /PAGE flag was added in Igor Pro 7.00.

/W=*winName*
Appends the object to the named page layout window. If /W is omitted or if *winName* is `$""`, the top page layout is used.

NewLayout, **ModifyLayout**, **LayoutPageAction**, **RemoveLayoutObjects**, **TextBox**, **Legend**

AppendMatrixContour

```
AppendMatrixContour [axisFlags][/F=formatStr /W=winName] zWave
   [vs {xWave, yWave}]
```

The AppendMatrixContour operation appends to the target or named graph a contour plot of a matrix of z values with autoscaled contour levels, using the Rainbow color table.

Note: There is no DisplayContour operation. Use `Display; AppendMatrixContour`.

Parameters

zWave must be a matrix (2D wave).

To contour a set of XYZ triplets, use **AppendXYZContour**.

If you provide the *xWave* and *yWave* specification, *xWave* provides X values for the rows, and *yWave* provides Y values for the columns. This results in an “uneven grid” of Z values.

If you omit the *xWave* and *yWave* specification, Igor uses the *zWave*’s X and Y scaled indices as the X and Y values. Igor also uses the *zWave*’s scaled indices if you use * (asterisk symbol) in place of *xWave* or *yWave*.

In a macro, to modify the appearance of contour levels before the contour is calculated and displayed with the default values, append "`;DelayUpdate`" and immediately follow the AppendMatrixContour command with the appropriate **ModifyContour** commands. All but the last ModifyContour command should also have `;DelayUpdate` appended. DelayUpdate is not needed in a function, but DoUpdate is useful in a function to force the contour traces to be built immediately rather than the default behavior of waiting until all functions have completed.

On the command line, the Display command and subsequent AppendMatrixContour commands and any ModifyContour commands can be typed all on one line with semicolons between:

```
Display; AppendMatrixContour MyMatrix; ModifyContour ...
```

Flags

axisFlags Flags /L, /R, /B, /T are the same as used by **AppendToGraph**.

/F=*formatStr* Determines the names assigned to the contour level traces. See **Details**.

/W=*winName* Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

AppendMatrixContour creates and displays contour level traces. You can modify these all together using the Modify Contour Appearance dialog or individually using the Modify Trace Appearance dialog. In most cases, you will not need to modify the individual traces.

By default, Contour level traces are automatically named with names that show the *zWave* and the contour level, for example, “zWave=1.5”. You will see these trace names in the Modify Trace Appearance dialog and in Legends. In most cases, the default trace names will be just fine.

If you want to control the names of the contour level traces (which you might want to do for names in a Legend), use the /F=*formatStr* flag. This flag uses a format string as described for the **printf** operation. The default format string is `"%.17s=%g"`, resulting in trace names such as “zWave=1.5”. *formatStr* must contain at least `%f` or `%g` (used to insert the contour level) or `%d` (used to insert the zero-based index of the contour level). Include `%s`, to insert the *zWave* name.

Here are some examples of format strings.

formatStr	**Examples of Resulting Name**	**Format**
`"%g"`	“100”, “1e6”, “-2.05e-2”	(<level>)
`"z=%g"`	“z=100”, “z=1e6”, “z=-2.05e-2”	(z=<level>)
`"%s %f"`	“zWave 100.000000”	(<wave>, space, <level>)
`"[%d]=%g"`	“[0]=100”, “[1]=1e6”	([<index>]=<level>)

Examples

```
Make/O/N=(25,25) w2D                    // Make a matrix
SetScale x -1, 1, w2D                   // Set row scaling
SetScale y -1, 1, w2D                   // Set column scaling
w2D = sin(x) * cos(y)                   // Store values in the matrix
Display; AppendMatrixContour w2D
ModifyContour w2D autoLevels={*,*,9}    // Roughly 9 automatic levels
```

See also

Display, **AppendToGraph**, **AppendXYZContour**, **ModifyContour**, **RemoveContour**, **FindContour**.

For general information on contour plots, see Chapter II-15, **Contour Plots**.

AppendText

AppendText [**/W=*winName*/N/NOCR** [**=*n***]] ***textStr***

The AppendText operation appends a carriage return and *textStr* to the most recently created annotation, or to the named annotation in the target or graph or layout window. Annotations include tags, textboxes, color scales, and legends.

Parameters

textStr can contain escape codes to control font, font size and other stylistic variations. See **Annotation Escape Codes** on page III-53 for details.

Flags

/N=*name*	Appends *textStr* to the named tag or textbox.
/NOCR[=*n*]	Omits the initial appending of a carriage return (allows a long line to be created with multiple AppendText commands). /NOCR=0 is the same as no /NOCR, and /NOCR=1 is the same as just /NOCR.
/W=*winName*	Appends to an annotation in the named graph, layout window, or subwindow. Without /W, AppendText appends to an annotation in the topmost graph or layout window or subwindow. This must be the first flag specified when AppendText is used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

A textbox, tag, or legend can contain at most 100 lines. A color scale can have at most one line, and this line is the color scale's main axis label.

See Also

The **Tag**, **TextBox**, **ColorScale**, **ReplaceText**, and **Legend** operations.

Annotation Escape Codes on page III-53.

AppendToGizmo

AppendToGizmo [***flags***] ***keyword*** [**=*value***]

The AppendToGizmo operation appends a Gizmo object or attribute operation to the top Gizmo window or to the Gizmo window specified by the /N flag.

Documentation for the AppendToGizmo operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "AppendToGizmo"
```

AppendToGraph

AppendToGraph [***flags***] ***waveName*** [, ***waveName***]...[**vs** ***xwaveName***]

The AppendToGraph operation appends the named waves to the target or named graph. By default the waves are plotted versus the left and bottom axes.

Parameters

The *waveNames* parameters are the names of existing waves.

vs *xwaveName* plots the data values of *waveNames* against the data values of *xwaveName*.

If you are appending a new trace to an existing category plot, *xwaveName* must be the same as the one already controlling the plot's X axis. If the existing X axis uses dimension labels from a Y wave, using the '_labels_' keyword, then *xwaveName* must be set to '_labels_'.

If you are appending a new category plot using a different X axis, *xwaveName* can refer any suitable text wave, or it may be '_labels_' to use dimension labels from the Y wave.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-321.

You can provide a custom name for a trace by appending /TN=traceName to the waveName specification. This is useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-89 for more information.

Flags

/B [=*axisName*] Plots X coordinates versus the standard or named bottom axis.

/C=(*r*,*g*,*b*[,*a*]) Sets the color of appended traces. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

/L [=*axisName*] Plots Y coordinates versus the standard or named left axis.

/NCAT Causes trace to be plotted normally on what otherwise is a category plot. X values are just category numbers but can be fractional. Category numbers start from zero. This can be used to overlay the original data points for a box plot.

See **Combining Numeric and Category Traces** on page II-362 for details.

/Q Uses a special, quick update mode when appending to a pair of existing axes. A side effect of this mode is that waves that are appended are marked as not modified. This will prevent other graphs containing these waves, if any, from being updated properly.

/R [=*axisName*] Plots Y coordinates versus the standard or named right axis.

/T [=*axisName*] Plots X coordinates versus the standard or named top axis.

/TN=*traceName* Allows you to provide a custom trace name for a trace. This is useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-89 for details.

/VERT Plots data vertically. Similar to SwapXY (**ModifyGraph (axes)**) but on a trace-by-trace basis.

/W=*winName* Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

The **Display** operation.

AppendToLayout

AppendToLayout [***flags***] ***objectSpec*** [, ***objectSpec***]…

The AppendToLayout operation appends the specified objects to the top layout.

The AppendToLayout operation can not be used in user-defined functions. Use the AppendLayoutObject operation instead.

Parameters

The optional *objectSpec* parameters identify a graph, table, textbox or PICT to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See the **Layout** operation for details.

Flags

/G=*g* Specifies grout, the spacing between tiled objects. Units are points unless /I, /M, or /R are specified.

/I *objectSpec* coordinates are in inches.

/M	*objectSpec* coordinates are in centimeters.
/R	*objectSpec* coordinates are in percent of printing part of the page.
/S	Stacks objects.
/T	Tiles objects.

See Also

The **Layout** and **AppendLayoutObject** operations for use with user-defined functions.

AppendToTable

```
AppendToTable [/W=winName] columnSpec [, columnSpec]…
```

The AppendToTable operation appends the specified columns to the top table. *columnSpec*s are the same as for the **Edit** operation; usually they are just the names of waves.

Flags

/W=*winName*	Appends columns to the named table window or subwindow. When omitted, action will affect the active window or subwindow. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

Edit for details about *columnSpec*s, and **RemoveFromTable**.

AppendViolinPlot

```
AppendViolinPlot [ flags ] wave[, wave, ...] [vs xWave]
```

The AppendViolinPlot operation appends a violin plot trace to the target or named graph. A violin plot (also called a “bean” plot) is a way to display a summary of the distribution of data values using a kernel density estimator curve (see **StatsKDE**). Another way to display a summary of data distribution is via a box plot.

AppendViolinPlot was added in Igor Pro 8.00.

A violin plot trace is treated within Igor as a single graph trace, and many of the operations such as removing from a graph or reordering traces work the same with a violin plot trace as with any other graph trace.

There is no DisplayViolinPlot operation. Use Display followed by AppendViolinPlot.

Parameters

The data for a single violin plot in a violin plot trace comes from either one entire 1D wave or from a single column of a multi-column wave. The number of violin plots in the trace is determined by either the number of 1D waves in the list of waves, or by the number of columns in the single multi-column wave. It is not permitted to mix 1D and multi-column waves.

You can list up to 100 individual 1D waves. If you want more violin plots than 100 in a violin plot trace you must use a multi-column wave or add to the list using the **AddWavesToViolinPlot** operation.

If you do not provide *xWave*, each violin plot is positioned on a numeric axis at X=0, 1, etc. If the data is in a multi-column wave, positioning comes by default from the X scaling of the matrix wave. Providing a numeric *xWave* allows you to position each violin plot at an arbitrary position on the X axis. A text *xWave* displays the violin plots using a category axis. If you use the /CATL flag with a multi-column wave, the result is a category X axis using the dimension labels as the category labels. See **Category Plots** on page II-355 and **Dimension Labels** on page II-93.

xWave must have at least as many points as you have 1D Y waves or columns in a multi-column wave. Because a list of waves may become too long for the command line, you can use an *xWave* that is longer than the list. Use **AddWavesToViolinPlot** to complete the list.

Flags

/L/R/B/T These axis flags are the same as used by **AppendToGraph**.

/CATL[=*doCatLabels*] Use the column dimension labels to produce violin plots on a category axis using the column dimension labels as the category labels. *doCatLabels* is 0 or 1 and /CATL is equivalent to /CATL=1.

/TN=*traceName* Allows you to provide a custom name for a trace. This is useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-89 for details, except that the /TN flag for AppendViolinPlot comes in the normal position in the command, after the command name.

/VERT[=*doVert*] Arranges the individual violin plots vertically along the Y axis. *doVert* is 0 or 1 and /VERT is equivalent to /VERT=1.

/VERT is similar to ModifyGraph SwapXY but on a trace-by-trace basis. To make a violin plot with horizontal violins, use either ModifyGraph SwapXY or AppendViolinPlot/VERT.

/W=*winName* Appends to the named graph window or subwindow. When omitted, AppendViolinPlot is directed to the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

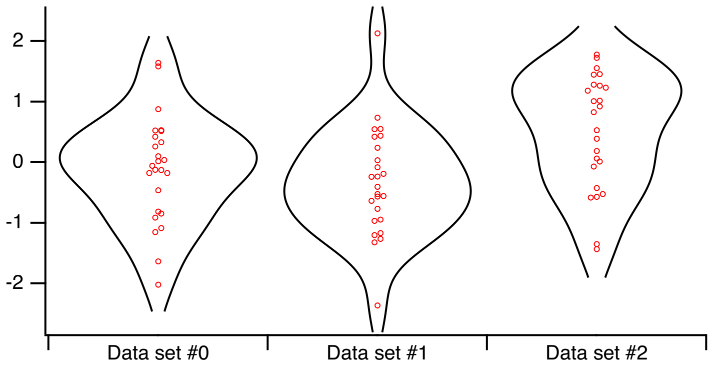
When identifying a subwindow with winName, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Some aspects of the overall appearance of a violin plot trace can be set using ModifyGraph. By default, the line color is black and markers for non-outlier data points are hollow circles half the size of the normal trace marker. Using the Modify Violin Plot dialog or the ModifyViolinPlot operation, you can choose to use trace color, line size, line dash style, marker and marker size as set by ModifyGraph just as for a regular trace. Detailed control of these characteristics for various parts of a violin plot trace is provided by **ModifyViolinPlot**.

Examples

```
// Demo vertical violin plot
Make/O/N=(25,3) multicol               // A three-column wave with 25 rows
SetRandomSeed(.5)
multicol = gnoise(1)                   // Three normally-distributed datasets
Make/O/N=3/T labels                    // A text wave to make a category plot
labels = "Dataset #"+num2str(p)        // Labels for the X axis of a category plot
Display; AppendViolinPlot multicol vs labels
```



```
// Demo horizontal violin plot
Make/O/N=50 ds1, ds2, ds3, ds4
Make/O/N=4 dsX
ds1 = gnoise(1)
ds2 = gnoise(2)
ds3 = logNormalNoise(0, 1)
```

```
ds4 = enoise(2)
dsX = p^2
Display; AppendViolinPlot ds1,ds2,ds3,ds4 vs dsX
ModifyGraph swapXY=1                    // Horizontal boxes
ModifyGraph margin(top)=20              // Top margin may be too small
```

AppendXYZContour

AppendXYZContour [**/W=*winName* /F=*formatStr***][***axisFlags***] ***zWave*** [**vs** {***xWave***, ***yWave***}]

The AppendXYZContour operation appends to the target or named graph a contour of a 2D wave consisting of XYZ triples with autoscaled contour levels and using the Rainbow color table.

To contour a matrix of Z values, use **AppendMatrixContour**.

Note: There is no DisplayContour operation. Use `Display; AppendXYZContour`.

Parameters

If you provide the *xWave* and *yWave* specification, *xWave* provides X values for the rows, and *yWave* provides Y values for the columns, *zWave* provides Z values and all three waves must be 1D. All must have at least four rows and must have the same number of rows.

If you omit the *xWave* and *yWave* specification, *zWave* must be a 2D wave with 4 or more rows and 3 or more columns. The first column is X, the second is Y, and the third is Z. Any additional columns are ignored.

If any of X, Y, or Z in a row is blank, (NaN), that row is ignored.

In a macro, to modify the appearance of contour levels before the contour is calculated and displayed with the default values, append "`;DelayUpdate`" and immediately follow the AppendXYZContour command with the appropriate **ModifyContour** commands. All but the last ModifyContour command should also have `;DelayUpdate` appended. DelayUpdate is not needed in a function, but DoUpdate is useful in a function to force the contour traces to be built immediately rather than the default behavior of waiting until all functions have completed.

On the command line, the **Display** command and subsequent AppendXYZContour commands and any **ModifyContour** commands can be typed all on one line with semicolons between:

```
Display; AppendXYZContour zWave; ModifyContour ...
```

Flags

axisFlags	Flags /L, /R, /B, and /T are the same as used by **AppendToGraph**.
/F=*formatStr*	Determines names assigned to the contour level traces. This is the same as for **AppendMatrixContour**.

/W=*winName* Appends to the named graph window or subwindow. When omitted, action affects the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

AppendXYZContour creates and displays contour level traces. You can modify these as a group using the Modify Contour Appearance dialog or individually using the Modify Trace Appearance dialog. In most cases, you will have no need to modify the traces individually.

See **AppendMatrixContour** for a discussion of how the contour level traces are named.

Examples

```
Make/O/N=(100) xW, yW, zW               // Make X, Y, and Z waves
xW = sawtooth(2*PI*p/10)                // Generate X values
yW = trunc(p/10)/10                     // Generate Y values
zW = sin(2*PI*xW)*cos(2*PI*yW)          // Generate Z values
Display; AppendXYZContour zW vs {xW, yW}; DelayUpdate
ModifyContour zW autoLevels={*,*,9}     // roughly 9 automatic levels
```

See Also

The **Display** operation. **AppendToGraph** for details about other axis flags. The **AppendMatrixContour**, **ModifyContour**, and **RemoveContour** operations. For general information on contour plots, see Chapter II-15, **Contour Plots**.

area

`area(`*`waveName`*` [, `*`x1`*`, `*`x2`*`])`

The area function returns the signed area between the named wave and the line y=0 from x=*x1* to x=*x2* using trapezoidal integration, accounting for the wave's X scaling. If your data are in the form of an XY pair of waves, see **areaXY**.

Details

If *x1* and *x2* are not specified, they default to -∞ and +∞, respectively.

If *x1* or *x2* are not within the X range of *waveName*, area limits them to the nearest X range limit of *waveName*.

If any values in the X range are NaN, area returns NaN.

The function returns NaN if the input wave has zero points.

Reversing the order of *x1* and *x2* changes the sign of the returned area.

The area function is intended to work on 1D real or complex waves only.

The area function returns a complex result for a complex input wave. The real part of the result is the area of the real components in the input wave, and the imaginary part of the result is the area of the imaginary components.

Examples

```
Make/O/N=100 data; SetScale/I x 0,Pi,data
data=sin(x)
Print area(data,0,Pi)          // the entire X range, and no more
Print area(data)               // same as -infinity to +infinity
Print area(data,Inf,-Inf)      // +infinity to -infinity
```

The following is printed to the history area:

```
Print area(data,0,Pi)          // the entire X range, and no more
  1.99983
Print Print area(data)         // same as -infinity to +infinity
  1.99983
Print area(data,Inf,-Inf)      // +infinity to -infinity
  -1.99983
```

The `-Inf` value was limited to 0 and `Inf` was limited to `Pi` to keep them within the X range of data.

See Also

The figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the **Details** section of the **faverage** function.

Integrate, **areaXY**, **faverage**, **faverageXY**, **Poly2D Example 3**

areaXY

`areaXY(`*`XWaveName, YWaveName`*` [, `*`x1, x2`*`])`

The areaXY function returns the signed area between the named *YWaveName* and the line y=0 from x=*x1* to x=*x2* using trapezoidal integration with X values supplied by *XWaveName*.

This function is identical to the **area** function except that it works on an XY wave pair and does not work with complex waves.

Details

If *x1* and *x2* are not specified, they default to -∞ and +∞, respectively.

If *x1* or *x2* are outside the X range of *XWaveName*, areaXY limits them to the nearest X range limit of *XWaveName*.

If any values in the Y range are NaN, areaXY returns NaN.

If any values in the entire X wave are NaN, areaXY returns NaN.

The function returns NaN if the input wave has zero points.

Reversing the order of *x1* and *x2* changes the sign of the returned area.

If *x1* or *x2* are not found in *XWaveName*, a Y value is found by linear interpolation based on the two bracketing X values and the corresponding values from *YWaveName*.

The values in *XWaveName* may be increasing or decreasing. AreaXY assumes that the values in *XWaveName* are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any X values are NaN, the result is NaN.

See the figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the **Details** section of the **faverage** function.

The areaXY operation is intended to work on 1D waves only.

Examples

```
Make/O/N=101 Xdata, Ydata
Xdata = x*pi/100
Ydata = sin(Xdata[p])
Print areaXY(Xdata, Ydata,0,Pi)         // the entire X range, and no more
Print areaXY(Xdata, Ydata)              // same as -infinity to +infinity
Print areaXY(Xdata, Ydata,Inf,-Inf)     // +infinity to -infinity
```

The following is printed to the history area:

```
Print areaXY(Xdata, Ydata,0,Pi)         // the entire X range, and no more
  1.99984
Print areaXY(Xdata, Ydata)              // same as -infinity to +infinity
  1.99984
Print areaXY(Xdata, Ydata,Inf,-Inf)     // +infinity to -infinity
  -1.99984
```

The `-Inf` value was limited to `0`, and `Inf` was limited to `Pi` to stay within the X range of data.

Integrate, **area**, **faverage**, **faverageXY**, **Poly2D Example 3**

asin

`asin(`*`num`*`)`

The asin function returns the inverse sine of num in radians in the range [-π/2,π/2].

In complex expressions, *num* is complex, and asin returns a complex value.

See Also

sin

asinh

asinh(*num*)

The asinh function returns the inverse hyperbolic sine of *num*. In complex expressions, *num* is complex, and asinh returns a complex value.

atan

atan(*num*)

The atan function returns the inverse tangent of *num* in radians. In complex expressions, *num* is complex, and atan returns a complex value. Results are in the range -π/2 to π/2.

See Also

tan, **atan2**

atan2

atan2(*y1, x1*)

The atan2 function returns the angle in radians whose tangent is *y1/x1*. Results are in the range -π to π.

See Also

tan, **atan**

atanh

atanh(*num*)

The atanh function returns the inverse hyperbolic tangent of *num*. In complex expressions, *num* is complex, and atanh returns a complex value.

AutoPositionWindow

AutoPositionWindow [**/E/M=*m*/R=*relWindow***][***windowName***]

The AutoPositionWindow operation positions the window specified by *windowName* relative to the next lower window of the same kind or relative to the window given by the /R flag. If *windowName* is not specified, AutoPositionWindow acts on the target window.

Flags

/E — Uses entire area of the monitor. Otherwise, it takes into account the command window.

/M=*m* — Specifies the window positioning method.

m=0: Positions *windowName* to the right of the other window, if possible. If there is no room, then it positions *windowName* just below the other window but at the left edge of the display area. If that is not possible, then the position is not affected.

m=1: Positions *windowName* just under the other window lined up on the left edge, if possible. If there is no room, then it positions *windowName* just to the right of the other window lined up on the bottom edges. If neither are possible then it positions *windowName* as far to the bottom and right as it will go.

/R=*relWindow* — Positions *windowName* relative to *relWindow*.

AxisInfo

`AxisInfo(`*`graphNameStr`*`, `*`axisNameStr`*`)`

The AxisInfo function returns a string containing a semicolon-separated list of information about the named axis in the named graph window or subwindow.

Parameters

graphNameStr can be `""` to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

axisNameStr is the name of the graph axis.

Details

The string contains groups of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are:

Keyword	Information Following Keyword
AXFLAG	Flag used to select the axis in any of the operations that display waves (Display, AppendMatrixContour, AppendImage, etc.).
AXTYPE	Axis type, such as “left”, “right”, “top”, or “bottom”.
CATWAVE	Wave supplying the categories for the axis if this is a category plot.
CATWAVEDF	Full path to data folder containing category wave.
CTRACE	Name of the trace controlling the names axis. See **Trace Names** on page II-282 for background information. This field was added in Igor Pro 9.00.
CWAVE	Name of wave controlling named axis.
CWAVEDF	Full path to data folder containing controlling wave.
FONT	Actual name of font used to draw axis tick labels.
FONTSIZE	Actual size of font used to draw axis tick labels, in points.
FONTSTYLE	Actual font style used to draw axis tick labels, in points. See **ModifyGraph (axes)** on page V-626 fstyle for the meaning of this integer value.
HOOK	Name set by ModifyFreeAxis with hook keyword.
ISCAT	Truth that this is a category axis (used in a category plot).
ISTFREE	Truth that this is truly free axis (created via NewFreeAxis).
MASTERAXIS	Name set by ModifyFreeAxis with master keyword.
RECREATION	List of keyword commands as used by ModifyGraph command. The format of these keyword commands is: *keyword*(x)=*modifyParameters*;
SETAXISCMD	Full SetAxis command.
SETAXISFLAGS	Flags that would be used with the SetAxis function to set the particular auto-scaling behavior that the axis uses. If the axis uses a manual axis range, SETAXISFLAGS is blank.
UNITS	Axis units, if any.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword up to the “`;`”, prepend “`ModifyGraph`”, replace the “`x`” with the name of an actual axis and then **Execute** the resultant string as a command.

Examples

```
Make/O data=x;Display data
Print StringByKey("CWAVE", AxisInfo("","left"))       // Prints data
```

```
// Get a numeric value from the RECREATION keyword nested keyword values
String info = AxisInfo("","left")
String key = ";RECREATION:"
Variable index = strsearch(info,key,0)
String recreation = info[index+strlen(key),inf]
Print recreation                          // Prints catGap(x)=0.1;barGap(x)=0.1;...
Print NumberByKey("barGap(x)",recreation,"=")     // Prints 0.1
```

See Also

GetAxis, **SetAxis**, **AxisLabel**, **StringByKey**, **NumberByKey**

The "Readback ModifyStr" procedure file is useful for parsing strings returned by AxisInfo.

AxisLabel

AxisLabel(*graphNameStr*, *axisNameStr* [, *escapeBackslashes*])

The AxisLabel function returns a string containing the axis label for the named axis in the named graph window or subwindow. The string returned is suitable for use with the Label operation. The AxisLabel function is primarily intended for copying the label from one axis to another.

The AxisLabel function was added in Igor Pro 9.00.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow via *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

axisNameStr is the name of the axis.

escapeBackslashes is an optional parameter which defaults to 0 (false).

Details

Specify *escapeBackslashes*=1 when using the result to create a command passed to the **Execute** operation. Otherwise omit *escapeBackslashes* or specify *escapeBackslashes*=0.

The "Axis Utilities.ipf" WaveMetrics procedure contains an AxisLabelText function that is very similar to AxisLabel. If you use AxisLabelText, you can replace it with AxisLabel for use with Igor Pro 9 or later.

Examples

```
// Label Graph0 left axis with something that has a backslash in it
Make/O data=x
Display/N=Graph0 data
Label/W=Graph0 left, "Area \\E (UV*Sec)"

// Reuse the left axis label from Graph0 for Graph1
Display/N=Graph1 data
String lblStr = AxisLabel("Graph0","left")
Label/W=Graph1 left, lblStr
```

See Also

AxisInfo, **Label**, **Backslashes in Annotation Escape Sequences** on page III-58

AxisList

AxisList(*graphNameStr*)

The AxisList function returns a semicolon-separated list of axis names from the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Examples

```
Make/O data=x;Display/L/T data
Print AxisList("")              // prints left;top;
```

AxisValFromPixel

`AxisValFromPixel(`*`graphNameStr`*`, `*`axNameStr`*`, `*`pixel`*`)`

The AxisValFromPixel function returns an axis value corresponding to the local graph pixel coordinate in the graph window or subwindow.

Parameters

graphNameStr can be `""` to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If the specified axis is not found and if the name is “left” or “bottom” then the first vertical or horizontal axis will be used. Sources for *pixel* value may be the GetWindow operation or a user window hook with the mousemoved and mousedown event messages (see the **SetWindow** operation).

If *graphNameStr* references a subwindow, *pixel* is relative to top left corner of base window, not the subwindow.

Axis ranges and other graph properties are computed when the graph is redrawn. Since automatic screen updates are suppressed while a user-defined function is running, if the graph was recently created or modified, you must call DoUpdate to redraw the graph so you get accurate axis information.

See Also

The **PixelFromAxisVal** and **TraceFromPixel** functions; the **GetWindow** and **SetWindow** operations.

BackgroundInfo

`BackgroundInfo`

The BackgroundInfo operation returns information about the current unnamed background task.

BackgroundInfo works only with the unnamed background task. New code should used named background tasks instead. See **Background Tasks** on page IV-319 for details.

Details

Information is returned via the following variables:

`V_flag`	0: No background task is defined. 1: Background task is defined, but not running (is idle). 2: Background task is defined and is running.
`V_period`	DeltaTicks value set by CtrlBackground. This is how often the background task runs.
`V_nextRun`	Ticks value when the task will run again. 0 if the task is not scheduled to run again.
`S_value`	Text of the numeric expression that the background task executes, as set by SetBackground.

See Also

The **SetBackground**, **CtrlBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and the **ticks** function. See **Background Tasks** on page IV-319 for usage details.

Base64Decode

`Base64Decode(`*`inputStr`*`)`

The Base64Decode function returns a decoded copy of the Base64-encoded string *inputStr*. The contents of *inputStr* are not checked for validity. Any invalid characters in *inputStr* are skipped, and decoding continues with subsequent characters.

The algorithm used to encode Base64-encoded data is defined in RFC 4648 (http://www.ietf.org/rfc/rfc4648.txt).

For an explanation of Base64 encoding, see https://en.wikipedia.org/wiki/Base64.

The Base64Decode function was added in Igor Pro 8.00.

Example

```
String encodedString = "SWdvciBpcyBncmVhdCE="
Print Base64Decode(encodedString)
  Igor is great!
```

See Also

Base64Encode, **URLRequest**

Base64Encode

Base64Encode(*inputStr*)

The Base64Encode function returns a copy of *inputStr* encoded as Base64.

The algorithm used to encode Base64-encoded data is defined in RFC 4648 (http://www.ietf.org/rfc/rfc4648.txt).

For an explanation of Base64 encoding, see https://en.wikipedia.org/wiki/Base64.

The Base64Encode function was added in Igor Pro 8.00.

Example

```
String theString = "Igor is great!"
Print Base64Encode(theString)
  SWdvciBpcyBncmVhdCE=
```

Base64Decode, **URLRequest**

Beep

Beep

The Beep operation plays the current alert sound (*Macintosh*) or the system beep sound (*Windows*).

Besseli

Besseli(*n*,*z*)

The Besseli function returns the modified Bessel function of the first kind, I*n*(*z*), of order *n* and argument *z*. Replaces the bessI function, which is supported for backwards compatibility only.

If *z* is real, Besseli returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders *n*, as well as real or complex arguments *z*.

See Also

The **Besselj**, **Besselk**, and **Bessely** functions.

Besselj

Besselj(*n*,*z*)

The Besselj function returns the Bessel function of the first kind, J*n* (*z*), of order *n* and argument *z*. Replaces the bessJ function, which is supported for backwards compatibility only.

If *z* is real, Besselj returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders *n*, as well as real or complex arguments *z*.

See Also

The **Besseli**, **Besselk**, and **Bessely** functions.

Besselk

Besselk(*n*,*z*)

The Besselk function returns the modified Bessel function of the second kind, K*n*(*z*), of order *n* and argument *z*. Replaces the bessK function, which is supported for backwards compatibility only.

If *z* is real, Besselk returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional orders *n*, as well as real or complex arguments *z*.

See Also

The **Besseli**, **Besselj**, and **Bessely** functions.

Bessely

Bessely(*n*,*z*)

The Bessely function returns the Bessel function of the second kind, Y*n*(*z*), of order *n* and argument *z*. Replaces the bessY function, which is supported for backwards compatibility only.

If *z* is real, Bessely returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders *n*, as well as real or complex arguments *z*.

See Also

The **Besseli**, **Besselj**, and **Besselk** functions.

bessI

bessI(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Besseli**.

The bessI function returns the modified Bessel function of the first kind, I*n*(*x*) of order *n* and argument *x*.

For real *x*, the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order *n* is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If *x* is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order *n* can be fractional, and must be real.

Details

The *algorithm* parameter has three options, each selecting a different calculation method:

Algorithm	What You Get
0 (default)	Uses a calculation method that has fractional accuracy better than 10^{-6} everywhere and is generally better than 10^{-8}. This method does not handle fractional order *n*; the order is truncated to an integer before the calculation is performed. Algorithm 0 is fastest by a large margin.
1	Allows fractional order. The calculation is performed using methods described in *Numerical Recipes in C*, 2nd edition, pp. 240-245. Using algorithm 1, *accuracy* specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 1e-7 (that is, 10^{-7}), that means that you wish that the absolute value of (f_{actual} - $f_{returned}$)/f_{actual} be better than 10^{-7}. Asking for less accuracy gives some increase in speed.

Algorithm	What You Get
	You pay a heavy price for higher accuracy or fractional order. When *algorithm* is nonzero, calculation time is increased by an order of magnitude for small *x*; at larger *x* the penalty is even greater. If accuracy is greater than 10^{-8} and *n* is an integer, algorithm 0 is used. The algorithm calculates bessI and bessK simultaneously. Both values are stored, and if a call to bessI is followed by a call to bessK (or bessK is followed by bessI) with the same *n*, *x*, and *accuracy* the previously-stored value is returned, making the second call very fast.
2	Fractional order is allowed. The calculation is performed using code from the SLATEC library. The accuracy achievable is often better than algorithm 1, but not always. Algorithm 2 is 1.5 to 3 times faster than algorithm 1, but still slower than algorithm 0. The accuracy parameter is ignored.

The achievable accuracy of algorithms 1 and 2 is a complicated function *n* and *x*. To see a summary of achievable accuracies choose File→Example Experiments→Testing and Misc→Bessel Accuracy menu item.

bessJ

`bessJ(`*`n`*`, `*`x`*` [, `*`algorithm`*` [, `*`accuracy`*`]])`

Obsolete — use **Besselj**.

The bessJ function returns the Bessel function of the first kind, J*n*(*x*) of order *n* and argument *x*.

For real *x*, the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order *n* is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If *x* is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order *n* can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for bessJ and bessY are calculated simultaneously. The values are stored, and a subsequent call to bessY after a call to bessJ (or vice versa) with the same *n*, *x*, and *accuracy* will be very fast.

bessK

`bessK(`*`n`*`, `*`x`*` [, `*`algorithm`*` [, `*`accuracy`*`]])`

Obsolete — use **Besselk**.

The bessK function returns the modified Bessel function of the second kind, K*n*(*x*) of order *n* and argument *x*.

For real *x*, the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order *n* is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If *x* is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order *n* can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for bessJ and bessY are calculated simultaneously. The values are stored, and a subsequent call to bessY after a call to bessJ (or vice versa) with the same *n*, *x*, and *accuracy* will be very fast.

bessY

bessY(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Bessely**.

The bessY function returns the Bessel function of the second kind, Y*n*(*x*) of order *n* and argument *x*.

For real *x*, the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order *n* is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If *x* is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order *n* can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for bessJ and bessY are calculated simultaneously. The values are stored, and a subsequent call to bessY after a call to bessJ (or vice versa) with the same *n*, *x*, and *accuracy* will be very fast.

beta

beta(*a*, *b*)

The beta function returns for real or complex arguments as

$$B(a,b)=\frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)},$$

with *Re*(*a*), *Re*(*b*)>0. Γ is the gamma function.

See Also

The **gamma** function.

betai

betai(*a*, *b*, *x* [, *accuracy*])

The betai function returns the regularized incomplete beta function I*x*(*a*,*b*),

$$I_x(a,b)=\frac{B(x;a,b)}{B(a,b)}.$$

Here

$$B(x;a,b)=\int_0^x t^{a-1}(1-t)^{b-1}\,dt.$$

where *a*,*b* > 0, and 0 ≤ *x* ≤ 1.

Optionally, *accuracy* can be used to specify the desired fractional accuracy.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7}, that means that you wish that the absolute value of (f_{actual} - $f_{returned}$)/f_{actual} be less than 10^{-7}.

Larger values of *accuracy* (poorer accuracy) result in evaluation of fewer terms of a series, which means the function executes somewhat faster.

A single-precision level of accuracy is about $3x10^{-7}$, double-precision is about $2x10^{-16}$. The betai function will return full double-precision accuracy for small values of *a* and *b*. Achievable accuracy declines as *a* and *b* increase:

a	*b*	*x*	betai	Accuracy Achievable
1	1.5	0.5	0.646447	2x10^{-16} (full double precision)
8	10	0.5	0.685470	6x10^{-16}
20	21	0.5	0.562685	2x10^{-15}
20	21	0.1	1.87186x10^{-10}	5x10^{-15}

BezierToPolygon

BezierToPolygon [***flags*** **]** ***bezXWave*, *bezYWave***

The BezierToPolygon operation creates an XY pair of waves approximating the Bezier curves described by bezXWave and bezYWave.

The BezierToPolygon operation was added in Igor Pro 9.00.

Flags

/DSTX=*destX*	Specifies the X destination wave to be created or overwritten. If you omit /DSTX, *destX* defaults to W_PolyX.
/DSTY=*destY*	Specifies the Y destination wave to be created or overwritten. If you omit /DSTY, *destY* defaults to W_PolyY.
/FREE	Creates output waves as free waves (see **Free Waves** on page IV-91). /FREE is allowed only in functions. If you use /DSTX or /DSTY then the specified parameter must be either a simple name or a valid wave reference.
/NSEG=nseg	The number of segments used to render each Bezier segment from 1 and 500. The default of 20 is usually sufficient.

Details

The Bezier waves *bezXWave* and *bezYWave* must be 1-dimensional real-valued floating point waves of the same length and type.

Each Bezier curve is a minimum of 1 segment comprised of 4 XY pairs. A Bezier curve of n segments consists of 1+n*3 XY pairs.

bezXWave and *bezYWave* may have NaN values between Bezier segments but not within a segment. BezierToPolygon issues an error at runtime if the data in the input waves does not conform to these requirements. NaNs in the input waves are copied to the polygon output waves.

If you omit /DSTX the output polygon X data is written to W_PolyX in the current data folder. If you omit /DSTY the output polygon Y data is written to W_PolyY in the current data folder. The output waves are created or redimensioned as single-precision or double-precision floating point waves to match the type of *bezXWave* and *bezYWave*.

Example

```
Function DemoBezierToPolygon()
   Make/O wx={0.5, 0.6, 0.9, 1}
   Make/O wy={0.0, 0.2, 0.5, 0.1}
   BezierToPolygon wx,wy
   Execute "BezierToPolygonExample()"
End

Window BezierToPolygonExample() : Graph
   PauseUpdate; Silent 1
   Display /W=(237,45,1419,669)/K=1  wy vs wx
   AppendToGraph W_PolyY vs W_PolyX
   ModifyGraph expand=-3
   ModifyGraph mode(wy)=4
   ModifyGraph marker(wy)=19
   ModifyGraph rgb(wy)=(1,16019,65535)
   Legend/C/N=text0/J/X=15.66/Y=68.34 "\\s(wy)\\[1 Bezier Control Points"
   AppendText "\\K(48059,48059,48059)\\y+15\\L1700\\X1\\M\\K(0,0,0) DrawBezier
                                        \n\\s(W_PolyY) Polygon Approximation to Bezier"
```

```
    SetDrawLayer UserBack
    SetDrawEnv xcoord= bottom,ycoord= left,save
    SetDrawEnv linethick= 3,linefgc= (48059,48059,48059)
    DrawBezier wx[0],wy[0],1,1,wx,wy
    SetDrawLayer UserFront
EndMacro
```

See Also

DrawBezier, **DrawPoly**, **Drawing Polygons and Bezier Curves** on page III-69

BinarySearch

BinarySearch(*waveName*, *val*)

The BinarySearch function performs a binary search of the one-dimensional *waveName* for the value *val*. BinarySearch returns an integer point number p such that *waveName*[p] and *waveName*[p+1] bracket *val*. If *val* is in *waveName*, then *waveName*[p]==*val*.

Details

BinarySearch is useful for finding the point in an XY pair that corresponds to a particular X coordinate.

WaveName must contain monotonically increasing or decreasing values.

BinarySearch returns -1 if *val* is not within the range of values in the wave, but would numerically be placed before the first value in the wave.

BinarySearch returns -2 if *val* is not within the range of values in the wave, but would fall after the last value in the wave.

BinarySearch returns -3 if the wave has zero points.

Examples

```
Make/O data = {1, 2, 3.3, 4.9}       // Monotonic increasing
Print BinarySearch(data,3)           // Prints 1
// BinarySearch returns 1 because data[1] <= 3 < data[2].
```

```
Make/O data = {9, 4, 3, -6}          // Monotonic decreasing
Print BinarySearch(data,2.5)         // Prints 2
// BinarySearch returns 2 because data[2] >= 2.5 > data[3].
Print BinarySearch(data,10)          // Prints -1, precedes first value
Print BinarySearch(data,-99)         // Prints -2, beyond last value
```

See Also

The **BinarySearchInterp** and **FindLevel** operations. See **Indexing and Subranges** on page II-76.

BinarySearchInterp

BinarySearchInterp(*waveName*, *val*)

The BinarySearchInterp function performs a binary interpolated search of the named wave for the value *val*. The returned value, pt, is a floating-point point index into the named wave such that *waveName*[pt] == *val*.

Details

BinarySearchInterp is useful for finding the point in an XY pair that corresponds to a particular X coordinate.

WaveName must contain monotonically increasing or decreasing values.

When the named wave does not actually contain the value *val*, BinarySearchInterp locates a value below *val* and a value above *val* and uses reverse linear interpolation to figure out where *val* would fall if a straight line were drawn between them. It includes that fractional amount in the resulting point index.

BinarySearchInterp returns NaN if *val* is not within the range of values in the wave.

Examples

```
Make/O data = {1, 2, 3.3, 4.9}          // Monotonic increasing
Print BinarySearchInterp(data,3)        // Prints 1.76923
Print data[1.76923]                     // Prints 3
```

```
Make/O data = {9, 4, 3, 1}              // Monotonic decreasing
Print BinarySearchInterp(data,2.5)      // Prints 2.25
Print data[2.25]                        // Prints 2.5
```

See Also

The **BinarySearch** and **FindLevel** operations. See **Indexing and Subranges** on page II-76.

binomial

`binomial(n, k)`

The binomial function returns the ratio:

$$\frac{n!}{k!(n-k)!}$$

It is assumed that *n* and *k* are integers and $0 \le k \le n$ and ! denotes the factorial function.

Note that although the binomial function is an integer-valued function, a double-precision number has 53 bits for the mantissa. This means that numbers over 2^{52} (about $4.5\text{x}10^{15}$) will be accurate to about one part in $2\text{x}10^{16}$.

If you encounter overflow when the arguments are large you can use **APMath** or **binomialln**. For example:

```
• Print binomial(2800,333)
  inf
• APMath/V result = binomial(2800,333)
  9.0019826685021446499850285037304473382191760312233OE+441

• Print/D binomialln(2800,333)
  1017.63747085995
• APMath/V result = log(binomial(2800,333))
  1.0176374708599488934351415800704506410635781326878 1E+3
```

binomialln

`binomialln(a, b)`

The binomialln function returns the natural log of the binomial coefficient for *a* and *b*.

$$\text{binomialln}(a,b) = \ln(a!) - \ln(b!) - \ln((a-b)!)$$

See Also

Chapter III-12, **Statistics** for an overview of the various functions and operations; **binomial**, **StatsBinomialPDF**, **StatsBinomialCDF**, and **StatsInvBinomialCDF**.

binomialNoise

`binomialNoise(n, p)`

The binomialNoise function returns a pseudo-random value from the binomial distribution

$$f(x) = \binom{n}{x} p^x (1-p)^{n-x}, \qquad \begin{array}{c} 0 \le p \le 1 \\ x = 0,1,2...n \end{array}$$

whose mean is *np* and variance is *np*(1-*p*).

When *n* is large such that p^n is zero to machine accuracy the function returns NaN. When *n* is large such that *np*(1-*p*)>5 and 0.1<*p*<0.9 you can replace the binomial variate with a normal variate with mean *np* and standard deviation sqrt(*n***p**(1-*p*)).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat the same sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

The **SetRandomSeed** operation.

Noise Functions on page III-390.

Chapter III-12, **Statistics** for an overview of the various functions and operations.

BoundingBall

BoundingBall [/F/Z] ***scatterWave***

The BoundingBall operation calculates a bounding circle or the bounding sphere for a set of scatter points. The operation accepts 2D waves that have two, three or more columns; data in the additional columns are ignored.

When *scatterWave* consists of two columns the operation computes the bounding circle. Otherwise it computes the bounding 3D sphere.

Parameters

scatterWave is a two-dimensional wave with X coordinates in column 0, Y in column 1, and optional Z coordinates in column 2.

Flags

/F	This flag applies to 3D scatter only. It uses an algorithm from "An Efficient Bounding Sphere" by Jack Ritter originally from *Graphics Gems*. Unfortunately it does not give an accurate bounding ball but something that is sufficiently large. This algorithm is less accurate but it produces a ball which is sufficiently large to contain all the points.
/Z	No error reporting.

Details

The center and radius of the bounding sphere are stored in the variables: V_CenterX, V_CenterY, V_CenterZ, and V_Radius.

If you are not using the /F flag, the operation also accepts a 2 column wave consisting of X, Y pairs for calculating the center and radius of a bounding circle in the plane.

Example

```
Make/N=(33,2) ddd=enoise(4)                // Create random data
BoundingBall ddd
Display ddd[][1] vs ddd[][0]
ModifyGraph mode=3
Make/n=360 xxx,yyy
yyy=v_centerY+V_radius*cos(p*2*pi/360)
xxx=v_centerX+V_radius*sin(p*2*pi/360)
AppendToGraph yyy vs xxx
```

References

Glassner, Andrew S., (Ed.), *Graphics Gems*, 833 pp., Academic Press, San Diego, 1990.

BoxSmooth

BoxSmooth ***box*****,** ***srcWave*****,** ***smoothedWave***

The BoxSmooth operation replaces *smoothedWave* with a smoothed copy of *srcWave*. The waves must both exist.

The BoxSmooth operation is used primarily by Igor Technical Note #20 and its variants. For most purposes, use the more flexible **Smooth** operation instead of BoxSmooth.

Parameters

box is the number of *srcWave* points averaged to form each *smoothedWave* point. If you specify an even number, the next-higher odd number is used.

Details

BoxSmooth is equivalent to the **Smooth** operation with the /B flag, except that BoxSmooth does not compute the result in-place like Smooth does. This command:

```
BoxSmooth box, srcWave, smoothedWave
```

is equivalent to:

```
Duplicate/O srcWave, smoothedWave
Smooth/B/DIM=-1/E=3/F=0 box, smoothedWave
```

break

`break`

The break flow control keyword immediately terminates execution of a loop, switch, or strswitch. Execution then continues with code following the loop, switch, or strswitch.

See Also

Break Statement on page IV-48, **Switch Statements** on page IV-43, and **Loops** on page IV-45 for usage details.

BrowseURL

`BrowseURL [/Z]` ***`urlStr`***

The BrowseURL operation opens the Web browser or FTP browser on your computer and asks it to display a particular Web page or to connect to an FTP server.

BrowseURL sets a variable named V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if an error occurs.

Parameters

urlStr specifies a Web page or FTP server directory to be browsed. It is constructed of a naming scheme (e.g., “http://” or “ftp://”), a computer name (e.g., “www.wavemetrics.com” or “ftp.wavemetrics.com” or “38.170.234.2”), and a path (e.g., “/Test/TestFile1.txt”). See **Examples** for sample usage.

Flags

/Z	Errors are not fatal. Will not abort procedure execution if the URL is bad or if the server is down. Your procedure can inspect the V_flag variable to see if the transfer succeeded. V_flag will be zero if it succeeded or nonzero if it failed. Syntactic errors, such as omitting the URL altogether or omitting quotes, are still fatal.

Examples

```
// Browse a Web page.
   String url = "http://www.wavemetrics.com/News/index.html"
   BrowseURL url
```

```
// Browse an FTP server.
   String url = "ftp://ftp.wavemetrics.com/pub/test"
   BrowseURL url
```

See Also

URLRequest

BuildMenu

`BuildMenu` ***`menuNameStr`***

The BuildMenu operation rebuilds the user-defined menu items in the specified menu the next time the user clicks in the menu bar.

Parameters

menuNameStr is a string expression containing a menu name or "`All`".

Details

Call BuildMenu when you’ve defined a custom menu using string variables for the menu items. After you change the string variables, call BuildMenu to update the menu.

BuildMenu "`All`" rebuilds all the menu items and titles and updates the menu bar.

Under the current implementation, if menuNameStr is not "`All`", Igor will rebuild *all* user-defined menu items if BuildMenu is called for *any* user-defined menu.

See Also

Dynamic Menu Items on page IV-129.

Button

Button [**/Z**] ***ctrlName*** [***keyword* = *value*** [, ***keyword* = *value*** …]]

The Button operation creates or modifies the named button control.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the Button control to be created or changed.

align=*alignment* Sets the alignment mode of the control. The alignment mode controls the interpretation of the *leftOrRight* parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

If *alignment*=0 (default), *leftOrRight* specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If *alignment*=1, *leftOrRight* specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

appearance={*kind* [, *platform*]} Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind=default:	Appearance determined by **DefaultGUIControls**.
kind=native:	Creates standard-looking controls for the current computer platform.
kind=os9:	Igor Pro 5 appearance (quasi-Macintosh OS 9 controls that look the same on Macintosh and Windows).
platform=Mac:	Changes the appearance of controls only on Macintosh; affects the experiment whenever it is used on Macintosh.
platform=Win:	Changes the appearance of controls only on Windows; affects the experiment whenever it is used on Windows.
platform=All:	Changes the appearance on both Macintosh and Windows computers.

disable=*d* Sets the state of the control. *d* is a bit field: bit 0 (the least significant bit) is set when the control is hidden. Bit 1 is set when the control is disabled:

d=0:	Normal (visible), enabled.
d=1:	Hidden.
d=2:	Visible and disabled. Drawn in grayed state, also disables action procedure.
d=3:	Hidden and disabled.

See the **ModifyControl** example for setting the bits individually.

fColor=(*r*,*g*,*b*[,*a*]) Sets color of the button. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. While accepted as an input, *a* has no effect.

Specify fColor=(0,0,0) to get the default button color. If you want a black button use fColor=(1,1,1). To get the default blue button appearance, use fColor(0,0,65535).To set the color of the title text, see valueColor.

focusRing=*fr* Enables or disables the drawing of a rectangle indicating keyboard focus:

fr=0:	Focus rectangle will not be drawn.
fr=1:	Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

font="*fontName*" Sets button font, e.g., `font="Helvetica"`.

fsize=*s* Sets font size.

fstyle=*fs* Specifies the font style. *fs* is a bitwise parameter with each bit controlling one aspect of the font style:

Bit 0:	Bold
Bit 1:	Italic
Bit 2:	Underline
Bit 4:	Strikethrough

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

help={*helpStr*} Specifies the help for the control.

helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).

You can insert a line break by putting "`\r`" in a quoted string.

labelBack=(*r*,*g*,*b*[,*a*]) or 0

Sets the background color for the control when using a picture to define the appearance of the button (see the picture keyword).

The labelBack keyword was added in Igor Pro 9.00.

r, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

For transparency to work, the picture must be inherently transparent. For example, each pixel in a PNG picture has its own internal alpha value so it can be inherently transparent or inherently opaque.

If you want the button background to be actually transparent, use the labelBack color to set the background color of the picture. In most cases, use transparent white: labelBack=(65535, 65535, 65535, 0).

If you omit labelBack or specify labelBack=0 then the button background color is the background color of the window in which the button is drawn.

noproc No procedure is executed when clicking the button.

picture= *pict* Draws the button using the named picture. The picture is taken to be three side-by-side frames that show the control appearance in the normal state, when the mouse is down, and in the disabled state. The picture may be either a global (imported) picture or a Proc Picture (see **Proc Pictures** on page IV-56).

By default, the button's rectangle is filled with the background color of the window it is drawn in before the picture is drawn. You can use the labelBack keyword to control the button's background color and transparency.

In Igor6, the size keyword is ignored when a picture is used with a button control. To make it easier to size graphics for high-resolution screens, as of Igor7, the size keyword is respected in this case.

pos={*leftOrRight*,*top*} Sets the position in **Control Panel Units** of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+={*dx*,*dy*} Offsets the position of the button in **Control Panel Units**.

proc=*procName* Names the procedure to execute when clicking the button.

rename=*newName* Gives the button a new name.

size={*width*,*height*} Sets *width* and *height* of button in **Control Panel Units**.

title=*titleStr* Sets title of button (text that appears in the button) to the specified string expression. If not given then title will be "New". If you use `""` the button will contain no text.

Using escape codes you can change the font, size, style, and color of the title. See **Annotation Escape Codes** on page III-53 or details.

userdata(*UDName*)=*UDStr*
Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to create named user data.

Names starting with “WM_” are reserved for WaveMetrics.

userdata(*UDName*)+=*UDStr*
Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

Names starting with “WM_” are reserved for WaveMetrics.

valueColor=(*r*,*g*,*b*[,*a*])

Sets initial color of the button's text (title). *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque black.

To further change the color of the title text, use escape sequences as described for title=*titleStr*.

win=*winName*
Specifies which window or subwindow contains the named button control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The target window must be a graph or panel.

Button Action Procedure

The action procedure for a Button control takes a predefined structure `WMButtonAction` as a parameter to the function:

```
Function ActionProcName(B_Struct) : ButtonControl
   STRUCT WMButtonAction &B_Struct
   …
   return 0
End
```

The “`: ButtonControl`” designation tells Igor to include this procedure in the Procedure pop-up menu in the Button Control dialog.

See **WMButtonAction** for details on the WMButtonAction structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format button action procedure in old code:

```
Function procName(ctrlName) : ButtonControl
   String ctrlName
   …
   return 0
End
```

This old format should not be used in new code.

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Control Panel Units on page III-444 for a discussion of the units used for controls.

The **ControlInfo** operation for information about the control.

The **GetUserData** function for retrieving named user data.

ButtonControl

`ButtonControl`

ButtonControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined button control. See **Procedure Subtypes** on page IV-204 for details. See **Button** for details on creating a button control.

cabs

`cabs(`*`z`*`)`

The cabs function returns the real-valued absolute value of complex number *z*.

See Also

The **magsqr** function.

CameraWindow

`CameraWindow`

CameraWindow is a procedure subtype keyword that identifies a macro as being a camera window recreation macro. It is automatically used when Igor creates a window recreation macro for a camera window. See **Procedure Subtypes** on page IV-204 and **Saving and Recreating Graphs** on page II-350 for details.

CaptureHistory

`CaptureHistory(`*`refnum, stopCapturing`*`)`

The CaptureHistory function returns a string containing text from the history area of the command window since a matching call to the **CaptureHistoryStart** function.

Parameters

refnum is a number returned from a call to CaptureHistoryStart. It identifies the starting point in the history for the returned string.

Set *stopCapturing* to nonzero to indicate that no more history should be captured for the given refnum. Subsequent calls to CaptureHistory with the same *refnum* will result in an error.

Set *stopCapturing* to zero to retrieve history text captured so far. Further calls to CaptureHistory with the same reference number will return this text, plus any additional history text added subsequently.

Details

You can have multiple captures active at one time. Each call to CaptureHistoryStart will return a unique reference number identifying a start point in the history. The capture corresponding to each reference number can be terminated at any time, regardless of the order of the CaptureHistoryStart calls.

CaptureHistoryStart

`CaptureHistoryStart()`

The CaptureHistoryStart function returns a reference number to identify a starting point in the history area text. Subsequently, the CaptureHistory function can be used to retrieve captured history text. See **CaptureHistory** for details.

catch

`catch`

The catch flow control keyword marks the beginning of code in a try-catch-endtry flow control construct for handling any abort conditions.

See Also

The **try-catch-endtry** flow control statement for details.

cd

`cd `*`dataFolderSpec`*

The cd operation sets the current data folder to the specified data folder. It is identical to the longer-named SetDataFolder operation.

cd is named after the UNIX "change directory" command.

See Also

SetDataFolder, **pwd**, **Dir**, **Data Folders** on page II-107

CDFFunc

`CDFFunc`

CDFFunc is a procedure subtype keyword that identifies a function as being suitable for calling from the **StatsKSTest** operation.

ceil

`ceil(`*`num`*`)`

The ceil function returns the closest integer greater than or equal to *num*.

The result for INF and NAN is undefined.

See Also

The **round**, **floor**, and **trunc** functions.

centerOfMass

`centerOfMass(`*`srcWave`*` [,`*`x1`*`,`*`x2`*`])`

The centerOfMass function returns the 1D center of mass for *srcWave* X values from x=*x1* to x=x2.

The centerOfMass function was added in Igor Pro 9.00.

Center of mass and center of gravity in a uniform gravity field are different terms for the same calculation. When the masses are of uniform density, the center of mass is also identical to the geometric centroid.

Details

The center of mass is defined as

$$centerMass = \frac{\sum x_i y_i}{\sum y_i},$$

where the summation is over all the points in *srcWave* or over the X range specified by the optional parameters x1 and x2.

Each term in the numerator above can be written as

$$x_i y_i = \left[DimOffset(srcWave,0) + i \cdot DimDelta(srcWave,0) \right] srcWave[i].$$

In this notation, y_i represents an individual mass at x = x_i, and the returned value x_c is the X location of the center of the aggregate mass.

See Also

centerOfMassXY, **mean**, **area**, **SumDimension**, **ImageAnalyzeParticles**

centerOfMassXY

`centerOfMassXY(waveX, waveY)`

The centerOfMassXY function returns the 1D center of mass xc for the pair of waves.

The centerOfMassXY function was added in Igor Pro 9.00.

You can obtain the center of mass in the orthogonal direction (yc) by reversing the order of arguments to the function.

Details

The center of mass is defined as

$$centrMassXY = \frac{\sum waveA[i]\ \ waveB[i]}{\sum waveB[i]}.$$

See Also

centerOfMass, **mean**, **areaXY**, **SumDimension**, **ImageAnalyzeParticles**

cequal

`cequal(`*`z1, z2`*`)`

The cequal function determines the equality of two complex numbers *z1* and *z2*. It returns 1 if they are equal, or 0 if not.

This is in contrast to the == operator, which compares only the real components of *z1* and *z2*, ignoring the imaginary components.

Examples

```
Function TestComplexEqualities()
   Variable/C z1= cmplx(1,2), z2= cmplx(1,-2)
   // This test compares only the real parts of z1 and z2:
   if( z1 == z2 )
      Print "== match"
   else
      Print "no == match"
   endif
   // This test compares both real and imaginary parts of z1 and z2:
   if( cequal(z1,z2) )
      Print "cequal match"
   else
      Print "no cequal match"
   endif
End
```

```
•TestComplexEqualities()
  == match
  no cequal match
```

See Also

The **imag**, **real**, and **cmplx** functions.

char2num

`char2num(`*`str`*`)`

The char2num function returns a numeric code representing the first byte of *str* or the first character of *str*.

If *str* contains zero bytes, char2num returns NaN.

If *str* contains exactly one byte, char2num returns the value of that byte, treated as a signed byte. For backward compatibility with Igor6, if the input is a single byte in the range 0x80..0xFF, char2num returns a negative number.

If *str* contains more than one byte, char2num returns a number which is the Unicode code point for the first character in *str* treated as UTF-8 text. If *str* does not start with a valid UTF-8 character, char2num returns NaN.

Prior to Igor Pro 7.00, char2num always returned the value of the first byte, treated as a signed byte.

Examples

```
Function DemoChar2Num()
   String str

   str = "A"
   Printf "Single ASCII character: %02X\r", char2num(str)          // Prints 0x41

   str = "ABC"
   Printf "Multiple ASCII characters: %02X\r", char2num(str)       // Prints 0x41

   str = U+2022        // Bullet character
   Printf "Valid UTF-8 text: U+%04X\r", char2num(str)               // Prints U+2022
   Printf "First byte value: %02X\r", char2num(str[0]) & 0xFF       // Prints E2
   Printf "Second byte value: %02X\r", char2num(str[1]) & 0xFF      // Prints 80

   str = num2char(0xE2, 0) + num2char(0x41, 0)                      // Invalid UTF-8 text
   Printf "Invalid UTF-8 text: U+%04X\r", char2num(str)             // Prints NaN

   str = ""
   Printf "Empty string: %g\r", char2num(str)                       // Prints NaN
End
```

See Also

The **num2char**, **str2num** and **num2str** functions.

Text Encodings on page III-459.

Chart

`Chart` `[`**`/Z`**`]` ***`ctrlName`*** `[`***`keyword = value`*** `[,` ***`keyword = value`*** `…]]`

The Chart operation creates or modifies a chart control. Charts are generally used in conjunction with data acquisition. Charts do not have to be connected to a FIFO, but they are not useful until they are.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the Chart control to be created or changed.

The following keyword=value parameters are supported:

align=*alignment* Sets the alignment mode of the control. The alignment mode controls the interpretation of the *leftOrRight* parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

If *alignment*=0 (default), *leftOrRight* specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If *alignment*=1, *leftOrRight* specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

chans={*ch#*, *ch#*,…} List of FIFO channel numbers that Chart is to monitor.

color(*ch#*)=(*r*,*g*,*b*[,*a*]) Sets the color of the specified trace. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

ctab=*colortableName* When a channel is connected to an image strip FIFO channel, the data is displayed as an image using this built-in color table. Valid names are the same as used in images. Invalid name will result in the default Grays color table being used.

disable=*d* Sets user editability of the control.

d=0: Normal.

d=1: Hide.

d=2: Disable user input.

Charts do not change appearance because they are read-only. When disabled, the hand cursor is not shown.

fbkRGB=(*r*,*g*,*b*[,*a*]) Sets frame background color. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

fgRGB=(*r*,*g*,*b*[,*a*]) Sets foreground color (text, etc.). *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

fifo=*FIFOName* Sets which named FIFO the chart will monitor. See the **NewFIFO** operation.

font="*fontName*" Sets the font used in the chart, e.g., `font="Helvetica"`.

fsize=*s* Sets font size for chart.

fstyle=*fs*
: Specifies the font style. *fs* is a bitwise parameter with each bit controlling one aspect of the font style:

Bit 0:	Bold
Bit 1:	Italic
Bit 2:	Underline
Bit 4:	Strikethrough

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

gain(*ch#*)=*g*
: Sets the display gain *g* of the specified channel relative to nominal. Values greater than unity expand the display.

gridRGB=(*r*,*g*,*b*[,*a*])
: Sets grid color. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

help={*helpStr*}
: Specifies help for the control.

helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).

You can insert a line break by putting "`\r`" in a quoted string.

jumpTo=*p*
: Jumps to point number *p*. This works in review mode only.

lineMode(*ch#*)=*lm*
: Sets the display line mode for the given channel.

lm=0: Dots mode. Draws values as dots. However, if the number of dots in a strip exceeds maxDots then Igor draws a vertical line from the min to the max of the values packed into the strip.

lm=1: Lines mode. Draws a vertical line encompassing the min and the max of the points in a given strip along with the last point of the preceding strip. Since which strip is the preceding strip depends on the direction of motion then the appearance may slightly shift depending on which direction the chart is moving.

lm=2: Dots mode. Draws values as dots. However, if the number of dots in a strip exceeds maxDots then Igor draws a vertical line from the min to the max of the values packed into the strip.

mass=*m*
: Sets the "feel" of the chart paper when you move it with the mouse. The larger the mass *m*, the slower the chart responds. Odd values cause the movement of the paper to stop the instant the mouse is clicked while even values continue with the illusion of mass.

maxDots=*md*
: Controls whether points in a given vertical strip of the chart are displayed as dots or as a solid line. See lineMode above. Default is 20.

offset(*ch#*)=*o*
: Sets the display offset of the specified channel. The offset value *o* is subtracted from the data before the gain is applied.

oMode=*om*
: Chart operation mode.

om=0: Live mode.

om=1: Review mode.

pbkRGB=(*r*,*g*,*b*[,*a*])
: Sets plot area background color. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

pos={*leftOrRight*,*top*}
: Sets the position in **Control Panel Units** of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

ppStrip=*pps*
: Number of data points packed into each vertical strip of the chart.

rSize(*ch#*)=*rs*
: Sets the relative vertical size allocated to the given channel. Nominal is unity. If the value of *rs* is zero then this channel shares space with the previous channel.

sMode=*sm* Status line mode.

- *sm*=0: Turns off fancy status line and positioning bar.
- *sm*=1: Normal mode.
- *sm*=2: Uses alternate style for bar.

sRate=*sr* Sets the scroll rate (vertical strips/second). If the chart control is in review mode negative numbers scroll in reverse.

title=*titleStr* Specifies the chart title. Use "" for no title.

uMode=*um* Status line mode.

- *um*=1: Fast update with no bells and whistles.
- *um*=2: Status line and positioning bar.
- *um*=3: Status line, positioning bar, and animated pens.

win=*winName* Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The action of some of the Chart keywords depends on whether or not data acquisition is taking place. If the chart is in review mode then all keywords cause the chart to be redrawn. If data acquisition is taking place and the chart is in live mode then some keywords affect new data but do not attempt to update the part of the "paper" that has already been drawn. The following keywords affect only new data during live mode:

```
ppStrip, maxDots, gain, offset, color, lineMode
```

Charts on page III-415 and **FIFOs and Charts** on page IV-313.

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Control Panel Units on page III-444 for a discussion of the units used for controls.

The **ControlInfo** operation for information about the control.

The **GetUserData** function for retrieving named user data.

chebyshev

chebyshev(*n*, *x*)

The chebyshev function returns the Chebyshev polynomial of the first kind and of degree *n*.

The Chebyshev polynomials satisfy the recurrence relation:

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$$

with:

$$T_0(x) = 1$$
$$T_1(x) = x$$
$$T_2(x) = 2x^2 - 1.$$

The orthogonality of the polynomial is expressed by the integral:

$$\int_{-1}^{1}\frac{T_n(x)T_m(x)}{\sqrt{1-x^2}}dx=\begin{cases}0 & m\neq n\\ \pi/2 & m=n\neq 0\\ \pi & m=m=0\end{cases}\quad .$$

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

See Also

chebyshevU.

chebyshevU

chebyshevU(*n*, *x*)

The chebyshevU function returns the Chebyshev polynomial of the second kind, degree *n* and argument *x*.

The Chebyshev polynomial of the second kind satisfies the recurrence relation

```
U(n+1,x)=2xU(n,x)-U(n-1,x)
```

which is also the recurrence relation of the Chebyshev polynomials of the first kind.

The first 10 polynomials of the second kind are:

$U(0,x)=1$

$U(1,x)=2x$

$U(2,x)=4x^2-1$

$U(3,x)=8x^3-4x$

$U(4,x)=16x^4-12x^2+1$

$U(5,x)=32x^5-32x^3+6x$

$U(6,x)=64x^6-80x^4+24x-1$

$U(7,x)=128x^7-192x^5+80x^3-8x$

$U(8,x)=256x^8-448x^6+240x^4-40x^2+1$

$U(9,x)\,512x^9-1024x^{\wedge 7}+672x^5-160x^3+10x$

See Also

The **chebyshev** function.

CheckBox

CheckBox [**/Z**] ***ctrlName*** [***keyword = value*** [, ***keyword = value*** …]]

The CheckBox operation creates or modifies a checkbox, radio button or disclosure triangle in the target or named window, which must be a graph or control panel.

ctrlName is the name of the checkbox.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the CheckBox control to be created or changed.

The following keyword=value parameters are supported:

align=*alignment*

Sets the alignment mode of the control. The alignment mode controls the interpretation of the *leftOrRight* parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

If *alignment*=0 (default), *leftOrRight* specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If *alignment*=1, *leftOrRight* specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

appearance={*kind* [, *platform*]}
Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of `default`, `native`, or `os9`.

platform can be one of `Mac`, `Win`, or *All*.

See **Button** and **DefaultGUIControls** for more appearance details.

disable=*d*
Sets user editability of the control.

d=0: Normal.
d=1: Hide.
d=2: Disable user input.

fsize=*s*
Sets font size for checkbox.

fColor=(*r*,*g*,*b*[,*a*])
Sets the initial color of the title. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque black.

To further change the color of the title text, use escape sequences as described for title=*titleStr*.

focusRing=*fr*
Enables or disables the drawing of a rectangle indicating keyboard focus:

fr=0: Focus rectangle will not be drawn.
fr=1: Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

help={*helpStr*}
Sets the help for the control.

helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).

You can insert a line break by putting "`\r`" in a quoted string.

mode=*m*
Specifies checkbox appearance.

m=0: Default checkbox appearance.
m=1: Display as a radio button control.
m=2: Display as a disclosure triangle (*Macintosh*) or treeview expansion node (*Windows*).

noproc
Specifies that no procedure is to execute when clicking the checkbox.

picture= *pict*
Draws the checkbox using the named picture. The picture is taken to be six side-by-side frames which show the control appearance in the normal state, when the mouse is down, and in the disabled state. The first three frames are used when the checked state is false and the next three show the true state. The picture may be either a global (imported) picture or a Proc Picture (see **Proc Pictures** on page IV-56).

pos={*leftOrRight*,*top*}
Sets the position in **Control Panel Units** of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+={*dx*,*dy*}
Offsets the position of the checkbox in **Control Panel Units**.

proc=*procName*
Specifies the procedure to execute when the checkbox is clicked.

rename=*newName*
Renames the checkbox to *newName*.

side=s
Sets the location of the title relative to the box:

s =0: Checkbox is on the left, title is on the right (default).
s =1: Checkbox is on the right, title is on the left.

size={*width*,*height*}
Sets checkbox size in **Control Panel Units**.

title=*titleStr*
Sets title of checkbox to the specified string expression. The title is the text that appears in the checkbox. If not given or if `""` then the title will be “New”.

Using escape codes you can change the font, size, style, and color of the title. See **Annotation Escape Codes** on page III-53 or details.

userdata(*UDName*)= *UDStr*
Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

userdata(*UDName*)+= *UDStr*
Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

value=*v*
Specifies whether the checkbox is selected (*v*=1) or not (*v*=0).

variable=*varName*
Specifies a global numeric variable to be set to the current state of a checkbox whenever it is clicked or when it is set by the value parameter. The variable is two-way: setting the variable also changes the state of the checkbox.

wave=*waveName*
Specifies a point from a wave to be set to the current state of a checkbox when it is clicked or when it is set by the value keyword. The point is specified using standard bracket notation with either a numeric point number or a row label, e.g., `value=awave[4]` or `value=awave[%alabel]`. You may also use a 2D, 3D, or 4D wave and specify a column, layer, and chunk index or dimension label in addition to the row index. This feature was added in Igor Pro 9.00.

win=*winName*
Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Flags

/Z
No error reporting.

Details

The target window must be a graph or panel.

Checkbox Action Procedure

The action procedure for a CheckBox control can takes a predefined structure `WMCheckboxAction` as a parameter to the function:

```
Function ActionProcName(CB_Struct) : CheckBoxControl
   STRUCT WMCheckboxAction &CB_Struct
   …
   return 0
End
```

The “`: CheckboxControl`” designation tells Igor to include this procedure in the Procedure pop-up menu in the Checkbox Control dialog.

See **WMCheckboxAction** for details on the WMCheckboxAction structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format checkbox action procedure in old code:

```
Function procName(ctrlName,checked) : CheckBoxControl
   String ctrlName
   Variable checked        // 1 if selected, 0 if not
   …
   return 0
End
```

This old format should not be used in new code.

When using radio button controls, it is the responsibility of the Igor programmer to turn off other radio buttons when one of a group of radio buttons is pressed.

Examples

```
// Create a radio button group

Window Panel0() : Panel
   PauseUpdate; Silent 1         // building window …
   NewPanel /W=(150,50,353,212)
   Variable/G gSelectedRadioButton = 1
   CheckBox radioButton1,pos={52,25},size={78,15},title="Radio 1"
   CheckBox radioButton1,value=1,mode=1,proc=MyRadioButtonProc
   CheckBox radioButton2,pos={52,45},size={78,15},title="Radio 2"
   CheckBox radioButton2,value=0,mode=1,proc=MyRadioButtonProc
   CheckBox radioButton3,pos={52,65},size={78,15},title="Radio 3"
   CheckBox radioButton3,value= 0,mode=1,proc=MyRadioButtonProc
EndMacro

static Function HandleRadioButtonClick(controlName)
   String controlName

   NVAR gSelectedRadioButton = root:gSelectedRadioButton

   strswitch(controlName)
      case "radioButton1":
         gSelectedRadioButton = 1
         break
      case "radioButton2":
         gSelectedRadioButton = 2
         break
      case "radioButton3":
         gSelectedRadioButton = 3
         break
   endswitch
   CheckBox radioButton1, value = gSelectedRadioButton==1
   CheckBox radioButton2, value = gSelectedRadioButton==2
   CheckBox radioButton3, value = gSelectedRadioButton==3
End

Function MyRadioButtonProc(cb) : CheckBoxControl
   STRUCT WMCheckboxAction& cb

   switch(cb.eventCode)
      case 2:          // Mouse up
         HandleRadioButtonClick(cb.ctrlName)
      break
   endswitch

   return 0
End
```

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Control Panel Units on page III-444 for a discussion of the units used for controls.

The **ControlInfo** operation for information about the control.

The **GetUserData** function for retrieving named user data.

CheckBoxControl

`CheckBoxControl`

CheckBoxControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined checkbox control. See **Procedure Subtypes** on page IV-204 for details. See **CheckBox** for details on creating a checkbox control.

CheckDisplayed

CheckDisplayed [/A/W] *waveName* [, *waveName*]…

The CheckDisplayed operation determines if named waves are displayed or otherwise used in a host window or subwindow.

Flags

/A	Checks all graphs, tables, page layout, panels, and Gizmo windows.
/W=*winName*	Checks only the named window When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

If neither /A nor /W are used, CheckDisplayed checks only the top graph, table, page layout, panel, or Gizmo window.

CheckDisplayed sets a bit in the variable V_flag for each wave that is displayed.

Waves that are not directly displayed in a window can still be used by it. For example, CheckDisplayed returns 1 for the following cases: waves associated with hidden traces, color index waves, waves used to specify error bars, and waves used to draw polygons in page layouts and control panels as well as in graphs.

Example

```
// Checks Graph0 to see if aWave, bWave, and cWave are displayed in it.
// Sets bit 0 of V_flag if aWave is displayed.
// Sets bit 1 of V_flag if bWave is displayed.
// Sets bit 2 of V_flag if cWave is displayed.
CheckDisplayed/W=Graph0 aWave,bWave,cWave
```

See Also

Setting Bit Parameters on page IV-12 for information about bit settings.

CheckName

CheckName(*nameStr*, *objectType* [, *windowNameStr*])

The CheckName function returns a number which indicates if the specified name is legal and unique among objects in the namespace of the specified object type.

In Igor Pro 9.00 or later, you can use the **CreateDataObjectName** function as a replacement for some combination of CheckName, CleanupName, and UniqueName to create names of waves, global variables, and data folders.

Waves, global numeric variables, and global string variables are all in the same namespace and need to be unique only within the data folder containing them. However, they also need to be distinct from names of Igor operations and functions and from names of user-defined procedures.

Data folders are in their own namespace and need to be unique only among other data folders at the same level of the data folder hierarchy.

windowNameStr is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of *objectType*.

Details

A result of zero indicates that the name is legal and unique within its namespace. Any nonzero result indicates that the name is illegal or not unique. You can use the **CleanupName** and **UniqueName** functions to guarantee legality and uniqueness.

nameStr should contain an unquoted name (i.e., no single quotes for liberal names), such as you might receive from the user through a dialog or control panel.

objectType is one of the following:

The *windowNameStr* argument is used only with *objectTypes* 14, 15, and 16. The *nameStr* is checked for uniqueness only within the named window (other windows might have objects with the given name). If a named window is given but does not exist, any valid *nameStr* is permitted

1: Wave.
2: Reserved.
3: Global numeric variable.
4: Global string variable.
5: XOP target window.
6: Graph window.
7: Table window.
8: Layout window.
9: Control panel window.
10: Notebook window.
11: Data folder.
12: Symbolic path.
13: Picture.
14: Annotation in the named or topmost graph or layout.
15: Control in the named topmost graph or panel.
16: Notebook action character in the named or topmost notebook.

CheckName Thread Safety

As of Igor Pro 8.00, you can call CheckName from an Igor preemptive thread but only if *objectType* is 1 (wave), 3 (global numeric variable), 4, (global string variable), 11 (data folder), or 12 (symbolic path). For any other value of *objectType*, CheckName returns a runtime error.

Examples

```
Variable waveNameIsOK = CheckName(proposedWaveName, 1) == 0
Variable annotationNameIsOK = CheckName("text0", 14, "Graph0") == 0

// Create a valid and unique wave name
Function/S CreateValidAndUniqueWaveName(proposedName)
   String proposedName

   String result = proposedName

   if (CheckName(result,1) != 0)           // 1 for waves
      result = CleanupName(result, 1)      // Make sure it's valid
      result = UniqueName(result, 1, 0)    // Make sure it's unique
   endif

   return result
End
```

Object Names on page III-501, **Programming with Liberal Names** on page IV-168, **CreateDataObjectName**, **CleanupName**, **UniqueName**

ChildWindowList

ChildWindowList(*hostNameStr*)

The ChildWindowList function returns a string containing a semicolon-separated list of immediate subwindow window names of the specified host window or subwindow.

Parameters

hostNameStr is a string or string expression containing the name of an existing host window or subwindow.

When identifying a subwindow with *hostNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Error if the host does not exist or if it is not an allowed host type.

See Also

WinList and **WinType** functions.

ChooseColor

ChooseColor [**/A[=a]/C=(*r*,*g*,*b*[,*a*])**]

The ChooseColor operation displays a dialog for choosing a color.

The color initially shown is black unless you specify a different color with /C.

Flags

/A[=*a*]	a=1 shows the alpha (opacity) channel. /A is the same as /A=1. a=0 hides the alpha channel. This is the default setting. The /A flag was added in Igor Pro 7.00.
/C=(*r*,*g*,*b*[,*a*])	Sets the color initially displayed in the dialog. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

Details

ChooseColor sets the variable V_flag to 1 if the user clicks OK in the dialog or to 0 otherwise.

If V_flag is 1 then V_Red, V_Green, V_Blue, and V_Alpha are set to the selected color as integers from 0 to 65535.

A fully opaque color sets V_Alpha=65535. A fully transparent color sets V_Alpha=0.

See Also

ImageTransform **rgb2hsl** and **hsl2rgb**.

CleanupName

CleanupName(*nameStr*, *beLiberal* [, *maxBytes*])

The CleanupName function returns the input name string, possibly altered to make it a legal object name.

The *maxBytes* parameter requires Igor Pro 8.00 or later.

In Igor Pro 9.00 or later, you can use the **CreateDataObjectName** function as a replacement for some combination of CheckName, CleanupName, and UniqueName to create names of waves, global variables, and data folders.

Parameters

nameStr must contain an unquoted (i.e., no single quotes for liberal names) name, such as you might receive from the user through a dialog or control panel.

beLiberal is 0 to use strict name rules or 1 to use liberal name rules. Strict rules allow only letters, digits and the underscore character. Liberal rules allow other characters such as spaces and dots. Liberal names are allowed for waves and data folders only.

maxBytes is the maximum number of bytes allowed in the result. This parameter requires Igor Pro 8.00 or later. *maxBytes* is optional, defaults to 255, and is clipped to the range 1..255.

Prior to Igor Pro 8.00, Igor names were limited to 31 bytes so CleanupName never returned names longer than 31 bytes. In Igor Pro 8.00 or later, names for most types of objects may be up to 255 bytes so CleanupName may return very long names. You may want to use the *maxBytes* parameter to prevent the use of inconveniently-long names.

If *nameStr* includes non-ASCII characters, which in UTF-8 consist of multiple bytes, CleanupName clips the name at a character boundary if clipping is required.

Details

A cleaned up name is not necessarily unique. Call **CheckName** to check for uniqueness or **UniqueName** to ensure uniqueness.

Prior to Igor8, all object names were limited to 31 bytes. Now, for most types of objects, names can be up to 255 bytes. CleanupName always allows up to 255 bytes. Global picture names and notebook ruler names are still limited to 31 bytes so, if you are cleaning up those names, you must test for long names yourself. See **Long Object Names** on page III-502 for details.

If a cleaned up name is liberal, you may need to quote it. See **Programming with Liberal Names** on page IV-168 for details.

Examples

```
String cleanStrVarName = CleanupName(proposedStrVarName, 0)
```

```
// In UTF-8, the "±" character consists of two bytes: 0xC2 and 0XB1
Print CleanupName("±", 1, 1)  // maxBytes=1; returns "" (empty string - 0 bytes)
Print CleanupName("±", 1, 2)  // maxBytes=2; returns "±" (2 bytes)
```

See Also

Object Names on page III-501, **Programming with Liberal Names** on page IV-168, **CreateDataObjectName**, **CheckName**, **UniqueName**

Close

```
Close [/A] fileRefNum
```

The Close operation closes a file previously opened by the **Open** operation or closes all such files if /A is used.

Parameters

fileRefNum is the file reference number of the file to close. This number comes from the Open operation. If /A is used, *fileRefNum* should be omitted.

Flags

/A	Closes all files. Mainly useful for cleaning up after an error during procedure execution occurs so that the normal Close operation is never executed.

CloseHelp

```
CloseHelp [ /ALL /FILE=fileNameStr /NAME=helpNameStr /P=pathName ]
```

The CloseHelp operation closes a help window.

The CloseHelp operation was added in Igor Pro 7.00.

Flags

/ALL	Closes all open help windows.
/FILE=*fileNameStr*	Identifies the help window to close using the help file's location on disk. The file is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-451 for details on forming the path.
/NAME=*helpNameStr*	Identifies the help window to close using the window's title as specified by *helpNameStr*. This is the text that appears in the help window title bar.
/P=*pathName*	Specifies the folder to look in for the file specified by /FILE. *pathName* is the name of an existing Igor symbolic path.

Details

You must provide one of the following flags: /ALL, /FILE, /NAME.

See Also

OpenHelp

CloseMovie

```
CloseMovie
```

The CloseMovie operation closes the currently open movie. You must close a movie before you can play it.

Flags

/Z	Suppresses error reporting. If you use /Z, check the V_Flag output variable to see if the operation succeeded.

Output Variables

`V_Flag`	Set to 0 if the operation succeeded or to a non-zero error code. V_Flag is set only if you use the /Z flag.

Movies on page IV-245, **NewMovie**

CloseProc

`CloseProc /NAME=`*`procNameStr`* `[`***`flags`***`]`

`CloseProc /FILE=`*`fileNameStr`* `[`***`flags`***`]`

The CloseProc operation closes a procedure window. You cannot call CloseProc on the main Procedure window.

CloseProc provides a way to programmatically create and alter procedure files. You might do this in order to make a user-defined menu-bar menu with contents that change.

Note: CloseProc alters procedure windows so it cannot be called while functions or macros are running. If you want to call it from a function or macro, use **Execute/P**.

Warning: If you close a procedure window that has no source file or without specifying a destination file, the window contents will be permanently lost.

Flags

/COMP[=*compile*] Specifies whether procedures should be compiled after closing the procedure window.

compile=1: Compiles procedures (same as /COMP only).

compile=0: Leaves procedures in an uncompiled state.

/D[=*delete*] Specifies whether the procedure file should be deleted after closing the procedure window.

delete=1: Deletes procedure file (same as /D only).

Warning: You cannot recover any file deleted this way.

delete=0: Leaves any associated file unaffected.

/FILE=*fileNameStr* Identifies the procedure window to close using the file name and path to the file given by *fileNameStr*. The string can be just the file name if /P is used to specify a symbolic path name of the enclosing folder. It can be a partial path if /P points to a folder enclosing the start of the partial path. It can also be a full path the file.

/NAME=*procNameStr* Identifies the procedure window to close with the string expression *procNameStr*. This is the same text that appears in the window title. If the procedure window is associated with a file, it will be the file name and extension.

To close a procedure file that is part of an independent module, you must include the independent module name in *procNameStr*. For example:

```
CloseProc /NAME="GraphBrowser.ipf [WM_GrfBrowser]"
```

Note that there is a space after the file name followed by the independent module name in brackets.

/P=*pathName* Specifies the folder to look in for the file specified by /FILE. *pathName* is the name of an existing symbolic path.

/SAVE[=*savePathStr*] Saves the procedure before closing the window. If the flag is used with no argument, it saves any changes to the procedure window to its source file before closing it. If *savePathStr* is present, it must be a full path naming a file in which to save the procedure window contents. The /P flag is not used with *savePathStr* so it must be a full path.

Details

CloseProc cannot be called from a macro or function. Call it from the command line or via Execute/P (see **Operation Queue** on page IV-278).

Specify which window to close using either the /NAME or /FILE flag. You must use one or the other. Usually you would use /NAME, as it is usually more convenient. If by some chance two procedures have the same name, /FILE can be used to distinguish between them.

You cannot call CloseProc on a nonmain procedure window that someone has had the bad taste to call "Procedure".

See Also

Chapter III-13, **Procedure Windows**.

The **Execute/P** operation.

cmplx

cmplx(*realPart*, *imagPart*)

The cmplx function returns a complex number whose real component is *realPart* and whose imaginary component is *imagPart*.

Use this to assign a value to a complex variable or complex wave.

Examples

Assume wave1 is complex. Then:

```
wave1(0) = cmplx(1,2)
```

sets the Y value of wave1 at x=0 such that its real component is 1 and its imaginary component is 2.

Assuming wave2 and wave3 are real, then:

```
wave1 = cmplx(wave2,wave3)
```

sets the real component of wave1 equal to the contents of wave2 and the imaginary component of wave1 equal to the contents of wave3.

You may get unexpected results if the number of points in wave2 or wave3 differs from the number of points in wave1. If wave2 or wave3 are shorter than wave1, the last element of the short wave is copied repeatedly to fill wave1.

See Also

conj, **imag**, **magsqr**, **p2rect**, **r2polar**, and **real** functions.

CmpStr

CmpStr(*str1*, *str2* [, *flags*])

The CmpStr function returns zero if *str1* is equal to *str2* or non-zero otherwise.

Parameters

flags controls the type of comparison that is done. It defaults to 0 and supports the following values:

0:	Case-insensitive text comparison
1:	Case-sensitive text comparison
2:	Binary comparison

Binary comparison (*flags*=2) was added Igor Pro 7.05 and is appropriate if *str1* and *str2* contain binary data, which may contain null bytes (bytes with the value 0), rather than human-readable strings.

Details

If *flags* is omitted, 0, or 1, CmpStr does a text comparison and returns the following values:

-1:	*str1* is alphabetically before *str2*
0:	*str1* and *str2* are equal
1:	*str1* is alphabetically after *str2*

The alphabetic order represented by -1 and 1 is valid only for ASCII text. It is not valid for non-ASCII text, such as text containing accented characters.

If *flags* is 2, CmpStr does a binary comparison and returns the following values:

0:	*str1* and *str2* are equal
1:	*str1* and *str2* are not equal

Usually strings do not contain null bytes. Text comparison treats a null byte as meaning "end of string". Binary comparison does not treat a null byte specially. The example below illustrates the treatment of null bytes.

Example

```
Function TestCmpStr()
    String str1 = "A" + num2char(0) + "B"       // num2char(0) is a null byte
    Print strlen(str1)                          // Prints 3

    String str2 = "A" + num2char(0) + "C"
    Print strlen(str2)// Prints 3

    Print CmpStr(str1,str2,0)                   // Prints 0 meaning "equal"
    Print CmpStr(str1,str2,1)                   // Prints 0 meaning "equal"
    Print CmpStr(str1,str2,2)                   // Prints 1 meaning "unequal"
End
```

The "Print strlen" statements illustrate that strlen does not treat null as meaning end of string.

The results from CmpStr with *flags*=0 and *flags*=1 illustrate that CmpStr treated null as meaning "end of string" and consequently compared only the first byte of *str1* to the first byte of *str2*. Both are "A" so CmpStr returned 0 meaning "equal".

The result from CmpStr with *flags*=2 illustrates that CmpStr did not treat null as meaning "end of string" and consequently compared all three bytes of *str1* to all three bytes of *str2*. The third bytes do not match so CmpStr returned 1 meaning "unequal".

ReplaceString, **Using Strings** on page IV-172

ColorScale

`ColorScale` [***`flags`***] [, ***`keyword = value,`*** …] [***`axisLabelStr`***]

The ColorScale operation adds a color scale (or “color legend”) annotation to the a graph, Gizmo plot or page layout. For background information, see **Color Scales** on page III-47.

The ability to add colorscales to a Gizmo plot was added in Igor Pro 8.00.

The ColorScale operation can be executed with no flags and no parameters. It acts on the current target window or the active subwindow or on the window or subwindow specified by the /W flag.

When the target is a graph, the color scale represents the colors and values associated with the first image plot that was added to the graph. If there is no image plot in the graph, the color scale represents the first contour plot or first f(z) trace added to the graph, one of which must exist for the command to execute without error when executed without parameters.

When the target is a Gizmo plot, the color scale represents the colors and values associated with the first surface object, preferring the surface fill color table over the surface gridlines color table. If there is no such surface object, the color scale represents the first scatter object using a color table. If there is no such scatter object, the color scale represents the first path object using a color table. If there is no such path object, the color scale represents the first ribbon object using a color table.

Executing ColorScale with no parameters when the target is a page layout displays a color bar as if the `ctab={0,100,Rainbow}` parameters had been specified.

Flags

Use the /W=*winName* flag to specify a specific graph or layout window. When used on the command line or in a Macro or Proc, /W must precede all other flags.

To change a color scale, use the /C/N=*name* flags. Annotations are automatically named “text0”, “text1”, etc. if no name is specified when it is created, and you must use that name to modify an existing annotation or else a new one will be created.

For explanations of all flags see the **TextBox** operation.

Parameters

The following keyword-value pairs are the important parameters to the ColorScale operation, because they specify what object the color scale is representing.

For use with page layouts, the keyword ={*graphName*,…} form is required.

For graphs it is simpler to use the image=*imageInstanceName* form (omitting graphName), though you can use `$""` to mean the top graph, or specify the name of another graph with the long form. See the **Image Plot ColorScale Examples**.

axisLabelStr

Contains the text printed beside the color scale's main axis.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See **Annotation Escape Codes** on page III-53 for details.

You can use **AppendText** or **ReplaceText** to modify this axis label string. The default value for axisLabelStr is `""`.

cindex=*cindexMatrixWave*

The colors shown are those in the named color index wave with axis values derived from the wave's X (row) scaling and units.

The image colors are determined by doing a lookup in the specified matrix wave. See the ModifyImage cindex keyword.

contour=*contourInstanceName*

contour={*graphName*,*contourInstanceName*}

The colors show the named contour plot's line colors and associated contour (Z) values and contour data units. All of the image plot's characteristics are represented, including color table, cindex, and fixed colors.

graphName can be just the name of a top-level graph window or a subwindow specification like Panel0#G0. See **Subwindow Syntax** on page III-92 for details on subwindow specifications.

contourFill=*contourInstanceName*

contourFill={*graphName*,*contourInstanceName*}

The colors show the named contour plot's fill colors and associated contour (Z) values and contour data units. All of the image plot's characteristics are represented, including color table, cindex, and fixed colors.

graphName can be just the name of a top-level graph window or a subwindow specification like Panel0#G0. See **Subwindow Syntax** on page III-92 for details on subwindow specifications.

The contourFill keyword was added in Igor Pro 8.00.

ctab={*zMin*,*zMax*,*ctName*, *reverse*}

The color table specified by `ctName` is drawn in the color legend.

zMin and *zMax* set the range of z values to map.

The color table name can be omitted if you want to leave it unchanged.

ctName can be any color table name returned by the CTabList function, such as Grays or Rainbow (see **Image Color Tables** on page II-392) or the name of a 3 column or 4 column color table wave (**Color Table Waves** on page II-399).

A color table wave name supplied to `ctab` must not be the name of a built-in color table (see **CTabList**). A 3 column or 4 column color table wave must have values that range between 0 and 65535. Column 0 is red, 1 is green, and 2 is blue. In column 3 a value of 65535 is fully opaque and 0 is fully transparent.

Set *reverse* to 1 to reverse the color table. Setting it to 0 or omitting it leaves the color table unreversed.

image=*imageInstanceName*

image={*graphName*,*imageInstanceName*}

The colors show the named image plot's colors and associated image (Z) values and image data units. All of the image plot's characteristics are represented, including color table, cindex, lookup wave, eval colors, and NaN transparency. **Note**: only false-color image plots can be used with ColorScale (see **Indexed Color Details** on page II-400).

graphName can be just the name of a top-level graph window or a subwindow specification like Panel0#G0. See **Subwindow Syntax** on page III-92 for details on subwindow specifications.

logLabel=*t*

t is the maximum number of decades before minor tick labels are suppressed. The default value is 3.

The logLabel keyword was added in Igor Pro 7.00.

logTicks=*t*

t=0 means "auto". This is the default value.

If *t* is not 0 then it represents the maximum number of decades before minor ticks are suppressed.

The logLabel keyword was added in Igor Pro 7.00.

lookup=*waveName*

Specifies an optional 1D wave used to modify the mapping of scaled Z values into the color table specified with the ctab keyword. Values should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the image. Used to apply gamma correction to grayscale images or for special effects. Use `lookup=$""` to remove option.

This keyword is not needed with the image keyword, even if the image plot uses a lookup wave. The image plot's lookup wave is used instead of the ColorScale lookup wave.

path=*gizmoObjectSpec*

path={*gizmoName*, *gizmoObjectSpec*}

The colors show the named Gizmo path plot's colors and associated X, Y, or Z values and units. Only the path plot's color table is represented. Other color modes such as color wave or solid colors are not supported.

gizmoName can be just the name of a top-level Gizmo window or a subwindow specification like Panel0#GZ0. See **Subwindow Syntax** on page III-92 for details on subwindow specifications.

gizmoObjectSpec can be just the name of the object like path0, or a colon-separated path to the object in a group like group0:path0. Unlike **ModifyGizmo** setCurrentGroup, *gizmoObjectSpec* does not start with the name of the Gizmo window.

The path keyword was added in Igor Pro 9.00.

ribbon=*gizmoObjectSpec*

ribbon={*gizmoName*, *gizmoObjectSpec*}

The colors show the named Gizmo ribbon plot's colors and associated X, Y, or Z values and units. Only the ribbon plot's color table is represented. Other color modes such as color wave or solid colors are not supported.

See the path keyword for {*gizmoName*, *gizmoObjectSpec*} details.

The ribbon keyword was added in Igor Pro 9.00.

scatter=*gizmoObjectSpec*

scatter={*gizmoName*, *gizmoObjectSpec*}

The colors show the named Gizmo scatter plot's marker colors and associated X, Y, or Z values and units. Only the scatter plot's color table is represented. Other color modes such as color wave or solid colors are not supported.

See the path keyword for {*gizmoName*, *gizmoObjectSpec*} details.

The scatter keyword was added in Igor Pro 9.00.

surface=*gizmoObjectSpec*

surface={*gizmoName*,*gizmoObjectSpec*}

The colors show the named Gizmo surface plot's grid line colors and associated surface X, Y, or Z values and surface matrix units. Unlike image plots, only the surface plot's color table is represented. Other color modes such as color wave or solid colors are not supported.

See the path keyword for {*gizmoName*, *gizmoObjectSpec*} details.

The surface keyword was added in Igor Pro 8.00.

surfaceFill=*gizmoObjectSpec*

surfaceFill={*gizmoName*,*gizmoObjectSpec*}

The colors show the named Gizmo surface plot's fill colors and associated surface X, Y, or Z values and surface matrix units. Unlike image plots, only the surface plot's color table is represented. Other color modes such as color wave or solid colors are not supported.

See the path keyword for {*gizmoName*, *gizmoObjectSpec*} details.

The surfaceFill keyword was added in Igor Pro 8.00.

trace=*traceInstanceName*

trace={*graphName*,*traceInstanceName*}

The colors show the color(s) of the named trace. This is useful when the trace has its color set by a “Z wave” using the `ModifyGraph zColor(`*`traceName`*`)=`... feature. In the Modify Trace Appearance dialog this is selected in the “Set as f(z)” subdialog. The color scale’s main axis shows the range of values in the Z wave, and displays any data units the wave may have.

graphName can be just the name of a top-level graph window or a subwindow specification like Panel0#G0. See **Subwindow Syntax** on page III-92 for details on subwindow specifications.

Size Parameters

The following keyword-value parameters modify the size of the color scale annotation. These keywords are similar to those used by the **Slider** control. The size of the annotation is indirectly controlled by setting the size of the “color bar” and the various axis parameters. The annotation sizes itself to accommodate the color bar, tick labels, and axis labels.

height=*h*
Sets the height of the color bar in points, overriding any heightPct setting. The default height is 75% of the plot area height if the color scale is vertical, or a constant of 15 points if the color scale is horizontal. The default is restored by specifying `height=0`. Specifying a heightPct value resets height to this default.

heightPct=*hpct*
Sets height as a percentage of the graph’s plot area, overriding any height setting. The default height is 75% of the plot area height if the color scale is vertical, or a constant of 15 points if the color scale is horizontal. The default height is restored by setting heightPct=0. Specifying a height value resets heightPct to this default.

side=*s*
Selects on which axis to draw main axis ticks.

s=1: Right of the color bar if vert=1, or below if vert=0.

s=2: Left of the color bar if vert=1, or above if vert=0.

vert=*v*
Specifies color scale orientation.

v=0: Horizontal.

v=1: Vertical (default).

width=*w*
Sets the width of the color bar in points, overriding any widthPct setting. The default width is a constant 15 points if the color scale is vertical, or 75% of the plot area width if the color scale is horizontal. The default is restored by specifying `width=0`. Specifying a widthPct value resets width to this default.

widthPct=*wpct*
Sets width as a percentage of the graph’s plot area, overriding any width setting. The default width is a constant 15 points if the color scale is vertical, or 75% of the plot area width if the color scale is horizontal. The default is restored by setting `widthPct=0`. Specifying a width value resets widthPct to this default.

Color Bar Parameters

The following keyword-value parameters modify the appearance of the color scale color bar.

colorBoxesFrame=*on*
Draws frames surrounding up to 99 swatches of colors in the color bar (*on*=1).

When specifying more than 99 colors in the color bar (such as the Rainbow color table, which has 100 colors), the boxes aren’t framed. Framing color boxes is effective only for small numbers of colors. Set the width of the frame with the frame keyword.

Use *on*=0 to turn off color box frames.

frame=*f*
Specifies the thickness of the frame drawn around the color bar in points (*f* can range from 0 to 5 points). The default is 1 point. Fractional values are permitted.

Turn frames off with *f*=0. Values less that 0.5 do not display on screen, but the thin frame will print.

frameRGB=(*r*,*g*,*b*[,*a*]) or 0
Sets the color of the frame around the color bar. *r*, *g*, and *b* specify the amount of red, green, and blue as integers from 0 to 65535. The frame includes the individual color bar colors when colorBoxesFrame=1.

The frame will use the colorscale foreground color, as set by the /G flag, when frameRGB=0.

Axis Parameters

The following keyword-value parameters modify the appearance of the color scale axes. These keywords are based on the **ModifyGraph** Axis keywords because they modify the main or secondary color scale axes.

axisRange={*zMin*, *zMax*}

Sets the color bar axis range to values specified by *zMin* and *zMax*. Use `*` to use the default axis range for either or both values.

Omit *zMin* or *zMax* to leave that end of the range unchanged. For example, use `{zMin, }` to change *zMin* and leave *zMax* alone, or use `{ ,*}` to set only the axis maximum value to the default value.

dateInfo={*sd*,*tm*,*dt*}

Controls formatting of date/time axes.

sd=0:	Show date in the date&time format.
sd=1:	Suppress date.
sd=2:	Suppress time. The time is always shown if *tm*=2. *sd*=2 requires Igor Pro 9.00 or later.
tm=0:	12 hour (AM/PM) time.
tm=1:	24 hour (military) time.
tm=2:	Elapsed time.
dt=0:	Short dates (2/22/90).
dt=1:	Long dates (Thursday, February 22, 1990).
dt=2:	Abbreviated dates (Thurs, Feb 22, 1990).

These have no effect unless the axis is controlled by a wave with 'dat' data units.

These date formats do not work with dates before 0001-01-01 in which case the axis displays an empty string. You can apply custom date formats using the dateFormat keyword.

To use a custom date format as specified by the dateFormat keyword, you must specify -1 for the *dt* parameter to dateInfo.

For an f(z) color scale:

```
SetScale d, 0,0, "dat", fOfZWave
```

For a contour plot or image plot color scale:

```
SetScale d, 0,0, "dat", ZorXYZorImageWave
```

See **Date/Time Axes** on page II-315 and **Date, Time, and Date&Time Units** on page II-69 for details on how date/time axes work.

font=*fontNameStr*

Name of font as string expression. If the font does not exist, the default font is used. Specifying “default” has the same effect. Unlike ModifyGraph, the *fontNameStr* is evaluated at runtime, and its absence from the system is not an error.

fsize=*s*

Sets the font size in points.

s=0:	Use the graph font size for tick labels and axis labels (default).

fstyle=*fs*

Sets the font style. *fs* is a bitwise parameter with each bit controlling one aspect of the font style for the tick mark labels:

Bit 0:	Bold
Bit 1:	Italic
Bit 2:	Underline
Bit 4:	Strikethrough

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

highTrip=*h*

If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation. The default highTrip is 100,000.

lblLatPos=*p*
Sets a lateral offset for the main axis label. This is an offset parallel to the axis. *p* is in points. Positive is down for vertical axes and to the right for horizontal axes. The default is 0.

lblMargin=*m*
Moves the main axis label by *m* points (default is 0) from the normal position. The default value is -5, which brings the axis label closer to the axis. Use more positive values to move the axis label away from the axis.

lblRot=*r*
Rotates the axis label by *r* degrees. *r* is a value from -360 to 360. Rotation is counterclockwise and starts from the label's normal orientation.

log=*l*
Specifies the axis type:

l=0: Linear (default).
l=1: Log base 10.
l=2: Log base 2.

logHTrip=*h*
Same as highTrip but for log axes. The default is 10,000.

logLTrip=*l*
Same as lowTrip but for log axes. The default is 0.0001.

logTicks=*t*
Specifies the maximum number of decades in log axis before minor ticks are suppressed.

lowTrip=*l*
If the axis extrema are between its lowTrip and its highTrip, then tick mark labels use fixed point notation. Otherwise, they use exponential (scientific or engineering) notation. The default lowTrip is 0.1.

minor=*m*
Controls minor tick marks:

m=0: Disables minor ticks (default).
m=1: Enables minor ticks.

notation=*n*
Controls tick label notation:

n=0: Engineering notation (default).
n=1: Scientific notation.

nticks=*n*
Specifies the approximate number of ticks to be distributed along the main axis. Ticks are labelled using the same automatic algorithm used for graph axes. The default is 5.

Set *n*=0 for no ticks.

prescaleExp=*exp*
Multiplies axis range by 10*exp* for tick labeling and *exp* is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. The default is 0 (no modification). See the discussion in the **ModifyGraph (axes) Details** section.

tickExp=*te*
Controls tick label exponential notation:

te=1: Forces tick labels to exponential notation when labels have units with a prefix.
te=0: Turns off exponential notation.

tickLen=*t* Sets the length of the ticks. *t* is the major tick mark length in points. This value must be between -100 and 50.

t= 0 to 50:	Draws tick marks between the tick labels and the colors box.
t= -1:	Default; auto tick length, equal to 70% of the tick label font size. Draws tick marks between the tick labels and the colors box.
t= -2 to -50:	Draws tick marks crossing the edge of the colors box nearest the tick labels. The actual total tick mark length is -*t*.
t= -100 to -51:	Draws tick marks inside the edge of the colors box nearest the tick labels. Actual tick mark length is -(*t*+50). For example, -58 makes in an inside tick mark that is 8 points long.

tickThick=*t* Sets the tick mark thickness in points (from 0 to 5 points). The default is 1 point. Fractional values are permitted.

t=0:	Turns tick marks off, but not the tick labels.

tickUnit=*tu* Turns on (*tu*=0) or off (*tu*=1) units labels attached to tick marks.

userTicks={*tvWave*,*tlblWave*}

Supplies user defined tick positions and labels for the main axis. *tvWave* contains the numeric tick positions while text wave *tlblWave* contains the corresponding labels.

Overrides normal ticking specified by nticks.

See **User Ticks from Waves** on page II-313 for details.

The tick mark labels can be multiline and use styled text. For more details, see **Fancy Tick Mark Labels** on page II-358.

ZisZ=*z* *z* =1 labels the zero tick mark (if any) with the single digit “0” regardless of the number of digits used for other labels. Default is *z*=0.

Secondary Axis Parameters

axisLabel2=*axisLabelString2*

Axis label for the secondary axis. This axis label is drawn only if userTicks2 is in effect. Text after any `\r` character is ignored, as is the `\r` character. The default is `""`.

lblLatPos2=*p* Sets lateral offset for secondary axis labels. This is an offset parallel to the axis. *p* is in points. Positive is down for vertical axes and to the right for horizontal axes. The default is 0.

lblMargin2=*m* Specifies the distance in points (default 0) to move the secondary axis label from the position that would be normal for a graph. The default is value is -5, which brings the axis label closer to the axis. Use more positive values to move the axis label away from the axis.

lblRot2=*r* Rotates the secondary axis label by *r* degrees counterclockwise starting from the normal label orientation. r is a value from -360 to 360.

userTicks2={*tvWave*,*tlblWave*}

Supplies user defined tick positions and labels for a second axis which is always on the opposite side of the color bar from the main axis. The tick mark labels can be multiline and use styled text. For more details, see **Fancy Tick Mark Labels** on page II-358. This is the only way to draw a second axis.

Image Plot ColorScale Examples

```
Make/O/N=(20,20) img=p*q; NewImage img         // Make and display an image
ColorScale                                     // Create default color scale
// First annotation is text0
ColorScale/C/N=text0 nticks=3,minor=1,"Altitude"
ModifyImage img ctab= {*,*,Relief19,0}         // 19-color color table
ColorScale/C/N=text0 axisRange={100,300}       // Detail for 100-300 range
ColorScale/C/N=text0 colorBoxesFrame=1         // Frame the color boxes
ColorScale/C/N=text0 frameRGB=(65535,0,0)      // Red frame
```

Demo

Choose File→Example Experiments→Feature Demos 2→ ColorScale Demo

ColorTab2Wave

ColorTab2Wave *colorTableName*

The ColorTab2Wave operation extracts colors from the built-in color table and places them in an Nx3 matrix of red, green, and blue columns named M_colors. Values are unsigned 16-bit integers and range from 0 to 65535.

N will typically be 100 but may be as little as 9 and as large as 476. Use

```
Variable N= DimSize(M_colors,0)
```

to determine the actual number of colors.

The wave M_colors is created in the current data folder. Red is in column 0, green is in column 1, and blue in column 2.

Parameters

colorTableName can be any of those returned by **CTabList**, such as Grays or Rainbow.

colorTableName can also be `Igor` or `IgorRecent`, to return either the 128 standard or 0-32 user-selected colors from Igor's color menu.

Details

See **Image Color Tables** on page II-392.

Complex

Complex *localName*

Declares a local complex 64-bit double-precision variable in a user-defined function or structure.

Complex is another name for Variable/C. It is available in Igor Pro 7.00 and later.

Concatenate

Concatenate [***type flags***][***flags***] ***waveListStr*, *destWave***

Concatenate [***type flags***][***flags***] **{*wave1*, *wave2*, *wave3*,…}, *destWave***

Concatenate [***type flags***][***flags***] **{*waveWave*}, *destWave***

The Concatenate operation combines data from the source waves into *destWave*, which is created if it does not already exist. If *destWave* does exists and overwrite is not specified, the source waves' data is concatenated with the existing data in the destination wave.

By default the concatenation increases the dimensionality of the destination wave if possible. For example, if you concatenate two 1D waves of the same length you get a 2D wave with two columns. The destination wave is said to be "promoted" to a higher dimensionality.

If you use the /NP (no promotion) flag, the dimensionality of the destination wave is not changed. For example, if you concatenate two 1D waves of the same length using /NP you get a 1D wave whose length is the sum of the lengths of the source waves.

If the source waves are of different lengths, no promotion is done whether /NP is used or not.

Parameters

waveListStr is a string expression containing a list of input wave names separated by semicolons with a semicolon at the end. There is no limit to the number of wave names in *waveListStr*.

The {*wave1*, *wave2*, ...} syntax is limited to 100 waves.

In the {*waveWave*} syntax, waveWave is a single WAVE reference wave containing references to the input waves. This syntax was added in Igor Pro 8.00.

Flags

/DL	Sets dimension labels. For promotion, it uses source wave names as new dimension labels otherwise it uses existing labels.
/FREE	Creates destWave as a free wave (see **Free Waves** on page IV-91). The /FREE flag was added in Igor Pro 8.00.
/KILL	Kills source waves.
/NP	Prevents promotion to higher dimension.
/NP=*dim*	Prevents promotion and appends data along the specified dimension (0= rows, 1= columns, 2=layers, 3=chunks). All dimensions other than the one specified by *dim* must be the same in all waves.
/O	Overwrites *destWave*.

Type Flags *(used only in functions)*

Concatenate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-73 and **WAVE Reference Type Flags** on page IV-74 for a complete list of type flags and further details.

Details

If *destWave* does not already exist or, if the /O flag is used, *destWave* is created by duplication of the first source wave. Waves are concatenated in order through the list of source waves. If *destWave* exists and the /O flag is not used, then the concatenation starts with *destWave*.

destWave cannot be used in the source wave list.

Source waves must be either all numeric or all text.

If promotion is allowed, the number of low-order dimensions that all waves share in common determines the dimensionality of *destWave* so that the dimensionality of *destWave* will then be one greater. The default behaviors will vary according to the source wave sizes. Concatenating 1D waves that are all the same length will produce a 2D wave, whereas concatenating 1D waves of differing lengths will produce a 1D wave. Similarly, concatenating 2D waves of the same size will produce a 3D wave; but if the 2D source waves have differing numbers of columns then *destWave* will be a 2D wave, or if the 2D waves have differing numbers of rows then *destWave* will be a 1D wave. Concatenating 1D and 2D waves that have the same number of rows will produce a 2D wave, but when the number of rows differs, *destWave* will be a 1D wave. See the examples.

Use the /NP flag to suppress dimension promotion and keep the dimensionality of *destWave* the same as the input waves.

Warning

Under some circumstances, such as in loops in user-defined functions, Concatenate may exhibit unexpected behavior.

When you have a statement like this in a user-defined function:

```
Concatenate/O ..., DestWaveName
```

at compile time, Igor creates an automatic local wave reference variable named DestWaveName. At runtime, if the wave reference variable is NULL, the name is taken to be a literal name and a wave of that name is created in the current data folder.

If the wave reference variable is not NULL, as would occur after the first call to Concatenate in a loop, then the referenced wave is overwritten no matter where it is located.

If your intention is to create or overwrite a wave in the current data folder, you should use one of the following two methods:

```
Concatenate/O ..., $"DestWaveName"
WAVE DestWaveName       // Needed only if you subsequently reference the dest wave
```

or

```
Concatenate/O ....., DestWaveName
// Then after you are finished using DestWaveName...
WAVE DestWaveName=$""
```

Examples

```
// Given the following waves:
Make/N=10 w1,w2,w3
Make/N=11 w4
Make/N=(10,7) m1,m2,m3
Make/N=(10,8) m4
Make/N=(9,8) m5

// Concatenate 1D waves
Concatenate/O {w1,w2,w3},wdest          // wdest is a 10x3 matrix
Concatenate {w1,w2,w3},wdest            // wdest is a 10x6 matrix
Concatenate/NP/O {w1,w2,w3},wdest       // wdest is a 30-point 1D wave
Concatenate/O {w1,w2,w3,w4},wdest       // wdest is a 41-point 1D wave

// Concatenate 2D waves
Concatenate/O {m1,m2,m3},wdest          // wdest is a 10x7x3 volume
Concatenate/NP/O {m1,m2,m3},wdest       // wdest is a 10x21 matrix
Concatenate/O {m1,m2,m3,m4},wdest       // wdest is a 10x29 matrix
Concatenate/O {m4,m5},wdest             // wdest is a 152-point 1D wave
Concatenate/O/NP=0 {m4,m5},wdest        // wdest is a 19x8 matrix

// Concatenate 1D and 2D waves
Concatenate/O {w1,m1},wdest             // wdest is a 10x8 matrix
Concatenate/O {w4,m1},wdest             // wdest is a 81-point 1D wave

// Append rows to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=0 {m6}, m7               // m7 is a 6x2 matrix

// Append columns to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=1 {m6}, m7               // m7 is a 3x4 matrix

// Append layer to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=2 {m6}, m7               // m7 is a 3x2x2 volume
// The last command has the same effect as:
// Concatenate {m6}, m7
// Both versions extend add a third dimension to m7
```

The **StrConstant** keyword for string types, **Constants** on page IV-51 and **Switch Statements** on page IV-43.

continue

`continue`

The continue flow control keyword returns execution to the beginning of a loop, bypassing the remainder of the loop's code.

See Also

Continue Statement on page IV-48 and **Loops** on page IV-45 for usage details.

ContourInfo

`ContourInfo(graphNameStr, contourWaveNameStr, instanceNumber)`

The ContourInfo function returns a string containing a semicolon-separated list of information about the specified contour plot in the named graph.

Parameters

graphNameStr can be `""` to refer to the top graph.

contourWaveNameStr is a string containing either the name of a wave displayed as a contour plot in the named graph, or a contour instance name (wave name with "#n" appended to distinguish the nth contour plot of the wave in the graph). You might get a contour instance name from the **ContourNameList** function.

If *contourWaveNameStr* contains a wave name, *instanceNumber* identifies which instance you want information about. *instanceNumber* is usually 0 because there is normally only one instance of a wave displayed as a contour plot in a graph. Set *instanceNumber* to 1 for information about the second contour plot of the wave, etc. If *contourWaveNameStr* is `""`, then information is returned on the *instanceNumber*th contour plot in the graph.

If *contourWaveNameStr* contains an instance name, and *instanceNumber* is zero, the instance is taken from *contourWaveNameStr*. If *instanceNumber* is greater than zero, the wave name is extracted from *contourWaveNameStr*, and information is returned concerning the *instanceNumber*th instance of the wave.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
DATAFORMAT	Either XYZ or Matrix.
LEVELS	A comma-separated list of the contour levels, including the final automatic levels, (or manual or from-wave levels), and the "more levels", all sorted into ascending Z order.
RECREATION	List of keyword commands as used by **ModifyContour** command. The format of these keyword commands is: ***keyword (x)=modifyParameters;***
TRACESFORMAT	The format string used to name the contour traces (see **AppendMatrixContour** or **AppendXYZContour**).

Keyword	Information Following Keyword
XAXIS	X axis name.
XWAVE	X wave name if any, else blank.
XWAVEDF	Full path to the data folder containing the X wave or blank if there is no X wave.
YAXIS	Y axis name.
YWAVE	Y wave name if any, else blank.
YWAVEDF	Full path to the data folder containing the Y wave or blank if there is no Y wave.
ZWAVE	Name of wave containing Z data from which the contour plot was calculated.
ZWAVEDF	Full path to the data folder containing the Z data wave.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “`;`”, prepend “`ModifyContour`”, replace the “`x`” with the name of a contour plot (“`data#1`” for instance) and then **Execute** the resultant string as a command.

Examples

The following command lines create a very unlikely contour display. If you did this, you would most likely want to put each contour plot on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack
Display;AppendMatrixContour jack
AppendMatrixContour/T/R jack        // Second instance of jack
```

This example accesses the contour information for the second contour plot of the wave “jack” (which has an instance number of 1) displayed in the top graph:

```
Print StringByKey("ZWAVE", ContourInfo("","jack",1))     // prints jack
```

See Also

The **Execute** and **ModifyContour** operations.

ContourNameList

`ContourNameList(`*`graphNameStr`*`, `*`separatorStr`*`)`

The ContourNameList function returns a string containing a list of contours in the graph window or subwindow identified by *graphNameStr*.

Parameters

graphNameStr can be `""` to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The parameter *separatorStr* should contain a single ASCII character such as “`,`” or “`;`” to separate the names.

A contour name is defined as the name of the wave containing the data from which a contour plot is calculated, with an optional #n suffix that distinguishes between two or more contour plots in the same graph window that have the same wave name. Since the contour name has to be parsed, it is quoted if necessary.

Examples

The following command lines create a very unlikely contour display. If you did this, you would most likely want to put each contour plot on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack,'jack # 2';
Display;AppendMatrixContour jack
AppendMatrixContour/T/R jack
AppendMatrixContour 'jack # 2'
AppendMatrixContour/T/R 'jack # 2'
Print ContourNameList("",";")
```

prints `jack;jack#1;'jack # 2';'jack # 2'#1;`

See Also

Another command related to contour plots and waves: **ContourNameToWaveRef**.

For commands referencing other waves in a graph: **TraceNameList**, **WaveRefIndexed**, **XWaveRefFromTrace**, **TraceNameToWaveRef**, **CsrWaveRef**, **CsrXWaveRef**, **ImageNameList**, and **ImageNameToWaveRef**.

ContourNameToWaveRef

`ContourNameToWaveRef(`*`graphNameStr`*`, `*`contourNameStr`*`)`

Returns a wave reference to the wave corresponding to the given contour name in the graph window or subwindow named by *graphNameStr*.

Parameters

graphNameStr can be `""` to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The contour name is identified by the string in *contourNameStr*, which could be a string determined using ContourNameList. Note that the same contour name can refer to different waves in different graphs, if the waves are in different data folders.

See Also

The **ContourNameList** function.

For a discussion of wave reference functions, see **Wave Reference Functions** on page IV-197.

ContourZ

`ContourZ(`*`graphNameStr`*`, `*`contourInstanceNameStr`*`, `*`x`*`, `*`y`*` [,`*`pointFindingTolerance`*`])`

The ContourZ function returns the interpolated Z value of the named contour plot data displayed in the named graph.

For gridded contour data, ContourZ returns the bilinear interpolation of the four surrounding XYZ values.

For XYZ triplet contour data, ContourZ returns the value interpolated from the three surrounding XYZ values identified by the Delaunay triangulation.

Parameters

graphNameStr can be `""` to specify the topmost graph.

contourNameStr is a string containing either the name of the wave displayed as a contour plot in the named graph, or a contour instance name (wave name with “#n” appended to distinguish the nth contour plot of the wave in the graph). You might get a contour instance name from the **ContourNameList** function.

If *contourNameStr* contains a wave name, *instance* identifies which contour plot of *contourNameStr* you want information about. *instance* is usually 0 because there is normally only one instance of a wave displayed as a contour plot in a graph. Set *instance* to 1 for information about the second contour plot of *contourNameStr*, etc. If *contourNameStr* is `""`, then information is returned on the *instance*th contour plot in the graph.

If *contourNameStr* contains an instance name, and *instance* is zero, the instance is taken from *contourNameStr*. If *instance* is greater than zero, the wave name is extracted from *contourNameStr*, and information is returned concerning the *instance*th instance of the wave.

x and *y* specify the X and Y coordinates of the value to be returned. This may or may not be the location of a data point in the wave selected by *contourNameStr* and *instance*.

Set *pointFindingTolerance* =1e-5 to overcome the effects of perturbation (see the perturbation keyword of the **ModifyContour** operation).

The default value is 1e-15 to account for rounding errors created by the triangulation scaling (see ModifyContour's equalVoronoiDistances keyword), which works well ModifyContour perturbation=0.

A value of 0 would require an exact match between the scaled x/y coordinate and the scaled and possibly perturbed coordinates to return the original z value; that is an unlikely outcome.

Details

For gridded contour data, ContourZ returns NaN if *x* or *y* falls outside the XY domain of the contour data. If *x* and *y* fall on the contour data grid, the corresponding Z value is returned.

For XYZ triplet contour data, ContourZ returns the null value if *x* or *y* falls outside the XY domain of the contour data. You can set the null value to *v* with this command:

```
ModifyContour contourName nullValue=v
```

If *x* and *y* match one of the XYZ triplet values, the corresponding Z value from the triplet usually won't be returned because Igor uses the Watson contouring algorithm which perturbs the x and y values by a small random amount. This also means that normally x and y coordinates on the boundary will return a null value about half the time if perturbation is on and *pointFindingTolerance* is greater than 1e-5.

Examples

Because ContourZ can interpolate the Z value of the contour data at any X and Y coordinates, you can use ContourZ to convert XYZ triplet data into gridded data:

```
// Make example XYZ triplet contour data
Make/O/N=50 wx,wy,wz
wx= enoise(2)          // x = -2 to 2
wy= enoise(2)          // y = -2 to 2
wz= exp(-(wx[p]*wx[p] + wy[p]*wy[p]))       // XY gaussian, z= 0 to 1

// ContourZ requires a displayed contour data set
Display; AppendXYZContour wz vs {wx,wy};DelayUpdate
ModifyContour wz autolevels={*,*,0}         // no contour levels are needed
ModifyContour wz xymarkers=1                // show the X and Y locations

// Set the null (out-of-XY domain) value
ModifyContour wz nullValue=NaN              // default is min(wz) - 1

// Convert to grid: Make matrix that spans X and Y
Make/O/N=(30,30) matrix
SetScale/I x, -2, 2, "", matrix
SetScale/I y, -2, 2, "", matrix
matrix= ContourZ("","wz",0,x,y)             // or = ContourZ("","",0,x,y)
AppendImage matrix
```

ControlBar

ControlBar [***flags***] ***barHeight***

The ControlBar operation sets the height and location of the control bar in a graph.

Parameters

barHeight is in points on Macintosh and pixels or points on Windows, depending on the screen resolution. See **Control Panel Resolution on Windows** on page III-456 for details.

Setting *barHeight* to zero removes the control bar.

Flags

/EXP=*e*	Sets the expansion of the panel control bar area. See the **NewPanel** operation /EXP flag for details. The /EXP flag was added in Igor Pro 9.00.
/L/R/B/T	Designates whether to use the left, right, bottom, or top (default) window edge, respectively, for the control bar location.
/W=*graphName*	Specifies the name of a particular graph containing a control bar.

Details

The control bar is an area at the top of graphs reserved for controls such as buttons, checkboxes and pop-up menus. A line is drawn between this area and the graph area. The control bar may be assigned a separate background color by pressing Control (*Macintosh*) or Ctrl (*Windows*) and clicking in the area, or by right-clicking it (*Windows*), or with the **ModifyGraph** operation. You cannot use draw tools in this area.

For graphs with no controls, you do not need to use this operation.

Use ControlInfo kwControlBar operation to determine the current size of the control bar.

Examples

```
Display myData
ControlBar 35       // 35 pixels high
Button button0,pos={56,8},size={90,20},title="My Button"
```

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Chapter V-1, **ControlInfo**

ControlInfo

ControlInfo [***/W=winName***] ***controlName***

The ControlInfo operation returns information about the state or status of the named control in a graph or control panel window or subwindow.

Flags

/G [=*doGlobal*]	If *doGlobal* is non-zero or absent, the position returned via V_top and V_left is in global screen coordinates rather relative to the window containing the control.
/W=*winName*	Looks for the control in the named graph or panel window or subwindow. If /W is omitted, ControlInfo looks in the top graph or panel window or subwindow. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Parameters

controlName is the name of a control in the window specified by /W or in the top graph or panel window. *controlName* may also be the keyword kwBackgroundColor to set V_Red, V_Green, V_Blue, and V_Alpha, the keyword kwControlBar or kwControlBarBottom to set V_Height, the keyword kwControlBarLeft or kwControlBarRight to set V_Width, or the keyword kwSelectedControl to set S_value and V_flag.

Details

Information for all controls is returned via the following string and numeric variables. Coordinates are returned in **Control Panel Units**.
The kind of control is returned in V_flag as a positive or negative integer. A negative value indicates the control is incomplete or not active. If V_flag is zero, then the named control does not exist. Information returned for specific control types is as follows:

S_recreation Commands to recreate the named control.

S_title Title of the named control.

V_disable Disable state of control:

0: Normal (enabled, visible).

1: Hidden.

2: Disabled, visible.

V_Height, V_Width, V_top, V_left, V_right, V_pos, V_align Dimensions and position of the named control in **Control Panel Units**s.

V_right, V_pos, and V_align were added in Igor Pro 8.00 and depend on whether the align keyword was applied to the control (e.g., Button <name> align=1).

V_align is 1 if the the align keyword was applied to the control or to 0 otherwise.

V_pos is the horizontal coordinate used to position the control. It represents the position of the left end of the control if the align keyword was omitted or of the right end if the align keyword was applied.

V_left and V_right are the the horizontal coordinates of the left and right ends of the control regardless of whether the align keyword was applied or not.

Buttons

V_flag 1

V_value Tick count of last mouse up.

S_UserData Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

Chart

V_flag 6 or -6

V_value Current point number.

S_UserData Keyword-packed information string. See **S_value for Chart Details** for more keyword information.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

Checkbox

V_flag 2

V_value 0 if it is deselected or 1 if it is selected.

S_UserData Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

CustomControl

V_flag 12

V_value Tick count of last mouse up.

S_UserData Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.

S_value Name of the picture used to define the control appearance.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

GroupBox

V_flag 9

S_value Title text.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

ListBox

V_flag 11

V_value Currently selected row (valid for mode 1 or 2 or modes 5 and 6 when no selWave is used). If no list row is selected, then it is set to -1.

V_selCol Currently selected column (valid for modes 5 and 6 when no selWave is used).

V_horizScroll Number of pixels the list has been scrolled horizontally to the right.

V_vertScroll Number of pixels the list has been scrolled vertically downwards.

V_rowHeight Height of a row in pixels.

V_startRow The current top visible row.

S_columnWidths A comma-separated list of column widths in pixels.

S_dataFolder Full path to listWave (if any).

S_UserData Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.

S_value Name of listWave (if any).

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

PopupMenu

V_flag 3 or -3

V_Red, V_Green, V_Blue. V_Alpha For color array pop-up menus, these are the encoded color values.

V_value Current item number (counting from one).

S_UserData Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.

S_value Text of the current item. If PopupMenu is a color array then it contains color values encoded as **RGBA Values**.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

SetVariable

V_flag 5 or -5

V_value Value of the variable. If the SetVariable is used with a string variable, then it is the interpretation of the string as a number, which will be NaN if conversion fails.

S_dataFolder Full path to the variable.

S_UserData Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.

S_value Name of the variable or, if the value was set using _STR: syntax, the string value itself.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

Slider

V_flag 7

V_value Numeric value of the variable.

S_dataFolder Full path to the variable.

S_UserData Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.

S_value Name of the variable.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

TabControl

V_flag 8

V_value Number of the current tab.

S_UserData Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.

S_value Tab text.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

TitleBox

V_flag 10

S_dataFolder Full path if text is from a string variable.

S_value Name if text is from a string variable.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, and V_left at the beginning of the Details section.

See **TitleBox Positioning** on page V-1040 for details on V_right, V_pos, and V_align.

ValDisplay

V_flag 4 or -4

V_value Displayed value.

S_value Text of expression that ValDisplay evaluates.

See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left, V_right, V_pos, and V_align at the beginning of the Details section.

kwBackgroundColor

V_Red, V_Green, V_Blue, V_Alpha	If *controlName* is kwBackgroundColor then this is the color of the control panel background. This color is usually the default user interface background color, as set by the Appearance control panel on the Macintosh or by the Appearance tab of the Display Properties on Windows, until changed by `ModifyPanel cbRGB`.

kwControlBar or kwControlBarTop

V_Height	The height in pixels of the top control bar area in a graph as set by **ControlBar**.

kwControlBarBottom

V_Height	The height in pixels of the bottom control bar area in a graph as set by **ControlBar**/B.

kwControlBarLeft

V_Width	The width in pixels of the left control bar area in a graph as set by **ControlBar**/L.

kwControlBarRight

V_Width	The width in pixels of the right control bar area in a graph as set by **ControlBar**/R.

kwSelectedControl

V_flag	Set to 1 if a control is selected or 0 if not. **SetVariable** and **ListBox** controls can be selected, most other controls can not.
S_value	Name of selected control (if any) or `""`.

S_value for Chart Details

The following applies *only* to the keyword-packed information string returned in S_value for a chart. S_value will consist of a sequence of sections with the format: "*keyword*:*value*;" You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions. Here are the S_value keywords:

Keyword	Type	Meaning
FNAME	string	Name of the FIFO chart is monitoring.
LHSAMP	number	Left hand sample number.
NCHANS	number	Number of channels displayed in chart.
PPSTRIP	number	The chart's points per strip value.
RHSAMP	number	Right hand sample number (same as V_value).

In addition, ControlInfo writes fields to S_value for each channel in the chart. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named "Pressure" then the following would appear in the S_value string: "CHNAME4:Pressure". In the following table, the channel's number is represented by #:

Keyword	Type	Meaning
CHCTAB#	number	Channel's color table value as set by Chart ctab keyword.
CHGAIN#	number	Channel's gain value as set by Chart gain keyword.
CHNAME#	string	Name of channel defined by FIFO.
CHOFFSET#	number	Channel's offset value as set by Chart offset keyword.

Examples

```
ControlInfo myChart; Print S_value
```

Prints the following to the history area:

```
FNAME:myFIFO;NCHANS:1;PPSTRIP:1100;RHSAMP:271;LHSAMP:-126229;
```

ControlNameList

`ControlNameList(`*`winNameStr`*` [, `*`listSepStr`*` [, `*`matchStr`*`]])`

The ControlNameList function returns a string containing a list of control names in the graph or panel window or subwindow identified by *winNameStr*.

Parameters

winNameStr can be `""` to refer to the top graph or panel window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The optional parameter *listSepStr* should contain a single ASCII character such as "," or ";" to separate the names; the default value is ";".

The optional parameter *matchStr* is some combination of normal characters and the asterisk wildcard character that matches anything. To use *matchStr*, *listSepStr* must also be used. See **StringMatch** for wildcard details.

Only control names that satisfy the match expression are returned. For example, "*_tab0" matches all control names that end with "_tab0". The default is "*", which matches all control names.

Examples

```
NewPanel
Button myButton
Checkbox myCheck
Print ControlNameList("")                    // prints "myButton;myCheck;"
Print ControlNameList("", ";", "*Check")    // prints "myCheck;"
```

ControlUpdate

`ControlUpdate [/A/W=`*`winName`*`][`*`controlName`*`]`

The ControlUpdate operation updates the named control or all controls in a window, which can be the top graph or control panel or the named graph or control panel if you use /W.

Flags

/A	Updates all controls in the window. You must omit *controlName*.
/W=*winName*	Specifies the window or subwindow containing the control. If you omit *winName* it will use the top graph or control panel window or subwindow. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

ControlUpdate is useful for forcing a pop-up menu to rebuild, to update a ValDisplay control, or to forcibly accept a SetVariable’s currently-being-edited value.

Normally, a pop-up menu rebuilds only when the user clicks on it. If you set up a pop-up menu so that its contents depend on a global string variable, on a user-defined string function or on an Igor function (e.g., **WaveList**), you may want to force the pop-up menu to be updated at your command.

Usually, a ValDisplay control displays the value of a global variable or of an expression involving a global variable. If the global variable changes, the ValDisplay will automatically update. However, you can create a ValDisplay that displays a value that does not depend on a global variable. For example, it might display the result of an external function. In a case like this, the ValDisplay will not automatically update. You can update it by calling ControlUpdate.

When a SetVariable control is being edited, the text the user types isn't "accepted" (or processed) until the user presses Return or Enter. ControlUpdate effectively causes the named control to act as though the user has pressed one of those keys. If /A is specified, the currently active SetVariable control (if any) is affected this way. The motivation here is that the user may have typed a new value without having yet pressed return, and then may click a button in a different panel which runs a routine that uses the SetVariable value as input. The user expected the typed value to have been accepted but the variable has not yet been set. Calling ControlUpdate/A on the first panel will read the typed value in the variable, avoiding a discrepancy between the visible value of the SetVariable control and the actual value of the variable.

Examples

```
NewPanel;DoWindow/C PanelX
String/G popupList="First;Second;Third"
PopupMenu oneOfThree value=popupList       // popup shows "First"
popupList="1;2;3"                          // popup is unchanged
ControlUpdate/W=PanelX oneOfThree          // popup shows "1"
```

ConvertGlobalStringTextEncoding

ConvertGlobalStringTextEncoding [flags] originalTextEncoding, newTextEncoding, [string , string, ...]

The ConvertGlobalStringTextEncoding operation converts the contents of the specified global string variables or the contents of all global string variables in the data folder specified with the /DF flag from one text encoding to another.

The ConvertGlobalStringTextEncoding operation was added in Igor Pro 7.00.

By default, the contents of global string variables containing control characters (codes less than 32) other than carriage return (13), linefeed (10), and tab (9) are not converted. To convert the contents of global string variables containing control characters, you must include the /SKIP=0 flag.

Also by default, in Igor Pro 9.00 or later, when converting to UTF-8, strings that are already valid as UTF-8 are skipped.

In Igor Pro 7 or later, the contents of all global string variables are assumed to be encoded as UTF-8. You should convert the text encoding of a global string variable if, for example, you have global string variables in experiments created prior to Igor7 and they contain non-ASCII characters. For those strings to be displayed and interpreted correctly, their contents need to be converted to UTF-8.

Most users will have no need to worry about the text encoding of Igor global string variables since most global string variables do not contain non-ASCII text. You should not use this operation unless you have a thorough understanding of text encoding issues or are instructed to use it by someone who has a thorough understanding.

See **String Variable Text Encodings** on page III-478 for essential background information.

ConvertGlobalStringTextEncoding can work on a list of specific global string variables or on all of the global string variables in a data folder (/DF flag). When working on a data folder, it can work on just the data folder itself or recursively on sub-data folders as well.

Conversion does not change the characters that make up text - it merely changes the numeric codes used to represent those characters.

Parameters

originalTextEncoding specifies the original (current) text encoding used by the specified global string variables. See **Text Encoding Names and Codes** on page III-490 for a list of codes. It will typically be 2 (MacRoman), 3 (Windows-1252) or 4 (Shift JIS), depending on the system on which the string variables were created.

newTextEncoding specifies the output text encoding. See **Text Encoding Names and Codes** on page III-490 for a list of codes. It will typically be 1 which stands for UTF-8.

string , *string* , ... is a list of targeted global string variables. Only the name of string variables, not a path specification plus the name, is allowed. Therefore, the string variables must be in the current data folder. The list is optional and must be omitted if you use the /DF flag. Using both the /DF flag and a list of string variables is treated as an error. Use of local string variables in this list is also an error. Use **ConvertTextEncoding** to convert local string variables.

Flags

/CONV={*errorMode* [, *diagnosticsFlags*]}

errorMode determines how ConvertGlobalStringTextEncoding behaves if the conversion can not be done because the text can not be mapped to the specified text encoding. This occurs if the string variable's original text is not valid in the specified *originalTextEncoding* or if it contains characters that can not be represented in the specified *newTextEncoding*.

errorMode takes one of these values:

1:	Generate error. SetWaveTextEncoding returns an error to Igor.
2:	Use a substitute character for any unmappable characters. The substitute character for Unicode is the Unicode replacement character, U+FFFD. For most non-Unicode text encodings it is either control-Z or a question mark.
3:	Skip unmappable input characters. Any unmappable characters will be missing in the output.
4:	Use escape sequences representing any unmappable characters or invalid source text. If the source text is valid in the source text encoding but can not be represented in the destination text encoding, unmappable characters are replaced with \uXXXX where XXXX specifies the UTF-16 code point of the unmappable character in hexadecimal. If the conversion can not be done because the source text is not valid in the source text encoding, invalid bytes are replaced with \xXX where XX specifies the value of the invalid byte in hexadecimal.

diagnosticsFlags is an optional bitwise parameter defined as follows:

Bit 0:	Emit diagnostic message if text conversion succeeds.
Bit 1:	Emit diagnostic message if text conversion fails.
Bit 2:	Emit diagnostic message if text conversion is skipped.
Bit 3:	Emit summary diagnostic message.

All other bits are reserved for future use.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

diagnosticsFlags defaults to 6 (bits 1 and 2 set) if the /DF flag is not present and to 14 (bits 1, 2 and 3 set) if the /DF flag is present.

ConvertGlobalStringTextEncoding skips text conversion if the global string variable's contents are detected as binary and you omit /SKIP=0.

/DF={*dfr, recurse, excludedDFR*}

dfr is a reference to a data folder. ConvertGlobalStringTextEncoding operates on all global string variables in the specified data folder. If *dfr* is null ($"") ConvertGlobalStringTextEncoding acts as if /DF was omitted.

If you use the /DF flag, you must omit the optional string variable list.

If *recurse* is 1, ConvertGlobalStringTextEncoding works recursively on all sub-data folders. Otherwise it affects only the data folder referenced by *dfr*.

excludedDFR is an optional reference to a data folder to be skipped by ConvertGlobalStringTextEncoding. For example, this command converts the string data for all global string variables in all data folders except for root:Packages and its sub-data folders:

```
ConvertGlobalStringTextEncoding /DF={root:,1,root:Packages} 4, 1
```

If *excludedDFR* is null ($"") ConvertGlobalStringTextEncoding acts as if *excludedDFR* was omitted and no data folders are excluded.

/SKIP=*skip* Skips conversion of a string variable as follows:

skip=0:	Do not skip conversion.
skip=1:	Skip conversion of string variables containing binary data.
skip=2:	When converting to UTF-8, skip conversion of strings that are already valid as UTF-8. This includes strings that contain only ASCII characters.
skip=3:	Skips both strings containing binary data and, when converting to UTF-8, strings that are already valid as UTF-8. This is the default behavior if /SKIP is omitted.

/SKIP=2 and /SKIP=3 require Igor Pro 9.00 or later.

/Z[=z] Prevents procedure execution from aborting if ConvertGlobalStringTextEncoding generates an error. Use /Z or the equivalent, /Z=1, if you want to handle errors in your procedures rather than having execution abort.

/Z does not suppress invalid parameter errors. It suppresses only errors in doing text encoding reinterpretation or conversion.

Details

For general background information on text encodings, see **Text Encodings** on page III-459.

For background information on string variable text encodings, see **String Variable Text Encodings** on page III-478.

Using ConvertGlobalStringTextEncoding

ConvertGlobalStringTextEncoding is used to change the numeric codes representing the text - i.e., to convert the content to a different text encoding. Its main use is to convert Igor Pro 6 global string variables from whatever text encoding they use to UTF-8. UTF-8 is a form of Unicode which is more modern but is not backward compatible with Igor Pro 6. Igor Pro 7 and later assume that string variables are encoded as UTF-8.

For example, if you have global string variables from Igor Pro 6 that are encoded in Japanese (Shift JIS), you should convert them to UTF-8. Otherwise you will get errors or garbled text when you print or display the strings. This also applies to western text containing non-ASCII characters encoded as MacRoman or Windows-1252.

If you have an Igor6 experiment containing non-ASCII string variables encoded as, for example, MacRoman, and you add some non-ASCII string variables in Igor7 or later, you now have a mix of MacRoman and UTF-8 non-ASCII string variables. In Igor9 or later, when you are converting to UTF-8, by default ConvertGlobalStringTextEncoding skips conversion of strings that are already valid as UTF-8. This allows you to convert the MacRoman string variables to UTF-8 without messing up the string variables that are already UTF-8.

Output Variables

The ConvertGlobalStringTextEncoding operation returns information in the following variables:

`V_numConversionsSucceeded` V_numConversionsSucceeded is set to the number of successful text conversions.

`V_numConversionsFailed` V_numConversionsFailed is set to the number of unsuccessful text conversions.

`V_numConversionsSkipped` V_numConversionsSkipped is set to the number of skipped text conversions. Text conversion is skipped if the string variable contains binary data and the /SKIP=0 flag is omitted.

Text conversion is skipped by default if the string variable contains binary data. Text conversion is also skipped by default if *newTextEncoding* is 1 (UTF-8) and the string variable is already valid as UTF-8. See the /SKIP flag for details.

Examples

```
// In the following examples 1 means UTF-8, 4 means Shift JIS.

// Convert specific strings' content from Shift JIS to UTF-8
ConvertGlobalStringTextEncoding 4, 1, string0, string1

// Convert all strings' content from Shift JIS to UTF-8
ConvertGlobalStringTextEncoding /DF={root:,1} 4, 1

// Same as before but exclude the root:Packages data folder
ConvertGlobalStringTextEncoding /DF={root:,1,root:Packages} 4, 1

// Convert all strings’ content from Shift JIS to UTF-8 except strings containing binary
ConvertGlobalStringTextEncoding /DF={root:,1}/SKIP=0 4, 1
```

ConvertTextEncoding, **SetWaveTextEncoding**

ConvertTextEncoding

ConvertTextEncoding(*sourceTextStr*, *sourceTextEncoding*, *destTextEncoding*, *mapErrorMode*, *options*)

ConvertTextEncoding converts text from one text encoding to another.

The ConvertTextEncoding function was added in Igor Pro 7.00.

All text in memory is assumed to be in UTF-8 format except for text stored in waves which can be stored in any text encoding. You might want to convert text from UTF-8 to Windows-1252 (Windows Western European), for example, to export it to a program that expects Windows-1252.

You might have text already loaded into Igor that you know to be in Windows-1252. To display it correctly, you need to convert it to UTF-8.

You can also use ConvertTextEncoding to test if text is valid in a given text encoding, by specifying the same text encoding for *sourceTextEncoding* and *destTextEncoding*.

Parameters

sourceTextStr is the text that you want to convert.

sourceTextEncoding specifies the source text encoding.

destTextEncoding specifies the output text encoding.

See **Text Encoding Names and Codes** on page III-490 for a list of acceptable text encoding codes.

mapErrorMode determines what happens if an input character can not be mapped to the output text encoding because the character does not exist in the output text encoding. It takes one of these values:

options is a bitwise parameter which defaults to 0 and with the bits defined as follows:

1: Generate error. The function returns "" and generates an error.

2: Return a substitute character for the unmappable character. The substitute character for Unicode is the Unicode replacement character, U+FFFD. For most non-Unicode text encodings it is either control-Z or a question mark.

3: Skip unmappable input character.

4: Return escape sequences representing unmappable characters and invalid source text.

If the source text is valid in the source text encoding but can not be represented in the destination text encoding, unmappable characters are replaced with \uXXXX where XXXX specifies the UTF-16 code point of the unmappable character in hexadecimal. The DemoUnmappable example function below illustrates this.

If the conversion can not be done because the source text is not valid in the source text encoding, invalid bytes are replaced with \xXX where XX specifies the value of the invalid byte in hexadecimal. The DemoInvalid example function below illustrates this.

If mapErrorMode is 2, 3 or 4, the function does not return an error in the event of an unmappable character.

Bit 0: If cleared, in the event of a text conversion error, a null string is returned and an error is generated. Use this if you want to abort procedure execution if an error occurs.

If set, in the event of a text conversion error, a null string is returned but no error is generated. Use this if you want to detect and handle a text conversion error. You can test for null using strlen as shown in the example below.

Bit 1: If cleared (default), null bytes in *sourceTextStr* are considered invalid and ConvertTextEncoding returns an error. If set, null bytes are considered valid.

Bit 2: If cleared (default) and *sourceTextEncoding* and *destTextEncoding* are the same, ConvertTextEncoding attempts to do the conversion anyway. If *sourceTextStr* is invalid in the specified text encoding, the issue is handled according to *mapErrorMode*. This allows you to check the validity of text whose text encoding you think you know, by passing 1 for *mapErrorMode* and 5 for *options*. Use **strlen** to test if the returned string is null, indicating that *sourceTextStr* is not valid in the specified text encoding.

If set and *sourceTextEncoding* and *destTextEncoding* are the same, ConvertTextEncoding merely returns *sourceTextStr* without doing any conversion.

All other bits are reserved and must be cleared.

Details

ConvertTextEncoding returns a null result string if *sourceTextEncoding* or *destTextEncoding* are not valid text encoding codes or if a text conversion error occurs. You can test for a null string using strlen which returns NaN if the string is null.

If bit 0 of the *options* parameter is cleared, Igor generates an error which halts procedure execution. If it is set, Igor generates no error and you should test for null and attempt to handle the error, as illustrated by the example below.

A text conversion error occurs if *mapErrorMode* is 1 and the source text contains one or more characters that are not mappable to the destination text encoding. A text conversion error also occurs if the source text contains a sequence of bytes that is not valid in the source text encoding.

The "binary" text encoding (255) is not a real text encoding. If either *sourceTextEncoding* or *destTextEncoding* are binary (255), ConvertTextEncoding does no conversion and just returns *sourceTextStr* unchanged.

See **Text Encodings** on page III-459 for further details.

Example

In reading these examples, keep in mind that Igor converts escape codes such as “\u8C4A”, when they appear in literal text, to the corresponding UTF-8 characters. See **Unicode Escape Sequences in Strings** on page IV-15 for details.

```
Function DemoConvertTextEncoding()
    // Get text encoding codes for text the text encodings used below
    Variable teUTF8 = TextEncodingCode("UTF-8")
    Variable teWindows1252 = TextEncodingCode("Windows-1252")
    Variable teShiftJIS = TextEncodingCode("ShiftJIS")

    // Convert from Windows-1252 to UTF-8
    String source = "Division sign: " + num2char(0xF7)
    String result = ConvertTextEncoding(source, teWindows1252, teUTF8, 1, 0)
    Print result

    // Convert unmappable character from UTF-8 to Windows-1252
    // \u8C4A is an escape sequence representing a Japanese character in Unicode
    // for which there is no corresponding character in Windows-1252

    // Demonstrate mapErrorMode = 1 (fail unmappable character)
    source = "Unmappable character causes failure: {\u8C4A}"
    // Pass 1 for options parameter to tell Igor to ignore error and let us handle it
    result = ConvertTextEncoding(source, teUTF8, teWindows1252, 1, 1)
    Variable len = strlen(result)     // Will be NaN if conversion failed
    if (NumType(len) == 2)
        Print "Conversion failed (as expected). Result is NULL."
        // You could cope with this error by trying again with the mapErrorMode
        // parameter set to 2, 3 or 4.
    else
        // We should not get here
        Print "Conversion succeeded (should not happen)."
        Print result
    endif

    // Demonstrate mapErrorMode = 2 (substitute for unmappable character)
    source = "Unmappable character replaced by question mark: {\u8C4A}"
    result = ConvertTextEncoding(source, teUTF8, teWindows1252, 2, 0)
    Print result                      // Prints "?" in place of unmappable character

    // Demonstrate mapErrorMode = 3 (skip unmappable character)
    source = "Unmappable character skipped: {\u8C4A}"
    result = ConvertTextEncoding(source, teUTF8, teWindows1252, 3, 0)
    Print result                      // Skips unmappable character

    // Demonstrate mapErrorMode = 4 (insert escape sequence for unmappable character)
    source = "Unmappable character replaced by escape sequence: {\u8C4A}"
    result = ConvertTextEncoding(source, teUTF8, teWindows1252, 4, 0)
    Print result        // Unmappable character represented as escape sequence

    // Demonstrate mapErrorMode = 4 (insert escape sequence for unmappable character)
    source = "Unmappable character replaced by escape sequence: {\u8C4A}"
    // First convert UTF-8 to Shift_JIS (Japanese). This will succeed.
    result = ConvertTextEncoding(source, teUTF8, teShiftJIS, 1, 0)
    // Next convert Shift_JIS (Japanese) to Windows-1252. The character can not
    // be mapped and is replaced by an escape sequence.
    result = ConvertTextEncoding(result, teShiftJIS, teWindows1252, 4, 0)
    Print result        // Unmappable character represented as escape sequence
End

// Demo unmappable character
// In this example, the source text is valid but not representable in destination
// text encoding. Because we pass 4 for the mapErrorMode parameter, ConvertTextEncoding
// uses an escape sequenceto represent the unmappable text.
Function DemoUnmappable()
    String input = "\u2135"// Alef symbol - available in UTF-8 but not in MacRoman
    String output = ConvertTextEncoding(input, 1, 2, 4, 0)
    Print output            // Prints "\u2135"
End

// Demo invalid input text
// In this example, the source text is invalid in the source text encoding.
// Because we pass 4 for the mapErrorMode parameter, ConvertTextEncoding uses an escape
    sequences
// to represent the invalid text.
Function DemoInvalidInput()
    String input = "\x8E"   // Represents "é" in MacRoman but is not valid in UTF-8
    String output = ConvertTextEncoding(input, 1, 2, 4, 0)
    Print output            // Prints "\x8E"
End
```

ConvexHull

`convexHull` `[`***`flags`***`]`***`xwave, ywave`***

`convexHull` `[`***`flags`***`]` ***`tripletWave`***

The ConvexHull operation calculates the convex hull in either 2 or 3 dimensions. The dimensionality is deduced from the input wave(s). If the input consists of two 1D waves of the same length, the number of dimensions is assumed to be 2. If the input consists of a single triplet wave (a wave of 3 columns), then the number of dimensions is 3.

In 2D cases the operation calculates the convex hull and produces the result in a pair of x and y waves, W_XHull and W_YHull.

In 3D cases the operation calculates the convex hull and stores it in a triplet wave M_Hull that describes ordered facets of the convex hull.

ConvexHull returns an error if the input waves have fewer than 3 data points.

Flags

/C	(2D convex hull only) adds the first point to the end of the W_XHull and W_YHull waves so that the first and the last points are the same.
/E	(3D case only) if you use this flag the operation also creates a wave that lists the indices of the vertices which are not part of the convex hull, i.e., vertices which are interior to the hull. The output is in the wave W_HullExcluded.
/I	(3D convex hull only) use this flag to get the corresponding index of the vertex as the fourth column in the M_Hull wave.
/S	(3D convex hull only) use this flag if you want the resulting M_Hull to have NaN lines separating each triangle.
/T=*tolerance*	(3D case only) default tolerance for measuring if a point is inside or outside the convex hull is $1.0\text{x}10^{-20}$. You can use any other positive value.
/V	(3D case only) if you use this flag the operation also creates a wave containing the output in a list of vertex indices. The wave M_HullVertices contains a row per triangle where each entry on a row corresponds to the index of the input vertex.
/Z	No error reporting.

Examples

```
Make/O/N=33 xxx=gnoise(5),yyy=gnoise(7)
Convexhull/c xxx,yyy
Display W_Yhull vs W_Xhull
Appendtograph yyy vs xxx
ModifyGraph mode(yyy)=3,marker(yyy)=8,rgb(W_YHull)=(0,15872,65280)
```

Convolve

`Convolve` `[`**`/A/C`**`]` ***`srcWaveName, destWaveName`*** `[,` ***`destWaveName`***`]`…

The Convolve operation convolves *srcWaveName* with each destination wave, putting the result of each convolution in the corresponding destination wave.

Convolve is not multidimensional aware. Some multidimensional convolutions are covered by the **MatrixConvolve**, **MatrixFilter**, and **MatrixOp** operations

Flags

/A	Acausal linear convolution.
/C	Circular convolution.

Details

Convolve performs linear convolution unless the /C or /A flag is used. See the diagrams in the examples below.

Depending on the type of convolution, the destination waves' lengths may increase. *srcWaveName* is not altered unless it also appears as a destination wave.

If *srcWaveName* is real-valued, each destination wave must be real-valued, and if *srcWaveName* is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; calculations are performed in the higher precision.

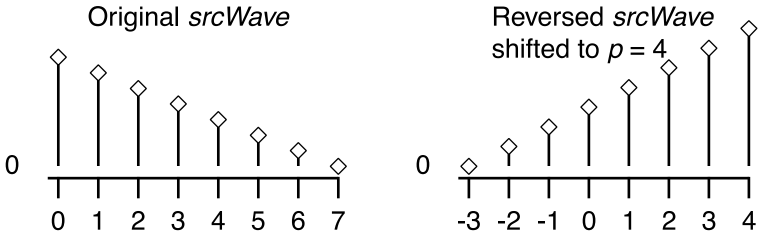
The linear convolution equation is:

$$destWaveOut[p] = \sum_{m=0}^{N-1} destWaveIn[m] \cdot srcWave[p-m]$$

where *N* is the number of points in the longer of *destWaveIn* and *srcWave*. For circular convolution, the index [*p* -*m*] is wrapped around when it exceeds the range of [0,numpnts(*srcWave*)-1]. For acausal convolution, when [*p* -*m*] exceeds the range a zero value is substituted for *srcWave* [*p* -*m*]. Similar operations are applied to *destWaveIn* [*m*].

Another way of looking at this equation is that, for all *p*, *destWaveOut*[*p*] equals the sum of the point-by-point products from 0 to *p* of the destination wave and an end-to-end reversed copy of the source wave that has been shifted to the right by *p*.

The following diagram shows the reversed/shifted *srcWave* that would be combined with *destWaveIn*. The points numbered 0 through 4 of the reversed *srcWave* would be multiplied with *destWaveIn*[0…4] and summed to produce *destWaveOut*[4]:



For linear and acausal convolution, the destination wave is first zero-padded by one less than the length of the source wave. This prevents the "wrap-around" effect that occurs in circular convolution. The zero-padded points are removed after acausal convolution, and retained after linear convolution. The X scaling of the waves is ignored.

The convolutions are performed by transforming the source and destination waves with the Fast Fourier Transform, multiplying them in the frequency domain, and then inverse-transforming them into the destination wave(s).

The convolution is performed in segments if the resulting wave has more than 256 points and the destination wave has twice as many points as the source wave. For acausal convolution, the length of the resulting wave is considered to be (numpnts(*srcWaveName*) +numpnts(*destWaveName*)-1) for this calculation.

Applications

The usual application of convolution is to compute the response of a linear system defined by its impulse response to an input signal. *srcWaveName* would contain the impulse response, and the destination wave would initially contain the input signal. After the Convolve operation has completed, the destination wave contains the output signal.

Use linear convolution when the source wave contains an impulse response (or filter coefficients) where the first point of *srcWave* corresponds to no delay (*t* = 0).

Use circular convolution for the case where the data in *srcWaveName* and *destWaveName* are considered to endlessly repeat (or “wrap around” from the end back to the start), which means no zero padding is needed.

Use acausal convolution when the source wave contains an impulse response where the middle point of *srcWave* corresponds to no delay (*t* = 0).

See Also

Convolution on page III-284 for illustrated examples. **MatrixOp**.

References

A very complete explanation of circular and linear convolution can be found in sections 2.23 and 2.24 of Rabiner and Gold, *Theory and Application of Digital Signal Processing*, Prentice Hall, 1975.

CopyDimLabels

`CopyDimLabels [`*`flags`*`]` ***`srcWave`*****`,`** ***`destWave`*****`, [`*`destWave`*`]...`**

The CopyDimLabels operation copies dimension labels from the source wave to the destination wave or waves.

CopyDimLabels was added in Igor Pro 8.00.

Support for multiple destination waves was added in Igor Pro 9.00.

Flags

In the following flags, *dim* is 0 for the rows dimension, 1 for the columns dimension, 2 for the layers dimension, and 3 for the chunks dimension.

/ROWS=*dim*	Copies the row dimension labels of *srcWave* into the *destWave* dimension specified by *dim*.
/COLS=*dim*	Copies the column dimension labels of *srcWave* into the *destWave* dimension specified by *dim*.
/LAYR=*dim*	Copies the layer dimension labels of *srcWave* into the *destWave* dimension specified by *dim*.
/CHNK=*dim*	Copies the chunk dimension labels of *srcWave* into the *destWave* dimension specified by *dim*.

Details

If you omit all flags, CopyDimLabels copies all dimension labels in *srcWave* to the corresponding dimension labels of *destWave* for dimensions that exist in *destWave*.

You can use /ROWS, /COLS, /LAYR and /CHNK to copy dimension labels from any existing source wave dimension into any existing destination wave dimension. For example, to copy the column dimension labels of wave1 into the row dimension labels of wave2 use:

```
CopyDimLabels /COLS=0 wave1, wave2
```

To copy the column dimension labels of wave1 into the layer dimension labels of wave2 and the row dimension labels of wave1 into the column dimension labels of wave 2 use:

```
CopyDimLabels /COLS=2 /ROWS=1 wave1, wave2
```

If the source dimension has N elements and the destination dimension has M>N elements then only the first N dimension labels are set in the destination. The remaining dimension labels in the destination are unchanged.

If the source dimension has N elements and the destination dimension has M<N elements then only the first M dimension labels are copied from the source to the destination.

It is an error to attempt to copy dimension labels to a non-existent dimension in the destination.

FindDimLabel, **GetDimLabel**, **SetDimLabel**, **Dimension Labels** on page II-93

CopyFile

`CopyFile [`*`flags`*`][`*`srcFileStr`*`] [as `*`destFileOrFolderStr`*`]`

The CopyFile operation copies a file on disk.

Parameters

srcFileStr can be a full path to the file to be copied (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the source file from *srcFileStr* and *pathName*, it displays a dialog allowing you to specify the source file.

destFileOrFolderStr is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with pathName.

If /D is specified, the source file is copied inside the folder using the source file's name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-451 for details on forming the path.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

Flags

/D Interprets *destFileOrFolderStr* as the name of (or path to) an existing folder (or "directory"). Without /D, *destFileOrFolderStr* is interpreted as the name of (or path to) a file.

If *destFileOrFolderStr* is not a full path to a folder, it is relative to the folder associated with pathName.

/I [=*i*] Specifies the level of user interactivity.

/I=0: Interactive only if one or *srcFileStr* or *destFileOrFolderStr* is not specified or if the source file is missing. (Same as if /I was not specified.)

/I=1: Interactive even if *srcFileStr* is specified and the source file exists.

/I=2: Interactive even if *destFileOrFolderStr* is specified.

/I=3: Interactive even if *srcFileStr* is specified, the source file exists, and *destFileOrFolderStr* is specified. Same as /I only.

/M=*messageStr* Specifies the prompt message in the Open File dialog. If /S is not used, then *messageStr* will be used for both Open File and for Save File dialogs.

/O Overwrites any existing destination file.

/P=*pathName* Specifies the folder to look in for the source file, and the folder into which the file is copied. *pathName* is the name of an existing symbolic path.

Using /P means that both *srcFileStr* and *destFileOrFolderStr* must be either simple file or folder names, or paths relative to the folder specified by *pathName*.

/S=*saveMessageStr* Specifies the prompt message in the Save File dialog.

/Z [=*z*] Prevents procedure execution from aborting if it attempts to copy a file that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution.

/Z=0: Same as no /Z.

/Z=1: Copies a file only if it exists. /Z alone has the same effect as /Z=1.

/Z=2: Copies a file if it exists or displays a dialog if it does not exist.

Variables

The CopyFile operation returns information in the following variables:

`V_flag`	Set to zero if the file was copied, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
`S_fileName`	Stores the full path to the file that was copied. If an error occurred or if the user cancelled, it is set to an empty string.
`S_path`	Stores the full path to the file copy. If an error occurred or if the user cancelled, it is set to an empty string.

Examples

Copy a file within the same folder using a new name:

```
CopyFile/P=myPath "afile.txt" as "destFile.txt"
```

Copy a file into subfolder using the original name (using /P):

```
CopyFile/D/P=myPath "afile.txt" as ":subfolder"
Print S_Path     // prints "Macintosh HD:folder:subfolder:afile.txt"
```

Copy file into subfolder using the original name (using full paths):

```
CopyFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"
```

Copy a file from one folder to another, assigning the copy a new name:

```
CopyFile "Macintosh HD:folder:afile.txt" as "Server:archive:destFile.txt"
```

Copy user-selected file in any folder as destFile.txt in myPath folder (prompt to save even if destFile.txt doesn't exist):

```
CopyFile/I=2/P=myPath as "destFile.txt"
```

Copy user-selected file in any folder as destFile.txt in any folder:

```
CopyFile as "destFile.txt"
```

See Also

The **Open**, **MoveFile**, **DeleteFile**, and **CopyFolder** operations. The **IndexedFile** function. **Symbolic Paths** on page II-22.

CopyFolder

CopyFolder [***flags***][***srcFolderStr***] [**as** ***destFolderStr***]

The CopyFolder operation copies a folder (and its contents) on disk.

Warning: *The CopyFolder command can destroy data* by overwriting another folder and contents!

When overwriting an existing folder on disk, CopyFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category.

If permission is denied, the folder will not be copied and V_Flag will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the /Z flag is specified.

Parameters

srcFolderStr can be a full path to the folder to be copied (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a folder inside the folder associated with *pathName*.

If Igor can not determine the location of the folder from *srcFolderStr* and *pathName*, it displays a dialog allowing you to specify the source folder.

If /P=*pathName* is given, but *srcFolderStr* is not, then the folder associated with *pathName* is copied.

destFolderStr can be a full path to the output (destination) folder (in which case /P is not needed), or a partial path relative to the folder associated with *pathName*.

An error is returned if the destination folder would be inside the source folder.

If Igor can not determine the location of the destination folder from *destFolderStr* and *pathName*, it displays a dialog allowing you to specify or create the destination folder.

If you use a full or partial path for either folder, see **Path Separators** on page III-451 for details on forming the path.

Flags

/D Interprets *destFolderStr* as the name of (or path to) an existing folder (or directory) to copy the source folder into. Without /D, *destFolderStr* is interpreted as the name of (or path to) the copied folder.

If *destFolderStr* is not a full path to a folder, it is relative to the folder associated with *pathName*.

/I [=*i*] Specifies the level of user interactivity.

/I=0:	Interactive only if the source or destination folder is not specified or if the source folder is missing. (Same as if /I was not specified.)
/I=1:	Interactive even if the source folder is specified and it exists.
/I=2:	Interactive even if *destFolderStr* is specified.
/I=3:	Interactive even if the source folder is specified, the source folder exists, and *destFolderStr* is specified. Same as /I only.

/M=*messageStr* Specifies the prompt message in the Select (source) Folder dialog. If /S is not used, then *messageStr* will be used for the Select Folder dialog and for the Create Folder dialog.

/O Overwrite existing destination folder, if any.

On Macintosh, a Macintosh-style overwrite-move is performed in which the source folder completely replaces the destination folder.

On Windows, a Windows-style mix-in move is performed in which the contents of the source folder are moved into the destination folder, replacing any same-named files but leaving other files in place.

/P=*pathName* Specifies the folder to look in for the source folder. *pathName* is the name of an existing symbolic path.

If *srcFolderStr* is not specified, the folder associated with *pathName* is copied.

Using /P means that *srcFolderStr* (if specified) and *destFolderStr* must be either simple folder names or paths relative to the folder specified by *pathName*.

/S=*saveMessageStr* Specifies the prompt message in the Create Folder dialog.

/Z [=z] Prevents procedure execution from aborting if it attempts to copy a file that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution.

/Z=0:	Same as no /Z.
/Z=1:	Copies a folder only if it exists. /Z alone has the same effect as /Z=1.
/Z=2:	Copies a folder if it exists or displays a dialog if it does not exist.

Variables

The CopyFolder operation returns information in the following variables:

`V_flag` Set to zero if the folder was copied, to -1 if the user cancelled either the Select Folder or Create Folder dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.

`S_fileName` Stores the full path to the folder that was copied, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.

`S_path` Stores the full path to the folder copy, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.

Details

You can use only /P=*pathName* (without *srcFolderStr*) to specify the source folder to be copied.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

See Also

Open, **MoveFile**, **DeleteFile**, **MoveFolder**, **NewPath**, and **IndexedDir** operations, and **Symbolic Paths** on page II-22.

CopyScales

`CopyScales [/I/P] srcWaveName, waveName [, waveName]…`

The CopyScales operation copies the x, y, z, and t scaling, x, y, z, and t units, the data Full Scale and data units from *srcWaveName* to the other waves.

Flags

/I	Copies the x, y, z, and t scaling in inclusive format.
/P	Copies the x, y, z, and t scaling in slope/intercept format (x0, dx format).

Details

Normally the x, y, z, and t (dimension) scaling is copied in min/max format. However, if you use /P, the dimension scaling is copied in slope/intercept format so that if *srcWaveName* and the other waves have differing dimension size (number of points if the wave is a 1D wave), then their dimension values will still match for the points they have in common. Similarly, /I uses the inclusive variant of the min/max format. See **SetScale** for a discussion of these dimension scaling formats.

If a wave has only one point, /I mode reverts to /P mode.

CopyScales copies scales only for those dimensions that *srcWaveName* and *waveName* have in common.

See Also

x, **y**, **z**, and **t** scaling functions.

Correlate

`Correlate [/AUTO/C/NODC] srcWaveName, destWaveName [, destWaveName]…`

The Correlate operation correlates *srcWaveName* with each destination wave, putting the result of each correlation in the corresponding destination wave.

Flags

/AUTO Auto-correlation scaling. This forces the X scaling of the destination wave's center point to be x=0, and divides the destination wave by the center point's value so that the center value is exactly 1.0.

If srcWaveName and destWaveName do not have the same number of points, this flag is ignored.

/AUTO is not compatible with /C.

/C Circular correlation. (See **Compatibility Note**.)

/NODC Removes the mean from the source and destination waves before computing the correlations. Removing the mean results in the un-normalized auto- or cross-covariance.

"DC" is an abbrevation of "direct current", an electronics term for the non-varying average value component of a signal.

Details

Note: To compute a single-value correlation number use the **StatsCorrelation** function which returns the Pearson's correlation coefficient of two same-length waves.

Correlate performs linear correlation unless the /C flag is used.

Depending on the type of correlation, the length of the destination may increase. *srcWaveName* is not altered unless it also appears as a destination wave.

If the source wave is real-valued, each destination wave must be real-valued and if the source wave is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; calculations are performed in the higher precision.

The linear correlation equation is:

$$destWaveOut[p] = \sum_{m=0}^{N-1} srcWave[m] \cdot destWaveIn[p+m]$$

where N is the number of points in the longer of *destWaveIn* and *srcWave*.

For circular correlation, the index [p +m] is wrapped around when it exceeds the range of `[0,numpnts(destWaveIn)-1]`. For linear correlation, when [p +m] exceeds the range a zero value is substituted for *destWaveIn*[p +m]. When m exceeds `numpnts(srcWave)-1`, 0 is used instead of *srcWave*[m].

Comparing this with the **Convolve** operation, which is the linear convolution:

$$destWaveOut[p] = \sum_{m=0}^{N-1} destWaveIn[m] \cdot srcWave[p-m]$$

you can see that the only difference is that for correlation the source wave is *not* reversed before shifting and combining with the destination wave.

The Correlate operation is not multidimensional aware. For details, see **Analysis on Multidimensional Waves** on page II-95 and in particular **Analysis on Multidimensional Waves** on page II-95.

Compatibility Note

Prior to Igor Pro 5, Correlate/C scaled and rotated the results improperly (the result was often rotated left by one and the X scaling was entirely negative).

Now the destination wave's X scaling is unaltered and it does not rotate the result. You can force the old behavior for compatibility with old procedures that depend on the old behavior by setting `root:V_oldCorrelationScaling=1`.

A better way to get identical Correlate/C results with all versions of Igor Pro is to use this code, which rotates the result so that x=0 is always the first point in *destWave*, no matter which Igor Pro version runs this code (currently, it doesn't change anything and runs extremely quickly because it does no rotation):

```
Correlate/C srcWave, destWave
Variable pointAtXEqualZero= x2pnt(destWave,0)     // 0 for Igor Pro 5
Rotate -pointAtXEqualZero,destWave
SetScale/P x, 0, DimDelta(destWave,0), "", destWave
```

Applications

A common application of correlation is to measure the similarity of two input signals as they are shifted by one another.

Often it is desirable to normalize the correlation result to 1.0 at the maximum value where the two inputs are most similar. To normalize *destWaveOut*, compute the RMS values of the input waves and the number of points in each wave:

```
WaveStats/Q srcWave
Variable srcRMS = V_rms
Variable srcLen = numpnts(srcWave)

WaveStats/Q destWave
Variable destRMS = V_rms
Variable destLen = numpnts(destWave)

Correlate srcWave, destWave                 // overwrites destWave

// now normalize to max of 1.0
destWave /= (srcRMS * sqrt(srcLen) * destRMS * sqrt(destLen))
```

Another common application is using autocorrelation (where *srcWaveName* and *destWaveName* are the same) to determine Power Spectral Density. In this case it better to use the **DSPPeriodogram** operation which provides more options.

See Also

Convolution on page III-284 and **Correlation** on page III-286 for illustrated examples. See the **Convolve** operation for algorithm implementation details, which are identical except for the lack of source wave reversal, and the lack of the /A (acausal) flag.

The **MatrixOp**, **StatsCorrelation**, **StatsCircularCorrelationTest**, **StatsLinearCorrelationTest**, and **DSPPeriodogram** operations.

References

An explanation of autocorrelation and Power Spectral Density (PSD) can be found in Chapter 12 of Press, William H., *et al*., *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

WaveMetrics provides Igor Technical Note 006, “DSP Support Macros” that computes the PSD with options such as windowing and segmenting. See the Technical Notes folder. Some of the techniques discussed there are available as Igor procedure files in the “WaveMetrics Procedures:Analysis:” folder.

Wikipedia: http://en.wikipedia.org/wiki/Cross_covariance

Wikipedia: http://en.wikipedia.org/wiki/Autocorrelation_function

cos

`cos(angle)`

The cos function returns the cosine of *angle* which is in radians.

In complex expressions, *angle* is complex, and `cos(angle)` returns a complex value:

$$\cos(x+iy)=\cos(x)\cosh(y)-i\sin(x)\sinh(y).$$

See Also

acos, **sin**, **tan**, **sec**, **csc**, **cot**

cosh

`cosh(num)`

The cosh function returns the hyperbolic cosine of *num*:

$$\cosh(x)=\frac{e^x+e^{-x}}{2}.$$

In complex expressions, *num* is complex, and `cosh(num)` returns a complex value.

See Also

sinh, **tanh**, **coth**

CosIntegral

`CosIntegral(z)`

The CosIntegral(*z*) function returns the cosine integral of *z*.

If *z* is real, a real value is returned. If *z* is complex then a complex value is returned.

The CosIntegral function was added in Igor Pro 7.00.

Details

The cosine integral is defined by

$$Ci(z) = \gamma + \ln(z) + \int_0^z \frac{\cos(t) - 1}{t} dt, \qquad \left(|\arg(z)| < \pi\right)$$

where γ is the Euler-Mascheroni constant 0.5772156649015328606065.

IGOR computes the CosIntegral using the expression:

$$Ci(z) = -\frac{Z^2}{4} \, {}_2F_3\left(1,1;2,2,\frac{3}{2};-\frac{z^2}{4}\right) + \ln(z) + \gamma,$$

See Also

SinIntegral, **ExpIntegralE1**, **hyperGPFQ**

cot

`cot(`*`angle`*`)`

The cot function returns the cotangent of *angle* which is in radians.

In complex expressions, *angle* is complex, and cot(*angle*) returns a complex value.

See Also

sin, **cos**, **tan**, **sec**, **csc**

coth

`coth(`*`num`*`)`

The coth function returns the hyperbolic cotangent of *num*:

$$\coth(x) = \frac{e^x + e^{-x}}{e^x - e^{-x}}.$$

In complex expressions, *num* is complex, and coth(*num*) returns a complex value.

See Also

sinh, **cosh**, **tanh**

CountObjects

`CountObjects(`*`sourceFolderStr`*`, `*`objectType`*`)`

The CountObjects function returns the number of objects of the specified type in the data folder specified by the string expression.

CountObjectsDFR is preferred.

Parameters

sourceFolderStr can be either `":"` or `""` to specify the current data folder. You can also use a full or partial data folder path. *objectType* should be one of the following values:

1	Waves
2	Numeric variables
3	String variables
4	Data folders

See Also

Chapter II-8, **Data Folders**, and the **GetIndexedObjName** function.

CountObjectsDFR

`CountObjectsDFR(dfr,objectType)`

The CountObjectsDFR function returns the number of objects of the specified type in the data folder specified by the data folder reference *dfr*.

CountObjectsDFR is the same as CountObjects except the first parameter, *dfr*, is a data folder reference instead of a string containing a path.

Parameters

dfr is a data folder reference.

objectType is one of the following values:

1	Waves
2	Numeric variables
3	String variables
4	Data folders

See Also

Data Folders on page II-107, **Data Folder References** on page IV-78, **Built-in DFREF Functions** on page IV-81, **GetIndexedObjNameDFR**

cpowi

`cpowi(num, ipow)`

This function is obsolete as the exponentiation operator ^ handles complex expressions with any combination of real, integer and complex arguments. See **Operators** on page IV-6. The cpowi function returns a complex number resulting from raising complex *num* to integer-valued power *ipow*. *ipow* can be positive or negative, but if it is not an integer cpowi returns (NaN, NaN).

CreateAliasShortcut

`CreateAliasShortcut [flags][targetFileDirStr] [as aliasFileStr]`

The CreateAliasShortcut operation creates an alias (*Macintosh*) or shortcut (*Windows*) file on disk. The alias can point to either a file or a folder. The file or folder pointed to is called the “target” of the alias or shortcut.

Parameters

targetFileDirStr can be a full path to the file or folder to make an alias or shortcut for, a partial path relative to the folder associated with /P=*pathName*, or the name of a file or folder in the folder associated with *pathName*.

If Igor can not determine the location of the file or folder from *targetFileDirStr* and *pathName*, it displays a dialog allowing you to specify a target file. Use /D to select a folder as the alias target, instead.

aliasFileStr can be a full path to the created alias file, a partial path relative to the folder associated with *pathName* if specified, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the alias or shortcut file from *aliasFileStr* and *pathName*, it displays a File Save dialog allowing you to create the file.

If you use a full or partial path for either *targetFileDirStr* or *aliasFileStr*, see **Path Separators** on page III-451 for details on forming the path.

Folder paths should not end with single path separators. See the **MoveFolder Details** section.

Flags

/D	Uses the Select Folder dialog rather than Open File dialog when *targetFileDirStr* is not fully specified.

/I [=*i*] Specifies the level of user interactivity.

/I=0: Interactive only if one or *targetFileDirStr* or *aliasFileStr* is not specified or if the target file is missing. (Same as if /I was not specified.)

/I=1: Interactive even if *targetFileDirStr* is fully specified and the target file exists.

/I=2: Interactive even if *targetFileDirStr* is specified.

/I=3: Interactive even if *targetFileDirStr* is specified and the target file exists. Same as /I only.

/M=*messageStr* Specifies the prompt message in the Open File or Select Folder dialog. If /S is not specified, then *messageStr* will be used for Open File (or Select Folder) and for Save File dialogs.

/O Overwrites any existing file with the alias or shortcut file.

/P=*pathName* Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.

/S=*saveMessageStr* Specifies the prompt message in the Save File dialog when creating the alias or shortcut file.

/Z[=*z*] Prevents procedure execution from aborting the procedure tries to create an alias or shortcut for a file or folder that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution.

/Z=0: Same as no /Z.

/Z=1: Creates an alias to a file or folder only if it exists. /Z alone has the same effect as /Z=1.

/Z=2: Creates an alias to a file or folder only if it exists and displays a dialog if it does not exist.

Variables

The CreateAliasShortcut operation returns information in the following variables:

`V_flag` Status output:

0 Created an alias or shortcut file.

1 User cancelled any of the Open File, Select Folder, or Save File dialogs.

Other: An error occurred, such as the target file does not exist.

`S_fileName` Full path to the target file or folder. If an error occurred or if the user cancelled, it is an empty string.

`S_path` Full path to the created alias or shortcut file. If an error occurred or if the user cancelled, it is an empty string.

Examples

Create a shortcut (*Windows*) to the current experiment, on the desktop:

```
String target= Igorinfo(1)+".pxp" // experiments are usually .pxp on Windows
CreateAliasShortcut/O/P=home target as "C:WINDOWS:Desktop:"+target
```

Create an alias (*Macintosh*) to the VDT XOP in the Igor Extensions folder:

```
String target= ":More Extensions:Data Acquisition:VDT"
CreateAliasShortcut/O/P=Igor target as ":Igor Extensions:VDT alias"
```

Create an alias to the “HD 2” disk. Put the alias on the desktop:

```
CreateAliasShortcut/D/O "HD 2" as "HD:Desktop Folder:Alias to HD 2"
```

See Also

Symbolic Paths on page II-22.

The **Open**, **MoveFile**, **DeleteFile**, and **GetFileFolderInfo** operations. The **IgorInfo** and **ParseFilePath** functions.

CreateBrowser

CreateBrowser [/M] [***keyword = value*** [, ***keyword = value*** …]]

The CreateBrowser operation creates a data browser window.

Documentation for the CreateBrowser operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "CreateBrowser"
```

CreateDataObjectName

CreateDataObjectName(*dfr*, nameInStr, *objectType*, *suffixNum*, *options*)

The CreateDataObjectName function returns a name suitable for use for a new object of the type specified by objectType. It can replace a combination of **CleanupName** and **UniqueName**.

CreateDataObjectName was added in Igor Pro 9.00 or later.

Parameters

dfr is a data folder reference for the data folder in which the objects are to be created. Pass : for the current data folder.

nameInStr must contain an unquoted (i.e., no single quotes for liberal names) name, such as you might receive from the user through a dialog or control panel.

objectType is one of the following:

1:	Wave
3:	Numeric variable
4:	String variable
11:	Data folder

suffixNum is a value used in generating a series of names from a base name when allowing overwriting. For other uses, pass 0 for *suffixNum*. See ***Generating a Series of Names from a Base Name*** below.

options is a bitwise parameter with the bits defined as follows:

Bit 0: Be liberal.

If cleared, CreateDataObjectName always returns a standard object name. If set, it returns a liberal object name if nameInStr is liberal. See **Object Names** on page III-501 for a discussion of standard and liberal object names.

If objectType is 3 (numeric variable) or 4 (string variable), the output name will not be liberal, even if this bit is set as Igor allows only wave and data folder names to be liberal.

Bit 1: Allow overwrite.

If cleared, CreateDataObjectName returns a name that is unique in the namespace of the type of object specified by objectType. If set, CreateDataObjectName returns a name that may be in use in that namespace.

Waves, numeric variables and string variables are in the same namespace and so must have unique names within a given data folder. Data folders are in their own namespace and so their names can be the same as the names of waves, numeric variables and string variables.

Bit 2: Input name is a base name.

If cleared, *nameInStr* is taken to be a proposed object name that CreateDataObjectName cleans up (i.e., makes legal). If the name is in use and allow overwrite is not specified, CreateDataObjectName makes the name unique by appending one or more digits.

If set, *nameInStr* is taken to be a proposed base name for a series of objects and the output name always has at least one digit appended. CreateDataObjectName cleans the name up and then appends one or more digits. If allow overwrite is not specified, the appended digits are chosen to return a unique name. If allow overwrite is specified, the appended digits represent suffixNum whether there is an existing object with the resulting name or not.

For an example using a base name, see ***Generating a Series of Names from a Base Name*** next.

Generating a Series of Names from a Base Name

If you are creating a series of waves, such as when loading a data file containing multiple columns, it is sometimes convenient to generate names of the form <baseName><number>, for example, wave0, wave1, wave2. To do this, you pass the base name as the nameInStr parameter and set bit 2 (input name is base name) of the options parameter.

If you disallow creation of names that are in use for existing objects (bit 1 of options cleared), CreateDataObjectName appends a number to the base name such that the output name is not in use for an object in the namespace of the type of object specified by objectType. In this case, suffixNum is not used and you should pass 0 for it.

If you allow creation of names that are in use for existing objects (bit 1 of options set), CreateDataObjectName appends the digits representing suffixNum to the base name to create the output name. In this case, you must pass the desired suffix number in each call to CreateDataObjectName.

Here is an example demonstrating this technique:

```
Function/S CreateSeriesOfWavesWithBaseName(dfr, baseName, beLiberal, allowOverwrite,
    numWavesToCreate)
    DFREF dfr                          // : for current data folder
    String baseName
    int beLiberal
    int allowOverwrite
    int numWavesToCreate

    int options = 4                    // inNameIsBaseName
    if (beLiberal)
        options += 1
    endif
    if (allowOverwrite)
        options += 2
    endif

    int suffixNum = 0
    String list = ""

    int i
    for(i=0; i<numWavesToCreate; i+=1)
        String outName = CreateDataObjectName(dfr, baseName, 1, suffixNum, options)
        Make/O/N=(100) dfr:$outName
        list += outName + ";"
        if (allowOverwrite)
            suffixNum += 1             // suffixNum for next call
        endif
    endfor

    return list
End
```

With overwrite disallowed, you must create the object each time through the loop because that is the only way that CreateDataObjectName can determine that the wave created in a previous iteration exists.

With overwrite allowed, you do not need to create the object each time through the loop although that is normally what you want.

See Also

Object Names on page III-501, **Programming with Liberal Names** on page IV-168, **CheckName**, **CleanupName**, **UniqueName**

CreationDate

CreationDate(*waveName*)

Returns creation date of wave as an Igor date/time value, which is the number of seconds from 1/1/1904.

The returned value is valid for waves created with Igor Pro 3.0 or later. For waves created in earlier versions, it returns 0.

See Also

ModDate.

Cross

Cross [**/DEST=destWave /FREE /T /Z**] ***vectorA*, *vectorB*** [, ***vectorC***]

The Cross operation computes the cross products *vectorA* x *vectorB* and *vectorA* x (*vectorB* x *vectorC*). Each vector is a 1D real wave containing 3 rows. Stores the result in the wave W_Cross in the current data folder.

Flags

/DEST=*destWave*	Stores the cross product in the wave specified by *destWave*. The destination wave is overwritten if it exists. The destination wave must be different from the input waves. The operation creates a wave reference for the destination wave if called in a user-defined function. See **Automatic Creation of WAVE References** on page IV-72 for details. If you omit /DEST, the operation stores the result in the wave W_Cross in the current data folder. Requires Igor7 or later.
/FREE	When used with /DEST, the destination wave is created as a free wave. See **Free Waves** on page IV-91 for details on free waves. /FREE is allowed in user-defined functions only. Requires Igor7 or later.
/T	Stores output in a row instead of a column in W_Cross.
/Z	Generates no errors for any unsuitable inputs.

csc

csc(*angle*)

The csc function returns the cosecant of *angle* which is in radians.

$$\csc(x) = \frac{1}{\sin(x)}.$$

In complex expressions, *angle* is complex, and csc(*angle*) returns a complex value.

See Also

sin, **cos**, **tan**, **sec**, **cot**

csch

csch(*x*)

The csch function returns the hyperbolic cosecant of *x*.

$$\mathrm{csch}(x) = \frac{1}{\sinh(x)} = \frac{2}{e^{x} - e^{-x}}.$$

In complex expressions, *x* is complex, and csch(*x*) returns a complex value.

See Also

cosh, **tanh**, **coth**, **sech**

CsrInfo

`CsrInfo(`*`cursorName`*` [, `*`graphNameStr`*`])`

The CsrInfo function returns a keyword-value pair list of information about the specified cursor (*cursorName* is A through J) in the top graph or graph specified by *graphNameStr*. It returns `""` if the cursor is not in the graph.

Details

The returned string contains information about the cursor in the following format:

```
TNAME:traceName; ISFREE:freeNum;POINT:xPointNumber;[YPOINT:yPointNumber;]
   RECREATION:command;
```

The *traceName* value is the name of the graph trace or image to which it is attached or which supplies the x (and y) values even if the cursor isn't attached to it.

If TNAME is empty, fields POINT, ISFREE, and YPOINT are not present.

The *freeNum* value is 1 if the cursor is not attached to anything, 0 if attached to a trace or image.

The POINT value is the same value **pcsr** returns.

The YPOINT keyword and value are present only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot or when the cursor is free. Its value is the same as returned by **qcsr**.

If cursor is free, POINT and YPOINT values are fractional relative positions (see description in the **Cursor** command).

The RECREATION keyword contains the Cursor commands (including /W) necessary to regenerate the current settings.

Examples

```
Variable aExists= strlen(CsrInfo(A)) > 0    // A is a name, not a string
Variable bIsFree= NumberByKey("ISFREE",CsrInfo(B,"Graph0"))
```

Cursors — Moving Cursor Calls Function on page IV-339.

Trace Names on page II-282, **Programming With Trace Names** on page IV-87.

CsrWave

`CsrWave(`*`cursorName`*` [, `*`graphNameStr`*` [, `*`wantTraceName`*`]])`

The CsrWave function returns a string containing the name of the wave the specified cursor (A through J) is on in the top (or named) graph. If the optional *wantTraceName* is nonzero, the trace name is returned. A trace name is the wave name with optional instance notation (see **ModifyGraph (traces)**).

Details

The name of a wave by itself is not sufficient to identify the wave because it does not specify what data folder contains the wave. Thus, if you are calling CsrWave for the purpose of passing the wave name to other procedures, you should use the **CsrWaveRef** function instead. Use CsrWave if you want the name of the wave to use in an annotation or a notebook.

Examples

```
String waveCursorAIsOn = CsrWave(A)            // not CsrWave("A")
String waveCursorBIsOn = CsrWave(B,"Graph0")   // in specified graph
String traceCursorBIsOn = CsrWave(B,"",1)      // trace name in top graph
```

See Also

Programming With Cursors on page II-321.

Trace Names on page II-282, **Programming With Trace Names** on page IV-87.

CsrWaveRef

CsrWaveRef(*cursorName* [, *graphNameStr*])

The CsrWaveRef function returns a wave reference to the wave the specified cursor (A through J) is on in the top (or named) graph.

Details

The wave reference can be used anywhere Igor is expecting the name of a wave (not a string containing the name of a wave).

CsrWaveRef should be used in place of the CsrWave() string function to work properly with data folders.

Examples

```
Print CsrWaveRef(A)[50]              // not CsrWaveRef("A")
Print CsrWaveRef(B,"Graph0")[50]     // in specified graph
```

See Also

Programming With Cursors on page II-321.

Wave Reference Functions on page IV-197.

CsrXWave

CsrXWave(*cursorName* [, *graphNameStr*])

The CsrXWave function returns a string containing the name of the wave supplying the X coordinates for an XY plot of the Y wave the specified cursor (A through J) is attached to in the top (or named) graph.

Details

CsrXWave returns an empty string ("") if the wave the cursor is on is not plotted versus another wave providing the X coordinates (that is, if the wave was not plotted with a command such as `Display theWave vs anotherWave`).

The name of a wave by itself is not sufficient to identify the wave because it does not specify what data folder contains the wave. Thus, if you are calling CsrXWave for the purpose of passing the wave name to other Igor procedures, you should use the **CsrXWaveRef** function instead. Use CsrXWave if you want the name of the wave to use in an annotation or a notebook.

Examples

```
Display ywave vs xwave
```

ywave supplies the Y coordinates and xwave supplies the X coordinates for this XY plot.

```
Cursor A ywave,0
Print CsrXWave(A)       // prints xwave
```

See Also

Programming With Cursors on page II-321.

CsrXWaveRef

CsrXWaveRef(*cursorName* [, *graphNameStr*])

The CsrXWaveRef function returns a wave reference to the wave supplying the X coordinates for an XY plot of the Y wave the specified cursor (A through J) is attached to in the top (or named) graph.

Details

The wave reference can be used anywhere Igor is expecting the name of a wave (not a string containing the name of a wave).

CsrXWaveRef returns a null reference (see **WaveExists**) if the wave the cursor is on is not plotted versus another wave providing the X coordinates (that is, if the wave was not plotted with a command such as `Display theWave vs anotherWave`). CsrXWaveRef should be used in place of the CsrXWave string function to work properly with data folders.

Examples

```
Display ywave vs xwave
```

ywave supplies the Y coordinates and xwave supplies the X coordinates for this XY plot.

```
Cursor A ywave,0
Print CsrXWaveRef(A)[50]      // prints value of xwave at point #50
```

See Also

Programming With Cursors on page II-321.

Wave Reference Functions on page IV-197.

CTabList

`CTabList()`

The CTabList function returns a semicolon-separated list of the names of built-in color tables. It is useful for creating pop-up menus in control panels.

Color tables available through Igor Pro 4:

Grays	Rainbow	YellowHot	BlueHot	BlueRedGreen
RedWhiteBlue	PlanetEarth	Terrain		

Additional color tables added for Igor Pro 5:

Grays256	Rainbow256	YellowHot256	BlueHot256	BlueRedGreen256
RedWhiteBlue256	PlanetEarth256	Terrain256	Grays16	Rainbow16
Red	Green	Blue	Cyan	Magenta
Yellow	Copper	Gold	CyanMagenta	RedWhiteGreen
BlueBlackRed	Geo	Geo32	LandAndSea	LandAndSea8
Relief	Relief19	PastelsMap	PastelsMap20	Bathymetry9
BlackBody	Spectrum	SpectrumBlack	Cycles	Fiddle
Pastels				

Additional color tables added for Igor Pro 6:

RainbowCycle	Rainbow4Cycles	GreenMagenta16	dBZ14	dBZ21
Web216	BlueGreenOrange	BrownViolet	ColdWarm	Mocha
VioletOrangeYellow	SeaLandAndFire			

Additional color tables added for Igor Pro 6.2:

Mud	Classification

Additional color tables added for Igor Pro 9:

Turbo

Image Color Tables on page II-392, **Color Table Waves** on page II-399, **ColorTab2Wave**

CtrlBackground

`CtrlBackground` `[`***`key`*** `[`**`=`** ***`value`***`]]`...

The CtrlBackground operation controls the unnamed background task.

CtrlBackground works only with the unnamed background task. New code should used named background tasks instead. See **Background Tasks** on page IV-319 for details.

Parameters

dialogsOK=1 *or* 0 — If 1, your task will be allowed to run while an Igor dialog is present. This can potentially cause crashes unless your task is well-behaved.

noBurst=1 *or* 0 — Normally (or noBurst=0), your task will be called at maximum rate if a delay causes normal run times to be missed. Using noBurst=1, will suppress this burst catch up mode.

period=*deltaTicks* Sets the minimum number of ticks that must pass between invocations of the background task.

start[=*startTicks*] Starts the background task (designated by SetBackground) when the tick count reaches *startTicks*. If you omit *startTicks* the task starts immediately.

stop Stops the background task.

See Also

The **BackgroundInfo**, **SetBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and **Background Tasks** on page IV-319.

CtrlNamedBackground

`CtrlNamedBackground` ***`taskName`*****`,`** ***`keyword`*** **`=`** ***`value`*** `[,` ***`keyword`*** **`=`** ***`value`*** …]

The CtrlNamedBackground operation creates and controls named background tasks.

We recommend that you see **Background Tasks** on page IV-319 for an orientation before working with background tasks.

Parameters

taskName *taskName* is the name of the background task or _all_ to control all named background tasks. You can use any valid standard Igor object name as the background task name.

burst [= *b*] Enable burst catch up mode (off by default, *b*=0). When on (*b*=1), the task is called at the maximum rate if a delay misses normal run times.

dialogsOK [= *d*] Use dialogsOK=1 to allow the background task to run when a dialog window is active. By default, dialogsOK=0 is in effect. See **Background Tasks and Dialogs** on page IV-321 for details.

kill [= *k*] Stops and releases task memory for reuse (*k*=1; default) or continues (*k*=0).

noEvent=*mode* Controls Igor's event processing while a background task function is executing. The noEvents keyword was added in Igor Pro 8.04.

If your background task function uses a large fraction of available processor time, you may find that it is difficult to type on the command line or anywhere else. That is because Igor normally discards events that arrive while a user-defined function is running, causing events to be lost. This is the default mode of operation and corresponds to noEvents=0.

Using noEvents=1 causes Igor to postpone event handling until after the background task function returns which improves the reliability of the user interface. A consequence of using noEvents=1 is that you can not abort a rogue background task function using **User Abort Key Combinations**.

The noEvents keyword applies to all background tasks, including the unnamed background task. You should use _all_ for the taskName parameter.

mode defaults to 0 when Igor starts. The mode set using noEvents remains in effect until Igor quits.

period=*deltaTicks* Sets the minimum number of ticks (*deltaTicks*) that must pass between background task invocations. *deltaTicks* is truncated to an integer and clipped to a value greater than zero. See **Background Task Period** on page IV-320 for details.

proc=*funcName* Specifies name of a background user function (see **Details**).

start [=*startTicks*] Starts when the tick count reaches *startTicks*. A task starts immediately without *startTicks*.

status Returns background task information in the S_info string variable.

stop [= *s*] Stops the background task (*s*=1; default) or continues (*s*=0).

Details

The user function you specify via the proc keyword must have the following format:

```
Function myFunc(s)
   STRUCT WMBackgroundStruct &s
   …
```

The members of the `WMBackgroundStruct` are:

Base `WMBackgroundStruct` Structure Members

Member	Description
`char name[MAX_OBJ_NAME+1]`	Background task name.
`uint32 curRunTicks`	Tick count when task was called.
`int32 started`	TRUE when CtrlNamedBackground start is issued. You may clear or set to desired value.
`uint32 nextRunTicks`	Precomputed value for next run but user functions may change this.

You may also specify a user function that takes a user-defined STRUCT as long as the first elements of the structure match the `WMBackgroundStruct` or, preferably, if the first element is an instance of `WMBackgroundStruct`. Use the started field to determine when to initialize the additional fields. Your structure may not include any String, WAVE, NVAR, DFREF or other fields that reference memory that is not part of the structure itself.

If you specify a user-defined structure that matches the first fields rather than containing an instance of `WMBackgroundStruct`, then your function will fail if, in the future, the size of the built-in structure changes. The value of `MAX_OBJ_NAME` is 255 but this may also change. It was changed from 31 to 255 in Igor Pro 8.00.

Your function should return zero unless it wants to stop in which case it should return 1.

You can call CtrlNamedBackground within your background function. You can even switch to a different function if desired.

Use the status keyword to obtain background task information via the S_info variable, which has the format:

`NAME:`*`name`*`;PROC:`*`fname`*`;RUN:`*`r`*`;PERIOD:`*`p`*`;NEXT:`*`n`*`;QUIT:`*`q`*`;FUNCERR:`*`e`*`;`

When parsing S_info, do not rely on the number of key-value pairs or their order. RUN, QUIT, and FUNCERR values are 1 or 0, NEXT is the tick count for the next firing of the task. QUIT is set to 1 when your function returns a nonzero value and FUNCERR is set to 1 if your function could not be used for some reason.

See Also

See **Background Tasks** on page IV-319 for examples.

Demos

Choose File→Example Experiments→Programming→ Background Task Demo.

CtrlFIFO

`CtrlFIFO` ***`FIFOName`*** `[,` ***`key = value`***`]…`

The CtrlFIFO operation controls various aspects of the named FIFO.

Parameters

close	Closes the FIFO’s output or review file (if any).
deltaT=*dt*	Documents the data acquisition rate.
doffset=*dataOffset*	Used only with rdfile. Offset to data. If not provided offset is zero.
dsize=*dataSize*	Used only with rdfile. Size of data in bytes. If not provided, then data size is assumed to be the remainder of file. If this assumption is not valid then unexpected results may be observed.
flush	New data in FIFO is flushed to disk immediately.

file=*oRefNum*	File reference number for the FIFO's output file. You obtain this reference number from the **Open** operation used to create the file.
note=*noteStr*	Stores the note string in the file header. It is limited to 255 bytes.
rdfile=*rRefNum*	Like rfile but for review of raw data (use Open/R command). Channel data must match raw data in file. Offset from start of file to start of data can be provided using doffset given in same command. If data does not extend all the way to the end of the file, then the number of bytes of data can be provided using dsize in the same command.
rfile=*rRefNum*	File reference number for the FIFO's review file. Use a review file when you are using a FIFO to review existing data. Obtain the reference number from the Open/R operation used to open the file. File may be either unified header/data or a split format where the header contains the name of a file containing the raw data.
size=*s*	Sets number of chunks in the FIFO. The default is 10000. A chunk of data consists of a single data point from each of the FIFO's channels.
start	Starts the FIFO running by setting the time/date in the FIFO header, writing the header to the output file and marking the FIFO active.
stop	Stops the FIFO by flushing data to disk and marking the FIFO as inactive.
swap	Used only with rdfile. Indicates that the raw data file requires byte-swapping when it is read. This would be the case if you are running on a Macintosh, reading a binary file from a PC, or vice versa.

Details

Once start has been issued, the FIFO can accept no further commands except stop.

The FIFO must be in the valid state for you to access its data (using a chart control or using the **FIFO2Wave** operation). When you create a FIFO, using **NewFIFO**, it is initially invalid. It becomes valid when you issue the start command via the CtrlFIFO operation. It remains valid until you change a FIFO parameter using CtrlFIFO.

FIFOs are used for data acquisition.

See Also

The **NewFIFO** and **FIFO2Wave** operations, and **FIFOs and Charts** on page IV-313.

Cursor

```
Cursor [flags] cursorName traceName x_value
Cursor /F[flags] cursorName traceName x_value, y_value
Cursor /K[/W=graphName] cursorName
Cursor /I[/F][flags] cursorName imageName x_value, y_value
Cursor /M[flags] cursorName
```

The Cursor operation moves the cursor specified by *cursorName* onto the named trace at the point whose X value is *x_value*. or the coordinates of an image pixel or free cursor position at *x_value* and *y_value*.

Parameters

cursorName is one of ten cursors A through J.

Flags

/A=*a*	Activates (*a*=1) or deactivates (*a*=0) the cursor. Active cursors move with arrow keys or the cursor panel.
/C=(*r*,*g*,*b*[,*a*])	Sets the cursor color. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque black.

/DF=*format*

Sets the format to use when displaying date/time data in the Graph Info Panel (see **Info Panel and Cursors** on page II-319).

The /DF flag was added in Igor Pro 9.00.

The values for format are:

0: Compact format: YYMMDD HHMM.

1: Compact format with seconds added: YYMMDD HHMMSS. The seconds portion may optionally show fractions of seconds - see the /SDGT flag below.

2: Date and Time using a more readable format, the same format you get on a graph axis if you select the "short date" format. Time is formatted as HH:MM.

3: Date and Time with seconds added. Time is formatted as HH:MM:SS. The seconds portion may optionally show fractions of seconds - see the /SDGT flag below.

4: Time without the date. Time is formatted as HH:MM:SS. May optionally show fractions of seconds - see the /SDGT flag below.

/DGTS=*nd*

Sets the number of digits precision to use when a cursor value is displayed in the Graph Info Panel (see **Info Panel and Cursors** on page II-319). The number of digits is set by *nd* and must be a value from 1 to 15.

The /DGTS flag was added in Igor Pro 9.00.

/F

Cursor roams free. The trace or image provides the axis pair that defines x and y coordinates for the setting and readout. Use /P to set in relative coordinates, where 0,0 is the top left corner of the rectangle defined by the axes and 1,1 is the right bottom corner.

/H=*h*

Specifies crosshairs on cursors.

h =0: Full crosshairs off.

h =1: Full crosshairs on.

h =2: Vertical hairline.

h =3: Horizontal hairline.

/I

Places cursor on specified image.

/K

Removes the named cursor from the top graph.

/L=*lStyle*

Line style for crosshairs (full or small).

lStyle=0: Solid lines.

lStyle=1: Alternating color dash.

/M

Modifies properties without having to specify trace or image coordinates. Does not work with the /F or /I flags.

/N=*noKill*

Determines if the cursor is removed ("killed") if the user drags it outside of the plot area:

noKill=0: Remove the cursor (default).

noKill=1: Do not remove the cursor.

/NUML=*n*

Used in conjunction with /H when *h* is non-zero. Sets the number of crosshair lines to draw. *n* must be between 1 and 3. When *n* is greater than 1, the line separation is set by the /T=*t* flag. If *n* = 2 or 3 and *t* is less than 3, the line appears as if *n* is 1. If *n* = 3 and *t* is less than 5, the appearance reverts to *n* = 2. Lines are symmetrically disposed around the cursor position. When *n* = 3, *t* sets the separation of the outer pair of lines.

/NUML was added in Igor Pro 7.00.

/P Interpret *x_value* as a point number rather than an X value. If the cursor is on a trace representing a subrange of a wave, the point numbers are “trace” point numbers. See **Details** below.

When used with the /I flag, *x_value* and *y_value* are row and column numbers.

When used with the /F flag, *x_value* and *y_value* are relative graph coordinates (0-1).

/S=*s* Sets cursor style.

s=0:	Original square or circle.
s=1:	Small crosshair with letter.
s=2:	Small crosshair without letter.

/SDGT=*nd* Set the number of places to the right of the decimal point to be displayed in the Graph Info Panel (see **Info Panel and Cursors** on page II-319) when the display is in one of the date/time modes that includes seconds, or if the corresponding axis is showing elapsed time. *nd* is a value from 0 to 6.

The /SDGT flag was added in Igor Pro 9.00.

/T=*t* Sets the thickness of crosshair lines for /H when *h* is non-zero. If /NUML sets the number of lines greater than 1 then /T sets the separation of the outer pair of lines.

t is the line thickness or separation distance in units of pixels. The default is /T=1.

The form /T={*mode*, *t1*, *t2*} provides finer control.

/T was added in Igor Pro 7.00.

/T={*mode*,*t1*,*t2*} Sets the thickness of crosshair lines for /H when h is non-zero. If /NUML sets the number of lines greater than 1 then /T sets the separation of the outer pair of lines.

If *mode*=1 then *t1* and *t2* are in units of screen pixels. *t1* is the vertical line thickness or separation distance and *t2* is the horizontal line thickness or separation distance.

The default crosshair appearance is equivalent to /T={1,1,1}.

If *mode*=0 then *t1* and *t2* are in units of axis coordinates and consequently track changes in axis range and graph size. Normally *t1* is the vertical line thickness or separation distance and *t2* is the horizontal line thickness or separation distance but they are swapped if the trace or graph is in swap XY mode.

/T was added in Igor Pro 7.00.

/W=*graphName* Specifies a particular named graph window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *graphName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Usually *traceName* is the same as the name of the wave displayed by that trace, but it could be a name in instance notation. See **ModifyGraph (traces)** and **Instance Notation** on page IV-20 for discussions of trace names and instance notation.

A string containing *traceName* can be used with the $ operator to specify the trace name.

x_value is an X value in terms of the X scaling of the wave displayed by *traceName*. If *traceName* is graphed as an XY pair, then *x_value* is *not* the same as the X axis coordinate. Since the X scaling is ignored when displaying an XY pair in a graph, we recommend you use the /P flag and use a point number for *x_value*.

cursorName is a name, *not* a string.

To get a cursor readout, choose ShowInfo from the Graph menu.

If a cursor is attached to a trace that represents a subrange of a wave, the /P flag causes *x_value* to be interpreted as a trace point number, not as a wave point number. For instance, if the trace was created by the command

```
Display yWave[4,25;3]
```

then *x_value*=0 references trace point 0 which corresponds to wave point 4, and *x_value*=1 references trace point 1 which corresponds to wave point 7.

Moving a cursor in a macro or function does not immediately erase the old cursor. DoUpdate has to be explicitly called.

Examples

```
Display myWave                          // X coordinates from X scaling of myWave
Cursor A, myWave, leftx(myWave)         //cursor A on first point of myWave

AppendToGraph yWave vs xWave            //X coordinates from xWave, not X scaling
Cursor/P B,yWave,numpnts(yWave)-1       //cursor B on last point of yWave
DoUpdate                                // erase any old A or B cursors
```

See Also

Programming With Cursors on page II-321 and the **DoUpdate** operation.

CursorStyle

`CursorStyle`

CursorStyle is a procedure subtype keyword that puts the name of the procedure in the “Style function” submenu of the Cursor Info pop-up menu. It is automatically used when Igor creates a cursor style function. To create a cursor style function, choose “Save style function” in the “Style function” submenu of the Cursor Info pop-up menu.

See also **Programming With Cursors** on page II-321.

CurveFit

`CurveFit` [***flags***] ***fitType***, [**kwCWave=*coefWaveName*,**] ***waveName*** [***flag parameters***]

The CurveFit operation fits one of several built-in functions to your data (for user-defined fits, see the **FuncFit** operation). When with CurveFit and built-in fit functions, automatic initial guesses will provide a good starting point in most cases.

The results of the fit are returned in a wave, by default W_coef. In addition, the results are put into the system variables K0, K1 … K*n* but the use of the system variables is limited and considered obsolete

As explained under **Fitting with Complex-Valued Functions** on page III-248, a user-defined fitting function can return complex values. A complex fitting function can be written to require a complex coefficient wave in which case the system variables are not supported.

You can specify your own wave for the coefficient wave instead of W_coef using the kwCWave keyword.

Virtually all waves specified to the CurveFit operation can be a sub-range of a larger wave using the same sub-range syntax as the Display operation uses for graphing. See **Wave Subrange Details** on page V-132.

See Chapter III-8, **Curve Fitting** for detailed information including the use of the Curve Fit dialog.

CurveFit operation parameters are grouped in the following categories: flags, fit type, parameters (kwCWave=*coefWaveName* and *waveName*), and flag parameters. The sections below correspond to these categories. Note that flags must precede the fit type and flag parameters must follow *waveName*.

Flags

/B=*pointsPerCycle* Used when *type* is sin; *pointsPerCycle* is the estimated number of data points per sine wave cycle. This helps provide initial guesses for the fit. You may need to try a few different values on either side of your estimated points/cycle.

/C Makes constraint matrix and vector. This only applies if you use the /C=*constraintSpec* parameter to specify constraints (see below). Creates the M_FitConstraint matrix and the W_FitConstraint vector. For more information, see **Fitting with Constraints** on page III-227.

/G Use values in variables K0, K1 … K*n* as starting guesses for a fit. If you specify a coefficient wave with the kwCWave keyword, the starting guesses will be read from the coefficient wave.

/H="*hhh…*"

Specifies coefficients to hold constant.

h is 1 for coefficients to hold, 0 for coefficients vary.

For example, `/H="100"` holds K0 constant, varies K1 and K2.

/K={*constants*}

Sets values of constants (not fit coefficients) in certain fitting functions. For instance, the exp_XOffset function contains an X offset constant. Built-in functions will set the constant automatically, but the automatic value can be overridden using this flag.

constants is a list of constant values, e.g., /K={1,2,3}. The length of the list must match the number of constants used by the chosen fit function.

This flag is not currently supported by the Curve Fit dialog. Use the To Cmd button and add the flag on the command line.

/L=*destLen*

Sets the length of the wave created by the AutoTrace feature, that is, /D without destination wave (see the /D parameter below, in the section Flag Parameters). The length of the wave fit_*waveName* will be set to *destLen*. This keyword also sets the lengths of waves created for confidence and prediction bands.

/M

Generates the covariance matrix, the waves CM_K*n*, where *n* is from 0 (for K0) to the number of coefficients minus one.

/M=*doMat*

Generates the covariance matrix. If *doMat* =2, the covariance matrix is put into a 2D matrix wave called M_Covar. If *doMat* =1 or is missing, the covariance matrix is generated as the 1D waves CM_K*n*, where *n* is from 0 (for K0) to the number of coefficients minus one. If *doMat* =0, the covariance matrix is not generated. *doMat* =1 is included for compatibility with previous versions; it is better to use *doMat* =2.

CurveFit does not generate the covariance matrix for line fits. Instead it reports the coefficient of correlation via the output variable V_rab.

/N[=*updateMode*]

Controls updating of windows during a curve fitting operation. Updating windows after each iteration can slow curve fitting down significantly.

updateMode = 0: An update is done every iteration so that you can monitor the progress of a fit. An update is performed when the fit finishes.

updateMode = 1: Suppresses updates after each fit iteration.If you use the /X flag, a screen update is done to ensure that the X range is accurate. /N is the same as /N=1. This is the default update mode.

updateMode = 2: Suppresses all updates including when using the /X flag. In a user-defined function, you must ensure that your graph has been updated by calling **DoUpdate** if you use the /X flag. This mode requires Igor Pro 9.00 or later.

See **Curve Fitting Screen Updates** for details.

/NTHR = *nthreads*

This flag is accepted but is obsolete and does nothing. See **Curve Fitting with Multiple Processors** on page III-249 for further information.

/O

Only generates initial guesses; doesn't actually do the fit.

Unless /ODR=2, this flag is ignored when used with linear fit types (line, poly, poly_XOffset, and poly2D). The **FuncFit** operation also ignores this flag.

/ODR=*fitMethod*

Selects a fitting method. Values for *fitMethod* are:

0: Default Levenberg-Marquardt least-squares method using old code.

1: Trust-region Levenberg-Marquardt ordinary least-squares method implemented using ODRPACK95 code. See **Curve Fitting References** on page III-267.

2: Trust-region Levenberg-Marquardt least orthogonal distance method implemented using ODRPACK95 code. This method is appropriate for fitting when there are measurement errors in the independent variables, sometimes called “errors in variables fitting”, “random regressor models,” or “measurement error models”.

3: Implicit fit. No dependent variable is specified; instead fitting attempts to adjust the fit coefficients such that the fit function returns zero for all dependent variables.

Implicit fitting will be of almost no use with the built-in fitting functions. Instead, use **FuncFit** and a user-defined fit function designed for an implicit fit.

/Q[=*quiet*]

If quiet = 1, prevents results from being printed in history. /Q is the same as /Q=1.

/TBOX = *textboxSpec*

If the top graph displays the fitted data, the /TBOX flag adds an annotation to the graph or updates the annotation if it already exists. Graphs other than the top graph are not affected.

The textbox contains a customizable set of information about the fit. The *textboxSpec* is a bitfield to select various elements to be included in the textbox:

1	Title “Curve Fit Results”
2	Date
4	Time
8	Fit Type (Least Squares, ODR, etc.)
16	Fit function name
32	Model Wave, the autodestination wave (includes a symbol for the trace if appropriate)
64	Y Wave, with trace symbol
128	X Wave
256	Coefficient value report
512	Include errors in the coefficient value report

Request inclusion of various parts by adding up the values for each part you want.

textboxSpec defaults to all bits on.

Setting *textboxSpec* to zero removes the textbox.

/X[=*fullRange*]

/X or /X=1 sets the X scaling of the auto-trace destination wave to match the appropriate X axis on the graph when the Y data wave is on the top graph. This is useful when you want to extrapolate the curve outside the range of X data being fit.

If you omit /X or specify /X=0, the X scaling of the auto-trace destination wave is set to the range of X values being fit.

/W=*wait*

Specifies behavior for the curve fit results window.

wait=1: Wait till user clicks OK button before dismissing curve fit results window. This is the default behavior from the command line or dialog.

wait=0: Display the curve fit window but do not wait for the user to click the OK button.

wait=2: Do not display the curve fit results window at all. This is the default for fits run from a procedure.

Fit Types

fitType is one of the built-in curve fit function types:

gauss

Gaussian peak: $y = K_0 + K_1 \exp\left[-\left(\frac{x - K_2}{K_3}\right)^2\right]$.

lor

Lorentzian peak: $y = K_0 + \frac{K_1}{(x - K_2)^2 + K_3}$.

Voight

Fits a Voigt peak, a convolution of a Lorentzian and a Gaussian peak. By changing the ratio of the widths of the Lorentzian and Gaussian peak components, the shape can grade between a Lorentzian shape and a Gaussian shape:

y = VoigtPeak(W_coef, x).

exp

Exponential: $y = K_0 + K_1 \exp(-K_2 x)$.

dblexp

Double exponential: $y = K_0 + K_1 \exp(-K_2 x) + K_3 \exp(-K_4 x)$.

exp_XOffset

Exponential: $y = K_0 + K_1 \exp(-(x - x_0)/K_2)$.

x_0 is a constant; by default it is set to the minimum x value involved in the fit. Inclusion of x_0 prevents problems with floating-point roundoff errors that can afflict the exp function.

dblexp_XOffset

Double exponential: $y = K_0 + K_1 \exp(-(x - x_0)/K_2) + K_3 \exp(-(x - x_0)/K_{4(2)})$.

x_0 is a constant; by default it is set to the minimum x value involved in the fit. Inclusion of x_0 prevents problems with floating-point roundoff errors that can afflict the exp function.

dblexp_peak

Double exponential with amplitudes of opposite sign, making a peak:

$$y = K_0 + K_1 \cdot \left\{-exp\left[\frac{-(x - K_4)}{K_2}\right] + exp\left[\frac{-(x - K_4)}{K_3}\right]\right\}$$

sin

Sinusoid: $y = K_0 + K_1 \sin(K_2 x + K_3)$.

line

Line: $y = K_0 + K_1 x$.

poly *n*

Polynomial: $y = k_0 + K_1 x + K_2 x^2 + \ldots$.

n is from 1 to 20. *n* is the number of terms or the degree plus one. Prior to Igor Pro 9.00, the minimum accepted value for *n* was 3.

n = 1 is equivalent to finding the mean of the Y values, and *n* = 2 fits a line to the data set, but doesn't output the special statistical information you get if you use the line fit type.

poly_XOffset n

Polynomial: y = K_0 + K_1*(x - x_0) + K_2*(x - x_0)^2 +...

n is from 1 to 20. *n* is the number of terms or the degree plus one. Prior to Igor Pro 9.00, the minimum accepted value for *n* was 3.

n = 1 is equivalent to finding the mean of the Y values, and *n* = 2 fits a line to the data set, but doesn't output the special statistical information you get if you use the line fit type.

x_0 is a constant; by default it is set to the minimum X value involved in the fit. Inclusion of x_0 prevents problems with floating-point roundoff errors when you have large values of X in your data set.

hillequation

Hill's Equation: $y = K_0 + \frac{(K_1 - K_0)}{1 + (K_3/x)^{K_2}}$.

This is a sigmoidal function. X values must be greater than 0.

sigmoid

$y = K_0 + \frac{K_1}{1 + \exp(K_2 - x/K_3)}$.

power

Power law: $y = K_0 + K_1 x^{K_2}$. X values must be greater than 0.

log

Log: $y = K_0 + K_1 \log(x)$. X values must be greater than 0.

lognormal

Log normal: $y = K_0 + K_1 \exp\left[-\left(\frac{\ln(x/K_2)}{K_3}\right)^2\right]$. X values must be greater than 0.

gauss2D

2D Gaussian: $z = K_0 + K_1 \exp\left[\frac{-1}{2(1 - K_6^2)}\left(\left(\frac{x - K_2}{K_3}\right)^2 + \left(\frac{y - K_4}{K_5}\right)^2 - \frac{2K_6(x - K_2)(y - K_4)}{K_3 K_5}\right)\right]$.

The cross-correlation coefficient (K_6) must be between -1 and 1. This coefficient is automatically constrained to lie in that range. If you are confident that the correlation is zero, it may greatly speed the fit to hold it at zero.

poly2D *n*

Two-dimensional polynomial: $z = K_0 + K_1 x + K_2 y + K_3 x^2 + K_4 xy + K_5 y^2 + \ldots$.

where *n* is the degree of the polynomial. All terms up to degree *n* are included, including cross terms. For instance, degree 3 terms are x^3, x^2y, xy^2, and y^3.

For more details on the built-in fit functions, see **Built-in Curve Fitting Functions** on page III-206.

Parameters

kwCWave=*coefWaveName* specifies an optional coefficient wave. If present, the specified coefficient wave is set to the final coefficients determined by the curve fit. If absent, a wave named W_coef is created and is set to the final coefficients determined by the curve fit.

If you use kwCWave=*coefWaveName* and you include the /G flag, initial guesses are taken from the specified coefficient wave.

waveName is the wave containing the Y data to be fit to the selected function *type*. You can fit to a subrange of the wave by supplying (*startX*,*endX*) after the wave name. Though not shown in the syntax description, you can also specify the subrange in points by supplying [*startP*,*endP*] after the wave name. See **Wave Subrange Details** on page V-132 for more information on subranges of waves in curve fitting.

If you are using one of the two-dimensional fit functions (gauss2D or poly2D) either *waveName* must name a matrix wave or you must supply a list of X waves via the /X flag.

Flag Parameters

These flag parameters must follow *waveName*.

/A=*appendResid*

appendResid =1 (default) appends the automatically-generated residual to the graph and *appendResid* =0 prevents appending (see /R[=*residwaveName*]). With *appendResid* =0, the wave is generated and filled with residual values, but not appended to the graph.

/AD[=*doAutoDest*]

If *doAutoDest* is 1, it is the same as /D alone. /AD is the same as /AD=1.

/C=*constraintSpec* Applies linear constraints during curve fitting. Constraints can be in the form of a text wave containing constraint expressions (/C=*textWaveName*) or a suitable matrix and vector (/C={*constraintMatrix*, *constraintVector*}). See **Fitting with Constraints** on page III-227. **Note**: Constraints are not available for the built-in line, poly and poly2D fit functions. To apply constraints to these fit functions you must create a user-defined fit function.

/D [=*destwaveName*] *destwaveName* is evaluated based on the equation resulting from the fit. *destwaveName* must have the same length as *waveName*.

If only /D is specified, an automatically-named wave is created. The name is based on the *waveName* with "fit_" as a prefix. This automatically named wave will be appended (if necessary) to the top graph if *waveName* is graphed there. The X scaling of the fit_ wave is set from the range of x data used during the fit.

By default the length of the automatically-created wave is 200 points (or 2 points for a straight line fit). This can be changed with the /L flag.

If *waveName* is a 1D wave displayed on a logarithmic X axis, Igor also creates an X wave with values exponentially spaced. The name is based on *waveName* with "fitX_" as a prefix.

If you fit to a user-defined function that returns complex values, the destination wave will also be complex.

/F={*confLevel*, *confType* [, *confStyleKey* [, *waveName*…]]}

Calculates confidence intervals for a confidence level of *confLevel*. The value of *confLevel* must be between 0 and 1 corresponding to confidence levels of 0 to 100 per cent.

confType selects what to calculate:

1:	Confidence bands for the model.
2:	Prediction bands for the model.
4:	Confidence intervals for the fit coefficients.

These values can be added together to select multiple options. That is, to select both a confidence band and fit coefficient confidence intervals, set *confType* to 5.

Confidence and prediction bands can be shown as waves contouring a given confidence level (use "Contour" for *confStyleKey*) or as error bars (use "ErrorBar" for *confStyleKey*). The default is Contour.

If no waves are specified, waves to contain the results are automatically generated and appended to the top graph (if the top graph contains the fitted data). See **Confidence Band Details** for details on the waves for confidence bands.

Note: Confidence bands and prediction bands are not available for multivariate curve fits.

/I [=*weightType*] If *weightType* is 1, the weighting wave (see /W parameter) contains standard deviations. If *weightType* is 0, the weighting wave contains reciprocal of the standard deviation. If the /I parameter is not present, the default is /I=0.

/M=*maskWaveName* Specifies that you want to use the wave named *maskWaveName* to select points to be fit. The mask wave must match the dependent variable wave in number of points and dimensions. Setting a point in the mask wave to zero or NaN (blank in a table) eliminates that point from the fit. The mask wave must be real even when fitting complex data.

/R [=*residwaveName*]

Calculates elements of *residwaveName* by subtracting model values from the data values. *residwaveName* must have the same length as *waveName*.

If only /R is specified, an automatically-named wave is created with the same number of points as *waveName*. The name is based on *waveName* with “Res_” as a prefix. If a new wave needs to be created, it is automatically filled with NaN, but if the wave already exists it is simply re-used.

During fitting the residual is computed only for points that actually participate in the fit. If you fit to a subrange or use a mask wave to fit to specific points, only those points are stored. See **Residuals Using Auto Trace** on page III-219 for details.

The automatically created residual wave is appended (if necessary) to the top graph if *waveName* is graphed there. The residual wave is appended to a new free axis named by prepending “Res_” to the name of the vertical axis used for plotting *waveName*. To the extent possible, the new free axis is formatted nicely.

If the graph containing the data to be fit has very complex formatting, you may not wish to automatically append the residual to the graph. In this case, use /A=0.

If you fit to a user-defined function that returns complex values, the residual wave will also be complex.

/AR=*doAutoResid*

If *doAutoResid* is 1, it is the same as /R alone. /AR is the same as /AR=1.

/W=*wghtwaveName*

wghtwaveName contains weighting values applied during the fit, and must have the same length as *waveName*. These weighting values can be either the reciprocal of the standard errors, or the standard errors. See the /I parameter above for details.

If you fit to a user-defined function that returns complex values, the weighting wave must also be complex.

/X=*xwaveName*

The X values for the data to fit come from *xwaveName*, which must have the same length and type as *waveName*.

If you are fitting to one of the two-dimensional fit functions and *waveName* is a matrix wave, *xwaveName* supplies independent variable data for the X dimension. In this case, *xwaveName* must name a 1D wave with the same number of rows as *waveName*.

When fitting to a complex-valued fit function, the X waves must be real or complex consistent with the X input or parameters declared by your fitting function.

/X={*xwave1*, *xwave2*}

For fitting to one of the two-dimensional fit functions when *waveName* is a 1D wave. *xwave1* and *xwave2* must have the same length as *waveName*.

/Y=*ywaveName*

For fitting using one of the 2D fit functions if *waveName* is a matrix wave. *ywaveName* must be a 1D wave with length equal to the number of columns in *waveName*.

/NWOK

Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to CurveFit is normally treated as an error. By using /NWOK, you are telling CurveFit that a null wave reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls CurveFit with optional waves.

The waves affected are the X wave or waves (/X), weight wave (/W), mask wave (/M) and constraint text wave (/C). The destination wave (/D=wave) and residual wave (/R=wave) are also affected, but the situation is more complicated because of the dual use of /D and /R to mean "do autodestination" and "do autoresidual". See /AR and /AD.

If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.

Note: To work properly this flag must be the last one in the command.

Flag Parameters for Nonzero /ODR

/XW=*xWeightWave*

/XW={*xWeight1*, *xWeight2*}

/ODR=2 or 3 only.

Specifies weighting values for the independent variables using *xWeightWave*, which must have the same length as *waveName*. When fitting to one of the multivariate fit functions such as poly2D or Gauss2D, you must supply a weight wave for each independent variable using the second form.

Weighting values can be either the reciprocal of the standard errors, or the standard errors. The choice of standard error or reciprocal standard error must be the same for both /W and /XW. See /I for details.

When fitting to a complex-valued fit function, the X weighting waves must be real or complex consistent with the X parameters declared by your fitting function.

/XHLD=*holdWave*

/XHLD={*holdWave1*, *holdWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to hold the values of the independent variables fixed during orthogonal distance regression. The waves must match the input X data; a one in a wave element fixes the value of the corresponding X value.

/CMAG=*scaleWave* Specifies a wave that indicates the expected scale of the fit coefficients at the solution. If different coefficients have very different orders of magnitude of expected values, this can improve the efficiency and accuracy of the fit.

/XD=*xDestWave*

/XD={*xDestWave1*, *xDestWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to receive the fitted values of the independent variables during a least orthogonal distance regression.

When fitting to a complex-valued fit function, the X destination waves must be real or complex consistent with the X parameters declared by your fitting function.

/XR=*xResidWave*

/XR={*xResidWave1*, *xResidWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to receive the differences between fitted values of the independent variables and the starting values during a least orthogonal distance regression. That is, they will be filled with the X residuals.

When fitting to a complex-valued fit function, the X residual waves must be real or complex consistent with the X parameters declared by your fitting function.

Details

CurveFit gets initial guesses from the K*n* system variables when user guesses (/G) are specified, unless a coefficient wave is specified using the kwCWave keyword. Final curve fit parameters are written into a wave name W_coef, unless you specify a coefficient wave with the kwCWave keyword.

Other output waves are M_Covar (see the /M flag), M_FitConstraint and W_FitConstraint (see /C parameter and **Fitting with Constraints** on page III-227) and W_sigma.

For compatibility with earlier versions of Igor, the parameters are also stored in the system variables Kn. This can be a source of confusion. We suggest you think of W_coef as the **output** coefficients and Kn as **input** coefficients that get overwritten.

Other output waves are M_Covar (see the /M flag), M_FitConstraint and W_FitConstraint (see /C parameter and **Fitting with Constraints** on page III-227), W_sigma. If you have selected coefficient confidence limits using the /F parameter, a wave called W_ParamConfidenceInterval is created with the confidence intervals for the fit coefficients.

CurveFit stores other curve fitting statistics in variables whose names begin with "V_". CurveFit also looks for certain V_ variables which you can use to modify its behavior. These are discussed in **Special Variables for Curve Fitting** on page III-232.

When fitting with /ODR=nonzero, fitting with constraints is limited to simple "bound constraints." That is, you can constrain a fit coefficient to be greater than or less than some value. Constraints involving combinations of fit coefficients are supported only with /ODR=0. The constraints are entered in the same way, using an expression like `K0>1`.

Wave Subrange Details

Almost any wave you specify to CurveFit can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command (see **Subrange Display Syntax** on page II-321 for details). However, the Display command allows only one dimension to have a range (multiple elements from the dimension); if a multidimensional wave is appropriate for CurveFit, you may use a range for more than one dimension.

Some waves must have the same number of points as other waves. For instance, a one-dimensional Y wave must have the same number of points as any X waves. Thus, if you use a subrange for an X wave, the number of points in the subrange must match the number of points being used in the Y wave (but see **Subrange Backward Compatibility** on page V-133 for a complication to this rule).

A common use of wave subranges might be to package all your data into a single multicolumn wave, along with the residuals and model values. For a univariate fit, you might need X and Y waves, plus a destination (model) wave and a residual wave. You can achieve all of that using a 4 column wave. For example:

```
Make/D/N=(100, 4) Data
... fill column zero with X data and column one with Y data ...
CurveFit poly 3, Data[][1] /X=Data[][0]/D=Data[][2]/R=Data[][3]
```

Note that because all the waves are full columns from a single multicolumn wave, the number of points is guaranteed to be the same.

The number of points used for X waves (*xwaveName* or {*xwave1*, *xwave2*, …}), weighting wave (*wghtwaveName*), mask wave (`maskWaveName`), destination wave (*destwaveName*) and residual wave (*residwaveName*) must be the same as the number of points used for the Y wave (*waveName*). If you specify your own confidence band waves (/F flag) they must match the Y wave; you cannot use subranges with confidence band waves. If you set /ODR = nonzero, the X weight, hold, destination and residuals waves must match the Y wave.

The total number of points in each wave does not need to match other waves, just the number of points in the specified subrange.

When fitting to a univariate fit function (that includes almost all the fit types) the Y wave must have effectively one dimension. That means the Y wave must either be a 1D wave, or it must have a subrange that makes the data being used one dimensional. For instance:

```
Make/N=(100,100) Ydata          // 2D wave
CurveFit gauss Ydata[][0]       // OK- a single column is one-dimensional
CurveFit gauss Ydata[2][]       // OK- s single row is one-dimensional
CurveFit gauss Ydata            // not OK- Ydata is two-dimensional
CurveFit gauss Ydata[][0,1]     // not OK- two columns makes 2D subrange
```

When fitting a multivariate function (**poly2D** or **Gauss2D**) you have the choice of making the Y data either one-dimensional or two-dimensional. If it is one-dimensional, then you must be fitting XYZ (or Y,X1,X2) triplets. In that case, you must provide a one-dimensional Y wave and two one-dimensional X waves, or 2 columns from a multicolumn wave. For instance:

These are OK:

```
Make/N=(100,3) myData
CurveFit Gauss2D myData[][0] /X={myData[][1],myData[][2]}
CurveFit Gauss2D myData[][0] /X=myData[][1,2]
```

These are not OK:

```
CurveFit Gauss2D myData /X={myData[][1],myData[][2]}// 2D Y wave with 1D X waves
CurveFit Gauss2D myData[][0] /X=myData            // too many X columns
```

If you use a 2D Y wave, the X1 and X2 data can come from the grid positions and the Y wave's X and Y index scaling, or you can use one-dimensional waves or wave subranges to specify the X1 and X2 positions of the grid:

```
Make/N=(20,30) yData
CurveFit Gauss2D yData        //OK- 2D Y data, X1 and X2 from scaling
Make/N=20 x1Data
Make/N=30 x2Data
// OK: 2D effective Y data, matching 1D X and Y flags
CurveFit Gauss2D yData[0,9][0,19] /X=x1Data[0,9]/Y=x2data[10,29]
// OK: effective 2D Y data
Make/N=(10,20,3) Y data
CurveFit Gauss2D yData[][][0]
```

There are, of course, lots of possible combinations, too numerous to enumerate.

Subrange Backward Compatibility

Historically, a Y wave could have a subrange. The same subrange applied to all other waves. For backward compatibility, if you use a subrange with the Y wave only, and other waves lack a subrange, these other waves must have either: 1) The same total number of points as the total number of points in the Y wave in which case the Y wave subrange will be applied; or 2) The same total number of points as the Y wave's subrange.

In addition, the Y wave can take a subrange in parentheses to indicate that the subrange refers to the Y wave's scaled indices (X scaling). If you use parentheses to specify an X range, you must satisfy the old subrange rules: All waves must have the same number of points. Subrange is allowed for the Y wave only. The Y wave subrange is applied to all other waves.

Confidence Band Details

Automatic generation of confidence and prediction bands occurs if the /F={…} parameter is used with no wave names. One to four waves are generated, or you can specify one to four wave names yourself depending on the *confKind* and *confStyle* settings.

Waves auto-generated by /F={*confLevel*, *confKind*, *confStyle*}:

confKind	*confStyle*	**What You Get**	**Auto Wave Names**
1	"Contour"	upper and lower confidence contours	UC_*dataName,* LC_*dataName*
2	"Contour"	upper and lower prediction contours	UP_*dataName,* LP_*dataName*
3	"Contour"	upper and lower confidence contours and prediction contours	UC_*dataName,* LC_*dataName,* UP_*dataName,* LP_*dataName*
1	"ErrorBar"	confidence interval wave	CI_*dataName*
2	"ErrorBar"	prediction interval wave	PI_*dataName*
3	"ErrorBar"	confidence and prediction interval waves	CI_*dataName,* PI_*dataName*

Note that *confKind* may have 4 added to it if you want coefficient confidence limits calculated as well.

The contour waves are appended to the top graph as traces if the data wave is displayed in the top graph. The wave names have *dataName* replaced with the name of the wave containing the Y data for the fit.

Waves you must supply for /F={*confLevel, confKind, confStyle, wave, wave…*}:

confKind	*confStyle*	**You Supply**
1	"Contour"	2 waves to receive upper and lower confidence contours.
2	"Contour"	2 waves to receive upper and lower prediction contours.
3	"Contour"	4 waves to receive upper and lower confidence and upper and lower prediction contours.
1	"ErrorBar"	1 wave to receive values of confidence band width.
2	"ErrorBar"	1 wave to receive values of prediction band width.
3	"ErrorBar"	2 waves to receive values of confidence and prediction band widths.

The waves you supply must have the same number of points as the dependent variable data wave. The band intervals will be calculated at the X values of the input data. These waves are not automatically appended to a graph; it is expected that you will display the contour waves as traces or use the error bar waves to make error bars on the model fit wave.

Residual Details

Residuals are calculated only for elements corresponding to elements of waveName that are included in the fit. Thus, you can calculate residuals automatically for a piecewise fit done in several steps.

The automatic residual wave will be appended to the top graph if the graph displays the Y data. It is appended to a new free axis positioned directly above the axis used to display the Y data, making a stacked graph. Other axes are shortened as necessary to make room for the new axis. You can alter the axis formatting later. See **Creating Stacked Plots** on page II-324 for details.

While Igor will go to some lengths to make a nicely formatted stacked graph, the changes made to the graph formatting may be undesirable in certain cases. Use /A=0 to suppress the automatic append to the graph. The automatic residual wave will be created and filled with residual values, but not appended to the graph.

Curve Fitting Screen Updates

A screen update redraws windows displaying data that has changed since the previous update, if any. Updates can take a significant amount of time, so the /N flag allows you to control them during a curve fitting operation.

Igor historically performed a screen update after each curve fitting iteration so that a graph showing the fit destination would display the latest trial solution after each iteration. This was default behavior, equivalent to /N=0.

As processors became faster, updating after every iteration became less useful because, in most cases, the time between iterations is short and the entire fit finishes quickly. Consequently, for Igor Pro 7.00, we changed the default to update only at the end of a fit, equivalent to /N=1.

There are some potential pitfalls to suppressing screen updates.

If you use the /X flag to tell Igor to extrapolate the fit curve to the entire X range of a graph, and if your procedures alter the X axis range, you need to call DoUpdate before calling CurveFit or FuncFit to allow Igor to finalize the change to the axis range.

If you call CurveFit or FuncFit from a user-defined function and use the /D flag, which turns on the auto-destination feature, then the fit curve will not update until all running functions in the call chain return. If it is important that the graph displaying the destination wave reflect the fit result before functions return, you must call DoUpdate.

When fitting to a user-specified function, see **FuncFit**. For multivariate user-specified fitting functions, see **FuncFit** and **FuncFitMD**. See **Confidence Bands and Coefficient Confidence Intervals** on page III-223 for a detailed description of confidence and prediction bands.

References

An explanation of the Levenberg-Marquardt nonlinear least squares optimization can be found in Chapter 14.4 of Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

CustomControl

CustomControl [**/Z**] ***ctrlName*** [***keyword* = *value*** [, ***keyword* = *value*** …]]

The CustomControl operation creates or modifies a custom control in the target window. A CustomControl starts out as a generic button, but you can customize both its appearance and its action.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the CustomControl to be created or changed. See **Button** for standard default parameters.

The following keyword=value parameters are supported:

align=*alignment*
Sets the alignment mode of the control. The alignment mode controls the interpretation of the *leftOrRight* parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

If *alignment*=0 (default), *leftOrRight* specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If *alignment*=1, *leftOrRight* specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

fColor=(*r*,*g*,*b*[,*a*])
Sets color of the button only when picture is not used and frame=1.

r, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

focusRing=*fr*
Enables or disables the drawing of a rectangle indicating keyboard focus:

fr=0: Focus rectangle will not be drawn.
fr=1: Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

frame=*f*
Sets frame style used only when picture is not used:

f=0: No frame (only the title is drawn).
f=1: Default, a button is drawn with a centered title. Set fColor to something other than black to colorize the button.
f=2: Simple box.
f=3: 3D sunken frame. On Macintosh, when "native GUI appearance" is enabled for the control, the frame is filled with the proper operating system color.
f=4: 3D raised frame.
f=5: Text well.

help={*helpStr*}
Sets the help for the control.

helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).

You can insert a line break by putting "\r" in a quoted string.

labelBack=(*r*,*g*,*b*[,*a*]) or 0

Sets background color for the control only when a picture is not used and frame is not 1 and is not 3 on Macintosh.

r, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. If not set (or labelBack=0), then background is transparent (not erased).

mode=*m*
Notifies the control that something has happened. Can be used for any purpose. See **Details** discussion of the `kCCE_mode` event.

noproc
Specifies that no procedure will execute when clicking the custom control.

picture= *pict*
Uses the named Proc Pictures to draw the control. The picture is taken to be three side-by-side frames, which show the control appearance in the normal state, when the mouse is down, and in the disabled state.

The control action function can overwrite the picture number using the picture={*pict*,*n*} syntax.

The picture size overrides the size keyword.

picture={*pict*,*n*} Uses the specified Proc Picture to draw the control. The picture is *n* side-by-side frames instead of the default three frames.

pos={*leftOrRight*,*top*} Sets the position in **Control Panel Units** of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+={*dx*,*dy*} Offsets the position of the control in **Control Panel Units**.

proc=*procName* Specifies the name of the action function for the control. The function must not kill the control or the window.

size={*width*,*height*} Sets size of the control in **Control Panel Units** but only when not using a Proc Picture.

title=*titleStr* Specifies text that appears in the control.

Using escape codes you can change the font, size, style, and color of the title. See **Annotation Escape Codes** on page III-53 or details.

userdata(*UDName*)=*UDStr*

Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

userdata(*UDName*)+=*UDStr*

Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

value=*varName* Sets the numeric variable, string variable, or wave that is associated with the control. With a wave, specify a point using the standard bracket notation with either a point number (`value=awave[4]`) or a row label (`value=awave[%alabel]`).

valueColor=(*r*,*g*,*b*[, *a*]) Sets initial color of the title for the button drawn only when picture is not used and frame=1.

r, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque black.

To further change the color of the title text, use escape sequences as described for title=*titleStr*.

Flags

/Z No error reporting.

Details

When you create a custom control, your action procedure gets information about the state of the control using the `WMCustomControlAction` structure. See **WMCustomControlAction** for details on the `WMCustomControlAction` structure.

Although the return value is not currently used, action procedures should always return zero.

When Igor calls your action procedure for the `kCCE_draw` event, the basic button picture (custom or default) will already have been drawn. You can use standard drawing commands such as **DrawLine** to draw on top of the basic picture. Unlike the normal situation when drawing commands merely add to a drawing operation list which only later is drawn, `kCCE_draw` event drawing commands are executed directly. The coordinate system, which you can not change, is **Control Panel Units** with (0,0) being the top left corner of the control. Most drawing commands are legal but because of the immediate nature of drawing, the /A (append) flag of **DrawPoly** is not allowed.

The `kCCE_mode` event, which Igor sends when you execute CustomControl with the mode keyword, can be used for any purpose, but it mainly serves as a notification to the control that something has happened. For example, to send information to a control, you can set a named (or the unnamed) userdata and then set the `mode` to indicate that the control should examine the userdata. For this signaling purpose, you should use a `mode` value of 0 because this value will not become part of the recreation macro.

The kCCE_frame event is sent just before drawing one of the *pict* frames, as set by the picture parameter. On input, the curFrame field is set to 0 (normal or mouse down outside button), to 1 (mouse down in button), or to 2 (disable). You may modify curFrame as desired but your value will be clipped to a valid value.

When you specify a *pict* with the picture parameter, you will get a kCCE_drawOSBM event when that *pict* is drawn into an offscreen bitmap. Once it is created, all updates use the offscreen bitmap until you specify a new picture parameter. Thus the custom drawing done at this event is static, unlike drawing done during the kCCE_draw event, which can be different each time the control is drawn. Because the *pict* can be contain multiple side-by-side frames, the width of the offscreen bitmap is the width derived from the ctrlRect field multiplied by the number of frames.

Because the action function is called in the middle of various control events, it must not kill the control or the window. Doing so will almost certainly cause a crash.

CustomControl Action Procedure

The action procedure for a CustomControl control can takes a predefined structure WMCustomControlAction as a parameter to the function:

```
Function ActionProcName(s)
   STRUCT WMCheckboxAction& s
   …
   return 0
End
```

See **WMCustomControlAction** for details on the WMCustomControlAction structure.

Although the return value is not currently used, action procedures should always return zero.

The action procedure may have drawing commands such as **SetDrawEnv**, **DrawRect**, etc. These commands include a /W flag that directs their action to a particular window or subwindow. However, in a CustomControl action procedure, the /W flag is ignored and all drawing commands are directed to the window or subwindow containing the control.

Because the action procedure runs during a drawing operation that cannot be interrupted without crashing Igor, the debugger cannot be invoked while it is running. Consequently breakpoints set in the function are ignored. Use **Debugging With Print Statements** on page IV-212 instead.

Examples

See **Creating Custom Controls** on page III-424 for some examples of custom controls.

For a demonstration of custom controls, choose File→Example Experiments→Feature Demos 2→Custom Control Demo.

CWT

CWT [***flags***] ***srcWave***

The CWT operation computes the continuous wavelet transform (CWT) of a 1D real-valued input wave (*srcWave*). The input can be of any numeric type. The computed CWT is stored in the wave M_CWT in the current data folder. M_CWT is a double precision 2D wave which, depending on your choice of mother wavelet and output format, may also be complex. The dimensionality of M_CWT is determined by the specifications of offsets and scales. The operation sets the variable V_flag to zero if successful or to a nonzero number if it fails for any reason.

Flags

/ENDM=*method* Selects the method used to handle the two ends of the data array with direct integration (/M=1).

method=0: Padded on both sides by zeros.

method=1: Reflected at both the start and end.

method=2: Entered with cyclical repetition.

/FSCL Use correction factor to the wave scaling of the second dimension of the output wave so that the numbers are more closely related to Fourier wavelength. See **References** for more information on the calculation of these correction factors. This flag does not affect the output from the Haar wavelet.

/M=*method* Specifies the CWT computation method.

method=0: Fast method uses FFT (default).

method=1: Slower method using direct integration.

You should mostly use the more efficient FFT method. The direct method should be reserved to situations where the FFT is not producing optimal results. Theoretically, when the FFT method fails, the direct method should also be fairly inaccurate, e.g., in the case of undersampled signal. The main advantage in the direct method is that you can use it to investigate edge effects.

/OSCW CWT creates an output scaing wave named W_CWTScaling that can be used as the Y wave in an image plot. For example:

```
Display; AppendImage M_CWT vs {*,W_CWTScaling}
```

If you omit /OSCW, CWT creates W_CWTScaling only if you include /SMP2=4.

/OSCW was added in Igor Pro 9.00.

/OUT=*format* Sets the format of the output wave M_CWT:

format=1: Complex.

format=2: Real valued.

format=4: Real and contains the magnitude.

Depending on the method of calculation and the choice of mother wavelet, the "native" output of the transform may be real or complex. You can force the output to have a desired format using this flag.

/Q Quiet mode; no results printed to the history.

/R1={*startOffset*, *delta1*, *numOffsets*

Specifies offsets for the CWT. Offsets are the first dimension in a CWT. Normally you will calculate the CWT for the full range of offsets implied by *srcWave* so you will not need to use this flag. However, when using the slow method, this flag restricts the output range of offsets and save some computation time. *startOffset* (integer) is the point number of the first offset in *srcWave*. *delta1* is the interval between two consecutive CWT offsets. It is expressed in terms of the number *srcWave* points. *numOffsets* is the number of offsets for which the CWT is computed.

By default *startOffset*=0, *delta1*=1, and *numOffsets* is the number of points in *srcWave*. If you want to specify just the *startOffset* and *delta1*, you can set *numOffsets*=0 to use the same number of points as the source wave.

/R2={*startScale*, *scaleStepSize*, *numScales*}

Specifies the range of scales for the CWT is computation. Scales are the second dimension in the output wave. Note however that there are limitations on the minimum and maximum scales having to do with the sampling of your data. Because there is a rough correspondence between a Fourier spatial frequency and CWT scale it should be understood that there is also a maximum theoretical scale. This is obvious if you compute the CWT using an FFT but it also applies to the slow method. If you specify a range outside the allowed limits, the corresponding CWT values are set to NaN.

Use NaN if you want to use the default value for any parameter.

The default value for *startScale* is determined by sampling of the source wave and the wavelet parameter or order.

At a minimum you must specify either *scaleStepSize* or *numScales*.

/SMP1=*offsetMode* Determines computation of consecutive offsets. Currently supporting only *offsetMode*=1 for linear, user-provided partial offset limits (see /R1 flag): *`val1=startOffset+numOffsets*delta1`*.

/SMP2=*scaleMode* Determines computation of consecutive scales. *scaleMode* is 1 by default if you specify the /R2 flag.

format=1: Linear:
```
theScale = startScale+index*scaleStepSize
```

format=2: Auto:
```
theScale = numScales * startScale/(index+1)
```

format=4: Power of 2 scaling interval:
```
theScale = startScale*2.^(index*scaleStepSize)
```

When using *scaleMode*=4 the operation saves the consecutive scale values in the wave W_CWTScaling. Note also that if you use *scaleMode*=4 without specifying a corresponding /R2 flag, the default *scaleStepSize* of 1 and 64 scale values gives rise to scale values that quickly exceed the allowed limits.

(See /R2 flag for details about the different parameters used in the equations above.)

/SUBM Subtracts the mean of the input before performing the transform. /SUBM was added in Igor Pro 9.00.

/SW2=*sWave* Provides specific scale values at which the transform is evaluated. Use instead of /R2 flag. It is your responsibility to make sure that the entries in the wave are appropriate for the sampling density of *srcWave*.

/WBI1={*Wavelet* [, *order*]}

Specifies the built-in wavelet (mother) function. *Wavelet* is the name of a wavelet function: Morlet (default), MorletC (complex), Haar, MexHat, DOG, and Paul.

Morlet:

$$\Psi_0(x) = \frac{1}{\pi^{1/4}} \cos(\omega x) \exp\left(-\frac{x^2}{2}\right).$$

By default, ω=5. Use the /WPR1 flag to specify other values for ω.

MorletC:

$$\Psi_0(x) = \frac{1}{\pi^{1/4}} \exp(i\omega x) \exp\left(-\frac{x^2}{2}\right).$$

By default, ω=5. Use the /WPR1 flag to specify other values for ω.

Haar:

$$\Psi_0(x) = \begin{cases} 1 & 0 \le x < 0.5 \\ -1 & 0.5 \le x < 1 \end{cases}.$$

DOG:

$$\Psi_0(x) = \frac{(-1)^{m+1}}{\sqrt{\Gamma\left(m + \frac{1}{2}\right)}} \frac{d^m}{dx^m}\left(\exp\left(-\frac{x^2}{2}\right)\right).$$

MexHat: Special case of DOG with *m*=2.

Paul:

$$\Psi_0(m,x) = \frac{2^m i^m m!}{\sqrt{\pi(2m)!}} (1 - ix)^{-(m+1)}.$$

order applies to DOG and Paul wavelets only and specifies *m*, the particular member of the wavelet family.

The default wavelet is the Morlet.

/WPR1={*param1*} *param1* is a wavelet-specific parameter for the wavelet function selected by /WBI1. For example, use /WPR1={6} to change the Morlet frequency from the default (5).

/Z No error reporting. If an error occurs, sets V_flag to -1 but does not halt function execution.

Details

The CWT can be computed directly from its defining integral or by taking advantage of the fact that the integral represents a convolution which in turn can be calculated efficiently using the fast Fourier transform (FFT).

When using the FFT method one encounters the typical sampling problems and edge effects. Edge effects are also evident when using the slow method but they only significant in high scales.

From sampling considerations it can be shown that the maximum frequency of a discrete input signal is 1/2dt where dt is the time interval between two samples. It follows that the smallest CWT scale is 2dt and the largest scale is Ndt where N is the total number of samples in the input wave.

The transform in M_CWT is saved with the wave scaling. *startOffset* and *delta1* are used for the X-scaling. Both *startOffset* and *delta1* are either specified by the /R1 flag or copied from *srcWave*. The Y-scaling of M_CWT depends on your choice of /SMP2. If the CWT scaling is linear then the wave scaling is based on *startScale* and *scaleStepSize*. If you are using power of 2 scaling interval then the Y wave scaling of M_CWT has a *start*=0 and *delta*=1 and the wave W_CWTScaling contains the actual scale values for each column of M_CWT. Note that W_CWTScaling has one extra data point to make it suitable for display using an operation like:

```
AppendImage M_CWT vs {*, W_CWTScaling}
```

We have encountered two different definitions for the Morlet wavelet in the literature. The first is a complex function (MorletC) and the second is real (Morlet). Instead of choosing one of these definitions we implemented both so you may choose the appropriate wavelet.

`<http://paos.colorado.edu/research/wavelets/>`.

DataFolderDir

`DataFolderDir(`*`mode`*` [, `*`dfr`*` ])`

The DataFolderDir function returns a string containing a listing of some or all of the objects contained in the current data folder or in the data folder referenced by *dfr*.

Parameters

mode is a bitwise flag for each type of object. Use -1 for all types. Use a sum of the bit values for multiple types.

Desired Type	Bit Number	Bit Value
All		-1
Data folders	0	1
Waves	1	2
Numeric variables	2	4
String variables	3	8

dfr is a data folder reference.

Details

The returned string has the following format:

1. FOLDERS:*name,name,…*;<CR>
2. WAVES:*name,name,…*;<CR>
3. VARIABLES:*name,name,…*;<CR>
4. STRINGS:*name,name,…*;<CR>

Where <CR> represents the carriage return character.

Tip

This function is mostly useful during debugging, used in a **Print** command. For finding the contents of a data folder programmatically, it will be easier to use the functions **CountObjects** and **GetIndexedObjName**.

Examples

```
Print DataFolderDir(8+4)       // prints variables and strings
Print DataFolderDir(-1)        // prints all objects
```

See Also

Chapter II-8, **Data Folders**.

Setting Bit Parameters on page IV-12 for information about bit settings.

DataFolderExists

`DataFolderExists(`*`dataFolderNameStr`*`)`

The DataFolderExists function returns the truth that the specified data folder exists.

dataFolderNameStr can bea a full path or partial path relative to the current data folder.

If *dataFolderNameStr* is empty (“”), DataFolderExists returns 1 because, for historical reasons, an empty data folder path is taken to refer to the current data folder.

See Also

Chapter II-8, **Data Folders**.

DataFolderList

`DataFolderList(`*`matchStr`*`, `*`separatorStr`*` [, `*`dfr`*` ] )`

The DataFolderList function returns a string containing a list of data folder names selected based on the *matchStr* parameter. The data folders listed are all within the current data folder or the folder specified by *dfr*.

The DataFolderList function was added in Igor Pro 9.00.

Details

For a data folder name to appear in the output string, it must match *matchStr*. *separatorStr* is appended to each data folder name as the output string is generated.

The name of each data folder is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*"	Matches all data folder names.
"xyz"	Matches data folder name xyz only.
"*xyz"	Matches data folder names which end with xyz.
"xyz*"	Matches data folder names which begin with xyz.
"*xyz*"	Matches data folder names which contain xyz.
"abc*xyz"	Matches data folder names which begin with abc and end with xyz.

matchStr may begin with the "!" character to return items that do not match the rest of *matchStr*. For example:

"!*xyz"	Matches data folder names which do not end with xyz.

The "!" character is considered to be a normal character if it appears anywhere else.

dfr is an optional data folder reference: a data folder name, an absolute or relative data folder path, or a reference returned by, for example, **GetDataFolderDFR**.

The returned list contains data folder names only, without data folder paths. Use **GetDataFolder** to get the data folder path prefix.

Liberal data folder names are quoted if necessary; see **Liberal Object Names** on page III-501.

Examples

```
NewDataFolder/O aSubDataFolder
NewDataFolder/O 'Another quoted subfolder'

// Print the list of data folders in the current data folder whose names begin with a or A
Print DataFolderList("a*",";")
  aSubDataFolder;'Another quoted subfolder';

// Print the list of all data folders in the root:Packages data folder.
Print DataFolderList("*",";", root:Packages)
  WM_MedianXY;WM_WaveSelectorList;WindowCoordinates;
```

See Also

Data Folders on page II-107, **GetDataFolderDFR**, **GetIndexedObjName**, **StringList**, **StringFromList**, **VariableList**, **WaveList**, **PossiblyQuoteName**

DataFolderRefChanges

DataFolderRefChanges(*dfr*, *changeType*)

The DataFolderRefChanges function returns the number of changes to the data folder specified by the data folder reference *dfr*.

Use DataFolderRefChanges to decide when to update something that depends on the data folder's state by comparing the current number of changes to the change count when your previous update was done. DataFolderRefChanges is not thread-safe so this must be done in the main thread.

Changes to the data folder and its contents are tracked by incrementing a count specific to kind of change. The *changeType* parameter select one of those counts.

The DataFolderRefChanges function was added in Igor Pro 9.00.

Parameters

dfr is a data folder reference.

changeType is one of the following values:

0:	Changes to any to the data folder's waves, numeric variables, strings, or child data folders.
1:	Changes to the data folder's waves.
2:	Changes to the data folder's numeric variables.
3:	Changes to the data folder's string variables.
4:	Changes to the data folder's child data folders.

Details

The definition of a "change" depends on the object.

For data folders, a "change" is when a child data folder is created, killed, or renamed.

For waves, a "change" is when a wave is created, killed, renamed, locked, or modified.

For string or numeric values, a "change" is when they are created, killed, renamed, or modified.

The change counts are reset to 0 when the experiment is reopened.

Examples

```
Variable oldWaveChanges = DataFolderRefChanges(GetDataFolderDFR(),1)
Make/O/N=10 aWave = p
Variable newWaveChanges = DataFolderRefChanges(GetDataFolderDFR(),1)
Variable dif = newWaveChanges - oldWaveChanges
Print dif        // Prints 2: 1 for Make, 1 for aWave=p
```

See Also

Data Folders on page II-107, **Data Folder References** on page IV-78, **Built-in DFREF Functions** on page IV-81.

DataFolderRefsEqual

DataFolderRefsEqual(*dfr1*, *dfr2*)

The DataFolderRefsEqual function returns the truth the two data folder references are the same.

See Also

Data Folders on page II-107, **Data Folder References** on page IV-78, **Built-in DFREF Functions** on page IV-81.

DataFolderRefStatus

DataFolderRefStatus(*dfr*)

The DataFolderRefStatus function returns the status of a data folder reference.

Details

DataFolderRefStatus returns zero if the data folder reference is invalid or non-zero if it is valid.

DataFolderRefStatus returns a bitwise result with bit 0 indicating if the reference is valid and bit 1 indicating if the reference data folder is free. Therefore the returned values are:

0:	The data folder reference is invalid.
1:	The data folder reference refers to a regular global data folder.
3:	The data folder reference refers to a free data folder.

A data folder reference is invalid if it was never assigned a value or if it is assigned an invalid value. For example:

```
DFREF dfr                                // dfr is invalid
DFREF dfr = root:                        // dfr is valid
DFREF dfr = root:NonExistentDataFolder   // dfr is invalid
DFREF dfr = root:ExistingDataFolder      // dfr is valid
KillDataFolder dfr                       // dfr is invalid
```

You should use DataFolderRefStatus to test any DFREF variables that might not be valid, such as after assigning a reference when you are not sure that the referenced data folder exists. For historical reasons, if you use an invalid DFREF variable it will often act like root.

See Also

Data Folders on page II-107, **Data Folder References** on page IV-78, **Built-in DFREF Functions** on page IV-81.

dateToJulian

dateToJulian(*year*, *month*, *day*)

The dateToJulian function returns the Julian day number for the specified date. The Julian day starts at noon. Use negative number for BC years and positive numbers for AD years. To exclude any ambiguity, there is no year zero in this calendar. For general orientation, Julian day 2450000 corresponds to October 9, 1995.

See Also

The **JulianToDate** function.

For more information about the Julian calendar see:
<http://www.tondering.dk/claus/calendar.html>.

date

date()

The date function returns a string containing the current date.

Formatting of dates depends on your operating system and on your preferences entered in the Date & Time control panel (*Macintosh*) or the Regional Settings control panel (*Windows*).

Examples

```
Print date()        // Prints Mon, Mar 15, 1993
```

See Also

The **Secs2Date**, **Secs2Time**, and **time** functions.

date2secs

date2secs(*year*, *month*, *day*)

The date2secs function returns the number of seconds from midnight on 1/1/1904 to the specified date.

The month and day parameters are one-based, so these series start at one.

Date2Secs is limited to the range -32768-01-01 to 32767-12-31. For dates outside that range, it returns NaN. It also returns NaN if the year is 0 because Igor uses the Gregorian calendar in which there is no year 0.

If *year*, *month*, and *day* are all -1 then date2secs returns the offset in seconds from the local time to the UTC (Universal Time Coordinate) time.

Examples

```
Print Secs2Date(date2secs(1993,3,15),1)        // Ides of March, 1993
```

Prints the following, depending on your system's date settings, in the history area:

```
  Monday, March 15, 1993
```

This next example sets the X scaling of a wave to 1 day per point, starting January 1, 1993:

```
Make/N=125 myData = 100 + gnoise(50)
SetScale/P x,date2secs(1993,1,1),24*60*60,"dat",myData
Display myData;ModifyGraph mode=5
```

See Also

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-85.

The **Secs2Date**, **Secs2Time**, and **time** functions.

DateTime

DateTime

The DateTime function returns number of seconds from 1/1/1904 to current local date and time.

To get the UTC date and time, subtract Date2Secs(-1,-1,-1) from the value returned by DateTime.

Unlike most Igor functions, DateTime is used without parentheses.

Examples

```
Variable localNow = DateTime
```

See Also

The **Secs2Date**, **Secs2Time** and **time** functions.

dawson

dawson(*x*)

The dawson function returns the value of the Dawson integral:

$$F(x) = \exp\left(-x^2\right)\int_0^x \exp\left(t^2\right)dt.$$

If x is real, dawson returns a real result. If x is complex, dawson returns a complex result.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 298 pp., Dover, New York, 1972.

The code used to implement the Dawson integral was written by Steven G. Johnson of MIT. See http://ab-initio.mit.edu/Faddeva

Debugger

Debugger

The Debugger operation breaks into the debugger if it is enabled.

See Also

The Debugger on page IV-212 and the **DebuggerOptions** operation.

DebuggerOptions

DebuggerOptions [**enable=*en*, debugOnAbort=*doa*, debugOnError=*doe*, NVAR_SVAR_WAVE_Checking=*nvwc***]

The DebuggerOptions operation programmatically changes the user-level debugger settings. These are the same three settings that are available in the Procedure menu (and the debugger source pane contextual menu)

Parameters

All parameters are optional. If none are specified, no action is taken, but the output variables are still set.

enable=*en* Turns the debugger on (*en*=1) or off (*en*=0).

If the debugger is disabled then the other settings are cleared even if other settings are on.

debugOnAbort=*doa* Turns Debugging On Abort on or off.

doa=0:	Disables Debugging On Abort.
doa=1:	Enables Debugging On Abort and also enables the debugger (implies enable=1).

The Debug on Abort feature was added in Igor Pro 9.00. See **Debugging on Abort** on page IV-214 for details.

debugOnError=*doe* Turns Debugging On Error on or off.

doe=0:	Disables Debugging On Error.
doe=1:	Enables Debugging On Error and also enables the debugger (implies enable=1).

See **Debugging on Error** on page IV-213 for details.

NVAR_SVAR_WAVE_Checking=*nvwc*

Turns NVAR, SVAR, and WAVE checking on or off.

nvwc=0:	Disables “NVAR SVAR WAVE Checking”. See **Accessing Global Variables and Waves** on page IV-65 for more details.
nvwc=1:	Enables this checking and also enables the debugger (implies enable=1).

Output Variables

DebuggerOptions sets the following variables to indicate the Debugger settings that are in effect *after* the command is executed. A value of zero means the setting is off, nonzero means the setting is on.

```
V_enable, V_debugOnError, V_debugOnAbort, V_NVAR_SVAR_WAVE_Checking
```

See Also

The Debugger on page IV-212 and the **Debugger** operation.

default

default:

The default flow control keyword is used in switch and strswitch statements. When none of the case labels in the switch or strswitch match the evaluation expression, execution will continue with code following the default label, if it is present.

See Also

Switch Statements on page IV-43.

DefaultFont

DefaultFont [**/U**] "***fontName***"

The DefaultFont operation sets the default font to be used in graphs for axis labels, tick mark labels and annotations, and in page layouts for annotations.

Parameters

"fontName" should be a font name, optionally in quotes. The quotes are not required if the font name is one word.

Flags

/U	Updates existing graphs and page layouts immediately to use the new default font.

DefaultGUIControls

DefaultGUIControls [**/Mac/W=*winName*/Win**] [***appearance***]

The DefaultGUIControls operation changes the appearance of user-defined controls.

Note: The recommended way to change the appearance of user-defined controls is to use the Miscellaneous Settings dialog's Native GUI Appearance for Controls checkbox in the Compatibility tab, which is equivalent to `DefaultGUIControls native` when checked, and to `DefaultGUIControls os9` when unchecked.

Use `DefaultGUIControls/W=`*`winName`* to override that setting for individual windows.

Parameters

appearance may be one of the following:

native	Creates standard-looking controls for the current computer platform. This is the default value.
os9	Igor Pro 5 appearance (quasi-Macintosh OS 9 controls that look the same on Macintosh and Windows).
default	Inherits the window appearance from either a parent window or the experiment-wide default (only valid with /W).

Flags

/Mac	Changes the appearance of controls only on Macintosh, and it affects the experiment whenever it is used on Macintosh.
/W=*winName*	Affects the named window or subwindow. When omitted, sets an experiment-wide default. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
/Win	Changes the appearance of controls only on Windows, and it affects the experiment whenever it is used on Windows.

Details

If *appearance* is not specified, nothing is changed. The current value for appearance is returned in S_value.

If *appearance* is specified the previous appearance value for the window- or experiment-wide default is returned in S_value.

With /W, the control appearance applies only to the specified window (Graph or Panel). If it is not used, then the settings are global to experiments on the current computer. **Tip**: Use `/W=#` to refer to the current active subwindow.

The /Mac and /Win flags specify the affected computer platform. If the current platform other than specified, then the settings are not used, but (if native or OS9) are remembered for use in window recreation macros or experiment recreation. This means you can create an experiment that with different appearances depending on the current platform.

If neither /Mac nor /Win are used, it is implied by the current platform. To set native appearance on both platforms, use two commands:

```
DefaultGUIControls/W=Panel0/Mac native
DefaultGUIControls/W=Panel0/Win native
```

Note: The setting for DefaultGUIControls without /W is not stored in the experiment file; it is a user preference set by the Miscellaneous Settings dialog's Native GUI Appearance for Controls checkbox in the Compatibility tab. If you use DefaultGUIControls native or DefaultGUIControls os9 commands, the checkbox will not show the current state of the experiment-wide setting. Clicking Save Settings in the Miscellaneous Settings dialog will overwrite the DefaultGUIControls setting (but not the per-window settings).

In addition to the experiment-wide appearance setting and the window-specific appearance setting, an individual control's appearance can be set with the appropriate control command's appearance keyword (or a ModifyControl appearance keyword). A control-specific appearance setting overrides a window-specific appearance, which in turn overrides the experiment-wide appearance setting.

Although meant to be used before controls are created, calling DefaultGUIControls will update all open windows.

DefaultGUIControls does not change control fonts or font sizes, which means you can create controls that look "native-ish" without having to readjust their positions to avoid avoid shifting or overlap. However, the smooth font rendering that the Native GUI uses on Macintosh does change the length of text slightly, so some shifting will occur that affects mostly controls that were aligned on their right sides.

The native appearance affects the way that controls are drawn in **TabControl** and **GroupBox** controls.

TabControl Background Details

Unlike the os9 appearance which draws only an outline to define the tab region (leaving the center alone) the native tab appearance fills the tab region. Fortunately, TabControls are drawn before all other kinds of controls which allows enclosed controls to be drawn on top of a tab control regardless of the order in which the buttons are defined in the window recreation macro.

However the drawing order of native TabControls does matter: the top-most TabControls draws over other TabControls. (The top-most TabControl is listed last in the window recreation macro.) The os9 appearance allows a smaller (nested) TabControl to be underneath the later (enclosing) TabControl because tabs normally aren't filled. Converting these tabs to native appearance will cause nested tab to be hidden.

To fix the drawing order problem in an existing panel, turn on the drawing tools, select the arrow tool, right-click the enclosing TabControl, and choose Send to Back to correct this situation. If the TabControl itself is inside another TabControl, select that enclosing TabControl and also choose Send to Back, etc.

To fix the window recreation macro or function that created the panel, arrange the enclosing TabControl commands to execute before the commands that create the enclosed TabControls.

A natively-drawn TabControl draws any drawing objects that are entirely enclosed by the tab region so that it behaves the same as an os9 unfilled TabControl with drawing objects inside.

Groupbox Control Background Details

GroupBox controls, unlike TabControls, are not drawn before all other controls, so the drawing order always matters if the GroupBox specifies a background (fill) color and it contains other controls.

You may find that enabling native appearance hides some controls inside the GroupBox. They are probably underneath (before) the GroupBox in the drawing order.

To fix this in an existing panel, turn on the drawing tools, right-click on the GroupBox and choose Send to Back. To fix the window recreation macro or function that created the panel, arrange the GroupBox commands to execute before the commands that create the enclosed controls.

A natively-drawn GroupBox draws any drawing objects that are entirely enclosed by the box; an os9 filled GroupBox does not.

See Also

The **DefaultGUIFont**, **ModifyControl**, **Button**, **GroupBox**, and **TabControl** operations.

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Control Panel Units on page III-444 for a discussion of the units used for controls.

DefaultGUIFont

`DefaultGUIFont` `[`**`/W=`*`winName`* `/Mac/Win`**`]` ***`group`* `= {`*`fNameStr`*`,`*`fSize`*`,`*`fStyle`*`}`** `[,…]`

The DefaultGUIFont operation changes the default font for user-defined controls and other Graphical User Interface elements.

Parameters

fNameStr is the name of a font, *fSize* is the font size, and *fStyle* is a bitwise parameter with each bit controlling one aspect of the font style. See **Button** for details about these parameters.

group may be one of the following:

all	All controls
button	Button and default CustomControl
checkbox	CheckBox controls
tabcontrol	TabControl controls
popup	Affects the icon (not the title) of a PopupMenu control. The text in the popped state is set by the system and can not be changed. The title of a PopupMenu is affected by the all group but the icon text is not.
panel	Draw text in a panel.
graph	Overlay graphs. Size is used only if `ModifyGraph gfSize= -1`; style is not used.
table	Overlay tables.

Flags

/Mac	Changes control fonts only on Macintosh, and it affects the experiment whenever it is used on Macintosh.
/W=*winName*	Affects the named window or subwindow. When omitted, sets an experiment-wide default. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
/Win	Changes control fonts only on Windows, and it affects the experiment whenever it is used on Windows.

Details

Although designed to be used before controls are created, calling DefaultGUIFont will update all affected windows with controls. This makes it easy to experiment with fonts. Keep in mind that fonts can cause compatibility problems when moving between machines or platforms.

The /Mac and /Win flags indicate the platform on which the fonts are to be used. If the current platform is not the one specified then the settings are not used but are remembered for use in window recreation macros or experiment recreation. This allows a user to create an experiment that will use different fonts depending on the current platform.

If the /W flag is used then the font settings apply only to the specified window (Graph or Panel.) If the /W flag is not used, then the settings are global to the experiment. Tip: Use `/W=#` to refer to the current active subwindow.

fNameStr may be an empty string (`""`) to clear a group. Setting the font name to `"_IgorSmall"`, `"_IgorMedium"`, or `"_IgorLarge"` will use Igor's own defaults. The standard defaults for controls are the equivalent to setting all to `"_IgorSmall"`, tabcontrol to `"_IgorMedium"`, and button to `"_IgorLarge"`. Use a *fSize* of zero to also get the standard default for size. On Windows, the three default fonts and sizes are all the same.

Although designed to be used before controls are created, calling DefaultGUIFont will update all affected windows with controls. This makes it easy to experiment with fonts. Keep in mind that fonts can cause compatibility problems when moving between machines or platforms.

To read back settings, use `DefaultGUIFont [/W=winName/Mac/Win/OVR] group` to return the current font name in S_name, the size in V_value, and the style in V_flag. With /OVR or if /Mac or /Win is not current, it returns only override values. Otherwise, values include Igor built-in defaults. If S_name is zero length, values are not defined.

Default Fonts and Sizes

The standard defaults for controls is the equivalent to setting all to `"_IgorSmall"`, tabcontrol to `"_IgorMedium"`, and button to `"_IgorLarge"`. Use a *fSize* of zero to also get the standard default for size. On Windows, the three default fonts and sizes are all the same.

	Macintosh		Windows	
Control	**Font**	**Font Size**	**Font**	**Font Size**
Button	Lucida Grande	13	MS Shell Dlg*	12
Checkbox	Geneva	9	MS Shell Dlg	12
GroupBox	Geneva	9	MS Shell Dlg	12
ListBox	Geneva	9	MS Shell Dlg	12
PopupMenu†	Geneva	9	MS Shell Dlg	12
SetVariable	Geneva	9	MS Shell Dlg	12
Slider	Geneva	9	MS Shell Dlg	12
TabControl	Geneva	12	MS Shell Dlg	12
TitleBox	Geneva	9	MS Shell Dlg	12
ValDisplay	Geneva	9	MS Shell Dlg	12

* MS Shell Dlg is a "virtual font name" which maps to Tahoma on Windows XP, to MS Sans Serif on Windows 7, and to Segoe UI on Windows 8 and Windows 10.

† On Macintosh, the PopupMenu font is Geneva 9 for the title and Lucida Grande 12 for the popup menu itself. On Windows, both fonts are MS Shell Dlg 12.

Examples

```
DefaultGUIFont/Mac all={"Zapf Chancery",12,0},panel={"geneva",12,3}
DefaultGUIFont/Win all={"Century Gothic",12,0},panel={"arial",12,3}
NewPanel
Button b0
DrawText 40,43,"Some text"
```

See Also

The **DefaultGUIControls** operation. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Window Position Coordinates on page III-455 and **Points Versus Pixels** on page III-455 for explanations of how font sizes in panels are interpreted for various screen resolutions.

Demos

Choose File→Example Experiments→Feature Demos 2→All Controls Demo.

DefaultTab

`#pragma DefaultTab={`*`mode`*`,`*`widthInPoints`*`,`*`widthInSpaces`*`}`

The DefaultTab pragma allows you to specify default tab settings by entering a pragma statement in a procedure file. Specifying tab widths in spaces rather than points provides better results if the procedure window font or font size is changed.

The DefaultTab pragma was added in Igor Pro 9.00. It is ignored by earlier versions of Igor.

See **Procedure Window Default Tabs** on page III-405 for details.

DefaultTextEncoding

DefaultTextEncoding [encoding=*textEncoding*, overrideDefault=*override*]

The DefaultTextEncoding operation programmatically changes the default text encoding and experiment text encoding override settings. These settings, which are discussed under **The Default Text Encoding** on page III-465, are also accessible via the Misc→Text Encoding→Default Text Encoding menu.

DefaultTextEncoding is rarely needed because typically you will change the default text encoding manually using the menu, if at all.

The DefaultTextEncoding operation was added in Igor Pro 7.00.

Parameters

All parameters are optional. If none are specified, no action is taken, but the output variables are still set.

encoding=*textEncoding*

textEncoding specifies the new default text encoding. See **Text Encoding Names and Codes** on page III-490 for a list of codes.

Pass 0 to set the default text encoding to the equivalent of selecting "Western" from the Default Text Encoding submenu.

The value 255, corresponding to the binary text encoding type, is treated as an invalid value for the *textEncoding* parameter.

overrideDefault=*override*

Turns overriding of the experiment's text encoding off or on.

0: Turns override off

1: Turns override on

Details

The default text encoding affects Igor’s behavior when opening a file whose text encoding is unknown. See **The Default Text Encoding** on page III-465 for details.

The experiment text encoding affects how files are loaded during experiment loading only. The override setting allows you to override the experiment text encoding stored in the experiment file. Normally you will not need to do this. See **The Default Text Encoding** on page III-465 for further discussion.

You may occasionally find it necessary to change the default text encoding because an Igor operation lacks a /ENCG flag that allows you to specify the text encoding and instead uses the current default text encoding. In such cases it is a good idea to save the original default text encoding, change it as necessary, and then change it back to the original text encoding. The example below demonstrates this technique.

Output Variables

DefaultTextEncoding sets the following output variables to indicate the settings that are in effect after the command executes:

`V_defaultTextEncoding`	A text encoding code.
`V_overrideExperiment`	A value of zero means the setting is off, nonzero means the setting is on.

Example

```
Function DemoDefaultTextEncoding()
   // Store the original default text encoding
   DefaultTextEncoding
   Variable originalTextEncoding = V_defaultTextEncoding

   // Set new default text encoding
   DefaultTextEncoding encoding = 3     // 3= Windows-1252

   [ Do something that depends on the default text encoding ]

   // Restore the original default text encoding
   DefaultTextEncoding encoding = originalTextEncoding
End
```

See Also

The Default Text Encoding on page III-465, **Text Encoding Names and Codes** on page III-490

defined

`defined(`*`symbol`*`)`

The defined function returns 1 if the symbol is defined 0 if the symbol is not defined.

symbol is a symbol possibly created by a #define statement or by SetIgorOption poundDefine=*symbol*.

symbol is a name, not a string. However you can use $ to convert a string expression to a name.

Details

The defined function can be used in three ways:

Outside of a procedure using a #if statement

Inside a procedure using a #if statement

Inside a procedure using an if statement

For example:

```
#define DEBUG

#if defined(DEBUG)                  // Outside of a function with #if
   Constant kSomeConstant = 100
#else
   Constant kSomeConstant = 50
#endif

Function Test1()                    // Inside a function with #if
   #if defined(DEBUG)
      Print "Debugging"
   #else
      Print "Not debugging"
   #endif
End

Function Test1()                    // Inside a function with if
   if (defined(DEBUG))
      Print "Debugging"
   else
      Print "Not debugging"
   endif
End
```

In these examples, we could have just as well used #ifdef instead of the defined function. For logical combinations of conditions however, only defined will do:

```
#if (defined(SYMBOL1) && defined(SYMBOL2)
   . . .
#endif
```

When used in a procedure window, defined(symbol) returns 1 if symbol is defined at the time the line is compiled. In a given procedure file, only the following symbols are visible:

Symbols defined earlier in that procedure file *

Symbols defined in the built-in procedure window †

Predefined symbols (see **Predefined Global Symbols** on page IV-110)

Symbols defined by **SetIgorOption** poundDefine=*symbol*

* When used in the body of a procedure, as opposed to outside of a procedure, a symbol defined anywhere in a given procedure window is visible. However, to avoid depending on this confusing exception, you should define all symbols before they are referenced in a procedure file.

† Symbols defined in the built-in procedure window are not available to independent modules.

When the defined function is used from the command line, only symbols defined in the built-in procedure window, predefined symbols, and symbols defined using SetIgorOption are visible.

See Also

#define, **Conditional Compilation** on page IV-108, **Predefined Global Symbols** on page IV-110

DefineGuide

`DefineGuide [/W= winName] newGuideName = {[guideName1, val [, guideName2]]} [,…]`

The DefineGuide operation creates or overwrites a user-defined guide line in the target or named window or subwindow. Guide lines help with the positioning of subwindows in a host window.

Parameters

newGuideName is the name for the newly created guide. When it is the name of an existing user-defined guide, the guide will be moved to the new position.

guideName1, *guideName2*, etc., must be the names of existing guides.

The meaning of *val* depends on the form of the command syntax. When using only one guide name, *val* is an absolute distance offset from to the guide. The directionality of *val* is to the right or below the guide for positive values. The units of measure are points except in panels where they are in **Control Panel Units**. When using two guide names, *val* is the fractional distance between the two guides.

Flags

/W=*winName*	Defines guides in the named window or subwindow. When omitted, action will affect the active window or subwindow. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The names for the built-in guides are as defined in the following table:

	Left	**Right**	**Top**	**Bottom**
Host Window Frame	FL	FR	FT	FB
Host Graph Rectangle	GL	GR	GT	GB
Inner Graph Plot Rectangle	PL	PR	PT	PB
Layout Margin Rectangle	ML	MR	MT	MB

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows. The layout margin rectangle guide types only apply to layout windows.

To delete a guide use `guideName={}`.

See Also

The **Display**, **Edit**, **NewPanel**, **NewImage**, and **NewWaterfall** operations.

The **GuideInfo** function.

DelayUpdate

`DelayUpdate`

The DelayUpdate operation delays the updating of graphs and tables while executing a macro.

Details

Use DelayUpdate at the end of a line in a macro if you want the next line in the macro to run before graphs or tables are updated.

This has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the **DoUpdate** operation.

See Also

The **DoUpdate**, **PauseUpdate**, and **ResumeUpdate** operations.

DeleteAnnotations

DeleteAnnotations [*flags*] [tagOffscreen, tagTraceHidden, invisible,
offsetOffscreen, tooSmall[=*size*]]

The DeleteAnnotations operation lists, in the S_name output variable, and optionally deletes annotations that are hidden for reasons specified by the flags and keywords.

The operation affects the window or subwindow specified by the /W flag or, if /W is omitted, the active window or subwindow.

Do not use DeleteAnnotations to progammatically delete a specific, single annotation. Instead use:

```
TextBox/W=winName/K/N=annotationName
```

The /LIST flag limits the action to only listing, instead of deleting, the annotations.

The DeleteAnnotations operation was added in Igor Pro 7.00.

Keywords

The keywords identify annotations based on the reasons for their being hidden:

invisible — Deletes or lists annotations hidden with /V=0.

offsetOffscreen — Deletes or lists annotations that are offscreen, usually because of excessive /X and /Y offsets.

tagOffscreen — Deletes or lists tags hidden because they are attached to trace points that are offscreen. This affects trace tags, axis tags, and image tags if their "if offscreen" setting, as set in the Position tab of the Modify Annotation dialog, is set to "hide the tag".

tagTraceHidden — Deletes or lists tags hidden because the tagged trace is hidden.

tooSmall [=*size*] — Deletes or lists annotations whose height or width is *size* points or smaller. *size* is expressed in points and defaults to 8. This is useful for deleting annotations that are too small to see or to double-click.

Flags

/A — All annotations, whether hidden or not, are listed or deleted. All keywords are ignored.

/LIST — Specifies that annotations identified by the other parameters are to be listed in the S_name output variable but not deleted.

/W=*winName* — Annotations in the named window or subwindow are considered. When omitted, annotations in the active window or subwindow are considered.

When identifying a subwindow with winName, see Subwindow Syntax for details on forming the window hierarchy.

Output Variables

`S_name` — A semicolon-separated list of the annotations that match the criteria set by the keywords and flags.

`V_flag` — Set to the number of annotations deleted or listed.

Examples

```
Function DeleteAnnotationsInWin(win)
   String win          // Specifies a top-level window or a subwindow

   // Handle specified top-level window or subwindow
   DeleteAnnotations/W=$win/A
   Variable numDeleted = V_Flag

   // Now handle subwindows, if any
   String children = ChildWindowList(win)
   Variable n = ItemsInList(children)
   Variable i
```

```
	for(i=0; i<n; i+=1)
		String child = StringFromList(i, children)
		numDeleted += DeleteAnnotationsInWin(child) // Recurse
	endfor

	return numDeleted
End
```

See Also

TextBox, **StringFromList**, **AnnotationList**

DeleteFile

DeleteFile [***flags***] [***fileNameStr***]

The DeleteFile operation deletes a file on disk.

Parameters

fileNameStr can be a full path to the file to be deleted (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not locate the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file to be deleted.

If you use a full or partial path for either file, see **Path Separators** on page III-451 for details on forming the path.

Flags

/I	Interactive mode displays the Open File dialog even if *fileNameStr* is specified and the file exists.
/M=*messageStr*	Specifies the prompt message for the Open File dialog.
/P=*pathName*	Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.
/Z[=z]	Prevents procedure execution from aborting if it attempts to delete a file that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort. /Z=0: Same as no /Z. /Z=1: Deletes a file only if it exists. /Z alone has the same effect as /Z=1. /Z=2: Deletes a file if it exists or displays a dialog if it does not exist.

Variables

The DeleteFile operation returns information in the following variables:

`V_flag`	Set to zero if the file was deleted, to -1 if the user cancelled the Open File dialog, and to some nonzero value if an error occurred, such as the specified file does not exist.
`S_path`	Stores the full path to the file that was deleted. If an error occurred or if the user cancelled, it is set to an empty string.

See Also

DeleteFolder, **MoveFile**, **CopyFile**, **NewPath**, and **Symbolic Paths** on page II-22.

DeleteFolder

```
DeleteFolder [flags] [folderNameStr]
```

The DeleteFolder operation deletes a disk folder and all of its contents.

Warning: *The DeleteFolder command destroys data!* The deleted folder and the contents are not moved to the Trash or Recycle Bin.

DeleteFolder will delete a folder only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category.

If permission is denied, the folder will not be deleted and V_Flag will return 1088 (Command is disabled) or 1276 (You denied permission to delete a folder). Command execution will cease unless the /Z flag is specified.

Parameters

folderNameStr can be a full path to the folder to be deleted, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a folder within the folder associated with *pathName*.

If Igor can not determine the location of the folder from *folderNameStr* and *pathName*, it displays a Select Folder dialog allowing you to specify the folder to be deleted.

If /P=*pathName* is given, but *folderNameStr* is not, then the folder associated with *pathName* is deleted.

If you use a full or partial path for either folder, see **Path Separators** on page III-451 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

Flags

/I	Interactive mode displays a Select Folder dialog even if *folderNameStr* is specified and the folder exists.
/M=*messageStr*	Specifies the prompt message for the Select Folder dialog.
/P=*pathName*	Specifies the folder to look in for the folder. *pathName* is the name of an existing symbolic path.
/Z[=z]	Prevents procedure execution from aborting if it attempts to delete a folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

/Z=0:	Same as no /Z.
/Z=1:	Deletes a folder only if it exists. /Z alone has the same effect as /Z=1.
/Z=2:	Deletes a folder if it exists or displays a dialog if it does not exist.

Variables

The DeleteFolder operation returns information in the following variables:

`V_flag`	Set to zero if the folder was deleted, to -1 if the user cancelled the Select Folder dialog, and to some nonzero value if an error occurred, such as the specified folder does not exist.
S_path	Stores the full path to the folder that was deleted, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.

Details

You can use only /P=*pathName* (without *folderNameStr*) to specify the source folder to be deleted.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

See Also

The **DeleteFile**, **MoveFolder**, **CopyFolder**, **NewPath**, and **IndexedDir** operations. **Symbolic Paths** on page II-22.

DeletePoints

DeletePoints [**/M=*dim***] ***startElement*, *numElements*, *waveName***
[, ***waveName***]…

The DeletePoints operation deletes *numElements* elements from the named waves starting from element *startElement*.

Flags

/M=*dim* — *dim* specifies the dimension from which elements are to be deleted. Values are:

0:	Rows.
1:	Columns.
2:	Layers.
3:	Chunks.

If /M is omitted, DeletePoints deletes from the rows dimension.

Details

A wave may have any number of points, including zero. Removing all elements from any dimension removes all points from the wave, leaving a 1D wave with zero points.

Except for the case of removing all elements, DeletePoints does not change the dimensionality of a wave. Use **Redimension** for that.

See Also

The **Redimension** operation.

deltax

deltax(*waveName*)

The deltax function returns the named wave's dx value. deltax works with 1D waves only.

Details

This is equal to the difference of the X value of point 1 minus the X value of point 0.

See Also

The **leftx** and **rightx** functions.

When working with multidimensional waves, use the **DimDelta** function.

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-68.

DFREF

DFREF *localName* [= *path* or *dfr*], [*localName1* [= *path* or *dfr*]]

DFREF is used to define a local data folder reference variable or input parameter in a user-defined function.

The syntax of the DFREF is:

```
DFREF localName [= path or dfr ][, localName1 [= path or dfr ]]...
```

where *dfr* stands for "data folder reference". The optional assignment part is used only in the body of a function, not in a parameter declaration.

Unlike the **WAVE** reference, a DFREF in the body without the assignment part does not do any lookup. It simply creates a variable whose value is null.

Examples

```
Function Test(dfr)
    DFREF dfr

    Variable dfrStatus = DataFolderRefStatus(dfr)

    if (dfrStatus == 0)
        Print "Invalid data folder reference"
        return -1
    endif
```

```
   if (dfrStatus & 2)            // Bit 1 set means free data folder
      Print "Data folder reference refers to a free data folder"
   endif

   if (dfrStatus == 1)
      Print "Data folder reference refers a global data folder"
      DFREF dfSav = GetDataFolderDFR()
      Print GetDataFolder(1)     // Print data folder path
      SetDataFolder dfSav
   endif

   Make/O dfr:jack=sin(x/8)      // Make a wave in the referenced data folder

   return 0
End
```

See Also

For information on programming with data folder references, see **Data Folder References** on page IV-78.

Differentiate

Differentiate [***type flags***][***flags***] ***yWaveA*** [**/X =** ***xWaveA***]
   [**/D =** ***destWaveA***][**,** ***yWaveB*** [**/X =** ***xWaveB***][**/D =** ***destWaveB***][**,** …]]

The Differentiate operation calculates the 1D numerical derivative of a wave.

Differentiate is multi-dimension-aware in the sense that it computes a 1D differentiation along the dimension specified by the /DIM flag or along the rows dimension if you omit /DIM.

Complex waves have their real and imaginary components differentiated individually.

Flags

/DIM=*d*	Specifies the wave dimension along which to differentiate when *yWave* is multidimensional. *d*=-1: Treats entire wave as 1D (default). *d*=0: Differentiates along rows. *d*=1: Differentiates along columns. *d*=2: Differentiates along layers. *d*=3: Differentiates along rows. For example, for a 2D wave, /DIM=0 differentiates each row and /DIM=1 differentiates each column.
/EP=*e*	Controls end point handling. *e*=0: Replaces undefined points with an approximation (default). *e*=1: Deletes the point(s).
/METH=*m*	Sets the differentiation method. *m*=0: Central difference (default). *m*=1: Forward difference. *m*=2: Backward difference.
/P	Forces point scaling.

Type Flags (*used only in functions*)

Differentiate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-73 and **WAVE Reference Type Flags** on page IV-74 for a complete list of type flags and further details.

For example, when the input (and output) waves are complex, the output wave will be complex. To get the Igor compiler to create a complex output wave reference, use the /C type flag with /D=destwave:

```
Make/O/C cInput=cmplx(sin(p/8), cos(p/8))
Make/O/C/N=0 cOutput
Differentiate/C cInput /D=cOutput
```

Wave Parameters

Note:	***All*** wave parameters must follow *yWave* in the command. All wave parameter flags and type flags must appear immediately after the operation name.
/D=*destWave*	Specifies the name of the wave to hold the differentiated data. It creates *destWave* if it does not already exist or overwrites it if it exists.
/X=*xWave*	Specifies the name of the corresponding X wave.

Details

If the optional /D = *destWave* flag is omitted, then the wave is differentiated in place overwriting the original data.

When using a method that deletes points (/EP=1) with a multidimensional wave, deletion is not done if no dimension is specified.

When using an X wave, the X wave must match the Y wave data type (excluding the complex type flag) and it must be 1D with the number points matching the size of the dimension being differentiated. X waves are not used with integer source waves.

`Differentiate/METH=1/EP=1` is the inverse of `Integrate/METH=2`, but `Integrate/METH=2` is the inverse of `Differentiate/METH=1/EP=1` only if the original first data point is added to the output wave.

Differentiate applied to an XY pair of waves does not check the ordering of the X values and doesn't care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves using **Sort**.

See Also

The **Integrate** operation.

digamma

`digamma(`*`x`*`)`

The digamma function returns the digamma, or psi function of *x*. This is the logarithmic derivative of the gamma function:

$$\Psi(z) \equiv \frac{d}{dz}\ln\left(\Gamma(z)\right) = \frac{\Gamma'(z)}{\Gamma(z)}.$$

In complex expressions, *x* is complex, and `digamma(x)` returns a complex value.

Limited testing indicates that the accuracy is approximately 1 part in 10^{16}, at least for moderately-sized values of *x*.

Dilogarithm

`Dilogarithm(`*`z`*`)`

Returns the Dilogarithm function for real or complex argument *z*. The dilogarithm is a special case of the polylogarithm defined by

$$Li_2(z) = \sum_{k=1}^{\infty} \frac{z^k}{k^2}.$$

The dilogarithm function was added in Igor Pro 7.00.

See Also

zeta

Reference

The function based on an algorithm by Didier Clamond.

DimDelta

`DimDelta(`*`waveName`*`, `*`dimNumber`*`)`

The DimDelta function returns the scale factor delta of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks.

If *dimNumber*=0 this is identical to `deltax(`*`waveName`*`)`.

See Also

DimOffset, **DimSize**, **SetScale**, **WaveUnits**, **ScaleToIndex**

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-68.

DimOffset

`DimOffset(`*`waveName`*`, `*`dimNumber`*`)`

The DimOffset function returns the scaling offset of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks.

If *dimNumber*=0 this is identical to `leftx(`*`waveName`*`)`.

See Also

DimDelta, **DimSize**, **SetScale**, **WaveUnits**, **ScaleToIndex**

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-68.

DimSize

`DimSize(`*`waveName`*`, `*`dimNumber`*`)`

The DimSize function returns the size of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks.

For a 1D wave, `DimSize(`*`waveName`*`,0)` is identical to `numpnts(`*`waveName`*`)`.

See Also

DimDelta, **DimOffset**, **SetScale**, **WaveUnits**

Dir

`Dir` `[`***`dataFolderSpec`***`]`

The Dir operation returns a listing of all the objects in the specified data folder.

Parameters

If you omit *dataFolderSpec* then the current data folder is used.

If present, *dataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

Details

The format of the printed information is the same as the format used by the string function **DataFolderDir**. Igor programmers may find it more convenient to use **CountObjects** and **GetIndexedObjName**.

Usually it is easier to use the Data Browser (Data menu). However, **Dir** is useful when you want to copy a name into the command line or when you want to document the current state of the folder in the history.

See Also

Chapter II-8, **Data Folders**.

Display

Display [***flags***] [***waveName*** [, ***waveName***]…[**vs** ***xwaveName***]]
[**as** ***titleStr***]

The Display operation creates a new graph window or subwindow, and appends the named waves, if any. Waves are displayed as 1D traces.

By default, waves are plotted versus the left and bottom axes. Use the /L, /B, /R, and /T flags to plot the waves against other axes.

Parameters

Up to 100 *waveName*s may be specified, subject to the 2500 byte command line length limit. If no wave names are specified, a blank graph is created and the axis flags are ignored.

If you specify "vs *xwaveName*", the Y values of the named waves are plotted versus the Y values of *xwaveName*. If you don't specify "vs *xwaveName*", the Y values of each *waveName* are plotted versus its own X values.

If *xwaveName* is a text wave or the special keyword '_labels_', the resulting plot is a category plot. Each element of *waveName* is plotted by default in bars mode (`ModifyGraph mode=5`) against a category labeled with the text of the corresponding element of *xwaveName* or the text of the dimension labels of the first Y wave..

The Y waves for a category plot should have point scaling (see **Changing Dimension and Data Scaling** on page II-68); this is how category plots were intended to work. However, if all the Y waves have the same scaling, it will work correctly.

titleStr is a string expression containing the graph's title. If not specified, Igor will provide one which identifies the waves displayed in the graph.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-321.

You can provide a custom name for a trace by appending /TN=traceName to the waveName specification. This is useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-89 for more information.

Flags

/B[=*axisName*] Plots X coordinates versus the standard or named bottom axis.

/FG=(*gLeft*, *gTop*, *gRight*, *gBottom*)

Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are `FL`, `FR`, `FT`, and `FB`, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use `*` to specify a default guide name.

Guides may override the numeric positioning set by /W.

/HIDE=*h* Hides (h = 1) or shows (h = 0, default) the window.

/HOST=*hcSpec* Embeds the new graph in the host window or subwindow specified by *hcSpec*.

When identifying a subwindow with *hcSpec*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/I Specifies that /W coordinates are in inches.

/K=*k* Specifies window behavior when the user attempts to close it.

k=0:	Normal with dialog (default).
k=1:	Kills with no dialog.
k=2:	Disables killing.
k=3:	Hides the window.

If you use /K=2 or /K=3, you can still kill the window using the **KillWindow** operation.

/L[=*axisName*] Plots Y coordinates versus the standard or named left axis.

/M — Specifies that /W coordinates are in centimeters.

/N=*name* — Requests that the created graph have this name, if it is not in use. If it is in use, then *name*0, *name*1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen graph name.

/NCAT — In Igor Pro 6.37 or later, allows subsequent appending of a category trace to a numeric plot. See for details.

/PG=(*gLeft*, *gTop*, *gRight*, *gBottom*)

Specifies the inner plot rectangle of the graph subwindow inside its host window.

The standard plot rectangle guide names are `PL`, `PR`, `PT`, and `PB`, for the left, right, top, and bottom plot rectangle guides, respectively, or user-defined guide names as defined by the host. Use `*` to specify a default guide name.

Guides may override the numeric positioning set by /W.

/R[=*axisName*] — Plots Y coordinates versus the standard or named right axis.

/T[=*axisName*] — Plots Y coordinates versus the standard or named top axis.

/TN=*traceName* — Allows you to provide a custom trace name for a trace. This is useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-89 for details.

/W=(*left*,*top*,*right*,*bottom*)

Gives the graph a specific location and size on the screen. Coordinates for /W are in points unless /I or /M are specified before /W.

When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings:

1: When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.

2: When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or **Control Panel Units** for control panel hosts, relative to the top left corner of the host frame.

When the subwindow position is fully specified using guides (using the /HOST, /FG, or /PG flags), the /W flag may still be used although it is not needed.

Details

If /N is not used, Display automatically assigns to the graph a name of the form “Graph*n*”, where *n* is some integer. In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the graph from a procedure. Use the **RenameWindow** operation to rename the graph.

Examples

To make a contour plot, use:

```
Display; AppendMatrixContour waveName
```

or

```
Display; AppendXYZContour waveName
```

To display an image, use:

```
Display; AppendImage waveName
```

or

```
NewImage waveName
```

See Also

The **AppendToGraph** operation.

The operations **AppendImage**, **AppendMatrixContour**, **AppendXYZContour**, and **NewImage**. For more information on Category Plots, see Chapter II-14, **Category Plots**.

The operations **ModifyGraph**, **ModifyContour**, and **ModifyImage** for changing the characteristics of graphs.

The **DoWindow** operation for changing aspects of the graph window.

DisplayHelpTopic

`DisplayHelpTopic [/K=`*`k`*` /Z] `*`TopicString`*

The DisplayHelpTopic operation displays a help topic as if a help link had been clicked in an Igor help file.

Parameters

TopicString is string expression containing the topic. It may be in one of three forms: <topic name>, <subtopic name>, <topic name>[<subtopic name>]. These forms are illustrated by the examples.

Make sure that your topic string is specific to minimize the likelihood that Igor will find the topic in a help file other than the one you intended. To avoid this problem, it is best to use the <topic name>[<subtopic name>] form if possible.

Flags

/K=*k* Determines when the help file is closed.

k=0: Leaves the help file open indefinitely (default). Use this if the help topic may be of interest in any experiment.

k=1: If the found topic is in a closed help file, the help file closes with the current experiment. Use this if the help topic is tightly associated with the current experiment.

/Z Ignore errors. If /Z is used, DisplayHelpTopic sets V_flag to 0 if the help topic was found or to a nonzero error code if it was not found. V_flag is set only when /Z is used.

Details

DisplayHelpTopic first searches for the specified topic in the open help files. If the topic is not found, it then searches all help files in the Igor Pro folder and subfolders.

If the topic is still not found, it then searches all help files in the current experiment's home folder, but not in subfolders. This puts a help file that is specific to a particular experiment in the experiment's home folder.

If the topic is still not found and if DisplayHelpTopic was called from a procedure and if the procedure resides in a stand-alone file on disk (i.e., it is not in the built-in procedure window or in a packed procedure file), Igor then searches all help files in the procedure file's folder, but not in subfolders. This puts a help file that is specific to a particular set of procedures in the same folder as the procedure file.

If Igor finds the topic, it displays it. If Igor can not find the topic, it displays an error message, unless /Z is used.

Examples

```
// This example uses the topic only.
DisplayHelpTopic "Modifying Traces"

// This example uses the subtopic only.
DisplayHelpTopic "Markers"

// This example uses the topic[subtopic] form.
DisplayHelpTopic "Modifying Traces[Markers]"
```

See Also

Chapter II-1, **Getting Help** for information about Igor help files and formats.

DisplayProcedure

`DisplayProcedure [flags] [`*`functionOrMacroNameStr`*`]`

The DisplayProcedure operation displays the named function, macro or line by bringing the procedure window it is defined in to the front with the function, macro or line highlighted.

Parameters

functionOrMacroNameStr is a string expression containing the name of the function or macro to display. If you omit *functionOrMacroNameStr* then you must use /W or /L.

functionOrMacroNameStr may be a simple name or may include independent module and/or module name prefixes to display static functions.

If you use /L to display a particular line then you must omit *functionOrMacroNameStr*.

To display a procedure window without changing its scrolling or selection, use /W and omit *functionOrMacroNameStr*.

Flags

/B=*winTitleOrName* Brings up the procedure window just behind the window with this name or title.

/L=*lineNum* If /W is specified, *lineNum* is a zero-based line number in the specified window.

If /W is not specified, *lineNum* is a "global" line number. Each procedure window line has a unique global line number as if all of the procedure files were concatenated into one big file. The order of concatenation of files can change when procedures are recompiled.

If you use /L then you must omit *functionOrMacroNameStr*.

/W=*procWinTitle* Searches in the procedure window with this title.

procWinTitle is a name, not a string, so you construct /W like this:

```
/W=$"New Polar Graph.ipf"
```

If you omit /W, DisplayProcedure searches all open (nonindependent module) procedure windows.

Details

If a procedure window has syntax errors that prevent Igor from determining where functions and macros start and end, then DisplayProcedure may not be able to locate the procedure.

winTitleOrName is not a string; it is a name. To position the found procedure window behind a window whose title has a space in the name, use the $ operator as in the second example, below.

If *winTitleOrName* does not match any window, then the found procedure window is placed behind the top target window.

lineNum is a zero-based line number: 0 is the first line of the window. Because each line of a procedure window is a paragraph, line numbers and paragraph numbers are the same. You can use the Procedure→Info menu item to show a selection's starting and ending paragraph/line number.

procWinTitle is also a name. Use `/W=$"New Polar Graph.ipf"` to search for the function or macro in only that procedure file.

Don't specify both *functionOrMacroNameStr* and /L=*lineNum* as this is ambiguous and not allowed.

Advanced Details

If `SetIgorOption IndependentModuleDev=1`, *procWinTitle* can also be a title followed by a space and, in brackets, an independent module name. In such cases searches for the function or macro are in the specified procedure window and independent module. (See **Independent Modules** on page IV-238 for independent module details.)

For example, if any procedure file contains these statements:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

The command

```
DisplayProcedure/W=$"Axis Utilities.ipf [myIM]" "HVAxisList"
```

opens the procedure window that contains the `HVAxisList` function, which is in the Axis Utilities.ipf file and the independent module `myIM`. The command uses the `$""` syntax because space and bracket characters interfere with command parsing.

Similarly, if `SetIgorOption IndependentModuleDev=1` then *functionOrMacroNameStr* may also contain an independent module prefix followed by the # character. The preceding command can be rewritten as:

```
DisplayProcedure/W=$"Axis Utilities.ipf" "myIM#HVAxisList"
```

or more simply

```
DisplayProcedure "myIM#HVAxisList"
```

You can use the same syntax to display a static function in a non-independent module procedure file using a module name instead of (or in addition to) the independent module name.s

procWinTitle can also be just an independent module name in brackets to display all procedure windows that belong to the named independent module and define the specified function:

```
DisplayProcedure/W=$"[myIM]" "HVAxisList"
```

Examples

```
DisplayProcedure "Graph0"
DisplayProcedure/B=Panel0 "MyOwnUserFunction"
DisplayProcedure/W=Procedure         // Shows the main Procedure window
DisplayProcedure/W=Procedure/L=5     // Shows line 5 (the sixth line)
DisplayProcedure/W=$"Wave Lists.ipf"
DisplayProcedure "moduleName#myStaticFunctionName"
SetIgorOption IndependentModuleDev=1
DisplayProcedure "WMGP#GizmoBoxAxes#DrawAxis"
```

do-while

```
do
   <loop body>
while(<expression>)
```

A do-while loop executes *loop body* until *expression* evaluates as FALSE (zero) or until a break statement is executed.

DoAlert

`DoAlert [/T=titleStr] alertType, promptStr`

The DoAlert operation displays an alert dialog and waits for user to click button.

Parameters

alertType=*t*	Controls the type of alert dialog:	
	t=0:	Dialog with an OK button.
	t=1:	Dialog with Yes button and No buttons.
	t=2:	Dialog with Yes, No, and Cancel buttons.
promptStr	Specifies the text that is displayed in the alert dialog.	

Flags

/T=*titleStr*	Changes the title of the dialog window from the default title.

Details

DoAlert sets the variable V_flag as follows:

1:	Yes clicked.
2:	No clicked.
3:	Cancel clicked.

The **Abort** operation.

DoIgorMenu

```
DoIgorMenu [/C /OVRD] MenuNameStr, MenuItemStr
```

The DoIgorMenu operation allows an Igor programmer to invoke Igor's built-in menu items. This is useful for bringing up Igor's built-in dialogs under program control.

Parameters

MenuNameStr	The name of an Igor menu or submenu, like "File", "Graph", or "Load Waves".
MenuItemStr	The text of an Igor menu item, like "Copy" (in the Edit menu) or "New Graph" (in the Windows menu) or "Load Igor Binary" (in the Load Waves submenu). If you include /C, *MenuItemStr* can be "".

Flags

Using both the /C and the /OVRD flag in one command is not permitted.

/C	Just Checking. The menu item is not invoked, but V_flag is set to 1 if the item was enabled or to 0 if it was not enabled. In Igor Pro 9.01 and later, if *MenuItemStr* is "", then V_Flag, V_isInvisible, and S_value pertain to the menu instead of a menu item.
/OVRD	Tells Igor to skip checks that it normally does before executing the menu command specified by *MenuNameStr* and *MenuItemStr*. You are responsible for ensuring that the menu command you are invoking is appropriate under conditions existing at runtime. The main use for the /OVRD flag is to allow an advanced programmer to invoke a menu command for a menu that is currently hidden when dealing with subwindows. For example, if you have a graph subwindow in a control panel which is in operate mode, the Graph menu is not visible in the menu bar. Normally the user could not invoke an item, such as Modify Trace Appearance. /OVRD allows you to invoke the menu command, but it is up to you to verify that it is appropriate. In the Modify Trace Appearance example, you should invoke the menu command only if the active window or subwindow is a graph that contains at least one trace. /OVRD was added in Igor Pro 7.00.

Details

All menu names and menu item text are in English to ensure that code developed for a localized version of Igor Pro will run on all versions. Note that no trailing "…" is used in *MenuItemStr*.

V_flag is set to 1 if the corresponding menu item was enabled, which usually means the menu item was successfully selected. Otherwise V_flag is 0. V_flag does not reflect the success or failure of the resulting dialog, if any.

V_isInvisible, added in Igor Pro 7, is set to 1 if the corresponding menu item was invisible. This is fairly rare - in most cases V_isInvisible will be set to 0. Invisible menu items are items like File→Adopt All which are hidden unless the user presses the shift key while summoning the menu. This is different from menus items hidden by HideIgorMenus for which V_isInvisible is set to 0.

S_value, added in Igor Pro 9.00, is set to the translated menu item text. This can be useful for always-enabled menu items that toggle between to states like Show Tools and Hide Tools.

If the menu item selection displays a dialog that generates a command, clicking the Do It button executes the command immediately without using the command line as if Execute/Z operation had been used. Clicking the To Cmd Line button appends the command to the command line rather than inserting the command at the front.

The DoIgorMenu operation will not attempt to select a menu during curve fitting or while a dynamic menu item's function is running. Doubtless there are other times during which using DoIgorMenu would be unwise.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the *MenuItemStr* parameter. Use “Save Window”, “Save Window As”, “Save Window Copy”, “Adopt Window”, and “Revert Window” instead of “Save Notebook” or “Save Procedure”, etc. Use “Page Setup” instead of “Page Setup For All Graphs”, etc. Use “Print” instead of “Print Graph”, etc.

The Edit→Insert File menu item was previously named Insert Text. For compatibility, you can specify either “Insert File” or “Insert Text” as *MenuItemStr* to invoke this item.

SetIgorMenuMode, **ShowIgorMenus**, **HideIgorMenus**, **Execute**

The SetIgorMenuModeProc.ipf WaveMetrics procedure file contains SetIgorMenuMode commands for every menu and menu item. You can load it using

```
#include <SetIgorMenuModeProc>
```

DoPrompt

`DoPrompt` `[`**`/HELP=`*`helpStr`***`]` ***`dialogTitleStr`***`,` ***`variable`*** `[,` ***`variable`***`]`…

The DoPrompt statement in a function invokes the simple input dialog. A DoPrompt specifies the title for the simple input dialog and which input variables are to be included in the dialog.

Flags
