You can enter * (an asterisk) for \(z M i n\) and \(z M a x\), which uses the minimum and maximum Z values of the data. The default is \(\left\{{ }^{*},{ }^{*}\right.\), Rainbow \(\}\).
Set parameter mode to 1 to reverse the color table; zero or missing does not reverse the color table.
ctName can be any color table name returned by the CTabList function, such as Grays or Rainbow. Also see Color Tables on page II-359.
If you use ctabLines, you must not use cIndexLines or rgbLines in the same command.
equalVoronoiDistances=e

Normally the \(x\) range and \(y\) range of the data are each normalized to a 0-1 range separately to generate the Voronoi triangulation. Voronoi triangulation is a distance-based ("nearest neighbor") algorithm that may benefit from scaling the \(X\) and \(Y\) ranges together to avoid numerical problems that occur when the triangles become very thin because of widely differing \(x\) and \(y\) ranges.
\(e=0: \quad\) The \(x\) and \(y\) ranges are scaled individually to the \(0-1\) range (default).
\(e=1: \quad\) The \(x\) and \(y\) ranges are scaled so that that maximum range of \(x\) or \(y\) is scaled to the 0-1 range, and the other is proportionally smaller. For example, if \(y\) Max- \(y\) Min \(=1000\) and \(x\) Max- \(x\) Min \(=\) 5 , then the y range is scaled to \(0-1\) and the \(y\) range is scaled to \(5 / 1000=0-0.005\).
The equalVoronoiDistances keyword is allowed only for \(X Y Z\) contour plots.
\begin{tabular}{|c|c|}
\hline \multirow[t]{6}{*}{interpolate \(=i\)} & XYZ contours can be interpolated to increase the apparent resolution, resulting in smoother contour lines. \\
\hline & This keyword is allowed only for XYZ contours, created by AppendXYZContour. \\
\hline & \(i=0\) : \(\quad\) Linear interpolation (default). This means that only the original Delaunay triangulation generates contour lines. \\
\hline & \begin{tabular}{l}
\(i=1\) : \(\quad\) Four times the resolution generates a smoother set of contour lines. \\
As expected, this takes longer than Linear interpolation.
\end{tabular} \\
\hline & \(i=2\) : \(\quad\) Sixteen times the resolution generates a much smoother set of contour lines. This is rather slow. \\
\hline & The interpolate parameter can be up to 8 . Each time you increase \(i\) by one, you quadruple the apparent resolution and get smoother contour lines at the expense of computation time. Values of \(i\) greater than two are impractical because of the computation time required. \\
\hline labelBkg \(=(r, g, b)\) & Sets the background color for all contour level labels to the specified color. \(r, g\), and \(b\) are values from 0 to 65535 . \\
\hline \multirow[t]{5}{*}{labelBkg= \(b\)} & Controls the background color of contour labels. \\
\hline & \(b=0\) : Uses each label's individual background color, as set via the Modify Annotation dialog. \\
\hline & \(b=1\) : Makes all contour level labels transparent. \\
\hline & \(b=2\) : Uses the plot area background color as the label background color (default). \\
\hline & \(b=3 \quad\) Uses the window background color as the label background color. \\
\hline labelDigits=d & \(d\) is the number of digits after the decimal point when using labelFormat=3 or labelFormat=5. \\
\hline labelFont=fontName & Default; specifies the font to use for contour level labels. If you pass " " for fontName, it will use the graph font (set via the Modify Graph dialog) for contour labels. \\
\hline \multirow[t]{5}{*}{labelFormat=l} & Controls the formatting of contour labels. See the printf operation for a discussion of formatting. \\
\hline & \(l=0\) : Uses general format that is suitable for most data. This is equivalent to "\%<sigDigits>g". \\
\hline & \(l=1\) : Uses integer format, equivalent to "\%<sigDigits>d". \\
\hline & \(l=3\) : Uses fixed point format, equivalent to "\%<decimalDigits>f". \\
\hline & \(l=5 \quad\) Uses exponential format, equivalent to "\%<decimalDigits>e". \\
\hline
\end{tabular}
labelFSize=s
labelFStyle=n
labelHV=hv
labelRGB \(=(r, g, b) \quad\) Sets the text color for all contour level labels. \(r, g\), and \(b\) are values from 0 to 65535. The default is black, labelRGB=(0,0,0).
labels \(=l \quad\) Controls the display of contour labels.
\(l=0: \quad\) Hides contour level labels.
\(l=1\) : Leaves any contour level labels in place but stops updating them and stops generation of new labels.
\(l=2: \quad\) Generates or updates labels for the existing contour levels and window size when the command executes, but disables further updating of labels when window size or contour plot changes. This is the recommended setting if updating the labels takes long enough to annoy you.
\(l=3: \quad\) Default; generates labels for all contour levels whenever the contoured data changes but not when the window size changes. If you resize the graph, the labels may overlap or be too sparse.
\(l=4: \quad\) Generates labels for all contour levels whenever the contoured data, contour levels, axis range, or the graph size changes. (Actually, there are too many causes to list here. If all this update annoys you, use labels=2 "update once, now".)
labelSigDigits= \(d \quad d\) is the number of significant digits when labelFormat= \(=0\) is used.
\(\log\) Lines \(=1\) or \(0 \quad 0\) sets the default linearly-spaced contour line colors.
1 turns on logarithmically-spaced line colors. This requires that the contour levels values be greater than 0 to display correctly.
Affects line color only when the cIndexLines or ctabLines parameter is used.
logLines does not affect the contour levels. To assign logarithmically-spaced contour levels, use the moreLevels parameter and disable autoLevels, for example:
```

ModifyContour ''\#0, autoLevels={*,*,0} // No auto levels
ModifyContour ''\#0, moreLevels=0
ModifyContour ''\#0, moreLevels={1e-07,1e-06,1e-05,1e-04}

```

The logLines keyword was added in Igor Pro 6.22.
manLevels \(=\{\) firstLevel, increment, numLevels \(\}\)
Explicitly specifies contour levels. ModifyContour will generate numLevels contour levels, evenly spaced starting from firstLevel and stepping by increment.
manLevels cancels the effect of any previous manLevels or autoLevels settings. manLevels= manLevelsWave

Explicitly specifies contour levels. ModifyContour will generate contour levels at the values in manLevelsWave.
manLevels cancels the effect of any previous manLevels or autoLevels settings.
moreLevels= \(\{\) level, level...\(\}\)
Explicitly specifies contour levels. ModifyContour will generate a contour trace for each of the listed levels. The maximum number of levels that you can specify in a single command is the 50 . However, you can concatenate any number of ModifyContour moreLevels commands. moreLevels adds levels in addition to any specified by manLevels or autoLevels. It does not override other parameters. moreLevels=0: Removes all levels generated by previous moreLevels settings.
nullValue \(=z\) Value \(\quad\) This keyword only affects the behavior of the ContourZ function. It is allowed only for XYZ contours, created by AppendXYZContour.
By default, ContourZ treats data outside the domain of the contour as NaN and so returns NaN if you ask for a contour value outside that domain.
The nullValue keyword allows you to change the default behavior to make ContourZ treat values outside the domain as the specified zValue.
nullValueAuto This keyword only affects the behavior of the ContourZ function. It is allowed only for XYZ contours, created by AppendXYZContour.
nullValueAuto acts like nullValue \(=z\) Value with \(z\) Value automatically set to the minimum value in the Z wave minus 1.
See the nullValue keyword for details.
To turn nullValueAuto off and return the contour to the default state, execute:
ModifyContour <contourInstanceName>, nullValue=NaN
perturbation \(=p\)
rgbLines \(=(r, g, b)\)
triangulation \(=t\)
xymarkers \(=x\)

\section*{Flags}
/W=winName

Enable or disable perturbation (alteration) of the \(x\) and \(y\) values by a miniscule amount to improve the natural neighbor triangulation of XYZ contours.
\(p=0\) : \(\quad\) Disables perturbation, preserving the original x and y values unchanged.
\(p=1\) : Enables \(x / y\) perturbation (default). The values are shifted by random values less than \(+/-0.000005\) times the \(x\) and \(y\) domain extents.

You can observe the perturbed \(x / y\) coordinates in the triangulation trace added by ModifyContour triangulation=1.
The perturbation keyword is allowed only for XYZ contour plots.
Specifies red, green, and blue values for all contour lines. \(r, g\), and \(b\) are values from 0 to 65535.

If you use rgbLines, you must not use cIndexLines or ctabLines in the same command.

Draws the Delaunay Triangulation. As part of the \(X Y Z\) contouring algorithm, the XY domain is subdivided into triangles in a process called Delaunay Triangulation. Like the contour lines, the triangulation is drawn using a graph trace, whose name is usually something like "contourInstanceName \(=\) triangulation".

The triangulation keyword is allowed only for XYZ contours, created by AppendXYZContour.
\(t=0\) : \(\quad\) Hides the Delaunay triangulation (default).
\(t=1\) : \(\quad\) Shows the Delaunay triangulation.
Sets the type of updating of contour traces when the data or contour settings change.
\(u=0\) : \(\quad\) Turns off dynamic updates, which might be advisable if updates take a long time.
\(u=1\) : Updates the contours only once, or until you next execute an update=1 command.
\(u=2\) : Updates are automatic (default).
\(u=3 \quad\) Marks the contour plot as having been updated once \((u=1)\) already. This option is used in recreation macros to prevent an extra redraw of a graph saved with \(u=1\) update mode in effect.
If you use it in a command, the result is similar to \(u=0\), but the Modify Contour Appearance dialog will automatically select "update once, now" from the Update Contours pop-up menu.

Controls the visibility of XY markers.
\(x=0\) : \(\quad\) Hides markers showing \(X Y\) coordinates of the \(Z\) data (default).
\(x=1\) : \(\quad\) Displays markers showing \(X Y\) coordinates of \(Z\) data. Initially, this uses marker number zero. You can change this using the Modify Trace Appearance dialog.

Applies to contours in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{ModifyControl}

ModifyControl [/Z] ctrlName [keyword = value [, keyword = value ...]]
The ModifyControl operation modifies the named control. ModifyControl works on any kind of existing control. To modify multiple controls, use ModifyControlList.

\section*{Parameters}
ctrlName specifies the name of the control to be created or changed. The control must exist.

\section*{Keywords}

The following keyword=value parameters are supported:
\begin{tabular}{llllll} 
activate & appearance & bodywidth & disable & fColor & font \\
fSize & fStyle & help & labelBack & noproc & pos \\
proc & rename & size & title & userdata & valueBackColor \\
valueColor & win & & & &
\end{tabular}

For details on these keywords, see the documentation for SetVariable on page V-641. The following keywords are not supported:
\begin{tabular}{lcc:c} 
mod & popmatch palue & variable \\
Flags & & \\
\(/ Z\) & No error reporting. &
\end{tabular}

\section*{Details}

Use ModifyControl to move, hide, disable, or change the appearance of a control without regard to its kind

\section*{Example}

Here is a TabControl procedure that shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are.
The "trick" here is that all controls that are to be shown within particular tab \(n\) have been assigned names that end with "_tabn" such as "_tab0" and "_tab1":
Function TabProc (ctrlName,tabNum) : TabControl
String ctrlName
Variable tabNum
String curTabMatch= "*_tab"+num2istr(tabNum)
String controls= ControlNameList("")
Variable i, \(\mathrm{n}=\) ItemsInList (controls)
for (i=0; i<n; i+=1)
String control= StringFromList(i, controls)
Variable isInATab= stringmatch(control,"*_tab*") if ( isInATab )

Variable show= stringmatch (control,curTabMatch)
ControlInfo \$control // gets V_disable
if ( show )
V_disable= V_disable \& ~0x1 // clear the hide bit
else
V_disable= V_disable | 0x1 // set the hide bit
endi \(\bar{f}\)
ModifyControl \$control disable=V_disable endif
endfor
return 0
End
```

// Action procedures which enable or disable the buttons
Function TablCheckProc(ctrlName,enableButton) : CheckBoxControl
String ctrlName
Variable enableButton
ModifyControl button_tab1, disable=(enableButton ? 0 : 2 )
End
Function Tab0CheckProc(ctrlName,enableButton) : CheckBoxControl
String ctrlName
Variable enableButton
ModifyControl button_tab0, disable=(enableButton ? 0 : 2 )
End
// Panel macro that creates a TabControl using TabProc
Window TabbedPanel() : Panel
PauseUpdate; Silent 1 // building window...
NewPanel /W=(381,121,614,237) as "Tab Demo"
TabControl tab, pos={12,9}, size={205,91},proc=TabProc,tabLabel(0)="Tab 0"
TabControl tab, tabLabel(1)="Tab 1",value= 0
Button button_tab0, pos={54,39}, size={110,20},disable=2
Button button tab0, title="Button in Tabo"
Button button_tab1, pos={54,63}, size={110,20}, disable=1
Button button_tab1, title="Button in Tab1"
CheckBox check1_tab1, pos={51,41}, size={117,14}, disable=1, value= 1
CheckBox check1_tab1, proc=TablCheckProc, title="Enable Button in Tab 1"
CheckBox check0_tab0, pos={51,73}, size={117,14}, proc=Tab0CheckProc
CheckBox check0_tab0, value= 0, title="Enable Button in Tab 0"
EndMacro
Run TabbedPanel to create the panel. Then click on "Tab 0" and "Tab 1" to run TabProc.
See Also

Related functions ModifyControlList and ControlNameList.
The Button, Chart, CheckBox, GroupBox, ListBox, PopupMenu, SetVariable, Slider, TabControl, TitleBox, and ValDisplay controls.

```

\section*{ModifyControlList}

ModifyControlList [/Z] listStr [, keyword = value]...
The ModifyControlList operation modifies the controls named in the listStr string expression.
ModifyControlList works on any kind of existing control.

\section*{Parameters}
listStr is a semicolon-separated list of names in a string expression. The expression can be an explicit list of control names such as "button0;checkbox1;" or it can be any string expression such as a call to the ControlNameList string function:
ModifyControlList ControlNameList("",";","*_tab0") disable=1
The controls must exist.

\section*{Keywords}

The following keyword=value parameters are supported:
\begin{tabular}{llllll} 
activate & appearance & bodywidth & disable & fColor & font \\
fSize & fStyle & help & labelBack & noproc & pos \\
proc & rename & size & title & userdata & valueBackColor \\
valueColor & win & & & &
\end{tabular}

For details on these keywords, see the documentation for SetVariable on page V-641.
The following keywords are not supported:
mod popmatch popvalue value variable

Flags
No error reporting.

\section*{Details}

Use ModifyControlList to move, hide, disable, or change the appearance of multiple controls without regard to their kind.
If listStr contains the name of a nonexistent control, an error is generated.
if listStr is " " (or any list element in listStr is " "), it is ignored and no error is generated.

\section*{Example}

Here is the TabControl procedure example from ModifyControl rewritten to use ModifyControlList. It shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are, but the code is simpler. This method does not, however, preserve the enable bit when a control is hidden.

The "trick" here is that all controls that are to be shown within particular tab \(n\) have been assigned names that end with "_tabn" such as "_tab0" and "_tab1":
```

// Action procedure
Function TabProc2(ctrlName,tabNum) : TabControl
String ctrlName
Variable tabNum
String controlsInATab= ControlNameList("",";","*_tab*")
String curTabMatch= "*_tab"+num2istr(tabNum)
String controlsInCurTa\overline{b}= ListMatch(controlsInATab, curTabMatch)
String controlsInOtherTabs=ListMatch(controlsInATab,"!"+curTabMatch)
ModifyControlList controlsInOtherTabs disable=1 // hide
ModifyControlList controlsInCurTab disable=0 // show
return 0
End
// Panel macro that creates a Tabcontrol using TabProc2():
Window TabbedPanel2() : Panel
PauseUpdate; Silent 1 // building window...
NewPanel /W= (35,208,266,374) as "Tab Demo"
TabControl tab, pos={12,9}, size={205,140},proc=TabProc2
TabControl tab,tabLabel(0)="Tab 0"
TabControl tab,tabLabel(1)="Tab 1",value= 0
Button button_tab0,pos={26,43},size={110,20},title="Button in Tab0"
Button button\overline{2}_tab0,pos={26,74}, size={110,20}, title="Button in Tabo"
Button button3-tab0,pos={26,106},size={110,20},title="Button in Tabo"
Button button_\overline{tab1,pos={85,43}, size={110,20}, title="Button in Tab1"}
Button button2_tab1, pos={85,75}, size={110,20},title="Button in Tab1"
Button button3-tab1,pos={84,108}, size={110,20},title="Button in Tab1"
ModifyControlLíst ControlNameList("",";","*_tabl") disable=1
EndMacro
Run TabbedPanel2 and then click on "Tab 0" and "Tab 1" to run TabProc2.

```

Related functions ModifyControl and ControlNameList.
The Button, Chart, CheckBox, GroupBox, ListBox, PopupMenu, SetVariable, Slider, TabControl, TitleBox, and ValDisplay controls.

\section*{ModifyFreeAxis}

ModifyFreeAxis [/W=winName] axisName, master=mastName
[, hook=funcName]
The ModifyFreeAxis operation designates the free axis (created with NewFreeAxis) to follow a controlling axis from which it gets axis range and units information. The free axis updates whenever the controlling axis changes. The axis limits and units can be modified by a user hook function.

\section*{Parameters}
axisName is the name of the free axis (which must have been created by NewFreeAxis).
masterName is the name of the master axis controlling axisName.
funcName is the name of the user function that modifies the limits and units properties of the axis. If funcName is \(\$ "\) ", the named hook function is removed.

\section*{Flags}
\(/ \mathrm{W}=\) winName \(\quad\) Modifies axisName in the named graph window or subwindow. If / W is omitted the command affects the top graph window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Details}

The free axis can also be designated to call a user-defined hook function that can modify limits and units properties of the axis. The hook function must be of the following form:
```

Function MyAxisHook(info)
STRUCT WMAxisHookStruct \&info
<code to modify graph units or limits>
return 0
End

```
where WMAxisHookstruct is a built-in structure with the following members:

\section*{WMAxisHookStruct Structure Members}

\section*{Member Description}
\begin{tabular}{ll}
\hline char win [MAX_WIN_PATH+1] & Host (sub)window. \\
char axName[MAX_OBJ_NAME+1] & Name of the axis. \\
char mastName [MAX_OBJ_NAME+1] & Name of controlling axis or nil. \\
char units [MAX_UNITS+1] & Axis units. User modifiable. \\
double min, max & Axis range minimum and maximum values. User modifiable.
\end{tabular}

The constants used to size the char arrays are internal to Igor and are subject to change in future versions.
The hook function is called when refreshing axis range information (generally early in the update of a graph). Your hook must never kill a graph or an axis.

\section*{Example}

This example demonstrates how to program a free axis hook function, whose most important task is to change the values of info.min and info.max to alter the axis range of the free axis. The example free axis displays Fahrenheit values for data in Celsius.
```

Function CentigradeAndFahrenheit()
Make/O/N=20 temperatures = -2+p/3+gnoise(0.5) // sample data
Display temperatures// default left axis will indicate data's centigrade range
String graphName = S_name
Label/W=$graphName left "oc"
    ModifyGraph/W=$graphName zero(left)=1
Legend/W=$graphName
    // make a right axis whose range will be Fahrenheit
    NewFreeAxis/R/O/W=$graphName fahrenheit
ModifyGraph/W=$graphName freePos(fahrenheit)={0,kwFraction},lblPos(fahrenheit)=43
    Label/W=$graphName fahrenheit "oF"
ModifyFreeAxis/W=$graphName fahrenheit, master=left, hook=CtoF_FreeAxisHook
    // NOTE master=left part which makes the "free" axis
    // actually a "slave" to the left ("master") axis.
End
Function CtoF_FreeAxisHook(info)
    STRUCT WMAXisHookStruct &info
    GetAxis/Q/W=$info.win \$info.mastName // get master axis range in V_min, V_Max

```
```

    Variable minF = V_min*9/5+32
    Variable maxF = V_max*9/5+32
    // SetAxis/W=\$info.win \$info.axName, minF, maxF
// SetAxis here is fruitless. These values get overwritten by Igor
// after reading info.min and info.max, which we now set:
info.min = minF // new min for free axis
info.max= maxF // new max for free axis
return 0
End

```

\section*{See Also}
```

The SetAxis, KillFreeAxis, and NewFreeAxis operations.
The ModifyGraph (axes) operation for changing other aspects of a free axis.

```

\section*{ModifyGraph (general)}

ModifyGraph [/W=winName/Z] key=value [, key=value]...
The ModifyGraph operation modifies the target or named graph. This section of ModifyGraph relates to general graph window settings.

\section*{Parameters}
\begin{tabular}{|c|c|}
\hline \multirow[t]{3}{*}{expand=e} & Specifies the onscreen expansion (or magnification) factor of a graph. e may be zero or 0.125 to 8 times expansion. \\
\hline & Graph magnification affects only base graphs (not subwindowed graphs), and it affects only the onscreen display; it has no effect on graph exporting or printing. \\
\hline & When magnification changes, the graph window will automatically resize except for negative values, which are used in recreation macros where the size is already correct. \\
\hline frameInset \(=i\) & Specifies the number of pixels by which to inset the frame of the graph subwindow. \\
\hline \multirow[t]{9}{*}{frameStyle \(=f\)} & Specifies the frame style for a graph subwindow. \\
\hline & \(f=0: \quad\) None. \\
\hline & \(f=1: \quad\) Single. \\
\hline & \(f=2: \quad\) Double. \\
\hline & \(f=3\) : \(\quad\) Triple. \\
\hline & \(f=4\) : \(\quad\) Shadow. \\
\hline & \(f=5: \quad\) Indented. \\
\hline & \(f=6: \quad\) Raised. \\
\hline & \(f=7: \quad\) Text well. \\
\hline
\end{tabular}

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the graph itself is a light shade of gray.

Multiplies font and marker size by \(f\) percent. Clipped to between \(25 \%\) and \(400 \%\); it is applied after all other font and marker size calculations.
Specifies the name of the default font for the graph, overriding the normal default font. The normal default font for a subgraph is obtained from its parent while a base graph uses the value set by the DefaultFont operation.
gfSize \(=g f s \quad\) Sets the default size for text in the graph. Normally, the default size for text is proportional to the graph size; gfSize will override that calculation as will the gfRelSize method. Use a value of -1 to make a subgraph get its default font size from its parent.
gfRelSize=pct
gmSize \(=g m s\)
height=heightSpec
swap \(X Y=s\)
useComma=uc
useLongMinus= \(m\)
width=widthSpec

Specifies the percentage of the graph size to use in calculating a default size for text in the graph. This overrides the normal method for setting default font size as a function of graph size. When used, the default marker size is set to one third the font size. Use a value of 0 to revert to the default method.

Sets the default size for markers in the graph. Use a value of -1 to make a subgraph get its default marker size from its parent.
Sets the height for the graph area. See the Examples.
Sets the orientation of the X and Y axes.
\[
s=0: \quad \text { Normal orientation of } X \text { and } Y \text { axes. }
\]
\(s=1: \quad\) Swap \(X\) and \(Y\) values to plot \(Y\) coordinates versus the horizontal axes and \(X\) coordinates versus the vertical axes. The effect is similar to mirroring the graph about the lowerleft to upper-right diagonal.

Controls the decimal separator used in tick mark labels.
\(u c=0: \quad\) Use period as decimal separator and comma as thousands separator (default) when displaying numbers in graph labels and annotations.
\(u c=1: \quad\) Use comma as decimal separator and period as the thousands separator. This does not alter the presentation of numbers in \(\backslash\{\) expression \(\}\) constructs in annotations.

Uses a normal ( \(m=0\); default) or long dash \((m=1)\) for the minus sign.
Sets the width of the graph area. See the examples.

\section*{Flags}
/W=winName Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
/Z Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

\section*{Examples}

The following code creates a graph where all the text expands and contracts directly in relation to the window size:
```

Make jack=sin(x/8);display jack
ModifyGraph mode=4,marker=8,gfRelSize= 5.0
TextBox/N=text0/A=MC "Some <br>Zr200big<br>]0 and <br>Zr050small<br>\0\rtext"

```

The widthSpec and heightSpecs set the width and height mode for the top graph. The following examples illustrate how to specify the various modes.
```

ModifyGraph width=0, height=0
Variable n=72*5
ModifyGraph width=n
ModifyGraph height=n

```

Set to auto height, width mode. The width, height of horizontal and vertical axes are automatically determined based on the overall size of the graph and other factors such as axis offset setting and effect of exterior textboxes. This is the normal, default mode.

Five inches as points absolute width mode, horizontal axis width constrained to \(n\) points.
Absolute height mode, \(n\) is in points. The height of the vertical axes is constrained to \(n\) points.
ModifyGraph
width={perUnit, n, bottom}
ModifyGraph height={Aspect,n}
ModifyGraph
width={Plan,n,bottom,left}
```

```
```

Variable n=2

```
```

```
Variable n=2
```

Per unit width mode. The width of the horizontal axes is $n$ points times the range of the bottom axis.

Aspect height mode, $n=$ aspect ratio. The height of the vertical axes is n times the width of the horizontal axes.

Plan width mode. The width of the horizontal axes is n times the height of the vertical axes times range of the bottom axis divided by the range of the left axis.

## ModifyGraph (traces)

ModifyGraph [/W=winName/Z] key [(traceName)] = value [, key [(traceName)] = value]...
This section of ModifyGraph relates to modifying the appearance of wave "traces" in a graph. A trace is a representation of the data in a wave, usually connected line segments.

## Parameters

Each key parameter may take an optional traceName enclosed in parentheses. Usually traceName is simply the name of a wave displayed in the graph, as in "mode (myWave) $=4$ ". If "(traceName)" is omitted, all traces in the graph are affected. For instance, "ModifyGraph 1Size $=0.5$ " sets the lines size of all traces to 0.5 points.
For multiple trace instances, traceName is followed by the " $\#$ " character and instance number. For example, "mode (myWave\#1) $=4$ ". See Instance Notation on page IV-16.
A string containing a trace name can be used with the $\$$ operator to specify traceName. For example, String MyTrace="myWave\#1"; mode (\$MyTrace)=4.
Though not shown in the syntax, the optional "(traceName)" may be replaced with " $[$ traceIndex]", where traceIndex is zero or a positive integer denoting the trace to be modified. " $[0]$ " denotes the first trace appended to the graph, " $[1]$ " denotes the second trace, etc. This syntax is used for style macros, in conjunction with the $/ \mathrm{Z}$ flag.
For certain modes and certain properties, you can set the conditions at a specific point on a trace by appending the point number in square brackets after the trace name. For more information, see the Customize at Point on page V-462. This feature was added in Igor Pro 6.20.
The parameter descriptions below omit the optional "(traceName)". When using ModifyGraph from a userdefined function, be careful not to pass wave references to ModifyGraph. ModifyGraph expects trace names, not wave references. See Trace Name Parameters on page IV-72 for details.
arrowMarker=0
arrowMarker=\{aWave, lineThick, headLen, headFat, posMode [, barbSharp=b, barbSide=s, frameThick=f]\}
Draws arrows instead of conventional markers at each data point in a wave. Arrows are not clipped to the plot area and will be drawn wherever a data point is within the plot area.
aWave contains arrow information for each data point. It is a two (or more) column wave containing arrow line lengths (in points) in column 0 and angles (in radians measured counterclockwise) in column 1. Zero angle is a horizontal arrow pointing to the right. If an arrow is below the minimum length of 4 points, a default marker is drawn.
You can change arrow markers into standard meteorological wind barbs by adding a column to aWave and giving it a column label of windBarb. Values are integers from 0 to 40 representing wind speeds up to 4 flags. Use positive integers for clockwise barbs and negative for the reverse. Use NaN to suppress the drawing. See Wind Barb Plots on page II-303 for an example.
Additional columns may be supplied in aWave to control parameters on a point by point basis. These optional columns are specified by dimension label and not by specific column numbers. The labels are lineThick, headLen, and headFat that correspond to the same parameters listed above.
lineThick is the line thickness in points.
headLen is the arrow head length in points.
headFat controls the arrow fatness. It is the width of the arrow head divided by the length.
posMode specifies the arrow location relative to the data point.
posMode=0: $\quad$ Start at point.
posMode=1: $\quad$ Middle on point.
posMode=2: End at point.
In addition to the wave specification, aWave can also be the literal _inline_to draw lines and arrows between points on the trace (see Examples). If aWave is _inline_, posMode values are:
posMode=0: Arrow at start.
posMode=1: Arrow in middle.
posMode=2: $\quad$ Arrow at end.
posMode=3: Arrow in middle pointing backwards.
You can also enable inline mode even if aWave is not inline_ by setting posMode to values between 4 and 7 . These are the same as modes 0-3 above.
Optional parameters must be specified using keyword = value syntax and can only be appended after posMode in any order.
barbSharp is the continuously variable barb sharpness between -1.0 and 1. 0:
barbSharp=1: No barb; lines only.
barbSharp=0: Blunt (default).
barbSharp=-1: Diamond.
barbSide specifies which side of the line has barbs relative to a right-facing arrow:
barbSide=0: None.
barbSide=1: Top.
barbSide=2: Bottom.
barbSide=3: Both (default).
frameThick specifies the stroke outline thickness of the arrow in points. The default is frameThick $=0$ for solid fill.
aWave can contain columns with data for each optional parameter using matching column names.
barStrokeRGB $=(r, g, b)$
Specifies a separate color for bar strokes (outlines) if useBarStrokeRGB is 1. $r, g$ and $b$ specify the amount of red, green and blue in the color of the stroked lines as an integer from 0 to 65535 . The default is black $(0,0,0)$.
Applies only to Histogram Bars drawing mode (mode=5).
The bar fill color continues to be set with the $\mathrm{rgb}=(r, g, b)$, $\mathrm{zColor}=\{\ldots\}$, usePlusRGB, plusRGB $=(r, g, b)$, useNegRGB, and negRGB $=(r, g, b)$ parameters.

Use barStrokeRGB and useBarStrokeRGB to put a differently-colored outline around Histogram Bars:

useBarStrokeRGB=0

useBarStrokeRGB=1
cmplxMode=c Display method for complex waves.

$$
\begin{array}{ll}
c=0: & \text { Default mode displays both real and imaginary parts (imaginary } \\
& \text { part offset by } \mathrm{d} x / 2) . \\
c=1: & \text { Real part only. } \\
c=2: & \text { Imaginary part only. } \\
c=3: & \text { Magnitude. } \\
c=4: & \text { Phase (radians). }
\end{array}
$$

cmplxMode=0 does not work when the trace is a subrange of a multi-dimensional wave.
column $=n \quad$ Changes the displayed column from a matrix. Out of bounds values are clipped.
gaps $=g \quad$ Controls treatment of $\mathrm{NaNs}:$
$g=0: \quad$ No gaps (ignores NaNs ).
$g=1: \quad$ Gaps (shows NaNs as gaps).
hBarNegFill= $n \quad$ Fill kind for negative areas if useNegPat is true. $n$ is the same as for the hbFill keyword.
hbFill $=n \quad$ Sets the fill pattern.
$n=0: \quad$ No fill.
$n=1$ : $\quad$ Erase.
$n=2: \quad$ Solid black.
$n=3: \quad 75 \%$ gray.
$n=4: \quad 50 \%$ gray.
$n=5: \quad 25 \%$ gray.
$n=6$ through 77 selects one of the 72 fill patterns:

| hideTrace $=h$ | Removes a trace from the graph display. |
| :--- | :--- |
| $h=0:$ | Shows the trace if it is hidden. |
| $h=1:$ | Hides the trace and removes it from autoscale calculations. |
| $h=2:$ | Hides the trace. |

When using $h=1$ to hide a graph trace, the hidden trace symbol and following text in annotations are also hidden. The amount of hidden text is the lesser of: the remaining text on the same line or the text up to but not including another trace symbol "\s (traceName)".
1Hair=lh Sets the hairline factor for traces printed on a PostScript® printer.
live $=l v \quad$ Turns Live Mode off $(l v=0)$ or on $(l v=1)$.
$\log Z$ Color $=l z c \quad$ Controls the interpretation of the $z$ Color parameter.
$l z c=0$ : $\quad$ Sets the default linearly-spaced $z$ Colors.
$l z c=1: \quad$ Turns on logarithmically-spaced zColors. This requires that the zWave values be greater than 0 to display correctly.
Affects trace line color only when the zColor parameter is used with a color table or color index wave - it has no effect if $\operatorname{rgb}=(r, g, b)$ parameter or zColor=\{...,directRGB\} are used.
$\log Z C o l o r$ was added in Igor Pro 6.22.
lOptions=options options is a bitwise parameter:
Bit 0: If set, dashed lines use round end caps. If cleared they use square end caps.
All other bits are reserved and must be cleared.
See Setting Bit Parameters on page IV-12 for details about bit settings.
Size=l Sets the line thickness, which can be fractional or zero, which hides the line.
1 Smooth $=l s \quad$ Sets the smoothing factor for traces printed on a PostScript ${ }^{\circledR}$ printer.
1Style=s Sets trace line style or dash pattern.
$s=0$ for solid lines. $s=1$ to $s=17$ for various dashed line styles.

marker $=n \quad \mathrm{n}=0$ to 62 designates various markers if mode $=3$ or 4.
Markers 51 through 62 require Igor Pro 6.1 and are available in new graphics only (see Graphics Technology). You can also create custom markers. See the SetWindow markerHook keyword.
See Markers on page II-253 for a table of marker values.
mask $=\{$ maskwave,mode,value $\}$ or 0

Specifies individual points for display by comparing values in maskWave with value as specified by mode.
mode $=0$ : $\quad$ Exclude if equal.
mode=1: Include if equal.
mode=2: Include if bitwise AND is true.
mode=3: Include if bitwise AND is false.
maskwave can be specified using subrange notation. The length of maskwave (or subrange) must match the size of specified trace's wave (or subrange.) Bitwise modes should be used with integer waves with the intent of using one mask wave with multiple traces. See Examples.
mode $=m \quad$ Sets trace display mode.

| $m=0:$ | Lines between points. |
| :--- | :--- |
| $m=1:$ | Sticks to zero. |
| $m=2:$ | Dots at points. |
| $m=3:$ | Markers. |
| $m=4:$ | Lines and markers. |
| $m=5:$ | Histogram bars. |
| $m=6:$ | Cityscape. |
| $m=7:$ | Fill to zero. |
| $m=8:$ | Sticks and markers. |

mrkStrokeRGB $=(r, g, b)$
Specifies the color for marker stroked lines if useMrkStrokeRGB $=1 . r, g$, and $b$ values are the amount of red, green, and blue in the color of the lines as an integer from 0 to 65535 . The default is black $(0,0,0)$.
The marker fill color continues to be set with the $\operatorname{rgb}=(r, g, b)$ or $\mathrm{zColor}=\{\ldots\}$ parameters.
Applies only to the nontext and nonarrow marker modes.
Use mrkStrokeRGB and useMrkStrokeRGB to put a colored outline around filled markers, such as marker=19:

useMrkStrokeRGB=0

useMrkStrokeRGB=1

Note: The stroke color of unfilled markers such as marker 8 is also affected by mrkStrokeRGB, but their fill color is only affected by the opaque parameter (and the opaque fill color is always white, so if you want a color-filled marker, don't use unfilled markers).
mrkThick $=t \quad$ Sets the thickness of markers in points, which can be fractional.
Specifies the marker size in points.
$m=0$ : Autosize markers.
$m>0$ : $\quad$ Sets marker size.
$m$ can be fractional, which will only make a difference when the graph is printed because fractional points can not be displayed on the screen.

| mskip $=n$ | Puts a marker on only every $n$th data point in Lines and Markers mode (mode=4). Useful for displaying many data points when you want to identify the traces with markers. The maximum value for $n$ is 32767 . |
| :---: | :---: |
| muloffset=\{mx,my\} | Sets the display multiplier for $\mathrm{X}(m x)$ and $\mathrm{Y}(m y)$. The effective value for a given X or Y data point then becomes muloffset*data+offset. A value of zero means "no multiplier" - not multiply by zero. |
| negRGB $=(r, g, b)$ | Specifies the color for negative areas if useNegRGB is $1 . r, g$, and $b$ specify the amount of red, green, and blue in the color of the trace as an integer from 0 to 65535. |
| offset $=\{x, y\}$ | Sets the display offset in horizontal ( X ) and vertical ( Y ) axis units. |
| opaque $=0$ | Displays transparent ( $o=0$ ) or opaque ( $o=1$ ) markers. |
| patBkgColor= 0, 1, 2 or (r,g,b) |  |
|  | Specifies the background color for fill patterns. |
|  | 0 , the default, is white, 1 is graph background, 2 is transparent (does not work when exporting in the Enhanced Metafile or Windows Metafile formats). |
|  | Use ( $\mathrm{r}, \mathrm{g}, \mathrm{b}$ ) for a specific RGB color. |
| plotClip $=p$ | $p=1$ clips the trace by the operating system (not by Igor) to the plot rectangle. This trims overhanging markers and thick lines. On Windows, this may not be supported for certain printers or by certain applications when importing. |
| plusRGB $=(r, g, b)$ | Specifies the color for positive areas if usePlusRGB is $1 . r, g$, and $b$ specify the amount of red, green, and blue in the color of the trace as an integer from 0 to 65535. |
| quickdrag=q | Controls dragging of traces. |
|  | $q=0: \quad$ Normal traces. |
|  | $\begin{array}{ll} q=1: \quad \begin{array}{l} \text { Traces that can be instantly dragged without the normal one second } \\ \text { delay. See the Quickdrag section below. } \end{array} \end{array}$ |
|  | $\begin{aligned} & q=2: \quad \begin{array}{l} \text { Causes the mouse cursor to change to } 4 \text { arrows when over the trace } \\ \text { and a reduced search is used. } \end{array} \end{aligned}$ |
| $\operatorname{rgb}=(r, g, b)$ | Specifies the amount of red, green, and blue ( $r, g$, and $b$ ) in the color of the trace as an integer from 0 to 65535. |
| textMarker=\{<char | wave>,font,style,rot,just, $x$ Offset,yOffset\} or 0 |

Uses the specified character or text from the specified wave in place of the marker for each point in the trace.
If the first parameter is a quoted string or a string expression of the form " "+strexpr in a user function, ModifyGraph uses the first three bytes of the string as the marker for all points (three bytes are provided mainly for multi-byte Asian fonts but can be used for 3 separate one byte characters). Otherwise, it interprets the first parameter as the name of a wave. If the wave is a text wave, it uses the value of each point in the text wave as the marker for the corresponding point in the trace. If the wave is a numeric wave, the value for each point is converted into text and the result is used as the marker for the corresponding point in the trace.
$x$ Offset and $y O f f s e t$ are offsets in fractional points. Each marker will be drawn offset from the location of the corresponding point in the trace by these amounts.
style is a font style code as used with the ModifyGraph fstyle keyword.
rot is a text rotation between -360 and 360 degrees.
just is a justification code as used in the DrawText operation except the $X$ and $Y$ codes are combined as $y^{*} 4+x$. Use 5 for centered.

The font size is $3^{*}$ marker size. Note that marker size and color can be dynamically set via the zColor and zmrkSize keywords.
toMode $=t$
Modifies the behavior of the display modes as determined by the mode parameter.
$t=0: \quad$ Fill to zero.
$t=1: \quad$ Fill to next trace. Applies to Sticks to zero (mode=1), histogram bars ( mode=5), and fill to zero (mode=7).
$t=2: \quad$ Add the current trace's $Y$ values to the next trace's $Y$ values. Works with all display modes.
$t=3$ : $\quad$ Stack on next and is the same as $t=2$ except that the added value is clipped to zero. Works with all display modes.
$t=-1: \quad$ This mode is used only with category plots and means "keep with next" (i.e., put in the same subcategory as the next trace). It is used for special effects only.
For modes 1, 2 and 3, both Y-waves must have the same number of points and must use the same $X$ values. Igor uses the $X$ values from the first wave for both $Y$ -
useBarStrokeRGB=u
If $u=1$ then bar stroked lines use the color specified by the barStrokeRGB keyword. Applies only to Histogram Bars drawing mode (mode=5).
The bar fill color continues to be set with the $\operatorname{rgb}=(r, g, b)$, $\mathrm{zColor}=\{\ldots\}$, usePlusRGB, plusRGB $=(r, g, b)$, useNegRGB, and negRGB $=(r, g, b)$ parameters.
If $u=0$ then the bar stroked line colors are set with the $\operatorname{rgb}=(r, g, b)$ or $\mathrm{zColor}=\{\ldots\}$ parameters, just like the bar fill color.
useMrkStrokeRGB=u
If $u=1$ then marker stroked lines use the color specified by the mrkStrokeRGB keyword. The marker fill color continues to be set with the $\operatorname{rgb}=(r, g, b)$ or $z C o l o r=\{\ldots\}$ parameters.
Applies only to the nontext and nonarrow marker modes.
If $u=0$ then the marker stroked line colors are set with the $\operatorname{rgb}=(r, g, b)$ or $z$ Color $=\{\ldots\}$ parameters, just like the marker fill color.
useNegPat= $u \quad$ If $u=1$, negative fills use the mode specified by the hBarNegFill keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.
useNegRGB $=u \quad$ If $u=1$, negative fills use the color specified by the negRGB keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.
usePlusRGB $=u \quad$ If $u=1$, positive fills use the color specified by the plusRGB keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.
userData $=\{$ udName, doAppend, data $\}$
Attaches arbitrary data to a trace. You should specify a trace name (userData(<traceName>)=\{...\}). Otherwise copies of the data will be attached to every trace, which is most likely not what you intend.

Use the GetUserData function to retrieve the data, with the trace name as the object ID.
udName: The name of your user data. Use $\$$ "" for unnamed user data.
doAppend=0: Do not append. Any pre-existing data is replaced.
doAppend $=1$ : Append the data. Data is added to the end of any pre-existing data.
data: A string expression containing the data you wish to attach to the trace.
zColor=\{zWave,zMin,zMax,ctName [,reverseMode [,ciWave]]\} or 0

Dynamically sets color based on the values in $z$ Wave and color table specified by $\operatorname{ctName}$. Use * or a missing parameter for $z$ Min and $z M a x$ to autoscale. See color index mode, below, for usage of $c i$ Wave.
$z$ Wave may be a subrange expression such as myZWave $[2,9]$ when $z$ Wave has more points than the trace, in which case myZWave [2] provides the $Z$ value for the first point of the trace, and autoscaled $z$ Min or $z M a x$ is determined over only the $z$ Wave subrange.
If a value in the $z$ Wave is NaN then a gap or missing marker will be observed. If a value is out of range it will be replaced with the nearest valid value. See also the zColorMax and zColorMin keywords.
ctName can be any color table name returned by the CTabList function, such as Grays or Rainbow (for color table mode), or it can be cindexRGB for color index mode, or directRGB for direct color mode.
For color table mode, set the reverseMode parameter to 1 to reverse the color table; zero sets the color table to unreversed. A reverseMode value of -1 (or if reverseMode is missing) leaves the color table reverse state unchanged. Also see Color Table Details on page II-363.
Normally the colors from the color table are linearly distributed between $z$ Min and $z M a x$. Use $\log Z C o l o r=1$ to distribute them logarithmically.
The $z$ Min and $z M a x$ parameters are not used and should be set to ${ }^{*}$. Set $c t$ Name to cindexRGB and reverseMode to 0 .

Specify a 3 column wave of RGB values for ciWave (not for $z$ Wave). The $z$ Wave values select the color from the row of ciWave whose X scaling is closest to the $z$ Wave value.
Example color table zColor command:
zColor (data) $=\{$ myZWave $[2,9], *, *, R a i n b o w, 1\}$
You can directly specify the color of each point in a trace by using directRGB for ctName. In this case, $z$ Wave is a 3 column wave of RGB values (column 0 is red, 1 is green, and 2 is blue) corresponding to each point in the trace. If $z$ Wave is 8 -bit unsigned integer, then color values range from 0 to 255 ; for other numeric types color values range from 0 to 65535 . The $z M i n$ and $z M a x$ parameters are not used and should be set to *. Also see the ColorTab2Wave operation (which generates such a wave) and Indexed Color Details on page II-366.
Example directRGB zColor command:

```
zColor(data) ={zWaveRGB,*,*,directRGB }
```

Color index mode uses both a $z$ Wave and a three-column RGB color index wave. See Color Index Wave on page II-336.

The $z$ Min and $z M a x$ parameters are not used and should be set to *, set ctName to cindexRGB. Specify a value for reverseMode, 0 for normal, 1 for reversed color indexing. Specify a a 3 column wave of RGB values for ciWave (not for $z$ Wave). Normally, the zWave values select the color from the row of ciWave whose X scaling is closest to the $z$ Wave value. ReverseMode $=1$ reverses the colors.
Example cindexRGB zColor command:
zColor (data) = \{myZWave, *, *, cindexRGB, 0, M_colors $\}$
(M_colors is generated by the ColorTab2Wave.)
$z$ Color $=0$ turns the $z$ Color modes off.
Normally the colors from the color index wave are linearly distributed between minimum and maximum $X$ scaling of the color index wave. Use $\log Z C o l o r=1$ to distribute them logarithmically.

Sets the color of the trace for $z$ Color $=\{z$ Wave,...$\}$ values greater than the $z$ Color's $z M a x$. Also turns on zColorMax mode.
The red, green, and blue color values are in the range of 0 to 65535.
zColorMax=1, 0 , or NaN
Turns zColorMax mode off, on, or transparent. These modes affect the color of zColor $=\{z$ Wave, ...\} values greater than the zColor's $z M a x$.
1: Turns on $z$ ColorMax mode. The color of the affected trace pixels is black or the last color set by zColorMax=(red, green, blue).
0: $\quad$ Turns off zColorMax mode (default). The color of the affected trace pixels is the last color in the zColor's ctname color table.
NaN: Transparent zColorMax mode. Affected trace pixels are not drawn.
zColorMin=(red, green, blue)
Sets the color of the trace for $z$ Color= $=\{$ Wave, ...\} values less than the zColor's zMin. Also turns zColorMin mode on.
The red, green, and blue color values are in the range of 0 to 65535 .
zColorMin=1, 0 , or NaN
Turns zColorMin mode off, on, or transparent. These modes affect the color of zColor=\{zWave, ...\} values less than the zColor's zMin.
1: Turns on $\quad$ ColorMin mode. The color of the affected image pixels is black or the last color set by zColorMin=(red, green, blue).
0: $\quad$ Turns off zColorMin mode (default). The color of the affected trace pixels is the first color in the zColor's ctname color table.
$\mathrm{NaN}: \quad$ Transparent $z$ ColorMin mode. Affected trace pixels are not drawn.
zmrkNum=\{zWave $\}$ or 0
Dynamically sets the marker number for each point to the corresponding value in $z$ Wave. The values in $z$ Wave are the marker numbers (as used with the marker keyword). If a value in the $z$ Wave is NaN then no marker will be drawn at the corresponding point. If a value is out of range it will be replaced with the nearest valid value.
zmrkNum=0 turns this mode off.
zmrkSize $=\{z$ Wave,zMin,zMax,mrkmin,mrkmax $\}$ or 0
Dynamically sets marker size based on values in $z$ Wave. Use * or a missing parameter for $z M i n$ and $z M a x$ to autoscale. mrkmin and mrkmax can be fractional. If a value in the $z$ Wave is NaN then a gap or missing mark will be observed. The marker size is clipped to 20 on the high end and 1 on the low end. If a value is out of range it will be replaced with the nearest valid value.
zmrkSize $=0$ turns this mode off.
zpatNum=\{zWave $\}$ or 0
Dynamically sets the positive fill type/pattern number for each point to the corresponding value in $z W a v e$. The values in $z W a v e$ are the pattern numbers (as used with the hbFill keyword). If a value in the $z$ Wave is NaN then the corresponding point will not be drawn. If a value is out of range it will be replaced with the nearest valid value.
zpatNum=0 turns this mode off.

## Flags

/W=winName
/Z

Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the Command Line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

## Details

Live Mode (live=1) improves graph update performance when one or more of the waves displayed in the graph is frequently modified, for example, if the waves are being acquired from a data acquisition system. Live Mode traces do not autoscale the axes.
Waves supplied with zmrkSize, zmrkNum, and zColor may use Subrange Display Syntax on page II-293.

## Quickdrag

Quick drag mode (quickdrag=1) is a special purpose mode for creating cross hair cursors using a package of Igor procedures. (See the Cross Hair Demo example experiment.) Normally you would have to click and hold on a trace for one second before entering drag mode. When quickdrag is in effect, there is no delay. If a trace is in quickdrag mode it should also be set to live mode. With this combination you can click a trace and immediately drag it to a new XY offset. In addition to quick drag mode, the cross hair package relies on Igor to store information about the drag in a string variable if certain conditions are in effect. The string variable name (that you have to create) is S_TraceOffsetInfo, which must reside in a data folder that has the same name as the graph (not title!) which in turn must reside in root:WinGlobals.. If these conditions are met, then after a trace is dragged, information will be stored in the string using the following key-value format: GRAPH:<name of graph>;XOFFSET:<x offset value>;YOFFSET:<y offset value>;TNAME:<trace name>;

## Customize at Point

You can customize the appearance of individual points on a trace in a graph for bar, marker, dot and lines to zero modes using key (tracename [pnt]) =value syntax. The point number must be a literal number and the trace name is not optional. To turn off a customization, use key (tracename [-pnt-1]) =value where value is not important but must match the syntax for the keyword. The offset of -1 is needed because point numbers start from zero.
Although the syntax is allowed for all trace modifiers, it has meaning only for the following: rgb, marker, msize, mrkThick, opaque, mrkStrokeRGB, barStrokeRGB, hbFill, patBkgColor and 1Size.
Note that useBarStrokeRGB and useMrkStrokeRGB are not needed. The act of using barStrokeRGB or mrkStrokeRGB is enough to customize the point. But as a convenience, since these are generated by the modify graph dialog, they are ignored if used with [pnt] syntax.
Also note that legend symbols can use [pnt] syntax like so:

```
\s(<tracename>[pnt])
```

Automatically generated legends automatically include symbols for customized points.
For example:

```
Make/O/N=10 jack=sin(x); Display jack
ModifyGraph mode=5,hbFill=6,rgb= (0,0,0)
ModifyGraph hbFill(jack[2])=7,rgb (jack[2])=(0,65535,0)
ModifyGraph rgb(jack[3])=(65535,0,0)
Legend/C/N=text1/F=0/A=MC
```

## Examples

Arrow markers.

```
Make/N=10 wave1= x; Display wave1
Make/N=(10,2) awave
awave[][0]= p*5 // length
awave[][1]= pi*p/9 // angle
ModifyGraph mode=3,arrowMarker(wave1)={awave,1,10,0.3,0}
```

```
// Now add an optional column to control headLen
Redimension/N=(-1,3) awave
awave[][2]= 7+p // will be head length
// Note: nothing changes until the following is executed
SetDimLabel 1,2,headLen, awave
Create meteorological wind barb symbols.
Make/O/N=50 jack= floor \((x / 10)\), jackx \(=\bmod (x, 10)\)
Display jack vs jackx
Make \(/ O / N=(50,3)\) jackbarb
jackbarb[][0] = \(40 \quad / /\) length of stem
jackbarb[][1]= 45*pi/180 // angle (45deg)
jackbarb[][2]= p \(/ /\) wind speed code
SetDimLabel 1,2, windBarb, jackbarb
ModifyGraph mode=3, arrowMarker \((\) jack \()=\{\) jackbarb, \(1,10,0.5,0\}\)
ModifyGraph margin (top) \(=62\), margin (right) \(=84\)
```

See also Wind Barb Plots on page II-303.
Inline arrows and barb sharpness.
Make/O/N=20 wavex=cos (x/3), wavey=sin (x)
Display wavey vs wavex
ModifyGraph mode=3, arrowMarker $=\{$ _inline_, $1,20, .5,0$, barbSharp $=0.2\}$
Use direct color mode to individually color each point in a trace:
Make jack=sin (x/8)
Make/N=(128,3)/B/U jackrgb
Display jack
ModifyGraph mode=3, marker=19
jackrgb= enoise(128)+128
ModifyGraph zColor (jack) =\{jackrgb,*,*, directRGB $\}$
Use masking.
Make/ $N=100$ jack= (p\&1) ? $\sin (x / 8): \cos (x / 8)$
Display jack
Make/N=100 mjack= (p\&1) ? $0: N a N \quad / /$ just to show NaN can be used
ModifyGraph mask (jack) $=\{$ mjack, $0, N a N\}$
// now switch which points are shown
mjack= (p\&I) ? NaN : 0

Trace Names on page II-243, Programming With Trace Names on page IV-72.

## ModifyGraph (axes)

ModifyGraph [/W=winName/Z] key [(axisName)] = value [, key [(axisName)] = value]...
This section of ModifyGraph relates to modifying the appearance of axes in a graph.

## Parameters

Each key parameter may take an optional axisName enclosed in parentheses.
axisName is "left", "right", "top", "bottom" or the name of a free axis such as "vertCrossing". For instance, "ModifyGraph axThick (left) $=0.5$ " sets the axis thickness for only the left axis.
If "(axisName)" is omitted, all axes in the graph are affected. For instance, "ModifyGraph standoff=0" disables axis standoff for all axes in the graph.
The parameter descriptions below omit the optional "(axisName)".
axisClip $=c \quad$ Specifies one of three clipping modes for traces.
$c=0$ : $\quad$ Clips traces to a plot rectangle as defined by the pair of axes used by a given trace (default).
$c=1$ : Plots traces on an axis with a restricted range (as set by axisEnab) to extend to the full range of the normal plot rectangle.
$c=2$ : $\quad$ Traces extend outside the normal plot rectangle to the full extent of the graph area.
axisEnab=\{lowFrac,highFrac $\}$
Restricts the length of an axis to a subrange of normal. The axis is drawn from lowFrac to highFrac of graph area height (vertical axis) or width (horizontal axis). For instance, $\{0.1,0.75\}$ specifies that the axis is drawn from $10 \%$ to $75 \%$ of the graph area height/width, instead of the normal $0 \%$ to $100 \%$. AxisEnab is discussed in Creating Split Axes on page II-303 and Creating Stacked Plots on page II-297.
axisOnTop $=t \quad$ Specifies drawing level of axis and associated grid lines.
$t=0$ : $\quad$ Draws axis before traces and images (default).
$t=1$ : Draws the axis after all traces and images.
$a x$ Offset $=a \quad$ Specifies the distance from default axis position to actual axis position in units of the width of a zero character (0) in a tick mark label. Unlike margin, axOffset adjusts to changes in the size of the graph.
axThick $=t \quad$ Specifies the axis thickness in points.
barGap=fraction Sets the fraction of the width available for bars to be used as gap between bars.
barGap sets the gap between bars within a single category while catGap sets the gap between categories.
btLen= $p \quad$ Sets the length of major (" $\mathrm{big}^{\prime \prime}$ ) tick marks to $p$ points. If $p$ is zero, it uses the default length. $p$ may be fractional.
btThick=p Sets the thickness of major ("big") tick marks to $p$ points. If $p$ is zero, it uses the default thickness. $p$ may be fractional.
catGap=fraction The value for catGap is the fraction of the category width to be used as gap. The gap is divided equally between the start and end of the category width. A value of 0.2 would use $20 \%$ of the available space for the gap and leave $80 \%$ of the available space for the bars.
catGap sets the gap between categories while barGap sets the gap between bars within a single category.
dateFormat=\{languageName, yearFormat, monthFormat, dayOfMonthFormat, dayOfWeekFormat, layoutStr, commonFormat $\}$

Sets the custom date format used in the active graph.
Note: Use a custom date format only if you turn it on via a ModifyGraph dateInfo command. The last parameter to the ModifyGraph dateInfo command must be -1 to turn on the custom date format.
Parameters are the same as for the LoadWave/R flag except for the last one.
commonFormat selects the common date format to use in the Modify Axis dialog. The legal values correspond to the choices in the Common Format pop-up menu of the Modify Axis dialog. They are:

| Value | Date Format | Value | Date Format |
| :--- | :--- | :--- | :--- |
| 1 | $\mathrm{~mm} / \mathrm{dd} / \mathrm{yy}$ | 16 | $\mathrm{~mm} / \mathrm{yy}$ |
| 2 | $\mathrm{~mm}-\mathrm{dd}-\mathrm{yy}$ | 17 | mm. yy |
| 3 | mm.dd.yy | 18 | Abbreviated month and year |
| 4 | mmddyy | 19 | Full month and year |
| 6 | $\mathrm{dd} / \mathrm{mm} / \mathrm{yy}$ | 21 | $\mathrm{~mm} / \mathrm{dd}$ |
| 7 | dd-mm-yy | 22 | dd.mm |
| 8 | dd.mm.yy | 23 | Abbreviated month and day |
| 9 | ddmmyy | 24 | Full month and day |
| 11 | yy/mm/dd | 26 | Abbreviated date without day of week |
| 12 | yy-mm-dd | 27 | Abbreviated date with day of week |
| 13 | yy.mm.dd | 28 | Full date without day of week |
| 14 | yymmdd | 29 | Full date with day of week |

If the commonFormat parameter is negative, then it will select the Use Custom Format radio button in the Modify Axis dialog rather than Use Common Format and will then use the absolute value of commonFormat to determine which item to select in the Common Format pop-up menu.
dateInfo $=\{s d, t m, d t\} \quad$ Controls formatting of date/time axes.
$s d=0$ : $\quad$ Show date in the date\&time format.
$s d=1$ : $\quad$ Suppress date.
$t m=0: \quad 12$ hour (AM/PM) time.
$t m=1: \quad 24$ hour (military) time.
$t m=2$ : Elapsed time.
$d t=-1: \quad$ Custom date as specified via the dateFormat keyword.
$d t=0: \quad$ Short dates $(2 / 22 / 90)$.
$d t=1: \quad$ Long dates (Thursday, February 22, 1990).
$d t=2: \quad$ Abbreviated dates (Thurs, Feb 22, 1990).
font="fontName" Sets the axis label font, e.g., font (left)="Helvetica". freePos $($ free $A x$ Name $)=p$

Sets the position of the free axis relative to the edge of the plot area to which the axis is anchored. $p$ is in points. i.e., if the axis was made via $/ \mathrm{R}=a x$ Name then the axis is placed $p$ points from the right edge of the plot area. Positive is away from the central plot area. freeAxName may not be any of the standard axes: "left", "bottom", "right" or "top".
freePos $($ free $A x$ Name $)=\{$ cross $A x$ Val,crossAxName $\}$
Positions the free axis so it will cross the perpendicular axis crossAxName where it has a value of crossAxVal. freeAxName may not be any of the standard axis names "left", "bottom", "right", or "top", though crossAxName may.
You can position a free axis as a fraction of the distance across the plot area by using kwFraction for crossAxName. crossAxVal must then be between 0 and 1 ; any values outside this range are clipped to valid values.

Also see the example experiment "Examples:Testing \& Misc:Graph Grid Demo".

| highTrip=h | If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation |
| :---: | :---: |
| lblLatPos $=p$ | Sets a lateral offset for the axis label. This is an offset parallel to the corresponding axis. $p$ is in points. Positive is down for vertical axes and to the right for horizontal axes. |
| lblMargin=l | Specifies the distance from the edge of graph to a label in points. |
| $\mathrm{lblPos}=p$ | Sets the distance from an axis to the corresponding axis label in points. If $p=0$, it automatically picks an appropriate distance. |
|  | This setting is used only if the given graph edge has at least one free axis. Otherwise, the lblMargin setting is used to position the axis label. |
| lblPosMode $=m$ | Affects the meaning and usage of lbIPos, IblLatPos, and lblMargin parameters. Mainly for use when you have multiple axes on a side and you need axis labels to be properly positioned even as you make graph windows dramatically larger or smaller. |
|  | $m=0$ : $\quad$ Default compatibility mode (Margin or Axis absolute depending on presence of free axis). |
|  | $m=1$ : Margin absolute. |
|  | $m=2$ : Margin scaled. |
|  | $m=3$ : Axis absolute. |
|  | $m=4$ : Axis scaled. |
|  | The absolute modes are measured in points whereas scaled modes have similar values but automatically expand or contract as the axis font height changes. Mode 0 is the default and results in no change relative to previous versions of Igor Pro that used lblMargin unless a given side used a free axis in which case it used lblPos in absolute mode. The margin modes measure relative to an edge of the graph while the axis modes measure relative to the position of the axis. When using stacked axes, use either margin modes. With multiple nonstacked axes, use Axis scaled if the graph edge is not using a fixed margin or use axis absolute if it is. |
| lblRot $=r$ | Rotates the axis label by $r$ degrees. $r$ is a value from -360 to 360 . Rotation is counterclockwise and starts from the label's normal orientation. |
| linTkLabel=tl | $t l=1$ attaches the data units with any exponent or prefix to each tick label on a normal axis. $t l=0$ removes them. |
| $\log =l$ | Controls axis log mode. |
|  | $g=0$ : Normal axis. |
|  | $g=1: \quad$ Log base 10. |
|  | $g=2: \quad$ Log base 2. |
| $\log$ HTrip $=h$ | Same as highTrip but for log axes. |
| logLabel=l | Sets the maximum number of decades in a log axis before minor tick labels are suppressed. |
| $\log$ LTrip $=l$ | Same as lowTrip but for log axes. |
| loglinear=l | Switches to a linear tick method $(l=1)$ on a $\log$ axis if the number of decades of ranges is less than 2. It switches to a linear tick exponent method if the number of decades is greater than five. |
| $\operatorname{logTicks}=t$ | Sets the maximum number of decades in log axis before minor ticks are suppressed. |

| lowTrip $=1$ | If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation. |
| :---: | :---: |
| manminor=\{number, emphasizeEvery\} |  |
|  | Specifies how to draw minor ticks in manual tick mode. There will be number ticks between each major (labeled) tick. You will usually want to set this to 4 to make 5 divisions, or 9 to make 10 divisions. A medium-sized tick (an emphasized minor tick) will be drawn every emphasizeEvery minor tick. |
| manTick=\{cantick, tickinc, exp, digitsrt [, timeUnit]\} |  |
|  | Turns on manual tick mode. The tick from which all other ticks are calculated is the cononic tick (cantick). The numerical spacing between ticks is set by tickinc. cantick and tickinc are multiplied by 10exp. The number of digits to the right of the decimal point displayed in the tick labels is set by digitsrt. |
|  | The optional parameter timeUnit is used with Date/Time axes to specify the units of tickinc. In this case, tickinc must be an integer. The value of timeUnit is one of the following keywords: |
|  | second, minute, hour, day, week, month, year |
|  | On a date/time axis, the exp and digitsrt keywords are ignored, but must be present. You can set them to zero. |
| manTick=0 | Turns off manual tick mode. |
| margin=m | Sets a fixed margin from the edge of the window to the axis in points. Used principally to make axes of multiple graphs on a page line up when "stacked". You can use the left, right, bottom, and top axis names (even if an axis with that name doesn't exist) to adjust the graph plot area. See Types of Axes on page II-242. |
|  | $m=0$ : Sets "automatic" margin size (dependent on the length and height of tick marks and labels). |
|  | $m=-1$ : Sets the margin to "none", or 0 . The axis is drawn at the graph window's edge. |
| minor $=m$ | Disables ( $m=0$ ) or enables ( $m=1$ ) minor ticks. |
| mirror $=m$ | Controls axis mirroring. |
|  | $m=1$ : Right axis mirroring left or top mirroring bottom. |
|  | $m=2$ : Mirror axis without tick marks. |
|  | $m=3$ : Mirror axis with tick marks and tick labels. |
|  | $m=0$ : No mirroring. |
| mirrorPos=pos | Specifies the position of the mirror axis relative to the normal position. pos is a value between 0 and 1 . |
| noLabel $=n$ | Controls axis labeling. |
|  | $n=0$ : Normal labels. |
|  | $n=1: \quad$ Suppresses tick mark labels. |
|  | $n=2$ : Suppresses tick mark labels and axis labels. |
| notation $=n$ | Uses engineering ( $n=0$ ) or scientific ( $n=1$ ) notation for tick mark labels. |
|  | Affects tick mark labels displayed exponentially. See highTrip and lowTrip. Does not affect $\log$ axes. |
| nticks=n | Specifies the approximate number of ticks marks ( $n$ ) on axis. |

| prescaleExp=exp | Multiplies axis range by $10^{\wedge} \exp$ for tick labeling and exp is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. (This affects the display only, not the source data.) |
| :---: | :---: |
| sep $=s$ | Specifies the minimum number of screen points (s) between minor ticks. |
| standoff $=s$ | Suppresses ( $s=0$ ) or enables ( $s=1$ ) axis standoff. |
|  | Axis standoff prevents waves or markers from covering the axis. |
| stLen $=p$ | Sets the length of minor ("small") tick marks to $p$ points. If $p$ is zero, it uses the default length. $p$ may be fractional. |
| stThick $=p$ | Sets the thickness of minor ("small") tick marks to $p$ points. If $p$ is zero, it uses the default thickness. $p$ may be fractional. |
| tick $=t$ | Sets tick position. |
|  | $t=0: \quad$ Outside axis. |
|  | $t=1$ : Crossing axis. |
|  | $t=2$ : Inside axis. |
|  | $t=3$ : None. |

In a category plot, adding 4 to the usual values for the tick keyword will place the tick marks in the center of each category rather than at the edges.
tickEnab=\{lowTick,highTick\}
Restricts axis ticking to a subrange of normal. Ticks are drawn and labelled only if they fall within this inclusive numerical range.
tickExp=te $\quad t e=1$ forces tick labels to exponential notation when labels have units with a prefix. $t e=0$ turns this off.
tickUnit=tu Suppresses $(t u=1)$ or turns on $(t u=0)$ units labels attached to tick marks.
tickZap=\{[v1 [,v2 [,v3]]]\}
Suppresses drawing of the tick mark label for values given in the list. This is useful when you have crossing axes to prevent tick mark labels from overlapping. The list may contain zero, one, two or three values. The values must be exact to suppress the label.
tkLbIRot $=r \quad$ Rotates the tick mark labels by $r$ degrees. $r$ is a value from -360 to 360. Rotation is counterclockwise and starts from the label's normal orientation.
tlOffset $=0 \quad$ Offsets the tick mark labels by $o$ fractional points relative to the default tick mark label position. Positive is away from the axis.
$\mathrm{ttLen}=p \quad$ Sets the length of subminor ("tiny") tick marks to $p$ points. If $p$ is zero, it uses the default length. $p$ may be fractional. Subminor ticks are used only in log axes.
ttThick= $p \quad$ Sets the thickness of subminor ("tiny") tick marks to $p$ points. If $p$ is zero, it uses the default thickness. $p$ may be fractional.
userticks=\{tickPosWave, tickLabelWave\}
Draws axes with purely user-defined tick mark positions and labels. tickPosWave is a numeric wave containing the desired positions of the tick marks, and tickLabelWave is a text wave containing the labels. See User Ticks from Waves on page II-278 for an example.
The tick mark labels can be multiline and use styled text. For more details, see Fancy Tick Mark Labels on page II-318.
tickPosWave need not be monotonic. Igor will plot a tick if a value is in the range of the axis. Both linear and $\log$ axes are supported.
Graph margins will adjust to accommodate tick labels. This will not prevent overlap between labels, which you will need fix yourself.

| useTSep=t | $t=1$ displays a thousand's separator character between every group of three digits in the tick mark label (e.g., " 1,000 " instead of " 1000 "). The default is $t=0$. |
| :---: | :---: |
| zapLZ= $t$ | Removes $(t=1)$ leading zeros from tick mark labels. For example 0.5 becomes .5 and 0.5 becomes -.5 . Default is $t=0$. |
| zapTZ= $t$ | Removes ( $t=1$ ) trailing zeros from tick mark labels. The the radix point will also be removed if all digits are zero. Default is $t=0$. |
| zero $=z$ | Controls the zero line. |
|  | $z=0$ : $\quad$ Zero line at $x=0$ or $\mathrm{y}=0$. |
|  | $z=1$ : No zero line. |
| zeroThick $=z t$ | Sets the thickness of the zero line in points, from 0.0 to 5.0 points. $z t=0.0$ means the zero line thickness automatically follows the thickness of the axis; this is the default. You can use 0.1 for a thin zero line thickness. |
| ZisZ=t | $t=1$ uses the single digit 0 as the zero tick mark label (if any) regardless of the number of digits used for other labels. Default is $t=0$. |

## Flags

/Z Does not generate an error if the named axis does not exist in a style macro.
/W=winName
Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## Details

With the prescaleExp parameter, you can force tick and axis label scaling to values different from the defaults. For example, if you have data whose $X$ scaling ranges from 9 pA to 120 pA and you display this on a log axis, the tick marks will be labelled 10pA and 100pA. But if you really want the tick marks labeled 10 and 100 with pA in the axis label, you can set the prescaleExp to 12 . To see this, execute the following commands:

```
Make/O jack=x
Display jack
SetScale x,9e-12,120e-12,"A",jack
ModifyGraph log(bottom)=1
then execute:
ModifyGraph prescaleExp(bottom)=12
```

The tickExp parameter applies to units that do not traditionally use SI prefix characters. For example, one usually speaks of $10^{-3}$ Torr and not mTorr. To see how this feature works, execute the following example commands:
Make/O jack=x
Display jack
SetScale x,1E-7,1E-5,"Torr",jack
ModifyGraph log (bottom)=1
then execute:

ModifyGraph tickExp (bottom) =1
at this point, the tick mark labels have Torr in them. If you want to eliminate the units from the tick marks, execute:
ModifyGraph tickUnit (bottom)=1
and if you now want Torr in the label string, use the $\backslash \mathrm{U}$ escape in the label string:
Label bottom "<br>U"
To see the effect of linTkLabel, execute these commands:
Make/O jack=x
Display jack
SetScale x, 1E-7,1E-5, "Torr", jack
then execute:
ModifyGraph linTkLabel (bottom)=1
and then try:
ModifyGraph tickExp (bottom) $=1$
and finally:
ModifyGraph tickUnit (bottom) =1

## ModifyGraph (colors)

ModifyGraph [/W=winName/Z] key [(axisName)] $=(r, g, b)$ [, key [(axisName)] $=(r, g, b)] \ldots$
This section of ModifyGraph relates to modifying the use of colors in a graph.
Parameters
Most (but not all) of the key parameters may take an optional axisName enclosed in parentheses. axisName is "left", "right", "top", "bottom" or the name of an free axis such as "vertCrossing".
Where the parameter descriptions indicate an "(axisName)", it may be omitted to change all axes in the graph. $r, g$, and $b$ are each an integer from 0 to 65535 where $(0,0,0)$ is black and $(65535,65535,65535)$ is white.

| Parameter Specification | Object Colored |
| :--- | :--- |
| alblRGB (axisName $)=(r, g, b)$ | Axis labels |
| axRGB (axisName $)=(r, g, b)$ | Axis |
| CbRGB $=(r, g, b)$ | Control bar background |
| gbRGB $=(r, g, b)$ | Graph background |
| gridRGB (axisName $)=(r, g, b)$ | Axis grid lines |
| tickRGB (axisName $)=(r, g, b)$ | Axis Tick marks |
| tlblRGB (axisName $)=(r, g, b)$ | Axis Tick labels |
| wbRGB $=(r, g, b)$ | Window background |

## Flags

/W=winName Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
/Z Does not generate an error if the named axis does not exist in a style macro.

## Details

On Windows, use maximum white to set the control bar background color to track the 3D Objects color in the Appearance Tab of the Display Properties control panel:
ModifyGraph $\operatorname{cbRGB}=(65535,65535,65535)$

## See Also

See Instance Notation on page IV-16.

## ModifyImage

```
ModifyImage [/W=winName] imageInstance, keyword = value
    [, keyword = value] ...
```

The ModifyImage operation changes properties of the given image in the top graph (or the specified graph if / W is used). imageInstance is the name of the image to be altered. This name is usually simply the name of the matrix wave containing the image data. If the same matrix wave is displayed more than once, you must append $\# 0, \# 1$ etc. to the name to distinguish which is which.
imageInstance can also take the form of a null name with an instance number to affect the instanceth image. That is,
ModifyImage ''\#1
modifies the appearance of the second image that was appended to the top graph, no matter what the image names are. Note: two single quotes are used, not a double quote.

## Parameters

Here are the keyword-value pairs. These apply to false color images in which the data in the matrix is used as an index into a color table. They do not apply to direct color images in which the data in the matrix specifies the color directly.
cindex=matrixWave Sets the Z value mapping mode such that image colors are determined by doing a lookup in the specified matrix wave.
matrixWave is a 3 column wave that contains red, green, and blue values from 0 to 65535. (The matrix can actually have more than 3 columns. It ignores any extra columns.)
The color at $\mathrm{Z}=\mathrm{z}$ is determined by finding the RGB values in the row of matrixWave whose scaled $X$ index is z . In other words, the red value is matrixWave(z)[0], the green value is matrixWave( z$)[1]$ and the blue value is matrixWave( z$)[2]$.
If matrixWave has default $X$ scaling, where the scaled $X$ index equals the point number, then row 0 contains the color for $\mathrm{Z}=0$, row 1 contains the color for $\mathrm{Z}=1$, etc.
If you use cindex, you should not use ctab in the same command.
ctab $=\{z M i n, z M a x, c t$ Name, reverse $\}$
Sets z mapping mode by which values in the matrix are mapped linearly into the color table specified by ctName. The color table name can be missing if you want to leave it as is. $z M i n$ and $z M a x$ set the range of $z$ values to map. Omit $z M i n$ or $z M a x$ to leave as is or use * to autoscale. ctName can be any color table name returned by the CTabList function, such as Grays or Rainbow. Also see Color Tables on page II-359. Set parameter reverse to 1 to reverse the color table; zero or missing does not reverse the color table.
ctabAutoscale=autoBits
Sets the range of data used for autoscaling ctab * values.
Bit 0: Autoscales only the $X Y$ subset being displayed.
Bit 1: Autoscales only the current plane being displayed.
If neither bit is set (if autoBits $=0$, the default), then all of the data in the image wave is used to autoscale the ${ }^{* \prime} \mathrm{~d} z M i n, z M a x$ values for ctab.
eval=\{value, red, green, blue\}
If the red, green, and blue values are in the valid range for a color value ( 0 to 65535) the explicit value-color pair is added (or updated if value already exists). If the color values are out of range ( -1 is suggested) then the value is removed from the list if it is present (no error if it is not).
explicit=1 or 0
Turns explicit (monochrome) mode on (1) or off (0). Meant to be used with unsigned byte data but will do the best it can for other types. If value of data is equal to one of the defined explicit values then its defined color is used otherwise the pixel will be blank. The default predefined values are:

| 255: | black |
| :--- | :--- |
| $0:$ | white |

You can add, change, or delete explicit values with the eval keyword.
imCmplxMode $=m$ Sets complex data display mode.

$$
m=0: \quad \text { Magnitude (default). }
$$

$m=1$ : Real only.
$m=2$ : Imaginary only.
$m=3$ : Phase in radians.
interpolate $=$ mode $\quad$ mode $=1$ turns on smoothing of the boundaries between pixels. Since this is implemented via system graphics calls and not by Igor actually doing the interpolation, it will not affect EPS or EMF export on Windows and will not affect EPS export on Mac. Although this may create a more esthetically pleasing display, it is not clear that it is appropriate for scientific data.
mode $=-1$ forces pixels to be drawn as individual rectangles. This is sometimes needed when a third-party program improperly interpolates PDF or EPS exported images.
$\log =1$ or $0 \quad 0$ sets the default linearly-spaced false-image colors.
1 turns on logarithmically-spaced false-image colors. This requires that the image values be greater than 0 to display correctly.
Affects the image colors for color table and color index images only (see Color Table Details on page II-363 and Indexed Color Details on page II-366).
The log keyword was added in Igor Pro 6.22.
lookup= waveName Specifies an optional 1D wave that can be used to modify the mapping of scaled z values into the color table specified with the ctab parameter. Values should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the image. Used to apply gamma correction to grayscale images or for special effects. Use a NULL wave (\$" ") to remove the option.
maxRGB=(red, green, blue)
Sets the color of image values greater than the ctab $z M a x$ or greater than the cindex of the matrixWave maximum $X$ scaling value. Also turns max color mode on.
The red, green, and blue color values are in the range of 0 to 65535 .
maxRGB=1 or 0 or NaN
Turns max color mode off, on, or transparent. These modes affect the display of image values greater than the ctab $z M a x$ or greater than the cindex of the matrixWave maximum $X$ scaling value.
1: Turns on max color mode. The color of the affected image pixels is black or the last color set by maxRGB=(red, green, blue).
0 : $\quad$ Turns off max color mode (default). The color of the affected image pixels is the last color table or color index color.
$\mathrm{NaN}: \quad$ Transparent max color mode. The affected image pixels are not drawn.
$\operatorname{minRGB}=($ red, green, blue)

Sets the color of image values less than the ctab zMin or less than the cindex of the matrixWave minimum $X$ scaling value. Also turns min color mode on.
The red, green, and blue color values are in the range of 0 to 65535.
$\operatorname{minRGB}=1$ or 0 or NaN
Turns min color mode off, on, or transparent. These modes affect the display of image values less than the ctab $z M i n$ or less than the cindex of the matrixWave minimum $X$ scaling value.
1: $\quad$ Turns on min color mode. The color of the affected image pixels is black or the last color set by minRGB=(red, green, blue).
0: $\quad$ Turns off min color mode (default). The color of the affected image pixels is the first color table or color index color.

NaN : Transparent min color mode. The affected image pixels are not drawn.
plane $=p \quad$ Determines which part of a 3D or 4D image wave to display.
The meaning of $p$ depends on the nature of the image wave. If the size of the layer dimension of the image wave is exactly three then the wave is treated as RGB data with R, G, and B data in the three layers. Otherwise each layer of the wave is treated as a separate grayscale image.

## Plane=p With RGB Data

If the wave is 3D, plane $=p$ has no effect.
If the wave is 4 D , each chunk contains a different set of $\mathrm{R}, \mathrm{G}$ and B layers and $p$ selects which chunk to display.

## Plane=p With Grayscale Data

If the wave is $3 \mathrm{D}, p$ selects which layer to display.
If the wave is 4 D , plane $=p$ acts as if all of the chunks were combined into a virtual 3D wave and $p$ selects which layer of this virtual 3D wave to display.
rgbMult $=m \quad$ If $m$ is non-zero, direct color values (3 plane RGB) are multiplied by $m$. This would typically be used for 10,12 or 14 bit integers in a 16 bit word. For example, if your image data is 14 bits, use rgbMult=4.

## Flags

$/ W=$ winName $\quad$ Directs action to a specific window or subwindow rather than the top graph window. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## See Also <br> AppendImage and RemoveImage.

## ModifyLayout

ModifyLayout [flags] key [(objectName)] =value [, key [(objectName)] =value]... The ModifyLayout operation modifies objects in the top layout or in the layout specified by the /W flag.

## Parameters

Each key parameter may take an optional objectName enclosed in parentheses. If "(objectName)" is omitted, all objects in the layout are affected.
Though not shown in the syntax, the optional "(objectName)" may be replaced with "[objectIndex]", where objectIndex is zero or a positive integer denoting the object to be modified. "[0]" denotes the first object appended to the layout, "[1]" denotes the second object, etc. This syntax is used for style macros, in conjunction with the $/ \mathrm{Z}$ flag.

The parameter descriptions below omit the optional "(objectName)".
The "units", "mag" and "bgRGB" keywords apply to the layout as a whole, not to a specific object and do not accept an objectName.

| $\operatorname{bgRGB}=(r, g, b)$ | Specifies the background color for the layout. $r, g$, and $b$ are integers from 0 to 65535. |
| :---: | :---: |
| columns=c | Specifies the number of columns for a table object. |
| fidelity $=f$ | Controls the drawing of layout objects. |
|  | $f=0$ : Low fidelity. |
|  | $f=1: \quad$ High fidelity. |
| frame $=f$ | Specifies the type of frame enclosing the object. |
|  | $f=0$ : $\quad$ No frame. |
|  | $f=1: \quad$ Single frame (default). |
|  | $f=2: \quad$ Double frame. |
|  | $f=3$ : $\quad$ Triple frame. |
|  | $f=4: \quad$ Shadow frame. |
| height=h | Sets the height of the object. |
| left=l | $l$ is the horizontal coordinate of the left edge of the object relative to the left edge of the paper. |
| mag $=m$ | Sets the layout magnification where $m=0.25,0.5,1$, or 2 . |
| rows=r | Specifies the number of rows for table object. |
| top $=t$ | $t$ is the vertical coordinate of the top edge of the object relative to the top edge of the paper. |
| trans= $t$ | Controls the transparency of the layout object: |
|  | $t=0: \quad$ Opaque (default). |
|  | $t=1: \quad$ Transparent. For this to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. PICTs may have been created transparent or opaque, and Igor cannot make an opaque PICT transparent. |
| units=u | Sets dimension units in the layout info panel and in the Modify Objects dialog. |
|  | $u=0$ : Points. |
|  | $u=1$ : Inches. |
|  | $u=2$ : Centimeters. |
| width= $w$ | Sets the object width. |

## Flags

Dimensions in inches.
/M
Dimensions in centimeters.
$/ \mathrm{W}=$ winName $\quad$ winName is the name of the page layout window to be modified. If $/ \mathrm{W}$ is omitted or if winName is $\$ "$ ", the top page layout is modified.
/Z Does not generate an error if the indexed or named object does not exist in a style macro.
The /I and /M flags affect the units of the parameters for the left, top, width and height keywords only. If neither /I nor / M is present then the parameters for the left, top, width and height keywords are points.

## Details

Note that the units keyword affects only the units used in the layout info panel and in the Modify Objects dialog. It has nothing to do with the units used for the left, top, width and height keywords. Those units are points unless the /I or / M flags is present.

See Also
NewLayout, AppendLayoutObject and RemoveLayoutObjects.

## ModifyPanel

ModifyPanel [/W=winName] keyword = value [, keyword = value ...]
The ModifyPanel operation modifies properties of the top or named control panel window or subwindow.

## Parameters

keyword is one of the following:
$\operatorname{cbRGB}=(r, g, b) \quad$ Specifies the background color of the entire control panel or the graph's control bar area. $r, g$, and $b$ are values from 0 to 65535.
fixedSize $=f \quad$ Controls the resizing of the panel window.
$f=0: \quad$ Panel can be resized (default).
$f=1: \quad$ Panel cannot be resized by adjusting the size box or frame (nor maximized on Windows), but the window can be minimized (on Windows) and the MoveWindow operation can still change the size.
frameInset $=i \quad$ Specifies the number of pixels by which to inset the frame of the panel subwindow. Mostly useful for overlaying panels in graphs to give a fake 3D frame a better appearance.
frameStyle $=f \quad$ Specifies the frame style for a panel subwindow.
$f=0$ : $\quad$ None.
$f=1: \quad$ Single.
$f=2: \quad$ Indented.
$f=3: \quad$ Raised.
$f=4: \quad$ Text well.
The last three styles are fake 3D and will look good only if the background color of the enclosing space and the panel itself is a light shade of gray.
noEdit $=e \quad$ Sets the editability of the panel.

$$
\begin{array}{ll}
e=0: & \text { Editable (default). } \\
e=1: & \text { Not editable. For a panel window, the Panel menu item is not } \\
& \text { present and the ShowTools command is ignored. For a panel } \\
& \text { subwindow, it can not be activated by clicking. }
\end{array}
$$

## Flags

/W= winName Modifies the control panel in the named graph or control panel window or subwindow. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## Details

On Windows, set $r, g$, and $b=65535$ (maximum white) to set the background color of the control panel to track the 3D Objects color in the Appearance Tab of the Display Properties control panel.

## See Also <br> The NewPanel operation.

Controls in Graphs on page III-390.

## ModifyTable

ModifyTable [/W=winName/Z] key [(columnSpec)] =value [, key [(columnSpec)] =value]... The ModifyTable operation modifies the appearance the top or named table window or subwindow.

## Parameters

Many of the parameter keywords take an optional columnSpec enclosed in parentheses. Usually columnSpec is simply the name of a wave displayed in the table. All table columns are affected when you omit (columnSpec).
More precisely, column specifications are wave names for waves in the current data folder or data folder paths leading to waves in any data folder optionally followed by the suffixes .i, .l, d, .id or.$l d$ to specify dimension indices, dimension labels, data values, dimension indices and data values, or dimension labels and data values of the wave. For example, ModifyTable font (myWave.i)="Helvetica". If the wave is complex, the column specification may be followed by .real or .imag suffixes.
One additional columnSpec is Point, which refers to the first column containing the dimension index numbers. If multidimensional waves are displayed in the table, this column may have the title "Row", "Column", "Layer", "Chunk" or "Element", but the columnSpec for this column is always Point. See Column Names on page II-200 for details.
Though not shown in the syntax, the optional (columnSpec) may be replaced with [columnIndex], where columnIndex is zero or a positive integer denoting the column to be modified. [0] denotes the Point column, [1] denotes the first column appended to the table, [2] denotes the second appended column, etc. This syntax is used for style macros, in conjunction with the $/ \mathrm{Z}$ flag.
As of Igor Pro 6 you can use a range of column numbers instead of just a single column number, for example [0,3].
The parameter descriptions below omit the optional (columnSpec).
alignment $=a \quad \begin{array}{ll}\text { Sets the alignment of table cell text. } \\ a=0: & \text { Left aligned. } \\ a=1: & \text { Center aligned. } \\ a=2: & \text { Right aligned. }\end{array}$
autosize $=\{$ mode, options, padding, perColumnMaxSeconds, totalMaxSeconds $\}$
Autosizes the specified column or columns.
mode=0: Sets width of each data column from a given multidimensional wave individually.
mode=1: $\quad$ Sets width of all data columns from a given multidimensional wave the same.
options is a bitwise parameter. Usually 0 is the best choice.
Bit 0: Ignores column names.
Bit 1: Ignores horizontal indices.
Bit 2: Ignores data cells.
All other bits are reserved and must be set to zero.
See Setting Bit Parameters on page IV-12 for details about bit settings.
padding specifies extra padding for each column in points. Use -1 to get the default amount of padding (16 points).
perColumnMaxSeconds specifies the maximum amount of time to spend autosizing a single column. Use 0 to get the default amount of time (one second).
totalmaxSeconds specifies the maximum amount of time for autosizing the entire table. Use 0 to get the default amount of time (ten seconds).
digits=d Specifies the number of digits after decimal point or, for hexadecimal and octal columns, the number of total digits.
elements=(row, col, layer, chunk)
Selects the view of a multidimensional wave in the table. The values given to row, col, layer, and chunk specify how to change the view.
-1: No change from current view.
-1: $\quad$ Display this dimension vertically.
-3: Display this dimension horizontally.
$\geq 0$ : $\quad$ For waves with 3 or 4 dimensions, display this element of the other dimensions.

See ModifyTable Elements Command on page II-223 for a detailed discussion of
entryMode $=m \quad$ Queries or sets the table's entry line mode.
$m=0$ : Just queries.
$m=1$ : Accepts any entry that was started if possible.
$m=2$ : Cancels any entry that was started if possible.
If $m$ is 0 then the entry line state is not changed but is returned via V_flag as follows:
0: $\quad$ No entry is in progress.
-1: $\quad$ An entry is in progress and is valid.
Other: An entry is in progress and is invalid.
If $m$ is 1 then the entry is accepted if it is valid and its state is returned via V_flag as follows:
0: $\quad$ No entry is in progress.
-1: $\quad$ The entry was accepted.
Other: The entry is invalid and was not accepted.
If $m$ is 2 then the entry is cancelled if possible and its state is returned via V_flag as follows:
0: $\quad$ No entry is in progress.
-1: $\quad$ The entry was cancelled.
font="fontName" Sets font used in the table, e.g., font="Helvetica".
format $=f \quad$ Sets the data format for the table.
$f=0: \quad$ General.
$f=1$ : $\quad$ Integer.
$f=2: \quad$ Integer with thousands (e.g., "1,234").
$f=3: \quad$ Fixed point (e.g., "1234.56").
$f=4: \quad$ Fixed point with thousands (e.g., "1,234.56").
$f=5: \quad$ Exponential (scientific only).
$f=6$ : $\quad$ Date format.
$f=7: \quad$ Time format (always 24 hour time).
$f=8: \quad$ Date\&time format (date followed by time).
$f=9$ : $\quad$ Octal.
$f=10: \quad$ Hexadecimal.
As of Igor Pro 6, you cannot apply date or date\&time formats to a wave that is not double-precision (see Date, Time, and Date\&Time Units on page II-85). To avoid this error, use Redimension to change the wave to double-precision.
frameInset $=i \quad$ Specifies the number of pixels by which to inset the frame of the table subwindow.
frameStyle $=f \quad$ Specifies the frame style for a table subwindow.

| $f=0:$ |  |
| :--- | :--- |
| $f=1:$ | None. |
| $f=2:$ | Single. |
| $f=3:$ | Double. |
| $f=4:$ | Shadiple. |
| $f=5:$ | Indented. |
| $f=6:$ | Raised. |
| $f=7:$ | Text well. |

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the table itself is a light shade of gray.
horizontalIndex $=h$ Controls what is displayed in the horizontal index row when multidimensional waves are displayed.
$h=0$ : Displays dimension labels if the multidimensional wave's label column is displayed, otherwise displays numeric indices (default).
$h=1$ : Always displays numeric indices for multidimensional waves.
$h=2$ : Always displays dimension labels for multidimensional waves.
The horizontal index row appears below the row of column names if the table contains a multidimensional wave. Use horizontalIndex to override the default behavior in order to display labels for the horizontal dimension while displaying numeric indices for the vertical dimension or vice versa.
horizontalIndex controls the horizontal index row only. To control what is displayed vertically, use AppendToTable to append a numeric index or dimension label column.
$\operatorname{rgb}=(r, g, b) \quad$ Sets color of text. $r, g$, and $b$ are red, green, and blue components of the color and range from 0 to 65,535 . Default is black: $(0,0,0)$.
selection=(firstRow, firstCol, lastRow, lastCol, targetRow, targetCol)
Sets the selected cells in the table.
If any of the parameters have the value -1 then the corresponding part of the selection is not changed.
Otherwise they set the first and last selected cell and the target cell. Row and column values are 0 or greater. The Point column can not be selected.
The proposed parameters are clipped to avoid invalid combinations, such as the last selected row being before the first selected row.
With one exception, it does not support selecting unused cells. Therefore the proposed selection is clipped to prevent this. The exception is that, if the parameters call for selecting the first cell in the first unused column, then this is permitted.
showFracSeconds=s Shows ( $s=1$ ) or hides ( $s=0$; default) fractional seconds.
showParts=parts Specifies what elements of the table should be visible. Other elements are hidden.
parts is a bitwise parameter specifying what to show.
bit 0: $\quad$ Entry line and other top line controls.
bit 1: Name row.
bit 2: Horizontal index row.
bit 3: Point column.
bit 4: Horizontal scroll bar.
bit 5: Vertical scroll bar.
bit 6: Insertion cells.
bit 7: Insertion cells.
All other bits are reserved and must be set to zero except that you can pass -1 to indicate that you want to show all parts of the table.
See Setting Bit Parameters on page IV-12 for details about bit settings.
Presentation tables in subwindows in graphs and page layouts do not have an entry line or scroll bars and therefore never show these items.

See Parts of a Table on page II-194 and Showing and Hiding Parts of a Table on page II-195 for further information.
sigdigits=d $d$ is the number of significant digits when the numeric format is general.
size $=s \quad$ Font size, e.g., size=14.
style $=n \quad n$ is a bitwise parameter with each bit controlling one aspect of the column's
font style as follows:
bit 0: Bold.
bit 1: Italic.
bit 2: Underline.
bit 3: Outline (Macintosh only).
bit 4: $\quad$ Shadow (Macintosh only).
bit 5: Condensed (Macintosh only).
bit 6: Extended (Macintosh only).
For example, bold underlined is $2^{0}+2^{2}=1+4=5$. See Setting Bit Parameters on page IV-12 for details about bit settings.
title="title" Sets the title of a column to title.
topLeftCell=(row, column)
Scrolls the table contents so that the cell identified by (row, column) is the top left visible data cell, or as close as possible.
If row is -1 then the table's vertical scrolling is not changed. If column is -1 then the table's horizontal scrolling is not changed.
If they are positive, row and column are zero-based numbers which are clipped to valid values before being used. row $=0$ refers to the first row of data in the table, column $=0$ refers to the first column of data.

The Point column can not be scrolled horizontally.
trailingZeros $=t \quad$ Shows trailing zeros $(t=1)$. This affects the general numeric format only.
width=w
Sets column width to $w$ points.
You will not always get the exact number of points that you request. This is because a column must have an even number of screen pixels, so that grid lines look good. Igor will modify your requested number of points to meet this requirement.

Flags
/W= winName Modifies the named table window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
/Z
No errors generated if the indexed or specified column does not exist in a style macro.

## Examples

ModifyTable size (myWave) $=14 \quad / /$ change font size of myWave column
ModifyTable width (Point) =0 // hide Point column
ModifyTable style (cmplxWave.imag) $=32 \quad / /$ condensed= bit $5=2 \wedge 5=32$

## See Also

See Column Names on page II-200 and ModifyTable Elements Command on page II-223.

## ModifyWaterfall

ModifyWaterfall [/W=winName] keyword = value [, keyword = value ...]
The ModifyWaterfall operation modifies the properties of the waterfall plot in the top or named graph.

## Parameters

keyword is one of the following:
angle $=a \quad$ Angle in degrees from horizontal of the angled $Y$ axis ( $a=10$ to 90).
axlen $=$ len $\quad$ Relative length of angled Y axis. len is a fraction between 0.1 and 0.9 .
hidden $=h \quad$ Controls the hidden line algorithm.
$h=0$ : $\quad$ Turns hidden lines off.
$h=1$ : Uses painter's algorithm.
$h=2$ : True hidden.
$h=3$ : Hides lines with bottom removed.
$h=4$ : Hides lines using a different color for the bottom. When specified, the top color is the normal color for lines and the bottom color is set using ModifyGraph negRGB=(r,g,b).

Hidden lines are active only when the mode is lines between points.

## Flags

$/ \mathrm{W}=$ winName $\quad$ Modifies waterfall plot in the named graph window or subwindow. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## Details

Painter's algorithm draws the traces from back to front and erases hidden lines while modes 2, 3 and 4 detect which line segments are hidden and suppresses the drawing of these segments.

## See Also <br> Waterfall Plots on page II-300.

The NewWaterfall and ModifyGraph operations.

## ModuleName

## \#pragma ModuleName = modName

The ModuleName pragma assigns a name, which must be unique, to a procedure file so that you can use static functions and Proc Pictures in a global context, such as in the action procedure of a control or on the Command Line.
Using the ModuleName pragma involves at least two steps. First, within the procedure file assign it a name using \#pragma ModuleName=modName, and then access objects in the named file by preceding the object name with the name of the module and the \# character, such as or example: ModName\#StatFuncName ( ).

## See Also

The Regular Modules on page IV-216, Static, Picture, and \#pragma.

## MoveDataFolder

## MoveDataFolder sourceDataFolderSpec, destDataFolderPath

The MoveDataFolder operation removes the source data folder (and everything it contains) and places it at the specified location with the original name.

## Parameters

sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.
destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

## Details

MoveDataFolder generates an error if a data folder of the same name already exists at the destination.

## Examples

Move data folder foo into data folder bar:
MoveDataFolder foo, root:bar:
Move data folder foo into data folder bar:
MoveDataFolder foo,:bar:

## See Also

See the DuplicateDataFolder operation. Chapter II-8, Data Folders.

## MoveFile

MoveFile [flags][srcFileStr] [as destFileOrFolderStr]
The MoveFile operation moves or renames a file on disk. A file is renamed by "moving" it to the same folder it is already in using a different name.

## Parameters

srcFileStr can be a full path to the file to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName.
If Igor can not determine the location of the file from srcFileStr and pathName, it displays an Open File dialog allowing you to specify the source file.
destFileOrFolderStr is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.
If destFileOrFolderStr is a partial path, it is relative to the folder associated with pathName.
If / $D$ is specified, the source file is moved inside the folder using the source file's name.
If Igor can not determine the location of the destination file from pathName, srcFileStr, and destFileOrFolderStr, it displays a Save File dialog allowing you to specify the destination file (and folder).
If you use a full or partial path for either srcFileStr or destFileOrFolderStr, see Path Separators on page III-400 for details on forming the path.
Folder paths should not end with single Path Separators. See the Details section for MoveFolder.

Flags

| /D | Interprets destFileOrFolderStr as the name of (or path to) an existing folder (or directory). Without /D, destFileOrFolderStr is the name of (or path to) a file. |
| :---: | :---: |
|  | If destFileOrFolderStr is not a full path to a folder, it is relative to the folder associated with pathName. |
| $/ \mathrm{I}[=i]$ | Specifies the level of interactivity with the user. |
|  | /I=0: Interactive only if srcFileStr or destFileOrFolderStr is not specified or if the source file is missing. (Same as if /I was not specified.) |
|  | /I=1: Interactive even if srcFileStr is specified and the source file exists. |
|  | /I=2: Interactive even if destFileOrFolderStr is specified. |
|  | /I=3: Interactive even if $\operatorname{srcFileStr}$ is specified and the source file exists. Same as /I only. |
| /M=messageStr | Specifies the prompt message in the Open File dialog. If /S is not specified, then messageStr will be used for both Open File and for Save File dialogs. |
| /O | Overwrite existing destination file, if any. Without / $O$, the user is asked if replacing the existing file is to be allowed. |
| /P=pathName | Specifies the folder to look in for the source file, and the folder into which the file is copied. pathName is the name of an existing symbolic path. |
|  | Using /P means that both srcFileStr and destFileOrFolderStr must be either simple file or folder names, or paths relative to the folder specified by pathName. |
| /S=saveMessageStr | Specifies the prompt message in the Save File dialog. |
| /Z[=z] | Prevents procedure execution trom aborting it it attempts to move a tile that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort. |
|  | $/ \mathrm{Z}=0$ : $\quad$ Same as no /Z. |
|  | $/ \mathrm{Z}=1: \quad$ Moves a file only if it exists. /Z alone is equivalent to $/ \mathrm{Z}=1$. |
|  | $/ \mathrm{Z}=2: \quad$ Moves a file if it exists or displays a dialog if it does not exist. |

## Variables

The MoveFile operation returns information in the following variables:

| V_flag | Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save <br> File dialogs, and to some nonzero value if an error occurred, such as the specified file <br> does not exist. |
| :--- | :--- |
| S_fileName | Stores the full path to where the file was moved from. If an error occurred or if the <br> user cancelled, it is set to an empty string. |
| S_path | Stores the full path where the file was moved to. If an error occurred or if the user <br> cancelled, it is set to an empty string. |

## Examples

Rename a file, using full paths:
MoveFile "HD:folder:aFile.txt" as "HD:folder:bFile.txt"
Rename a file, using a symbolic path:
MoveFile/P=myPath "aFile.txt" as "bFile.txt"
Move a file into a subfolder (the subfolder must exist):
MoveFile/D "Macintosh HD:folder:aFile.txt" as ":subfolder"
Move a file into an unrelated folder (the subfolder must exist):
MoveFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"
Move a file from one folder to another and rename it:

MoveFile "Macintosh HD:folder:afile.txt" as "Server:archive:destFile.txt"
Move user-selected file into a particular folder:
MoveFile/D as "C:My Data:Selected Files Folder"
Move user-selected file in any folder as bFile.txt in same folder:
MoveFile as "bFile.txt"
Move user-selected file in any folder as bFile.txt in any folder:
MoveFile/I=2 as "bFile.txt"

## See Also

The Open, MoveFolder, CopyFolder, NewPath, and CreateAliasShortcut operations. The IndexedFile function. Symbolic Paths on page II-34.

## MoveFolder

MoveFolder [flags][srcFolderStr] [as destFolderStr]
The MoveFolder operation moves or renames a folder on disk. A folder is renamed by "moving" it into the same folder it is already in, but with a different name.

Warning: The MoveFol der command can destroy data by overwriting another folder and its contents! If you overwrite an existing folder on disk, MoveFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category. For further details see Misc Settings on page III-416.
If permission is denied, the folder will not be moved and V_Flag will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the / Z flag is specified.

## Parameters

srcFolderStr can be a full path to the folder to be moved or renamed (in which case/P is not needed), a partial path relative to the folder associated with pathName, or the name of a folder within the folder associated with pathName.

If the location of the source folder cannot be determined from srcFolderStr and pathName, it displays a Select Folder dialog allowing you to specify the source.

If $/ \mathrm{P}=$ pathName is given, but srcFolderStr is not, then the folder associated with pathName is moved or renamed. destFolderStr specifies the final location of the folder or, if / D is used, the parent of the final location of the folder. destFolderStr can be a full path to the output (destination) folder (in which case / P is not needed), or a partial path relative to the folder associated with pathName.
If the location of the destination folder cannot be determined from destFolderStr and pathName, it displays a Save Folder dialog allowing you to specify the destination.

If you use a full or partial path for either file, see Path Separators on page III-400 for details on forming the path.

## Flags

Interprets destFolderStr as the name of (or path to) an existing folder (or "directory") to move the source folder into. Without /D, it interprets destFolderStr as the name of (or path to) the moved folder.

If destFolderStr is not a full path to a folder, it is relative to the source folder.
$/ \mathrm{I}[=i] \quad$ Specifies the level of interactivity with the user.
$/ \mathrm{I}=0$ : Interactive only if $s r c F o l d e r$ Str or destFolderStr is not specified or if the source folder is missing. (Same as if /I was not specified.)
$/ \mathrm{I}=1$ : Interactive even if $\operatorname{srcFolder}$ Str is specified and the source folder exists.
/I=2: $\quad$ Interactive even if destFolderStr is specified.
/I=3: Interactive even if $s r c F o l d e r S t r$ is specified and the source folder exists. Same as /I only.

| / $\mathrm{M}=$ messageStr | Specifies the prompt message in the Open File dialog. If / S is not used, then messageStr will be used for both Open File and for Save File dialogs. |
| :---: | :---: |
| /O | Overwrite existing destination folder, if any. This deletes the existing destination folder. When /O is specified, the source folder can't be moved into an existing folder without specifying the name of the moved folder in destFolderStr. |
| / $\mathrm{P}=$ pathName | Specifies the folder for relative paths in srcFolderStr and destFolderStr. pathName is the name of an existing symbolic path. |
|  | If srcFolderStr is omitted, the folder associated with pathName is moved. If destFolderStr is omitted, the source folder is moved into the folder associated with pathName. |
|  | Using /P means that srcFolderStr (if specified) and destFolderStr must be either simple folder names or paths relative to the folder specified by pathName. |
| /S=saveMessageStr | Specifies the prompt message in the Save File dialog. |
| /Z[ $=z$ ] | Prevents procedure execution from aborting it it attempts to move a folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort. |
|  | $/ \mathrm{Z}=0$ : $\quad$ Same as no /Z. |
|  | $/ \mathrm{Z}=1: \quad$ Moves a folder only if it exists. / Z alone is equivalent to $/ \mathrm{Z}=1$. |
|  | $/ \mathrm{Z}=2$ : $\quad$ Moves a folder if it exists or displays a dialog if it does not exist. |

## Variables

The MoveFolder operation returns information in the following variables:

| V_flag | Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save <br> File dialogs, and to some nonzero value if an error occurred, such as the specified file <br> does not exist. |
| :--- | :--- |
| S_fileName | Stores the full path to the folder that was moved, with a trailing colon. If an error <br> occurred or if the user cancelled, it is set to an empty string. |
| S_path | Stores the full path of the moved folder, with a trailing colon. If an error occurred or <br> if the user cancelled, it is set to an empty string. |

## Details

You can use only $/ \mathrm{P}=$ pathName (omitting srcFolderStr) to specify the source folder to be moved.
A folder path should not end with single Path Separators. For example:

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder:"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder:"
```

will do weird, unexpected things (and probably damaging things when / O is also used). Instead, use:
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"
Beware of PathInfo and other command which return paths with an ending path separator. (They can be removed with the RemoveEnding function.)
A folder may not be moved into one of its own subfolders.
Conversely, the command:
MoveFolder/O/P=myPath "afolder"
which attempts to overwrite the folder associated with myPath with a folder that is inside it (namely "afolder") is not allowed. Instead, use:
MoveFolder/O/P=myPath ": :afolder"
On Windows, renaming or moving a folder never updates the value of any Igor Symbolic Paths that point to a moved folder:
// Create a folder
NewPath/O/C myPath "C: <br>My Data<br>My Work"

```
// Move the folder
MoveFolder/P=myPath as "C:\\My Data\\Moved"
// Display the path's value
PathInfo myPath // (or use the Path Status dialog)
Print S_Path
- C:My Data:My Work
```

You can use PathInfo to determine if a folder referred to by an Igor symbolic path exists and where it is on the disk. Use NewPath/O to reset the path's value.
On the Macintosh, however, renaming or moving a folder on the same volume does alter the value of symbolic path. This is because MoveFolder uses a Mac OS alias to keep track of the folder. A folder renamed or moved on the same volume retains the original "volume refnum" and "directory ID" stored in the alias mechanism, so that the alias (and hence Igor's symbolic path) remains pointing to the moved folder. After moving the folder, using the unchanged volume refnum and directory ID (in PathInfo or when you use / $\mathrm{P}=$ pathName) returns the updated path.
Moving the folder to a different volume actually creates a new folder with new volume refnum and directory IDs, and symbolic paths pointing to or into the moved folder aren't updated. They will be pointing at a deleted folder (they're probably invalid).

## Examples

Rename a folder ("move" it to the same folder):
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"
Rename a folder referred to by only a path:
NewPath/O myPath "Macintosh HD:folder"
MoveFolder/P=myPath as "::Renamed Folder"
Move a folder from one volume to another. This moves "Macintosh HD:My Folder" inside "Server:My Folder" if "Server:My Folder" already exists:
MoveFolder "Macintosh HD:My Folder" as "Server:My Folder"
Move a folder from one volume to another. This overwrites "Server:My Folder" (if it existed) with the moved "Macintosh HD:My Folder":
MoveFolder/O "Macintosh HD:My Folder" as "Server:My Folder"
Move user-selected folder in any folder as "Renamed Folder" into a user-selected folder (possibly the same one):
MoveFolder as "Renamed Folder"
Move user-selected file in any folder as "Moved Folder" in any folder:
MoveFolder/I=3 as "Moved Folder"

## See Also

MoveFile, CopyFolder, IndexedDir, PathInfo, and RemoveEnding. Symbolic Paths on page II-34.

## MoveString

MoveString sourceString, destDataFolderPath [newname]
The MoveString operation removes the source string variable and places it in the specified location optionally with a new name.

## Parameters

sourceString can be just the name of a string variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.
destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

## Details

An error is issued if a variable or wave of the same name already exists at the destination.

## Examples

MoveString :foo:sl,:bar: // Move string s1 into data folder bar
MoveString :foo:sl,:bar:ssl // Move string sl into bar with new name ssl

## See Also

The MoveVariable, MoveWave, and Rename operations; andChapter II-8, Data Folders.

## MoveSubwindow

MoveSubwindow [/W=winName] key = (values) [, key = (values)]...
The MoveSubwindow operation moves the active or named subwindow to a new location within the host window. This command is primarily for use by recreation macros; users should use layout mode for repositioning subwindows.

## Parameters

fguide $=(g L e f t, ~ g T o p, ~ g$ Right, $g$ Bottom $)$
Specifies the frame guide name(s) to which the outer frame of the subwindow is attached inside the host window.
The frame guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.
When the host is a graph, additional standard guides are available for the outer graph rectangle and the inner plot rectangle (where traces are plotted).
See Details for standard guide names.
fnum=(left, top, right, bottom)
Specifies the new location of the subwindow. The location coordinates of the subwindow sides can have one of two possible meanings:
When all values are less than 1 , coordinates are assumed to be fractional relative to the host frame size.
When any value is greater than 1 , coordinates are taken to be fixed locations measured in points, or pixels for control panels, relative to the top left corner of the host frame.
pguide $=(g L e f t$, , $g$ Top,,$g$ Right, gBottom $)$
Specifies the guide name(s) to which the plot rectangle of the graph subwindow is attached inside the host window.
Guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.
See Details for standard guide names.
Flags
$/ \mathrm{W}=$ winName $\quad$ Moves the subwindow in the named window or subwindow. When omitted, action will affect the active subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## Details

When moving an exterior subwindow, only the fnum keyword may be used. The values are the same as the NewPanel/W flag for exterior subwindows.
The names for the built-in guides are as defined in the following table:

|  | Left | Right | Top | Bottom |
| :--- | :--- | :--- | :--- | :--- |
| Subwindow Frame | FL | FR | FT | FB |
| Outer Graph Rectangle | GL | GR | GT | GB |
| Inner Plot Rectangle | PL | PR | PT | PB |

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows.

## See Also

The MoveWindow operation. Chapter III-4, Embedding and Subwindows for further details and discussion.

## MoveVariable

MoveVariable sourceVar, destDataFolderPath [newname]
The MoveVariable operation removes the source numeric variable and places it in the specified location optionally with a new name.

## Parameters

sourceVar can be just the name of a numeric variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.
destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

## Details

An error is issued if a variable or wave of the same name already exists at the destination.

## Examples

```
MoveVariable :foo:v1,:bar: // Move v1 into data folder bar
MoveVariable :foo:v1,:bar:vv1 // Move v1 into bar with new name vv1
```

## See Also

The MoveString, MoveWave, and Rename operations; and Chapter II-8, Data Folders.

## MoveWave

MoveWave sourceWave, destDataFolderPath [newname]
The MoveWave operation removes the source wave and places it in the specified location optionally with a new name.

## Parameters

sourceWave can be just the name of a wave in the current data folder, a partial path (relative to the current data folder) and wave name or an absolute path (starting from root) and wave name.
destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

## Details

An error is issued if a variable or wave of the same name already exists at the destination.

## Examples

```
MoveWave :foo:w1,:bar: // Move wave w1 into data folder bar
MoveWave :foo:w1,:bar:ww1 // Move w1 into bar with new name ww1
```

## See Also

The MoveString, MoveVariable, and Rename operations; and Chapter II-8, Data Folders.

## MoveWindow

MoveWindow [flags] left, top, right, bottom
The MoveWindow operation moves the target or specified window to the given coordinates.

## Flags

/C Moves Command window instead of the target window.
/F Windows: Moves the Igor Pro application "frame" and the frame is then adjusted so that no part is offscreen.
Macintosh: Moves nothing.
/I Coordinates are in inches.
/ $\mathrm{P}=$ procedureTitleAsName
Moves the specified procedure window instead of the target window.
$/ \mathrm{W}=$ winName $\quad$ Moves the named window.

## Details

Note that neither winName nor procedureTitleAsName is a string but is the actual window name or procedure window title. If the procedure window's title (procedure windows don't have names) has a space in it, use $\$$ and quotes:

MoveWindow/P=\$"Log Histogram" 0,0,600,400
If /W, /F, /C, and /P are omitted, MoveWindow moves the target window.
The coordinates are in points if neither /I nor / M is used.
On Windows, you can use the MoveWindow operation to minimize, restore, or maximize a window by specifying 0,1 , or 2 for all of the coordinates, respectively, as follows:
MoveWindow $0,0,0,0$ // Minimize target window.
MoveWindow 1, 1, 1, 1 // Restore target window.
MoveWindow 2, 2, 2, 2 // Maximize target window.
These special commands are of use on Windows only. Macintosh Igor Pro 3.1 or later ignores these special commands. In earlier versions, the commands set the target window to its smallest allowed size.

## See Also

The MoveSubwindow and DoWindow operations.

## MultiThread

## MultiThread wave $=$ expression

In user-defined functions, the MultiThread keyword can be inserted in front of wave assignment statements to speed up execution on multiprocessor computer systems.

Warning: Misuse of this keyword can result in a performance penalty or even a crash. Be sure to read Automatic Parallel Processing with MultiThread on page IV-289 before using MultiThread.

The expression must be thread-safe. This means that if it calls a function, the function must be thread-safe. This goes for both built-in and user-defined functions.
Not all built-in functions are thread-safe. Use the Command Help tab in the Igor Help Browser to see which functions are thread-safe.

User-defined functions are thread-safe if they are defined using the ThreadSafe keyword. See ThreadSafe Functions on page IV-87 for details.

## See Also

Automatic Parallel Processing with MultiThread on page IV-289.
Waveform Arithmetic and Assignments on page II-94.
The "MultiThread Mandelbrot Demo" experiment.

## NameOfWave

NameOfWave (wave)
The NameOfWave function returns a string containing the name of the specified wave.
In a user-defined function that has a parameter or local variable of type WAVE, NameOfWave returns the actual name of the wave identified by the WAVE reference. It can also be used with wave reference functions such as WaveRefIndexedDFR.

NameOfWave does not return the full data folder path to the wave. Use GetWavesDataFolder for this information.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using WaveRefIndexedDFR in a loop to act on all waves in a data folder, and the loop has incremented beyond the highest valid index.

## Examples

Function ZeroWave(w)
Wave w
$\mathrm{w}=0$
Print "Zeroed the contents of", NameOfWave(w)
End
See Also
See WAVE; the GetWavesDataFolder and WaveRefIndexed functions; and Wave Reference Functions on page IV-177.

NaN
NaN
The NaN function returns the "Not a Number" value according to the IEEE standards.
Comparison operators do not work with NaN parameters because, by definition, NaN compared to anything, even another NaN , is false. Use numtype to test if a value is NaN .

## NeuralNetworkRun

NeuralNetworkRun [/Q/Z] Input=testWave, WeightsWave1=w1, WeightsWave2=w2
The NeuralNetworkRun operation uses the interconnection weights generated by NeuralNetworkTrain, and saved in the waves M_Weights1 and M_Weights2, to execute the network for a given input. The input can contain a single run represented by a 1D wave or M runs represented by M columns of a 2D wave. The output of the calculation is saved in the wave W_NNResults or M_NNResults depending on the dimensionality of the input wave. The structure of the network is completely specified by the two weights waves and must match the number of rows in the input wave.

## Flags

Suppresses printing information in the History area.
/Z
No error reporting.

## Parameters

Input=testWave
Specifies the input to the neural network. testWave must be a single or double precision wave containing entries in the range [0,1] and have the correct number of rows to match the weights. Execute the network for multiple runs by using a 2D input wave where each column corresponds to a single run. For a 2D input, the result will be stored in M_NNResults with a corresponding column structure.

WeightsWave1=w1 Specifies the interconnection weights between the input and the hidden layer.
WeightsWave2=w2 Specifies the interconnection weights between the hidden layer and the output.

## See Also

The NeuralNetworkTrain operation.

## NeuralNetworkTrain

NeuralNetworkTrain [/Q/Z] [keyword = value]...
The NeuralNetworkTrain operation trains a three-layer neural network. The training produces two 2D waves that store the interconnection weights between the network neurodes. Once you obtain the weights, you can use them with NeuralNetworkRun.

## Flags

/Q
/Z
Suppresses printing information in the History area.
No error reporting.

## Parameters

keyword is one of the following:

| Input=inWave | Specifies the input patterns for training. inWave is a 2D wave where each row corresponds <br> to a single training event and each column corresponds to the input values. The number <br> of rows in inWave (the number of training sets) and in the output wave must be equal. <br> inWave must be single or double precision and all entries must be in the range [0,1]. |
| :--- | :--- |
| Iterations=num | Specifies the number of iterations. Default is 10000. |
| MinError=val | Terminates training when the total error drops below val (default is 1e-8). The total <br> error is normalized, and is defined as the sum of the squared errors divided by the <br> number of training sets times outputs. |
| Momentum=valSpecifies a coefficient for the back-propagation algorithm. This coefficient adds to the <br> change in a particular weight a contribution proportional to the error in a previous <br> iteration. Default momentum is 0.075. |  |
| NHidden=num $\quad$Specifies the number of hidden neurodes. You do not need to use the Structure <br> keyword with NHidden because the network is completely specified by the training <br> waves and NHidden. |  |
| Output=outWaveSpecifies over how many iterations (default is 1000) to print the global RMS error to <br> the history window. Ignored with /Q. <br> Specifies the expected outputs corresponding to the entries in the input wave. The <br> number of rows in outWave (the number of training sets) and in the input wave must <br> be equal. outWave must be single or double precision and all entries must be in the <br> range [0,1]. |  |
| RestartSets the network learning rate, which is used in the backpropagation calculation. |  |
| Default is 0.15. |  |

Structure $=\{N i, N h, N o\}$
Specifies the structure of the network. $N i$ is the number of neurodes at the input, $N h$ is the number of hidden neurodes, and No is the number of output neurodes. Structure is unnecessary when using NHidden is because the remaining numbers are determined by the sizes of the input and output waves.
WeightsWave1=w1 Specifies the weights for propagation from the first layer to the second. The 2D wave must be double precision and the dimensions must match the specified neurodes with the same numbers of rows and inputs and with matching numbers of columns and hidden neurodes.

WeightsWave2=w2 Specifies the weights for propagation from the second to the third layer. The 2D wave must be double precision and the dimensions must match the specified neurodes with the same numbers of rows and hidden neurodes and with matching numbers of columns and outputs.

## Details

NeuralNetworkTrain is the first half of the implementation of a three-layer neural network in which both in inputs and outputs are taken as normalized quantities in the range [0,1]. Network training is based on back-propagation to iteratively minimize the error between the output and the expected output for any given training set. Training creates in two 2D waves that contain the interconnection weights between the
neurodes. M_Weights1 contains the weights between the input layer and the hidden layer and M_Weights2 contains the weights between the hidden layer and the output layer. During the iteration stage, global error information can be printed in the history window.
The algorithm computes the output of the $k$ th neurode by
$V_{k}=\left[1+\exp \left(-\sum_{i=1}^{n} w_{i} s_{i}\right)\right]^{-1}$
where $w_{i}$ is the weight corresponding to input $i, s_{i}$ is the signal corresponding to that input, and $n$ is the number of inputs connected to the neurode.
The total error is defined as the sum (over all training sets and all outputs) of the squared differences between the network outputs and the expected values. The sum is normalized by the product of the number of training sets and the number of outputs. The history reports (see NReport parameter) the square root of the total error (RMS error). The square root of the error computed at the end of the last iteration is stored in the variable V_rms.

## See Also

The NeuralNetworkRun operation.

## NewDataFolder

## NewDataFolder [/O/S] dataFolderSpec

The NewDataFolder operation creates a new data folder of the given name.

## Parameters

dataFolderSpec can be just a data folder name, a partial path (relative to the current data folder) with name or a full path (starting from root) with name. If just a data folder name is used then the new data folder is created in the current data folder. If a full or partial path is used, all data folders except for the last in the path must already exist.

Flags
/O No error if a data folder of the same name already exists.
/S Sets the current data folder to dataFolderSpec after creating the data folder.

## Examples

```
NewDataFolder foo // Creates foo in the current data folder
NewDataFolder :bar:foo // Creates foo in bar in current data folder
NewDataFolder root:foo // Creates foo in the root data folder
```

## See Also

Chapter II-8, Data Folders.

## NewFIFO

## NewFIFO FIFOName

The NewFIFO operation creates a new FIFO.

## Details

Useless until channel info is added with NewFIFOChan.
An error is generated if a FIFO of same name already exists. FIFOName needs to be unique only among FIFOs. You can not overwrite a FIFO.

## See Also

FIFOs are used for data acquisition. See FIFOs and Charts on page IV-282 and the NewFIFOChan operation for more information.

## NewFIFOChan

NewFIFOChan [flags] FIFOName, channelName, offset, gain, minusFS, plusFS, unitsStr [, vectPnts]
The NewFIFOChan operation creates a new channel for the named FIFO.

## Parameters

channelName must be unique for the specified FIFO.
The offset, gain, plusFS, minusFS and unitsStr parameters are used when the channel's data is displayed in a chart or transferred to a wave. If given, vectPnts must be between 1 and 65535 .

## Flags

The flags define the type of data to be stored in the FIFO channel:

| /B | 8-bit signed integer. Unsigned if /U is present. |
| :--- | :--- |
| /C | Complex. |
| /D | Double precision IEEE floating point. |
| /I | 32-bit signed integer. Unsigned if /U is present. |
| /S | Single precision IEEE floating point (default). |
| /U | Unsigned integer data. |
| /W | 16-bit signed integer. Unsigned if /U is present. |
| /Y=type | Specifies wave data type. See details below. |

## Wave Data Types

As a replacement for the above number type flags you can use $/ \mathrm{Y}=n u m$ Type to set the number type as an integer code. See the WaveType function for code values. Do not use /Y in combination with other type flags.

Details
You can not invoke NewFIFOChan while the named FIFO is running.
If you provide a value for vectPnts, you will create a channel capable of holding a vector of data rather than just a single data value. When such a channel is used in a Chart, it is displayed as an image using one of the built-in color tables.
Igor scales values in the FIFO channel before displaying them in a chart or transferring them to a wave as follows:
scaled_value = (FIFO_value - offset) * gain
Igor uses the plusFS and minusFS parameters (plus and minus full scale) to set the default display scaling for charts.
The unitsStr parameter is limited to a maximum of three characters.
When you transfer a channel's data to a wave, using the FIFO2Wave operation, Igor stores the plusFS and minusFS values and the unitsStr in the wave's Y scaling.

## See Also

FIFOs are used for data acquisition. See FIFOs and Charts on page IV-282 and the NewFIFO and
FIFO2Wave operations for more information.
The Chart operation for displaying FIFO data.

## NewFreeAxis

NewFreeAxis[flags] axisName
The NewFreeAxis operation creates a new free axis that has no controlling wave.

## Parameters

axisName is the name for the new free axis.

## Flags

/L/R/B/T Specifies whether to attach the free axis to the Left, Right, Bottom, or Top plot edge, respectively. The Left edge is used by default.
/O Replaces axisName if it already exists, which means any existing axis is marked as truly free.
/W=winName Draws in the named graph window. winName may also be the name of a subwindow. winName must not conflict with other axis names except when using the /O flag. If /W is omitted, it creates a new axis in the active graph window or subwindow.

## Details

A truly free axis does not use any scaling or units information from any associated waves (which need not exist.) You can set the properties of a free axis using SetAxis or ModifyFreeAxis.

## Example

Copy this function to your Procedure window and compile:

```
Function axhook(s)
    STRUCT WMAxisHookStruct &s
    Variable t= s.max
    s.max= s.min
    s.min= t
    return 0
End
Now execute this code on the Command line:
```

```
Make jack=x
```

Make jack=x
Display jack
NewFreeAxis fred
ModifyFreeAxis fred, master=left, hook=axhook

```

\section*{See Also}

The SetAxis, KillFreeAxis, and ModifyFreeAxis operations.

\section*{NewFreeDataFolder}

\section*{NewFreeDataFolder()}

The NewFreeDataFolder function creates a free data folder and then returns its data folder reference.
Requires Igor Pro 6.1 or later.
Recommended for advanced programmers only.

\section*{Details}

Free data folders are those that are not a part of the normal data folder hierarchy and can not be located by name.

See Also
Chapter II-8, Data Folders, Free Data Folders on page IV-79 and Data Folder References on page IV-62.

\section*{NewFreeWave}

\section*{NewFreeWave (type, numpoints)}

The NewFreeWave function creates a free 1D wave of the given type and number of points and then returns its wave reference.
Requires Igor Pro 6.1 or later.
Recommended for advanced programmers only.

\section*{Details}

NewFreeWave creates a free wave named ' \(f\) '.
You can also create free waves using Make/FREE and Duplicate/FREE. These are preferable for creating multidimensional free waves and also fine for general use.

The type parameter can be either a code as documented for WaveType or can be \(0 \times 100\) to create a data folder reference wave or \(0 \times 200\) to create a wave reference wave.
You can redimension free waves as desired but, for maximum efficiency, you should create the wave with the desired type and total number of points and then use the \(/ E=1\) flag with Redimension to simply reshape without moving data.
A free wave is automatically discarded when the last reference to it disappears.

\section*{See Also \\ Free Waves on page IV-75, Make, Duplicate.}

\section*{NewImage}

NewImage [flags] matrix
The NewImage operation creates a new image graph much like "Display;AppendImage matrix" except the graph is prepared using a style more appropriate for images. Rather than using preferences, NewImage provides several discrete styles to choose from.

\section*{Parameters}
matrix is usually an MxN matrix containing image data. See AppendImage for details.

\section*{Flags}
\begin{tabular}{|c|c|}
\hline /F & By default, the image is flipped vertically to correspond to normal image orientation. if / F is present then the image is not flipped. \\
\hline \multirow[t]{3}{*}{\(/ \mathrm{G}=\mathrm{g}\)} & Controls treatment of three-plane images as direct (RGB) color. \\
\hline & \(g=1: \quad\) Suppresses the autodetection of three-plane images as direct (RGB) color. \\
\hline & \(g=1: \quad\) Same as no /G flag (default). \\
\hline /HIDE=h & Hides ( \(\mathrm{h}=1\) ) or shows ( \(\mathrm{h}=0\), default) the window. \\
\hline \multirow[t]{2}{*}{\(/ \mathrm{HOST}=h\) CSpec} & Embeds the new image plot in the specified host window or subwindow hcSpec. \\
\hline & When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-97 for details on forming the window hierarchy. \\
\hline \multirow[t]{6}{*}{/K=k} & Specifies window behavior when the user attempts to close it. \\
\hline & \(k=0\) : \(\quad\) Normal with dialog (default). \\
\hline & \(k=1: \quad\) Kills with no dialog. \\
\hline & \(k=2\) : Disables killing. \\
\hline & \(k=3\) : Hides the window. \\
\hline & If you use \(/ \mathrm{K}=2\) or \(/ \mathrm{K}=3\), you can still kill the window using the KillWindow operation. \\
\hline / \(\mathrm{N}=\) name & Requests that the created graph have this name, if it is not in use. If it is in use, then name0, name1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen graph name. Use DoWindow/k name to ensure that name is available. \\
\hline \multirow[t]{4}{*}{\(/ \mathrm{S}=\mathrm{s}\)} & Specifies one of several window styles. \\
\hline & \(s=0: \quad\) Fills entire window with image. No axes. However, this can result in the lower-right corner not being visible due to the target icon or grow icon (Macintosh). \\
\hline & \(s=1: \quad\) Like \(s=0\) but insets image to avoid corner icon. \\
\hline & \(s=2: \quad\) Provides minimalist axes (default). \\
\hline
\end{tabular}

\section*{Details}

The graph is sized to make the image pixels a multiple of the screen pixels with the graph size constrained to be not too small and not too large.

If matrix appears to fit Igor's standard monochrome category, then explicit mode is set (See ModifyImage explicit). To be considered monochrome the wave must be unsigned byte and contain only values of 0,64 or 255 .
Once the graph is created it is a normal graph and has no special properties other than the settings it was created with. Specifically, it will not autosize itself if the dimensions of matrix are changed. NewImage is just a shortcut for creating a graph window with a style appropriate for images.
This operation is limited in scope by design. If you need to specify the position, size or title, then use the operations Display and AppendImage.
If the styles provided are not what you desire, touch up an image graph to meet your needs and then use
Capture Graph Prefs from the Graphs menu. Then use "Display ; AppendImage" rather than NewImage.

\section*{See Also}

The Display, DoWindow, AppendImage, and ModifyImage operations.

\section*{NewLayout}

NewLayout [flags] [as titleStr]
The NewLayout operation creates a page layout.
Unlike the Layout operation, NewLayout can be used in user-defined functions. Therefore, NewLayout should be used in new programming instead of Layout.
NewLayout just creates the layout window. Use AppendLayoutObject to add objects to the window.

\section*{Parameters}

The optional titleStr parameter is a string expression containing the layout's title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

\section*{Flags}
\(/ \mathrm{B}=(r, g, \mathrm{~b}) \quad\) Specifies the background color for the layout. \(r, g\), and \(b\) are integers from 0 to 65535 . Defaults to white ( \(65535,65535,65535\) ).
/C=colorOnScreen Obsolete; still accepted but has no effect. Prior to Igor Pro 5, this switched the layout display mode between black and white and color, but now layouts are always in color.
\(/ \mathrm{HIDE}=h \quad\) Hides \((\mathrm{h}=1)\) or shows \((\mathrm{h}=0\), default) the window.
\(/ K=k \quad\) Specifies window behavior when the user attempts to close it.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2\) : \(\quad\) Disables killing.
\(k=3\) : \(\quad\) Hides the window.
If you use \(/ K=2\) or \(/ K=3\), you can still kill the window using the KillWindow operation.
/ \(\mathrm{N}=\) name \(\quad\) Requests that the layout have this name, if it is not in use. If it is in use, then name0, name1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen layout name. Use DoWindow/K name to ensure that name is available.

If / N is not used, a name of the form "Layout \(n\) ", where \(n\) is some integer, is assigned. In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the page layout window from a procedure. Use the RenameWindow operation to rename the window.
\(/ \mathrm{P}=\) orientation \(\quad\) Sets the orientation of the page in the layout to either Portrait or Landscape (e.g., Layout / P=Landscape). See Details.
/W=(left,top,right,bottom)
Gives the layout window a specific location and size on the screen. Coordinates for /W are in points.

\section*{Details}

The orientation of the page is controlled by the page setup record associated with the layout. When you create a new layout window, the page setup record comes from your preferred page setup (which you specify via the Capture Layout Prefs dialog) or from a default page setup that Igor creates by calling the current printer driver. When you recreate a layout window using a Window macro, Igor reuses the page setup originally used for the layout window.

\section*{See Also}

AppendLayoutObject, DoWindow, RemoveLayoutObjects, and ModifyLayout.

\section*{NewMovie}

\section*{NewMovie [flags] [as fileNameStr]}

The NewMovie operation opens a movie file in preparation for adding frames. QuickTime is used by default but on Windows if QuickTime is not installed or if the /A flag is present, then Windows AVI files will be created. Prior to Igor Pro 6.12, QuickTime was required on Windows.

\section*{Parameters}

The file to be opened is specified by fileNameStr and / \(\mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If NewMovie can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
On Macintosh, the name of the movie file is limited to 31 characters because Igor calls Apple routines that have this limit.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.

\section*{Flags}
\(\left.\begin{array}{ll}\text { /A } & \begin{array}{l}\text { On Windows, creates an AVI file even if QuickTime is present. On Macintosh /A is } \\
\text { ignored. Requires Igor Pro } 6.12 \text { or later. }\end{array} \\
\text { /F=frameRate } & \begin{array}{l}\text { Frames per second between } 1 \text { and } 60 \text {. Defaults to } 10 \text {. }\end{array} \\
\text { Presents a system-provided dialog in which you can change the compression settings. } \\
\text { The selections you make become the new default settings but only until you quit Igor } \\
\text { Pro. }\end{array}\right]\)\begin{tabular}{l} 
Flattens a QuickTime movie when done. Use this option when transferring the movie \\
to a different platform. Creates the movie as a single file rather than two files \\
(Windows) or a file with both a data fork and resource fork (Macintosh). This flag has \\
no effect on AVI movies.
\end{tabular}

\section*{Details}

If either the path or the file name is omitted then NewMovie displays a Save File dialog to let you create a movie file. If both are present, NewMovie creates the file automatically.
If you use \(/ \mathrm{P}=\) pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd: Folder1:" or "C : \\Folder1 \\". See Symbolic Paths on page II-34 for details.
There can be only one open movie at a time.
The target window at the time you invoke NewMovie must be a graph (unless the /PICT flag is present) and the graph size should remain constant while adding frames to the movie. The graph and optional sound wave are used to determine the size and sound properties only; they do not specify the first frame.
The /PICT flag allows you to create a movie from a page layout in conjunction with the SavePICT/P=_PictGallery_method. See SavePICT on page V-617.

See Also
Movies on page IV-225.
The AddMovieFrame, AddMovieAudio, CloseMovie, PlayMovie, PlayMovieAction and SavePICT operations.

\section*{NewNotebook}

NewNotebook [flags] [as titleStr]
The NewNotebook operation creates a new notebook document.

\section*{Parameters}

The optional titleStr is a string containing the title of the notebook window.
Flags
\(/\) HOST \(=h c\) Spec Embeds the new notebook in the host window or subwindow specified by hcSpec. The host window or subwindow must be a control panel. Graphs and page layouts are not supported as hosts for notebook subwindows.
When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
See Notebooks as Subwindows in Control Panels on page III-96 for more information.
\(/ \mathrm{F}=\) format \(\quad\) Specifies the format of the notebook:
format=0: \(\quad\) Normal with dialog (default).
format=1: \(\quad\) Kills with no dialog.
format=-1: Disables killing.
\(/ K=k \quad\) Specifies window behavior when the user attempts to close it.
\(k=0: \quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2\) : \(\quad\) Disables killing.
\(k=3: \quad\) Hides the window.
If you use \(/ \mathrm{K}=2\) or \(/ \mathrm{K}=3\), you can still kill the window using the KillWindow operation.
\(/ \mathrm{N}=\) winName \(\quad\) Sets the notebook's window name to winName.
/OPTS=options Sets special options. options is a bitwise parameter interpreted as follows:
Bit 0: \(\quad\) Hide the vertical scroll bar.
Bit 1: Hide the horizontal scroll bar.
Bit 2: Set the write-protect icon initially to on.
Bit 3: Sets the changeableByCommandOnly bit. When set, the user can not make any modifications.

All other bits are reserved and must be set to zero.
If /OPTS is omitted, all bits default to zero.
See Setting Bit Parameters on page IV-12 for details about bit settings.
\(/ \mathrm{V}=\) visible \(\quad\) Specifies whether the notebook window is visible (visible=1; default) or invisible (visible=0).
/W=(left,top,right,bottom)
Sets window location. Coordinates are in points for normal notebook windows.
When used with the /HOST flag, the specified location coordinates can have one of two possible meanings:
When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.
When any value is greater than 1 , coordinates are taken to be fixed locations measured in pixels relative to the top left corner of the host frame.

\section*{Details}

A notebook has a file name, a window name, and a window title. In the simplest case these will all be the same.
The file name is the name by which the operating system identifies the notebook once it is saved to disk.
When you initially create a notebook, it is not associated with any file. However it still has a file name. This is the name that will be used when the file is saved to disk.
The window name is the name by which Igor identifies the window and therefore the name you specify in operations that act on the notebook.
The window title is what appears in the window's title bar. If you omit the title, NewNotebook uses a default title that is the same as the window name.
If you specify the window name and the notebook format and omit the window title, this is the simplest case. NewNotebook creates the document with no user interaction. The file name, window name and window title will all be the same. For example:
NewNotebook/N=Notebook1/F=0
If you omit the window name, NewNotebook chooses a default name (e.g., "Notebook0") and presents the standard New Notebook dialog.
If you omit the format or specify a format of -1 (either plain or formatted text), NewNotebook presents the standard New Notebook dialog. For example:
NewNotebook/N=Notebook1 // no format specified

\section*{See Also}

The Notebook and OpenNotebook operations, and Chapter III-1, Notebooks.
Notebooks as Subwindows in Control Panels on page III-96.

\section*{NewPanel}

NewPanel [flags] [as titleStr]
The NewPanel operation creates a control panel window or subwindow, which may contain Igor controls and drawing objects.
```

Flags
/EXT=e Creates an exterior subwindow in combination with /HOST.e specifies the host
window side location:
e=0: Right.
e=1: Left.
e=2: Bottom.
e=3: Top.
/FG=(gLeft, gTop, gRight, gBottom)
Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.
The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.
Guides may override the numeric positioning set by /W.
/FLT[=f] /FLT or /FLT=1 makes the panel a floating panel.
/FLT=2 makes it a floating panel with no close box.
/FLT=0 is the same as omitting /FLT and creates a regular (non-floating) control panel.
You must execute the following after the NewPanel command:
SetActiveSubwindow _endfloat_
See Floating Panels below for further information.
/HIDE $=h \quad$ Hides $(\mathrm{h}=1)$ or shows $(\mathrm{h}=0$, default) the window.
$/$ HOST $=h c S p e c \quad$ Embeds the new control panel in the specified host window or subwindow hcSpec.
When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
/I Sets coordinates to inches.
$/ K=k \quad$ Specifies window behavior when the user attempts to close it.
$k=0$ : $\quad$ Normal with dialog (default).
$k=1: \quad$ Kills with no dialog.
$k=2: \quad$ Disables killing.
$k=3: \quad$ Hides the window.
If you use $/ K=2$ or $/ K=3$, you can still kill the window using the KillWindow operation.
Exterior subwindows never display a dialog when killed.
/M Sets coordinates to centimeters.
$/ \mathrm{N}=$ name $\quad$ Requests that the created panel have this name, if it is not in use. If it is in use, then name 0 , name1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen panel name. Use DoWindow/K name to ensure that name is available.
Note that a function or macro with the same name will cause a name conflict.

```
\(/ \mathrm{NA}=n \quad\) Sets panel no-activate mode.
\(n=0\) : \(\quad\) Normal (default).
\(n=1\) : \(\quad\) Button click doesn't activate window but click outside of any control does.
\(n=2: \quad\) No activation even if click is outside controls. Title bar clicks still activate.
/W=(left,top,right,bottom)
Sets the initial coordinates of the panel window (in pixels unless /I or / M are used before \(/ \mathrm{W}\) ).
When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings:
When all values are less than 1 , coordinates are assumed to be fractional relative to the host frame size.
When any value is greater than 1 , coordinates are taken to be fixed locations measured in pixels relative to the top left corner of the host frame.
When the subwindow position is fully specified using guides (using the /HOST or /FG flags), the /W flag may still be used although it is not needed.

\section*{Details}

If/ N is not used, NewPanel automatically assigns to the panel a window name of the form "Panel \(n\) ", where \(n\) is some integer. In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the panel from a procedure. Use the RenameWindow operation to rename the panel.

\section*{Floating Panels}

Floating control panels float above all other windows except dialogs. Because floating panels cover up other windows, you should use them sparingly and you should take care to make them small and unobtrusive.
Floating panels are not resizable by default. To allow panel resizing use
ModifyPanel fixedSize=0
Because floating panels always act as if they are on top, the standard rules for target windows and keyboard focus do not apply.
Normally, a floating panel is never the target window and control procedures will need to explicitly designate the target. But a newly-created floating panel is the default target and will remain so until you execute
SetActiveSubwindow _endfloat_
It also becomes the default target when the tools are showing and in any non-Operate mode. Similarly, a floating panel with tools not in Operate mode has keyboard focus. To avoid confusion, do not attempt to work on other windows when a floating panel is the default target.
When working with a floating panel, you can show or hide tools or create a recreation macro by Controlclicking (Macintosh) or right-clicking (Windows) in the panel.
A floating panel does not have keyboard focus. However, a floating panel gains keyboard focus when a control that needs focus is clicked. Focus remains until you press Enter or Escape for a text entry in a setvariable, press Tab until no control has the focus, or until you click outside a focusable control.
On Macintosh, if a floating panel has focus and you activate another window, focus will leave the panel. However on Windows, if a floating panel has focus and you activate another window, the activate sequence will be fouled up leaving the windows in an indeterminate state. Consequently, it is important that you always finish any keyboard interaction started in a floating panel before moving on to other windows. If this can cause confusion, you should not use controls such as SetVariable and ListBox in a floating panel.
On Macintosh, floating panels are hidden when dialogs are up or when Igor Pro is not the front application.

\section*{Exterior Subwindows}

Exterior subwindows are automatically positioned along the designated side of a host graph window. You can designate fixed sizes or automatic size with minima. Subwindows are stacked beside the designated side in their creation order with the first one closest.
Subwindow dimensions have various meanings depending on their location. Interior values are taken to be additional grout, exterior values are taken to be sizes. For left or right panels, top is taken to be the
minimum height and bottom, if not zero, is height. For top and bottom, left is taken to be the minimum width and right, if not zero, is width. Zero values default to 50 for width and height or size of host.
Exterior subwindows are nonresizable by default. Use ModifyPanel fixedSize=0 to allow manual resizing. If you resize a panel, the original window dimensions are lost. You can also use MoveSubwindow to resize the subwindow.
Unlike normal subwindows, exterior subwindows have a tools palette. Click in the window and then choose the Show Tools or Hide Tools menu item.
Exterior subwindows have hook functions independent of the host window.

\section*{Examples}

In a new experiment, execute these commands on the command line to create two exterior subwindows:
```

Display
// Create panel on right with min height of 200 pixels, width of 100.
NewPanel/HOST=Graph0/EXT=0/W=(0, 200,100,0)
// Create another panel on right with grout of 10 and height= width= 100.
NewPanel/HOST=Graph0/EXT=0/W=(10,0,100,100)

```

Now try resizing and moving the graph.
For a demonstration of how the various exterior panels work, copy the following code to the procedure window in a new experiment:
```

Function bpNewExSw(ba) : ButtonControl
STRUCT WMButtonAction \&\&a
switch( ba.eventCode )
case 2: // mouse up
ControlInfo/W=$ba.win ckUseRect
            Variable useR= V_Value
            ControlInfo/W=$b\overline{a}.win popSide
Variable side= V_Value-1
ControlInfo/W=$b\overline{a}.win ckResizeable
            Variable resizeable= V_Value
            WAVE w=root:epsizes
            if( useR )
                NewPanel/HOST=$ba.win/EXT=(side)/W=(w[0],w[1],w[2],w[3])
else
NewPanel/HOST=\$ba.win/EXT=(side)
endif
if( resizeable )
ModifyPanel fixedSize=0 // default is 1 for floating and exterior sw
endif
break
endswitch
return 0
End
Window ExSwTest() : Graph
PauseUpdate; Silent 1 // building window...
Display /W=(803,377,1158,591)
Button bNewSW, pos ={35,21}, size={181,30},proc=bpNewExSw,title="Exterior Subwindow"
SetVariable svLeft,pos={118,82},size={96,15},title="left"
SetVariable svLeft,limits={0,100,1},value= epsizes[0],bodyWidth= 76
SetVariable svTop,pos={120,97}, size={94,15},title="top"
SetVariable svTop,limits={0,100,1},value= epsizes[1],bodyWidth= 76
SetVariable svRight,pos={112,113},size={102,15},title="right"
SetVariable svRight,limits={0,100,1},value= epsizes[2],bodyWidth= 76
SetVariable svBottom, pos={103,129}, size={111,15},title="bottom"
SetVariable svBottom,limits={0,100,1},value= epsizes[3],bodyWidth= 76
CheckBox ckUseRect, pos={70,62}, size={61,14},title="Use Rect:",value= 0
PopupMenu popSide,pos={73,149}, size={78,20},title="Side"
PopupMenu popSide,mode=1,popvalue="Right",value= \#"\"Right;Left;Bottom;Top\""
CheckBox ckResizeable,pos={76,176},size={65,14},title="Resizeable",value= 0
EndMacro
Function test()
Make/O/N=4 epsizes=0
Execute "ExSwTest()"
End

```

After compiling the procedures, execute test () on the command line. You can now experiment with different sides and size values.

\section*{See Also}

Chapter III-14, Controls and Control Panels, for details about control panels and controls.
The ModifyPanel operation.

\section*{NewPath}

NewPath [flags] pathName [, pathToFolderStr]
The NewPath operation creates a new symbolic path name that can be used as a shortcut to refer to a folder on disk.

\section*{Parameters}
pathToFolderStr is a string containing the path to the folder for which you want to make a symbolic path. pathToFolderStr can also point to an alias (Macintosh) or shortcut (Windows) for a folder.
If you use a full path for pathToFolderStr, see Path Separators on page III- 400 for details on forming the path. If you use a partial path or just a simple name for pathToFolderStr, and you use the /C flag, a new folder is created relative to the Igor Pro folder. No dialog is presented.
If you omit pathToFolderStr, you get a chance to select a folder or create a new folder from a dialog.
Flags
/C Create the folder specified by pathToFolderStr if it does not already exist.
\(/ \mathrm{M}=\) messageStr \(\quad\) Specifies the prompt message in the dialog.
/O
Overwrites the symbolic path if it exists.
/Q
Suppresses printing path information in the history.
/Z Doesn't generate an error if the folder does not exist.

\section*{Details}

Symbolic paths help to isolate your experiments from specific file system paths that contain files created or used by Igor. By using a symbolic path, if the actual location or name of the folder changes, you won't need to change all of your commands. Instead, you need only to change the symbolic path so that it points to the changed folder location.
NewPath sets the variable V_flag to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel when you use NewPath to display a choose-folder dialog.
On the Macintosh, pressing Command-Option as the Choose Folder dialog comes up will allow you to choose package folders and folders inside packages.

\section*{Examples}

NewPath Path1, "hd:IgorStuff:Test 1" // Macintosh
NewPath Path1, "C:IgorStuff:Test 1" // Windows
creates the symbolic path named Path1 which refers to the specified folder (the path's "value"). You can then refer to this folder in many Igor operations and dialogs by using the symbolic path name Path1.

\section*{Windows Note:}

You can use either the colon or the backslash character to separate folders. However, the backslash character is Igor's escape character in strings. This means that you have to double each backslash to get one backslash like so:
```

NewPath stuff, "C:<br>IgorStuff<br>Test 1"

```

Because of this complication, it is recommended that you use Macintosh path syntax even on Windows. See Path Separators on page III-400 for details.

\section*{See Also}

The PathInfo operation; especially if you need to preset a starting path for the dialog. KillPath

\section*{NewWaterfall}

NewWaterfall [flags] mwave [vs \{wavex, wavez\}]
The NewWaterfall operation creates a new waterfall plot window or subwindow using each column in the 2D matrix wave, mwave, as a waterfall trace.

You can manually set x and z scaling by specifying wavex and wavez to override the default scalings. Either wavex or wavez may be omitted by using a "*".

\section*{Flags}
/FG=(gLeft, gTop, gRight, gBottom)
Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.
Guides may override the numeric positioning set by /W.
\(/\) HIDE \(=h \quad\) Hides \((\mathrm{h}=1)\) or shows \((\mathrm{h}=0\), default \()\) the window.
\(/ \mathrm{HOST}=h c S p e c \quad\) Embeds the new waterfall plot in the specified host window or subwindow hcSpec.
When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
/I Sets window coordinates to inches.
\(/ K=k \quad\) Specifies window behavior when the user attempts to close it.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
\(k=3: \quad\) Hides the window.
If you use \(/ K=2\) or \(/ K=3\), you can still kill the window using the KillWindow operation.
/M Sets window coordinates to centimeters.
/ \(\mathrm{N}=\) name \(\quad\) Requests that the created waterfall plot window have this name, if it is not in use. If it is in use, then name 0 , name 1 , etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen name. Use DoWindow/K name to ensure that name is available.
/PG \(=(g L e f t\), gTop, gRight, gBottom \()\)
Specifies the inner plot rectangle of the waterfall plot subwindow inside its host window.

The standard plot rectangle guide names are PL, PR, PT, and PB, for the left, right, top, and bottom plot rectangle guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.
Guides may override the numeric positioning set by /W.
/W=(left,top,right,bottom)

Specifies window size. Coordinates are in points unless \(/ \mathrm{I}\) or / M is specified before \(/ \mathrm{W}\). When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings:
When all values are less than 1 , coordinates are assumed to be fractional relative to the host frame size.
When any value is greater than 1 , coordinates are taken to be fixed locations measured in points relative to the top left corner of the host frame.
When the subwindow position is fully specified using guides (using the /HOST, /FG, or /PG flags), the /W flag may still be used although it is not needed.

\section*{Details}

The \(X\) and \(Z\) axes are always at the bottom and left, whereas the \(Y\) axis runs at a default 45 degrees along the right-hand side. The angle and length of the \(Y\) axis can be changed using the ModifyWaterfall operation. Other features of the graph can be changed using normal graph operations.
Each column from mwave is plotted in (and clipped by) a rectangle defined by the X and Z axes with the rectangle displaced along the angled Y axis as a function of the y value.
Except when hidden lines are active, the traces are drawn from back to front.
To modify certain properties of a waterfall plot, you need to use the ModifyWaterfall operation. For other properties, use the usual axis and trace dialogs.

\section*{See Also}

Waterfall Plots on page II-300.
The ModifyWaterfall and ModifyGraph operations.

\section*{norm}
norm (srcWave)
The norm function evaluate the norm of srcWave. It returns: \(\sqrt{\sum^{\mathrm{abs}(w[i])^{2}}}\).
This function does not support TEXT waves.

\section*{note}

\section*{note (waveName)}

The note function returns a string containing the note associated with the specified wave.

\section*{See Also}

To create a wave note, use the Note operation.

\section*{Note}

Note [/K/NOCR] waveName [, str]
The Note operation appends str to the wave note for the named wave.

\section*{Parameters}
\(s t r\) is a string expression.
Flags
/K Kills existing note for specified wave.
/NOCR Appends note without a preceding carriage return ( \(\backslash \mathrm{r}\) character). No effect when used with /K.

\section*{Examples}

Note/K wave0 // remove existing note
Note wave0, "This is the first line of the note"

Note wave0, "This is the second line of the note"
Note/K wave0, "This is now the only line of the note"

\section*{See Also}

To get the contents of a wave note, use the note function.

\section*{Notebook}

Notebook winName, keyword=value [, keyword=value]...
The Notebook operation sets various properties of the named notebook window. Notebook also inserts text and graphics. See Chapter III-1, Notebooks, for general information on notebooks.
Notebook returns an error if the notebook is open for read-only. Keywords that don't materially change the notebook, including findText, findPicture, selection, visible, magnification, statusWidth, userKillMode, showRuler and rulerUnits, are still permitted. See Notebook Read/Write Properties on page III-12 for further information.

\section*{Parameters}
winName is either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0\#nb0. See Subwindow Syntax on page III-97 for details on hostchild specifications.
If winName is an hcSpec, the host window or subwindow must be a control panel. Graphs and page layouts are not supported as hosts for notebook subwindows.
The parameters to the Notebook operation are of the form keyword=value where keyword says what to do and value is a parameter or list of parameters. Igor limits the parameters that you specify to legal values before applying them to the notebook.
The parameters are classified into related groups of keywords.

\section*{See Also}

To create or modify a notebook action special character, see NotebookAction.
To create a notebook subwindow in a control panel, see Notebooks as Subwindows in Control Panels on page III-96.

\section*{Notebook (Document Properties)}

\section*{Notebook document property parameters}

This section of Notebook relates to setting the document properties of the notebook.

\section*{Notebook (Headers and Footers)}

\section*{Notebook headers and footers}

You can turn headers and footers on and off and position headers and footers using the keywords in this section.

There is currently no way to set the content of headers and footers except manually through the Document Settings dialog. You may be able to use stationery files to create files with specific headers and footers.
footerControl=\{defaultFooter, firstFooter, evenOddFooter\}
defaultFooter is 1 to turn the default footer on, 0 to turn it off.
firstFooter is 1 to turn the first page footer on, 0 to turn it off.
evenOddFooter is 1 to turn different footers for even and odd pages on, 0 to use the same footer for even and odd pages.
footerPos=pos pos is the position of the footer relative to the bottom of the page in points.
headerControl=\{defaultHeader, firstHeader, evenOddHeader\}
defaultHeader is 1 to turn the default header on, 0 to turn it off.
firstHeader is 1 to turn the first page header on, 0 to turn it off.
evenOddHeader is 1 to turn different headers for even and odd pages on, 0 to use the same header for even and odd pages.
headerPos=pos pos is the position of the header relative to the top of the page in points.

\section*{Notebook (Miscellaneous)}

\section*{Notebook miscellaneous parameters}

This section of Notebook relates to setting miscellaneous properties of the notebook.
autoSave \(=v \quad\) Controls auto-save mode.
\(v=0: \quad\) Notebook subwindow contents will not be saved in recreation macros.
\(v=1: \quad\) Notebook subwindow contents will be saved in recreation macros (default).
This affects notebook subwindows in control panels only. Use autoSave=0 if you do not want the notebook's contents to be saved and restored when the control panel is recreated. Otherwise the notebook subwindow's contents will be restored when recreated.
status \(=\{\) messageStr, flags \(\}\)
Sets the message in the status area at the bottom left of the notebook window.
flags is interpreted bitwise. Message is erased when:
Bit 0: Selection changes.
Bit 1: Window is activated.
Bit 2: Window is deactivated.
Bit 3: Document is modified.
If all bits are zero, the message stays until a new message comes along. All other bits are reserved for future use and should be zero. See Setting Bit Parameters on page IV-12 for details about bit settings.
updating=\{flags, \(r\}\) Sets parameters related to the updating of special characters.
flags is interpreted bitwise:
Bit 0: Suppress automatic periodic updating of date and time special characters. By default this bit is set so date and time special characters are updated only when the user explicitly requests it or during printing when they appear in headers and footers.
Bit 1: Allow manual updating of special characters via the specialUpdate keyword or via the Special menu. By default this is cleared so manual updating is not allowed.

All other bits are reserved for future use and should be zero. See Setting Bit Parameters on page IV-12 for details about bit settings.
\(r\) is the update rate in seconds for updating date and time special characters.
These settings have no effect on the updating of special characters in headers or footers. These characters are always automatically updated when the document is printed.

We recommend that you leave automatic updating off (set bit 0 of the flags parameter to 1) so that updating occurs only via the specialUpdate keyword or via the Special menu.
visible \(=v \quad\) Sets notebook visibility.
\begin{tabular}{ll}
\(v=0:\) & Hides notebook. \\
\(v=1:\) & Shows notebook but does not make it top window. \\
\(v=2:\) & Shows notebook and makes it top window.
\end{tabular}

\section*{Notebook (Paragraph Properties)}

\section*{Notebook paragraph property parameters}

This section of Notebook relates to setting the paragraph properties of the current selection in the notebook.
The margins, spacing, justification, tabs and rulerDefaults keywords provide control over paragraph properties which are governed by rulers. These keywords, in conjunction with the ruler and newRuler keywords, allow you to set paragraph properties. They are allowed for formatted text notebooks only, not for plain text notebooks.
The ruler keywords are described in detail below. Before we get to the detail, you should understand the different things you can do with rulers.
There are four things you can do with a ruler:
modify it (analogous to manually adjusting a ruler).
redefine it (analogous to the Redefine Ruler dialog).
create it (analogous to the Define New Ruler dialog).
apply it (analogous to selecting a ruler name from Ruler pop-up menu).
Igor's behavior in response to ruler keywords depends on the order in which the keywords appear.
To modify the ruler(s) for the selected paragraph(s), use the margins, spacing, justification, tabs and rulerDefaults keywords without using the newRuler or ruler keywords. For example:
Notebook Notebook0 tabs=\{36,144,288\},justification=1
To redefine an existing ruler, invoke the ruler=rulerName keyword before any other keywords. For example: Notebook Notebook0 ruler=Ruler1,tabs=\{36,144,288\},justification=1
Unlike redefining the ruler manually, when you redefine an existing ruler using ruler=rulerName, it does not apply the ruler to the selected text. However, it does update any text governed by the redefined ruler.
To create a new ruler, invoke the newRuler=rulerName keyword before any other keywords. For example: Notebook Notebook0 newRuler=Ruler1,tabs=\{36,144,288\},justification=1

Unlike creating it manually, when you create a new ruler using newRuler=rulerName, it does not apply the new ruler to the selected text. If you do not set a particular ruler property when creating a new ruler, the property will be the same as for the Normal ruler. If the specified ruler already exists, newRuler=rulerName overwrites the existing ruler.

To apply an existing ruler to the selected text, invoke the ruler=rulerName keyword without any other keywords. For example:

Notebook Notebook0 ruler=ruler1
You and Igor will get confused if you mix ruler keywords with other types of keywords in the same command. It is alright, however to put a selection keyword at the start of the command. Mixing will not cause a crash or any drastic problem but it will likely produce results that you don't understand.
To keep things clear, follow these rules:
- If you use ruler=rulerName or newRuler=rulerName, put them before any other ruler keywords.
- Do not mix ruler keywords with other kinds, except that it is alright to use the selection keyword at the start of the command.
justification=j Sets text justification:
\(j=0\) : Left aligned.
\(j=1\) : Center aligned.
\(j=2\) : Right aligned.
\(j=3: \quad\) Fully justified.
margins=\{indent,left,right\}
indent sets the indentation of first line from left page margin.
left sets the paragraph's left margin in points measured from the left page margin.
right sets the paragraph's right margin in points measured from the left page margin.
newRuler=rulerName
Creates a new ruler with the specified name. If a ruler with this name already exists, it is overwritten.
ruler=rulerName Applies the named ruler to the selected text or to redefine the named ruler, as explained above.
rulerDefaults=\{"fontName", fSize, fStyle, \((r, g, b)\}\)
"fontName" sets the ruler's text font, e.g., "Helvetica".
fSize sets the ruler's text size.
\(f S t y l e\) sets the ruler's text style.
\((r, g, b)\) sets the ruler's text color. \(r, g\), and \(b\) are integers from 0 to 65535.
You can only use rulerDefaults if you are redefining an existing ruler, using ruler=rulerName, or you are creating a new ruler using newRuler=rulerName.
spacing=\{spaceBefore,spaceAfter,lineSpace\}
spaceBefore sets the extra space before paragraph in points.
spaceAfter sets the extra space after paragraph in points.
lineSpace sets the extra space between lines of a paragraph in points.
tabs=\{tabSpec\} tabSpec is list of tab stops in points added to special values that change the tab stop type.
Tab stops have two parts: the tab stop position and the tab type. Each integer in the list of tabs encodes both of these parts as follows:
The low 11 bits contains the tab stop position in points.
The next two bits are reserved for future use and must be zero.

The high three bits are used to contain the tab type as follows:
\begin{tabular}{lll} 
left tab & 0 & \\
center tab & 1 & add \(1^{*} 8192\) to tab stop position. \\
right tab & 2 & add \(2^{*} 8192\) to tab stop position. \\
\begin{tabular}{l} 
decimal tab \\
comma tab
\end{tabular} & 3 & add \(3^{*} 8192\) to tab stop position. \\
& 4 & add \(4^{*} 8192\) to tab stop position.
\end{tabular}

\section*{Tabs Example}

The following puts a left tab at 1 inch, a center tab at 3 inches and a decimal tab at 5 inches:
Notebook Notebook1 tabs \(=\{1 * 72,3 * 72+8192,5 * 72+3 * 8192\}\)

\section*{Notebook (Selection)}

\section*{Notebook selection parameters}

This section of Notebook relates to selecting a range of the content of the notebook.
```

findPicture={graphicNameStr, flags}

```

Searches for the picture containing the named graphic (Macintosh only) or the next picture if you pass " ". Sets V_flag to 1 if the picture was found or to 0 if not found.
flags is a bitwise parameter interpreted as follows:
Bit 0: Show selection after the find.
All other bits are reserved for future use. Set bit 0 by setting flags \(=1\).
The search is always forward from the end of the current selection to the end of the document.
findSpecialCharacter=\{specialCharacterNameStr, flags\}
Searches for the special character with the specified name or the next special character if you pass " ". Selects the special character if it is found.
Sets V_flag to 1 if the special character was found or to 0 if not. Sets S_name to the name of the found special character or to " " if it was not found.
flags is a bitwise parameter interpreted as follows:
Bit 0: Show selection after the find.
All other bits are reserved for future use. Set bit 0 by setting flags \(=1\).
If specialCharacterNameStr is empty (" "), the search proceeds from the end of the current selection to the end of the document. Otherwise the search always covers the entire document.
findText=\{textToFindStr, flags\}
Searches for the specified text. Sets V_flag to 1 if the text was found or to 0 if not found.
textToFindStr is a string expression for the text you want to find. If the text contains a carriage return, Igor considers only the part of the text before the carriage return.
flags is a bitwise parameter interpreted as follows:
Bit 0: Show selection after the find.
Bit 1: Do case-sensitive search.
Bit 2: Search for whole words.
Bit 3: Wrap around.
Bit 4: Search backward.
All other bits are reserved and must be set to zero.
To set bit 0 and bit 3 , use \(2^{0}+2^{3}=9\) for flags. See Setting Bit Parameters on page IV-12 for details about bit settings.
If you are searching forward, the search starts from the end of the current selection. If you are searching backward, the search starts from the start of the current selection.
If you specify " " as the text to search for, it "finds" the current selection. This displays the current selection using findText \(=\{"\) ", 1\(\}\).
selection=\{selStart, selEnd\}
selStart and selEnd are locations within the document. You can specify these document locations by using the following expressions:
\begin{tabular}{|c|c|}
\hline \multirow[t]{3}{*}{(paragraph, pos)} & paragraph and pos are numeric expressions. \\
\hline & paragraph is a paragraph number from 0 to \(n-1\) where \(n\) is the number of paragraphs in the document. \\
\hline & \(p o s\) is a character position from 0 to \(n\) where \(n\) is the number of characters in the paragraph. Position 0 is to the left of the first character in the paragraph. Position \(n\) is to the right of the last character in the paragraph. \\
\hline startOfFile & Start of the document. \\
\hline endOfFile & End of the document. \\
\hline startOfParagraph & Start of current selStart paragraph. \\
\hline endOfParagraph & End of current selStart paragraph. \\
\hline startOfNextParagraph & Start of paragraph after current selStart paragraph. \\
\hline endOfNextParagraph & End of paragraph after current selStart paragraph. \\
\hline startOfPrevParagraph & Start of paragraph before current selStart paragraph. \\
\hline endOfPrevParagraph & End of paragraph before current selStart paragraph. \\
\hline endOfChars & Just before the carriage return of current selStart paragraph. \\
\hline
\end{tabular}

Igor clips the specified locations to legal values. It also sets the V_flag variable to 0 if the selStart location that you specified was valid, to 1 if the start paragraph was out of bounds and to 2 if the start position was out of bounds. You can use the startOfNextParagraph keyword to step through the document one paragraph at a time. When V_flag is nonzero, you are at the end of the document.
The terms next and prev are relative to the paragraph containing the start of the selected text before the selection keyword was invoked.
The selection keyword just sets the selection. If you also want to scroll the selected text into view you must also use the findText keyword as shown in the examples.

\section*{Selection Examples}

Following are some examples of setting the selection:
```

// select all text in notebook
Notebook Notebook1 selection={startOfFile, endOfFile}
// move selection to the start of the notebook and display the selection
Notebook Notebookl selection={startOfFile,startOfFile}, findText={"",1}
// move selection to the end of the notebook and display the selection
Notebook Notebook1 selection={endOfFile,endOfFile}, findText={"",1}
// select all of paragraph 3
Notebook Notebook1 selection={(3,0), (4,0)}
// select all of paragraph 3 and display the selection
Notebook Notebook1 selection={(3,0), (4,0)}, findText={"",1}
// select all of current paragraph except for trailing CR, if any
Notebook Notebook1 selection={startOfParagraph, endOfChars}
// select the first occurrence of "Hello" in the document and display the selection
Notebook Notebook1 selection={startOfFile,startOfFile}, findText={"Hello",1}
// select the first picture in the document
Notebook Notebook1 selection={startOfFile,startOfFile}, findPicture={"",1}
See Also
The GetSelection operation to "copy" the selection.

```

\section*{Notebook (Text Properties)}

\section*{Notebook text property parameters}

This section of Notebook relates to setting the text properties of the current selection in the notebook.
\begin{tabular}{|c|c|}
\hline \multirow[t]{2}{*}{font="fontName"} & "fontName" is the name of the font. Use "default" to specify the paragraph's ruler font. \\
\hline & If you specify an unavailable font, it does nothing. This is so that, when you share procedures with a colleague, using a font that the colleague does not have will not cause your procedures to fail. The downside of this behavior is that if you misspell a font name you will get no error message. \\
\hline \multirow[t]{2}{*}{fSize=fontSize} & Text size from 3 to 32000 points. \\
\hline & Use -1 to specify the paragraph's ruler size. \\
\hline \multirow[t]{6}{*}{fStyle=fontStyle} & A binary coded integer with each bit controlling one aspect of the text style as follows: \\
\hline & Bit 0: Bold. \\
\hline & Bit 1: Italic. \\
\hline & Bit 2: Underline. \\
\hline & Bit 3: Outline (Macintosh only). \\
\hline & Bit 4: Shadow (Macintosh only). \\
\hline
\end{tabular}

Use -1 to specify the paragraph's ruler style. To set bit 0 and bit 1 (bold italic), use \(2^{0}+2^{1}=3\) for fontStyle. See Setting Bit Parameters on page IV-12 for details about bit settings.
textRGB=( \(r, g, b) \quad\) Specifies text color. \(r, g\), and \(b\) are integers from 0 to \(65535 .(0,0,0)\) specifies black. ( \(65535,65535,65535\) ) specifies white.
vOffset \(=v \quad\) Sets the vertical offset in points (positive offset is down, negative is up). Use this to create subscripts and superscripts. vOffset is allowed for formatted text files only, not for plain text files.

\section*{Notebook (Writing Graphics)}

\section*{Writing notebook graphics parameters}

This section of Notebook relates to inserting graphics at the current selection in the notebook.
These graphics keywords are allowed for formatted text files only, not for plain text files.
convertToPNG \(=x\) Converts all pictures in the current selection to cross-platform PNG format. If the picture is already PNG, it does nothing.
\(x\) is the resolution expansion factor, an integer from 1 to 16 times screen resolution. \(x\) is clipped to legal limits.
frame \(=f \quad\) Sets the frame used for the picture and insertPicture keywords.
\(f=0: \quad\) No frame (default).
\(f=1: \quad\) Single frame.
\(f=2: \quad\) Double frame.
\(f=3\) : \(\quad\) Triple frame.
\(f=4: \quad\) Shadow frame.
insertPicture=\{pictureName, pathName, filePath, options\}
Inserts a picture from a file specified by pathName and filePath. The supported graphics file formats are listed under Inserting Pictures on page III-16.
pictureName is the special character name (see Special Character Names on page III-17) to use for the inserted notebook picture or \$"" to automatically assign a name. pathName is the name of an Igor symbolic path created via NewPath or \(\$ " \mathrm{l}\) " to use no path.
filePath is a full path to the file to be loaded or a partial path or simple file name relative to the specified symbolic path.
If pathName and filePath do not fully specify a file, an Open File dialog is displayed from which the user can choose the file to be inserted.
options is a bitwise parameter interpreted as follows:
Bit 0: If set, an Open File dialog is displayed even if the file is fully specified by pathName and filePath.
Bit 1: Determines what to do in the event of a name conflict. If set, the existing special character with the conflicting name is overwritten. If cleared, a unique name is created and used as the special character name for the inserted picture.
All other bits are reserved and must be set to zero.
See Setting Bit Parameters on page IV-12 for details about bit settings.
The variable V_flag is set to 1 if the picture was inserted or to 0 otherwise, for example, if the user canceled from the Open File dialog.

The string variable S_name is set to the special character name of the picture that was inserted or to "" if no picture was inserted.

The string variable S_fileName is set to the full path of the file that was inserted or to "" if no picture was inserted.
picture=\{objectSpec, mode, flags\}
Inserts a picture based on the specified object.
objectSpec is usually just an object name, which is the name of a graph, table, page layout or picture from Igor's picture gallery (Misc \(\rightarrow\) Pictures). See further discussion below.
mode controls what happens when you insert a picture of a graph, table or page layout window. It does not affect insertions of pictures from the picture gallery.
mode specifies the format of the graph, table, or page layout picture as follows:
\begin{tabular}{lll} 
mode & Macintosh & Windows \\
\hline-5 & PNG & PNG \\
-4 & HiRes bitmap & Device-independent bitmap \\
-2 & HiRes PICT & Enhanced metafile \\
-1 & Quartz PDF & Enhanced metafile \\
0 & Quartz PDF & Enhanced metafile \\
1 & 1X PICT & Enhanced metafile \\
2 & 2X PICT & Enhanced metafile \\
4 & 4 PICT & Enhanced metafile \\
8 & 8 P PICT & Enhanced metafile \\
\hline
\end{tabular}

Mode 0 is recommended unless you are concerned about cross-platform compatibility in which case you must use mode -5 (PNG).
See Chapter III-5, Exporting Graphics (Macintosh), or Chapter III-6, Exporting
Graphics (Windows), for further discussion of these formats. The PNG format is discussed further in Picture Compatibility on page III-397.
flags is a bitwise parameter interpreted as follows:
Bit 0: 0 for black and white, 1 for color.
All other bits are reserved and must be set to zero.
For color, set flags \(=2^{0}=1\).
See Setting Bit Parameters on page IV-12 for details about bit settings.
scaling \(=\{h, v\} \quad\) Sets the horizontal \((h)\) and vertical \((v)\) scaling for the selected picture or the picture and insertPicture keywords. \(h\) and \(v\) are in percent.

When using the picture keyword, you may include a coordinate specification after the object name in objectSpec. For example:
Notebook Notebook1 picture \(=\{\) Layout \(0(100,50,500,700), 1,1\}\)
The coordinates are in points. A coordinate specification of ( \(0,0,0,0\) ) behaves the same as no coordinate specification at all.
If the object is a graph, the coordinate specification determines the width and height of the graph. If you omit the coordinate specification, Igor takes the width and height from the graph window.

If the object is a layout, the coordinate specification identifies a section of the layout. If you omit the coordinate specification, Igor selects a section of the layout that includes all objects in the layout plus a small margin.
For any other kind of object, Igor ignores the coordinate specification if it is present.
The scaling and frame keywords affect the selected picture, if any. If no picture is selected, they affect the insertion of a picture using the picture or insertPicture keywords. For example, this command inserts a picture of Graph0 with \(50 \%\) scaling and a double frame:
Notebook Test1 scaling=\{50, 50\}, frame=2, picture=\{Graph0, 1, 1\}
If no picture is selected and no picture is inserted, scaling and frame have no effect.

\section*{InsertPicture Example}
```

Function InsertPictureFromFile(nb)
String nb // Notebook name or "" for top notebook
if (strlen(nb) == 0)
nb = WinName(0, 16, 1)
endif
if (strlen(nb) == 0)
Abort "There are no notebooks"
endif
// Display Open File dialog to get the file to be inserted
Variable refNum // Required for Open but not really used
String fileFilter = "Graphics Files:.eps,.jpg,.png;All Files:.*;"
Open /D /R /F=fileFilter refNum
String filePath = S_fileName
if (strlen(filePath)}==0
Print "You cancelled"
return -1
endif
Notebook $nb, insertPicture={$"", \$"", filePath, 0}
if (V flag)
Print "Picture inserted"
else
Print "No picture inserted"
endif
return 0
End

```

\section*{Save notebook pictures to files}

The savePicture keyword is allowed for formatted text files only, not for plain text files. savePicture \(=\{\) pictureName, pathName, filePath, options \(\}\)

Saves a picture from a formatted text notebook to a file specified by pathName and filePath.
pictureName is the special character name (see Special Character Names on page
III-17) of the picture to be saved or \(\$ " "\) to save the selected picture in which case one picture and one picture only must be selected in the notebook.
pathName is the name of an Igor symbolic path created via NewPath or \$"" to use no path.
filePath is a full path to the file to be written or a partial path or simple file name relative to the specified symbolic path.
If pathName and filePath do not fully specify a file, a Save File dialog is displayed in which the user can specify the file to be written.
options is a bitwise parameter interpreted as follows:
Bit 0: If set, a Save File dialog is displayed even if the file is fully specified by pathName and filePath.
Bit 1: If set, a file with the same name is overwritten if it exists. If cleared, a Save File dialog is displayed if the specified file already exists.
Bit 2: If set then the leaf name specified by filePath is ignored and a name is automatically generated based on the picture name.

All other bits are reserved and must be set to zero.
See Setting Bit Parameters on page IV-12 for details about bit settings.
The variable V_flag is set to 1 if the picture was written or to 0 otherwise, for example, if the user canceled from the Save File dialog.
The string variable S_name is set to the special character name of the picture that was saved or to "" if no picture was saved.
The string variable S_fileName is set to the full path of the file that was written or to "" if no picture was written.

\section*{Notebook (Writing Special Characters)}

\section*{Writing special character parameters}

This section of Notebook relates to inserting special characters at the current selection in the notebook. To insert a notebook action, see NotebookAction.
The special characters are page break, short date, long date, abbreviated date and time. They act in some respects like a single character but have special properties. You can insert the special characters using the specialChar keyword.
The specialChar keyword is allowed for formatted text files only, not for plain text files.
Other special characters are allowed in headers and footers only and you can not insert them in a document using the specialChar keyword. These are window title, page number and total pages.
The special characters other than page break character are dynamic and update periodically.
```

specialChar={type, flags,optionsStr}

```
type is the special character type as follows:
\begin{tabular}{ll} 
1: & Page break. \\
\(2:\) & Short date. \\
3: & Long date. \\
\(4:\) & Abbreviated date. \\
5: & Time.
\end{tabular}
flags is reserved for future use. You should pass 0 for flags.
optionsStr is reserved for future use. You should pass " " for optionsStr.

\section*{specialUpdate=flags}

Updates special characters in the notebook.
flags is interpreted bitwise:
Bit 0: 0 to update all special characters.
Bit 1: 1 to update special characters in the selected text.
If 1, updates regardless of whether updating is enabled or not.
All other bits are reserved and must be set to zero.
See Setting Bit Parameters on page IV-12 for details about bit settings.
The specialUpdate keyword can update pictures of graphs, tables, and page layouts that were created from windows in the current experiment.

\section*{See Also}

Chapter III-1, Notebooks. The NewNotebook, NotebookAction, and OpenNotebook operations; the SpecialCharacterInfo and SpecialCharacterList functions.

\section*{Notebook (Accessing Contents)}

\section*{Accessing Notebook Contents}
getData=mode \(\quad\) Causes Igor to return the contents of the notebook in the S_value variable. The contents are binary data in a private Igor format encoded as text. The only use for this keyword is to transfer data from one notebook to another by calling getData followed by setData.

Causes Igor to return the contents of the notebook in the S_value variable. The contents are binary data in a private Igor format encoded as text. The only use for this keyword is to transfer data from one notebook to another by calling getData followed by setData.
mode=1: \(\quad\) Stores in S_value plain text or formatted text data, depending on the type of the notebook, from the entire notebook.
mode \(=2\) : \(\quad\) Stores in S_value plain text data, regardless of the type of the notebook, from the entire notebook.
mode=3: \(\quad\) Stores in S_value plain text or formatted text data, depending on the type of the notebook, from the notebook selection only.
mode \(=4\) : Stores in S_value plain text data, regardless of the type of the notebook, from the notebook selection only.

See the Notebook In Panel example experiment for examples using getData and setData.

\section*{Notebook (Writing Text)}

\section*{Writing notebook text parameters}

This section of Notebook relates to inserting text at the current selection in the notebook.
\begin{tabular}{ll} 
text=textStr & \begin{tabular}{l} 
Inserts the text at the current selection. \\
Before the text is inserted, Igor converts escape sequences in textStr as described in \\
Escape Characters in Strings on page IV-13.
\end{tabular} \\
Then, it checks for illegal characters. The only character code that is illegal is zero \\
(ASCII NUL character). If it finds an illegal character, Igor generates an error and does \\
not insert the text.
\end{tabular}

\section*{NotebookAction}

NotebookAction [/W=winName] keyword = value [, keyword = value ...]
The NotebookAction operation creates or modifies an "action" in a notebook. A notebook action is an object that executes commands when clicked.
See Chapter III-1, Notebooks, for general information about notebooks.
NotebookAction returns an error if the notebook is open for read-only. See Notebook Read/Write Properties on page III-12 for further information.

\section*{Parameters}

The parameters are in keyword =value format. Parameters are automatically limited to legal values before being applied to the notebook.
\(\operatorname{bgRGB}=(r, g, b) \quad\) Specifies the action background color. \(r, g\), and \(b\) are values from 0 to 65535.
commands=str Specifies the command string to be executed when clicking the action. For multiline commands, add a carriage return ( \(\backslash r\) ) between lines.
enableBGRGB=enable
Uses the background color specified by bgRGB (enable=1). Background color is ignored for enable=0.
frame \(=f \quad\) Specifies the frame enclosing the action.
\[
\begin{array}{ll}
f=0: & \text { No frame. } \\
f=1: & \text { Single frame (default). } \\
f=2: & \text { Double frame. } \\
f=3: & \text { Triple frame. } \\
f=4: & \text { Shadow frame. }
\end{array}
\]
helpText=helpTextStr

Specifies the help string for the action. The text is limited to 255 characters. On Macintosh, help appears when the cursor is over the action after choosing Help \(\rightarrow\) Show Igor Tips. On Windows, help appears in the status line when the cursor is over the action.
ignoreErrors=ignore
Controls whether an error dialog will appear (ignore \(=0\) ) or not (ignore is nonzero) if an error occurs while executing the action commands.
linkStyle=linkStyle Controls the action title text style. If linkStyle=1, the style is the same as a help link (blue underlined). If linkStyle \(=0\), the style properties are the same as the preceding text.
name=name \(\quad\) Specifies the name of the new or modified notebook action. This is a standard Igor name. See Standard Object Names on page III-417 for details.
padding \(=\{\) leftPadding, rightPadding, topPadding, bottomPadding, internalPadding \(\}\)
Sets the padding in points. internalPadding sets the padding between the title and the picture when both elements are present.
picture=name Specifies a picture for the action icon. name is the name of a picture in the picture collection (see Pictures on page III-423).
If name is null (\$" "), it clears the picture parameter.
procPICTName=name
Specifies a Proc Picture for the action icon (see Proc Pictures on page IV-44). name is the name of a Proc Picture or null (\$"") to clear it. This will be a name like ProcGlobal\#myPictName or MyModuleName\#myPictName. If you use a module name, the Proc Picture must be declared static.
If you specify both picture and procPICTName, picture will be used.
quiet=quiet \(\quad\) Displays action commands in the history area (quiet=0), otherwise (quiet=1) no commands will be recorded.
scaling \(=\{h, v\} \quad\) Scales the picture in percent horizontally, \(h\), and vertically, \(v\).
showMode=mode Determines if the title or picture are displayed.
mode=1: Title only.
mode=2: \(\quad\) Picture only.
mode=3: Picture below title.
mode=4: Picture above title.
mode=5: Picture to left of title.
mode \(=6\) : \(\quad\) Picture to right of title.
Without a picture specification, the action will use title mode regardless of what you specify.
title=titleStr Sets the action title to titleStr, which is limited to 255 characters.

\section*{Flags}
/W= winName Specifies the notebook window of interest.
winName is either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0\#nb0. See
Subwindow Syntax on page III-97 for details on host-child specifications.
If / W is omitted, NotebookAction acts on the top notebook window.

\section*{Examples}

String nb \(=\) WinName \((0,16,1) \quad / /\) Top visible notebook
```

NotebookAction name=Action0, title="Beep", commands="Beep"// Create action
NotebookAction name=Action0, enableBGRGB=1, padding={4,4,4,4,4}
Notebook \$nb, findSpecialCharacter={"Action0",1} // Select action
Notebook \$nb, frame=1 // Set frame

```

\section*{See Also}

Chapter III-1, Notebooks.
The Notebook, NewNotebook, and OpenNotebook operations; the SpecialCharacterInfo and SpecialCharacterList functions.

\section*{num2char}
num2 char (num)
The num2char function returns a string containing a single byte whose value is the low 8 bits of num.

\section*{Examples}

Print num2char(65) // prints A
Print num2char(97) // prints a

\section*{See Also}

The char2num, str2num and num2str functions.

\section*{num2istr}
num2istr (num)
The num2istr function returns a string representing num after rounding to the nearest integer.

\section*{num2str}
num2str (num)
The num2str function returns a string representing the number num.
Precision is limited to only five decimal places. This can cause unexpected and confusing results. For this reason, we recommend that you use num2istr or sprintf for better control of the format and precision of the number conversion.

\section*{See Also}

The sprintf operation.
The str2num, char2num and num2char functions.

\section*{NumberByKey}

NumberByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]]) The NumberByKey function returns a numeric value extracted from kwListStr based on the specified key contained in keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1, KEY2=value2" or "Key:value1; KEY2: value2", depending on the values for keySepStr and listSepStr.
Use NumberByKey to extract a numeric value from a strings containing "key1=value1; key2=value2;" style lists such as those returned by functions like AxisInfo or TraceInfo.
If the key is not found or if any of the arguments is " " or if the conversion to a number fails then it returns NaN . keySepStr, listSepStr, and matchCase are optional; their defaults are ":", ";", and 0 respectively.

\section*{Details}
keyStr is limited to 255 characters.
\(k w L i s t S t r\) is searched for an instance of the key string bound by listSepStr on the left and a keySepStr on the right. The text up to the next listSepStr is converted to the returned number.
\(k w L i s t S t r\) is treated as if it ends with a listSepStr even if it doesn't.
Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional matchCase parameter to 1 makes the comparisons case sensitive.
Only the first characters of keySepStr and listSepStr are used.

If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

\section*{Examples}

\section*{See Also}

The StringByKey, RemoveByKey, ReplaceNumberByKey, ReplaceStringByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

\section*{numpnts}
numpnts (waveName)
The numpnts function returns the total number of data points in the named wave. To find the number of elements in a dimension of a multidimensional wave, use the DimSize function.

\section*{numtype}
numtype (num)
The numtype function returns a number which indicates what kind of value num contains.

\section*{Details}

If num is a real number, numtype returns a real number whose value is:
\(0: \quad\) If num contains a normal number.
1: If num contains +/-INF.
2: If num contains NaN .

If num is a complex number, numtype returns a complex number in which the real part is the number type of the real part of num and the imaginary part is the number type of the imaginary part of num.

\section*{NumVarOrDefault}

NumVarOrDefault (pathStr, defVal)
The NumVarOrDefault function checks to see if the pathStr points to a numeric variable. If the numeric variable exists, NumVarOrDefault returns its value. If the numeric variable does not exist, it returns defVal instead.

\section*{Details}

NumVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. String variables use the corresponding numeric function, StrVarOrDefault.

\section*{Examples}
```

Macro foo(nval,sval)
Variable nval=NumVarOrDefault("root:Packages:mypack:nvalSav",2)
String sval=StrVarOrDefault("root:Packages:mypack:svalSav","Hi")
String dfSav= GetDataFolder(1)
NewDataFolder/O/S root:Packages
NewDataFolder/O/S mypack
Variable/G nvalSav= nval
String/G svalSav= sval
SetDataFolder dfSav
End

```

\section*{NVAR}

NVAR [/C] [/Z] localName [= pathToVar] [, localName1 [= pathToVarl]]...
NVAR is a declaration that creates a local reference to a global numeric variable accessed in a user-defined function.

The NVAR reference is required when you access a global numeric variable in a function. At compile time, the NVAR statement specifies the local name referencing a global numeric variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global numeric variable must exist when the NVAR statement is executed.
When localName is the same as the global numeric variable name and you want to reference a global variable in the current data folder, you can omit pathToVar. Prior to Igor Pro 4.0, pathToVar was always required.
pathToVar can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or \$ followed by string variable containing a computed path (see Converting a String into a Reference Using \$ on page IV-48).
You can also use a data folder reference or the /SDFR flag to specify the location of the numeric variable if it is not in the current data folder. See Data Folder References on page IV-62 and The /SDFR Flag on page IV-64 for details.
If the global variable may not exist at runtime, use the /Z flag and call NVAR_Exists before accessing the variable. The /Z flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:
```

NVAR/Z nv=<pathToPossiblyMissingNumericVariable>
if( NVAR_Exists(nv) )
<do something with nv>
endif

```

Note that to create a global numeric variable, you use the Variable/G operation.

\section*{Flags}
/C Variable is complex.
/Z Ignores variable reference checking failures.

\section*{See Also}

NVAR_Exists function.
Accessing Global Variables and Waves on page IV-50.
Converting a String into a Reference Using \$ on page IV-48.

\section*{NVAR_Exists}

NVAR_Exists (name)
The NVAR_Exists function returns one if specified NVAR reference is valid or zero if not. It can be used only in user-defined functions.
For example, in a user function you can test if a global numeric variable exists like this:
```

NVAR /Z var1 = gVar1
// /Z prevents debugger from flagging bad NVAR
if (!NVAR_Exists(varl)) // No such global numeric variable?
Variable/G gVar1 = 0 // Create and initialize it
endif

```

See Also
WaveExists, SVAR_Exists, and Accessing Global Variables and Waves on page IV-50.

\section*{Open}

Open [flags] refNum [as fileNameStr]
The Open operation can, depending on the flags passed to it:
- Open an existing file to read data from (/R flag without /D).
- Open a to append results to (/A flag without /D).
- Create a new file or overwrite an existing file to write results to (no /D, /R or /A flags).
- Display an Open File dialog (/D/R or /D/A flags with or without /MULT).
- Display a Save File dialog (/D flag without /R or /A).

\section*{Parameters}
refNum is the name of a numeric variable to receive the file reference number. refNum is set by Open if Open actually opens a file for reading or writing (cases 1, 2 and 3). You use refNum with the FReadLine, FStatus,

FSetPos, FBinWrite, FBinRead, fprintf, and wfprintf operations to read from or write to the file. When you're finished, use pass refNum to the Close operation to close the file.
Open does not set the file reference number when the /D flag is used (cases 4 and 5) but you must still supply a refNum parameter.
The following discussion of the pathName and fileNameStr parameters applies when you are attempting to open a file for reading or writing (cases 2,3 , and 5 above).

The targeted file is specified by a combination of the pathName parameter and the fileNameStr parameter. There are three ways to specify the targeted file:
\begin{tabular}{ll} 
Method & How To Use It \\
\hline \begin{tabular}{l} 
Symbolic path and \\
simple file name
\end{tabular} & \begin{tabular}{l} 
Use /P=pathName and fileNameStr, where pathName is the name of an Igor \\
symbolic path (see Symbolic Paths on page II-34) that points to the folder \\
containing the file and fileNameStr is the name of the file.
\end{tabular} \\
\begin{tabular}{l} 
Symbolic path and \\
partial path
\end{tabular} & \begin{tabular}{l} 
Use /P=pathName and fileNameStrs, where pathName is the name of an Igor \\
symbolic path that points to the folder containing the file and fileNameStr is a \\
partial path starting from the folder and leading to the file.
\end{tabular} \\
Full path & Use just fileNameStr, where fileNameStr is a full path to the file.
\end{tabular}

If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.
The targeted file is fully specified if fileNameStr is a full path or if both pathName and fileNameStr are present and not empty strings.
The targeted file is not fully specified in any of these cases:
- as fileNameStr is omitted
- fileNameStr is an empty string
- fileNameStr is not a full path and no symbolic path is specified

\section*{Opening an Existing File For Reading Only}

This covers cases 1 (/R without /D).
If the file is fully-specified but does not exist, an error is generated. If you want to detect and handle the error yourself, use the \(/ \mathrm{Z}\) flag.
If the file is not fully-specified, Open displays an Open File dialog.
If a file is opened, refNum is set to the file reference number.

\section*{Opening an Existing File For Appending}

This covers cases 1 (/R without /D) and 2 (/A without /D).
If the file is fully-specified and exists, it is opened for read/write and the current file position is moved to the end of the file.
If the file is fully-specified but does not exist, the file is created and opened for read/write.
If the file is not fully-specified, Open displays an Open File dialog.
If a file is opened, refNum is set to the file reference number.

\section*{Opening a File For Write}

This covers case 3 (no /R, /A or /D).
If the targeted file exists, it is overwritten.
If the targeted file does not exist and it is fully-specified and targets a valid path, a new file is created.
If the file is fully-specified and targets an invalid path, an error is generated. If you want to detect and handle the error yourself, use the /Z flag.
If the file is not fully-specified, Open displays a Save File dialog.
If a file is opened, refNum is set to the file reference number.

Displaying an Open File Dialog To Select a Single File
This covers cases 4 (/D with /R or /A).
Open does not actually open the file but just displays the Open File dialog.
If the user chooses a file in the Open File dialog, the S_fileName output string variable is set to a full path to the file. You can use this in subsequent commands. If the user cancels, S_fileName is set to "".
See the documentation for the /D, /F and /M flags and then read Displaying an Open File Dialog on page IV-130 for details.
refNum is left unchanged.

\section*{Displaying an Open File Dialog To Select Multiple Files}

This covers cases 4 (/D with /R or /A) with the /MULT=1 flag.
Open does not actually open the file but just displays the Open File dialog.
If the user chooses one or more files in the Open File dialog, the S_fileName output string variable is set to a carriage-return-delimited list of full paths to one or more files. You can use this in subsequent commands. If the user cancels, S_fileName is set to "".
See the documentation for the /D, /F, /M and /MULT flags and then read Displaying a Multi-Selection Open File Dialog on page IV-130 for details.
refNum is left unchanged.

\section*{Displaying a Save File Dialog}

This covers cases 5 (/D without /R or /A).
Open does not actually open the file but just displays the Save File dialog.
If the user chooses a file in the Save File dialog, the S_fileName output string variable is set to a full path to the file. You can use this in subsequent commands. If the user cancels, S_fileName is set to "".
See the documentation for the /D, /F and /M flags and then read Displaying a Save File Dialog on page IV-132 for details.
refNum is left unchanged.

\section*{Flags}
/A Opens an existing file for appending or, if the file does not exist, creates a new file and opens it for appending.
\(/ \mathrm{C}=\) creatorStr \(\quad\) Specifies the file creator code. This is meaningful on Macintosh only and is ignored on Windows. For opening an existing file, creator defaults to "????" which means "any creator". For creating a new file, creatorStr defaults to "IGR0" which is Igor's creator code.
\(/ \mathrm{D}[=\) mode \(] \quad\) Specities dialog-only mode.
/D: A dialog is always displayed.
\(/ D=1: \quad\) Same as \(/ D\).
\(/ \mathrm{D}=2\) : \(\quad\) A dialog is displayed only if pathName and fileNameStr do not specify a valid file.

The \(/ D=1\) and \(/ D=2\) forms of this command were added in Igor Pro 6.1.
Use this mode to allow the user to choose a file to be opened by a subsequent operation, such as LoadWave.
With /D or / \(D=1\), open presents a dialog from which the user can select a file but does not actually open the file. Instead, Open puts the full path to the file into the string variable S_fileName.
/ \(\mathrm{D}=2\) does the same thing except that it skips the dialog if pathName and fileNameStr specify a valid file. In this case, if pathName and fileNameStr refer to an alias (Macintosh) or shortcut (Windows), the target of the alias or shortcut is returned.
If the user clicks the Cancel button, S_fileName is set to an empty string.
\begin{tabular}{ll} 
& \begin{tabular}{l} 
Use Open/D/R to bring up an Open File dialog. See Displaying an Open File Dialog \\
on page IV-130 for details. \\
Use Open/D/R/MULT=1 to bring up an Open File dialog to select multiple files. See \\
Displaying a Multi-Selection Open File Dialog on page IV-130 for details. \\
Use Open/D to bring up a Save File dialog. See Displaying a Save File Dialog on page
\end{tabular} \\
& IV-132 for details. \\
See Using Open in a Utility Routine on page IV-133 for an example using /D=2. \\
Do not use /Z with /D. \\
/F=fileFilterStr & /F provides control over the file filter menu in the Open File dialog./F was added in \\
Igor Pro 6.10. See Open File Dialog File Filters on page IV-131 and Save File Dialog \\
File Filters on page IV-132 for details. \\
/M=messageStr & Prompt message text in the dialog used to select the file, if any. \\
/MULT=m & Use /D/R/MULT=1 to display a multi-selection Open File dialog. \\
& /D/R/MULT=0 or just /D/R displays a single-selection Open File dialog. \\
/MULT=1 is allowed only if /D or /D=1 and /R are specified.
\end{tabular}

\section*{Details}

When Open returns, if a file was actually opened, the refNum parameter will contain a file reference number that you can pass to other operations to read or write data. If the file was not opened because of an error or because the user canceled or because / D was used, refNum will be unchanged.
If you use \(/ \mathrm{R}\) (open for read), Open opens an existing file for reading only.

If you use /A, Open opens an existing file for appending. If the file does not exist, it is created and then opened for appending.
If both /R and / A are omitted then Open creates and opens a file. If the specified file does not already exist, Open creates it and opens it for writing. If the file does already exist then Open opens it and sets the current file position to the start of the file. The current file position determines where in the file data will be written. Thus, you will be overwriting existing data in the file.

Warning: If you open an existing file for writing (you do not use \(/ R\) ) then you will overwrite or truncate existing data in the file. To avoid this, open for read (use \(/ R\) ) or open for append (use /A).

\section*{Output Variables}

The Open operation returns information in the following variables:
V_flag \begin{tabular}{l} 
Set only when the /Z flag is used. \\
V_flag is set to zero if the file was opened, to -1 if Open displayed a dialog (because \\
the file was not fully-specified) and the user canceled, and to some nonzero value if \\
an error occurred.
\end{tabular}
S_fileName
\begin{tabular}{l} 
Stores the full path to the file that was opened. \\
If \(/ M U L T=1\) is used, S_fileName is a carriage-return-separated list of full paths to one \\
or more files.
\end{tabular} or more files.
If an error occurred or if the user canceled, S_fileName is set to an empty string.
When using /D, the value of V_flag is undefined. Do not use /Z with /D. Use S_fileName to determine if the user selected a file or canceled.

\section*{Examples}

This example function illustrates using Open to open a text file from which data will be read. The function takes two parameters: an Igor symbolic path name and a file name. If either of these parameters is an empty string, the Open operation will display a dialog allowing the user to choose the file. Otherwise, the Open operation will open the file without displaying a dialog.
```

Function DemoOpen(pathName, fileName)
String pathName // Name of symbolic path or "" for dialog.
String fileName // File name, partial path, full path or "" for dialog.
Variable refNum
String str
// Open file for read.
Open/R/Z=2/P=\$pathName refNum as fileName
// Store results from Open in a safe place.
Variable err = V flag
String fullPath = s_fileName
if (err == -1)
Print "DemoOpen canceled by user."
return -1
endif
if (err != 0)
DoAlert 0, "Error in DemoOpen"
return err
endif
Printf "Reading from file \"%s\". First line is:\r", fullPath
FReadLine refNum, str // Read first line into string variable
Print str
Close refNum
return 0
End

```

\section*{OpenNotebook}

OpenNotebook [flags] [fileNameStr]
The OpenNotebook operation opens a file for reading or writing as an Igor notebook.
Unlike the Open operation, OpenNotebook will not create a file if the specified file does not exist. To create a new notebook, use the NewNotebook operation.

\section*{Parameters}

The file to be opened is specified by fileNameStr and \(/ \mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.

\section*{Flags}
\begin{tabular}{|c|c|}
\hline /A & Moves the notebook's selection to the end of the notebook. \\
\hline \multirow[t]{6}{*}{\(/ \mathrm{K}=k\)} & Specifies window behavior when the user attempts to close it. \\
\hline & \(k=0\) : \(\quad\) Normal with dialog (default). \\
\hline & \(k=1\) : Kills with no dialog. \\
\hline & \(k=2\) : Disables killing. \\
\hline & \(k=3\) : Hides the window. \\
\hline & If you use \(/ K=2\) or \(/ K=3\), you can still kill the window using the KillWindow operation. \\
\hline / \(\mathrm{M}=\) messageStr & Prompt message text in the dialog used to find the file, if any. \\
\hline / \(\mathrm{N}=\) winName & Specifies the window name to be assigned to the new notebook. If omitted, it assigns a name like "Notebook0". \\
\hline /P=pathName & Specifies the folder to look in for the file. pathName is the name of an existing symbolic path. \\
\hline /R & Opens the file as read only. \\
\hline /T=typeStr & Specifies the type or types of files that can be opened. \\
\hline /V=visible & Hides (visible \(=0\) ) or shows (visible \(=1\); default) the notebook. \\
\hline \multicolumn{2}{|l|}{/W=(left,top,right,bottom)} \\
\hline & Specifies window size and position. Coordinates are in points. \\
\hline /Z & Suppresses error generation. Use this to check if a file exists. If you use \(/ Z\), OpenNotebook sets the variable V_flag to 0 if the notebook was opened or to nonzero if there was an error, usually because the specified file does not exist. \\
\hline
\end{tabular}

\section*{Details}

The /A (append) flag has no effect other than to move the selection to the end of the notebook after it is opened. If you use \(/ \mathrm{P}=\) pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd: Folder1:" or "C : \(\backslash \backslash\) Folder \(1 \backslash \backslash\) ". See Symbolic Paths on page II-34 for details.

The /T=typeStr flag affects only the dialog that OpenNotebook presents if you do not specify a path and filename. The dialog presents only those files whose type is specified by \(/ \mathrm{T}=\) typeStr. There are two file types that are allowed for notebooks: 'TEXT' which is a plain text file and 'WMTO ' which is a WaveMetrics formatted text file. Therefore, the file type, if you use it, should be either "TEXT" or "WMT0". If /T=typeStr is missing, it defaults to "TEXTWMTO". This opens either type of notebook file. On Windows, Igor considers files with ".txt" extensions to be of type TEXT and considers files with ".ifn" to be of type WMT0. See File Types and Extensions on page III-406 for details.

\section*{See Also}

The Notebook and NewNotebook operations, and Chapter III-1, Notebooks.

\section*{OpenProc}

\section*{OpenProc [flags] [fileNameStr]}

The OpenProc operation opens a file as an Igor procedure file.
Note: This operation is used automatically to open procedure files when you open an Igor experiment. You can invoke OpenProc only from the command line. Do not invoke it from a procedure. To open procedure files from a procedure or from a menu definition, use the Execute/P operation.

\section*{Parameters}

The file to be opened is specified by fileNameStr and \(/ \mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.

\section*{Flags}
\begin{tabular}{ll} 
/A & Moves the procedure window's selection to the end of the window. \\
\(/ \mathrm{M}=\) messageStr & \begin{tabular}{l} 
Prompt message text in the dialog used to find the file, if any.
\end{tabular} \\
\(/ \mathrm{P}=\) pathName & \begin{tabular}{l} 
Specifies the folder to look in for the file. pathName is the name of an existing symbolic \\
path.
\end{tabular} \\
\(/ \mathrm{R}\) & \begin{tabular}{l} 
The file is opened read only.
\end{tabular} \\
\(/ \mathrm{T}=\) typeStr & Specifies the type or types of files that can be opened. \\
\(/ \mathrm{V}=\) visible & \begin{tabular}{l} 
Hides (visible= 0 ) or shows (visible= \(1 ;\) default) the procedure window. \\
\(/ \mathrm{Z}\)
\end{tabular}
\end{tabular}

\section*{Details}

The /A (append) flag has no effect other than to move the selection to the end of the procedure file after it is opened.
If you use \(/ \mathrm{P}=\) pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd: Folder1:" or "C: \\Folder1 \(\backslash \backslash\) ". See Symbolic Paths on page II-34 for details.
OpenProc automatically opens procedure files when you open an Igor experiment. Normally, you will have no use for it. You can not open a procedure file while procedures are executing. Thus, you can't invoke OpenProc from within a procedure. You can only invoke it from the command line or from a user menu definition (actually, you may get away with it in a macro, but it's not recommend).

\section*{See Also}

Chapter III-13, Procedure Windows.
The Execute operation.

\section*{OperationList}

OperationList(matchStr, separatorStr, optionsStr)
The OperationList function returns a string containing a list of internal (built-in) or external operation names corresponding to matchstr.

\section*{Parameters}

Only operation names that match matchStr string are listed. Use " * " to match all names. See WaveList for examples.
The first character of separatorStr is appended to each operation name as the output string is generated. separatorStr is usually ";" for list processing (See Processing Lists of Waves on page IV-178 for details).
Use optionsStr to further qualify the list of operations. optionsStr is a (case-insensitive) string containing one of these values:
"internal" Restricts the list to built-in operations.
"external" Restricts the list to external operations (see Igor Extensions on page III-425).
Any other value for optionsStr ("all" is recommended) will return both internal and external operations.

\section*{See Also}

The DisplayProcedure operation and the FunctionList, MacroList, StringFromList, and WinList functions.

\section*{Optimize}

Optimize [flags] funcspec, pWave
The Optimize operation determines extrema (minima or maxima) of a specified nonlinear function. The function must be defined in the form of an Igor user function.
Use the first form for univariate functions (one dimensional functions; functions taking just one variable). Use the second form with multivariate functions (functions in more than one dimension; functions of more than one variable).
Optimize uses Brent's method for univariate functions. For multivariate functions you can choose several variations of quasi-Newton methods or simulated annealing.

Flags
/A [= findMax]

Finds a maximum (/A=1 or \(/ A\) ) or minimum (/A=0 or no flag).
\(/ \mathrm{D}=n\) Digits
Specifies the number of good digits returned (default is 15) by the function being optimized. If you use \(/ \mathrm{X}=x\) Wave with a single-precision wave, the default is seven. Ignored with simulated annealing (/ \(\mathrm{M}=\{3,0\}\) ).
/DSA=destWave Sets a wave to track the current best model only found with simulated annealing (/ \(\mathrm{M}=\{3,0\}\) ). destWave must have the same number of points as the \(X\) vector.
\(/ \mathrm{F}=\) trustRegion \(\quad\) Sets the initial trust region when \(/ \mathrm{M}=\{1\) or \(2, \ldots\}\) with multivariate functions. The value is a scaled step size (see Multivariate Details). After the first iteration the trust region is adjusted according to conditions.
Ignored with simulated annealing ( \(/ \mathrm{M}=\{3,0\}\) ).
/H= highBracket
/L= lowBracket
Find the extrema of a univariate function. lowBracket and highBracket are X values on either side of the extreme point. An extreme point is found between the bracketing values.
If lowBracket and highBracket are equal, Optimize adds 1.0 to highBracket before looking for an extreme point.
Default values for lowBracket and highBracket are zero. Thus, if neither lowBracket nor highBracket is present, this is the same as \(/ \mathrm{L}=0 / \mathrm{H}=1\).
Ignored with simulated annealing ( \(/ \mathrm{M}=\{3,0\}\) ).
/I=maxIters Sets the maximum number of iterations in searching for an extreme point to maxIters. Default is 100 for stepMethod (/M flag) \(0-2,10000\) for stepMethod \(=3\) (simulated annealing).
If you use this form of the /I flag with simulated annealing, maxItersAtT is set to maxIters/2 and maxAcceptances is set to maxIters/10.
\(/ \mathrm{I}=\{\) maxIters, maxItersAtT, maxAcceptances\}
Specifies the number of iterations for simulated annealing. The maximum number of iterations is set by maxIters, maxIters \(A t T\) sets the maximum number of iterations at a given temperature in the cooling schedule, and maxAcceptances sets the total number of accepted changes in the \(X\) vector (whether they increase or decrease the function) at a given temperature.
If you use this form of the flag with any stepMethod (/M flag) other than 3, maxItersAtT and maxAcceptances are ignored.
Defaults for stepMethod \(=3\) are \(\{10000,5000,500\}\).
/M=\{stepMethod, hessMethod \(\}\)
Specifies the method used for selecting the next step (stepMethod) and the method for calculating the Hessian (matrix of second derivatives) with multivariate functions.
\begin{tabular}{|c|c|c|c|}
\hline stepMethod & Method & hessMethod & Method \\
\hline 0 & Line Search & 0 & secant (BFGS) \\
\hline 1 & Dogleg & 1 & finite differences \\
\hline 2 & More-Hebdon & & \\
\hline 3 & Simulated Annealing & & \\
\hline
\end{tabular}

Default values are \(\{0,0\}\). The hessMethod variable is ignored if you select stepMethod \(=3\).
/Q Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.
\(/ \mathrm{R}=\{\operatorname{typ} \mathrm{X} 1, \operatorname{typ} \mathrm{X} 2, \ldots\}\)
\(/ \mathrm{R}=\) typXWave \(\quad\) Specifies the expected size of X values with multivariate functions. These values are used to scale \(X\) values. If the \(X\) values you expect are very different from one, you will get more accurate results if you can give a reasonable estimate. Optimize will use typXi to scale \(X_{i}\) to reduce floating-point truncation error.
You must provide the same number of values in either a wave or a list of values as you provide to the /X flag.
Ignored with simulated annealing (/M=\{3,0\}).
/S=stepMax Limits the largest scaled step size allowed with multivariate functions. Optimize will stop if five consecutive steps exceed stepMax.
Ignored with simulated annealing (/ \(\mathrm{M}=\{3,0\}\) ).
/SSA=stepWave Name of a 3-column wave having number of rows equal to the length of the X vector only when used with simulated annealing (/ \(\mathrm{M}=\{3,0\}\) ). stepWave sets information about the step size used to generate new \(X\) vectors. The step sizes are in terms of normalized \(X\) values. The normalization is such that the \(X_{i}\) ranges from -1 to 1 based on the ranges set by the /XSA flag.
Column zero sets the step size used when creating new trial X vectors. Default is 1.0 . Column one sets the minimum step size. Default is 0.001.
Column two sets the maximum step size. Default is 1.0.
/T=tol
Sets the stopping criterion with univariate functions. Optimize will attempt to find a minimum within \(\pm\) tol.

When this form is used with a multivariate function, gradTol is set to tol and stepTol is set to gradTol \(^{2}\).
Ignored with simulated annealing (/ \(\mathrm{M}=\{3,0\}\) ).
\(/ \mathrm{T}=\{\) gradtol, stepTol \(\}\) Sets the stopping criteria for multivariate functions. Iterations stop if a point is found with estimated scaled gradient less than gradTol, or if an iteration takes a scaled step shorter than stepTol. Default values are \(\left\{8.53618 \times 10^{-6}, 7.28664 \times 10^{-11}\right\}\). These values are \(\left(6.022 \times 10^{-16}\right)^{1 / 3}\) and \(\left(6.022 \times 10^{-16}\right)^{2 / 3}\) as suggested by Dennis and Schnabel. \(6.022 \times 10^{-16}\) is the smallest double precision floating point number that, when added to 1 , is different from 1.

Ignored with simulated annealing (/ \(\mathrm{M}=\{3,0\}\) ).
/TSA=\{InitialTemp, CoolingRate \(\}\)
Used only with simulated annealing ( \(/ \mathrm{M}=\{3,0\}\) ).
InitialTemp sets the initial temperature. If InitialTemp is set to zero, Optimize calls your function 100 times to estimate the best initial temperature. This is the recommended setting unless your function is very expensive to evaluate (in which case, you may not want to use simulated annealing at all).

CoolingRate sets the factor by which the temperature is decreased.
\(/ \mathrm{X}=x\) Wave \(\quad\) Sets the starting point for searching for an extreme point with multivariate functions or with simulated annealing (/ \(\mathrm{M}=\{3,0\}\) ). The starting point can be specified with a wave having as many points as the number of independent variables, or you can write out a list of \(X\) values in braces. If you are finding extreme points of a univariate function, use /L and /H instead unless you are using the simulated annealing method. If you specify a wave, this wave is also used to receive the result of the extreme point search.
/XSA=XLimitWave Name of a 2-column wave having number of rows equal to the length of the \(X\) vector only when used with simulated annealing (/ \(\mathrm{M}=\{3,0\}\) ).
Column zero sets the minimum value allowed for each element of the X vector.
Column one sets the maximum value allowed for each element of the \(X\) vector.
Default is \(\pm X_{i}^{*} 10\) if \(X_{i}\) is nonzero, or \(\pm 1\) if \(X_{i}\) is zero. While a default is provided, it is highly recommended that you provide an XLimitWave.
\(/ Y=f u n c S i z e \quad\) Specifies expected sizes of function values with multivariate functions. If you expect your function will return values very different from one, you should set funcSize to the expected size. Optimize will use this value to scale the function results to reduce floating-point truncation error.

\section*{Parameters}
func specifies the name of your user-defined function that will be optimized.
pwave gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified by Igor. It is intended for your private use to pass adjustable constants to your function.

\section*{Function Format}

Finding extreme points of a nonlinear function requires that you realize the function as a Igor user function of a certain form. See Finding Minima and Maxima of Functions on page III-291 for detailed examples.

Your function must look like this:
```

Function myFunc(w,x1, x2, ...)
Wave w
Variable x1, x2
return f(x1, x2, ...) // an expression ...
End

```

A univariate function would have only one \(X\) variable.
A multivariate function can use a wave to pass in the \(X\) values:
```

Function myFunc (w, xw)
Wave w
Wave xw
return $\mathrm{f}(\mathrm{xw}) \quad$ // an expression ...
End

```

Replace " \(\mathrm{f}(\ldots)\) " with an appropriate numerical expression.

\section*{Univariate Details}

The method used by Optimize to find extreme points of univariate functions requires that the point be bracketed before starting. If you don't use /L and /H to specify the bracketing \(X\) values, the defaults are zero and one. Optimize first attempts to find the requested extreme point using the bracketing values (or the default). If that is unsuccessful, it attempts to bracket an extreme point by expanding the bracketing interval. If a suitable interval is found (the search is by no means perfectly reliable), then the search for an extreme point is made again.
Optimize uses Brent's method for univariate functions, which requires no derivatives. This combines a quadratic extrapolation with checking for wild results. In the case of wild results (points beyond the best current bracketing values) the method reverts to a golden section bisection algorithm. For well-behaved functions, the quadratic extrapolation converges superlinearly. The golden section bisection algorithm converges more slowly but features global convergence, that is, if an extremum is there, it will be found.
The stopping criterion is \(\left|\frac{x-(a+b)}{2}\right|+\frac{a-b}{2} \leq \frac{2}{3} \cdot t o l\).
In this expression, \(a\) and \(b\) are the current bracketing values, and \(x\) is the best estimate of the extreme point within the bracketing interval.
The left side of this expression works out to being simply the distance from the current solution to the boundary of the bracketing interval.

Note: Optimizing a univariate function with the simulated annealing method (/ \(\mathrm{M}=\{3,0\}\) ) works like a multivariate function, and this section does not apply. See the sections devoted to simulated annealing.

\section*{Multivariate Details}

With multivariate functions, Optimize scales certain quantities to reduce floating point truncation error. You enter scaling factors using the \(/ \mathrm{R}\) and \(/ \mathrm{Y}\) flags. The \(/ \mathrm{R}\) flag specifies the expected magnitude of \(X\) values; Optimize then uses \(X_{i} /\) typ \(X_{i}\) in all calculations. Likewise, \(/ Y\) specifies the expected magnitude of function values.

This scaling can be important for maintaining accuracy if your X's or Y's are very different from one, and especially if your X's have values spanning orders of magnitude.
The Optimize operation uses a quasi-Newton method with derivatives estimated numerically. The function gradient is calculated using finite differences. For estimation of the Hessian (second derivative matrix) you can use either a secant method (hessMethod \(=0\) ) or finite differences (hessMethod \(=1\) ). The finite difference method gives a more accurate estimate and may succeed with difficult functions but requires more function evaluations per iteration. The finite difference method's greater accuracy may reduce the total number of iterations required, so the overall number of function evaluations depends on details of the problem being solved. Usually the secant method requires fewer function evaluations and is preferred for functions that are expensive to evaluate.
Once a Newton step is calculated, there are three choices for the method used to find the best next valueline search along the Newton direction (stepMethod \(=0\) ), double dogleg (stepMethod \(=1\) ), or More-Hebdon (stepMethod \(=2\) ). The best method can be found only by experimentation. See Dennis and Schnabel (cited in References) for details.
The \(/ \mathrm{F}=\) trustRegion, \(/ \mathrm{S}=\) stepMax and \(/ \mathrm{T}=\{\ldots\), stepTol \(\}\) all refer to scaled step sizes. That is,
step \(X_{i}=\left\{\frac{\left|\Delta x_{i}\right|}{\max \left(x_{i}, t y p X_{i}\right)}\right\}\).

The Optimize operation presumes that an extreme point has been found when either the gradient at the latest point is less than gradTol or when the last step taken was smaller than stepTol. These criteria both refer to scaled quantities:
\[
\max _{1 \leq i \leq n}\left\{\left|g_{i}\right| \cdot \frac{\max \left(\left|x_{i}\right|, \text { typ } X_{i}\right)}{\max (|f|, f u n c S i z e)}\right\} \leq \text { gradTol or } \max _{1 \leq i \leq n}\left\{\frac{\left|\Delta x_{i}\right|}{\max \left(x_{i}, t y p X_{i}\right)}\right\} \leq \text { stepTol }
\]

\section*{Simulated Annealing Introduction}

The simulated annealing or Metropolis algorithm optimizes a function using a random search of the \(X\) vector space. It does not use derivatives to guide the search, making it a good choice if the function to be optimized is in some way poorly behaved. For instance, it is a good method for functions with discontinuities in the function value or in the derivatives.
Simulated annealing also has a good chance of finding a global minimum or maximum of a function having multiple local minima or maxima.

Because simulated annealing uses a random search method, it may require a large number of function evaluations to find a minimum, and it is not guaranteed that it will stop at an actual minimum. For these reasons, it is best to use one of the other methods unless those methods have failed.

The simulated annealing method generates new trial solutions by adding a random vector to the current \(X\) vector. The elements of the random vector are set to stepsize \(e_{i}^{*} R_{i}\), where \(R_{i}\) is a random number in the interval \((-1,1)\). As the solution progresses, the stepsize is gradually decreased.
Bad trials, that is, those that change the function value in the wrong direction are accepted with a probably that depends on the simulated temperature. It is this aspect that allows simulated annealing to find a global minimum.

Function values are generated and accepted or rejected for some number of iterations at a given temperature, then the temperature is reduced. The probability of a bad iteration being accepted decreases with decreasing temperature. A too-fast cooling rate can freeze in a bad solution.

\section*{Simulated Annealing Details}

It is highly recommended that you use the XSA flag to specify XLimitWave. This wave sets bounds on the values of the elements of the \(X\) vector during the random search. The defaults may be adequate but are totally ad hoc. You are better off to specify bounds that make sense to the problem you are solving.
The values of XLimitWave in addition to bounding the search space also scale the \(X\) vector during computations of probabilities, temperatures, etc. Consequently, the \(X\) limits can affect the performance of the algorithm.
A large number of iterations is required to have a good probability of finding a reasonable solution.
It is recommended that you set the initial temperature to zero so that Optimize can estimate a good initial temperature. If you can't afford the 100 function evaluations required, you probably shouldn't be using simulated annealing.
Optimize uses an exponential cooling schedule in which \(T_{i+1}=\) CoolingRate* \(T_{i}\) (see the /TSA flag).
CoolingRate must be in the range 0 to 1 . A fast cooling rate (small value of CoolingRate) can cause simulated quenching; that is, a bad solution can be frozen in. Very slow cooling will result in slow convergence.
When simulated annealing is selected, the optimization is treated as multivariate even if your function has only a single X input. That is, the output variables and waves are the ones listed under multivariate functions.

\section*{Variables and Waves for Output}

The Optimize operation reports success or failure via the V_flag variable. A nonzero value is an error code.
Variables for a univariate function:
\begin{tabular}{lll} 
V_flag & \(0:\) & Search for an extreme point was successful. \\
\(57:\) & User abort. \\
\(785:\) & Function returned NaN. \\
& \(786:\) & Unable to find bracketing values for an extreme point.
\end{tabular}

If you searched for a minimum:
\begin{tabular}{ll} 
V_minloc & \(X\) value at the minimum. \\
V_min & Function value \((\mathrm{Y})\) at the minimum.
\end{tabular}

If you searched for a maximum:
\begin{tabular}{ll} 
V_maxloc & X value at the maximum. \\
V_max & Function value \((\mathrm{Y})\) at the maximum.
\end{tabular}

For simulated annealing only:
\begin{tabular}{ll} 
V_SANumIncreases & Number of "bad" iterations accepted. \\
V_SANumReductions & Number of iterations resulting in a better solution.
\end{tabular}

Variables for a multivariate function:
V_flag 0: Search for an extreme point was successful.
57: User abort.
788: Iteration limit was exceeded.
789: Maximum step size was exceeded in five consecutive iterations.
790: \(\quad\) The number of points in the typical \(X\) size wave specified by \(/ R\) does not match the number of \(X\) values specified by the \(/ X\) flag

791: \(\quad\) Gradient nearly zero and no iterations taken. This means the starting point is very nearly a critical point. It could be a solution, or it could be so close to a saddle point or a maximum (when searching for a minimum) that the gradient has no useful information. Try a slightly different starting point.

V_OptTermCode Indicates why Optimize stopped. This may be useful information even if V_flag is zero. Values are:

1: Gradient tolerance was satisfied.
2: \(\quad\) Step size tolerance was satisfied.
3: \(\quad\) No step was found that was better than the last iteration. This could be because the current step is a solution, or your function may be too nonlinear for Optimize to solve, or your tolerances may be too large (or too small), or finite difference gradients are not sufficiently accurate for this problem.

4: Iteration limit was exceeded.
5: Maximum step size was exceeded in five consecutive iterations. This may mean that the maximum step size is too small, or that the function is unbounded in the search direction (that is, goes to -inf if you are searching for a minimum), or that the function approaches the solution asymptotically (function is bounded but doesn't have a well-defined extreme point).
6: \(\quad\) Same as V_flag \(=791\).
If you searched for a minimum:
V_min Function value \((\mathrm{Y})\) at the minimum.

\section*{Override}

If you searched for a maximum:
V_max Function value \((\mathrm{Y})\) at the maximum.
Variables for all functions:
V_OptNumIters Number of iterations taken before Optimize terminated.
V_OptNumFunctionCalls Number of times your function was called before Optimize terminated.
Waves for a multivariate function:
W_extremum Solution if you didn't use \(/ X=\langle x W a v e\rangle\). Otherwise the solution is returned in your X wave.
W_OptGradient Estimated gradient of your function at the solution.

See Also
Finding Minima and Maxima of Functions on page III-291 for further details and examples.

\section*{References}

The Optimize operation uses Brent's method for univariate functions. Numerical Recipes has an excellent discussion (see section 10.2) of this method (but we didn't use their code):
Press, William H., Saul A. Teukolsky, William T. Vetterling, and Brian P. Flannery, Numerical Recipes in C, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

For multivariate functions Optimize uses code based on Dennis and Schnabel. To truly understand what Optimize does, read their book:
Dennis, J. E., Jr., and Robert B. Schnabel, Numerical Methods for Unconstrained Optimization and Nonlinear Methods, 378 pp., Society for Industrial and Applied Mathematics, Philadelphia, 1996.

\section*{Override}

Override constant objectName = newVal
Override strconstant objectName = newVal
Override Function funcName()
The Override keyword redefines a constant, strconstant, or user function. The objectName or funcName must be the same as the name of the original object or function that is being redefined. The override must be defined before the target object appears in the compile sequence.

See Also
Function Overrides on page IV-88 and Constants on page IV-40 for further details.

\section*{p}
p
The \(p\) function returns the row number of the current row of the destination wave when used in a wave assignment statement. The row number is the same as the point number for a 1 D wave.

\section*{Details}

Outside of a wave assignment statement p acts like a normal variable. That is, you can assign a value to it and use it in an expression.

See Also
Waveform Arithmetic and Assignments on page II-94.
For other dimensions, the \(\mathbf{q}, \mathbf{r}\), and \(\mathbf{s}\) functions.
For scaled dimension indices, the \(\mathbf{x}, \mathbf{y}, \mathbf{z}\), and \(\mathbf{t}\) functions.

\section*{p2rect}
```

p2rect(z)

```

The p2rect function returns a complex value in rectangular coordinates derived from the complex value \(z\) which is assumed to be in polar coordinates (magnitude is stored in the real part and the angle, in radians, in the imaginary part of \(z\) ).

\section*{Examples}

Assume waveIn and waveOut are complex, then:
```

waveOut = p2rect(waveIn)

```
sets each point of waveOut to the rectangular coordinates based on the magnitude in the real part and the angle (in radians) in the imaginary part of the points in waveIn.
You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.
See Also
The functions cmplx, conj, imag, r2polar, and real.

\section*{PadString}

PadString(str, finallength, padValue)
The PadString function returns a string identical to str except that it has been extended to a total length of finalLength using bytes of padValue. Use zero to create a C-language style string or use \(0 \times 20\) to pad with spaces (FORTRAN style). This is useful when reading or writing binary files using FBinRead and FBinWrite.

See Also
The UnPadString function.

\section*{Panel}

\section*{Panel}

Panel is a procedure subtype keyword that identifies a macro as being a control panel recreation macro. It is automatically used when Igor creates a window recreation macro for a control panel. See Procedure Subtypes on page IV-183 and Saving a Window as a Recreation Macro on page II-61 for details.

\section*{ParamIsDefault}

\section*{ParamIsDefault (pName)}

The ParamIsDefault function determines if an optional user function parameter \(p N a m e\) was specified during the function call. It returns 1 when \(p N a m e\) is default (not specified) or it returns 0 when it was specified.

\section*{Details}

ParamIsDefault works only in the body of a user function and only with optional parameters. The variable \(p\) Name must be valid at compile time; you can not defer lookup to runtime with \(\$\).

\section*{See Also}

Optional Parameters on page IV-30 and Using Optional Parameters on page IV-46.

\section*{ParseFilePath}

ParseFilePath(mode, pathInStr, separatorStr, whichEnd, whichElement)
The ParseFilePath function provides the ability to manipulate file paths and to extract sections of file paths.

\section*{Parameters}

Several of the modes refer to elements of the file path. In these modes, whichEnd is 0 to select an element relative to the beginning of pathInStr, 1 to select an element relative to the end. whichElement is zero-based. pathInStr is the input path, assumed to either a full path, a partial path (starts with the separator specified by separatorStr) or a simple file or folder name (contains no separators).
For modes 0 through 4, separatorStr is ":" if pathInStr is a Macintosh path or " \(\backslash \backslash\) " if pathInStr is a Windows path. See Path Separators on page III-400 for details about Macintosh versus Windows paths.
For mode 5, separatorStr is as shown above.

\section*{mode Information Returned}
\(0 \quad\) Element specified by whichEnd and whichElement.
1 Entire pathInStr, up to but not including the element specified by whichEnd and whichElement.
2 Entire pathInStr with a trailing separator added if it is not already there. This is useful when you have a path to a folder and want to tack on a file name.

3 Last element of pathInStr with the extension, if any, removed. The extension is anything after the last dot in pathInStr.
4 Extension in pathInStr or " " if there is no extension. The extension is anything after the last dot in pathInStr.

5 Entire pathInStr but converts it to a format determined by separatorStr.
separatorStr = ":"
Converts the path to Macintosh style if it is Windows style. Does nothing to a Macintosh path. separatorStr \(=" \backslash \backslash "\)
Converts the path to Windows style if it is Macintosh style. Does nothing to a Windows path. separatorStr = "*"
Converts the path to the native style of the operating system Igor is running on. Does nothing to a native path.
separatorStr = "/"
Macintosh-only: Converts the Macintosh-style pathInStr input to a Posix (UNIX) path. Unlike the other conversions, the directory or file to which pathInStr refers must exist, otherwise "" is returned.

To generate a Posix path for a non-existent file, generate the path for the existing folder and append the file name.
This always returns "'" on Windows.
6 UNC volume name ("\\Server \Share") if pathIn starts with a UNC volume name or "" if not. Pass "*" as separatorStr.
7 UNC server name ("Server" from " \(\backslash\) Server \(\backslash\) Share") if pathIn starts with a UNC volume name or "" if not. Pass "*" as separatorStr.

8 UNC share name ("Share" from " \(\backslash\) \Server \(\backslash\) Share") if pathIn starts with a UNC volume name or "" if not. Pass "*" as separatorStr.

For modes 6, 7 and 8, separatorStr must be non-empty - pass "*" for it.
whichEnd is 0 to extract an element from the beginning of pathInStr or 1 to extract if from the end. whichEnd is used only if mode is 0 or 1 . For other modes, pass 0 .
whichElement is a zero-based index to the element that you want to extract. whichElement is used only if mode is 0 or 1 . For other modes, pass 0 .

\section*{Details}

When dealing with Windows paths, you need to be aware that Igor treats the backslash character as an escape character. When you want to put a backslash in a literal string, you need to use two backslashes. See see Escape Characters in Strings on page IV-13 and Path Separators on page III-400 for details.
On Windows two types of file paths are used: drive-letter paths and UNC ("Universal Naming Convention") paths. For example:
```

// This is a drive-letter path.
C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe
// This is a UNC path.
<br>BigServer\SharedApps\Igor Pro Folder\Igor.exe

```

In this example, ParseFilePath considers the volume name to be C : in the first case and \(\backslash\) BigServer \(\backslash\) SharedApps in the second. The volume name is treated as one element by ParseFilePath, except for modes 7 and 8 which permit you to extract the components of the UNC volume name.
Except for the leading backslashes in a UNC path, ParseFilePath modes 0 and 1 internally strip any leading or trailing separator (as defined by the separatorStr parameter) from pathInStr before it starts parsing. So if you pass ": Igor Pro Folder:WaveMetrics Procedures:", it is the same as if you had passed "Igor Pro Folder:WaveMetrics Procedures".
If there is no element corresponding to whichElement and mode is 0 , ParseFilePath returns " ".
If there is no element corresponding to whichElement and mode is 1, ParseFilePath returns the entire pathInStr.

\section*{Examples}
```

String pathIn, pathOut
// Full path
pathIn= "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf"
// Extract first element.
Print ParseFilePath(0, pathIn, ":", 0, 0) // Prints "hd"
// Extract second element.
Print ParseFilePath(0, pathIn, ":", 0, 1) // Prints "Igor Pro Folder"
// Extract last element.
Print ParseFilePath(0, pathIn, ":", 1, 0) // Prints "Wave Lists.ipf"
// Extract next to last element.
Print ParseFilePath(0, pathIn, ":", 1, 1) // Prints "Waves"
// Get path to folder containing the file.
// Prints "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:"
Print ParseFilePath(1, pathIn, ":", 1, 0)
// Extract the file name without extension.
Print ParseFilePath(3, pathIn, ":", 0, 0) // Prints "Wave Lists"
// Extract the extension.
Print ParseFilePath(4, pathIn, ":", 0, 0) // Prints "ipf"
// Make sure the given path ends with a colon and concatenate file name.
String path = <routine that returns a Macintosh-style path to a folder>
path = ParseFilePath(2, path, ":", 0, 0)
path += "AFile.txt"

```

\section*{See Also}

Escape Characters in Strings on page IV-13, UNC Paths on page III-401, and Path Separators on page III-400 for details. The RemoveEnding function.

\section*{ParseOperationTemplate}

ParseOperationTemplate [flags] cmdTemplate
The ParseOperationTemplate operation helps XOP programmers and WaveMetrics programmers write code to implement Igor operations. If you are not an XOP programmer nor a WaveMetrics programmer, it will be of no interest.
ParseOperationTemplate generates starter code for programmers who are creating Igor operations. The starter code is copied to the clipboard, overwriting any previous clipboard contents.

\section*{Flags}
\(/ C=c \quad\) If \(c\) is nonzero, ParseOperationTemplate stores code for your ExecuteOperation and RegisterOperation functions in the clipboard.
\[
c=0: \quad \text { Do not generate code }
\]
\(c=1\) : \(\quad\) Generate simplified \(C\) code - not recommended
\(c=2: \quad\) Generate \(C\) code
\(c=6: \quad\) Generate \(\mathrm{C}++\) code - added in Igor Pro 6.22
The only difference between \(/ \mathrm{C}=6\) and \(/ \mathrm{C}=2\) is that the ExecuteOperation function is declared as extern "C" instead of static. C++ files that use static work fine although extern " C " is correct.
\(/ S=s \quad\) Stores a definition of your runtime parameter structure in the clipboard if \(s\) is nonzero.
\(s=0\) : Do not generate the runtime parameter structure
\(s=1\) : Use your mnemonic names - recommended
\(s=2\) : Automatically generate mnemonic names - not recommended
We recommend that you use \(/ \mathrm{S}=1\) and provide unique mnemonic parameter names in your template. ParseOperationTemplate then uses your parameter names as structure field names.

If you use \(/ \mathrm{S}=2\), ParseOperationTemplate creates unique field names by concatenating flag or keyword text and your mnemonic names. This is left over from the early days of Operation Handler and is not recommended.
/T Stores a comment listing your command template in the clipboard.
/TS Identifies a ThreadSafe operation by adding an extra field to the runtime parameter structure. This is only of use to WaveMetrics programmers.

\section*{Parameters}
cmdTemplate is the template that describes the syntax for your operation. See the Igor XOP Toolkit Reference Manual for details.

\section*{Details}

ParseOperationTemplate parses your command template, generating structures that embody the syntax of your operation. It then uses these structures to generate code that can serve as a starting point for implementing your operation. The starter code is stored in the clipboard.
For most uses, the recommended flags are:
\(\begin{array}{ll}\text { /T/S=1/C=2 } & \text { // For non-threadsafe operations } \\ / T / S=1 / C=2 / T S & / / \text { For threadsafe operations }\end{array}\)
ParseOperationTemplate sets the following output variable, but only when called from a function or macro:
V_flag
0: \(\quad\) cmdTemplate was successfully parsed.
-1 : cmdTemplate was not successfully parsed.

If V_flag is nonzero, this indicates that your cmdTemplate syntax is incorrect. See the Igor XOP Toolkit Reference Manual for details.

\section*{Examples}
```

Function Test()
String cmdTemplate
cmdTemplate = "MyTest"
cmdTemplate += " /A={number:aNum1, string:aStrH}"
cmdTemplate += " /B=wave:bWaveH"
cmdTemplate += " key1={name:k1N1[,wave:k1WaveH,name:k1N2,string[2]:k1StrHArray]}"
// If your XOP is C instead of C++, use /C=2 instead of /C=6
TestOperationParser/T/S=1/C=6 cmdTemplate

```
```

    Print V_flag, S_value
    End

```

See Also
Igor Extensions on page III-425.

\section*{PathInfo}

\section*{PathInfo [/S /SHOW ] pathName}

The PathInfo operation stores information about the named symbolic path in the following variables:
```

V_flag: 0 if the symbolic path does not exist, 1 if it does exist.
S_path: The full path (e.g., "hd:This:That:").

```

The path returned is a colon-separated path which can be used on Macintosh or Windows. See Path Separators on page III-400 for details.

Flags
/S Presets the next otherwise undirected open or save file dialog to the given disk folder.
/SHOW Shows the folder, if it exists, in the Finder (Mac OS X) or Windows Explorer (Windows).

\section*{Examples}
// The following lines perform equivalent actions:
PathInfo/s myPath;Open refNum
Open/P=myPath refNum
// Show Igor's Preferences folder in the Finder/Windows Explorer.
String fullpath= SpecialDirPath("Preferences", 0,0,0)
NewPath/O/Q tempPathName, fullpath
PathInfo/SHOW tempPathName
See Also
Symbolic Paths on page II-34.
The NewPath, GetFileFolderInfo, ParseFilePath and SpecialDirPath operations.

\section*{PathList}

PathList(matchStr, separatorStr, optionsStr)
The PathList function returns a string containing a list of symbolic paths selected based on the matchStr parameter.

Details
For a path name to appear in the output string, it must match matchStr. The first character of separatorStr is appended to each path name as the output string is generated.
PathList works like the WaveList function, except that the optionsStr parameter is reserved for future use. Pass " " for it.

\section*{Examples}

When a new experiment is created there is only one path:
Print PathList("*",";","")
Prints the following in the history area:
Igor;

\section*{See Also}

The WaveList function for an explanation of the matchStr and separatorStr parameters and for examples. See also Symbolic Paths on page II-34 for an explanation of symbolic paths.

\section*{PauseForUser}

PauseForUser [/C] mainWindowName [, targetWindowName]
The PauseForUser operation pauses procedure execution to allow the user to manually interact with a window. For example, you can call PauseForUser from a loop to allow the user to move the cursors on a graph. In this scenario, targetWindowName would be the name of the graph and mainWindowName would be the name of a control panel containing a message telling the user to adjust the cursors and then click, for example, the Continue button.
If targetWindowName is omitted then mainWindowName plays the role of target window.
PauseForUser works with graph, table, and panel windows only.
Flags
/C Tells PauseForUser to return immediately after handling any pending events. See Details.

\section*{Details}

During execution of PauseForUser, only mouse and keyboard activity directed toward either mainWindowName or targetWindowName is allowed.
While waiting for user action, PauseForUser disables double-clicks and any contextual menus that can lead to dialogs in order to prevent changes on the command line. It also disables killing windows by clicking the close icon in the title bar unless the window was originally created with the \(/ \mathrm{K}=1\) flag (kill with no dialog).
If /C is omitted, PauseForUser returns only when the main window has been killed.
If /C is present, PauseForUser handles any pending events, sets V_Flag to the truth the target window still exists, and then returns control to the calling user-defined function. Use PauseForUser/C in a loop if you need to do something while waiting for the user to finish interacting with the target window. The /C flag requires Igor Pro 6.1 or later.

\section*{See Also}

Pause For User on page IV-134 for examples and further discussion.

\section*{PauseUpdate}

\section*{PauseUpdate}

The PauseUpdate operation delays the updating of graphs and tables until you invoke a corresponding ResumeUpdate command.

\section*{Details}

PauseUpdate is useful in a macro that changes a number of things relating to the appearance of a graph. It prevents the graph from being updated after each change. Its effect ends when the macro in which it occurs ends. It also affects updating of tables.

This operation is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the DoUpdate operation.

\section*{See Also}

The DelayUpdate, DoUpdate, ResumeUpdate, and Silent operations.

\section*{PCA}

PCA [flags] [wave0, wave1,... wave99]
The PCA operation performs principal component analysis. Input data can be in the form of a list of 1D waves, a single 2D wave, or a string containing a list of 1D waves. The operation can produce multiple output waves depending on the specified flags.

\section*{Flags}
/ALL
Shortcut for the combination of commonly used flags:/CVAR,/SL,/NF,/IND,/IE, and /RMS.
\begin{tabular}{|c|c|}
\hline /COV & Calculates the input wave(s) covariance matrix, which as the input for the remainder of the analysis. The covariance matrix is computed by first creating a matrix copying each input 1D wave into sequential columns and then multiplying that matrix by its transpose. \\
\hline /CVAR & Computes the cumulative percent variance defined as \(100^{*}\) sum of first \(m\) eigenvalues divided by the sum of all eigenvalues. The results are stored in the wave W_CumulativeVAR in the current data folder. See also /VAR. \\
\hline /IE & Computes the imbedded error. Returns errors in the wave W_IE in the current data folder. The wave is scaled using SetScale/P x 1,1," ", \(\overline{\mathrm{W}}\) _IE. The imbedded error is a function of the number of factors, the number of rows and columns and the sum of the eigenvectors not included in the significant factors. The behavior of IE determines the number of significant factors. \\
\hline /IND & Computes the factor indicator function. Note that if you specify /IND the residual standard deviation will also be calculated. Returns results in the wave W_IND in the current data folder. The wave is scaled using SetScale/P x 1,1," ", W_IND. \\
\hline /LEIV & Limits eigenvalues so that the SVD calculation does not require too much memory. The limit is set to the minimum of the number of rows or columns of the input. \\
\hline /NF & Finds the number of significant factors and stores it in the variable V_npnts. You must use /IND in order to compute the significant factors. \\
\hline /O & Overwrites input waves. \\
\hline /Q & Suppresses printing of factors in the history area. \\
\hline /RSD[=rsdMode] & \begin{tabular}{l}
Computes the Residual Standard Deviation (RSD) and returns the RSD in the wave W_RSD in the current data folder. The first element in W_RSD is NaN and all remaining wave elements correspond to the number of significant factors. \\
\(r s d\) Mode \(=0\) : Covariance about the origin. \\
\(r s d\) Mode \(=1\) : Correlation about the origin.
\end{tabular} \\
\hline /RMS & Computes the RMS error. Returns results in the wave W_RMS in the current data folder. The wave is scaled using SetScale/P x 1, 1,"", W_RMS. \\
\hline /SCMT & Saves C matrix after the singular value decomposition (SVD) in the wave M_C in the current data folder. \\
\hline /SCR & Converts the individual wave input into standard scores. Does not work when the input is a single 2D wave. It is an error to convert to standard scores when one or more entries in the waves are NaN or INF. If you use this feature make sure to use the appropriate form of the RSD calculation. \\
\hline /SDM & Saves a copy of the data matrix at the end of the calculation. This is useful if your input consists of individual waves or if you want to save the computed standard scores. If the input is a 2D matrix, you will get a copy of the input matrix in the wave M_D. \\
\hline /SEVC & Saves the eigenvalue vector in the wave W_Eigen, which are the raw eigenvalues generated by the SVD, in the current data folder. Normally, if the SVD was applied to a raw data matrix, i.e., not covariance or correlation matrix, you must square each element of the wave to obtain the PCA eigenvalues. Note that this wave has default wave scaling. \\
\hline /SL & Computes percent significance level and stores it in the wave W_PSL in the current data folder. \\
\hline /SQEV & Does not square SVD eigenvalues. If you specify /COV there is no need to use this flag. \\
\hline & Use only if your input is already a covariance matrix. In this case the results of the SVD are the eigenvalues not their square roots. \\
\hline /SRMT & Saves R matrix after the SVD in the wave M_R in the current data folder. \\
\hline
\end{tabular}
/U
/VAR
/WSTR=waveListStr
Leaves the input waves unchanged only when the input is a 2D wave. Note that
covariance calculations will not be made even if the appropriate flag is used.
Computes the variance associated with each eigenvalue. The variance is defined as
the ratio of the eigenvalue to the sum of all eigenvalues. The results are stored in the
wave in the current data folder. See also /CVAR above.

\section*{Details}

The input is either via /WSTR=waveListStr or a list of up to 1001 D waves or a single 2 D wave following the last flag.
waveListStr is string containing a semicolon-separated list of 1D waves to be used for the data matrix.
waveListStr can include any legal path to a wave. Liberal names can be quoted or not quoted. It is assumed that all waves are of the same numerical type (either single or double precision) and that all waves have the same number of points.
Regardless of the inputs, the operation expects that the number of rows in the resulting matrix is greater than or equal to the number of columns.

The operation starts by creating the data matrix from the input wave(s). If you provide a list of 1D waves they become the columns of the data matrix. You can choose to use the covariance matrix (/COV) as the data matrix and you can also choose to normalize each column of the data matrix to convert it into standard scores. This involves computing the average and standard deviation of each column and then setting the new values to be:
newValue \(=\frac{\text { oldValue }- \text { colAverage }}{\text { colStdv }}\).
You can pre-process the input data using MatrixOp with the SubtractMean, NormalizeRows, and NormalizeCols functions.
After creating the data matrix the operation computes the singular value decomposition (SVD) of the data matrix. Results of the SVD can be saved or processed further. Save the C and R matrices using /SCMT and /SRMT. These are related to the input data matrix through: \(D=R \cdot C\).

The remainder of the operation lets you compute various statistical quantities defined by Malinowski (see References). Use the flags to determine which ones are computed.
The operation generates a number of output waves. All waves are stored in the current data folder.
You can save the input matrix D in the wave M_D, the optional SVD results are stored in the waves M_C that contains the column matrix \(C, M_{-}\)R that contains the row matrix R, and W_Eigen that contains the eigenvalues of the data matrix. Note that these can be the eigenvalues or the square of the eigenvalues depending on the input matrix being a covariance matrix or not (see /SQEV).

The optional 1D output waves (W_RSD, W_RMS, W_IE, W_IND, W_PSL) are saved with wave scaling to make it easier to display the wave as a function of the number of factors.

\section*{pcsr}
pcsr(cursorName [, graphNameStr])
The pcsr function returns the point number of the point which the specified cursor (A through J) is on in the top (or named) graph. When used with cursors on images or waterfall plots, pcsr returns the row number, and when used with a free cursor, it returns the relative \(X\) coordinate.

\section*{Parameters}
cursorName identifies the cursor, which can be cursor A through J.
graphNameStr specifies the graph window or subwindow.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Details}

The pcsr result is not affected by any \(X\) axis.
See Also
The hcsr, qcsr, vcsr, xcsr, and zcsr functions.
Programming With Cursors on page II-292.

\section*{Pi}

Pi
The Pi function returns \(\pi\) (3.141592...).

\section*{PICTInfo}

\section*{PICTInfo (pictNameStr)}

The PICTInfo function returns a string containing a semicolon-separated list of information about the named picture. If the named picture does not exist, then " " is returned. Valid picture names can be found in the Pictures dialog.

Details
The string contains six pieces of information, each prefaced by a keyword and colon and terminated with a semicolon.

Keyword Information Following Keyword
\begin{tabular}{ll}
\hline TYPE & \begin{tabular}{l} 
One of: "PICT", "PNG", "JPEG", "Enhanced metafile", "Windows metafile", "DIB", \\
BYTES
\end{tabular} \\
\begin{tabular}{ll} 
WIDTH & Amount of memory used by the picture. \\
HEIGHT & Width of the picture in pixels. \\
PHYSWIDTH & Height of the picture in pixels. \\
PHySHEIGHT & Physical height of the picture in points. \\
\hline
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}
print PictInfo("PICT_0")
will print the following in the history area:
TYPE:PICT;BYTES :55734;WIDTH:468;HEIGHT:340;PHYSWIDTH:468;PHYSHEIGHT:340;

\section*{See Also}

The ImageLoad operation for loading PICT and other image file types into waves, and the PICTList function. The StringFromList operation for parsing the information string.
See Pictures on page III-423 and Pictures Dialog on page III-425 for general information on picture handling.

\section*{PICTList}

PICTList(matchStr, separatorStr, optionsStr)
The PICTList function returns a string containing a list of pictures based on matchStr and optionsStr parameters. See Details for information on listing pictures in graphs, panels, layouts, and the picture gallery.

\section*{Details}

For a picture name to appear in the output string, it must match matchStr and also must fit the requirements of optionsStr. The first character of separatorStr is appended to each picture name as the output string is generated.
The name of each picture is compared to matchStr, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:
\[
\begin{array}{ll}
\text { "*" } & \text { Matches all picture names. } \\
\text { "xyz" } & \text { Matches picture name xyz only. } \\
\text { "*xyz" } & \text { Matches picture names which end with xyz. } \\
\text { "xyz*" } & \text { Matches picture names which begin with xyz. } \\
\text { "*xyz*" } & \text { Matches picture names which contain xyz. }
\end{array}
\]
"abc*xyz" Matches picture names which begin with abc and end with xyz.
matchStr may begin with the ! character to return windows that do not match the rest of matchStr. For example:
"!*xyz" Matches picture names which do not end with xyz.
The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.
optionsStr is used to further qualify the picture.
Use " " accept all pictures in the Pictures Dialog that are permitted by matchStr.
Use the WIN: keyword to limit the pictures to the named or target window:
"WIN: " Match all pictures displayed in the top graph, panel, or layout.
"WIN : windowName" Match all pictures displayed in the named graph, panel, or layout window.

\section*{Examples}
```

PICTList("*",";","") Returns a list of all pictures in the Pictures Dialog.
PICTList("*", ";","WIN:") Returns a list of all pictures displayed in the top panel, graph,or
layout.
PICTList("*_bkg", ";", "WIN:Layout0")

```

Returns a list of pictures whose names end in "_bkg" and which are displayed in Layout0.

\section*{See Also}

The ImageLoad operation for loading PICT and other image file types into waves, and the PICTInfo function. Also the StringFromList function for retrieving items from lists.
See Pictures on page III-423 and Pictures Dialog on page III-425 for general information on picture handling.

\section*{Picture}

Picture pictureName
The Picture keyword introduces an ASCII code picture definition of binary image data.
See Also
Proc Pictures on page IV-44 for further information.

\section*{PixelFromAxisVal}

PixelFromAxisVal (graphNameStr, axNameStr, val)
The PixelFromAxisVal function returns the local graph pixel coordinate corresponding to the axis value in the graph window or subwindow.

\section*{Parameters}
graphNameStr can be " " to refer to the top graph window.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
If the specified axis is not found and if the name is "left" or "bottom" then the first vertical or horizontal axis will be used.
If graphNameStr references a subwindow, the returned pixel value is relative to top left corner of base window, not the subwindow.

\section*{See Also}

The AxisValFromPixel and TraceFromPixel functions.

\section*{PlayMovie}

PlayMovie [flags] [as fileNameStr]
The PlayMovie operation opens a QuickTime movie file into a window and plays it.

\section*{Parameters}

The file to be opened is specified by fileNameStr and \(/ \mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.
On Windows, if QuickTime is not installed or cannot open the file, the file is passed to the operating system to be opened with the default program for the given filename extension. This allows PlayMovie to display movies without QuickTime. If this happens, the /W parameters are ignored.

\section*{Flags}
/I Coordinates are in inches.
/M
/P=pathName
/W=(left,top,right,bottom)
/Z

Coordinates are in centimeters.
Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

Sets the initial coordinates of the movie window (in points unless/I or \(/ \mathrm{M}\) are used before /W).
No error reporting; an error is indicated by nonzero value of the variable V_flag. If the user clicks the cancel button in the Open File dialog, V_flag is set to -1 .

\section*{Details}

Coordinates are the initial coordinates of the movie window in points unless /I or / M are used before \(/ \mathrm{W}\). Only the top and left coordinates are used. The window has the standard width and height for movies.
If either the path or fileNameStr is omitted then PlayMovie will bring up a dialog to let you find a movie file. If both are present, PlayMovie opens the file automatically.
If you use / \(\mathrm{P}=\) pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:Folder1:" or "C: \\Folder1 \\". See Symbolic Paths on page II-34 for details.
Any movie file can be played, not just movies made by Igor. There is no limit on the number of movie windows opened for playing.

Movie windows are considered transient and are not restored when an experiment is reopened.
See Also
Movies on page IV-225.
The PlayMovieAction operation.

\section*{PlayMovieAction}

PlayMovieAction [/z] keyword [=value] [, keyword [=value]]
PlayMovieAction operates on the top movie window, opened via PlayMovie, or on a movie file opened via the open keyword (requires Igor Pro 6.12 or later).
If the /Z flag is present, errors are not fatal. \(V_{-}\)flag is set to error return regardless.

\section*{Parameters}
\begin{tabular}{ll} 
extract & \begin{tabular}{l} 
Extracts current frame into an 8-bit RGB image wave named M_MovieFrame. (Can be \\
combined with frame=f.)
\end{tabular} \\
extract=e & \begin{tabular}{l} 
Extracts \(e\) frames into a single multiframe wave, M_MovieChunk. This wave will have \\
3 planes for RGB and will have \(e\) chunks.
\end{tabular} \\
frame=f & \begin{tabular}{l} 
Moves to specified movie frame (and stops movie).
\end{tabular} \\
getID \\
getTime & Returns top movie ID number in V_Value. Do not use in same call with getTime. \\
gotoBeginning & \begin{tabular}{l} 
Reads current movie time into variable V_value (in seconds). \\
Goes to beginning of movie.
\end{tabular} \\
gotoEnd & \begin{tabular}{l} 
Goes to end of movie.
\end{tabular} \\
kill & \begin{tabular}{l} 
Kills movie window. \\
Windows only: when used with the ref keyword, closes the open movie file.
\end{tabular} \\
open=fullPath & \begin{tabular}{l} 
This keyword is supported on Windows only and fullPath must point to an AVI file \\
with a ".avi" extension.
\end{tabular} \\
Opens the specifed movie file to enable frame extraction. No movie window is \\
involved. V_Flag is set to zero if no error occurred and V_Value is set to the file \\
reference number. Requires Igor Pro 6.12 or later.
\end{tabular}

\section*{Flags}

No error reporting; an error is indicated by nonzero value of the variable V_flag.

\section*{Details}

Operations are performed in the following order: kill, stop, gotoBeginning, gotoEnd, frame, step, getTime, extract, start. kill overrides all other parameters.

If you want to extract a grayscale image, you can convert the RGB image into grayscale using the ImageTransform command as follows:

PlayMovieAction extract
ImageTransform rgb2gray M_MovieFrame
NewImage M_RGB2Gray

\section*{Windows Only Features}

The open and ref keywords support extracting frames from AVI files on Windows only. They require Igor Pro 6.12 or later.

When accessing a file using the open keyword, none of the keywords related to movie windows or playing a movie are supported. Each command that targets the file must include the ref keyword using the file reference number returned in the open step.

When you are finished extracting frames, use the kill keyword to close the file.
To get a full path for use with the open keyword, use the PathInfo or Open /D/R commands.

\section*{Examples}

How to determine the number of frames in a simple movie:
```

PlayMovie
PlayMovieAction stop,gotoEnd,getTime
Variable tend= V value
PlayMovieAction \overline{step=-1,getTime}
Print "frames= ",tend/(tend-V_value)
PlayMovieAction kill

```

\section*{See Also}

Movies on page IV-225.
The PlayMovie operation.

\section*{PlaySnd}

PlaySnd [flags] fileNameStr
Note: PlaySnd is obsolete. Use PlaySound instead.
Available only on the Macintosh.
The PlaySnd operation plays a sound from the file's data fork, or from an 'snd ' resource.

\section*{Parameters}

The file containing the sound is specified by fileNameStr and / \(\mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.

\section*{Flags}
/I=resourceIndex Specifies the 'snd ' resource to load by resource index, starting from 1.
\(/ \mathrm{M}=\) promptStr \(\quad\) Specifies a prompt if PlaySnd needs to put up a dialog to find the file.
\(/ \mathrm{N}=\) resNameStr \(\quad\) Specifies the resource to load by resource name.
\(/ \mathrm{P}=\) pathName \(\quad\) Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.
/Q Quiet: suppresses the insertion of 'snd ' info into the history area.
\(/ \mathrm{R}=\) resourceID Specifies the 'snd ' resource to load by resource ID.
/Z Does not play the sound, just checks for its existence.

\section*{Details}

If none of /I, /N or /R are specified, PlaySnd tries to play a sound stored in the data fork of the file. If the file dialog is used, only files of type 'sfil' are shown.

If any of \(/ \mathrm{I}, / \mathrm{N}\) or \(/ \mathrm{R}\) are specified, PlaySnd tries to play a sound from an 'snd ' resource. Most programs store sounds in 'snd ' resources. If the file dialog is used, files of all types are shown.
If \(/ \mathrm{P}=p a t h N a m e ~ i s ~ o m i t t e d, ~ t h e n ~ f i l e N a m e S t r ~ c a n ~ t a k e ~ o n ~ t h r e e ~ s p e c i a l ~ v a l u e s: ~\)
"Clipboard" Loads data from Clipboard.
"System" Loads data from System file.
"Igor" Loads data from Igor Pro application.
If you specify \(/ \mathrm{P}=\) pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd: Folder1:" or "C: \(\backslash \backslash\) Folder \(1 \backslash \backslash\) ". See Symbolic Paths on page II-34 for details.
There are no sounds in the Igor Pro application file.
If the file is not fully specified and fileNameStr is not one of these special values, then PlaySnd presents a dialog from which you can select a file. "Fully specified" means that Igor can determine the name of the file (from the fileNameStr parameter) and the folder containing the file (from the \(/ \mathrm{P}=\) pathName flag or from the fileNameStr parameter).
PlaySnd sets the variable V_flag to 1 if the sound exists and fits in available memory or to 0 otherwise.
If the sound exists, PlaySnd also sets the string variable S_Info to:
"SOURCE: sourceName; RESOURCENAME : resourceName; RESOURCEID: resourceID"
If the sound is not a resource then resourceName is " " and resourceID is 0 . sourceName will be the name of the file that was loaded or "Clipboard", "System" or "Igor".

\section*{Examples}
```

PlaySnd/I=1/P=mySnds/Z "Wild Eep"
If (V flag) // Any 'snd ' in the "Wild Eep" file?
Print S_info // Yes, print resource number, etc.

```
Endif

This prints the following into the history area:
```

SOURCE:resource fork;RESOURCENAME:Wild Eep;RESOURCEID:8;

```

\section*{PlaySound}

PlaySound [/A[=a] /C] soundWave
PlaySound /A [=a] \{soundWave1, soundWave2 [, soundWaveN...]\}
The PlaySound operation plays the audio samples in the named wave. The various sound output parameters - number of samples, sample rate, number of channels, and number of bits of resolution - are determined by the corresponding parameters of the wave.

\section*{Flags}
\(/ \mathrm{A}[=a] \quad\) Plays sounds asynchronously so that sounds will continue to play after the command itself has executed.
/ \(\mathrm{A}=0\) : \(\quad\) Same as no /A flag.
/ \(\mathrm{A}=1\) : \(\quad\) Plays sounds asynchronously; same as /A.
\(/ A=2: \quad\) Stop playing any current sound before starting this one.
/ \(\mathrm{A}=3\) : \(\quad\) Return with user abort error if output buffers are full (rather than waiting.) Use GetRTError (1) to detect and clear the error condition.
/C Obsolete - do not use.
On Windows /C causes sound wave data greater than 16-bits to be converted to 16-bit integer. Such data should range from -32768 to +32767 .

On Macintosh /C is ignored.

\section*{Details}

The wave's time per point, as determined by its \(X\) scaling, must be a valid sampling rate. A value of \(1 / 44100\) (CD standard) is typical.

Sound waves should be 16 bit integers with a range of -32768 to +32767 . On Macintosh as of Igor version 6.11, 32-bit floating point data with a range of -1 to +1 can also be used. For backward compatibility, 8-bit integer data with a range of -128 to +127 is also supported.
With the /A flag, the sound plays asynchronously (i.e., the command returns before the sound is finished). If another command is issued before the sound is finished then the new command will wait until the last sound finishes. A PlaySound without the /A flag can play on top of the current sound. The transition between sounds should be seamless on Macintosh but may be slightly delayed on Windows.
It is OK to kill a sound wave immediately after PlaySound returns even if the /A flag is used.
To play a stereo sound, provide a 2 column wave with the left channel in column 0 . Actually, the software will attempt to play as many channels as there are columns in the wave. You can also use multiple1D waves with the /A flag. To use this method, enclose the list of 1D waves in braces

Note: The SoundInput operations provide matching sound recording capabilities. See the SoundInStatus operation.

\section*{Examples}

Under Windows, support for sound is somewhat idiosyncratic so these sound examples may not work correctly with your particular hardware configuration.
```

Make/B/O/N=1000 sineSound
// 8 bit samples
SetScale/P x,0,1e-4, sineSound // Set sample rate to lokhz
sineSound= 100*sin(2*Pi*1000*x) // Create 1Khz sinewave tone

```
PlaySound sineSound

The following example will create a rising pitch in the left channel and a falling pitch in the right channel:
```

Make/W/O/N=(20000,2) stereoSineSound // 16 bit data
SetScale/P x,0,le-4,stereoSineSound // Set sample rate to l0Khz
stereoSineSound= 20000*sin(2*Pi*(1000 + (1-2*q)*150*x)*x)
PlaySound/A stereoSineSound // 16 bit, asynchronous

```

Multichannel sounds as in the previous example but from multiple 1D waves:
Make/W/O/N=20000 stereoSineSoundL, stereoSineSoundR // 16 bit data
SetScale/P x, 0,1e-4, stereoSineSoundL, stereoSineSoundR// set sample rate to 10 Khz
stereoSineSoundL= \(20000 * \sin (2 * P i *(1000+150 * x) * x) / /\) rising pitch in left
stereoSineSoundR \(=20000 * \sin (2 * P i *(1000-150 * x) * x) / /\) falling in right
PlaySound/A \{stereoSineSoundL, stereoSineSoundR\} // two 1D waves

\section*{pnt2x}
pnt2x(waveName, pointNum)
The pnt \(2 x\) function returns the \(X\) value of the named wave at the point pointNum. The point number is truncated to an integer before use.

\section*{Details}

The result is derived from the wave's \(X\) scaling, not any \(X\) axis of a graph it may be displayed in. If you would like to convert a fractional point number to an \(X\) value you can use:
leftx (waveName) +deltax (waveName) *pointNum.
There is no equivalent function for multidimensional waves. To calculate this information for other dimensions, use this expression:
DimOffset (waveName, dim) + ScaledDimPos*DimDelta (waveName, dim)
This expression calculates the scaled position of an element in the dimension \(\operatorname{dim}(\mathrm{x}, \mathrm{y}, \mathrm{z}, \mathrm{or} \mathrm{t})\). ScaledDimPos is the element number in that dimension ( \(p, q, r\), or \(s\) ). dim is 0 for rows, 1 for columns, 2 for layers or 3 for chunks. Setting dim \(=0\) is equivalent to using pnt2x. You may want to use round, ceil, or floor to truncate the result to an integer.

\section*{See Also}

The functions DimDelta and DimOffset.
Waveform Model of Data on page II-77 and Changing Dimension and Data Scaling on page II-83 for an explanation of waves and dimension scaling.

\section*{Point}

The point structure is used as a substructure usually to store the location of the mouse on the screen.
```

Structure Point

```
    Int16 v
    Int16 h
EndStructure

\section*{poissonNoise}
poissonNoise (num)
The poissonNoise function returns a pseudo-random value from the Poisson distribution whose probability distribution function is
\[
f(x ; \lambda)=\frac{e^{-\lambda} \lambda^{x}}{x!}, \quad \begin{gathered}
\lambda>0 \\
x=0,1,2 \ldots
\end{gathered}
\]
with mean and variance equal to \(n u m I(=\lambda)\).
The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

\section*{See Also}

The SetRandomSeed operation.
Noise Functions on page III-334.
Chapter III-12, Statistics for a function and operation overview.

\section*{poly}
poly(coefsWaveName, x1)
The poly function returns the value of a polynomial function at \(\mathrm{x}=x 1\).
coefsWaveName is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial.

\section*{Examples}

To fill wave 0 with 100 points containing the polynomial \(1+2^{*} x+3^{*} x^{2}+4^{*} x^{3}\) evaluated over the range from \(x=-1\) to \(x=1\) (and graph it):
Make coefs \(=\{1,2,3,4\} \quad / / f(x)=1+2 * x+3 * x^{\wedge} 2+4 * x^{\wedge} 3\)
Make/N=100/O wave0; SetScale/I x, -1, 1, wave0; Display wave0
wave0 \(=\) poly (coefs, \(x\) )

\section*{poly2D}
poly2d (coefsWaveName, \(x 1, y 1\) )
The poly2D function returns the value of a 2 D polynomial function at \(\mathrm{x}=x 1, \mathrm{y}=y 1\).
coefsWaveName is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial and therefore the polynomial degree.

\section*{Details}

The coefficients wave contains polynomial coefficients for low degree terms first. All coefficients for terms of a given degree must be present, even if they are zero. Among coefficients for a given degree, those for terms having higher powers of \(X\) are first. Thus, poly2D returns, for a coefficient wave cw:
\(f(x, y)=\operatorname{cw}[0]+c w[1]^{*} x+c w[2]^{*} y+c w[3]^{*} x^{\wedge} 2+c w[4]^{*} x^{*} y+c w[5]^{*} y^{\wedge} 2+\ldots\)
A 2D polynomial of degree N has \((\mathrm{N}+1)(\mathrm{N}+2) / 2\) terms.

\section*{Examples}

To fill wave 0 with 400 points ( 20 by 20 ) containing the polynomial \(1+2^{*} x+2.5^{*} y+3^{*} x^{2}+3.5^{*} x y+4^{*} y^{2}\) evaluated over the range \(x=(-1,1)\) and \(y=(-1,1)\) and make a contour plot of it:
```

Make/O coefs = {1, 2, 2.5, 3, 3.5, 4}
Make/N=(20,20)/O wave0
SetScale/I x, -1, 1, wave0
SetScale/I y, -1, 1, wave0

```
wave0 \(=\) poly2D (coefs, \(x, y\) )
Display; AppendMatrixContour waveo
The polynomial is second degree, so the first command above made the wave coefs with six elements because \((2+1)(2+2) / 2=6\).
To fill wave 0 with 100 points containing the polynomial \(1+2^{*} x+3^{*} y+4^{*} x^{2}+4^{*} y^{2}+5^{*} x^{3}+6^{*} y^{3}\) (note the lack of cross terms) evaluated over the range \(x=(-1,1)\) and \(y=(-1,1)\) (the contour plot already made should update with the new data). The first zero eliminates the second-order cross term \(x^{*} y\) and the second and third zeros eliminate the third-order cross terms \(x^{2 *} y\) and \(x^{*} y^{2}\) :
Make/O coefs \(=\{1,2,3,4,0,4,5,0,0,6\}\)
wave0 \(=\) poly2D (coefs, \(x, y)\)

\section*{PolygonArea}

\section*{PolygonArea (xWave, yWave)}

The PolygonArea function returns the area of a simple, closed, convex or nonconvex planar polygon described by consecutive vertices in \(x\) Wave and \(y\) Wave.
A simple polygon has no internal "holes" and its boundary curve does not intersect itself. Both \(x\) Wave and yWave must be 1D, real, numerical waves of the same dimensions. The minimum number of vertices is 3 . The function uses the shoelace algorithm to compute the area (see theorem 1.3.3 in the reference below). If there is any error in the input, the function returns NaN .

\section*{Example}
```

Function estimatePi(num)
Variable num
Make/O/N=(num+1) xxx, Yyy
xxx=sin(2*pi*x/num)
Yyy=cos(2*pi*x/num)
printf "Relative Error=%g\r",(pi-PolygonArea(xxx,yyy))/pi
End

```

\section*{popup}
popup menuList
The popup keyword is used with Prompt statements in Functions and Macros. It indicates that you want a pop-up menu instead of the normal text entry item in a DoPrompt simple input dialog (or a Macro's missing parameter dialog (archaic)). menuList is a string expression containing a list of items, separated by semicolons, that are to appear in the pop-up menu.
Pop-up menus accept both numeric and string parameters. For numeric parameters, the number of the item selected is placed in the variable. Numbering starts from one. For string parameters, the selected item's text is placed in the string variable.
Pop-up items support all of the special characters available for user-defined menu definitions (see Special Characters in Menu Item Strings on page IV-118) with the exception that items in pop-up menus are
limited to 50 characters, keyboard shortcuts are not supported, and special characters must be enabled.

\section*{See Also}

Prompt, DoPrompt, and Pop-Up Menus in Simple Dialogs on page IV-127.
See WaveList, TraceNameList, ContourNameList, ImageNameList, FontList, MacroList, FunctionList, StringList, and VariableList for functions useful in generating lists of Igor objects.
Chapter III-14, Controls and Control Panels for details about control panels and controls.

\section*{PopupContextualMenu}

PopupContextualMenu [/C=(xpix, ypix) /N] popupStr
The PopupContextualMenu operation displays a popup menu until the user makes a selection or cancels the menu by clicking outside of its window.
The menu appears at the current mouse position or at the location specified by the /C flag.
The content of the menu is contained in popupStr as a semicolon-separated list of items or in a user-defined menu definition referred to by the name contained in popupStr.

\section*{Parameters}

If popupStr specifies the pop-up menu's items (/ N is not specified), then popupStr is a semicolon-separated list of items such as "yes;no;maybe;", or a string expression that returns such a list, such as TraceNameList.

The menu items can be formatted and checkmarked, like user-defined menus can. See Special Characters in Menu Item Strings on page IV-118.
If / N is specified, popupStr must be the name of a user-defined menu that also has the popupcontextualmenu keyword. See Example 3.

Flags
\(/ \mathrm{C}=(\) xpix, ypix \() \quad\) Sets the coordinates of the menu's top left corner. Units are in pixels relative to the top-most window, such as the MOUSEX and MOUSEY values passed to a window hook. See the window hook example, below and SetWindow.
If /C is not specified, the menu's top left corner appears at the current mouse position.
/N
Indicates that popupStr contains the name of a menu definition instead of containing a list of menu items.

\section*{Details}

If the / N flag is not set, PopupContextualMenu sets the following variables:
\begin{tabular}{ll} 
V_flag=0 & \begin{tabular}{l} 
User cancelled the menu without selecting an item, or there was an error such as an \\
empty popupStr.
\end{tabular} \\
\(\mathrm{V}_{-} f l a g=>=1\) & 1 if the first menu item was selected, 2 for the second, etc. \\
S_selection & \(" "\) if the user cancelled or error, else the text of the selected menu item.
\end{tabular}

If the / N flag is set, PopupContextualMenu sets the following variables in a manner similar to (though different from) PopupContextualMenu:

V_kind The kind of menu that was selected:
\begin{tabular}{ll} 
V_kind & Menu Kind \\
\hline 0 & \begin{tabular}{l} 
Normal text menu item, including Optional Menu Items (see \\
page IV-114) and Multiple Menu Items (see page IV-115).
\end{tabular} \\
3 & "*FONT*" \\
6 & "*LINESTYLEPOP*" \\
7 & "*PATTERNPOP*" \\
8 & "*MARKERPOP*" \\
9 & "*CHARACTER*" \\
10 & "*COLORPOP*" \\
13 & "*COLORTABLEPOP*"
\end{tabular}

See Specialized Menu Item Definitions on page IV-116 for details about these special user-defined menus.

V_flag
-1 if the user didn't select any item, otherwise V_flag returns a value which depends on the kind of menu the item was selected from:
\begin{tabular}{ll} 
V_kind & V_flag Meaning \\
\hline 0 & Text menu item number (the first menu item is number 1). \\
3 & Font menu item number (use S_selection, instead). \\
6 & \begin{tabular}{l} 
Line style number (0 is solid line) \\
7
\end{tabular} \\
\begin{tabular}{l} 
Pattern number (1 is the first selection, a SW-NE light \\
diagonal).
\end{tabular} \\
9 & \begin{tabular}{l} 
Marker number (1 is the first selection, the X marker). \\
10
\end{tabular} \\
\begin{tabular}{l} 
Character as an integer, = char2num(S_selection). Use \\
13
\end{tabular} & \begin{tabular}{l} 
Color menu item (use V_red, V_green, and V_blue instead).
\end{tabular} \\
& Color table list menu item (use S_selection instead).
\end{tabular}

S_selection The menu item text, depending on the kind of menu it was selected from:
\begin{tabular}{ll} 
V_kind & S_selection Meaning \\
\hline 0 & Text menu item text. \\
3 & Font name or "default". \\
6 & Name of the line style menu or submenu. \\
7 & Name of the pattern menu or submenu. \\
8 & Name of the marker menu or submenu. \\
9 & Character as string. \\
10 & Name of the color menu or submenu. \\
13 & Color table name.
\end{tabular}

In the case of Specialized Menu Item Definitions (see page IV-116), S_selection will be the title of the menu or submenu, etc.

\section*{V_Red, V_Green, V_Blue}

If a user-defined color menu ("*COLORPOP*" menu item) was selected then these values hold the red, green, and blue values of the chosen color. The values range from 0 to 65535.
Will be 0 if the last user-defined menu selection was not a color menu selection.

\section*{Examples}

\section*{Example 1 - popupStr contains a list of menu items}
```

// Menu formatting example
String checked= "<br>M0:!" + num2char(18) + ":" // checkmark code
String items= "first;\M1-;"+checked+"third;" // 2nd is divider, 3rd is checked
PopupContextualMenu items
switch( V_Flag )
case 1:
// do something because first item was chosen
break;
case 3:
// do something because first item was chosen
break;
endswitch

```

\section*{Example 2 - popupStr contains a list of menu items}
// Window hook example
```

SetWindow kwTopWin hook=TableHook, hookevents=1 // mouse down events
Function TableHook(infoStr)

```
    String infoStr
    Variable handledEvent=0
    String event= StringByKey("EVENT", infoStr)
    strswitch (event)
        case "mousedown":
            Variable isContextualMenu= NumberByKey("MODIFIERS",infoStr) \& 0xl0
            if ( isContextualMenu )
                    Variable xpix= NumberByKey("MOUSEX", infoStr)
                    Variable ypix= NumberByKey ("MOUSEY", infoStr)
                    PopupContextualMenu/C=(xpix,ypix) "yes;no;maybe;"
                    strswitch (S_selection)
                    case "yes":
                            // do something because "yes" was chosen
                    break
                case "no":
                    break
                case "maybe":
                    // do something because "maybe" was chosen
                    break
                    endswitch
                    handledEvent=1
            endif
    endswitch
    return handledEvent
End

\section*{Example 3 - popupStr contains the name of a user-defined menu}
// User-defined contextual menu example
// dynamic menu (to keep WaveList items updated), otherwise not required.
// contextualmenu keyword is required, and implies /Q for all menu items.
//1
// NOTE: Actions here are accomplished by the menu definition's
// execution text, such as DoSomethingWithColor.
// See Example 4 for another approach.
//
Menu "ForContext", contextualmenu, dynamic
"Hello", Beep
Submenu "Color"
"*COLORPOP*", DoSomethingWithColor()
End
Submenu "Waves"
WaveList("*",";",""), /Q, DoSomethingWithWave()
End
End
Function DoSomethingWithColor()
GetLastUserMenuInfo
Print V_Red, V_Green, V_Blue
End
Function DoSomethingWithWave()
GetLastUserMenuInfo
WAVE w = \$S_value
Print "User \({ }^{-}\)selected "+GetWavesDataFolder(w,2)
End
// Use this code in a function or macro:
PopupContextualMenu/N "ForContext"
if ( V_flag < 0 )
Print "User did not select anything"
endif
Example 4 - popupStr contains the name of a user-defined menu
// User-defined contextual menu example
Menu "JustColorPop", contextualmenu
"*COLORPOP* \((65535,0,0)\) ", ;// initially red, empty execution text
End
```

// Use this code in a function or macro
PopupContextualMenu/C=(xpix, ypix)/N "JustColorPop"
if( V_flag < O )
Print "User did not select anything"
else
Print V_Red, V_Green, V_Blue
endif

```

\section*{See Also}

Creating a Contextual Menu on page IV-143.
Special Characters in Menu Item Strings on page IV-118 and Chapter III-14, Controls and Control Panels, for details about control panels and controls.
The SetWindow and PopupMenu operations.

\section*{PopupMenu}

PopupMenu [/Z] ctrlName [keyword = value [, keyword = value ...]]
The PopupMenu operation creates or modifies a pop-up menu control in the target or named window.
For information about the state or status of the control, use the ControlInfo operation.

\section*{Parameters}
ctrlName is the name of the PopupMenu control to be created or changed.
The following keyword=value parameters are supported:
```

appearance={kind [, platform]}

```

Sets the appearance of the control. platform is optional. Both parameters are names, not strings.
kind can be one of default, native, or os 9 .
platform can be one of Mac, Win, or All.
See Button and DefaultGUIControls for more appearance details.
bodyWidth=width Specifies an explicit size for the body (nontitle) portion of a PopupMenu control. By default (bodyWidth=0), the body portion autosizes depending on the current text. If you supply a bodyWidth \(>0\), then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.
disable \(=d \quad\) Sets user editability of the control.
\(d=0: \quad\) Normal.
\(d=1: \quad\) Hide.
\(d=2: \quad\) Draw in gray state; disable control action.
fColor \(=(r, g, b) \quad\) Sets the initial color of the title. \(r, g\), and \(b\) range from 0 to 65535. fColor defaults to black \((0,0,0)\). To further change the color of the title text, use escape sequences as described for title=titleStr.
font="fontName" Sets the font used for the pop-up title, e.g., font="Helvetica".
fsize \(=s \quad\) Sets the font size for the pop-up title.
\begin{tabular}{|c|c|}
\hline fstyle \(=f\) s & \(f_{s}\) is a bitwise parameter with each bit controlling one aspect of the font style as follows: \\
\hline & Bit 0: Bold. \\
\hline & Bit 1: Italic. \\
\hline & Bit 2: Underline. \\
\hline & Bit 3: Outline (Macintosh only). \\
\hline & Bit 4: Shadow (Macintosh only). \\
\hline & See Setting Bit Parameters on page IV-12 for details about bit settings. \\
\hline help=\{helpStr \(\}\) & Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting " \(\backslash \mathrm{r}\) " in a quoted string. \\
\hline mode \(=m\) & Specifies the pop-up title location. \\
\hline & \(m=0: \quad\) Title is in pop-up menu. \\
\hline & \(m=1\) : \(\quad\) Title is to the left of pop-up menu, the chosen menu item appears in the pop-up menu, and menu item number \(m\) is initially selected. \\
\hline noproc & Specifies that no procedure is to execute when choosing in the pop-up menu. \\
\hline popColor=( \(r, g, b\) ) & Specifies the color initially chosen in the color pop-up palette. \(r, g\), and \(b\) are integers from 0 to 65535. See the Colors, Color Tables, Line Styles, Markers, and Patterns section. \\
\hline popmatch=matchSt & \\
\hline & Sets mode to the enabled menu item that matches matchStr. matchStr may be a "wildcard" expression. See StringMatch. If no item is matched, mode is unchanged. \\
\hline popvalue=valueStr & Sets the string displayed by the menu when first created, if mode is not zero. See Popvalue Keyword section. \\
\hline pos \(=\{l e f t, t o p\}\) & Sets the position of the pop-up menu in pixels. \\
\hline pos \(+=\{d x, d y\}\) & Offsets the position of the pop-up in pixels. \\
\hline proc \(=\) procName & Specifies the procedure to execute when the pop-up menu is clicked. See Action Procedure below. \\
\hline rename=newName & Gives pop-up menu a new name. \\
\hline size \(=\{\) width,height \(\}\) & Sets pop-up menu size in pixels. \\
\hline title=titleStr & Sets title of pop-up menu to the specified string expression. Defaults to "" (no title). titleStr can contain formatting escape codes in order to create fancy, styled results. The escape codes are the same as used by the TextBox operation. The easiest way to generate fancy text is to make selections from the Insert popup in the PopupMenu Control dialog. \\
\hline userdata(UDName) & \(=U D S t r\) \\
\hline
\end{tabular}

Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create. You can retrieve the data using GetUserData.
userdata(UDName)+=UDStr
Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr.
value=itemListSpec Specifies the pop-up menu's items. itemListSpec can take several forms as described below under Setting The Popup Menи Items.
win=winName Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Flags}
/Z No error reporting.

\section*{Details}

The target window, or the window named with the win=winName keyword, must be a graph or panel.

\section*{Action Procedure}

The action procedure is called when the user chooses a menu item. It can take one of two forms.
The original form of the action procedure takes there parameters:
```

Function PopupMenuAction (ctrlName,popNum,popStr) : PopupMenuControl
String ctrlName
Variable popNum // which item is currently selected (1-based)
String popStr // contents of current popup item as string
End

```
The ": PopupMenuControl" designation tells Igor to include this procedure in the list of available popup
menu action procedures in the PopupMenu Control dialog used to create a popup menu.

The second form of the action procedure takes one parameter, a reference to the built-in WMPopupAction structure:
```

Function PopupMenuAction(PU_Struct) : PopupMenuControl
STRUCT WMPopupAction \&PU_Struct
End
The WMPopupAction structure has members as described in the following table:
WMPopupAction Structure Members
Member Description
char ctrlName [MAX_OBJ_NAME+1] Control name.
char win[MAX_WIN_PATH+1] Host (sub)window.
STRUCT Rect winRect Local coordinates of host window.
STRUCT Rect ctrlRect Enclosing rectangle of the control.
STRUCT Point mouseLoc Mouse location.
Int32 eventCode Event that executed the procedure.

| eventCode | Event |
| :--- | :--- |
| -1 | Control being killed |
| 2 | Mouse up |

Int32 eventMod
String userData Primary (unnamed) user data. If this changes, it is written back
to the control automatically.

```

WMPopupAction Structure Members
\begin{tabular}{ll} 
Member & Description \\
\hline Int32 blockReentry & Prevents reentry of control action procedure. See Control \\
& Structure blockReentry Field on page III-388. \\
Int32 popNum & Item number currently chosen (1-based). \\
char popStr [MAXCMDLEN] & Contents of current popup item. \\
\hline
\end{tabular}

Action procedures should respond only to documented event Code values. Other event codes may be added along with more fields. Although the return value is not currently used, action procedures should always return zero.

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

\section*{Setting The Popup Menu Items}

This section discusses popup menus containing lists of text items. The next section discusses popup menus for choosing colors, line styles, markers and patterns.
The items in the popup menu are determined by the itemListSpec parameter used with the value keyword. itemListSpec can take several different forms from simple to complex.
No matter what the form, Igor winds up storing an expression that returns a string in the popup menu's internal structure. This expression may be a literal string ("Red;Green;Blue;"), a call to a built-in or userdefined function that returns a string, or the path to a global string variable. Igor evaluates this expression when the popup menu is first created and again each time the user clicks on the menu. You can see the string expression for a given popup menu using the PopupMenu Control dialog.
The right form for itemListSpec depends on your application. Here is a guide to choosing the right form with the simpler forms first.

\section*{A literal string expression}

Use this if you know the items you want in your popup menu when you write the PopupMenu call. For example:
```

Function PopupDemo1() // Literal string
NewPanel
PopupMenu popup0, value="Red;Green;Blue;"

```
End

This method is limited to 400 characters of menu item text.

\section*{A function call}

Use this if you need to compute the popup menu item list when the user clicks the popup menu. The function must return a string containing a semicolon-separated list of menu items. This example creates a popup menu which displays the name of each wave in the current data folder at the time the menu is clicked:
```

Function PopupDemo2() // Built-in function
NewPanel
PopupMenu popup0, value=WaveList("*", ";", "")
End
data folder:

```
```

Function/S MyPopupWaveList()

```
Function/S MyPopupWaveList()
    String saveDF
    String saveDF
    // Create some waves for demo purposes
    // Create some waves for demo purposes
    saveDF = GetDataFolder(1)
    saveDF = GetDataFolder(1)
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S PopupMenuDemo
    NewDataFolder/O/S PopupMenuDemo
    Make/O demo0, demo1, demo2
    Make/O demo0, demo1, demo2
    SetDataFolder saveDF
    SetDataFolder saveDF
    saveDF = GetDataFolder(1)
    saveDF = GetDataFolder(1)
    SetDataFolder root:Packages:PopupMenuDemo
    SetDataFolder root:Packages:PopupMenuDemo
    String list = WaveList("*", ";", "")
```

    String list = WaveList("*", ";", "")
    ```
You can also use a user-defined function. This example shows how to list waves from other than the current
```

    SetDataFolder saveDF
    return list
    End
Function PopupDemo3() // User-defined function
NewPanel
PopupMenu popup0, value=MyPopupWaveList()
End

```

\section*{\# followed by a local string variable specifying items}

Use this when the popup menu item list is not known when you write the code but you can compute it at runtime. For example:
```

Function PopupDemo4() // Local string variable specifying items
NewPanel
String quote = "\""
String list
if (CmpStr(IgorInfo(2),"Windows") == 0)
list = quote + "Windows XP; Windows VISTA;" + quote
else
list = quote + "Mac OS X 10.4;Mac OS X 10.5;" + quote
endif
PopupMenu popupo, value=\#list
End

```

The strange-looking use of the quote string variable is necessary because the parameter passed to the value=\# keyword is evaluated once when the PopupMenu command executes and the result of that evaluation is evaluated again when the PopupMenu is created or clicked. The result of the first evaluation must be a legal string expression.
This method is limited to 400 characters of menu item text.

\section*{\# followed by a local string variable specifying a function}

Use this when you need to compute the popup menu item list at click time and you need to select the function which computes the list when the popup menu is created. For example:
```

Function/S WindowsItemList()
String list
list = "Windows XP; Windows VISTA;"
return list
End
Function/S MacItemList()
String list
list = "Mac OS X 10.4;Mac OS X 10.5;"
return list
End
Function PopupDemo5() // Local string variable specifying function
String listFunc
if (CmpStr(IgorInfo(2),"Windows") == 0)
listFunc = "WindowsItemList()"
else
listFunc = "MacItemList()"
endif
NewPanel
PopupMenu popupo, value=\#listFunc
End

```

This form is useful when you create a control panel in an independent module. Since the control panel runs in the global name space, you must specify the independent module name in the invocation of the function that provides the popup menu items. For example:
```

// Calling a non-static function in an independent module from \#included code
\#pragma IndependentModuleName=IM
String listFunc= GetIndependentModuleName() +"\#PublicFunctionInIndepMod()"
PopupMenu popup0, value=\#listFunc
// Calling a static function in an independent module from \#included code
\#pragma IndependentModuleName=IM
\#pragma ModuleName=ModName

```

String listFunc= GetIndependentModuleName() + "\#ModName\#StaticFunctionInIndepMod()"
PopupMenu popupo, value=\#listFunc
We use GetIndependentModuleName rather than hard-coding the name of the independent module so that the code will continue to work if the name of the independent module is changed. Also, because this code does not depend on the specific name of the independent module, it can be added to an independent module via a \#included procedure file.
Also see GetIndependentModuleName and Independent Modules and Popup Menus on page IV-222.

\section*{\# followed by a quoted literal path to a global string variable}

Use this if you want to compute the popup menu item list before it is clicked, not each time it is clicked. This would be advantageous if it takes a long time to compute the item list, and the list changes only at welldefined times when you can set the global string variable.
The global string variable must exist when the PopupMenu command executes and when the menu is clicked. In this example, the gPopupMenuItems global string variable is created and initialized when the popup menu is created but can be changed to a different value later before the menu is clicked:
```

Function PopupDemo6() // Global string variable containing list
NewDataFolder/O root:Packages
NewDataFolder/O root:Packages:PopupMenuDemo
String/G root:Packages:PopupMenuDemo:gPopupMenuItems = "Red;Green;Blue;"
NewPanel
PopupMenu popup0 ,value=\#"root:Packages:PopupMenuDemo:gPopupMenuItems"
End

```
\# followed by a local string variable containing a path to a global string variable
Use this when the popup menu item list contents will be stored in a global string variable whose location is not known until the popup menu is created. For example:
```

Function PopupDemo7() // Local string containing path to global string
String graphName = WinName(0, 1, 1)// Name of top graph
if (strlen(graphName) == 0)
Print "There are no graphs."
return -1
endif
NewDataFolder/O root:Packages
NewDataFolder/O root:Packages:PopupMenuDemo
// Create data folder for graph
NewDataFolder/O root:Packages:PopupMenuDemo:$(graphName)
    String list = "Red;Green;Blue;"
    String/G root:Packages:PopupMenuDemo:$(graphName):gPopupMenuItems = list
NewPanel
String path // Local string containing path to global string
path = "root:Packages:PopupMenuDemo:" + graphName + ":gPopupMenuItems"
PopupMenu popup0, value=\#path
return 0
End

```

\section*{Colors, Color Tables, Line Styles, Markers, and Patterns}

You can create PopupMenu controls for color, color tables, line style (dash modes), markers, and patterns. To do so, simply specify the itemListSpec parameter to the value keyword as one of "*COLORPOP*",
"*COLORTABLEPOP*", " *COLORTABLEPOPNONAMES*",
"*LINESTYLEPOP*", "*MARKERPOP*", or "*PATTERNPOP*". In these modes
 the body of the control will contain a color box, a color table (gradient), a line style sample, a marker, or a pattern sample.
For these special pop-up menus, mode=0 ("Title in Box" checked) is not used.
For a line style pop-up menu, the mode value is the line style number plus one. Thus line style 0 (a solid line) is mode \(=1\).

For a marker pop-up, the mode value is the marker number plus one, and marker 0 (the + marker) is mode \(=1\). For a pattern pop-up, the mode value is the SetDrawEnv fillPat number minus 4 , so mode \(=1\) corresponds to fillpat=5, the SW-NE lines fill pattern shown above.

For a color table pop-up, the mode value is the CTabList() index plus 1 , so mode=1 corresponds to the first item in the list returned by CTabList, which is "Grays":
```

ControlInfo \$ctrlName
// Sets V_Value
Print StringFromList(V_Value-1,CTabList()) // Prints-"Grays"

```

ControlInfo also returns the color table name in S_Value.
To set the pop-up to a given color table name, you can use code like this:
```

Variable m=1 + WhichListItem(ctabName, CTabList())
PopupMenu \$ctrlName mode=m

```

For color pop-up menus, you set the current value using the popColor= \((r, g, b)\) keyword. On output (via the popStr parameter of your action procedure or via the S_value output from ControlInfo) the color is encoded as " \((r, g, b)\) " where \(r, g\), and \(b\) are numbers. To get these numerical values, you can extract them from the string using the MyRGBstrToRGB function below or use ControlInfo which sets V_Red, V_Green, V_Blue.
The following example demonstrates the line style and color pop-up menus. To run the example, copy the following code to the procedure window of a new experiment and then run the panel macro.
```

Window PanelO() : Panel
PauseUpdate; Silent 1 // building window ...
NewPanel /W=(150,50,400,182)

print "style:",popNum-1
End

```

\section*{Popvalue Keyword}

There are times when the displayed value cannot be determined and saved such that it can be displayed when the pop-up menu is recreated. For instance, because window recreation macros are evaluated in the root folder, a pop-up menu of waves may not contain the correct list when a panel is recreated. That is, the intention may be to have the menu show a particular wave from a data folder other than root. When the panel recreation macro runs, the function that lists waves will list waves in the root data folder. The desired selection may be wrong or nonexistent.

Similarly, a pop-up menu of fonts may need to display a particular font upon recreation on a different computer having a different list of fonts. The mode \(=m\) keyword probably won't pick the correct font from the new list.
The solution to these problems is to save the correct selection with the popvalue=valueStr keyword. The list function will not be executed when the menu is first created. If the menu is popped, the list function will be evaluated, and the correct list will be displayed then.
It is a good idea to set the mode \(=m\) keyword to the correct number, if it is known. That way, when the menu is popped the correct item is chosen.
Normally you can let Igor redraw the pop-up menu when it redraws the graph or control panel containing it. However, there are situations in which you may want to force the pop-up menu to be redrawn. This can be done using the ControlUpdate operation.

\section*{See Also}

The ControlInfo operation for information about the control. The ControlUpdate, WaveList, and
TraceNameList operations. Chapter III-14, Controls and Control Panels, for details about control panels and controls. The GetUserData operation for retrieving named user data. Special Characters in Menu Item Strings on page IV-118.

\section*{PopupMenuControl}

\section*{PopupMenuControl}

PopupMenuControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined pop-up menu control. See Procedure Subtypes on page IV-183 for details. See PopupMenu for details on creating a popup menu control.

\section*{PossiblyQuoteName}

PossiblyQuoteName (nameStr)
The PossiblyQuoteName function returns the input name string if it conforms to the rules of standard wave or Data Folder names. If it does not, then the name is returned in single quotes. This is used when generating a command string that you will pass to the Execute command. You might get the input name string from a function such as NameOfWave or CsrXWave.

\section*{Examples}

Print PossiblyQuoteName("wave0") // prints wave0
Print PossiblyQuoteName("wave 0") // prints 'wave 0'

\section*{Details}

See Programming with Liberal Names on page IV-151 for an example.

\section*{Preferences}

Preferences [/Q] [newPrefsstate]
The Preferences operation sets or displays the state of user preferences.
User preferences affect the creation of new graphs, panels, tables, layouts, notebooks, procedure windows, and the command window. They also affect the appearance of waves appended to graphs and tables, and objects appended to layouts.

\section*{Parameters}

If newPrefsState is present, it sets the state of user preferences as follows:
newPrefsState=0: Preferences off (use factory defaults).
newPrefsState=1: \(\quad\) Preferences on.
If newPrefsState is omitted, the state of user preferences is printed in the history area.

Flags
/Q
Disables printing to the history.

\section*{Details}

The Preferences operation sets the variable V_flag to the state of user preferences that were in effect before the Preferences command executed: 1 for on, 0 for off.

You can also set the state of Preferences with the Misc menu.
Under most circumstances we want procedures to be independent of preferences so that a particular procedure will do the same thing regardless of the state of preferences. To achieve this, preferences are automatically off when you initiate procedure execution. When execution is complete, the state of preferences is restored to what it was before.
If you want preferences to be in effect during procedure execution, you must turn it on with the Preferences operation.

If the preferences setting is changed by a procedure, the effect of the call is propagated down the calling chain. If a macro changes the preferences setting, that change is undone when the macro returns. If a function changes the preferences setting, the change persists after the function returns. However, even with a function, the changed preferences state does not persist when Igor regains control.

\section*{Examples}
```

Function Test()
Variable oldPrefState
Preferences 1; oldPrefState=V_flag // remember prefs setting
Make wave0=x
Display wave0 // Display uses preferences
Preferences oldPrefState // put prefs back, like a macro would
End
See Also
Chapter III-17, Preferences.

```

\section*{PrimeFactors}

PrimeFactors [/Q] inNumber
PrimeFactors calculates the prime factors of inNumber. By default factors are printed in the history and are also stored in the wave W_PrimeFactors in the current data folder.

Flags
Suppresses printing of factors in the history area.
Details
The largest number that this operation can handle is \(2^{32}-1\).

\section*{Print}

Print [flags] expression [, expression]...
The Print operation prints the evaluated expressions in the history area.

\section*{Parameters}

An expression can be a wave, a numeric expression (e.g., \(3 * \pi / 4\) ), a string expression (e.g., "Today is " + date ()), or a individual structure element or an entire structure variable.

\section*{Flags}
/C Evaluates all numeric expressions as complex.
/D Prints a greater number of digits.
/F Prints numeric wave data (1D and 2D waves only) using "nice," easily readable formatting.
/LEN=len \(\quad\) Sets the string break length to len number of characters (default is 200).
/S Obsolete. Numeric results are printed with a moderate number of digits whether you use /S or not. To print more digits, use /D.
/SR Prints a wave subrange for expressions that start as "waveName [". Without /SR, such an expression is taken as the start of a numeric expression such as wave [3] -wave [2]. (You can still use wave[pnt] but only if it does not start the numeric expression.)
Wave subrange printing is not done with /F.
You can specify a single row or column using [ \(r\) ] syntax. For example, to print column 4 of a matrix, use:

Print mymat [] [4]

\section*{Details}

Numeric expressions are always evaluated in double precision. The /D flag just controls the number of digits displayed.
Print determines if an expression is real, complex, or string from the first symbol in the expression. Usually this works fine, but occasionally Print guesses wrong and you may have to rearrange your expression. For example:
Print \(1+\mathrm{cmplx}(1,2)\)
will give an error because the first symbol, " 1 ", is real but the expression should be complex. Changing this to
Print cmplx \((1,2)+1\)
will work.
Printing numeric or string expressions involving structure elements must not start with the structure element. Instead an appropriate numeric or string literal must appear first so that Igor can determine what kind of expression to compile. For example rather than
Print astruct.astring + "hello"
use
Print "" + astruct.astring + "hello"
Print will break long string expressions into multiline pieces. If there are no natural breaks (carriage returns or semicolons) within a default length, then it will break the string arbitrarily.
The default line length is 200 chars or it can be set using the /LEN flag. The maximum number of characters that can be printed on a line in the History area is 400.
When printing waves, you can use either formatted (specified by /F) or unformatted (default) methods. Unformatted output is in an executable syntax for each printed line: wave \(=\{ \}\).

Note: \(\quad\) Executing lines printed from floating point waves will not exactly reproduce the source data due to round-off or insufficient digits in the printed output.

Printing formatted wave data gives easily (human) readable output, and works best for small 1D and 2D waves. If the data are too large or in an unsupported format (3D or greater, or the wave is text), then the output will be unformatted. Formatting is done using spaces, so the output will look best in a fixed-width font.
Printed wave data, both formatted and unformatted, are limited to no more than 100 lines of output. When the line limit is exceeded a warning message will be printed at the end of the truncated output. For text waves, output is limited to 50 characters of each string element, and there is no warning when a string is truncated.

\section*{See Also}

The printf operation.
The PrintGraphs, PrintTable, PrintLayout andPrintNotebook operations.

\section*{printf}
printf formatStr [, parameter [, parameter]...]
The printf operation prints formatted output to the history area.

\section*{Parameters}
formatStr is a string which specifies the formatting of the output.

The type of the parameter, string or numeric, must agree with the corresponding conversion specification in formatStr, or else the results will be indeterminate.
The printf parameters can be numeric or string expressions. Numeric and string structure fields are allowed except that complex structure fields and non-numeric (e.g., WAVE, FUNCREF) structure fields are not allowed.

\section*{Details}

The formatStr contains literal text and conversion specifications.
A conversion specification starts with the \(\%\) character and ends with a conversion character (for example, \(\mathrm{g}, \mathrm{e}, \mathrm{f}, \mathrm{d}\), or s as illustrated below). In between the \(\%\) and the conversion character you may include one or more flag characters, a field width specifier, and a precision specifier. The first \(\%\) corresponds to the first parameter, the second \(\%\) corresponds to the second parameter, etc. If formatStr contains no \(\%\) characters, no parameters are expected.
Here are some simple examples. numVar is a numeric variable and strVar is a string variable.
printf "The answer is: \%g\r", numVar
printf "Created wave \%s\r", strVar
printf "Created wave \%s, \%d points\r", strVar, numVar
\(\% \mathrm{~g}\) is a general-purpose format (floating point or scientific notation) that represents the value of numVar. \%d is an integer format that represents the value of numVar. \%s specifies that the corresponding parameter (strVar) is a string.
The " \(\backslash r\) " in these examples appends a carriage return to the end of the printed text.
Here is a complex example using all of these elements of a conversion specification:
printf "\%+015.4f\r", le6*PI
This prints:
The answer is: +003141592.6536
" + " is a flag character that tells printf to put a + or - sign in front of the number.
" 015 " is a field width specifier that tells printf to print the number in a field of at least 15 characters, padded with leading zeros. Using " 15 " instead of " 015 " would cause printf to pad with spaces before the + sign instead of zeros after it.
". 4 " is a precision specifier that tells printf to print four digits after the decimal point.
" \(f\) " tells printf to use a floating point format.
The most common conversions characters are " f " for floating point, " g " for general, " d " for decimal, and " s " for string. They are interpreted as for the printf() function in the C programming language.

The escape codes \(\backslash t\) and \(\backslash \mathrm{r}\) represent the tab and return characters respectively. See Escape Characters in Strings on page IV-13 for more information.
The supported flag characters and their meanings are as follows:
```

- Left align the result in the field.
+ Put a plus or minus sign before the number.
<space> Put a space before a positive number.

# Specifies alternate form for e, f,g, and x formats.

```

The meaning of the precision specifier depends on the numeric format ( \(\% \mathrm{~g}, \% \mathrm{e}, \% \mathrm{f}, \% \mathrm{~d}\), etc.) being used:
e, \(\mathrm{E}, \mathrm{f} \quad\) Precision specifies number of digits after decimal point.
g, G Precision specifies maximum number of significant digits.
\(\mathrm{d}, \mathrm{o}, \mathrm{u}, \mathrm{x}, \mathrm{X} \quad\) Precision specifies minimum number of digits.
You can replace both the field width and precision specifiers with an asterisk. This gets the field width or precision specifier from a parameter. For example:
printf "\%*.*f\r" 4, 3, 1e6*PI
means that the field width is 4 and the precision is 3 . You could use numeric expressions instead of the literal numbers to control the field width and precision algorithmically.
Here is a complete list of the conversion characters supported by printf:
f Converts a numeric parameter as [-]ddd.ddd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6 . If the \# flag is present, a decimal point will be used even if there are no digits to the right of it.
This conversion character uses the "round-to-half-even" rule, also known as "banker's rounding". When the truncated digits are exactly \(0.5000 \ldots\), the quantity is rounded to an even number. For example:
```

Printf "%.0f\r", 15.5 // Prints 16 (rounded up to even)
Printf "%.0f\r", 16.5 // Prints 16 (rounded down to even)

```
e, E Converts a numeric parameter as [-]d.ddde+/-dd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6 . If you use " E " instead of " e " then printf uses a capital " E " in the number. If the \# flag is present, a decimal point will be used even if there are no digits to the right of it.
g , G Converts a numeric parameter using " f " or " e " style conversion depending on the magnitude of the number. " \(e\) " is used if the exponent is less than -4 or greater than the precision. " G " uses " f " or " E " style conversion. If the \# flag is present, a decimal point will be used even if there are no digits to the right of it and trailing zeros will not be removed.
\(\mathrm{d}, \mathrm{o}, \mathrm{u} \quad\) Converts a numeric parameter as a signed decimal integer, unsigned octal integer or unsigned decimal integer, truncating any fractional part. The precision defaults to one and specifies the minimum number of digits to print.
These conversion characters use the "round-away-from-zero" rule, like Igor's round function. For example:
```

Printf "%d\r", 15.5 // Prints 16 (rounded away from zero)
Printf "%d\r", 16.5 // Prints 17 (rounded away from zero)

```
\(\mathrm{x}, \mathrm{X} \quad\) Converts a numeric parameter as an unsigned hexadecimal integer, truncating any fractional part. The "x" style uses lower case for the hexadecimal numerals "abcdef" where the " X " style uses upper case. The precision defaults to one and specifies the minimum number of digits to print. If the \# flag is present, the string " \(0 x\) " or " 0 X " is prepended to the number if it is not zero.
s Converts a numeric parameter as an unsigned hexadecimal integer, truncating any fractional part. The " \(x\) " style uses lower case for the hexadecimal numerals "abcdef" where the " X " style uses upper case. The precision defaults to one and specifies the minimum number of digits to print. If the \# flag is present, the string " \(0 x\) " or " \(0 X\) " is prepended to the number if it is not zero.
b WaveMetrics extension. Converts a numeric parameter to binary.
c Converts a numeric parameter to a single character.
\(\% \quad\) Prints a \(\%\) sign. No parameter is used.
\%W WaveMetrics extension. See description below.
Igor also supports a non-C, WaveMetrics extension to the conversion characters recognized by printf. This conversion specification starts with "\%W". It is followed by a flag digit and a format character. For example,
printf "ஃWOPs", 12.345E-6
prints \(12.345000 \mu \mathrm{~s}\). In this example, the "\%W0" introduces the WaveMetrics conversion specification. The " 0 " (zero) following the " W " is the flag digit. The " P " that follows is the format specifier character, which prints the number using a prefix, in this case, " \(\mu\) ".
There is only one WaveMetrics format specifier character, " P ", which prints using a prefix such as \(\mu, \mathrm{m}, \mathrm{k}\), or M. It recognizes two flag-digits, " 0 " or " 1 ". Option " 0 " prints with no space between the numeric part and the prefix character while flag " 1 " prints with 1 space. Numbers greater than tera or less than femto print using a power of ten notation. Here are a few examples:
```

printf "%.2WOPHz", 12.342E6 // prints 12.34MHz
printf "%.2W1PHz", 12.342E6 // prints 12.34 MHz
printf "%.OWOPs", 12.342E-6 // prints 12\mus
printf "%.OW1Ps", 12.342E-9 // prints 12 ns

```

\section*{See Also}

The sprintf, fprintf, and wfprintf operations; Creating Formatted Text on page IV-235 and Escape Characters in Strings on page IV-13.

\section*{PrintGraphs}

PrintGraphs [flags] graphSpec [, graphSpec]...
The PrintGraphs operation prints one or more graphs.
PrintGraphs prints one or more graphs on a single page from the command line or from a procedure. The graphs can be overlaid or positioned any way you want.

\section*{Parameters}

The graphSpec specifies the name of a graph to print, the position of the graph on the page and some other options.

\section*{Flags}
/C=num \(\quad\) Renders graphs in black and white (num=0) or in color (num=1; default).
/D Disables high resolution printing. This flag is of use only on Macintosh. It has no effect on Windows.
/ \(\mathrm{G}=\) grout Specifies grout, the spacing between objects, for tiling in prevailing units.
/I Coordinates are in inches.
\(/ \mathrm{M} \quad\) Coordinates are in centimeters.
/R Coordinates are in percent of page size (see Examples).
/PD Displays print dialog. This allows the user to use Print Preview or to print to a file.
/S Stacks graphs.
/T Tiles graphs.

\section*{Details}

Graph coordinates are in inches (/I) or centimeters (/M) relative to the top left corner of the physical page. If none of these options is present, coordinates are assumed to be in points.
The form of a graphSpec is:
```

graphName [(left, top, right, bottom)] [/F=f] [/T]

```

Here are some examples:
```

// Take size and position from window size and position.
PrintGraphs Graph0, Graph1
// Specify size and position explicitly.
PrintGraphs/I Graph0(1, 1, 6, 5)/F=1, Graph1(1, 6, 6, 10)/F=1

```

If the coordinates are missing and the /T or /S flags are present before graphSpec then the graphs are tiled or stacked. If the coordinates are missing but no /T or /S flags are present then the graph is sized and positioned based on its position on the desktop.

Finally there are these graphSpec options, which appear after the graph name:
\(/ \mathrm{F}=f \quad\)\begin{tabular}{lll} 
& Specifies a frame around the grap \\
& \(f=0:\) & No frame (default). \\
\(f=1:\) & Single frame. \\
\(f=2:\) & Double frame. \\
\(f=3:\) & Triple frame. \\
& \(f=4:\) & Shadow frame.
\end{tabular}
/T Graph is transparent. This allows special effects when graphs are overlaid.
For this to be effective, the graph and its contents must also be transparent. Graphs are transparent only if their backgrounds are white. Annotations have their own transparent/opaque settings. PICTs may have been created transparent or opaque; an opaque PICT cannot be made transparent.

\section*{Examples}

You can put an entire graphSpec into a string variable and use the string variable in its place. In this case the name of the string variable must be preceded by the \(\$\) character. This is handy for printing from a procedure and also keeps the PrintGraphs command down to a reasonable number of characters. For example:
```

String spec0, specl, spec2
spec0 = "Graph0(1, 1, 6, 5)/F=1"
spec1 = "Graph1(1, 6, 6, 10)/F=1"
spec2 = """ // PrintGraphs will ignore spec2.
PrintGraphs/I \$spec0, \$spec1, \$spec2

```

If you use a string for a graphSpec and that string contains no characters then PrintGraphs will ignore that graphSpec.

\section*{See Also}

The PrintSettings, PrintTable, PrintLayout and PrintNotebook operations.

\section*{PrintLayout}

PrintLayout [/C=num /D] winName
The PrintLayout operation prints the named page layout window.

\section*{Parameters}
winName is the window name of the page layout to print.

\section*{Flags}
\(/ C=\) num \(\quad\) Renders graphs, tables, and annotations in black-and-white (num=0) or in color (num=1; default). It has no effect on pictures, which are colored independently.
/D Prints the layout at the default resolution of the output device. Otherwise it is printed at the highest resolution. This flag is of use only on Macintosh. It has no effect on Windows.

\section*{Details}

Normally page layouts are printed at the highest available resolution of the output device (printer, plotter, or whatever). On Macintosh, it may not work properly at high resolution with some unusual output devices. If this happens, you can try using the /D flag to see if it works properly at the default resolution.

\section*{See Also}

The PrintSettings, PrintGraphs, PrintTable and PrintNotebook operations.

\section*{PrintNotebook}

\section*{PrintNotebook [flags] notebookName}

The PrintNotebook operation prints the named notebook window.

\section*{Parameters}
notebookName is either kwTopWin for the top notebook window, the name of a notebook window or a hostchild specification (an hcSpec) such as Panel0\#nb0. See Subwindow Syntax on page III-97 for details on host-child specifications.

Flags
/ \(\mathrm{B}=h i\) ResMethod Macintosh only; this flag has no effect on Windows.
hiResMethod=1: \(\quad\) Print HiRes PICTs using high resolution bitmaps.
hiResMethod=0: Don't print HiRes PICTs using high resolution bitmaps.
hiResMethod=-1: Print using the default method. Prints HiRes PICTs using high resolution bitmaps and is the same as method 1 .
\(/ \mathrm{P}=(\) startPage,endPage) \(\quad\) Specifies a page range to print. 1 is the first page.
\(/ S=\) selection Controls what is printed.
selection=0: Print entire notebook (default).
selection=1: Print selection only.

\section*{Details}

If no /B flag is given, the default method of handling HiRes PICTs is used (/B=1). Printing of HiRes PICTs is not well supported on the Macintosh, so by default it prints them using temporary high resolution bitmaps. If a future version of the Mac OS improves in this respect, we will change the default method to print directly.

\section*{See Also}

Chapter III-1, Notebooks.
The PrintSettings, PrintGraphs, PrintTable and PrintLayout operations.

\section*{PrintSettings}

PrintSettings [/I /M /W=winName] [copySource=source, orientation=o, margins=\{left, top, right, bottom\}, scale=s, colorMode=m, getPrinterList, getPrinter, setPrinter=printerNameStr, getPageSettings, getPageDimensions]
The PrintSettings operation gets or sets parameters associated with printing, such as a list of available printers or page setup information for a particular window.
When getting or setting page setup information, PrintSettings acts on a particular window called the destination window. The destination window is the top graph, table, page layout, or notebook window or the window specified by the / W flag.
PrintSettings can not act on page setup records associated with the command window, procedure windows, help windows, control panel, XOP windows, or any type of window other than graphs, tables, page layouts, and notebooks.
The PrintSettings operation services the keywords in the order shown above, not in the order in which they appear in the command. Thus, for example, the getPageSettings and getPageDimensions keywords report the settings after all other keywords are executed.

Flags
/I
/M Measurements are in centimeters. If both \(/ \mathrm{I}\) and \(/ \mathrm{M}\) are omitted, measurements are in points.
/W=winName

\section*{Keywords}

\author{
colorMode \(=m\)
copySource=source
}

Sets the color mode for the page setup to monochrome ( \(m=0\) ) or to color ( \(m=1\) ).
This keyword does nothing on Macintosh because it is not supported by Mac OS X.
Copies page setup settings from the specified source to the destination window. source can be the name of a graph, table, page layout, or notebook window or it can be one of the following special keywords:
Default_Settings: Sets the page setup record to the default for the associated printer as specified by the printer driver.
Factory_Settings: Sets the page setup record to the WaveMetrics factory default. This is the page setup you get when creating a new window with user preferences turned off.
Preferred_Settings: Sets the page setup record to the user preferred page setup. This is the page setup you get when creating a new window with user preferences turned on. Because there is only one page setup for all graphs and one page setup for all tables, this has no effect when the destination window is a graph or table. It does work for layouts and notebooks.
getPageDimensions Returns page dimensions via the string variable S_value, which contains keywordvalue pairs that can be extracted using NumberByKey and StringByKey. See Details for keyword-value pair descriptions.
getPageSettings Returns page setup settings in the string variable S_value, which contains keywordvalue pairs that can be extracted using NumberByKey and StringByKey. See Details for keyword-value pair descriptions.
getPrinter Returns the name of the selected printer for the destination window in the string variable S_value. On Macintosh the returned value will be " " if the setPrinter keyword was never used on the destination window. This means that the window will use the operating system's "current printer".
getPrinterList Returns a semicolon-separated list of printer names in the string variable S_value.
Mac OS X: \(\quad\) Returns a list of printers added through Print Center. Windows: \(\quad\) Returns the names of any local printers and names of network printers to which the user has made previous connections.
margins \(=\{l e f t\), top, right, bottom \(\}\)

Sets the page margins. Dimensions are in points unless /I or / \(M\) is used.
The margins are clipped so that they are no smaller than the minimum allowed by the printer driver and no larger than one-half the size of the paper.
The terms left, top, right, and bottom refer to the sides of the page after possible rotation for landscape orientation.
Passing zero for all four margins sets the margins to the minimum margin allowed by the printer.
On Macintosh only, passing - 1 for all four margins sets the margins to whatever minimum margin is allowed by the printer, even if the printer is changed later. This is how Igor Pro behaved on Macintosh prior to the creation of the PrintSettings operation, when the minimum printer margins were always used.
orientation \(=0 \quad\) Sets the paper orientation to portrait \((0=0)\) or to landscape ( \(0=\) nonzero).
scale \(=s \quad\) Sets the page scaling in percent. \(s\) is clipped to the range 5 to 5000 . A value of 50 prints graphics at one-half the normal size. Some printer drivers do not support scaling in which case the scale keyword does nothing. Many Windows printer drivers that do support scaling still do not work with the scale keyword because their scaling support does not use the standard Windows technique.

\section*{setPrinter=printerNameStr}

Sets the selected printer for the destination window.
SetPrinter attempts to preserve orientation, margins, scale, and color mode but other settings may revert to the default state.
printerNameStr is a name as returned by the getPrinterList keyword and may not be identical to the name displayed in various dialogs. For example, on Mac OS X, the printer name "DESKJET 840C" is returned by getPrinterList as "DESKJET_840C". The latter is the "Queue Name" displayed by the Mac OS X Print Center or Printer Setup Utility programs.

If printerNameStr is " ", the printer for the destination window is set to the default state. This means different things depending on the operating system:
Mac OS X: The destination window will use the operating system's "current printer", as if the setPrinter keyword had never been used.
Windows: The destination window will use the system default printer.

If you receive an error when using setPrinter, use the getPrinterList keyword to verify that the printer name you are using is correct. Verify that the printer is connected and turned on.
Windows printer names are sometimes UNC names of the form
" \(\backslash\) Server \(\backslash\) Printer". You must double-up backslashes when using a UNC name in a literal string. See UNC Paths on page III-401 for details.

\section*{Details}

All graphs in the current experiment share a single page setup record so if you change the page setup for one graph, you change it for all graphs.
All tables in the current experiment share a single page setup record.
Each page layout window has its own page setup record.
Each notebook window has its own page setup record.
The keyword-value pairs for the getPageSettings keyword are as follows:

\section*{Keyword Information Following Keyword}

ORIENTATION: 0 if the page is in portrait orientation, 1 if it is in landscape orientation.
MARGINS: The left, top, right, and bottom margins in points, separated by commas.
SCALE: The page scaling expressed in percent. 50 means that the graphics are drawn at \(50 \%\) of their normal size.

COLORMODE: 0 for black\&white, 1 for color. This is not supported on Macintosh and always returns 1.
The keyword-value pairs for the getPageDimensions keyword are as follows:
\begin{tabular}{ll} 
Keyword & Information Following Keyword \\
\hline PAPER: & \begin{tabular}{l} 
The left, top, right, and bottom coordinates of the paper in points, separated by \\
commas. The top and left are negative numbers so that the page can start at \((0,0)\).
\end{tabular} \\
PAGE: & \begin{tabular}{l} 
The left, top, right, and bottom coordinates of the page in points, separated by commas. The \\
term page refers to the part of the paper inside the margins. The top/left corner of the page \\
is always at \((0,0)\).
\end{tabular} \\
PRINTAREA: \(\quad\)\begin{tabular}{l} 
The left, top, right, and bottom coordinates of the page in points, separated by commas. \\
The print area is the part of the paper on which printing can occur, as determined by \\
the printer. This is equal to the paper inset by the minimum supported margins. The top \\
and left are negative numbers so that the page can start at \((0,0)\).
\end{tabular}
\end{tabular}

\section*{Examples}

For an example using the PrintSettings operation, see the PrintSettings Tests example experiment file in the "Igor Pro Folder:Examples:Testing \& Misc" folder.
Here are some simple examples showing how you can use the PrintSettings operation.
```

Function GetOrientation(name) // Returns 0 (portrait) or 1 (landscape)
String name // Name of graph, table, layout or notebook
PrintSettings/W=$name getPageSettings
    Variable orientation = NumberByKey("ORIENTATION", S_value)
    return orientation
End
Function SetOrientationToLandscape(name)
    String name // Name of graph, table, layout or notebook
    PrintSettings/W=$name orientation=1
End
Function/S GetPrinterList()
PrintSettings getPrinterList
return S_value
End
Function SetPrinter(destWinName, printerName)
String destWinName, printerName
PrintSettings/W=\$destWinName setPrinter=printerName
return 0
End

```

\section*{See Also}
```

The PrintGraphs, PrintTable, PrintLayout and PrintNotebook operations.

```

\section*{PrintTable}

PrintTable [/P=(startPage,endPage) /S=selection] winName
The PrintTable operation prints the named table window.

\section*{Parameters}
winName is the window name of the table to print.

\section*{Flags}
\(/ \mathrm{P}=(\) startPage,endPage \() \quad\) Specifies a page range to print. 1 is the first page.
If \(/ \mathrm{P}\) is omitted all pages are printed unless \(/ \mathrm{S}\) is used.
\(/ S=\) selection Controls what is printed.
selection \(=0\) : Print entire table (default).
selection=1: Print selection only.

\section*{See Also}

Chapter II-11, Tables.
The PrintSettings, PrintGraphs, PrintLayout and PrintNotebook operations.

\section*{Proc}

Proc macroName([parameters]) [:macro type]
The Proc keyword introduces a macro that does not appear in any menu. Otherwise, it works the same as Macro. See Macro Syntax on page IV-102 for further information.

\section*{ProcedureText}

ProcedureText (macroOrFunctionNameStr [, linesOfContext [, procedureWinTitlestr]])
The ProcedureText function returns a string containing the text of the named macro or function as it exists in some procedure file, optionally with additional lines that are before and after to provide context or to collect documenting comments.
Alternatively, all of the text in the specified procedure window can be returned.

\section*{Parameters}
macroOrFunctionNameStr identifies the macro or function. It may be just the name of a global (nonstatic) procedure, or it may include a module name, such as "myModule\#myFunction" to specify the static function myFunction in a procedure window that contains a \#pragma ModuleName=myModule statement.
If macroOrFunctionNameStr is set to "", and procedureWinTitleStr specifies the title of a single procedure window, then all of the text in the procedure window is returned.
linesOfContext optionally specifies the number of lines around the function to include in the returned string. The default is 0 (no additional contextual lines of text are returned). This parameter is ignored if macroOrFunctionNameStr is "" and procedureWinTitleStr specifies the title of a single procedure window.
Setting linesOfContext to a positive number returns that many lines before the procedure and after the procedure. Blank lines are not omitted.
Setting linesOfContext to -1 returns lines before the procedure that are not part of the preceding macro or function. Usually these lines are comment lines describing the named procedure. Blank lines are omitted.
Setting linesOfContext to \(-n\), where \(n>1\), returns at most \(n\) lines before the procedure that are not part of the preceding macro or function. Blank lines are not omitted in this case. n can be -inf, which acts the same as -1 but includes blank lines.
The optional procedureWinTitleStr can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf"). The text of the named macro or function in the specified procedure window is returned.
You can use procedureWinTitleStr to select one of several static functions with identical names among different procedure windows, even if they do not use a \#pragma moduleName=myModule statement.

\section*{Advanced Parameters}

If SetIgorOption IndependentModuleDev=1, procedureWinTitleStr can also be a title followed by a space and, in brackets, an independent module name. In such cases ProcedureText retrieves function text from the specified procedure window and independent module. (See Independent Modules on page IV-218 for independent module details.)
For example, in a procedure file containing:
\#pragma IndependentModule=myIM
\#include <Axis Utilities>
A call to ProcedureText like this:
String text=ProcedureText("HVAxisList",0,"Axis Utilities.ipf [myIM]")
will return the text of the HVAxisList function located in the Axis Utilities.ipf procedure window, which is normally a hidden part of the myIM independent module.
You can see procedure window titles in this format in the Windows \(\rightarrow\) Procedure Windows menu when SetIgorOption IndependentModuleDev=1 and when an experiment contains procedure windows that comprise an independent module, as does \#include <New Polar Graphs>.
procedureWinTitleStr can also be just an independent module name in brackets to retrieve function text from any procedure window that belongs to the named independent module:
String text=ProcedureText("HVAxisList",0,"[myIM]")

\section*{See Also}

Regular Modules on page IV-216 and Independent Modules on page IV-218.
The WinRecreation and FunctionList functions.

\section*{ProcGlobal}

\section*{ProcGlobal\#procPictureName}

The ProcGlobal keyword is used with Proc Pictures to avoid possible naming conflicts with any other global pictures in the experiment. When you add a picture to an experiment using the Pictures dialog, such a picture is global in scope and may potentially have the same name as a Proc Picture. When a Proc Picture is global (and only then), you should use the ProcGlobal keyword to make sure that the Proc Picture is used with your code and to avoid confusion with pictures in the Pictures dialog.

\section*{See Also \\ See Proc Pictures on page IV-44 for details. Pictures Dialog on page III-425.}

\section*{Project}

Project [/C=\{long, lat \(\} / \mathrm{M}=\operatorname{method} / \mathrm{P}=\{\mathrm{p} 1, \mathrm{p} 2, \ldots\}\) ] longitudeWave, latitudeWave
The Project operation calculates projections of XY data, which most often are longitude and latitude waves of geographic coordinates. The output waves are W_XProjection and W_YProjection. Longitude and Latitude are in degrees.

\section*{Parameters}
longitudeWave is the name of the wave supplying the longitude or equivalent coordinates. latitudeWave is the name of the wave supplying the latitude or equivalent coordinates.

\section*{Flags}
\(/ \mathrm{C}=\{\) long,lat \(\} \quad\) Specifies longitude and latitude center of projection. By default long=0 and lat=90.
/ \(\mathrm{M}=\) method Indicates the type of projection. method can be one of the following:
0: Orthographic (default).
1: Stereographic.
2: Gnomonic.
3: General perspective.
4: Lambert equal area.
5: Equidistant.
6: Mercator.
7: Transverse Mercator.
8: Albers Equal Area conic.
\(/ \mathrm{P}=\{p 1, p 2, \ldots\} \quad\) One or more parameters required by a particular projection. See the following sections for parameters required by the various projections.

\section*{Gnomonic}

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that \(\cos (\mathrm{c})\) in Eq. (5-3) of Snyder is greater than the specified parameter:
\(/ P=\{\cos (c)\}\)
The actual transformation uses Eqs. (22-4) and (22-5) of Snyder with k' given by (22-3).

\section*{General Perspective}

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that \(\cos (\mathrm{c})\) in Eq. (5-3) of Snyder is greater than the specified parameter.
The actual transformation uses Eqs. (22-4) and (22-5) with k' given by (22-3). Here we specify the height H is units of sphere radius. The tilt of the plane is specified by omega and gamma following the notation of Snyder page 175.
The parameters actually specified by the command are:
\(/ P=\{H\), omega, gamma, deltax, deltay \(\}\)
\(H\) is the height (in radii) above the surface of the earth, gamma is the azimuth east of north of the Y axis, and omega is the tilt angle or the angle between the projection plane and the tangent plane. The x output will be limited to \(\pm\) deltax and the y output will be limited to the range \(\pm\) deltay.

\section*{Mercator}

This projection requires the following parameters:
\(/ \mathrm{P}=\{\) minLong, maxLong, minLat, maxLat \(\}\)
If \(/ \mathrm{P}\) is not specified, the default is \(\{0,360,-90,90\}\)
Note that this projection flips the sign of \(y\) when \(\cos\) (longitude-long_0) changes sign. If you are plotting a continuous path in which consecutive points exhibit the sign change, you should add a NaN entry in the wave so that the path does not wrap.

\section*{Albers Equal Area Conic}

This projection requires:
\(/ \mathrm{P}=\{\) minLong, maxLong, minLat, maxLat, Phi1, Phi2\}
Phi1 and Phi2 are the specification of the two standard parallels, the other four parameters determine the boundary of the map area for display.

\section*{References}

Snyder, John P., Map Projections - A Working Manual, U.S.G.S. Professional Paper 1395, U.S. Government Printing Office, Washington D.C., 1987, reprinted 1989, 1994, 1997 with corrections.

\section*{Prompt}

Prompt variableName, titleStr [, popup, menuListStr]
The Prompt command is used in functions for the simple input dialog and in macros for the missing parameter dialog. Prompt supplies text to describe variableName to the user, and optionally provides a popup menu of choices for the value of variableName.

\section*{Parameters}
variableName is the name of a macro input parameter or function variable.
titleStr is a string or string expression containing the text to present in the dialog to describe what variableName is. This string should be short if the number of items exceeds 5 (when the dialog uses two columns).
The optional keyword popup is used to provide a pop-up list of choices for the values of variableName. If popup is used, then menuListStr is required.
menuListStr is a string or string expression that contains a semicolon-separated list of choices for the value of variableName. If variableName is a string, choosing from this list will set the string to the selection. If it is a numeric variable, then it is set to the item number of the selection (if the first item is selected, the numeric variable is set to 1 , etc.).

\section*{Details}

In macros, there must be a blank line after the set of input parameter declarations and prompt statements and there must not be any blank lines within the set.
In user-defined functions, Prompt may be used anywhere within the body of the function, but must precede any DoPrompt that uses the Prompt variable.
menuListStr may be continued on succeeding lines only in macros, as long as no comment is appended to the Prompt line. The additional lines should start with a semicolon, and are appended to the menuListStrs on preceding lines.

\section*{See Also}

For use in user-defined functions, see The Simple Input Dialog on page IV-126.
For use in macros, see The Missing Parameter Dialog on page IV-105.
For use in functions and macros, see the DoPrompt and popup keywords.

\section*{PulseStats}

\section*{PulseStats [flags] waveName}

The PulseStats operation produces simple statistics on a region of the named wave that is expected to contain three edges as shown below. If more than three edges exist, PulseStats works on the first three edges it finds.

PulseStats handles other cases in which there are only one or two edges.

Flags
\(/ \mathrm{A}=n \quad\) Determines startLevel and endLevel automatically by averaging \(n\) points centered at start \(X\) and endX. This does not work in case 2, which requires that you use the /L flag. Default is \(/ \mathrm{A}=1\).
\(/ B=b o x \quad\) Sets box size for sliding average. This should be an odd number. If \(/ B=b o x\) is omitted or box equals 1 , no averaging is done.
\(/ \mathrm{F}=f \quad\) Specifies levels 1, 2, and 3 as a fraction of (endLevel-startLevel):
levell \(=\) level \(2=\) level \(3=f *(e n d L e v e l-s t a r t L e v e l)+\) startLevel
\(f\) must be between 0 and 1 . The default value is 0.5 which sets the levels to midway between the base levels.
/L=(startLevel, endLevel)

Sets startLevel and endLevel explicitly.
\begin{tabular}{|c|c|}
\hline \(/ \mathrm{M}=d x\) & Sets minimum edge width. Once an edge is found, the search for the next edge starts \(d x\) units beyond the found edge. Default \(d x\) is 0 . \\
\hline /P & Output edge locations (see Details) are set in terms of point number. If /P is omitted, edge locations are set in terms of \(X\) values. \\
\hline /Q & Prevents results from being printed in history and prevents error if edge is not found. \\
\hline /R=(startX,endX) & Specifies an \(X\) range of the wave to search. You may exchange start \(X\) and end \(X\) to reverse the search direction. \\
\hline /R=[startP,endP] & Specifies a point range of the wave to search. You may exchange startP and endP to reverse the search direction. \\
\hline & If you specify the range as \(/ \mathrm{R}=[\) start \(P\) ] then the end of the range is taken as the end of the wave. If / R is omitted, the entire wave is searched. \\
\hline \(/ \mathrm{T}=d x\) & Forces search in two directions for a possibly more accurate result. \(d x\) controls where the second search starts. \\
\hline
\end{tabular}

\section*{Details}

The /B=box, /T=dx, /P and /Q flags behave the same as for the FindLevel operation.
PulseStats considers a region of the input wave between two \(X\) locations, called start \(X\) and endX. start \(X\) and end \(X\) are set by the \(/ \mathrm{R}=(\operatorname{start} X\), end \(X\) ) flag. If this flag is missing, start \(X\) and endX default to the start and end of the entire wave.
The startLevel and endLevel values define the base levels of the pulse. You can explicitly set these levels with the /L=(startLevel, endLevel) flag or you can let PulseStats find the base levels for you by using the / \(\mathrm{A}=n\) flag. With this flag, PulseStats determines startLevel and endLevel by averaging \(n\) points centered at startX and at endX. In case 2 , you must use / \(\mathrm{L}=(\) startLevel, endLevel) since startLevel is not at point 0 .
Given startLevel and endLevel and an \(f\) value (which you can set with the /F=f flag), PulseStats computes level1, level2 and level3 which are always equal. With the default \(f\) value of 0.5 , level1 is midway between startLevel and endLevel.
With these levels defined, PulseStats searches the wave from startX to endX looking for one, two or three level crossings. PulseStats sets the following variables:
\begin{tabular}{ll} 
V_flag & \begin{tabular}{l} 
0: All three level crossings were found. \\
1: One or two level crossings were found.
\end{tabular} \\
2: No level crossings were found.
\end{tabular}

X locations and distances are in terms of the X scaling of the source wave, unless you use the/P flag in which case they are in terms of point number.

If any level crossings are missing then PulseStats sets the associated variables to NaN (Not a Number). If one crossing is missing, variables depending on point 3 are set to NaN. If two crossings are missing, variables depending on points 2 and 3 are set to NaN . If all crossings are missing, variables depending on points 1, 2, and 3 are set to NaN. You can use the numtype function to test a variable to see if it is NaN.
The PulseStats operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-110 for details.

\section*{See Also}

The FindLevel operation about the \(/ \mathrm{B}=b o x, / \mathrm{T}=d x, / \mathrm{P}\) and \(/ \mathrm{Q}\) flags, EdgeStats and the numtype function.

\section*{PutScrapText}

PutScrapText textStr
The PutScrapText operation places textStr on the Clipboard (aka "scrap"). This text will be used when the user subsequently chooses Paste from the Edit menu.

\section*{Details}

All contents of the Clipboard (including pictures) are cleared before the text is placed there.

\section*{Examples}

Put two lines of text into the Clipboard:
String text \(=\) "This is the first line. \rAnd this is the second."
PutScrapText text
Empty the Clipboard:
PutScrapText ""

\section*{See Also}

The GetScrapText function and the SavePICT operation.

\section*{pwd}
pwd
The pwd operation prints the full path of the current data folder to the history area. It is equivalent to Print GetDataFolder(1).
pwd is named after the UNIX "print working directory" command.
See Also
GetDataFolder, cd, Dir, Data Folders on page II-121

\section*{q}
q
The \(q\) function returns the current column index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled column index is available as the \(y\) function.

\section*{Details}

Unlike p, outside of a wave assignment statement, q does not act like a normal variable.
See Also
Waveform Arithmetic and Assignments on page II-94.
For other dimensions, the \(\mathbf{p}, \mathbf{r}\), and \(\mathbf{s}\) functions.
For scaled dimension indices, the \(\mathbf{x}, \mathbf{y}, \mathbf{z}\) and \(\mathbf{t}\) functions.

\section*{qCsr}
qcsr(cursorName [, graphNameStr])
The qcsr function can be used with cursors on images or waterfall plots to return the column number. It can also be used with free cursors to return the relative Y coordinate.

\section*{Parameters}
cursorName identifies the cursor, which can be cursor A through J.
graphNameStr specifies the graph window or subwindow.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{See Also}

The hcsr, pcsr, vcsr, xcsr, and zcsr functions.
Programming With Cursors on page II-292.

\section*{Quit}

Quit [/N/Y]
The Quit operation quits Igor Pro.
Flags
/N Quits without saving changes and without dialog.
/Y Saves current experiment before quitting without putting up dialog unless current experiment is "Untitled".
r
r
The \(r\) function returns the current layer index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled layer index is available as the \(\mathbf{z}\) function.

\section*{Details}

Unlike p, outside of a wave assignment statement, r does not act like a normal variable.

\section*{See Also}

Waveform Arithmetic and Assignments on page II-94. For other dimensions, the p,q,s, and \(\mathbf{t}\) functions. For scaled dimension indices, the \(\mathbf{x}, \mathbf{y}, \mathbf{z}\), and \(\mathbf{t}\) functions.

\section*{r2polar}
r2polar(z)
The r2polar function returns a complex value in polar coordinates derived from the complex value \(z\), which is assumed to be in rectangular coordinates. The magnitude is stored in the real part and the angle (in radians) is stored in the imaginary part of the returned complex value.

\section*{Examples}

Assume waveIn and waveOut are complex.
waveOut= r2polar(waveIn)
sets each point of waveOut to the polar coordinates derived from the real and imaginary parts of waveIn.
You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.

\section*{See Also}

The functions cmplx, conj, imag, p2rect, and real.

\section*{RatioFromNumber}

RatioFromNumber [flags] num
The RatioFromNumber operation computes two integers whose ratio is equal to num \(\pm\) maxError (/MERR flag). The ratio is returned in V_numerator and V_denominator.

\section*{Parameters}
num is the number to approximate by V_numerator/V_denominator.

\section*{Flags}
/MERR=maxError
/MITS = maxIterations
\(/ \mathrm{V}=v] \quad\) Prints output variables to history.
\(v=1\) : Prints variables (same as \(/ \mathrm{V}\) ).
\(v=0\) : Nothing printed (same as no \(/ \mathrm{V}\) ).

\section*{Details}

The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking num - (V_numerator/V_denominator) against maxError.
Setting maxError \(=0\) computes a maximally accurate ratio. The returned values can be surprisingly large:
```

RatioFromNumber/V/MERR=0 (1/1666)
V_numerator= 4398046511104; V_denominator= 7.3271454874993e+15;
ratio= 0.00060024009603842; V_difference= 0;

```

Using the default /MERR returns the expected 1 and 1666. The difference is attributable to floating-point roundoff errors.
The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking num - (V_numerator/V_denominator) against /MERR.

Prior to Igor Pro 6.22, RatioFromNumber iterated one less time than specified by maxIterations. This was corrected in Igor Pro 6.22.

\section*{Output Variables}

RatioFromNumber sets the following output variables:
```

V_difference V_numerator/V_denominator - num (positive if the approximation is too big).
V_flag 0: V_difference less than or equal to /MERR.
1: V_difference greater than /MERR.
V_numerator, V_denominator
Values for the numerator and denominator. The ratio of V_numerator/V_denominator
approximates num.
V_iterations The number of iterations actually used.

```

\section*{Examples}

RatioFromNumber/V pi
V_numerator \(=355\); V_denominator= 113; ratio \(=3.141592920354\);
V_difference= 2.6676418940497e-07; V_iterations= 3;
RatioFromNumber/V/MITS=2 pi
V_numerator \(=22\); V_denominator= 7; ratio= 3.1428571428571;
V_difference= 0.0012644892673497; V_iterations= 1;

\section*{See Also}

The gcd and trunc functions.

\section*{Rect}

The Rect structure is used as a substructure usually to store the coordinates of a window or control.
```

Structure Rect
Int16 top
Int16 left
Int16 bottom

```

Int16 right
EndStructure

\section*{ReadVariables}

ReadVariables
The ReadVariables operation reads variables into an experiment.
ReadVariables is used automatically when you open an experiment. You need not invoke it.

\section*{real}
real (z)
The real function returns the real component of the complex value \(z\).

\section*{See Also}

The functions cmplx, conj, imag, p2rect, and r2polar.

\section*{Redimension}
```

Redimension [flags] waveName [, waveName]...

```

The Redimension operation remakes the named waves, preserving their contents as much as possible.
Flags
/B Converts waves to 8-bit signed integer or unsigned integer if / U is present.
/C Converts real waves to complex.
/D Converts single precision waves to double precision.
\(/ E=e \quad\) Controls the redimension mode:
\(e=0: \quad\) No special action (default).
\(e=1: \quad\) Force reshape without converting or moving data.
\(e=2: \quad\) Perform endian swap. See FBinRead for a discussion of endian byte ordering.
/I Converts waves to 32-bit signed integer or unsigned integer if / U is present.
\(/ \mathrm{N}=n \quad n\) is the new number of points each wave will have. Multidimensional waves are converted to 1 dimension. If \(n=-1\), the wave is converted to a 1 -dimensional wave with the original number of rows.
\(/ \mathrm{N}=(n 1, n 2, n 3, n 4)\)
\(n 1, n 2, n 3, n 4\) specify the number of rows, columns, layers, and chunks each wave will have.
Trailing zeros can be omitted (e.g., \(/ \mathrm{N}=(n 1, n 2,0,0)\) can be abbreviated as \(/ \mathrm{N}=(n 1, n 2)\) ). If any dimension size is to remain unchanged, pass -1 for that dimension.
/R Converts complex waves to real by discarding the imaginary part.
/S Converts double precision waves to single precision.
/U Converts integer waves to unsigned.
/W Converts waves to 16-bit integer (unsigned integer if / U is present).
\(/ \mathrm{Y}=\) type \(\quad\) Specifies wave data type. See details below.

\section*{Wave Data Types}

As a replacement for the above number type flags you can use \(/ Y=n u m T y p e\) to set the number type as an integer code. See the WaveType function for code values. Do not use /Y in combination with other type flags. This technique cannot be used to change the number type without changing the real/complex setting.

\section*{Details}

The waves must already exist. New points in waves that are extended are zeroed.

In general, Redimension does not move data from one dimension to another. For instance, if you have a \(6 \times 6\) matrix wave, and you would like it to be \(3 \times 12\), the rows have been shortened and the data for the last three rows is lost.
As a special case, if converting to or from a 1D wave, Redimension will leave the data in place while changing the dimensionality of the wave. For example, you can use Redimension to convert a 36-element 1D wave into a \(6 \times 6\) matrix in which the elements in the first column (column 0 ) are the first 6 elements of the 1D wave, the elements of the second column are the next 6 , etc. When redimensioning from a 1D wave, columns are filled first, then layers, followed by chunks.

\section*{Examples}

Reshaping a 1D wave having 4 elements to make a \(2 \times 2\) matrix:

Make/ \(\mathrm{N}=4\) vector=x

Redimension/ \(\mathrm{N}=(2,2)\) vector

\section*{See Also}

Lists of Values on page II-96; the DeletePoints and Make operations.

\section*{Remove}

\section*{Remove}

When interpreting a command, Igor treats the Remove operation as RemoveFromGraph,
RemoveFromTable, or See Also, depending on the target window. This does not work when executing a user-defined function. Therefore, we recommend that you use RemoveFromGraph, RemoveFromTable, or
RemoveLayoutObjects rather than Remove.

\section*{RemoveByKey}

RemoveByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]])
The RemoveByKey function returns kwListStr after removing the keyword-value pair specified by keyStr.
kwListStr should contain keyword-value pairs such as "KEY=value1, KEY2=value2" or
"Key:value1; KEY2: value2", depending on the values for keySepStr and listSepStr.
Use RemoveByKey to remove information from a string containing a "key1:value1;key2:value2;" or "keyl=value1, key2=value2," style list such as those returned by functions like AxisInfo or TraceInfo.
If keyStr is not found then \(k w L i s t S t r\) is returned unchanged.
keySepStr, listSepStr, and matchCase are optional; their defaults are ":", ";", and 0 respectively.

\section*{Details}
keyStr is limited to 255 characters.
\(k w L i s t S t r\) is searched for an instance of the key string bound by listSepStr on the left and a keySepStr on the right. The key, the keySepStr, and the text up to and including the next listSepStr (if any) are removed from the returned string.
If the resulting string contains only listSepStr characters, then an empty string (" ") is returned.
\(k w L i s t S t r\) is treated as if it ends with a listSepStr even if it doesn't.
Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional matchCase parameter to 1 makes the comparisons case sensitive.
Only the first characters of keySepStr and listSepStr are used.
If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

\section*{Examples}

Print RemoveByKey("AKEY", "AKEY:123;BKEY:val") // prints "BKEY:val"
Print RemoveByKey ("AKEY", "akey=1;BK=b;", "=") // prints "BK=b;"
Print RemoveByKey("AKEY", "AKEY=1,BK=b,", "=", ",")
// prints "BK=b,"
Print RemoveByKey ("ckey", "CKEY:1;BKEY:2") // prints "BKEY:2"
Print RemoveByKey("ckey","CKEY:1;BKEY:2",":",";",1) // prints "CKEY:1;BKEY:2"

\section*{See Also}

The NumberByKey, StringByKey, ReplaceNumberByKey, ReplaceStringByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

\section*{RemoveContour}

\section*{RemoveContour [/W=winName] contourInstanceName [, contourInstanceName]...}

The RemoveContour operation removes the traces, and releases memory associated with the contour plot of contourInstanceName in the target or named graph.

\section*{Parameters}
contourInstanceName is usually simply the name of a wave. More precisely, contourInstanceName is a wave name, optionally followed by the \# character and an instance number to identify which contour plot of a given wave is to be removed.

Flags
\(/ \mathrm{W}=\) winName \(\quad\) Removes contours from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Details}

If the axes used by the contour plot are no longer in use, they will also be removed.
An contour instance name in a string can be used with the \(\$\) operator to specify imageInstance.

\section*{Examples}

Display;AppendMatrixContour zw
//new graph, contour of zw matrix
AppendMatrixContour zw
//two contours of zw
RemoveContour zw\#1
//remove the second contour

\section*{See Also}

The AppendMatrixContour and AppendXYZContour operations.

\section*{RemoveEnding}

\section*{RemoveEnding(str [, endingStr])}

The RemoveEnding function removes one character from the end of \(s t r\), or it removes the endingStr from the end of \(s t r\).
endingStr is optional. If missing, one character is removed from the end of \(s t r\).

\section*{Details}
endingStr is compared to the end of str using a case insensitive comparison (such as cmpstr uses). If the end of \(s t r\) does not match endingStr, the unaltered str is returned.

\section*{Examples}
```

Print RemoveEnding("123")
// prints "12"
Print RemoveEnding("no semi" , ";") // prints "no semi"
Print RemoveEnding("trailing semi;" , ";") // prints "trailing semi"
Print RemoveEnding("file.txt" , ".TXT") // prints "file"

```

\section*{See Also}

The cmpstr and ParseFilePath functions.

\section*{RemoveFromGraph}

RemoveFromGraph [/W=winName/Z] traceName [, traceName]...
The RemoveFromGraph operation removes the specified wave traces from the target or named graph. A trace is a representation of the data in a wave, usually connected line segments.

\section*{Parameters}
traceName is usually just the name of a wave.
More generally, traceName is a wave name, optionally followed by the \# character and an instance number - for example, wave0\#1. See Instance Notation on page IV-16 for details.

Flags
\(/ \mathrm{W}=\) winName \(\quad\) Removes traces from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
/Z Suppresses errors if specified trace or image is not on the graph.

\section*{Details}

Up to 100 traceNames may be specified, subject to the 400 character command limit.
If the axes used by the given trace are not in use after removing the trace, they will also be removed.
A string containing a trace name can be used with the \(\$\) operator to specify traceName.
Specifying \(\$ " \# 0 "\) for traceName removes the first trace in the graph. \(\$ " \# 1 "\) removes the second trace in the graph, and so on. \(\$ " \mathrm{l}\) is equivalent to \(\$ " \# 0 "\).
Note that removing all the contour traces from a contour plot is not the same as removing the contour plot itself. Use the RemoveContour operation.

\section*{Examples}

The command:
Display myWave, myWave; Modify mode (myWave\#1)=6
appends two instances of myWave to the graph.The first/backmost instance of myWave is instance 0 , and its trace name is just myWave as a synonym for myWave\#0. The second or frontmost instance of myWave is myWave\#1 and it is displayed with the cityscape mode.
To remove the second instance from the graph requires the command:
RemoveFromGraph myWave\#1
or
String MyTraceName="myWave\#1"
RemoveFromGraph \$MyTraceName

\section*{See Also}

Trace Names on page II-243, Programming With Trace Names on page IV-72.

\section*{RemoveFromLayout}

RemoveFromLayout objectSpec [, objectSpec]...
Deprecated - use RemoveLayoutObjects.
The RemoveFromLayout operation removes the specified objects from the top layout.

\section*{Parameters}
objectSpec is either an object name (e.g., Graph0) or an objectName with an instance (e.g., Graph0\#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0\#0 and Graph0\#1 refers to the second instance of Graph0 in the layout.

\section*{See Also}

The RemoveLayoutObjects operation.

\section*{RemoveFromList}

RemoveFromList(itemOrListStr, listStr [, listSepStr [, matchCase]])
The RemoveFromList function returns listStr after removing the item or items specified by itemOrListStr. listStr should contain items separated by the listSepStr character, such as "abc;def;".
If itemOrListStr contains multiple items, they should be separated by the listSepStr character, too.
Use RemoveFromList to remove item(s) from a string containing a list of items separated by a single character, such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.
If all items in itemOrListStr are not found or if any of the arguments is " " then listStr is returned unchanged (unless listStr contains only list separators, in which case an empty string is returned).
listSepStr and matchCase are optional; their defaults are ";" and 1 respectively.

\section*{Details}
itemStr may have any length.
listStr is searched for an instance of the item string(s) bound by listSepStr on the left and right. All instances of the item(s) and any trailing listSepStr (if any) are removed from the returned string.
If the resulting string contains only listSepStr characters, then an empty string (" ") is returned.
listStr is treated as if it ends with a listSepStr even if it doesn't.
Searches for listSepStr are case-sensitive. Searches for items in itemOrListStr are usually case-sensitive.
Setting the optional matchCase parameter to 0 makes the comparisons case insensitive.
Only the first character of listSepStr is used.
If matchCase is specified, then listSepStr must also be specified.

\section*{Examples}
```

Print RemoveFromList("wave1", "wave0;wave1;") // prints "wave0;"
Print RemoveFromList("wave1", ";wave1;;;;") // prints ""
Print RemoveFromList("KEY=joy", "AX=3,KEY=jOY", ",") // prints "AX=3,"
Print RemoveFromList("fred", "fred\twilma", "\t") // prints "wilma"
Print RemoveFromList("fred;barney","fred;wilma;barney")// prints "wilma;"
Print "X"+RemoveFromList("",";;;;")+"Y" // prints "XY"
Print RemoveFromList("FRED", "fred;wilma") // prints "fred;wilma"
Print RemoveFromList("FRED", "fred;wilma", ";", 0) // prints "wilma"

```

\section*{See Also}

The FindListItem, FunctionList, ItemsInList, RemoveByKey, RemoveListItem, StringFromList, StringList, TraceNameList, UpperStr, VariableList, and WaveList functions.

\section*{RemoveFromTable}

RemoveFromTable [/W=winName] columnSpec [, columnSpec]...
The RemoveFromTable operation removes the specified columns from the top table.

\section*{Parameters}
columnSpecs are the same as for the Edit operation; usually they are just the names of waves.

\section*{Flags}
/W=winName Removes columns from the named table window or subwindow. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{See Also \\ Edit about columnSpecs, and AppendToTable.}

\section*{RemoveImage}

RemoveImage [/W=winName/Z] imageInstance [, imageInstance]...
The RemoveImage operation removes the given image from the target or named graph.

\section*{Parameters}
imageInstance is usually simply the name of a wave. More precisely, imageInstance is a wave name, optionally followed by the \# character and an instance number to identify which image of a given wave is to be removed.

Flags
/W=winName
/Z

Removes an image from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. Must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

Details
If the axes used by the given image are not in use after removing the image, they will also be removed.
An image name in a string can be used with the \(\$\) operator to specify imageInstance.

\section*{See Also}

The AppendImage operation.

\section*{RemoveLayoutObjects}

RemoveLayoutObjects [/W=winName/Z] objectSpec [, objectSpec]
The RemoveLayoutObjects operation removes the specified object or objects from the top page layout, or from the layout specified by the /W flag.
Unlike the RemoveFromLayout operation, RemoveLayoutObjects can be used in user-defined functions. Therefore, RemoveLayoutObjects should be used in new programming.

\section*{Parameters}
objectSpec is either an object name (e.g., Graph0) or an objectName with an instance (e.g., Graph0\#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0\#0 and Graph0\#1 refers to the second instance of Graph0 in the layout.

Flags
/W=winName winName is the name of the page layout window from which the object is to be removed. If /W is omitted or if winName is \(\$ "\) ", the top page layout is used.
\(/ Z \quad\) Does not report errors if the specified layout object does not exist.

\section*{See Also \\ NewLayout, AppendLayoutObject and ModifyLayout.}

\section*{RemoveListItem}

RemoveListItem (itemNum, listStr [, listSepStr])
The RemoveListItem function returns listStr after removing the item specified by the list index itemNum. listStr should contain items separated by the listSepStr character, such as "abc;def;". itemNum should be a number between 0 (the index of the first item in a list) and ItemsInList(listStr) - 1 .
RemoveListItem removes an item from a string containing a list of items separated by a single character, such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.
listSepStr is optional. If missing, listSepStr is presumed to be ";".

\section*{Details}

RemoveListItem differs from RemoveFromList in that RemoveListItem specifies the item to be removed by index and removes only that item, while RemoveFromList specifies the item to be removed by value, and removes all matching items.
If itemNum less than 0 or greater than ItemsInList(listStr) - 1 , or if listSepStr is " " then listStr is returned unchanged (unless listStr contains only list separators, in which case an empty string is returned).
If the resulting string contains only listSepStr characters, then an empty string (" ") is returned.
listStr is treated as if it ends with a listSepStr even if it doesn't. Searches for itemStr and listSepStr are casesensitive.
Only the first character of listSepStr is used.

\section*{Examples}
```

Print RemoveListItem(1, "wave0;wave1;w2;") // prints "wave0;w2;"
Print RemoveListItem(0, "wave1;;;;") // prints ""
Print RemoveListItem(1, "AX=3,KEY=joy", ",") // prints "AX=3,"
Print RemoveListItem(1, "fred\twilma", "\t") // prints "fred\t"

```

\section*{See Also}

The AddListItem, FindListItem, FunctionList, ItemsInList, RemoveByKey, RemoveFromList, StringFromList, StringList, TraceNameList, VariableList, WaveList, and WhichListItem functions.

\section*{RemovePath}

RemovePath [/A/Z] pathName
The RemovePath operation removes a path from the list of symbolic paths. RemovePath is an old name for the new KillPath operation, which we recommend you use instead.

\section*{Rename}

\section*{Rename oldName, newName}

The Rename operation renames waves, strings, or numeric variables from oldName to newName.

\section*{Parameters}
oldName may be a simple object name or a data folder path and name. newName must be a simple object name.

\section*{Details}

You can not rename an object using a name that already exists. The following will result in an error:
Make wave0, wave1
// Rename wave0 and overwrite wavel.
Rename wave0, wavel // This will not work.
However, you can achieve the desired effect as follows:
Make wave0, wave1
Duplicate/O wave0, wavel; KillWaves wave0

\section*{See Also}

The Duplicate operation.

\section*{RenameDataFolder}

\section*{RenameDataFolder sourceDataFolderSpec, newName}

The RenameDataFolder operation changes the name of the source data folder to the new name.
sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.
newName is just the new name for the data folder, without any path.

\section*{Details}

RenameDataFolder generates an error if the new name is already in use as a data folder contained within the source data folder.

\section*{Examples}

RenameDataFolder root:foo,foo2 // Change name of foo to foo2

\section*{See Also}

Chapter II-8, Data Folders.

\section*{RenamePath}

RenamePath oldName, newName
The RenamePath operation renames an existing symbolic path from oldName to newName.
See Also
Symbolic Paths on page II-34

\section*{RenamePICT}

RenamePICT oldName, newName
The RenamePICT operation renames an existing picture to from oldName to newName.
See Also
Pictures on page III-423.

\section*{RenameWindow}

\section*{RenameWindow oldName, newName}

The RenameWindow operation renames an existing window or subwindow from oldName to newName.

\section*{Parameters}
oldName is the name of an existing window or subwindow.
When identifying a subwindow with oldName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

See Also
The DoWindow operation.

\section*{ReorderImages}

ReorderImages [/W=winName] anchorImage, \{imageA, imageB, ...\}
The ReorderImages operation changes the ordering of graph images to that specified in the braces.

\section*{Flags}
/W=winName Reorders images in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Details}

Igor keeps a list of images in a graph and draws the images in the listed order. The first image drawn is consequently at the bottom. All other images are drawn on top of it. The last image is the top one; no other image obscures it.
ReorderImages works by removing the images in the braces from the list and then reinserting them at the location specified by anchorImage. If anchorImage is not in the braces, the images in braces are placed before anchorImage.

If the list of images is \(\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{F}, \mathrm{G}\) and you execute the command
ReorderImages \(F\), \(\{B, C\}\)
images B and C are placed just before \(\mathrm{F}: \mathrm{A}, \mathrm{D}, \mathrm{E}, \mathrm{B}, \mathrm{C}, \mathrm{F}, \mathrm{G}\).
The result of

ReorderImages \(\mathrm{E},\{\mathrm{D}, \mathrm{E}, \mathrm{C}\}\)
is to reorder C, D and E and put them where E was. Starting from the initial ordering this gives A, B, D, E, C, F, G.
ReorderImages generates an error if the same trace is in the list twice.

\section*{See Also}

The ReorderTraces operation.

\section*{ReorderTraces}

ReorderTraces [/W=winName] anchorTrace, \{traceA, traceB, ...\}
The ReorderTraces operation changes the ordering of graph traces to that specified in the braces.

\section*{Flags}
\(/ \mathrm{W}=\) winName \(\quad\) Reorders traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Details}

Igor keeps a list of traces in a graph and draws the traces in the listed order. The first trace drawn is consequently at the bottom. All other traces are drawn on top of it. The last trace is the top one; no other trace obscures it.
ReorderTraces works by removing the traces in the braces from the list and then reinserting them at the location specified by anchorTrace. If anchorTrace is not in the braces, the traces in braces are placed before anchorTrace.
If the list of traces is \(A, B, C, D, E, F, G\) and you execute the command
ReorderTraces \(F,\{B, C\}\)
traces B and C are placed just before F: A, D, E, B, C, F, G.
The result of
ReorderTraces E, \(\{\mathrm{D}, \mathrm{E}, \mathrm{C}\}\)
is to reorder \(\mathrm{C}, \mathrm{D}\) and E and put them where E was. Starting from the initial ordering results in \(\mathrm{A}, \mathrm{B}, \mathrm{D}, \mathrm{E}\), C, F, G.
ReorderTraces generates an error if the same trace is in the list twice.

\section*{See Also}

Trace Names on page II-243, Programming With Trace Names on page IV-72.
The ReorderImages operation.

\section*{ReplaceNumberByKey}

ReplaceNumberByKey(keyStr, kwListStr, newNum [, keySepStr
[, listSepStr [, case]]])
The ReplaceNumberByKey function returns kwListStr after replacing the numeric value of the keyword-value pair specified by keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1, KEY2=value2" or "Key:value1; KEY2:value2", depending on the values for keySepStr and listSepStr.
Use ReplaceNumberByKey to add or modify numeric information in a string containing a
"key1:value1; key2: value2;" style list such as those returned by functions like AxisInfo or TraceInfo.
If keyStr is not found in \(k w L i s t S t r\), then the key and the value are appended to the end of the returned string. keySepStr, listSepStr, and case are optional; their defaults are ":", ";", and 0 respectively.

\section*{Details}

The actual string appended is:
[listSepStr] keyStr keySepStr newNum listSepStr
The optional leading list separator listSepStr is added only if \(k w L i s t S t r\) does not already end with a list separator.
keyStr is limited to 255 characters.
\(k w L i s t S t r\) is searched for an instance of the key string bound by listSepStr on the left and a keySepStr on the right. The text up to the next ";" is replaced by newNum after conversion to text using the \(\% .15 \mathrm{~g}\) format (see printf for format conversion specifications).
\(k w L i s t S t r\) is treated as if it ends with a listSepStr even if it doesn't.
Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional case parameter to 0 makes the comparisons case sensitive.
Only the first characters of keySepStr and listSepStr are used.
If listSepStr is specified, then keySepStr must also be specified. If case is specified, keySepStr and listSepStr must be specified.

\section*{Examples}

Print ReplaceNumberByKey("K1", "K1:7;", 4) // prints "K1:4;"
Print ReplaceNumberByKey("k2", "K2=8;", 5, "=") // prints "K2=5;"
Print ReplaceNumberByKey ("K3", "K3:9,", 6, ":", ",") // prints "K3:6,"
Print ReplaceNumberByKey ("k3", "K0:9", 6, ":", ",") // prints "K0:9,k3:6,"
Print ReplaceNumberByKey("k3", "K3:9,", 6, ":", ",") // prints "K3:6,"
Print ReplaceNumberByKey ("k3", "K3:9,", 6, ":", ",", 1) // prints "K3:9,k3:6,"
See Also
The ReplaceStringByKey, NumberByKey, StringByKey, RemoveByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

\section*{ReplaceString}

ReplaceString(replaceThisStr, inStr, withThisStr [, caseSense [, maxReplace]])
The ReplaceString function returns inStr after replacing any instance of replaceThisStr with withThisStr.
The comparison of replaceThisStr to the contents of inStr is case-insensitive. Setting the optional caseSense parameter to nonzero makes the comparison case-sensitive.
Usually all instances of replaceThisStr are replaced. Setting the optional maxReplace parameter limits the replacements to that number.

\section*{Details}

If replaceThisStr is not found, inStr is returned unchanged.
If maxReplace is less than 1 , then no replacements are made. Setting maxReplace \(=\) Inf is the same as omitting it.

\section*{Examples}
```

Print ReplaceString("hello", "say hello", "goodbye")// prints "say goodbye"
Print ReplaceString("\r\n", "line1\r\nline2", "") // prints "linelline2"
Print ReplaceString("A", "an Ack-Ack", "a", 1) // prints "an ack-ack"
Print ReplaceString("A", "an Ack-Ack", "a", 1, 1) // prints "an ack-Ack"
Print ReplaceString("", "input", "whatever") // prints "input" (no change)

```

\section*{See Also}

The ReplaceStringByKey, cmpstr, StringMatch, and strsearch functions.

\section*{ReplaceStringByKey}

ReplaceStringByKey(keyStr, kwListStr, newTextStr [, keySepStr [, listSepStr [, matchCase]]])
The ReplaceStringByKey function returns kwListStr after replacing the text value of the keyword-value pair specified by keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1, KEY2=value2" or "Key:value1; KEY2: value2", depending on the values for keySepStr and listSepStr.
Use ReplaceStringByKey to add or modify text information in a string containing a
"key1:value1; key2:value2;" style list such as those returned by functions like AxisInfo or TraceInfo.
If keyStr is not found in kwListStr, then the key and the value are appended to the end of the returned string.
keySepStr, listSepStr, and matchCase are optional; their defaults are ":", ";", and 0 respectively.

\section*{Details}

The actual string appended is:
[listSepStr] keyStr keySepStr newTextStr listSepStr
The optional leading list separator listSepStr is added only if kwListStr does not already end with a list separator. keyStr is limited to 255 characters.
\(k w L i s t S t r\) is searched for an instance of the key string bound by a ";" on the left and a ":" on the right. The text up to the next ";" is replaced by newTextStr.
If newTextStr is " ", any existing value is deleted, but the key, the key separator, and the list separator are retained. To remove a keyword-value pair, use the RemoveByKey function.
\(k w L i s t S t r\) is treated as if it ends with a listSepStr even if it doesn't.
Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are caseinsensitive. Setting the optional matchCase parameter to 1 makes the comparisons case-sensitive.
Only the first characters of keySepStr and listSepStr are used.
If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

\section*{Examples}
```

Print ReplaceStringByKey("KY", "KY:a;KZ:c", "b") // prints "KY:b;KZ:c"
Print ReplaceStringByKey("KY", "ky=a;", "b", "=") // prints "ky=b;"
Print ReplacestringByKey("KY", "KY:a,", "b", ":", ",")// prints "KY:b,"
Print ReplaceStringByKey("ky", "ZZ:a,", "b", ":", ",")// prints "ZZ:a,ky:b,"
Print ReplaceStringByKey("kz", "KZ:a,", "b", ":", ",")// prints "KZ:b,"
Print ReplaceStringByKey("kz", "KZ:a,", "b", ":", ",", 1)// prints "KZ:a,kz:b,"

```

\section*{See Also}

The ReplaceString, ReplaceNumberByKey, NumberByKey, StringByKey, ItemsInList, RemoveByKey, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

\section*{ReplaceText}

ReplaceText [/W=winName/N=name] textStr
The ReplaceText operation replaces the text in the most recently created or changed annotation or in the annotation specified by \(/ \mathrm{W}=\) winName and/ \(\mathrm{N}=\) name.

\section*{Parameters}
textStr can contain escape codes to control font, font size and other stylistic variations.
If the annotation is a color scale, this command replaces the text of the color scale's main axis label.

\section*{Flags}
\begin{tabular}{ll} 
/N=name & Replaces the text of the named tag or textbox. \\
/W=winName & \begin{tabular}{l} 
Replaces text in the named graph window or subwindow. When omitted, action will \\
affect the active window or subwindow. This must be the first flag specified when \\
used in a Proc or Macro or on the command line.
\end{tabular} \\
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 \\
for details on forming the window hierarchy.
\end{tabular}

\section*{See Also}

See the Tag and TextBox operations for details about the textStr parameter.
The ColorScale operation.

\section*{ReplaceWave}

ReplaceWave [/W=winName] allincDF
ReplaceWave [/X/W=winName] trace=traceName, waveName
ReplaceWave [/X/Y/W=winName] image=imageName, waveName
ReplaceWave [/X/Y/W=winName] contour=contourName, waveName
The ReplaceWave operation replaces waves displayed in a graph with other waves. The waves to be replaced, and the replacement waves are chosen by the flags, the keyword and the wave names on the command line.

\section*{Flags}
/W=winName Replaces the wave in the named graph window or subwindow. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
/X Replaces the wave defining the \(X\) data spacing.
/Y Replaces the wave defining the Y data spacing.

\section*{Keywords}
allinCDF
contour=contourName Replaces the wave supplying the Z data for contourName. If /X or /Y is used, replaces the wave used to set the \(X\) or \(Y\) data spacing (if the \(Z\) data are in a matrix) or the wave used to supply the \(X\) or \(Y\) positions if \(X Y Z\) triplets were specified with three separate waves.
image=imageName Replaces the wave supplying the Z data for imageName. If / X or \(/ \mathrm{Y}\) is used, replaces the wave used to set the \(X\) or \(Y\) data spacing.
trace=traceName
Searches the current data folder for waves with the same names as waves used in the graph. If found and if the waves are of the correct type, they replace the existing waves. Thus, if you have several data folders with identically-named waves containing data from different experimental runs, you can browse through the runs by moving from one data folder to another, using ReplaceWave allinCDF to update the graph.
-

Replaces the wave associated with traceName. With the /X flag, waveName will replace the X wave associated with traceName, otherwise it will replace the Y wave. Note that traceName is derived from the Y wave name; if you created a graph using Display jack vs sam, you would use ReplaceWave/X trace=jack, newsam to replace the \(X\) wave.

\section*{Details}

Waves are replaced in the graph specified by /W=winName otherwise waves are replaced in the top graph.
Updating a contour plot in response to replacing a wave can be time-consuming. If you must replace more than one wave, put all the commands separated by semicolons on a single line. In a macro, use
DelayUpdate to prevent updates between command lines.
When using the allinCDF keyword, ReplaceWave cannot find waves buried in dynamic annotation text (for instance, using the \(\backslash\}\) syntax in an annotation). ReplaceWave will not replace waves used for error bars, either.
Subsets of data, including individual rows or columns from a matrix, may be specified using Subrange
Display Syntax on page II-293.

\section*{Examples}

Make XY plot, then replace the waves:
Make fred=x, sam=log(x)
Display fred vs sam
Make fred2=2*x, sam2=ln(x)
ReplaceWave/X trace=fred, sam2
ReplaceWave trace=fred, fred2 // trace is now named fred2

Make contour plot with XYZ triplet waves, then replace the waves. Note the DelayUpdate commands after the first two ReplaceWave commands:
```

Make/N=100 junkx, junky, junkz // Waves for XYZ triplets
junkx=trunc(x/10) // X wave for XYZ triplets
junky=mod(x,10) // Y wave for XYZ triplets
junkz=sin(junkx[p])*Cos(junky[p]) // Z wave for XYZ triplets
Display; AppendXYZContour junkz vs {junkx, junky} // Make contour plot
Make/O/N=150 junkx2, junky2, junkz2 // Make replacement waves
junkx2=trunc(x/15)
junky2=mod (x,15)
junkz2=sin(junkx2[p]) * cos(junky2[p])
ReplaceWave/X contour=junkz,junkx2; DelayUpdate
ReplaceWave/Y contour=junkz,junky2; DelayUpdate
ReplaceWave contour=junkz,junkz2

```

This example is suitable for copying all the lines and pasting into the command line, or for use in a macro. If you are typing on the command line, you would want to put the ReplaceWave commands all on one line: ReplaceWave/X contour=junkz,junkx2; ReplaceWave/Y contour=...

\section*{See Also}

Trace Names on page II-243, Programming With Trace Names on page IV-72.

\section*{Resample}

Resample [flags] waveName [, waveName]...
The Resample operation resamples waveName by interpolating or up-sampling (set by /UP=upSample), lowpass filtering, and decimating or down-sampling (set by /DOWN=downSample).
Lowpass filtering is specified with/N and/WINF or with/COEF=coefsWaveName.
The sampling frequency ( \(1 / \mathrm{DimDelta}\) ) of a resampled output wave waveName is changed by the ratio of downSample/upSample. For example, if \(u p S a m p l e=4\) and downSample \(=3\), then the final sampling rate is \(3 / 4\) of the original value.
Straight interpolation can be accomplished by setting upSample to the interpolation factor and downSample=1, in which case the sample rate is multiplied by upSample. Deltax(waveName) will be proportionally smaller.
For decimation only, set upSample=1 and downSample to the decimation factor. The sample rate is divided by downSample, and deltax(waveName) will be proportionally larger.
Use RatioFromNumber to choose appropriate values for upSample and downSample, or use /SAME=sWaveName or /RATE=sampRate. See Resampling Rates Example for details.
When using /COEF=coefsWaveName, the filter coefficients should implement a low-pass filter appropriate for the upSample and downSample values or aliasing (filtering errors) will result. See Advanced ExternallySupplied Low Pass Filter Example for details.

\section*{Resampling Rates Flags}

The upSample and downSample values define how much interpolation and decimation to perform. They can be set directly with /UP and /DOWN or indirectly with /SAME or /RATE
/DOWN=downSample Down-samples or decimates the filtered result by this integer factor after upsampling and lowpass filtering. The default is 1 (no down-sampling).
For example, /DOWN=3 places only every third value in the output wave.
Down-sampling divides the sampling rate of the filtered data by a factor of downSample. The DimDelta(waveName, dim) value is multiplied by the same factor.
/RATE=sampRate
/SAME=sWaveName

Converts the output waveName to the specified sampling rate frequency (normally Hz).
The necessary upSample and downSample values for each waveName are computed internally as if you had executed:
```

RatioFromNumber (deltax(waveName)*sampRate)
upSample = V_numerator
downSample = V_denominator

```
/RATE returns V_numerator and V_denominator set to these automaticallydetermined values for the last waveName.

Converts the output waveName to the same sampling rate as sWaveName, 1/DimDelta(sWaveName, dim). The necessary upSample and downSample values are computed internally as if you had executed:
```

Variable dd = DimDelta(waveName,dim)
RatioFromNumber dd/DimDelta(sWaveName,dim)
upSample = V numerator
downSample = V_denominator

```
/SAME returns V_numerator and V_denominator set to these automatically determined values for the last waveName.
/UP=upSample Up-samples or interpolates the input by this integer factor. The default is 1 (no up-sampling).
For example, /UP=4 inserts three extra points between each input point (producing 4 times as many values) before the lowpass filtering and downsampling occurs.
Up-sampling multiplies the sampling rate of the input data by a factor of upSample, though no additional signal information is created. The DimDelta(waveName, dim) value is divided by the same factor.

\section*{Internal Sinc Reconstruction Filter Flags}

If /COEF=coefsWaveName is not specified, Resample computes a windowed sinc filter from / N, /DOWN, /UP, and /WINF flag values.
If /COEF=coefsWaveName is specified, then coefsWaveName supplies the filter, and /N and /WINF are ignored. See Externally-Supplied Low Pass Filter Flags.
/COEF Replaces the first waveName with coefficients generated by downSample, upSample, numReconstructionSamples, and windowKind, a windowed sinc impulse response.
When resampling multiple waveNames with different filters (because /RATE or /SAME were specified and the multiple waveNames had different sampling rates), the filter used to resample the last waveName is returned.
/ \(\mathrm{N}=\) numReconstructionSamples
Specifies the number of input values used to created the up-sampled values (default is 21 ).
The value of numReconstructionSamples must be odd.
The size of the computed filter is (numReconstructionSamples-1) * upSample +1 .
Bigger is better: 15 is usually on the low side for yielding reasonably accurate results, and although 101 will nearly always give very good results, it will be slow.

Use /COEF to output the impulse response, and the FFT to display the frequency response of the interpolator:
```

Make/O coefs
Variable numReconstructionSamples= 51, upSample= 5
Resample/COEF/N=(numReconstructionSamples)/UP=(upSample) coefs
Variable evenNum= 2*floor((numpnts(coefs)+1)/2)
FFT/OUT=3/PAD={evenNum}/DEST=coefs_FFT coefs
Display coefs_FFT

```

Bigger is also slower: the filtering is computed in the time-domain, and execution time is linearly related to
upSample/downSample * numReconstructionSamples.
/WINF=windowKind
Applies the window, windowKind, to the computed filter coefficients. If /WINF is omitted, the Hanning window is used. For no coefficient windowing, use /WINF=None, though this is discouraged.
Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when numReconstructionSamples is large.
Choices for windowKind are:
Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.
See FFT for window equations and details.

\section*{Externally-Supplied Low Pass Filter Flags}
/COEF =coefsWaveName
Identifies the wave, coefsWaveName, containing filter coefficients that implement a low-pass filter with a cutoff frequency of the lesser of \(0.5 /\) upSample and \(0.5 /\) downSample, where 0.5 corresponds to the Nyquist frequency of the up-sampled data.
For example, if upSample=2, then the filter must contain the classic "half-band" filter, which stops the higher half of the frequencies and passes the lower half. If upSample \(=10\), then the filter must pass only the lowest \(1 / 10\) th of the frequencies.
For downSample > upSample, the low-pass filter's cutoff frequency must be \(0.5 /\) downSample. This prevents the decimation from introducing aliasing to the resampled data.
To avoid shifting the output with respect to the input, coefsWaveName must have an odd length with the "center" coefficient in the middle of the wave.
The length of coefsWaveName must be \(1+u p S a m p l e e^{*} n\), where \(n\) is any even integer.
Note: Instead of using / N=numReconstructionSamples with /COEF=coefsWaveName, numReconstructionSamples is computed from upSample and the number of points in coefsWaveName:
numReconstructionSamples=1+(numpnts(coefsWaveName)-1)/upSample.
Coefficients are usually symmetrical about the middle point, but this is not enforced. coefsWaveName must not be a destination waveName.
coefsWaveName must be single- or double-precision numeric and one-dimensional.

\section*{Data Range Flags}
/DIM=d Specifies the wave dimension to resample.
For \(d=0,1, \ldots\), resampling is along rows, columns, etc.
The default is \(/ \mathrm{DIM}=0\), which resamples each individual column (each one a channel, say left and right) in a multidimensional waveName where each row comprises all sound samples at a particular time.
To resample in multiple dimensions, execute the command once for each dimension. For example, use /DIM=0 followed by another command with /DIM=1 to resample a two-dimensional wave in each direction.
\(E=e n d E f f e c t \quad\) Determines how to handle the ends of the resampled wave(s) (w) when fabricating missing neighbor values.
endEffect \(=0\) : \(\quad\) Bounce method. Uses \(w[i]\) in place of the missing \(w[-i]\) and \(\mathrm{w}[n-i]\) in place of the missing \(\mathrm{w}[n+i]\).
endEffect=1: Wrap method. Uses \(\mathrm{w}[n-i]\) in place of the missing \(\mathrm{w}[-i]\) and vice versa.
endEffect=2: \(\quad\) Zero method (default). Uses 0 for any missing value.
endEffect=3: Repeat method. Uses \(\mathrm{w}[0]\) in place of the missing \(\mathrm{w}[-i]\) and \(\mathrm{w}[n]\) in place of the missing \(\mathrm{w}[n+i]\).

\section*{Parameters}
waveName can be a wave with any number of dimensions. Only one dimension is resampled. Use multiple Resample calls to resample across multiple dimensions.
Without /DIM, resampling is done along the row (first) dimension. Each column is resampled as if it were a separate one-dimensional row. This allows multichannel audio to be resampled to another frequency.
If /DIM=1, then resampling proceeds across all the columns of each row.
If /COEF is specified without coefsWaveName, then the first waveName is overwritten by the filter coefficients instead of being resampled.

\section*{Details}

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length (/N or the length of coefsWaveName) should be small in comparison to the resampled waves.
Resample assumes that the middle point of coefsWaveName corresponds to the delay=0 point. The "middle" point number \(=\) trunc(numpnts(coefsWaveName -1)/2). coefsWaveName usually contains the two-sided impulse response of a filter, an odd number of points, and implements a low-pass filter whose cutoff frequency is the lesser of \(0.5 /\) upSample and 0.5 /downSample ( 0.5 corresponds to the Nyquist frequency \(=1 / 2\) sampling frequency).
When /COEF creates a coefficients wave it sets the \(X\) scale deltax to 1 and alters the leftx value so that the zero-phase (center) coefficient is located at \(\mathrm{x}=0\).

\section*{Simple Examples}

Interpolation by factor of 4 , default filter:
Resample/UP=4 data
Decimation by factor of 3, default filter:
Resample/DOWN=3 data
Match sampling rates, default filter:
Resample/SAME=dataAtDesiredRate dataAtWrongRate1, dataAtWrongRate2,...
Resample waves to 10 KHz sampling rate:
Resample/RATE=10e3 dataAtWrongRate1, dataAtWrongRate2,...
Interpolate an image by a factor of 2 :

Resample/UP=2 image
// default is /DIM=0, resample rows
Resample/UP=2/DIM=1 image
// resample across columns

Note: Interpolating by a factor of two does not produce an image with twice as many rows and columns. The new number of rows \(=(\text { original rows }-1)^{*}\) upSample +1 , and a similar computation applies to columns.

\section*{Resampling Rates Example}

Suppose we have an audio wave sampled at \(44,100 \mathrm{~Hz}\) and we wish to resample it to a higher \(192,000 \mathrm{~Hz}\) frequency.
We can use /RATE= 192000 and let Resample determine the correct values (provided waveName has its X scaling set properly to reflect sampling at 44100 Hz ), but let's compute upSample and downSample ourselves.
Because the sampling rate \(=1 /\) deltax(wave), we can recast the /SAME formula to RatioFromNumber (desiredSamplingRate/currentSamplingRate):
```

- RatioFromNumber/V (192000 / 44100)
V numerator $=640$; $V$ denominator $=147$;
rātio= 4.3537414965986;
V_difference= 0;
Then upSample $=640$ and downSample $=147$.

```

The 44100 Hz input data will be interpolated by 640 to \(28,224,000 \mathrm{~Hz}\).
The result is low-pass filtered with a "cutoff frequency" of \(1 / 640\) th of the interpolated Nyquist frequency \(=\) \((28224000 / 2) / 640=22,050 \mathrm{~Hz}\), the same as the input signal's original Nyquist frequency.
The result will be decimated by 147 to \(192,000 \mathrm{~Hz}\), which is the desired output sampling frequency.
Note: If downSample had been greater than upSample, then the low-pass filter's cutoff frequency would have been 1/downSampleth of the interpolated Nyquist frequency \(=\)
\((28224000 / 2) /\) downSample. This prevents the decimation from introducing aliasing to the resampled data.
```

Resample/UP=640/DOWN=147 sound // convert 44.1 KHz to 192 KHz

```

\section*{Advanced Externally-Supplied Low Pass Filter Example}

You can generate an appropriate filter by executing commands like these:
```

// Compute a filter for after the input is upsampled
// to restore the frequency content to the original range.
Variable fc = min(0.5 / upSample, 0.5 * upSample / downSample)
// Transition width, small widths need big n
Variable tw= fc/10
// set end of pass band
Variable fl= fc-tw/2
// Set start of stop band
Variable f2= fc+tw/2
// Use bigger values of n to make the filter smoother
Variable nReconstruct= 31
Variable n= (nReconstruct-1)*upSample+1 // odd = no phase shift
// Create a wave to hold the coefficients; it gets resized to n
Make/O/N=0 coefsWaveName
FilterFIR/COEF/LO={f1,f2,n} coefsWaveName

```

However, FilterFIR does not create windowed sinc lowpass filters that have the endearing property that the original input values are unaltered in the filtered output, though only if upSample \(>\) downSample. This is called a "Nyquist filter" or "Kth-band filter" in the literature.
If upSample > downSample, you can enforce the Nyquist criterion by "zeroizing" the designed filter by setting every upSampleth value to 0 except the center one.
```

// coefsWaveName length must be l+upSample*n, where n is any even integer
Function Zeroize(w, upSample)
Wave w // coefsWaveName
Variable upSample // upSample value
Variable n= DimSize(w,0)
Variable centerP= floor((n-1)/2) // if n=101, centerP= 50
Variable i
for (i=0; i<n; i+=upSample)

```
```

        if( i != centerP )
            w[i] = 0
        endif
    endfor
    End

```

Resample zeroizes the internally-generated low pass filter when upSample > downSample.
Additionally, the FilterFIR command generates a low-pass filter whose gain needs to be multiplied by upsample:
coefsWaveName * \(=\) upSample
When designing an externally supplied filter, you should also consider the filter's "polyphase" nature; coefsWaveName is actually a set of upSample interleaved filters, each with its own response. It makes sense to adjust these filters to produce consistent responses. If you don't, the results will contain ringing with a period of upSample/downSample. This is most apparent when downSample is 1 .
Using the filter we've designed so far with upSample=4, here's the output of a constant-input wave:

Resample/COEF=coefsWaveName/UP=4 constantData

The graph shows that the filter response at 0 Hz for the first of 4 filters is 1.0010 , the second and fourth filter's responses are very close to 1.0 , and the third filter's response at 0 Hz is a little less than 1.0.
These variations can be eliminated by normalizing the sum of each polyphase filter to 1.0 :
```

Function PolyphaseNormalize(w, upSample)
Wave w // coefsWaveName
Variable upSample // upSample value
Variable n= DimSize(w,0)
Variable filt
// for each filter (0..upSample-1)
for (filt=0; filt<upSample; filt+=1)
Variable total=0
Variable pt
// compute total for this filter
for (pt=filt; pt<n; pt+=upSample)
total += w[pt]
endfor
// divide by total to normalize total to 1
for (pt=filt; pt<n; pt+=upSample)
w[pt] /= total
endfor
endfor
End

```

Now the filter is ready to be used to filter data:

Resample/COEF=CoefsWaveName/UP=(upSample)/DOWN=(downSample) dataWave
You can see that designing an externally-supplied lowpass filter is much more complicated than using the internal sinc reconstruction filter, which does all this zeroizing, scaling, and polyphase normalization for you.

\section*{ResumeUpdate}

\section*{ResumeUpdate}

The ResumeUpdate operation cancels the corresponding PauseUpdate.
This operation is of use in macros. It is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the DoUpdate operation.

\section*{See Also}

The DelayUpdate, DoUpdate, and PauseUpdate operations.

\section*{return}
return [expression]
The return flow control keyword immediately stops execution of the current procedure. If called by another procedure, it returns expression and control to the calling procedure.
Functions can return only a single value directly to the calling procedure with a return statement. The return value must be compatible with the function type. A function may contain any number of return statements; only the first one encountered during procedure execution is evaluated.
A macro has no return value, so return simply quits the macro.

\section*{See Also}

The Return Statement on page IV-31.

\section*{Reverse}

Reverse [type flags] [/DIM=d /P] waveA [/D = destWaveA] [, waveB [/D = destWaveB] [, ...]] The Reverse operation reverses data in a wave in a specified dimension. Reverse does not accept text waves.

Flags
\(/ \mathrm{DIM}=d \quad\) Specifies the wave dimension to reverse.
\(d=-1\) : Treats entire wave as 1D (default).
For \(d=0,1, \ldots\), operates along rows, columns, etc.
/P Suppresses adjustment of dimension scaling. Without / P the scaled dimension value of reversed points remains the same.

Type Flags (used only in functions)
Reverse also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it is needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See WAVE Reference Types on page IV-58 and WAVE Reference Type Flags on page IV-59 for a complete list of type flags and further details.

\section*{Wave Parameters}

Note: All wave parameters must follow wave in the command. All wave parameter flags and type flags must appear immediately after the operation name (Reverse).
\(/ \mathrm{D}=\) destWave \(\quad\) Specifies the name of the wave to hold the reversed data. It creates destWave if it does not already exist or overwrites it if it exists.

\section*{Details}

If the optional \(/ \mathrm{D}=\) destWave flag is omitted, then the wave is reversed in place.

\section*{See Also}

The Sort operation and Sorting on page III-136.

\section*{RGBColor}

The RGBColor structure is used as a substructure usually to store various color settings.
```

Structure RGBColor
UInt16 red
UInt16 green
UInt16 blue
EndStructure

```

\section*{rightx}
```

rightx (waveName)

```

The rightx function returns the \(X\) value corresponding to point \(N\) of the named 1 D wave of length N .

\section*{Details}

Note that the point numbers in a wave run from 0 to \(N-1\) so there is no point with this \(X\) value. To get the \(X\) value of the last point in a wave (point \(\mathrm{N}-1\) ), use the following:
pnt \(2 x\) (waveName, numpnts (waveName) - 1) // N = numpnts (waveName)
which is more accurate than:
rightx (waveName) - deltax (waveName)
The rightx function is not multidimensional aware. See Analysis on Multidimensional Waves on page II-110 for details. The equivalent information for any dimension can be calculated this way:
IndexN = DimSize(wave, dim)*DimDelta(wave, dim) + DimOffset(wave, dim)
Here Index \(N\) is the value of the scaled dimension index corresponding to element N of the dimension dim in a wave named wave that has N elements in that dimension.

\section*{See Also}

The deltax and leftx functions, also the pnt2x and numpnts functions.
For an explanation of waves and dimension scaling, see Changing Dimension and Data Scaling on page II-83.
For multidimensional waves, see DimDelta, DimOffset, and DimSize.

\section*{root}
root [: dataFolderName[:dataFolderName[:...]] [ [:objectName]
Igor's data folder hierarchy starts with the root folder as its basis. The root data folder always exists and it contains all other objects (waves, variables, strings, and data folders). By default, the root data folder is the current data folder in a new experiment. In commands, root is used as part of a path specifying the location of a data object in the folder hierarchy.

\section*{See Also \\ Chapter II-8, Data Folders.}

\section*{Rotate}

Rotate rotPoints, waveName [, waveName]...
The Rotate operation rotates the Y values of waves in wavelist by rotPoints points.

\section*{Parameters}

If rotPoints is positive then values are rotated from the start of the wave toward the end and rotPoints values from the end of a wave wrap around to the start of the wave.
If rotPoints is negative then values are rotated from the end of the wave toward the start and rotPoints values from the start of a wave wrap around to the end of the wave.

\section*{Details}

The \(X\) scaling of the named waves is changed so that the \(X\) values for the \(Y\) values remains the same except for the points that wrap around.
The Rotate operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-110 for details.
The Rotate operation is not multidimensional aware. To rotate rows or columns of 2D waves, see the rotateRows and rotateCols keywords for the Matrix Op and ImageTransform operations.
For general information about multidimensional analysis, see Analysis on Multidimensional Waves on page II-110.

\section*{See Also}

The shift parameter of the WaveTransform operation.

\section*{round}

\section*{round (num)}

The round function returns the integer value closest to num.
The rounding method is "away from zero".

\section*{See Also}

The ceil, floor, and trunc functions.

\section*{rtGlobals}
\#pragma rtGlobals \(=0,1,2\), or 3
\#pragma rtglobals=<n> is a compiler directive that controls compiler and runtime behaviors for the procedure file in which it appears.
This statement must be flush against the left edge of the procedure file with no indentation. It is usually placed at the top of the file.
\#pragma rtglobals=0 turns off runtime creation of globals. This is obsolete.
\#pragma rtglobals=1 is a directive that turns on runtime lookup of globals. This is the default behavior if \#pragma rtGlobals is omitted from a given procedure file.
\#pragma rtGlobals=2 turns off compatibility mode. This is mostly obsolete. See Legacy Code Issues on page IV-94 for details.
\#pragma rtglobals=3 turns on runtime lookup of globals, strict wave reference mode and wave index bounds checking.
If your procedures will run only with Igor Pro 6.20 or later, rtGlobals \(=3\) is recommended. Otherwise rtGlobals \(=1\) is recommended.
See The rtGlobals Pragma on page IV-41 for a detailed explanation of rtGlobals.

\section*{s}

The s function returns the current chunk index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled chunk index is available as the \(\mathbf{t}\) function.

\section*{Details}

Unlike p, outside of a wave assignment statement, s does not act like a normal variable.

\section*{See Also}

Waveform Arithmetic and Assignments on page II-94.
For other dimensions, the \(\mathbf{p}, \mathbf{r}\), and \(\mathbf{q}\) functions.
For scaled dimension indices, the \(\mathbf{x}, \mathbf{y}, \mathbf{z}\) and \(\mathbf{t}\) functions.

\section*{Save}

Save [flags] waveList [as fileNameStr]
The Save operation saves the named waves to disk as text (/F, /G or /J) or as Igor binary.

\section*{Parameters}
waveList is either a list of wave names or, if the /B flag is present, a string list of references to waves. For example, the following commands are equivalent, assuming that the waves in question are in the root data folder and root is the current data folder:
```

Save/J wave0,wave1 as "Test.dat"
Save/J root:wave0,root:wave1 as "Test.dat"
Save/J/B "wave0;wave1;" as "Test.dat"
Save/J/B "root:wave0;root:wave1;" as "Test.dat"
String list="root:wave0;root:wave1;"; Save/J/B list as "Test.dat"

```

The form using the /B flag and a string containing a list of references to waves saves a very large number of waves using one command. This is not possible using a list of wave names because of the 400 character limit in a command. When using this form, the string must contain semicolon-separated wave names or data folder paths leading to waves. Liberal names in the string may be quoted or unquoted.
The file to be written is specified by fileNameStr and \(/ \mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If it cannot determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.

\section*{Flags}
\begin{tabular}{|c|c|}
\hline \multirow[t]{4}{*}{\(/ \mathrm{A}[=a]\)} & Appends to the file rather than overwriting it (with /T, /G or /J). \\
\hline & \(a=0\) : \(\quad\) Does not append. \\
\hline & \(a=1: \quad\) Appends to the file with a blank line before the appended data (same as /A only). \\
\hline & \(a=2: \quad\) Appends to the file with no blank line before the appended data. \\
\hline /B & The waveList parameter is a string containing a list of references to waves instead of a literal list of waves. \\
\hline /C & Saves a copy of the wave when saving as Igor binary. \\
\hline /DSYM=dsStr & Specifies a string containing the character to use as the decimal symbol for all numbers (default is a period). If \(d s S t r\) is empty ( \("\) "), then the decimal symbol is as defined in system preferences. \\
\hline
\end{tabular}
/E=useEscapeCodes Determines whether to use escape sequences for special characters.
/ \(\mathrm{E}=1\) : \(\quad\) Converts carriage-return, linefeed, tab, and backslash characters to escape sequences when writing general or delimited text files (default; same as no /E).
\(/ E=0: \quad\) No escape sequences used in general or delimited text files. When saving text waves containing backslashes (such as Windows paths) in a file intended for another program, you probably should use \(/ E=0\).
/F
Writes delimited and general text files with numeric formatting as it appears in the top table. Has no effect if there is no top table or if the wave being saved does not appear in the top table.
Note: The text written to the file is exactly as displayed in the table. Set the table to display as many digits of precision as you want in the file.
Note: When saving a multi-column wave (1D complex wave or multi-dimensional wave), all columns of the wave are saved using the table format for the first table column from the wave.
/G Saves waves in general text format.
/H "Adopts" the waves specified by waveList.
"Adopt" means that any connection between the waves and external files is severed. The waves become part of the current experiment. When the experiment is next saved, the waves are saved in the experiment file (for an packed experiment) or in the experiment folder (for an unpacked experiment).
When you use the /H flag, all other flags and the fileNameStr parameter are ignored. The wave is not actually saved but rather is marked for saving as part of the current experiment.
You would normally do this to make an experiment more self-contained which makes it easier to send to other people. See Sharing Versus Copying Igor Binary Files on page II-165 and the LoadWave /H flag.
/I Presents a dialog from which you can specify file name and folder.
/J Saves waves in tab-delimited text format.
\(/ \mathrm{M}=\) termStr \(\quad\) Specifies the terminator character or characters to use at the end of each line of text. The default is \(/ M=\) " \(\backslash r\) ", which uses a carriage return character. This is the Macintosh convention. To use the Windows convention, carriage return plus linefeed, specify \(/ M=" \backslash r \backslash n "\). To use the Unix convention, just a linefeed, specify \(/ M=" \backslash n "\).
/O Overwrites file if it exists already.
/P=pathName Specifies the folder to store the file in. pathName is the name of an existing symbolic path.
/T
Saves waves in Igor Text format.
\(/ \mathrm{U}=\{\) writeRowLabels, rowPositionAction, writeColLabels, colPositionAction \(\}\)
These parameters affect the saving of a matrix (2D wave) to a delimited text (/J) or general text (/G) file. They are accepted no matter what the save type is but are ignored when they don't apply.
If writeRowLabels is nonzero, Save writes the row labels of the matrix as the first column of data in the file.
rowPositionAction has one of the following values:
0: \(\quad\) Don't write a row position column.
1: \(\quad\) Writes a row position column based on the row scaling of the matrix wave.
2: Writes a row position column based on the contents of the row position wave for the matrix. The row position wave is an optional 1D wave whose name is the same as the matrix wave but with the suffix "_RP".
writeColumnLabels and columnPositionAction have analogous meanings. The suffix used for the column position wave is "_CP".
See Chapter II-9, Importing and Exporting Data, for further details.

\section*{Details}

The Save operation saves only the named waves; it does not save the entire experiment.
Waves saved in Igor binary format are saved one wave per file. If you are saving more than one wave, you must not specify a fileNameStr. Save will give each file a name which consists of the wave name concatenated with ".ibw".
When you save a wave as Igor binary, unless you use the /C flag to save a copy, the current experiment subsequently references the file to which the wave was saved. See References to Files and Folders on page II-37 for details.
In a general text file (/G), waves with different numbers of points are saved in different groups. Waves with different precisions and number types are saved in same group if they have the same number of points.
In a tab-delimited text file (/J), all waves are saved in one group whether or not they have the same number of points.
If you save multiple 2D waves, the blocks of data are written one after the other.
If you save 3D waves, the data for each wave is written as a contiguous block having as many columns as there are columns in the wave, and \(\mathrm{R}^{*} \mathrm{~L}\) rows, where R is the number of rows in the multidimensional wave and L is the number of layers. All rows for layer 0 are saved followed by all rows for layer 1, and so on.
If you save 4 D waves, the data for each wave is written as a contiguous block having \(\mathrm{R}^{*} \mathrm{~L}^{*} \mathrm{C}\) rows, where R is the number of rows, L is the number of layers and C is the number of chunks. Igor writes all data for chunk 0 followed by all data for chunk 1 , and so on.
The Save operation will always present a save dialog if you try to save to an existing file without using the overwrite flag.
Here are some details about saving an Igor binary file.
If you omit the path or the file name, the Save operation will normally present a save dialog. However, if the wave has already been saved to a stand-alone file and if you use the overwrite flag, it will save the wave to the same file without a dialog. Also, if the wave has never been saved and the current experiment is an unpacked experiment, it will save to the home folder without a dialog.
If you use \(/ \mathrm{P}=\) pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd: Folder1:" or "C: \\Folder1 \\". See Symbolic Paths on page II-34 for details.

\section*{Examples}

This function uses the string list of references to waves to save some or all of the waves in the current data folder:
```

Function SaveWavesFromCurrentDF(matchStr)
String matchStr // As for the WaveList function.
String list
list = WaveList(matchStr, ";", "")
Save/O/J/W/I/B list
End
For example, to save all of the waves in the current data folder, execute:
SaveWavesFromCurrentDF("*")

```

To save those waves in the current data folder whose name starts with "wave", execute:
SaveWavesFromCurrentDF ("wave*")
This function saves all of the waves used in a particular graph:
```

Function SaveWavesFromGraph(graphName)
// Saves all waves in graph.
String graphName // "" for top graph.
String list, traceList, traceName
Variable index = 0
list = ""
traceList = TraceNameList(graphName, ";", 1)
do
traceName = StringFromList(index, traceList, ";")
if (strlen(traceName) == 0)
break
endif
Wave w = TraceNameToWaveRef (graphName, traceName)
list += GetWavesDataFolder(w,2) + ";"
index += 1
while(1)
if (strlen(list) > 0)
Save/O/J/W/I/B list
endif
End
See Also
Saving Waves on page II-175.

```

\section*{SaveData}

\section*{SaveData [flags] fileOrFolderNameStr}

The SaveData operation writes data from the current data folder of the current experiment to a packed experiment file on disk or to a file system folder. "Data" means Igor waves, numeric and string variables, and data folders containing them. The data is written as a packed experiment file or as unpacked Igor binary files in a file-system folder.

Warning: If you make a mistake using SaveData, it is possible to overwrite critical data, even entire folders containing critical data. It is your responsibility to make sure that any file or folder that you can not afford to lose is backed up. If you provide procedures for use by other people, you should warn them as well.

SaveData provides a way to save data for archival storage or unload data from memory during a lengthy process like data acquisition. The file or files that SaveData writes are disassociated from the current experiment.

Use SaveData to save experiment data using Igor procedures. To save experiment data interactively, use the Save Copy button in the Data Browser (Data menu).

\section*{Parameters}
fileOrFolderNameStr specifies the packed experiment file (if /D is omitted) or the file system folder (if /D is present) in which the data is to be saved. The documentation below refers to this file or folder as the "target".
If you use a full or partial path for fileOrFolderNameStr, see Path Separators on page III-400 for details on forming the path.
If fileOrFolderNameStr is omitted or is empty (" "), SaveData displays a dialog from which you can select the target. You also get a dialog if the target is not fully specified by fileOrFolderNameStr or the \(/ \mathrm{P}=\) pathName flag.

\section*{Flags}
\(/ \mathrm{D}[=d] \quad\) Writes to a file-system folder (a directory). If omitted, SaveData writes to an Igor packed experiment file.
\(d=1\) : If the target folder already exists, the new data is "mixed-in" with the data already there (same as /D).
\(d=2: \quad\) If the target folder already exists, it is completely deleted before the writing of data starts.

If in doubt, use \(/ D=1\). See Details below.
/I
\(/ \mathrm{J}=\) objectNamesStr \(\quad\) Saves only the objects named in the semicolon-separated list of object names. See Details below.
\(/ \mathrm{L}=\) saveFlags \(\quad\) Controls what kind of data objects are saved with a bit for each data type:
\begin{tabular}{lll} 
saveFlags & Bit Number & Saves this Type of Object \\
\hline 1 & 0 & Waves \\
2 & 1 & Numeric variables \\
4 & 2 & String variables \\
\hline
\end{tabular}

To save multiple data types, sum the values shown in the saveFlags column. For example, \(/ L=1\) saves waves only, \(/ L=2\) saves numeric variables only and \(/ L=3\) saves both waves and numeric variables.
If / \(L\) is not specified, all of these object types are saved. This is equivalent to / \(L=7\). All other bits are reserved and must be set to zero. See Setting Bit Parameters on page IV-12 for details about bit settings.
\(/ \mathrm{M}=\) modDateTime \(\quad\) Saves waves modified on or after the specified modification date/time. Waves modified before modDateTime will not be saved. Applies to waves only (not variables or strings).
modDateTime is in standard Igor time format - seconds since 1/1/1904. If modDateTime is zero, all waves will be saved, as if there were no /M flag at all.
Overwrites existing files or folders on disk.
Warning: If you use the / O flag and if the target already exists, it will be overwritten without any warning. If you use \(/ \mathrm{O}\) with \(/ \mathrm{D}=2\), you will completely overwrite the target folder and all of its contents, including subfolders. Do not use /O with /D unless you are absolutely sure you know what your doing.
\(/ \mathrm{P}=\) pathName \(\quad\) Specifies the folder in which to save the specified file or folder. pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:Folder1:" or "C: \(\backslash \backslash\) Folder1 \(\backslash\) ". See Symbolic Paths on page II-34 for details.

When used with the /D flag, if /P=pathName is present and fileOrFolderNameStr is ":", the target is the directory specified by \(/ \mathrm{P}=\) pathName.
Suppresses normal messages in the history area.
Recursively saves subdata folders.
/T [=topLevelName] Creates an enclosing data folder in the target with the specified name, topLevelName, and writes the data to the new data folder.
If just / \(T\) is specified, it creates an enclosing data folder in the target using the name of the data folder being saved. However, if the data folder being saved is the root data folder, the name Data is used instead of root. In packed experiment files and unpacked experiment folders, the root data folder is implicit.
If / \(T\) is omitted, the contents of the current data folder are saved with no enclosing data folder.

\section*{Details}

If /J=objectNamesStr is used, then only the objects named in objectNamesStr are saved. For example, specifying /J= "wave0; wave1; " will save only the two named waves, ignoring any other data in all data folders.
The list of object names used with/J must be semicolon-separated. A semicolon after the last object name in the list is optional. The object names must not be quoted even if they are liberal. The list is limited to 1000 characters.
Using / \(\mathrm{J}=\mathrm{"}\) " acts like no /J at all.

The \(/ \mathrm{M}=\) modDateTime flag can be used in data acquisition projects to save only those waves modified since the previous save. For example, assume that we have a global variable in the root data folder named
gLastWaveSaveDateTime. Then this function will write out only those waves modified since the previous save:
Function SaveModifiedWaves (savePath)
String savePath // Symbolic path pointing to output directory
NVAR lastSave = root:gLastWaveSaveDateTime
SaveData/O/P=\$savePath/D=1/L=1/M=(lastSave) ":"
lastSave = datetime
End
Because the datetime function and the wave modification date have a coarse resolution (one second), this function may sometimes save the same wave twice.
The /M flag makes sense only in conjunction with the / \(D=1\) flag because / \(D=1\) is the only way to mix-in new data with existing data.

\section*{Writing to a Packed Experiment File}

When writing to a packed file, SaveData creates a standard packed Igor experiment file which you can open as an experiment, browse using the Data Browser, or access using the LoadData operation.
If you do not use the /O (overwrite) flag and the packed file already exists on disk, SaveData will present a dialog to confirm which file you want to write to. If you use the /O flag, SaveData will overwrite without presenting a dialog. When writing a packed file, SaveData always completely overwrites the preexisting packed file.
Appending to a packed experiment file is not supported because dealing with the possibility of name conflicts (e.g., two waves with the same name in the same data folder in the packed experiment file) would be technically difficult, very slow and errors would result in corrupted files.

\section*{Writing to a File-System Folder}

When saving to a folder on disk, SaveData writes wave files, variables files, and subfolders. This resembles the experiment folder of an unpacked experiment, but it does not contain other unpacked experiment files, such as history or procedures. You can browse the folder using the Data Browser or access it using the LoadData operation.
If the target directory does not exist, SaveData creates it.
If you do not use the /O (overwrite) flag and the target folder already exists on disk, SaveData will present a dialog to confirm that you want to write to it. SaveData checks for the existence of the top file system folder only. For example, if you write data to hd:Data:Run1, SaveData will display a dialog if hd:Data:Run1 exists. But SaveData will not display a dialog for any folders inside hd:Data:Run1.
If you use the /O flag, SaveData will write without presenting a dialog.
When writing to a directory, SaveData can operate in one of two modes. If you use / \(D=1\) or just \(/ D\), SaveData operates in "mix-in" mode. If you use /D=2, SaveData operates in "delete" mode.

\section*{Warning: If the target directory exists and delete mode is used, SaveData deletes the target directory and all of its contents. Then SaveData creates the target directory and writes the data to it. This is a complete overwrite operation.}

If the target directory exists and mix-in mode is used, SaveData does not do any explicit deletion. It writes data to the target directory and any subdirectories. Conflicting files in any directory are overwritten but other files are left intact.
To prevent you from inadvertently deleting an entire volume, SaveData will not permit you to target the root directory of any volume. You must target a subdirectory.
The/J flag will not work as expected when writing numeric and string variables in mix-in mode. Instead of mixing-in the specified variables, SaveData will overwrite all variables already in the target. This is because all numeric and string variables in a particular data folder are stored in a single file-system folder (named "variables"), so it is not possible to mix-in. Since waves are written one-to-a-file, /J will work as expected for waves.
When SaveData writes a wave to a file-system folder, the file name for the wave is the same as the wave name, with the extension ".ibw" added. This is true even if the wave in the experiment was loaded from a file with a different name.

\section*{Outputs}

SaveData sets the variable V_flag to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel during an interactive save. This would occur if you use the /I flag or if you omit / \(O\) and the target already exists. V_flag will also be nonzero if an error occurs during the save.
SaveData sets the string variable S_path to the full file system path to the file or folder that was written. S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. When saving unpacked, S_path includes a trailing colon.

\section*{Examples}

Write the contents of the current data folder and all subdata folders to a packed experiment file:
```

Function SaveDataInPackedFile(pathName, fileName)
String pathName // Name of symbolic path
String fileName // Name of packed file to be written
SaveData/R/P=\$pathName fileName
End

```

Write the contents of the current data folder and all subdata folders to an unpacked file-system folder:
```

Function SaveDataInUnpackedFolder(pathName, folderName)
String pathName // Name of symbolic path
String folderName // Name of file-system folder
SaveData/D=1/R/P=\$pathName folderName
End

```

Copy the contents of an unpacked file-system folder to a packed experiment file:
```

Function TransferUnpackedToPacked(path1, folderName, path2, fileName)
String path1 // Points to parent of unpacked folder
String folderName // Name of folder containing unpacked data
String path2 // Points to folder where file is to be written
String fileName // Name of packed file to be written
String savedDF = GetDataFolder(1)
NewDataFolder/O/S :TempTransfer
// Load all data from the unpacked folder.
LoadData/D/Q/R/P=$path1 folderName
    // Save all data to the packed file.
    SaveData/R/P=$path2 fileName
KillDataFolder : // Kill TempTransfer
SetDataFolder savedDF
End

```

\section*{See Also}

The LoadData and SaveGraphCopy operations; the SpecialDirPath function. Saving Package Preferences on page IV-231; Chapter II-9, Importing and Exporting Data; Data Browser on page II-130.

\section*{SaveExperiment}

SaveExperiment [flags] [as fileName]
The SaveExperiment operation saves the current experiment.
Warning: SaveExperiment overwrites any previously-existing file named fileName.
Parameters
The optional fileName string contains the name of the experiment to be saved. fileName can be the currently open experiment, in which case it overwrites the experiment file.
If fileName and pathName are omitted and the experiment is Untitled, you will need to locate where the experiment file will be saved interactively via a dialog.
If you use a full or partial path for pathName, see Path Separators on page III-400 for details on forming the path.

\section*{Flags}
/C Saves an experiment copy (valid only when fileName or pathName is provided or both if experiment is Untitled).
/ \(\mathrm{F}=\{\) format, unpackedExpFolderNameStr, unpackedExpFolderMode\}
Specifies the experiment file format.
See Experiment File Format below for details.
\(/ \mathrm{P}=\) pathName \(\quad\) Specifies folder in which to save the experiment. pathName is the name of an existing symbolic path.

\section*{Details}

SaveExperiment acts like the Save menu command in the File menu. If the experiment is associated with an already saved file, then SaveExperiment with no parameters will simply save the current experiment. If the experiment resides only in memory and has not yet been saved, then a dialog will be presented unless the path and file name are specified.
If you use a full path in the name you will not need the /P flag. If instead you use \(/ \mathrm{P}=\) pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd: Folder1:" or "C: \(\backslash \backslash\) Folder \(1 \backslash \backslash\) ". See Symbolic Paths on page II-34 for details.

\section*{Experiment File Format}

For background information on experiment file formats, see Experiments on page II-29.
The /F flag was added in Igor Pro 6.23 to provide control of the file format of a previously-unsaved experiment independent of the user's preferences as set in the Experiment Settings section of the Miscellaneous Settings dialog. It also allows you to save a previously-saved experiment using a different experiment file format.
If you just want to save the current experiment in its current format, you don't need to use /F.
If you use \(/ F\), you must fully-specify the location of the experiment file through the \(/ \mathrm{P}\) flag and the fileName parameter or through fileName alone if it contains a full path.
The format parameter controls the experiment file format used by SaveExperiment:
```

format =-1: Default format.
format =0: Unpacked experiment file
format =1: Packed experiment file

```

If /F is omitted or if format is -1 then the experiment is saved in its current format or, if it was never saved to disk, in the format specified in the Experiment Settings section of the Miscellaneous Settings dialog.
If format \(=0\), the experiment is saved in unpacked experiment file format. fileName must end with ".uxp" or ".uxt".

If format \(=1\), the experiment is saved in packed experiment file format. fileName must end with ".pxp" or ".pxt".

\section*{Unpacked Experiment Folder}

The unpacked experiment folder is the folder in which wave files, the history file, the variables file, and other experiment files are stored for an unpacked experiment. See Saving as an Unpacked Experiment File on page II-30 for details.

The /F unpackedExpFolderNameStr parameter specifies the name of the experiment folder for an unpacked experiment. It contains a folder name, not a full or partial path. It is ignored unless saving in unpacked experiment format.
The unpacked experiment folder is created in the same directory as the experiment file.
If / \(\mathrm{F}=0\) is used and unpackedExpFolderNameStr is "" then the experiment folder name is the same as the experiment file name with the extension removed and a space and "Folder" added.

If the specified unpacked experiment folder already exists and is the current experiment's unpacked experiment folder, it is reused. "Reuse" means that SaveExperiment saves files in the unpacked experiment folder, possibly overwriting files already in it, but does not delete any files or folders already in it.
The unpackedExpFolderMode parameter controls what happens if the folder to be used as the unpacked experiment folder already exists and is not the current experiment's unpacked experiment folder:
unpackedExpFolderMode=0: SaveExperiment returns an error.
unpackedExpFolderMode=1: SaveExperiment displays a dialog asking the user if it is OK to reuse the folder. If the user answers yes, the operation proceeds. Otherwise, it returns an error.
unpackedExpFolderMode=2: SaveExperiment reuses the folder without asking the user.

Warning: If you pass 2 for unpackedExpFolderMode, files and folders in the unpacked experiment folder may be overwritten without the user's express permission.

\section*{SaveGraphCopy}

SaveGraphCopy [flags] [as fileNameStr]
The SaveGraphCopy operation saves a graph and its waves in an Igor packed experiment file.

\section*{Parameters}

The file to be written is specified by fileNameStr and \(/ \mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case / P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.

\section*{Flags}
/I Presents a dialog from which you can specify file name and folder.
/O
Overwrites file if it exists already.
\(/ \mathrm{P}=\) pathName Specifies the folder to store the file in. pathName is the name of an existing symbolic path.
\(/ \mathrm{W}=\) winName \(\quad\) winName is the name of the graph to be saved. If / W is omitted or if winName is " " , the top graph is saved.
/Z Errors are not fatal and error dialogs are suppressed. See Details.

\section*{Details}

The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see Merging Experiments on page II-32). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the graph starting from the "top" data folder, which is the data folder that encloses all waves displayed in the graph. The top data folder becomes the root data folder of the resulting experiment file. Only the graph, its waves, dashed line settings, and any pictures used in the graph are saved in the packed experiment file, not procedures, variables, strings or any other objects in the experiment.
SaveGraphCopy does not work well with graphs containing controls. First, the controls may depend on waves, variables or FIFOs (for chart controls) that SaveGraphCopy will not save. Second, controls typically rely on procedures which are not saved by SaveGraphCopy.
SaveGraphCopy does not know about dependencies. If a graph contains a wave, wave0, that is dependent on another wave, wave 1 which is not in the graph, SaveGraphCopy will save wave 0 but not wave1. When the saved experiment is open, there will be a broken dependency.
SaveGraphCopy sets the variable V_flag to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check V_flag after calling SaveGraphCopy.

The SaveData operation also has the ability to save data from a graph to a packed experiment file. SaveData is more complex but a bit more flexible than SaveGraphCopy.

\section*{Examples}

This function saves all graphs in the experiment to individual packed experiment files.
```

Function SaveAllGraphsToPackedFiles (pathName)
String pathName // Name of an Igor symbolic path.
String graphName
Variable index
index = 0
do
graphName = WinName(index, 1)
if (strlen(graphName) == 0)
break
endif
String fileName
sprintf fileName, "%s.pxp", graphName
SaveGraphCopy/P=$pathName/W=$graphName as fileName
index += 1
while(1)
End
See Also
SaveTableCopy and SaveData operations; Merging Experiments on page II-32.

```

\section*{SaveNotebook}

SaveNotebook [flags] notebookName [as fileNameStr]
The SaveNotebook operation saves the named notebook.

\section*{Parameters}
notebookName is either kwTopWin for the top notebook window, the name of a notebook window or a hostchild specification (an hcSpec) such as Panel0\#nb0. See Subwindow Syntax on page III-97 for details on host-child specifications.
If notebookName is an host-child specification, /S must be used and saveType must be 3 or higher.
The file to be written is specified by fileNameStr and \(/ \mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case / P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.

\section*{Flags}
\(/ \mathrm{H}=\{\) encodingName, writeParagraphProperties, writeCharacterProperties, PNGOrJPEG, quality, bitDepth\}
Controls the creation of an HTML file.
encodingName specifies the HTML file encoding. The recommended value for most purposes is "UTF-8". See Details for more information.
writeParagraphProperties determines what paragraph properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:
Bit 0: Write paragraph alignment.
Bit 1: Write first indent.
Bit 2: Write minimum line spacing.
Bit 3: Write space-before and space-after paragraph.
All other bits are reserved for future use and should be set to zero.
/I
/M=messageStr
/O
/P=pathName
\(/ \mathrm{S}=\) saveType \(\quad\) Controls the type of save.
saveType=1: \(\quad\) Normal save (default).
saveType=2: Save-as.
saveType=3: Save-a-copy.
saveType=4: Export as RTF (Rich Text Format).
saveType=5: Export as HTML (Hypertext Markup Language).
saveType=6: Export as plain text.
save Type=7: \(\quad\) Export as formatted notebook.

\section*{Details}

Interactive (/I) means that Igor displays the Save, Save As, or Save a Copy dialog.
The save will be interactive under the following conditions:
- You include the /I flag and the saveType is 2, 3, 4, 5, 6, or 7 .
- saveType is \(2,3,4,5,6\), or 7 and you do not specify the path or filename.

If the saveType is normal and the notebook has previously been saved to a file then the /I flag, the path and file name that you specify, if any, are ignored and the notebook is saved to its associated file without user intervention.

The full path to the saved file is stored in the string S_path. If the save was unsuccessful, S_path will be " ". If you use \(/ \mathrm{P}=\) pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd: Folder1:" or "C: \(\backslash \backslash\) Folder \(1 \backslash \backslash\) ". See Symbolic Paths on page II-34 for details.
For background information on writing RTF files, see Import and Export Via Rich Text Format Files on page III-24.
For background information on writing HTML files, see Exporting a Notebook as HTML on page III-26.
For background information regarding the HTML encodingName parameter, see HTML Character
Encoding on page III-29. This table lists how Igor responds to various values for this parameter:
"UTF-8" Encodes the document using the UTF-8 encoding which is a kind of packed Unicode. It is good for documents that contain non-Roman text, such as symbols and Asian text. This is the best choice for most documents.
"UTF-2" Encodes the document using the UTF-2 encoding which is 16-bit Unicode. It is generally not recommended because some browsers don't support it. However, as time goes by, browser support will improve.
"Native" Writes the document using the native character set of the operating system. On Macintosh, this equates to "mac" (the Mac OS Roman character set). On Windows, it equates to "Windows-1252" (the Windows Western character set). This may give better results than UTF-8 for some documents and with some browsers but you should use it only if you determine that UTF-8 doesn't work for your application.
" " Writes the document using the native character set of the operating system but omits the Content-Type meta tag.

In addition, you can provide any other string of 63 or fewer bytes. The main use for this is for documents that are primarily in an Asian language. For example, if your document is primarily in Japanese, then the characters in the document are already in the Shift-JIS encoding. You can specify "Shift-JIS" as the encodingName. This uses "Shift-JIS" in the Content-Type meta tag and to write the text out without any special encoding. The main advantage of this technique over the UTF-8 encoding is that a file written using Shift-JIS can be edited in Igor or other commonly-available text editors while UTF-8 can not.
When creating an HTML file, SaveNotebook can write pictures using the PNG or JPEG graphics formats. PNG support is built into Igor Pro. Built-in JPEG support was added in Igor Pro 5. Previously Igor used QuickTime to write JPEG files. It still does if QuickTime is available but if not, it uses built-in routines. For most applications, the only reason to use JPEG rather than PNG is that some old web browsers do not support PNG.

\section*{See Also}

Chapter III-1, Notebooks.
Setting Bit Parameters on page IV-12 for further details about bit settings.

\section*{SavePackagePreferences}

SavePackagePreferences [/FLSH=flush /KILL /P=pathName] packageName, prefsFileName, recordID, prefsstruct
The SavePackagePreferences operation saves preference data in the specified structure so that it can be accessed later via by the LoadPackagePreferences operation.

Note: The package preferences structure must not use fields of type Variable, String, WAVE, NVAR, SVAR or FUNCREF because these fields refer to data that may not exist when LoadPackagePreferences is called.

The structure can use fields of type char, uchar, int16, uint16, int32, uint32, float and double as well as fixedsize arrays of these types and substructures with fields of these types.

The data is stored in memory and by default flushed to disk when the current experiment is saved or closed and when Igor quits.
If the \(/ \mathrm{P}\) flag is present then the location on disk of the preference file is determined by pathName and prefsFileName. However in the usual case the/P flag will be omitted and the preference file is located in a file named prefsFileName in a directory named packageName in the Packages directory in Igor's preferences directory.
Note: You must choose a very distinctive name for packageName as this is the only thing preventing collisions between your package and someone else's package.

See Saving Package Preferences on page IV-231 for background information and examples.

\section*{Parameters}
packageName is the name of your package of Igor procedures. It is limited to 31 characters and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else's package.
prefsFileName is the name of a preference file to be saved by SavePackagePreferences. It should include an extension, typically ".bin".
prefsStruct is the structure containing the data to be saved in the preference file on disk.
recordID is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct recordIDs to identify which structure you want to save. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the recordID.

\section*{Flags}
/FLSH=flush Controls when the data is actually written to the preference file:
flush=0: The data will be flushed to disk when the current experiment is saved, reverted or closed or when Igor quits. This is the default behavior used when/FLSH is omitted and is recommended for most purposes.
flush=1: The data is flushed to disk immediately.
/KILL Instead of saving prefsStruct under the specified record ID, that record is deleted from the package's preference if it exists. If it does not exist, nothing is done and no error is returned.
\(/ \mathrm{P}=\) pathName \(\quad\) Specifies the directory in which to save the file specified by prefsFileName.
pathName is the name of an existing symbolic path. See Symbolic Paths on page II-34 for details.
\(/ \mathrm{P}=\$<\) empty string variable> acts as if the / P flag were omitted.

\section*{Details}

SavePackagePreferences sets the following output variables:
V_flag Set to 0 if preferences were successfully saved or to a nonzero error code if they were not saved. The latter case is unlikely and would indicate some kind of corruption such as if Igor's preferences directory were deleted.

V_structSize Set to the size in bytes of prefsStruct. This may be useful in handling structure version changes.

\section*{Example}

See the example under Saving Package Preferences in a Special-Format Binary File on page IV-232.

\section*{See Also \\ LoadPackagePreferences.}

\section*{SavePICT}

SavePICT [flags] [as fileNameStr]
The SavePICT operation creates a picture file representing the top graph, table or layout. The picture file can be opened by many word processing, drawing, and page layout programs.
To use any of the QuickTime graphic export formats (/T flag), you will need to have QuickTime 4 or later installed (full install) in your system.

\section*{Parameters}

The file to be written is specified by fileNameStr and \(/ \mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case / P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.
If you omit fileNameStr but include / \(\mathrm{P}=\) pathName, SavePICT writes the file using a default file name. The default file name is the window name followed by an extension, such as ".png", ".emf" or ".PICT", that depends on the graphic format being exported.
If you specify the file name as "Clipboard", and do not specify a / \(\mathrm{P}=p a t h N a m e\), Igor copies the picture to the Clipboard, rather than to a file. EPS is a file-only format and can not be stored in the clipboard. Also QuickTime formats (/T) can not be stored in the clipboard.
If you specify the file name as "_string_" the output will be saved into a string variable named S_Value, which is used with the ListBox \(\overline{\text { binary }}\) bitmap display mode.
If you use the special name _PictGallery_ with the /P flag, then the picture will be stored in Igor's picture collection (see Pictures on page III-423) with the name you provide via fileNameStr. QuickTime formats (/T) can not be put in the picture collection. This feature was added in support of making movies using the /PICT flag with NewMovie. It requires Igor Pro 6.12 or later.

\section*{Flags}
\(/ \mathrm{B}=d p i \quad\) Controls image resolution in dots-per-inch (dpi). The legal values for \(d p i\) are \(n^{*} 72\) where \(n\) can be from 1 to 8 . The actual image \(d p i\) is not used. Igor calculates \(n\) from your value of \(d p i\) and then multiplies \(n\) by your computer's screen resolution. This is because bitmap images that are not an integer multiple of the screen resolution look quite bad. The /B flag can be used with QuickTime export types (/T).
Also see the /RES flag.
\(/ C=c \quad\) Specifies color mode.
\(c=0: \quad\) Black and white.
\(c=1: \quad\) RGB color (default).
\(c=2: \quad\) CMYK color (EPS and native TIFF only).
\(/ \mathrm{D}=\mathrm{d} \quad\) Specifies bit depth for QuickTime image export. \(d\) may be 1, 8, 16, 24 (default), or 32 bits. Not all formats use depth. An intermediate picture at the current screen depth is used and may limit the quality.
\(/ E=e \quad\) Sets graphics format used when exporting a graphic. See Details for formats. See also Chapter III-5, Exporting Graphics (Macintosh), or Chapter III-6, Exporting Graphics (Windows), for a description of these modes and when to use them.
\begin{tabular}{|c|c|}
\hline \multirow[t]{4}{*}{\(/ \mathrm{EF}=e\)} & Sets font embedding. \\
\hline & \(e=0: \quad\) No font embedding. \\
\hline & \(e=1: \quad\) Embed nonstandard fonts. \\
\hline & \(e=2: \quad\) Embed all fonts. \\
\hline /I & Specifies that / W coordinates are inches. \\
\hline /M & Specifies that/W coordinates are centimeters. \\
\hline / \(\mathrm{N}=\) winSpec & Deprecated: Igor Pro 4.09-compatibility version of /WIN. \\
\hline /O & Overwrites file if it exists. \\
\hline / \(\mathrm{P}=\) pathName & Saves file into a folder specified by pathName, which is the name of an existing symbolic path. \\
\hline /PICT \(=\) pict & Saves specified named picture rather than the target window. Native format of the picture is used and all format flags are ignored. \\
\hline \(/ \mathrm{PLL}=p\) & Specifies Postscript language level when used in conjunction with EPS export. \\
\hline & \(p=1: \quad\) For very old Postscript printers. \\
\hline & \(p=2: \quad\) For all other uses (default). \\
\hline \(/ \mathrm{Q}=q\) & Sets quality factor ( 0.0 is lowest, 1.0 is highest). Default is dependent on individual format. Used only by lossy formats such as QuickTime JPEG. \\
\hline \(/ \mathrm{R}=\) resID & Saves the picture in a resource fork with resource ID=resID, where resID is between 1 and 32767. \\
\hline & This flag is meaningful on Macintosh only. It is ignored on Windows. Also, it does not work with EPS or PNG graphics. \\
\hline \(/ \mathrm{RES}=d p i\) & Controls the resolution of image formats in dots-per-inch. Unlike the similar /B flag, the value for /RES is the actual output resolution and is useful when your publisher demands a specific resolution. The /RES flag can be used with QuickTime export types (/T). \\
\hline /S & Suppresses the preview that is normally included with an EPS file. \\
\hline \multirow[t]{4}{*}{\(/ \mathrm{SNAP}=\) S} & Saves a snapshot (screen dump) of a graph or panel window. \\
\hline & \(s=1: \quad\) Include all controls in capture. \\
\hline & \(s=2\) : Capture only window data content. \\
\hline & Snapshot mode is available only for graphs and panels and only for bitmap export formats PNG, JPEG, and TIFF at screen resolution. When using/W to specify the size of a graph, the capture is sized to fit within the specified rectangle while maintaining the window aspect ratio. Coordinates used with / W are in pixels. \\
\hline \(/ \mathrm{T}=t\) & Specifies a QuickTime export type. An error will be generated if QuickTime is not present or if the desired export type is not available. \(t\) is a string containing a 4 character code for the export type. Valid types include "PNGf" for PNG, "TIFF" for TIFF, "JPEG" for JPEG. GIF is "GIFf" but is not currently supported by QuickTime presumably due to the patent situation. This might change in the future if Apple or a third party provides a component for GIF writing. \\
\hline \multirow[t]{2}{*}{/TRAN[=1 or 0 ]} & Makes white background areas transparent using an RGBA type PNG when used with native PNG export of graphs or page layouts. In layouts, only embedded graphs and textboxes marked as transparent will be transparent. Nonembedded graphs, pictures, and tables will be opaque. PNG transparency is not honored when placed in Igor. \\
\hline & On Macintosh in new graphics mode (see Graphics Technology on page III-423) under some versions of OS X, you may find text is not properly transparent. In this instance, you can use /TRAN=2 to turn off font smoothing which is the source of the problem. \\
\hline
\end{tabular}
/W=(left,top,right,bottom)
Specifies the size of the picture when exporting a graph. If /W is omitted, it uses the graph window size.
When exporting a page layout, specifies the part of the page to export. Only objects that fall completely within the specified area are exported. If / W is omitted, the area of the layout containing objects is exported. Specify \(/ W=(0,0,0,0)\) to use a full page size.
Coordinates for \(/ \mathrm{W}\) are in points unless \(/ \mathrm{I}\) or \(/ \mathrm{M}\) are specified before \(/ \mathrm{W}\).
/WIN=winSpec Saves the named window or subwindow. winSpec can be just a window name, or a window name following by a " \(\#\) " character and the name of the subwindow, as in /WIN=Panelo\#GO.
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

\section*{Details}

SavePICT sets the variable V_flag to 0 if the operation succeeds or to a nonzero error code if it fails.
If you specify a path using the \(/ \mathrm{P}=\) pathName flag, then Igor saves the file in the folder identified by the path. Note that pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd: Folder1:" or "C : \\Folder1 \\". See Symbolic Paths on page II-34 for details. Otherwise, with no path specified, Igor presents a standard save dialog to let you specify where the file is to be saved.
When writing an EPS file, it normally includes a screen preview. On Macintosh, this is a PICT in the resource fork of the file. On Windows, it is a TIFF embedded in the EPS file. Using the /S flag, you can suppress the preview to save disk space, to work around a program that is confused by the preview, or to create a completely platform-neutral file.
On Macintosh, the picture is normally written to the data fork of the file. Most applications read it from the data fork. Some, however, read PICTs from the resource fork. If you use \(/ \mathrm{R}=\) resID, it writes the PICT to the resource fork of the file, using resID as the resource ID.
Graphics formats, specified via / E , are as follows:
\begin{tabular}{|c|c|c|}
\hline /E Value & Macintosh File Format & Windows File Format \\
\hline -8 & PDF file. & PDF file. \\
\hline -7 & \multicolumn{2}{|l|}{TIFF file. Lossless but larger file than PNG; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. You can specify the resolution with the /B or /RES flag. Cross-platform compatible.} \\
\hline -6 & \multicolumn{2}{|l|}{JPEG file. Lossy compression; best used for grayscale and color images with smooth tones. The /Q flag specifies compression quality and the/B or /RES flag sets the resolution. Cross-platform compatible.} \\
\hline -5 & \multicolumn{2}{|l|}{PNG (Portable Network Graphics) file. Lossless compression; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi . Specify the resolution with /B or /RES. Cross-platform compatible.} \\
\hline -4 & High resolution bitmap PICT file. Default resolution is 288 dpi. Specify the resolution with /B or /RES. & Device-independent bitmap file (DIB). Default resolution is 4 x screen resolution. Specify the resolution with /B or /RES. \\
\hline -3 & Encapsulated PostScript (EPS) file. & Encapsulated PostScript (EPS) file. \\
\hline & Use /S to suppress the screen preview if exporting to Latex. & Use /S to suppress the screen preview if exporting to Latex. \\
\hline -2 & Quartz PDF. & High-resolution Enhanced Metafile (EMF). \\
\hline -1 & Quartz PDF (was PostScript PICT). & Obsolete (was PostScript-enhanced metafile). \\
\hline 0 & Quartz PDF (was PostScript PICT with QuickDraw text). & Obsolete (was PostScript-enhanced metafile). \\
\hline 1 & Low resolution Quartz PDF at 1x normal siz & High-resolution Enhanced Metafile (EMF). \\
\hline
\end{tabular}
\begin{tabular}{lll} 
/E Value & Macintosh File Format & Windows File Format \\
\hline 2 & Low resolution Quartz PDF at 2x normal size. & High-resolution Enhanced Metafile (EMF). \\
4 & Low resolution Quartz PDF at 4x normal size. & High-resolution Enhanced Metafile (EMF). \\
8 & Low resolution Quartz PDF at \(8 \times\) normal size. & High-resolution Enhanced Metafile (EMF). \\
\hline
\end{tabular}

Prior to Igor Pro 6.1, e=-2 on Macintosh created a high-resolution Macintosh PICT.
The low resolution PDF formats on Macintosh are probably not useful and are just placeholders for compatibility with old procedures. Prior to Igor Pro 6.1, \(e=1, e=2, e=4\) and \(e=8\) created Macintosh PICTs on Macintosh.
On Windows, for \(e>=1\), Enhanced Metafile (EMF) is used except for graph and table windows when old graphics mode is in effect (see Graphics Technology on page III-423) in which case Windows Metafile (WMF) is used at \(e\) times screen resolution.

\section*{See Also}

The ImageSave operation for saving waves as PICTs and other image file formats. The LoadPICT operation.
See Chapter III-5, Exporting Graphics (Macintosh), or Chapter III-6, Exporting Graphics (Windows), for a description of the /E modes.

\section*{SaveTableCopy}

SaveTableCopy [flags] [as fileNameStr]
The SaveTableCopy operation saves a copy of the data displayed in a table on disk. The saved file can be an Igor packed experiment file, a tab-delimited text file, or a comma-separated values text file.
When saving as text, the data format matches the format shown in the table. Keep in mind that this will cause truncation if the underlying data has more precision than shown in the table. The point column is never saved.
To save data as text with full precision, use the Save operation.
When saving 3D and 4D waves as text, only the visible layer is saved. To save the entirety of a 3D or 4D wave, use the Save operation.

\section*{Parameters}

The file to be written is specified by fileNameStr and \(/ \mathrm{P}=\) pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-400 for details on forming the path.
Flags
\(/ \mathrm{A}=a \quad\) Appends data to the file rather than overwriting.
\(a=0: \quad\) Does not append.
\(a=1: \quad\) Appends to the file with a blank line before the appended data.
\(a=2: \quad\) Appends to the file with no blank line before the appended data.
/A applies when saving text files and is ignored when saving packed experiment
files.
If the file does not exist, a new file is created and /A has no effect.
/I Presents a dialog from which you can specify file name and folder.
\(/ \mathrm{M}=\) termStr \(\quad\) Specifies the terminator character or characters to use at the end of each line of text. The default is \(/ M=\) " \(\backslash r\) " on Macintosh and \(/ M=" \backslash r \backslash n\) " on Windows; it is used when \(/ \mathrm{M}\) is omitted. To use the Unix convention, just a linefeed, specify \(/ \mathrm{M}=\mathrm{"} \backslash \mathrm{n}\) ".
\(/ \mathrm{N}=n\)

\section*{/O}
/ \(\mathrm{P}=\) pathName
\(/ S=s\)
/T=saveType
/W= winName

Specifies whether to use column names, titles, or dimension labels. \(n\) is a bitwise parameter with the bits defined as follows:
Bit 0: Include column names or titles. The column title is included if it is not empty. If it is empty, the column name is included.
Bit 1: Include horizontal dimension labels if they are showing in the table.
The default setting for \(n\) is 1 . All other bits are reserved and must be zero.
Overwrites file if it exists already.
Specifies the folder to store the file in. pathName is the name of an existing symbolic path.
Saves all of the data in the table ( \(s=0\); default) or the selection only ( \(s=1\) ).
/ S applies when saving text files and is ignored when saving packed experiment files.
Specifies the file format of the saved table.
saveType=0: \(\quad\) Packed experiment file.
saveType=1: \(\quad\) Tab-delimited text file.
saveType=2: \(\quad\) Comma-separated values text file.
saveType=3: Space-delimited values text file.
winName is the name of the table to be saved. If / W is omitted or if winName is " ", the top table is saved.
/Z Errors are not fatal and error dialogs are suppressed. See Details.

\section*{Details}

The main uses for saving a table as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see Merging Experiments on page II-32). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the table starting from the "top" data folder, which is the data folder that encloses all waves displayed in the table. The top data folder becomes the root data folder of the resulting experiment file. Only the table and its waves are saved in the packed experiment file, not variables or strings or any other objects in the experiment.
SaveTableCopy does not know about dependencies. If a table contains a wave, wave0, that is dependent on another wave, wave1 which is not in the table, SaveTableCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.
The main use for saving as a tab or comma-delimited text file is for exporting data to another program.
When calling SaveTableCopy from a procedure, you should call DoUpdate before calling SaveTable copy. This insures that the table is up-to-date if your procedure has redimensioned or otherwise changed the number of points in the waves in the table.
SaveTableCopy sets the variable V_flag to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check V_flag after calling SaveTableCopy.
The SaveData operation also has the ability to save a table to a packed experiment file. SaveData is more complex but a bit more flexible than SaveTableCopy.

\section*{Examples}

This function saves all tables to a single tab-delimited text file.
```

Function SaveAllTablesToTextFile(pathName, fileName)
String pathName // Name of an Igor symbolic path.
String fileName
String tableName
Variable index
index = 0
do
tableName = WinName(index, 2)
if (strlen(tableName) == 0)

```
```

            break
            endif
            SaveTableCopy/P=$pathName/W=$tableName/T=1/A=1 as fileName
            index += 1
        while(1)
    End
See Also
SaveGraphCopy and SaveData operations; Merging Experiments on page II-32.

```

\section*{sawtooth}

\section*{sawtooth (num)}

The sawtooth function returns \(((n u m+\mathrm{n} 2 \pi) \bmod 2 \pi) / 2 \pi\) where n is used to correct if \(n u m\) is negative. Sawtooth is used to create arbitrary periodic waveforms like sine and cosine.

\section*{Examples}
wave1 = sawtooth (x)
creates a sawtooth in wave 1 whose \(Y\) values range from 0 to 1 as its \(X\) values go through \(2 \pi\) units.
wave1 = exp(sawtooth(x))
creates a series of exponentials in wave 1 of amplitude \(\exp (1)\) and period \(2 \pi\).
You can also use sawtooth to create periodic repetitions of a given part of a wave:
wave1 = wave2 (sawtooth (x))
creates a periodic repetition of wave 2 in wave 1 given the correct \(X\) scaling for the waves.

\section*{ScreenResolution}

\section*{ScreenResolution}

The ScreenResolution function returns the logical resolution of your video display screen in dots per inch (dpi). On Macintosh this is always 72. On Windows it is usually 96 (small fonts) or 120 (large fonts).

\section*{Examples}
// 72 is the number of points in an inch which is constant.
Variable pixels = numPoints * (ScreenResolution/72) // Convert points to pixels
Variable points \(=\) numPixels * (72/ScreenResolution) // Convert pixels to points
sec
sec (angle)
The sec function returns the secant of angle which is in radians:
\[
\sec (x)=\frac{1}{\cos (x)}
\]

In complex expressions, angle is complex, and sec(angle) returns a complex value.
See Also
sin, cos, tan, csc, cot

\section*{Secs2Date}

Secs2Date (seconds, format [, sep])
The Secs2Date function returns a string containing a date.
With format values 0,1 , and 2 , the formatting of dates depends on your operating system and on your preferences entered in the Date \& Time control panel (Macintosh) or the Regional Settings control panel (Windows).
If format is -1 , the format is independent of the operating system. The fixed-length format is "day /month /year (dayOfWeekNum)", where dayOfWeekNum is 1 for Sunday, 2 for Monday... and 7 for Saturday.
If format is -2 , the format is YYYY-MM-DD.

The optional sep parameter affects format -2 only. If sep is omitted, the separator character is "-". Otherwise, sep specifies the separator character.

\section*{Parameters}
seconds is the number of seconds from \(1 / 1 / 1904\) to the date to be returned.
format is a number between -2 and 2 which specifies how the date is to be constructed.

\section*{Examples}
```

Print Secs2Date(DateTime,-2) // 1993-03-14
Print Secs2Date(DateTime,-2,"/") // 1993/03/14
Print Secs2Date(DateTime,-1) // 15/03/1993 (2)
Print Secs2Date(DateTime,0) // 3/15/93
Print Secs2Date(DateTime,1) // Monday, March 15, 1993
Print Secs2Date(DateTime,2) // Mon, Mar 15, 1993

```

\section*{See Also}

For further discussion of how Igor represents dates, see Date/Time Waves on page II-102.
The date, date2secs and DateTime functions.

\section*{Secs2Time}

Secs 2 Time(seconds, format, [fracDigits])
The Secs2Time function returns a string containing a time.

\section*{Parameters}
seconds is the number of seconds from \(1 / 1 / 1904\) to the time to be returned.
format is a number between 0 and 5 that specifies how the time is to be constructed. It is interpreted as follows:
0: \(\quad\) Normal time, no seconds.
1: Normal time, with seconds.
2: \(\quad\) Military time, no seconds.
3: Military time, with seconds and optional fractional seconds.
4: Elapsed time, no seconds.
5: Elapsed time, with seconds and optional fractional seconds.
"Normal" formats (0 and 1) follow the preferred formatting of the short time format as set in the International control panel (Macintosh) or in the Regional and Language Options control panel (Windows). "Military" means that the hour is a number from 0 to 23 . Hours greater than 23 are wrapped.
"Elapsed" means that the hour is a number from -9999 to 9999 . The result for hours outside that range is undefined.

The fracDigits parameter is optional and specifies the number of digits of fractional seconds. The default value is 0 . The fracDigits parameter is ignored for format \(=0,1,2\), and 4.

\section*{Examples}
```

Print Secs2Time(DateTime,0) // prints 1:07 PM
Print Secs2Time(DateTime,1) // prints 1:07:28 PM
Print Secs2Time(DateTime,2) // prints 13:07
Print Secs2Time(DateTime,3) // prints 13:07:29
Print Secs2Time(30*60*60+45*60+55,4) // Prints 30:45
Print Secs2Time(30*60*60+45*60+55,5) // Prints 30:45:55

```

\section*{See Also}

For a discussion of how Igor represents dates, see Date/Time Waves on page II-102.
The Secs2Date, date, date2secs and DateTime functions. Also, Operators on page IV-5 for ?: details.

\section*{SelectNumber}

SelectNumber(whichOne, vall, val2 [, val3])
The SelectNumber function returns one of val1, val2, or (optionally) val3 based on the value of whichOne.
SelectNumber(whichOne, val1, val2) returns val1 if whichOne is zero, else it returns val2.
SelectNumber(whichOne, val1, val2, val3) returns val1 if whichOne is negative, val2 if whichOne is zero, or val3 if whichOne is positive.
Details
SelectNumber works with complex (or real)val1, val2, and val3 when the result is assigned to a complex wave or variable. (Print expects a real result, see the "causes error" example, below).
If whichOne is NaN , then NaN is returned.
whichOne must always be a real value.
Unlike the ? : conditional operator, SelectNumber always evaluates all of the numeric expression parameters val1, val2, ...
SelectNumber works in a macro, whereas the conditional operator does not.

\section*{Examples}
```

Print SelectNumber(0,1,2) // prints 1
Print SelectNumber (0,1,2,3) // prints 2
wv=SelectNumber(numtype(wv[p])==2,wv[p],0) // replace NaNs with zeros
// chooses among complex values
Variable/C cx= SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))
// causes error because Print expects a real value (not complex)
Print SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))
// The real function expects a complex result
Print real(SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1)))

```

\section*{See Also}

The SelectString and limit functions, and Waveform Arithmetic and Assignments on page II-94. Also,
Operators on page IV-5 for details about the ?: operator.

\section*{SelectString}

SelectString (whichOne, str1, str2 [, str3])
The SelectString function returns one of \(\operatorname{str1} 1, \operatorname{str} 2\), or (optionally) \(\operatorname{str} 3\) based on the value of whichOne.
SelectString(whichOne, str1, str2) returns str1 if whichOne is zero, else it returns str2.
SelectString(whichOne, str1, str2, str3) returns str1 if whichOne is negative, str2 if whichOne is zero, or str3 if whichOne is positive.

\section*{Details}

If whichOne is NaN , then " " is returned.
whichOne must always be a real value.
Unlike the ? : conditional operator, SelectString always evaluates all of the string expression parameters str1, str2, ...
SelectString works in a macro, whereas the conditional operator does not.

\section*{Examples}

Print SelectString(0,"hello","there") // prints "hello"
Print SelectString(1,"hello","there") // prints "there"
Print SelectString(-3,"hello","there","jack") // prints "hello"
Print SelectString(0,"hello","there","jack") // prints "there"
Print SelectString(100,"hello","there","jack") // prints "jack"

\section*{See Also}

The SelectNumber function and String Expressions on page IV-12. Also, Operators on page IV-5 for details about the ?: operator.

\section*{SetActiveSubwindow}

\section*{SetActiveSubwindow subWinSpec}

The SetActiveSubwindow operation specifies the subwindow that is to be activated. This operation is mainly for use by recreation macros.

\section*{Parameters}
subWinSpec specifies an existing subwindow. See Subwindow Syntax on page III-97 for details on subwindow specifications.
Use _endfloat_for subWinSpec to make a newly-created floating panel not be the default target.

\section*{SetAxis}

SetAxis [flags] axisName [, num1, num2]
The SetAxis operation sets the extent (or "range") of the named axis.

\section*{Parameters}
axisName is usually "left", "right", "top" or "bottom", but it can also be the name of a free axis, such as "vertCrossing".

If axisName is a vertical axis such as "left" or "right" then num1 sets the bottom end of the axis and num2 sets the top end of the axis.
If axisName is a horizontal axis such as "top" or "bottom" then num1 sets the left end of the axis and num2 sets the right end of the axis.
You can flip the graph by reversing num1 and num2 (or by using /A/R). This is particularly useful for images, because Igor plots an image inverted.
If you pass * (asterisk) for num1 and/or num2 then the corresponding end of the axis will be autoscaled.

\section*{Flags}
\begin{tabular}{|c|c|}
\hline \multirow[t]{4}{*}{/ \(\mathrm{A}[=a]\)} & Autoscale axis (when used, num1, num2 should be omitted). \\
\hline & \(a=0\) : No autoscale. Same as no /A flag. \\
\hline & \(a=1: \quad\) Normal autoscale. Same as /A. \\
\hline & \(a=2\) : \(\quad\) Autoscale Y axis to a subset of the data defined by the current X axis range. \\
\hline \multirow[t]{5}{*}{\(/ \mathrm{E}=z\)} & Sets the treatment of zero when the axis is in autoscale mode. \\
\hline & \(z=0\) : Normal mode where zero is not treated special. \\
\hline & \(z=1\) : Forces the smaller end of the axis to be set to zero (autoscale from zero). \\
\hline & \(z=2: \quad\) Axis is symmetric about zero. \\
\hline & \(z=3\) : If the data is unipolar (all positive or all negative), this behaves like / \(E=1\) (autoscale from zero). If the data is bipolar, it behaves like / \(\mathrm{E}=0\) (normal autoscaling). \\
\hline \multirow[t]{4}{*}{\(/ \mathrm{N}=n\)} & Sets the algorithm for axis autoscaling. \\
\hline & \(n=0\) : Normal mode; sets the axis limits equal to the data limits. \\
\hline & \(n=1\) : Picks nice values for the axis limits. \\
\hline & \(n=2\) : Picks nice values; also ensures that the data is inset from the axis ends. \\
\hline /R & Reverses the autoscaled axis (smaller values at the left for horizontal axes, at the top for vertical axes) when used with /A. Although it only has an effect for autoscale, it can be used with nonautoscale version of SetAxis so that the next time the Axis Range tab is used the "reverse axis" checkbox will already be set. \\
\hline /W=winName & Sets axes in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. \\
\hline
\end{tabular}

When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
/Z No error reporting if named axis doesn't exist in a style macro.

\section*{SetBackground}

\section*{SetBackground numericExpression}

The SetBackground operation sets numericExpression as the current unnamed background task.
SetBackground works only with the unnamed background task. New code should used named background tasks instead. See Background Tasks on page IV-285 for details.
The background task runs while Igor is not busy with other things. Normally, there won't be a background task. The most common use for the background task is to monitor or drive a continuous data acquisition process.

\section*{Parameters}
numericExpression is a single precision numeric expression that Igor executes when it isn't doing anything else.

\section*{Details}
numericExpression is expected to return one of three numeric values:
0: Background task executed normally.
1: Background task wants to stop.
2: Background task encountered error and wants to stop.
Usually the expression will be a call to a user-defined numeric function or external function to drive or monitor data acquisition. The expression should be designed to execute very quickly and it should not present a dialog to the user nor should it create or destroy windows. Generally, it should do nothing more than store data into waves or variables. You can use Igor's dependency mechanism to perform more extensive tasks.
SetBackground designates the background task but you must use CtrlBackground to start it. You can also use KillBackground to stop it. You can not call SetBackground from the background function itself.

\section*{See Also}

The BackgroundInfo, CtrlBackground, CtrlNamedBackground, KillBackground, and SetProcessSleep operations, and Background Tasks on page IV-285.

\section*{SetDashPattern}

SetDashPattern dashNumber, \(\{d 1, s 1[, d 2, s 2] \ldots\}\)
The SetDashPattern operation defines a dashed-line pattern for a user-defined dashed line. These dashed lines are used by the drawing tools and the Modify Waves Appearance dialog, and are elsewhere referred to as "line styles".

\section*{Parameters}
dashNumber specifies which dash pattern is to be set. It must be between 1 and 17. Dash pattern 0 is reserved for a solid line.

\(\{d 1, s 1[, d 2, s 2] \ldots\}\) defines the dash pattern. The dash pattern consists of 1 to 8 "dash,skip" pairs. Each pair consists of the number of drawn points followed by the number of skipped points.
\(d 1\) specifies the number of drawn points and \(s 1\) specifies the number of skipped points in the first
"dash,skip" pair. \(d 2\) and \(s 2\) specify the number of drawn and skipped points in the second pair and so on. Each draw or skip value must be between 1 and 127.

\section*{Details}

SetDashPattern updates all graphs, panels and layouts so that any dashed lines will be updated with the new pattern. If you repeatedly call SetDashPattern from within a macro, you should precede the commands with the PauseUpdate operation to prevent multiple updates (which would be slow).
Dashed lines may also be redefined by the Dashed Lines dialog which you can choose from the Misc menu.
The dashed line patterns are saved as part of the experiment. When a new experiment is opened, the preferred dash patterns are restored.
Some programs and printer drivers do not properly render dashed lines with many "dash,skip" pairs.

\section*{Examples}

Make test; Display test
SetDashPattern \(17,\{20,3,15,8\} \quad / /\) sets last dashed line pattern
ModifyGraph lstyle(test)=17
// apply pattern to trace

\section*{See Also}

PauseUpdate and ResumeUpdate operations, and Dashed Lines on page III-412.

\section*{SetDataFolder}

\section*{SetDataFolder dataFolderSpec}

The SetDataFolder operation sets the current data folder to the specified data folder.

\section*{Parameters}
dataFolderSpec can be a simple name (MyDataFolder), a path (root:MyDataFolder) or a string expression containing a name or path. It can also be a data folder reference created by the DFREF keyword or returned by GetDataFolderDFR.
If dataFolderSpec is a path it can be a partial path relative to the current data folder (:MyDataFolder) or an absolute path starting from root (root:MyDataFolder).

\section*{Examples}
```

SetDataFolder foo // Sets CDF to foo in the current data folder.
SetDataFolder :bar:foo // Sets CDF to foo in bar current data folder.
SetDataFolder root:foo // Sets CDF to foo in the root data folder.
String savedDF= GetDataFolder(1) // Remember CDF in a string.
NewDataFolder/O/S root:MyDataFolder // set CDF to a new data folder.
Variable/G newVariable=1 // Do work in the new data folder.
SetDataFolder savedDF // Restore CDF from the string value.

```

\section*{See Also}

Chapter II-8, Data Folders and Data Folder References on page IV-62.

\section*{SetDimLabel}

SetDimLabel dimNumber, dimIndex, label, wavelist
The SetDimLabel operation sets the dimension label or dimension element label to the specified label.

\section*{Parameters}

Use dimNumber=0 for rows, 1 for columns, 2 for layers and 3 for chunks.
If dimindex is -1 , it sets the label for the entire dimension. For dimIndex \(\geq 0\), it sets the dimension label for that element of the dimension.
label is a name (e.g., time), not a string (e.g., "time").
label is limited to 31 characters.
See Also
GetDimLabel, FindDimLabel

Dimension Labels on page II-109 and Example: Wave Assignment and Indexing Using Labels on page II-99 for further usage details and examples.

\section*{SetDrawEnv}

SetDrawEnv [/W=winName] keyword [=value] [, keyword [=value]]... The SetDrawEnv operation sets properties of the drawing environment.
If one or more draw objects are selected in the top window then the SetDrawEnv command will apply only to those objects.
If no objects are selected and if the keyword save is not used then the command applies only to the next object drawn.
If no objects are selected and if the keyword "save" is used then the command sets the environment for all following objects.
Each draw layer has its own draw environment settings.

\section*{Parameters}

SetDrawEnv can accept multiple keyword=value parameters on one line.
In the following descriptions, \((r, g, b)\) specifies a color. \(r, g\), and \(b\) are each a number from 0 to \(65535 .(0,0,0)\) specifies black. \((65535,65535,65535)\) specifies white.
Also note that the abs and rel values for the coordinate keywords "xcoord" and "ycoord" are the literal characters "abs" and "rel"; they are not substitute names for numbers, names, or strings.
\begin{tabular}{|c|c|}
\hline arrow=arr & Specifies the arrow head position on lines. \\
\hline & \(a r r=0\) : \(\quad\) No arrowhead (default). \\
\hline & \(a r r=1: \quad\) Arrowhead at end. \\
\hline & arr=2: Arrowhead at start. \\
\hline & \(a r r=3: \quad\) Arrowhead at start and end. \\
\hline arrowfat=afat & Sets ratio of arrowhead width to length (default is 0.5 ). \\
\hline arrowlen=alen & Sets length of arrowhead in points (default is 10). \\
\hline arrowSharp=s & Specifies the continuously variable barb sharpness between -1.0 and 1.0. \\
\hline & \(s=1: \quad\) No barb; lines only. \\
\hline & \(s=0: \quad\) Blunt (default). \\
\hline & \(s=-1: \quad\) Diamond. \\
\hline arrowframe= \(f\) & Specifies the stroke outline thickness of the arrow in points (default is \(f=0\) for solid fill). \\
\hline astyle=s & Specifies which side of the line has barbs relative to a right-facing arrow. \\
\hline & \(s=0: \quad\) None. \\
\hline & \(s=1: \quad\) Top. \\
\hline & \(s=2: \quad\) Bottom. \\
\hline & \(s=3: \quad\) Both (default). \\
\hline dash=dsh & \(d s h\) is a dash pattern number between 0 and 17 (see SetDashPattern for patterns). 0 (solid line) is the default. \\
\hline fillbgc \(=(r, g, b)\) & Specifies fill background color. Default is the window's background color. \\
\hline fillfgc \(=(r, g, b)\) & Specifies fill foreground color. The default is white. \\
\hline
\end{tabular}
\begin{tabular}{lll} 
fillpat=fpatt & \multicolumn{2}{l}{ Specifies fill pattern density. } \\
& \(f p a t t=-1:\) & Erase to background color. \\
\(f p a t t=0:\) & No fill. \\
& \(f p a t t=1:\) & \(100 \%\) (solid pattern, default). \\
& \(f p a t t=2:\) & \(75 \%\) gray. \\
& \(f p a t t=3:\) & \(50 \%\) gray. \\
& \(f p a t t=4:\) & \(25 \%\) gray.
\end{tabular}
fname="fontName" Sets font name, default is the default font or the graph font.
fsize=size Sets text size, default is 12 points.
fstyle=style \(\quad\) Sets text style (same as for the TextBox operation), default is plain.
gedit=flag Supplies optional edit flag for a group of objects. Use with gstart.
flag=0: \(\quad\) Select entire group, moveable (default).
flag=1: Individual components editable as if not grouped. Allows
objects to be grouped by name but still be editable.
\begin{tabular}{ll} 
gname \(=\) name & Supplies optional name for an object group. Use with gstart. \\
gstart & Marks the start of a group of objects. \\
gstop & Marks the end of a group of objects. \\
linebgc \(=(r, g, b)\) & Sets the line background color. Default is window's background color. \\
linefgc= \(=(r, g, b)\) & Sets the line foreground color, default is black. \\
linepat=patt & Specifies the line pattern/density. \\
& patt=1: \(\quad 100 \%\) (solid pattern, default). \\
patt=2: \(\quad 75 \%\) gray. \\
& patt \(=3: \quad 50 \%\) gray. \\
patt=4: \(\quad 25 \%\) gray.
\end{tabular}
linethick=thick thick is a line thickness \(\geq 0\), default is 1 point.
origin \(=x 0, d 0 \quad\) Moves coordinate system origin to \(x 0, d 0\). Unlike translate, rotate, and scale, this survives a change in coordinate system and is most useful that way. See Coordinate Transformation.
pop
Pops a draw environment from the stack. Pops should always match pushes.
push
Pushes the current draw environment onto a stack (limited to 10).
rotate \(=d e g \quad\) Rotates coordinate system by deg degrees. Only makes sense if \(X\) and \(Y\) coordinate systems are the same. See Coordinate Transformation.
rounding=rnd \(\quad\) Radius for rounded rectangles in points, default is 10.
rsabout Redefines coordinate system rotation or scaling to occur at the translation point instead of the current origin. To use, combine rotate or scale with translate and rsabout parameters.
save Stores the current drawing environment as the default environment.
scale \(=s x, s y \quad\) Scales coordinate system by \(s x\) and \(s y\). Affects only coordinates - not line thickness or arrow head sizes. See Coordinate Transformation.
textrgb \(=(r, g, b) \quad\) Sets text color, default is black.

\section*{Flags}
/W=winName
Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Coordinate Transformation}

The execution order for the translate, rotate, scale, and origin parameters is important. Translation followed by rotation is different than rotation followed by translation. When using multiple keywords in one SetDrawEnv operation, the order in which they are applied is origin, translate, rotate followed by scale
regardless of the command order (with the exception of the rsabout parameter). Before using origin with the save keyword, you should use push to save the current draw environment and then use pop after drawing objects using the new origin.

\section*{Examples}

Following is a simple example of arrow markers:
NewPanel
SetDrawEnv arrow= 1, arrowlen= 30, save
SetDrawEnv arrowsharp= 0.3
DrawLine 61,67,177,31
SetDrawEnv arrowsharp= 1
DrawLine 65,95,181,59
SetDrawEnv astyle= 1
DrawLine 69,123,185,87
SetDrawEnv arrowframe= 1
DrawLine 73,151,189,115
You can position objects in one coordinate system and then draw them in another with the origin keyword. In the following coordinate transformation example, we position arrows in axis units but size them in absolute units.
```

Make/O jack=sin(x/8)
Display jack
SetDrawEnv xcoord=bottom,ycoord=left, save
SetDrawEnv push
SetDrawEnv origin=50,0
SetDrawEnv xcoord=abs,ycoord=abs,arrow=1, arrowlen=20, arrowsharp=0.2, save
DrawLine 0,0,50,0 // arrow 50 points long pointing to the right
DrawLine 0,0,0,50 // arrow 50 points long pointing down
// now let's move over, rotate a bit and draw the same arrows:
SetDrawEnv translate=100,0
SetDrawEnv rotate=30,save
DrawLine 0,0,50,0
DrawLine 0,0,0,50
SetDrawEnv pop

```

Now try zooming in on the graph. You will see that the first pair of arrows always starts at 50 on the bottom axis and 0 on the left axis whereas the second pair is 100 points to the right of the first.

See Also
Chapter III-3, Drawing, and the TextBox and DrawAction operations.

\section*{SetDrawLayer}

\section*{SetDrawLayer [/K/W=winName] layerName}

The SetDrawLayer operation makes all future drawing operations use the named layer.

\section*{Parameters}

Valid layerNames for graphs:
ProgBack UserBack ProgAxes UserAxes ProgFront UserFront

Valid layerNames for panels and page layouts:
ProgBack UserBack ProgFront UserFront
Flags
/K Kills (erases) the given layer.
\(/ \mathrm{W}=\) winName \(\quad\) Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Details}

There are really only two layers for Panels but ProgFront is allowable as an alias for ProgBack. Likewise UserFront is an alias for UserBack.
The back-to-front order of the layers is shown by the Environment pop-up menu if you hold down Option (Macintosh) or Alt (Windows). This is the Environment pop-up menu for graphs:

See Also
Layers on page III-80 and the DrawAction operation.

\section*{SetFileFolderInfo}

SetFileFolderInfo [flags][fileOrFolderNameStr]
The SetFileFolderInfo operation changes the properties of a file or folder.

\section*{Parameters}
fileOrFolderNameStr specifies the file or folder to be changed.
If you use a full or partial path for fileOrFolderNameStr, see Path Separators on page III-400 for details on forming the path.
Folder paths should not end with single Path Separators. See the MoveFolder Details section.
If Igor can not determine the location of the file or folder from fileOrFolderNameStr and \(/ \mathrm{P}=\) pathName, it displays a dialog allowing you to specify the file to be deleted. Use / D to select a folder in this event, otherwise Igor prompts your for a file.

\section*{Flags}

At least one of the seven following flags is required, or nothing is actually accomplished:
/CDAT=cdate Specifies the number of seconds since midnight January 1, 1904 when the file or folder was first created.
/INV[=inv] Sets the visibility of a file.
inv=0: \(\quad\) File is visible.
inv=1: Default; file is invisible (Macintosh) or Hidden (Windows).
\(/\) MDAT \(=m\) Date \(\quad\) Specifies the number of seconds since midnight January 1, 1904 when the file or folder was modified most recently.
\(/ \mathrm{RO}[=r o] \quad\) Sets the read/write state of a file or folder.
\(r o=0: \quad\) File or folder is writable.
\(r o=1: \quad\) File or folder is locked (default).
On Macintosh, locking the file or folder is equivalent to setting the locked property manually using the Get Info window in the Finder.
On Windows, locking the file or folder is equivalent to setting the read-only property manually using the Properties window in Windows Explorer.

If fileOrFolderNameStr refers to a file (not a folder), SetFileFolderInfo updates the file properties to reflect values given with the following keywords:
/CRE8=creatorStr Sets the four-character creator code string, such as 'IGR0' (Igor Pro creator code).
Ignored on Windows, where files have no "creator code"; instead file extensions are "registered" or "owned" by one, and only one, application. You cannot change that ownership from Igor Pro.
/FTYP=fTypeStr Sets the four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment). Ignored on Windows. Use MoveFile to change the file extension.
\(/ \mathrm{STA}[=s t] \quad\) Specifies whether the file is a stationery file or not.
\(s t=1: \quad\) Stationery file (default).
\(s t=0: \quad\) Normal file.
Ignored on Windows. Use MoveFile to change the file extension.

\section*{Optional Flags}

\section*{/D}
/P=pathName
\(/ \mathrm{R}[=r] \quad\) Recursively applies change(s) to all files or folders in the folder specified by /P=pathName or fileOrFolderNameStr, and the folder itself:
\(r=0\) : No recursion. Same as no /R.
\(r=1: \quad\) Recursively apply changes to files.
\(r=2: \quad\) Recursively apply changes to folders, including the folder specified by pathName or fileOrFolderNameStr.
\(r=3: \quad\) Recursively apply changes to both files and folders (default).
\(/ \mathrm{R}\) requires \(/ \mathrm{D}\) and a folder specification.
\[
\begin{array}{ll}
/ \mathrm{Z}[=z] & \begin{array}{l}
\text { Prevents procedure execution trom aborting it SettileFolderInto tries to set } \\
\text { information about a file or folder that does not exist. Use } / \mathrm{Z} \text { if you want to handle } \\
\text { this case in your procedures rather than having execution abort. }
\end{array} \\
/ \mathrm{Z}=0: & \begin{array}{l}
\text { Same as no } / \mathrm{Z} \text { at all. } \\
/ \mathrm{Z}=1:
\end{array} \\
& \begin{array}{l}
\text { Used for setting information for a file or folder only if it exists. / } \mathrm{Z} \\
\text { alone has the same effect as } / \mathrm{Z}=1 .
\end{array} \\
/ \mathrm{Z}=2: & \begin{array}{l}
\text { Used for setting information for a file or folder if it exists and } \\
\text { displaying a dialog if it does not exist. }
\end{array}
\end{array}
\]

\section*{Variables}

SetFileFolderInfo returns information about the file or folder in the following variables:
\begin{tabular}{lll} 
V_flag & \(0:\) & File or folder was found. \\
& \(-1:\) & User cancelled the Open File dialog. \\
& \(>0:\) & An error occurred, such as the specified file or folder does not exist.
\end{tabular}

S_path File system path of the selected file or folder.

\section*{Examples}

Change the file creator code; no complaint if it doesn't exist:
```

SetFileFolderInfo/z /CRE8="CWIE", "Macintosh HD:folder:afile.txt"

```

Set the file modification date:
```

Variable mDate= Date2Secs(2000,12,25) + hrs*3600+mins*60+secs
SetFileFolderInfo/P=myPath/MDAT=(mDate), "afile.txt"
Remove read-only property from a folder and everything within it:
SetFileFolderInfo/P=myPath/D/R/RO=0

```

\section*{See Also}

The GetFileFolderInfo, ImageFileInfo, MoveFile, and FStatus operations. The IndexedFile, date2secs, and ParseFilePath functions.

\section*{SetFormula}

SetFormula waveName, expressionStr
SetFormula variableName, expressionstr
The SetFormula operation binds the named wave, numeric or string variable to the expression or, if the expression is " ", unbinds it from any previous expression. In user functions, SetFormula must be used to create dependencies.

\section*{Parameters}
expressionStr is a string containing a numeric or string expression, depending on the type of the bound object.
Pass an empty string (" ") for expressionStr to clear any previous dependency expression associated with the wave or variable.

\section*{Details}

The dependent object (the wave or variable) will depend on the objects referenced in the string expression. The expression will be reevaluated any time an object referred to in the expression is modified.
Besides being set from a string expression this differs from just typing:
name := expression
in that syntax errors in expressionStr are not reported and are not fatal. You end up with a dependency assignment that is marked as needing to be recompiled. The recompilation will be attempted every time an object is created or when the procedure window is recompiled.
Use the Object Status dialog in the Misc menu to check up on dependent objects.

\section*{Examples}

This command makes the variable v_sally dependent on the user-defined function anotherFunction, waves wave_fred and wave_sue, and the system variable K2:
SetFormula v_sally, "anotherFunction(wave_fred[1]) + wave_sue[0] + K2"
This is equivalent to:
v_sally := anotherFunction(wave_fred[1]) + wave_sue[0] + K2
except that no error will be generated for the SetFormula if, for instance, wave_fred does not exist.
A string variable dependency can be created by a command such as:
SetFormula myStringVar, "note(wave_joe)"
observe that expressionStr is a string containing a string expression, and that:
SetFormula myStringVar, note (wave_joe)
is not the same thing. In this case the note of wave_joe would contain the expression that myStringVar would depend on! Also, wave_joe would have to exist for Igor to understand the statement.

\section*{See Also}

Chapter IV-9, Dependencies, and the GetFormula function.

\section*{SetIgorHook}

SetIgorHook [/K/L] [hookType = [procName]]
The SetIgorHook operation tells Igor to call a user-defined "hook" function at the following times:
- After procedures have been successfully compiled (AfterCompiledHook)
- After a file is opened (AfterFileOpenHook)
- After the MDI frame window is resized on Windows (AfterMDIFrameSizedHook)
- After a window is created (AfterWindowCreatedHook)
- Before the debugger is opened (BeforeDebuggerOpensHook)
- Before an experiment is saved (BeforeExperimentSaveHook)
- Before a file is opened (BeforeFileOpenHook)
- Before a new experiment is opened (IgorBeforeNewHook)
- Before Igor quits (IgorBeforeQuitHook)
- When a menu item is selected (IgorMenuHook)
- During Igor's quit processing (IgorQuitHook)
- When Igor starts or a new experiment is created (IgorStartOrNewHook)

The term "hook" is used as in the phrase "to hook into", meaning to intercept or to attach.
Hook functions are typically used by a sophisticated procedure package to make sure that the package's private data is consistent.

In addition to using SetIgorHook, you can designate hook functions using fixed function names (see UserDefined Hook Functions on page IV-257). The advantage of using SetIgorHook over fixed hook names is that you don't have to worry about name conflicts.
You can designate hook functions for specific windows using window hooks (see SetWindow on page V-646).

\section*{Flags}
/K Removes procName from the list of functions called for the hookType events.
If procName is not specified all hookType functions are removed.
If hookType is not specified all functions are removed for all hookType events, returning Igor to the pre-SetIgorHook state.

Executes procName last. Without/L, a newly added hook function runs before previously registered hook functions.
A function that has been previously registered with SetIgorHook can be moved from being called first to being called last by calling SetIgorHook again with /L.
To move a function from being called last to being called first requires removing the hook function with /K and then calling SetIgorHook without/L.

\section*{Parameters}
hookType Specifies one of the fixed-name hook function names:
AfterCompiledHook
AfterFileOpenHook
AfterMDIFrameSizedHook
AfterWindowCreatedHook
BeforeDebuggerOpensHook

\section*{BeforeExperimentSaveHook}

BeforeFileOpenHook
IgorBeforeNewHook
IgorBeforeQuitHook

\section*{IgorMenuHook}

\section*{IgorQuitHook}

\section*{IgorStartOrNewHook}

See the note below about these hookType names.
hookType is required except with /K.
procName Names the user-defined hook function that is called for the hookType event.

\section*{Details}

The parameters and return type of the user-defined function procName varies depending on the hookType it is registered for.
For example, a function registered for the AfterFileOpenHook type must have the same parameters and return type as the shown for the AfterFileOpenHook on page IV-259.
The procName function is called after any window-specific hook for these hookTypes, and the procName function is called before any other hook functions previously registered by calling SetIgorHook unless the /L flag is given, in which case it still runs after window-specific hook functions, but also after all other previously registered hook functions.
The procName function should return a nonzero value ( 1 is typical) to prevent later functions from being called. Returning 0 allows successive functions to be called.
SetIgorHook does not work at Igor start or new experiment time, so SetIgorHook IgorStartOrNewHook is disallowed. Define a global or static fixed-name IgorStartOrNewHook function (see page IV-269).
The saved Igor experiment file remembers the SetIgorHooks that are in effect when the experiment is saved:

\section*{Hook Function Interactions}

After all the SetIgorHook functions registered for hookType have run (and all have returned 0), any static fixedname hook functions are called and then the (only) fixed-name user-defined hook function, if any, is called. As an example, when a menu event occurs, Igor handles the event by calling routines in this order:
1. The top window's hook function as set by SetWindow
2. Any SetIgorHook-registered hook functions
3. Any static fixed-named IgorMenuHook functions (in any independent module)
4. The one-and-only non-static fixed-named IgorMenuHook function (in only the ProcGlobal independent module)
1. SetWindow event (called first)
enableMenu
menu

\section*{2. SetIgorHook hookType \\ (called second)}
\begin{tabular}{ll} 
IgorMenuHook & IgorMenuHook \\
IgorMenuHook & IgorMenuHook
\end{tabular}

Note: Although you can technically use one of the fixed-name functions, as described in UserDefined Hook Functions on page IV-257, for procName, the result would be that the function will be called twice: once as a registered named hook function and once as the fixed-named hook function. That is, don't use SetIgorHook this way:

SetIgorHook AfterFileOpenHook=AfterFileOpenHook // NO

\section*{Variables}

SetIgorHook returns information in the following variables:
S_info Semicolon-separated list of all current hook functions associated with hookType, listed in the order in which they are called. As of Igor 6.13 the S_info includes the full independent module paths (e.g.,"ProcGlobal\#MyMenuHook;MyIM\#MyModule\#MyMenuHook;").

\section*{Examples}

This hook function invokes the Export Graphics menu item when Command-C (Macintosh) or Ctrl+C (Windows) is selected for a graph, preventing the usual Copy.
```

SetIgorHook IgorMenuHook=CopyIsExportHook
Function CopyIsExportHook(isSelection,menuName, itemName,itemNo,win,wType)
Variable isSelection
String menuName,itemName
Variable itemNo
String win
Variable wType
Variable handledIt= 0
if( isSelection \&\& wType==1 ) // menu was selected, window is graph
if( Cmpstr(menuName,"Edit")==0 \&\& CmpStr(itemName,"Copy")==0 )
DoIgorMenu "Edit", "Export Graphics" // dialog instead
handledIt= 1 // don't call other IgorMenuHook functions.
endif
endif
return handledIt
End

```

To unregister CopyIsExportHook as a hook procedure:
SetIgorHook/K IgorMenuHook=CopyIsExportHook // unregister CopyIsExportHook
To discover which functions are associated with a hookType, use a command such as:
```

SetIgorHook IgorMenuHook // inquire about names registered for IgorMenuHook
Print S_info // list of functions

```

To remove (or "unregister") named hooks:
\begin{tabular}{lll} 
SetIgorHook/K & // removes all hook functions for all hookTypes \\
SetIgorHook/K IgorMenuHook & // removes all IgorMenuHook functions \\
SetIgorHook/K IgorMenuHook=CopyIsExportHook// removes only this hook function
\end{tabular}

\section*{See Also}

The SetWindow operation and User-Defined Hook Functions on page IV-257.
Independent Modules on page IV-218.

\section*{SetIgorMenuMode}

\section*{SetIgorMenuMode MenuNameStr, MenuItemStr, Action}

The SetIgorMenuMode operation allows an Igor programmer to disable or enable Igor's built-in menus and menu items. This is useful for building applications that will be used by end-users who shouldn't have access to all Igor's extensive and confusing functionality.

\section*{Parameters}

MenuNameStr The name of an Igor menu, like "File", "Graph", or "Load Waves".
MenuItemStr The text of an Igor menu item, like "Copy" (in the Edit menu) or "New Graph" (in the Windows menu).
Action One of DisableItem, EnableItem, DisableAllitems, or EnableAllItems.
DisableItem and EnableItem disable or enable just the single item named by MenuNameStr and MenuItemStr. If MenuItemStr is " ", then the menu itself is disabled.
DisableAllItems and EnableAllItems disable and enable all the items in the menu named by MenuNameStr.

\section*{Details}

All menu names and menu item text are in English. This ensures that code developed for a localized version of Igor will run on all versions. Note that no trailing "..." is used in MenuItemStr.
The SetIgorMenuModeProc.ipf procedure file includes procedures and commands that disable or enable every menu and item possible. It is in your Igor Pro folder, in WaveMetrics Procedures:Utilities. It is not intended to be used as-is. You should make a copy and edit the copy to include just the parts you need.
The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the MenuItemStr parameter. Use "Save Window", "Save Window As", "Save Window Copy", "Adopt Window" and "Revert Window" instead of "Save Notebook" or "Save Procedure", etc. Use "Page Setup" instead of "Page Setup For All Graphs", etc. Use "Print" instead of "Print Graph", etc.
The Edit \(\rightarrow\) Insert File menu item was previously named Insert Text. For compatibility reasons, you can specify either "Insert File" or "Insert Text" as MenuItemStr to modify this item.

\section*{See Also}

The DoIgorMenu operation.

\section*{SetIgorOption}
```

SetIgorOption [mainKeyword,] keyword= value
SetIgorOption [mainKeyword,] keyword= ?

```

The SetIgorOption operation makes unusual and temporary changes to Igor Pro's behavior. This operation is not compilable and you will need to use the Execute operation to use it in a user function. The details of the syntax depend on the application and are documented where the alternate behaviors are described. In most cases the current value of a setting can be read using the keyword=? syntax. Simple numeric options are stored in V_flag and color options are stored in V_Red, V_Green, and V_Blue. The settings last for the life of the Igor session.

\section*{See Also \\ Syntax Coloring on page III-354 for some usage examples; Macintosh and LAPACK Library on page III-144; SetIgorOption IndependentModuleDev=1 on page IV-219; Conditional Compilation on page IV-90; Pre-Carbon Page Setup Records on page III-399. MarkPerfTestTime operation.}

\section*{SetMarquee}

SetMarquee [/W=winName] left, top, right, bottom
The SetMarquee operation creates a marquee on the target graph or layout window or the specified window or subwindow.
The left, top, right, bottom coordinates are the same as those returned by the GetMarquee operation (screen units measured in points).
If the coordinates are all 0 , the marquee, if it exists, is killed.

The optional axis modes supported by GetMarquee are not supported by SetMarquee.

\section*{Flags}
\(/ W=\) winName Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{See Also}

The GetMarquee operation.

\section*{SetProcessSleep}

SetProcessSleep sleepTicks
The SetProcessSleep operation determines how much time Igor will give to background tasks or other Macintosh applications executing in the background. This operation does nothing on Windows.

\section*{Parameters}
sleepTicks is the amount of time given to background tasks in sixtieths of a second. sleepTicks values between 0 and 60 are valid.

\section*{Details}

Igor starts up with sleepTicks \(=1\). Use 0 to give Igor maximum time, use a larger number to give other applications more time.
Background tasks are used mainly by data acquisition programs.
See Also
Background Tasks on page IV-285 and the SetBackground operation.

\section*{SetRandomSeed}

\section*{SetRandomSeed seed}

The SetRandomSeed operation seeds the random number generator used for the enoise and gnoise functions. Use SetRandomSeed if you need "random" numbers that are reproducible. If you don't use SetRandomSeed, the random number generator is initialized using the system clock when Igor starts. This almost guarantees that you will never get the same sequence twice unless you use SetRandomSeed.

\section*{Flags}
/BETR[=better] If better is absent or non-zero, a better method is used for seeding the Mersenne Twister random number generator.

\section*{Parameters}
seed should be a number in the interval \((0,1]\). For any given seed, enoise or gnoise or any of the other randomnumber generator functions generates a particular sequence of pseudorandom numbers. Calling SetRandomSeed with the same seed restarts and repeats the sequence.

\section*{Details}

Internally seed is scaled to a 32-bit unsigned integer. Consequently, the number of different values for the internally-scaled seed is less than the resolution of the double-precision numbers in the \((0,1]\) range.
You should use/BETR unless you need consistency with older versions of Igor./BETR was introduced in Igor Pro 6.20.
The Mersenne Twister random number generator is used for most of Igor's noise functions (and optionally for enoise and gnoise), and internally for operations that need random sequences, such as StatsSample or StatsResample.
Without the /BETR flag, SetRandomSeed maps seed to an internal 16-bit integer for seeding the Mersenne Twister random number generator. With /BETR it maps to an internal 32-bit integer seed. So using /BETR reduces the chance that two values of seed will map to the same internal integer seed.

\section*{See Also}

The enoise and gnoise functions. Noise Functions on page III-334.

\section*{SetScale}

SetScale [/I/P] dim, num1, num2 [, unitsStr] , waveName [, waveName]...
SetScale d, num1, num2 [, unitsStr], waveName [, waveName]...
The SetScale operation sets the dimension scaling or the data full scale for the named waves.
Parameters
The first parameter dim must be one of the following:
\begin{tabular}{ll} 
Character & Signifies \\
\hline d & Data full scale. \\
t & Scaling of the chunks dimension (t scaling). \\
x & Scaling of the rows dimension (x scaling). \\
y & Scaling of the columns dimension (y scaling). \\
z & Scaling of the layers dimension (z scaling). \\
\hline
\end{tabular}

If setting the scaling of any dimension \((x, y, z\), or \(t), n u m 1\) is the starting index value - the scaled index for the first point in the dimension. The meaning of num2 changes depending on the \(/ \mathrm{I}\) and \(/ \mathrm{P}\) flags. If you use \(/ \mathrm{P}\), then num 2 is the delta value - the difference in the scaled index from one point to the next. If you use /I, num 2 is the "ending value" - the index value for the last element in the dimension. If you use neither flag, num 2 is the "right value" - the index value that the element after the last element in the dimension would have.
These three methods are just three different ways to specify the two scaling values, the starting value and the delta value, that are stored for each dimension of each wave.
If setting the data full scale (d), then num1 is the nominal minimum and num2 is the nominal maximum data value for the waves. The data full scale values are not used. They serve only to document the minimum and maximum values the waves are expected to attain. No flags are used when setting the data full scale.
The unitsStr parameter is a string that identifies the natural units for the \(\mathrm{x}, \mathrm{y}, \mathrm{z}, \mathrm{t}\), or data values of the named waves. Igor will use this to automatically label graph axes. This string must be one to 49 characters such as " m " for meters, " g " for grams or " \(s\) " for seconds. If the waves have no natural units you can pass " " for this parameter.

Setting unitsStr to "dat" (case-sensitive) tells Igor that the wave is a date/time wave containing data in Igor date/time format (seconds since midnight on January 1, 1904). Date/time waves must be double-precision.

\section*{Flags}

At most one flag is allowed, and then only if dimension scaling (not data full scale) is being set:
/I Inclusive scaling. num2 is the ending index - the index value for the very last element in the dimension.
/P Per-point scaling. num2 is the delta index value - the difference in scaled index value from one element to the next.

\section*{Details}

SetScale will not allow the delta scaling value to be zero. If you execute a SetScale command with a delta value of zero, it will set the delta value to 1.0.
If you do not use the /P flag, SetScale converts num1 and num2 into a starting index value and a delta index value. If you call SetScale on dimension with fewer than two elements, it does this conversion as if the dimension had two elements.
Prior to Igor Pro 3.0, Igor supported only 1D waves. "SetScale \(x\) " was used to set the scaling for the rows dimensions and "SetScale y" was used to set the data full scale. With the addition of multidimensional waves, "SetScale y" is now used to set the scaling of the columns dimension and "SetScale d" is used to set the data full scale. For backward compatibility, "SetScale y" on a 1D wave sets the data full scale.
When setting the dimension scaling of a numeric wave, you can omit the unitsStr parameter. Igor will set the wave's scaling but not change its units. However, when setting the dimension scaling of a text wave,
you must supply a unitsStr parameter (use " " if the wave has no units). If you don't, Igor will think that the text wave is the start of a string expression and will attempt to treat it as the unitsStr.

Note: \(\quad\) Prior to Igor Pro 3.0, SetScale with no wave names would set the default characteristics for waves made subsequently with the Make command. In Igor Pro 2.0, this behavior was considered obsolete and the manual warned that it was not recommended. As of Igor Pro 3.0 SetScale will still set the default x scaling, but will beep and put up a warning dialog. In future versions, SetScale without a wave name will not work. At present, you cannot set the default \(\mathrm{y}, \mathrm{z}\), or t scaling with SetScale.

\section*{See Also}

See Also
CopyScales, DimDelta, DimOffset, DimSize, WaveUnits
For an explanation of waves and dimension scaling, see Changing Dimension and Data Scaling on page II-83.
For further discussion of how Igor represents dates, see Date/Time Waves on page II-102.

\section*{SetVariable}

SetVariable [/Z] ctrlName [keyword = value [, keyword = value ...]]
The SetVariable operation creates or modifies a SetVariable control in the target window.
A SetVariable control sets the value of a global numeric or string variable or a point in a wave when you type or click in the control. As of Igor Pro 6.1, a SetVariable can also hold its own value without the need for a global or wave.
For information about the state or status of the control, use the ControlInfo operation.

\section*{Parameters}
ctrlName is the name of the SetVariable control to be created or changed.
The following keyword=value parameters are supported:
activate Activates the control and selects the text that sets the value. Use ControlUpdate to deactivate the control and deselect the text.
appearance \(=\{\) kind \([\), platform \(]\}\)
Sets the appearance of the control. platform is optional. Both parameters are names, not strings.
kind can be one of default, native, or os9.
platform can be one of Mac, Win, or All.
See Button and DefaultGUIControls for more appearance details.
bodyWidth=width Specifies an explicit size for the body (nontitle) portion of a SetVariable control. By default (bodyWidth=0), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size or text of the title changes, then the body portion may grow or shrink. If you supply a bodyWidth \(>0\), then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.
disable \(=d \quad\) Sets user editability of the control.
\(d=0\) : \(\quad\) Normal.
\(d=1: \quad\) Hide.
\(d=2\) : \(\quad\) No user input.
\begin{tabular}{|c|c|}
\hline fColor \(=(r, g, b)\) & Sets the initial color of the title. \(r, g\), and \(b\) range from 0 to 65535 . fColor defaults to black ( \(0,0,0\) ). To further change the color of the title text, use escape sequences as described for title=titleStr. \\
\hline font="fontName" & Sets the font used to display the value of the variable, e.g., font="Helvetica". \\
\hline format=formatStr & Sets the numeric format of the displayed value, e.g., format="\%g". Not used with string variables. Never use leading text or the "\%W" formats, because Igor reads the value back without interpreting the units. For a description of formatStr, see the printf operation. \\
\hline \multirow[t]{3}{*}{frame \(=f\)} & Sets the frame for the value readout. \\
\hline & \(f=0\) : Value unframed. \\
\hline & \(f=1: \quad\) Value framed (default). \\
\hline fsize \(=s\) & Sets the size of the type used to display the variable's value. \\
\hline \multirow[t]{7}{*}{fstyle \(=f\) s} & \(f s\) is a bitwise parameter with each bit controlling one aspect of the font style as follows: \\
\hline & Bit 0: Bold. \\
\hline & Bit 1: Italic. \\
\hline & Bit 2: Underline. \\
\hline & Bit 3: Outline (Macintosh only). \\
\hline & Bit 4: Shadow (Macintosh only). \\
\hline & See Setting Bit Parameters on page IV-12 for details about bit settings. \\
\hline help=\{helpStr \(\}\) & Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting " \(\backslash \mathrm{r}\) " in a quoted string. \\
\hline labelBack \(=(r, g, b)\) or 0 & Specifies the background fill color for labels. \(r, g\), and \(b\) are integers from 0 to 65535. The default is 0 , which uses the window's background color. \\
\hline limits \(=\{\) low,high,inc \(\}\) & Sets the limits of the allowable values (low and high) for the variable. inc sets the amount by which the variable is incremented if you click the control's up/down arrows. This applies to numeric variables, not to string variables. If inc is zero then the up/down arrows will not be drawn. \\
\hline \multirow[t]{3}{*}{live= \(l\)} & Determines when the readout is updated. \\
\hline & \(l=0\) : \(\quad\) Update only after variable changes (default). \\
\hline & \(l=1: \quad\) Update as variable changes. \\
\hline \multirow[t]{3}{*}{noedit=val} & noedit=1 prevents the user from clicking (or tabbing into) a SetVariable control to directly edit its value. This is useful when you want to make a string read-only or when you want to restrict a numeric setting to those available only via the control's up or down arrow buttons. \\
\hline & noedit=0 reactivates user editing. \\
\hline & noedit=2 is deprecated as of Igor 6.34 but still supported. It allows the use of fancy text using the escape codes defined for the TextBox operation. Use styledText=1, instead. \\
\hline noproc & No procedure is to execute when the control's value is changed. \\
\hline pos=\{left,top \(\}\) & Sets the position of the control in pixels. \\
\hline pos+=\{dx, dy\} & Offsets the position of the control in pixels. \\
\hline proc=procName & Sets the procedure to execute when the control's value is changed. \\
\hline
\end{tabular}
rename=newName styledText=val
size=\{width,height \(\}\) title=titleStr

Gives control a new name.
styledText=1 allows the use of fancy text using the escape codes defined for the TextBox operation. See Annotation Escape Codes on page V-778.
For example:
SetVariable sv0 value=_STR:"\\JC\\K(65535,0,0) Centered Red Text"
styledText \(=0\) treats escape codes as plain text.
The styledText keyword was added in Igor 6.34. For compatibility with earlier versions of Igor, the combination of noedit \(=1\) and styledText=1 is recorded as noedit=2 in recreation macros. Only Igor 6.34 and later support simultaneous editing and styled text values.

Sets width of control in pixels. height is ignored.
Sets title of control to the specified string expression. The title is displayed to the left of the control. If titleStr is empty (" "), the name of the controlled variable is displayed as the title. Use title=" " (put a space within the quotation marks) to create a "blank" title.
titleStr can contain formatting escape codes in order to create fancy, styled results. The escape codes are the same as used by the TextBox operation. The easiest way to generate fancy text is to make selections from the Insert popup in the SetVariable Control dialog.
userdata \((\) UDName \()=\) UDStr
Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create.
userdata(UDName)+=UDStr
Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr.
value=varOrWaveName Sets the numeric or string variable or wave element to be controlled.
If varOrWaveName references a wave, the point is specified using standard bracket notation with either a numeric point number or a row label, for example: value=awave [4] or value=awave [\%alabel].
You may also use a matrix wave and specify a column index in addition to the row index.
As of Igor Pro 6.1, you can have the control store the value internally rather than in a global variable. In place of varName, use _STR:str or _NUM:num. For example:
NewPanel; SetVariable sv1,value=_NUM:123
valueColor \(=(r, g, b) \quad\) Sets the color of the value text. \(r, g\), and \(b\) range from 0 to 65535 . valueColor defaults to black \((0,0,0)\).
valueBackColor= \((r, g, b)\) Sets the background color under the value text. \(r, g\), and \(b\) range from 0 to 65535.
valueBackColor \(=0 \quad\) Sets the background color under the value text to the default color, the standard document background color used on the current operating system, which is usually white.
win=winName Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Flags}
/Z No error reporting.

\section*{Details}

The target window must be a graph or panel.
The procedure, which may be a function or a macro, has the format:
```

Function procName(ctrlName,varNum,varStr,varName) : SetVariableControl
String ctrlName
Variable varNum // value of variable as number
String varStr // value of variable as string
String varName // name of variable
End

```

The ": SetVariableControl" designation tells Igor to include this procedure in the Procedure pop-up menu in the SetVariable Control dialog.
As of Igor Pro 6.1, you can use ctrl-return to enter a carriage return in a string SetVariable. A carriage return in a string SetVariable appears as a symbol representing a carriage return.
As of Igor Pro 6.1, if you set noedit to 2, you can use fancy text using the escape codes defined for the TextBox operation. See Annotation Escape Codes on page V-778.
The action procedure for a SetVariable control can also use a predefined structure WMSetVariableAction as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a SetVariable control, otherwise it will use the old-style method.
A SetVariable action procedure using a structure has the format:
Function newActionProcName(SV_Struct) : SetVariableControl
STRUCT WMSetVariableAction \&SV_Struct
End
For a SetVariable control, the WMSetVariableAction structure has members as described in the following table:

\section*{WMSetVariableAction Structure Members}
\begin{tabular}{ll} 
Member & Description \\
\hline char ctrlName[MAX_OBJ_NAME+1] & Control name. \\
char win [MAX_WIN_PATH+1] & Host (sub)window. \\
STRUCT Rect winRect & Local coordinates of host window. \\
STRUCT Rect ctrlRect & Enclosing rectangle of the control. \\
STRUCT Point mouseLoc & Mouse location. \\
Int32 eventCode & Event that executed the procedure.
\end{tabular}
\begin{tabular}{|c|c|}
\hline \multicolumn{2}{|r|}{wMSetVariableAction Structure Members} \\
\hline Member & Description \\
\hline & -1: Control being killed \\
\hline & 1: Mouse up \\
\hline & 2: Entery key \\
\hline & 3: Live update \\
\hline & 4: Mouse scroll wheel up \\
\hline & 5: Mouse scroll wheel down \\
\hline & 6: Value changed by dependency update \\
\hline & Code - 1 is never sent to an old-style (non-structure parameter) action procedure. \\
\hline & Codes 4 and 5 (Igor Pro 6.1 or later) are sent only for string SetVariables or numeric SetVariables whose increment setting is zero. \\
\hline & For numeric SetVariables whose increment is non-zero, the mouse scroll wheel acts like a mouse click on the increment or decrement arrows. \\
\hline & Code 6 (Igor Pro 6.1 or later) is by default sent to only structure-based action procedures. \\
\hline & Use SetIgorOption EnableSVE6=0 to disable sending this event at all, \(=2\) to send the event to both structure-based and old-style SetVariable action procedures. (The default is \(=1\) ). \\
\hline Int32 eventMod & Bitfield of modifiers. See Control Structure eventMod Field on page III-387. \\
\hline String userData & Primary (unnamed) user data. If this changes, it is written back automatically. \\
\hline Int32 blockReentry & Prevents reentry of control action procedure. See Control Structure blockReentry Field on page III-388. \\
\hline Int32 isStr & TRUE for a string variable. \\
\hline double dval & Numeric value of variable. \\
\hline char sval [MAXCMDLEN] & Value of variable as a string. \\
\hline \multicolumn{2}{|l|}{char vName [MAX_OBJ_NAME+2+MAX_OBJ_NAME + 4 + 1]} \\
\hline & Name of variable or wave. Dimension labels can be used for waves. \\
\hline WAVE svWave & Valid if using wave. \\
\hline Int32 rowIndex & Row index for a wave, if rowLabel is empty. \\
\hline char rowLabel [MAX_OBJ_NAME+1] & Wave row label. \\
\hline nt32 colindex & Column index for a wave, if collabel is empty. \\
\hline char colLabel [MAX_OBJ_NAME+1] & Wave column label. \\
\hline
\end{tabular}

Action functions should respond only to documented event Code values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

\section*{Examples}

Executing the commands:
Variable/G globalVar=99
SetVariable setvar0 size \(=\{120,20\}\)
SetVariable setvar0 font="Helvetica", value=globalVar
creates this SetVariable control: gobalVar 99 图

\section*{See Also}

The printf operation for an explanation of formatStr, and Set Variable on page III-364.
The ControlInfo operation for information about the control. Chapter III-14, Controls and Control Panels, for details about control panels and controls. The GetUserData operation for retrieving named user data.

\section*{SetVariableControl}

\section*{SetVariableControl}

SetVariableControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined SetVariable control. See Procedure Subtypes on page IV-183 for details. See SetVariable for details on creating a SetVariable control.

\section*{SetWaveLock}

\section*{SetWaveLock lockVal, waveList}

The SetWaveLock operation locks a wave or waves and protects them from modification. Such protection is not absolute, but it should prevent most common attempts to change or kill a wave.

\section*{Parameters}
lockVal can be 0 , to unlock, or 1 , to lock the wave(s).
waveList is a list of waves or it can be allinCDF to act on all waves in the current data folder.
See Also
WaveInfo to check if a wave is locked.

\section*{SetWindow}

SetWindow winName [, keyword = value]...
The SetWindow operation sets the window note and user data for the named window or subwindow. SetWindow can also set hook functions for a base window or exterior subwindow (interior subwindows not supported).

\section*{Parameters}
winName can be a window or subwindow name. It can also be the keyword kwTopWin to specify the topmost graph, panel, layout, table, or notebook window.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
\[
\text { hide }=h \quad \text { Hides or unhides widows or subwindows } .
\]
\(h=0\) : Unhides a subwindow or base window.
\(h=1\) : Hides a subwindow or base window.
\(h=2\) : \(\quad\) Unhides without restoring minimized windows (Windows only).
When unhiding subwindows, you should combine with needUpdate=1 if conditions require the subwindow to be redrawn since the window was hidden.
hook=procName Sets the window hook function that Igor will call when certain events happen. Use SetWindow hook=\$" " to specify no hook function.

See Unnamed Window Hook Functions on page IV-276 for further details.
hook(hName)=procName

Defines a named window hook \(h\) Name and sets the function that Igor will call when certain events happen. hName can be any legal name. Named hooks are called before any unnamed hooks.
Use \$" " for procName to specify no hook.
See Named Window Hook Functions on page IV-271 for further details.
To hook a subwindow, see Window Hooks and Subwindows on page IV-271.
hookcursor=number Sets the mouse cursor. This keyword is antiquated. See Setting the Mouse Cursor on page IV-274 for the preferred technique.
hookevents=flags Bitfield of flags to enable certain events for the unnamed hook function:
Bit 0: Mouse button clicks.
Bit 1: \(\quad\) Mouse moved events.
Bit 2: Cursor moved events.
To set bit 0 and bit 1 (mouse clicks and mouse moved), use \(2^{0}+2^{1}=1+2=3\) for flags. Use 7 to also enable cursor moved events. See Setting Bit Parameters on page IV-12 for details about bit settings.
This keyword applies to the unnamed hook function only. It does not affect named hook functions which always receive all events.
markerHook \(=\{\) hookFuncName, start, end \(\}\)
Specifies a user function and marker number range for custom markers. The marker range can be any positive integers less than 1000 and can overlap built-in marker numbers. See Custom Marker Hook Functions on page IV-279 for details.
Use \$"" for hookFuncName to specify no hook.
needUpdate \(=n \quad\) Marks a window as needing an update \((n=1)\) or takes no action \((n=0)\).
note \(=\) noteStr \(\quad\) Sets the window note to noteStr, replacing any existing note.
note \(+=\) noteStr \(\quad\) Appends noteStr to current contents of the window note.
userdata=UDStr
userdata(UDName \()=\) UDStr
Sets the window or subwindow user data to UDStr. Use the optional (UDName) to specify a named user data to create.
userdata+=UDStr
userdata(UDName)+=UDStr
Appends UDStr to the current window or subwindow user data. Use the optional (UDName) to append to the named user data.

\section*{Details}

For details on named window hooks, see Window Hook Functions on page IV-270.
Unnamed window hook functions are supported for backward compatibility only. New code should use named window hook functions. For details on unnamed window hooks, see Unnamed Window Hook Functions on page IV-276.
For details on marker hooks, see Custom Marker Hook Functions on page IV-279.

\section*{See Also}

NumberByKey, PopupContextualMenu, and TraceFromPixel functions. The GetUserData operation for retrieving named user data.

\section*{ShowIgorMenus}

ShowIgorMenus [MenuNameStr [, MenuNameStr] ...
The ShowIgorMenus operation shows the named built-in menus or, if none are explicitly named, shows all built-in menus in the menu bar.

User-defined menus attached to built-in menus are also affected by this operation.
Parameters
MenuNameStr The name of an Igor menu, like "File", "Data", or "Graph".
Details
See HideIgorMenus for details.
See Also
Chapter IV-5, User-Defined Menus.
The HideIgorMenus, DoIgorMenu, and SetIgorMenuMode operations.

\section*{ShowInfo}

ShowInfo [/CP=num /W=winName]
The ShowInfo operation puts an information box on the target or named graph. The information box contains cursors and readouts of values associated with waves in the graph.

\section*{Flags}
\(/ \mathrm{CP}=\) num \(\quad\) Selects a cursor pair to display in the info panel.
num=0: \(\quad\) Selects cursor A and cursor B.
num=1: \(\quad\) Selects cursor C and cursor D.
num=2: \(\quad\) Selects cursor E and cursor F .
num=3: \(\quad\) Selects cursor G and cursor H .
num=4: \(\quad\) Selects cursor I and cursor J.
/W=winName Displays info box in the named window.

\section*{See Also}

Info Box and Cursors on page II-290.
The HideInfo operation.
Programming With Cursors on page II-292.

\section*{ShowTools}

ShowTools [/A/W=winName] [toolName]
The ShowTools operation puts a tool palette for drawing along the left hand side of the target or named graph or control panel, and optionally activates the named tool.

Flags
/A Sizes window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.
/W=winName Shows tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

\section*{Parameters}

If you specify a toolName (which can be one of: normal, arrow, text, line, rect, rrect, oval, or poly) the named tool is activated. Specifying the "normal" tool has the same effect as issuing the GraphNormal command for a graph that has the drawing tools selected.

\section*{Details}

The activated tool is not highlighted until the top graph or control panel becomes the topmost (activated) window. Use DoWindow/F to bring a window to the top (or "front").

\section*{See Also}

The DoWindow, GraphNormal, GraphWaveDraw, GraphWaveEdit, and HideTools operations.

\section*{sign}
sign (num)
The sign function returns - 1 if num is negative or 1 if it is not negative.

\section*{Silent}

\section*{Silent num}

The Silent operation enables or disables the display of macro commands in the command line as they are executed.

\section*{Parameters}

If num is one, the display of macro commands is disabled. If num is zero, it is enabled.
When executed from the command line, "Silent 100 " activates a compatibility mode that can run legacy macro code containing old-style comments, which use I instead of //, without causing errors. To exit this mode, execute "Silent 101" on the command line. Also see Comments on page IV-2.
If you create procedure files for use by others and you want to use the new logic operations such as II that require that Silent 101 be in effect, then you can specify
\#pragma rtGlobals=2
in place of the normal \(r\) tGlobal \(s=1\).
If your procedure file is included in an experiment running in compatibility mode (Silent 100) then an alert dialog will allow the user to switch the experiment to the new syntax. However, keep in mind that when the procedures are recompiled in the new mode, the user's other procedures may not compile due to obsolete use of the vertical bar (I) as a comment character.

\section*{Details}

Macros run faster if this display is disabled. If Silent is used in a macro its effect ends when the macro ends.
This has no effect in user-defined functions. During execution of a user-defined function, Igor does not display anything in the command line.
Commands sent to Igor Pro from another program via PPC or Apple events are normally logged into the history area. You can turn off the logging of these commands with the Silent operation. See also The Silent Option on page IV-106.

\section*{See Also}

The PauseUpdate operation and rtGlobals.

\section*{\(\sin\)}

\section*{\(\sin (a n g l e)\)}

The sin function returns the sine of angle which is in radians.
In complex expressions, angle is complex, and \(\sin (\) angle \()\) returns a complex value:
\[
\sin (x+i y)=\sin (x) \cosh (y)+i \cos (x) \sinh (y) .
\]

\section*{See Also}
asin, cos, tan, sec, csc, cot

\section*{sinc}
sinc (num)
The sinc function returns \(\sin (n u m) /\) num. The sinc function returns 1.0 when num is zero. num must be real.

\section*{sinh}
\(\sinh (n u m)\)
The sinh function returns the hyperbolic sine of num:
\[
\sinh (x)=\frac{e^{x}-e^{-x}}{2}
\]

In complex expressions, num is complex, and \(\sinh (\) num \()\) returns a complex value.
```

See Also
cosh, tanh, coth

```

\section*{Sleep}

Sleep [flags] timespec
The Sleep operation puts Igor to sleep for a while. After the while is up, Igor continues execution. You could use this, for example, to print a graph late at night, when the load on your printer is light.

\section*{Parameters}

The format of timeSpec depends on which flags, if any, are present.
If no flags are present, then timeSpec is in \(h h: m m: s s\) format and specifies the number of elapsed hours, minutes and seconds to sleep.

\section*{Flags}
timeSpec is an absolute time in 24 hour format (e.g., 16:00:00).
/A/W
/B
/C=cursor
/Q
/S
/T

Wait until tomorrow if absolute time has passed.
Stop sleeping if the user clicks the mouse button.
Controls what kind of cursor to display during sleep.
cursor=-1: No cursor change.
cursor=0: Hour glass (default).
cursor=1: Arrow.
cursor=2: "Click".
Other: Watch.
Continue executing the procedure containing the Sleep operation even if Commandperiod (Macintosh) or Ctrl+Break (Windows) was pressed.
timeSpec is a numeric expression in seconds.
timeSpec is a numeric expression in ticks (about \(1 / 60\) of a second).

\section*{Details}

The Sleep operation does not let the user choose menus, move cursors, run procedures, draw in graphs, or do any other interactive task.
Normally timeSpec specifies an amount of elapsed time. If the /A flag is present, then timeSpec is an absolute time when sleep is to end. If the specified absolute time has already passed, no sleep occurs unless you also use /W, which makes it wait until tomorrow.
If you specify time in hh:mm:ss format, you can also specify the time indirectly through a string variable. See the examples.
You can end sleep by pressing Command-period (Macintosh) or Ctrl+Break (Windows). Normally when you do this, it aborts any procedure that is running. However, if you use the \(/ \mathrm{Q}\) flag, the procedure continues running normally.

\section*{Examples}

These examples assume the current time is 4 pm :
```

Sleep 00:01:30 // sleeps for 1 minute, 30 seconds
Sleep/A 23:30:00 // sleeps until 11:30 PM
Sleep/A 03:00:00 // doesn't sleep at all because time is past
Sleep/A/W 03:00:00 // sleeps until 3 AM tomorrow
String strl= "03:00:00" // put wakeup call time in string
Sleep/A/W \$str1 // sleeps until 3 AM tomorrow
Sleep/B/C=2/S/Q 60 // sleep 60 seconds, or until user clicks,
// and keep going (don't abort)

```

\section*{Slider}

Slider [/Z] controlName [key [= value]][, key [= value]]...
The Slider operation creates or modifies a Slider control in the target window.
A Slider control sets or displays a single numeric value. The user can adjust the value by dragging a thumb along the length of the Slider.

For information about the state or status of the control, use the ControlInfo operation.

\section*{Parameters}
ctrlName is the name of the Slider control to be created or changed.
The following keyword=value parameters are supported:
\(\left.\begin{array}{l}\text { appearance }=\{\text { kind }[\text {, platform }]\} \\ \\ \text { Sets the appearance of the control. platform is optional. Both parameters are names, } \\ \text { not strings. } \\ \\ \text { kind can be one of default, nat ive, or os } 9 . \\ \\ \text { platform can be one of Mac, Win, or All. } \\ \\ \text { Note: The Slider control reverts to os } 9 \text { appearance on Macintosh if thumbColor isn't } \\ \text { the default blue ( } 0,0,65535 \text { ). } \\ \text { See Button and DefaultGUIControls for more appearance details. }\end{array}\right\}\)
\begin{tabular}{|c|c|}
\hline pos+=\{dx, dy & Offsets the position of the slider in pixels. \\
\hline proc=procName & Specifies the procedure to execute when the control's thumb is moved by the user. \\
\hline rename=newName & Gives control a new name. \\
\hline \multirow[t]{4}{*}{side \(=s\)} & Controls slider thumb. \\
\hline & \(s=0\) : \(\quad\) Thumb is blunt. \\
\hline & \(s=1: \quad\) Thumb points right or down (default). \\
\hline & \(s=2: \quad\) Thumb points up or left. \\
\hline size \(=\{\) width,height \(\}\) & Sets width or height of control in pixels. height is ignored if vert=0 and width is ignored if vert=1. \\
\hline thumbColor \(=(r, g, b)\) & Sets dominant foreground color of thumb. \(r, g\), and \(b\) are integers from 0 to 65535 . Only the hue and saturation are used. Therefore \((0,1000,0)\) is the same tint of green as (0,10000,0). \\
\hline \multirow[t]{4}{*}{ticks= \(t\)} & Controls slider ticks. \\
\hline & \(t=0: \quad\) No ticks. \\
\hline & \[
t=1: \quad \begin{aligned}
& \text { Number of ticks is calculated from limits (no ticks drawn if } \\
& \text { calculated value is less than } 2 \text { or greater than 100). Default value. }
\end{aligned}
\] \\
\hline & \(t>1\) : \(\quad t\) is the number of ticks distributed between the start and stop position. Ticks are labeled using the same automatic algorithm used for graph axes. Use negative tick values to force ticks to not be labeled. Ticks are shown on the side specified by the side keyword and are not drawn if side \(=0\). \\
\hline tkLblRot \(=\) deg & Rotates tick labels. deg is a value between -360 and 360. Prior to Igor Pro 6.1, rotation was supported in multiples of 90 degrees only. \\
\hline userdata(UDName) & =UDStr \\
\hline
\end{tabular}

Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create.
userdata(UDName)+=UDStr
Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr.
userTicks \(=\{\) tvWave, tlblWave \(\}\)
User-defined tick positions and labels. toWave contains the tick positions, and text wave \(t l b l W a v e ~ c o n t a i n s ~ t h e ~ l a b e l s . ~ S e e ~ M o d i f y G r a p h ~ u s e r t i c k s ~ f o r ~ m o r e ~ i n f o . ~\)
Overrides normal ticking specified by ticks keyword.
value \(=v \quad v\) is the new value for the Slider.
valueColor \(=(r, g, b) \quad\) Sets the color of the tick labels. \(r, g\), and \(b\) range from 0 to 65535 . valueColor defaults to black \((0,0,0)\).
variable \(=\) var \(\quad\) Sets the variable (var) that the slider will update. It is not necessary to connect a Slider to a variable - you can get a Slider's value using the ControlInfo operation.
vert \(=v \quad\) Set vertical \((v=1\); default) or horizontal \((v=0)\) orientation of the slider.
win=winName Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

Flags
```

/Z No error reporting

```

\section*{Details}

The target window must be a graph or panel.
The format of the action procedure (set by the proc keyword) that will be called as the user drags the Slider's thumb is:
```

Function MySliderProc(name, value, event) : SliderControl
String name // name of this slider control
Variable value // value of slider
Variable event // bit field:bit 0:value set; 1:mouse down,
// 2:mouse up, 3:mouse moved
return 0 // other return values reserved
End

```

The ": SliderControl" designation tells Igor to include this procedure in the Procedure pop-up menu in the Slider Control dialog.
If you use negative ticks to suppress automatic labeling, you can label tick marks using drawing tools (panels only).
The action procedure for a Slider control can also use a predefined structure WMSliderAction as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a Slider control, otherwise it will use the old-style method.
A Slider action procedure using a structure has the format:
```

Function newActionProcName(S Struct) : SliderControl
STRUCT WMSliderAction \&\overline{S}_Struct
End

```

For a Slider control, the WMSliderAction structure has members as described in the following table:
WMSIiderAction Structure Members
\begin{tabular}{ll} 
Member & Description \\
\hline char ctrlName [MAX_OBJ_NAME+1] & Control name. \\
char win [MAX_WIN_PATH+1] & Host (sub)window. \\
STRUCT Rect winRect & Local coordinates of host window. \\
STRUCT Rect ctrlRect & Enclosing rectangle of the control. \\
STRUCT Point mouseLoc & Mouse location. \\
Int32 eventCode & Event that caused the procedure to execute. Sets bit fields: \\
& \begin{tabular}{l} 
bit 0: value set. \\
bit 1: mouse down. \\
\\
bit 2: mouse up. \\
bit 3: mouse moved. \\
\\
Int32 eventMod \\
String userData \\
Int32 blockReentry
\end{tabular} \\
& \begin{tabular}{l} 
Bitfield of modifiers. See Control Structure eventMod Field on \\
page III-387. \\
\end{tabular} \\
\hline
\end{tabular}
double curval Value of slider.

Action functions should respond only to documented event Code values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

\section*{Examples}
```

Function SliderExample()
NewPanel /W=(150,50,501,285)
Variable/G var1
Execute "ModifyPanel cbRGB=(56797,56797,56797)"
SetVariable setvar0,pos={141,18}, size={122,17},limits={-Inf,Inf,1},value=var1
Slider foo,pos={26,31},size={62,143},limits={-5,10,1},variable=var1
Slider foo2,pos={173,161},size={150,53}
Slider foo2,limits={-5,10,1},variable=var1, vert=0,thumbColor=(0,1000,0)
Slider foo3,pos={80,31},size={62,143}
Slider foo3,limits={-5,10,1},variable=var1,side=2,thumbColor=(1000,1000,0)
Slider foo4,pos={173,59},size={150,13}
Slider foo4,limits={-5,10,1},variable=varl, side=0,vert=0
Slider foo4,thumbColor=(1000,1000,1000)
Slider foo5,pos={173,90}, size={150,53}
Slider foo5,limits={-5,10,1},variable= varl,side=2,vert=0
Slider foo5,ticks=5,thumbColor=(500,1000,1000)
End

```

\section*{See Also}

The ControlInfo operation for information about the control. Chapter III-14, Controls and Control Panels, for details about control panels and controls. The GetUserData operation for retrieving named user data.

\section*{Slow}

\section*{Slow ticks}

The Slow operation slows down execution of macros for debugging purposes.

\section*{Parameters}
ticks is in units of \(1 / 60\) second. A value of 30 is about right to allow you to read the macro command lines as they are executed. Slow 0 resumes normal macro execution.

\section*{Details}

This has no effect in user-defined functions.

\section*{Smooth}

Smooth [flags] num, waveName [, waveName...]
The Smooth operation smooths the named waves using binomial (Gaussian) smoothing, boxcar (sliding average) smoothing, Savitzky-Golay (polynomial) smoothing, or running-median filtering.

\section*{Parameters}
num is the number of smoothing operations to be applied for binomial smoothing or the integer number of points in the smoothing window for boxcar, Savitzky-Golay, and running-median smoothing.
Each waveName is smoothed in-place, overwriting the values with the smoothed result. waveName may be a floating point or integer wave.
If waveName complex, the real and imaginary parts are smoothed independently.
If waveName contains NaNs, the results are undefined. (The Loess operation and the Interpolate XOP can fill in NaNs).

\section*{Flags}
\(/ \mathrm{B}[=b] \quad\) Invokes boxcar smoothing algorithm. If given, \(b\) specifies the number of passes to use when smoothing the data with smoothing factor num (box width). The number of passes can be any value between 1 and 32767 .
/DIM=d Specifies the wave dimension to smooth.
\(d=-1\) : Treats entire wave as 1D (default).
For \(d=0,1, \ldots\), operates along rows, columns, etc.
\(/ E=e n d E f f e c t \quad\) Determines how to handle the ends of the wave (w) when fabricating missing neighbor values.
endEffect=0: \(\quad\) Bounce method (default). Uses w[i] in place of the missing \(\mathrm{w}[-\) \(i]\) and \(\mathrm{w}[n-i]\) in place of the missing \(\mathrm{w}[n+i]\).
endEffect=1: Wrap method. Uses \(\mathrm{w}[n-i]\) in place of the missing \(\mathrm{w}[-i]\) and vice versa.
endEffect=2: \(\quad\) Zero method. Uses 0 for any missing value.
endEffect=3: Repeat method. Uses \(\mathrm{w}[0]\) in place of the missing \(\mathrm{w}[-i]\) and \(\mathrm{w}[n]\) in place of the missing \(\mathrm{w}[n+i]\).
/EVEN [=evenAllowed]
Specifies the smoothing increment for boxcar smoothing (/B). Values are:
0: \(\quad\) Increments even values of num to the next odd value. Default when /EVEN omitted.
1: \(\quad\) Uses even values of num for boxcar smoothing despite the halfsample shifting this introduces in the smoothed output (prior to version 6, this shift was prevented). Same as/EVEN alone.
/F [=f] Selects the boxcar or multipass binomial smoothing method:
\(f=0\) : \(\quad\) Slow, but accurate, method (default).
\(f=1: \quad\) Fast method. Same as \(/ F\) alone.
\(/ \mathrm{M}=\) threshold \(\quad\) Invokes running-median smoothing and specifies an absolute numeric threshold used to optionally replace "outliers". Points that differ from the central median by an amount exceeding threshold are replaced, either with the replacement value specified by \(/ R\), or otherwise with the median value.
Special threshold values are:
0: \(\quad\) Replace all values with running-median values or the replacement value.
( NaN ): Replace only NaN input values with running-median values or the replacement value.

The smoothing factor num is the number of points in the smoothing window used to compute each median.
/MPCT=percentile Used with /M to compute a smoothed value that is a different percentile than the median. /M must be present if /MPCT is used.
percentile is a value from 0 to 100 .

Roughly speaking, the smoothed value returned is the smallest value in the smoothing window that is greater than the smallest percentile \% of the values. See "Median and Percentile Smoothing Details", below.
percentile \(=0\) : \(\quad\) The smoothed value is the minimum value in the smoothing window.
percentile=50: \(\quad\) The smoothed value is the median of the values in the smoothing window. This is the default if /MPCT is omitted.
percentile \(=100\) : The smoothed value is the maximum value in the smoothing window.
\(/ \mathrm{R}=\) replacement \(\quad\) Specifies the value that replaces input values that exceed the central median by threshold (requires /M). threshold can be any value (including NaN or \(\pm\) Inf if waveName is floating point).
\(/ \mathrm{S}=\) sgOrder \(\quad\) Invokes Savitzky-Golay smoothing algorithm and specifies the smoothing order. sgOrder must be either 2 or 4 .

\section*{Binomial Smoothing Details}

For binomial smoothing, use no flags (other than /DIM, /E, and /F) and a num value from 1 to 32767.
The binomial smooth algorithm automatically switches to a nearly equivalent (but much faster) multipass box smooth at smooth factor of 50 . The original algorithm can be used when you set this global variable:
Variable/G root:V_doOrigBinomSmooth=1
To get the pre-Igor Pro 6 behavior you also need to add the /F flag.
The /F (fast boxcar smoothing) algorithm creates small errors when the data has a large offset. For some data sets you may want to subtract the mean of the data before smoothing and add it back in afterwards.
The binomial smoothing algorithm does not detect and ignore NaNs in the input data.

\section*{Boxcar Smoothing Details}

For boxcar smoothing, use the /B flag and a num value from 1 to 32767.
For num \(<2\), no smoothing is done.
If num is even and /EVEN is not specified, num is incremented to the next (odd) integer.
If num is even and /EVEN is specified, each smoothed output is formed from one more previous value than future values.

The boxcar smoothing algorithm detects and ignores NaNs in the input data. If num is less than the number of NaNs near the output point, then the result is NaN . Otherwise the average of the non-NaN neighboring points is used to compute the smoothed result.

\section*{Savitzky-Golay Smoothing Details}

For Savitzky-Golay smoothing, use the /S flag and an odd num value from 5 to 25 . An even value for num returns an error. If \(\operatorname{sgOrder}=4\), then \(n u m=5\) gives no smoothing at all so num should be at least 7 .
The Savitzky-Golay smoothing algorithm does not detect and ignore NaNs in the input data.

\section*{Median and Percentile Smoothing Details}

For running-median smoothing, use the / M flag and a num value from 1 to 32767 . When num is 1 , no smoothing is done.
If num is even, the median is the average of the two middle values.
For example, the median of 6 values around data[i] is the median of data[i-3], data[i-2], data[i-1], data[i], data[ \(\mathrm{i}+1]\), and data[ \(\mathrm{i}+2\) ], and if these values were already sorted, the median would be the average of data[i1] and data[i].
Use / \(M=0\) to replace all values with the median over the smoothing window or use
/M=threshold/R=(NaN) to replace outliers with NaNs.
Use / M = ( NaN ) to replace only NaN input values with the running-median values or the replacement value.

The running-median smoothing algorithm detects and ignores NaNs in the input data. If num is less than the number of NaNs near the output point, then the result is NaN. Otherwise the median of the non-NaN neighboring points is used to compute the smoothed result.
The running-median is a special case of running-percentile, with percentile=50.
The /M and /MPCT algorithm uses an interpolated rank to compute the value of percentiles other than 0 and 100 .

Using Example 1 from <http://cnx.org/content/m10805/latest/> ("A Third Definition"), the 25th percentile (/MPCT=25) of the 8 values:
```

Make/O sortedData={3,5,7,8,9,11,13,15}// Already sorted, rank 1 to 8

```

The first step is to compute the \(\operatorname{rank}(R)\) of the 25 th percentile. This is done using the following formula: \(\mathrm{R}=\) (percentile/100)* \({ }^{*}\) num +1 ), where percentile is 25 and num is 8 , so here \(\mathrm{R}=2.25\).
If \(R\) were an integer, the Pth percentile would be the number with rank \(R\); if \(R\) were 2 the result would be the 2 nd value \(=5\).

Since R is not an integer, we compute the Pth percentile by interpolation as follows:
1. Define \(I R\) as the integer portion of \(R\) (the number to the left of the decimal point). For this example, \(I R=2\).
2. Define FR as the fractional portion of \(R\). For this example, \(F R=0.25\)
3. Find the values with Rank IR and with Rank IR +1 . For this example, this means the values with Rank 2 and the score with Rank 3. The values are 5 and 7.
4. Interpolate by multiplying the difference between the values by FR and add the result to the lower values. For these data, this is \(0.25(7-5)+5=5.5\)
Therefore, the 25 th percentile is 5.5 :
```

Smooth/M=0/MPCT=(percentile) 8, sortedData // 8-point smoothing window
Print sortedData[3] // prints 5.5, the 25th percentile of all 8 values

```

\section*{Smoothing Window and End Effects Details}

These smoothing algorithms compute the output value for a given point using each point's neighbors. Except for running-median smoothing, each algorithm combines neighboring points before and after the point being smoothed. At the start or end of a wave some points will not have enough neighbors so some method for fabricating neighbor values must be implemented. The /E flag specifies the method.
The running-median filter, however, ignores /E. At each end of the data fewer values are included in the median calculation, so that values "beyond" the end of data are not needed.
The first output value is the median of wave \([0\), floor ( (num-1)/2)]. For example, if num = 7, then the first output value is the median of wave[0], wave[1], wave[2], and wave[3]. Because that is an even number of points, the median is the average of the two middle values. Continuing the example, if the values were \(3,1,7\), and 5 , the two middle values are 3 and 5 . The computed median would be \((3+5) / 2=4\).

\section*{Examples}

Box smoothing example:
```

Make/N=100 wv; Display wv
wv=gnoise(1)
Smooth/B/E=3 3,wv // output[p] = average of wv[p-1], wv[p] and wv[p+1]
// /E=3 causes wv[0] = (w[0]+w[0]+w[1])/3
// and wv[n-1] = (w[n-2]+w[n-1]+w[n-1])/3

```

Demonstrate the impulse response of Savitzky-Golay Smoothing:
```

Make/O/N=100 wv
Wv= p==50 // 1 at center of wave, 0 elsewhere; an impulse
SetScale/P x, 0, 1/1000, "s", wv // 1000 Hz sampling rate
Smooth/S=2 5,wv
Display wv
ModifyGraph mode=8,marker=19
FFT/MAG/DEST=fftMag wv
Display fftMag

```

Replace NaN with median:
\(\begin{array}{lll}\text { Make/O/N=100 data= enoise }(1)>.9 & \text { NaN }: \sin (x / 8) & / / \text { signal with NaNs } \\ \text { Duplicate/O data, dataMedian } & \\ \text { Smooth/M= (NaN) 5, dataMedian } & / / \text { replace (only) NaNs with 5-point median }\end{array}\)

\section*{See Also}

See the Loess, MatrixConvolve, and MatrixFilter operations for true 2D smoothing.
The FilterFIR, FilterIIR, and Loess operations; the Interpolate XOP.
Also see the Smooth Operation Responses example experiment.

\section*{SmoothCustom}

SmoothCustom [/E=endEffect] coefsWaveName, waveName [, waveName]...
Note: \(\quad\) SmoothCustom is obsolete. Use the FilterFIR operation instead. For multidimensional data use the MatrixConvolve or MatrixFilter operations.

The SmoothCustom operation smooths waves by convolving them with coefsWaveName.

\section*{Parameters}
coefsWaveName must be single or double floating point, must not be one of the destination waveNames, must not be complex.
waveName is a numeric destination wave that is overwritten by the convolution of itself and coefsWaveName.

\section*{Flags}
\(/ E=\) endEffect End effect method, a value between 0 and 3. See the Smooth operation for a description of the /E flag.

\section*{Details}

The convolution is in the time domain. That is, the FFT is not employed. For this reason the length of coefsWaveName should be small or small in comparison to the destination waves.
SmoothCustom presumes that the middle point of coefsWaveName corresponds to the delay \(=0\) point. The "middle" point number = trunc(numpnts(coefsWaveName-1)/2). coefsWaveName usually contains the twosided impulse response of a filter, and contains an odd number of points. This is the type of wave created by FilterFIR.
SmoothCustom ignores the X scaling of all the waves.
The SmoothCustom operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-110 for details.

\section*{Sort}

Sort [ /A /DIML /C /R ] sortKeyWaves, sortedWaveName [, sortedWaveName]... The Sort operation sorts the sortedWaveNames by rearranging their \(Y\) values to put the data values of sortKeyWaves in order.

\section*{Parameters}
sortKeyWaves is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.
All waves must be of the same length.
The sortKeyWaves must not be complex.

\section*{Flags}
/A Alphanumeric sort. When sortKeyWaves includes text waves, the normal sorting places "wave1" and "wave10" before "wave9". Use /A to sort the number portion numerically, so that "wave9" is sorted before "wave10".
/C Case-sensitive sort. When sortKeyWaves includes text waves, the sort is case-insensitive unless you use the /C flag to make it case-sensitive.
/DIML Moves the dimension labels with the values (keeps any row dimension label with the row's value).
/R Reversed sort; sort from largest to smallest.

\section*{Details}
sortKeyWaves are not actually sorted unless they also appear in the list of destination waves.
The sort algorithm does not maintain the relative position of items with the same key value.

\section*{Examples}
```

Sort/R myWave,myWave // sorts myWave in decreasing order
Sort xWave,xWave,yWave // sorts x wave in increasing order,
M
Make/O/T myWave={"1st","2nd","3rd","4th"}
Make/O keyl={2,1,1,1} // places 2nd, 3rd, 4th before 1st.
Make/O key2={0,1,3,2} // arranges 2nd, 3rd, 4th as 2nd, 4th, 3rd.
Sort {key1,key2},myWave // sorts myWave in increasing order by key1.
// For equal keyl values, sorted by key2.
// Result is myWave={"2nd","4th","3rd","1st"}
Make/O/T tw={"w1","w10","w9","w-2.1"}
Sort/A tw,tw // sorts tw in increasing number-aware order:
// Result is tw={"w-2.1","w1","w9","w10"}

```

\section*{See Also}

The MakeIndex, IndexSort, Reverse and SortList operations. See Sorting on page III-136.

\section*{SortList}

SortList(listStr [, listSepStr [, options])
The SortList function returns listStr after sorting it according to the default or listSepStr and options parameters. listStr should contain items separated by the listSepStr character, such as "the first item;second item;".
Use SortList to sort the items in a string containing a list of items separated by a single character, such as those returned by functions like TraceNameList or WaveList, or a line of text from a delimited text file.
listSepStr and options are optional; their defaults are ";" and 0 (alphabetic sort), respectively.

\section*{Details}
listStr is treated as if it ends with a listSepStr even if it doesn't. The returned list will always have an ending listSepStr character.
Only the first character of listSepStr is used. If listSepStr is " " then the default of ";" is used.
options is a literal number which controls the sorting method. options is one of:
0: Default sort (ascending case-sensitive alphabetic ASCII sort).
1: Descending sort.
2: Numeric sort.
4: Case-insensitive sort.
8: Case-sensitive alphanumeric sort using system script.
16: Case-insensitive alphanumeric sort that sorts wave0 and wave9 before wave10.
or a bitwise combination of the above with the following restriction: only one of \(2,4,8\), or 16 may be specified. The legal values are thus \(0,1,2,3,4,5,8,9,16\), and 17 . Other values will produce undefined sorting criteria.

\section*{Examples}
// alphabetic sorts
Print SortList("b;c;a;") // prints "a;b;c;"
Print SortList ("you,me,i", ",", 4) // prints "i,me,you,"
Print SortList ("9,93,91,33,15,3", ",") // prints "15,3,33,9,91,93,"
Print SortList("Zx;abc;All;", ";", 0) // prints "All;Zx;abc;"
Print SortList("Zx;abc;All;", ";", 8) (/ prints "abc;All;Zx;"
Print SortList("w9;w10;w02;", ";", 16) // prints "w02;w9;w10;"
// numeric sorts
Print SortList("9,93,91,33,15,3",",",2) // prints "3,9,15,33,91,93,"
// (reversed)
Print SortList("9,93,91,33,15,3",",",3) // prints "93,91,33,15,9,3,"

\section*{See Also}

The Sort, StringFromList and WaveList functions.
See Setting Bit Parameters on page IV-12 for details about bit settings.

\section*{SoundInRecord}

SoundInRecord [/Z] wave
The SoundInRecord operation records audio input at the sample rate obtained from the wave's \(X\) scaling and for the number of points determined by the length of the wave. The recording is done synchronously.
The number type of the wave must be one of the types reported by the SoundInStatus operation in the V_SoundInSampSize variable. On Windows this will typically be 8- or 16-bit integer while on Macintosh 16-bit integer and 32-bit floating point (the OS X native type) will be supported.
To record in stereo, provide a 2 column wave. (The software is designed to handle any number of channels but has not been tested on more than 2.)

Flags
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

\section*{Details}

SoundInRecord requires a computer with sound inputs. Several sample experiments using sound input can be found in your Igor Pro Folder in the Examples folder.

\section*{See Also}

The SoundInSet, SoundInStartChart, and SoundInStatus operations.

\section*{SoundInSet}

SoundInSet [/Z] [gain=g, agc=a]
The SoundInSet operation is used to setup the input device for recording.

\section*{Parameters}

SoundInSet can accept multiple keyword =value parameters on one line.
\(\operatorname{agc}=a \quad\) Turns automatic gain control mode on \((a=1)\) or off \((a=0)\). Will generate an error if device does not support setting agc. Use SoundInStatus to check or use /Z flag to make errors nonfatal.
Windows: This is not supported and V_SoundInAGC from the SoundInStatus command always returns -1 .
gain \(=g \quad\) Sets input gain, 0 is lowest gain and 1 is highest. Will generate an error if device does not support setting gain. Use SoundInStatus to check or use /Z flag to make errors nonfatal.

Windows: SoundInSet attempts to adjust the master gain of the sound input device but not all sound cards have a master gain. If V_SoundInGain from the SoundInStatus command returns -1 , you will have to use your sound card software to adjust the input gain for the particular input source your are using. On some cards there are separate line-in and microphone-in sources.

\section*{Flags}
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

\section*{Details}

SoundInSet requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

\section*{See Also}

The SoundInRecord, SoundInStartChart, and SoundInStatus operations.

\section*{SoundInStartChart}

SoundInStartChart [/Z] buffersize, destFIFOname
The SoundInStartChart operation starts audio data acquisition into the given FIFO.

\section*{Parameters}
buffersize is the number of bytes to allocate for the interrupt time buffer which then feeds into the given Igor named FIFO destFIFOname. The FIFO must be set up with the correct number of channels and number type - use SoundInStatus to find legal values. The sample rate is read from the FIFO also, so that also needs to be correct.

\section*{Flags}
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

\section*{Details}

SoundInStartChart requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

On systems where 32-bit floating point data is supported, you can use NewFIFOChan with no flags and a range of -1 to 1 .
See Also
The SoundInRecord, SoundInSet, SoundInStatus and SoundInStopChart operations, and FIFOs and Charts on page IV-282.

\section*{SoundInStatus}

\section*{SoundInStatus}

The SoundInStatus operation creates and sets a set of variables and strings with information about the current sound input device. The variable V_flag is set to an error code and will be zero if the device is available. If not then none of the following are valid.
\begin{tabular}{|c|c|}
\hline Variables & Contents \\
\hline S_SoundInName & String with name of device. \\
\hline V_SoundInAGC & Automatic gain control on or off (1 or 0 ). This is an optional item and if the current device does not support AGC then V_SoundInAGC will be set to -1. \\
\hline V_SoundInChansAv & Available number of channels (e.g., 1 for mono, 2 for stereo). \\
\hline V_SoundInGain & Current input gain. Ranges from 0 (lowest) to 1 . This is an optional item and if the current device does not support gain then V_SoundInGain will be set to -1 . \\
\hline V_SoundInSampSize & \begin{tabular}{l}
Bits set depending on number of bits available in a sample. \\
Bit 0: Set if can do 8 bits. \\
Bit 1: Set if can do 16 bits. \\
Bit 3: Set if 32-bit floating point is supported (range is -1 to 1 ).
\end{tabular} \\
\hline W_SoundInRates & Wave containing sample rate info: if point zero contains zero then points 1 and 2 contain the lower and upper limits of a continuous range else point zero contains the number of discrete rates which follow in the wave. The usual rates are 44100 Hz and 4800 Hz . \\
\hline
\end{tabular}

\section*{See Also}

The SoundInRecord, SoundInSet, and SoundInStartChart operations.

\section*{SoundInStopChart}

SoundInStopChart [/Z]
The SoundInStopChart operation stops audio data acquisition started by SoundInStartChart.
Flags
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

\section*{Details}

SoundInStopChart requires a computer equipped with sound input hardware.
Audio data acquisition also stops automatically when an experiment is closed.

\section*{See Also}

The SoundInStartChart and SoundInStatus operations.

\section*{SpecialCharacterInfo}

SpecialCharacterInfo(notebookNameStr, specialCharacterNameStr, whichStr) The SpecialCharacterInfo function returns a string containing information about the named special character in the named notebook window.

\section*{Parameters}

If notebookNameStr is "", the top visible notebook is used. Otherwise notebookNameStr contains either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0\#nb0. See Subwindow Syntax on page III-97 for details on host-child specifications. specialCharacterNameStr is the name of a special character in the notebook.
If specialCharacterNameStr is "" and if exactly one special character is selected, the selected special character is used. If other than exactly one special character is selected, an error is returned.
whichStr identifies the information item you want. Because SpecialCharacterInfo can return several items that may contain semicolons, it does not return a semicolon-separated keyword-value list like other info functions. Instead it returns just one item as specified by whichStr.

\section*{Details}

Here are the supported values for whichStr.
\begin{tabular}{ll} 
Keyword & Returned Information \\
\hline NAME & The name of the special character. \\
FRAME & 0: None \\
& 1: Single \\
& 2: Double \\
& 3: Triple \\
& 4: Shadow \\
LOC & Paragraph and character position (e.g., 1,3). \\
SCALING & \begin{tabular}{l} 
Horizontal and vertical scaling in units of one tenth of a percent (e.g., 1000,1000). \\
TYPE
\end{tabular} \\
& Special character type is: Picture, Graph, Table, Layout, Action, ShortDate, \\
& LongDate, AbbreviatedDate, Time, Page, TotalPages, or WindowTitle.
\end{tabular}

These keywords apply to Igor-object pictures only. If the specified character is not an Igor-object picture, """ is returned.
\begin{tabular}{ll} 
Keyword & Returned Information \\
\hline WINTYPE & 1 for graphs, 2 for tables, 3 for layouts. \\
OBJECTNAME & The name of the window with which the special character is associated. \\
\hline
\end{tabular}

The remaining keywords apply to notebook action characters only. If the specified special character is not a notebook action character, " " is returned.
\begin{tabular}{ll} 
Keyword & Returned Information \\
\hline BGRGB & Background color in RGB format (e.g., 65535,65534,49151). \\
COMMANDS & Command string. \\
ENABLEBGRGB & 1 if the action's background color is enabled, 0 if not. \\
HELPTEXT & Help text string. \\
IGNOREERRORS & 0 or 1. \\
LINKSTYLE & 0 or 1. \\
PADDING & \begin{tabular}{l} 
The value of the left, right, top, bottom and internal padding properties, in that \\
order (.e.g, 4,4,4,4,8). \\
PICTURE
\end{tabular} \\
PROCPICTNAME & \begin{tabular}{l} 
The name of the action Proc Picture or " " if none.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{ll} 
Keyword & Returned Information \\
\hline QUIET & 0 or 1. \\
SHOWMODE & 1: Title only \\
& 2: Picture only \\
& 3: Picture below title \\
& 4: Picture above title \\
& 5: Picture to the left of title \\
& 6: Picture to the right of title \\
TITLE & Title string. \\
\hline
\end{tabular}

If whichStr is an unknown keyword, SpecialCharacterInfo returns " " but does not generate an error.

\section*{Examples}
```

Function PrintSpecialCharacterInfo(notebookName, specialCharacterName)
String notebookName, specialCharacterName
String typeStr=SpecialCharacterInfo(notebookName, specialCharacterName, "TYPE")
String locStr=SpecialCharacterInfo(notebookName, specialCharacterName, "LOC")
Printf "TYPE: %s\r", typeStr
Printf "LOC: %s\r", locStr
End

```

See Also
The Notebook and NotebookAction operations; the SpecialCharacterList function; Using Igor-Object Pictures on page III-21.

\section*{SpecialCharacterList}

SpecialCharacterList(notebookNameStr, separatorStr, mask, flags)
The SpecialCharacterList function returns a string containing a list of names of special characters in a formatted text notebook.

\section*{Parameters}

If notebookNameStr is "", the top visible notebook is used. Otherwise notebookNameStr contains either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0\#nb0. See Subwindow Syntax on page III-97 for details on host-child specifications. separatorStr should contain a single character, usually semicolon, to separate the names.
mask determines which types of special characters are included. mask is a bitwise parameter with values:
1: Pictures including graphs, tables and layouts.
2: Notebook actions.
4: All other special characters such as dates and times.
or a bitwise combination of the above for more than one type. See Setting Bit Parameters on page IV-12 for details about bit settings.
flags is a bitwise parameter. Pass 0 to include all special characters or 1 to include only selected special characters. All other bits are reserved and should be passed as zero.

\section*{Details}

Only formatted text notebooks have special characters. When called for a plain text notebook, SpecialCharacterList always returns " ".

\section*{Examples}

Print a list of all special characters in the top notebook:
Print SpecialCharacterList("", ";", -1, 0)
Prints a list of notebook action characters in Notebook0:
Print SpecialCharacterList("Notebook0", ";", 2, 0)

Print a list of selected notebook action characters in Notebook0:
Print SpecialCharacterList("Notebook0", ";", 2, 1)

\section*{See Also}

The Notebook and NotebookAction operations; the SpecialCharacterInfo function.

\section*{SpecialDirPath}

SpecialDirPath(dirIDStr, domain, flags, createDir)
The SpecialDirPath function returns a full path to a file system directory specified by dirIDStr and domain. It provides a programmer with a way to access directories of special interest, such as the preferences directory and the desktop directory.
The path returned always ends with a separator character which may be a colon, backslash, or forward slash depending on the operating system and the flags parameter.
SpecialDirPath depends on operating system behavior. The exact path returned depends on the locale, the operating system, the specific installation, the current user, and possibly other factors.

\section*{Parameters}
dirIDStr is one of the following strings:
\[
\begin{array}{ll}
\text { "Packages" } & \begin{array}{l}
\text { Place for advanced programmers to put preferences for their procedure } \\
\text { packages. }
\end{array} \\
\text { "Documents" } & \begin{array}{l}
\text { The OS-defined place for users to put documents. } \\
\text { "Preferences" }
\end{array} \\
\text { "Desktop" } & \begin{array}{l}
\text { The desktop. }
\end{array} \\
\text { "Temporary" } & \text { The OS-defined place for applications to put temporary files. } \\
\text { "Igor Application" } & \begin{array}{l}
\text { The folder in which Igor.app or Igor.exe is installed. Use only with domain = } \\
0 \text { (the current user). }
\end{array} \\
\text { "Igor Preferences" } & \begin{array}{l}
\text { The folder in which Igor's own preference files are stored. }
\end{array} \\
\text { "Igor Pro User Files" } & \begin{array}{l}
\text { A guaranteed-writable folder for the user to store their own Igor files, and to put preferences. } \\
\text { activate extensions, help, and procedure files by creating shortcuts or aliases } \\
\text { in the appropriate subfolders. Use only with domain = 0 (the current user). }
\end{array} \\
\text { This is the folder opened using the Show Igor Pro User Files menu item in the } \\
\text { Help menu. }
\end{array}
\]
domain permits discriminating between, for example, the preferences folder for all users versus the preferences folder for the current user. It is supported only for certain dirIDStrs. It is one of the following:
\(0: \quad\) The current user (recommended value for most purposes).
1: \(\quad\) All users (may generate an error or return the same path as 0 ).
2: \(\quad\) System (may generate an error or return the same path as 1 ).
flags a bitwise parameter:
Bit 0: If set, the returned path is a native path (Macintosh-style on Mac OS 9, Unix-style on Mac OS X, Windows-style on Windows). If cleared, the returned path is a Macintosh-style path regardless of the current platform. In most cases you should set this bit to zero since Igor accepts Macintosh-style paths on all operating systems. You must set this bit to one if you are going to pass the path to an external script.

All other bits are reserved and must be set to zero.
See Setting Bit Parameters on page IV-12 for details about bit settings.
createDir is 1 if you want the directory to be created if it does not exist or 0 if you do not want it to be created. This flag will not work if the current user does not have sufficient privileges to create the specified directory. In almost all cases it is not needed, you can't count on it, and you should pass 0 .

\section*{Details}

The domain parameter has no effect in most cases. In almost all cases you should pass 0 (current user) for this parameter. For values other than 0, SpecialDirPath might return an error which you must be prepared to handle.
In the event of an error, SpecialDirPath returns a NULL string and sets a runtime error code. You can check for an error like this:
```

String fullPath = SpecialDirPath("Packages", 0, 0, 0)
Variable len = strlen(fullPath) // strlen(NULL) returns NaN
if (numtype(len) == 2) // fullPath is NULL?
Print "SpecialDirPath returned error."
endif

```

Here is sample output from SpecialDirPath("Packages", \(0,0,0\) ):
```

Mac OS X hd:Users:<user>:Library:Preferences:WaveMetrics:Igor Pro 6 Intel:Packages:
Windows C:Documents and Settings:<user>:Application Data:WaveMetrics:Igor Pro 6:Packages:

```
where <user> is the name of the current user. The preferences directory may be hidden by some operating systems.

\section*{Example}

For an example using SpecialDirPath, see Saving Package Preferences on page IV-231.

\section*{sphericalBessJ}
sphericalBessJ( \(n\), x [, accuracy])
The sphericalBessJ function returns the spherical Bessel function of the first kind and order \(n\).
\(j_{n}(x)=\sqrt{\frac{\pi}{2 x}} J_{n+1 / 2}(x)\).
For example:
\[
j_{0}(x)=\frac{\sin (x)}{x} \quad j_{1}(x)=\frac{\sin (x)}{x^{2}}-\frac{\cos (x)}{x} \quad j_{2}(x)=\left(\frac{3}{x^{3}}-\frac{1}{x}\right) \sin (x)-\frac{3}{x^{2}} \cos (x) .
\]

Arfken, G., Mathematical Methods for Physicists, Academic Press, New York, 1985.

\section*{SphericalInterpolate}

SphericalInterpolate triangulationDataWave, dataPointsWave, newLocationsWave The SphericalInterpolate operation works in conjunction with the SphericalTriangulate operation to calculate interpolated values on a surface of a sphere. Given a set of \(\left\{x_{i}, y_{i}, z_{i}\right\}\) points on the surface of a sphere with their associated values \(\left\{\mathrm{v}_{\mathrm{i}}\right\}\), the SphericalTriangulate operation performs the Delaunay triangulation and creates an output that is used by the SphericalInterpolate operation to calculate values at any other point on the surface of a sphere. The interpolation calculation uses Voronoi polygons to weigh the contribution of the nearest neighbors to any given location on the sphere.

\section*{Parameters}
triangulationDataWave is a 13 column wave that was created by the SphericalTriangulate operation. dataPoints is a 4 column wave. The first 3 columns are the \(\left\{x_{i}, y_{i}, z_{i}\right\}\) locations that were used to create the triangulation, and the last column corresponds to the \(\left\{\mathrm{v}_{\mathrm{i}}\right\}\) values at the triangulation locations.
newLocationsWave is a 3 column wave that specifies the \(x, y, z\) locations on the sphere at which the interpolated values are calculated. Note that internally, each triplet is normalized to a point on the unit sphere before it is used in the interpolation.

\section*{Details}

You will always need to use the SphericalTriangulate operation first to generate the triangulationDataWave input for this operation.

The result of the operation are put in the wave W_SphericalInterpolation.

\section*{See Also}

The SphericalTriangulate operation.

\section*{SphericalTriangulate}

SphericalTriangulate [/Z] tripletWaveName
The SphericalTriangulate operation triangulates an arbitrary XYZ triplet wave on a surface of a sphere.
It starts by normalizing the data to make sure that \(\operatorname{sqrt}\left(x^{2}+y^{2}+z^{2}\right)=1\), and then proceeds to calculate the Delaunay triangulation.

Flags
/Z No error reporting.
Details
The result of the triangulation is the wave M_SphericalTriangulation. This 13 column wave is used in SphericalInterpolate to obtain the interpolated values.

\section*{See Also}

The SphericalInterpolate operation.

\section*{SplitString}

SplitString /E=regExprStr str [, substring1 [, substring2,... substringN]]
The SplitString operation uses the regular expression regExprStr to split str into subpatterns. See
Subpatterns on page IV-166 for details. Each matched subpattern is returned sequentially in the corresponding substring parameter.

\section*{Parameters}
str is the input string to be split into subpatterns.
The substring1...substring \(N\) output parameters must be the names of existing string variables if you need to use the matched subpatterns. The first matched subpattern is returned in substring1, the second in substring2, etc.

\section*{Flags}
\(/ \mathrm{E}=\) regExprStr \(\quad\) Specifies the Perl-compatible regular expression string containing subpattern definition(s).

\section*{Details}
regExprStr is a regular expression with successive subpattern definitions, such as shown in the examples. (Subpatterns are regular expressions within parentheses.)
For unmatched subpatterns, the corresponding substring is set to " ". If you specify more substring parameters than subpatterns, the extra parameters are also set to " ".
The number of matched subpatterns is returned in V_flag.
The part of str that matches regExprStr (often all of str) is stored in S_value.

\section*{Examples}
```

// Split the output of the date() function:
Print date()
Mon, May 2, 2005
String expr="([[:alpha:]]+), ([[:alpha:]]+) ([[:digit:]]+), ([[:digit:]]+)"
String dayOfWeek, monthName, dayNumStr, yearStr

```
```

SplitString/E=(expr) date(), dayOfWeek, monthName, dayNumStr, yearStr
Print V_flag
4
Print dayOfWeek
Mon
Print monthName
May
Print dayNumStr
2
Print yearStr
2005
Print S_value
Mon, May 2, 2005
// Get the part of str that matches regExprStr
SplitString/E=",.*," "stuff in front,second value,stuff at end"
Print S_value
,second value,

```

\section*{See Also}

Regular Expressions on page IV-156 and Subpatterns on page IV-166.
The sscanf and Grep operations. The strsearch and str2num functions.

\section*{sprintf}
sprintf stringName, formatStr [, parameter]...
The sprintf operation is the same as printf except it prints the formatted output to the string variable stringName rather than to the history area.

\section*{Parameters}
formatStr See printf.
parameter See printf.
stringName \(\quad\) Results are "printed" into the named string variable.

\section*{See Also}

The printf operation for complete format and parameter descriptions and Creating Formatted Text on page IV-235.

\section*{sqrt}
sqrt (num)
The sqrt function returns the square root of num or NaN if num is negative.
In complex expressions, num is complex, and sqrt(num) returns the complex value \(x+i y\).

\section*{sscanf}
sscanf scanStr, formatStr, var [, var]
The sscanf operation is useful for parsing text that contains numeric or string data. It is based on the C sscanf function and provides a subset of the features available in C.
Here is a trivial example:
Variable v1
sscanf "Value= 1.234", "Value= \%f", v1
This skips the text "Value=" and the following space and then converts the text "1.234" (or whatever number appeared there) into a number and stores it in the local variable v 1.
The sscanf operation sets the variable V_flag to the number of values read. You can use this as an initial check to see if the scanStr is consistent with your expectations.

Note: The sscanf operation is supported in user functions only. It is not available using the command line, using a macro, or using the Execute operation.

\section*{Parameters}
scanStr contains the text to be parsed.
formatStr is a format string which describes how the parsing is to be done.
formatStr is followed by the names of one or more local numeric or string variables or NVARs (references to global numeric variables) or SVARs (references to global string variables), which are represented by var above.
sscanf can handle a maximum of 100 var parameters.

\section*{Details}

The format string consists of the following:
- Normal text, which is anything other than a percent sign ("\%") or white space.
- White space (spaces, tabs, linefeeds, carriage returns).
- A percent (" \(\%\) ") character, which is the start of a conversion specification.

The trivial example illustrates all three of these components.
Variable v1
sscanf "Value= 1.234", "Value= \%f", v1
sscanf attempts to match normal text in the format string to the identical normal text in the scan string. In the example, the text "Value=" in the format string skips the identical text in the scan string.
sscanf matches a single white space character in the format string to 0 or more white space characters in the scan string. In the example, the single space skips the single space in the scan string.
When sscanf encounters a percent character in the format string, it attempts to convert the corresponding text in the scan string into a number or string, depending on the conversion character following the percent, and stores the resulting number or string in the corresponding variable in the parameter list. In the example, "\%f" converts the text " 1.234 " into a number which it stores in the local variable v1.

A conversion specification consists of:
- A percent character ("\%").
- An optional "*", which is a conversion suppression character.
- An optional number, which is a maximum field width.
- A conversion character, which specifies how to interpret text in the scan string.

Don't worry about the suppression character and the maximum width specification for now. They will be explained later.

The sscanf operation supports a subset of the conversion characters supported by the C sscanf operation. The supported conversion characters, which are case-sensitive, are:
\(d \quad\) Converts text representing a decimal number into an integer numeric value.
i Converts text representing a decimal, octal or hexadecimal number into an integer value. If the text starts with " \(0 x\) " (zero-x), it is interpreted as hexadecimal. Otherwise, if it starts with " 0 " (zero), it is interpreted as octal. Otherwise it is interpreted as decimal.

Converts text representing an octal number into an integer numeric value.
Converts text representing an unsigned decimal number into an integer numeric value.
Converts text representing a hexadecimal number into an integer numeric value.
c Converts a single character into an integer value which is the ASCII code representing that character.
e
Converts text representing a decimal number into a floating point numeric value.
f \(\quad\) Same as e.
```

g Same as e.
S
[
Stores text up to the next white space into a string.
Stores text that matches a list of specific characters into a string. The list consists of the characters inside the brackets (" $\%[a b c]$ "). If the first character is " $\wedge$ ", this means to match any character that is not in the list. You can specify a range of characters to match. For example "\% $[\mathrm{A}-\mathrm{Z}]$ " matches all of the upper case letters and "\% $[\mathrm{A}-\mathrm{Za}-\mathrm{z}]$ " matches all of the upper and lower case letters.

```

Here are some simplified examples to illustrate each of these conversions.
```

Variable v1

```

String sl
Convert text representing a decimal number to an integer value:
sscanf "1234", "\%d", v1
Convert text representing a decimal, octal, or hexadecimal number:
```

sscanf "1.234", "%i", v1 // Convert from decimal.
sscanf "01234", "%i", v1 // Convert from octal.
sscanf "0x123", "%i", v1 // Convert from hex.

```

Convert text representing an octal number:
sscanf "1234", "\%o", v1
Convert text representing an unsigned decimal number:
sscanf "1234", "\%u", v1
Convert text representing a hexadecimal number:
sscanf "1FB9", "\%x", v1
Convert a single character:
sscanf "A", "\%c", v1
Convert text representing a decimal number to an floating point value:
```

sscanf "1.234", "%e", v1
sscanf "1.234", "%f", v1
sscanf "1.234", "%g", v1

```

Copy a string of text up to the first white space:
sscanf "Hello There", "\%s", s1
Copy a string of text matching the specified characters:
sscanf "+4.27", "\%[+-]", s1
In a C program, you will sometimes see the letters " 1 " (ell) or " \(h\) " between the percent and the conversion character. For example, you may see "\%lf" or "\%hd". These extra letters are not needed or tolerated by Igor's sscanf operation.
When sscanf matches the format string to the scan string, it reads from the scan string until a character that would be inappropriate for the section of the format string that sscanf is trying to match. In the following example, sscanf stops reading characters to be converted into a number when it hits the first character that is not appropriate for a number.
Variable v1
String s1, s2
sscanf "1234Volts DC", "\%d\%s \%s", v1, s1, s2
sscanf stops matching text for "\%d" when it hits "V" and stores the converted number in v1. It stops matching text for the first "\%s" when it hits white space and stores the matched text in s1. It then skips the space in the scan string because of the corresponding space in the format string. Finally, it matches the remaining text to the second "\%s" and stores the text in s2.
The maximum field width must appear just before the conversion character (" d " in this case).
Variable v1, v2
sscanf "12349876", "\%4d\%4d", v1, v2
The suppression character ("*") is used in a conversion specification to skip values in the scan string. It parses the value, but sscanf does not store the value in any variable. In the following example, we read one number into local variable v1, skip a colon, and read another number into local variable v2, skip a colon, and read another number into local variable v3.
```

Variable v1, v2, v3
sscanf "12:30:45", "%d%*[:]%d%*[:]%d", v1, v2, v3

```

Here "\%* \([:]\) " means "read a colon character but don't store it anywhere". The "*" character must appear immediately after the percent. Note that there is nothing in the parameter list corresponding to the suppressed strings.
If the text in the scan string is not consistent with the text in the format string, sscanf may not read all of the values that you expected. You can check for this using the V_flag variable, which is set to the number of values read. This kind of inconsistency does not cause sscanf to return an error to Igor, which would cause procedure execution to abort. It is a situation that you can deal with in your procedure code.
The sscanf operation returns the following kinds of errors:
- Out-of-memory.
- The number of parameters implied by formatStr does not match the number of parameters in the var list.
- formatStr calls for a numeric variable but the parameter list expects a string variable.
- formatStr calls for a string variable but the parameter list expects a numeric variable.
- formatStr includes an unsupported, unknown or incorrectly constructed conversion specification.
- The var list references a global variable that does not exist.

\section*{Examples}

Here is a simple example to give you the general idea:
```

Function SimpleExample()
Variable v1, valuesRead
sscanf "Value=1.234", "Value=%g", v1
valuesRead = V_flag
if (valuesRead`!= 1)
Printf "Error: Expected 1 value, got %d values\r", valuesRead
else
Printf "Value read = %g\r", v1
endif
End

```

For an example that uses sscanf to load data from a text file, see the Load File Demo example in "Igor Pro Folder:Examples:Programming".

See Also
str2num, strsearch, and StringMatch.

\section*{Stack}

Stack [flags] [objectName][, objectName]...
The Stack operation stacks the named layout objects in the top page layout.

\section*{Parameters}
objectName is the name of a graph, table, picture or annotation object in the top page layout.

\section*{Flags}
\begin{tabular}{llll} 
/ \(\mathrm{A}=(\) rows, cols \()\) & /I & / \(\mathrm{O}=\) objTypes & /S \\
\(/ \mathrm{G}=\) grout & /M & /R & / \(\mathrm{W}=(\) left,top,right,bottom \()\)
\end{tabular}

See Also
The Tile operation for details on the flags and parameters.

\section*{StackWindows}

StackWindows [flags] [windowName [, windowName]...]
The StackWindows operation stacks the named windows on the desktop.
Flags
\(/ \mathrm{A}=(\) rows,cols \() \quad / \mathrm{G}=\) grout \(\quad / \mathrm{O}=\) objTypes \(\quad / \mathrm{P} \quad / \mathrm{W}=(\) left,top,right,bottom \()\)
/C /I /M /R
See Also
See the TileWindows operation for details on the flags and parameters.

\section*{startMSTimer}

\section*{startMSTimer}

The startMSTimer function creates a new microsecond timer and returns a timer reference number.

\section*{Details}

You can create up to ten different microsecond timers using startMSTimer. A valid timer reference number is a number between 0 and 9. If startMSTimer returns -1, there are no free timers available. startMSTimer works in conjunction with stopMSTimer.

See Also
The stopMSTimer and ticks functions.

\section*{Static}

Static constant objectName = value
Static strconstant objectName = value
Static Function funcName()
Static Structure structureName
Static Picture pictName
The Static keyword specifies that a constant, user-defined function, structure, or Proc Picture is local to the procedure file in which it appears. Static objects can only be used by other functions; they cannot be accessed from macros; they cannot be accessed from other procedure files or from the command line.

\section*{See Also}

Static Functions on page IV-86, Proc Pictures on page IV-44, and Constants on page IV-40.

\section*{StatsAngularDistanceTest}

StatsAngularDistanceTest [flags] [srcWave1, srcWave2, srcWave3...]
The StatsAngularDistanceTest operation performs nonparametric tests on the angular distance between sample data and reference directions for two or more samples in individual waves. The angular distance is the shortest distance between two points on a circle (in radians). Specify the sample waves using /WSTR or by listing them following the flags. Set reference directions with /ANG, /ANGW, or the sample mean direction.

\section*{Flags}
/ALPH=val
\(\mid \mathrm{ANG}=\{d 1, d 2\}\)
/ANGM
/ANGW=dWave

Sets the significance level (default 0.05).
Sets reference directions (in radians) for two samples; for more than two samples use /ANGW.

Computes the mean direction of each sample and uses it as the reference direction.
Sets reference directions (in radians) for more than two samples using directions in \(d\) Wave, which must be single or double precision.
\(/ \mathrm{APRX}=m \quad\) Controls the approximation method for computing the P-value in the case of two samples (Mann-Whitney Wilcoxon). See StatsWilcoxonRankTest for more details. The default value is 0 , which may require long computation times if your sample size is large. Use \(/ \mathrm{APRX}=1\) if you have a large sample and you expect ties in the data.
/Q
No results printed in the history area.
\(/ \mathrm{T}=k\)
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1\) : Kills with no dialog.
\(k=2: \quad\) Disables killing.
/TAIL=tail tail is a bitwise parameter that specifies the tails tested.
Bit 0: Lower tail.
Bit 1: Upper tail (default).
Bit 2: Two tail.
See Setting Bit Parameters on page IV-12 for details about bit settings.
The P value corresponding to the last tail calculated will be entered in the table.
/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

\section*{/Z}

Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

The inputs for StatsAngularDistanceTest are two or more waves each corresponding to individual sample. The waves must be single or double precision expressing the angles in radians. There is no restriction on the number of points or dimensionality of the waves but the data should not contain NaNs or INFs. We recommend that you use double precision waves, especially if there are ties in the data. The reference directions should also be in radians. For two samples, StatsAngularDistanceTest computes the angular distances between the input data and the reference directions and then uses the Mann-Whitney-Wilcoxon test (StatsWilcoxonRankTest). Results are stored in the W_WilcoxonTest wave and in the corresponding table. For more than two samples, StatsAngularDistanceTest uses the Kruskal-Wallis test, storing results in the wave W_KWTestResults wave in the current data folder.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{References}

See, in particular, Chapter 27 of:
Zar, J.H., Biostatistical Analysis, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

\section*{See Also}

Examples:Statistics:Circular Statistics:AngularDistanceTest.pxp.

\section*{StatsANOVA1Test}

StatsANOVA1Test [flags] [wave1, wave2,... wave100]
The StatsANOVA1Test operation performs a one-way ANOVA test (fixed-effect model). The standard ANOVA test results are stored in the M_ANOVA1 wave in the current data folder.

Flags
\begin{tabular}{|c|c|}
\hline /ALPH=val & Sets the significance level (default 0.05). \\
\hline /BF & Performs the Brown and Forsythe test computing F" and degrees of freedom. The W_ANOVA1BnF wave in the current data folder contains the output. \\
\hline /Q & No results printed in the history area. \\
\hline \multirow[t]{5}{*}{/T=k} & Displays results in a table; additional tables are created with /BF and /W. \\
\hline & \(k\) specifies the table behavior when it is closed. \\
\hline & \(k=0\) : \(\quad\) Normal with dialog (default). \\
\hline & \(k=1: \quad\) Kills with no dialog. \\
\hline & \(k=2: \quad\) Disables killing. \\
\hline /W & Performs the Welch test \(\mathrm{F}^{\prime}\) and computes degrees of freedom. The W_ANOVA1Welch wave in the current data folder contains the output. \\
\hline
\end{tabular}
/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

Inputs to StatsANOVA1Test are two or more 1D numerical waves containing (one wave for each group of samples). Use NaN for missing entries or use waves with different numbers of points. The standard ANOVA results are in the M_ANOVA1 wave with corresponding row and column labels. Use /T to display the results in a table. In each case you will get the two degrees of freedom values, the F value, the critical value Fc for the choice of alpha and the degrees of freedom, and the P-value for the result. V_flag will be set to -1 for any error and to zero otherwise.
In some cases the ANOVA test may not be appropriate. For example, if groups do not exhibit sufficient homogeneity of variances. Although this may not be fatal for the ANOVA test, you may get more insight by performing the variances test in StatsVariancesTest.
If there are only two groups this test should be equivalent to StatsTTest.
You can evaluate the power of an ANOVA test for a given set of degrees of freedom and noncentrality parameter using:
power=1-StatsNCFCDF (StatsInvFCDF ((1-alpha), n1, n2), n1, n2, delta)
Here n 1 is the Groups' degrees of freedom, n 2 is the Error degrees of freedom, and delta is the noncentrality parameter. For more information see ANOVA Power Calculations Panel and the associated example experiment.

Zar, J.H., Biostatistical Analysis, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsVariancesTest, StatsTTest, StatsNCFCDF, and StatsInvFCDF.

\section*{StatsANOVA2NRTest}

\section*{StatsANOVA2NRTest [flags] srcWave}

The StatsANOVA2NRTest operation performs a two-factor analysis of variance (ANOVA) on the data that has no replication where there is only a single datum for every factor level. srcWave is a 2D wave of any numeric type. Output is to the M_ANOVA2NRResults wave in the current data folder or optionally to a table.

Flags
\begin{tabular}{|c|c|}
\hline /ALPH=val & Sets the significance level (default 0.05). \\
\hline /FOMD & Estimates one missing value. You will also have to use a single or double precision wave for srcWave and designate the single missing value as NaN . The estimated value is printed to the history as well as the bias used to correct the sum of the squares of factor A. \\
\hline \multirow[t]{9}{*}{/INT=val} & Sets the degree of interactivity. \\
\hline & Sets the degree of interactivity. \\
\hline & val=0: \(\quad\) No interaction between the factors (default). \\
\hline & val=1: Significant interaction effect between factors. \\
\hline & Combination with /MODL determines which factors to test: \\
\hline & val Model 1 Model 2 Model 3 \\
\hline & 1 A\&B A \\
\hline & 0 A\&B A\&B A\&B \\
\hline & As indicated in the table, factor \(B\) is not tested for significant interaction under Model 3 and neither factor A nor factor B are tested for Model 1. If you are willing to accept an increase in Type II error you can obtain the relevant values by specifying Model 2. None of the models support a test for interaction A x B. \\
\hline \multirow[t]{4}{*}{\(/ \mathrm{MODL}=m\)} & Sets the model number. \\
\hline & \(m=1: \quad\) Factor A and factor B are fixed. \\
\hline & \(m=2\) : Both factors are random. \\
\hline & \(m=3\) : Factor A is fixed and factor B is random (default). \\
\hline /Q & No results printed in the history area. \\
\hline \multirow[t]{4}{*}{\(/ \mathrm{T}=k\)} & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\hline & \(k=0: \quad\) Normal with dialog (default). \\
\hline & \(k=1\) : Kills with no dialog. \\
\hline & \(k=2: \quad\) Disables killing. \\
\hline
\end{tabular}

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

Input to StatsANOVA2NRTest is a 2D wave in which the Factor A corresponds to rows and Factor B corresponds to columns. H0 provides that there is no difference in the means of the respective populations, i.e., if H 0 is rejected for Factor A but accepted for Factor B that means that there is no difference in the means of the columns but the means of the rows are different.

NaN and INF entries are not supported although you may use a single NaN value in combination with the /FOMD flag. If srcWave contains dimension labels they will be used to designate the two factors in the output.
The contents of the M_ANOVA2NRResults output wave columns are as follows:

Column \(0 \quad\) Sum of the squares (SS) values
Column \(1 \quad\) Degrees of freedom (DF)
Column 2 Mean square (MS) values
Column 3 Computed F value for this test
Column \(4 \quad\) Critical \(F\) value ( Fc ) for the specified alpha
Column 5 Conclusion with 0 to reject H 0 or 1 to accept it
The variable V_flag is set to zero if the operation succeeds or to -1 otherwise.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test and StatsANOVA2Test.

\section*{StatsANOVA2RMTest}

\section*{StatsANOVA2RMTest [flags] srcWave}

The StatsANOVA2RMTest operation performs analysis of variance (ANOVA) on srcWave where replicates consist of multiple measurements on the same subject (repeated measures). srcWave is a 2D wave of any numeric type. Output is to the M_ANOVA2RMResults wave in the current data folder or optionally to a table.

\section*{Flags}
```

/ALPH=val
/Q
$/ \mathrm{T}=k$

```

Sets the significance level (default 0.05).
No results printed in the history area.
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

Input to StatsANOVA2RMTest is the 2D srcWave in which the factor A (Groups) are columns and the different subjects are rows. It does not support NaNs or INFs.
The contents of the M_ANOVA2RMResults output wave columns are: the first contains the sum of the squares (SS) values, the second contains the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the single F value for this test, the fifth contains the critical F value for the specified alpha and degrees of freedom, and the last column contains the conclusion with 0 to reject \(\mathrm{H}_{0}\) or 1 to accept it. In each case \(\mathrm{H}_{0}\) corresponds to the mean level, which is the same for all subjects.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsANOVA2NRTest and StatsANOVA2Test.

\section*{StatsANOVA2Test}

\section*{StatsANOVA2Test [flags] srcWave}

The StatsANOVA2Test operation performs a two-factor analysis of variance (ANOVA) on srcWave. Output is to the M_ANOVA2Results wave in the current data folder or optionally to a table.

Flags
/ALPH=val
/FAKE=nит
\(/ \mathrm{MODL}=m\)
/Q
/T=k
/Z

Sets the significance level (default 0.05 ).
Specifies the number of points in srcWave obtained by "estimation". num is subtracted from the total and error degrees of freedom.

Sets the model number.
\(m=1\) : \(\quad\) Factor A and factor B are fixed.
\(m=2\) : Both factors are random.
\(m=3\) : \(\quad\) Factor A is fixed and factor \(B\) is random (default).
No results printed in the history area.
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2\) : \(\quad\) Disables killing.
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

Input to StatsANOVA2Test is the single or double precision 3D srcWave in which the factor A levels are columns, the factor B levels are rows, and the replicates are layers. If srcWave contains dimension labels they will be used to designate the factors in the output.
Ideally, the number of replicates must be equal for each factor and each level. StatsANOVA2Test supports both equal replication and proportional replication. Proportional replication allows for different number of data in each cell with missing data represented as NaN and the number of points in each cell is given by
Nij=(sum of data in row i)*(sum of data in column j)/number of samples.
If you have no replicates (a single datum per cell) use StatsANOVA2NRTest instead. If the number of replicates in your data does not satisfy these conditions you may be able to "estimate" additional replicates using various methods. In that case use the /FAKE flag so that the operation can account for the estimated data by reducing the total and error degrees of freedom. /FAKE only accounts for the number of estimates being used. You must provide an appropriate number of estimated values.
The contents of the M_ANOVA2Results output wave columns are: the first contains the sum of the squares (SS) values, the second the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the computed F value for this test, the fifth contains the critical Fc value for the specified alpha and degrees of freedom, and the last contains the conclusion with 0 to reject \(\mathrm{H}_{0}\) or 1 to accept it. In each case \(\mathrm{H}_{0}\) corresponds to the mean level, which is the same for all populations.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test and StatsANOVA2NRTest.

\section*{StatsBetaCDF}

StatsBetaCDF (x, \(p, q[, a, b])\)
The StatsBetaCDF function returns the beta cumulative distribution function
\[
\mathrm{F}(\mathrm{x}, \mathrm{p}, \mathrm{q}, \mathrm{a}, \mathrm{~b})=\frac{1}{\mathrm{~B}(\mathrm{p}, \mathrm{q})} \int_{0}^{\frac{x-a}{b-a}} t^{p-1}(1-t)^{q-1} d t, \quad \begin{gathered}
p, q>0 \\
a \leq x \leq b
\end{gathered}
\]
where \(B(p, q)\) is the beta function
\[
B(p, q)=\int_{0}^{1} t^{p-1}(1-t)^{q-1} d t
\]

The defaults ( \(a=0\) and \(b=1\) ) correspond to the standard beta distribution were \(a\) is the location parameter, ( \(b\) \(a)\) is the scale parameter, and \(p\) and \(q\) are shape parameters.

Evans, M., N. Hastings, and B. Peacock, Statistical Distributions, 3rd ed., Wiley, New York, 2000.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsBetaPDF and StatsInvBetaCDF.

\section*{StatsBetaPDF}

StatsBetaPDF ( \(x, p, q[, a, b]\) )
The StatsBetaPDF function returns the beta probability distribution function
\[
f(x ; p, q, a, b)=\frac{(x-a)^{p-1}(b-x)^{q-1}}{B(p, q)(b-a)^{p+q-1}}, \quad a \leq x \leq b
\]
where \(B(p, q)\) is the beta function
\[
B(p, q)=\int_{0}^{1} t^{p-1}(1-t)^{q-1} d t
\]

The defaults ( \(a=0\) and \(b=1\) ) correspond to the standard beta distribution were \(a\) is the location parameter, \((b-\) \(a)\) is the scale parameter, and \(p\) and \(q\) are shape parameters. When \(p<1, f(x=a)\) returns Inf.

Chapter III-12, Statistics for a function and operation overview; StatsBetaCDF and StatsInvBetaCDF.

\section*{StatsBinomialCDF}

StatsBinomialCDF ( \(x, p, N\) )
The StatsBinomialCDF function returns the binomial cumulative distribution function
\[
F(x ; p, N)=\sum_{i=1}^{x}\binom{N}{i} p^{i}(1-p)^{N-i}, \quad x=1,2, \ldots
\]
where
\[
\binom{N}{i}=\frac{N!}{i!(N-i)!}
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsBinomialCDF and StatsBinomialPDF.

\section*{StatsBinomialPDF}

StatsBinomialPDF ( \(x, p, N\) )
The StatsBinomialPDF function returns the binomial probability distribution function
\[
f(x ; p, N)=\binom{N}{x} p^{x}(1-p)^{N-x}, \quad x=0,1,2, \ldots
\]
where
\[
\binom{N}{x}=\frac{N!}{x!(N-x)!}
\]
is the probability of obtaining \(x\) good outcomes in \(N\) trials where the probability of a single successful outcome is \(p\).

Chapter III-12, Statistics for a function and operation overview; StatsBinomialCDF and StatsInvBinomialCDF.

\section*{StatsCauchyCDF}

StatsCauchyCDF (x, \(\mu, \sigma\) )
The StatsCauchyCDF function returns the Cauchy-Lorentz cumulative distribution function
\[
F(x ; \mu, \sigma)=\frac{1}{2}+\frac{1}{\pi} \tan ^{-1}\left(\frac{x-\mu}{\sigma}\right)
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsCauchyCDF and StatsCauchyPDF.

\section*{StatsCauchyPDF}

StatsCauchyPDF ( \(x, \mu, \sigma\) )
The StatsCauchyPDF function returns the Cauchy-Lorentz probability distribution function
\(f(x ; \mu, \sigma)=\frac{1}{\sigma \pi} \frac{1}{1+\left(\frac{x-\mu}{\sigma}\right)^{2}}\),
where \(\mu\) is the location parameter and \(\sigma\) is the scale parameter. Use \(\mu=0\) and \(\sigma=1\) for the standard form of the Cauchy-Lorentz distribution.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsCauchyCDF and StatsInvCauchyCDF.

\section*{StatsChiCDF}

StatsChiCDF ( \(x, n\) )
The StatsChiCDF function returns the chi-squared cumulative distribution function for the specified value and degrees of freedom \(n\).
\[
F(x ; n)=\frac{\gamma\left(\frac{n}{2}, \frac{x}{2}\right)}{\Gamma\left(\frac{n}{2}\right)}
\]
where is \(\gamma(a, b)\) the incomplete gamma function. The distribution can also be expressed as
\[
F(x ; n)=1-\operatorname{gammq}\left(\frac{n}{2}, \frac{x}{2}\right) .
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsChiPDF, StatsInvChiCDF, and gammq.

\section*{StatsChiPDF}

StatsChiPDF ( \(x, n\) )
The StatsChiPDF function returns the chi-squared probability distribution function for the specified value and degrees of freedom as
\(f(x ; n)=\frac{\exp \left(-\frac{x}{2}\right) x^{\frac{n}{2}-1}}{2^{\frac{n}{2}} \Gamma\left(\frac{n}{2}\right)}\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsChiCDF and StatsChiPDF.

\section*{StatsChiTest}

StatsChiTest [flags] srcWave1, srcWave2
The StatsChiTest operation computes a \(\chi^{2}\) statistic for comparing two distributions or a \(\chi^{2}\) statistic for comparing a sample distribution with its expected values. In both cases the comparison is made on a bin-by-bin basis. Output is to the W_StatsChiTest wave in the current data folder or optionally to a table.

\section*{Flags}
\begin{tabular}{|c|c|}
\hline /ALZR & Allows zero entries in source waves. If you are using / S zero entries in srcWave2 are skipped. \\
\hline \(/ \mathrm{NCON}=n \mathrm{Con}\) & Specifies the number of constraints ( 0 by default), which reduces the number degrees of freedom and the critical value by \(n\) Con. \\
\hline /S & Sets the calculation mode to a single distribution where srcWave1 represents an array of binned measurements and srcWave2 represents the corresponding expected values. \\
\hline /T=k & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\hline & \(k=0\) : \(\quad\) Normal with dialog (default). \\
\hline & \(k=1: \quad\) Kills with no dialog. \\
\hline & \(k=2\) : Disables killing. \\
\hline /Z & Ignores errors. V_flag will be set to -1 for any error and to zero otherwise. \\
\hline
\end{tabular}

\section*{Details}

The source waves, \(s r c W a v e 1\) and \(s r c W a v e 2\), must have the same number of points and can be any real numeric data type. Any nonpositive values (including NaN ) in either wave removes the entry in both waves from consideration and reduces the degrees of freedom by one. The number degrees of freedom is initially the number of points in srcWave1-1-nCon. By default it is assumed that srcWave1 and srcWave 2 represent two distributions of binned data.
When you specify /S, srcWave1 must consist of binned values of measured data and srcWave2 must contain the corresponding expected values. The calculation is:
\(\chi^{2}=\sum_{i=0}^{n-1} \frac{\left(Y_{i}-V_{i}\right)^{2}}{V_{i}}\).
Here \(Y_{i}\) is the sample point from srcWave1, \(V_{i}\) is the expected value of \(Y_{i}\) based on an assumed distribution ( \(s r c W a v e 2\) ), and \(n\) is the number of points in the each wave. If you do not use \(/ S\), it calculates:
\(\chi^{2}=\sum_{i=0}^{n-1} \frac{\left(Y_{1 i}-Y_{2 i}\right)^{2}}{Y_{1 i}+Y_{2 i}}\),
where \(Y_{1 i}\) and \(Y_{2 i}\) are taken from srcWave1 and srcWave2 respectively.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsContingencyTable.

\section*{StatsCircularCorrelationTest}

StatsCircularCorrelationTest [flags] waveA, waveB
The StatsCircularTwoSampleTest operation peforms a number of tests for two samples of circular data. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data expressed in radians and an optional second column contains associated vector lengths. The waves must be either single or double precision floating point. Results are stored in the W_StatsCircularCorrelationTest wave in the current data folder and optionally displayed in a table. Some flags generate additional outputs, described below.

\section*{Flags}
\begin{tabular}{ll}

\end{tabular}

\section*{Details}

The nonparametric test (/NAA) follows Fisher and Lee's modification of Mardia's statistic, which is an analogue of Spearman's rank correlation. The test ranks the angles of each sample and computes the quantities \(r^{\prime}\) and \(r^{\prime \prime}\) as follows:
\[
r^{\prime}=\frac{\left\{\sum_{i=0}^{n-1} \cos \left[\frac{2 \pi}{n}\left(r_{a i}-r_{b i}\right)\right]\right\}^{2}+\left\{\sum_{i=0}^{n-1} \sin \left[\frac{2 \pi}{n}\left(r_{a i}-r_{b i}\right)\right]\right\}^{2}}{n^{2}}
\]
\[
r^{\prime \prime}=\frac{\left\{\sum_{i=0}^{n-1} \cos \left[\frac{2 \pi}{n}\left(r_{a i}+r_{b i}\right)\right]\right\}^{2}+\left\{\sum_{i=0}^{n-1} \sin \left[\frac{2 \pi}{n}\left(r_{a i}+r_{b i}\right)\right]\right\}^{2}}{n^{2}}
\]

Here \(n\) is the number of data pairs and \(r_{a i}\) and \(r_{b i}\) are the ranks of the \(i\) th member in the first and second samples respectively.
The test statistic is \((n-1)\left(r^{\prime}-r^{\prime \prime}\right)\), which is compared with the critical value (for one and two tails). The CDF of the statistic is a highly irregular function. The critical value is computed by a different methods according to \(n\). For \(3 \leq n \leq 8\), a built-in table of CDF transitions gives a "conservative" estimate of the critical value. For \(9 \leq n \leq 30\), the CDF is approximated by a 7th order polynomial in the region \(\mathrm{x}>0\). For \(n \geq 30\), the CDF is from the asymptotic expression. For \(3 \leq n \leq 30\), CDF values are obtained by Monte-Carlo simulations using 1e6 random samples for each \(n\).
The parametric test for angular-angular correlation (/PAA) involves computation of a correlation coefficient \(r_{a a}\) and then evaluating the mean \(\overline{r_{a a}}\) and variance \(s_{r_{a a}}^{2}\) of equivalent correlation coefficients computed from the same data but by deleting a different pair of angles each time. The mean and variance are then used to compute confidence limits L1 and L2:
\[
\begin{aligned}
& L 1=n r_{a a}-(n-1) \overline{r_{a a}}-Z_{\alpha(2)} \sqrt{\frac{s_{r_{a a}^{a}}^{2}}{n}}, \\
& L 2=n r_{a a}-(n-1) \overline{r_{a a}}+Z_{\alpha(2)} \sqrt{\frac{s_{r_{a a}^{2}}^{2}}{n}}
\end{aligned}
\]
where \(Z_{\alpha(2)}\) is the normal distribution two-tail critical value at the a level of significance. \(\mathrm{H}_{0}\) (corresponding to no correlation) is rejected if zero is not contained in the interval [L1,L2].
The parametric test for angular-linear correlation (/PAL) involves computation of the correlation coefficient \(r_{a l}\) which is then compared with a critical value from \(\chi^{2}\) for alpha significance and two degrees of freedom.
\[
r_{a l}=\sqrt{\frac{r_{x c}^{2}+r_{x s}^{2}-2 r_{x c} r_{x s} r_{c s}}{1-r_{c s}^{2}}}
\]
where:
\[
\begin{aligned}
& r_{x c}=\frac{\sum_{i=0}^{n-1} X_{i} \cos \left(a_{i}\right)-\frac{1}{n} \sum_{i=0}^{n-1} X_{i} \sum_{i=0}^{n-1} \cos \left(a_{i}\right)}{\sqrt{\left(\sum_{i=0}^{n-1} X_{i}^{2}-\frac{1}{n}\left(\sum_{i=0}^{n-1} X_{i}\right)^{2}\right)\left(\sum_{i=0}^{n-1} \cos ^{2}\left(a_{i}\right)-\frac{1}{n}\left(\sum_{i=0}^{n-1} \cos \left(a_{i}\right)\right)^{2}\right)}}, \\
& r_{x s}=\frac{\sum_{i=0}^{n-1} X_{i} \sin \left(a_{i}\right)-\frac{1}{n} \sum_{i=0}^{n-1} X_{i} \sum_{i=0}^{n-1} \sin \left(a_{i}\right)}{\sqrt{\left(\sum_{i=0}^{n-1} X_{i}^{2}-\frac{1}{n}\left(\sum_{i=0}^{n-1} X_{i}\right)^{2}\right)\left(\sum_{i=0}^{n-1} \sin ^{2}\left(a_{i}\right)-\frac{1}{n}\left(\sum_{i=0}^{n-1} \sin \left(a_{i}\right)\right)^{2}\right)}},
\end{aligned}
\]
\[
r_{c s}=\frac{\sum_{i=0}^{n-1} \cos \left(a_{i}\right) \sin \left(a_{i}\right)-\frac{1}{n} \sum_{i=0}^{n-1} \sin \left(a_{i}\right) \sum_{i=0}^{n-1} \cos \left(a_{i}\right)}{\sqrt{\left(\sum_{i=0}^{n-1} \sin ^{2}\left(a_{i}\right)-\frac{1}{n}\left(\sum_{i=0}^{n-1} \sin \left(a_{i}\right)\right)^{2}\right)\left(\sum_{i=0}^{n-1} \cos ^{2}\left(a_{i}\right)-\frac{1}{n}\left(\sum_{i=0}^{n-1} \cos \left(a_{i}\right)\right)^{2}\right)}} .
\]

\section*{StatsCircularMeans}

StatsCircularMeans [flags] srcWave
The StatsCircularMeans operation calculates the mean of a number of circular means, returning the mean angle (grand mean), the length of the mean vector, and optionally confidence interval around the mean angle. Output is to the history area and to the W_CircularMeans wave in the current data folder.

\section*{Flags}
/ALPH=val
/CI
/NSOA
/PSOA

Sets the significance level (default 0.05).
Calculates the confidence interval (labeled CI_t1 and CI_t2) around the mean angle.
Performs nonparametric second order analysis according to Moore's version of Rayleigh's test where \(\mathrm{H}_{0}\) corresponds to uniform distribution around the circle. Moore's test ranks entries by the lengths of the mean radii (second column of the input) from smallest (rank 1) to largest (rank \(n\) ) and then computes the statistic:
\[
R^{\prime}=\sqrt{\frac{\left(\frac{1}{n} \sum_{i=0}^{n-1}(i+1) \cos \left(a_{i}\right)\right)^{2}+\left(\frac{1}{n} \sum_{i=0}^{n-1}(i+1) \sin \left(a_{i}\right)\right)^{2}}{n}}
\]
where \(a_{i}\) are the mean angle entries (from column 1) corresponding to vector length rank \((i+1)\). The critical value is obtained from Moore's distribution

\section*{StatsInvMooreCDF.}

Perform parametric second order analysis where \(\mathrm{H}_{0}\) corresponds to no mean population direction. It assumes that the second order quantities are from a bivariate normal distribution. If this is not the case, use /NSOA above. The test statistic is:
\[
F=\frac{k(k-2)}{2}\left[\frac{\bar{X}^{2} S_{y^{2}}-2 \bar{X} \bar{Y} S_{x y}+\bar{Y}^{2} S_{x^{2}}}{S_{x^{2}} S_{y^{2}}-S_{x y}^{2}}\right.
\]
where
\[
\begin{aligned}
& \bar{X}=\frac{1}{n} \sum_{i=0}^{n-1} X_{i}=\frac{1}{n} \sum_{i=0}^{n-1} r_{i} \cos \left(a_{i}\right) \\
& \bar{Y}=\frac{1}{n} \sum_{i=0}^{n-1} Y_{i}=\frac{1}{n} \sum_{i=0}^{n-1} r_{i} \sin \left(a_{i}\right) \\
& S_{x^{2}}=\sum_{i=0}^{n-1} X_{i}^{2}-\frac{1}{n}\left(\sum_{i=0}^{n-1} X_{i}\right)^{2} \\
& S_{y^{2}}=\sum_{i=0}^{n-1} Y_{i}^{2}-\frac{1}{n}\left(\sum_{i=0}^{n-1} Y_{i}\right)^{2} \\
& S_{x y}=\sum_{i=0}^{n-1} X_{i} Y_{i}-\frac{1}{n} \sum_{i=0}^{n-1} X_{i} \sum_{i=0}^{n-1} Y_{i}
\end{aligned}
\]

Here \(n\) is the number of means in srcWave and the critical value is computed from the \(F\) distribution, equivalent to executing:
Print StatsInvFCDF (1-alpha, 2, n-2)
/Q
\(/ \mathrm{T}=k \quad\) Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2\) : \(\quad\) Disables killing.
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

The srcWave input to StatsCircularMeans must be a single or double precision two column wave containing in each row a mean angle (radians) and the length of a mean radius (the first column contains mean angles and the second column contains mean vector lengths). srcWave must not contain any NaNs or INFs. The confidence interval calculation follows the procedure outlined by Batschelet.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{References}

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsCircularMoments,
StatsInvMooreCDF, and StatsInvFCDF.

\section*{StatsCircularMoments}

StatsCircularMoments [flags] srcWave
The StatsCircularMoments operation computes circular statistical moments and optionally performs angular uniformity tests for the data in srcWave. The extent of the calculation is determined by the requested moment. The default results are stored in the W_CircularStats wave in the current data folder and are optionally displayed in a table. Additional results are listed under the corresponding flags.

\section*{Flags}
/ALPH=alpha Sets an alpha value for computing confidence intervals (default is 0.05).
\begin{tabular}{|c|c|}
\hline \(/ \mathrm{AXD}=p\) & Designates the input as p -axial data. For example, if the input represents undirected lines then \(p=2\) and the operation multiplies the angles by a factor \(p\) (after shifting /ORGN and accounting for /CYCL). It does not back-transform the mean or median axis. \\
\hline /CYCL=cycle & Specifies the length of the data cycle. You do not need to do so if you are using one of the built-in modes, but this is still a useful option, as for setting the length of a particular month when using /MODE=5. \\
\hline \multicolumn{2}{|l|}{/GRPD=\{start, delta\}} \\
\hline & Computes circular statistics for grouped data. In this case srcWave contains frequencies or the number of events that belong to a particular angle group. There are as many groups as there are elements in srcWave. The first group is centered at start radians and each consecutive group is centered delta radians away. You must set both the start and delta to sensible values. srcWave may contain NaNs but it is an error if all values are NaN . The only other flags that work in combination with this flag are / Q , \(/ T\), and \(/ Z\). \\
\hline \multirow[t]{6}{*}{/KUPR} & Tests the uniformity of the distribution for ungrouped data using Kuiper statistic. The data are converted into a set \(\left\{x_{i}\right\}\) by normalizing the input angles to the range [ 0,1\(]\), ranking the results then using the two quantities \(\mathrm{D}_{+}\)and \(\mathrm{D}_{-}\)to compute the Kuiper statistic \\
\hline & \(\mathrm{V}=\left(D_{+}+D_{-}\right)(\sqrt{\mathrm{n}}+0.155+0.24 / \sqrt{\mathrm{n}})\), \\
\hline & where \\
\hline & \[
D_{+}=\operatorname{Max} \text { of: } \frac{1}{\mathrm{n}}-\mathrm{x}_{0}, \frac{2}{\mathrm{n}}-\mathrm{x}_{1}, \ldots, 1-\mathrm{x}_{\mathrm{n}-1},
\] \\
\hline & \[
D=\text { Max of: } x_{0}, x_{1-\frac{1}{n}}, \ldots, x_{n-1-\frac{n-1}{n}},
\] \\
\hline & and \(n\) is the number of valid points in \(s r c\) Wave. You can find the results in the wave W_CircularStats under row label "Kuiper V" and "Kuiper CDF(V)". See Fisher and Press et al. for more information. \\
\hline /LOS & Computes Linear Order Statistics by sorting the angle values from small to large, dividing each angle by \(2 \pi\) and shifting the origin so that the output range is \([0,1]\). The results are stored in the wave W_LinearOrderStats in the current data folder. The X scaling of the wave is set so that the offset and the delta are \(1 /(n+1)\) where \(n\) is the number of non-NaN points in the input. \\
\hline /M=moment & Computes specified moments. By default, it computes the second order moments as well as skewness, kurtosis, median, and mean deviation. Use \(/ \mathrm{M}=1\) for the first moment. For higher moments, both the specified moment and all the default quantities are computed. \\
\hline
\end{tabular}
/MODE=mode Handles special types of data.
\begin{tabular}{ll} 
mode & Data in srcWave \\
\hline 0 & Angles in radians \([0,2 \pi]\) \\
1 & Angles in radians \([-\pi, \pi]\) \\
2 & Angles in degrees \([0,360]\) \\
3 & Angles in degrees \([-180,180]\) \\
4 & Igor date format for one year cycles. \\
5 & Igor date format for one month cycles. \\
6 & Igor date format for one week cycles. \\
7 & Igor date format for one day cycles. \\
8 & Igor date format for one hour cycles. \\
\hline
\end{tabular}
/ORGN=origin \(\quad\)\begin{tabular}{l} 
Specifies the origin of the data (the value corresponding to an angle of zero degrees). \\
For example, if you are using Igor date format and you want the origin to be the first \\
second in year YYYY, use /ORGN \(=(\) date \(2 \operatorname{secs}(Y Y Y Y, 1,1))\).
\end{tabular}
/Q
No results printed in the history area.

Performs the Rayleigh test for uniformity. If the "alternative" mean direction is specified (in radians), the test computes
rOBar=rBar cos(tBar-meanDirection)
and then computes the significance probability of rOBar. The null hypothesis \(\mathrm{H}_{0}\) corresponds to uniformity. It is rejected when r0Bar is too large. If the mean direction is not specified then rOBar is rBar which is always calculated as part of the first moments so the operation only computes the relevant significance probability ( P Value). The critical values for both cases are computed according to Durand and Greenwood.
/SAW Saves the translated angle data in the wave W_AngleWave in the current data folder.
\(/ \mathrm{T}=k \quad\) Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists, but does not display the output wave from the current data folder, the table is renamed and a new table is created.
/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

StatsCircularMoments is equivalent to WaveStats but it applies to circular data, which are distributed on the perimeter of a circle representing some period or cycle. If your data are not described by one of the builtin modes, you can specify the value of the origin (/ORGN), which is mapped to zero degrees and the size of a cycle or period.
When you use Igor date formats with the built-in modes for dates, the default origin is set to zero. The default cycle in the case of Mode 4 is 366 . This is done in order to handle both leap and nonleap years. Similarly, Mode 5 uses a cycle of 31 days. Note that the internal conversion from Igor date to (year, month,
day) is independent of the cycle specification and is therefore not affected by this choice. You should use the /CYCL flag if you use one of these modes with a fixed size of year or month.
The parameters listed below are computed and displayed (see row labels) in the table. Here \(N\) is the number of valid (non-NaN) angles \(\left\{\theta_{i}\right\}\)
\[
\begin{aligned}
& \mathrm{C}=\sum_{i=1}^{n} \cos \theta_{i} \\
& \mathrm{~S}=\sum_{i=1}^{n} \sin \theta_{i} \\
& R=\sqrt{C^{2}+S^{2}} \\
& \text { cBar }=\bar{C}=C / n \\
& s B a r=\bar{S}=S / n \\
& \text { rBar }=\bar{R}=R / n
\end{aligned}
\]
\(t\) Bar \(=\bar{\theta}=\left\{\begin{array}{l}\operatorname{atan}(S / C) \\ \operatorname{atan}(S / C)+\pi \\ \operatorname{atan}(S / C)+2 \pi\end{array}\right.\)
\[
S>0, C>0
\]
\[
C<0
\]
\[
S<0, C>0
\]
\(V=1-\bar{R}\)
\(v=\sqrt{-2 \log (1-V)}\)
median is the value which minimizes
\[
d(\theta)=\pi-\frac{1}{n} \sum_{i=1}^{n}\left|\pi-\left|\theta_{i}-\bar{\theta}\right|\right|
\]
mean deviation \(=\) The minimum of the last equation when \(\theta \rightarrow\) median.
Higher order moments are denoted with the moment number such that t 3 Bar is the uncentered third moment of the angle while primed quantities are relative to mean direction tBar. Using this notation
\(\widehat{\rho_{2}}=\frac{1}{n} \sum_{i=1}^{n} \cos 2\left(\theta_{i}-\bar{\theta}\right)\)
circular dispersion \(=\frac{1-\widehat{\rho_{2}}}{2 \bar{R}^{2}}\)
skewness \(=\frac{\widehat{\rho_{2}} \sin \left(\hat{\mu}_{2}^{\prime}-2 \bar{\theta}\right)}{(1-\bar{R})^{3 / 2}}\)
\[
\text { kurtosis }=\frac{\widehat{\rho_{2}} \cos \left(\hat{\mu}_{2}^{\prime}-2 \bar{\theta}\right)-\bar{R}^{4}}{(1-\bar{R})^{2}}
\]
where
\[
\hat{\mu}_{p}^{\prime}= \begin{cases}\operatorname{atan}\left(S_{p} / C_{p}\right) & S_{p}>0, C_{p}>0 \\ \operatorname{atan}\left(S_{p} / C_{p}\right)+\pi & C_{p}<0 \\ \operatorname{atan}\left(S_{p} / C_{p}\right)+2 \pi & S_{p}<0, C_{p}>0\end{cases}
\]
and
\[
C_{p}=\frac{1}{n} \sum_{i=1}^{n} \cos p \theta_{i}, \quad S_{p}=\frac{1}{n} \sum_{i=1}^{n} \sin p \theta_{i}
\]

StatsHodgesAjneTest, StatsWatsonUSquaredTest, StatsWatsonWilliamsTest, and StatsWheelerWatsonTest.

\section*{StatsCircularTwoSampleTest}

StatsCircularTwoSampleTest [flags] waveA, waveB
The StatsCircularTwoSampleTest operation performs second order analysis of angles. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data (mean angles) expressed in radians and an optional second column that contains associated vector lengths. The waves must be either single or double precision. Results are stored in the W_StatsCircularTwoSamples wave in the current data folder and optionally displayed in a table. Some of the tests may have additional outputs.

Flags
/ALPH = val Sets the significance level (default val=0.05).
/NPR Performs nonparametric paired-sample test (Moore). The input waves must contain paired angular data so both must have single column and the same number of points.
/NSOA Perform nonparametric second order two-sample test. Input waves must each contain two columns.
/PPR Performs parametric paired-sample test. Input waves must contain paired data and must have the same number of points.
/PSOA Performs parametric second order analysis of two samples. The input waves must each contain two columns.
/Q
No information printed in the history area.
\(/ \mathrm{T}=k \quad\) Displays results in a table. \(k\) specifies the table behavior when it is closed.
\[
k=0: \quad \text { Normal with dialog (default). }
\]
\(k=1: \quad\) Kills with no dialog.
\(k=2\) : \(\quad\) Disables killing.
/Z
Ignores any errors.

\section*{Details}

The nonparametric paired-sample test (/NPR) is Moore's test for paired angles applied in second order analysis. The input can consist of one or two column waves. When both waves contain a single column the operation proceeds as if all the vector length were identically 1 . The Moore statistic \(\left(\mathrm{H}_{0} \rightarrow\right.\) pair equality \()\) is computed and compared to the critical value from the Moore distribution (see StatsInvMooreCDF).
The nonparametric second-order two-sample test (/NSOA) consists of pre-processing where the grand mean is subtracted from the two inputs followed by application of Watson's \(\mathrm{U}^{2}\) test
(StatsWatsonUSquaredTest) with \(\mathrm{H}_{0}\) implying that the two samples came from the same population. The results of this test are stored in the wave \(W_{-}\)WatsonUtest.
The parametric paired-sample test (/PPR) is due to Hotelling. In this test the input should consist of both angular and vector length data. The test statistic is compared with a critical value from the \(F\) distribution (StatsInvFCDF).
The parametric second order two-sample test (/PSOA) is an extension of Hotelling one-sample test to second order analysis where an F-like statistic is computed corresponding to \(\mathrm{H}_{0}\) of equal mean angles.

Zar, J.H., Biostatistical Analysis, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsInvMooreCDF,
StatsWatsonUSquaredTest, and StatsInvFCDF.

\section*{StatsCMSSDCDF}

StatsCMSSDCDF ( \(C, n\) )
The StatsCMSSDCDF function returns the cumulative distribution function of the \(C\) distribution (mean square successive difference), which is
\[
f(C, n)=\frac{\Gamma(2 m+2)}{a 2^{2 m+1}[\Gamma(m+1)]^{2}}\left(1-\frac{C^{2}}{a^{2}}\right)^{m}
\]
where
\[
\begin{aligned}
& a^{2}=\frac{\left(n^{2}+2 n-12\right)(n-2)}{\left(n^{3}-13 n+24\right)}, \\
& m=\frac{\left(n^{4}-n^{3}-13 n^{2}+37 n-60\right)}{2\left(n^{3}-13 n+24\right)}
\end{aligned}
\]

The distribution \((C>0)\) can then be expressed as
\[
F(C, n)=\frac{\Gamma(2 m+2)}{a 2^{2 m+1}[\Gamma(m+1)]^{2}} C_{2} F_{1}\left(\frac{1}{2},-m, \frac{3}{2}, \frac{C^{2}}{a^{2}}\right),
\]
where \({ }_{2} F_{1}\) is the hypergeometric function hyperG2F1.

\section*{References}

See Also
Chapter III-12, Statistics for a function and operation overview; StatsCMSSDCDF and StatsSRTest.

\section*{StatsCochranTest}

StatsCochranTest [flags] [wave1, wave2,... wave100]
The StatsCochranTest operation performs Cochran's \((Q)\) test on a randomized block or repeated measures dichotomous data. Output is to the M_CochranTestResults wave in the current data folder or optionally to a table.

Flags
\(/ \mathrm{ALPH}=\) val \(\quad\) Sets the significance level (default val=0.05).

No results printed in the history area.
/T=k
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.
/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

StatsCochranTest computes Cochran's statistic and compares it to a critical value from a Chi-squared distribution, which depends only of the significance level and the number of groups (columns). The null hypothesis for the test is that all columns represent the same proportion of the effect represented by a nonzero data.

The Chi-square distribution is appropriate when there are at least 4 columns and at least 24 total data points.
Dichotomous data are presumed to consist of two values 0 and 1, thus StatsCochranTest distinguishes only between zero and any nonzero value, which is considered to be 1 ; it does not allow NaNs or INFs. Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with \(/ W S T R\). In the standard terminology, data rows represent blocks and data columns represent groups. \(\mathrm{H}_{0}\) corresponds to the assumption that all groups have the same proportion of 1's.
With the / T flag, it displays the results in a table that contains the number of rows, the number of columns, the Cochran statistic, the critical value, and the conclusion ( 1 to accept \(\mathrm{H}_{0}\) and 0 to reject it).
V_flag will be set to -1 for any error and to zero otherwise.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsFriedmanTest.

\section*{StatsContingencyTable}

StatsContingencyTable [flags] srcWave
The StatsContingencyTable operation performs contingency table analysis on 2D and 3D tables. Output is to the W_ContingencyTableResults wave in the current data folder or optionally to a table or the history area.

\section*{Flags}
/ALPH = val
/COR=mode
\(/\) FEXT \(=\{r o w, c o l\}\)

Sets the significance level (default val=0.05).
Sets the correction type for \(2 \times 2\) tables. By default there is no correction. Use mode \(=1\) for Yates and mode \(=2\) for Haber correction.

Computes Fisher's Exact P-value with \(2 \times 2\) contingency tables. row and col are zerobased indices of the table entry where it computes the probability of getting the results in the table or more extreme values. Without the \(/ \mathrm{Q}\) flag, it prints the probabilities of each individual table in the history.
Given the contingency table:
\begin{tabular}{lll} 
& Succeeded & Failed \\
\hline Group1 & 11 & 8 \\
Group2 & 4 & 9 \\
\hline
\end{tabular}

Example 1: When you use \(/ \operatorname{FEXT}=\{0,0\}\) the \(P\)-value represents the sum of the probabilities of the first group having in the Succeeded column 11 or more extreme values, i.e., \(12,13,14\), and 15 . In each case the remaining table elements are adjusted so that row and column sums remain constant.

Example 2: When you needed to evaluate the sum of the probabilities of Group2 having 4 counts or less in the Succeeded column, then the appropriate flag is \(/ \operatorname{FEXT}=\{1,1\}\), which effectively computes the equivalent of having \(9,10,11,12\), and 13 Failed counts. In each case it computes the upper, the lower, and the two-tail probabilities.
Tests for heterogeneity between tables stored as layers of 3D wave.
Computes log likelihood statistic.
No results printed in the history area.
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2\) : \(\quad\) Disables killing.
The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

StatsContingencyTable supports 2D waves representing single contingency tables or 3D waves representing multiple 2D tables (where each table is a layer) or a single 3D table. Each entry in the wave must contain a frequency value and must be a positive number; it does not support 0 's, NaNs, or INFs. In the special case of \(2 \times 2\) tables, use the /COR flag to compute the statistic using either the Yates or Haber corrections. Except for the heterogeneity option you can also compute the log likelihood statistic. In all the tests, \(\mathrm{H}_{0}\) corresponds to independence between the tested variables.
For 3D tables StatsContingencyTable provides Chi-squared, degrees of freedom, the critical value, and optionally the log likelihood G statistic (/LLIK flag) for each of the following cases:
- Mutual independence by testing if all three variables are independent of each other.
- Partial dependence (rows) by testing if rows independent of columns and layers.
- Partial dependence (columns) by testing if columns independent of rows and layers.
- Partial dependence (layers) by testing if layers independent of rows and columns.

In each case you should compare the statistic with the critical value and reject \(\mathrm{H}_{0}\) if the statistic exceeds or equals the critical value.
You should examine the table entries to determine if the Chi-square statistic is appropriate (if the frequency is smaller than 6 for /ALPH= 0.05 you should consider computing the Fisher exact test).
V_flag will be set to -1 for any error and to zero otherwise.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsInvChiCDF.

\section*{StatsCorrelation}

StatsCorrelation(waveA [, waveB])
The StatsCorrelation function computes Pearson's correlation coefficient between two real valued arrays of data of the same length. Pearson \(r\) is give by:
\[
r=\frac{\sum_{i=0}^{n-1}(w a v e A[i]-A)(\text { wave } B[i]-B)}{\sqrt{\sum_{i=0}^{n-1}(w a v e A[i]-A)^{2} \sum_{i=0}^{n-1}(w a v e B[i]-B)^{2}}}
\]

Here \(A\) is the average of the elements in wave \(A, B\) is the average of the elements of wave \(B\) and the sum is over all wave elements.

\section*{Details}

If you use both waveA and waveB then the two waves must have the same number of points but they could be of different number type. If you use only the waveA parameter then waveA must be a 2 D wave. In this case StatsCorrelation will return 0 and create a 2D wave M_Pearson where the ( \(i, j\) ) element is Pearson's r corresponding to columns \(i\) and \(j\).
Fisher's z transformation converts Person's r above to a normally distributed variable \(z\) :
\[
z=\frac{1}{2} \ln \left(\frac{1+r}{1-r}\right)
\]
with a standard error
\[
\sigma_{z}=\frac{1}{\sqrt{n-3}}
\]

You can convert between the two representations using the following functions:
```

Function pearsonToFisher(inr)
Variable inr
return 0.5*(ln(1+inr)-ln(1-inr))
End
Function fisherToPearson(inz)
Variable inz
return tanh(inz)
End

```

\section*{See Also}

Correlate, StatsLinearCorrelationTest, and StatsCircularCorrelationTest.

\section*{StatsDExpCDF}

StatsDExpCDF ( \(x, m, s\) )
The StatsDExpCDF function returns the double-exponential cumulative distribution function
\[
F(x ; \mu, \sigma)= \begin{cases}\exp \left(\frac{x-\mu}{\sigma}\right) & \text { when } x<\mu \\ 1-\frac{1}{2} \exp \left(-\left|\frac{x-\mu}{\sigma}\right|\right) & \text { when } x \geq \mu\end{cases}
\]
for \(\sigma>0\). It returns NaN when \(\sigma=0\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsDExpPDF and StatsInvDExpCDF.

\section*{StatsDExpPDF}

StatsDExpPdf (x, m, s)
The StatsDExpPdf function returns the double-exponential probability distribution function
\[
\mathrm{f}(\mathrm{x} ; \mu, \sigma)=\frac{1}{2 \sigma} \exp \left[-\left|\frac{x-\mu}{\sigma}\right|\right],
\]
where \(\mu\) is the location parameter and \(\sigma>0\) is the scale parameter. Use \(\mu=0\) and \(\sigma=1\) for the standard form of the double exponential distribution. It returns NaN when \(\sigma=0\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsDExpCDF and StatsInvDExpCDF.

\section*{StatsDIPTest}

StatsDIPTest [/Z] srcWave
The StatsDIPTest operation performs Hartigan test for unimodality.

\section*{Flags}
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

The input to the operation srcWave is any real numeric wave. Outputs are: V_Value contains the dip statistic; V_min is the lower end of the modal interval; and V_max is the higher end of the modal interval. Percentage points or critical values for the dip statistic can be obtained from simulations using an identical sample size as in this example:
```

Function getCriticalValue(sampleSize,alpha)
Variable sampleSize,alpha
Make/O/N=(sampleSize) dataWave
Make/O/N=100000 dipResults
Variable i
for(i=0;i<100000;i+=1)
dataWave=enoise (100)
StatsDipTest dataWave
dipResults[i]=V_Value
endfor
Histogram/P/B=4 dipResults // Compute the PDF.
Wave W_Histogram
Integräte/METH=1 W_Histogram/D=W_INT // Compute the CDF.
Findlevel/Q W_int,(l-alpha) // Find the critical value.
return V_Level\overline{X}
End

```

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview.

\section*{StatsDunnettTest}

StatsDunnettTest [flags] [wave1, wave2,... wave100]
The StatsDunnettTest operation performs the Dunnett test by comparing multiple groups to a control group. Output is to the M_DunnettTestResults wave in the current data folder or optionally to a table. StatsDunnettTest usually follows StatsANOVA1Test.

Flags
\begin{tabular}{|c|c|}
\hline / \(\mathrm{ALPH}=\) val & Sets the significance level (default val=0.05). \\
\hline /CIDX=cIndex & Specifies the (zero based) index of the input wave corresponding to the control group. The default is zero (the first wave corresponds to the control group). \\
\hline /Q & No results printed in the history area. \\
\hline /SWN & Creates a text wave, T_DunnettDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use / T to append the text wave to the last column. \\
\hline \multirow[t]{4}{*}{\(/ \mathrm{T}=k\)} & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\hline & \(k=0: \quad\) Normal with dialog (default). \\
\hline & \(k=1: \quad\) Kills with no dialog. \\
\hline & \(k=2: \quad\) Disables killing. \\
\hline \multirow[t]{5}{*}{\(/ \mathrm{TAIL}=t c\)} & Specifies \(\mathrm{H}_{0}\). \\
\hline & \(t c=1: \quad\) Default; one tailed test ( \(\left.\mu_{\mathrm{c}} \leq \mu_{\mathrm{a}}\right)\). \\
\hline & \(t c=2: \quad\) One tailed test ( \(\left.\mu_{\mathrm{c}} \geq \mu_{\mathrm{a}}\right)\). \\
\hline & \(t c=4: \quad\) Two tailed test \(\left(\mu_{\mathrm{c}}=\mu_{\mathrm{a}}\right)\). \\
\hline & Code combinations are not allowed. \\
\hline
\end{tabular}
/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

StatsDunnettTest inputs are two or more 1D numeric waves (one wave for each group of samples). The input waves may contain different number of points, but they must contain two or more valid entries per wave.
For output to a table (using /T), each labelled row represents the results of the test for comparing the means of one group to the control group, and rows are ordered so that all comparisons are computed sequentially starting with the group having the smallest mean. The contents of the labeled columns are:
\begin{tabular}{ll} 
First & The difference between the group means \\
Second & SE (which is computed for possibly unequal number of points) \\
Third & The q statistic for the pair which may be positive or negative \\
Fourth & The critical q' value \\
Fifth & 0 if the conclusion is to reject \(\mathrm{H}_{0}\) or 1 to accept \(\mathrm{H}_{0}\) \\
Sixth & The P-value
\end{tabular}

\footnotetext{
V_flag will be set to -1 for any error and to zero otherwise.
}

\section*{StatsErlangCDF}

StatsErlangCDF ( \(x, b, c\) )
The StatsErlangCDF function returns the Erlang cumulative distribution function
\(F(x ; b, c)=1-\frac{\Gamma\left(c, \frac{x}{b}\right)}{\Gamma(c)}\).
where \(b>0\) (also as \(\lambda=1 / b\) ) is the scale parameter, \(c>0\) the shape parameter, \(\Gamma(x)\) the gamma function, and \(\Gamma(a, x)\) the incomplete gamma function gammaInc.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsErlangPDF.

\section*{StatsErlangPDF}

StatsErlangPDF ( \(x, b, c\) )
The StatsErlangPDF function returns the Erlang probability distribution function
\[
f(x ; b, c)=\frac{\left(\frac{x}{b}\right)^{c-1} \exp \left(-\frac{x}{b}\right)}{b(c-1)!}
\]
where \(b>0\) (also as \(\lambda=1 / b\) ) is the scale parameter and \(c>0\) the shape parameter.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsErlangCDF.

\section*{StatsErrorPDF}

StatsErrorPDF (x, a, b, c)
The StatsErrorPDF function returns the error probability distribution function or the exponential power distribution
\[
f(x ; a, b, c)=\frac{\exp \left[-\frac{1}{2}\left(\frac{|x-a|}{b}\right)^{\frac{2}{c}}\right]}{b 2^{\frac{c}{2}+1} \Gamma\left(1+\frac{c}{2}\right)}
\]
where \(a\) is the location parameter, \(b>0\) is the scale parameter, \(c>0\) is the shape parameter, and \(\Gamma(x)\) is the gamma function.

See Also
Chapter III-12, Statistics for a function and operation overview.

\section*{StatsEValueCDF}

StatsEValueCDF ( \(x, \mu, \sigma\) )
The StatsEValueCDF function returns the extreme-value (type I, Gumbel) cumulative distribution function
\[
F(x ; \mu, \sigma)=1-\exp \left(-\exp \left(\frac{x-\mu}{\sigma}\right)\right)
\]
where \(\sigma>0\). This is also known as the "minimum" form or distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of \(\sigma\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsEValuePDF and StatsInvEValueCDF.

\section*{StatsEValuePDF}

StatsEValuePDF ( \(x, \mu, \sigma\) )
The StatsEValuePDF function returns the extreme-value (type I, Gumbel) probability distribution function
\[
F(x ; \mu, \sigma)=1-\exp \left(-\exp \left(\frac{x-\mu}{\sigma}\right)\right)
\]
where \(\sigma>0\). This is also known as the "minimum" form or the distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of \(\sigma\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsEValueCDF and StatsInvEValueCDF.

\section*{StatsExpCDF}

StatsExpCDF ( \(x, \mu, \sigma\) )
The StatsExpCDF function returns the exponential cumulative distribution function
\[
F(x ; \mu, \sigma)=1-\exp \left(-\frac{x-\mu}{\sigma}\right)
\]
where \(x \geq \mu\) and \(\sigma>0\). It returns NaN for \(\sigma=0\).
See Also
Chapter III-12, Statistics for a function and operation overview; StatsExpPDF and StatsInvExpCDF.

\section*{StatsExpPDF}

StatsExpPDF ( \(x, \mu, \sigma\) )
The StatsExpPDF function returns the exponential probability distribution function
\[
f(x ; \mu, \sigma)=\frac{1}{\sigma} \exp \left(-\frac{x-\mu}{\sigma}\right)
\]
where \(\mu\) is the location parameter and \(\sigma>0\) is the scale parameter. Use \(\mu=0\) and \(\sigma=1\) for the standard form of the exponential distribution. It returns NaN for \(\sigma=0\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsExpCDF and StatsInvExpCDF.

\section*{StatsFCDF}

StatsFCDF (x, n1, n2)
The StatsFCDF function returns the cumulative distribution function for the \(F\) distribution with shape parameters \(n 1\) and \(n 2\)
\[
F\left(x ; n_{1}, n_{2}\right)=1-\operatorname{Betai}\left(\frac{n_{2}}{2}, \frac{n_{1}}{2}, \frac{n_{2}}{n_{2}+n_{1} x}\right)
\]
where Betai is the incomplete beta function.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsFPDF and StatsInvFCDF.

\section*{StatsFPDF}

StatsFPDF (x, n1, n2)
The StatsFPDF function returns the probability distribution function for the F distribution with shape parameters \(n 1\) and \(n 2\)
\[
f\left(x ; n_{1}, n_{2}\right)=\frac{\Gamma\left(\frac{n_{1}+n_{2}}{2}\right)\left(\frac{n_{1}}{n_{2}}\right)^{\frac{n_{1}}{2}} x^{\frac{n_{1}}{2}-1}}{\Gamma\left(\frac{n_{1}}{2}\right) \Gamma\left(\frac{n_{2}}{2}\right)\left(1+\frac{n_{1} x}{n_{2}}\right)^{\frac{n_{1}+n_{2}}{2}}}
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsFCDF and StatsInvFCDF.

\section*{StatsFriedmanCDF}

StatsFriedmanCDF (x, \(n, m, m e t h o d, ~ u s e T a b l e) ~\)
The StatsFriedmanCDF function returns the cumulative probability distribution of the Friedman distribution with \(n\) rows and \(m\) columns. The exact Friedman distribution is computationally intensive, taking on the order of \((n!)^{m}\) iterations. You may be able to use a range of precomputed exact values by passing a nonzero value for useTable, which will use method only if the value is not in the table. For large \(m\), consider using the Chi-squared or the Monte-Carlo approximations. To abort execution, press Commandperiod (Macintosh) or Ctrl+Break (Windows).
\begin{tabular}{ll} 
method & What It Does \\
\hline 0 & Exact computation. \\
1 & Chi-square approximation. \\
2 & Monte-Carlo approximation. \\
3 & Use built-table only and return NaN if not in table.
\end{tabular}

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsInvFriedmanCDF and StatsFriedmanTest.

\section*{StatsFriedmanTest}

StatsFriedmanTest [flags] [wave1, wave2,... wave100]
The StatsFriedmanTest operation performs Friedman's test on a randomized block of data. It is a nonparametric analysis of data contained in either individual 1D waves or in a single 2D wave. Output is to the M_FriedmanTestResults wave in the current data folder or optionally to a table.

\section*{Flags}
/ALPH = val
/Q

Sets the significance level (default val=0.05).
No results printed in the history area.
/RW
\(/ \mathrm{T}=k \quad\) Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.

\section*{/WSTR=waveListString}

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

The Friedman test ranks the input data on a row-by-row basis, sums the ranks for each column, and computes the Friedman statistic, which is proportional to the sum of the squares of the ranks.
Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with /WSTR. All 1D waves must have the same number of points. A 2D wave must not contain any NaNs.
The critical value for the Friedman distribution is fairly difficult to compute when the number of rows and columns is large because it requires a number of permutations on the order of (numColumns!)^numRows. A certain range of these critical values are supported by precomputed tables. When the exact critical value is not available you can use one of the two approximations that are always computed: the Chi-squared approximation or the Iman and Davenport approximation, which converts the Friedman statistic is converted to a new value Ff then compares it with critical values from the F distribution using weighted degrees of freedom.
With the /T flag, it displays the results in a table that contains the number of rows, the number of columns, the Friedman statistic, the exact critical value (if available), the Chi-squared approximation, the Iman and Davenport approximation, and the conclusion ( 1 to accept \(\mathrm{H}_{0}\) and 0 to reject it).
V_flag will be set to -1 for any error and to zero otherwise.

\section*{References}

Iman, R.L., and J.M. Davenport, Approximations of the critical region of the Friedman statistic, Comm. Statist. A9, 571-595, 1980.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsFriedmanCDF and StatsInvFriedmanCDF.

\section*{StatsFTest}

StatsFTest [flags] wave1, wave2
The StatsFTest operation performs the F-test on the two distributions in wave1 and wave2, which can be any real numeric type, must contain at least two data points each, and can have an arbitrary number of dimensions. Output is to the W_StatsFTest wave in the current data folder or optionally to a table.

\section*{Flags}
/ALPH = val Sets the significance level (default val=0.05).
/Q
No results printed in the history area.
\(/ \mathrm{T}=k\)
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1\) : Kills with no dialog.
\(k=2: \quad\) Disables killing.

\title{
/TAIL=tc
}

Specifies the tail tested.
\[
\begin{array}{ll}
t c=1: & \text { Lower one-tail test with } \mathrm{H}_{\mathrm{a}}: \text { sigma1>sigma2. } \\
t c=2: & \text { Upper one-tail test with } \mathrm{H}_{\mathrm{a}}: \text { sigma1<sigma2. } \\
t c=3: & \text { Default; the null hypothesis } \mathrm{H}_{0}: \\
& \text { sigma1=sigma2 with } \mathrm{H}_{\mathrm{a}}: \text { sigma1!=sigma2. }
\end{array}
\]
/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

The F statistic is the ratio of the variance of wave1 to the variance of wave2. We assume the waves have equal wave variances and that \(H_{0}\) is sigma1=sigma2. For the upper one-tail test we reject \(H_{0}\) if \(F\) is greater than the upper critical value or if F is smaller than the lower critical value in the lower one-tail test. In the twotailed test we reject \(\mathrm{H}_{0}\) if F is either greater than the upper critical value or smaller than the lower critical value. The critical values are computed by numerically solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by
\[
F\left(x, n_{1}, n_{2}\right)=1-\operatorname{betai}\left(\frac{n_{2}}{2}, \frac{n_{1}}{2}, \frac{n_{2}}{n_{2}+n_{1} x}\right)
\]
where the degrees of freedom \(n_{1}\) and \(n_{2}\) equal the number of valid (non-NaN) points in each wave - 1 , and betai is the incomplete beta function. To get the critical value for the upper one-tail test we solve \(\mathrm{F}(\mathrm{x})=1\) alpha. For the lower one-tail test we solve \(F(x)=\) alpha. In the two-tailed test the lower critical value is a solution for \(F(x)=a l p h a / 2\) and the upper critical value is a solution for \(F(x)=1-\mathrm{alpha} / 2\).
The F-test requires that the two samples are from normally distributed populations.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsVariancesTest, StatsFCDF, and betai.

\section*{StatsGammaCDF}

StatsGammaCDF (x, \(\mu, \sigma, \gamma\) )
The StatsGammaCDF function returns the gamma cumulative distribution function
\[
F(x ; \mu, \sigma, \gamma)=\frac{\Gamma_{i n c}\left(\gamma, \frac{x-\mu}{\sigma}\right)}{\Gamma(\gamma)} . \quad \begin{array}{cc} 
& x \geq \mu \\
\sigma, \gamma>0
\end{array}
\]
where \(\Gamma\) is the gamma function and \(\Gamma_{i n c}\) is the incomplete gamma function gammaInc.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsGammaPDF and StatsInvGammaCDF.

\section*{StatsGammaPDF}

StatsGammaPDF (x, \(\mu, \sigma, \gamma)\)
The StatsGammaPDF function returns the gamma probability distribution function
\[
f(x ; \mu, \sigma, \gamma)=\frac{\left(\frac{x-\mu}{\sigma}\right)^{\gamma-1} \exp \left(-\frac{x-\mu}{\sigma}\right)}{\sigma \Gamma(\gamma)} . \quad \begin{array}{cc}
x \geq \mu \\
\sigma, \gamma>0
\end{array}
\]
where \(\mu\) is the location parameter, \(\sigma\) is the scale parameter, \(\gamma\) is the shape parameter, and \(\Gamma\) is the gamma function.

\section*{StatsGeometricCDF}

StatsGeometricCDF ( \(x, p\) )
The StatsGeometricCDF function returns the geometric cumulative distribution function
\(F(x, p)=1-(1-p)^{x+1}\).
where \(p\) is the probability of success in a single trial and \(x\) is the number of trials for \(x \geq 0\).
See Also
Chapter III-12, Statistics for a function and operation overview; StatsGeometricPDF and StatsInvGeometricCDF.

\section*{StatsGeometricPDF}

StatsGeometricPDF (x, p)
The StatsGeometricPDF function returns the geometric probability distribution function
\(f(x, p)=p(1-p)^{x}\),
where the \(p\) is the probability of success in a single trial and \(x\) is the number of trials \(x \geq 0\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsGeometricCDF and StatsInvGeometricCDF.

\section*{StatsHodgesAjneTest}

StatsHodgesAjneTest [flags] srcWave
The StatsHodgesAjneTest operation performs the Hodges-Ajne nonparametric test for uniform distribution around a circle. Output is to the W_HodgesAjne wave in the current data folder or optionally to a table.

Flags
\begin{tabular}{|c|c|}
\hline / \(\mathrm{ALPH}=\) val & Sets the significance level (default val=0.05). \\
\hline /Q & No results printed in the history area. \\
\hline /SA=specAngle & Uses the Batschelet modification of the Hodges-Ajne test to test for uniformity against the alternative of concentration around the specified angle. specAngle must be expressed in radians modulus \(2 \pi\). \\
\hline \multirow[t]{4}{*}{\(/ \mathrm{T}=k\)} & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\hline & \(k=0\) : \(\quad\) Normal with dialog (default). \\
\hline & \(k=1: \quad\) Kills with no dialog. \\
\hline & \(k=2: \quad\) Disables killing. \\
\hline /Z & Ignores errors. V_flag will be set to -1 for any error and to zero otherwise. \\
\hline
\end{tabular}

\section*{Details}

The input srcWave must contain angles in radians, can be any number of dimensions, can be single or double precision, and should not contain NaNs or INFs.
StatsHodgesAjneTest performs the standard Hodges-Ajne test, which simply tests for uniformity against the hypothesis that the population is not uniformly distributed around the circle. This test finds a diameter that divides the circle into two halves such that one contains the least number of data \(m\), the test statistic.

Use /SA to perform the modified (Batschelet) test, which tests against the alternative that the population is concentrated somehow about the specified angle. The modified test counts the number of points \(m^{\prime}\) in 90degree neighborhoods around the specified angle. The test statistic is given by \(C=n-m^{\prime}\) where \(n\) is the number of points in the wave. The critical value is computed from the binomial probability density.

In both cases \(\mathrm{H}_{0}\) is rejected if the statistic is smaller than the critical value.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{StatsHyperGCDF}

StatsHyperGCDF ( \(x, m, n, k\) )
The StatsHyperGCDF function returns the hypergeometric cumulative distribution function, which is the probability of getting \(x\) marked items when drawing (without replacement) \(k\) items out of a population of \(m\) items when \(n\) out of the \(m\) are marked.

\section*{Details}

The hypergeometric distribution is
\[
F(x ; m, n, k)=\sum_{L=0}^{x} \frac{\binom{n}{L}\binom{m-L}{k-L}}{\binom{m}{k}}
\]
where \(\binom{a}{b}\) is the binomial function. All parameters must be positive integers and must have \(m>n\) and \(x<k\); otherwise it returns NaN .

\section*{StatsInvBetaCDF}

StatsInvBetaCDF (cdf, \(p, q[, a, b])\)
The StatsInvBetaCDF function returns the inverse of the beta cumulative distribution function. There is no closed form expression for the inverse beta CDF; it is evaluated numerically.
The defaults ( \(a=0\) and \(b=1\) ) correspond to the standard beta distribution.
See Also
Chapter III-12, Statistics for a function and operation overview; StatsBetaCDF and StatsBetaPDF.

\section*{StatsInvBinomialCDF}

StatsInvBinomialCDF (cdf, \(p, N\) )
The StatsInvBinomialCDF function returns the inverse of the binomial cumulative distribution function. The inverse function returns the value at which the binomial \(C D F\) with probability \(p\) and total elements \(N\), has the value 0.95 . There is no closed form expression for the inverse binomial CDF; it is evaluated numerically.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsBinomialCDF and StatsBinomialPDF.

\section*{StatsInvCauchyCDF}

StatsInvCauchyCDF (cdf, \(\mu, \sigma\) )
The StatsInvCauchyCDF function returns the inverse of the Cauchy-Lorentz cumulative distribution function
\[
x=\mu+\sigma \tan \left[\pi\left(c d f-\frac{1}{2}\right)\right]
\]

It returns NaN for \(c d f<0\) or \(c d f>1\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsCauchyCDF and StatsCauchyPDF.

\section*{StatsInvChiCDF}

\section*{StatsInvChiCDF ( \(x, n\) )}

The StatsInvChiCDF function returns the inverse of the chi-squared distribution of \(x\) and shape parameter \(n\). The inverse of the distribution is also known as the percent point function.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsChiCDF and StatsChiPDF.

\section*{StatsInvCMSSDCDF}

StatsInvCMSSDCDF (cdf, n)
The StatsInvCMSSDCDF function returns the critical values of the \(C\) distribution (mean square successive difference distribution), which is given by
\[
f(C, n)=\frac{\Gamma(2 m+2)}{a 2^{2 m+1}[\Gamma(m+1)]^{2}}\left(1-\frac{C^{2}}{a^{2}}\right)^{m},
\]
where
\[
\begin{aligned}
& a^{2}=\frac{\left(n^{2}+2 n-12\right)(n-2)}{\left(n^{3}-13 n+24\right)}, \\
& m=\frac{\left(n^{4}-n^{3}-13 n^{2}+37 n-60\right)}{2\left(n^{3}-13 n+24\right)} .
\end{aligned}
\]

Critical values are computed from the integral of the probability distribution function.

\section*{References}

Young, L.C., On randomness in ordered sequences, Annals of Mathematical Statistics, 12, 153-162, 1941.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsCMSSDCDF and StatsSRTest.

\section*{StatsInvDExpCDF}

StatsInvDExpCDF (cdf, \(\mu, \sigma\) )
The StatsInvDExpCDF function returns the inverse of the double-exponential cumulative distribution function
\[
x= \begin{cases}\mu+\sigma \ln (2 c d f) & \text { when } c d f<0.5 \\ \mu-\sigma \ln [2(1-c d f)] & \text { when } c d f \geq 0.5\end{cases}
\]

It returns NaN for \(c d f<0\) or \(c d f>1\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsDExpCDF and StatsDExpPDF.

\section*{StatsInvEValueCDF}

StatsInvEValueCDF (cdf, \(\mu, \sigma\) )
The StatsInvEValueCDF function returns the inverse of the extreme-value (type I, Gumbel) cumulative distribution function
\[
x=\mu-\sigma \ln (1-c d f)
\]
where \(\sigma>0\). It returns NaN for \(c d f<0\) or \(c d f>1\). This inverse applies to the "minimum" form of the distribution. Reverse the sign of \(\sigma\) to obtain the inverse distribution of the maximum form.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsEValueCDF and StatsEValuePDF.

\section*{StatsInvExpCDF}

StatsInvExpCDF (cdf, \(\mu, \sigma\) )
The StatsInvExpCDF function returns the inverse of the exponential cumulative distribution function
\[
x=\mu-\sigma \ln (1-c d f)
\]

It returns NaN for \(c d f<0\) or \(c d f>1\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsExpCDF and StatsExpPDF.

\section*{StatsInvFCDF}

StatsInvFCDF (x, n1, n2)
The StatsInvFCDF function returns the inverse of the F distribution cumulative distribution function for \(x\) and shape parameters \(n 1\) and \(n 2\). The inverse is also known as the percent point function.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsFCDF and StatsFPDF.

\section*{StatsInvFriedmanCDF}

StatsInvFriedmanCDF (cdf, \(n, m\), method, useTable)
The StatsInvFriedmanCDF function returns the inverse of the Friedman distribution cumulative distribution function of \(c d f\) with \(n\) rows and \(m\) columns. Use this typically to compute the critical values of the distribution Print StatsInvFriedmanCDF ( 1 -alpha, \(n, m, 0,1\) )
where alpha is the significance level of the associated test.
The complexity of the computation of Friedman CDF is on the order of \((n!)^{m}\). For nonzero values of useTable, searches are limited to the built-in table for distribution values. If \(n\) and \(m\) are not in the table the calculation may still proceed according to the method.
\begin{tabular}{ll} 
method & What It Does \\
\hline 0 & Exact computation(slow, not recommended). \\
1 & Chi-square approximation. \\
2 & Monte-Carlo approximation (slow). \\
3 & Use built-in table only and return a NaN if not in table. \\
\hline
\end{tabular}

For large \(m\) and \(n\), consider using the Chi-squared or the Iman and Davenport approximations. To abort execution, press Command-period (Macintosh) or Ctrl+Break (Windows).

Note: Table values are different from computed values for both methods. Table values use more conservative criteria than computed values. Table values are more consistent with published values because the Friedman distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the \(X\) value of the next vertical transition to the one on which the specified \(P\) is found.

Precomputed tables use these values:
\begin{tabular}{ll}
\(n\) & \(m\) \\
\hline 3 & \(2,3,4,5,6,7,8,9,10,11,12,13,14,15,16\) \\
4 & \(2,3,4,5,6,7,8,9\) \\
5 & \(2,3,4,5,6\) \\
6 & \(2,3,4,5\) \\
\hline
\end{tabular}
\begin{tabular}{ll}
\(\boldsymbol{n}\) & \(\boldsymbol{m}\) \\
\hline 7 & \(2,3,4\) \\
8 & 2,3 \\
9 & 2,3 \\
\hline
\end{tabular}

\section*{References}

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsFriedmanCDF and StatsFriedmanTest.

\section*{StatsInvGammaCDF}

StatsInvGammaCDF (cdf, \(\mu, \sigma, \gamma\) )
The StatsInvGammaCDF function returns the inverse of the gamma cumulative distribution function. There is no closed form expression for the inverse gamma distribution; it is evaluated numerically.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGammaCDF and StatsGammaPDF.

\section*{StatsInvGeometricCDF}

StatsInvGeometricCDF (cdf, p)
The StatsInvGeometricCDF function returns the inverse of the geometric cumulative distribution function
\[
x=\frac{\ln (1-c d f)}{\ln (1-p)}-1
\]
where \(p\) is the probability of success in a single trial and \(x\) is the number of trials.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsGeometricCDF and StatsGeometricPDF.

\section*{StatsInvKuiperCDF}

StatsInvKuiperCDF (cdf)
The StatsInvKuiperCDF function returns the inverse of Kuiper cumulative distribution function.
There is no closed form expression. It is mapped to the range of 0.4 to 4 , with accuracy of \(1 \mathrm{e}-10\).

\section*{References}

See in particular Section 14.3 of
Press, William H., et al., Numerical Recipes in C, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsKuiperCDF.

\section*{StatsInvLogisticCDF}

StatsInvLogisticCDF (cdf, a, b)
The StatsInvLogisticCDF function returns the inverse of the logistic cumulative distribution function
\[
x=a+b \log \left(\frac{c d f}{1-c d f}\right)
\]
where the scale parameter \(b>0\) and the shape parameter is \(a\).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogisticCDF and StatsLogisticPDF functions.

\section*{StatsInvLogNormalCDF}

StatsInvLogNormalCDF (cdf, sigma, theta, mu)
The StatsInvLogNormalCDF function returns the numerically evaluated inverse of the lognormal cumulative distribution function.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogNormalCDF and StatsLogNormalPDF functions.

\section*{StatsInvMaxwellCDF}

StatsInvMaxwellCDF (cdf, k)
The StatsInvMaxwellCDF function returns the evaluated numerically inverse of the Maxwell cumulative distribution function. There is no closed form expression.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsMaxwellCDF and StatsMaxwellPDF functions.

\section*{StatsInvMooreCDF}

StatsInvMooreCDF (cdf, N)
The StatsInvMooreCDF function returns the inverse cumulative distribution function for Moore's \(\mathrm{R}^{*}\), which is used as a critical value in nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range \(3 \leq N \leq 120\) and does not change appreciably for \(N>120\).
The inverse distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

\section*{References}

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsCircularMeans function.

\section*{StatsInvNBinomialCDF}

StatsInvNBinomialCDF (cdf, \(k, p\) )
The StatsInvNBinomialCDF function returns the numerically evaluated inverse of the negative binomial cumulative distribution function. There is no closed form expression.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNBinomialCDF and StatsNBinomialPDF functions.

\section*{StatsInvNCChiCDF}

StatsInvNCChiCDF (cdf, \(n, d)\)
The StatsInvNCChiCDF function returns the inverse of the noncenteral chi-squared cumulative distribution function. It is computationally intensive because the inverse is computed numerically and involves multiple evaluations of the noncentral distribution, which is evaluated from a series expansion.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNCChiCDF, StatsNCChiPDF, StatsChiCDF, and StatsChiPDF functions.

\section*{StatsInvNCFCDF}

StatsInvNCFCDF (cdf, n1, n2, d)
The StatsInvNCFCDF function returns the numerically evaluated inverse of the cumulative distribution function of the noncentral F distribution. \(n 1\) and \(n 2\) are the shape parameters and \(d\) is the noncentrality measure. There is no closed form expression for the inverse.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNCFCDF and StatsNCFPDF functions.

\section*{StatsInvNormalCDF}

StatsInvNormalCDF (cdf, \(m, s\) )
The StatsInvNormalCDF function returns the numerically computed inverse of the normal cumulative distribution function. There is no closed form expression.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsNormalCDF and StatsNormalPDF functions.

\section*{StatsInvParetoCDF}

StatsInvParetoCDF (cdf, \(a, c\) )
The StatsInvParetoCDF function returns the inverse of the Pareto cumulative distribution function
\[
x=\frac{a}{(1-c d f)^{(1 / c)}}
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsParetoCDF and StatsParetoPDF functions.

\section*{StatsInvPoissonCDF}

StatsInvPoissonCDF (cdf, \(\lambda\) )
The StatsInvPoissonCDF function returns the numerically evaluated inverse of the Poisson cumulative distribution function. There is no closed form expression for the inverse Poisson distribution.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPoissonCDF and StatsPoissonPDF functions.

\section*{StatsInvPowerCDF}

StatsInvPowercDF (cdf, b, c)
The StatsInvPowerCDF function returns the inverse of the Power Function cumulative distribution function
\[
x=b / c d f^{(1 / c)}
\]
where the scale parameter \(b\) and the shape parameter \(c\) satisfy \(b, c>0\).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPowerCDF, StatsPowerPDF and StatsPowerNoise functions.

\section*{StatsInvQCDF}

StatsInvQCDF (cdf, \(r, c, d f)\)
The StatsInvQCDF function returns the critical value of the Q cumulative distribution function for \(r\) the number of groups, \(c\) the number of treatments, and \(d f\) the error degrees of freedom ( \(d f=r^{*} c^{*}(n-1)\) with sample size \(n\) ).

\section*{Details}

The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use \(r=1\).

\section*{Examples}

The critical value for a Tukey test comparing 5 treatments with 6 samples and 0.05 significance is:
Print StatsInvQCDF (1-0.05, 1,5,5*(6-1))

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsTukeyTest function.

\section*{StatsInvQpCDF}

StatsInvQpCDF (ng, nt, df, alpha, side, sSizeWave)
The StatsInvQpCDF function returns the critical value of the \(Q^{\prime}\) cumulative distribution function for \(n g\) the number of groups, \(n t\) the number of treatments, and \(d f\) the error degrees of freedom. side \(=1\) for upper-tail or side \(=2\) for two-tailed critical values.
sSizeWave is an integer wave of \(n g\) columns and \(n t\) rows specifying the number of samples in each treatment. If sSizeWave is a null wave ( \(\${ }^{\prime \prime}\) ") StatsInvQpCDF computes the number of samples from \(d f=n g^{*} n t^{*}(n-1)\) with \(n\) truncated to an integer.

\section*{Details}

StatsInvQpCDF is a modified Q distribution typically used with Dunnett's test, which compares the various means with the mean of the control group or treatment.
StatsInvQpCDF differs from other StatsInvXXX functions in that you do not specify a cdf value for the inverse (usually 1-alpha for the critical value). Here alpha selects one- or two-tailed critical values.
It is computationally intensive, taking longer to execute for smaller alpha values.

\section*{Examples}

The critical value for a Dunnett test comparing 4 treatments with 4 samples and (upper tail) 0.05 significance is:
```

// here n=4 because 12=1*4* (4-1).
Print StatsInvQpCDF (1,4,12,0.05,1,\$"")
2.28734

```

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsDunnettTest and StatsInvQCDF functions.

\section*{StatsInvRayleighCDF}

StatsInvRayleighCDF (cdf [, s [, m] ])
The StatsInvRayleighCDF function returns the inverse of the Rayleigh cumulative distribution functiongiven by
\[
x=\mu+\sigma \sqrt{-2 \ln (1-c d f)}
\]
with defaults \(s=1\) and \(m=0\). It returns NaN for \(s \leq 0\) and zero for \(\mathrm{x} \leq m\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsRayleighCDF and StatsRayleighPDF functions.

\section*{StatsInvRectangularCDF}

\section*{StatsInvRectangularCDF (cdf, a, b)}

The StatsInvRectangularCDF function returns the inverse of the rectangular (uniform) cumulative distribution function
\[
x=a+c d f(b-a), \quad a<b
\]
where \(a<b\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsRectangularCDF and StatsRectangularPDF functions.

\section*{StatsInvSpearmanCDF}

StatsInvSpearmanCDF (cdf, N)
The StatsInvSpearmanCDF function returns the inverse cumulative distribution function for Spearman's \(r\), which is used as a critical value in rank correlation tests.
The inverse distribution is computed by finding the value of \(r\) for which it attains the \(c d f\) value. The result is usually lower than in published tables, which are more conservative when the first derivative of the distribution is discontinuous.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsRankCorrelationTest, StatsSpearmanRhoCDF, and StatsKendallTauTest functions.

\section*{StatsInvStudentCDF}

StatsInvStudentCDF (cdf, \(n\) )
The StatsInvStudentCDF function returns the numerically evaluated inverse of Student cumulative distribution function. There is no closed form expression.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsStudentCDF and StatsStudentPDF functions.

\section*{StatsInvTopDownCDF}

\section*{StatsInvTopDownCDF (cdf, N)}

The StatsInvTopDownCDF function returns the inverse cumulative distribution function for the top-down distribution. For \(3 \leq N \leq 7\) it uses a lookup table CDF and returns the next higher value of \(r\) for which the distribution value is larger than \(c d f\). For \(8 \leq N \leq 50\) it returns the nearest value for which the built-in distribution returns \(c d f\). For \(N>50\) it returns the scaled normal approximation.
Tabulated values are from Iman and Conover who pick as the critical value the very first transition of the distribution following the specified \(c d f\) value. These tabulated values tend to be slightly higher than calculated values for \(7<N<15\).

\section*{References}

Iman, R.L., and W.J. Conover, A measure of top-down correlation, Technometrics, 29, 351-357, 1987.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsRankCorrelationTest and StatsTopDownCDF functions.

\section*{StatsInvTriangularCDF}

StatsInvTriangularCDF (cdf, \(a, b, c\) )
The StatsInvTriangularCDF function returns the inverse of the triangular cumulative distribution function
\[
x= \begin{cases}a+\sqrt{c d f(b-a)(c-a)} & 0 \leq c d f \leq \frac{c-a}{b-a} \\ b-\sqrt{(1-c d f)(b-a)(b-c)} & \frac{c-a}{b-a} \leq c d f \leq 1\end{cases}
\]
where \(a<c<b\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsTriangularCDF and StatsTriangularPDF functions.

\section*{StatsInvUSquaredCDF}

StatsInvUSquaredCDF (cdf, \(n, m\) method, useTable)
The StatsInvUSquaredCDF function returns the inverse of Watson's \(\mathrm{U}^{2}\) cumulative distribution function integer sample sizes \(n\) and \(m\). Use a nonzero value for useTable to search a built-in table of values. If \(n\) and \(m\) cannot be found in the table, it will proceed according to method:
\begin{tabular}{ll} 
method & What It Does \\
\hline 0 & Exact computation using Burr algorithm (could be slow). \\
1 & Tiku approximation using chi-squared. \\
2 & Use built-in table only and return a NaN if not in table.
\end{tabular}

For large \(n\) and \(m\), consider using the Tiku approximation. To abort execution, press Command-period (Macintosh) or Ctrl+Break (Windows). Because \(n\) and \(m\) are interchangeable, \(n\) should always be the smaller value. For \(n>8\) the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with \(m\) values exceeding these limits.
The inverse is obtained from precomputed tables of Watson's \(\mathrm{U}^{2}\) (see StatsUSquaredCDF).
Note: Table values are different from computed values. These values use more conservative criteria than computed values. Table values are more consistent with published values because the \(\mathrm{U}^{2}\) distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the \(X\) value of the next vertical transition to the one on which the specified P is found. See StatsInvFriedmanCDF.

\section*{References}

Burr, E.J., Small sample distributions of the two sample Cramer-von Mises' W \({ }^{2}\) and Watson's \(\mathrm{U}^{2}\), Ann. Mah. Stat. Assoc., 64, 1091-1098, 1964.
Tiku, M.L., Chi-square approximations for the distributions of goodness-of-fit statistics, Biometrica, 52, 630633, 1965.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsWatsonUSquaredTest and StatsUSquaredCDF functions.

\section*{StatsInvVonMisesCDF}

StatsInvVonMisesCDF (cdf, \(a, b\) )
The StatsInvVonMisesCDF function returns the numerically evaluated inverse of the von Mises cumulative distribution function where the value of the integral of the distribution matches \(c d f\). Parameters are as for StatsVonMisesCDF.

\section*{References}

Evans, M., N. Hastings, and B. Peacock, Statistical Distributions, 3rd ed., Wiley, New York, 2000.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsVonMisesPDF and StatsVonMisesNoise functions.

\section*{StatsInvWeibullCDF}

StatsInvWeibullCDF (cdf, \(m, s, g\) )
The StatsInvWeibullCDF function returns the inverse of the Weibull cumulative distribution function
\[
x=\mu+\sigma[-\ln (1-c d f)]^{1 / \gamma}
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsWeibullCDF and StatsWeibullPDF functions.

\section*{StatsJBTest}

StatsJBTest [flags] srcWave
The StatsJBTest operation performs the Jarque-Bera test on srcWave. Output is to the W_JBResults wave in the current data folder.

\section*{Flags}
\(/ \mathrm{ALPH}=\) val \(\quad\) Sets the significance level (default val=0.05).
/Q
No results printed in the history area.
\(/ \mathrm{T}=k \quad\) Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

StatsJBTest computes the Jarque-Bera statistic
\[
J B=\frac{n}{6}\left(S^{2}+\frac{K^{2}}{4}\right),
\]
where \(S\) is the skewness, \(K\) is the kurtosis, and \(n\) is the number of points in the input wave. We can express \(S\) and \(K\) terms of the \(j\) th moment of the distribution for n samples \(X_{i}\)
\[
\mu_{j}=\frac{1}{n} \sum_{i=1}^{n}\left(X_{i}-\bar{X}\right)^{j}
\]
as
\[
S=\frac{\mu_{3}}{\left(\mu_{2}\right)^{3 / 2}},
\]
and
\[
K=\frac{\mu_{4}}{\left(\mu_{2}\right)^{2}}-3
\]

The Jarque-Bera statistic is asymptotically distributed as a Chi-squared with two degrees of freedom. For values of \(n\) in the range [7,2000] the operation provides critical values obtained from Monte-Carlo simulations. For further details or if you would like to run your own simulation to obtain critical values for other values of \(n\), use the JarqueBeraSimulation example experiment.
StatsJBTest reports the number of finite data points, skewness, kurtosis, Jarque-Bera statistic, asymptotic critical value, and the critical value obtained from Monte-Carlo calculations as appropriate; it ignores NaNs and INFs.

\section*{References}

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsKSTest, WaveStats, and StatsCircularMoments.

\section*{StatsKendallTauTest}

StatsKendallTauTest [flags] wave1 [, wave2]
The StatsKendallTauTest operation performs the nonparametric Mann-Kendall test, which computes a correlation coefficient \(\tau\) (similar to Spearman's correlation) from the relative order of the ranks of the data. Output is to the W_StatsKendallTauTest wave in the current data folder.
Flags
/Q
\(/ \mathrm{T}=k\)
/Z
No results printed in the history area.
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

Inputs may be a pair of \(X Y\) (1D) waves of any real numeric type or a single 1D wave, which is equivalent to using a pair of \(X Y\) waves where the \(X\) wave is monotonically increasing function of the point number. StatsKendallTauTest ignores wave scaling.
Kendall's \(\tau\) is 1 for a monotonically increasing input and -1 for monotonically decreasing input. The significance of the test is computed from the normal approximation
\[
\operatorname{Var}(\tau)=\frac{4 n+10}{9 n(n-1)}
\]
where \(n\) is the number of data points in each wave. The significance is expressed as a P-value for the null hypothesis of no correlation.

\section*{References}

Kendall, M.G., Rank Correlation Methods, 3rd ed., Griffin, London, 1962.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsRankCorrelationTest.
For small values of \(n\) you can compute the exact probability using the procedure WM_KendallSProbability().

\section*{StatsKSTest}

StatsKSTest [flags] srcWave [, distWave]
The StatsKSTest operation performs the Kolmogorov-Smirnov (KS) goodness-of-fit test for two continuous distributions. The first distribution is srcWave and the second distribution can be expressed either as the optional wave distWave or as a user function with /CDFF. Output is to the W_KSResults wave in the current data folder.

\section*{Flags}
/ALPH = val \(\quad\) Sets the significance level (default val=0.05).
/CDFF=func
Specifies a user function expressing the cumulative distribution function. See Details.

\section*{/Q \\ \(/ \mathrm{T}=k\)}
/Z

No results printed in the history area.
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.

\section*{Details}

The Kolmogorov-Smirnov (KS) goodness-of-fit test applies only to continuous distributions and cases where the compared distribution (expressed as a user function) is completely specified without estimating parameters from the data. It compares the cumulative distribution function (CDF) of two distributions and sets the test statistic D to the largest difference between the CDFs. Because CDFs are in the range [0,1], D is also bound by this range.
When specifying the distributions with two waves, StatsKSTest first sorts the data in the waves and then computes the CDFs and D. You can also specify one of the distributions with a user function. For example, the following function tests if the data in srcWave is normally distributed with zero mean and stdv=5:
```

Function getUserCDF(inX)
Variable inX
return statsNormalCDF(inX,0,5)
End
Outputs are the number of elements, the KS statistic D, and the critical value. When both distributions are
specified by waves, the number of elements is the weighted value (n1*n2)/(n1+n2).

```

\section*{References}

Critical values are based on:
Birnbaum, Z. W., and Fred H. Tingey, One-sided confidence contours for probability distribution functions, The Annals of Mathematical Statistics, 22, 592-596, 1951.

A statistically more powerful modification of the classic KS test can be found in:
Khamis, H.J., The two-stage delta-corrected Kolmogorov-Smirnov test, Journal of Applied Statistics, 27, 439450, 2000.
StatsKSTest implements the original KS test. The difficulty in implementing the modified tests for all the cases defined by Stephens is in obtaining the critical values which have to be derived by time consuming Monte-Carlo simulations.
Critiques can be found in:
D'Agostino, R.B., and M. Stephens, eds., Goodness-Of-Fit Techniques, Marcel Dekker, New York, 1986.

\section*{StatsKuiperCDF}

StatsKuiperCDF (V)
The StatsKuiperCDF function returns the Kuiper cumulative distribution function
\[
F(V)=1-2 \sum_{j=1}^{\infty}\left(4 j^{2} V^{2}-1\right) \exp \left(-2 j^{2} V^{2}\right)
\]

Accuracy is on the order of \(1 \mathrm{e}-15\). It returns 0 for values of \(V<0.4\) or 1 for \(V>3.1\).

\section*{References}

Press, William H., et al., Numerical Recipes in C, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsInvKuiperCDF.

\section*{StatsKWTest}

StatsKWTest [flags] [wave1, wave2,... wave100]
The StatsKWTest operation performs the nonparametric Kruskal-Wallis test which tests variances using the ranks of the data. Output is to the \(W_{-}\)KWTestResults wave in the current data folder.
Flags
\begin{tabular}{ll} 
/ALPH = val & Sets the significance level (default val=0.05). \\
/E & \begin{tabular}{l} 
Computes the exact P-value using the Klotz and Teng algorithm, which may require \\
long computation times for large data sets. You can stop the calculation by pressing \\
Command-period (Macintosh) or Ctrl+Break (Windows) after which all remaining \\
results remain valid and the exact P-value is set to NaN.
\end{tabular} \\
No results printed in the history area.
\end{tabular}

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

Inputs are two or more 1D numerical waves (one for each group of samples). Use NaNs for missing data or use waves with different number of points.
StatsKWTest always computes the critical values using both the Chi-squared and Wallace approximations. If appropriate (small enough data set) you can also use / E to obtain the exact P value. When the calculation involves many waves or many data points the calculation of the exact critical value can be very lengthy. All the results are saved in the wave \(W_{-} K W T e s t R e s u l t s ~ i n ~ t h e ~ c u r r e n t ~ d a t a ~ f o l d e r ~ a n d ~ a r e ~ o p t i o n a l l y ~ d i s p l a y e d ~\) in a table (/T). The wave contains the following information:
\begin{tabular}{ll} 
Row & Data \\
\hline 0 & Number of groups \\
1 & Number of valid data points (excludes NaNs) \\
2 & Alpha \\
3 & Kruskal-Wallis Statistic H \\
4 & Chi-squared approximation for the critical value Hc \\
5 & Chi-squared approximation for the P value \\
6 & Wallace approximation for the critical value Hc \\
7 & Wallace approximation for the P value \\
8 & Exact P value (requires /E) \\
\hline
\end{tabular}
\(\mathrm{H}_{0}\) for the Kruskal-Wallis test is that all input waves are the same. If the test fails and the input consisted of more than two waves, there is no indication for possible agreement between some of the waves. See StatsNPMCTest for further analysis.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{StatsLinearCorrelationTest}

StatsLinearCorrelationTest [flags] waveA, waveB
The StatsLinearCorrelationTest operation performs correlation tests on waveA and waveB, which must be real valued numeric waves and must have the same number of points. Output is to the W_StatsLinearCorrelationTest wave in the current data folder or optionally to a table.
Flags
\begin{tabular}{|c|c|}
\hline / \(\mathrm{ALPH}=\) val & Sets the significance level (default val=0.05). \\
\hline /CI & Computes confidence intervals for the correlation coefficient. \\
\hline /Q & No results printed in the history area. \\
\hline / \(\mathrm{RHO}=\) rhoValue & Tests hypothesis that the correlation has a nonzero value \(|\mathrm{r}| \leq 1\). \\
\hline /T=k & \begin{tabular}{l}
Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\(k=0\) : \(\quad\) Normal with dialog (default). \\
\(k=1: \quad\) Kills with no dialog. \\
\(k=2: \quad\) Disables killing.
\end{tabular} \\
\hline /Z & Ignores errors. \\
\hline
\end{tabular}

\section*{Details}

The linear correlation tests start by computing the linear correlation coefficient for the \(n\) elements of both waves:
\[
r=\frac{\sum_{i=1}^{n} X_{i} Y_{i}-\frac{1}{n} \sum_{i=1}^{n} X_{i} \sum_{i=1}^{n} Y_{i}}{\sqrt{\left(\sum_{i=1}^{n} X_{i}^{2}-\frac{1}{n}\left(\sum_{i=1}^{n} X_{i}\right)^{2}\right)\left(\sum_{i=1}^{n} Y_{i}^{2}-\frac{1}{n}\left(\sum_{i=1}^{n} Y_{i}\right)^{2}\right)}}
\]

Next it computes the standard error of the correlation coefficient
\[
s r=\sqrt{\frac{1-r^{2}}{n-2}}
\]

The basic test is for hypothesis \(\mathrm{H}_{0}\) : the correlation coefficient is zero, in which case \(t\) and \(F\) statistics are applicable. It computes the statistics:
\(t=r / s r\)
and
\[
F=\frac{1+|r|}{1-|r|}
\]
and then the critical values for one and two tailed hypotheses (designated by \(t_{c 1}, t_{c 2}, F_{c 1}\), and \(F_{c 2}\) respectively). Critical value for \(r\) are computed using
\[
\mathrm{rc}_{\mathrm{i}}=\sqrt{\frac{t_{c}^{2}}{t_{c}^{2}+n}}
\]
where \(i\) takes the values 1 or 2 for one and two tailed hypotheses. Finally, it computes the power of the test at the alpha significance level for both one and two tails (Power1 and Power2).
If you use /RHO it uses the Fisher transformation to compute
FisherZ \(=\frac{1}{2} \ln \left(\frac{1+r}{1-r}\right)\)
\[
\text { zeta }=\frac{1}{2} \ln \left(\frac{1+\rho}{1-\rho}\right)
\]
the standard error approximation
\[
\begin{aligned}
& \text { sigmaZ }=\sqrt{\frac{1}{n-3}}, \\
& \text { Zstatistic }=\frac{\text { Fisher } Z-z e t a}{\text { sigmaZ }}
\end{aligned}
\]
and the critical values from the normal distribution \(Z_{c i}\).
The confidence intervals are calculated differently depending on the hypothesis for the value of the correlation coefficient. If / RHO is not used the confidence intervals are computed using the critical value \(F_{c 2}\), otherwise they are computed using the critical \(Z_{c 2}\) and sigmaZ.

\section*{References}

Zar, J.H., Biostatistical Analysis, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsCircularCorrelationTest,
StatsMultiCorrelationTest, and StatsRankCorrelationTest.

\section*{StatsLinearRegression}

StatsLinearRegression [flags] [wave0, wave1,...]
The StatsLinearRegression operation performs regression analysis on the input wave(s). Output is to the W_StatsLinearRegression wave in the current data folder or optionally to a table. Additionally, the M_DunnettMCElevations, M_TukeyMCSlopes, and M_TukeyMCElevations waves may be created as specified.

\section*{Flags}
/ \(\mathrm{ALPH}=\) val
/ \(\mathrm{B}=\) beta 0
/BCIW

Sets the significance level (default val=0.05).
Tests the hypothesis that the slope \(b=b e t a 0\) (default is 0 ). The results are expressed by the \(t\)-statistic, which can be compared with the tc value for the two-tailed test. Get the critical value for a one-tailed test using StatsStudentCDF (1-alpha, N-2). It does not work with /MYVW.
Computes two confidence interval waves for the high side and the low side of the confidence interval. The new waves are named with _CH and _CL suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
/BPIW[=mAdditional]
Computes prediction interval waves for the high side and the low side of the confidence interval on a single additional measurement (default). Use mAdditional to specify additional measurements. The new waves are named with _PH and _PL suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
/DET=controlIndex Performs Dunnett's multicomparison test for the elevations. The test requires more than two Y waves for regression, the test for the slopes should not reject the equal slope hypothesis, and the test for the elevations should reject the equal elevation hypothesis. controlIndex is the zero-based index of the Y wave representing the control ( X waves do not count in the index specification). The test compares the elevation of every Y wave with the specified control.
Output is to the M_DunnettMCElevations wave in the current data folder or optionally to a table. For every Y wave and control Y wave combination, the results include SE, q, q' (shown as qp), and the conclusion with 1 to accept the hypothesis of equal elevations or 0 to reject it. Use /TAIL to determine the critical value and the sense of the test. If you use /TUK you will also get the Tukey test for the set of elevations.
\(/ \mathrm{MYVW}=\{x\) Wave, \(y\) Wave \(\}\)
Specifies that the input consists of multiple \(Y\) values for each \(X\) value. It ignores all other inputs and the results are appropriate only for multiple \(Y\) values at each \(X\) point.
\(y\) Wave is a 2D wave of values arranged in columns. Use NaNs for padding where rows do not have the same number of entries as others. It will use the \(X\) scaling of \(y\) Wave when \(x\) Wave is null, \(/ \mathrm{MYVW}=\{*, y\) Wave \(\}\).
It first tests the hypothesis \(\left(\mathrm{H}_{0}\right)\) that the population regression is linear in an analysis of variance calculation. It generates results 1-7 (see Details) as well as: Among Groups SS, Among Groups DF, Within Groups SS, Within Groups DF, Deviations from Linearity SS, Deviations from Linearity DF, F statistic defined by the ratio of Deviation from Linearity MS to Within Groups MS, and the critical value Fc.

Next, it tests the hypothesis that the slope beta \(=0\). If the original \(H_{0}\) was accepted, the new F statistic=regressionMS/residualMS. Otherwise the with the critical \(\mathrm{F}=\) regressionMS/WithinGroupsMS with a corresponding critical value. Finally, it reports the values of the coefficient of determination r 2 and the standard error of the estimate \(S_{Y X}\).
/PAIR
Specifies that the input waves are \(X Y\) pairs, where each pair must be an \(X\) wave followed by a Y wave.
/Q No results printed in the history area.
/RTO Reflects the regression through the origin.
/T=k \begin{tabular}{l} 
Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\(k=0: \quad\)\begin{tabular}{l} 
Normal with dialog (default). \\
\(k=1: \quad\) Kills with no dialog. \\
\(k=2: \quad\) Disables killing.
\end{tabular} \\
/TAIL=tCode \(\quad\)\begin{tabular}{l} 
Sets the sense of the test when applying Dunnett's test (see /DET). \\
one-tail critical value and 4 for a two-tail critical value.
\end{tabular} \\
\begin{tabular}{l} 
Performs a Tukey-type test on multiple regressions on two or more 1 or 2 waves. There \\
are two possible Tukey-type tests: The first is performed if the hypothesis of equal \\
slopes is rejected. It compares all combinations of two Y waves to identify if some of \\
the waves have equal slopes. Output is to the M_TukeyMCSlopes wave in the current \\
data folder or optionally to a table. For every Y wave pair, the results include the \\
difference between slopes (absolute value), \(q\), the critical value qc, and the conclusion \\
set to 1 for accepting the equality of the pair of slopes or 0 for rejecting the hypothesis.
\end{tabular} \\
\begin{tabular}{l} 
The second Tukey-type test is performed if all the slopes are the same but the \\
elevations are not. The test (see /DET) compares all possible pairs of elevations to \\
determine which satisfy the hypothesis of equality. Output is to the \\
M_TukeyMCElevations wave in the current data folder.
\end{tabular}
\end{tabular}

\section*{/WSTR=waveListString}

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors.

\section*{Details}

Inputs may consist of \(Y\) waves or \(X Y\) wave pairs. If \(X\) data are not used, the \(X\) values are inferred from the Y wave scaling. For multiple waves where only some have pairs, use the/PAIR flag and enter * in each place where the \(X\) values should be computed.
For each input StatsLinearRegression calculates:
1. Least squares regression line \(y=a+b^{*} x\).
2. Mean value of \(\mathrm{X}: ~ x B a r\).
3. Mean value of \(Y: y B a r\).
4. Sum of the squares \(\left(\mathrm{x}_{\mathrm{i}}-\mathrm{xBar}\right)^{2}\).
5. Sum of the squares \(\left(y_{i}-y B a r\right)^{2}\).
6. Sum of the product ( \(\mathrm{x}_{\mathrm{i}} \mathrm{y}_{\mathrm{i}}\)-xyBar).
7. Standard error of the estimate \(S_{Y X}=\).
8. F statistic for the hypothesis beta \(=0\).
9. Critical F value Fc .
10. Coefficient of determination r 2 .
11. Standard error of the regression coefficient \(S_{b}\).
12. t -statistic for the hypothesis beta \(=b e t a 0, \mathrm{NaN}\) if \(/ \mathrm{B}\) is not specified.
13. Critical value te for the \(t\)-statistic above (used to calculate L1 and L2).
14. Lower confidence interval boundary (L1) for the regression coefficient.
15. Upper confidence interval boundary (L2) for the regression coefficient.

For two Y waves with the same slope, it computes a common slope (bc) and then tests the equality of the elevations (a). In both cases it computes a \(t\)-statistic and compares it with a critical value. If the elevations are also the same then it computes the common elevation (ac) and the pooled means of \(X\) and \(Y\) in ( xp ) and ( yp ).
For more than two Y waves it computes:
\[
\begin{array}{ll}
A_{c}=\sum_{j=1}^{W} A_{j} ; & A_{j} \equiv \sum x_{i}^{2}=\sum_{i=0}^{n_{j}-1} X_{i}^{2}-\frac{1}{n_{j}}\left(\sum_{i=0}^{n_{j}-1} X_{i}\right)^{2} \\
B_{c}=\sum_{j=1}^{W} B_{j} ; & B_{j} \equiv \sum x y=\sum_{i=0}^{n_{j}-1} X Y-\frac{1}{n_{j}}\left(\sum_{i=0}^{n_{j}-1} X_{i}\right)\left(\sum_{i=0}^{n_{j}-1} Y_{i}\right) \\
C_{c}=\sum_{j=1}^{W} C_{j} ; \\
S S p=\sum_{j=1}^{W} C_{j}-\frac{B_{j}^{2}}{A_{j}} \\
S S c=C c-\frac{B_{c}^{2}}{A_{c}^{2}} \\
S S t=\sum_{j=1}^{W} \sum_{i=0}^{n_{j}} Y_{j i}^{2}-\frac{1}{N}\left(\sum_{j=1}^{W} \sum_{i=0}^{n_{j}} Y_{j i}\right)^{2}-\frac{\left(\sum_{i=0}^{n_{j}-1} Y_{i}^{2}-\frac{1}{n_{j}}\left(\sum_{i=0}^{n_{j}-1} Y_{i}\right)^{2}\right.}{\left.\sum_{i=0}^{n_{j}} X_{j i} Y_{j i}-\frac{1}{N}\left(\sum_{j=1}^{W} \sum_{i=0}^{n_{j}} X_{j i}\right)\left(\sum_{j=1}^{W} \sum_{i=0}^{n_{j}} Y_{j i}\right)\right)^{2}} \\
\sum_{j=1}^{W} \sum_{i=0}^{n_{j}} X_{j i}^{2}-\frac{1}{N}\left(\sum_{j=1}^{W} \sum_{i=0}^{n_{j}} X_{j i}\right)^{2} \\
D F t=\sum_{j=1}^{W} n_{i}-2
\end{array}
\]

Here \(W\) is the number of Y-waves and \(N=\sum_{j=1}^{W} n_{j}\) is the total number of data points in all Y-waves.
The test statistic F for equality of slopes is given by:
\[
F=\left(\frac{S S c-S S p}{\text { numWaves }-1}\right) / \frac{S S p}{D F p} .
\]

Fc is the corresponding critical value.
Output is to the W_LinearRegressionMC wave in the current data folder.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{StatsLogisticCDF}

StatsLogisticCDF ( \(x, a, b\) )
The StatsLogisticCDF function returns the logistic cumulative distribution function
\[
F(x ; a, b)=\frac{1}{1+\exp \left(-\frac{x-a}{b}\right)}
\]
where the scale parameter \(b>0\) and the shape parameter is \(a\).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogisticPDF and StatsInvLogisticCDF functions.

\section*{StatsLogisticPDF}

StatsLogisticPDF ( \(x, a, b\) )
The StatsLogisticPDF function returns the logistic probability distribution function
\[
f(x ; a, b)=\frac{\exp \left(-\frac{x-a}{b}\right)}{b\left[1+\exp \left(-\frac{x-a}{b}\right)\right]^{2}}
\]
where the scale parameter \(b>0\) and the shape parameter is \(a\).

\section*{StatsLogNormalCDF}

StatsLogNormalCDF (x, \(\sigma[, \theta, \mu]\) )
The StatsLogNormalCDF function returns the lognormal cumulative distribution function
\[
F(x ; \sigma, \theta, \mu)=\frac{1}{\sigma \sqrt{2 \pi}} \int_{0}^{x} \frac{1}{t-\theta} \exp \left\{-\left[\ln \left(\frac{t-\theta}{\mu}\right)\right]^{2} / 2 \sigma^{2}\right\} d t
\]
for \(x \geq \theta\) and \(\sigma, \mu>0\). The standard lognormal distribution is for \(\theta=0\) and \(\mu=1\), which are the optional parameter defaults.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsLogNormalPDF and StatsInvLogNormalCDF functions.

\section*{StatsLogNormalPDF}

StatsLogNormalPDF (x, \(\sigma[, \theta, \mu]\) )
The StatsLogNormalPDF function returns the lognormal probability distribution function
\[
f(x ; \sigma, \theta, \mu)=\frac{1}{\sigma \sqrt{2 \pi}} \frac{1}{x-\theta} \exp \left\{-\left[\ln \left(\frac{x-\theta}{\mu}\right)\right]^{2} / 2 \sigma^{2}\right\}
\]
for \(x \geq \theta\) and \(\sigma, \mu>0\), where \(\theta\) is the location parameter, \(\mu\) is the scale parameter and, \(\sigma\) is the shape parameter. The standard lognormal distribution is for \(\theta=0\) and \(\mu=1\), which are the optional parameter defaults.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsLogNormalCDF and StatsInvLogNormalCDF functions.

\section*{StatsMaxwellCDF}

StatsMaxwellCDF ( \(\mathbf{x}, \boldsymbol{k}\) )
The StatsMaxwellCDF function returns the Maxwell cumulative distribution function
\[
F(x ; k)=\operatorname{gammp}\left(\frac{3}{2}, \frac{k x^{2}}{2}\right), \quad x>0
\]
where gammp is the regularized incomplete gamma function.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsMaxwellPDF and StatsInvMaxwellCDF functions.

\section*{StatsMaxwellPDF}

\section*{StatsMaxwellPDF (x, k)}

The StatsMaxwellPDF function returns Maxwell's probability distribution function
\[
f(x ; k)=\sqrt{\frac{2}{\pi}} k^{3 / 2} x^{2} \exp \left(-\frac{k x^{2}}{2}\right), \quad x>0
\]

The Maxwell distribution describes, for example, the speed distribution of molecules in an ideal gas.
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsMaxwellCDF and StatsInvMaxwellCDF functions.

\section*{StatsMedian}

StatsMedian (waveName)
The StatsMedian function returns the median value of a numeric wave waveName, which must not contain NaNs.

\section*{Example}

Make \(/ \mathrm{N}=5\) sample1 \(=\{1,2,3,4,5\}\)
Print StatsMedian (sample1)
3
Make/ \(\mathrm{N}=6\) sample2 \(=\{1,2,3,4,5,6\}\)
Print StatsMedian (sample2)
3.5

\section*{StatsMooreCDF}

\section*{StatsMooreCDF (x, N)}

The StatsMooreCDF function returns the cumulative distribution function for Moore's \(\mathrm{R}^{*}\), which is used in a nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range \(3 \leq N \leq 120\) and does not change appreciably for \(N>120\).

The distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

\section*{References}

Moore, B.R., A modification of the Rayleigh test for vector data, Biometrica, 67, 175-180, 1980.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsCircularMeans function.

\section*{StatsMultiCorrelationTest}

StatsMultiCorrelationTest [flags] corrWave, sizeWave
The StatsMultiCorrelationTest operation performs various tests on multiple correlation coefficients. Inputs are two 1D waves: corrWave, containing correlation coefficients, and sizeWave, containing the size (number of elements) of the corresponding samples. Although you can do all the tests at the same time, it rarely makes sense to do so.

\section*{Flags}
/ALPH = val Sets the significance level (default val=0.05).
/CON=\{controlRow,tails\}
Performs a multiple comparison test using the controlRow element of corrWave as a control. It is one- or two-tailed test according to the tails parameter. Output is to the M_ControlCorrTestResults wave in the current data folder.
/CONT \(=c\) Wave Performs a multiple contrasts test on the correlation coefficients. The contrasts wave, \(c\) Wave, contains the contrast factor, \(c_{i}\), entry for each of the \(n\) correlation coefficients \(r_{i}\) in corrWave, and satisfying the condition that the sum of the entries in cWave is zero. \(\mathrm{H}_{0}\) corresponds to
\[
\sum_{i=0}^{n-1} c_{i} r_{i}=0
\]

The test statistic \(S\) is
\[
S=\frac{1}{\sqrt{\frac{c_{i}^{2}}{n_{i}-3}}}\left|\sum_{i=0}^{n-1} c_{i} z_{i}\right|
\]
where \(z_{i}\) is the Fisher z transform of the correlation coefficient \(r_{i}\) :
\[
z_{i}=\frac{1}{2} \ln \left(\frac{1+r_{i}}{1-r_{i}}\right)
\]

It produces the SE value, the contrast statistic S , and the critical value, which are labeled ContrastSE, ContrastS, and Contrast_Critical, respectively, in the W_StatsMultiCorrelationTest wave.
No results printed in the history area.
\(/ \mathrm{T}=k\)
/TUK
/Z

Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2\) : \(\quad\) Disables killing.
Performs a Tukey-type multi comparison testing between the correlation coefficients by comparing every possible combination of pairs of correlation coefficients, computing the difference in their z-transforms, the SE, and the \(q\) statistic:
\[
q=\frac{\left|z_{j}-z_{i}\right|}{\sqrt{\frac{1}{2}\left(\frac{1}{n_{i}-3}+\frac{1}{n_{j}-3}\right)}}
\]

The critical value is computed from the \(q\) CDF (StatsInvQCDF) with degrees of freedom numWaves and infinity. Output is to the M_TukeyCorrTestResults wave in the current data folder or optionally to a table.

\section*{Details}

Without any flags, StatsMultiCorrelationTest computes \(\chi^{2}\) for the correlation coefficients and compares it with the critical value.
\[
\chi^{2}=\sum_{i=0}^{n-1} z_{i}^{2}\left(n_{i}-3\right)-\frac{\left(\sum_{i=0}^{n-1} z_{i}\left(n_{i}-3\right)\right)^{2}}{\sum_{i=0}^{n-1}\left(n_{i}-3\right)}
\]
where \(z_{i}\) is the Fisher's \(z\) transform of the correlation coefficients and \(n_{i}\) is the corresponding sample size. It computes the common correlation coefficient rw and its transform zw.
\[
z_{w}=\frac{\sum_{i=0}^{n-1} z_{i}\left(n_{i}-3\right)}{\sum_{i=0}^{n-1}\left(n_{i}-3\right)}
\]

These values are calculated even when not appropriate, such as when \(\chi^{2}\) exceeds the critical value and \(\mathrm{H}_{0}\) (all samples came from populations of identical correlation coefficients) is rejected.
The operation also computes ChiSquaredP (due to S.R. Paul), a different variant of \(\chi^{2}\) that is corrected for bias and should be compared with the same critical value. Output is to the W_StatsMultiCorrelationTest wave in the current data folder or optionally to a table.

\section*{References}

StatsLinearCorrelationTest, StatsCircularCorrelationTest, StatsDunnettTest, StatsTukeyTest, StatsInvQCDF, and StatsScheffeTest.

\section*{StatsNBinomialCDF}

StatsNBinomialCDF ( \(x, k, p\) )
The StatsNBinomialCDF function returns the negative binomial cumulative distribution function
\[
F(x ; k, p)=\operatorname{Betai}(k, x+1 ; p)
\]
where betai is the regularized incomplete beta function.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsNBinomialPDF and StatsInvNBinomialCDF functions.

\section*{StatsNBinomialPDF}

StatsNBinomialPDF ( \(x, k, p\) )
The StatsNBinomialPDF function returns the negative binomial probability distribution function
\[
f(x ; k, p)=\binom{x+k-1}{k-1} p^{k}(1-p)^{x}, \quad x=0,1,2 \ldots
\]
where \(\binom{a}{b}\) is the binomial function.
The binomial distribution expresses the probability of the \(k\) th success in the \(x+k\) trial for two mutually exclusive results (success and failure) and \(p\) the probability of success in a single trial.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsNBinomialCDF and StatsInvNBinomialCDF functions.

\section*{StatsNCChiCDF}

StatsNCChiCDF (x, \(n, d)\)
The StatsNCChiCDF function returns the noncentral chi-squared cumulative distribution function
\[
F(x ; n, d)=\sum_{i=1}^{\infty} \exp (d / 2) \frac{(d / 2)^{i}}{i!} F_{c}(x ; n+2 i)
\]
where \(n>0\) corresponds to degrees of freedom, \(d \geq 0\) is the noncentrality parameter, and \(F_{c}\) is the central chisquared distribution.

\section*{StatsNormalPDF}

StatsNormalPDF ( \(x, m, s\) )
The StatsNormalPDF function returns the normal probability distribution function
\[
f(x, \mu, \sigma)=\frac{1}{\sigma \sqrt{2 \pi}} \exp \left(-\frac{(x-\mu)^{2}}{2 \sigma^{2}}\right)
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsNormalCDF and StatsInvNormalCDF functions.

\section*{StatsNPMCTest}

StatsNPMCTest [flags] [wave1, wave2,... wave100]
The StatsNPMCTest operation performs a number of nonparametric multiple comparison tests. Output waves are saved in the current data folder according to the test(s) performed. Some tests are only appropriate when you have the same number of samples in all groups. StatsNPMCTest usually follows StatsANOVA1Test or StatsKWTest.

Flags
/ALPH = val Sets the significance level (default val=0.05).
\begin{tabular}{|c|c|}
\hline /CIDX=controlIndex & Performs nonparametric multiple comparisons on a control group specified by the zero-based controlIndex wave in the input list. Output is to the M_NPCCResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the rank sums of the control and each of the other waves; the second contains the standard error (SE); the third contains the statistic q, defined as the ratio of the difference in rank sums to SE; the fourth contains the critical value which also depends on the tails specification (see /TAIL); and the fifth contains the conclusion with 0 to reject \(\mathrm{H}_{0}\) and 1 to accept it. One version of this test applies when all inputs contain the same number of samples. When that is not the case, it uses the Dunn-Hollander-Wolfe approach to compute an appropriate SE and to handle possible ties. \\
\hline \multirow[t]{6}{*}{/CONW=cWave} & Performs a nonparametric multiple contrasts tests. cWave has one point for each input wave. The cWave value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave. \\
\hline & The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If \(c\) Wave \(=\{0,1,1,1,2\}\), then the contrast is computed as \\
\hline & \[
\text { contrast: } \frac{1}{3}\left[\mathrm{R}_{\mathrm{n} 1}+\mathrm{R}_{\mathrm{n} 2}+\mathrm{R}_{\mathrm{n} 3}\right]-\mathrm{R}_{\mathrm{n} 4}
\] \\
\hline & where \(R_{n i}\) is the normalized rank sum of the samples from the corresponding input wave. Note the significance of allowing zeros in the contrast wave because the actual ranking is performed on the pool of all the samples. \\
\hline & Output is to the M_NPMConResults wave in the current data folder or optionally to a table. The output column contents are: the first is the contrast value; the second is the standard error (SE); the third is the statistic S, which is the ratio of the absolute value of the contrast to SE; the fourth is the critical value (from \(\chi^{2}\) the approximation); and the fifth is the conclusion with 0 to reject \(\mathrm{H}_{0}\) and 1 indicating acceptance. \\
\hline & This test supports input waves with different number of samples and can also handle tied ranks. Note that the contrast wave used here is structured differently than for StatsMultiCorrelationTest. \\
\hline /DHW & Performs the Dunn-Holland-Wolfe test, which supports unequal number of samples and accounts for ties in the rank sums. Output is to the M_NPMCDHWResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the means of the rank sums (rank sums divided by the number of samples in the group), the second contains the standard error (SE), the third contains the DHW statistic Q, the fourth contains the critical value, and the fifth contains the conclusion ( 0 to reject \(\mathrm{H}_{0}\) and 1 to accept). \\
\hline /Q & No results printed in the history area. \\
\hline \multirow[t]{5}{*}{/SWN} & Creates a text wave containing wave names corresponding to each row of the comparison table. Depending on your choice of tests, the following wave names are created: \\
\hline & /CIDX test: T_NPCCResultsDescriptors \\
\hline & /DHW test: T_NPMCDHWDescriptors \\
\hline & /SNK test: T_NPMCSNKResultsDescriptors \\
\hline & /TUK test: T_NPMCTukeyDescriptors \\
\hline \multirow[t]{4}{*}{\(/ \mathrm{T}=k\)} & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\hline & \(k=0\) : \(\quad\) Normal with dialog (default). \\
\hline & \(k=1: \quad\) Kills with no dialog. \\
\hline & \(k=2: \quad\) Disables killing. \\
\hline
\end{tabular}

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.

> /TAIL=tc

Specifies \(\mathrm{H}_{0}\) with /CIDX.
\(t c=1: \quad\) One tailed test \(\left(\mu_{\mathrm{c}} \leq \mu_{\mathrm{a}}\right)\).
\(t c=2: \quad\) One tailed test \(\left(\mu_{\mathrm{c}} \geq \mu_{\mathrm{a}}\right)\).
\(t c=4: \quad\) Default; two tailed test \(\left(\mu_{\mathrm{c}}=\mu_{\mathrm{a}}\right)\).
Code combinations are not allowed.
/SNK Performs a nonparametric variation on the Student-Newman-Keuls test where the standard error SE is a function of \(p\) (the rank difference). This test requires equal numbers of samples in all groups; use /DHW for unequal sizes.

Output is to the M_NPMCSNKResults wave in the current data folder. The output column contents are: the first contains the difference between rank sums, the second contains the standard error (SE), the third contains the \(p\) value (rank difference), the fourth the statistic, the fifth contains the critical value, and the sixth contains the conclusion ( 0 to reject \(\mathrm{H}_{0}\) and 1 to accept). This test is more sensitive to differences than the Tukey test (/TUK).
/TUK Perform a Tukey-type (Nemenyi) multiple comparison test using the difference between the rank sums. This is the default that is performed if you do not specify any of the test flags. This test requires equal numbers of points in all waves; use /DHW for unequal sizes.
Output is to the M_NPMCTukeyResults wave in the current data folder. The output column contents are: the first contains the difference between the rank sums, the second contains the SE values, the third contains the statistic \(q\), the fourth contains the critical value for this specific alpha and the number of groups; and the last contains a conclusion flag with 0 indicating a rejection of \(\mathrm{H}_{0}\) and 1 indicating acceptance. \(\mathrm{H}_{0}\) postulates that the paired means are the same.

\section*{/WSTR=waveListString}

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors.

\section*{Details}

Inputs to StatsNPMCTest are two or more 1D numerical waves (one wave for each group of samples) containing two or more valid entries. The waves must have the same number of points for the use /SNK and /TUK tests, otherwise, for waves of differing lengths you must use the Dunn-Hollander-Wolfe test (/DHW).
V_flag will be set to zero for no execution errors. Individual tests may fail if, for example, there are different number of samples in the input waves for a test that requires an equal number of points. StatsNPMCTest skips failed tests and V_flag will be a binary combination identifying the failed test(s):
```

V_flag \& 1 Tukey method failed (/TUK).
V_flag \& 2 Student-Newman-Keuls failed (/SNK).

```

V_flag will be set to -1 for any other errors.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test and StatsKWTest.
For multiple comparisons in parametric tests see: StatsDunnettTest and StatsScheffeTest.

\section*{StatsNPNominalSRTest}

StatsNPNominalSRTest [flags] [srcWave]
The StatsNPNominalSRTest operation performs a nonparametric serial randomness test for nominal data consisting of two types. The null hypothesis is that the data are randomly distributed. Output is to the W_StatsNPSRTest wave in the current data folder.

\section*{Flags}
/ALPH = val
/Q
\(/ \mathrm{P}=\{m, n, u\}\)
\(/ \mathrm{T}=k \quad\) Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
/Z Ignores errors.

\section*{Details}

The input wave to StatsNPNominalSRTest is specified with srcWave or /P. The wave must contain exactly two values. If srcWave is a text wave, then each type can be designated by a letter or by a short string (less than 200 characters). If \(s r c\) Wave is numeric, you should avoid the usual floating point waves, which can give rise to internal representations of more than two distinct values. Output to W_StatsNPSRTest includes the total number of points \((N)\), the number of occurrences \((m)\) of the first variable, the number of occurrences \((n)\) of the second variable, and the number of runs \((u)\). When both \(m\) and \(n\) are less than 300 , it computes the P value (probability \(\left.\mathrm{P}\left(u^{\prime}<u\right)\right)\) and the critical values using the Swed and Eisenhart algorithm. When \(m\) or \(n\) are larger than 300, it computes the mean and standard deviation of an equivalent normal distribution with the corresponding critical value.

\section*{References}

See, in particular, Chapter 25 of:
Zar, J.H., Biostatistical Analysis, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsSRTest.

\section*{StatsParetoCDF}

StatsParetoCDF (x, a, c)
The StatsParetoCDF function returns the Pareto cumulative distribution function
\[
F(x ; a, c)=1-\left(\frac{a}{x}\right)^{c}
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsParetoPDF and StatsInvParetoCDF functions.

\section*{StatsParetoPDF}

StatsParetoPDF (x, a, c)
The StatsParetoPDF function returns the Pareto probability distribution function
\[
\mathrm{f}(\mathrm{x} ; \mathrm{a}, \mathrm{c})=\frac{\mathrm{c}}{\mathrm{x}}\left(\frac{a}{x}\right)^{c}, \quad \begin{aligned}
& a, c>0 \\
& \\
& x \geq a .
\end{aligned}
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsParetoCDF and StatsInvParetoCDF functions.

\section*{StatsPermute}

\section*{StatsPermute (waveA, waveB, dir)}

The StatsPermute function permutes elements in wave \(A\) based on the lexicographic order of waveB and the direction dir. It returns 1 if a permutation is possible and returns 0 otherwise. Use dir=1 for the next permutation and \(d i r=-1\) for a previous permutation.

\section*{Details}

Both waveA and waveB must be numeric. The lexicographic order of elements in the index wave is set so that permutations start with the index wave waveB in ascending order and end in descending order. Elements of wave \(A\) are permuted in place according to the order of the indices in wave \(B\) which are clipped (after permutation) to the valid range of entries in wave \(A\). wave \(B\) is also permuted in place in order to allow you to obtain sequential permutations. If wave \(A\) consists of real numbers you can permute them using the lexicographic value of the entries directly. To do so pass \(\$ " "\) for waveB. Whenever it returns 0 , neither wave \(A\) and waveB are changed.

\section*{Examples}
```

Function allPermutations (num)
Variable num
Variable i,nf=factorial (num)
Make/O/N=(num) wave0=p+1, waveA, waveB=p
Print wave0
for(i=0;i<nf;i+=1)
waveA=wave0
if(statsPermute(waveA, waveB,1)==0)
break
endif
print waveA
endfor
end
Executing allPermutations(3) prints:
wave0 [0]={1,2,3}
waveA[0]={1,3,2}
waveA[0]={$$
\begin{array}{l}{2,1,3}\end{array}
$$}
waveA [0] = {2,3,1 }
waveA[0]={3,1,2}
waveA[0]={3,2,1}

```

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview.

\section*{StatsPoissonCDF}

StatsPoissonCDF ( \(x, \lambda\) )
The StatsPoissonCDF function returns the Poisson cumulative distribution function
\[
F(x ; \lambda)=\sum_{i=0}^{x} \frac{\exp (-\lambda) \lambda^{i}}{i!}, \quad x=0,1,2 \ldots
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsPoissonPDF and StatsInvPoissonCDF functions.

\section*{StatsPoissonPDF}

StatsPoissonPDF ( \(x, \lambda\) )
The StatsPoissonPDF function returns the Poisson probability distribution function
\[
f(x ; \lambda)=\frac{\exp (-\lambda) \lambda^{x}}{x!}, \quad x=0,1,2 \ldots
\]
where \(\lambda\) is the shape parameter.
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPoissonCDF and StatsInvPoissonCDF functions.

\section*{StatsPowerCDF}

StatsPowerCDF ( \(x, b, c\) )
The StatsPowerCDF function returns the Power Function cumulative distribution function
\[
F(x ; b, c)=\left(\frac{x}{b}\right)^{c}
\]
where the scale parameter \(b\) and the shape parameter \(c\) satisfy \(b, c>0\) and \(b \geq x \geq 0\).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPowerPDF, StatsInvPowerCDF and StatsPowerNoise functions.

\section*{StatsPowerNoise}

StatsPowerNoise ( \(b, c\) )
The StatsPowerNoise function returns a pseudorandom value from the power distribution function with probability distribution:
\[
f(x ; b, c)=\frac{c}{x}\left(\frac{x}{b}\right)^{c} .
\]

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

\section*{See Also}

The SetRandomSeed operation.
The StatsPowerPDF StatsInvPowerCDF and StatsInvPowerCDF functions.
Noise Functions on page III-334.
Chapter III-12, Statistics for a function and operation overview.

\section*{StatsPowerPDF}

StatsPowerPDF ( \(x, b, c\) )
The StatsPowerPDF function returns the Power Function probability distribution function
\[
f(x, b, c)=\frac{|c|}{x}\left(\frac{\mathrm{x}}{b}\right)^{c}
\]
where \(b\) is a scale parameter and \(c\) is a shape parameter.
For \(b, c>0, x\) is drawn from \(b>=x>=0\).

For \(b>0, c<0, x\) is drawn from \(x>b\).
For \(b<0, c>0, x\) is drawn from \(-b<=x<=0\).
For \(b<0, c<0, x\) is drawn from \(x<-b\).
Note that for \(-1<c<0\) the average diverges and the magnitude of a mean calculated from N samples will increase indefinitely with N .

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsPowerCDF, StatsInvPowerCDF and StatsPowerNoise functions.

\section*{StatsQCDF}

StatsQCDF ( \(q, r, c, d f\) )
The StatsQCDF function returns the value of the Q cumulative distribution function for \(r\) the number of groups, \(c\) the number of treatments, and \(d f\) the error degrees of freedom \((f=r c(n-1)\) with sample size \(n)\).

Details
The \(Q\) distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use \(r=1\).

\section*{References}

Copenhaver, M.D., and B.S. Holland, Multiple comparisons of simple effects in the two-way analysis of variance with fixed effects, Journal of Statistical Computation and Simulation, 30, 1-15, 1988.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsTukeyTest function.

\section*{StatsQpCDF}

StatsQpCDF (q, nr, nt, dt, side, sSizeWave)
The StatsQpCDF function returns the the Q' cumulative distribution function associated with Dunnett's test.

Here \(n r\) is the number of groups (should be set to 1 ), \(n t\) is the number of treatments, \(d f\) is the error degrees of freedom.
Set side \(=1\) for upper-tail or side \(=2\) for two-tailed CDF.
sSizeWave is an integer wave of nt rows specifying the number of samples in each treatment.

\section*{Details}

StatsQpCDF is a modified Q distribution typically used with Dunnett's test, which compares the various means with the mean of the control group or treatment

\section*{References}
"Algorithm AS 251: Multivariate Normal Probability Integrals with Product Correlations Structure", C. W. Dunnett, Appl. Stat., 38 (1989) 564-579.
A short correction for the algorithm was published in: Appl. Stat., 42 (1993) 709.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsDunnettTest, StatsInvQpCDF, and StatsInvQCDF functions.

\section*{StatsQuantiles}

StatsQuantiles [flags] srcWave
The StatsQuantiles operation computes quantiles and elementary univariate statistics for a set of data in srcWave.
Flags
/ALL Invokes all flags except /Q, /QM, and /Z.
/BOX
Computes parameters necessary to construct a box plot.
\begin{tabular}{|c|c|}
\hline /iNaN & Ignores NaNs, which are sorted to the end of the array by default. \\
\hline /IW & Creates an index wave W_QuantilesIndex. W_QuantilesIndex[ \(i\) ] corresponds to the position of \(\operatorname{srcWave}[i]\) when sorted from minimum to maximum. \\
\hline /Q & No information printed in the history area. \\
\hline \multirow[t]{6}{*}{/QM=qMethod} & Specifies the method for computing quartiles. qMethod has one of these values: \\
\hline & 0 : Tukey (default). \\
\hline & 1: Minitab. \\
\hline & 2: Moore and McCabe. \\
\hline & 3: Mendenhall and Sincich. \\
\hline & See Details for more information. \\
\hline /QW & Creates a single precision wave W_QuantileValues containing the quantile value corresponding to each entry in \(s r c\) Wave. \\
\hline /STBL & Uses a stable sort, which may require significant computation time for multiple entries with the same value. \\
\hline /TM & Computes the tri-mean: \(0.25^{*}\) (V_Q25+2*median+V_Q75). \\
\hline /TRIM \(=t\) Val & Computes the trimmed mean which is the mean value of the entries between the quantiles \(t \mathrm{Val}\) (in \%) and 100-tVal. By default \(t\) Val \(=25\) and the trimmed mean corresponds to the midmean. \\
\hline /Z & Ignores any errors. \\
\hline
\end{tabular}

\section*{Details}

StatsQuantiles produces quick five-number summaries or more detailed results for univariate data. Values are returned in the wave W_StatsQuantiles and in the variables:
\begin{tabular}{ll} 
V_min & Minimum value. \\
V_max & Maximum value. \\
V_Median & Median value. \\
V_Q25 & Lower quartile. \\
V_Q75 & Upper quartile. \\
V_IQR & Inter-quartile range V_Q75-VQ25, which is also known as the H-spread.
\end{tabular}

Entries in the wave W_StatsQuantiles depend on your choice of flags. Each row has a row label explicitly defining its value. If you use the /ALL flag, W_StatsQuantiles will contain the following row labels:
\begin{tabular}{ll} 
minValue & lowerInnerFence \\
maxValue & lowerOuterFence \\
Median & upperInnerFence \\
Q25 & upperOuterFence \\
Q75 & triMean \\
IQR & trimmedMean
\end{tabular}

Otherwise, W_StatsQuantiles will contain the first five entries and any additionally requested value. You should always access values using the dimension labels (see Dimension Labels on page II-109).
There is frequently some confusion in comparing statistical results computed by different programs because each may use a different definition of quartiles. You can specify the method of computing the quartiles as you prefer with the /QM flag. If you neglect to choose a method, StatsQuantiles uses Tukey's method, which computes quartiles (also called hinges) as the lower and upper median values between the
median of the data and the edges of the array. The Moore and McCabe method is similar to Tukey's method except you do not include the median itself in computing the quartiles. Mendenhall and Sincich compute the quartiles using \(1 / 4\) and \(3 / 4\) of (numDataPoints +1 ) and round to the nearest integer (if the fraction part is exactly 0.5 they round up for the lower quartile and down for the upper quartile). Minitab uses the same expressions but instead of rounding it uses linear interpolation.
StatsQuantiles uses a stable index sorting routine so that
IndexSort W_QuantilesIndex, srcWave
is a monotonically increasing wave.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; WaveStats, StatsMedian, Sort, and MakeIndex.

\section*{StatsRankCorrelationTest}

\section*{StatsRankCorrelationTest [flags] waveA, waveB}

The StatsRankCorrelationTest operation performs Spearman's rank correlation test on waveA and waveB, \(1 D\) waves containing the same number of points. Output is to the W_StatsRankCorrelationTest wave in the current data folder.

\section*{Flags}
\[
\text { /ALPH = val } \quad \text { Sets the significance level (default val=0.05). }
\]
/Q
No results printed in the history area.
\(/ \mathrm{T}=k\)
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
/Z Ignores errors.

\section*{Details}

StatsRankCorrelationTest ranks wave \(A\) and wave \(B\) and then computes the sum of the squared differences of ranks for all rows. Ties are assigned an average rank and the corrected Spearman rank correlation coefficient is computed with ties. It reports the sum of the squared ranks (sumDi2), the sums of the ties coefficients (sumTx and sumTy respectively), the Spearman rank correlation coefficient (in the range [-1,1]), and the critical value. \(\mathrm{H}_{0}\) corresponds to zero correlation against the alternative of nonzero correlation. The critical value is usually lower than the one in published tables. When the first derivative of the CDF is discontinuous, tables tend to use a more conservative value by choosing the next transition of the CDF as the critical value. StatsRankCorrelationTest is not as powerful as StatsLinearCorrelationTest.
See Also
Chapter III-12, Statistics for a function and operation overview.
StatsLinearCorrelationTest, StatsCircularCorrelationTest, StatsKendallTauTest, StatsSpearmanRhoCDF, and StatsInvSpearmanCDF.

\section*{StatsRayleighCDF}

StatsRayleighCDF (x [, s [, m] ])
The StatsRayleighCDF function returns the Rayleigh cumulative distribution function
\[
F(x ; \sigma, \mu)=1-\exp \left(-\frac{(x-\mu)^{2}}{2 \sigma^{2}}\right), \quad \quad \sigma>0, x>\mu .
\]
with defaults \(s=1\) and \(m=0\). It returns NaN for \(s \leq 0\) and zero for \(\mathrm{x} \leq m\).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRayleighPDF and StatsInvRayleighCDF functions.

\section*{StatsRayleighPDF}

StatsRayleighPDF(x [, s [, m] ])
The StatsRayleighPDF function returns the Rayleigh probability distribution function
\[
f(x ; \sigma, \mu)=\frac{x-\mu}{\sigma^{2}} \exp \left(-\frac{(x-\mu)^{2}}{2 \sigma^{2}}\right), \quad \quad \sigma>0, x>\mu
\]
with defaults \(s=1\) and \(m=0\). It returns NaN for \(s \leq 0\) and zero for \(\mathrm{x} \leq m\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsRayleighCDF and StatsInvRayleighCDF functions.

\section*{StatsRectangularCDF}

StatsRectangularCDF (x, a, b)
The StatsRectangularCDF function returns the rectangular (uniform) cumulative distribution function
\[
F(x, a, b)= \begin{cases}0 & x \leq a \\ \frac{x-a}{b-a} & a \leq x \leq b \\ 1 & x \geq b\end{cases}
\]
where \(a<b\).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRectangularPDF and StatsInvRectangularCDF functions.

\section*{StatsRectangularPDF}

StatsRectangularPDF (x, a, b)
The StatsRectangularPDF function returns the rectangular (uniform) probability distribution function
\[
f(x ; a, b)= \begin{cases}\frac{1}{b-a} & a \leq x \leq b \\ 0 & \text { otherwise }\end{cases}
\]
where \(a<b\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsRectangularCDF and StatsInvRectangularCDF functions.

\section*{StatsResample}

\section*{StatsResample /N=numPoints [flags] srcWave}

The StatsResample operation resamples srcWave by drawing (with replacement) numPoints values from srcWave and storing them in the wave W_Resampled or M_Resampled if /MC is used. You can iterate the process and compute various statistics on the data samples.

Flags
/ITER=n
/JCKN=ufunc
Repeats the resampling for \(n\) iterations, which is useful only when combined with /WS or /SQ.

Performs Jack-Knife analysis. Here ufunc is a user function of the format:
```

Function ufunc(inWave)
wave inWave
... compute some statistic for inWave
return someValue
End

```

The results are stored in the wave W_JackKnifeStats in the current data folder. Use Edit W_JackKnifeStats.ld
to display the wave with dimension labels.
The idea behind this method is that ufunc returns some statistic \(z\) for inWave which is a subsample of srcWave of size ( \(n-1\) ). There are exactly \(n\) iterations and in each iteration the operation calls ufunc with one element of srcWave missing and stores the result in an internal array. At the end of iterations it uses the array to compute the various Jack-Knife estimates.

The standard estimator is defined as:
\[
Z=u f u n c(\text { srcWave }) .
\]

The Jack-Knife estimator is simply:
\[
\hat{z}=\frac{1}{n} \sum_{i=1}^{n} z_{i}
\]

The Jack-Knife t-estimator is slightly less biased. It is given by:
\[
t=n Z-(n-1) \hat{z}
\]

The estimate of the standard error is given by:
\[
\hat{\sigma}_{\hat{z}}=\sqrt{\frac{n-1}{n} \sum_{i=1}^{n}\left(z_{i}-\hat{z}\right)^{2}}
\]

Kills W_Resampled after passing it to WaveStats. When /ITER is used, W_Resampled is not saved.
/MC Use/MC when you want to sample random (complete) rows from a multi-column 2D srcWave. The combination of \(/ \mathrm{N}=\mathrm{n}\) with / MC results in the wave M_Resampled in the current data folder. M_Resampled will have n rows, the same number of columns and the same data type as srcWave.
/ \(\mathrm{N}=\) numPoints
Specifies the number of points sampled from srcWave.
/Q
\(/ \mathrm{SQ}=m\)
/WS=m
/Z Ignores any errors.

\section*{Details}

StatsResample can perform Bootstrap Analysis, permutations tests, and Monte-Carlo simulations. It draws the specified number of data points (with replacement) from srcWave and places them in a destination wave W_Resampled.
Specify /WS or /SQ to use the WaveStats or StatsQuantiles operations, respectively, to compute results directly from the data. StatsResample normally creates the wave W_Resampled and, optionally, the M_WaveStats and W_StatsQuantiles waves. Both options also create various \(V_{-}\)variables described below. If you use more than one iteration, StatsResample creates instead the waves M_WaveStatsSamples and M_StatsQuantilesSamples for the results.
M_WaveStatsSamples (with/WS) contains a column for each iteration. Each column is equivalent to the contents of M_WaveStats for that iteration. You can use the command
Edit M_WaveStatsSamples.ld
to display the results in a table using row labels, and, for example, to display a graph of the rms of the samples as a function of iteration number execute:
Display M_WaveStatsSamples [5] []
M_StatsQuantilesSamples (with /SQ) contains a column for each iteration. Each column consists of the contents of W_StatsQuantiles for the corresponding data. Here again you can execute the command Edit M_StatsQuantilesSamples.ld
to display the wave in a table using row labels. To display a graph of the median as a function of iteration execute:
Display M_statsQuantilesSamples[2] []

\section*{Output Variables}

StatsResample creates the following variables: V_Median, V_Q25, V_Q75, V_IQR, V_min, V_max, V_numNaNs, V_numINFs, V_avg, V_sdev, V_rms, V_adev, V_skew, V_kurt, and V_Sum.
These variables are valid only if you use either /SQ or /WS, but not both, and only if you do not use /ITER. Unused variables are set to NaN .

If you use /SQ the operation sets V_Median, V_Q25, V_Q75, V_IQR, V_min, and V_max.
If you use /WS the operation sets V_min, V_max, V_numNaNs, V_numINFs, V_avg, V_sdev, V_rms, V_adev, V_skew, V_kurt, and V_Sum.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsSample, WaveStats and StatsQuantiles.

\section*{StatsSample}

StatsSample /N=numPoints [flags] srcWave
StatsSample creates a random, non-repeating sample from srcWave.
It samples srcWave by drawing without replacement numPoints values from srcWave and storing them in the output wave W_Sampled or M_Sampled if /MC or /MR are used.

\section*{Flags}
/ \(\mathrm{N}=\) numPoints \(\quad\) Specifies the number of points sampled from srcWave. When combined with /MC, numPoints is the number of sampled rows and when combined with /MR, it is the number of sampled columns.
/MC Use /MC (multi-column) to randomly sample full rows from srcWave, i.e., the output consists of all columns of each selected row. /MC and /MR are mutually exclusive flags.
/MR Use /MR (multi-row) to randomly sample full columns from srcWave, i.e., the output consists of all rows of each of the selected columns. /MC and /MR are mutually exclusive flags.
/Z Ignores errors.

\section*{Details}

If you omit /MC and /MR, the output is a 1D wave named W_Sampled where the samples are chosen from srcWave without regard to its dimensionality.
If you use either /MC or /MR the output is a 2D wave named M_Sampled which will have either the same number of columns (/MC) as srcWave or the same number of rows (/MR) as srcWave.

\section*{See Also}

Chapter III-12, Statistics, StatsResample

\section*{StatsRunsCDF}

StatsRunsCDF ( \(n, r\) )
The StatsRunsCDF function returns the cumulative distribution function for the up and down runs distribution for total number of runs \(r\) in a random linear arrangement of \(n\) unequal elements. There is no closed form expression. It is computed numerically from the recursion of the probability density
\[
f(r, n)=\frac{r f(r, n-1)+2 f(r-1, n-1)+(n-r) f(r-2, n-1)}{n}
\]
with the initial condition
\[
f(1, n)=\frac{2}{n!}
\]

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsSRTest function.

\section*{StatsScheffeTest}

StatsScheffeTest [flags] [wave1, wave2,... wave100]
The StatsScheffeTest operation performs Scheffe's test for the equality of the means. It supports two basic modes: the default tests all possible combinations of pairs of waves; the second tests a single combination
where the precise form of \(\mathrm{H}_{0}\) is determined by the coefficients of a contrast wave (see /CONT). Output is to the M_ScheffeTestResults wave in the current data folder.

\section*{Flags}
/ALPH=val
/CONW=cWave
/Q
/SWN
\(/ \mathrm{T}=k\)
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

The default of StatsScheffeTest (also known as the \(S\) test) tests the hypotheses of equality of means for each possible pair of samples. It is not as powerful as Tukey's test (StatsTukeyTest) and is more useful for hypotheses formulated as multiple contrasts (see /CONT).

\section*{References}

See, in particular, Chapter 11 of:
Zar, J.H., Biostatistical Analysis, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.
See Also
Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test, StatsDunnettTest and StatsTukeyTest.

\section*{StatsSignTest}

StatsSignTest [flags] wave1, wave2
The StatsSignTest operation performs the sign test for paired-sample data contained in wave1 and wave2.

\section*{Flags}
\begin{tabular}{ll} 
/ALPH=val & Sets the significance level (default 0.05\().\) \\
\(/ \mathrm{Q}\) & No results printed in the history area. \\
\(/ \mathrm{T}=k\) & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
& \(k=0:\) \\
& \begin{tabular}{ll}
\(k=1:\) & Normal with dialog (default). \\
& \(k=2:\)
\end{tabular}\(\quad\) Kills with no dialog. \\
&
\end{tabular}
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

The input waves must be the equal length, real numeric waves and must not contain any NaNs or INFs. Results are saved in the wave W_SignTest and are optionally displayed in a table. StatsSignTest computes the differences in each pair and counts the total number of entries with positive and negative differences, and tests the results using a binomial distribution. When the number of data pairs exceeds 1024 it uses a normal approximation to the binomials for calculating the probabilities and the power of the test.

Chapter III-12, Statistics for a function and operation overview; the StatsRankCorrelationTest, StatsInvSpearmanCDF, and StatsKendallTauTest functions.

\section*{StatsSRTest}

StatsSRTest [flags] srcWave
The StatsSRTest operation performs a parametric or nonparametric serial randomness test on srcWave, which must contain finite numerical data. The null hypothesis of the test is that the data are randomly distributed. Output is to the W_StatsSRTest wave in the current data folder.

\section*{Flags}
\begin{tabular}{|c|c|}
\hline /ALPH = val & Sets the significance level (default val=0.05). \\
\hline /GCD & Tests the output of a random number generator (RNG). srcWave consists of values between 0 and \(2^{32}\) (converted to unsigned 32-bit integers). GCD computes the gcd for consecutive pairs of data in srcWave. The number of steps in the GCD and the distribution of the GCD's are compared with ideal distributions and corresponding \(P\) values are reported. This test is part of Marsaglia's Die-Hard battery of tests. P-values close to either 0 or 1 indicate a nonideal RNG. You should use the reported minimum and maximum values to check that the input is indeed in the proper range. Typically
srcWave consists of at leastle6 entries. \\
\hline /NAPR & Use the normal approximation even when the number of points is below 150. \\
\hline /NP & Performs a nonparametric serial randomness test by counting the numbers of runs up and down and computing the probability that such a value is obtained by chance. \\
\hline /P & Performs a parametric serial randomness test. \\
\hline /Q & No results printed in the history area. \\
\hline /T=k & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\hline & \(k=0\) : \(\quad\) Normal with dialog (default). \\
\hline & \(k=1: \quad\) Kills with no dialog. \\
\hline & \(k=2\) : Disables killing. \\
\hline /Z & Ignores errors. \\
\hline
\end{tabular}

Details
The parametric test for serial randomness is according to Young. \(C\) is given by
\[
C=1-\frac{\sum_{i=0}^{n-2}\left(X_{i}-X_{i+1}\right)^{2}}{2 \sum_{i=0}^{n-1}\left(X_{i}-\bar{X}\right)^{2}},
\]
where \(\bar{X}\) is the mean and n is the number of points in srcWave. The critical value is obtained from mean square successive difference distribution StatsInvCMSSDCDF. For more than 150 points, StatsSRTest uses the normal approximation and provides the critical values from the normal distribution. For samples from a normal distribution, \(C\) is symmetrically distributed about 0 with positive values indicating positive correlation between successive entries and negative values corresponding to negative correlation.
The nonparametric test consists of counting the number of runs that are successive positive or successive negative differences between sequential data. If two sequential data are the same it computes two numbers of runs by considering the two possibilities where the equality is replaced with either a positive or a negative difference. The results of the operation include the number of runs up and down, the number of unchanged values (the number of places with no difference between consecutive entries), the size of the longest run and its associated probability, the number of converted equalities, and the probability that the number of runs is less than or equal to the reported number (StatsRunsCDF). When equalities are encountered the operation computes the probabilities that the computed number of runs or less can be found in an equivalent random sequence.

Converted equalities are those with the same sign on both sides so that when we replace the equality by the opposite sign we increase the number of runs. The equalities that are not converted are found between two different signs and therefore regardless of the sign that we give them they do not affect the total number of runs. We implicitly assume that the data does not contain more than one sequential equalities.
The longest run is determined without taking into account equalities or their conversions. The probability of the longest run is computed from Equation 6 of Olmstead, which is accurate within 0.001 when the number of runs is 5 or more. This probability applies to either positive or negative differences and should be divided by two if a specific sign is selected.

\section*{StatsStudentCDF}

StatsStudentCDF ( \(t, n\) )
The StatsStudentCDF function returns the Student (uniform) cumulative distribution function
\[
F(t, n)= \begin{cases}\frac{1}{2}\left\{1+I\left(\frac{n}{2}, \frac{1}{2} ; 1\right)-I\left(\frac{n}{2}, \frac{1}{2} ; \frac{n}{n+t^{2}}\right)\right\} & t>0 \\ \frac{1}{2}\left\{1+I\left(\frac{n}{2}, \frac{1}{2} ; \frac{n}{n+t^{2}}\right)-I\left(\frac{n}{2}, \frac{1}{2} ; 1\right)\right\} & t<0 \\ \frac{1}{2} & t=0\end{cases}
\]
where \(n>0\) is degrees of freedom and is the incomplete beta function betai.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsStudentPDF and StatsInvStudentCDF functions.

\section*{StatsStudentPDF}

StatsStudentPDF ( \(t, n\) )
The StatsStudentPDF function returns the Student (uniform) probability distribution function
\[
f(t, n)=\frac{\left(\frac{n}{n+t^{2}}\right)^{(n+1) / 2}}{\sqrt{n} B\left(\frac{n}{2}, \frac{1}{2}\right)}
\]
where \(n>0\) is degrees of freedom and \(B()\) is the beta function.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsStudentCDF and StatsInvStudentCDF functions.

\section*{StatsTopDownCDF}

StatsTopDowncDF ( \(\mathrm{r}, \mathrm{N}\) )
The StatsTopDownCDF function returns the cumulative distribution function for the top-down correlation coefficient. It is computationally intensive because it must evaluate many permutations [ \(\mathrm{O}\left((n!)^{2}\right)\) ]. It exactly calculates the distribution for \(3 \leq N \leq 7\); outside this range it uses Monte-Carlo estimation for \(8 \leq N \leq 50\) and asymptotic Normal approximation for \(N>50\). The Monte-Carlo estimate uses 1 e 6 random permutations fitted with two 9 -order polynomials for the range \([-1,0]\) and \([0,1]\). The results are within \(0.2 \%\) of exact values where known.

\section*{References}

\section*{StatsTriangularCDF}

StatsTriangularCDF ( \(x, a, b, c\) )
The StatsTriangularCDF function returns the triangular cumulative distribution function
\[
F(x ; a, b, c)=\left\{\begin{array}{cc}
\frac{(x-a)^{2}}{(b-a)(c-a)} & a \leq x \leq c \\
1-\frac{(b-x)^{2}}{(b-a)(c-a)} & c \leq x \leq b
\end{array}\right.
\]
where \(a<c<b\).

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; the StatsTriangularPDF and StatsInvTriangularCDF functions.

\section*{StatsTriangularPDF}

StatsTriangularPDF ( \(x, a, b, c\) )
The StatsTriangularPDF function returns the triangular probability distribution function
\[
f(x ; a, b, c)= \begin{cases}\frac{2(x-a)}{(b-a)(c-a)} & a \leq x \leq c \\ \frac{2(b-x)}{(b-a)(c-a)} & c<x<b \\ 0 & \text { otherwise }\end{cases}
\]
where \(a<c<b\).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsTriangularCDF and StatsInvTriangularCDF functions.

\section*{StatsTrimmedMean}

StatsTrimmedMean (waveName, trimValue)
The StatsTrimmedMean function returns the mean of the wave waveName after removing trimValue fraction of the values from both tails of the distribution. trimValue is a number in the range [0,0.5]. waveName can be any real numeric type.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsQuantiles and mean.

\section*{StatsTTest}

StatsTTest [flags] wave1 [, wave2]
The StatsTTest operation performs two kinds of T-tests: the first compares the mean of a distribution with a specified mean value (/MEAN) and the second compares the means of the two distributions contained in wave1 and wave2, which must contain at least two data points, can be any real numeric type, and can have an arbitrary number of dimensions. Output is to the W_StatsTTest wave in the current data folder or optionally to a table.

\section*{Flags}
/ALPH = val
/CI
/DFM=m
\(/ \mathrm{MEAN}=\) mean \(V \quad\) Compares mean \(V\) with the mean of the distribution in wave1. Outputs are the number of points in the wave, the degrees of freedom (accounting for any NaNs ), the average, standard deviation ( \(\sigma\) ),
\[
s_{\bar{X}}=\frac{\sigma}{\sqrt{D F+1}}
\]
the statistic
\[
t=\frac{\bar{X}-\text { mean } V}{s_{\bar{X}}}
\]
and the critical value, which depends on /TAIL.
/PAIR Specifies that the input waves are pairs and computes the difference of each pair of data to get the average difference \(\bar{d}\) and the standard error of the difference \(S_{\bar{d}}\). The t statistic is the ratio of the two
\[
t=\frac{\bar{d}}{s_{\bar{d}}}
\]

In this case \(\mathrm{H}_{0}\) is that the difference \(\bar{d}\) is zero.
This mode does not support /CI and /DFM.
No results printed in the history area.

\section*{\(/ \mathrm{T}=k\)}

Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/TAIL=tailCode
Specifies \(\mathrm{H}_{0}\).
```

tailCode=1: One tailed test ( }\mp@subsup{\mu}{1}{}\leq\mp@subsup{\mu}{2}{})
tailCode=2: One tailed test ( }\mp@subsup{\mu}{1}{}\geq\mp@subsup{\mu}{2}{})
tailCode=4: Default; two tailed test ( }\mp@subsup{\mu}{1}{}!=\mp@subsup{\mu}{2}{})

```
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

When comparing the mean of a single distribution with a hypothesized mean value, you should use /MEAN and only one wave (wave1). If you use two waves StatsTTest performs the T-test for the means of the corresponding distributions (which is incompatible with /MEAN).
When comparing the means of two distributions, the default \(t\)-statistic is computed from Welch's approximate t :
\[
t^{\prime}=\frac{\bar{x}_{1}-\bar{x}_{2}}{\sqrt{\frac{s_{1}^{2}}{n_{1}}+\frac{s_{2}^{2}}{n_{2}}}}
\]
where \(s_{i}{ }^{2}\) are variances, \(n_{i}\) the number of samples, and \(\bar{X}_{i}\) the averages of the respective waves. This expression is appropriate when the number of points and the variances of the two waves are different. If you want to compute the t-statistic using pooled variance you can use the /AEVR flag. In this case the pooled variance is given by
\[
s_{p}^{2}=\frac{\left(n_{1}-1\right) s_{1}^{2}+\left(n_{2}-1\right) s_{2}^{2}}{n_{1}+n_{2}-2}
\]
and the t -statistic is
\[
t=\frac{\bar{x}_{1}-\bar{x}_{2}}{s_{p} \sqrt{\frac{1}{n_{1}}+\frac{1}{n_{2}}}}
\]

The different test are:
\begin{tabular}{ll}
\(\mathbf{H}_{\mathbf{0}}\) & Rejection Condition \\
\hline\(\mu_{1}=\mu_{2}\) & \(|t| \geq \operatorname{Tc}(\) alpha, \(v)\) \\
\(\mu_{1}>\mu_{2}\) & \(t \leq \operatorname{Tc}(\) alpha, \(v)\) \\
\(\mu_{1}<\mu_{2}\) & \(t \geq\) Tc (alpha, \(v)\) \\
\hline
\end{tabular}

Tc is the critical value and \(v\) is the effective number of degrees of freedom (see /DFM flag).When accounting for possibly unequal variances, \(v\) is given by
\[
v=\frac{\left(\frac{s_{1}^{2}}{n_{1}}+\frac{s_{2}^{2}}{n_{2}}\right)^{2}}{\frac{\left(\frac{s_{1}^{2}}{n_{1}}\right)^{2}}{n_{1}-1}+\frac{\left(\frac{s_{2}^{2}}{n_{2}}\right)^{2}}{n_{2}-1}}
\]

The critical values (Tc) are computed by numerically by solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by
\[
F(x)= \begin{cases}\frac{1}{2} \operatorname{betai}\left(\frac{v}{2}, \frac{1}{2}, \frac{v}{v+x^{2}}\right) & x<0 \\ 1-\frac{1}{2} \operatorname{betai}\left(\frac{v}{2}, \frac{1}{2}, \frac{v}{v+x^{2}}\right) & x \geq 0\end{cases}
\]

To get the critical value for the upper one-tail test we solve \(\mathrm{F}(\mathrm{x})=1\)-alpha. For the lower one-tail test we solve for \(x\) the equation \(F(x)=\) alpha. In the two-tailed test the lower critical value is a solution for \(F(x)=a l p h a / 2\) and the upper critical value is a solution for \(F(x)=1\)-alpha/2.
The T-test assumes both samples are randomly taken from normal population distributions.

\section*{References}

Zar, J.H., Biostatistical Analysis, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999. See in particular Section 8.1.

\section*{StatsTukeyTest}

StatsTukeyTest [flags] [wave1, wave2,... wave100]
The StatsTukeyTest operation performs multiple comparison Tukey (HSD) test and optionally the Newman-Keuls test. Output is to the M_TukeyTestResults wave in the current data folder. StatsTukeyTest usually follows StatsANOVA1Test.

\section*{Flags}
\begin{tabular}{ll} 
/ALPH = val & Sets the significance level (default val=0.05). \\
/NK & Computes the Newman-Keuls test. \\
/Q & No results printed in the history area. \\
/SWN & \begin{tabular}{l} 
Creates a text wave, T_TukeyDescriptors, containing wave names corresponding to \\
each row of the comparison table (Save Wave Names). Use /T to append the text wave \\
to the last column.
\end{tabular} \\
& \begin{tabular}{lll} 
Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\(k=0:\) & Normal with dialog (default). \\
\(k=1:\) & Kills with no dialog. \\
\(k=2:\) & Disables killing.
\end{tabular}
\end{tabular}
/WSTR=waveListString

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors.

\section*{Details}

Inputs to StatsTukeyTest are two or more 1D numeric waves (one wave for each group of samples) containing any numbers of points but with at least two or more valid entries.
The contents of the M_TukeyTestResults columns are: the first contains the difference between the group means \(\bar{X}_{i}-\bar{X}_{i}\), the second contains SE (supports unequal number of points), the third contains the \(q\) statistic for the pair, and the fourth contains the critical q value, the fifth contains the conclusion with 0 to reject \(\mathrm{H}_{0}\) ( \(\mu_{i}=\mu_{j}\) ) or 1 to accept \(\mathrm{H}_{0}\), with \(/ \mathrm{NK}\), the sixth contains the \(p\) values
\[
p=\operatorname{rank}\left[\bar{X}_{i}\right]-\operatorname{rank}\left[\bar{X}_{j}\right]+1
\]
the seventh contains the critical values, and the eighth contains the Newman-Keuls conclusion (with 0 to reject and 1 to accept \(\mathrm{H}_{0}\) ). The order of the rows is such that all possible comparisons are computed sequentially starting with the comparison of the group having the largest mean with the group having the smallest mean.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{StatsUSquaredCDF}
```

StatsUSquaredCDF(u2, n, m, method, useTable)

```

The StatsUSquaredCDF function returns the cumulative distribution function for Watson's \(\mathrm{U}^{2}\) with parameters \(u 2\) ( \(\mathrm{U}^{2}\) statistic) and integer sample sizes \(n\) and \(m\). The calculation is computationally intensive, on the order of \(\operatorname{binomial}(n+m, m)\). Use a nonzero value for useTable to search a built-in table of values. If \(n\) and \(m\) cannot be found in the table, it will proceed according to method:
\begin{tabular}{ll} 
method & What It Does \\
\hline 0 & Exact computation using Burr algorithm (could be slow). \\
1 & Tiku approximation using chi-squared. \\
2 & Use built-in table only and return a NaN if not in table. \\
\hline
\end{tabular}

For large \(n\) and \(m\), consider using the Tiku approximation. To abort execution, press Command-period (Macintosh) or Ctrl+Break (Windows).
Precomputed tables, using the algorithm described by Burr, contain these values:
\begin{tabular}{ll}
\(n\) & \(m\) \\
\hline 4 & \(4-30\) \\
5 & \(5-30\) \\
6 & \(6-30\) \\
7 & \(7-30\) \\
8 & \(8-26\) \\
9 & \(9-22\) \\
10 & \(10-18\) \\
\hline
\end{tabular}
\begin{tabular}{ll}
\(\boldsymbol{n}\) & \(\boldsymbol{m}\) \\
\hline 11 & \(11-16\) \\
12 & \(12-14\) \\
13 & 13 \\
\hline
\end{tabular}

Because \(n\) and \(m\) are interchangeable, \(n\) should always be the smaller value. For \(n>8\) the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with \(m\) values exceeding these limits.

\section*{StatsVariancesTest}

StatsVariancesTest [flags] [wave1, wave2,... wave100]
The StatsVariancesTest operation performs Bartlett's or Levene's test to determine if wave variances are equal. Output is to the W_StatsVariancesTest wave in the current data folder or optionally to a table.

Flags
\begin{tabular}{|c|c|}
\hline / \(\mathrm{ALPH}=\) val & Sets the significance level (default val=0.05). \\
\hline \multirow[t]{5}{*}{\(/ \mathrm{METH}=m\)} & Specifies the test type. \\
\hline & \(m=0: \quad\) Bartlett test (default). \\
\hline & \(m=1\) : Levene's test using the mean. \\
\hline & \(m=2: \quad\) Modified Levene's test using the median. \\
\hline & \(m=3\) : Modified Levene's test using the 10\% trimmed mean. \\
\hline /Q & No results printed in the history area. \\
\hline \(/ \mathrm{T}=k\) & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
\hline & \(k=0\) : \(\quad\) Normal with dialog (default). \\
\hline & \(k=1: \quad\) Kills with no dialog. \\
\hline & \(k=2\) : Disables killing. \\
\hline
\end{tabular}

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\section*{Details}

All tests define the null hypothesis by
\[
H_{0}: \quad \sigma_{1}^{2}=\sigma_{2}^{2}=\ldots=\sigma_{k}^{2}
\]
against the alternative
\[
H_{a}: \quad \sigma_{i}^{2} \neq \sigma_{j}^{2} \text { for at least one } i \neq j
\]

Bartlett's test computes:
\[
T=\frac{(n-k) \ln \left(\sigma_{w}^{2}\right)-\sum_{i=1}^{k}\left(n_{i}-1\right) \ln \left(\sigma_{i}^{2}\right)}{1+\frac{1}{3(k-1)}\left[\sum_{i=1}^{k} \frac{1}{n_{i}-1}-\frac{1}{N-k}\right]}
\]

Here \(\sigma_{i}^{2}\) is the variance of the \(i\) th wave, \(N\) is the sum of the points of all the waves, \(n_{i}\) is the number of points in wave \(i\), and \(k\) is the number of waves. The weighted variance is given by
\[
\sigma_{w}^{2}=\sum_{i=1}^{k} \frac{\left(n_{i}-1\right) \sigma_{i}^{2}}{N-k} .
\]
\(\mathrm{H}_{0}\) is rejected if T is greater than the critical value taken from the \(\chi^{2}\) distribution computed by solving for \(x\) :
\[
1-\operatorname{alpha}=1-\operatorname{gammq}\left(\frac{k-1}{2}, \frac{x}{2}\right) .
\]

Levene's test computes:
\[
W=\frac{(N-k) \sum_{i=1}^{k} n_{i}\left(\bar{Z}_{i}-\bar{Z}\right)^{2}}{(k-1) \sum_{i=1}^{k} \sum_{j=1}^{k}\left(Z_{i j}-\bar{Z}_{i}\right)^{2}},
\]
where
\[
\begin{aligned}
& Z_{i j}=\left|Y_{i j}-\bar{Y}_{i}\right|, \\
& \bar{Z}_{i}=\frac{1}{n_{i}} \sum_{j=1}^{k} Z_{i j}, \\
& \bar{Z}=\frac{1}{N} \sum_{i=1}^{k} \sum_{j=1}^{k} Z_{i j} .
\end{aligned}
\]
\(\bar{Y}_{i}\) depends on /METH.
\(\mathrm{H}_{0}\) is rejected if \(W\) is greater than the critical value from the F distribution computed by solving for \(x\) :
\[
1-\text { alph } a=1-\text { betai }\left(\frac{v_{2}}{2}, \frac{v_{1}}{2}, \frac{v_{2}}{v_{2}+v_{1} x}\right) .
\]

\section*{StatsWaldCDF}

StatsWaldCDF (x, m, 1)
The StatsWaldCDF function returns the numerically evaluated inverse Gaussian or Wald cumulative distribution function.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsWaldPDF function.

\section*{StatsWaldPDF}

StatsWaldPDF (x, m, l)
The StatsWaldPDF function returns the inverse Gaussian or Wald probability distribution function
\[
f(x ; \mu, \lambda)=\sqrt{\frac{\lambda}{2 \pi x^{3}}} \exp \left[-\frac{\lambda(x-\mu)^{2}}{2 \mu^{2} x}\right]
\]
where \(x, m, l>0\).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsWaldCDF function.

\section*{StatsWatsonUSquaredTest}

StatsWatsonUSquaredTest [flags] srcWave1, srcWave2
The StatsWatsonUSquaredTest operation performs Watson's nonparametric two-sample \(U^{2}\) test for samples of circular data. Output is to the \(W_{-}\)WatsonUtest wave in the current data folder or optionally to a table.

Flags
/ALPH = val
/Q
/T=k
/Z

Sets the significance level (default val=0.05).
No results printed in the history area.
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

Ignores errors.

\section*{Details}

The input waves, srcWave1 and srcWave2, each must contain at least two angles in radians (mod \(2 \pi\) ), can have any number of dimensions, and can be single or double precision. They must not contain any NaNs or INFs.
The Watson \(\mathrm{U}^{2} \mathrm{H}_{0}\) postulates that the two samples came from the same population against the different populations alternative. In the calculation, StatsWatsonUSquaredTest ranks the two inputs, accounts for possible ties, computes the test statistic \(\mathrm{U}^{2}\), and compares it with the critical value. Because of the difficulty of computing the critical values, it always computes first the approximation due to Tiku and if possible it computes the exact critical value using the method outlined by Burr. You can evaluate the U2 CDF to get more information about the critical region.

V_flag will be set to -1 for any error and to zero otherwise.

\section*{References}

We have found that this method leads to slightly different results depending on the compiler and the system on which it is implemented:
Burr, E.J., Small sample distributions of the two sample Cramer-von Mises' W2 and Watson's U2, Ann. Mah. Stat. Assoc., 64, 1091-1098, 1964.

\section*{See Also}

Chapter III-12, Statistics for a function and operation overview; StatsWatsonWilliamsTest, StatsWheelerWatsonTest, StatsUSquaredCDF, and StatsInvUSquaredCDF.

\section*{StatsWatsonWilliamsTest}

StatsWatsonWilliamsTest [flags] [srcWave1, srcWave2, srcWave3,...]
The StatsWatsonWilliamsTest operation performs the Watson-Williams test for two or more sample means. Output is to the W_WatsonWilliams wave in the current data folder or optionally to a table.

\section*{Flags}
\begin{tabular}{ll} 
/ALPH = val & Sets the significance level (default val=0.05). \\
\(/ \mathrm{Q}\) & No results printed in the history area. \\
\(/ \mathrm{T}=k\) & Displays results in a table. \(k\) specifies the table behavior when it is closed. \\
& \(k=0:\) \\
& \begin{tabular}{ll}
\(k=1:\) & Normal with dialog (default). \\
\(k=2:\) & Kills with no dialog. \\
&
\end{tabular}
\end{tabular}

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

\section*{/WSTR=waveListString}

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors.

\section*{Details}

The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians, can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.
The Watson-Williams \(\mathrm{H}_{0}\) postulates the equality of the means from all samples against the simple inequality alternative. The test computes the sums of the sines and cosines from which it obtains a weighted \(r\) value (rw). According to Mardia, you should use different statistics depending on the size of rw: for rw \(>0.95\) use the simple F statistic, but for \(0.95>r w>0.7\) you should use the F-statistic with the K correction factor. Otherwise you should use the t-statistic. StatsWatsonWilliamsTest computes both the (corrected) Fstatistic and the \(t\)-statistic as well as their corresponding critical values.
V_flag will be set to -1 for any error and to zero otherwise.

Chapter III-12, Statistics for a function and operation overview; the StatsWeibullCDF and StatsInvWeibullCDF functions.

\section*{StatsWheelerWatsonTest}

StatsWheelerWatsonTest [flags] [srcWave1, srcWave2, srcWave3,...]
The StatsWheelerWatsonTest operation performs the nonparametric Wheeler-Watson test for two or more samples. Output is to the \(W_{-}\)WheelerWatson wave in the current data folder or optionally to a table.

\section*{Flags}
\(/ \mathrm{ALPH}=\) val \(\quad\) Sets the significance level (default val=0.05).
/Q
No results printed in the history area.
\(/ \mathrm{T}=k\)
Displays results in a table. \(k\) specifies the table behavior when it is closed.
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2\) : \(\quad\) Disables killing.
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors.

\section*{Details}

The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians (mod \(2 \pi\) ), can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Wheeler-Watson \(\mathrm{H}_{0}\) postulates that the samples came from the same population. The extension of the test to more than two samples is due to Mardia. The Wheeler-Watson test is not valid for data with ties, in which case you should use Watson's \(\mathrm{U}^{2}\) test.
V_flag will be set to -1 for any error and to zero otherwise.

\section*{References}

Mardia, K.V., Statistics of Directional Data, Academic Press, New York, New York, 1972.
See, in particular, Chapter 27 of:
Zar, J.H., Biostatistical Analysis, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.
See Also
Chapter III-12, Statistics for a function and operation overview; StatsWatsonUSquaredTest and StatsWheelerWatsonTest.

\section*{StatsWilcoxonRankTest}

StatsWilcoxonRankTest [flags] waveA, waveB
The StatsWilcoxonRankTest operation performs the nonparametric Wilcoxon-Mann-Whitney two-sample rank test or the Wilcoxon Signed Rank test (for paired data) on waveA and waveB. Output is to the W_WilcoxonTest wave in the current data folder or optionally to a table.
wave \(A\) and waveB must not contain NaNs or INFs.
Flags
/ALPH = val Sets the significance level (default val=0.05).
/APRX=m
/Q
\(/ \mathrm{T}=k\)
/TAIL=tail

Sets the approximation method. It computes an exact critical value by default.
\(m=1\) : \(\quad\) Standard normal approximation with ties (Zar P. 151).
\(m=2\) : \(\quad\) Improved normal approximation (Zar P. 152).
Approximations may be appropriate for large sample sizes when computation may take a long time.
No results printed in the history area.
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
tail is a bitwise parameter that specifies the tails tested.
Bit 0: Lower tail.
Bit 1: Upper tail (default).
Bit 2: Two tail.
See Setting Bit Parameters on page IV-12 for details about bit settings.
You can perform any combination of tests by adding their corresponding tail values (/TAIL=7 tests all tail possiblities). Note that H0 changes according to the selected tail.
/WSRT
Performs the Wilcoxon Signed Rank Test for paired data. The testh computes statistics Tp and Tm, lower-tail, upper-tail, and two-tail P-values. If the number of samples is less than 200 it computes exact P-values, otherwise they are computed using the normal approximation. Do not use /ALPH, /APRX, and /TAIL with this flag.

\section*{Details}

The Wilcoxon-Mann-Whitney test combines the two samples and ranks them to compute the statistic U. If wave \(A\) has \(m\) points and wave \(B\) has \(n\) points, then \(U\) is given by
\[
U=m n+\frac{m(m+1)}{2}-R_{1},
\]
with the corresponding statistic \(U^{\prime}\) given by
\[
U^{\prime}=n m+\frac{n(n+1)}{2}-R 2 .
\]
where \(R_{i}\) is the ranks of data in the \(i\) th wave (ranked in ascending order).
The distribution of \(U\) is difficult to compute, requiring the number of possible permutations of \(m\) elements of wave \(A\) and \(n\) elements of waveB that give rise to \(U\) values that do not exceed the one computed. The distribution is computed according to the algorithm developed by Klotz. With increasing sample size one can avoid the time consuming distribution computation and use a normal approximation instead. Klotz recommends this approximation for \(N=m+n \sim 100\).
Use \(/ \mathrm{APRX}=2\) for the best approximation. The two approximations are discussed by Zar.
The Wilcoxon Signed Rank Test, or Wilcoxon Paired-Sample Test, ranks the difference between pairs of values and computes the sums of the positive ranks (Tp) and the negative ranks ( Tm ). It calculates Tp and Tm and P -values for all tail combinations. The P -values are:
```

P_lower_tail P(Wp<=Tp)
P_upper_tail P(Wp>=Tp)
P_two_tail 2*Min(P_lower_tail,P_upper_tail)

```

Wp is the generic symbol for the sum of positive ranks for the given number of pairs.
V_flag will be set to -1 for any error and to zero otherwise.
In both Wilcoxon-Mann-Whitney two-sample rank test and the Wilcoxon Signed Rank test H0 is that the data in the two input waves are statistically the same.

\section*{StatsWRCorrelationTest}

\section*{StatsWRCorrelationTest [flags] waveA, waveB}

The StatsWRCorrelationTest operation performs a Weighted Rank Correlation test on waveA and waveB, which contain the ranks of sequential factors. The waves are 1-based, integer ranks of factors in the range 1-2^31.

StatsWRCorrelationTest computes a top-down correlation coefficient using Savage sums as well as the critical and P-values. Output is to the W_StatsWRCorrelationTest wave in the current data folder or optionally to a table.

Flags
/ALPH = val Sets the significance level (default val=0.05).
/Q
No results printed in the history area.
/T=k
Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\) : \(\quad\) Normal with dialog (default).
\(k=1: \quad\) Kills with no dialog.
\(k=2: \quad\) Disables killing.
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/Z
Ignores errors.

\section*{Details}

The StatsWRCorrelationTest input waves must be one-dimensional and have the same length. The waves are 1based, integer ranks of factors corresponding to the point number. Ranks may have ties in which case you should repeat the rank value. For example, if the second and third entries have the same rank you should enter \(\{1,2,2,4\}\). \(\mathrm{H}_{0}\) stipulates that the same factors are most important in both groups represented by waveA and waveB.
The top-down correlation is the sum of the product of Savage sums for each row:
\[
r_{T D}=\frac{\sum_{i=1}^{n} S_{i A} S_{i B}-n}{n-S_{1}}
\]
where \(n\) is the number of rows and the Savage sum \(S_{i}\) is
\[
S_{i}=\sum_{j=i}^{n} \frac{1}{j}
\]
and \(S_{i A}\) corresponds to the \(S_{i}\) value of the rank of the data in row \((i-1)\) of waveA.

\section*{stopMSTimer}

\section*{stopMSTimer(timerRefNum)}

The stopMSTimer function frees up the timer associated with the timerRefNum and returns the number of elapsed microseconds since startMSTimer was called for this timer.

\section*{Parameters}
timerRefNum is the value returned by startMSTimer or the special values -1 or -2 . If timerRefNum is not valid then stopMSTimer returns 0 . Passing -1 returns the clock frequency of the timer and, on the Macintosh, performs a calibration. Passing -2 returns the time in microseconds since the computer was started.

\section*{Details}

If you want to make sure that all timers are free, call stopMSTimer ten times with timerRefNum equal to 0 through 9. It is OK to stop a timer that you never started.
On the Macintosh, the first call to stopMSTimer will take longer (approximately 0.1 sec . more) because of a clock frequency calibration. This will also happen when calling with a value of -1 . If the extra time for the first call will cause problems, be sure to force the calibration before your first real timing run.

\section*{Examples}

How long does an empty loop take on your computer?
```

Function TestMSTimer()
Variable timerRefNum
Variable microSeconds
Variable n
timerRefNum = startMSTimer
if (timerRefNum == -1)
Abort "All timers are in use"
endif
n=10000
do
n -= 1
while (n > 0)
microSeconds = stopMSTimer(timerRefNum)
Print microSeconds/10000, "microseconds per iteration"
End
See Also
The startMSTimer and ticks functions.

```

\section*{str2num}
str2num(str)
The str2num function returns a number represented by the string expression str.

\section*{Details}
str2num returns NaN if str does not contain the text for a number.
str2num skips leading spaces and tabs and then reads up to the first non-numeric character.

\section*{See Also}

The char2num, num2char and num2str functions.
The sscanf operation for more complex parsing jobs.

\section*{Strconstant}

\section*{Strconstant ksName="literal string"}

The Strconstant declaration defines the string literal string under the name \(k s N a m e\) for use by other code, such as in a switch construct.

\section*{See Also}

The Constant keyword for numeric types, Constants on page IV-40, and Switch Statements on page IV-34.

\section*{String}

String [/G] strName [=strExpr] [, strName [=strExpr] ...]
The String declaration creates string variables and gives them the specified names.

\section*{Flags}
/G Creates a global string. Overwrites any existing string with the same name.

\section*{Details}

The string variable is initialized when it is created if you supply the =strExpr initializer. However, when String is used to declare a function parameter, it is an error to attempt to initialize it.
You can create more than one string variable at a time by separating the names and optional initializers with commas.
If used in a procedure, the new string is local to that procedure unless the / \(G\) (global) flag is used. If used on the command line, String is equivalent to String/G.
strName can optionally include a data folder path.

\section*{StringByKey}

StringByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]])
The StringByKey function returns a substring extracted from \(k w L i s t S t r\) based on the specified key contained in keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1, KEY2=value2 " or "Key:value1; KEY2: value2", depending on the values for keySepStr and listSepStr.
Use StringByKey to extract a string value from a string containing a "key1:value1;key2: value2;" style list such as those returned by functions like AxisInfo or TraceInfo.
If the key is not found or if any of the arguments is " " then a zero-length string is returned.
keySepStr, listSepStr, and matchCase are optional; their defaults are ":", ";", and 0 respectively.
Details
keyStr is limited to 255 characters.
\(k w L i s t S t r\) is searched for an instance of the key string bound by listSepStr on the left and a keySepStr on the right. The text up to the next listSepStr is returned.
\(k w L i s t S t r\) is treated as if it ends with a listSepStr even if it doesn't.
Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional matchCase parameter to 1 makes the comparisons case sensitive.
Only the first characters of keySepStr and listSepStr are used.
If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

\section*{Examples}
```

Print StringByKey("BKEY", "AKEY:hello;BKEY:nok-nok") // prints "nok-nok"
Print StringByKey("KY", "KX=1;ky=hello", "=") // prints "hello"
Print StringByKey("KY", "KX:1,KY:joey,", ":", ",") // prints "joey"
Print StringByKey("kz", "KZ:1st,kz:2nd,", ":", ",") // prints "1st"
Print StringByKey("kz", "KZ:1st,kz:2nd,", ":", ",", 1)// prints "2nd"

```

\section*{See Also}

The NumberByKey, RemoveByKey, ReplaceNumberByKey, ReplaceStringByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

\section*{StringCRC}

StringCRC (inCRC, str)
The StringCRC function returns a 32-bit cyclic redundancy check value of bytes in str starting with inCRC. Pass 0 for \(i n C R C\) the first time you call StringCRC for a particular stream of bytes as represented by the string data.

Pass the last-returned value from StringCRC for \(i n C R C\) if you are creating a CRC value for a given stream of bytes through multiple calls to StringCRC.
Details
Polynomial used is:
\(x^{\wedge} 32+x^{\wedge} 26+x^{\wedge} 23+x^{\wedge} 22+x^{\wedge} 16+x^{\wedge} 12+x^{\wedge} 11+x^{\wedge} 10+x^{\wedge} 8+x^{\wedge} 7+x^{\wedge} 5+x^{\wedge} 4+x^{\wedge} 2+x+1\)
See crc32.c in the public domain source code for zlib for more information.
See Also
The WaveCRC function.

\section*{StringFromList}

StringFromList(index, listStr [, listSepStr])
The StringFromList function returns the indexth substring extracted from listStr. listStr should contain items separated by the listSepStr character, such as "abc;def;".
Use StringFromList to extract an item from a string containing a list of items separated by a single character, such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.
index is zero-based (set index to zero to get the first item in the string list).
If index \(<0\), or index \(\geq\) the number of items in list, or if listStr or listSepStr is " ", then a zero-length string is returned.
listSepStr is optional. When omitted, listSepStr is presumed to be ";".

\section*{Details}
listStr is searched for an instance of the key string bound by listSepStr on the left and right. The text between the bounding listSepStrs is returned.
listStr is treated as if it ends with a listSepStr even if it doesn't.
Only the first character of listSepStr is used.

\section*{Examples}
```

Print StringFromList(0, "wave0;wave1;") // prints "wave0"
Print StringFromList(2, "wave0;wave1;") // prints ""
Print StringFromList(1, "wave0;;wave2") // prints ""
Print StringFromList(2, "fred\twilma\tbarney", "\t") // prints "barney"

```

A function that applies a unique line style to each trace in the top graph:
```

Function LineStyler()
String traces= TraceNameList("",";",1) // Traces in top graph
String traceName
Variable i=0
do
traceName= StringFromList(i,traces)
if( strlen(traceName) == 0 )
break
endif
ModifyGraph lstyle(\$traceName)= mod(i,18) // 0 to 17, then repeat
i += 1
while (1) // exit is via break statement
End

```

A function that converts a string list into a text wave:
```

Function List2Wave()
String traces= TraceNameList("",";",1) // Traces in top graph
Variable n= ItemsInList(traces)
Make/O/T/N=(n) textWave= StringFromList(p,traces)
End

```

\section*{See Also}

The AddListItem, ItemsInList, FindListItem, RemoveFromList, WaveList, WhichListItem, StringByKey, ListMatch, ControlNameList, TraceNameList, StringList, VariableList, and FunctionList functions.

\section*{StringList}

StringList(matchStr, separatorStr)
The StringList function returns a string containing a list of global string variables selected based on the matchStr parameter. The string variables listed are all in the current data folder.

\section*{Details}

For a string variable name to appear in the output string, it must match matchStr. The first character of separatorStr is appended to each string variable name as the output string is generated.
The name of each string variable is compared to matchStr, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:
```

"*" Matches all string variable names
"xyz" Matches name xyz only
"*xyz" Matches names which end with xyz
"xyz*" Matches names which begin with xyz
"*xyz*" Matches names which contain xyz
"abc*xyz" Matches names which begin with abc and end with xyz

```

The list contains names only, without data folder paths. Thus, they are not suitable for accessing string variables outside the current data folder.
matchStr may begin with the ! character to return windows that do not match the rest of matchStr. For example:
\[
\text { "!*xyz" } \quad \text { Matches variable names which do not end with xyz }
\]

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.

\section*{Examples}
```

StringList("*",";") Returns a list of all string variables in the current data folder.
StringList("S_*", ";") Returns a list of all string variables in the current data folder
whose names begin with "S_".

```

\section*{See Also}

See the VariableList and WaveList functions.

\section*{StringMatch}

StringMatch(string, matchStr)
The StringMatch function tests string for a match to matchStr. You may include asterisks in matchStr as a wildcard character.
StringMatch returns 1 to indicate a match, 0 for no match or NaN if it ran out of memory.

\section*{Details}
matchStr is some combination of normal characters and the asterisk wildcard character that matches anything. For example:
"*" Matches any string.
"xyz" Matches the string "xyz" only.
"*xyz" Matches strings ending with "xyz", for instance "abcxyz".
"xyz*" Matches strings beginning with xyz, for instance "xyzpqr".
"*xyz*" Matches strings containing xyz, for instance "abcxyzpqr".
"abc*xyz" Matches strings beginning with \(a b c\) and ending with xyz, for instance "abcpqrxyz".

If matchStr begins with the ! character, a match is indicated if string does not match matchStr. For example:
"!*xyz" Matches strings which do not end with xyz.
The ! character is considered to be a normal character if it appears anywhere else.
Note that matching is case-insensitive, so "xyz" also matches "XYZ" or "Xyz".
Also note that it is impossible to match an asterisk in string: use GrepString instead.
Among other uses, the StringMatch function can be used to build your own versions of the WaveList function, using NameOfWave and stringmatch to qualify names of waves found by WaveRefIndexedDFR.

\section*{See Also}

The GrepString, cmpstr, strsearch, SplitString, ListMatch, and ReplaceString functions and the sscanf operation.

\section*{strlen}
strlen (str)
The strlen function returns the number of characters in the string expression str.
strlen returns NaN if the \(s t r\) is NULL. A local string variable or a string field in a structure that has never been set is NULL. NULL is not the same as zero length. Use numtype to test if the result from strlen is NaN .

\section*{Examples}
```

String zeroLength = ""
String neverSet
Print strlen(zeroLength), strlen(neverSet)
// Test if a string is null
Variable len = strlen(neverSet) // NaN if neverSet is null
if (numtype(len) == 2) // strlen returned NaN?
Print "neverSet is null"
endif

```

\section*{strsearch}
```

strsearch(str, findThisStr, start[, options])

```

The strsearch function returns the numeric position of the string expression findThisStr in the string expression str.

\section*{Details}
strsearch performs a case-sensitive search.
strsearch returns -1 if findThisStr does not occur in str.
The search starts from the character position in str specified by start; 0 is the first character in str.
strsearch limits start to one less than the length of str, so it is useful to use Inf for start when searching backwards to ensure that the search is from the end of str.
The optional options parameter is a bitmask specifying the search options:
1: Search backwards from start.
2: Ignore case.
3: \(\quad\) Search backwards and ignore case.

\section*{Examples}
```

String str="This is a test isn't it?"
Print strsearch(str,"test",0) // prints 10
Print strsearch(str,"TEST",0) // prints -1
Print strsearch(UpperStr(str),"TEST",0) // prints 10
Print strsearch(str,"TEST",0,2) // prints 10
Print strsearch(str,"is",0) // prints 2
Print strsearch(str,"is",3) // prints 5
Print strsearch(str,"is",Inf,1) // prints 15

```

\section*{See Also}

The sscanf operation and FindListItem and ReplaceString functions.
See Setting Bit Parameters on page IV-12 for details about bit settings.

\section*{strswitch-case-endswitch}
```

strswitch(<string expression>)
case <literal><constant>:
<code>
[break]
[default:
<code>]
endswitch

```

A strswitch-case-endswitch statement evaluates a string expression and compares the result to the case labels using a case-insensitive comparison. If a case label matches string expression, then execution proceeds with code following the matching case label. When none of the cases match, execution will continue at the default label, if it is present, or otherwise the strswitch will be exited with no action taken. Note that although the break statement is optional, in almost all case statements it will be required for the strswitch to work correctly.

\section*{See Also}

Switch Statements on page IV-34, default and break for more usage details.

\section*{STRUCT}

STRUCT structureName localName
STRUCT is a reference that creates a local reference to a Structure accessed in a user-defined function. When a Structure is passed to a user function, it can only be passed by reference, so in the declaration within the function you must use \&localStructName to define the function input parameter.

\section*{See Also}

Structures in Functions on page IV-82 for further information.
See the Structure keyword for creating a Structure definition.

\section*{StructGet}

StructGet [/B=b] structVar, waveStruct[[colNum]]
StructGet /S [/B=b] structVar, strStruct
The StructGet operation reads binary numeric data from a specified column of a wave or from a string variable and copies the data into the designated structure variable. The source wave or string will have been filled beforehand by StructPut.

\section*{Parameters}
structVar is the name of an existing structure that is to be filled with new data values.
waveStruct is the name of a wave containing binary numeric data that will be used to fill structVar. Use the optional colNum parameter to specify a column from the structure wave. The contents of waveStruct are created beforehand using StructPut.
strStruct is the name of a string variable containing binary numeric data. The contents of strStruct are created beforehand using StructPut.

\section*{Flags}
\(/ B=b \quad\) Sets the byte ordering for reading of structure data.
\(b=0: \quad\) Reads in native byte order.
\(b=1: \quad\) Reads bytes in reversed order.
\(b=2: \quad\) Default; reads data in big-endian, high-byte-first order (Motorola).
\(b=3: \quad\) Reads data in little-endian, low-byte-first order (Intel).
Reads binary data from a string variable, which was set previously with StructPut.

\section*{Details}

The data that are stored in waveStruct and strStruct are in binary format so you can not directly view a meaningful representation of their contents by printing them or viewing the wave in a table. To view the contents of waveStruct or strStruct you must use StructGet to export them back into a structure and then retrieve the members.

If colNum is out of bounds it will be clipped to valid values and an error reported. If the row dimension does not match the structure size, as much data as possible will be copied to the structure.
By default, data are read in big-endian, high-byte order (Motorola). This allows data written on one platform to be read on the other.

\section*{See Also}

The StructPut operation for writing structure data to waves or strings.

\section*{StructPut}

StructPut [/B=b] structVar, waveStruct[[colNum]]
StructPut /S [/B=b] structVar, strStruct
The StructPut operation copies the binary numeric data in a structure variable to a specified column in a wave or to a string variable. The data in the wave or string can be read out into another structure using StructGet.

\section*{Parameters}
structVar is the name of a structure from which data will be exported.
waveStruct is the name of an existing wave to which data will be exported. Use the optional colNum parameter to specify a column in waveStruct to contain the data. The first column of waveStruct will be filled if colNum is omitted.
strStruct is the name of an existing string variable to which data will be exported.

\section*{Flags}
\begin{tabular}{lll}
\(/ \mathrm{B}=b\) & \multicolumn{1}{l}{ Sets the byte ordering for writing of structure data. } \\
\(b=0:\) & Writes in native byte order. \\
\(b=1:\) & Writes bytes in reversed order. \\
\(b=2:\) & Default; writes data in big-endian, high-byte-first order (Motorola). \\
\(b=3:\) & Writes data in little-endian, low-byte-first order (Intel). \\
& \\
& & Writes binary data to a string variable.
\end{tabular}

\section*{Details}

The structure to be exported must contain only numeric data in either integer, floating point, or double precision format. If the structure contains any objects such as String, NVAR, WAVE, etc., then an error will result at compile time.
If needed, StructPut will redimension waveStruct to unsigned byte format, will set the number of rows to equal the size of the structure, and set the column dimension large enough to accommodate the size specified by colNum. You can think of waveStruct as a one-dimensional array of structure contents indexed by colNum although the wave is actually two-dimensional with each column containing a copy of a separate structure.
By default, data are written in big-endian, high-byte order (Motorola). This allows data written on one platform to be read on the other.

After you have exported the structure data to waveStruct or strStruct they will contain binary data that you cannot inspect directly. To view the contents of waveStruct or strStruct, you must use the original structure or use StructGet to export them into another structure.

\section*{See Also}

The StructGet operation for reading structure data from waves or strings.

\section*{Structure}

Structure structureName
memType memName [arraySize] [, memName [arraySize]]
...
EndStructure
The Structure keyword introduces a structure definition in a user function. Within the body of the structure you declare the member type (memType) and the corresponding member name(s) (memName). Each memName may be declared with an optional array size.

\section*{Details}

Structure member types (memType) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, DFREF, FUNCREF, or STRUCT.
Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.
\begin{tabular}{lll} 
Igor Member Type & C Equivalent & Byte Size \\
\hline char & signed char & 1 \\
uchar & unsigned char & 1 \\
int16 & short int & 2 \\
uint16 & unsigned short int & 2 \\
int32 & long int & 4 \\
uint32 & unsigned long int & 4 \\
float & float & 4 \\
double & double & 8 \\
\hline
\end{tabular}

The Variable and double types are identical although Variable can be also specified as complex (using the /C flag).
Each structure member may have an optional arraySize specification, which gives the number of elements contained by the structure member. The array size is an integer number from 1 to 400 except for members of type STRUCT for which the upper limit is 100 .

\section*{See Also}

Structures in Functions on page IV-82 for further information.
See the STRUCT declaration for creating a local reference to a Structure.

\section*{StrVarOrDefault}

StrVarOrDefault(pathStr, defStrVal)
The StrVarOrDefault function checks to see if pathStr points to a string variable and if so, it returns its value. If the string variable does not exist, returns defStrVal instead.

\section*{Details}

StrVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. Numeric variables use the corresponding numeric function, NumVarOrDefault.

\section*{Examples}
```

Macro foo(nval,sval)
Variable nval=NumVarOrDefault("root:Packages:mypack:nvalSav", 2)
String sval=StrVarOrDefault("root:Packages:mypack:svalSav","Hi")
String dfSav= GetDataFolder(1)
NewDataFolder/O/S root:Packages
NewDataFolder/O/S mypack
Variable/G nvalSav= nval
String/G svalSav= sval

```
```

    SetDataFolder dfSav
    End

```

\section*{StudentA}
```

StudentA(t, DegFree)

```

Note: \(\quad\) This function is deprecated. New code should use the more accurate StatsStudentCDF.
The StudentA function returns the area from \(-t\) to \(t\) under the Student's T distribution having DegFree degrees of freedom. That is, it returns the probability that a random sample from Student's T is between \(-t\) and \(t\).
Note that this is the bi-tail result. That is, it gives the area from \(-t\) to \(t\), rather than the cumulative area from \(-\infty\) to \(t\). It is this latter number that is commonly tabulated- StudentA returns the probability 1- \(\alpha\) where the area from \(-\infty\) to \(t\) is the probability \(1-\alpha / 2\).
StudentA tests whether a normally-distributed statistic is significantly different from a certain value. You could use it to test whether an intercept from a line fit is significantly different from zero:
```

Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
CurveFit line Data /D
Print "Prob = ", StudentA(W_coef[0]/W_sigma[0], V_npnts-2)

```

Because the noise is random, the results will differ slightly each time this is tried. When we did it, the result was:
Prob \(=0.999898\)
which indicates that the intercept of the line fit was different from zero with 99.99 per cent probability.

\section*{See Also}

StatsStudentCDF, StatsStudentPDF, StatsInvStudentCDF

\section*{StudentT}

\section*{StudentT (Prob, DegFree)}

Note: This function is deprecated. New code should use the more accurate StatsInvStudentCDF.

The StudentT function returns the \(t\) value corresponding to an area Prob under the Student's T distribution from - \(t\) to \(t\) for DegFree degrees of freedom.
Note that this is a bi-tail result, which is what is usually desired. Tabulated values of the Student's T distribution are commonly the one-sided result.
StudentT calculates confidence intervals from standard deviations for normally-distributed statistics. For instance, you can use it to calculate a confidence interval for the coefficients from a curve fit:
```

Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
CurveFit line Data /D
print "intercept = ", W coef[0], "\pm", W_sigma[0]*StudentT(0.95, V npnts-2)
print "slope = ", W_coe\overline{f}[1], "\pm", W_sigma[1]*StudentT(0.95, V_npnEs-2)
See Also
StatsStudentCDF, StatsStudentPDF, StatsInvStudentCDF

```

\section*{Submenu}

Submenu menuNameStr
The Submenu keyword introduces a submenu definition. It is used inside a Menu definition. See Chapter IV-5, User-Defined Menus for further information.

\section*{sum}
sum (waveName [, \(\mathrm{x} 1, \mathrm{x} 2]\) )
The sum function returns the sum of the wave elements for points from \(x=x 1\) to \(x=x 2\).

\section*{Details}

The \(X\) scaling of the wave is used only to locate the points nearest to \(x=x 1\) and \(x=x 2\). To use point indexing, replace \(x 1\) with pnt 2 x (waveName, pointNumber 1 ), and a similar expression for \(x 2\).
If \(x 1\) and \(x 2\) are not specified, they default to \(-\infty\) and \(+\infty\), respectively.
If the points nearest to \(x 1\) or \(x 2\) are not within the point range of 0 to numpnts(waveName)-1, sum limits them to the nearest of point 0 or point numpnts(waveName)-1.
If any values in the point range are NaN , sum returns NaN .

\section*{Examples}

Make/O/N=100 data;SetScale/I x 0,Pi,data
data=sin(x)
Print sum(data,0,Pi) // the entire point range, and no more
Print sum(data) // same as -infinity to +infinity
Print sum(data,Inf,-Inf) // +infinity to -infinity
The following is printed to the history area:
```

\bulletPrint sum(data,0,Pi) // the entire point range, and no more
63.0201
-Print sum(data) // same as -infinity to +infinity
63.0201
\bulletPrint sum(data,Inf,-Inf) // +infinity to -infinity
63.0201

```

\section*{See Also}
mean and area functions.

\section*{SVAR}

SVAR [/Z] localName [= pathToStr] [, localName1 [= pathToStri]]...
SVAR is a declaration that creates a local reference to a global string variable accessed in a user-defined function.
The SVAR reference is required when you access a global string variable in a function. At compile time, the SVAR statement specifies a local name referencing a global string variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global string variable must exist when the SVAR statement is executed.
When localName is the same as the global string variable name and you want to reference a global variable in the current data folder, you can omit pathToStr. Prior to Igor Pro 4.0, pathToStr was always required.
pathToStr can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or \$ followed by string variable containing a computed path (see Converting a String into a Reference Using \$ on page IV-48).
You can also use a data folder reference or the /SDFR flag to specify the location of the string variable if it is not in the current data folder. See Data Folder References on page IV-62 and The /SDFR Flag on page IV-64 for details.
If the global variable may not exist at runtime, use the /Z flag and call SVAR_Exists before accessing the variable. The /Z flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:
```

SVAR/z nv=<pathToPossiblyMissingStringVariable>
if( SVAR Exists(sv) )
<do something with sv>
endif

```

Note that to create a global string variable, you use the String/G operation.

\section*{Flags}
/Z An SVAR reference to a null string variable does not cause an error or a debugger break.

\section*{See Also}

SVAR_Exists function.
Accessing Global Variables and Waves on page IV-50.
Converting a String into a Reference Using \$ on page IV-48.

\section*{SVAR_Exists}

SVAR_Exists (name)
The SVAR_Exists function returns 1 if the specified SVAR reference is valid or 0 if not. It can be used only in user-defined functions.
For example, in a user function you can test if a global string variable exists like this:
```

SVAR /Z str1 = gStrl // /Z prevents debugger from flagging bad SVAR
if (!SVAR_Exists(strl)) // No such global string variable?
String/G gStr1 = ""
endif

```

See Also
WaveExists, NVAR_Exists, and Accessing Global Variables and Waves on page IV-50.

\section*{switch-case-endswitch}
```

switch(<numeric expression>)
case <literal><constant>:
<code>
[break]
[default:
<code>]
endswitch

```

A switch-case-endswitch statement evaluates a numerical expression. If a case label matches numerical expression, then execution proceeds with code following the matching case label. When no cases match, execution continues at the default label, if present, or otherwise the switch exits with no action taken. Note that although the break statement is optional, in almost all case statements it is required for the switch to work correctly.

\section*{See Also}

Switch Statements on page IV-34, default and break for more usage details.

\section*{\(t\)}

\section*{t}

The \(t\) function returns the \(T\) value for the current chunk of the destination wave when used in a multidimensional wave assignment statement. T is the scaled chunk index while \(\mathbf{s}\) is the chunk index itself.

\section*{Details}

Unlike \(\mathbf{x}\), outside of a wave assignment statement, t does not act like a normal variable.

\section*{See Also}

Waveform Arithmetic and Assignments on page II-94.
For other dimensions, the \(\mathbf{p}, \mathbf{q}, \mathbf{r}\), and \(\mathbf{s}\) functions.
For scaled dimension indices, the \(\mathbf{x}, \mathbf{y}\), and \(\mathbf{z}\) functions.

\section*{TabControl}

TabControl [/Z] ctrlName [keyword = value [, keyword = value ...]]
The TabControl operation creates tab panels for controls.
For information about the state or status of the control, use the ControlInfo operation.

\section*{Parameters}
ctrlName is the name of the TabControl to be created or changed.
The following keyword=value parameters are supported:
```

appearance={kind [, platform]}

```

Sets the appearance of the control. platform is optional. Both parameters are names, not strings.
kind can be one of default, native, or os9.
platform can be one of Mac, Win, or All.
See DefaultGUIControls Default Fonts and Sizes for how enclosed controls are affected by native TabControl appearance.
See Button for more appearance details.
disable \(=d\)

\[
10-1
\]
tabLabel \((n)=l b l\)
Sets \(n\)th tab label to \(l b l\). Set the label of the last tab to " " to reduce the number of tabs.
You can use escape sequences, as with the TextBox operation, in \(l b l\) to change text color and style. For example:
TabControl tab0 tabLabel(1)=" \(\backslash K(0,0,65535) \backslash\) f01Bold Blue Text"
userdata \((\) UDName \()=\) UDStr
Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create.
userdata(UDName)+=UDStr
Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr.
value \(=v \quad\) Sets current tab number. Tabs count from 0.
win=winName Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.
When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Flags}
/Z No error reporting.

\section*{Details}

The action procedure for a TabControl can use a predefined structure WMTabControlAction as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a TabControl, otherwise it will use the old-style method.
A TabControl action procedure using a structure has the format:
```

Function newActionProcName(TC_Struct) : TabControl
STRUCT WMTabControlAction \&\&C_Struct
End
The ": TabControl" designation tells Igor to include this procedure in the Procedure pop-up menu in
the Tab Control dialog.
For a TabControl, the WMTabControlAction structure has members as described in the following table:
WMTabControlAction Structure Members
Member Description
char ctrlName [MAX_OBJ_NAME+1] Control name.
char win [MAX_WIN_PATH+1] Host (sub)window.
STRUCT Rect winRect Local coordinates of host window.
STRUCT Rect ctrlRect Enclosing rectangle of the control.
STRUCT Point mouseLoc Mouse location.
Int32 eventCode Event that executed the procedure.

| eventCode | Event |
| :--- | :--- |
| -1 | Control being killed |
| 2 | Mouse up |

Int32 eventMod

```

Bitfield of modifiers. See Control Structure eventMod Field on page III-387.

\section*{WMTabControlAction Structure Members}
\begin{tabular}{ll} 
Member & Description \\
\hline String userData & \begin{tabular}{l} 
Primary (unnamed) user data. If this changes, it is written back \\
automatically.
\end{tabular} \\
Int32 blockReentry & \begin{tabular}{l} 
Prevents reentry of control action procedure. See Control \\
Structure blockReentry Field on page III-388.
\end{tabular} \\
& Tab number.
\end{tabular}

Action functions should respond only to documented event Code values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.
The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.
When clicking a TabControl with the selector arrow, click in the title region. The control will not be selected if you click in the body. This is to make it easier to select controls in the body rather than the TabControl itself.
TabControls may be used to simplify complex control panels. If you are not already familiar with the concept of a TabControl, see Modifying Axes on page II-266 for an illustration of tabs as used in the Modify Axis dialog.
Designing a TabControl with all the accompanying interior controls can be somewhat difficult. Here is a suggested technique:
First, create and set the size and label for one tab. Then create the various controls for this first tab. Before starting on the 2nd tab, create the TabControl's procedure so that it can be used to hide the first set of controls. Then add the 2nd tab, click it to run your procedure and start adding controls for this new tab. When done, update your procedure so the new controls will be hidden when you start on the third tab. You may find it useful to create a recreation macro of your panel to get a convenient listing of the controls. Here is an example:
(The commands given include size and position information obtained by manual adjustment.)
1. Create a panel and a TabControl:

NewPanel \(/ W=(150,50,478,250)\)
ShowTools
TabControl foo, pos=\{29,38\}, size=\{241,142\},tabLabel(0)="first tab", value=0
2. Add a few controls to the interior of the TabControl:

Button button0, pos=\{52,72\}, size \(=\{50,20\}\), title="First"
CheckBox check0, pos=\{52,105\}, size=\{102,15\},title="Check first", value=0
3. Write a function:
```

Function fooProc(name,tab)
String name
Variable tab
Button button0,disable= (tab!=0)
CheckBox check0,disable= (tab!=0)
End
4. Set proc and add a new tab:
TabControl foo,proc=fooProc,tabLabel(1)="second tab"
5. Click the second tab (which hides the first tab's controls) and then add new controls like so:

```
```

Button button1,pos={58,73},size={50,20},title="Second"
CheckBox check1, pos={60,105},size={114,15},title="Check second",value= 0

```
6. Finally, change fooProc by adding these lines at the end:

Button button1,disable= (tab!=1)
CheckBox check1,disable= (tab!=1)

\section*{Table}

\section*{Table}

\section*{Table}

Table is a procedure subtype keyword that identifies a macro as being a table recreation macro. It is automatically used when Igor creates a window recreation macro for a table. See Procedure Subtypes on page IV-183 and Killing and Recreating a Table on page II-199 for details.

\section*{TableStyle}

TableStyle
TableStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Table dialog and in the Table Macros menu. See Table Style Macros on page II-231 for details.

\section*{TableInfo}

TableInfo(winNameStr, itemIndex)
The TableInfo function returns a string containing a semicolon-separated list of keywords and values that describe a column in a table or overall properties of the table. The main purpose of TableInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges a table or which manipulates the table selection.

\section*{Parameters}
winNameStr is the name of an existing table window or " " to refer to the top table.
itemIndex is one of the following:
\begin{tabular}{ll} 
itemIndex Value & Returns \\
\hline-2 & Information about the table as a whole. \\
-1 & Information about the Point column \\
\(\geq 0\) & \begin{tabular}{l} 
Information about a column other than the Point column. 0 refers to the first column \\
after the Point column, 1 refers to the second column after the Point column, and so on.
\end{tabular}
\end{tabular}

TableInfo returns " " in the following situations:
- winNameStr is " " and there are no table windows.
- winNameStr is a name but there are no table windows with that name.
- itemIndex not -2 and is out of range for an existing column.

\section*{Details}

If itemIndex is -2 , the returned string describes the table as a whole and contains the following keywords, with a semicolon after each keyword-value pair.
\begin{tabular}{ll} 
Keyword & Information Following Keyword \\
\hline TABLENAME & \begin{tabular}{l} 
The name of the table. \\
HOST
\end{tabular} \\
The host specification of the table's host window if it is a subwindow or " " if \\
it is a top-level table window. \\
COLUMNS & Number of used rows in the table. \\
SELECTION & \begin{tabular}{l} 
Number of used columns in the table including the Point column. \\
A description of the table selection as you would specify it when invoking the \\
ModifyTable operation's selection keyword. \\
An identification of the first visible data cell in the top/left corner of the table \\
in row-column format. The first data cell is at location \(0,0\).
\end{tabular}
\end{tabular}
\begin{tabular}{ll} 
Keyword & Information Following Keyword \\
\hline LASTCELL & \begin{tabular}{l} 
An identification of the last visible data cell in the bottom/right corner of the \\
table in row-column format.
\end{tabular} \\
TARGETCELL & \begin{tabular}{l} 
An identification of the target (highlighted) data cell in row-column format. \\
ENTERING
\end{tabular} \\
\hline
\end{tabular}

If itemIndex is -1 up to but not including the number of used columns to the right of the Point column, the returned string describes the specified column and contains the following keywords, with a semicolon after each keyword-value pair.
\begin{tabular}{|c|c|}
\hline Keyword & Information Following Keyword \\
\hline TABLENAME & The name of the table. \\
\hline HOST & The host specification of the table's host window if it is a subwindow or " " if it is a top-level table window. \\
\hline COLUMNNAME & Name of the column as you would specify it to the Edit operation if you were creating a table showing just the column of interest. \\
\hline TYPE & Column's type which will be one of the following: Unused, Point, Index, Label, Data, RealData, ImagData. "Index" identifies a index column such as the X values of a wave. "Label" identifies a column of dimension labels. "Data" identifies a data column of a scalar wave. RealData and ImagData identify a real or imaginary column of a complex wave. \\
\hline INDEX & Column's position. -1 refers to the Point column, 0 to the first data column, and so on. \\
\hline DATATYPE & Numeric data type of the wave or zero for text waves. See WaveType for a definition of data type codes. \\
\hline WAVE & A full data folder path to the wave displayed in the column or " " for the Point column. \\
\hline COLUMNS & The total number of columns in the table from the wave for the column for which you are getting information. This can be used to skip over all of the columns of a multidimensional wave. \\
\hline HDIM & The wave dimension displayed horizontally as you move from one column to the next. 0 means rows, 1 means columns, 2 means layers, 3 means chunks. \\
\hline VDIM & The wave dimension displayed vertically in the column. 0 means rows, 1 means columns, 2 means layers, 3 means chunks. \\
\hline TITLE & As specified for the ModifyTable operation's title keyword. \\
\hline WIDTH & Column's width in points. \\
\hline FORMAT & As specified for the ModifyTable operation's format keyword. \\
\hline DIGITS & As specified for the ModifyTable operation's digits keyword. \\
\hline SIGDIGITS & As specified for the ModifyTable operation's sigDigits keyword. \\
\hline TRAILINGZEROS & As specified for the ModifyTable operation's trailingZeros keyword. \\
\hline SHOWFRACSECONDS & As specified for the ModifyTable operation's showFracSeconds keyword. \\
\hline FONT & The name of the column's font. \\
\hline SIZE & Column's font size. \\
\hline STYLE & As specified for the ModifyTable operation's style keyword. \\
\hline
\end{tabular}
\begin{tabular}{ll} 
Keyword & Information Following Keyword \\
\hline ALIGNMENT & \(0=\) left, \(1=\) center, \(2=\) right. \\
RGB & The column's color in R,G,B format. \\
ELEMENTS & As specified for the ModifyTable operation's elements keyword.
\end{tabular}

\section*{Examples}

This example makes the table's target cell advance by one position within the range of selected cells each time it is called. To try it, create a table, select a range of cells and then run the function using the Macros menu.
```

Menu "Macros"
"Test/1", /Q, AdvanceTargetCell("")
End
Function AdvanceTargetCell(tableName)
String tableName // Name of table or "" for top table.
String info = TableInfo(tableName, -2)
if (strlen(info) == 0)
return-1 // No such table
endif
String selectionInfo
selectionInfo = StringByKey("SELECTION", info)
Variable fRow, fCol, lRow, lCol, tROw, tCol
sscanf selectionInfo, "%d,%d,%d,%d,%d,%d", fRow, fCol, lRow, lCol, tRow, tCol
tCol += 1
if (tCol > lCol)
tCol = fCol
tRow += 1
if (tRow > lRow)
tROW = fROw
endif
endif
ModifyTable selection=(-1, -1, -1, -1, tRow, tCol)
End

```

\section*{See Also}

The ModifyTable operation.
Tag
Tag [flags] [traceOrAxisName, xAttach [, textStr]]
The Tag operation puts a tag on the target or named graph window or subwindow. A tag is an annotation that is attached to a particular point on a trace, image, waterfall plot, or axis in a graph.

\section*{Parameters}
traceOrAxisName is an optional trace or axis name. A trace name can be optionally followed by the \# character and an instance number in order to distinguish multiple instances of the same wave in a graph. It identifies the trace or image to which the tag is to be attached. An axis name can be one of the standard axis names (Bottom, Top, Left, or Right) or a user-defined custom axis name.
A string containing traceOrAxisName must be used with the \(\$\) operator to specify traceOrAxisName.
\(x\) Attach is the X value of the point on the trace to which the tag is to be attached. For a multidimensional image, it is the linear index into the matrix array. For an axis, \(x\) Attach can be the X or Y point depending on the particular axis to which the tag is attached; specifying NaN for \(x\) Attach will center the tag on the axis. textStr is the text that is to appear in the tag.

\section*{Flags}
\begin{tabular}{lll} 
/A=anchorCode & \multicolumn{2}{l}{ Specifies position of tag anchor point. anchorCode is a literal, not a string. } \\
& LT & left top \\
LC & left center \\
& LB & left bottom \\
MT & middle top \\
MC & middle center (default) \\
MB & middle bottom \\
RT & right top \\
RC & right center \\
RB & right bottom
\end{tabular}

The anchor point is on the tag itself. Any line or arrow drawn from the tag to the wave starts at the tag's anchor point. The anchor point also determines the precise spot on the tag which represents its position.
\(/ \mathrm{AO}=a 0 \quad\) Sets the text's auto-orientation mode. A non-zero \(a 0\) value overrides the \(/ \mathrm{O}\) value. /AO is for trace tags only. Setting /AO for any other kind of annotation has no effect.
An auto-oriented tag's text rotates whenever it is redrawn, usually when the underlying data changes, the graph is resized, or when the tag is attached to a new point.

The values for ao are:
\(a 0=0: \quad\) No auto-orientation. Use the /O value (default).
\(a o=1: \quad\) Tangent to the trace line at the attachment point.
\(a o=2: \quad\) Tangent to the trace line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.
\(a o=3: \quad\) Perpendicular to the trace line.
\(a o=4\) : Perpendicular to the trace line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.
\(/ \mathrm{B}=(r, g, b) \quad\) Sets color of the tag's background. \(r, g\), and \(b\) specify the amount of red, green, and blue as an integer from 0 to 65535.
\(/ \mathrm{B}=b \quad\) Controls the tag background.
\(b=0\) : Opaque background.
\(b=1\) : Transparent background.
\(b=2\) : \(\quad\) Same background as the graph plot area background.
\(b=3\) : \(\quad\) Same background as the window background.
/C Changes the existing tag.
/F=frame Controls the tag frame.
frame=0: No frame.
frame=1: Underline frame.
frame=2: Box frame.
\(/ \mathrm{G}=(r, g, b) \quad\) Sets color of the text in the tag. \(r, g\), and \(b\) specify the amount of red, green, and blue as an integer from 0 to 65535 .

\section*{/H=legendSymbolWidth}
legendSymbolWidth sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.
\begin{tabular}{|c|c|c|}
\hline \multirow[t]{3}{*}{\(/ \mathrm{I}=i\)} & \multicolumn{2}{|l|}{Controls the tag visibility.} \\
\hline & \(i=1\) : & Tag will be invisi attachment point esthetically pleas drag the tag back \\
\hline & \(i=0\) : & Tag will always extreme edge of \\
\hline /K & \multicolumn{2}{|l|}{Kills existing tag.} \\
\hline \multirow[t]{6}{*}{/L=line} & \multicolumn{2}{|l|}{Controls the line attaching the tag to the tagged point.} \\
\hline & line=0: & No line from tag to \\
\hline & line=1: & Line connecting tag \\
\hline & line=2: & Line with arrow p \\
\hline & line=3: & Line with arrow p \\
\hline & line=4: & Line with arrows \\
\hline /LS= linespace & \multicolumn{2}{|l|}{Specifies a tweak to the normal line spacing where linespace is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.} \\
\hline \multirow[t]{2}{*}{/M [=sameSize]} & \multicolumn{2}{|l|}{\(/ M\) or \(/ M=1\) specifies that legend markers should be the same size as the marker in the graph.} \\
\hline & \multicolumn{2}{|l|}{\(/ M=0\) turns same-size mode off so that the size of the marker in the legend is based on text size.} \\
\hline / \(\mathrm{N}=\) name & Specifie & name of the tag to c \\
\hline \multirow[t]{3}{*}{\(/ \mathrm{O}=r o t\)} & \multicolumn{2}{|l|}{Sets the text's rotation. rot is in (integer) degrees, counterclockwise and must be a number from -360 to 360 .} \\
\hline & \multicolumn{2}{|l|}{0 is normal horizontal left-to-right text, 90 is vertical bottom-to-top text.} \\
\hline & \multicolumn{2}{|l|}{If the tag is attached to a trace (not an image or axis), any non-zero / AO value will overwrite this rotation value.} \\
\hline / \(\mathrm{P}=\) tipOffset & Sets the tagging. it autom & fsset from the tip of Offset is a positive ically chooses an a \\
\hline \multirow[t]{3}{*}{/Q[=contourInstance]} & \multicolumn{2}{|l|}{Associates a tag with a particular contour level trace in a graph recreation macro. Of interest mainly to hard-core programmers.} \\
\hline & \multicolumn{2}{|l|}{When "=contourInstance" is present, / Q associates the tag with the contour wave. Igor will feel free to change or delete the tag, as appropriate, when it recalculates the contour (because you changed the contour data or appearance, the graph size or the axis range). contourInstance is a contour instance name, such as zWave or zWave\#1 if you have the same wave contoured twice in the graph.} \\
\hline & \multicolumn{2}{|l|}{/Q by itself, with "=contourInstance" not present, disassociates the tag from the contour wave. Igor will no longer modify or delete the tag (unless the contour level to which it is attached is deleted). If you manually tweak a contour label, using the Modify Annotation dialog, Igor uses this flag.} \\
\hline /R=newName & \multicolumn{2}{|l|}{Renames the tag.} \\
\hline \multirow[t]{5}{*}{/S=style} & \multicolumn{2}{|l|}{Controls the tag frame style.} \\
\hline & style=0: & Single frame. \\
\hline & style=1: & Double frame. \\
\hline & style=2: & Triple frame. \\
\hline & style=3: & Shadow frame. \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline /T=tabSpec & tabSpec is a single number in points, such as /T=72, for evenly spaced tabs or a list of tab stops in points such as \(/ \mathrm{T}=\{50,150,225\}\). \\
\hline \multirow[t]{10}{*}{/TL=extLineSpec} & Specifies extended tag line parameters similar to the SetDrawEnv arrow settings. extLineSpec \(=\{\) keyword \(=\) value, \(\ldots\}\) or zero to turn off all extended specifications. \\
\hline & Valid keyword-value pairs are: \\
\hline & len=l Length of arrow head in points (l=0 for auto). \\
\hline & fat \(=f \quad\) Width to length ratio of arrow head (default is 0.5 same as \(f=0\) ). \\
\hline & style \(=s \quad\) Sets barb side mode (see SetDrawEnv astyle for values). \\
\hline & shar \(=s \quad\) Sets sharpness between -1 and 1 (default is 0; blunt). \\
\hline & frame \(=f \quad\) Sets frame thickness in outline mode. \\
\hline & lThick \(=l \quad\) Sets line thickness in points (default is 0.5 for \(l=0\) ). \\
\hline & line \(\mathrm{RGB}=(r, g, b)\) Sets color for lines. Default is all zeros (black); the same as the tag frame. \\
\hline & \[
\begin{array}{ll}
\text { dash=d } & \begin{array}{l}
\text { Specifies dash pattern number between } 0 \text { and } 17 \text { (see } \\
\text { SetDashPattern for patterns). }
\end{array}
\end{array}
\] \\
\hline \multirow[t]{2}{*}{/W=winName} & Operates on the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. \\
\hline & When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy. \\
\hline \multirow[t]{3}{*}{\(/ \mathrm{V}=\) vis} & Controls annotation visibility. \\
\hline & \[
\begin{array}{ll}
\text { vis=0: } & \text { Invisible annotation; not selectable. The annotation is still listed } \\
\text { in AnnotationList. }
\end{array}
\] \\
\hline & vis=1: Visible annotation (default). \\
\hline \(/ \mathrm{X}=x \mathrm{Offset}\) & Distance from point to tag as percentage of graph width. For axis tags, the offsets are proportional to the size of the text used for the axis labels. \\
\hline \(/ \mathrm{Y}=y\) Offset & Distance from point to tag as percentage of graph height. For axis tags, the offsets are proportional to the size of the text used for the axis labels. \\
\hline \multirow[t]{3}{*}{/Z=freeze} & Controls freezing of tag position. \\
\hline & freeze=1: Freezes tag position (you can't move it with the mouse). \\
\hline & freeze \(=0\) : Unfreezes it. \\
\hline
\end{tabular}

\section*{Details}

If the /C flag is used, it must be the first flag in the command and must be followed immediately by the / \(\mathrm{N}=\) name flag.
If the /K flag is used, it must be the first flag in the command and must be followed immediately by the / \(\mathrm{N}=\) name flag with no further flags or parameters.
traceOrAxisName, \(x\) Attach, and textStr are all optional. If traceOrAxisName is specified, then \(x\) Attach must be specified, and vice versa. textStr may be specified only if traceOrAxisName and \(x\) Attach are specified.
This syntax allows changes to the tag to be made through the flags parameters without needing to respecify the other parameters. Similarly, the tag's attachment point can be changed without needing to respecify the textStr parameter.
\(x\) Attach is in terms of the wave's X scaling. If traceOrAxisName is displayed as an XY pair, we recommend that you use "point scaling" for the waves, so that \(x\) Attach can be a point number (because \(x\) Attach will not be an \(X\) axis value).
A tag can have at most 100 lines.

\section*{Annotation Escape Codes}
textStr can contain the following escape codes which affect subsequent characters in string.
Note: These escape codes contain backslashes, which must themselves be preceded with another backslash in literal text. These are automatically inserted by the Add Annotation dialog, but must be manually added when writing a procedure or in the command line. See the discussion in the TextBox operation about backslashes in textStr.

The characters "<??>" in a tag indicate that you specified an invalid escape code or used a font that is not available.
The escape codes are:
\begin{tabular}{|c|c|}
\hline \B & Use subscript (smaller type). \\
\hline \(\backslash\) F'fontName' & Use specified font (e.g., \F'Helvetica'). \\
\hline \multirow[t]{7}{*}{\(\backslash \mathrm{f} d \mathrm{~d}\)} & \(d d\) is a bitwise parameter with each bit controlling one aspect of the font style as follows: \\
\hline & Bit 0: Bold. \\
\hline & Bit 1: Italic. \\
\hline & Bit 2: Underline. \\
\hline & Bit 3: Outline (Macintosh only). \\
\hline & Bit 4: Shadow (Macintosh only). \\
\hline & For example, bold underline is \(2^{0}+2^{2}=1+4=5\). See Setting Bit Parameters on page IV-12 for details about bit settings. \\
\hline \(\backslash \mathrm{JR}\) & Right aligned text. \\
\hline \JC & Center aligned text. \\
\hline \(\backslash \mathrm{JL}\) & Left aligned text. \\
\hline \(\backslash \mathrm{K}(r, g, b)\) & Use specified color for text. \(r, g\), and \(b\) are integers from 0 to 65535. \\
\hline \(\backslash \mathrm{M}\) & Use normal (main) script (reverts to main line and size). \\
\hline \multicolumn{2}{|l|}{\\$PICT\$name=pictName\$/PICT\$} \\
\hline & Inserts specified picture. pictName can be a ProcPict or the name of a picture as listed in the Pictures dialog (Misc menu). This is useful for inserting fancy math expressions created by another program. Available in new graphics only (see Graphics Technology on page III-423). \\
\hline \(\backslash\) S & Use superscript (uses smaller type). \\
\hline \(\backslash\) sa+dd & Adds extra space above line. \(d d\) is two digits in units of half points (1/144 inch). Can go anywhere in a line. \\
\hline \sa-dd & Reduces space above line. \(d d\) is two digits in units of half points ( \(1 / 144\) inch). Can go anywhere in a line. \\
\hline \(\backslash \mathrm{sb}+d d\) & Adds extra space below line. \(d d\) is two digits in units of half points (1/144 inch). Can go anywhere in a line. \\
\hline \(\backslash \mathrm{sb}-\mathrm{dd}\) & Reduces space below line. \(d d\) is two digits in units of half points (1/144 inch). Can go anywhere in a line. \\
\hline \(\backslash\) Znn & Use font size \(n n\) ( \(n n\) must be exactly two digits). \\
\hline \(\ \mathrm{Zr} n n n\) & \(n n n\) is a 3 digit percentage by which to change the current font size. ( \(n n n\) must be exactly three digits). \\
\hline
\end{tabular}
textStr can also contain escape codes to manipulate text info variables (see About Text Info Variables on page III-66).

When specifying an axis tag, you can also use additional dynamic escape codes that are available with the Label operation.
textStr can also contain the following escape codes which insert dynamically computed substrings:
\begin{tabular}{ll}
\(\backslash \mathrm{ON}\) & Inserts name of wave to which tag is attached. \\
\(\backslash \mathrm{On}\) & Inserts name of trace and its instance number, if greater than 0. \\
\(\backslash \mathrm{OP}\) & Inserts point number to which tag is attached. \\
\(\backslash \mathrm{OX}\) & Inserts X value of point to which tag is attached (xAttach). \\
\(\backslash \mathrm{OY}\) & Inserts Y value of point to which tag is attached. \\
\(\backslash \mathrm{OZ}\) & \begin{tabular}{l} 
Inserts Z value of point to which tag is attached for contour level traces. Inserts NaN \\
for other traces.
\end{tabular} \\
\(\backslash\{d y n T e x t\}\) & \begin{tabular}{l} 
dynText is dynamically evaluated text, which is discussed below.
\end{tabular}
\end{tabular}

Dynamically evaluated text (dynText) may contain numeric and string expressions. Igor automatically reevaluates dynText when a numeric or string variable or wave referenced in dynText changes.

Note: When used in dynText expressions, user-defined numeric and string variables in macros or functions must be declared as global variables for the expression to evaluate correctly.
dynText can take two forms, an easy one for a single numeric expression and a more complex form that provides precise control over the formatting of the result.
The easy form is:
\\{numeric-expression\} }
This evaluates the expression and prints with generic ("\%g") formatting.
The full form is:
```

\{formatStr, list-of-numeric-or-string-expressions}
formatStr and list-of-numeric-or-string-expressions are treated as for printf.

```

As an aid in typing the expressions, Igor considers carriage returns between the braces to be equivalent to spaces. Rather than typing (in the Add Annotation dialog):
```

\{"twice K0 is %g, and today is %s",2*K0,date()}

```
you can type:
\\{ }
    "twice KO is \%g, and today is \%s",
    2*KO,
    date()
\}

Carriage returns can be typed directly in the Add Annotations dialog, or they can be typed as " \(\backslash \mathrm{r}\) " in a macro, function or the command line. Since \(\backslash r\) is not a tag escape sequence, only one backslash is needed. See the examples.

\section*{Examples}

Tag \(/ \mathrm{C} / \mathrm{N}=\mathrm{t} 1 / \mathrm{X}=25 / \mathrm{Y}=50\)
moves the tag named t 1 to the location defined by \(\mathrm{X}=25\) and \(\mathrm{Y}=50\).
Tag/C/N=t1 wave1, 50
moves the tag named t 1 to wave1 at \(\mathrm{x}=50\).
Tag/N=t2 wave1, 50,"\\JC\\\{numpnts(wave1)\} points \(\backslash\) rin this wave"
creates a new tag on wave1 that looks like this:

Tag w, 0,"\\\{\"\%g is first, \%g is last \(\backslash\) " \(\backslash r w[0], w[n u m p n t s(w)-1]\} "\)
creates a new tag on w that looks like this:
0 is first, 31.75 is last

Observe how the " \(\backslash \mathrm{r}\) " in the textStr breaks the annotation text by examining the Modify Annotation dialog:

Following is an example of various ways in which axis tags can be used:
Make/O jack=sin (x/8)
SetScale x,0,14e9,"y" jack
Display jack
Label bottom "\\u\#2" // turn off default axis label
ModifyGraph axOffset (bottom) \(=1.16667 / /\) make room for tag (manual adustment)
Tag/N=text0/F=0/A=MT/X=0.20/Y=-4.29/L=0 bottom, Nan, "\\JCTime (\\U) \r2nd line"
// now a few "important location" tags...
Tag/N=text1/F=0/A=LB/X=1.20/Y=3.00 bottom, 0, "Big Bang"
Tag \(/ \mathrm{N}=\operatorname{text} 2 / \mathrm{F}=0 / \mathrm{A}=\mathrm{MB} / \mathrm{X}=0.00 / \mathrm{Y}=2.86\) bottom, 8000000000 , "Earth formed"
\(\mathrm{Tag} / \mathrm{N}=\operatorname{text} 3 / \mathrm{F}=0 / \mathrm{A}=\mathrm{RB} / \mathrm{X}=-0.80 / \mathrm{Y}=4.71\) bottom, 13040000000 , "Dinosaurs ruled"

TagVal, TagWaveRef, Legend, TextBox, AppendText, AnnotationInfo, AnnotationList.
See About Text Info Variables on page III-66 for textStr escape codes that manipulate text info variables and see the discussion in the TextBox operation about backslashes in textStr. The AppendText operation. For an explanation of graphing XY pairs, and \(X\) versus point scaling, see Chapter II-5, Waves.

For additional axis tag escape codes see the Label operation and Axis Labels on page II-284.
Trace Names on page II-243, Programming With Trace Names on page IV-72.

\section*{TagVal}

TagVal (code)
TagVal is a very specialized function that is only valid when called from within the text of a tag as part of a \(\backslash\}\) dynamic text escape sequence. It returns a number reflecting some property of the tag and helps you to display information about the tagged wave. The property is selected by the code parameter:
\begin{tabular}{|c|c|}
\hline code & Return Value \\
\hline 0 & Similar to \OP, returns the tag attach point number. \\
\hline 1 & Similar to \(\backslash O X\), returns the \(X\) coordinate of tag attachment in the graph. When a tag is attached to an XY pair of traces, the X coordinate will most likely be different than the tag's X scaling attachment value specified in the Tag command. \\
\hline 2 & Similar to \(\backslash \mathrm{OY}\), returns the Y coordinate of tag attachment in the graph or the Y axis value in a Waterfall plot. \\
\hline 3 & Similar to \(\backslash O Z\), returns the \(Z\) coordinate of tag attachment in a contour, image, or Waterfall plot. \\
\hline 4 & Similar to \(\backslash \mathrm{Ox}\), returns the trace x offset. \\
\hline 5 & Similar to \Oy, returns the trace y offset. \\
\hline 6 & Returns the X muloffset (with the not set value 0 translated to 1 ). \\
\hline 7 & Returns the Y muloffset (with the not set value 0 translated to 1 ). \\
\hline
\end{tabular}

Because TagVal returns a numeric value, the result can be formatted any way you wish using the printf formatting codes. In contrast, the \(\backslash O\) codes insert preformatted text, and you don't have control over the format.
TagVal is sometimes used in conjunction with the TagWaveRef function. For example, you might write a user-defined function that calculates a value as a function of a wave and a point number.

\section*{Examples}

Tag wave0, 0, "Y value is \\\{\"\%g\", TagVal(2)\}"
Tag wave0, 0, "Y value is \(\backslash \backslash\{\backslash " \% g \backslash ", T a g W a v e R e f()[T a g V a l(0)]\} "\)
Tag wave0, 0, "Y value is \\OY"
These examples all produce identical results.

\section*{See Also}

The Tag operation, the TagWaveRef function.
For a discussion of wave references, see Wave Reference Functions on page IV-177.

\section*{TagWaveRef}

\section*{TagWaveRef ()}

TagWaveRef is a very specialized function that is only valid when called from within the text of a tag as part of a \(\backslash\}\) dynamic text escape sequence. It returns a wave reference to the wave that the tag is on and helps you to display information about the tagged wave. It is often used in conjunction with the TagVal function. You can pass the result of TagWaveRef to any function that takes a Wave parameter.

\section*{Examples}

Show the name of the data folder containing the tagged wave:
Tag wave0, 0,"\\ON is in \(\backslash \backslash\{\backslash " \% s \backslash ", G e t W a v e s D a t a F o l d e r(T a g W a v e R e f(), 0)\} "\)

\section*{See Also}

The Tag operation, the TagVal function
For a discussion of wave references, see Wave Reference Functions on page IV-177.

\section*{tan}
\(\tan (\) angle)
The tan function returns the tangent of angle which is in radians.
In complex expressions, angle is complex, and \(\tan\) (angle) returns a complex value:
\[
\tan (x+i y)=\frac{\sin (x+i y)}{\cos (x+i y)}=\frac{\sin (2 x)+i \sinh (2 y)}{\cos (2 x)+\cosh (2 y)}
\]

\section*{See Also}
atan, atan2, sin, cos, sec, csc, cot

\section*{tanh}
tanh (num)
The tanh function returns the hyperbolic tangent of num:
\[
\tanh (x)=\frac{e^{x}-e^{-x}}{e^{x}+e^{-x}}
\]

In complex expressions, num is complex, and \(\tanh (\) num \()\) returns a complex value.

\author{
See Also \\ sinh, cosh, coth
}

\section*{TextBox}

TextBox [flags] [textStr]
The TextBox operation puts a textbox on the target or named graph window. A textbox is an annotation that is not associated with any particular trace.

\section*{Parameters}
textStr is the text that is to appear in the textbox. It is optional.

\section*{Flags}
/ \(\mathrm{A}=\) anchorCode \(\quad\) Specifies position of textbox anchor point.
\begin{tabular}{llllll}
\multicolumn{5}{l}{ anchorCode } & Position \\
& & & anchorCode & Position \\
\cline { 1 - 2 } LT & left top & & RT & right top \\
LC & left center & & RC & right center \\
LB & left bottom & & RB & right bottom \\
MT & middle top & & \\
MC & middle center & & \\
MB & middle bottom & &
\end{tabular}
anchorCode is a literal, not a string.
For interior textboxes, the anchor point is on the rectangular edge of the plot area of the graph window (where the left, bottom, right, and top axes are drawn).
For exterior textboxes, the anchor point is on the rectangular edge of the entire graph window.
\(/ \mathrm{B}=(r, g, b) \quad\) Sets the color of the tag's background. \(r, g\), and \(b\) specify the amount of red, green, and blue as an integer from 0 to 65535.
\(/ \mathrm{B}=b \quad\) Controls the textbox background.
\(b=0\) : Opaque background.
\(b=1\) : \(\quad\) Transparent background.
\(b=2\) : \(\quad\) Same background as the graph plot area background.
\(b=3\) : \(\quad\) Same background as the window background.
/C Changes existing textbox.
/D=\{thickMult [, shadowThick [, haloThick]]\}
thickMult multiplies the normal frame thickness of a text-box. The thickness may be set using just / \(\mathrm{D}=\) thickMult.
shadowThick, if present, overrides Igor's normal shadow thickness. It is in units of fractional points.
haloThick governs the annotation's halo thickness (a surrounding band of the annotation's background color), which can be -1 to 10 points wide.

The default haloThick value is -1 , which preserves the behavior of previous versions of Igor where the halo of all annotations was set by the global variable root:V_TBBufZone. Any negative value of haloThick (-0.5, for example) will be overridden by V_TBBufZone if it exists, otherwise the absolute value of haloThick will be used. A zero or positive value overrides V_TBBufZone.

Any of the parameters may be missing. To set haloThick to 0 without changing other parameters, use \(/ D=\{, 0\}\).
\begin{tabular}{|c|c|}
\hline \multirow[t]{2}{*}{/E[=exterior \(]\)} & /E or \(/ \mathrm{E}=1\) forces textbox (or legend) to be exterior to graph (provided anchorCode is not MC) and pushes the graph margins away from the anchor edge(s). \(/ E=2\) also forces exterior mode but does not push the margins. \\
\hline & / \(\mathrm{E}=0\) returns it to the default (an "interior textbox" which can be anywhere in the graph window). \\
\hline \multirow[t]{4}{*}{/F=frame} & Controls the textbox frame. \\
\hline & frame=0: No frame. \\
\hline & frame=1: Underline frame. \\
\hline & frame=2: Box frame. \\
\hline \(/ \mathrm{G}=(r, g, b)\) & Sets color of the text in the tag. \(r, g\), and \(b\) specify the amount of red, green, and blue as an integer from 0 to 65535 . \\
\hline \multicolumn{2}{|l|}{/H=legendSymbolWidth} \\
\hline & legendSymbolWidth sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width. \\
\hline /K & Kills existing textbox. \\
\hline /LS= linespace & Specifies a tweak to the normal line spacing where linespace is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line. \\
\hline \multirow[t]{2}{*}{/M[=sameSize]} & \(/ M\) or \(/ M=1\) specifies that legend markers should be the same size as the marker in the graph. \\
\hline & \(/ M=0\) turns same-size mode off so that the size of the marker in the legend is based on text size. \\
\hline / \(\mathrm{N}=\) name & Specifies the name of the textbox to change or create. \\
\hline \multirow[t]{2}{*}{\(/ \mathrm{O}=r o t\)} & Sets the text's rotation. rot is in (integer) degrees, counterclockwise and must be a number from -360 to 360 . \\
\hline & 0 is normal horizontal left-to-right text, 90 is vertical bottom-to-top text. \\
\hline /R=newName & Renames the textbox. \\
\hline \multirow[t]{5}{*}{/S=style} & Controls the textbox frame style. \\
\hline & style=0: \(\quad\) Single frame. \\
\hline & style=1: Double frame. \\
\hline & style=2: \(\quad\) Triple frame. \\
\hline & style=3: Shadow frame. \\
\hline /T=tabSpec & tabSpec is a single number in points, such as \(/ T=72\), for evenly spaced tabs or a list of tab stops in points such as \(/ \mathrm{T}=\{50,150,225\}\). \\
\hline \multirow[t]{3}{*}{\(/ \mathrm{V}=\) vis} & Controls annotation visibility. \\
\hline & vis=0: Invisible annotation; not selectable. The annotation is still listed in AnnotationList. \\
\hline & \(v i s=1: \quad\) Visible annotation (default). \\
\hline \multirow[t]{2}{*}{/W=winName} & Operates in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. \\
\hline & When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy. \\
\hline
\end{tabular}
\begin{tabular}{ll}
\(/ X=x O f f s e t\) & \begin{tabular}{l} 
For interior textboxes \(x O f f s e t\) is the distance from anchor to textbox as a percentage of \\
the plot area width. \\
For exterior textboxes \(x O f f s e t ~ i s ~ t h e ~ d i s t a n c e ~ f r o m ~ a n c h o r ~ t o ~ t e x t b o x ~ a s ~ a ~ p e r c e n t a g e ~ o f ~\) \\
the graph window width. See /E and /A.
\end{tabular} \\
\(/ \mathrm{Y}=y O\) Ofset & \begin{tabular}{l}
\(y O f f s e t\) is the distance from anchor to textbox as a percentage of the plot area height \\
(interior textboxes) or graph window height (exterior textboxes). See /E and /A.
\end{tabular} \\
\(/ \mathrm{Z=freeze}\) & \begin{tabular}{l} 
Controls freezing of textbox position. \\
freeze=1: Freezes textbox position (you can't move it with the mouse). \\
freeze=0: Unfreezes it.
\end{tabular}
\end{tabular}

\section*{Details}

Use the optional /W=winName flag to specify a specific graph or layout window. When used on the command line or in a Macro, Proc, or Window procedure, /W must precede all other flags.
If the /C flag is used, it must be the first flag in the command (except that if may follow an initial \(/ \mathrm{W}\) ) and must be followed immediately by the \(/ \mathrm{N}=\) name flag.
If the /K flag is used, it must be the first flag in the command (or follow an initial \(/ \mathrm{W}\) ) and must be followed immediately by the / \(\mathrm{N}=\) name flag with no further flags or parameters.
textStr is optional. If missing, the textbox text is unchanged. This allows changes to the textbox to be made through the flags without changing the text.
A textbox can have at most 100 lines.
textStr can contain the following escape codes which affect subsequent characters in string. See Notes about Backslashes.
The characters "<??>" in a textbox indicate that you specified an invalid escape code or used a font that is not available.
The escape codes are:
\begin{tabular}{|c|c|}
\hline \[<digit> & Store info variable. \\
\hline \]<digit> & Recall info variable. \\
\hline \(\backslash \mathrm{B}\) & Use subscript (in smaller type above baseline). \\
\hline \(\backslash\) F'fontName' & Use specified font (e.g., \F'Helvetica'). \\
\hline \multirow[t]{7}{*}{\(\backslash \mathrm{fdd}\)} & \(d d\) is a bitwise parameter with each bit controlling one aspect of the font style as follows: \\
\hline & Bit 0: Bold. \\
\hline & Bit 1: Italic. \\
\hline & Bit 2: Underline. \\
\hline & Bit 3: Outline (Macintosh only). \\
\hline & Bit 4: Shadow (Macintosh only). \\
\hline & For example, bold underline is \(2^{0}+2^{2}=1+4=5\). See Setting Bit Parameters on page IV-12 for details about bit settings. \\
\hline \(\backslash \mathrm{JR}\) & Right align text. \\
\hline \JC & Center align text. \\
\hline \JL & Left align text. \\
\hline \multirow[t]{2}{*}{\(\backslash \mathrm{K}(r, g, b)\)} & Use specified color for text. \(r, g\), and \(b\) are integers from 0 to 65535. \\
\hline & \(\backslash K\) also sets the marker fill color for markers added by \(\backslash W\). For setting the marker stroke color, use \(\backslash \mathrm{k}\). \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline \(\backslash \mathrm{k}(r, g, b)\) & Use specified color for marker stroke (line color). \(r, g\), and \(b\) are integers from 0 to 65535. Use before \Wtdd to change marker stroke color from the default of black ( \(0,0,0\) ). \\
\hline & For setting the marker fill color for markers added by \W, use \(\backslash \mathrm{K}\). \\
\hline \(\backslash\) Ldtss & Draws a line from x position specified in text info variable \(d\) to the current \(\times\) position. Uses current text color. Thickness is encoded by digit \(t\) with values of \(4,5,6\) and 7 giving \(0.25,0.5,1.0\) and 1.5 pt . Line style is specified by 2 digit number \(s s\). \\
\hline \M & Use normal (main) script (reverts to main line and size). \\
\hline \S & Use superscript (in smaller type below baseline). \\
\hline \Wtdd & Draws a marker symbol using current font size and color. \\
\hline & The marker outline thickness is specified by the one-digit number \(t\) with \(1,4,5\) and 6 giving \(0.0,0.25,0.5\) and 1.0 point. A \(t\) value of 1 , which sets the outline thickness to zero, is useful only for filled markers as it makes unfilled markers disappear. \\
\hline & The marker symbol number is specified by the two-digit number \(d d\). \\
\hline & Use \(\backslash \mathrm{k}\) to set the marker stroke color. Use \(\backslash \mathrm{K}\) to set the marker fill color. \\
\hline \ \(\mathrm{X}<\) digit> & Recall X position. \\
\hline \(\ \mathrm{x}+\mathrm{dd}\) & Moves X position right by \(2^{*} d d\) percent of the current font max width. \\
\hline \x-dd & Moves X position left by \(2^{*} d d\) percent of the current font max width. \\
\hline \ \(\mathrm{<}\) <digit> & Recall Y position. \\
\hline \(\backslash \mathrm{y}+\mathrm{dd}\) & Moves Y position up by \(2^{*} d d\) percent of the current font height. \\
\hline \y-dd & Moves Y position down by \(2^{*} d d\) percent of the current font height. \\
\hline \(\backslash\) Znn & Use font size \(n n\) ( \(n n\) must be exactly two digits). \\
\hline \(\\) Zrnnn & \(n n n\) is a 3 digit percentage by which to change the current font size. ( \(n n n\) must be exactly three digits). \\
\hline
\end{tabular}
textStr can also contain escape codes to manipulate text info variables (see About Text Info Variables on page III-66).
textStr can also contain the following escape code which inserts the symbol used to display the named wave: \s(traceName)
\s is mainly used in Legends, where legend symbols are automatically created and removed, but it can also be used in Tags, Textboxes, and axis labels where the symbol is updated, but not automatically added or removed. See Freezing the Legend Text on page III-55.
textStr can also contain an escape code which inserts dynamically evaluated text:
\(\backslash\{d y n T e x t\}\)
Dynamically evaluated text (dynText) may contain numeric and string expressions. Igor automatically reevaluates dynText when a numeric or string variable or wave referenced in dynText changes.
Note: When used in dynText expressions, user-defined numeric and string variables in macros or functions must be declared as global variables for the expression to evaluate correctly.
dynText can take two forms, an easy one for a single numeric expression and a more complex form that provides precise control over the formatting of the result.
The easy form is:
\\{numeric-expression\} }
This evaluates the expression and prints with generic ("\%g") formatting.
The full form is:
\\{formatStr, list-of-numeric-or-string-expressions\} }
formatStr and list-of-numeric-or-string-expressions are treated as for printf.
As an aid in typing the expressions, Igor considers carriage returns between the braces to be equivalent to spaces. Rather than typing (in the Add Annotation dialog):
\(\backslash\{" t w i c e ~ K 0\) is \(\% g\), and today is \%s", 2*K0, date() \}
you can type:
\\{ }
"twice KO is \%g, and today is \%s",
2*K0,
date()
\}
These carriage returns can be typed directly in the Add Annotations dialog, or be typed as " \(\backslash \mathrm{r}\) " in a macro, function or the command line.

\section*{Notes about Backslashes}

Each backslash character in textStr must be preceded by another backslash when it appears in literal text a procedure or on the command line. This is because backslash is itself a special escape character for strings. Future versions of Igor may require this double-backslash syntax; currently Igor accepts either the single or double backslash as synonyms for inserting a single backslash into a string.
For example:
String myStr = "\\OK"
Print myStr
Prints the following in the history area:
\ok
myStr contains a single backslash character. See Escape Characters in Strings on page IV-13 for more about the backslash character. This behavior affects how escape sequences in textStr should be written:
TextBox/C/N=text0 "\Z14Bigger" // no: Future Igors may see "Z14Bigger"
TextBox/C/N=text0 "\\Z14Bigger" // yes
TextBox/C/N=text0 "first line\rsecond line // carriage return uses one \}
Since \(\backslash r\) (carriage return) is not a textbox escape sequence, only one backslash is needed.
You can see how backslashes in textStr should be entered by using the Add Annotation dialog and observing the command it creates. You will observe many double backslash sequences. Single backslash sequences were used by Igor 1.2, which Igor Pro currently accepts for backward compatibility reasons.

\section*{Examples}

TextBox/C/N=t1/X=25/Y=50
moves the textbox named t 1 to the location defined by \(\mathrm{X}=25\) and \(\mathrm{Y}=50\).
TextBox/C/N=t1 "New Text"
changes the text for t 1 .

\section*{See Also}

Legend, Tag, AppendText, AnnotationInfo, AnnotationList.
See About Text Info Variables on page III-66 for textStr escape codes that manipulate text info variables.
See the discussion above in Notes about Backslashes and Escape Characters in Strings on page IV-13 for still more about the backslash character.

See the printf operation for formatting codes used in formatStr.
Trace Names on page II-243, Programming With Trace Names on page IV-72.

\section*{TextFile}

TextFile (pathName, index [, creatorStr])
Note: \(\quad\) TextFile is antiquated. Use IndexedFile instead.
The TextFile function returns a string containing the name of the indexth TEXT file from the folder specified by pathName.
On Macintosh, TextFile returns only files whose file type property is TEXT, regardless of the file's extension.

On Windows, Igor considers files with ".txt" extensions to be of type TEXT.

\section*{Details}

TextFile returns an empty string (" ") if there is no such file.
pathName is the name of an Igor symbolic path; it is not a string.
index starts from zero.
creatorStr is an optional string argument containing four characters such as "IGR0". Only files of the specified Macintosh creator code are indexed. Set creatorStr to "? ? ? ?" to index all text files (or omit the argument altogether). This argument is ignored on Windows systems.
The order of files in a folder is determined by the operating system.

\section*{Examples}

You can use TextFile in a procedure to sequence through each TEXT file in a folder, put the name of the text file into a string variable, and use this string variable as a parameter to the LoadWave or Open operations:
```

Function/S PrintFirstLineOfTextFiles(pathName)
String pathName // Name of an Igor symbolic path.
Variable refNum, index
String str, fileName
index = 0
do
fileName = TextFile($pathName, index)
        if (strlen(fileName) == 0)
            break // No more files
        endif
        Open/R/P=$pathName refNum as fileName
FReadLine refNum, str // Read first line including CR/LF
Print fileName +":" + str // Print file name and first line
Close refNum
index += 1 // Next file
while (1)
End

```

\section*{See Also}
```

See the IndexedFile function, which is similar to TextFile but works on files of any type, and also
IndexedDir. Also see the LoadWave and Open the operations.

```

\section*{ThreadGroupCreate}

\section*{ThreadGroupCreate (nt)}

The ThreadGroupCreate function creates a thread group containing \(n t\) threads and returns a thread ID number. Use the number of computer processors for \(n t\) when trying to improve computation speed using parallel threads. A background worker might use just one thread regardless of the number of processors.

\section*{See Also}

ThreadSafe Functions on page IV-87 and ThreadSafe Functions and Multitasking on page IV-295.

\section*{ThreadGroupGetDF}

\section*{ThreadGroupGetDF (tgID, waitms)}

For use with Igor Pro 6.20 or later, ThreadGroupGetDFR should be used instead of ThreadGroupGetDF which causes memory leaks.
The ThreadGroupGetDF function retrieves a data folder path string from a thread group queue and removes the data folder from the queue.
When called from a preemptive thread it returns a data folder from the thread group's input queue. When called from the main thread it returns a data folder from the thread group's output queue.
\(\operatorname{tgID}\) is a thread group ID returned by ThreadGroupCreate. You can pass 0 for \(\operatorname{tgID}\) when calling ThreadGroupGetDF from a preemptive thread. You must pass a valid thread group ID when calling ThreadGroupGetDF from the main thread.
waitms is the maximum number of milliseconds to wait for a data folder to become available in the queue.
Pass 0 to test if a data folder is available immediately. Pass INF to wait indefinitely or until a user abort.

ThreadGroupGetDF returns "" if the timeout period specified by waitms expires and no data folder is available in the queue.
See Also
ThreadSafe Functions on page IV-87 and ThreadSafe Functions and Multitasking on page IV-295. The ThreadGroupGetDFR function.

\section*{ThreadGroupGetDFR}

\section*{ThreadGroupGetDFR(tgID, waitms)}

The ThreadGroupGetDF function retrieves a data folder reference from a thread group queue and removes the data folder from the queue. The data folder becomes a free data folder.
When called from a preemptive thread it returns a data folder from the thread group's input queue. When called from the main thread it returns a data folder from the thread group's output queue.
\(\operatorname{tgID}\) is a thread group ID returned by ThreadGroupCreate. You can pass 0 for \(\operatorname{tgID}\) when calling ThreadGroupGetDFR from a preemptive thread. You must pass a valid thread group ID when calling ThreadGroupGetDFR from the main thread.
waitms is the maximum number of milliseconds to wait for a data folder to become available in the queue. Pass 0 to test if a data folder is available immediately. Pass INF to wait indefinitely or until a user abort.
ThreadGroupGetDFR returns a NULL data folder reference if the timeout period specified by waitms expires and no data folder is available in the queue. You can test for NULL using DataFolderRefStatus. ThreadGroupGetDFR was added in Igor Pro 6.20.

See Also
ThreadSafe Functions on page IV-87, ThreadSafe Functions and Multitasking on page IV-295 and Free Data Folders on page IV-79.

\section*{ThreadGroupPutDF}

ThreadGroupPutDF tgID, datafolder
The ThreadGroupPutDF operation posts data to a preemptive thread group.

\section*{Parameters}
tgID is thread group ID returned by ThreadGroupCreate, datafolder is the data folder you wish to send to the thread group.
datafolder can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

\section*{Details}

When you call it from the main thread, ThreadGroupPutDF removes datafolder from the main thread's data hierarchy and posts to the input queue of the thread group specified by \(\operatorname{tgID}\).
When you call it from a preemptive thread, use 0 for \(\operatorname{tgID}\) and the data folder will be posted to the output queue of thread group to which thread belongs.
Input and output data folders may be retrieved from the queues by calling the string function
ThreadGroupGetDF or ThreadGroupGetDFR. If your code is to run on Igor Pro 6.20 or later only, use ThreadGroupGetDFR.

Warning: Take care not to use any stale WAVE, NVAR, or SVAR variables that might contain references to objects in the data folder. Use WAVEClear on all WAVE reference variables that might contain references to waves that are in the data folder being posted before calling ThreadGroupPutDF. An error will occur if any waves in the data folder are in use or referenced in a WAVE variable.

Warning: Any DFREF variables that refer to the data folder (or any child thereof) must be cleared prior to executing this command. You can clear a DFREF using dfr=\$" ".

From the standpoint of the source thread, ThreadGroupPutDF is conceptually similar to KillDataFolder and, like KillDataFolder, if the current data folder is within datafolder, the current data folder is set to the parent of datafolder. You can not pass root : as datafolder.

\section*{See Also}

The ThreadGroupCreate function, ThreadSafe Functions on page IV-87, and ThreadSafe Functions and Multitasking on page IV-295.

\section*{ThreadGroupRelease}

\section*{ThreadGroupRelease (tgID)}

The ThreadGroupRelease function releases thread group (and tgID is no longer valid). \(\operatorname{tgID}\) is the thread group ID returned by ThreadGroupCreate.
If threads are still running, they are killed. An attempt is made to safely stop running threads but, if they continue to run, they will be force quit.
ThreadGroupRelease returns zero if successful, - 1 if an error occurred (probably invalid \(\operatorname{tgID}\) ), or -2 if a force quit was needed. In the latter case, you should restart Igor Pro.
Any data folders remaining in the group's input or output queues will be discarded.

\section*{See Also}

The ThreadGroupCreate function, ThreadSafe Functions on page IV-87, and ThreadSafe Functions and Multitasking on page IV-295.

\section*{ThreadGroupWait}

ThreadGroupWait(tgID, waitms)
The ThreadGroupWait function returns index +1 of the first thread found still running after waitms milliseconds or returns zero if all are done.
tgID is the thread group ID returned by ThreadGroupCreate and waitms is milliseconds to wait.
If any of the threads of the group encountered a runtime error, the first such error will be reported now.
Use zero for waitms to just test or provide a large value to cause the main thread to sleep until the threads are finished. You can use INF to wait forever or until a user abort. If you know the maximum time the threads should take, you can use that value so you can print an error message or take other action if the threads don't return in time.
When ThreadGroupWait is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling ThreadReturnValue.
Prior to Igor Pro 6.23, ThreadGroupWait did not update the thread return value for thread i until threads 0 to i-1 were finished. As of Igor Pro 6.23, ThreadGroupWait updates the internal state of all threads in the group.

\section*{Finding a Free Thread}

In Igor Pro 6.23 and later, if you pass -2 for waitms, ThreadGroupWait returns index+1 of the first free (not running) thread or 0 if all threads in the group are running.
This allows you to dispatch a thread anytime a free thread is available. See Parallel Processing - Thread-at-a-Time Method on page IV-298 for an example.

\section*{See Also}

The ThreadGroupCreate function, ThreadSafe Functions on page IV-87, and ThreadSafe Functions and Multitasking on page IV-295.

\section*{ThreadProcessorCount}

ThreadProcessorCount
The ThreadProcessorCount function returns the number of processors in your computer. For example, on a Macintosh Core Duo, it would return 2.

\section*{ThreadReturnValue}

ThreadReturnValue (tgID, index)
The ThreadReturnValue function returns the value that the specified thread function returned when it exited. Returns NAN if thread is still running. \(\operatorname{tgID}\) is the thread group ID returned by ThreadGroupCreate and index is the thread number.
When ThreadGroupWait is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling ThreadReturnValue.

\section*{See Also}

The ThreadGroupCreate function, ThreadSafe Functions on page IV-87, and ThreadSafe Functions and Multitasking on page IV-295.

\section*{ThreadSafe}

ThreadSafe Function funcName()
The ThreadSafe keyword declaration specifies that a user function can be used for preemptive multitasking background tasks on multiprocessor computer systems.
A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads. Such functions are generally limited to numeric or utility functions. Functions that access windows are not ThreadSafe. To determine if an operation is ThreadSafe, use the Command Help tab of the Help Browser and choose ThreadSafe from the pop-up menu.
ThreadSafe functions can call other ThreadSafe functions but may not call non-ThreadSafe functions. NonThreadSafe functions can call ThreadSafe functions.

\section*{See Also}

ThreadSafe Functions on page IV-87 and ThreadSafe Functions and Multitasking on page IV-295.

\section*{ThreadStart}

ThreadStart tgID, index, WorkerFunc (param1, param2,...)
The ThreadStart operation starts the specified function running in a preemptive thread.

\section*{Parameters}
\(\operatorname{tgID}\) is thread group ID returned by ThreadGroupCreate, index is the desired thread of the group to set up to execute the specified ThreadSafe WorkerFunc.

\section*{Details}

The worker function starts running immediately.
The worker function must be defined as ThreadSafe and must return a real or complex numeric result.
The worker function's return value can be obtained after the function finishes by calling
ThreadReturnValue. Igor records the fact that a thread has terminated when you call ThreadGroupWait so you must call ThreadGroupWait before calling ThreadReturnValue.
The worker function can take variable and wave parameters. It can not take pass-by-reference parameters or data folder reference parameters.
Any waves you pass to the worker are accessible to both the main thread and to your preemptive thread. Such waves are marked as being in use by a thread and Igor will refuse to perform any manipulations that could change the size of the wave.

\section*{See Also}

The ThreadGroupCreate and ThreadReturnValue functions; ThreadSafe Functions on page IV-87, and ThreadSafe Functions and Multitasking on page IV-295.

\section*{ticks}

\section*{ticks}

The ticks function returns the number of ticks (approximately \(1 / 60\) second) elapsed since the operating system was initialized.

\section*{See Also}

The stopMSTimer function.
Tile
Tile [flags] [objectName [, objectName]...]
The Tile operation tiles the specified objects in the top page layout.

\section*{Parameters}
objectName is the name of a graph, table, picture or annotation object in the top page layout.

\section*{Flags}
\begin{tabular}{ll}
\(/ \mathrm{A}=(\) rows, cols \()\) & Specifies number of rows/columns in which to tile objects. \\
\(/ \mathrm{G}=\) grout & \begin{tabular}{l} 
Specifies grout, the spacing between window tiles, in prevailing coordinates (points \\
unless preceded by \(/ \mathrm{I}, / \mathrm{M}\) or \(/ \mathrm{R})\).
\end{tabular} \\
\(/ \mathrm{I}\) & Specifies coordinates in inches. \\
\(/ \mathrm{M}\) & Specifies coordinates in centimeters. \\
\(/ \mathrm{O}=\) objTypes & Adds objects of type(s) specified by bitwise mask to list of objects to be tiled: \\
& Bit \(0: \quad\) Tile graphs. \\
& Bit 1: \(\quad\) Tile tables. \\
& Bit 3: \(\quad\) Tile pictures. \\
& Bit \(5:\) \\
& Tile textboxes.
\end{tabular}

See Setting Bit Parameters on page IV-12 for details about bit settings.
/R Specifies coordinates measured in percent of the printable page.
/S Adds selected objects to objects to be tiled.
/W=(left,top,right,bottom)
Specifies page layout area in which to tile objects. Coordinates are in points unless /I, /M or /R are specified before /W.

\section*{Details}

If \(/ \mathrm{A}=(\) rows,cols \()\) is not used, Tile uses an appropriate number of rows and columns. If \(/ \mathrm{A}=(\) rows, cols \()\) is used, objects are tiled in a grid of that many rows and columns. If rows or cols is zero, it substitutes an appropriate number for the zero parameter.
Objects to be tiled are determined by the \(/ \mathrm{S}\) and \(/ \mathrm{O}=\) objTypes flags and by any objectNames.
If no /S or /O flags are present and there are no objectNames, then all objects in the layout are tiled.
Otherwise the objects to be tiled are determined as follows:
- All objectNames are tiled.
- If the /S flag is present, the selected objects (if any) are also tiled.
- If the \(/ \mathrm{O}=\) objTypes flag is present then any objects specified by objTypes are also tiled. objTypes is a bitwise mask, so \(/ \mathrm{O}=3\) tiles both graphs and tables.

\section*{See Also}

The Stack operation.

\section*{TileWindows}

TileWindows [flags] [windowName [, windowName]...]
The TileWindows operation tiles the specified windows on the desktop (Macintosh) or in the Igor frame window (Windows).

\section*{Flags}
/A=(rows,cols) Specifies number of rows/columns in which to tile windows.
/C Adds the command window to the windows to be tiled.
\(/ \mathrm{G}=\) grout \(\quad\) Specifies grout, the spacing between tiles, in prevailing units (points unless \(/ \mathrm{I}\) or \(/ \mathrm{M}\) are used).
/I Specifies coordinates in inches.
/M Specifies coordinates in centimeters.
\(/ \mathrm{O}=\) objTypes \(\quad\) Adds windows of types specified by objTypes to windows to be tiled.
objTypes is a bitwise mask where:
Bit 0: Graphs.
Bit 1: Tables.
Bit 2: Page layouts.
Bit 4: Notebooks.
Bit 6: Control panels.
Bit 7: Procedure windows.
Bit 9: Help windows.
Bit 12: XOP target windows.
Other bits should always be zero. See Setting Bit Parameters on page IV-12 for details about bit settings.
/P Adds the main procedure window to the windows to be tiled.
\(/ \mathrm{R} \quad\) Specifies coordinates measured as \(\%\) of tiling rectangle.
/W=(left,top,right,bottom)
Specifies tiling rectangle on the screen. Coordinates are in points unless /I, /M, or /R are specified before /W.

\section*{Details}

The windows to be tiled are determined by the \(/ \mathrm{C}, / \mathrm{P}\), and \(/ \mathrm{O}=o b j T y p e s\) flags and by the windowNames. If no /C, /P or /O flags are present and there is no windowNames then all windows are tiled.
Otherwise the windows to be tiled are determined as follows:
- All named windows are tiled.
- If the /C flag is present, the command window is also tiled.
- If the /P flag is present, the procedure window is also tiled.
- If the \(/ \mathrm{O}=o b j\) Types flag is present, any windows specified by objTypes are also tiled.

\section*{Examples}

To tile all the procedure windows, including the main one, use:
TileWindows/P/O=128
// 2^7=128

\section*{See Also}

The StackWindows operation.

\section*{time}
time ()
The time function returns a string containing the current time. The empty parentheses are required.

\section*{See Also}

The date, date2secs and DateTime functions.

\section*{TitleBox}

TitleBox [/Z] ctrlName [keyword = value [, keyword = value ...]]
The TitleBox operation creates the named title box in the target window.
For information about the state or status of the control, use the ControlInfo operation.
Parameters
ctrlName is the name of the TitleBox control to be created or changed.
The following keyword=value parameters are supported:
anchor= \(h v \quad\) Specifies the anchor mode using a two letter code, \(h v . h\) may be L, M, or R for left, middle, and right. \(v\) may be T, C, or B for top, center and bottom. Default is LT.

If fixedSize=1, the anchor code sets the positioning of text within the frame.
appearance \(=\{\) kind \([\), platform \(]\}\)
Sets the appearance of the control. platform is optional. Both parameters are names, not strings.
kind can be one of default, native, or os9.
platform can be one of Mac, Win, or All.
See Button and DefaultGUIControls for more appearance details.
disable \(=d \quad\) Sets user editability of the control.
\(d=0\) : Normal.
\(d=1\) : \(\quad\) Hide.
\(d=2\) : \(\quad\) Draw in gray state.
fColor \(=(r, g, b) \quad\) Sets color of the titlebox. \(r, g\), and \(b\) are integers from 0 to 65535.
fixedSize \(=f \quad\) Controls title box sizing:
\(f=0: \quad\) The titlebox automatically sizes itself to fit the title text (default).
\(f=1\) : \(\quad\) The size settings are honored, and the titlebox does not automatically size itself to fit the title text.
font="fontName" Sets the font used for the control, e.g., font="Helvetica".
frame \(=f \quad\) Sets frame style:
\(f=0: \quad\) No frame.
\(f=1: \quad\) Default (same as \(f=3\) ).
\(f=2\) : \(\quad\) Simple box.
\(f=3: \quad\) 3D sunken frame.
\(f=4: \quad\) 3D raised frame.
\(f=5: \quad\) Text well.
fsize \(=s \quad\) Sets font size.
fstyle \(=f s\)
\(f_{s}\) is a bitwise parameter with each bit controlling one aspect of the font style as follows:
Bit 0: Bold.
Bit 1: Italic.
Bit 2: Underline.
Bit 3: \(\quad\) Outline (Macintosh only).
Bit 4: \(\quad\) Shadow (Macintosh only).
See Setting Bit Parameters on page IV-12 for details about bit settings.
labelBack \(=(r, g, b)\) or 0
Sets background color for title box. \(r, g\), and \(b\) are integers from 0 to 65535. If not set (or labelBack \(=0\) ), then background is transparent (not erased).
pos \(=\{l e f t, t o p\} \quad\) Sets the location of the top left corner in pixels.
pos \(+=\{d x, d y\} \quad\) Offsets the position of the control in pixels.
size \(=\{w, h\} \quad\) Set the width and height in pixels.
title=titleStr Sets text of title box to titleStr. Limited to 63 characters.
variable \(=\) svar \(\quad\) Specifies an optional global string variable from which to get the TitleBox text.
win=winName Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Flags}
/Z No error reporting.

\section*{Details}

The text can come from either the title=titleStr or variable=svar method. Whichever is used last is the current method. The maximum length of text with the title=titleStr method is 100 characters while the variable=svar method has no limit.
The text can contain escape codes to create fancy results with multiple lines, font changes etc. The escape codes are essentially the same as those for the TextBox operation. The easiest way to generate fancy text is to create a dummy TextBox, set up the text as desired and then click the To Cmd Line button followed by editing of the command line.
By default, the titlebox automatically resizes itself relative to the anchor point on the rectangle that encloses the text. Therefore you can specify a size of 0,0 along with a pos value in order to place the anchor point at the desired position. When fixedSize \(=1\) is used, the titlebox does not resize itself and instead honors the values specified via the size keyword.
TitleBoxes can be used not only for titles but also as status or results readout areas, especially in conjunction with the variable= svar mode. When using a titlebox like this, you may find it useful to use fixedSize=1 so that the titlebox doesn't change size as the text changes.

\section*{Examples}

NewPanel /W=(94,72,459,294)
DrawLine 150,32,150,140
DrawLine 70,100,213,100 // draw crossing lines at 150,100
// illustrate a default box
TitleBox tbl,title="A title box 1 rwith 2 lines", pos \(=\{150,100\}\)
// Move center to 150,100
TitleBox tb1, \(\operatorname{pos}=\{150,100\}\), size \(=\{0,0\}\), anchor \(=M C\)
// Set background color and therfore opaque mode
TitleBox tb1,labelBack=(55000,55000,65000)
```

// Now a few frame styles. Run these one at a time
TitleBox tb1,frame= 0 // no frame
TitleBox tbl,frame= 2 // plain frame
TitleBox tbl,frame= 3 // 3D sunken
TitleBox tbl,frame= 4 // 3D raised
TitleBox tbl,frame= 5 // text well
// Now some fancy text...
TitleBox tbl,frame= 1 // back to default (3D raised)

TitleBox tb1,title= "\Z18\[020 log<br>B10<br>M| [1 + 2K(jwt) + (jwt)<br>S2<br>M]|<br>S-1"
// Create a string variable and hook up to the TitleBox
String sl= "text from a string variable"
TitleBox tbl,variable=sl
// Change string variable contents \& note automatic update of TitleBox
s1= "something new"

```

\section*{See Also}

The TextBox operation for additional text formatting escape codes and the ControlInfo operation for information about the control. Chapter III-14, Controls and Control Panels, for details about control panels and controls. The GetUserData operation for retrieving named user data.

\section*{ToCommandLine}

\section*{ToCommandLine commandsStr}

The ToCommandLine operation sends command text to the command line without executing the command(s).
The intended usage is for user-created panel windows with "To Cmd Line" buttons that are mimicking built-in Igor dialogs. You'll usually want to use Execute, instead.

\section*{Parameters}
commandsStr
The text of one or more commands.

\section*{Details}

To send more than one line of commands, separate the commands with " \(\backslash\) r" characters.
Note: ToCommandLine does not work when typed on the command line; use it only in a Macro, Proc, or Function.

\section*{Examples}
```

Macro CmdPanel()
PauseUpdate; Silent 1
NewPanel /W=(150,50,430,229)
Button toCmdLine, pos={39,148}, size={103,20},title="To Cmd Line"
Button toCmdLine,proc=ToCmdLineButtonProc
End
Function ToCmdLineButtonProc(ctrlName) : ButtonControl
String ctrlName
String cmd="MyFunction(xin,yin,\"YResult\")"// line 1: generate results
cmd +="\rDisplay yOutput vs wx as \"results\"" // line 2: display results
ToCommandLine cmd
End

```

\section*{See Also}

The Execute and DoIgorMenu operations.

\section*{ToolsGrid}

ToolsGrid [/W=winName] keyword = value [, keyword = value ...]
The ToolsGrid operation controls the grid you can use for laying out draw or control objects.

\section*{Parameters}

ToolsGrid can accept multiple keyword = value parameters on one line.
snap \(=n \quad\) Turns snap to grid on \((n=1)\) or off \((n=0)\).
visible \(=n\)
grid=( \(x y 0, d x y, n d i v)\) Defines both X and Y grids where \(n d i v\) is the number of subdivisions between major grid lines and \(x y 0\) and \(d x y\) define the origin and spacing. Units are in points.
grid \(\mathrm{x}=(x 0, d x, n d i v) \quad\) Defines the X grid where \(n d i v\) is the number of subdivisions between major grid lines and \(x 0\) and \(d x\) define the origin and spacing. Units are in points.
gridy \(=(y 0, d y, n d i v) \quad\) Defines the Y grid where \(n d i v\) is the number of subdivisions between major grid lines and \(y 0\) and \(d y\) define the origin and spacing. Units are in points.

\section*{Flags}
/W=winName

Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

\section*{Details}

The default grid is 1 inch with 8 subdivisions. The grid is visible only in draw or selector mode and appears in front of the currently active draw layer.

\section*{TraceFromPixel}

TraceFromPixel (xpixel, ypixel, optionsString)
The TraceFromPixel function returns a string based on an attempt to hit test the provided \(X\) and \(Y\) coordinates. Used to determine if the mouse was clicked on a trace in a graph.
When a trace is found, TraceFromPixel returns a string containing the following KEY: value ; pairs:
TRACE: tracename
HITPOINT: pnt
tracename will be quoted if necessary and may contain instance notation. pnt is the point number index into the trace's wave when the hit was detected. If a trace is not found near the coordinate point, a zero length string is returned.

\section*{Parameters}
xpixel and ypixel are the X and Y pixel coordinates.
optionsString can contain the following:
WINDOW : winName;
PREF: traceName;
ONLY: traceName;
DELTAX: \(d x ;\) DELTAY: \(d y\);
Use the WINDOW option to hit test in a graph other than the top graph. Use the ONLY option to search only for a special target trace. If the PREF option is used then the search will start with the specified trace but if no hit is detected, it will go on to the others.

When identifying a subwindow with WINDOW : winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
The DELTAX and DELTAY values must both be specified to alter the region that Igor searches for traces. The \(d x\) and \(d y\) values are in pixels and the region searched is the rectangle from \(x\) pixel- \(d x\) to \(x p i x e l+d x\) and ypixel-dy to ypixel+dy.
If DELTAX or DELTAY are omitted, the search region depends on whether PREF or ONLY are specified. If either are specified then Igor first searches for the trace using \(d x=3\) and \(d y=3\). If the trace is not identified, Igor searches again using \(d x=6\) and \(d y=6\). If the trace is still not identified, Igor gives up and returns a zerolength result string.
If neither PREF nor ONLY are specified then Igor uses tries \(3,6,12\), and 24 for \(d x\) and \(d y\) until it finds a trace or gives up and returns a zero-length result string.

\section*{See Also}

The NumberByKey, StringByKey, AxisValFromPixel, and PixelFromAxisVal functions.
ModifyGraph (traces) and Instance Notation on page IV-16 for discussions of trace names and instance notation.

Trace Names on page II-243, Programming With Trace Names on page IV-72.

\section*{TraceInfo}

TraceInfo(graphNameStr, ywavenameStr, instance)
The TraceInfo function returns a string containing a semicolon-separated list of information about the trace in the named graph window or subwindow.

\section*{Parameters}
graphNameStr can be " " to refer to the top graph.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
\(y\) WaveNameStr is either the name of a wave containing data displayed as a trace in the named graph, or a trace name (wave name with "\#n" appended to distinguish the nth image of the wave in the graph). You might get a trace name from the TraceNameList function.
If \(y\) WaveNameStr contains a wave name, instance identifies which trace of \(y\) WaveNameStr you want information about. instance is usually 0 because there is normally only one instance of a given wave displayed in a graph. Set instance to 1 for information about the second trace of the wave named by \(y\) WaveNameStr, etc. If \(y\) WaveNameStr is " ", then information is returned on the instanceth trace in the graph.
If \(y\) WaveNameStr is a trace name, and instance is zero, the instance is extracted from \(y\) WaveNameStr. If instance is greater than zero, the wave name is extracted from \(y\) WaveNameStr, and information is returned concerning the instanceth instance of the wave.

\section*{Details}

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:
\begin{tabular}{|c|c|}
\hline Keyword & Information Following Keyword \\
\hline AXISFLAGS & Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults. \\
\hline AXISZ & Z value of a contour level trace or NaN if the trace is not a contour trace. \\
\hline ERRORBARS & The ErrorBars command for the trace, as it would appear in the recreation macro (without the beginning tab character). \\
\hline RECREATION & \begin{tabular}{l}
List of keyword commands as used by ModifyGraph command. The format of these keyword commands is: \\
keyword \((\mathrm{x})=\) modifyParameters;
\end{tabular} \\
\hline XAXIS & \(X\) axis name. \\
\hline XRANGE & \begin{tabular}{l}
Point subrange of the trace's X data wave in "[startPoint, pendPoint : increment]" format. \\
Note: Unlike the actual syntax of a trace subrange specification where increment is preceded by a semicolon character, here it is preceded by a colon character to preserve the notion that semicolon is what separates the keyword-value groups. \\
If the entire \(X\) wave is displayed (the usual case), the XRANGE value is " \([\text { * }]^{\text {" }}\). \\
If an \(X\) wave is not used to display the trace, then the XRANGE value is " ".
\end{tabular} \\
\hline XWAVE & \(X\) wave name if any, else blank. \\
\hline XWAVEDF & Full path to the data folder containing the \(X\) wave or blank if no \(X\) wave. \\
\hline YAXIS & Y axis name. \\
\hline YRANGE & Point subrange of the trace's Y data wave or "[*]". \\
\hline
\end{tabular}

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the ";", prepend "ModifyGraph ", replace the "x" with the name of a trace ("data\# 1 " for instance) and then Execute the resultant string as a command.

Note: The syntax of any subrange specifications in the RECREATION information are modified in the same way as for XRANGE and YRANGE. Currently only the zColor, zmrkSize, and zmrkNum keywords might have a subrange specification.

\section*{Examples}

This example shows how to extract a string value from the keyword-value list returned by TraceInfo:
String YAxisName= StringByKey("YAXIS", TraceInfo("","",0))
This example shows how to extract a subrange and put the semicolon back:
```

String yRange= StringByKey("YRANGE", TraceInfo("","",0))
Print yRange // prints "[30,40:2]"
yRange= ReplaceString(":", yRange, ";")
Print yRange // prints "[30,40;2]"

```

The next example shows the trace information for the second instance of the wave "data" (which has an instance number of 1) displayed in the top graph:
```

Make/O data=x;Display/L/T data,data // two instances of data: 0 and 1
Print TraceInfo("","data",1)[0,64] // error if you try to print all
Print TraceInfo("","data",1) [65,128]
Prints the following in the history area:

```
```

XWAVE:;YAXIS:left;XAXIS:top;AXISFLAGS:/T;AXISZ:NAN (255);XWAVEDF:;

```
XWAVE:;YAXIS:left;XAXIS:top;AXISFLAGS:/T;AXISZ:NAN (255);XWAVEDF:;
RECREATION:zColor (x)=0;zmrkSize (x)=0;zmrkNum(x)=0;textMarker (x)=
```

Following is a function that returns the marker code from the given instance of a named wave in the top graph. This example uses the convenient GetNumFromModifyStr() function provided by the \#include <Readback ModifyStr> procedures, which are useful for parsing strings returned by TraceInfo.
\#include <Readback ModifyStr>
Function MarkerOfWave (wv,instance)
Wave wv
Variable instance
Variable marker
String info = TraceInfo("",NameOfWave (wv), instance)
marker = GetNumFromModifyStr(info,"marker", " ", 0)
return marker
End

## See Also

Trace Names on page II-243, Programming With Trace Names on page IV-72.
The Execute operation.

## TraceNameList

TraceNameList(graphNameStr, separatorStr, optionsFlag)
The TraceNameList function returns a string containing a list of trace names in the graph window or subwindow identified by graphNameStr.

## Parameters

graphNameStr can be " " to refer to the top graph window.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
The parameter separatorStr should contain a single character such as "," or ";" to separate the names.

## Details

The bits of optionsFlag have the following meanings:
See Setting Bit Parameters on page IV-12 for details about bit settings.

| Bit Number | Bit Value | Meaning |
| :--- | :--- | :--- |
| 0 | 1 | Include normal graph traces |
| 1 | 2 | Include contour traces |
| 2 | 4 | Omit hidden traces (the default is to list even hidden traces) |

A trace name is defined as the name of the $Y$ wave that defines the trace with an optional \#ddd suffix that distinguishes between two or more traces that have the same wave name. Since the trace name has to be parsed, it is quoted if necessary.
Commands that take a trace name as a parameter or in a keyword can use a string containing a trace name with the \$ operator to specify traceName. For instance, to change the display mode of a wave, you might use

```
ModifyGraph mode(myWave#1)=3
but
String myTraceName="myWave#1"
ModifyGraph mode($myTraceName)=3
will also work.
```

## Examples

Make/O jack,'jack \# 2';Display jack,jack,'jack \# 2','jack \# 2'
Print TraceNameList("",";",1)
Prints: jack;jack\#1;'jack \# 2';'jack \# 2'\#1;
// Generate a list of hidden traces
Make/O jack,jill,joy;Display jack,jill,joy
ModifyGraph hideTrace (joy)=1// hide joy
// (hidden + visible) - visible = hidden
String visibleTraces=TraceNameList("",";",1+4)// only visible normal traces
String allNormalTraces=TraceNameList("",";",1)// hidden + visible normal traces
String hiddenTraces= RemoveFromList(visibleTraces,allNormalTraces)
Print hiddenTraces
// Prints: joy;

For other commands related to waves and traces: WaveRefIndexed, XWaveRefFromTrace, TraceNameToWaveRef, CsrWaveRef, and CsrXWaveRef.

For a description of traces: ModifyGraph. For a discussion of contour traces: All About Contour Traces on page II-334.
For commands referencing other waves in a graph: ImageNameList, ImageNameToWaveRef, ContourNameList, and ContourNameToWaveRef.
ModifyGraph (traces) and Instance Notation on page IV-16 for discussions of trace names and instance notation.

## TraceNameToWaveRef

TraceNameToWaveRef (graphNameStr, traceNameStr)
The TraceNameToWaveRef function returns a wave reference to the $Y$ wave corresponding to the given trace in the graph window or subwindow named by graphNameStr.

## Parameters

graphNameStr can be " " to refer to the top graph window.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
The trace is identified by the string in traceNameStr, which could be a string determined using
TraceNameList. Note that the same trace name can refer to different waves in different graphs.
Use Instance Notation (see page IV-16) to choose from traces in a graph that represent waves of the same name. For example, if traceNameStr is "myWave\#2", it refers to the third instance of wave "myWave" in the graph ("myWave\#0" or just "myWave" is the first instance).

## Triangulate3D

Triangulate3D [/OUT=format] srcWave
The Triangulate3D operation creates a Delaunay "triangulation" of a 3D scatter wave. The output is a list of tetrahedra that completely span the convex volume defined by srcWave. Triangulate3D can also generate the triangulation needed for performing 3D interpolation for the same domain. Normally srcWave is a triplet wave (a 2D wave of 3 columns), but can use any 2D wave that has more than 3 columns (the operation ignores all but the first 3 columns).

## Flags

/OUT=format Specifies how to save the output triangulation data.
format=1: Default; saves the triangulation result in the wave M_3DVertexList, which contains in each row, indices to rows in srcWave that describe the $\mathrm{X}, \mathrm{Y}, \mathrm{Z}$ coordinates of a single tetrahedral vertex. Each tetrahedron is described by one row in M_3DVertexList.
format=2: Saves the triangulation result in the wave M_TetraPath, which is a triplet path wave describing the tetrahedra edges. For each tetrahedron, there are four rows (triangles) separated by row of NaNs. The total number of rows in M_TetraPath is 20 times the number of tetrahedra in the triangulation.
format=4: Saves a wave containing internal diagnostic information generated during the triangulation process.

## Details

Triangulate3D implements Watson's algorithm for tetrahedralization of a set of points in three dimensions. It starts by creating a very large tetrahedron which inscribes all the data points followed by a sequential insertion of one datum at a time. With each new datum the algorithm finds the tetrahedron in which the datum falls. It then proceeds to subdivide the tetrahedron so that the datum becomes a vertex of new tetrahedra.
The algorithm suffers from two known problems. First, it may, due to numerical instabilities, result in tetrahedra that are too thin. You can get around this problem by introducing a slight random perturbation in the input wave. For example:

```
srcWave+=enoise (amp)
```

Here amp is chosen so that it is much smaller than the smallest cartesian distance between two input points.
The second problem has to do with memory allocations which may exhaust available memory for some pathological spatial distributions of data points. The operation reports both problems in the history window.

## Examples

```
Make/O/N=(10,3) ddd=gnoise(5) // create random 10 points in space
Triangulate3d/out=2 ddd
// now display the triangulation in Gizmo:
Window Gizmo0() : GizmoPlot
    PauseUpdate; Silent 1
    if(exists("NewGizmo") !=4)
            DoAlert 0, "Gizmo XOP must be installed"
            return
    endif
```

```
    NewGizmo/N=Gizmo0 /W=(309,44,642, 373)
    ModifyGizmo startRecMacro
    ModifyGizmo scalingMode=2
    AppendToGizmo Scatter=root:ddd,name=scatter0
    ModifyGizmo ModifyObject=scatter0 property={ scatterColorType,0}
    ModifyGizmo ModifyObject=scatter0 property={ Shape, 2}
    ModifyGizmo ModifyObject=scatter0 property={ size,0.2}
    ModifyGizmo ModifyObject=scatter0 property={ color,0,0,0,1}
    AppendToGizmo Path=root:M_TetraPath, name=path0

## trunc

trunc (num)
The trunc function returns the integer closest to num in the direction of zero.

## See Also

The round, floor, and ceil functions.

## try-catch-endtry

try
<possible abort code>
catch
<code to handle abort>
endtry
A try-catch-endtry flow control statement provides a means for catching and responding to abort conditions in user functions.
When code executes in the try-catch area, any programmatic aborts will immediately jump to code within the catch-endtry area rather than jumping to the end of the user function. Normal flow (no aborts) will skip all code within the catch-endtry area.

## Details

During execution of code in the catch-endtry area, user aborts are suppressed. This means that when the user attempts to abort procedure execution by holding down the appropriate abort key combination, it will not abort the catch code itself.
Whenever an abort occurs, information about the cause of the abort is returned via the V_AbortCode variable as follows:
-4: $\quad$ Abort triggered by AbortOnRTE.
-3: Abort caused by Abort operation.
-2: Stack overflow abort.
-1: User abort.
$>=1: \quad$ Abort triggered by AbortOnValue.

See Also
Flow Control for Aborts on page IV-38 and try-catch-endtry Flow Control on page IV-38 for further details.
The AbortOnRTE and AbortOnValue keywords, and the Abort operation.

## UniqueName

UniqueName (baseName, objectType, startSuffix [, windowNameStr])
The UniqueName function returns the concatenation of baseName and a number such that the result is not in conflict with any other object name.
windowNameStr is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of objectType.

Details
baseName should be an unquoted name, such as you might receive from the user via a dialog or control panel. objectType is one of the following:

1 Wave.
2 Reserved.
3 Numeric variable.
4 String variable.
5 XOP target window.
6 Graph window.
7 Table window.
8 Layout window.

9 Control panel window.
10 Notebook window.
11 Data folder.
12 Symbolic path.
13 Picture.
14 Annotation in the named or topmost graph or layout.
15 Control in the named or topmost graph or panel.
16 Notebook action character in the named or topmost notebook.
startSuffix is the number used as a starting point when generating the numeric suffix that makes the name unique. Normally you should pass zero for startSuffix. If you know that names of the form base0 through baseN are in use, you can make UniqueName run a bit faster by passing $N+1$ as the startSuffix.
The windowNameStr argument is used only with objectTypes 14, 15, and 16 . The returned name is unique only to the window (other windows might have objects with the same name). If a named window is given but does not exist, UniqueName returns baseName startSuffix. windowNameStr is ignored for other objectTypes

## Examples

String uniqueWaveName $=$ UniqueName (baseWaveName, 1, 0)
String uniqueControlName = UniqueName("ctrl", 15, 0, "Panelo")
See Also
CheckName and CleanupName.

## UnPadString

UnPadString(str, padValue)
UnPadString returns str after removing all trailing characters whose value is padValue. This undoes the action of PadString.
UnPadString can be used to recover the values of text waves created with Make/T=size. This is useful for speeding up access to very long text waves. Such waves are set by assigning the output of PadString to their elements.
UnPadString allows for the storage of variable length C strings (padValue of zero) in text waves created with preallocated string sizes.
See Also
The PadString function. The Make operation.

## Unwrap

Unwrap modulus, waveName [, waveName]...
The Unwrap operation scans through each named wave trying to undo the effect of a modulus operation.

## Parameters

modulus is the value applied to the named waves through the mod function as if the command:
waveName $=\bmod (w a v e N a m e, m o d u l u s)$
had been executed. It is this calculation which Unwrap attempts to undo.

## Details

The unwrap operation works with 1D waves only. See ImageUnwrapPhase for phase unwrapping in two dimensions.

## Examples

If you perform an FFT on a wave, the result is a complex wave in rectangular coordinates. You can create a real wave that contains the phase of the result of the FFT with the command:

```
wave2 = imag(r2polar(wave1))
```

However, the rectangular to polar conversion leaves the phase information modulo $2 \pi$. You can restore the phase information with the command:

```
Unwrap 2*pi, wave2
```

Because the first point of a wave that has been FFTed has no phase information, in this example you would precede the Unwrap command with the command:
wave2[0] = wave2[1]

## See Also

The ImageUnwrapPhase operation and mod function.

## UpperStr

Upperstr (str)
The UpperStr function returns a string expression in which all lower-case characters in str are converted to upper-case.

## See Also

The LowerStr function.

## URLDecode

URLDecode (inputStr)
The URLDecode function returns a percent-decoded copy of the percent-encoded string inputStr. It is unlikely that you will need to use this function; it is provided for completeness.
For an explanation of percent-encoding, see Percent Encoding on page IV-245.

## Example

String theURL = "http://google.com?key1=35\%\ larger"
theURL = URLDecode (theURL)
Print theURL
http://google.com?key1=35\% larger

## See Also

URLEncode, URLs on page IV-244.

## URLEncode

## URLEncode (inputStr)

The URLEncode function returns a percent-encoded copy of inputStr.
Percent-encoding is useful when encoding the query part of a URL or when the URL contains special characters that might otherwise be misinterpreted by a web server. For an explanation of percent-encoding, see Percent Encoding on page IV-245.

## Example

String baseURL = "http://google.com"
String keyl = "keyl"
String value1 = URLEncode("35\% larger")
String theURL = ""
sprintf theURL, "\%s?\%s=\%s", baseURL, key1, value1
Print theURL
http://google.com?keyl=35\%\ larger
See Also
URLDecode, URLs on page IV-244.

## ValDisplay

ValDisplay [/Z] ctrlName [keyword = value [, keyword = value ...]]
The ValDisplay operation creates or modifies the named control that displays a numeric value in the target window. The appearance of the control varies; see the Examples section.
For information about the state or status of the control, use the ControlInfo operation.

## Parameters

ctrlName is the name of the ValDisplay control to be created or changed.
The following keyword=value parameters are supported:

```
appearance={kind [, platform]}
```

Sets the appearance of the control. platform is optional. Both parameters are names, not strings.
kind can be one of default, native, or os9.
platform can be one of Mac, Win, or All.
See Button and DefaultGUIControls for more appearance details.
barBackColor $=(r, g, b) \quad$ Sets the background color under the bar (if any). $r, g$, and $b$ range from 0 to 65535.
barBackColor=0 Sets the background color under the bar to the default color, the standard document background color used on the current operating system, which is usually white.
barmisc $=\{l t s$, valwidth $\} \quad$ Sets the "limits text size" and the size of the type showing the bar limits. If lts is zero, the bar limits are not displayed. Otherwise, lts must be between 5 and 100 .
valwidth is the "value readout width". It claims the amount of horizontal space for the numeric part of the display.
If valwidth equals or exceeds the control width available to it, the numeric readout uses all the room, and prevents display of any bar.
If valwidth is zero, there is no numeric readout, and only the bar is displayed.
valwidth can range from zero to 4000, and it defaults to 1000 (which usually leaves no room for the display bar).
bodyWidth=width
Specifies an explicit size for the body (nontitle) portion of a ValDisplay control. By default (bodyWidth=0), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size, or text of the title changes, then the body portion may grow or shrink. If you supply a bodyWidth $>0$, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.

| limitsBackColor=0 | Sets the background color under the limits text to the default color, the standard document background color used on the current operating system, which is usually white. |
| :---: | :---: |
| lowColor=( $r, g, b$ ) | Specifies the bar color when the value is less than base in the limits keyword. $r, g$, and $b$ are integers from 0 to 65535. |
| mode $=m$ | Specifies the type of LED display to use, if any. |
|  | $m=0$ : Bar mode (default). |
|  | $m=1: \quad$ Oval LED. |
|  | $m=2: \quad$ Rectangular LED. |
|  | $m=3$ : Bar mode with no fractional part. |
|  | $m=4$ : Candy-stripe effect for the bar area to support indefinite-style progress windows. The value is taken to be the phase of the candy stripe. When using value = _NUM:n, $n$ is taken as an increment value so you would normally just use 1. Uses the native platform appearance if the high and low colors are left as default. Note native formats may not fill vertical space. See Progress Windows on page IV-138 for an example. |

| pos $=\{l e f t, t o p\}$ | Sets the position of the display in pixels, from 0 to 32767. |
| :---: | :---: |
| pos $+=\{d x, d y\}$ | Offsets the position of the display in pixels. |
| rename=newName | Gives the ValDisplay control a new name. |
| size $=\{$ width,height $\}$ | Sets width and height of display in pixels. width can range from 10 to 200 pixels, height from 5 to 200 pixels. Default width is 50, default height is determined by the numeric readout font size. |
| title=titleStr | Sets title of display to the specified string expression. The title appears to the left of the display. If this title is too long, it won't leave enough room to display the bar or even the numeric readout! Defaults to "" (no title). |
|  | titleStr can contain formatting escape codes in order to create fancy, styled results. The escape codes are the same as used by the TextBox operation. The easiest way to generate fancy text is to make selections from the Insert popup in the ValDisplay Control dialog. |
| value=valExpr | Displays the numeric expression valExpr. It is not a string. |
|  | As of version 6.1, you can use the syntax _NUM:num to specify a numeric value without using a dependency. |
| valueColor= $(r, g, b)$ | Sets the color of the value readout text, if any. $r, g$, and $b$ range from 0 to 65535. valueColor defaults to black $(0,0,0)$. |
| valueBackColor $=(r, g, b)$ | Sets the background color under the value readout text. $r, g$, and $b$ range from 0 to 65535. |
| valueBackColor=0 | Sets the background color under the value readout text to the default color, the standard document background color used on the current operating system, which is usually white. |
| win=winName | Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. |
|  | When identifying a subwindow with winName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy. |
| zeroColor $=(r, g, b)$ | Governs the LED color (in LED mode only). $r, g$, and $b$ are integers from 0 to 65535. Used in conjunction with the limits keyword such that zeroColor determines one endpoint color when base is between low and high, or LED color when the value is less than low. | when the value is less than low.

Flags
/Z No error reporting.

## Details

The target window must be a graph or panel.
The appearance of the ValDisplay control depends primarily on the width and valwidth parameters and the width of the title. Space for the individual elements is allocated from left to right, with the title receiving first priority. If the control width hasn't all been used by the title, then the value display gets either valwidth pixels of room, or what is left. If the control width hasn't been used up, the bar is displayed in the remaining control width:

If you use the bodyWidth keyword, the value readout width and bar width occupy the body width. The total control width is then bodyWidth+title width, and the width from the size keyword is ignored.
The limits values low, high, and base and the value of valExpr control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the base value to an ending position determined by the value of valExpr, low and high. low corresponds to the left side of the bar, and high corresponds to the right. The position that corresponds to the base value is linearly interpolated between low and high.
For example, with low $=-10$, high $=10$, and base $=0$, a valExpr value of 5 will draw from the center of the bar area ( 0 is centered between -10 and 10 ) to the right, halfway from the center to the right of the bar area ( 5 is halfway from 0 to 10):

The valExpr must be executable at any time. The expression is stored and executed when the ValDisplay needs to be updated. However, execution will occur outside the routine that creates the ValDisplay, so you must not use local variables in the expression.
valExpr may be enclosed in quotes and preceded with a \# character (see When Dependencies are Updated on page IV-210) to defer evaluation of the validity of the numeric expression, which may be needed if the expression references as-yet-nonexistent global variables or user-defined functions:
ValDisplay valdispo value=notAVar*2
ValDisplay valdisp0 value=\#"notAVar*2"
// "unknown name or symbol" error
// still not valid, no error
Variable notAVar=3
// now valid; ValDisplay works
In a ValDisplay, the \#" " syntax permits use of a string expression. Normally, the \# prefix signifies that the following text must be a literal quoted string. String expressions are evaluated at runtime to obtain the final expression for the ValDisplay. In other words, there is a level of indirection.

## Examples

Here is a sampling of the various types of ValDisplay controls available:

You can use a ValDisplay to replace the bar mode with a solid color fill designed to look like an LED. Use the mode keyword with mode $=1$ to create an oval LED or mode $=2$ to create a rectangular LED. You can specify different frames with the rectangular LED but only a simple frame is available for the oval mode. Use mode $=0$ to revert to bar mode.
The color and brightness of the LED depends on the value that the ValDisplay is monitoring combined with the limits=\{low, high, base) setting, the two color settings used in bar mode along with a third color (zeroColor) that is used only in LED mode. When the value is between low and high, the color is a linear combination of endpoint colors. If base is between low and high, the endpoint colors are the low color and the zero color, or the zero color and the high color. For values outside the limits, the appropriate limiting color is chosen.
If base is less than the low, the endpoint colors are the low color and the high color. In this case, if the value is less than low the LED takes on the zero color.
You should use the bodyWidth setting in conjunction with LED mode to keep the LED from dramatically changing size or disappearing when the title is changed or if your experiment is moved to a different platform (Macintosh vs PC).
Try the ValDisplay Demo example experiment to see these different modes in action. The experiment file is in your Igor Pro folder, in the "Examples:Feature Demos" subfolder.

## See Also

See ValDisplay on page III-382 for more examples, and the printf operation about formatStr.

Progress Windows on page IV-138 for an example of candy-stripe mode=4.

## Variable

Variable [flags] varName [=numExpr] [, varName [=numExpr]]...
The Variable declaration creates real or complex variables and gives them the specified name.
Flags
/C Declares a complex variable.
/D Obsolete, included only for backward compatibility (see Details).
/G Creates a variable with global scope and overwrites any existing variable.

## Details

The variable is initialized when it is created if you supply the initial value. However, when Variable is used to declare a function parameter, it is an error to attempt to initialize it.

You can create more than one variable at a time by separating the names and optional initializers for multiple variables with a comma.
As of Igor Pro 2.02 for Power Macintosh, Igor Pro 3.0 for all Macintoshes, and for all Windows versions, all numeric variables are double precision. Previously variables could be single or double precision and the /D flag meant double precision. The/D flag is allowed for backward compatibility but is no longer needed and should not be used in new code.
If used in a macro or function the new variable is local to that macro or function unless the /G (global) flag is used. If used on the command line, the new variable is global.
varName can include a data folder path.

## Examples

To initialize a complex variable, use the cmplx function. For example:
variable/C cv1 $=\operatorname{cmplx}(1,2)$
sets the real part of cv1 to 1 and the imaginary part to 2 .

## Variance

Variance(inWave [, x1, x2 ] )
Returns the variance of the real-valued inWave. The function ignores NaN and INF values in inWave.

## Parameters

inWave is expected to be a real-valued numeric wave. If inWave is a complex or text wave, Variance returns NaN .
$x 1$ and $x 2$ specify a range in inWave over which the variance is to be calculated. They are used only to locate the points nearest to $x=x 1$ and $x=x 2$. The variance is then calculated over that range of points. The order of $x 1$ and $x 2$ is immaterial.
If omitted, $x 1$ and $x 2$ default to $-\infty$ and $+\infty$ respectively and the variance is calculated for the entire wave.

## Details

The variance is defined by

$$
\operatorname{var}=\frac{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}}{n-1}
$$

where

$$
\bar{x}=\frac{\sum_{i=1}^{n} X_{i}}{n}
$$

## Examples

```
Make/O/N=5 test = p
SetScale/P x, 0, .1, test
// Print variance of entire wave
Print Variance(test)
// Print variance from x=0 to x=.2
Print Variance(test, 0, .2)
// Print variance for points 1 through 3
Variable x1=pnt2x(test, 1)
Variable x2=pnt2x(test, 3)
Print Variance(test, x1, x2)
```

## See Also <br> mean, WaveStats

## VariableList

VariableList(matchStr, separatorStr, variableTypeCode)
The VariableList function returns a string containing a list of global variables selected based on the matchStr and variableTypeCode parameters. The variables listed are all in the current data folder.

## Details

For a variable name to appear in the output string, it must match matchStr and also must fit the requirements of variableTypeCode. The first character of separatorStr is appended to each variable name as the output string is generated.
The name of each variable is compared to matchStr, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:
"*" Matches all variable names.
"xyz" Matches variable name xyz only.
"*xyz" Matches variable names which end with xyz.
"xyz*" Matches variable names which begin with xyz.
"*xyz*" Matches variable names which contain xyz.
"abc*xyz" Matches variable names which begin with abc and end with xyz.
matchStr may begin with the ! character to return windows that do not match the rest of matchStr. For example:
"!*xyz" Matches variable names which do not end with xyz.
The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.
variableTypeCode is used to further qualify the variable. The variable name goes into the output string only if it passes the match test and its type is compatible with variableTypeCode. variableTypeCode is any one of:
2: $\quad$ System variables (K0, K1 . . )
4: Scalar variables
5: Complex variables

## Examples

```
VariableList("*",";",4) Returns a list of all scalar variables.
VariableList("!V_*", ";",5) Returns a list of all complex variables except those whose names
    begin with "V_".
```

## See Also

See the StringList and WaveList functions.
See Setting Bit Parameters on page IV-12 for details about bit settings.

## VCSI

vcsr(cursorName [, graphNameStr])
The vcsr function returns the Y (vertical) value of the point which the specified cursor (A through J) is attached to in the top (or named) graph.

## Parameters

cursorName identifies the cursor, which can be cursor A through J.
graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## Details

The result is computed from the coordinate system of the graph's Y axis. The Y axis used is the one used to display the wave on which the cursor is placed.

## See Also

The hcsr, pcsr, qcsr, xcsr, and zcsr functions.
Programming With Cursors on page II-292.

## version

\#pragma version $=$ versNum
In the File Information dialog, \#pragma version=versNum provides file version information that is displayed next to the file name in the dialog. This line must not be indented and must appear in the first fifty lines of the file. See Procedure File Version Information on page IV-149.

## See Also

The The version Pragma on page IV-42, Procedure File Version Information on page IV-149, the IgorInfo function, and \#pragma.

## WAVE

WAVE [/C] [/T][/Z] localName [=pathToWave][, localName1 [=pathToWave1]]... WAVE is a declaration that identifies the nature of a user-defined function parameter or creates a local reference to a wave accessed in the body of a user-defined function.

The optional parameter pathToWave is used only in the body of a function, not in a parameter declaration. The WAVE reference is required when you use a wave in an assignment statement in a function. At compile time, the WAVE statement specifies that the local name references a wave. At runtime, it makes the connection between the local name and the actual wave. For this connection to be made, the wave must exist when the WAVE statement is executed.
When localName is the same as the global wave name and you want to reference a wave in the current data folder, you can omit the pathToWave. Prior to Igor Pro 4.0, pathToWave was always required.
pathToWave can be a full literal path (e.g., root:FolderA:wave0), a partial literal path (e.g., :FolderA:wave0) or $\$$ followed by string variable containing a computed path (see Converting a String into a Reference Using \$ on page IV-48).
You can also use a data folder reference or the /SDFR flag to specify the location of the wave if it is not in the current data folder. See Data Folder References on page IV-62 and The /SDFR Flag on page IV-64 for details.
If the wave may not exist at runtime, use the /Z flag and call WaveExists before accessing the wave. The /Z flag prevents Igor from flagging a missing wave as an error and dropping into the debugger. For example:
WAVE/Z wv=<pathToPossiblyMissingWave>
if ( WaveExists(wv) )
<do something with wv>
endif
Note that to create a wave, you use the Make operation.

## Flags

/C Complex wave.
/T Text wave.
/Z Ignores wave reference checking failures.

## See Also

WaveExists function.
WAVE Reference Type Flags on page IV-59 for additional wave type flags and information.

Accessing Global Variables and Waves on page IV-50.
Accessing Waves in Functions on page IV-66.
Converting a String into a Reference Using \$ on page IV-48.

## WAVEClear

WAVEClear localName [, localName1 ...]
The WAVEClear operation clears out a WAVE reference variable. WAVEClear is equivalent to WAVE/Z localName= \$"".

Details
Use WAVEClear to avoid unexpected results from certain operations such as Duplicate or Concatenate, which will reuse the contents of a WAVE reference variable and may not generate the wave in the desired data folder or with the desired name.

WAVEClear ensures that memory is deallocated after waves are killed as in this example:

```
Function foo()
    Make wave1
    FunctionThatKillsWave1()
    WAVEClear wavel
    AnotherFunction()
End
```

Although memory used for wave 1 will be deallocated when foo returns, that memory will not be automatically released while the function executes because the WAVE variable still contains a reference to the wave. In this example, WAVEClear deallocates that memory before AnotherFunction executes.

You can also use WAVEClear before passing a data folder to preemptive threads using ThreadGroupPutDF.

See Also
Accessing Waves in Functions on page IV-66, Wave Reference Counting on page IV-185, and ThreadSafe Functions and Multitasking on page IV-295.

## WaveCRC

WaveCRC(inCRC, waveName [, checkHeader])
The WaveCRC function returns a 32-bit cyclic redundancy check value of the bytes in the named wave starting with inCRC.
Pass 0 for in $C R C$ the first time you call WaveCRC for a particular stream of bytes as represented by the wave data.

Pass the last-returned value from WaveCRC for $\operatorname{in} C R C$ if you are creating a $C R C$ value for a given stream of bytes through multiple calls to WaveCRC.
waveName may be a numeric or text wave.
The optional checkHeader parameter determines how much of the wave is checked:

| checkHeader | What It Does |
| :--- | :--- |
| 0 | Check only the wave data (default). |
| 1 | Check only the internal binary header. |
| 2 | Check both. |

## Details

Polynomial used is:
$x^{\wedge} 32+x^{\wedge} 26+x^{\wedge} 23+x^{\wedge} 22+x^{\wedge} 16+x^{\wedge} 12+x^{\wedge} 11+x^{\wedge} 10+x^{\wedge} 8+x^{\wedge} 7+x^{\wedge} 5+x^{\wedge} 4+x^{\wedge} 2+x+1$
See crc32.c in the public domain source code for zlib for more information.

## See Also <br> The StringCRC function.

## WaveDims

WaveDims (wave)
The WaveDims function returns the number of dimensions used by wave.
Returns zero if wave reference is null. See WaveExists for a discussion of null wave references.
Also returns zero if wave has zero rows. A matrix will return 2.

## WaveExists

WaveExists (wave)
The WaveExists function returns one if wave reference is valid or zero if the wave reference is null. For example if, in a user function, you have:
Wave w= \$"no such wave"
then WaveExists (w) will return zero.
WaveExists should be used in functions only. In macros, use the exists function instead.
See Also
exists, NVAR_Exists, SVAR_Exists, and Accessing Global Variables and Waves on page IV-50.

## WaveInfo

WaveInfo (waveName, 0)
The WaveInfo function returns a string containing a semicolon-separated list of information about the named wave.

The second parameter is reserved for future use and must be zero.

## Details

The string contains six kinds of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are:

| Keyword | Information Following Keyword |
| :---: | :---: |
| DUNITS | The wave's data units. |
| FULLSCALE | Three numbers indicating whether the wave has any data full scale information, and the min and max data full scale values. The format of the FULLSCALE description is: <br> FULLSCALE: validFS, minFS, maxFS; <br> validFS is 1 if $\operatorname{minFS}$ and maxFS have been set via a SetScale d command; otherwise it is 0 . |
| LOCK | Reads back the value set by SetWaveLock. |
| MODIFIED | 1 if the wave has been modified since the experiment was last saved, else 0 . |
| MODTIME | The date and time that the wave was last modified in seconds since January 1, 1904. |
| NUMTYPE | A number denoting the data type of the wave. |
|  | For text waves this is 0 . |
|  | For wave reference waves it is 16384. |
|  | For data folder reference waves it is 256. |

| Keyword | Information Following Keyword |
| :--- | :--- |
|  | For numeric waves it is one of the following: |
| $1:$ | Complex, added to one of the following |
| $2:$ | 32-bit (single precision) floating point |
| $4:$ | 64-bit (double precision) floating point |
| $8:$ | 8-bit signed integer |
| $16:$ | 16-bit signed integer |
| $32:$ | 32-bit signed integer |
|  | $64: \quad$ Unsigned, added to 8, 16, or 32 if wave is unsigned |
| PATH | For example, the number denoting a complex double precision wave is 5 (i.e., 1+4). |
|  | The name of the symbolic path in which the wave file is stored (e.g., PATH:home;) or |
|  | nothing if there is no path for the wave (PATH:;). |
|  | The wave's $X$ units. |

Always pass 0 as the second input parameter. In future versions of Igor, this parameter may request other kinds of information to be returned.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using WaveRefIndexedDFR in a loop to act on all waves in a data folder, and the loop has incremented beyond the highest valid index.

```
Examples
Make/O wave1;SetScale x,0,1,"dyn",wave1;SetScale y, 3, 20,"v",wave1
String info = WaveInfo(wave1,0)
Print NumberByKey("NUMTYPE", info) // Prints 2
Print StringByKey("DUNITS", info) // Prints "v"
```

The functions and operations listed under "About Waves" categories in the Command Help tab of the Igor Help Browser; among them are CreationDate, modDate, WaveType, note, and numpnts.
NumberByKey and StringByKey functions for parsing the returned keyword list.
WaveInfo lacks information about multidimensional waves. Individual functions are provided to return dimension-related information: DimDelta, DimOffset, DimSize, WaveUnits, and GetDimLabel.

## WaveList

WaveList (matchStr, separatorstr, optionsStr)
The WaveList function returns a string containing a list of waves selected from the current data folder based on matchStr and optionsStr parameters. See Details for information on listing waves in graphs, and for references to newer, data folder-aware functions.

## Details

For a wave name to appear in the output string, it must match matchStr and also must fit the requirements of optionsStr and it must be in the current data folder. The first character of separatorStr is appended to each wave name as the output string is generated.

The name of each wave is compared to matchStr, which is some combination of normal characters and the asterisk wildcard character that matches anything.
For example:

| "*" | Matches all wave names in current data folder. |
| :--- | :--- |
| "xyz" | Matches wave name xyz only, if xyz is in the current data folder. |
| "*xyz" | Matches wave names which end with xyz and are in the current data folder. |
| "xyz*" | Matches wave names which begin with xyz and are in the current data folder. |

"*xyz*" Matches wave names which contain xyz and are in the current data folder.
"abc*xyz" Matches wave names which begin with abc and end with xyz and are in the current data folder.
matchStr may begin with the ! character to return windows that do not match the rest of matchStr. For example:
"!*xyz" Matches wave names which do not end with xyz.
The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.
optionsStr is used to further qualify the wave.
Use " " to accept all waves in the current data folder that are permitted by matchStr.
Set optionsStr to one or more of the following comma-separated keyword-value pairs:

| optionsStr | Selection Criteria |
| :---: | :---: |
| "BYTE:0" or "BYTE:1" | Waves that are not 8-bit integer (if 0 ) or only waves that are 8-bit integer (if 1 ). |
| "CMPLX: 0" or <br> "CMPLX:1" | Waves that are not complex (if 0) or only waves that are complex (if 1 ). |
| "DIMS: numberOfDims" | All waves in current data folder that have numberOfDims dimensions. This is the number of dimensions reported by WaveDims. |
|  | Use "DIMS : 0 " for all waves having no points (numpnts (w) ==0). |
|  | Use "DIMS:1" for graph traces (or one of the $\mathrm{X}, \mathrm{Y}$, and Z waves of a contour plot). |
|  | Use "DIMS:2" for false color and indexed color images (see Indexed Color Details on page II-366). |
|  | Use "DIMS:3" for direct color images (see Direct Color Details on page II-368). |
| "DF:0"or "DF:1" | Consider waves that are not data folder reference waves (if 0 ) or only waves that are data folder reference waves (if 1). You can create waves that contain data folder references using the Make /DF flag. |
| "DP:0" or "DP:1" | Waves that are not double precision floating point (if 0 ) or only waves that are double precision floating point (if 1). |
| "INT64:0" or <br> "INT64:1" | Consider waves that are not 64 -bit integer (if 0 ) or only waves that are 64 -bit integer (if 1). 64-bit integer waves are supported in Igor 7 and later. |
| "INTEGER:0" or <br> "INTEGER:1" | Waves that are not 32-bit integer (if 0) or only waves that are 32-bit integer (if 1 ). |
| "MAXCHUNKS : max" | Waves having no more than max chunks. |
| "MAXCOLS: max" | Waves having no more than max columns. |
| "MAXLAYERS : max" | Waves having no more than max layers. |
| "MAXROWS: max" | Waves having no more than max rows. |
| "MINCHUNKS: min" | Waves having at least min chunks. |
| "MINCOLS:min" | Waves having at least min columns. |
| "MINLAYERS: min" | Waves having at least min layers. |
| "MINROWS:min" | Waves having at least min rows. |
| "SP:0" or "SP:1" | Waves that are not single precision floating point (if 0 ) or only waves that are single precision floating point (if 1). |

| optionsStr | Selection Criteria |
| :---: | :---: |
| "TEXT:0" or "TEXT: 1 " | Waves that are not text (if 0 ) or only waves that are text (if 1 ). |
| "UNSIGNED:0" or <br> "UNSIGNED:1" | Waves that are not unsigned integer (if 0 ) or only waves that are unsigned integer (if 1). |
| "WAVE:0" or "WAVE: 1" | Consider waves that do not contain wave references (if 0 ) or only waves that contain wave references (if 1 ). You can create waves that contain wave references using the Make/WAVE flag. |
| "WIN: " | All waves in the current data folder that are displayed in the top graph or table. |
| "WIN: windowName" | All waves in the current data folder that are displayed in the named table or graph window or subwindow. |
| "WORD: 0" or "WORD: 1 " | Waves that are not 16-bit integer (if 0 ) or only waves that are 16-bit integer (if 1 ). |

You can specify more than one option by separating the options with a comma. See the Examples.
Note: Even when optionsStr is used to list waves used in a graph or table, the waves must be in the current data folder.

Note: In addition to waves displayed as normal graph traces, WaveList will list matrix waves used with AppendImage or NewImage and the $X, Y$, and $Z$ waves used with AppendXYZContour.

Note: Individual contour traces are not listed because they have no corresponding waves. See All About Contour Traces on page II-334.

There are several functions that are more useful for listing waves in graphs and tables.
WaveList with WIN : windowName gives only the names of the waves in the graph or table and does not include the data folder for each wave. If you need to know what data folder the waves are in, use WaveRefIndexed to get the wave itself and then if needed use GetWavesDataFolder to get the path.
When identifying a subwindow with WIN : windowName, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

To list the actual waves used in a graph, or to distinguish two or more instances of the same named wave in a graph, use TraceNameList. This function can be used in conjunction with TraceNameToWaveRef, and XWaveRefFromTrace.

Use ContourNameList to list contour plots in a given window and ContourNameToWaveRef to access the waves used to generate the contour plot.
To list the contour traces (that is, the contour lines themselves) use TraceNameList with the appropriate option. Use ImageNameList to list images in a given window and ImageNameToWaveRef to access the waves used to generate the images.

## Processing Lists of Waves

Contrary to what you might expect, you can not use the output of WaveList directly with operations that have a list of waves as their parameters. See Processing Lists of Waves on page IV-178 for ways of dealing with this.

## Examples

// Returns a list of all waves in the current data folder.
WaveList("*",";","")
// Returns a list of all waves in the current data folder and displayed in the top table or graph.
WaveList("*", ";","WIN:")
// Returns a list of waves in the current data folder whose names
// end in "_bkg" and which are displayed in Graph0 as 1D traces.
WaveList("*_bkg", ";", "WIN:Graph0")
// Returns a list of waves in the current data folder whose names do not
// end in "X" and which are displayed in Grapho as 1D traces or as one
// of the X, Y, and Z waves of an AppendXYZContour plot.
WaveList("!*X", ";", "WIN:Graph0,DIMS:1")

## WaveMax

WaveMax (waveName [, x1, x2])
The WaveMax function returns the maximum value in the wave for points between $x=x 1$ to $x=x 2$, inclusive.

## Details

If $x 1$ and $x 2$ are not specified, they default to -inf and +inf, respectively.
The $X$ scaling of the wave is used only to locate the points nearest to $x=x 1$ and $x=x 2$. To use point indexing, replace $x 1$ with pnt 2 x (waveName, pointNumber 1 ), and a similar expression for $x 2$.
If the points nearest to $x 1$ or $x 2$ are not within the point range of 0 to numpnts(waveName) -1 , WaveMax limits them to the nearest of point 0 or point numpnts(waveName)-1.
For a floating-point wave, WaveMax runs about three times faster than getting the same information using WaveStats. For an integer wave, WaveMax runs about ten times faster than WaveStats. The advantage may not hold for short waves.

## See Also

The WaveMin function and WaveStats operation.

## WaveMeanStdv

## WaveMeanStdv srcWave binSizeWave

The WaveMeanStdv operation calculates the standard deviation of the means for the specified bin distribution saving the result in the wave W_MeanStdv.
For each entry in binSizeWave, srcWave is divided into the specified number of bins. Values in each bin are averaged and then the mean and standard deviation of the averages (among all bins) are calculated. The value of the standard deviation of the bin averages divided by the mean is then stored in W_MeanStdv corresponding to the bin size entry in binSizeWave.
All entries in binSizeWave must be positive integers.

## Details

When the number of points in srcWave does not divide evenly into the bin size entry from binSizeWave, the last bin will have a smaller number of data points. In order not to skew the results the values corresponding to the last bin will be dropped. If your data set is small compared to the bin size you might want to pad srcWave with additional values (e.g., duplicate values from the beginning of the wave).
This operation does not support $\mathrm{NaNs}$. . If you get a NaN as an entry in the output wave then there is either a NaN in srcWave or something is wrong with the calculation for that entry.

## WaveMin

WaveMin(waveName [, x1, x2])
The WaveMin function returns the minimum value in the wave for points between $x=x 1$ to $x=x 2$, inclusive.

## Details

If $x 1$ and $x 2$ are not specified, they default to -inf and +inf, respectively.
The $X$ scaling of the wave is used only to locate the points nearest to $x=x 1$ and $x=x 2$. To use point indexing, replace $x 1$ with pnt 2 x (waveName, pointNumber 1 ), and a similar expression for $x 2$.
If the points nearest to $x 1$ or $x 2$ are not within the point range of 0 to numpnts(waveName)-1, WaveMin limits them to the nearest of point 0 or point numpnts(waveName)-1.
For a floating-point wave, WaveMin runs about three times faster than getting the same information using WaveStats. For an integer wave, WaveMin runs about ten times faster than WaveStats. The advantage may not hold for short waves.

## See Also

The WaveMax function and WaveStats operation.

## WaveName

WaveName (winNameStr, index, type)
The WaveName function returns a string containing the name of the indexth wave of the specified type in the named window or subwindow.

## Parameters

winNameStr can be " " to refer to the top graph or table.
When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## Details

WaveName works on waves displayed in a graph, in a table or on the list of waves in the current data folder. If the window is a table, WaveName returns the column name (e.g., "wave0.d"), rather than the name of the wave itself (e.g., "wave0").

For most uses, we recommend that you use WaveRefIndexed or WaveRefIndexedDFR instead of WaveName. WaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a data folder that is not the current data folder, you will not be able to refer to the named wave. Use WaveRefIndexedDFR instead.
winNameStr is a string expression containing the name of a graph or table or an empty string (" "). If the string is empty and type is 4 then WaveName works on the list of all waves in the current data folder. If the string is empty and the type parameter is not 4 then WaveName works on the top graph or table.
index starts from zero.
type is a number from 1 to 4 . When type is 4 and winNameStr is " ", WaveName works on the list of all waves in the current data folder.
For graph windows, type is 1 for y waves, 2 for x waves, 3 for either y or x waves.
For table windows, type is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.
WaveName returns an empty string (" ") if there is no wave matching the parameters.

## Examples

```
WaveName("",0,4) // Returns name first wave current data folder.
WaveName("",0,1) // Returns name of first Y wave in the top graph.
WaveName("Graph0",1,2) // Returns name of second X wave in Graph0.
WaveName("Table0",1,3) // Returns name of second column in Table0.
```

## WaveRefsEqual

WaveRefsEqual (w1, w2)
The WaveRefsEqual function returns the truth the two wave references are the same.
Requires Igor Pro 6.20 or later.
See Also
Wave Reference Functions on page IV-177

## WaveRefIndexed

## WaveRefIndexed (winNameStr, index, type)

The WaveRefIndexed function returns a wave reference to the indexth wave of the specified type in the named window or subwindow.

In Igor Pro 6.30 or later, to iterate through the waves in a data folder, use WaveRefIndexedDFR instead of WaveRefIndexed.

## Parameters

winNameStr can be " " to refer to the top graph or table window or the current data folder.
When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## Details

WaveRefIndexed is analogous to WaveName but works better with data folders. We recommend that you use it instead of WaveName.
winNameStr is a string expression containing the name of a graph or table or an empty string (" "). If the string is empty and type is 4 then WaveRefIndexed works on Igor's list of all waves in the current data folder. If the string is empty and the type parameter is not 4 then WaveRefIndexed works on the top graph or table.
index starts from zero.
type is a number from 1 to 4 . When type is 4 and winNameStr is " ", WaveRefIndexed works on the list of all waves in the current data folder.
For graph windows, type is 1 for y waves, 2 for x waves, 3 for either y or x waves.
For table windows, type is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.
WaveRefIndexed returns a null reference (see WaveExists) if there is no wave matching the parameters.

## Examples

$\begin{array}{ll}\text { WaveRefIndexed ("", 0,1) } & \text { // Returns first Y wave in the top graph. } \\ \text { WaveRefIndexed ("Graph0", 1,2) } & \text { // Returns second X wave in Graph0. }\end{array}$
WaveRefIndexed ("Table0",1,3) // wave in second column in Table0.
See Also
WaveRefIndexedDFR, NameOfWave, GetWavesDataFolder
For a discussion of wave references, see Wave Reference Functions on page IV-177.

## WaveRefIndexedDFR

WaveRefIndexedDFR (dfr, index)
The WaveRefIndexedDFR function returns a wave reference to the indexth wave in the specified data folder. WaveRefIndexedDFR requires Igor Pro 6.30 or later.

## Parameters

$d f r$ is a data folder reference.
index is the zero-based index of the wave you want to access.

## Details

WaveRefIndexedDFR returns a null reference (see WaveExists) if there is no wave corresponding to index in the specified data folder.

## Example

```
// DemoWaveRefIndexedDFR can be called like this:
// DemoWaveRefIndexedDFR(root:, 0) // Work on root
// DemoWaveRefIndexedDFR(root:SubDataFolder, 0) // Work on root:SubDataFolder
// DemoWaveRefIndexedDFR(:, 0) // Work on current data folder
Function DemoWaveRefIndexedDFR(dfr, recurse)
    DFREF dfr
    Variable recurse
```

```
    Variable index = 0
    do
        Wave/Z w = WaveRefIndexedDFR(dfr, index)
        if (!WaveExists(w))
            break
        endif
        String path = GetWavesDataFolder(w, 2)
        Print path
        index += 1
    while(1)
    if (recurse)
    Variable numChildDataFolders = CountObjectsDFR(dfr, 4)
    Variable i
    for(i=0; i<numChildDataFolders; i+=1)
        String childDFName = GetIndexedObjNameDFR(dfr, 4, i)
        DFREF childDFR = dfr:$childDFName
        DemoWaveRefIndexedDFR(childDFR, 1)
    endfor
    endif
End
See Also
WaveRefIndexed, NameOfWave, GetWavesDataFolder
For a discussion of wave references, see Wave Reference Functions on page IV-177.
```

## WaveStats

WaveStats [flags] waveName
The WaveStats operation computes several statistics on the named wave.
Flags
/ALPH=val Sets the significance level for the confidence interval of the mean (default val=0.05).
$/ C=m e t h o d \quad$ Calculates statistics for complex waves only. Does not affect real waves.
You can use method in various combinations to process the real, imaginary, magnitude, and phase of the wave. The result is stored in the wave M_WaveStats (see Details for format).
method is defined as follows:
method=0: Default; ignores the imaginary part of waveName. Use / W to also store statistics in M_WaveStats.
method=1: Calculates statistics for real part of waveName and stores it in M_WaveStats.
method=2: Calculates statistics for imaginary part of waveName and stores the result in M_WaveStats.
method=4: Calculates statistics for magnitude of waveName, i.e., sqrt (real^2 ${ }^{\text {+ }}$ mag ${ }^{\wedge} 2$ ), and stores the result in M_WaveStats.
method=8: Calculate statistics for phase of waveName using atan2 (imag,real).

If you use a single method the results are stored both in M_WaveStats and in the standard variables (e.g., V_avg, etc.). If you specify method as a combination of more than one binary field then the variables reflect the results for the lowest chosen field and all results are stored in the wave M_WaveStats.

For example, if you use $/ C=12$, the variables will be set for the statistics of the magnitude and M_WaveStats will contain columns corresponding to the magnitude and to the phase.
In this mode V_numInfs will always be zero.

Note: If you invoke this operation and M_WaveStats already exists in the current data folder, it will be either overwritten or initialized to NaN .
$/ \mathrm{M}=$ moment $\quad$ Calculates statistical moments.
moment is defined as follows:
moment=1: Calculates only lower moments: V_avg, V_npnts, V_numInfs, and V_numNaNs. Use it if you do not need the higher moments.
moment=2: Default; calculates both lower moments and higher order quantities: V_sdev, V_rms, V_adev, V_skew, and v_kurt.
/Q Prevents results from being printed in history.
$/ \mathrm{R}=($ start $X$, end $X) \quad$ Specifies an $X$ range of the wave to evaluate.
$/ \mathrm{R}=[\operatorname{start} P, e n d P] \quad$ Specifies a point range of the wave to evaluate.
If you specify the range as $/ \mathrm{R}=[\operatorname{start} P]$ then the end of the range is taken as the end of the wave. If / R is omitted, the entire wave is evaluated.
/W Stores results in the wave M_WaveStats in addition to the various V_ variables when $/ \mathrm{C}=0$.
$/ Z \quad$ No error reporting.
/ZSCR Computes z scores, $z_{i}=\left(Y_{i}-\bar{Y}\right) / \sigma$, saved in W_ZScores.

## Details

WaveStats uses a two-pass algorithm to produce more accurate results than obtained by computing the binomial expansions of the third and fourth order moments.
WaveStats returns the statistics in the automatically created variables:
V_npnts Number of points. Does not include points whose value is NaN or INF.
V_numNans Number of NaNs.
V_numINFs Number of INFs.
V_avg Average of Y values.
V_sum Sum of Y values.
V_sdev Standard deviation of $Y$ values, $\sigma=\sqrt{\frac{1}{V_{-} n p n t s-1} \sum\left(Y_{i}-V_{-} a v g\right)^{2}}$.
("Variance" is V_sdev ${ }^{2}$.)
V_sem Standard error of the mean $\operatorname{sem}=\sigma / \sqrt{V_{-} \text {numPnts }}$.

V_rms $\quad$ RMS (Root Mean Square) of Y values $=\sqrt{\frac{1}{V \_n p n t s} \sum Y_{i}^{2}}$.

V_adev $\quad$ Average deviation $=\frac{1}{V_{-} n p n t s} \sum_{i=0}\left|x_{i}-x\right|$.
V_skew $\quad$ Skewness $=\frac{1}{V_{-} n p n t s} \sum_{i=0}^{V_{-} n p n t s-1}\left[\frac{x_{i-x}}{\sigma}\right]^{3}$.

| V_kurt | Kurtosis $=\frac{1}{V_{-} n p n t s} \sum_{i=0}^{V_{-} n p n t s-1}\left[\frac{x_{i}-x}{\sigma}\right]^{4}-3$. |
| :--- | :--- |
| V_minloc | X location of minimum Y value. |
| V_min | Minimum Y value. |
| V_maxloc | X location of maximum Y value. |
| V_max | Maximum Y value. |
| V_minRowLoc | Row containing minimum data value. |
| V_maxRowLoc | Row containing maximum data value. |
| V_minColLoc | Column containing minimum $Z$ value (2D or higher waves). |
| V_maxColLoc | Column containing maximum Z value (2D or higher waves). |
| V_minLayerLoc | Layer containing minimum Z value (3D or higher waves). |
| V_maxLayerLoc | Layer containing maximum Z value (3D or higher waves). |
| V_minChunkLoc | Chunk containing minimum Z value (4D waves only). |
| V_maxChunkLoc | Chunk containing maximum Z value (4D waves only). |
| V_startRow | First wave point. Zero if you do not use /R. |
| V_endRow | Last wave point. Last point if you do not use /R. |

WaveStats prints the statistics in the history area unless / $Q$ is specified. The various multidimensional min and max location variables will only print to the history area for waves having the appropriate dimensionality.

The format of the M_WaveStats wave is:

| Row | Statistic | Row | Statistic | Row | Statistic |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | numPoints | 9 | minLoc | 18 | maxColLoc |
| 1 | numNaNs | 10 | min | 19 | maxLayerLoc |
| 2 | numInfs | 11 | maxLoc | 20 | maxChunkLoc |
| 3 | avg | 12 | max | 21 | startRow |
| 4 | sdev | 13 | minRowLoc | 22 | endRow |
| 5 | rms | 14 | minColLoc | 23 | sum |
| 6 | adev | 15 | minLayerLoc | 24 | meanL1 |
| 7 | skew | 16 | minChunkLoc | 25 | meanL2 |
| 8 | kurt | 17 | maxRowLoc | 26 | sem |

meanL1 and meanL2 are the confidence intervals for the mean

$$
\operatorname{MeanL1}=V_{-} a v g-t_{\alpha, v} \frac{V_{-} s d e v}{\sqrt{V_{-} n p n t s}}, \quad \text { and } \quad \text { MeanL } 2=V_{-} a v g+t_{\alpha, v} \frac{V_{-} s d e v}{\sqrt{V_{-} n p n t s}}
$$

where $t_{a, v}$ is the critical value of the Student T distribution for alpha significance and degree of freedom $v=V \_n p n t s-1$.

Use Edit M_WaveStats.ld to display the results in a table with dimension labels identifying each of the row statistics.
WaveStats is not entirely multidimensional aware. Even so, much of the information computed by WaveStats is useful. See Analysis on Multidimensional Waves on page II-110 for details.

The WaveMax, WaveMin, mean and Variance functions.

## WaveTransform

WaveTransform [flags] keyword srcWave
The WaveTransform operation transforms srcWave in various ways. If the /O flag is not specified then unless otherwise indicated the output is stored in the wave W_WaveTransform, which will be of the same data type as srcWave and saved in the current data folder.

## Parameters

keyword is one of the following:

| abs | Calculates the absolute value of the entries in srcWave. It stores results in W_Abs if srcWave is 1D or M_Abs otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave. |
| :---: | :---: |
| acos | Calculates the inverse cosine of the entries in srcWave. It stores results in W_Acos if srcWave is 1D or M_Acos otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave. |
| asin | Calculates the inverse sine of the entries in srcWave. It stores results in W_Asin if srcWave is 1D or M_Asin otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave. |
| atan | Calculates the inverse tangent of the entries in srcWave. It stores results in W_Atan if srcWave is 1D or M_Atan otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave. |
| cconjugate | Calculates the complex conjugate of $\operatorname{srcWave}$. Stores results in W_CConjugate or M_CConjugate, depending on wave dimensionality, or overwrites srcWave if/O is used |
| cos | Calculates the cosine of the entries in srcWave. It stores results in W_Cos if srcWave is 1D or M_Cos otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave. |
| crystalToRect | Converts triplet (three column $\{x, y, z\}$ ) waves from nonorthogonal crystallographic coordinates to rectangular cartesian system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by $\{\mathrm{a}, \mathrm{b}, \mathrm{c}$, alpha, beta, gamma\}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation sets the first component parallel to the vector a and the third component parallel to $c^{*}$. The output is stored in the current data folder in the wave M_CrystalToRect which has the same data type. If the /O flag is specified, the output overwrites the original data. |
| flip | Flips the data in srcWave about its center. If /O flag is used, $s r c W a v e ~ i s ~ o v e r w r i t t e n . ~$ Otherwise a new wave is created in the current data folder. The wave is named W_flipped or M_flipped according to the dimensionality of srcWave. |
| index | Fills srcWave as in jack=p. |
|  | If /P is specified then jack=p+param1. |
|  | The /O flag does not apply here. |
| inverse | Computes 1/srcWave [i] for each point in srcWave and stores it in W_Inverse or M_Inverse depending on the dimensionality of srcWave. |

| inverseIndex | Fills srcWave as in jack=numPnts-1-p. |
| :---: | :---: |
|  | If /P is specified the jack=numPnts-1-p+paramı. |
| magnitude | Creates a real-valued wave that is the magnitude of $\operatorname{srcWave}$. If you do not specify the /O flag, the output is stored in W_Magnitude or M_Magnitude depending on the dimensionality of srcWave; the output precision will be the same as srcWave. |
| magsqr | Creates a real-valued wave that is the magnitude squared of $s r c W a v e$. If $s r c W a v e$ is a double precision complex wave, the output is also double precision, otherwise the output is a single precision wave. Stores the result in wave W_MagSqr or M_MagSqr, depending on the dimensionality of srcWave, or overwrites srcWave if / O is used. |
| max | Calculates the maximum of a point in srcWave and a fixed number specified as a single parameter with the /P flag. It stores results in W_max if srcWave is 1D or M_max otherwise. It will overwrite srcWave when used with the /O flag. See also the min keyword and the example below. |
| min | Calculates the minimum of a point in $s r c$ Wave and a fixed number specified as a single parameter with the /P flag. It stores results in W_min if srcWave is 1D or M_min otherwise. It will overwrite srcWave when used with the /O flag. See also the max keyword and the example below. |
| normalizeArea | Calculates the area under the curve and rescales the wave so that the area is 1 . Note that waves with negative areas will be rescaled to positive values. Applies to 1D realvalued waves. It does not affect wave scaling. Stores the result in the wave W_normalizedArea or overwrites srcWave if / O is used. |
| phase | Creates a real-valued wave containing the phase of the complex input wave. If the / O flag is not used, the output is stored in W_Phase or M_Phase depending on the dimensionality of imageMatrix. You can also use $/ \mathrm{P}=\{$ norm $\}$ to divide the output wave by the value of norm. |
| rectToCrystal | Converts triplet (three column $\{x, y, z\}$ ) waves from cartesian coordinates to nonorthogonal crystallographic coordinate system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by $\{\mathrm{a}, \mathrm{b}, \mathrm{c}$, alpha, beta, gamma\}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation assumes the first component parallel to the vector a and the third component parallel to $c^{*}$. The output is stored in the current data folder in the wave M_RectToCrystal which has the same data type. If the /O flag is specified, the output overwrites the original data. |
| sgn | Sets the value to -1 if the entry is negative, 1 otherwise. Stores the results in W_Sgn or overwrites srcWave if /O is used. This operation will not work on UNSIGNED waves. |
| shift | Shifts the position of data in srcWave by the specified number of points. |
|  | Unlike Rotate, WaveTransform discards data points that shift outside existing wave boundaries. After the shift, vacated wave points are set to the specified fillValue. The shift and the fillValue are specified with the / P flag using the syntax: / $\mathrm{P}=\{$ numPoints, fillValue\}. If you do not provide a fill value, it will be 0 for integer waves and NaN for SP and DP. |
| $\sin$ | Calculates the sine of the entries in srcWave. Stores results in W_Sin if srcWave is 1D or M_Sin otherwise. Overwrites srcWave when used with the /O flag. srcWave must be a real single or double precision floating point wave. |
| sqrt | Calculates the square root of the entries in srcWave. It stores results in W_sqrt if srcWave is 1D or M_sqrt otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single- or double-precision real wave. |
| $\tan$ | Calculates the tangent of the entries in srcWave. The results are stored in W_tan if srcWave is 1D or M_tan otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single- or double-precision real wave. |

| zapINFs | Deletes elements whose value is infinity or -infinity. This is relevant for 1D singleprecision and double-precision floating point waves only and does nothing for other types of 1D waves. It is not suitable for multi-dimensional waves and returns an error if $s$ rcWave is multi-dimensional. Use MatrixOp replace for multi-dimensional waves. |
| :---: | :---: |
| zapNaNs | Deletes elements whose value is NaN. This is relevant for 1D single-precision and double-precision floating point waves only and does nothing for other types of 1D waves. It is not suitable for multi-dimensional waves and returns an error if $\operatorname{srcWave}$ is multi-dimensional. Use MatrixOp replaceNaNs for multi-dimensional waves. |

## Flags

If present, angles in wave data are interpreted as in degrees. Otherwise they are interpreted as in radians.
/O Overwrites input wave.
$/ \mathrm{P}=\{$ param1... $\} \quad$ Specifies parameters as appropriate for the keyword that you are using. The number of parameters and their order depends on the keyword.

## Examples

// Produce output values in the range [-1,1]:
WaveTransform $/ P=\{(p i)\}$ phase complexWave
// Faster than myWave=myWave>1 ? 1 : myWave
WaveTransform / $\mathrm{P}=\{1\} / \mathrm{O}$ min myWave

## See Also

The Rotate operation.

## References

Shmueli, U. (Ed.), International Tables for Crystallography, Volume B: 3.3, Kluwer Academic Publishers, Dordrecht, The Netherlands, 1996.

## WaveType

WaveType (waveName [, selector ])
The WaveType function returns the type of data stored in the wave.
The optional selector parameter requires Igor Pro 6.1 or later.
If selector $=1$, WaveType returns 0 for a null wave, 1 if numeric, 2 if text, 3 if the wave holds data folder references or 4 if the wave holds wave references.

If selector $=2$, WaveType returns 0 for a null wave, 1 for a normal global wave or 2 for a free wave or a wave that is stored in a free data folder.

If selector is omitted or zero, the returned value for non-numeric waves (text waves, wave-reference waves and data folder-reference waves) is 0 .
If selector is omitted or zero, the returned value for numeric waves is a combination of bit values shown in the following table:

| Type | Bit Number | Decimal Value | Hexadecimal Value |
| :--- | :--- | :--- | :--- |
| complex | 0 | 1 | 1 |
| 32-bit float | 1 | 2 | 2 |
| 64-bit float | 2 | 4 | 4 |
| 8-bit integer | 3 | 8 | 8 |
| 16-bit integer | 4 | 16 | 10 |

| Type | Bit Number | Decimal Value | Hexadecimal Value |
| :--- | :--- | :--- | :--- |
| 32-bit integer | 5 | 32 | 20 |
| unsigned | 6 | 64 | 40 |

The unsigned bit is used only with the integer types while the complex bit can be used with any numeric type. Only one of the bits 1-5 are set at a time. See Setting Bit Parameters on page IV-12 for details about bit settings.

## Examples

Variable waveIsComplex = WaveType (wave) \& 0x01
Variable waveIs32BitFloat = WaveType (wave) \& 0x02
Variable waveIs64BitFloat = WaveType (wave) \& 0x04
Variable waveIs8BitInteger = WaveType (wave) \& 0x08
Variable waveIs16BitInteger = WaveType (wave) \& 0x10
Variable waveIs32BitInteger = WaveType (wave) \& 0x20
Variable waveIsUnsigned = WaveType (wave) \& 0x40

## See Also

For concepts related to selector $=1$ or 2, see Free Waves on page IV-75, Wave Reference Waves on page IV-61 and Data Folder Reference Waves on page IV-66.

## WaveUnits

WaveUnits (waveName, dimNumber)
The WaveUnits function returns a string containing the units for the given dimension.
Use dimNumber $=0$ for rows, 1 for columns, 2 for layers, and 3 for chunks. Use -1 to get the data units. If the wave is just 1D, dimNumber $=0$ returns X units and 1 returns data units. This behavior is just like the WaveMetrics procedure WaveUnits found in the WaveMetrics Procedures folder in previous versions of Igor Pro.

## See Also

DimDelta, DimOffset, DimSize, SetScale

## wfprintf

wfprintf refNumOrStr, formatStr [flags] waveName [, waveName]...
The wfprintf operation is like the printf operation except that it prints the contents of the named waves to a file whose file reference number is in refNum.
The Save operation also outputs wave data to a text file. Use Save unless you need the added flexibility provided by wfprintf.

## Parameters

refNumOrStr is a numeric expression, a string variable or an SVAR pointing to a global string variable.
If a numeric expression, then it is a file reference number returned by the Open operation or an expression that evaluates to 1.
If refNumOrStr is 1, Igor prints to the history area instead of to a file.
If refNumOrStr is the name of a string variable, the wave contents are "printed" to the named string variable. refNumOrStr can also be the name of an SVAR to print to a global string:

```
SVAR sv = root:globalString
```

wfprintf sv, "", wave0
refNumOrStr can not be an element of a text wave.
The value of each named wave is printed to the file according to the conversion specified in formatStr.
formatStr contains one numeric conversion specification per column. See printf. If formatStr is " ", wfprintf uses a default format which gives tab-delimited columns.

## Flags

Note: $\quad / \mathrm{R}$ must follow the formatStr parameter directly without an intervening comma.

$$
\begin{array}{ll}
/ \mathrm{R}=(\operatorname{start} X, e n d X) & \text { Specifies an } X \text { range in the wave(s) to print. } \\
/ \mathrm{R}=[\operatorname{start} P, e n d P] & \text { Specifies a point range in the wave(s) to print. }
\end{array}
$$

## Details

A complex wave in the wavelist is treated as two separate columns and requires two separate conversion specifications if you do not use the default " " specification.
The number of conversion characters must exactly match the number of columns (one column per real wave, two columns per complex wave) in the wave list. The wave list is limited to 100 waves. You can output up to 200 columns by using complex waves instead of real waves.
The only conversion characters allowed are: fFeEgdouxXcs (the floating point, integer and string conversion characters). You cannot use an asterisk to specify field width or precision.
If any of these restrictions is intolerable, you can use fprintf in a loop.
The wfprintf operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-110 for details.

## Examples

```
Function Example1()
    Make/O/N=10 wave0=sin(p*pi/10) // test numeric wave
    Make/O/N=10/T textWave= "row "+num2istr(p) // test text wave
    Variable refNum
    Open/P=home refNum as "output.txt"// open file for write
    wfprintf refNum, "%s = %g\r"/R=[0,5], textWave, wave0 // print 6 values each
    Close refNum
End
```

The resulting output.txt file contains:

```
row 0 = 0
row 1 = 0.309017
row 2 = 0.587785
row 3 = 0.809017
row 4 = 0.951057
row 5 = 1
Function/S NumericWaveToStringList(w)
    Wave w // numeric wave (if text, use /T here and %s below)
    String list
    wfprintf list, "%g;" w // semicolon-separated list
    return list
End
Print NumericWaveToStringList(wave0)
    0;0.309017;0.587785;0.809017;0.951057;1;0.951057;0.809017;0.587785;0.309017;
```

The Save operation.

## WhichListItem

WhichListItem(itemStr, listStr [, listSepStr [, startIndex [, matchCase]]])
The WhichListItem function returns the index of the first item of listStr that matches itemStr. listStr should contain items separated by the listSepStr character, such as "abc;def;". If the item is not found in the list, -1 is returned.
Use WhichListItem to locate an item in a string containing a list of items separated by a single character, such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.
listSepStr, startIndex, and matchCase are optional; their defaults are ";", 0 , and 1 respectively.

## Details

WhichListItem differs from FindListItem in that WhichListItem returns a list index, while FindListItem returns a character offset into a string.
listStr is searched for itemStr bound by listSepStr on the left and right.
listStr is treated as if it ends with a listSepStr even if it doesn't.
Searches for listSepStr are always case-sensitive. The comparison of itemStr to the contents of listStr is usually case-sensitive. Setting the optional matchCase parameter to 0 makes the comparison case insensitive.
If itemStr is not found, if listStr is " ", or if startIndex is not within the range of 0 to ItemsInList(listStr)-1, then -1 is returned.
Only the first character of listSepStr is used.
Items can be empty. The lists "abc ; def ; ; ghi" and "; abc ; def ; ; ghi ; " have four items (the third item is ""). Use WhichListItem ("", listStr) to find the first empty item.

If startIndex is specified, then listSepStr must also be specified. If matchCase is specified, startIndex and listSepStr must be specified.

## Examples

| Prin | WhichListItem("wave0", "wave0;wave1;") | // prints |
| :---: | :---: | :---: |
| Print | WhichListItem("c", "a;b;") | // prints -1 |
| Print | WhichListItem("", "a; ; ${ }^{\text {c }}$ ") | // prints |
| Print | WhichListItem("c", "a,b,c,x,c", ", ") | // prints 2 |
| Print | WhichListItem("c", "a,b,c,x,c", ", ", 3) | // prints 4 |
| Print | WhichListItem("C", "x;c; C;") | // prints 2 |
| Print | WhichListItem("C", "x;c;C;", ";", 0, 0) | // prints |

## WignerTransform

WignerTransform [/Z][/WIDE=wSize] [/GAUS=gaussianWidth] [/DEST=destWave] srcWave The WignerTransform operation computes the Wigner transformation of a 1D signal in srcWave, which is the name of a real or complex wave. The result of the WignerTransform is stored in destWave or in the wave M_Wigner in the current data folder.

## Flags

/DEST=destWave $\quad$ Creates by default a real wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-57 for details.

| /GAUS $=g$ Width | Computes the Gaussian Wigner Transform, which is a convolution of the Wigner <br> Transform with a two-dimensional Gaussian (in the two parameters of the <br> transform). The computation of the transform simplifies significantly when the <br> product of the widths of the two Gaussians is unity (minimum uncertainty ellipse). <br> gWidth uses the same units as the srcWave scaling. |
| :--- | :--- |
| /WIDE=wSize | Computes Wigner Transform and sets the transform width to wSize. This is the <br> default transformation with $w$ Size set to the size of srcWave. |

/Z No error reporting.

## Details

The Wigner transform maps a time signal $U(t)$ into a 2D time-frequency representation:
$W(t, v)=\int_{-\infty}^{\infty} U\left(t+\frac{x^{\prime}}{2}\right) U^{*}\left(t-\frac{x^{\prime}}{2}\right) e^{-2 \pi i x^{\prime} v} d x^{\prime}$.
The computation of the Wigner transform evaluates the offset product
$U\left(t+\frac{x^{\prime}}{2}\right) U^{*}\left(t-\frac{x^{\prime}}{2}\right)$
over a finite window and then Fourier transforms the result. The offset product can be evaluated over a finite window width, which can vary from a few elements of the input wave to the full length of the wave. You can control the width of this window using the /WIDE flag. If you do not specify the output destination, WignerTransform saves the results in the wave M_Wigner in the current data folder.
The input wave can be of any numeric data type, and the output data type and precision will be the same as the input. Although the Wigner transform is real, the output will be complex when srcWave is complex. By inspecting the complex wave you can gain some insight into the numerical stability of the algorithm. The X-scaling of the output wave is identical to the scaling of srcWave. The Y-scaling of the input wave is taken from the Fourier Transform of the offset product, which in turn is determined by the X-scaling of srcWave. Specifically, if $d x=D i m D e l t a(s r c W a v e, 0)$ and srcWave has N points then
$d y=D i m D e l t a\left(M \_W i g n e r, 1\right)=1 /(d x * N)$. WignerTransform does not set the units of the output wave.
The Ambiguity Function is related to the Wigner Transform by a Fourier Transform, and is defined by
$A(\tau, v)=\int_{-\infty}^{\infty} U\left(t+\frac{\tau}{2}\right) U^{*}\left(t-\frac{\tau}{2}\right) e^{-2 \pi i t v} d t$.
Convolving the Wigner Transform with a 2D Gaussian leads to what is sometimes called the Gaussian Wigner Transform or GWT. Formally the GWT is given by the equation:
$G W T\left(t, v ; \delta_{t}, \delta_{v}\right)=\frac{1}{\delta_{t} \delta_{v}} \iint d t^{\prime} d v^{\prime} W\left(t^{\prime}, v^{\prime}\right) e^{-2 \pi\left(\frac{t-t^{\prime}}{\delta_{t}}\right)^{2}} e^{-2 \pi\left(\frac{v-v^{\prime}}{\delta_{v}}\right)^{2}}$
Computationally this equation simplifies if the respective widths of the two Gaussians satisfy the minimum uncertainty condition $\delta_{t}^{*} \delta_{v}=1$. The /Gaus flag calculates the Gaussian Wigner Transform using your specified width, $\delta_{t}$, and it selects a $\delta_{v}$ such that it satisfies the minimum uncertainty condition.

## Window

Window macroName([parameters]) [:macro type]
The Window keyword introduces a macro that recreates a graph, table, layout, or control panel window. The macro appears in the appropriate submenu of the Windows menu. Window macros are automatically created when you close a graph, table, layout, control panel, or XOP target window. You should use Macro, Proc, or Function instead of Window for your own window macros. Otherwise, it works the same as Macro.

See Also
The Macro, Proc, and Function keywords. Data Folders and Window Macros on page II-125 for details.
Macro Syntax on page IV-102 for further information.

## WindowFunction

WindowFunction [/FFT[=f] /DEST=destWave] windowKind, srcWave
The WindowFunction operation multiplies a one-dimensional (real or complex) srcWave by the named window function.
By default the result overwrites srcWave.

## Parameters

srcWave
A one-dimensional wave of any numerical type. See ImageWindow for windowing two-dimensional data.
windowKind Specifies the windowing function. Choices for windowKind are:
Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.

See FFT for window equations and details. The equations assume that /FFT=1.
Flags
/DEST=destWave Creates or overwrites destWave with the result of the multiplication of srcWave and the window function.
When used in a function, the WindowFunction operation by default creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-57 for details.
/FFT [=1] The window interval is $0 . . . \mathrm{N}=$ numpnts ( srcWave). This sets the first value of srcWave to zero, but not the last value. This is appropriate for windowing data in preparation for Fourier Transforms, and is the same algorithm used by FFT.

The window interval is $0 . . . \mathrm{N}=$ numpnts (srcWave) - 1 if /FFT is missing or $/ \mathrm{FFT}=0$. This sets the first and last value of srcWave to 0 . This is the (only) algorithm that the Hanning operation uses.

## Details

A "window function" alters the input data by decreasing values near the start and end of the data smoothly towards zero, so that when the FFT of the data is computed the effects of nonintegral-periodic signals are diminished. This improves the ability of the FFT to distinguish among closely-spaced frequencies. Each window function has advantages and disadvantages, usually trading off rejection of "leakage" against the ability to discriminate adjacent frequencies. For more details, see the References.
WindowFunction stores the window function's normalization value (the average squared window value) in V_value. This is the value you would get from WaveStats's V_rms*V_rms for a wave of srcWave's length whose values were all equal to 1 :

```
Make/O data = 1
WindowFunction Bartlet, data // Bartlet allowed as synonym for Bartlett
Print V_value // Prints 0.330709, mean of squared window values
```

WaveStats/Q data
Print V_rms*V_rms // Prints 0.330709

## WinList

## WinList(matchStr, separatorStr, optionsStr)

The WinList function returns a string containing a list of windows selected based on the matchStr and optionsStr parameters.

## Details

For a window name to appear in the output string, it must match matchStr and also must fit the requirements of optionsStr. The first character of separatorStr is appended to each window name as the output string is generated.
The name of each window is compared to matchStr, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

| "*" | Matches all window names |
| :--- | :--- |
| "xyz" | Matches window name xyz only |
| "*xyz" | Matches window names which end with xyz |
| "xyz*" | Matches window names which begin with xyz |
| "*xyz*" | Matches window names which contain xyz |
| "abc*xyz" | Matches window names which begin with abc and end with xyz |

matchStr may begin with the ! character to return windows that do not match the rest of matchStr. For example:
"!*xyz" Matches window names which do not end with xyz

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.
optionsStr is used to further qualify the window. The acceptable values for optionsStr are:

| " " | Consider all windows. |
| :---: | :---: |
| "WIN: " | The target window. |
| "WIN: windowTypes" | Consider windows that match windowTypes. |
| "INCLUDE:includeTypes" | Consider procedure windows that match includeTypes. |
|  | Using INCLUDE: implies WIN:128. |
| "INDEPENDENTMODULE: 1 " | Consider procedure windows that are part of any independent module as well as those that are not. Matching windows names are actually the window titles followed by " [<independent module name>] ". |
|  | Using INDEPENDENTMODULE: implies WIN:128. |
| "INDEPENDENTMODULE: 00 | Consider procedure windows only if they are not part of any independent module. Matching windows names are actually the window titles, which for an external file includes the file extension, such as "WMMenus.ipf". |
|  | Using INDEPENDENTMODULE: implies WIN:128. |
| "FLT:1" | Return only panels that were created with NewPanel/FLT=1. Specifying "FLT" also implies "WIN:64". |
|  | Omit FLT or use "FLT:0" to return windows that do not float (and most do not). |
| "FLT:2" | Return only panels that were created with NewPanel/FLT=2. Specifying "FLT" also implies "WIN:64". |
| "VISIBLE:1" | Return only visible windows (ignore hidden windows). |

windowTypes is a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with windowTypes. windowTypes is a bitwise parameter:
1: $\quad$ Graphs

2: Tables
4: Layouts
16: Notebooks
64: Panels
128: $\quad$ Procedure windows
512: Help windows
4096: XOP target windows
See Setting Bit Parameters on page IV-12 for details about bit settings.
Procedure windows and help windows don't have names. WinList returns the window title instead. includeTypes is also a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with includeTypes. includeTypes is one of:
1: Procedure windows that are not \#included.
2: Procedure windows included by \#include "someFileName".
4: Procedure windows included by \#include <someFileName>.
or a bitwise combination of the above for more than one type of inclusion.
You can combine the WIN, INCLUDE and INDEPENDENTMODULE options by separating them with a comma.
When the INDEPENDENTMODULE option is used, the title of any procedure window that is part of an independent module will be followed by " [<independent module name>] ".
For example, if a procedure file contains:
\#pragma IndependentModule=myIndependentModule
\#include <Axis Utilities>
A call to WinList like this:
String list = WinList("* [myIndependentModule] ", ";", "INDEPENDENTMODULE:1")
will store "Axis Utilities.ipf [myIndependentModule];" in the list string, along with any other procedure windows that are part of that independent module.
When the INDEPENDENTMODULE option is omitted, the returned procedure window titles do not include any independent module name suffix, and the procedure files "visible" to WinList depend on the setting of SetIgorOption independentModuleDev (which must be done after opening the experiment):

```
SetIgorOption Consider procedure windows only if they are not part of
independentModuleDev=0
SetIgorOption
independentModuleDev=1
```

Consider procedure windows only if they are not part of any independent module and if they are not hidden (using \#pragma hide, for example).

Consider all procedure windows including those in independent modules or hidden.

## Examples

Command

## Returned List

WinList("*", ";","")
All existing non-floating windows.
WinList ("*", ";","WIN:3") All graph and table windows.
WinList("Result_*", ";", "WIN:1") Graphswhosenames start with "Result_".
WinList("*", ";","WIN:64,FLT:1,FLT:2")
All floating panel windows.
WinList("*", ";","INCLUDE:6")
All \#included procedure windows.
WinList("*", ";","WIN:1,INCLUDE:6") All graphs and \#included procedure windows.

## See Also

Independent Modules on page IV-218. The ChildWindowList and WinType functions.

## WinName

WinName(index, windowTypes [, visibleWindowsOnly [, floatKind]])
The WinName function returns a string containing the name of the indexth window of the specified type, or an empty string (" ") if no window fits the parameters.

If the optional visibleWindowsOnly parameter is nonzero, only visible windows are considered. Otherwise both visible and hidden windows are considered.

If the optional floatKind parameter is 1, only floating windows created with NewPanel/FLT=1 are considered. If floatKind is 2 , only NewPanel/FLT=2 windows are considered. windowTypes must contain at least 64 (panels).
If floatKind is omitted or is 0 only non-floating ("normal") windows are considered.
Procedure windows don't have names. WinName returns the procedure window title instead.

## Details

index starts from zero, and returns the top-most window matching the parameters.
The window names are ordered in window-stacking order, as returned by WinList.
DoWindow/B moves the window to the back and changes the index needed to retrieve its name to the greatest index that returns any name.
Hiding or showing a window (with SetWindow hide=1 or Notebook visible=0 or by manual means) does not affect the index associated with the window.
windowTypes is a bitwise parameter:
1: Graphs.
2: Tables.
4: Layouts.
16: Notebooks.
64: Panels.
128: Procedure windows.
4096: XOP target windows.

See Setting Bit Parameters on page IV-12 for details about bit settings.

## Examples

Print WinName $(0,1) \quad / /$ Prints the name of the top graph.
Print WinName (0,3) // Prints the name of the top graph or table.
String win=WinName (0,1) // The name of the top visible graph.
SetWindow \$win hide=1 // Hide the graph (it may already be hidden).
Print WinName (0,1) // Prints the name of the now-hidden graph.

Print WinName (0,1,1) // Prints the name of the top visible graph.
Print WinName $(0,64,1,1) \quad / /$ Name of the top visible NewPanel/FLT=1 window.
See Also
WinList, DoWindow (/F and /B flags), SetWindow (hide keyword), Notebook (Miscellaneous) (visible keyword), NewPanel (/FLT flag).

## WinRecreation

WinRecreation (winstr, options)
The WinRecreation function returns a string containing the window recreation macro (or style macro) for the named window.

## Parameters

winStr is the name of a graph, table, page layout, panel, notebook, or XOP target window or the title of a procedure window or help file. If winStr is "" and options is 0 or 1, information for the top graph, table, page layout, panel, notebook, or XOP target window is returned.
The meaning of options depends on the type of window as described in the following sections.

## Target Window Details

Target windows include graphs, tables, page layouts, panels, notebooks, and XOP target windows.
If options is 0, WinRecreation returns the window recreation macro.
If options is 1 , WinRecreation returns the style macro or an empty string if the window does not support style macros.

## Graphs Details

If options is 2 , WinRecreation returns a recreation macro in which all occurrences of wave names are replaced with an ID number having the form \#\#<number>\#\# (for instance, \#\#25\#\#). These ID numbers can be found easily using the strsearch function. This is intended for applications that need to alter the recreation macro by replacing wave names with something else, usually other wave names. The ID numbers are the same as those returned by the GetWindow operation with the wavelist keyword.

## Graphs and Panels Details

If options is 4, WinRecreation returns the window recreation macro without the default behavior of causing the graph to revert to "normal" mode (as if the GraphNormal operation had been called). This allows the use of WinRecreation when a graph or panel is in drawing tools mode without exiting that mode. For windows other than graphs or panels, this is equivalent to an options value of 0 .

## Notebooks Details

If options is -1 , WinRecreation returns the same text that the Generate Commands menu item would generate with the Selected paragraphs radio button selected and all the checkboxes selected (includes text commands).
If options is 0 , WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes except "Generate text commands" selected).
If options is 1 , WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes selected (includes text commands).
Regardless of the value of options the text returned by WinRecreation for notebook always ends with 5 lines of file-related information formatted as comments:

```
// File Name: MyNotebook.txt
// Path: "Macintosh HD:Desktop Folder:"
// Symbolic Path: home
// Selection Start: paragraph 100, position 31
// Selection End: paragraph 100, position 31
```

## Help Windows Details

WinRecreation returns the same 5 lines of file-related information as described above for notebooks.
Set options to -3 to ensure that winStr is interpreted as a help window title (help windows have only titles, not window names).

## Procedures Details

WinRecreation returns the same 5 lines of file-related information as described above for notebooks.

Set options to -2 to ensure that winStr is interpreted as a procedure window title (procedure windows have only titles, not window names).
If SetIgorOption IndependentModuleDev=1 is in effect, winStr can also be a procedure window title followed by a space and, in brackets, an independent module name. In such cases WinRecreation returns text from or information about the specified procedure file which is part of that independent module. (See Independent Modules on page IV-218 for independent module details.)
For example, in an experiment containing:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
code like this:
```

String text=WinRecreation("Axis Utilities.ipf [myIM] ",-2)
will return the file-related information for the Axis Utilities.ipf procedure window, which is normally a hidden part of the myIM independent module.
To get the text content of a procedure window, use the ProcedureText function.

## Examples

```
WinRecreation("Graph0",0) // Returns recreation macro for Graph0.
WinRecreation("",1) // Style macro for top window.
String win= WinName(0,16,1) // top visible notebook
String str= WinRecreation(str,-1) // selected Text commands
Variable line= itemsInList(str,"\r")-5 // First file info line
Print StringFromList(line, str,"\r") // Print File Name:
Print StringFromList(line+1, str,"\r") // Print Path:
Print StringFromList(line+2, str,"\r") // Print Symbolic Path:
Print StringFromList(line+3, str,"\r") // Selection Start:
Print StringFromList(line+4, str,"\r") // Selection End:
```

## See Also

Saving a Window as a Recreation Macro on page II-61.

## WinType

WinType (winNameStr)
The WinType function returns a value indicating the type of the named window.

## Details

winNameStr is a string or string expression containing the name of a window or subwindow, or " " to signify the target window. When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
WinType returns the following values:
0 : No window by that name.
1: Graph.
2: Table.
3: Layout.
5: $\quad$ Notebook.
7: Panel.
13: XOP target window.
Because command and procedure windows do not have names (they only have titles), WinType can not even be asked about those windows.

See Also<br>The WinName, ChildWindowList, and WinList functions.

## WMAxisHookStruct

See NewFreeAxis for further explanation of WMAxisHookStruct.

```
Structure WMAxisHookStruct
    char win[200] // Host window or subwindow name
    char axName[32] // Name of axis
    char mastName[32] // Name of controlling axis or ""
    char units[50] // Axis units.
    Variable min // Current axis range minimum value
    Variable max // Current axis range maximum value
EndStructure
```

## WMBackgroundStruct

See CtrlNamedBackground, Background Tasks on page IV-285, and Preemptive Background Task on page IV-300 for further explanation of WMBackgroundStruct.

```
Structure WMBackgroundStruct
    char name[32] // Background task name
    UInt32 curRunTicks // Tick count when task was called
    Int32 started // TRUE when CtrlNamedBackground start is issued
    UInt32 nextRunTicks // Precomputed value for next run
    // but user functions may change this
EndStructure
```

## WMButtonAction

See Button for further explanation of WMButtonAction.

```
Structure WMButtonAction
    char ctrlName[32] // Control name
    char win[200] // Host window or subwindow name
    STRUCT Rect winRect // Local coordinates of host window
    STRUCT Rect ctrlRect // Enclosing rectangle of the control
    STRUCT Point mouseLoc // Mouse location
    Int32 eventCode // -1: Control being killed
// 1: Mouse down
// 2: Mouse up
// 3: Mouse up outside control
// 4: Mouse moved
// 5: Mouse enter
// 6: Mouse leave
// See Control Structure eventMod Field on page III-387
    String userData // Primary unnamed user data.
    Int32 blockReentry // See Control Structure blockReentry Field on page III-388
EndStructure
```

## WMCheckboxAction

See CheckBox for further explanation of WMCheckboxAction.

```
Structure WMCheckboxAction
    char ctrlName[32] // Control name
    char win[200] // Host window or subwindow name
    STRUCT Rect winRect // Local coordinates of host window
    STRUCT Rect ctrlRect // Enclosing rectangle of the control
    STRUCT Point mouseLoc // Mouse location
    Int32 eventCode // -1: Control being killed
    // 2: Mouse up
    Int32 eventMod // See Control Structure eventMod Field on page III-387
    String userData // Primary unnamed user data
    Int32 blockReentry // See Control Structure blockReentry Field on page III-388
    Int32 checked // Checkbox state
EndStructure
```

## WMCustomControlAction

See CustomControl for further explanation of WMCustomControlAction.
Structure WMCustomControlAction

| char ctrlName[32] | // Control name |
| :--- | :--- |
| char win[200] | // Host window or subwindow name |
| STRUCT Rect winRect | // Local coordinates of host window |

// Valid if isWave and not isString
// If isWave, this is the row index
// unless rowLabel is not empty
// Keyboard key character code
// Keyboard key modifiers bit field
// Bit 0: Command pressed (Macintosh)
// Bit 1: Shift pressed
// Bit 2: Alpha pressed lock
// Bit 3: Option (Mac) or Alt (Windows) pressed
// Bit 4: Control pressed
    Int32 curFrame
// Input and output, used with kCCE_frame event
// See CustomControl for details
```

## WMFitInfoStruct

See The WMFitInfoStruct Structure on page III-230 for further explanation of WMFitInfoStruct.

```
Structure WMFitInfoStruct
    char IterStarted // Nonzero on the first call of an iteration
    char DoingDestWave // Nonzero when called to evaluate autodest wave
    char StopNow // Fit function sets this to nonzero to
    // indicate that a problem has occurred
    // and fitting should stop
    Int32 IterNumber // Number of iterations completed
    Int32 ParamPerturbed // See The WMFitInfoStruct Structure on page III-230
EndStructure
```

## WMGizmoHookStruct

See ModifyGizmo in the Gizmo Reference help file for further explanation of WMGizmoHookStruct.

```
Structure WMGizmoHookStruct
    Int32 version
    char winName[32]
    char eventName[32]
    Int32 width
    Int32 height
    Int32 mouseX
    Int32 mouseY
    Variable xmin
    Variable xmax
    Variable ymin
    Variable ymax
    Variable zmin
    Variable zmax
    Variable eulerA
    Variable eulerB
    Variable eulerC
    Variable wheelDx
    Variable wheelDy
EndStructure
```

## WMListboxAction

See ListBox for further explanation of WMListboxAction.
Structure WMListboxAction

| char ctrlName[32] | // Control name |
| :--- | :--- |
| char win[200] | $/ /$ Host window or subwindow name |

## WMMarkerHookStruct

See Custom Marker Hook Functions on page IV-279 for further explanation of WMMarkerHookStruct.

```
Structure WMMarkerHookStruct
    Int32 usage // 0= normal draw, l= legend draw
    Int32 marker // Marker number minus start
    float x, Y // Location of desired center of marker
    float size // Half width/height of marker
    Int32 opaque // 1 if marker should be opaque
    float penThick // Stroke width
    STRUCT RGBColor mrkRGB // Fill color
    STRUCT RGBColor eraseRGB // Background color
    STRUCT RGBColor penRGB // Stroke color
    WAVE ywave
    double ywIndex
EndStructure
```

## WMPopupAction

See PopupMenu for further explanation of WMPopupAction.

```
Structure WMPopupAction
    char ctrlName[32] // Control name
    char win[200] // Host window or subwindow name
    STRUCT Rect winRect // Local coordinates of host window
    STRUCT Rect ctrlRect // Enclosing rectangle of the control
    STRUCT Point mouseLoc // Mouse location
    Int32 eventCode // -1: Control being killed
    // 2: Mouse up
    // See Control Structure eventMod Field on page III-387
    // Primary unnamed user data
    // See Control Structure blockReentry Field on page III-388
    // Item number currently selected (1-based)
// Contents of current popup item
char popStr[400]
```

## WMSetVariableAction

See SetVariable for further explanation of WMSetVariableAction.

```
Structure WMSetVariableAction
char ctrlName[32] // Control name
char win[200] // Host window or subwindow name
STRUCT Rect winRect // Local coordinates of host window
STRUCT Rect ctrlRect // Enclosing rectangle of the control
STRUCT Point mouseLoc // Mouse location
```

Int32 eventCode

Int32 eventMod
String userData
Int32 blockReentry
Int32 isStr
Variable dval
char sval [400]
char vName [106]
WAVE svWave
Int32 rowIndex
char rowLabel[32]
Int32 collndex
char colLabel[32]
EndStructure

```
// -1: Control being killed
// 1: Mouse up
// 2: Enter key
// 3: Live update
// 4: Scroll wheel up if increment is zero
// 5: Scroll wheel down if increment is zero
// 6: Value changed by dependency update
// See Control Structure eventMod Field on page III-387
// Primary unnamed user data
// See Control Structure blockReentry Field on page III-388
// TRUE for a string variable
// Numeric value of variable
// Value of variable as a string
// Name of variable or wave
// Valid if using wave
// Row index for a wave if rowLabel is empty
// Wave row label
// Column index for a wave if colLabel is empty
// Wave column label
```

## WMSliderAction

See Slider for further explanation of WMSliderAction.

```
Structure WMSliderAction
    char ctrlName[32] // Control name
    char win[200] // Host window or subwindow name
    STRUCT Rect winRect // Local coordinates of host window
    STRUCT Rect ctrlRect // Enclosing rectangle of the control
    STRUCT Point mouseLoc // Mouse location
    Int32 eventCode // -1 if control about to be killed
// or bit field:
// Bit 0: Value set
// Bit 1: Mouse down
// Bit 2: Mouse up
// Bit 3: Mouse moved
Int32 eventMod // See Control structure eventMod Field on page III-387
String userData // Primary unnamed user data
Int32 blockReentry // See Control Structure blockReentry Field on page III-388
Variable curval // Value of slider
EndStructure
```

## WMTabControlAction

See TabControl for further explanation of WMTabControlAction.

```
Structure WMTabControlAction
    Char ctrlName[32] // Control name 
    STRUCT Rect winRect // Local coordinates of host window
    STRUCT Rect ctrlRect // Enclosing rectangle of the control
    STRUCT Point mouseLoc // Mouse location
    Int32 eventCode // -1: Control being killed
    // 2: Mouse up
    Int32 eventMod // See Control structure eventMod Field on page III-387
    String userData // Primary unnamed user data
    Int32 blockReentry // See Control Structure blockReentry Field on page III-388
    Int32 tab // Tab number
EndStructure
```

## WMWinHookStruct

See Named Window Hook Functions on page IV-271 for further explanation of WMWinHookStruct.

```
Structure WMWinHookStruct
    char winName[200] // Host window or subwindow name
    STRUCT Rect winRect // Local coordinates of the affected (sub) window
    STRUCT Point mouseLoc
    Variable ticks
    Int32 eventCode
    char eventName[32]
    Int32 eventMod
    char menuName[256]
    char menuItem[256]
// Mouse location
// Tick count when event happened
// See Named Window Hook Events on page IV-272
// See Named Window Hook Events on page IV-272
// See Control Structure eventMod Field on page III-387
// Name of the menu item as for SetIgorMenuMode
// Text of the menu item as for SetIgorMenuMode
```

```
        char traceName[32] // See Named Window Hook Functions on page IV-271

```

// 1 if the cursor is not attached to anything
// Simple name of the window or subwindow
// Simple name of the window or subwindow
// Set to 1 to change cursor to cursorCode

```
// Set to 1 to change cursor to cursorCode
```

## wnoise

## wnoise (shape, scale)

The wnoise function returns a pseudo-random value from the two-parameter Weibull distribution characterized by the shape and scale, the respective gamma and alpha parameters. The two-parameter Weibull probability distribution function is

$$
f(x ; \alpha, \gamma)=\frac{\gamma}{\alpha} x^{\gamma-1} \exp \left[-\frac{1}{\alpha} x^{\gamma}\right] \quad \begin{aligned}
& x \geq 0 \\
& \\
& \\
& \\
& \\
& \\
& \gamma>0
\end{aligned}
$$

The mean of the Weibull distribution is

$$
\alpha^{\frac{1}{\gamma}} \Gamma\left(1+\frac{1}{\gamma}\right)
$$

and the variance is

$$
\alpha^{\frac{2}{\gamma}} \Gamma\left(1+\frac{2}{\gamma}\right)-\alpha^{\frac{2}{\gamma}}\left[\Gamma\left(1+\frac{1}{\gamma}\right)\right]^{2} .
$$

Note that this definition of the PDF uses different scaling than the one used in StatsWeibullPDF. To match the scaling of StatsWeibullPDF multiply the result from Wnoise by the factor scale^(1-1/shape).
The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

## See Also

The SetRandomSeed operation.
Noise Functions on page III-334.
Chapter III-12, Statistics for a function and operation overview.

## X

x
The $x$ function returns the scaled row index for the current point of the destination wave in a wave assignment statement. This is the same as the X value if the destination wave is a vector (1D wave).

## Details

Outside of a wave assignment statement, x acts like a normal variable. That is, you can assign a value to it and use it in an expression.

## See Also

The p function and Waveform Arithmetic and Assignments on page II-94.

## x2pnt

x2pnt (waveName, $x 1$ )
The $x 2$ pnt function returns the point number on the wave whose X value is closest to $x 1$.

## Details

There are no equivalent functions for multidimensional waves. To calculate this information for other dimensions, use this expression:
(ScaledDimPos - DimOffset(waveName, dim))/DimDelta(waveName,dim)
This expression calculates the number of an element in the dimension $\operatorname{dim}(\mathrm{p}, \mathrm{q}, \mathrm{r}$, or s ). ScaledDimPos is the scaled position in that dimension ( $\mathrm{x}, \mathrm{y}, \mathrm{z}$, or t ). $\operatorname{dim}$ is 0 for rows, 1 for columns, 2 for layers or 3 for chunks. Setting $\operatorname{dim}=0$ is equivalent to using $\times 2$ pnt. The point number includes a fractional part; you may wish to use ceil, round, trunc, or floor to calculate an integer point number.

## See Also

The functions DimDelta, and DimOffset.
For an explanation of waves and X scaling, see Changing Dimension and Data Scaling on page II-83.

## XCSr

xcsr(cursorName [, graphNameStr])
The xcsr function returns the $X$ value of the point which the named cursor (A through J) is on in the top or named graph.

Parameters
cursorName identifies the cursor, which can be cursor A through J.
graphNameStr specifies the graph window or subwindow.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

## Details

The result is derived from the wave that the cursor is on, not from the X axis of the graph. If the wave is displayed as an $X Y$ pair, the $X$ axis and the wave's X scaling will usually be different.

See Also
The hcsr, pcsr, qcsr, vcsr, and zcsr functions.
Programming With Cursors on page II-292.

## XWaveName

xWaveName (graphNameStr, traceNameStr)
The XWaveName function returns a string containing the name of the wave supplying the X coordinates for the named trace in the named graph window or subwindow.

## Parameters

graphNameStr can be " " to refer to the top graph window.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.
traceNameStr is the name of the trace in question.

## Details

XWaveName returns an empty string (" ") if the trace is not plotted versus an X wave.
For most uses, we recommend that you use XWaveRefFromTrace instead of WaveName. XWaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the X wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a folder that is not the current data folder, you will not be able to refer to the named wave.
graphNameStr and traceNameStr are strings, not names.

## Examples

Display ywave vs xwave // XY graph
Print XWaveName("", "ywave") // prints xwave

## See also

Trace Names on page II-243, Programming With Trace Names on page IV-72.

## XWaveRefFromTrace

XWaveRefFromTrace (graphNameStr, traceNameStr)
The XWaveRefFromTrace function returns a wave reference to the wave supplying the $X$ coordinates against which the named trace is displayed in the named graph window or subwindow.

## Parameters

graphNameStr can be " " to refer to the top graph window.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

Details
XWaveRefFromTrace returns a null reference (see WaveExists) if the wave is not plotted versus an X wave. graphNameStr and traceNameStr are strings, not names.

## Examples

Display ywave vs xwave // XY graph
Print XWaveRefFromTrace("","ywave") [50] // prints value of xwave at point 50

ContourNameList, and ContourNameToWaveRef.
For a discussion of wave references, see Wave Reference Functions on page IV-177.

## See Also

Trace Names on page II-243, Programming With Trace Names on page IV-72.

## y

y
The $y$ function returns the $Y$ value for the current column of the destination wave when used in a multidimensional wave assignment statement. Y is the scaled column index whereas $\mathbf{q}$ is the column index itself.

Details
Unlike $\mathbf{x}$, outside of a wave assignment statement, $\mathbf{y}$ does not act like a normal variable.

## See Also

$\mathbf{x}, \mathbf{z}$, and $\mathbf{t}$ functions for other dimensions.
$\mathbf{p}, \mathbf{q}, \mathbf{r}$, and $\mathbf{s}$ functions for the scaled indices.
Z
$\mathbf{z}$
The z function returns the Z value for the current layer of the destination wave when used in a multidimensional wave assignment statement. $\boldsymbol{z}$ is the scaled layer index whereas $\mathbf{r}$ is the layer index itself.

## Details

Unlike $\mathbf{x}$, outside of a wave assignment statement, z does not act like a normal variable.
See Also
$\mathbf{x}, \mathbf{y}$, and $\mathbf{t}$ functions for other dimensions.
$\mathbf{p}, \mathbf{q}, \mathbf{r}$, and $\mathbf{s}$ functions for the scaled indices.

## ZCSr

zcsr(cursorName [, graphNameStr])
The zcsr function returns a Z value when the specified cursor is on a contour, image, or waterfall plot. Otherwise, it returns NaN .

## Parameters

cursorName identifies the cursor, which can be cursor A through J.
graphNameStr specifies the graph window or subwindow.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-97 for details on forming the window hierarchy.

Examples
Print zcsr(A) // not zcsr("A")
Print zcsr(A,"Graph0") // specifies the graph

## See Also

The hcsr, pcsr, qcsr, vcsr, and xcsr functions.
Programming With Cursors on page II-292.

## ZernikeR

ZernikeR ( $n, m, r$ )
The ZernikeR function returns the Zernike radial polynomials of degree $n$ that contains no power of $r$ that is less than $m$. Here $m$ is even or odd according to whether $n$ is even or odd, and $r$ is in the range 0 to 1 .
Note that the full circle polynomials are complex. For any angle $t$ (theta), they are given by: ZernikeR ( $n, m, r$ ) *exp (imt).
