The discrete Gauss transform can be computed as a direct sum. An exact calculation is practical only for moderate number of sources and observation points and for low spatial dimensionality. With increasing dimensionality and increasing number of sources it is more efficient to take advantage of some properties of the Gaussian function. The FastGaussianTransform operation does so in two ways: It first arranges the sources in N-dimensional spatial clusters so that it is not necessary to compute the contributions of all source points that belong to remote clusters (see **FPClustering**). The second component of the algorithm is an approximation that factorizes the sum into a factor that depends only on source points and a factor that depends only on observation points. The factor that depends only on source points is computed only once while the factor that depends on observation points is evaluated once for each observation point.

The trade-off between computation efficiency and accuracy can be adjusted using multiple parameters. By default, the operation calculates the number of terms it needs to use in the Taylor expansion of the Gaussian. You can modify the default approximate error value using /AERR or you can directly set the number of terms in the expansion using /TET.

FastGaussianTransform supports calculations in dimensions that may exceed the maximum allowed wave dimensionality. **srcLocationsWave** must be a 2D, real-valued single- or double-precision wave in which each row corresponds to a single source position and columns represent the components in each dimension (e.g., a triplet wave would represent 3D source locations). **srcWeightsWave** must have the same number of rows as **srcLocationsWave** and it must be a real-valued single- or double-precision wave. In most applications **srcWeightsWave** will have a single column so that the output \( G \) will be scalar. However, if **srcWeightsWave** has multiple columns than \( G \) is a vector. This can be handy if you need to test multiple sets of coefficients at one time. If you specify observation points using /OUTW then **locWave** must have the same number of columns as **srcLocationsWave** (the number of rows in the output is arbitrary). The operation does not support wave scaling.

References

FastOp

```
FastOp destWave = prod1 [± prod2 [± prod3]]
FastOp destWave += prod1 [± prod2]
```

The FastOp operation can be used to get improved speed out of certain wave assignment statements. The syntax was designed so that you can simply insert **FastOp** in front of any wave assignment statement that meets the syntax requirements. The += syntax was added in Igor Pro 9.00.

Parameters

- **destWave**: An existing destination wave for the assignment expression. An error will be reported at runtime if the waves are not all the same length or number type.
- **prod1, prod2, prod3**: Products with the following formats:
  - constexpr * wave1 * wave2
  - or
  - constexpr * wave1 / wave2

**constexpr** may be a literal numeric constant or a constant expression in parentheses. Such expressions are evaluated only once. Any component in a prod expression may be omitted.
FastOp

Flags

/C

The /C flag is obsolete in Igor Pro 9.00 and later and is ignored. For floating point waves, the type of expressions, real or complex, is determined by the type of the destination wave.

In Igor Pro 8 and before /C is required when using a complex destination wave.

FastOp supports real and complex for floating point waves but only real for integer waves.

Details

FastOp supports real and complex for floating point waves. It supports real only for integer waves.

If your waves are complex, make sure to use WAVE/C when declaring wave references in user-defined functions.

Certain combinations, listed in the following table, are evaluated using faster optimized code rather than more general but slower generic code. SP means "single-precision floating point" and DP means "double-precision floating point".

<table>
<thead>
<tr>
<th>Statement</th>
<th>Optimized Data Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest = 0</td>
<td>All</td>
</tr>
<tr>
<td>dest = waveA</td>
<td>All</td>
</tr>
<tr>
<td>dest += C0 * waveA</td>
<td>SP and DP, real and complex</td>
</tr>
<tr>
<td>dest = dest + C0 * waveA</td>
<td>SP and DP, real and complex</td>
</tr>
<tr>
<td>dest = dest + waveA * C0</td>
<td>SP and DP, real and complex</td>
</tr>
<tr>
<td>dest = C0</td>
<td>SP and DP and integer, real only</td>
</tr>
<tr>
<td>dest = waveA + C1</td>
<td>SP and DP and integer, real only</td>
</tr>
<tr>
<td>dest = C0 * waveA + C1</td>
<td>SP and DP, real only</td>
</tr>
<tr>
<td>dest = waveA + waveB + C2</td>
<td>Integer only, real only</td>
</tr>
</tbody>
</table>

In the statements above, plus may be minuses and the trailing constant (C0, C1, C2) may be omitted.

Note: Except for the optimized cases listed above which use integer calculations for integer waves, integer results are evaluated using double precision intermediate values. This limits precision for 64-bit integer waves to 53 bits.

Speedups generally range from 10 to 40 times faster than the equivalent statement with FastOp removed. The speedup is dependent on the computer and on the length of the waves with the greatest improvement occurring for waves with 1000 to 100,000 points.

Examples

Valid expressions:

FastOp dest = 3
FastOp dest = waveA + waveB
FastOp dest = 0.5*waveA + 0.5*waveB
FastOp dest = waveA*waveB
FastOp dest = (2*3)*waveA + 6
FastOp dest = (locvar)*waveA
FastOp dest += waveA + waveB

Expressions that are not valid:

FastOp dest = 3*4
FastOp dest = (waveA + waveB)
FastOp dest = waveA*0.5 + 0.5*waveB
FastOp dest = waveA*waveB/2
FastOp dest = 2*3*waveA + 6
FastOp dest = locvar*waveA
FastOp dest += waveA + waveB + waveC
faverage

**faverage (waveName [, x1, x2])**
The faverage function returns the trapezoidal average value of the named wave from \( x=x_1 \) to \( x=x_2 \).
If your data are in the form of an XY pair of waves, see faverageXY.

**Details**
If \( x1 \) and \( x2 \) are not specified, they default to \(-\infty\) and \(+\infty\), respectively.
If \( x1 \) or \( x2 \) are not within the X range of \( \text{waveName} \), faverage limits them to the nearest X range limit of \( \text{waveName} \).
faverage returns the area divided by \((x_2-x_1)\). In other words, the X scaling of \( \text{waveName} \) is eliminated when computing the average.
If any Y values in the specified X range are NaN, faverage returns NaN.
Unlike the area function, reversing the order of \( x1 \) and \( x2 \) does not change the sign of the returned value.
The faverage function is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.
The faverage function returns a complex result for a complex input wave. The real part of the result is the average of the real components in the input wave and the imaginary part of the result is the average of the imaginary components.

**Examples**

Comparison of area, faverage and mean functions over interval (12.75,13.32)

![Comparison graph](image)

area(wave,12.75,13.32) = 0.05 \cdot (43+55) / 2 \quad // first trapezoid
+ 0.20 \cdot (55+88) / 2 \quad // second trapezoid
+ 0.20 \cdot (88+100) / 2 \quad // third trapezoid
+ 0.12 \cdot (100+92.2) / 2 \quad // fourth trapezoid
= 47.082

faverage(wave,12.75,13.32) = area(wave,12.75,13.32) / (13.32-12.75)
= 47.082/0.57 = 82.6

mean(wave,12.75,13.32) = (55+88+100+87)/4 = 82.5

See Also
Integrate, area, areaXY, faverageXY and Poly2D Example 3

faverageXY

**faverageXY (XWaveName, YWaveName [, x1, x2])**
The faverageXY function returns the trapezoidal average value of \( YWaveName \) from \( x=x_1 \) to \( x=x_2 \), using X values from \( XWaveName \).
This function operates identically to faverage, except that it uses an XY pair of waves for X and Y values and it does not work with complex waves.

**Details**
If \( x1 \) and \( x2 \) are not specified, they default to \(-\infty\) and \(+\infty\), respectively.
If \( x_1 \) or \( x_2 \) are not within the X range of \( XWaveName \), \( faverageXY \) limits them to the nearest X range limit of \( XWaveName \).

\( faverageXY \) returns the area divided by \( (x_2 - x_1) \).

If any values in the X range are NaN, \( faverageXY \) returns NaN.

Reversing the order of \( x_1 \) and \( x_2 \) does not change the sign of the returned value.

The values in \( XWaveName \) may be increasing or decreasing. \( faverageXY \) assumes that the values in \( XWaveName \) are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any X values are NaN, the result is NaN.

The \( faverageXY \) function is not multidimensional aware. See Chapter II-6, Multidimensional Waves for details on multidimensional waves, particularly Analysis on Multidimensional Waves on page II-95.

Integrate, area, areaXY, faverage and Poly2D Example 3

**FBinRead**

FBinRead [flags] refNum, objectName

The FBinRead operation reads binary data from the file specified by refNum into the named object.

For simple applications of loading binary data into numeric waves you may find the GBLoadWave operation simpler to implement.

**Parameters**

refNum is a file reference number from the Open operation used to open the file.

objectName is the name of a wave, numeric variable, string variable, or structure.

**Flags**

/B[=b] Specifies file byte ordering.

\( b=0: \) Native (same as no /B).

\( b=1: \) Reversed (same as /B).

\( b=2: \) Big-endian (Motorola).

\( b=3: \) Little-endian (Intel).

/F[=f] Controls the number of bytes read and how the bytes are interpreted.

\( f=0: \) Native binary format of the object (default).

\( f=1: \) Signed byte; one byte.

\( f=2: \) Signed 16-bit word; two bytes.

\( f=3: \) Signed 32-bit word; four bytes.

\( f=4: \) 32-bit IEEE floating point; four bytes.

\( f=5: \) 64-bit IEEE floating point; eight bytes.

\( f=6: \) 64-bit integer; eight bytes. Requires Igor Pro 7.00 or later.

/U Integer formats (/F=1, 2, or 3) are unsigned. If /U is omitted, integers are signed.

**Details**

If objectName is the name of a string variable then /F does not apply. The number of bytes read is the number of bytes in the string before the FBinRead operation is called. You can use the PadString function to set the size of a string.

The binary format that FBinRead uses for a numeric variable depends on the /F flag. If you omit /F, the native data type of the variable, which is 8-byte double-precision floating point, is used. So, when reading into a real numeric variable, depending on /F, FBinRead reads 1, 2, 4, or 8 bytes from the file, converts those bytes to double-precision floating point if necessary, and stores the resulting value in the variable. When reading into a complex numeric variable, this process is repeated twice, once for the real part and once for the imaginary part.
FBinWrite

Reading real waves works like reading real variables except that a real wave has multiple elements each of which is 1, 2, 4, or 8 bytes depending on the wave's data type. For each element of a real wave, FBinRead reads the number of bytes implied by /F or by the wave's native data type, converts those bytes to the wave's data type if necessary, and stores the resulting value in the corresponding wave element. When reading into a complex wave, this process is repeated twice, once for the real part of each element and once for the imaginary part.

Reading structures is different. The /F flag has no effect. FBinReads reads the number of bytes required to fill the structure which depends on the sizes of the individual fields and the fact that Igor uses 2-byte structure alignment. After the bytes are read from the file into the structure, FBinRead byte-swaps the individual fields if you include the /B flag.

The FBinRead operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.

See Also
FBinWrite, Open, FGetPos, FSetPos, FStatus, GBLoadWave

FBinWrite

FBinWrite [flags] refNum, objectName
The FBinWrite operation writes the named object in binary to a file.

Parameters
refNum is a file reference number from the Open operation used to open the file.
objectName is the name of a wave, numeric variable, string variable, or structure.

Flags
/B=[b] specifies file byte ordering.
  b=0: Native (same as no /B).
  b=1: Reversed (same as /B).
  b=2: Big-endian (Motorola).
  b=3: Little-endian (Intel).

/F=[f] controls the number of bytes written and how the bytes are formatted.
  f=0: Native binary format of the object (default).
  f=1: Signed byte; one byte.
  f=2: Signed 16-bit word; two bytes.
  f=3: Signed 32-bit word; four bytes.
  f=4: 32-bit IEEE floating point; four bytes.
  f=5: 64-bit IEEE floating point; eight bytes.
  f=6: 64-bit integer; eight bytes. Requires Igor Pro 7.00 or later.

/P Adds an IgorBinPacket to the data. This is used for PPC or Apple event result packets (refNum = 0) and is not normally of use when writing to a file.

/U Integer formats (/F=1, 2, or 3) are unsigned. If /U is omitted, integers are signed.

Details
A zero value of refNum is used in conjunction with Program-to-Program Communication (PPC) or Apple events (Macintosh) or ActiveX Automation (Windows). The data that would normally be written to a file is appended to the PPC or Apple event or ActiveX Automation result packet.

If the object is a string variable then /F doesn’t apply. The number of bytes written is the number of bytes in the string.

The binary format that FBinWrite uses for numeric variables or waves depends on the /F flag. If no /F flag is present, FBinWrite uses the native binary format of the named object.
Byte ordering refers to the order in which a multibyte datum is written to a file. For example, a 16-bit word (sometimes called a “short”) consists of a high-order byte and a low-order byte. Under big-endian byte ordering, which is commonly used on Macintosh, the high-order byte is written to the file first. Under little-endian byte ordering, which is commonly used on Windows, the low-order byte is written to the file first.

FBinWrite will write an entire structure to a disk file. The individual fields of the structure will be byte-swapped if the /B flag is designated.

The FBinWrite operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.

FBinRead, Open, FGetPos, FSetPos, FStatus, GBLoadWave

FetchURL

FetchURL(urlStr)
The FetchURL function returns a string containing the server's response to a request to get the contents of the URL specified by urlStr. If urlStr contains a URL that uses the file:// scheme, the contents of the local file is returned.

Parameters

urlStr is a string containing the URL to retrieve. You can include a username, password, and server port number as part of the URL.

FetchURL expects that urlStr has been percent-encoded if it contains reserved characters. See Percent Encoding on page IV-268 for additional information on when percent-encoding is necessary and how to do it.

See URLs on page IV-267 for details about how to correctly specify the URL.

FetchURL supports only the http://, https://, ftp://, and file:// schemes. See Supported Network Schemes on page IV-268 for details.

There are two special values of urlStr that can be used to get information about the network library that Igor uses. The keyword=value pairs returned when urlStr is "curl_version_info" may be useful to programmers in that the features and protocols available in the library are specified.

FetchURL("curl_version")
FetchURL("curl_version_info")

Details

If FetchURL encounters an error, it returns a NULL string. You should check for errors before using the returned string. In a user-defined function, use the GetRTError function.

String urlStr = "http://www.badserver"
String response = FetchURL(urlStr)
Variable error = GetRTError(1) // Check for error before using response
if (error != 0)
   // FetchURL produced an error
   // so don't try to use the response.
endif

Limitations

It is possible for FetchURL to return a valid server response even though the URL you requested does not exist on the server or requires a username and password that you did not provide. In this situation, the response returned by the server will usually be a web page stating that the page was not found or another error message. You can check for this kind of error in your own code by examining the response.

FetchURL does not support advanced features such as network proxies, file or data uploads, setting the timeout period, or saving the server's response directly to a file. When using the http:// scheme, only the GET method is supported. This means that you cannot use FetchURL to submit form data to a web server that requires using the http POST method. Use the URLRequest operation if you need any of these features.

Igor Pro is not capable of displaying the contents of a URL in a rendered form like a web browser.

Examples

// Retrieve the contents of the WaveMetrics home page.
String response
response = FetchURL("http://www.wavemetrics.com")

// Get a binary image file from a web server and then
// save the image to a file on the desktop.
String url = "http://www.wavemetrics.net/images/tbg.gif"
String imageBytes = FetchURL(url)
Variable error = GetRTError(1)
if (error != 0)
    Print "Error downloading image."
else
    Variable refNum
    String localPath = SpecialDirPath("Desktop", 0, 0, 0) + "tbg.gif"
    Open/T=".gif" refNum as localPath
    FBinWrite refNum, imageBytes
    Close refNum
endif

FFT

FFT [flags] srcWave
The FFT operation computes the Discrete Fourier Transform of srcWave using a multidimensional prime factor decomposition algorithm. By default, srcWave is overwritten by the FFT.

Output Wave Name
For compatibility with earlier versions of Igor, if you use FFT with no flags or with just the /Z flag, the operation overwrites srcWave.

If you use any flag other than /Z, FFT uses default output wave names: W_FFT for a 1D FFT and M_FFT for a multidimensional FFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting srcWave.

Flags
/COLS Computes the 1D FFT of 2D srcWave one column at a time, storing the results in the destination wave.

\[ I[t_1][n] = \sum_{k=0}^{N-1} f[t_1][k] \exp\left(\frac{i2\pi kn}{N}\right). \]

You must specify a destination wave using the /DEST flag. No other flags are allowed with this flag. The number of rows must be even. If srcWave is a real (NxM) wave, the output matrix will be (1+N/2,M) in analogy with 1D FFT. To avoid changes in the number of points you can convert srcWave to complex data type. This flag applies only to 2D source waves. See also the /ROWS flag.

/DEST=destWave Specifies the output wave created by the FFT operation.
It is an error to attempt specify the same wave as both srcWave and destWave.

The default output wave name is W_FFT for a 1D FFT and M_FFT for a multidimensional FFT.

When used in a function, the FFT operation by default creates a complex wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-72 for details.
/FREE  Creates destWave as a free wave.
/FREE is allowed only in functions and only if destWave, as specified by /DEST, is a simple name or wave reference structure field.
See Free Waves on page IV-91 for more discussion.
The /FREE flag was added in Igor Pro 7.00.

/HCC  Hypercomplex transform (cosine). Computes the integral
\[
I_c(\omega_1, \omega_2) = \int \int f(t_1, t_2) \cos(t_1 \omega_1) \exp(it_2 \omega_2) dt_1 dt_2
\]
using the 2D FFT (see Details).

/HCS  Hypercomplex transform (sine). Computes the integral
\[
I_s(\omega_1, \omega_2) = \int \int f(t_1, t_2) \sin(t_1 \omega_1) \exp(it_2 \omega_2) dt_1 dt_2
\]
using the 2D FFT (see Details).

/MAG  Saves just the magnitude of the FFT in the output wave. See comments under /OUT.

/MAGS  Saves the squared magnitude of the FFT in the output wave. See comments under /OUT.

/OUT=mode  Sets the output wave format.
  mode=1: Complex output (default)
  mode=2: Real output
  mode=3: Magnitude
  mode=4: Magnitude square
  mode=5: Phase
  mode=6: Scaled magnitude
  mode=7: Scaled magnitude squared
You can also identify modes 2-4 using the convenience flags /REAL, /MAG, and /MAGS. The convenience flags are mutually exclusive and are overridden by the /OUT flag.
The scaled quantities apply to transforms of real valued inputs where the output is normally folded in the first dimension (because of symmetry). The scaling applies a factor of 2 to the squared magnitude of all components except the DC. The scaled transforms should be used whenever Parseval's relation is expected to hold.

/PAD={dim1 [, dim2, dim3, dim4]}  Converts srcWave into a padded wave of dimensions dim1, dim2,... The padded wave contains the original data at the start of the dimension and adds zero entries to each dimension up to the specified dimension size. The dim1... values must be greater than or equal to the corresponding dimension size of srcWave. If you need to pad just the lowest dimension(s) you can omit the remaining dimensions; for example, /PAD=dim1 will set dim2 and above to match the dimensions in srcWave.

/REAL  Saves just the real part of the transform in the output wave. See comments under /OUT.
The data type of `srcWave` is arbitrary. The first dimension of `srcWave` must be an even number and the minimum length of `srcWave` is four points. When `srcWave` is a double precision wave, the FFT is computed in double precision. All other data types are transformed using single precision calculations. The result of the FFT operation is always a floating point number (single or double precision).

Depending on your choice of outputs, you may not be able to invert the transform in order to obtain the original `srcWave` or any of its intervals must have at least four data points and must not contain NaNs or INFs.

The FFT algorithm is based on prime number decomposition, which decomposes the number of points in each dimension of the wave into a product of prime numbers. The FFT is optimized for primes < 5. In time consuming applications it is frequently worthwhile to pad the data so that the total number of points factors into small prime numbers.

The hypercomplex transforms are computed by writing the sine and cosine as a sum of two exponentials. Let the 2D Fourier transform of the input signal be

\[
F[n_1][n_2] = \sum_{k_1=0}^{N_1} \sum_{k_2=0}^{N_2} f[k_1][k_2] \exp\left(i2\pi k_1 \frac{n_1}{N_1}\right) \exp\left(i2\pi k_2 \frac{n_2}{N_2}\right)
\]

then the two hypercomplex transforms are given by

\[
I_c[n_1][n_2] = \frac{1}{2} \left(F[n_1][n_2] + F[-n_1][n_2]\right)
\]

and
\[
I_s[n_1][n_2] = \frac{1}{2i} (F[n_1][n2] - F[-n_1][n2])
\]

Window Functions
The `/F=windowKind` flag premultiplies a 1D `srcWave` with the selected window function.

In the following window definitions, \( w(n) \) is the value of the window function that multiplies the signal, \( N \) is the number of points in the signal wave (or range if `/R` is specified), and \( n \) is the wave point index. With `/R`, \( n=0 \) for the first datum in the range.

Choices for `windowKind` are in bold.

Bartlet:
A synonym for Bartlett.

Bartlett:

\[
w(n) = \begin{cases} 
\frac{2n}{N} & n = 0,1,...,\frac{N}{2} \\
2 - \frac{2n}{N} & n = \frac{N}{2},...N-1 
\end{cases}
\]

Blackman367, Blackman361, Blackman492, Blackman474:

\[
w(n) = a_0 - a_1 \cos \left( \frac{2\pi}{N} n \right) + a_2 \cos \left( \frac{2\pi}{N} 2n \right) - a_3 \cos \left( \frac{2\pi}{N} 3n \right).
\]

\( n = 0,1,2...N-1 \).

Riemann:

\[ w(n) = \frac{\sin \left( \frac{2\pi n}{N} \right)}{\left( \frac{2\pi n}{N} \right)} \quad 0 \leq |n| \leq \frac{N}{2}. \]

Flat-Top:

The flat-top windows are defined as a sum of cosine terms:

\[ w(n) = \sum_{k=0}^{m} c_k \cos(kz), \quad z = \frac{2\pi j}{N}, \quad j = 0, 1, \ldots, N - 1. \]

Here are the supported flat-top window keywords for use as \textit{windowKind} with the /WINF flag. These keywords require Igor Pro 8.00 or later:

FGetPos

FGetPos refNum
The FGetPos operation returns the file position for a file.
FGetPos is a faster alternative to FStatus if the only thing you are interested in is the file position.
The FGetPos operation was added in Igor Pro 7.00.

Parameters
refNum is a file reference number obtained from the Open operation.

Details
FGetPos supports very big files theoretically up to about 4.5E15 bytes in length.
FGetPos sets the following variables:

V_flag Nonzero (true) if refNum is valid.
V_filePos Current file position for the file in bytes from the start.

Open, FSetPos, FStatus

FIFO2Wave

FIFO2Wave [/R/S] FIFOName, channelName, waveName
The FIFO2Wave operation copies FIFO data from the specified channel of the named FIFO into the named wave. FIFOs are used for data acquisition.

Flags
/R=[startPoint,endPoint] Dumps the specified FIFO points into the wave.
/S=s Controls the wave’s X scaling and number type:
s=0: Same as no /S.
s=1: Sets the wave’s X scaling x0 value to the number of the first sample in the FIFO.
s=2: Changes the wave’s number type to match the FIFO channel’s type.
s=3: Combination of s=1 and s=2.

Details
The FIFO must be in the valid state for FIFO2Wave to work. When you create a FIFO, using NewFIFO, it is initially invalid. It becomes valid when you issue the start command via the CtrlFIFO operation. It remains valid until you change a FIFO parameter using CtrlFIFO.
If you specify a range of FIFO data points, using \(/R=[startPoint,endPoint]\) then \texttt{FIFO2Wave} dumps the specified FIFO points into the wave after clipping \texttt{startPoint} and \texttt{endPoint} to valid point numbers. The valid point numbers depend on whether the FIFO is running and on whether or not it is attached to a file. If the FIFO is running then \texttt{startPoint} and \texttt{endPoint} are truncated to number of points in the FIFO. If the FIFO is buffering a file then the range can include the full extent of the file.

If you specify no range then \texttt{FIFO2Wave} transfers the most recently acquired FIFO data to the wave. The number of points transferred is the smaller of the number of points in the FIFO and number of points in the wave. \texttt{FIFO2Wave} may or may not change the wave’s X scaling and number type, depending on the current X scaling and on the \texttt{/S} flag. Think of the wave’s X scaling as being controlled by two values, \(x_0\) and \(dx\), where the X value of point \(p\) is \(x_0 + p*dx\). \texttt{FIFO2Wave} always sets the wave’s \(dx\) value equal to the FIFO’s \(deltaT\) value (as set by the \texttt{CtrlFIFO} operation). If you use no \texttt{/S} flag, \texttt{FIFO2Wave} does not set the wave’s \(x_0\) value nor does it set the wave’s number type.

If you are using \texttt{FIFO2Wave} to update a wave in a graph as quickly as possible, the \texttt{/S=0} flag gives the highest update rate. The other \texttt{/S} values trigger more recalculation and slow down the updating.

If the wave’s number type (possibly changed to match the FIFO channel) is a floating point type, \texttt{FIFO2Wave} scales the FIFO data before transferring it to the wave as follows:

\[
\text{scaled\_value} = (\text{FIFO\_value} - \text{offset}) * \text{gain}
\]

If the FIFO channel’s gain is one and its offset is zero, the scaling would have no effect so \texttt{FIFO2Wave} skips it. If the specified FIFO channel is an image strip channel (one defined using the optional \texttt{vectPnts} parameter to \texttt{NewFIFOChan}), then the resultant wave will be a matrix with the number of rows set by \texttt{vectPnts} and the number of columns set by the number of points described above for one-dimensional waves. To create an image plot that looks the same as the corresponding channel in a Chart, you will need to transpose the wave using \texttt{MatrixTranspose}.

\section*{See Also}

The \texttt{NewFIFO} and \texttt{CtrlFIFO} operations, and \texttt{FIFOs and Charts} on page IV-313 for more information on FIFOs and data acquisition. For an explanation of waves and wave scaling, see \texttt{Changing Dimension and Data Scaling} on page II-68.

\chapter*{FIFOStatus}

\texttt{FIFOStatus [/Q] FIFOName}

The \texttt{FIFOStatus} operation returns miscellaneous information about a FIFO and its channels. FIFOs are used for data acquisition.

\section*{Flags}

\begin{itemize}
  \item \texttt{/Q} \hspace{1cm} Doesn’t print in the history area.
\end{itemize}

\section*{Details}

\texttt{FIFOStatus} sets the variable \texttt{V\_flag} to nonzero if a FIFO of the given name exists. If the named FIFO does exist then \texttt{FIFOStatus} stores information about the FIFO in the following variables:

\begin{itemize}
  \item \texttt{V\_FIFORunning} \hspace{1cm} Nonzero if FIFO is running.
  \item \texttt{V\_FIFOChunks} \hspace{1cm} Number of chunks of data placed in FIFO so far.
  \item \texttt{V\_FIFOChans} \hspace{1cm} Number of channels in the FIFO.
  \item \texttt{S\_Info} \hspace{1cm} Keyword-packed information string.
\end{itemize}

The keyword-packed information string consists of a sequence of sections with the following form: \texttt{keyword:value;}

You can pick a value out of a keyword-packed string using the \texttt{NumberByKey} and \texttt{StringByKey} functions. Here are the keywords for \texttt{S\_Info}:

In addition, \texttt{FIFOStatus} writes fields to \texttt{S\_Info} for each channel in the FIFO. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named “Pressure” then the following would appear in the \texttt{S\_Info} string: \texttt{name4:Pressure}.

FilterFIR

FilterFIR [flags] waveName [, waveName]...

The FilterFIR operation convolves each waveName with automatically-designed filter coefficients or with coefsWaveName using time-domain methods.

The automatically-designed filter coefficients are simple lowpass and highpass window-based filters or a maximally-flat notch filter. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first waveName or just used to filter the data in waveName.

FilterFIR filters data faster than Convolve when there are many fewer filter coefficient values than data points in waveName.

Note: FilterFIR replaces the obsolete SmoothCustom operation.

Parameters
waveName is a destination wave that is overwritten by the convolution of itself and the filter.

waveName may be multidimensional, but only one dimension selected by /DIM is filtered (for two-dimensional filtering, see MatrixFilter).

If waveName is complex, the real and imaginary parts are filtered independently.

Flags
/COEF [=coefsWaveName]
Replaces the first output *waveName* by the filter coefficients instead of the filtered results or, when *coefsWaveName* is specified, replaces the output wave(s) by the result of convolving *waveName* with coefficients in *coefsWaveName*.

*coefsWaveName* must not be one of the destination *waveNames*. It must be single- or double-precision numeric and one-dimensional.

To avoid shifting the output with respect to the input, *coefsWaveName* must have an odd length with the “center” coefficient in the middle of the wave.

The coefficients are usually symmetrical about the middle point, but FilterFIR does not enforce this.

/DIM=d

Specifies the wave dimension to filter.

  *d*=1: Treats entire wave as 1D (default).
  *d*=0: Operates along rows.
  *d*=1: Operates along columns.
  *d*=2: Operates along layers.
  *d*=3: Operates along chunks.

Use /DIM=0 to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all of the sound samples at a particular time.

/E=endEffect

Determines how the ends of the wave (w) are handled when fabricating missing neighbor values. *endEffect* has values:

  0: Bounce method (default). Uses w[i] in place of the missing w[-i] and w[n+i].
  1: Wrap method. Uses w[n-i] in place of the missing w[-i] and vice versa.
  2: Fill with 0. Same as /ENDV=[0].
  3: Fill method. Uses w[0] in place of the missing w[-i] and w[n] in place of the missing w[n+i].

/ENDV=[sv [, ev]]

When fabricating missing neighbor values for each filtered wave, missing values before the start of data are replaced with *sv*. Missing values after the end of data are replaced with *ev* if specified, or with *sv* if *ev* is omitted. /ENDV implies /E=2.

/ENDV was added in Igor Pro 9.00.

/Hi=\[/f1, f2, n\]

Creates a high-pass filter based on the windowing method, using the Hanning method unless another window is specified by /WINF.

*f1* and *f2* are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

*f1* is the end of the reject band, and *f2* is the start of the pass band:

  0 < \( f1 < f2 < 0.5 \)

*n* is the number of FIR filter coefficients to generate. A larger number gives better stop-band rejection. A good number to start with is 101.

Use both /HI and /LO to create a bandpass filter.

/LO=\[/f1, f2, n\]

Creates a low-pass filter. *f1* is the end of the pass band, *f2* is the start of the reject band, and *n* is the number of FIR filter coefficients. See /HI for more details.

/NMF=[fc, fw [, eps, nMult]]
FilterFIR

Creates a maximally-flat notch filter centered at \( f_c \) with a \(-3\)dB width of \( f_w \). \( f_c \) and \( f_w \) are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

The longest filter length allowed is 400,001 points, which requires \( f_w \geq 0.000789 \) (0.0789% of the sampling frequency).

Prior to Igor Pro 8.03 the longest filter length was 4,001 points, with \( f_w \geq 0.00789 \) (0.789% of the sampling frequency).

Coefficients at the ends that are smaller than the optional \( \text{eps} \) parameter are removed, making the filter shorter (and faster), though less accurate. The default is \( 2^{-40} \). Use 0 to retain all coefficients, no matter how small, even zero coefficients. Retaining all coefficients will substantially increase the execution time as \( f_w \) is made smaller.

\( nMult \) specifies how much longer the filter may be to obtain the most accurate notch frequency. The default is 2 (potentially twice as many coefficients). Set \( nMult \leq 1 \) to generate the shortest possible filter.

The maximally flat notch filter design is based on Zahradnik and Vlcek, and uses arbitrary precision math (see \APMath\) to compute the coefficients.

\(/\text{WINF=windowKind}\)

Applies the named “window” to the filter coefficients. Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when many filter coefficients are used.

If /WINF is not specified, the Hanning window is used. For no coefficient filtering, use /WINF=None.

Choices for \text{windowKind} are:

See \FFT\ for window equations and details.

Details

If \coefsWaveName is specified, then /HI, /LO, and /NMF are ignored.

If more than one of /HI, /LO, and /NMF are specified, the filters are combined using linear convolution. The length of the combined filter is slightly less than the sum of the individual filter lengths.

A band pass or band reject filter results when both /LO and /HI are specified. A band pass filter results from /LO frequencies greater than the /HI frequencies (the pass bands of the low pass and high pass filters overlap). Beginning with Igor Pro 9.00, a band reject filter results when /LO frequencies are less than the /HI frequencies (the stop bands of the filters overlap).

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length should be small in comparison to the destination waves.

FilterFIR assumes that the middle point of \coefsWaveName corresponds to the delay = 0 point. The “middle” point number = \text{trunc(numpnts(coefsWaveName)-1)/2}. \coefsWaveName usually contains the two-sided impulse response of a filter, and usually contains an odd number of points. This is the kind of coefficients data generated by /HI, /LO, and /NMF.

FilterFIR ignores the X scaling of all waves, except when /COEF creates a coefficients wave, which preserves the X scale deltax and alters the leftx value so that the zero-phase (center) coefficient is located at x=0.

Examples

// Make test sound from three sine waves
Variable/G fs= 44100 // Sampling frequency
Variable/G seconds= 0.5 // Duration
Variable/G n= 2*round(seconds*fs/2)

PlaySound sound  // This has a very high frequency tone
PlaySound soundFiltered  // This doesn't

References

See Also
Smoothing on page III-292; the Smooth, Convolve, MatrixConvolve, and MatrixFilter operations.
The FilterIIR operation applies to each `waveName` either the automatically-designed IIR filter coefficients or the IIR filter coefficients in `coefsWaveName`. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first `waveName` or just used to filter the data in `waveName`.

The automatically-designed filter coefficients are bilinear transforms of the Butterworth analog prototype with an optional variable-width notch filter.

To design more advanced IIR filters, see Designing the IIR Coefficients.

**Parameters**

`waveName` may be multidimensional, but only the one dimension selected by `/DIM` is filtered (for two-dimensional filtering, see MatrixFilter).

`waveName` may be omitted for the purpose of checking the format of `coefsWaveName`. If the format is detectably incorrect an error code will be returned in V_flag. Use `/Z` to prevent command execution from stopping.

**Flags**

- **/CASC**
  Specifies that `coefsWaveName` contains cascaded bi-quad filter coefficients. The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form 1 filtering. See Cascade Details.

- **/COEF [=coefsWaveName]**
  Replaces the first output `waveName` by the filter coefficients instead of the filtered results or, when `coefsWaveName` is specified, replaces the output wave(s) by the result of filtering `waveName` with the IIR coefficients in `coefsWaveName`.

  `coefsWaveName` must not be one of the destination `waveName`s. It must be single- or double-precision numeric and two-dimensional.

  When used with `/CASC`, `coefsWaveName` must have 6 columns, containing real-valued coefficients for a product of ratios of second-order polynomials (cascaded bi-quad sections).

  If `/ZP` is specified, it must be complex, otherwise it must be real.

  See Details for the format of the coefficients in `coefsWaveName`.

- **/DIM=d**
  Specifies the wave dimension to filter.

  - `d=1:` Treats entire wave as 1D (default).
  - `d=0:` Operates along rows.
  - `d=1:` Operates along columns.
  - `d=2:` Operates along layers.
  - `d=3:` Operates along chunks.

  Use `/DIM=0` to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional `waveName` where each row comprises all of the sound samples at a particular time.

- **/ENDV=ev**
  Values before the beginning of each filtered wave are replaced with `ev`. If you omit `/ENDV` they are replaced with zeros. To prevent filter startup artifacts set `ev` to the first value or a localized mean value at the start of the wave to be filtered.

  `/ENDV` was added in Igor Pro 9.00.

- **/HI=fHigh**
  Creates a high-pass Butterworth filter with the -3dB corner at `fHigh`. The order of the filter is controlled by the `/ORD` flag.

  `fHigh` is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).
FilterIIR

/LO=fLow
Creates a low-pass Butterworth filter with the -3dB corner at fLow. The /ORD flag controls the order of the filter.

fLow is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

Create bandpass and bandreject filters by specifying both /HI and /LO. For a bandpass filter, set fLow > fHigh, and for a band reject filter, set fLow < fHigh.

/N={fNotch, notchQ}
Creates a notch filter with the center frequency at fNotch and a -3dB width of fNotch/notchQ.

fNotch is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

notchQ is a number greater than 1, typically 10 to 100. Large values produce a filter that “rings” a lot.

/ORD=order
Sets the order of the Butterworth filter(s) created by /HI and /LO. The default is 2 (second order), and the maximum is 100.

/Z=z
Prevents procedure execution from aborting when an error occurs. Use /Z=1 to handle this case in your procedures using GetRTError(1) rather than having execution abort. /Z=0 is the same as no /Z at all.

/ZP
Specifies that coefsWaveName contains complex z-domain zeros (in column 0) and poles (in column 1) or, if coefsWaveName is not specified, that the first output waveName is to be replaced by filter coefficients in the zero-pole format. See Zeros and Poles Details.

Details
FilterIIR sets V_flag to 0 on success or to an error code if an error occurred. Command execution stops if an error occurs unless the /Z flag is set. Omit /Z and call GetRTError and GetRTErrMessage under similar circumstances to see what the error code means.

Direct Form 1 Details
Unless /CASC or /ZP are specified, the coefficients in coefsWaveName describe a ratio of two polynomials of the Z transform:

\[ H(z) = \frac{Y(z)}{X(z)} = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2} + \ldots}{b_0 + b_1 z^{-1} + b_2 z^{-2} + \ldots} \]

where \( x \) is the input wave waveName and \( y \) is the output wave (either waveName again or destWaveName). FilterIIR computes the filtered result using the Direct Form I implementation of \( H(z) \).
The rational polynomial numerator \( (a_i) \) coefficients in are column 0 and denominator \( (b_i) \) coefficients in column 1 of `coefsWaveName`.  

The coefficients in row 0 are the nondelayed coefficients \( a_0 \) (in column 0) and \( b_0 \) (in column 1).  

The coefficients in row 1 are the \( z^{-1} \) coefficients, \( a_1 \) and \( b_1 \).  

The coefficients in row \( n \) are the \( z^{-n} \) coefficients, \( a_n \) and \( b_n \).  

The number of coefficients for the numerator can differ from the number of coefficients for the denominator. In this case, specify 0 for unused coefficients.  

**Note:** If all the coefficients of the denominator are 0 \( (b_i = 0 \text{ except } b_0 = 1) \), then the filter is actually a causal FIR filter (Finite Impulse Response filter with delay of \( n-1 \)). In this sense, FilterIIR implements a superset of the FilterFIR operation.  

**Alternate Direct Form 1 Notation**  
The designation of \( a_i \), etc. as the numerator is at odds with many textbooks such as *Digital Signal Processing*, which uses \( b \) for the numerator coefficients of the rational function, \( a \) for the denominator coefficients with an implicit \( a_0 = 1 \), in addition to reversing the signs of the remaining denominator coefficients so that they can write \( H(z) \) as:  

\[
H(z) = \frac{Y(z)}{X(z)} = \frac{\sum_{i=0}^{n} b_i z^{-i}}{1 - \sum_{i=1}^{n} a_i z^{-i}}. 
\]

Coefficients derived using this notation need their denominator coefficients sign-reversed before putting them into rows 1 through \( n \) of column 1 (the second column), and the “missing” nondelayed denominator coefficient of 1.0 placed in row \( 0 \), column 1.  

**Cascade Details**  
When using `/CASC`, coefficients in `coefsWaveName` describe the product of one or more ratios of two quadratic polynomials of the Z transform:  

\[
H(z) = \frac{Y(z)}{X(z)} = \prod_{k=1}^{K} \frac{a_{0_k} + a_{1_k} z^{-1} + a_{2_k} z^{-2}}{b_{0_k} + b_{1_k} z^{-1} + b_{2_k} z^{-2}}. 
\]

Each product term implements a “cascaded bi-quad section”, and \( H(z) \) can be realized by feeding the output of one section to the next one.  

The cascade coefficients filter the data using a Direct Form II cascade implementation:  

\[
w_i = \frac{x_i - b_1 w_{i-1} - b_2 w_{i-2}}{b_0} \\
y_i = a_0 w_i + a_1 w_{i-1} + a_2 w_{i-2} 
\]
The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form I filtering. Cascade IIR filtering is recommended when the filter order exceeds 16 (a 16th-order Direct Form I filter has 17 numerator coefficients and 17 denominator coefficients).

coevsWaveName must be a six-column real-valued numeric wave. Each row describes one bi-quad section. The coefficients for the second term (or “section”) of the product \((k=2)\) are in the following row, etc.:

<table>
<thead>
<tr>
<th>(k)</th>
<th>Row</th>
<th>Col 0</th>
<th>Col 1</th>
<th>Col 2</th>
<th>Col 3</th>
<th>Col 4</th>
<th>Col 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>(a_{0_1})</td>
<td>(a_{1_1})</td>
<td>(a_{2_1})</td>
<td>(b_{0_1})</td>
<td>(b_{1_1})</td>
<td>(b_{2_1})</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>(a_{0_2})</td>
<td>(a_{1_2})</td>
<td>(a_{2_2})</td>
<td>(b_{0_2})</td>
<td>(b_{1_2})</td>
<td>(b_{2_2})</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The number of coefficients for the numerator (\(a\)’s) is allowed to differ from the number of coefficients for the denominator (\(b\)’s). In this case, specify 0 for unused coefficients.

For example, a third order filter (three poles and three zeros) cascade implementation is a single-order section combined with a second order section. The values for \(a_{2_1}, b_{2_1}\) for that section \((k)\) would be 0. Here the second section is specified as the first-order section:

<table>
<thead>
<tr>
<th>(k)</th>
<th>Row</th>
<th>Col 0</th>
<th>Col 1</th>
<th>Col 2</th>
<th>Col 3</th>
<th>Col 4</th>
<th>Col 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>(a_{0_1})</td>
<td>(a_{1_1})</td>
<td>(a_{2_1})</td>
<td>(b_{0_1})</td>
<td>(b_{1_1})</td>
<td>(b_{2_1})</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>(a_{0_2})</td>
<td>(a_{1_2})</td>
<td>0</td>
<td>(b_{0_2})</td>
<td>(b_{1_2})</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Alternate Cascade Notation
In the DSP literature, the \(b_{0_1}\) gain values are typically one and the \(H(z)\) expression contains an overall gain value, usually \(K\). Here each product term (or “section”) has a user-settable gain value. Computing the correct gain values to control overflow in integer implementations is the responsibility of the user. For floating implementations, you might as well set all \(b_{0_1}\) values to one except, say, \(b_{0_1}\), to control the overall gain.

Zeros and Poles Details
When using /ZP, coefficients in coefsWaveName contains complex zeros and poles in the (also complex) \(Z\) transform domain:

\[
H(z) = \frac{Y(z)}{X(z)} = \frac{(z - z_0)(z - z_1)(z - z_2)\ldots}{(z - p_0)(z - p_1)(z - p_2)\ldots}
\]

coevsWaveName must be a two-column complex wave with zero0, zero1, … zeroN in the first column of N+1 rows, and pole0, pole1, … poleN in the second column of those same rows:

<table>
<thead>
<tr>
<th>(k)</th>
<th>Row</th>
<th>Col 0</th>
<th>Col 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>(zero0Real, zero0Imag)</td>
<td>(pole0Real, pole0Imag)</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>(zero1Real, zero1Imag)</td>
<td>(pole1Real, pole1Imag)</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>(zero2Real, zero2Imag)</td>
<td>(pole2Real, pole2Imag)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If a zero or pole has a nonzero imaginary component, the conjugate zero or pole must be included in coefsWaveName. For example, if a zero is placed at \((0.7, 0.5)\), the conjugate is \((0.7, -0.5)\), and that value must also appear in column 0. These two zeros form what is known as a “conjugate pair”. The conjugate values must match within the greater of 1.0e-6 or 1.0e-6 * |zeroOrPole|.

Use \((0,0)\) for unused poles or zeros, as a zero or pole at \(z=(0,0)\) has no effect on the filter frequency response.
The /ZP format for the coefficients is internally converted into the Direct Form 1 implementation, or into the Cascade Direct Form 2 implementation if /CASC is specified. There is no option for returning these implementation-dependent coefficients in a wave.

Designing the IIR Coefficients
Simple IIR filters can be used or created by specifying the /LO, /HI, /ORD, /N, /CASC, and /ZP flags. Use /COEF without coefsWaveName to put these simple IIR filter coefficients into the first waveName.

More advanced IIR filters (Bessel, Chebyshev) can be designed using the separate Igor Filter Design Laboratory (IFDL). IFDL is an Igor package that you use to design FIR (Finite Impulse Response) and IIR (Infinite Impulse Response) filters and to apply them to your data. The IIR design software creates IIR coefficients based on bilinear transforms of analog prototype filters such as Bessel, Butterworth, and Chebyshev.

Even without IFDL, you can create custom IIR filters by manually placing poles and zeros in the Z plane using the Pole and Zero Filter Design procedures. Copy the following line to your Procedure window and click the Compile button at the bottom of the procedure window:

```
#include <Pole And Zero Filter Design>
```

Then choose Pole and Zero Filter Design from the Analysis menu.

Examples

```
// Make test sound from three sine waves
Variable/G fs= 44100 // Sampling frequency
Variable/G seconds= 0.5 // Duration
Variable/G n= 2*round(seconds*fs/2)
Make/O/W/N=(n) sound // 16-bit integer sound wave
SetScale/p x, 0, 1/fs, "s", sound
Variable/G f1= 200, f2= 1000, f3= 7000
Variable/G a1=100, a2=3000,a3=1500
sound= a1*sin(2*pi*f1*x)
sound += a2*sin(2*pi*f2*x)
sound += a3*sin(2*pi*f3*x)+gnoise(10) // Add a noise floor
   // Compute the sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundMag sound
soundMag= 20*log(soundMag)
SetScale d, 0, 0, "dB", soundMag
   // Apply a 5 kHz, 6th order low-pass filter to the sound wave
Duplicate/O sound, soundFiltered
FilterIIR/LO=(5000/fs)/ORD=6 soundFiltered // Second order by default
   // Compute the filtered sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundFilteredMag soundFiltered
soundFilteredMag= 20*log(soundFilteredMag)

FindContour

FindContour [flags] matrixWave, level

The FindContour operation creates an XY pair of waves representing the locus of the solution to matrixWave=level.

The FindContour operation was added in Igor Pro 7.00.
FindDimLabel

Flags

/DSTX=destX Saves the output X data in the specified destination wave. The destination wave is created or overwritten if it already exists.

/DSTY=destY Saves the output Y data in the specified destination wave. The destination wave is created or overwritten if it already exists.

Details

FindContour uses a contour-following algorithm to generate a pair of waves describing the locus of the solution to matrixWave=level.

If you omit /DSTX the output X data is written to W_XContour in the current data folder.

If you omit /DSTY the output Y data is written to W_YContour in the current data folder.

The output waves are written as double-precision floating point. They use NaNs to separate different contiguous solution points.

Example

Make/N=(100,200) dataWave = 1e4*gauss(x,50,10,y,100,20)
FindContour dataWave,4 // Find solution to dataWave=4
NewImage dataWave
AppendToGraph/T W_YContour vs W_XContour

See Also

AppendMatrixContour, ContourZ

FindDimLabel

FindDimLabel(waveName, dimNumber, labelString)

Returns the index value corresponding to the label for the given dimension. Returns -1 if the label is for the entire dimension. Returns -2 if the label is not found.

Use dimNumber = 0 for rows, 1 for columns, 2 for layers, or 3 for chunks.

See Also

GetDimLabel, SetDimLabel, CopyDimLabels

FindDuplicates

FindDuplicates [flags] srcWave

The FindDuplicates operation identifies duplicate values in a wave and optionally creates various output waves. srcWave can be either numeric or text.

When srcWave is numeric, the /DN, /INDX, /RN and /SN flags create output waves as described below. If you omit all of these flags then FindDuplicates does nothing.

When srcWave is text, the /DT, /INDX, /RT and /ST flags create output waves as described below. If you omit all of these flags then FindDuplicates does nothing.

The FindDuplicates operation was added in Igor Pro 7.00.

Flags

/FREE Creates all output waves as free waves. The /FREE flag was added in Igor Pro 8.00.

/FREE is permitted in user-defined functions only. If you use /FREE then all output wave parameters must be simple names, not paths or $ expressions.

See Free Waves on page IV-91 for details on free waves.

/INDX=indexWave Creates a numeric output wave containing the index of each encountered duplicate. The index is the point number in srcWave where a duplicate value was encountered. This flag applies to both numeric and text inputs.

/Z Do not report any errors.
**FindDuplicates**

### Flags for Numeric Source Wave

- **/DN=dupsWave**  
  Creates a numeric output wave that contains the duplicates.

- **/RN=dupsRemovedWave**  
  Creates a numeric output wave that contains the source data with all duplicates removed.

- **/SN=replacement**  
  Creates a numeric output wave with all duplicates replaced with *replacement*. *replacement* can be any numeric value including NaN or INF.

  The output wave is W_ReplacedDuplicates in the current data folder unless you specify a different output wave using the /SNDS flag.

- **/SNDS=dupsReplacedWave**  
  Specifies the output wave generated by /SN. If you omit /SNDS then the output wave created by /SN is W_ReplacedDuplicates in the current data folder. /SNDS without /SN has no effect.

- **/TOL=tolerance**  
  Specifies the tolerance value for single-precision and double-precision numeric source waves.

  Two values are considered duplicates if

  \[ \text{abs(value1-value2)} \leq \text{tolerance} \]

  By default *tolerance* is zero.

- **/UN=uniqueNumbersWave**  
  Creates a numeric output wave that contains the unique numbers in srcWave sorted from small to large. When srcWave contains NaN entries they are sorted as the last point in uniqueNumbersWave.

  /UN is incompatible with /RN which maintains the order of entries in srcWave.

  The /UN flag was added in Igor Pro 9.00.

- **/UNC=uniqueCounts**  
  Creates a numeric output wave that contains the count of each entry in the uniqueNumbersWave created by the /UN flag.

  The /UNC flag was added in Igor Pro 9.00.

### Flags for Text Source Wave

- **/CI**  
  Performs case-insensitive text comparisons on ASCII characters only. For example, "A" and "a" are considered duplicates.

  The /CI flag was added in Igor Pro 9.00.

- **/DT=dupsWave**  
  Performs locale-aware text comparisons which take case into account for both ASCII and non-ASCII characters. For example, the non-ASCII characters "Å" and "ä" are considered duplicates as well as the ASCII characters "A" and "a".

  /LOC is ignored unless you also include /CI.

  The /LOC flag was added in Igor Pro 9.00.

- **/RT=dupsRemovedWave**  
  Creates a text output wave that contains the source data with all duplicates removed.

- **/ST=replacementStr**  
  Creates a text output wave with all duplicates replaced with *replacementStr*. *replacementStr* can be any text value including "."

  The output wave is T_ReplacedDuplicates in the current data folder unless you specify a different output wave using the /STDS flag.
Details
FindDuplicates scans srcWave and identifies duplicate values. The first instance of any value is not considered a duplicate. Duplicates are either identical, as is the case with integer or text waves, or values that are within a specified tolerance in the case of single-precision or double-precision numeric waves.

Text comparison is case-sensitive unless you use /CI or /CI/LOC.

The operation creates wave references for the waves specified by the various flags above. See Automatic Creation of WAVE References on page IV-72 for details.

Example
Function DemoFindDuplicates(mode)
  int mode // 0=case sensitive; 1=/CI; 2=/CI/LOC
  Make/O/T sourceText={"A", "a", "Å", "å", "B", "b"}
  switch(mode)
    case 0: // Case sensitive
      // Returns {"A", "a", "Å", "å", "B", "b"}
      FindDuplicates/FREE/RT=output sourceText
      break
    case 1: // Case insensitive for ASCII only
      // Returns {"Å", "å", "B"}
      FindDuplicates/FREE/RT=output/CI sourceText
      break
    case 2: // Case insensitive, locale aware
      // Returns {"Å", "Å", "B"}
      FindDuplicates/FREE/RT=output/CI/LOC sourceText
      break
  endswitch
  Print sourceText
  Print output
End

FindLevels, FindValue, Sort, TextHistogram

FindLevel
FindLevel [flags] waveName, level

The FindLevel operation searches the named wave to find the X value at which the specified Y level is crossed.

Flags

/B=box

Sets box size for sliding average. If /B=box is omitted or box equals 1, no averaging is done. If you specify an even box size then the next higher (odd) integer is used. If you use a box size greater than 1, FindLevel will be unable to find a level crossing that occurs in the first or last (box-1)/2 points of the wave since these points don’t have enough neighbors for computing the derived average wave values.

/EDGE=e

Sets box size for sliding average. If /B=box is omitted or box equals 1, no averaging is done. If you specify an even box size then the next higher (odd) integer is used. If you use a box size greater than 1, FindLevel will be unable to find a level crossing that occurs in the first or last (box-1)/2 points of the wave since these points don’t have enough neighbors for computing the derived average wave values.

Specifies searches for either increasing or decreasing level crossing.

e=1: Searches only for crossing where Y values are increasing as level is crossed from wave start towards wave end.

e=2: Searches only for crossing where the Y values are decreasing as level is crossed from wave start towards wave end.

e=0: Same as no /EDGE flag (searches for either increasing and decreasing level crossing).
FindLevel scans through the wave comparing level to values derived from the Y values of the wave. Each derived value is a sliding average of the Y values. FindLevel searches for two derived wave values that straddle level. If it finds these values it computes the X value at which level is located by linearly interpolating between the straddling Y values. FindLevel does not locate values exactly equal to level; it locates transitions through level. See BinarySearch for one method of locating exact values.

FindLevel reports its results by setting these variables:

- **V_flag**: 0: level was found. 1: level was not found.
- **V_LevelX**: Interpolated X value at which level was found, or the corresponding point number if /P is specified.
- **V_rising**: 0: Y values at the crossing are decreasing from wave start towards wave end. 1: Y values at the crossing are increasing.

If you omit the /Q flag then FindLevel also reports its results by printing them in the history area. If level is not found, and if you omit the /Q flag, FindLevel generates an error which puts up an error alert and halts execution of any command line or macro that is in progress. V_LevelX is returned in terms of the X scaling of the named wave unless you use the /P flag, in which case it is in terms of point number.

**FindLevel Handling of NaNs**

In Igor Pro 8.00 and later, FindLevel handles NaN values differently than previous versions. Now if level falls between two non-NaN wave Y values with NaNs between them, those two Y values and their associated X scaling values are used to linearly interpolate the X location of the level crossing. Igor7 and earlier fail to find a crossing and set V_LevelX to NaN.

For example:

```cpp
// Prints 2.5 in Igor8 or later, NaN in Igor7 or before
Make/O wave0 = {0, 1, NaN, NaN, 4, 5}
FindLevel/Q wave0, 2.5; Print V_levelX
```

You can revert to the pre-Igor 8 behavior by executing:

```
SetIgorOption UseIP6FindLevel = 1
```
FindLevels

FindLevel and Multidimensional Waves
The FindLevel operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.

See Also
The EdgeStats, FindLevels, FindValue, and PulseStats operations and the BinarySearch and BinarySearchInterp functions.

FindLevels

FindLevels [flags] waveName, level
The FindLevels operation searches the named wave to find one or more X values at which the specified Y level is crossed.

To find where the wave is equal to a given value, use FindValue instead.

Flags

/B=box Sets box size for sliding average. See the FindLevel operation.

/D=destWaveName Specifies wave into which FindLevels is to store the level crossing values. If /D and /DEST are omitted, FindLevels creates a wave named W_FindLevels to store the level crossing values in.

/DEST=destWaveName
Same as /D. Both /D and /DEST create a real wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-72 for details.

/EDGE=e Specifies searches for either increasing or decreasing level crossing.

e=1: Searches only for crossings where the Y values are increasing as level is crossed from wave start towards wave end.

e=2: Searches only for crossings where the Y values are decreasing as level is crossed from wave start towards wave end.

e=0: Same as no /EDGE flag (searches for both increasing and decreasing level crossings).

/M=minWidthX Sets the minimum X distance between level crossings. This determines where FindLevels searches for the next crossing after it has found a level crossing. The search starts minWidthX X units beyond the crossing. The default value for minWidthX is 0.

/N=maxLevels Sets a maximum number of crossings that FindLevels is to find. The default value for maxLevels is the number of points in the specified range of waveName.

/P Compute crossings in terms of points. See the FindLevel operation.

/Q Doesn’t print to history and doesn’t abort if no levels are found.

/R=(startX,endX) Specifies X range. See the FindLevel operation.

/R=[startP,endP] Specifies point range. See the FindLevel operation.

/T=dx Search for two level crossings. dx must be less than minWidthX, so you must also specify /M if you use /T. (FindLevels limits dx so that second search start isn’t beyond where the first search for next edge will be.) See FindLevel for more about /T.

Details
The algorithm for finding a level crossing is the same one used by the FindLevel operation.
If FindLevels finds maxLevels crossings or can not find another level crossing, it stops searching.
FindLevels sets the following variables:

V_flag
0: maxLevels level crossings were found.
1: At least one but less than maxLevels level crossings were found.
2: No level crossings were found.

V_LevelsFound Number of level crossings found.

Example
Macro FindLevelsExample()
// Sample data
Make/O/N=1024 peaks;SetScale/P x,0,0.001,"" peaks // 1ms sampling
peaks=(exp(sin(x-1)*300/3))/(exp(1)-1)
SetRandomSeed 0; peaks += gnoise(0.05)
// locate rising and falling x crossings of y = 0.5
Variable minDX=20*deltax(peaks) // min 20 samples between crossings
Variable level = 0.5 // peaks y range nominally 0..1
FindLevels/Q/D=risingEdges/EDGE=1/M=(minDX) peaks, level
FindLevels/Q/D=fallingEdges/EDGE=2/M=(minDX) peaks, level

// Indicate found edges
Duplicate/O risingEdges, risingYs; risingYs = peaks(risingEdges[p])
Duplicate/O fallingEdges, fallingYs = peaks(fallingEdges[p])
// show level
Make/O/N=2 showLevel = level;CopyScales/I peaks, showLevel
Display /W=(35.25,41,856.5,249.5) peaks
AppendToGraph risingYs vs risingEdges
AppendToGraph fallingYs vs fallingEdges
AppendToGraph showLevel
ModifyGraph mode(risingYs)=8,mode(fallingYs)=8
ModifyGraph marker(risingYs)=17,marker(fallingYs)=23
ModifyGraph lStyle(showLevel)=1
ModifyGraph rgb(risingYs)=(19675,39321,1),rgb(fallingYs)=(0,0,0),rgb(showLevel)=(1,16019,65535)
Legend/C/N=text0/X=3.55/Y=1.90
End

See Also
The FindLevel operation for details about the level crossing detection algorithm and the /B, /P, /Q, /R, and /T flag values.

The FindLevels operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.

FindListItem

FindListItem(itemStr, listStr [, listSepStr [, start [, matchCase ]]])

The FindListItem function returns the byte offset into listStr where itemStr begins. listStr should contain items separated by the listSepStr.

Use FindListItem to locate the start of an item in a string containing a "wave0;wave1;" style list such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.

Use WhichListItem to determine the index of an item in the list.

If itemStr is not found, if listStr is "", or if start is not within the range of 0 to strlen(listStr)-1, then -1 is returned.
listSepStr, startIndex, and matchCase are optional; their defaults are "", 0, and 1 respectively.

Details
ItemStr may have any length.
listStr is searched for the first instance of the item string bound by a listSepStr on the left and a listSepStr on the right. The returned number is the byte index where the first character of itemStr was found in listStr.

The search starts from the byte position in listStr specified by start. A value of 0 starts with the first character in listStr, which is the default if start is not specified.
listString is treated as if it ends with a listSepStr even if it doesn’t.
FindAPeak

Searches for `listSepStr` are always case-sensitive. The comparison of `itemStr` to the contents of `listStr` is usually case-sensitive. Setting the optional `matchCase` parameter to 0 makes the comparison case insensitive.

In Igor6, only the first byte of `listSepStr` was used. In Igor7 and later, all bytes are used.

If `startIndex` is specified, then `listSepStr` must also be specified. If `matchCase` is specified, `startIndex` and `listSepStr` must be specified.

**Examples**

```plaintext
Print FindListItem("w1", "w0;w1;w2;") // prints 3
Print FindListItem("v2", "v1,v2,v3,", ",") // prints 3
Print FindListItem("v2", "v0,v2,v2,", ",", 4) // prints 6
Print FindListItem("C", "a;c;C;") // prints 4
Print FindListItem("C", "a;c;C;", ";", 0, 0) // prints 2
```

FindAPeak

**FindAPeak [/B=baseWaveName] minamp, pol, box, peakWave [ (startX,endX) ]**

FindAPeak locates the maximum or minimum of a peak by analyzing smoothed first and second derivatives.

The FindAPeak operation is used primarily by the Igor Technical Note #20 and its variants. For most purposes, use the more flexible `FindPeak` operation instead of FindAPeak.

**Parameters**

- `minamp` is minimum amplitude ("threshold") of a peak. Use it to reject small or spurious peaks.
- `pol` is the expected peak polarity. Specify 1 to search for a positive-going peak or 2 to search for a negative-going peak.
- `box` is the number of peak values to include in the sliding average when smoothing the derivatives. If you specify an even number, the next-higher odd number is used.
- `peakWave` specifies the wave containing the peak.
- `[startX,endX]` is an optional subrange to search in point numbers.
- `(startX,endX)` is an optional subrange to search in X values.

If you omit the subrange, `startX` defaults to the first point in `peakWave` and `endX` defaults to the last point in `peakWave`.

The search always with `startX` and ends at `endX`, regardless of whether `startX` is less than or greater than `endX`. You can use this to control the direction of the search.

**Flags**

- `/B=baseWave` Specifies a base wave containing values to subtract from `peakWave` to compute the derived data which FindAPeak searches for peaks.

**Details**

FindAPeak creates a temporary smoothed version of `peakWave` and a temporary first derivative of the smoothed data. It scans through the first derivative for the first zero-crossing where the smoothed data exceeds the minimum amplitude as specified by `minamp`. The location of the zero-crossing is then more accurately determined by reverse linear interpolation. The smoothed second derivative is computed at that point to see if the peak is a positive-going or negative-going peak.

**Output Variables**

FindAPeak reports results through these output variables:

- `V_Flag` 0 if a peak is found and to 1 if no peak is found.
- `V_peakX` The interpolated X value of the peak center.
- `V_peakP` The interpolated fractional point number of the peak center.
FindPeak

FindPeak [flags] waveName

The FindPeak operation searches for a minimum or maximum by analyzing the smoothed first and second
derivatives of the named wave. Information about the peak position, amplitude, and width are returned in
the output variables.

Flags

Some of the flags have the same meaning as for the FindLevel operation.

/B=box

Sets box size for sliding average.

/I

Modify the search criteria to accommodate impulses (peaks of one sample) by
requiring only one value to exceed minLevel.

The default criteria requires that two successive values exceed minlevel for a peak to
be found (or two successive values be less than the /M level when searching for
negative peaks).

Impulses can also be found by omitting minLevel, in which case /I is superfluous.

/M=minLevel

Defines minimum level of a peak. /N changes this to maximum level (see Details).

/N

Searches for a negative peak (minimum) rather then a positive peak (maximum).

/P

Location output variables (see Details) are reported in terms of (floating point) point
numbers. If /P is omitted, they are reported as X values.

/Q

Doesn’t print to history and doesn’t abort if no peak is found.

/R=(startX,endX)

Specifies X range and direction for search.

/R=[startP,endP]

Specifies point range and direction for search.

Details

FindPeak sets the following variables:

V_flag

Set only when using the /Q flag.

0: Peak was found.

Any nonzero value means the peak was not found.

V_LeadingEdgeLoc

Interpolated location of the peak edge closest to startX or startP. If you use the /P
flag, V_LeadingEdgeLoc is a point number rather than to an X value. If the edge
was not found, this value is NaN.

V_PeakLoc

Interpolated X value at which the peak was found. If you use the /P flag, FindPeak
sets V_PeakLoc to a point number rather than to an X value. Set to NaN if peak
wasn’t found.

V_PeakVal

The approximate Y value of the found peak. If the peak was not found, this value
is NaN (Not a Number).

V_PeakWidth

Interpolated peak width. If you use the /P flag, V_PeakWidth is expressed in
point numbers rather than as an X value. V_PeakWidth is never negative. If either
peak edge was not found, this value is NaN.

V_TrailingEdgeLoc

Interpolated location of the peak edge closest to endX or endP. If you use the /P
flag, V_TrailingEdgeLoc is a point number rather than to an X value. If the edge
was not found, this value is NaN.

FindPeak computes the sliding average of the input wave using the BoxSmooth algorithm with the box
parameter. The peak center is found where the derivative of this smoothed result crosses zero. The peak
edges are found where the second derivative of the smoothed result crosses zero. Linear interpolation of
the derivatives is used to more precisely locate the center and edges. The peak value is simply the greater of the two unsmoothed values surrounding the peak center (if /N, then the lesser value).

FindPeak is not a high-accuracy measurement routine; it is intended as a simple peak-finder. Use the PulseStats operation for more precise statistics.

Without /M, a peak is found where the derivative crosses zero, regardless of the peak height.

If you use the /M=minLevel flag, FindPeak ignores peaks that are lower than minLevel (i.e., the Y value of a found peak will exceed minLevel) in the box-smoothed input wave. If /N is also specified (search for minimum), FindPeak ignores peaks whose amplitude is greater than minLevel (i.e., the Y value of a found peak will be less than minLevel).

Without /I, a peak must have two successive values that exceed minLevel. Use /I when you are searching for peaks that may have only one value exceeding minLevel.

The search for the peak begins at startX (or the first point of the wave if /R is not specified), and ends at endX (or the last point of the wave if no /R). Searching backwards is permitted, and exchanges the values of V_LeadingEdgeLoc and V_TrailingEdgeLoc.

A simple automatic peak-finder is implemented in the "Peak Autofind.ipf" procedure file used in the Multipeak Fitting package. Execute DisplayHelpTopic "Multipeak Fitting" for details.

The FindPeak operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.

See Also
The PulseStats operation, the FindLevel operation for details about the /B, /P, /Q, and /R flag values.

FindPointsInPoly

FindPointsInPoly xWaveName, yWaveName, xPolyWaveName, yPolyWaveName

The FindPointsInPoly operation determines if points fall within a certain polygon. It can be used to write procedures that operate on a subset of data identified graphically in a graph.

Details
FindPointsInPoly determines which points in yWaveName vs xWaveName fall within the polygon defined by yPolyWaveName vs xPolyWaveName.

xWaveName must have the same number of points as yWaveName and xPolyWaveName must have the same number of points as yPolyWaveName.

FindPointsInPoly creates an output wave named W_inPoly with the same number of points as xWaveName. FindPointsInPoly indicates whether the point yWaveName[p] vs xWaveName[p] falls within the polygon by setting W_inPoly[p]=1 if it is within the polygon, or W_inPoly[p]=0 if it is not.

FindPointsInPoly uses integer arithmetic with a precision of about 1 part in 1000. This should be good enough for visually determined (hand-drawn) polygons but might not be sufficient for mathematically generated polygons.

The FindPointsInPoly operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.

See Also
GraphWaveDraw, PolygonOp

FindRoots

FindRoots [flags] funcspec, pWave [, funcspec, pwave [, ...]]
FindRoots /P=PolyCoefsWave

The FindRoots operation determines roots or zeros of a specified nonlinear function or system of functions. The function or system of functions must be defined in the form of Igor user procedures.

Using the second form of the command, FindRoots finds all the complex roots of a polynomial with real coefficients. The polynomial coefficients are specified by PolyCoefsWave.
Flags for roots of nonlinear functions

/B [= doBracket] Specifies bracketing for roots of a single nonlinear function only.

   doBracket=0: Skips an initial check of the root bracketing values and the possible search for bracketing values. This means that you must provide good bracketing values via the /L and /H flags. See /L and /H flags for details on bracketing of roots. /B alone is the same as /B=0.

   doBracket=1: Uses default root bracketing.

/F=trustRegion Sets the expansion factor of the trust region for the search algorithm when finding roots of systems of functions. Smaller numbers will result in a more stable search, although for some functions larger values will allow the search to zero in on a root more rapidly. Default is 1.0; useful values are usually between 0.1 and 100.

/L=lowBracket /H=highBracket /L and /H are used only when finding roots of a single nonlinear function. lowBracket and highBracket are X values that bracket a zero crossing of the function. A root is found between the bracketing values.

   If lowBracket and highBracket are on the same side of zero, it will try to find a minimum or maximum between lowBracket and highBracket. If it is found, and it is on the other side of zero, Igor will find two roots.

   If lowBracket and highBracket are on the same side of zero, but no suitable extreme point is found between, it will search outward from these values looking for a zero crossing. If it is found, Igor determines one root.

   If lowBracket and highBracket are equal, it adds 1.0 to highBracket before looking for a zero crossing.

   The default values for lowBracket and highBracket are zero. Thus, not using either lowBracket or highBracket is the same as /L=0/H=1.

/Q Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.

/T=tol Sets the acceptable accuracy to tol. That is, the reported root should be within ±tol of the real root.

/X=xWave /X={x1, x2, …} Sets the starting point for searching for a root of a system of functions. There must be as many X values as functions. The starting point can be specified with a wave having as many points as there are functions, or you can write out a list of X values in braces.

   If you are finding roots of a single function, use /L and /H instead.

   If you specify a wave, this wave is also used to receive the result of the root search.

/Z=yValue Finds other solutions, that is, places where f(x) = yValue. FindRoots usually finds zeroes — places where f(x) = 0.

Flag for roots of polynomials

/P=PolyCoefsWave Specifies a wave containing real polynomial coefficients. With this flag, it finds polynomial roots and does not expect to find user function names on the command line.

   The /P flag causes all other flags to be ignored.

   Use of this flag is not permitted in a thread-safe function.

Parameters

func specifies the name of a user-defined function.

pwave gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified. It is intended for your private use to pass adjustable constants to your function.
These parameters occur in pairs. For a one-dimensional problem, use a single func, pwave pair. An N-dimensional problem requires N pairs unless you use the combined function form (see Combined Format for Systems of Functions).

**Function Format for 1D Nonlinear Functions**

Finding roots of a nonlinear function or system of functions requires that you realize the function in the form of an Igor user function of a certain form. In the FindRoots command you then specify the functions with one or more function names paired with parameter wave names. See Finding Function Roots on page III-338 for detailed examples.

The functions must have a particular form. If you are finding the roots of a single 1D function, it should look like this:

```igor
Function myFunc(w,x)
    Wave w
    Variable x
    return f(x) // an expression ...
End
```

Replace “f(x)” with an appropriate expression. The FindRoots command might then look like this:

```igor
FindRoots /L=0 /H=1 myFunc, cw // cw is a parameter wave for myFunc
```

**Function Format for Systems of Multivariate Functions**

If you need to find the roots of a system of multidimensional functions, you can use either of two forms. In one form, you provide N functions with N independent variables. You must have a function for each independent variable. For instance, to find the roots of two 2D functions, the functions must have this form:

```igor
Function myFunc1(w, x1, x2)
    Wave w
    Variable x1, x2
    return f1(x1, x2) // an expression ...
End

Function myFunc2(w, x1, x2)
    Wave w
    Variable x1, x2
    return f2(x1, x2) // an expression ...
End
```

In this case, the FindRoots command might look like this (where cw1 and cw2 are parameter waves that must be made before executing FindRoots):

```igor
FindRoots /X={0,1} myFunc1, cw1, myFunc2, cw2
```

You can also use a wave to pass in the X values. Make sure you have the right number of points in the X wave — it must have N points for a system of N functions.

```igor
Function myFunc1(w, xW)
    Wave w, xW
    return f1(xW[0], xW[1]) // an expression ...
End

Function myFunc2(w, xW)
    Wave w, xW
    return f2(xW[0], xW[1]) // an expression ...
End
```

**Combined Format for Systems of Functions**

For large systems of equations it may get tedious to write a separate function for each equation, and the FindRoots command line will get very long. Instead, you can write it all in one function that returns N Y values through a Y wave. The X values are passed to the function through a wave with N elements. The parameter wave for such a function must have N columns, one column for each equation. The parameters for equation N are stored in column N-1. FindRoots will complain if any of these waves has other than N rows.

Here is an template for such a function:

```igor
Function myCombinedFunc(w, xW, yW)
    Wave w, xW, yW
    yW[0] = f1(w[0][...], xW[0], xW[1],..., xW[N-1])
    yW[1] = f2(w[1][...], xW[0], xW[1],..., xW[N-1])
End
```
FindRoots

\[ y_{W[N-1]} = f_N(w_{N-1}[...], x_{W[0]}, x_{W[1]}, ..., x_{W[N-1]}) \]

End

When you use this form, you only have one function and parameter wave specification in the FindRoots command:

Make/N=(nrows, nequations) paramWave
fill in paramWave with values
Make/N=(number of equations) guessWave
guessWave = \{x_0, x_1, ..., x_N\}
FindRoots /X=guessWave myCombinedFunc, paramWave

FindRoots has no idea how many actual equations you have in the function. If it doesn’t match the number of rows in your waves, your results will not be what you expect!

Coefficients for Polynomials
To find the roots of a polynomial, you first create a wave with the correct number of points. For a polynomial of degree N, create a wave with N+1 points. For instance, to find roots of a cubic equation you need a four-point wave.

The first point (row zero) of the wave contains the constant coefficient, the second point contains the coefficient for \(X\), the third for \(X^2\), etc.

There is no hard limit on the maximum degree, but note that there are significant numerical problems associated with computations involving high-degree polynomials. Roundoff error most likely limits reasonably accurate results to polynomials with degree limited to 20 to 30.

Ultimately, if you are willing to accept very limited accuracy, the numerical problems will result in a failure to converge. In limited testing, we found no failures to converge with polynomials up to at least degree 100. At degree 150, we found occasional failures. At degree 200 the failures were frequent, and at degree 500 we found no successes.

Note that you really can’t evaluate a polynomial with such high degree, and we have no idea if the computed roots for a degree-100 polynomial have any practical relationship to the actual roots.

While FindRoots is a thread-safe operation, finding polynomial roots is not. Using FindRoots/P=polyWave in a ThreadSafe function results in a compile error.

Results for Nonlinear Functions and Systems of Functions
The FindRoots operation reports success or failure via the V_flag variable. A nonzero value of V_flag indicates the reason for failure.

V_flag=0: Success, but check V_YatRoot, V_YatRoot2 or W_YatRoot to make sure that the convergence point is sufficiently small to indicate a true root. It is very unlikely for the Y values to be exactly zero. “Sufficiently small” depends on the scale of your problem.

V_flag=1: User abort.

V_flag=3: Exceeded maximum allowed iterations

V_flag=4: /T=tol was too small. Reported by the root finder for systems of nonlinear functions.

V_flag=5: The search algorithm wasn’t making sufficient progress. It may mean that /T=tol was set to too low a value, or that the search algorithm has gotten trapped at a false root. Try restarting from a different starting point.

V_flag=6: Unable to bracket a root. Reported when finding roots of single nonlinear functions.

V_flag=7: Fewer roots than expected. Reported by the polynomial root finder. This may indicate that roots were successfully found, but some are doubled. Happens only rarely.

V_flag=8: Decreased degree. Reported by the polynomial root finder. This indicates that one or more of the highest-order coefficients was zero, and a lower degree polynomial was solved.

V_flag=9: Convergence failure or other numerical problem. Reported by the polynomial root finder. This indicates that a numerical problem was detected during the computation. The results are not valid.
The results of finding roots of a single 1D function are put into several variables:

- **V_numRoots**: The number of roots found. Either 1 or 2.
- **V_Root**: The root.
- **V_YatRoot**: The Y value of the function at the root. *Always* check this; some discontinuous functions may give an indication of success, but the Y value at the found root isn’t even close to zero.
- **V_Root2**: Second root if FindRoots found two roots.
- **V_YatRoot2**: The Y value at the second root.

Results for roots of a system of nonlinear functions are reported in waves:

- **W_Root**: X values of the root of a system of nonlinear functions. If you used /X=xWave, the root is reported in your wave instead.
- **W_YatRoot**: The Y values of the functions at the root of a system of nonlinear functions.

Only one root is found during a single call to FindRoots.

Roots of a polynomial are reported in a wave:

- **W_polyRoots**: A complex wave containing the roots of a polynomial. The number of roots should be equal to the degree of the polynomial, unless a root is doubled.

See Also

**Finding Function Roots** on page III-338.

The FindRoots operation uses the Jenkins-Traub algorithm for finding roots of polynomials:

## FindSequence

**FindSequence**

### [flags] srcWave

The FindSequence operation finds the location of the specified sequence starting the search from the specified start point. The result of the search stored in V_value is the index of the entry in the wave where the first value is found or -1 if the sequence was not found.

### Flags

- **/FNAN**: Specifies searching for a NaN value when srcWave is floating point. This flag was added in Igor Pro 7.00.
- **/I=wave**: Specifies an integer sequence wave for integer search.
- **/M=val**: If there are repeating entries in the match sequence, *val* is a tolerance value that specifies the maximum difference between the number of repeats. So, for example, if the match sequence is aaabbcc and the srcWave contains a sequence aabbc then the sequence will not be considered a match if *val* = 0 but will be considered a match if *val* = 1.
- **/R**: Searches in reverse from the point in srcWave specified by /S or, if you omit /S, from the end of srcWave. /R was added in Igor Pro 9.00.
- **/S=start**: Sets starting point of the search. If you omit /S, the search starts from the start of srcWave or, if you include /R, from the end of srcWave.
- **/T=tolerance**: Defines the tolerance (value ± *tolerance* will be accepted) when comparing floating point numbers.
- **/U=uValueWave**: Specifies the match sequence wave in case of unsigned long range.
Details
If the match sequence is specified via the /V flag, it is considered to be a floating point wave (i.e., single or double precision) in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the /T flag, the default value 1.0-7.

If the match sequence is specified via the /I flag, the sequence is assumed to be an integer wave (this includes both signed and unsigned char, signed and unsigned short as well as long). In this case srcWave must also be of integer type and the operation searches for the sequence based on exact equality between the match sequence and entries in the wave as signed long integers.

If the match sequence is unsigned long wave use the /U flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

\[ \text{col} = \text{floor}(V\_value/\text{rowsInWave}) \]
\[ \text{row} = V\_value - \text{col} \times \text{rowsInWave} \]

See Also
FindValue, StringToUnsignedByteWave

FindValue

\textbf{FindValue [flags] srcWave}
\textbf{FindValue [flags] txtWave}

The FindValue operation finds the location of the specified value starting the search from the specified start point. It stores the results of the search in the variables V_value, V_row, V_col, V_layer, and V_chunk.

Flags

/\text{FNAN} \quad \text{Specifies searching for a NaN value when srcWave is floating point.}
The /\text{FNAN} flag was added in Igor Pro 7.00.

/\text{I=ivalue} \quad \text{Specifies an integer value for integer search.}

/R \quad \text{Reverses the order of the search.}
In the absence of /S and /RMD, the search starts from the end of the wave.
/R is not compatible with /UOFV.
The /R flag was added in Igor Pro 9.00.

/\text{RMD=[firstRow,lastRow][firstColumn,lastColumn][firstLayer,lastLayer][firstChunk,lastChunk]}
Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 8.00.
You can include all higher dimensions by leaving off the corresponding brackets. For example:

/\text{RMD=[firstRow,lastRow]}
includes all available columns, layers and chunks.
You can use empty brackets to include all of a given dimension. For example:

/\text{RMD=[[]][firstColumn,lastColumn]}
means "all rows from column A to column B".
You can use a * to specify the end of any dimension. For example:

/\text{RMD=[firstRow,*]}
means "from firstRow through the last row".
FindValue

/S=start  Sets start of search in the wave. If /S is not specified, start is set to 0.
/T=tolerance  Use this flag when comparing floating point numbers to define a non-negative tolerance such that the specified value ± tolerance will be accepted.
/TEXT=templateString  Specifies a template string that will be searched for in txtWave.
/TXOP=txOptions  Specifies the search options using a combination of binary values.
  1: Case sensitive
  2: Whole word
  4: Whole wave element
/U=uValue  Specifies the match value in case of unsigned long range.
/UOFV  The /UOFV (unordered find value) flag, which was added in Igor Pro 8.00, runs the search using multiple threads with each thread searching a different section of the wave. The search terminates when any thread finds a matching value.
  Use /UOFV when you need the fastest result and you do not care if it finds the first matching value in the wave or a subsequent matching value.
  By default /UOFV is ignored if srcWave contains fewer than 2,000 points. You can modify this value using MultiThreadingControl. /UOFV is also ignored if you use the /RMD flag.
/N=rValue  Specifies the match value in the case of single/double precision numbers. For most purposes you should also use /T to specify the tolerance.
/Z  No error reporting.

Details
If the match value is specified via the /V flag, it is considered to be a floating point value in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the /T flag, the value $10^{-7}$ is used.
If the match value is specified via the /I flag, the value is assumed to be an integer. In this case srcWave must be of integer type and the operation searches for the value based on exact equality between the match value and entries in the wave as signed long integers.
If the match value is unsigned long use the /U flag to specify the value for an integer comparison.
The result of the search is stored in the output variables V_value, V_row, V_col, V_layer, and V_chunk. V_value is set to the index in srcWave, treating it as 1D regardless of its dimensionality, where the searched value was found or to -1 if it was not found. V_row, V_col, V_layer, and V_chunk are set to the row, column, layer, and chunk number where the searched value was found or to -1 if it was not found but the latter three are set to NaN if the corresponding dimension does not exist in srcWave.
When searching for text in a text wave the operation creates the variable V_value as above but it also creates the variable V_startPos to specify the position of templateString from the start of the particular wave element.

Example
Make jack = sin(x/8)  // Single-precision floating point
Display jack

// This prints -1 because 0.5 +/- 1.0E-7 does not occur in wave jack
FindValue /V=.5 jack; Print V_value

// This prints 21 because 0.5 +/- 0.01 does occur in wave jack
FindValue /V=.5 /T=.01 jack; Print V_value

// The value of jack(21), to 6 decimal digits of precision, is 0.493920
Print jack(21)

FindSequence, FindLevel, FindLevels, FindDuplicates
FitFunc

Marks a user function as a user-defined curve fit function. By default, only functions marked with this keyword are displayed in the Function menu in the Curve Fit dialog.

If you wish other functions to be displayed in the Function menu, you can select the checkbox labelled “Show old-style functions (missing FitFunc keyword)”.

See Also
User-Defined Fitting Functions on page III-250.

floor

floor(num)
The floor function returns the closest integer less than or equal to num.
The result for INF and NAN is undefined.

See Also
The round, ceil, and trunc functions.

FMaxFlat

FMaxFlat [/SYM=sym] /Z=z] beta, gamma, coefsWave
The FMaxFlat operation calculates the coefficients of Kaiser's maximally flat filter.
FMaxFlat is primarily used for the Kaiser maximally flat filter feature of the Igor Filter Design Laboratory (IFDL) package.

Flags

/SYM=sym] Return symmetrical FIR filter coefficients without a leading length point (see Details below). The /SYM flag was added in Igor Pro 8.00.
/Z=z] Prevents procedure execution from aborting if FMaxFlat generates an error. The /Z flag was added in Igor Pro 8.00.
V_Flag is set to a non-zero error code or zero if no error occurred.
Use /Z or the equivalent, /Z=1, if you want to handle errors in your procedures rather than having execution abort. Unlike some other operations /Z does suppress invalid beta and gamma value parameter errors.

Parameters

beta is the transition frequency ("cutoff") expressed as a fraction of the sampling frequency, more than 0 and less than 0.5.
gamma is the transition width in fraction of sampling frequency, a number more than 0 and less than 0.5, and less than both beta*2 and 1-2*beta.
coefsWave is the 1D single- or double-precision floating point wave that receives the resulting coefficients. In Igor8 or later, FMaxFlat resizes coefsWave as necessary to fit the number of returned values. The upper bound on the number of coefficients can be computed as: ceil(5/16/gamma/gamma)+1

Details
The operation is based on the "mxflat" program as found in Elliot and Kaiser (see references below).
Use the /SYM flag to return a coefsWave with symmetrical coefficients suitable for use with FilterFIR, in which case the number of points in coefsWave identifies the number of filter coefficients.
If you omit /SYM or specify /SYM=0, only half of the coefficients are computed by FMaxFlat. The rest can be obtained by symmetry, but the first point of coefsWave contains the number of computed coefficients in the designed filter. This unusual format is compatible with pre-Igor8 IFDL procedures.

Example

// Make a maximally-flat low pass filter with cutoff at 1/4 sampling frequency
Make/O/D/N=0 coefs // coefs will be resized
FMaxFlat/SYM 0.25, 0.05, coefs // Make symmetrical FIR filter
Display coefs

// Analyze the filter's frequency response
FFT/OUT=3/PAD={256}/DEST=coefs_FFT coefs
Display coefs_FFT // Filter response for 1Hz sample rate

// Make sample data: a sweep from 0 to 20500 Hz
Make/O/N=1000 data= sin(p*p/1000*pi/2) // 0 to fs/2
SetScale/P x, 0, 1/41000, "s" data // 41000 Hz sample rate
Display data

// Analyse unfiltered data's frequency content
FFT/OUT=3/PAD={1000}/DEST=data_FFT data // Data frequency response
Display data_FFT

// Apply filter to copy of data
Duplicate/O data, filtered; DelayUpdate
FilterFIR/DIM=0/COEF=coefs filtered
Display filtered

// Analyse filtered data's frequency content
FFT/OUT=3/PAD={1000}/DEST=filtered_FFT filtered // Filtered data frequency response
Display filtered_FFT
TileWindows/O=1 // Tile Graphs

Remez, FilterFIR

FontList

FontList(separatorStr [, options])
The FontList function returns a list of the installed fonts, separated by the characters in separatorStr.

Parameters
A maximum of 10 bytes from separatorStr are appended to each font name as the output string is generated. separatorStr is usually ";".

Use options to limit the returned font list according to font type. It is restricted to returning only scalable fonts (TrueType, PostScript, or OpenType), which you can do with options = 1.

To get a list of nonscalable fonts (bitmap or raster), use:
String bitmapFontList = RemoveFromList(FontList(";",1), FontList(";"))
(Most Mac OS X fonts are scalable, so bitmapFontList may be empty.)

Examples
Function SetFont(fontName)
  String fontName
  Prompt fontName,"font name:",popup,FontList(";")+"default;"
  DoPrompt "Pick a Font", fontName
  Print fontName
  Variable type= WinType("") // target window type
  String windowName= WinName(0,127)
  if((type=1) || (type=3) || (type=7)) // graph, panel, layout
    Print "Setting drawing font for "+windowName
    Execute "SetDrawEnv fname="+fontName+""
  else
    if( type == 5 ) // notebook
      Print "Setting font for selection in "+windowName
      Notebook $windowName font=fontName
  endif
See Also
The FontSizeStringWidth, FontSizeHeight, and WinType functions, and the Execute, SetDrawEnv, and Notebook Operations.

FontSizeHeight

FontSizeHeight(fontNameStr, fontSize, fontstyle [,appearanceStr])
The FontSizeHeight function returns the line height in pixels of any string when rendered with the named font and the given font style and size.

Parameters
fontNameStr is the name of the font, such as "Helvetica".
fontSize is the size (height) of the font in pixels.
fontStyle is text style (bold, italic, etc.). Use 0 for plain text.

Details
The returned height is the sum of the font’s ascent and descent heights. Variations in fontStyle and typeface design cause the actual font height to be different than fontSize would indicate. (Typically a font “height” refers to only the ascent height, so the total height will be slightly larger to accommodate letters that descend below the baseline, such as g, p, q, and y).

FontSize is in pixels. To obtain the height of a font specified in points, use the ScreenResolution function and the conversion factor of 72 points per inch (see Examples).

If the named font is not installed, FontSizeHeight returns NaN.

FontSizeHeight understands “default” to mean the current experiment’s default font.

fontSize is a binary coded integer with each bit controlling one aspect of the text style as follows:

Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

To set bit 0 and bit 2 (bold, underline), use $2^0+2^2 = 1+4 = 5$ for fontStyle. See Setting Bit Parameters on page IV-12 for details about bit settings.

The optional appearanceStr parameter has no effect on Windows.

On Macintosh, the appearanceStr parameter is used for determining the height of a string drawn by a control. Set appearanceStr to "native" if you are measuring the height of a string drawn by a "native GUI" control or to "os9" if not.

Set appearanceStr to "default" to use the appearance set by the user in the Miscellaneous Settings dialog. "os9" is the default value.

Usually you will want to set appearanceStr to the S_Value output of DefaultGUIControls/W=winName when determining the height of a string drawn by a control.

Examples

Variable pixels= 12 * ScreenResolution/72  // convert 12 points to pixels
Variable pixelHeight= FontSizeHeight("Helvetica",pixels,0)
Print "Height in points= ", pixelHeight * 72/ScreenResolution

Function FontIsInstalled(fontName)
  String fontName
  if( numtype(FontSizeHeight(fontName,10,0)) == 2 )
    return 0  // NaN returned, font not installed
  else
    return 1
  endif
End
**FontSizeStringWidth**

The FontSizeStringWidth function returns the width of a string drawn by a control. The function takes a named font, a font size and style, and a string as parameters. The width is returned in pixels.

**Parameters**

- `fontNameStr` is the name of the font, such as "Helvetica".
- `fontSize` is the size (height) of the font in pixels.
- `fontStyle` is text style (bold, italic, etc.). Use 0 for plain text.
- `text` is the string whose width is being measured.

**Details**

- If the named font is not installed, FontSizeStringWidth returns NaN.
- FontSizeStringWidth understands "default" to mean the current experiment’s default font.
- `fontSize` is in pixels. To obtain the width of a font specified in points, use the `ScreenResolution` function and the conversion factor of 72 points per inch (see Examples).
- `fontStyle` is a binary coded integer with each bit controlling one aspect of the text style as follows:
  - Bit 0: Bold
  - Bit 1: Italic
  - Bit 2: Underline
  - Bit 4: Strikethrough

**Examples**

**Example 1**

```plaintext
Variable fsPix= 10 * ScreenResolution/72 // 10 point text in pixels
String text= "How long is this text?"
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text)
Print "width in inches= ", WidthPix / ScreenResolution
```

**Example 2**

```plaintext
Variable fsPix= 13 * ScreenResolution/72 // 13 point text in pixels
String text= "text for a control"
DefaultGUIControls/W=Panel0 // Sets S_Value
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text,S_Value)
Print "width in points= ", WidthPix / ScreenResolution * 72
```

**See Also**

The FontList, FontSizeHeight, ScreenResolution and DefaultGUIControls functions.
for-endfor

```plaintext
for(<initialization>;<continuation test>;<update>)
    <loop body>
endfor
```

A for-endfor loop executes the loop body code until the continuation test evaluates as false (zero) or until a break statement is executed in the body code. When the loop starts, the initialization expressions are evaluated once. For each iteration, the continuation test is evaluated at the beginning and the update expressions are evaluated at the end.

```plaintext
for(<type> varName : <wave>) // Range-based for loop added in Igor Pro 9.00
    <loop body>
endfor
```

A range-based for loop iterates over each element of a wave. The specified loop variable contains the value of the current wave element.

See Also
For Loop, Range-Based For Loop, break

for-var-in-wave

```plaintext
for(<type> varName : <wave>) // Range-based for loop added in Igor Pro 9.00
    <loop body>
endfor
```

A range-based for loop iterates over each element of a wave. The specified loop variable contains the value of the current wave element.

See Also
Range-Based For Loop, For Loop, break

FPCLustering

```plaintext
FPCLustering [flags] srcWave
```

The FPCLustering operation performs cluster analysis using the farthest-point clustering algorithm. The input for the operation `srcWave` defines M points in N-dimensional space. Outputs are the waves `W_FPCenterIndex` and `W_FPClusterIndex`.

Flags

- `/CAC` Computes all the clusters specified by `/MAXC`.
- `/CM` Computes the center of mass for each cluster. The results are stored in the wave `M_clustersCM` in the current data folder. Each row corresponds to a single cluster with columns providing the respective dimensional components.
- `/DSO` Returns the distance map of `srcWave` in `M_DistanceMap`. No other output is generated and all other flags are ignored.

/DSO was added in Igor Pro 8.00.

The distance map is the Cartesian distance between any two rows in `srcWave`. The results are stored in the upper triangle of the double-precision output wave `M_DistanceMap`. The lower triangle is set to zero (results can be obtained by symmetry).

Each element of the distance map is given by:

\[
M_{DistanceMap}_{rc} = \sqrt{\sum_{i=0}^{nCols-1} (srcWave[r][i] - srcWave[c][i])^2}
\]
The input for FPClustering is a 2D wave \( \text{srcWave} \) which consists of \( M \) rows by \( N \) columns where each row represents a point in \( N \)-dimensional space. \( \text{srcWave} \) can contain only finite real numbers and must be of type SP or DP. The operation computes the clustering and produces the wave \( W_{\text{FPCenterIndex}} \) which contains the centers or “hubs” of the clusters. The hubs are specified by the zero-based row number in \( \text{srcWave} \) which contains the cluster center. In addition, the operation creates the wave \( W_{\text{FClusterIndex}} \) where each entry maps the corresponding input point to a cluster index. By default, the operation continues to add clusters as long as the largest possible distance is greater than the average intercluster distance. You can also stop the processing when the operation has formed a specified number of clusters (see \( /\text{MAXC} \)).

The variable \( V_{\text{max}} \) contains the maximum distance between any element and its cluster hub.

It is possible that in some circumstances you can get slightly different clustering depending on your starting point. The default starting hub is row zero of \( \text{srcWave} \) but you can use the \( /\text{SHUB} \) flag to specify a different starting point.

FPClustering computes the Cartesian distance between points. As a result, if the scale of any dimension is significantly larger than other dimensions it might bias the clustering towards that dimension. To avoid this situation you can use the \( /\text{NOR} \) flag which normalizes each column to the range \([0,1]\) so that even when \( \text{srcWave} \) contains columns that may be different by several orders of magnitude, the algorithm is not biased by a larger implied cartesian distance.

The variable \( V_{\text{max}} \) contains the maximum distance between any element and its cluster hub.

It is possible that in some circumstances you can get slightly different clustering depending on your starting point. The default starting hub is row zero of \( \text{srcWave} \) but you can use the \( /\text{SHUB} \) flag to specify a different starting point.

FPClustering computes the Cartesian distance between points. As a result, if the scale of any dimension is significantly larger than other dimensions it might bias the clustering towards that dimension. To avoid this situation you can use the \( /\text{NOR} \) flag which normalizes each column to the range \([0,1]\) and hence equalizes the weight of each dimension in the clustering process.

**See Also**
The \text{KMeans} operation.

**References**

---

**fprintf**

\[
\text{fprintf} \, \text{refNum, formatStr} \, [, \, \text{parameter}] \ldots
\]

The fprintf operation prints formatted output to a text file.

**Parameters**
- \text{refNum} is a file reference number from the \text{Open} operation used to open the file.
- \text{formatStr} is the format string, as used by the \text{printf} operation.
- \text{parameter} varies depending on \text{formatStr}.

**Details**
If \( \text{refNum} \) is 1, fprintf will print to the history area instead of to a file, as if you used printf instead of fprintf. This useful for debugging purposes.
A zero value of `refNum` is used in conjunction with Program-to-Program Communication (PPC), Apple events (*Macintosh*) or *ActiveX Automation* (*Windows*). Data that would normally be written to a file is appended to the PPC, Apple event or ActiveX Automation result packet.

The `fprintf` operation supports numeric (real only) and string fields from structures. All other structures field types cause a compile error.

**Output to Standard Streams**

If `refNum` is -1, Igor prints to the standard output stream (stdout).

If `refNum` is -2, Igor prints to the standard error stream (stderr).

This feature was added in Igor Pro 8.00. It is useful primarily when you launch Igor from a custom application. The application may be able to capture Igor’s standard stream output.

On Macintosh, output printed to either of the standard streams is typically visible only if Igor is started from the Terminal. On Windows, stdout and stderr output is not visible even if Igor is started from the command line.

**See Also**

The `printf` operation for complete format and parameter descriptions. The `Open` operation and *Creating Formatted Text* on page IV-259.

**FReadLine**

```
FReadLine [/N /ENCG=textEncoding /T] refNum, stringVarName
```

The `FReadLine` operation reads bytes from a file into the named string variable. The read starts at the current file position and continues until a terminator character is read, the end of the file is reached, or the maximum number of bytes is read.

**Parameters**

`refNum` is a file reference number from the `Open` operation used to create the file.

**Flags**

- `/N=n` Specifies the maximum number of bytes to read.
  - `FReadLine` can read lines text of length up to about 2 billion bytes.

- `/ENCG=textEncoding`

- `/ENCG=[{textEncoding, tecOptions, mapErrorMode}]`

  Specifies the text encoding of the plain text file being loaded.

  This flag was added in Igor Pro 9.00.

  See *Text Encoding Names and Codes* on page III-490 for a list of accepted values for `textEncoding`. The 32-bit Unicode text encodings UTF-32BE and UTF-32LE are currently not supported.

  If you omit `/ENCG`, `textEncoding` defaults to binary (255) and does no text encoding conversion but does look for and skip a UTF-8 byte order mark.

  For most purposes the default values for `tecOptions` (3) and `mapErrorMode` (1) are fine and you can use `/ENCG=textEncoding` instead of `/ENCG=[{textEncoding, tecOptions, mapErrorMode}]`.

  `tecOptions` is an optional bitwise parameter that controls text encoding conversion. See *Setting Bit Parameters* on page IV-12 for details about bit settings.
FReadLine

 tecOptions is defined as follows:

 Bit 0: If cleared, the presence of null bytes causes FReadLine to consider the text invalid in all byte-oriented text encodings.

 If set (default), null bytes are allowed in byte-oriented text encodings.

 Bit 1: If cleared FReadLine does not validate text if the specified text encoding is UTF-8.

 If set (default), FReadLine validates text even if the text encoding is UTF-8.

 Bit 2: If cleared (default) FReadLine validates the text in the specified text encoding except that validation for UTF-8 is skipped if bit 1 is cleared.

 If set, FReadLine assumes that the text is valid in the specified text encoding and does not validate it. Setting this bit makes FReadLine slightly faster but it is usually inconsequential.

 UTF-8 because it is not valid in the input text encoding. mapErrorMode is one of these values:

 1: FReadLine generates an error.

 2: Return a substitute character for the unmappable character. The substitute character for Unicode is the Unicode replacement character, U+FFFD. For most non-Unicode text encodings it is either control-Z or a question mark.

 3: Skip unmappable input character.

 4: Return an escape sequence representing the unmappable code point.

 If mapErrorMode is 2, 3 or 4, FReadLine does not return an error in the event of an unmappable character.

 See the discussion of mapErrorMode and the examples for ConvertTextEncoding for further discussion.

 See FReadLine and Byte Order Marks on page V-263 below for further discussion.

/T=termcharStr Specifies the terminator character.

 /T=(num2char(13)) specifies carriage return (CR, ASCII code 13).

 /T=(num2char(10)) specifies linefeed (LF, ASCII code 10).

 /T=";" specifies the terminator as a semicolon.

 /T="" specifies the terminator as null (ASCII code 0).

 See Details for default behavior regarding the terminator.

 Details

 If /N is omitted, there is no maximum number of bytes to read. When reading lines of text from a normal text file, you will not need to use /N. It may be of use in specialized cases, such as reading text embedded in a binary file.

 FReadLine can read lines text of length up to about 2 billion bytes.

 If /T is omitted, FReadLine will terminate on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.) FReadLine reads whichever of these appears in the file, terminates the read, and returns just a CR in the output string. This default behavior transparently handles files that use CR, LF, CRLF, or LFCR as the terminator and will be suitable for most cases.

 If you use the /T flag, then FReadLine will terminate on the specified character only and will return the specified character in the output string.

 Once you have read all of the bytes in the file, FReadLine will return zero bytes via stringVarName. The example below illustrates testing for this.
**FReadLine and Text Encodings**

For background information on text encodings, see Text Encodings on page III-459.

In Igor Pro 9.00 and later, you can specify the text encoding of the file you are reading using the /ENCG flag.

If you omit /ENCG, FReadLine treats the data as binary and does no text encoding conversion. However, it does skip a UTF-8 byte order mark at the start of the file if present. Treating the data as binary works if the data you are loading is pure ASCII or is valid UTF-8 text.

If you specify a text encoding using /ENCG, the FReadLine converts the text from the text encoding you specify into UTF-8 for internal storage. See Text Encoding Names and Codes on page III-490 for a list of accepted values for textEncoding. The 32-bit Unicode text encodings UTF-32BE and UTF-32LE are currently not supported.

In general it is not possible to accurately determine the text encoding of a plain text file programmatically so you need to know it a priori.

If the text is Unicode and includes a byte order mark then you can programmatically determine the text encoding by examining the byte order mark. You can do this using FBinRead to examine the first bytes of the file:

- 0xEF, 0xBB, 0xBF UTF-8 byte order mark, textEncoding=1
- 0xFE, 0xFF UTF-16BE byte order mark, textEncoding=100
- 0xFF, 0xFE UTF-16LE byte order mark, textEncoding=101

If the file starts with a pattern other than these then you will need a priori knowledge or will need to make an assumption about the text encoding.

**FReadLine and Byte Order Marks**

For background information on byte order marks, see Byte Order Marks on page III-471.

If you want to check for the presence of a byte order mark, use FBinRead instead of FReadLine.

The default text encoding, used if you omit /ENCG, is binary (255). In this case, FReadLine does no text encoding conversion. However, it does look for a UTF-8 byte order mark and skips it if present.

If you specify UTF-8 or UTF-16 as the text encoding using the /ENCG flag, and if the file data begins with a byte order mark, then FReadLine skips it.

**Example**

Function PrintAllLinesInFile()
    Variable refNum
    Open/R refNum as ""
    if (refNum == 0)
        return -1
    endif
    Variable lineNumber, len
    String buffer
    lineNumber = 0
    do
        FReadLine refNum, buffer
        len = strlen(buffer)
        if (len == 0)
            break
        endif
        printf "Line number %d: %s", lineNumber, buffer
        if (CmpStr(buffer[len-1],"\r") != 0) // Last line has no CR ?
            printf "\r"
        endif
        lineNumber += 1
    while (1)
    Close refNum
    return 0
End

**fresnelCos**

The `fresnelCos` function returns the Fresnel cosine function \( C(x) \).

\[
C(x) = \int_0^x \cos \left( \frac{\pi}{2} t^2 \right) dt.
\]

**See Also**
The `fresnelSin` and `fresnelCS` functions.

**References**

**fresnelCS**

The `fresnelCS` function returns both the Fresnel cosine in the real part of the result and the Fresnel sine in the imaginary part of the result.

**See Also**
The `fresnelSin` and `fresnelCos` functions.

**fresnelSin**

The `fresnelSin` function returns the Fresnel sine function \( S(x) \).

\[
S(x) = \int_0^x \sin \left( \frac{\pi}{2} t^2 \right) dt.
\]

**See Also**
The `fresnelCos` and `fresnelCS` functions.

**References**

**FSetPos**

The `FSetPos` operation attempts to set the current file position to the given position.

**(FSetPos refNum, filePos)**

**Parameters**
- `refNum` is a file reference number obtained from the `Open` operation when the file was opened.
- `filePos` is the desired position of the file in bytes from the start of the file.

**Details**
- `FSetPos` generates an error if `filePos` is greater than the number of bytes in the file. You can ascertain this limit with the `FStatus` operation.
- When a file that is open for writing is closed, any bytes past the end of the current file position are deleted by the operating system. Therefore, if you use `FSetPos`, make sure to set the current file position properly before closing the file.
- `FSetPos` supports files of any length.

**See Also**
Open, `FGetPos`, `FStatus`
FStatus

FStatus refNum
The FStatus operation provides file status information for a file.

Parameters
refNum is a file reference number obtained from the Open operation.

Details
FStatus supports files of any length.
FStatus sets the following variables:

- V_flag: Nonzero (true) if refNum is valid, in which case FStatus sets the other variables as well.
- V_filePos: Current file position for the file in bytes from the start.
  In Igor7 or later, if you only want to know the current file position, use FGetPos instead of FStatus, which is slower.
- V_logEOF: Total number of bytes in the file.
- S_fileName: Name of the file.
- S_path: Path from the volume to the folder containing the file. For example, "hd:Folder1:Folder2:". This is suitable for use as an input to the NewPath operation. Note that on the Windows operating system Igor uses a colon between folders instead of the Windows-standard backslash to avoid confusion with Igor’s use of backslash to start an escape sequence (see Escape Sequences in Strings on page IV-14).
- S_info: Keyword-packed information string.

The keyword-packed information string for S_info consists of a sequence of sections with the following form: keyword:value; You can pick a value out of a keyword-packed string using the NumberByKey and StringByKey functions.

Here are the keywords for S_info:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>PATH</td>
<td>string</td>
<td>Name of the symbolic path in which the file is located. This will be empty if there is no such symbolic path.</td>
</tr>
<tr>
<td>WRITEABLE</td>
<td>number</td>
<td>1 if file can be written to, 0 if not.</td>
</tr>
</tbody>
</table>

Open, FGetPos, FSetPos

FTPCreateDirectory

FTPCreateDirectory [flags] urlStr
The FTPCreateDirectory operation creates a directory on an FTP server on the Internet.

For background information on Igor’s FTP capabilities and other important details, see File Transfer Protocol (FTP) on page IV-272.

FTPCreateDirectory sets V_flag to zero if the operation succeeds or to a non-zero error code if it fails.

If the directory specified by urlStr already exists on the server, the server contents are not touched and V_flag is set to -1. This is not treated as an error.

Parameters
urlStr specifies the directory to create. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/test/newDirectory"). For example:

urlStr must always end with a directory name, and must not end with a slash.
To indicate that `urlStr` contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
```

If you do not specify that the path in `urlStr` is absolute, it is interpreted as relative to the FTP user's base directory. Since `pub` is the base directory for an anonymous user at wavemetrics.com, these URLs reference the same directory for an anonymous user:

```
```

Special characters, such as punctuation, that are used in `urlStr` may be incorrectly interpreted by the operation. If you get unexpected results and `urlStr` contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-268 for additional information.

**Flags**

`/N=portNumber` Specifies the server’s TCP/IP port number to use (default is 21). In almost all cases, the default will be correct so you won’t need to use the `/N` flag.

`/U=userNameStr` Specifies the user name to be used when logging in to the FTP server. If `/U` is omitted or if `userNameStr` is “”, the login is done as an anonymous user. Use `/U` if you have an account on the FTP server.

`/V=diagnosticMode` Determines what kind of diagnostic messages FTPCreateDirectory will display in the history area. `diagnosticMode` is a bitwise parameter, with the bits defined as follows:

- Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.
- Bit 1: Show errors. This displays additional information when errors occur.
- Bit 2: Show status. This displays commands sent to the server and the server’s response.

The default value for `diagnosticMode` is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server’s response.

See **FTP Troubleshooting** on page IV-275 for other troubleshooting tips.

`/W=passwordStr` Specifies the password to be used when logging in to the FTP server. Use `/W` if you have an account on the FTP server.

If `/W` is omitted, the login is done using a default password that will work with most anonymous FTP servers.

See **Safe Handling of Passwords** on page IV-270 for information on handling sensitive passwords.

`/Z` Errors are not fatal. Will not abort procedure execution if an error occurs.

Your procedure can inspect the `V_flag` variable to see if the transfer succeeded. `V_flag` will be zero if it succeeded, -1 if the specified directory already exists, or another nonzero value if an error occurred.

**Examples**

```
// Create a directory.
FTPCreateDirectory url
```

**See Also**

File Transfer Protocol (FTP) on page IV-272.

FTPDelete, FTPDownload, FTPUpload, URLEncode
FTPDelete

**FTPDelete**  
*flags*  
*urlStr*

The FTPDelete operation deletes a file or a directory from an FTP server on the Internet.

**Warning:** If you delete a directory on an FTP server, all contents of that directory and any subdirectories are also deleted.

For background information on Igor's FTP capabilities and other important details, see File Transfer Protocol (FTP) on page IV-272.

FTPDelete sets V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if an FTP error occurs.

**Parameters**

*urlStr* specifies the file or directory to delete. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/test/TestFile1.txt"

*urlStr* must always end with a file name if you are deleting a file or with a directory name if you are deleting a directory. In the case of a directory, *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:  

```
```

If you do not specify that the path in *urlStr* is absolute, it is interpreted as relative to the FTP user's base directory. Since pub is the base directory for an anonymous user at wavemetrics.com, these URLs reference the same directory for an anonymous user:

```
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See Percent Encoding on page IV-268 for additional information.

**Flags**

- **/D** Deletes a complete directory and all its contents. Omit /D if you are deleting a file.
- **/N=portNumber** Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, the default will be correct so you won't need to use the /N flag.
- **/U=userStrName** Specifies the user name to be used when logging in to the FTP server. If /U is omitted or if userNameStr is "", the login is done as an anonymous user. Use /U if you have an account on the FTP server.
- **/V=диагностика** Determines what kind of diagnostic messages FTPDelete will display in the history area. диагностика is a bitwise parameter, with the bits defined as follows:
  - Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.
  - Bit 1: Show errors. This displays additional information when errors occur.
  - Bit 2: Show status. This displays commands sent to the server and the server's response.

The default value for диагностика is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.

See FTP Troubleshooting on page IV-275 for other troubleshooting tips.
Examples

// Delete a file.
FTPDelete url

// Delete a directory.
String url = "ftp://ftp.wavemetrics.com/test/TestDir1"
FTPDelete/D url

See Also
File Transfer Protocol (FTP) on page IV-272.
FTPCreateDirectory, FTPDownload, FTPUpload, URLEncode

FTPDownload

FTPDownload [flags] urlStr, localPathStr
The FTPDownload operation downloads a file or a directory from an FTP server on the Internet.

Warning: When you download a file or directory using the path and name of a file or directory that already exists on your local hard disk, all previous contents of the local file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see File Transfer Protocol (FTP) on page IV-272.

FTPDownload sets a variable named V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if a FTP error occurs.

If the operation succeeds, FTPDownload sets a string named S_Filename to the full file path of the downloaded file or, if the /D flag was used, the full path to the base directory that was downloaded. This is useful in conjunction with the /I flag.

If the operation fails, S_Filename is set to "".

Parameters

urlStr specifies the file or directory to download. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/Test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt".

urlStr must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, urlStr must not end with a slash.

To indicate that urlStr contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

If you do not specify that the path in urlStr is an absolute path, it is interpreted as a path relative to the FTP user's base directory. Since pub is the base directory for an anonymous user, this URL references the same directory:

Special characters such as punctuation that are used in \urlStr may be incorrectly interpreted by the operation. If you get unexpected results and \urlStr contains such characters, you can try percent-encoding the special characters. See Percent Encoding on page IV-268 for additional information.

localPathStr and pathName specify the name to use for the file or directory that will be created on your hard disk. If you use a full or partial path for localPathStr, see Path Separators on page III-451 for details on forming the path.

localPathStr must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, localPathStr must not end with a colon or backslash.

FTPDownload displays a dialog through which you can identify the local file or directory in the following cases:

1. You have used the /I (interactive) flag.
2. You did not completely specify the location of the local file or directory via pathName and localPathStr.
3. There is an error in localPathStr. This can be either a syntactical error or a reference to a nonexistent file or directory.
4. The specified local file or directory exists and you have not used the /O (overwrite) flag.

See Examples for examples of constructing a URL and local path.

Flags

/D Downloads a complete directory. Omit it if you are downloading a file.
/I Interactive mode which will prompt you to specify the name and location of the file or directory to be created on the local hard disk.
/M=messageStr Specifies the prompt message used by the dialog in which you specify the name and location of the file or directory to be created.
/N=portNumber Specifies the server’s TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won’t need to use the /N flag.
/O[=mode] Controls whether a local file or directory whose name is in conflict with the file or directory being downloaded is overwritten without prompting the user.
  mode=0: Prompts the user to allow the overwrite. This is the default behavior if /O is omitted.
  mode=1: Overwrites without prompting the user. If the /D flag is also used, all contents of the destination directory are deleted if it already exists. /O=1 is the same as /O.
  mode=2: Merges files and subdirectories downloaded with the contents of the destination directory. Unlike /O=1, the contents of the destination directory are not deleted, however files and directories downloaded from the server will overwrite existing files and directories of the same name. When downloading a file this mode is accepted but has the same effect as /O=1.

/P=pathName Contributes to the specification of the file or directory to be created on your hard disk. pathName is the name of an existing symbolic path. See Examples.

/S=showProgress Determines if a progress dialog is displayed.
  0: No progress dialog.
  1: Show a progress dialog (default).

/T=transferType Controls the FTP transfer type.
  0: Image (binary) transfer (default).
  1: ASCII transfer.

See FTP Transfer Types on page IV-275 for more discussion.
FTPDownload

/U=userNameStr  Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if userNameStr is "," you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.

/V=diagnosticMode  Determines what kind of diagnostic messages FTPDownload will display in the history area. diagnosticMode is a bitwise parameter, with the bits defined as follows:

  Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.
  Bit 1: Show errors. This displays additional information when errors occur.
  Bit 2: Show status. This displays commands sent to the server and the server's response.

  The default value for diagnosticMode is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.

See FTP Troubleshooting on page IV-275 for other troubleshooting tips.

/W=passwordStr  Specifies the password to be used when logging in to the FTP server. Use this flag if you have an account on the FTP server.

  If this flag is omitted, “nopassword” will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the /W="<your email address>" flag.

  If /W is omitted, the login is done using a default password that will work with most anonymous FTP servers.

See Safe Handling of Passwords on page IV-270 for information on handling sensitive passwords.

/Z  Errors are not fatal. Will not abort procedure execution if an error occurs.

  Your procedure can inspect the V_flag variable to see if the transfer succeeded. V_flag will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.

Examples
Download a file using a full local path:

String localPath = "hd:Test Folder:TestFile1.txt"
FTPDownload url, localPath

Download a file using a local symbolic path and file name:

String pathName = "Igor" // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPDownload/P=$pathName url, fileName

Download a directory using a full local path:

String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPDownload/D url, localPath

File Transfer Protocol (FTP) on page IV-272.
FTPCreateDirectory, FTPDelete, FTPUpload, URLEncode, FetchURL
FTPUpload

**FTPUpload [flags] urlStr, localPathStr**

The FTPUpload operation uploads a file or a directory to an FTP server on the Internet.

**Warning:** When you upload a file or directory to an FTP server, all previous contents of the server file or directory are obliterated.

For background information on Igor’s FTP capabilities and other important details, see File Transfer Protocol (FTP) on page IV-272.

FTPUpload sets a variable named V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if a FTP error occurs. If the operation succeeds, FTPUpload sets a string named S_Filename to the full file path of the uploaded file or, if the /D flag was used, to the full path to the base directory that was uploaded. This is useful in conjunction with the /I flag.

If the operation fails, S_Filename is set to "".

**Parameters**

- **urlStr** specifies the file or directory to create. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/Test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt".

  - **urlStr** must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory, in which case urlStr must not end with a slash.

  - To indicate that urlStr contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

  - If you do not specify that the path in urlStr is an absolute path, it is interpreted as a path relative to the FTP user's base directory. Since pub is the base directory for an anonymous user, this URL references the same directory:

Special characters such as punctuation that are used in urlStr may be incorrectly interpreted by the operation. If you get unexpected results and urlStr contains such characters, you can try percent-encoding the special characters. If you get unexpected results and urlStr contains such characters, you can try percent-encoding the special characters. See Percent Encoding on page IV-268 for additional information.

- **localPathStr** and **pathName** specify the name and location on your hard disk of the local file to be uploaded. If you use a full or partial path for localPathStr, see Path Separators on page III-451 for details on forming the path.

  - **localPathStr** must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory. In the case of a directory, localPathStr must not end with a colon or backslash.

FTPUpload displays a dialog that you can use to identify the file or directory to be uploaded in the following cases:

1. You used the /I (interactive) flag.
2. You did not completely specify the location of the file or folder to be uploaded via pathName and localPathStr.
3. There is an error in localPathStr. This can be either a syntactical error or a reference to a nonexistent directory.

See Examples for examples of constructing a URL and local path.

**Flags**

- **/D** Uploads a complete directory. Omit it if you are uploading a file.

- **/I** Interactive mode which displays a dialog for choosing the local file or directory to be uploaded.
### FTPUpload

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/M=messageStr</td>
<td>Specifies the prompt message used by the dialog in which you choose the local file or directory to be uploaded.</td>
</tr>
<tr>
<td>/N=portNumber</td>
<td>Specifies the server’s TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won’t need to use the /N flag.</td>
</tr>
</tbody>
</table>
| /O[=mode]    | Overwrite. FTPUpload *always* overwrites the specified server file or directory, whether /O is used or not.  
If /O=2 is *not* used, all files and subdirectories in the destination directory on the server are first deleted and then the local files and directories are uploaded to the server.  
If /O=2 is used, the existing contents the contents of the local source directory are merged into the remote directory instead of completely overwriting it.  |
| /P=pathName   | Contributes to the specification of the file or directory to be uploaded. *pathName* is the name of an existing symbolic path. See **Examples**. |
| /S=showProgress| Determines if a progress dialog is displayed.  
0: No progress dialog.  
1: Show a progress dialog (default). |
| /T=transferType| Controls the FTP transfer type.  
0: Image (binary) transfer (default).  
1: ASCII transfer.  
See **FTP Transfer Types** on page IV-275 for more discussion.  |
| /U=userNameStr | Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if *userNameStr* is "", you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.  |
| /V=diagnosticMode| Determines what kind of diagnostic messages FTPUpload will display in the history area. *diagnosticMode* is a bitwise parameter, with the bits defined as follows:  
Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.  
Bit 1: Show errors. This displays additional information when errors occur.  
Bit 2: Show status. This displays commands sent to the server and the server’s response.  
The default value for *diagnosticMode* is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server’s response.  
See **FTP Troubleshooting** on page IV-275 for other troubleshooting tips. |
| /W=passwordStr | Specifies the password used when logging in to the FTP server. Use this flag if you have an account on the FTP server.  
If this flag is omitted, “nopassword” will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the /W="<your email address>" flag.  
If /W is omitted, the login is done using a default password that will work with most anonymous FTP servers.  
See **Safe Handling of Passwords** on page IV-270 for information on handling sensitive passwords. |
Examples

Upload a file using a full local path:

String localPath = "hd:Test Folder:TestFile1.txt"
FTPUpload url, localPath

Upload a file using a local symbolic path and file name:

String pathName = "Igor" // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPUpload/P=${pathName} url, fileName

Upload a directory using a full local path:

String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPDUpload/D url, localPath

FuncFit

FuncFit [flags] fitFuncName, cwaveName, waveName [flag parameters]
FuncFit [flags] {fitFuncSpec}, waveName [flag parameters]

The FuncFit operation performs a curve fit to a user defined function, or to a sum of fit functions using the second form (see Fitting Sums of Fit Functions on page V-275). Fitting can be done using any method that can be selected using the /ODR flag (see CurveFit for details).

FuncFit operation parameters are grouped in the following categories: flags, parameters (fitFuncName, cwaveName, waveName or {fitFuncSpec}, waveName), and flag parameters. The sections below correspond to these categories. Note that flags must precede the fitFuncName or fitFuncSpec and flag parameters must follow waveName.

In Igor Pro 9.00 and later, your fitting function can return complex values. The sections below indicate requirements for complex fitting functions. For details, see Fitting with Complex-Valued Functions on page III-248.

Flags

See CurveFit for all available flags.

Parameters

fitFuncName

The user-defined function to fit to, which can be a function taking multiple independent variables (see also FuncFitMD). Multivariate fitting with FuncFit requires /X=xwaveSpec. To fit complex data waves, your fitting function must be declared complex (Function/C).

cwaveName

Wave containing the fitting coefficients. If the fitting function is declared with a complex wave for the coefficient wave, then this wave must be complex.

waveName

The wave containing the dependent variable data to be fit to the specified function. For functions of just one independent variable, the dependent variable data is often referred to as "Y data". You can fit to a subrange of the wave by supplying (startX,endX) or [startP,endP] after the wave name. See Wave Subrange Details below for more information on subranges of waves in curve fitting. If your fitting function returns complex values then this wave must be complex.
Flag Parameters
These flag parameters must follow waveName.

/E=ewaveName A wave containing the epsilon values for each parameter. Must be the same length as
the coefficient wave. If your fitting function requires a complex coefficient wave then
your epsilon wave must be complex. Not supported with complex fitting functions.

/STRC=structureInstance
Used only with Structure Fit Functions on page III-261. When using a structure fit
function, you must specify an instance of the structure to FuncFit. This will be an
instance that has been initialized by a user-defined function that you write in order to
invoke FuncFit.

/X=xwaveSpec An optional wave containing X values for each of the input data values. If the fitting
function has more than one independent variable, xwaveSpec is required and must be
either a 2D wave with a column for each independent variable, or a list of waves, one
for each independent variable. A list must be in braces: /X={xwave0, xwave1,…}. There
must be exactly one column or wave for each independent variable in the fitting
function. If your fitting function takes complex X values then your X waves must be
complex.

/NWOK Allowed in user-defined functions only. When present, certain waves may be set to
null wave references. Passing a null wave reference to FuncFit is normally treated as
an error. By using /NWOK, you are telling FuncFit that a null wave reference is not
an error but rather signifies that the corresponding flag should be ignored. This
makes it easier to write function code that calls FuncFit with optional waves.
The waves affected are the X wave or waves (/X), weight wave (/W), epsilon wave (/E)
and mask wave (/M). The destination wave (/D=wave) and residual wave (/R=wave)
are also affected, but the situation is more complicated because of the dual use of /D
and /R to mean "do autodestination" and "do autoresidual". See /AR and /AD.
If you don’t need the choice, it is better not to include this flag, as it disables useful
error messages when a mistake or run-time situation causes a wave to be missing
unexpectedly.
Note: To work properly this flag must be the last one in the command.

Other parameters are used as for the CurveFit operation, with some exceptions for multivariate fits.

Details for Multivariate Fits
The dependent variable data wave, waveName, must be a 1D wave even for multivariate fits. For fits to data
in a multidimensional wave, see FuncFitMD.

For multivariate fits, the auto-residual (/R with no wave specified) is calculated and appended to the top
graph if the dependent variable data wave is graphed in the top graph as a simple 1D trace. Auto residuals
are calculated but not displayed if the data are displayed as a contour plot.
The autodest wave (/D with no wave specified) for multivariate fits has the same number of points as the
data wave, with a model value calculated at the X values contained in the wave or waves specified with
/X=xwaveSpec.
Confidence bands are not supported for multivariate fits.

Wave Subrange Details
Almost any wave you specify to FuncFit can be a subrange of a wave. The syntax for wave subranges is the
same as for the Display command (see Subrange Display Syntax on page II-321 for details). See Wave
Subrange Details on page V-132 for a discussion of the use of subranges in curve fitting.
The backwards compatibility rules for CurveFit apply to FuncFit as well.
In addition to the waves discussed in the CurveFit documentation, it is possible to use subranges when specifying the coefficient wave and the epsilon wave. Since the coefficient wave and epsilon wave must have the same number of points, it might make sense to make them two columns from a single multicolumn wave. For instance, here is an example in which the first column is used as the coefficient wave, the second is used as the epsilon wave, and the third is used to save a copy of the initial guesses for future reference:

```plaintext
Make/D/N=(5, 3) myCoefs
myCoefs[[0]] = {1, 2, 3, 4, 5} // hypothetical initial guess
myCoefs[[1]] = 1e-6 // reasonable epsilon values
myCoefs[[2]] = myCoefs[p][0] // save copy of initial guess
FuncFit myFitFunc, myCoefs[0] myData /E=myCoefs[[1]] ...
```

You might have a fit function that uses a subset of the coefficients that are used by another. It might be useful to use a single wave for both. Here is an example in which a function that takes four coefficients is used to fit a subset of the coefficients, and then that solution is used as the initial guess for a function that takes six coefficients:

```plaintext
Make/D/N=6 Coefs6={1,2,3,4,5,6}
FuncFit Fit4Coefs, Coefs6[0,3] fitfunc4Coefs ...
FuncFit Fit6Coefs, Coefs6 ...
```

Naturally, the two fit functions must be worked out carefully to allow this.

### Fitting Sums of Fit Functions

If Igor encounters a left brace at the beginning of the fit function name, it expects a list of fit functions to be summed during the fit. This is useful for, for instance, fitting several peaks in a data set to a sum of peak functions.

The fit function specification includes at least the name of the fitting function and an associated coefficient wave. A sum of fit functions requires multiple coefficient waves, one for each fit function. Any coefficient wave-related options must be specified in the fit function specification via keyword-value pairs.

The syntax of the sum-of-fit-functions specification is as follows:

```plaintext
{{func1, coef1, keyword=value1}, {func2, coef2, keyword=value2}, ...}
```

or

```plaintext
{string=fitSpecStr}
```

Within outer braces, each fit function specification is enclosed within inner braces. You can use one or more fit function specifications, with no intrinsic limit on the number of fit functions.

The second format is available to overcome limitations on the length of a command line in Igor. This format is just like the first, but everything inside the outer braces is contained in a string expression (which may be just a single string variable).

You can use any fit function that can be used for ordinary fitting, including the built-in functions that are available using the CurveFit operation. If you should write a user-defined fitting function with the same name as a built-in fit function, the user-defined function will be used (this is strongly discouraged).

Every function specification must include an appropriate coefficient wave, pre-loaded with initial guesses. The comma between each function specification is optional.

The keyword-value pairs are optional, and are used to communicate further options on a function-by-function basis. Available keywords are:

- **HOLD=holdstr**
  Indicates that a fit coefficient should be held fixed during fitting. holdstr works just like the hold string specified via the /H flag for normal fitting, but applies only to the coefficient wave associated with the fit function it appears with.

  If you include HOLD in a string expression (the `{string=fitSpecStr}` syntax), you must escape the quotation marks around the hold string.

  If you use the command-line syntax {{func1,coef1,HOLD=holdStr}, .....}, holdStr may be a reference to a global variable acquired using SVAR, or it may be a quoted literal string.

  If you use `{string=fitSpecStr}`, fitSpecStr is parsed at run-time outside the context of any running function. Consequently, you cannot use a general string expression. You can use either HOLD="quotedLiteralString" or HOLD=root:globalString.
For more details, and for examples of sums of fit functions in use, see Fitting Sums of Fit Functions on page III-244.

See Also
The CurveFit operation for parameter details. See also FuncFitMD for user-defined multivariate fits to data in a multidimensional wave.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See Using the Curve Fitting Dialog on page III-181, especially the section Fitting to a User-Defined Function on page III-190.

For details on the form of a user-defined function, see User-Defined Fitting Functions on page III-250.

FuncFitMD

FuncFitMD [flags] fitFuncName, cwaveName, waveName [flag parameters]

The FuncFitMD operation performs a curve fit to the specified multivariate user-defined fitFuncSpec. FuncFitMD handles gridded data sets in multidimensional waves. Most parameters and flags are the same as for the CurveFit and FuncFit operations; differences are noted below.

cwaveName is a 1D wave containing the fitting coefficients, and functionName is the user-defined fitting function, which has 2 to 4 independent variables.

FuncFitMD operation parameters are grouped in the following categories: flags, parameters (fitFuncName, cwaveName, waveName), and flag parameters. The sections below correspond to these categories. Note that flags must precede the fitFuncName and flag parameters must follow waveName.
### Flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/L=dimSize</td>
<td>Sets the dimension size of the wave created by the auto-trace feature, that is, /D without destination wave. The wave fit_waveName will be a multidimensional wave of the same dimensionality as waveName that has dimSize elements in each dimension. That is, if you are fitting to a matrix wave, fit_waveName will be a square matrix that has dimensions dimSize XdimSize. <strong>Beware:</strong> dimSize =100 requires 100 million points for a 4-dimensional wave!</td>
</tr>
</tbody>
</table>

### Parameters

- fitFuncName: User-defined function to fit to, which must be a function taking 2 to 4 independent variables.
- cwaveName: 1D wave containing the fitting coefficients.
- waveName: The wave containing the dependent variable data to be fit to the specified function. For functions of just one independent variable, the dependent variable data is often referred to as "Y data". You can fit to a subrange of the wave by supplying (startX,endX) or [startP,endP] for each dimension after the wave name. See Wave Subrange Details below for more information on subranges of waves in curve fitting.

### Flag Parameters

These flag parameters must follow waveName.

- /E=ewaveName: A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave.
- /T=twaveName: Like /X except for the T independent variable. This is a 1D wave having as many elements as waveName has chunks.
- /X=xwaveName: The X independent variable values for the data to fit come from xwaveName instead of from the X scaling of waveName. This is a 1D wave having as many elements as waveName has rows.
- /Y=ywaveName: Like /X except for the Y independent variable. This is a 1D wave having as many elements as waveName has columns.
- /Z=zwaveName: Like /X except for the Z independent variable. This is a 1D wave having as many elements as waveName has layers.
- /NWOK: Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to FuncFitMD is normally treated as an error. By using /NWOK, you are telling FuncFitMD that a null wave reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls FuncFitMD with optional waves. The waves affected are the X wave or waves (/X), the Y spacing wave (/Y), the Z spacing wave (/Z) the T spacing wave (/T), weight wave (/W), epsilon wave (/E) and mask wave (/M). The destination wave (/D=wave) and residual wave (/R=wave) are also affected, but the situation is more complicated because of the dual use of /D and /R to mean "do autodestination" and "do autoresidual". See /AR and /AD. If you don’t need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly. **Note:** To work properly this flag must be the last one in the command.

### Details

Auto-residual (/R with no wave specified) and auto-trace (/D with no wave specified) for functions having two independent variables are plotted in a separate graph window if waveName is plotted as a contour or image in the top graph. An attempt is made to plot the model values and residuals in the same way as the input data.
By default the auto-trace and auto-residual waves are 50x50 or 25x25x25 or 15x15x15x15. Use /L=dimSize for other sizes. Make your own wave and use /D=waveName or /R=waveName if you want a wave that isn’t square. In this case, the wave dimensions must be the same as the dependent data wave.

Confidence bands are not available for multivariate fits.

Wave Subrange Details
Almost any wave you specify to FuncFitMD can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command; see Subrange Display Syntax on page II-321 for details. Note that the dependent variable data (waveName) must be a multidimensional wave; this requires an extension of the subrange syntax to allow a multidimensional subrange. See Wave Subrange Details on page V-274 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for CurveFit apply to FuncFitMD as well.

A subrange could be used to pick a plane from a 3D wave for fitting using a fit function taking two independent variables:

```plaintext
Make/N=(100,100,3) DepData FuncFitMD fitfunc2D, myCoefs, DepData[][][0] ...
```

See Also
The CurveFit operation for parameter details.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See Using the Curve Fitting Dialog on page III-181, especially the section Fitting to a User-Defined Function on page III-190.

For details on the form of a user-defined function, see User-Defined Fitting Functions on page III-250.

**FUNCREF**

**FUNCREF** protoFunc func [ = funcSpec ]

Within a user function, FUNCREF is a reference that creates a local reference to a function or a variable containing a function reference.

When passing a function as an input parameter to a user function, the syntax is:

```plaintext
FUNCREF protoFunc func
```

In this FUNCREF reference, protoFunc is a function that specifies the format of the function that can be passed by the FUNCREF, and func is a function reference used as an input parameter.

When you declare a function reference variable within a user function, the syntax is:

```plaintext
FUNCREF protoFunc func = funcSpec
```

Here, the local FUNCREF variable, func, is assigned a funcSpec, which can be a literal function name, a $ string expression that evaluates at runtime, or another FUNCREF variable.

See Also
Function References on page IV-107 for an example and further usage details.

**FuncRefInfo**

**FuncRefInfo** (funcRef)

The FuncRefInfo function returns information about a FUNCREF.

**Parameters**

`funcRef` is a function reference variable declared by a FUNCREF statement in a user-defined function.

**Details**

FuncRefInfo returns a semicolon-separated keyword/value string containing the following information:

See Also
Function References on page IV-107 and FUNCREF on page V-278.
Function

Function \([ \text{/C} / \text{D} / \text{S} / \text{DF} / \text{WAVE} ] \) functionName([parameters])

The Function keyword introduces a user-defined function in a procedure window.

The optional flags specify the return value type, if any, for the function.

Flags

\begin{itemize}
  \item /C Returns a complex number.
  \item /D Returns a double-precision number. Obsolete, accepted for backward compatibility.
  \item /S Returns a string.
  \item /DF Returns a data folder reference. See Data Folder Reference Function Results on page IV-81.
  \item /WAVE Returns a wave reference. See Wave Reference Function Results on page IV-76.
\end{itemize}

Details

If you omit all flags, the result is a scalar double-precision number.

The /D flag is not needed because all numeric return values are double-precision.

See Also

Chapter IV-3, User-Defined Functions and Function Syntax on page IV-31 for further information.

FunctionInfo

FunctionInfo(functionNameStr \[, procedureWinTitleStr\])

The FunctionInfo function returns a keyword-value pair list of information about the user-defined or external function name in functionNameStr.

Parameters

functionNameStr a string expression containing the name or multipart name of a user-defined or external function. functionNameStr is usually just the name of a function, or "" to return information about the function that called FunctionInfo.

To return information about a static function, supply both the module name and the function name in MyModule#MyFunction format (see Regular Modules on page IV-236), or specify the function name and procedureWinTitleStr (see below).

To return information about a function in a different independent module, supply the independent module name in addition to any module name and function name (a double or triple name):

\begin{tabular}{|l|l|}
  \hline
  Name & What It Refers To \tabularnewline
  \hline
  MyIndependentModule#MyFunction & Refers to a non-static function in an independent module. \tabularnewline
  MyIndependentModule#MyModule#MyFunction & Refers to a static function in a procedure file with #pragma moduleName=MyModule in an independent module. \tabularnewline
  \hline
\end{tabular}

(See Independent Modules on page IV-238 for details on independent modules.)
The optional `procedureWinTitleStr` can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf") in which to search for the named user-defined function. The information about the named function in the specified procedure window is returned.

The `procedureWinTitleStr` parameter makes it possible to select one of several static functions with identical names among different procedure windows, even if they do not contain a `#pragmamoduleName=myModule` statement.

The `procedureWinTitleStr` parameter can also be a title followed by an independent module name in brackets to return information about the named function in the procedure window of the given title that belongs to named independent module. You can use this syntax in an independent module when inquiring about a function not in that independent module. For example, use "Procedure [ProcGlobal]" to return information about functions in the main procedure window.

`procedureWinTitleStr` can also be just an independent module name in brackets to return information about the named nonstatic function in any procedure window that belongs to named independent module. Omit the `procedureWinTitleStr` parameter or set it to "" when `functionNameStr` is "".

**Details**

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

**User-Defined and External Functions**

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>The name of the function. Same as contents of <code>functionNameStr</code> in most cases. Just the function name if you use the <code>module#function</code> format.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Value is &quot;UserDefined&quot; or &quot;XFunc&quot;.</td>
</tr>
<tr>
<td>THREADSAFE</td>
<td>Either &quot;yes&quot; or &quot;no&quot;. See ThreadSafe Functions on page IV-106.</td>
</tr>
<tr>
<td>RETURNTYPE</td>
<td>The return type or types of the function. See Return Type and Parameter Type Codes on page V-281.</td>
</tr>
<tr>
<td>N_PARAMS</td>
<td>Number of parameters for this function.</td>
</tr>
<tr>
<td>PARAM_n_TYPE</td>
<td>Number encoding the type of each parameter. There will be N of these keywords, one for each parameter. The part shown as n will be a number from 0 to N-1.</td>
</tr>
</tbody>
</table>

See Examples for a method for decoding these keywords.

**User-Defined Functions Only**

<tr>
<td>SPECIAL</td>
<td>The value part has one of three values:</td>
</tr>
<tr>
<td></td>
<td>no: Not a &quot;special&quot; function (not static or override).</td>
</tr>
</tbody>
</table>
Igor functions can return a numeric value, a string value, a wave reference, or a data folder reference. A returned numeric value is always double precision and may be complex. The return type for a normal numeric function is 4, for a complex function (Function/C) is 5 (4 for number +1 for complex). A string function (Function/S) is 8192 (string). A Function/WAVE has a return type of 16384.

</tbody>
</table>

Igor functions can return a numeric value, a string value, a wave reference, or a data folder reference. A returned numeric value is always double precision and may be complex. The return type for a normal numeric function is 4, for a complex function (Function/C) is 5 (4 for number +1 for complex). A string function (Function/S) is 8192 (string). A Function/WAVE has a return type of 16384.
FunctionInfo

The return and parameter codes may be combined to indicate combinations of attributes. For instance, the code for a variable is 4 and the code for complex is 1. Consequently, the code for a complex variable parameter is 5. The code for a complex variable parameter passed by reference is (4 + 1 + 4096) = 4101.

Variables are always double-precision, hence the code of 4.

Waves may have a variety of codes. Numeric waves will combine with one of the number type codes such as 2 or 16. This does not reflect the numeric type of any actual wave, but rather any flag you may have used in the Wave reference. Thus, if the beginning of your function looks like

Function myFunc(w)
  Wave w

the code for the parameter w will be 16386 (16384 + 2) indicating a single-precision wave. You can use a numeric type flag with the Wave reference:

Function myFunc(w)
  Wave/I w

In this case, the code will be 16416 (16384 + 32).

Such codes are not very useful, as it is very rare to use a numeric type flag because the numeric type will be resolved correctly at runtime regardless of the flag.

A text wave has no numeric type, so its code is exactly 16384 or 49152 if /Z is also specified. Thus, the numeric type part of the code for a numeric wave serves to distinguish a numeric wave from a text wave. And a Wave/WAVE (a wave that contains references to other waves) has a code of 16512 (16384 + 128), unless /Z is also specified, which adds 32768, resulting in a code of 49280.

When a function uses the multi-valued return syntax, the return value types indicate that they are passed by reference. For example, the type code for a string returned this way is 0x2000 + 0x1000 = 0x3000 (12288 decimal).

Examples

This function formats function information nicely and prints it in the history area in an organized fashion. You can copy it into the Procedure window to try it out. It uses the function InterpretType() below to print a human-readable version of the parameter and return types. To try PrintFuncInfo(), you will need to copy the code for InterpretType() as well.

Function PrintFuncInfo(functionName)
  String functionName
  String infostr = FunctionInfo(functionName)
  if (strlen(infostr) == 0)
    print "The function \""+functionName+\"\" does not exist."
    return -1
  endif
  print "Name: ", StringByKey("NAME", infostr)
  String typeStr = StringByKey("TYPE", infostr)
  print "Function type: ", typeStr
  Variable IsUserDefined = CmpStr(typeStr, "UserDefined")==0
  // It’s not really necessary to use an IF statement here;
  // it simply prevents lines with blank information being
  // printed for an XFUNC.
  if (IsUserDefined)
    print "Module: ", StringByKey("MODULE", infostr)
    print "Procedure window: ", StringByKey("PROCWIN", infostr)
    print "Subtype: ", StringByKey("SUBTYPE", infostr)
    print "Special? ", StringByKey("SPECIAL", infostr)
    // Note use of NumberByKey to get a numeric key value
    print "Line number: ", NumberByKey("PROCLINE", infostr)
  endif
  // See function InterpretType() below for example of
  // interpreting type information.
  Variable returnType = NumberByKey("RETURNTYPE", infostr)
  String returnTypeStr = InterpretType(returnType, 1)
FunctionInfo

printf "Return type: %d (0x%X) %s\r", returnType, returnType, returnTypeStr

Variable nparams = NumberByKey("N_PARAMS", infostr)
print "Number of Parameters: ", nparams

Variable nOptParams = 0
if (isUserDefined)
    nOptParams = NumberByKey("N_OPT_PARAMS", infostr)
    print "Optional Parameters: ", nOptParams
endif

Variable i
for (i = 0; i < nparams; i += 1)
    // Note how the PARAM_n_TYPE keyword string is constructed here:
    String paramKeyStr = "PARAM_" + num2istr(i) + "_TYPE"
    Variable ptype = NumberByKey(paramKeyStr, infostr)
    String ptypeStr = InterpretType(ptype, 0)
    String format = "Parameter %d; type as number: %g (0x%X); type as string: %s"
    String output
    sprintf output, format, i, ptype, ptype, pTypeStr
    print output
endfor

return 0
End

Function that creates a human-readable string with information about parameter and return types. Note that various attributes of the type info is tested using the bitwise AND operator (&) to test for individual bits. The constants are expressed as hexadecimal values (prefixed with “0x”) to make them more readable (at least to a programmer). Otherwise, 0x4000 would be 16384; at least, 0x4000 is clearly a single-bit constant.

Function/S InterpretType(type, isReturnType)
Variable type
Variable isReturnType // 0: type is parameter type; 1: type is return type.

String typeStr = ""

// limit type to unsigned 16-bit values (remove sign extensions caused by 0x8000)
type = type & 0xFFFF

// isNumeric is flag to tell whether to print out "complex" and "real";
// we don't want that information on strings, text waves or wave of wave references.
Variable isNumeric = 1

if (type & 0x4000) // test for WAVE bit set
    typeStr += "Wave"
    if( !isReturnType )
        // For parameter types, if no numeric bits are set, it is a text wave.
        // A numeric wave has some other bits set causing the value
        // to be different from 0x4000 or 0xC000.
        if (type & 0x80) // test for WAVE/WAVE bit set
            typeStr += "/WAVE"
            // don't print "real" or "complex" for wave waves
            isNumeric = 0
            endif
        if (type & 0x8000) // test for WAVE/Z bit set
            typeStr += "/Z"

StringByKey, NumberByKey, and FunctionList functions.
Regular Modules on page IV-236 and Independent Modules on page IV-238.

FunctionList

FunctionList(matchStr, separatorStr, optionsStr)
The FunctionList function returns a string containing a list of built-in or user-defined function names
satisfying certain criteria. This is useful for making a string to list functions in a pop-up menu control. Note
that if the procedures need to be compiled, then FunctionList will not list user-defined functions.

Parameters
Only functions having names that match matchStr string are listed. Use "*" to match all names. See
WaveList for examples.
separatorStr is appended to each function name as the output string is generated. separatorStr is usually ";" for
list processing (See Processing Lists of Waves on page IV-198 for details on list processing).
Use optionsStr to further qualify the list of functions. optionsStr is a string containing keyword-value pairs
separated by commas. Available options are:

KIND:nk Controls the kinds of functions returned.
    nk=1: List built-in functions.
    nk=2: List normal and override user-defined functions.
    nk=4: List external functions (defined by an XOP).
    nk=8: List only curve fitting functions; must be summed with 1, 2, 4, or 16.
        For example, use 10 to list user-defined fitting functions.
    nk=16: Include static user-defined functions; requires WIN: option, must be
        summed with 1, 2, or 8. To list only static functions, subtract the non-
        static functions using RemoveFromList.

SUBTYPE:typeName
Lists functions that have the type typeName. That is, you could use ButtonControl as
typeName to list only functions that are action procedures for buttons.

</tbody>
</table>
**FunctionList**

Lists functions that are defined in the named procedure window that belongs to the independent module `independentModuleName`. See Independent Modules on page IV-238 for details. Requires `SetIgorOption IndependentModuleDev=1`, otherwise no functions are listed.

Requires `independentModuleName=ProcGlobal` or `SetIgorOption independentModuleDev=1`, otherwise no functions are listed.

**Note:** The syntax is literal and strict: the window title must be followed by one space and a left bracket, followed directly by the independent module name and a closing right bracket.

**WIN:[independentModuleName]**

Lists functions that are defined in any procedure file that belongs to the named independent module.

Requires `independentModuleName=ProcGlobal` or `SetIgorOption independentModuleDev=1`, otherwise no functions are listed.

**Note:** The syntax is literal and strict: 'WIN:' must be followed by a left bracket, followed directly by the independent module name and a closing right bracket, like this:

```
FunctionList(...,"WIN:[myIndependentModuleName]"
```

**Return Type and Parameter Type Codes**

These codes are used with the PARAM_N_TYPE and RETURN_N_TYPE keywords:

<tr>
<td>/Z</td>
<td>32768</td>
<td>0x8000</td>
</tr>
</tbody>
</table>

**Special Return Type and Parameter Type Codes**

These special codes are used with the PARAM_N_TYPE and RETURN_N_TYPE keywords:

Any real-valued numeric wave   -2
Any complex-valued numeric wave -3
Function Path

**FunctionPath**

The FunctionPath function returns a path to the file containing the named function. This is useful in certain specialized cases, such as if a function needs access to a lookup table of a large number of values.

The most likely use for this is to find the path to the file containing the currently running function. This is done by passing "" for functionNameStr, as illustrated in the example below.

The returned path uses Macintosh syntax regardless of the current platform. See Path Separators on page III-451 for details.

If the procedure file is a normal standalone procedure file, the returned path will be a full path to the file.

If the function resides in the built-in procedure window the returned path will be ":Procedure". If the function resides in a packed procedure file, the returned path will be ":<packed procedure window title>".

If FunctionPath is called when procedures are in an uncompiled state, it returns "./".

**Parameters**

If functionNameStr is "", FunctionPath returns the path to the currently executing function or "" if no function is executing.
Otherwise FunctionPath returns the path to the named function or "" if no function by that name exists.

**Examples**

This example loads a lookup table into memory. The lookup table is stored as a wave in an Igor binary wave file.

Function LoadMyLookupTable()
    String path
    path = FunctionPath("") // Path to file containing this function.
    if (CmpStr(path[0], ":") == 0)
        // This is the built-in procedure window or a packed procedure
        // file, not a standalone file. Or procedures are not compiled.
        return -1
    endif
    // Create path to the lookup table file.
    path = ParseFilePath(1, path, ":", 1, 0) + "MyTable.ibw"
    DFREF dfSave = GetDataFolderDFR()
    // A previously-created place to store my private data.
    SetDataFolder root:Packages:MyData
    // Load the lookup table.
    LoadWave/O path
    SetDataFolder dfSave
    return 0
End

**See Also**
The FunctionList function.

**GalleryGlobal**

*GalleryGlobal* pictureName

The GalleryGlobal keyword is used in an independent module to reference a picture in the global picture gallery which you can view by choosing Misc→Pictures.

**See Also**
See Independent Modules and Pictures on page IV-244.

**gamma**

**gamma**(num)

The gamma function returns the value of the gamma function of num. If num is complex, it returns a complex result. Note that the return value for num close to negative integers is NaN, not ±Inf.

**See Also**
The gammln function.

**gammaEuler**

**gammaEuler**

The gammaEuler function returns the Euler-Mascheroni constant 0.5772156649015328606065. The gammaEuler function was added in Igor Pro 7.00.

**gammaInc**

**gammaInc**(a, x [, upperTail])

The gammaInc function returns the value of the incomplete gamma function, defined by the integral

\[ \Gamma(a,x) = \int_x^\infty e^{-t}t^{a-1} \, dt. \]

If upperTail is zero, the limits of integration are 0 to x. If upperTail is absent, it defaults to 1, and the limits of integration are x to infinity, as shown. Note that \( \gamma(a,x) = \Gamma(a) - \gamma(a,x,0). \)
gammaNoise

**gammaNoise**

\[ \text{gammaNoise}(a, b) \]

The gammaNoise function returns a pseudo-random value from the gamma distribution

\[
f(x) = \frac{x^{a-1} \exp \left( -\frac{x}{b} \right)}{b^a \Gamma(a)} \quad x > 0, \quad a > 0, \quad b > 0,
\]

whose mean is \( ab \) and variance is \( ab^2 \). For backward compatibility you can omit the parameter \( b \) in which case its value is set to 1. When \( a \to 1 \) gammaNoise reduces to \( \text{expNoise} \).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use \( \text{SetRandomSeed} \). The algorithm uses the Mersenne Twister random number generator.

**References**

**See Also**

The \( \text{SetRandomSeed} \) operation.

**Noise Functions** on page III-390.

Chapter III-12, **Statistics** for a function and operation overview.

gammln

**gammln**

\[
\text{gammln}(\text{num}, \text{accuracy})
\]

The gammln function returns the natural log of the gamma function of \( \text{num} \), where \( \text{num} > 0 \). If \( \text{num} \) is complex, it returns a complex result. Optionally, \( \text{accuracy} \) can be used to specify the desired fractional accuracy. If \( \text{num} \) is complex, it returns a complex result. In this case, \( \text{accuracy} \) is ignored.

**Details**

The \( \text{accuracy} \) parameter specifies the fractional accuracy that you desire. That is, if you set \( \text{accuracy} \) to \( 10^{-7} \), that means that you wish that the absolute value of \( f_{\text{actual}} - f_{\text{returned}} \)/\( f_{\text{actual}} \) be less than \( 10^{-7} \).

For backward compatibility, if you don’t include \( \text{accuracy} \), gammln uses older code that achieves an accuracy of about \( 2 \times 10^{-10} \).

With \( \text{accuracy} \), newer code is used that is both faster and more accurate. The output has fractional accuracy better than \( 1 \times 10^{-15} \) except for values near zero, where the absolute accuracy \( f_{\text{actual}} - f_{\text{returned}} \) is better than \( 2 \times 10^{-16} \).

The speed of calculation depends only weakly on accuracy. Higher accuracy is significantly slower than lower accuracy only for \( \text{num} \) between 6 and about 10.

**See Also**

The gamma function.

gammp

**gammp**

\[
\text{gammp}(a, x, \text{accuracy})
\]

The gammp function returns the regularized incomplete gamma function \( \text{P}(a, x) \), where \( a > 0, \ x \geq 0 \). Optionally, \( \text{accuracy} \) can be used to specify the desired fractional accuracy. Same as \( \text{gammaInc}(a, x, 0)/\text{gamma}(a) \).

**Details**

The \( \text{accuracy} \) parameter specifies the fractional accuracy that you desire. That is, if you set \( \text{accuracy} \) to \( 10^{-7} \), that means that you wish that the absolute value of \( f_{\text{actual}} - f_{\text{returned}} \)/\( f_{\text{actual}} \) be less than \( 10^{-7} \).
gammq

For backward compatibility, if you don’t include accuracy, gammp uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

The ability of gammp to return a value having full fractional accuracy is limited by double-precision calculations. This means that it will mostly have fractional accuracy better than about $10^{-15}$, but this is not guaranteed, especially for extreme values of $a$ and $x$.

See Also
The gammaInc and gammq functions.

gammq

gammq(a, x [ , accuracy])
The gammq function returns the regularized incomplete gamma function $1 - P(a,x)$, where $a > 0$, $x \geq 0$. Optionally, accuracy can be used to specify the desired fractional accuracy. Same as gammaInc(a, x)/gamma(a).

Details
The accuracy parameter specifies the fractional accuracy that you desire. That is, if you set accuracy to $10^{-7}$, that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$ be less than $10^{-7}$.

For backward compatibility, if you don’t include accuracy, gammq uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

The ability of gammq to return a value having full fractional accuracy is limited by double-precision calculations. This means that it will mostly have fractional accuracy better than about $10^{-15}$, but this is not guaranteed, especially for extreme values of $a$ and $x$.

See Also
The gammaInc and gammp functions.

Gauss

Gauss(xc, yc, zc, tc, wx, wy, wz, wt)
The Gauss function returns a normalized Gaussian for the specified dimension.

$$Gauss(r, c, w) = \prod_{i=1}^{n} \frac{1}{w_i \sqrt{2\pi}} \exp \left[ -\frac{1}{2} \left( \frac{r_i - c_i}{w_i} \right)^2 \right],$$

where $n$ is the number of dimensions.

Parameters
$xc$, $yc$, $zc$, and $tc$ are the centers of the Gaussian in the X, Y, Z, and T directions, respectively.
$wx$, $wy$, $wz$, and $wt$ are the widths of the Gaussian in the X, Y, Z, and T directions, respectively.

Note that $w_i$ here is the standard deviation of the Gaussian. This is different from the width parameter in the gauss curve fitting function, which is $\sqrt{2}$ times the standard deviation.

Note also that the Gauss function lacks the cross-correlation parameter that is included in the Gauss2D curve fitting function.

Examples
Make/N=100 eee=gauss(x, 50, 10)
Print area(eee, -inf, inf)
  0.999999
Make/N=(100, 100) ddd=gauss(x, 50, 10, y, 50, 15)
Print area(ddd, -inf, inf)
  0.999137

See Also
Gauss1D (duplicates the Gauss built-in curve fitting function)
Gauss2D (duplicates the Gauss2D built-in curve fitting function)
Gauss1D

\[ \text{Gauss1D}(w, x) \]
The Gauss1D function returns the value of a Gaussian peak defined by the coefficients in the wave \( w \). The equation is the same as the Gauss curve fit:

\[ w[0] + w[1] \exp \left[ -\frac{(x - w[2])^2}{w[3]} \right]. \]

Examples
Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range:

```plaintext
Make/O/N=100 junkg // fake data wave
Setscale/I x -1,1,junkg
Display junkg
junkg = 1+2.5*exp(-((x-.5)/.3)^2)+gnoise(.1)
Duplicate/O junkg, junkgfit
junkgfit = NaN
AppendToGraph junkgfit
CurveFit gauss junkg[50,99] /D=junkgfit
// now extend the model trace
junkgfit = Gauss1D(w_coef, x)
```

See Also
The CurveFit operation.

Gauss2D

\[ \text{Gauss2D}(w, x, y) \]
The Gauss2D function returns the value of a two-dimensional Gaussian peak defined by the coefficients in the wave \( w \). The equation is the same as the Gauss2D curve fit:

\[ w[0] + w[1] \exp \left[ \frac{-1}{2(1-w[6])^2} \left\{ \left( \frac{x - w[2]}{w[3]} \right)^2 + \left( \frac{y - w[4]}{w[5]} \right)^2 - \left( \frac{2w[6](x - w[2])(y - w[4])}{w[3]w[5]} \right) \right\} \right]. \]

Examples
Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range (watch out for the very long wave assignment to junkg2D):

```plaintext
Make/O/N=(100,100) junkg2D // fake data wave
Setscale/I x -1,1,junkg2D
Setscale/I y -1,1,junkg2D
Display; AppendImage junkg2D
// Caution! Next command wrapped to fit page:
junkg2D = -1 + 2.5*exp((-1/(2*(1-.4^2)))^2+((x-.1)/.2)^2+((y+.2)/.35)^2+2*.4*(x-.1)/.2*(y+.2)/.35))
junkg2D += gnoise(.01)
Duplicate/O junkg2D, junkg2Dfit
junkg2Dfit = NaN
AppendMatrixContour junkg2Dfit
CurveFit gauss2D junkg2D[20,80][10,70] /D=junkg2Dfit[20,80][10,70]
// now extend the model trace
junkg2Dfit = Gauss2D(w_coef, x, y)
```

See Also
The CurveFit operation.

GBLoadWave

\[ \text{GBLoadWave} [\text{flags}] [\text{fileNameStr}] \]
The GBLoadWave operation loads data from a binary file into waves.

For more complex applications such as loading structured data into Igor structures see the FBinRead operation.
**GBLoadWave**

**Parameters**

If `fileNameStr` is omitted or is "", or if the /I flag is used, GBLoadWave presents an Open File dialog from which you can choose the file to load.

If you use a full or partial path for `fileNameStr`, see **Path Separators** on page III-451 for details on forming the path.

**Flags**

/A  Automatically assigns arbitrary wave names using "wave" as the base name. Skips names already in use.

/A=baseName  Same as /A but it automatically assigns wave names of the form baseName0, baseName1.

/D=d  New programming should use the /T flag instead of the /D, /L and /F flags.

\[d=0: \text{ Creates single-precision waves.} \]
\[d=1: \text{ Creates double-precision waves.} \]

/D by itself is equivalent to /D=1.

/F=f  New programming should use the /T flag instead of the /D, /L and /F flags.

\[f=1: \text{ Signed integer (8, 16, 32 bits allowed)} \]
\[f=2: \text{ Creates double-precision waves} \]
\[f=3: \text{ Floating point (default, 32, 64 bits allowed)} \]

/FILT=fileFilterStr  Provides control over the file filter menu in the Open File dialog. This flag was added in Igor Pro 7.00.

The construction of the `fileFilterStr` parameter is the same as for the /F=fileFilterStr flag of the Open operation. See **Open File Dialog File Filters** on page IV-149 for details.

/I [{macFilterStr, winFilterStr}]  Specifies interactive mode which displays the Open File dialog.

In Igor7 and later, the `macFilterStr` and `winFilterStr` parameters are ignored. Use the /FILT flag instead.

/J=j  Specifies how input floating point data is interpreted.

\[j=0: \text{ IEEE floating point (default)} \]
\[j=1: \text{ VAX floating point} \]

/L=length  New programming should use the /T flag instead of the /D, /L and /F flags.

\[length\] specifies the data length of the data in the file in bits (default = 32). Allowable data lengths are 8, 16, 32, 64.

/N  Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.

/N=baseName  Same as /N except that it automatically assigns wave names of the form baseName0, baseName1.

/O=o  Controls overwriting of waves in case of a name conflict.

\[o=0: \text{ Use unique wave names.} \]
\[o=1: \text{ Overwrite existing waves.} \]

/O by itself is equivalent to /O=1.

/P=pathName  Specifies the folder to look in for `fileNameStr`. `pathName` is the name of an existing symbolic path.
GBLoadWave

/Q=q  Controls messages written to the history area of the command window.
   q=0:  Write messages.
   q=1:  Suppress messages.

/Q by itself is equivalent to /Q=1.

/S=s  s is the number of bytes at the start of the file to skip. It defaults to 0.

/T={fType,wType}  Specifies the data type of the file (fType) and the data type of the wave or waves to be created (wType). The allowed codes for both fType and wType are:
   2:  Single-precision floating point
   4:  Double-precision floating point
   8:  8-bit signed integer
  16:  16-bit signed integer
  32:  32-bit signed integer
 128:  64-bit signed integer (Igor7 or later)
  72:  8-bit unsigned integer (8+64)
  80:  16-bit unsigned integer (16+64)
  96:  32-bit unsigned integer (32+64)
 192:  64-bit unsigned integer (128+64) (Igor7 or later)

/U=u  Specifies the number of points of data per array in the file.

   The default is 0 which means “auto”. In this case GBLoadWave calculate the number of data pointers per array based on the number of bytes in the file, the number of bytes to be skipped at the start of the file (/S flag), and the number of arrays in the file (/W flag).

/V=v  v=0:  Data in file is not interleaved (default)
   v=1:  Data in file is interleaved

/V by itself is equivalent to /V=1.

/W=w  Specifies the number of arrays in the file. The default is 1.

   If you omit /W but specify the number of points per data array in the file via /U then GBLoadWave calculates the number of waves to be loaded based on the number of bytes in the file, the number of bytes to be skipped at the start of the file (/S flag), and the specified number of points per data array in the file (/U flag). Therefore, if you specify /U and want to load just one wave you must also specify /W=1.

/Y={offset, mult}  Data loaded into waves is scaled using offset and mult:
   output data = (input data + offset) * multiplier
   This is useful to convert integer data into scaled, real numbers.

Details
The /N flag instructs Igor to automatically name new waves "wave" (or baseName if /N=baseName is used) plus a nimer. The nimer starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The /A flag is like /N except that Igor skips names already in use.

The /T flag allows you to specify a data type for both the input (data in the file) and the output (data in the waves). You should use the /T flag instead of the /D, /L and /F flags. These flags are obsolete but are still supported.

GBLoadWave Open File Dialog
If you include the /I flag, or if the /P=pathName and fileNameStr parameters do not fully specify the file to be loaded, GBLoadWave displays the Open File dialog.
The /FILT=\texttt{fileFilterStr} flag provides control over the file filter menu in the Open File dialog. This flag was added in Igor Pro 7.00. The construction of the \texttt{fileFilterStr} parameter is the same as for the /F=\texttt{fileFilterStr} flag of the Open operation. See Open File Dialog File Filters on page IV-149 for details.

In Igor7 and later, the \texttt{macFilterStr} and \texttt{winFilterStr} parameters of the /I flag are ignored. Use the /FILT flag instead.

**Output Variables**

\texttt{GBLoadWave} sets the following output variables:

- \texttt{V\_flag} Number of waves loaded or -1 if an error occurs during the file load.
- \texttt{S\_fileName} Name of the file being loaded.
- \texttt{S\_path} File system path to the folder containing the file.
- \texttt{S\_waveNames} Semicolon-separated list of the names of loaded waves.

\texttt{S\_path} uses Macintosh path syntax (e.g., “\texttt{hd:FolderA:FolderB:}”), even on Windows. It includes a trailing colon.

When GBLoadWave presents an Open File dialog and the user cancels, \texttt{V\_flag} is set to 0 and \texttt{S\_fileName} is set to “”.

**Example**

```plaintext
// Load 128 point single precision version 2 Igor binary wave file
GBLoadWave/S=126/U=128 "fileName"

// Load 8 256 point arrays of 16 bit signed integers into single-precision waves
// after skipping 128 byte header
GBLoadWave/S=128/T={16,2}/W=8/U=256 "fileName"

// Load n 100 point arrays of double-precision floating point numbers
// into double-precision Igor waves with names like temp0, templ, etc,
// overwriting existing waves. n is determined by the number of bytes
// in the file.
GBLoadWave/O/N=temp/T={4,4}/U=100 "fileName"

// Load a file containing a 1024 byte header followed by a 512 row
// by 384 column array of unsigned bytes into an unsigned byte matrix
// and display it as an image
GBLoadWave/S=1024/T={8+64,8+64}/N=temp "fileName"
Rename temp0, image
Redimension/N=(512,384) image
if (<file uses row-major order>)
    MatrixTranspose image
endif
Display; AppendImage image
```

“Row-major order” relates to how a 2D array is stored in memory. In row-major order, all data for a given row is stored contiguously in memory. In column-major order, all data for a given column is stored contiguously in memory. Igor uses column-major order but row-major is more common.

**See Also**

Loading General Binary Files on page II-166.

\texttt{FBinRead} operation for more complex applications such as loading structured data into Igor structures.

**gcd**

\texttt{gcd} \((A, B)\)

The \texttt{gcd} function calculates the greatest common divisor of \(A\) and \(B\), which are both assumed to be integers.

**Examples**

Compute least common multiple (LCM) of two integers:

```plaintext
Function LCM(a,b)
    Variable a, b
    return((a*b)/gcd(a,b))
End
```
GeometricMean

GeometricMean(a, b)
The GeometricMean function returns the arithmetic–geometric mean of two positive real numbers \(a\) and \(b\). The mean is computed by creating two sequences \(\{a_i\}\) and \(\{b_i\}\) initialized to the input values: \(a_0=a\) and \(b_0=b\) with

\[
a_{n+1} = \frac{1}{2}(a_n + b_n),
\]

\[
b_{n+1} = \sqrt{a_n b_n}.
\]

The two sequences converge in a few iterations to a single value which is the arithmetic-geometric mean.

See Also
EllipticK, EllipticE

GetAxis

GetAxis [ /W=winName /Q] axisName
The GetAxis operation determines the axis range and sets the variables \(V_{\text{min}}\) and \(V_{\text{max}}\) to the minimum and maximum values of the named axis.

Parameters
axisName is usually "left", "right", "top" or "bottom", though it may also be the name of a free axis such as "VertCrossing".

Flags
/Q Prevents values of \(V_{\text{flag}}, V_{\text{min}},\) and \(V_{\text{max}}\) from being printed in the history area.
The results are still stored in the variables.

/W=winName Retrieves axis info from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with \(\text{winName}\), see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
GetAxis sets \(V_{\text{min}}\) according to the bottom of vertical axes or left of horizontal axes and \(V_{\text{max}}\) according to the top of vertical axes or right of horizontal axes. It also sets the variable \(V_{\text{flag}}\) to 0 if the specified axis is actually used in the graph, or to 1 if it is not.

Axis ranges and other graph properties are computed when the graph is redrawn. Since automatic screen updates are suppressed while a user-defined function is running, if the graph was recently created or modified, you must call DoUpdate to redraw the graph so you get accurate axis information.

See Also
The AxisInfo function.

GetBrowserLine

GetBrowserLine(fullPathStr [, mode])
The GetBrowserLine function returns the zero-based line number of the data folder referenced by \(\text{fullPathStr}\).
GetBrowserSelection

Documentation for the GetBrowserLine function is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "GetBrowserLine"

GetBrowserSelection

GetBrowserSelection(index [, mode])
The GetBrowserSelection function returns a string containing the full path, quoted if necessary, to a selected Data Browser item.

Documentation for the GetBrowserSelection function is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "GetBrowserSelection"

GetCamera

GetCamera [flags] [keywords]
The GetCamera operation provides information about a camera window.

Documentation for the GetCamera operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "GetCamera"

GetDataFolder

GetDataFolder(mode [, dfr])
The GetDataFolder function returns a string containing the name of or full path to the current data folder or, if dfr is present, the specified data folder.

GetDataFolderDFR is preferred.

Parameters
If mode=0, it returns just the name of the data folder.
If mode=1, GetDataFolder returns a string containing the full path to the data folder.

dfr, if present, specifies the data folder of interest.

Details
GetDataFolder can be used to save and restore the current data folder in a procedure. However GetDataFolderDFR is preferred for that purpose.

Examples

String savedDataFolder = GetDataFolder(1) // Save
SetDataFolder root:
Variable/G gGlobalRootVar
SetDataFolder savedDataFolder // and restore

See Also
Chapter II-8, Data Folders.
The SetDataFolder operation and GetDataFolderDFR function.

GetDataFolderDFR

GetDataFolderDFR()
The GetDataFolderDFR function returns the data folder reference for the current data folder.

Details
GetDataFolderDFR can be used to save and restore the current data folder in a procedure. It is like GetDataFolder but returns a data folder reference rather than a string.

Example

DFREF saveDFR = GetDataFolderDFR() // Save
SetDataFolder root:
Variable/G gGlobalRootVar
SetDataFolder saveDFR // and restore
GetDefaultFont

GetDefaultFont(winName)

The GetDefaultFont function returns a string containing the name of the default font for the named window or subwindow.

Parameters

If winName is null (that is, "") returns the default font for the experiment.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

Only graph windows and the experiment as a whole have default fonts. If winName is the name of a window other than a graph (e.g., a layout), or if winName is not the name of any window, GetDefaultFont returns the experiment default font.

In user-defined functions, font names are usually evaluated at compile time. To use the output of GetDefaultFont in a user-defined function, you will usually need to build a command as a string expression and execute it with the Execute operation.

Examples

String fontName = GetDefaultFont("Graph0")
String command= "SetDrawEnv fname="" + fontName + ", save"
Execute command

See Also

The GetDefaultFontSize, GetDefaultFontStyle, FontSizeHeight, and FontSizeStringWidth functions.

GetDefaultFontSize

GetDefaultFontSize(graphNameStr, axisNameStr)

The GetDefaultFontSize function returns the default font size of the graph or of the graph’s axis (in points) in the specified window or subwindow.

Details

If graphNameStr is "" the top graph is examined.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

If axisNameStr is "", the font size of the default font for the graph is returned.

If named axis exists, the default font size for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

See Also

The GetDefaultFont, GetDefaultFontStyle, FontSizeHeight, and FontSizeStringWidth functions.

GetDefaultFontStyle

GetDefaultFontStyle(graphNameStr, axisNameStr)

The GetDefaultFontStyle function returns the default font style of the graph or of the graph’s axis in the specified window or subwindow.

Details

If graphNameStr is "" the top graph is examined.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
If \( n \) is "", the font style of the default font for the graph is returned.

If named axis exists, the default font style for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

The function result is a bitwise value with each bit identifying one aspect of the font style as follows:

- Bit 0: Bold
- Bit 1: Italic
- Bit 2: Underline
- Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

See Also

The GetDefaultFont, GetDefaultFontSize, FontSizeHeight, and FontSizeStringWidth functions.

GetDimLabel

\texttt{GetDimLabel(waveName, dimNumber, dimIndex)}

The GetDimLabel function returns a string containing the label for the given dimension or dimension element.

Use \( \text{dimNumber}=0 \) for rows, 1 for columns, 2 for layers and 3 for chunks.

If \( \text{dimIndex} \) is -1, it returns the label for the entire dimension. If \( \text{dimIndex} \geq 0 \), it returns the dimension label for that element of the dimension.

See Also

SetDimLabel, FindDimLabel, CopyDimLabels

Dimension Labels on page II-93 for further usage details and examples.

GetEnvironmentVariable

\texttt{GetEnvironmentVariable(varName)}

The GetEnvironmentVariable function returns a string containing the current value of the specified environment variable for the currently running Igor process. If the variable does not exist, an empty string ("") is returned.

The GetEnvironmentVariable function was added in Igor Pro 7.00.

Parameters

- \( \text{varName} \)

  The name of an environment variable which may or may not exist. It must not be an empty string and may not contain an equals sign (=).

  As a special case, if a single equals sign ("=") is passed for \( \text{varName} \), a carriage return (\r) separated list of all current key=value environment variable pairs is returned.

Details

The environment of Igor’s process is composed of a set of key=value pairs that are known as environment variables.

Any child process created by calling ExecuteScriptText inherits the environment variables of Igor’s process. On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

GetEnvironmentVariable returns an empty string if \( \text{varName} \) does not exist or if it does exist but its value is empty. If you need to know whether or not the environment variable itself actually exists, you can use the following function:

\texttt{Function EnvironmentVariableExists(varName)}

\texttt{String varName}

\texttt{String varList = GetEnvironmentVariable("=")}
GetErrMessage

GetErrMessage(errorCode [, substitutionOption])
GetErrMessage returns a string containing an explanation of the error associated with errorCode. It is most useful for programmers providing custom error handling in user-defined functions.

The GetRTErrMessage provides a simpler way to get a description of an error in a user-defined function.

For an overview of error handling, see Flow Control for Aborts on page IV-48.

Details

errorCode is an Igor error code. Usually you obtain the error code during execution of a user-defined function via the GetRTError function or from the V_Flag variable created by many Igor operations.

If multiple errors occur in a user-defined function, this may result in GetErrMessage returning an incomplete error message. See the MultipleErrors example below. You can achieve more reliable error reporting by calling GetRTErrMessage from a try-catch-endtry block.

Substitution

For a few error codes, the corresponding error message is designed to be combined with "substituted" information available only immediately after the error occurs. An example is the "parameter out of range" error which produces an error message such as "expected number between x and y". The optional substitutionOption parameter gives you control over substitution.

To get the correct error message, you must call GetErrMessage immediately after calling the function or operation that generated the error and you must pass the appropriate value for substitutionOption.

Igor maintains two contexts which store the substitution information: one for user-defined functions and one for all other contexts (command line execution, macros, and the Execute operation).

Set substitutionOption to one of these values:

<table>
<thead>
<tr>
<th>substitutionOption</th>
<th>GetErrMessage Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Substitution values are filled in with &quot;,_Not Available,&quot;. This is the default when substitutionOption is not specified.</td>
</tr>
<tr>
<td>1</td>
<td>Substitution values are blank.</td>
</tr>
<tr>
<td>2</td>
<td>Substitution is performed based on the assumption that the error was received while executing a macro or a command using Igor’s command line. This includes a command executed via the Execute operation even from a user-defined function because such commands are executed as if entered in the command line.</td>
</tr>
<tr>
<td>3</td>
<td>Substitution is performed based on the assumption that the error was received while executing a user-defined function.</td>
</tr>
</tbody>
</table>

For most purposes you should pass 3 for substitutionOption when the error was generated in a user-defined function other than through the Execute operation and pass 2 otherwise.

Examples

// Macro, Execute or command line example
Execute/Q/Z "Duplicate/O nonexistentWave, dup"
Print GetErrMessage(V_Flag,2)  // Prints "expected wave name"
// Function example
Function Test()
    Make/O/N=(2,2) data= 0
    FilterIIR/COEF=data/LO=999/Z data // Purposely wrong /LO value
    Print GetErrMessage(V_Flag,3) // Substitution assuming user-defined function
End
// Executing Test() prints: "expected /LO frequency between 0 and 0.5"

// Multiple error example
// Because of the first error, an assignment to a null wave reference,
// the substitution information for the FilterIIR operation is not available.
Function MultipleErrors()
    Make/O/N=(2,2) data= 0
    WAVE ww = "$"
    // Generates error because ww is not valid
    ww = 0
    // Generates another error because of purposely wrong /LO value
    FilterIIR/COEF=data/LO=999/Z data
    Print GetErrMessage(V_Flag,3) // Substitution assuming user-defined function
End
// Executing MultipleErrors() prints:
// "expected between and " // Wave error masks /LO error reporting

See Also
Flow Control for Aborts on page IV-48, GetRTErrMessage, GetRTErr

GetFileFolderInfo

GetFileFolderInfo [flags][fileOrFolderNameStr]
The GetFileFolderInfo operation returns information about a file or folder.

Parameters
fileOrFolderNameStr specifies the file (or folder) for which information is returned. It is optional if /P=pathname
and /D are specified, in which case information about the directory associated with pathname is returned.
If you use a full or partial path for fileOrFolderNameStr, see Path Separators on page III-451 for details on
forming the path.
Folder paths should not end with single Path Separators. See the MoveFolder Details section.
If Igor can not determine the location of the file from fileOrFolderNameStr and pathname, it displays a dialog
allowing you to specify the file to be examined. Use /D to select a folder.

Flags
/D          Uses the Select Folder dialog rather than Open File dialog when pathname and
dfileOrFolderNameStr do not specify an existing file or folder.
/Omit
/P=pathname  Specifies the folder to look in for the file. pathname is the name of an existing symbolic
path.
/Q
/UTC[=u]    If you include /UTC or /UTC=1, GetFileFolderInfo returns creation and modification
dates in UTC (coordinated universal time). If you omit /UTC or specify /UTC=0,
GetFileFolderInfo returns creation and modification dates in local time.
The default, used if you omit /UTC, is local time.
The /UTC flag was added in Igor Pro 9.00.
GetFileFolderInfo

/\[e=2\]  Prevents procedure execution from aborting if GetFileFolderInfo tries to get information about a file or folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

/Z=0:  Same as no /Z.
/Z=1:  Used for getting information for a file or folder only if it exists. /Z alone has the same effect as /Z=1.
/Z=2:  Used for getting information for a file or folder if it exists and displaying a dialog if it does not exist.

Output Variables

GetFileFolderInfo returns information in the following output variables:

V_flag  0: File or folder was found.
        -1: User cancelled the Open File dialog.
        Other: An error occurred, such as the specified file or folder does not exist.

S_path  Full file system path to the specified file or folder using Macintosh path syntax.

V_isFile 1: fileOrFolderNameStr is a file.

V_isFolder 1: fileOrFolderNameStr is a folder.

V_isInvisible 1: File is invisible (Macintosh) or Hidden (Windows).

V_isReadOnly Set if the file is locked (Macintosh) or is read-only (Windows).

On Macintosh, V_isReadOnly is either 0 (unlocked) or 1 (locked). To set this manually, display the Finder Info window for the file and then check or uncheck the “Locked” checkbox.

On Windows, V_isReadOnly is either 0 (unlocked) or 1 (locked). To set this manually, display the Properties window for the file and then check or uncheck the “Read-only” checkbox.

On both Macintosh and Windows, V_isReadOnly tells you only about the property set in the Finder or Windows desktop. It does not tell you if you have write permission for the file or for the folder containing the file. If your goal is to determine if you can write to the file, the only way to do that is to try to write to it and catch any resulting error.

V_creationDate  Number of seconds since midnight on January 1, 1904 when the file or folder was first created in local time or UTC depending on the /UTC flag. Use Secs2Date to format the date as text.

V_modificationDate  Number of seconds since midnight on January 1, 1904 when the file or folder was last modified in local time or UTC depending on the /UTC flag. Use Secs2Date to format the date as text.

V_isAliasShortcut 1: File is an alias (Macintosh) or a shortcut (Windows) and S_aliasPath is also set.

If fileOrFolderNameStr refers to a file (not a folder), GetFileFolderInfo returns additional information in the following variables:

S_aliasPath  If the specified file is an alias or shortcut, S_aliasPath is the full path to the target of the specified file. Otherwise it is “”.

S_aliasPath uses Macintosh path syntax. When the source is a folder, it ends with a “:" character.

V_isStationery 1: The stationery bit is set (Macintosh) or (Windows) the file type is one of the stationery file types (.pxt, .uxt, .ift).
GetFileFolderInfo

| **S_fileType** | Four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment). On Windows, these codes are fabricated by translating from the equivalent file name extensions, such as .txt and .pxp. |
| **S_creator** | Four-character creator code, such as 'IGR0' (Igor Pro creator code). On Windows, S_creator is set to 'IGR0' if the file name extensions is one of those registered to Igor Pro, such as .pxp or .bwav (but not .txt). For other registered extensions, S_creator is set to the full file path of the registered application. Otherwise it is set to "". |
| **V_logEOF** | Number of bytes in the file data fork. For other forks, use Open/F and FStatus. |
| **V_version** | Version number of the file. On Macintosh, this is the value in the vers(1) resource. On Windows, a file version such as 3.10.2.1 is returned as 4.021: use S_fileVersion to avoid the problem of the second digit overflowing into the first digit. “0”: File version can’t be determined, or the file can’t be examined because it is already open. |
| **S_fileVersion** | The file version as a string. On Macintosh, this is just a string representation of V_Version. On Windows, a file version such as 3.10.2.1 is returned as “3.10.2.1”. “0”: (Macintosh) file version can’t be determined. “0.0.0.0”: (Windows) file version can’t be determined. |

**Details**
You can change some of the file information by using **SetFileFolderInfo**.

On Windows shortcuts have ".lnk" file name extensions that are hidden on the desktop. Prior to Igor Pro 9, **fileOrFolderNameStr** was required to include the ".lnk" extension. For consistency with operations such as NewPath and OpenNotebook, in Igor Pro 9.00 and later, it is optional. When **fileOrFolderNameStr** refers to a shortcut, the **S_path** output variable includes the ".lnk" extension.

**Examples**
Print the modification date of a file:

GetFileFolderInfo/Z "Macintosh HD:folder:afile.txt"
if( V_Flag == 0 && V_isFile ) // file exists
    Print Secs2Date(V_modificationDate,0), Secs2Time(V_modificationDate,0)
endif

Determine if a folder exists (easier than creating a path with NewPath and then using PathInfo):

GetFileFolderInfo/Z "Macintosh HD:folder:subfolder"
if( V_Flag && V_isFolder )
    Print "Folder Exists!"
endif

Find the source for a shortcut or alias:

GetFileFolderInfo/Z "Macintosh HD:fileThatIsAlias"
if( V_Flag && V_isAliasShortcut )
    Print S_aliasPath
endif

The **SetFileFolderInfo**, **PathInfo**, and **FStatus** operations. The **IndexedFile**, **Secs2Date**, and **ParseFilePath** functions.
GetFormula

GetFormula(objName)
The GetFormula function returns a string containing the named object’s dependency formula. The named object must be a wave, numeric variable or string variable.

Details
Normally an object will have an empty dependency formula and GetFormula will return an empty string (""). If you assign a expression to an object using the := operator or the SetFormula operation, the text on the right side of the := or the parameter to SetFormula is the object’s dependency formula and this is what GetFormula will return.

Examples
Variable/G dependsOnIt
Make/O wave0 := dependsOnIt*2       //wave0 changes when dependsOnIt does
Print GetFormula(wave0)
Prints the following in the history area:
    dependsOnIt*2

See Also
See Dependency Formulas on page IV-230, and the SetFormula operation.

GetGizmo

GetGizmo [flags] keyword [=value]
The GetGizmo operation provides information about a Gizmo display window.

Documentation for the GetGizmo operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "GetGizmo"

GetIndependentModuleName

GetIndependentModuleName()
The GetIndependentModuleName function returns the name of the currently running Independent Module. If no independent module is running, it returns “ProcGlobal”.

See Also
Independent Modules on page IV-238.
IndependentModuleList.

GetIndexedObjName

GetIndexedObjName(sourceFolderStr, objectType, index)
The GetIndexedObjName function returns a string containing the name of the indexth object of the specified type in the data folder specified by the string expression.

GetIndexedObjNameDFR is preferred.

Parameters
sourceFolderStr can be either ":" or "" to specify the current data folder. You can also use a full or partial data folder path. index starts from zero. If no such object exists a zero length string ("") is returned.

objectType is one of the following values:

<table>
<thead>
<tr>
<th>objectType</th>
<th>What You Get</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Waves</td>
</tr>
<tr>
<td>2</td>
<td>Numeric variables</td>
</tr>
<tr>
<td>3</td>
<td>String variables</td>
</tr>
<tr>
<td>4</td>
<td>Data folders</td>
</tr>
</tbody>
</table>

Examples

Function PrintAllWaveNames()
    String objName
    Variable index = 0
    do
        objName = GetIndexedObjName(":", 1, index)
        if (strlen(objName) == 0)
            break
        endif
        Print objName
        index += 1
    while(1)
End

See Also
The CountObjects function, and Chapter II-8, Data Folders.

GetIndexedObjNameDFR

GetIndexedObjNameDFR(dfr, objectType, index)

The GetIndexedObjNameDFR function returns a string containing the name of the indexth object of the specified type in the data folder referenced by dfr.

GetIndexedObjNameDFR is the same as GetIndexedObjName except the first parameter, dfr, is a data folder reference instead of a string containing a path.

Parameters
index starts from zero. If no such object exists a zero length string ("") is returned.

objectType is one of the following values:

<table>
<thead>
<tr>
<th>objectType</th>
<th>What You Get</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Waves</td>
</tr>
<tr>
<td>2</td>
<td>Numeric variables</td>
</tr>
<tr>
<td>3</td>
<td>String variables</td>
</tr>
<tr>
<td>4</td>
<td>Data folders</td>
</tr>
</tbody>
</table>

Examples

Function PrintAllWaveNames()
    String objName
    Variable index = 0
    DFREF dfr = GetDataFolderDFR() // Reference to current data folder
    do
        objName = GetIndexedObjNameDFR(dfr, 1, index)
        if (strlen(objName) == 0)
            break
        endif
        Print objName
        index += 1
    while(1)
End

Data Folders on page II-107, Data Folder References on page IV-78, Built-in DFREF Functions on page IV-81, CountObjectsDFR

GetKeyState

GetKeyState(flags)

The GetKeyState function returns a bitwise numeric value that indicates the state of certain keyboard keys.

To detect keyboard events directed toward a window that you have created, such as a panel window, use the window hook function instead of GetKeyState. See Window Hook Functions on page IV-293 for details.
GetKeyState is normally called from a procedure that is invoked directly through a user-defined button or user-defined menu item. The procedure tests the state of one or more modifier keys and adjusts its behavior accordingly.

Another use for GetKeyState is to determine if Escape is pressed. This can be used to detect that the user wants to stop a procedure.

GetKeyState tests the keyboard at the time it is called. It does not tell you if keys were pressed between calls to the function. Consequently, when a procedure uses the escape key to break a loop, the user must press Escape until the running procedure gets around to calling the function.

Parameters
flags is a bitwise parameter interpreted as follows:

- Bit 0: If set, GetKeyState reports keys keys even if Igor is not the active application. If cleared, GetKeyState reports keys only if Igor is the active application.

All other bits are reserved and must be zero.

Details
When set, the return value is interpreted bitwise as follows:

- Bit 0: Command (Macintosh) or Ctrl (Windows) pressed.
- Bit 1: Option (Macintosh) or Alt (Windows) pressed.
- Bit 2: Shift pressed.
- Bit 3: Caps Lock pressed.
- Bit 4: Control pressed (Macintosh only).
- Bit 5: Escape pressed.
- Bit 6: Left arrow key pressed. Supported in Igor Pro 7.00 or later.
- Bit 7: Right arrow key pressed. Supported in Igor Pro 7.00 or later.
- Bit 8: Up arrow key pressed. Supported in Igor Pro 7.00 or later.
- Bit 9: Down arrow key pressed. Supported in Igor Pro 7.00 or later.

To test if a particular key is pressed, do a bitwise AND of the return value with the mask value 1, 2, 4, 8, 16, 32, 64, 128, 256 and 512 for bits 0 through 9 respectively. To test if a particular key and only that key is pressed compare the return value with the mask value.

On Macintosh, it is currently possible to define a keyboard shortcut for a user-defined menu item and then, in the procedure invoked by the keyboard shortcut, to use GetKeyState to test for modifier keys. This is not possible on Windows because the keyboard shortcut will not be activated if a modifier key not specified in the keyboard shortcut is pressed. It is also possible that this ability on Macintosh will be compromised by future operating system changes. On both operating systems, however, you can test for a modifier key when the user chooses a user-defined menu item or clicks a user-defined button using the mouse.

Examples
Function ShiftKeyExample()
    Variable keys = GetKeyState(0)
    if (keys == 0)
        Print "No modifier keys are pressed."
    endif
    if (keys & 4)
        if (keys == 4)
            Print "The Shift key and only the Shift key is pressed."
        else
            Print "The Shift key is pressed."
        endif
    endif
End
GetLastUserMenuInfo

Function EscapeKeyExample()
    Variable keys
    do
        keys = GetKeyState(0)
        if ((keys & 32) != 0) // User is pressing escape?
            break
        endif
    while(1)
End

See Also
Keyboard Shortcuts on page IV-136. Setting Bit Parameters on page IV-12 for details about bit settings.

GetLastUserMenuInfo

GetLastUserMenuInfo
The GetLastUserMenuInfo operation sets variables in the local scope to indicate the value of the last selected user-defined menu item.

Details
GetLastUserMenuInfo creates and sets these special variables:

V_flag The kind of menu that was selected:

<table>
<thead>
<tr>
<th>V_flag</th>
<th>Menu Kind</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal text menu item, including Optional Menu Items (see page IV-130) and Multiple Menu Items (see page IV-131).</td>
</tr>
<tr>
<td>3</td>
<td>&quot;<em>FONT</em>&quot;</td>
</tr>
<tr>
<td>6</td>
<td>&quot;<em>LINESTYLEPOP</em>&quot;</td>
</tr>
<tr>
<td>7</td>
<td>&quot;<em>PATTERNPOP</em>&quot;</td>
</tr>
<tr>
<td>8</td>
<td>&quot;<em>MARKERPOP</em>&quot;</td>
</tr>
<tr>
<td>9</td>
<td>&quot;<em>CHARACTER</em>&quot;</td>
</tr>
<tr>
<td>10</td>
<td>&quot;<em>COLORPOP</em>&quot;</td>
</tr>
<tr>
<td>13</td>
<td>&quot;<em>COLORTABLEPOP</em>&quot;</td>
</tr>
</tbody>
</table>

See Specialized Menu Item Definitions on page IV-132 for details about these special user-defined menus.

V_value Which menu item was selected. The value also depends on the kind of menu the item was selected from:

<table>
<thead>
<tr>
<th>V_flag</th>
<th>V_value meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Text menu item number (the first menu item is number 1).</td>
</tr>
<tr>
<td>3</td>
<td>Font menu item number (use S_Value, instead).</td>
</tr>
<tr>
<td>6</td>
<td>Line style number (0 is solid line)</td>
</tr>
<tr>
<td>7</td>
<td>Pattern number (1 is the first selection, a SW-NE light diagonal).</td>
</tr>
<tr>
<td>8</td>
<td>Marker number (1 is the first selection, the X marker).</td>
</tr>
<tr>
<td>9</td>
<td>Character as an integer, = char2num(S_Value). Use S_Value instead.</td>
</tr>
<tr>
<td>10</td>
<td>Color menu item (use V_Red, V_Green, V_Blue, and V_Alpha instead).</td>
</tr>
<tr>
<td>13</td>
<td>Color table list menu item (use S_Value instead).</td>
</tr>
</tbody>
</table>
GetLastUserMenuInfo

S_value The menu item text, depending on the kind of menu it was selected from:

<table>
<thead>
<tr>
<th>V_flag</th>
<th>S_value meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Text menu item text.</td>
</tr>
<tr>
<td>3</td>
<td>Font name or “default”.</td>
</tr>
<tr>
<td>6</td>
<td>Name of the line style menu or submenu.</td>
</tr>
<tr>
<td>7</td>
<td>Name of the pattern menu or submenu.</td>
</tr>
<tr>
<td>8</td>
<td>Name of the marker menu or submenu.</td>
</tr>
<tr>
<td>9</td>
<td>Character as string.</td>
</tr>
<tr>
<td>10</td>
<td>Name of the color menu or submenu.</td>
</tr>
<tr>
<td>13</td>
<td>Color table name.</td>
</tr>
</tbody>
</table>

In the case of Specialized Menu Item Definitions (see page IV-132), S_value will be the title of the menu or submenu, etc.

V_Red, V_Green, V_Blue, V_Alpha

If a user-defined color menu ("COLORPOP" menu item) was chosen then these values hold the red, green, and blue values of the selected color. The values range from 0 to 65535 - see RGBA Values.

These outputs are set to 0 if the last user-defined menu selection was not a color menu selection.

S_graphName, S_traceName, V_mouseX, V_mouseY

These variables are set only when the user chooses a user-defined menu item from the TracePopup, AllTracesPopup, or GraphPopup contextual menu.

S_graphName and S_traceName are initially "" until a user-defined menu selection is made from one of these contextual menus, and are not reset for each user-defined menu selection.

S_graphName is the full host-child specification for the graph. If the graph is embedded into a host window, S_graphName might be something like "Panel0#G0". See Subwindow Syntax on page III-92.

S_traceName is name of the trace that was selected by the trace contextual menu, or "" if the AllTracesPopup or GraphPopup menu was chosen. See Trace Names on page II-282.

V_mouseX and V_mouseY, added in Igor Pro 8.00, are the mouse location of the click that invoked the contextual menu. The location is in pixels; use AxisValFromPixel to determine the X and Y axis values that correspond to the pixel location.

S_tableName, S_firstColumnPath, S_columnName, V_mouseX, V_mouseY
GetLastUserMenuInfo

Added in Igor Pro 9.00.
These variables are set only when the user chooses a user-defined menu item from the
TablePopup contextual menu.
S_tableName, S_firstColumnPath and S_columnName are initially "" until a user-defined menu selection is made from a TablePopup contextual menus, and are not reset for
each user-defined menu selection.
S_tableName is the full host-child specification for the table. If the table is embedded into a
host window, S_tableName might be something like 'Panel0#T0'. See Subwindow Syntax on
page III-92.
S_firstColumnPath is full path to the wave selected by the table contextual menu, or "" if
multiple columns from different waves were chosen. The full path is identical to
GetWavesDataFolder(wave,2).
S_columnName is name of the selected column as used in the ModifyTable command, or ""
if multiple columns from different waves were selected.
You can obtain additional information about the selected cells in the table using the
GetSelection operation.
V_mouseX and V_mouseY are the mouse location of the click that invoked the contextual
menu. The location is in pixels relative to the top-left corner of the table.

Examples

A Multiple Menu Items menu definition:
Menu "Wave List", dynamic
        "Menu Item 1", <some command>
        "Menu Item 2", <some command>
        WaveList("*",";",""), DoSomethingWithWave()
End
The last item can create multiple menu items - one for each wave name returned by WaveList. If the user
selects one of these items, the DoSomethingWithWave user function can call GetLastUserMenuInfo to
determine which wave was selected:
Function DoSomethingWithWave()
    GetLastUserMenuInfo
    WAVE/Z selectedWave = $S_value
    // Use selectedWave for something
End
A trivial user-defined color menu definition:
Menu "Color"
        "%COLORPOP%", DoSomethingWithColor()
End
Function DoSomethingWithColor()
    GetLastUserMenuInfo
    ... do something with V_Red, V_Green, V_Blue, V_Alpha ...
End

See Specialized Menu Item Definitions on page IV-132 for another color menu example.

A Trace contextual menu Items menu definition:
Menu "TracePopup", dynamic     // menu when a trace is right-clicked
        "-", // separator divides this from built-in menu items
        ExportTraceName(), ExportSelectedTrace()
        "Draw XY Here", DrawXYHere()
End
Function/S ExportTraceName()
    GetLastUserMenuInfo
    if (strlen(S_traceName) > 0)
        String item = "Export "+S_traceName
        return item
    endif
    return ""     // No item is added to the menu
End
Function ExportSelectedTrace()
    GetLastUserMenuInfo
    // Do something with S_graphName, S_traceName
End

Function DrawXYHere()
    GetLastUserMenuInfo
    // Figure out mouse position within graph (requires Igor 8)
    String info = traceinfo(S_graphName, S_traceName, 0)
    String xaxis = stringbykey("XAXIS", info)
    String yaxis = stringbykey("YAXIS", info)
    Variable x_pos = AxisValFromPixel(S_graphName, xaxis, V_mouseX)
    Variable y_pos = AxisValFromPixel(S_graphName, yaxis, V_mouseY)
    GetAxis/W=$S_graphName/Q $yaxis
    Variable miny=V_min, maxy=V_max
    GetAxis/W=$S_graphName/Q $xaxis
    Variable minx=V_min, maxx=V_max
    SetDrawLayer/W=$S_graphName/K userFront
    SetDrawEnv/W=$S_graphName push
    SetDrawEnv/W=$S_graphName xcoord= $xaxis,ycoord=$yaxis,save
    DrawLine/W=$S_graphName minx, y_pos, maxx, y_pos  // horizontal line
    DrawLine/W=$S_graphName x_pos, miny, x_pos, maxy  // vertical line
    SetDrawEnv/W=$S_graphName pop
End

GetMarquee

GetMarquee [/K=w=winName/Z] [axisName [, axisName]]

The GetMarquee operation provides a way for you to use the marquee as an input mechanism in graphs
and page layout windows. It puts information about the marquee into variables.

Parameters
If you specify axisName (allowed only for graphs) the coordinates are in axis units. If you specify an axis that
does not exist, Igor generates an error.

If you specify only one axis then Igor sets only the variables appropriate to that axis. For example, if you execute
“GetMarquee left” then Igor sets the V_bottom and V_top variables but does not set V_left and V_right.

Flags

/K Kills the marquee. Usually you will want to kill the marquee when you call
GetMarquee, so you should use the /K flag. This is modeled after what happens when
you create a marquee in a graph and then choose Expand from the Marquee menu.
There may be some situations in which you want the marquee to persist. Igor also
automatically kills the marquee anytime the window containing the marquee is
deactivated, including when a dialog is summoned.

/W=winName Specifies the named window or subwindow. When omitted, action will affect the
active window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-92
for details on forming the window hierarchy.

/Z No runtime error generated if the target window isn’t a graph or layout, but V_flag
will be zero. /Z does not prevent other kinds of problems from generating a runtime error.
GetMarquee

Details
GetMarquee is intended to be used in procedures invoked through user menu items added to the graph Marquee menu and the layout Marquee menu.

GetMarquee sets the following variables and strings:

- **V_flag**: 0: There was no marquee when GetMarquee was invoked. 1: There was a marquee when GetMarquee was invoked.
- **V_left**: Marquee left coordinate.
- **V_right**: Marquee right coordinate.
- **V_top**: Marquee top coordinate.
- **V_bottom**: Marquee bottom coordinate.
- **S_marqueeWin**: Name of window containing the marquee, or "" if no marquee. If subwindow, subwindow syntax will be used.

When called from the command line, GetMarquee sets global variables and strings in the current data folder. When called from a procedure, it sets local variables and strings.

In addition, creating, adjusting, or removing a marquee may set additional marquee global variables (see the Marquee Globals section, below).

The target window must be a layout or a graph. Use /Z to avoid generating a runtime-error (V_flag will be 0 if the target window was not a layout or graph).

If the target is a layout then Igor sets the variables in units of points relative to the top/left corner of the paper.

If the target is a graph then Igor sets V_left and V_right based on the specified horizontal axis. If no horizontal axis was specified, V_left and V_right are set relative to the left edge of the base window in points.

If the target is a graph then Igor sets V_bottom and V_top based on the specified vertical axis. If no vertical axis was specified, V_top and V_bottom are set relative to the top edge of the base window in points.

If there is no marquee when you invoke GetMarquee then Igor sets V_left, V_top, V_right, V_bottom based on the last time the marquee was active.

GetMarquee Example
Menu "GraphMarquee"
  "Print Marquee Coordinates", PrintMarqueeCoords()
End

Function PrintMarqueeCoords()
  GetMarquee left, bottom
  if (V_flag == 0)
    Print "There is no marquee"
  else
    printf "marquee left in bottom axis terms: %g", V_left
    printf "marquee right in bottom axis terms: %g", V_right
    printf "marquee top in left axis terms: %g", V_top
    printf "marquee bottom in left axis terms: %g", V_bottom
  endif
End

You can run this procedure by putting it into the procedure window, making a marquee in a graph, clicking in the marquee and choosing Print Marquee Coordinates:
The procedure calls GetMarquee to set the local marquee variables and then prints their values in the history area:

```
GetMarquee()
    marquee left in bottom axis terms: 32.1149
    marquee right in bottom axis terms: 64.7165
    marquee top in left axis terms: 0.724075
    marquee bottom in left axis terms: -0.131061
```

**Marquee Globals**

You can cause Igor to update global marquee variables whenever the user adjusts the marquee (without the need for you to invoke GetMarquee) by creating a global variable named V_marquee in the root data folder:

```
Variable/G root:V_marquee = 1  //Creates V_marquee and sets bit 0 only
```

When the user adjusts the marquee Igor checks to see if root:V_marquee exists and which bits are set, and updates (and creates if necessary) these globals:

- **Variable/G root:V_left**: Marquee left coordinate.
- **Variable/G root:V_right**: Marquee right coordinate.
- **Variable/G root:V_top**: Marquee top coordinate.
- **Variable/G root:V_bottom**: Marquee bottom coordinate.
- **String/G root:S_marqueeWin**: Name of window that contains marquee, or "" if no marquee.
  
  Set only if root:V_Marquee has bit 15 (0x8000) set.

Unlike the local variables, for graphs these global variables are never in points. Root:V_left and V_right will be axis coordinates based on the first bottom axis created for the graph (if none, then for the first top axis). The axis creation order is the same as is returned by **AxisList**. Similarly, root:V_top and root:V_bottom will be axis coordinates based on the first left axis or the first right axis.

Igor examines the global root:V_marquee for bitwise flags to decide which globals to update, and when:

<table>
<thead>
<tr>
<th>root:V_marquee Bit Meaning</th>
<th>Bit Number</th>
<th>Bit Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update global variables for graph marquees</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Update global variables for layout marquees</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>Update S_marqueeWin when updating global variables</td>
<td>15</td>
<td>0x8000</td>
</tr>
</tbody>
</table>

**Marquee Globals Example**

By creating the global variable root:V_marquee this way:

```
Variable/G root:V_marquee = 1 + 4 + 0x8000
```

whenever the user creates, adjusts, or removes a marquee in any graph or layout Igor will create and update the global root:V_left, etc. coordinate variables and set the global string root:S_marqueeWin to the name of the window which has the marquee in it. When the marquee is removed, root:S_marqueeWin will be set to "".

This mechanism does neat things by making a **ValDisplay** or **SetVariable** control depend on any of the globals. See the Marquee Demo experiment in the Examples:Feature Demos folder for an example.

You can also cause a function to run whenever the user creates, adjusts, or removes a marquee by setting up a dependency formula using **SetFormula** to bind one of the marquee globals to one of the function’s input arguments:

```
Variable/G root:dependencyTarget
SetFormula root:dependencyTarget, "MyMarqueeFunction(root:S_marqueeWin)"
```

Function **MyMarqueeFunction**

```
String MyMarqueeFunction(marqueeWindow)
    String marqueeWindow  // this will be root:S_marqueeWin
    if( strlen(marqueeWindow) )
        NVAR V_left= root:V_left, V_right= root:V_right
        NVAR V_top= root:V_top, V_bottom= root:V_bottom
        printf marqueeWindow + " has a marquee at: ">
        printf "%d, %d, %d, %d\r", V_left, V_right, V_top, V_bottom
    else
```

```
GetMouse

GetMouse [/W=winName]
The GetMouse operation returns information about the position of the input mouse, and the state of the
mouse buttons.
GetMouse is useful in situations such as background tasks where the mouse position and state aren’t
available as they are in control procedures and window hook functions.

Flags
/W=winName       Returns the mouse position relative to the named window or subwindow. When
                 identifying a subwindow with winName, see Subwindow Syntax on page III-92.
/W=kwTopWin      Returns the mouse position relative to the currently frontmost non-floating window.
/W=kwCmdHist     Returns the mouse position relative to the command window.
/W=Procedure     Returns the mouse position relative to the main Procedure window.

Details
GetMouse returns the mouse position in local coordinates relative to the specified window unless /W is
omitted in which case the returned coordinates are global.

On Windows, global coordinates are actually relative to the frame window. See GetWindow wsizeDC
kwFrameInner.

Information is returned via the following string and numeric variables:

V_left  Horizontal mouse position, in pixels.
V_top   Vertical mouse position, in pixels.
V_flag  Mouse button state. V_flag  is a bitwise value with each bit reporting the mouse button states:
         Bit 0: 1 if the primary mouse button (usually the left) is down, 0 if it is up.
         Bit 1: 1 if the secondary mouse button (usually the right) is down, 0 if it is up.

On Macintosh, the secondary mouse button can be invoked by pressing the control key while clicking the primary (often the only) mouse button, but GetMouse does not report this with bit 1 set. Use GetKeyState’s bit 4 to test if the control key is pressed.

See Setting Bit Parameters on page IV-12 for details about bit settings.

S_name  Name of the window or subwindow which the position is relative to, or ”” if not a
         nameable window or if /W was omitted. Most useful with /W=kwTopWin. The result
         can be kwCmdHist or Procedure, or the name of a target window.

Background Tasks on page IV-319, Subwindow Syntax on page III-92

GetRTError

GetRTError(flag)
The GetRTError function returns information about the error state of Igor’s user-defined function runtime
execution environment.
If flag is 0, GetRTError returns an error code if an error has occurred or 0 if no error has occurred.

If flag is 1, GetRTError returns an error code if an error has occurred or 0 if no error has occurred and it clears the error state of Igor's runtime execution environment. Use this if you want to detect and handle runtime errors yourself.

If flag is 2, GetRTError returns the state of Igor's internal abort flag but does not clear it.

For flag=0 and flag=1, you can call GetErrMessage to obtain the error message associated with the returned error code, if any.

In Igor Pro 7.00 or later, using GetRTError(1) on the same line as a command that causes an error overrides the debugger "debug on error" setting and prevents the debugger from activating for that error.

Example

// Detect and handle a runtime error rather than allowing it to cause
// Igor to abort execution or invoke the debugger. The error must be
// recorded, using GetErrMessage, and cleared, using GetRTError,
// on the same line as the error.
Function Demo()
  String msg
  Variable err
  Make/O/N=(-2) wave0; msg=GetErrMessage(GetRTError(0),3); err=GetRTError(1)
  if (err != 0)
    Print "Error in Demo: " + msg
    Print "Continuing execution"
  endif
  // Do more things here
End

See also

The GetErrMessage and GetRTErrMessage functions.

GetRTErrMessage

GetRTErrMessage()

In a user function, GetRTErrMessage returns a string containing the name of the operation that caused the error, a semicolon, and an error message explaining the cause of the error. This is the same information that appears in the alert dialog displayed. If no error has occurred, the string will be of zero length. GetRTErrMessage must be called before the error is cleared by calling GetRTError with a nonzero argument.

For an overview of error handling, see Flow Control for Aborts on page IV-48.

See also

Flow Control for Aborts on page IV-48, GetRTError, GetErrMessage

GetRTLocation

GetRTLocation(sleepMs)

GetRTLocation is used for profiling Igor procedures.

You will typically not call GetRTLocation directly but instead will use it through FunctionProfiling.ipf which you can access using this include statement:

#include <FunctionProfiling>

GetRTLocation is called from an Igor preemptive thread to monitor the main thread. It returns a code that identifies the current location in the procedure files corresponding to the procedure line that is executing in the main thread.

Parameters

sleepMs is the number of milliseconds to sleep the preemptive thread after fetching a value. sleepMs must be between 0.001 and 100.

Details

The result from GetRTLocation is passed to GetRTLocInfo to determine the location in the procedures. This samples the main thread only and the location becomes meaningless after any procedure editing.
GetRTLocInfo

See Also
GetRTLocInfo

GetRTLocInfo

GetRTLocInfo(code)

GetRTLocInfo is used for profiling Igor procedures.

You will typically not call GetRTLocInfo directly but instead will use it through FunctionProfiling.ipf which you can access using this include statement:

#include <FunctionProfiling>

GetRTLocInfo is called from an Igor preemptive thread to monitor the main thread. It returns a key/value string containing information about the procedure location associated with code or "" if the location could not be found.

Parameters

code is the result from a very recent call to GetRTLocation.

Details

The format of the result string is:

"PROCNAME:name;LINE:line;FUNCNAME:name;"

As of Igor Pro 7.03, if the code is in an independent module other than ProcGlobal then this appears at the beginning of the result string:

IMNAME:inName;

The line number is padded with zeros to facilitate sorting.

See Also
GetRTLocation

GetRTStackInfo

GetRTStackInfo(selector)

The GetRTStackInfo function returns information about “runtime stack” (the chain of macros and functions that are executing).

Details

If selector is 0, GetRTStackInfo returns a semicolon-separated list of the macros and procedures that are executing. This list is the same you would see in the debugger’s stack list.

The currently executing macro or function is the last item in the list, the macro or function that started execution is the first item in the list.

If selector is 1, it returns the name of the currently executing function or macro.

If selector is 2, it returns the name of the calling function or macro.

If selector is 3, GetRTStackInfo returns a semicolon-separated list of routine names, procedure file names and line numbers. This is intended for advanced debugging by advanced programmers only.

For example, if RoutineA in procedure file ProcA.ipf calls RoutineB in procedure file ProcB.ipf, and RoutineB calls GetRTStackInfo(3), it will return:

RoutineA,ProcA.ipf,7;RoutineB,ProcB.ipf,12;

The numbers 7 and 12 would be the actual numbers of the lines that were executing in each routine. Line numbers are zero-based.

When called from a function started by MultiThread or ThreadStart the runtime stack information begins with the function that started threaded execution.

In future versions of Igor, selector may request other kinds of information.

Main Thread Example

Function Called()

    Print "Called by " + GetRTStackInfo(2) + "()"

V-314
Print "Routines in calling chain: " + GetRTStackInfo(0)
End

Function Calling()
    Called()
End

Macro StartItUp()
    Calling()
End

// Executing StartItUp() prints:
    Called by Calling()
    Routines in calling chain: StartItUp;Calling;Called;

MultiThread Example

Macro BeginMultiThread(code)
    Variable code=3
    BeginMultiThreadFunc(code)
End

Function BeginMultiThreadFunc(Variable code)
    Make/O/N=4/T/FREE textWave
    MultiThread textWave = tworker(code)
    Print textWave[0]
End

ThreadSafe Function/S tworker(Variable code)
    String str= tssubr(code)
    return str
End

ThreadSafe Function/S tssubr(Variable code)
    String str= GetRTStackInfo(code)
    return str
End

// Executing BeginMultiThread(3) prints details for only the two threaded routines:
    tworker,TSExample,16;tssubr,TSExample,21;

See Also

The Stack and Variables Lists, ThreadSafe Functions and Multitasking, GetRTError

GetScrapText

GetScrapText()

The GetScrapText function returns a string containing any plain text on the Clipboard (aka “scrap”). This is the text that would be pasted into a text document if you used Paste in the Edit menu.

See Also

The PutScrapText and LoadPICT operations.

GetSelection

GetSelection winType, winName, bitflags

The GetSelection operation returns information about the current selection in the specified window.

Parameters

winType is one of the following keywords:
graph, panel, table, layout, notebook, procedure

winName is the name of a window of the specified type.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

If winType is procedure then winName is actually a procedure window title inside a "$" wrapper, such as:
GetSelection procedure "$DemoLoader.ipf", 3

bitflags is a bitwise parameter that is used in different ways for different window types, as described in Details. You should use 0 for undefined bits. Setting Bit Parameters on page IV-12 for further details about bit settings.
Details
For all window types, GetSelection sets V_flag:

V_flag
0: No selection when GetSelection was invoked.
1: There was a selection when GetSelection was invoked.

Here is a description of what GetSelection does for each window type:

<table>
<thead>
<tr>
<th>winType</th>
<th>bitFlags</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>graph</td>
<td></td>
<td>Does nothing.</td>
</tr>
<tr>
<td>panel</td>
<td></td>
<td>Does nothing.</td>
</tr>
<tr>
<td>table</td>
<td>1</td>
<td>Sets V_startRow, V_startCol, V_endRow, and V_endCol based on the selected cells in the table. The top/left cell, not including the Point column, is (0, 0).</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Sets S_selection to a semicolon-separated list of column names.</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>Sets S_dataFolder to a semicolon-separated list of data folders, one for each column.</td>
</tr>
<tr>
<td>layout</td>
<td>2</td>
<td>Sets S_selection to a semicolon separated list of selected objects in the layout layer (not any drawing layers). S_selection will be &quot;&quot; if no objects are selected.</td>
</tr>
<tr>
<td>notebook</td>
<td>1</td>
<td>Sets V_startParagraph, V_startPos, V_endParagraph, and V_endPos based on the selected text in the notebook.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Sets S_selection to the selected text.</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>Requires Igor Pro 8.05 or later. Sets V_startParagraph and V_endParagraph to the left margin and right margin respectively of the current ruler in points relative to the ruler 0 position. Sets V_startPos, and V_endPos to the left edge and right edge respectively of the selection in points relative to the ruler 0 position.</td>
</tr>
<tr>
<td>procedure</td>
<td>1</td>
<td>Sets V_startParagraph, V_startPos, V_endParagraph, V_endPos based on the selected text in the procedure window.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Sets S_selection to the selected text.</td>
</tr>
</tbody>
</table>

Examples
In a new experiment, make a table named “Table0” with some columns, and select some combination of rows and columns:

Make wave0 = p
Make wave1 = p + 1
Edit wave0, wave1
ModifyTable selection = (3,0,8,1,3,0)

Now execute these commands in a procedure or in the command line:

GetSelection table, Table0, 3
Print V_flag, V_startRow, V_startCol, V_endRow, V_endCol
Print S_selection

This will print the following in the history area:

```
1 3 0 8 1
wave0.d;wave1.d;
```

GetUserData

GetUserData(winName, objID, userdataName)
The GetUserData function returns a string containing the user data for a window, subwindow graph trace or control. The return string will be empty if no user data exists.
You set user data on a window or subwindow using the userData keyword of the SetWindow operation. You set it on a graph trace using the userData keyword of the ModifyGraph operation. You set it on a control using the userData keyword of the various control operations.

**Parameters**

*winName* may specify a window or subwindow name. Use "" for the top window.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*objID* is a string specifying the name of a control or graph trace. Use "" for a window or subwindow.

*userdataName* is the name of the user data or "" for the default unnamed user data.

**See Also**
The **ControlInfo**, **GetWindow**, and **SetWindow** operations.

**GetWavesDataFolder**

GetWavesDataFolder(*waveName*, *kind*)

The GetWavesDataFolder function returns a string containing the name of a data folder containing the wave named by *waveName*. Variations on the theme are selected by *kind*.

The most common use for this is in a procedure, when you want to create a wave or a global variable in the data folder containing a wave passed as a parameter.

GetWavesDataFolderDFR is preferred.

**Details**

<table>
<thead>
<tr>
<th><em>kind</em></th>
<th>GetWavesDataFolder Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Only the name of the data folder containing <em>waveName</em>.</td>
</tr>
<tr>
<td>1</td>
<td>Full path of data folder containing <em>waveName</em>, without wave name.</td>
</tr>
<tr>
<td>2</td>
<td>Full path of data folder containing <em>waveName</em>, including possibly quoted wave name.</td>
</tr>
<tr>
<td>3</td>
<td>Partial path from current data folder to the data folder containing <em>waveName</em>.</td>
</tr>
<tr>
<td>4</td>
<td>Partial path including possibly quoted wave name.</td>
</tr>
</tbody>
</table>

Kinds 2 and 4 are especially useful in creating command strings to be passed to **Execute**.

**Examples**

Function DuplicateWaveInDataFolder(w)

Wave w

DFREF dfSav = GetDataFolderDFR()

SetDataFolder GetWavesDataFolder(w,1)

Duplicate/O w, $(NameOfWave(w) + "]_2")

SetDataFolder dfSav

End

**See Also**

Chapter II-8, **Data Folders**.

**GetWavesDataFolderDFR**

GetWavesDataFolderDFR(*waveName*)

The GetWavesDataFolderDFR function returns a data folder reference for the data folder containing the specified wave.

GetWavesDataFolderDFR is the same as GetWavesDataFolder except that it returns a data folder reference instead of a string containing a path.

**See Also**

**Data Folders** on page II-107, **Data Folder References** on page IV-78, **Built-in DFREF Functions** on page IV-81.
GetWindow

GetWindow [/Z] winName, keyword
The GetWindow operation provides information about the named window or subwindow. Information is returned in variables, strings, and waves.

Parameters

winName can be the name of any target window (graph, table, page layout, notebook, control panel, Gizmo, camera, or XOP target window) or subwindow. It can also be the title of a procedure window or one of these four special keywords:

kwTopWin Specifies the topmost target window.
kwCmdHist Specifies the command history area.
kwFrameOuter Specifies the “frame” or “application” window that Igor Pro has only under Windows. This is the window that contains Igor’s menus and status bar.
kwFrameInner Specifies the inside of the same “frame” window under Windows. This is the window that all other Igor windows are inside.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Only one of the following keywords may follow winName. The keyword chosen determines the information stored in the output variables:

active Sets V_Value to 1 if the window is active or to 0 otherwise. Active usually means the window is the frontmost window.
activeSW Stores the window “path” of currently active subwindow in S_Value. See Subwindow Syntax on page III-92 for details on the window hierarchy.
axsize Reads graph axis area dimensions (where the traces are, including axis standoff) into V_left, V_right, V_top, and V_bottom in local coordinates. Dimensions are in points.
axsizeDC Same as axSize but dimensions are in device coordinates (pixels).
backRGB Sets V_Red, V_Green, V_Blue, and V_Alpha as RGBA Values to the background color of the window. The background color is set with ModifyGraph (colors) wbRGB, ModifyLayout bgRGB, and Notebook backRGB. Also returns the background color of procedure windows and the command/history windows. Other windows set these values to 65535 (opaque white).
Added in Igor Pro 7.00.
exterior Sets V_value to 1 if the window is an exterior panel window or to 0 otherwise. Useful for window hook functions that must work for both regular windows and exterior panel windows, since exterior panels use their own hook function.
bgRGB Another name for backRGB.
Added in Igor Pro 7.00.
cbRGB Sets V_Red, V_Green, V_Blue, and V_Alpha as RGBA Values to the control panel area background color of the window in graphs and panel windows, as set by ModifyGraph (colors) cbRGB and ModifyPanel cbRGB. Other windows set these values to 65535 (opaque white).
Added in Igor Pro 7.00.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>doScroll</td>
<td>If the window is a graph or panel window with scroll bars added by SetWindow doScroll, the variable V_value is set to 1. If the window is a graph or panel window without scroll bars added by SetWindow doScroll, the variable V_value is set to 0. If the window is other than a graph or panel window, an error is generated. Added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>drawLayer</td>
<td>If the specified window is a graph, layout, or panel window then the window’s current drawing layer is returned in S_value. S_value is set to &quot;&quot; for other windows. See Drawing Layers on page III-68. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>expand</td>
<td>Graph windows set V_Value to the expand value set by ModifyGraph (general) expand=value, a value normally 0 or 1, where 1.5 means 150%. Notebook, procedure and command windows set V_Value to the magnification, normally 100. See the Notebook magnification=m documentation for details. Layout windows set V_Value to the ModifyLayout mag=m value, usually 0.5 (50%). In Igor Pro 9.01 and later, panel windows set V_Value to the expand value set by ModifyPanel expand=value, a value normally 0 or 1, where 1.5 means 150%. This is the same value returned by PanelResolution(winName)/PanelResolution(&quot;&quot;). Table windows set V_Value to 0, panels and other unsupported windows to NaN. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>file</td>
<td>Works for notebook and procedure windows only. Returns via S_value a semicolon-separated list containing: - the file name - the Mac path to the folder containing the file with a colon at the end - the name of a symbolic path pointing to that folder, if any If the window was never saved to a standalone file then &quot;&quot; is returned in S_value. If the specified window is not a notebook or procedure window then &quot;&quot; is returned in S_value.</td>
</tr>
<tr>
<td>gbRGB</td>
<td>Sets V_Red, V_Green, V_Blue, and V_Alpha as RGBA Values to the plot area background color of the window in graph windows, as set by ModifyGraph (colors) gbRGB. Other windows set these values to 65535 (opaque white). Use wbRGB to get the color of window background (the area outside of the axes). Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>gsize</td>
<td>Reads graph outer dimensions into V_left, V_right, V_top, and V_bottom in local coordinates. This includes axes but not the tool palette, control bar, or info panel. Dimensions are in points.</td>
</tr>
<tr>
<td>gsizeDC</td>
<td>Same as gsize but dimensions are in device coordinates (pixels).</td>
</tr>
<tr>
<td>hide</td>
<td>Sets V_Value bit 0 if the window or subwindow is hidden. Sets bit 1 if the host window is minimized. Sets bit 2 if the subwindow is hidden only because an ancestor window or subwindow is hidden. Added in Igor Pro 7.00. On Macintosh, if you execute MoveWindow 0,0,0,0 to minimize a window to the dock, and then you immediately call GetWindow hide, bit 1 may not be correctly set because of the delay caused by the animation of the window sliding into the dock.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>hook</td>
<td>Copies name of window hook function to S_value. See <strong>Unnamed Window Hook Functions</strong> on page IV-305.</td>
</tr>
<tr>
<td>hook(hName)</td>
<td>For the given named hook hName, copies name of window hook function to S_value. See <strong>Named Window Hook Functions</strong> on page IV-295.</td>
</tr>
<tr>
<td>logicalpapersize</td>
<td>Returns logical paper size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points. If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page. V_left and V_top are 0 and correspond to the left top corner of the physical page.</td>
</tr>
<tr>
<td></td>
<td>On the Macintosh, using a Scale of 50% multiplies all of these dimensions by 2.</td>
</tr>
<tr>
<td>logicalprintablesize</td>
<td>Returns logical printable size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points. If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page minus the margins. V_left and V_top are the number of points from the left top corner of the physical page to the left top corner of the printable area of page.</td>
</tr>
<tr>
<td></td>
<td>On the Macintosh, using a page setup scale of 50% multiplies all of these dimensions by 2.</td>
</tr>
<tr>
<td>magnification</td>
<td>Sets V_Value exactly the same way that expand does.</td>
</tr>
<tr>
<td></td>
<td>Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>maximize</td>
<td>Sets V_Value to 1 if the window is maximized, 0 otherwise. On Macintosh, V_Value is always 0.</td>
</tr>
<tr>
<td>needUpdate</td>
<td>Sets V_Value to 1 if window or subwindow is marked as needing an update.</td>
</tr>
<tr>
<td>note</td>
<td>Copies window note to S_value.</td>
</tr>
<tr>
<td>psize</td>
<td>Reads graph plot area dimensions (where the traces are) into V_left, V_right, V_top, and V_bottom in local coordinates. Dimensions are in points.</td>
</tr>
<tr>
<td>psizeDC</td>
<td>Same as psize but dimensions are in device coordinates (pixels).</td>
</tr>
<tr>
<td>sizeLimit</td>
<td>Returns the size limits imposed on a window via <code>SetWindow sizeLimit</code> in the V_minWidth, V_minHeight, V_maxWidth and V_maxHeight. The values are scaled for screen resolution to the same units as GetWindow wsize, which is points. Very large limits are returned as INF.</td>
</tr>
<tr>
<td></td>
<td>The sizeLimit keyword was added in Igor Pro 7.00.</td>
</tr>
<tr>
<td></td>
<td>Also returns a sizeLimit status value in V_Value. 0 means no SetWindow sizeLimit command will appear in the window’s recreation macro, usually because no SetWindow sizeLimit command was applied to the window. 1 means a SetWindow sizeLimit command will appear in the window’s recreation macro. -1 means it won’t appear because of conflicts with graph absolute sizing modes.</td>
</tr>
<tr>
<td>title</td>
<td>Gets the title (set by as titleStr with NewPanel, Display, etc., or by the Window Control dialog) and puts it into S_value. S_value is set to &quot;&quot; if winName specifies a subwindow. See also the wtitle keyword, below.</td>
</tr>
<tr>
<td>userdata</td>
<td>Returns the primary (unnamed) user data for a window in S_value. Use <strong>GetUserData</strong> to obtain any named user data.</td>
</tr>
<tr>
<td>wavelist</td>
<td>Creates a 3 column text wave called W_WaveList containing a list of waves used in the graph in winName. Each wave occupies one row in W_WaveList. This list includes all waves that can be in a graph, including the data waves for contour plots and images.</td>
</tr>
</tbody>
</table>
### GetWindow

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>wbRGB</strong></td>
<td>Another name for backRGB. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td><strong>wssize</strong></td>
<td>Reads window dimensions into V_left, V_right, V_top, and V_bottom in points from the top left of the screen. For subwindows, values are local coordinates in the host. If the window is a graph or panel window with scroll mode turned on using SetWindow doScroll, then V_left and V_top are set to zero, and V_right and V_bottom are set to the width and height in points of the window content area.</td>
</tr>
<tr>
<td><strong>wssizeDC</strong></td>
<td>Same as wssize but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle. If the window is a graph or panel window with scroll mode turned on using SetWindow doScroll, then V_left and V_top are set to zero, and V_right and V_bottom are set to the width and height in pixels of the window content area.</td>
</tr>
<tr>
<td><strong>wssizeForControls</strong></td>
<td>Reads window width into V_right and the window height into V_bottom in panel units. &quot;Panel units&quot; are scaled so that a control having the dimensions of V_right and V_bottom exactly fills the window. The wssizeForControls keyword was added in Igor Pro 9.00. See Examples below for an example.</td>
</tr>
<tr>
<td><strong>wssizeOuter</strong></td>
<td>Reads window dimensions into V_left, V_right, V_top, and V_bottom in points from the top left of the screen. Dimensions are for the entire window including any frame and title bar. For subwindows, values are for the host window.</td>
</tr>
<tr>
<td><strong>wssizeOuterDC</strong></td>
<td>Same as wssizeOuter but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window’s active rectangle, so V_top will be negative for a window with a title bar. V_left will be negative for windows with a frame; windows on Macintosh OS X have no frame, so V_left will be zero.</td>
</tr>
<tr>
<td><strong>wssizeRM</strong></td>
<td>Generally the same as wssize, but these are the coordinates that would actually be used by a recreation macro except that the coordinates are in points even if the window is a panel. Also, if the window is minimized or maximized, the coordinates represent the window’s restored location. On Windows, GetWindow kwFrameOuter wssizeRM returns the pixel coordinates of the MDI frame even when the frame is maximized. wssizeDC returns 2,2,2,2 in this case.</td>
</tr>
<tr>
<td><strong>wtitle</strong></td>
<td>Gets the actual window title displayed in the window’s title bar, regardless of whether it was set by the user (see the title keyword above) or is the default title created by Igor, and puts it into S_value. S_value is set to &quot;&quot; if winName specifies a subwindow. If winName is kwFrameOuter or kwFrameInner, on Macintosh S_Value is set to the name of the Igor application. On Windows it is set to the full title of the application as seen on the frame’s window, which can be altered using DoWindow/T kwFrame.</td>
</tr>
</tbody>
</table>

### Flags

/Z Suppresses error if, for instance, winName doesn’t name an existing window. V_flag is set to zero if no error occurred or to a non-zero error code.

### Details

**winName** can be the title of a procedure window. If the title contains spaces, use:

```
GetWindow "$"Title With Spaces"" wssize
```

However, if another window has a name which matches the given procedure window title, that window’s properties are returned instead of the procedure window.

The wssize parameter is appropriate for all windows.
**GetWindow**

The gsize, psize, gbRGB, and wavelist parameters are appropriate only for graph windows.

The logicalpapersize, logicalprintablesize and expand/magnification parameters are appropriate for all printable windows except for control panels and Gizmo plots.

**Local Coordinates**

“Local coordinates” are relative to the top left of the graph area, regardless of where that is on the screen or within the graph window. All dimensions are reported in units of points (1/72 inch) regardless of screen resolution. On the Macintosh, this is the same as screen pixels.

**Frame Window Coordinates**

kwCmdHist, kwFrameInner, and kwFrameOuter may be used with only the wsize keyword.

On Windows computers, kwFrameInner and kwFrameOuter return coordinates into V_left, V_right, V_top, and V_bottom. On the Macintosh, they always return 0, because Igor has no frame on the Macintosh.

kwFrameOuter coordinates are the location of the outer edges of Igor’s application window, expressed in screen (pixel) coordinates suitable for use with MoveWindow/F to restore, minimize, or maximize the Igor application window.

If Igor is currently minimized, kwFrameOuter returns 0 for all values. If maximized, it returns 2 for all values. Otherwise, the screen (pixel) coordinates of the frame are returned in V_left, V_right, V_top, and V_bottom. This is consistent with MoveWindow/F.

kwFrameInner coordinates, however, are the location of the inner edges of the application window, expressed in Igor window coordinates (points) suitable for positioning graphs and other windows with MoveWindow.

If Igor is currently minimized, kwFrameInner returns the inner frame coordinates Igor would have if Igor were “restored” with MoveWindow/F 1,1,1,1.

V_left and V_top will always both be 0, and V_Bottom and V_Right will be the maximum visible (or potentially visible) window (not screen) coordinates in points.

**The Wavelist Keyword**

The format of W_WaveList, created with the wavelist keyword, is as follows:

<table>
<thead>
<tr>
<th>Column 1</th>
<th>Column 2</th>
<th>Column 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wave name</td>
<td>partial path to the wave</td>
<td>special ID number</td>
</tr>
</tbody>
</table>

The wave name in column 1 is simply the name of the wave with no path. It may be the same as other waves in the list, if there are waves from different data folders.

The partial path in column 2 includes the wave name and can be used with the $ operator to get access to the wave.

The special ID number in column 3 has the format ##<number>##. A version of the recreation macro for the graph can be generated that uses these ID numbers instead of wave names (see the WinRecreation function). This makes it relatively easy to find every occurrence of a particular wave using a function like strsearch.

**Examples**

```cpp
// These commands draw a red foreground rectangle framing // the printable area of a page layout window.
GetWindow Layout0 logicalpapersize
DoWindow/F Layout0
SetDrawLayer/K userFront
SetDrawEnv linlinefgc=(65535,0,0), fillpat=0 // Transparent fill
DrawRect V_left+1, V_top+1, V_right-1, V_bottom-1

// These commands demonstrate the difference between title and wtitle.
Make/O data=x
Display/N=MyGraph data
GetWindow MyGraph title;Print S_Value // Prints nothing (S_Value = ””)
GetWindow MyGraph wtitle;Print S_Value // Prints ”MyGraph: data"
DoWindow/T MyGraph, ”My Title for My Graph"
GetWindow MyGraph title;Print S_Value // Prints ”My Title for My Graph"
GetWindow MyGraph wtitle;Print S_Value // Prints ”My Title for My Graph"

// Create a panel expanded at 200% with a ListBox that fills the entire panel.
String list = CTabList() // List of color tables
Make/O/T/N=(ItemsInList(list)) tw = StringFromList(p,list)
```

V-322
GetWindowBrowserSelection

GetWindowBrowserSelection (mode)
The GetWindowBrowserSelection function returns a semicolon separated string that represents the selection in the Window Browser.
GetWindowBrowserSelection was added in Igor Pro 9.00.

Parameters
mode specifies which selection should be returned:

mode=0: Returns the window names of the selected windows in the main window list.
Other values for mode are reserved for possible future use.

If there is no selection, GetWindowBrowserSelection returns an empty string.
If the Window Browser is not open, GetWindowBrowserSelection returns an empty string and generates an error.
The order in which the selection is returned is undefined. If the order matters to you, you must sort the list yourself.

See Also
The Window Browser on page II-49, SortList

GizmoInfo

GizmoInfo (nameStr, key)
The GizmoInfo function is used to determine if a particular name is valid and unique as a Gizmo item names.
Documentation for the GizmoInfo function is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "GizmoInfo"

GizmoPlot

GizmoPlot is a procedure subtype keyword that identifies a macro as being a Gizmo recreation macro. It is automatically used when Igor creates a window recreation macro for a Gizmo plot. See Procedure Subtypes on page IV-204 and Saving and Recreating Graphs on page II-350 for details.

GizmoScale

GizmoScale (dataValue, dimNumber [, gizmoNameStr] )
The GizmoScale function returns a scaled dataValue for the specified dimension. The scaled values are used to position non-data drawing objects in the Gizmo window.
Documentation for the GizmoScale function is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "GizmoScale"

gnoise

gnoise (num [, RNG] )
The gnoise function returns a random value drawn from a Gaussian distribution such that the standard deviation of an infinite number of such values would be num.
gnoise returns a complex result if `num` is complex or if it is used in a complex expression. See **Use of gnoise With Complex Numbers** on page V-324.

The random number generator is initialized using a seed derived from the system clock when you start Igor. This almost guarantees that you will never get the same sequence twice. If you want repeatable “random” numbers, use `SetRandomSeed`.

The Gaussian distribution is achieved using a Box-Muller transformation of uniform random numbers.

The optional parameter RNG selects one of three pseudo-random number generators used to create the uniformly-distributed random numbers providing the input to the Box-Muller transformation.

If you omit the RNG parameter, `gnoise` uses RNG number 3, named "Xoshiro256**". This random number generator was added in Igor Pro 9.00 and is recommended for all new code. In earlier versions of Igor, the default was 1 (Linear Congruential Generator).

The available random number generators are:

<table>
<thead>
<tr>
<th>RNG</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Linear Congruential Generator by L’Ecuyer with added Bayes-Durham shuffle. The algorithm is described in <em>Numerical Recipes</em> as the function <code>ran2()</code>. This option has nearly $2^{32}$ distinct values and the sequence of random numbers has a period in excess of $10^{18}$. This RNG is provided for backward compatibility only. New code should use RNG=3 (Xoshiro256**).</td>
</tr>
<tr>
<td>2</td>
<td>Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of $2^{19937} - 1$. See Matsumoto, M., and T. Nishimura, Mersenne Twister: A 623-dimensionally equidistributed uniform pseudorandom number generator, <em>ACM Trans. on Modeling and Computer Simulation</em>, 8, 3-30, 1998. This RNG is provided for backward compatibility only. New code should use RNG=3 (Xoshiro256**).</td>
</tr>
<tr>
<td>3</td>
<td>Xoshiro256** by David Blackman and Sebastiano Vigna. It has a period of $2^{256} - 1$, is 4 dimensionally equidistributed and passes all statistical tests at the time of writing. For technical details, see &quot;Scrambled linear pseudorandom number generators&quot;, 2019 (<a href="http://vigna.di.unimi.it/ftp/papers/ScrambledLinear.pdf">http://vigna.di.unimi.it/ftp/papers/ScrambledLinear.pdf</a>).</td>
</tr>
</tbody>
</table>

**Use of gnoise With Complex Numbers**

`gnoise` returns a complex result if `num` is complex or if it is used in a complex expression.

Function DemoGNoiseComplex()
  // gnoise(rv) in a complex expression returns a complex result
  // and is equivalent to cmplx(gnoise(rv),gnoise(rv))
  Variable rv = 1          // A real variable
  SetRandomSeed 1
  Variable/C cv1 = gnoise(rv)    // Real parameter, complex result
  SetRandomSeed 1
  Variable/C cv2 = cmplx(gnoise(rv),gnoise(rv))   // Equivalent
  Print cv1, cv2
  // gnoise(cv) is equivalent to cmplx(gnoise(real(cv)),gnoise(imag(cv)))
  Variable/C cv = cmplx(1,1)      // A complex variable
  SetRandomSeed 1
  Variable/C cv3 = gnoise(cv)   // Complex parameter, complex result
  SetRandomSeed 1
  Variable/C cv4 = cmplx(gnoise(real(cv)),gnoise(imag(cv))) // Equivalent
  Print cv3, cv4
End

Graph

Graph
Graph is a procedure subtype keyword that identifies a macro as being a graph recreation macro. It is automatically used when Igor creates a window recreation macro for a graph. See Procedure Subtypes on page IV-204 and Saving and Recreating Graphs on page II-350 for details.

GraphMarquee

GraphMarquee
GraphMarquee is a procedure subtype keyword that puts the name of the procedure in the graph Marquee menu. See Marquee Menu as Input Device on page IV-163 for details.

GraphNormal

GraphNormal [\texttt{/W=winName}]\nThe GraphNormal operation returns the target or named graph to the normal mode, exiting any drawing mode that it may be in.

You would usually enter normal mode by choosing ShowTools from the Graph menu and clicking the graph tool (the top icon in the tool panel).

Flags
\texttt{/W=winName} Reverts the named graph window. This must be the first flag specified when used in a Proc or Macro or on the command line.

See Also
The GraphWaveDraw and GraphWaveEdit operations.

GraphStyle

GraphStyle
GraphStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Graph dialog and in the Graph Macros menu. See Graph Style Macros on page II-350 for details.

GraphWaveDraw

GraphWaveDraw \texttt{[flags]} \texttt{[yWave, xWave]}
The GraphWaveDraw operation initiates drawing a curve composed of \texttt{yWave} vs \texttt{xWave} in the target or named graph. The user draws the curve using the mouse, and the values are stored in a pair of waves as XY data.

The user can manually initiate drawing by choosing ShowTools from the Graph menu and clicking in the appropriate tool.

Parameters
\texttt{yWave} and \texttt{xWave} can be simple names of waves in the current data folder or partial or full data folder paths to waves. If the waves already exist, GraphWaveDraw overwrites them. \texttt{yWave} and \texttt{xWave} can also be wave references pointing to existing waves in which case GraphWaveDraw overwrites them. Prior to Igor Pro 9.00, only simple names were accepted.

If \texttt{yWave} and \texttt{xWave} already exist, an error is generated unless you include the /O flag.
If you omit \texttt{yWave} and \texttt{xWave} then waves named \texttt{W_YPoly0} and \texttt{W_XPoly0} are created in the current data folder. \texttt{n} is an integer used to make the output wave names unique in their data folder, so Igor might create waves named \texttt{W_XPoly0} and \texttt{W_YPoly0}, for example.

If there is no \texttt{yWave} vs \texttt{xWave} trace in the graph, GraphWaveDraw appends it.

Flags
\texttt{/F=}\texttt{f} Initiates freehand drawing. In normal drawing, you click where you want a data point. In freehand drawing, you click once and then draw with the mouse button held down. If present, \texttt{f} specifies the smoothing factor. Max value is 8 (which is really slow), min value is 0 (default). The drawing tools use a value of 3 which is the recommended value.
GraphWaveEdit

/L/R/B/T  Specifies which axes to use (Left, Right, Bottom, Top). Bottom and Left axes are used by default. Can specify free axes using /L=axis name type notation. See AppendToGraph for details. If necessary, the specified axes will be created. If an axis is created its range is set to -1 to 1.

/M  Specifies that the curve being edited must be monotonic in the X dimension. The user is not allowed drag points so that they cross horizontally.

/O  Overwrites yWave and xWave if they already exist.

/W=winName  Draws in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

Details
Once drawing starts no other user actions are allowed.

In normal mode, drawing stops when you double-click or when you click the first point (in which case the last point is set equal to the first point). When drawing finishes, the edit mode is entered.

In freehand mode, drawing stops when the mouse is released or when 10000 points have been drawn.

If you include /O and the waves are already on the graph then the first trace instance on the graph displaying them is used even if the trace uses a different pair of axes than specified by /L, /R, /B, and /T.

Output Variables

S_xWave  Path to the X wave relative to the current data folder. S_xWave is create in Igor Pro 9.00 and later.

S_yWave  Path to the X wave relative to the current data folder. S_yWave is create in Igor Pro 9.00 and later.

See Also
The GraphNormal, GraphWaveEdit and DrawAction operations.

GraphWaveEdit

GraphWaveEdit [flags] traceName
The GraphWaveEdit operation initiates editing a wave trace in a graph. The wave trace must already be in the graph.

Normally, you would initiate editing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using GraphWaveEdit.

Parameters
traceName is a wave name, optionally followed by the # character and an instance number: “myWave#1” is the second instance of myWave appended to the graph (“myWave” is the first).

If traceName is omitted then you get to pick the wave trace to edit by clicking it.

Flags

/M  Specifies that the edited trace must be monotonic in the X dimension. You cannot drag points so that they cross horizontally.

/ND  Suppresses deletion of a data point when the user presses Option (Macintosh) or Alt (Windows) and clicks on the point.

/NI  Suppresses insertion of a new data point when the user clicks between points.
The GraphWaveEdit operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.

The GraphNormal, GraphWaveDraw and DrawAction operations.

Trace Names on page II-282, Programming With Trace Names on page IV-87.

### Grep

Grep ![flags] ![srcFileStr ![srcTextWaveName ![as ![destFileOrFolderStr ![destTextWaveName]]]]

The Grep operation copies lines matching a search expression from a file on disk, the Clipboard, or rows from a text wave to a new or existing file, an existing text wave, the History area, the Clipboard, or to `S_value` as a string list.

#### Source Parameters
The optional `srcFileStr` can be

- The full path to the file to copy lines from (in which case `/P` is not needed).
- The partial path relative to the folder associated with `pathName`.
- The name of a file in the folder associated with `pathName`.
- “Clipboard” to read lines of text from the Clipboard (in which case `/P` is ignored).

If Igor cannot determine the location of the source file from `srcFileStr` and `pathName`, it displays a dialog allowing you to specify the source file.

The optional `srcTextWaveName` is the name or path to a text wave.

Only one of `srcFileStr` or `srcTextWaveName` may be specified. If neither is specified then an Open File dialog is presented allowing you to specify a source file.

#### Destination Parameters
The optional `destFileOrFolderStr` can be

- The name of (or path to) an existing folder when `/D` is specified.
- The name of (or path to) a possibly existing file.
- “Clipboard”, in which case the matching lines are copied to the Clipboard (and `/P` and `/D` are ignored). The text can be retrieved with the `GetScrapText` function.

If `destFileOrFolderStr` is a partial path, it is relative to the folder associated with `pathName`.

If `/D` is specified, the source file is created inside the folder using the source file name.

If Igor cannot determine the location of the destination file from `pathName`, `srcFileStr`, and `destFileOrFolderStr`, it displays a Save File dialog allowing you to specify the destination file (and folder).

The optional `destTextWaveName` is the name or path to an existing text wave. It may be the same wave as `srcTextWaveName`.

Only one of `destFileOrFolderStr` or `destTextWaveName` may be specified.

/T=t Sets the trace mode.
- `t=0`: Lines and small square markers (default).
- `t=1`: User settings unchanged.

/W=winName Edits traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with `winName`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
If no destination file or text wave is specified then matching lines are printed in the history area, unless the /Q flag is specified, in which case the matching lines aren’t printed or copied anywhere (though the output variables are still set).

Use /LIST to set S_value to a string list containing the matching lines or rows.
Use /INDX to create a wave W_index containing the zero-based row or line number where matches were found.

**Parameter Details**

If you use a full or partial path for either srcFileStr or destFileOrFolderStr, see **Path Separators** on page III-451 for details on forming the path.

Folder paths should not end with single path separators. See **MoveFolder**’s Details section.

**Flags**

/A
Appends matching lines to the destination file, creating it if necessary, appends text to the Clipboard if the destFileOrFolderStr is “Clipboard”, or appends rows to the destination text wave. Has no effect on output to the History area.

/D
Interprets destFileOrFolderStr as the name of (or path to) an existing folder (or directory). Without /D, destFileOrFolderStr is the name of (or path to) a file. It is ignored if the destination is a text wave, the Clipboard, or the History area.

If destFileOrFolderStr is not a full path to a folder, it is relative to the folder associated with pathName.

/DCOL={colNum}
Useful only when the destination is destTextWaveName.
Copies matching lines of text from the source file, Clipboard, or srcTextWaveName to column colNum of destTextWaveName, with any terminator characters removed.

The default when the source is a file or the Clipboard is /DCOL={0}, which copies matching lines into the first column of destTextWaveName.

The default when the source is srcTextWaveName is to copy each column of a matched row to the corresponding column in destTextWaveName.

/DCOL must be used with the /A flag, otherwise the destination wave will have only 1 column.

/DCOL=[{colNum} [, delimStr], …]
Useful only when the source is srcTextWaveName and the destination is a file, the Clipboard, History area, or S_value.
Copies multiple columns in any order from matching rows of srcTextWaveName to the destination file, Clipboard, History area, or S_value.
Construct the line by appending the contents of the numbered column and the delimStr parameters in the order specified. The output line is terminated as described in **Line Termination**.

/E=regExprStr
Specifies the Perl-compatible regular expression string. A line must match the regular expression to be copied to the output file. See **Regular Expressions**.

*Multiple /E flags may be specified*, in which case a line is copied only if it matches every regular expression.

/E={regExprStr, reverse}
Specifies the Perl-compatible regular expression string, regExprStr, for which the sense of the match can be changed by reverse.

(reverse=1): Matching expressions are taken to **not** match, and vice versa. For example, use /E={"CheckBox", 1} to list all lines that do not contain “CheckBox”.

(reverse=0): Same as /E=regExprStr.

/ENC=encoding
Specifies the text encoding of named text file. This flag applies if the source is a file and is ignored if the source is the clipboard or a text wave.

See Text Encoding Names and Codes on page III-490 for a list of accepted values for textEncoding.

If you omit /ENCG, Grep uses the default text encoding as specified by the Misc→Text Encoding→Default Text Encoding menu.

Passing 0 for textEncoding acts as if /ENCG were omitted. Passing 255 (binary) for textEncoding is treated as an error because the source text must be internally converted to UTF-8 and there is no valid conversion from binary to UTF-8.

/GCOL=grepCol
Grep the specified column of srcTextWaveName, which is a two-dimensional text wave. The default search is on the first column (grepCol=0). Use grepCol=-1 to match against any column of srcTextWaveName.

Does not apply if the source is a file or Clipboard.

/I
Requires interactive searching even if srcFileStr and destFileOrFolderStr are specified and if the source file exists. Same as /I=3.

/I=i
Specifies the degree of file search interactivity with the user.

i=0: Default; interactive only if srcFileStr is not specified or if the source file is missing. Same as if /I were not specified.

Note: This is different behavior than other commands such as CopyFile.

i=1: Interactive even if srcFileStr is specified and the source file exists.

i=2: Interactive even if destFileOrFolderStr is specified.

i=3: Interactive even if srcFileStr is specified, the source file exists, and destFileOrFolderStr is specified.

/INDX
Creates in the current data folder an output wave W_Index containing the line numbers (or row numbers) where matching lines were found. If this is the only output you need, also use the /Q flag.

/LIST=listSepStr
Creates an output string variable S_value containing a semicolon-separated list of the matching lines. If listSepStr is specified, then it is used to separate the list items. See StringFromList for details on string lists. If this is the only output you need, also use the /Q flag.

/M=messageStr
Specifies the prompt message in any Open File dialog. If /S is not specified, then messageStr will be used for both the Open File and Save File dialogs.

/O
Overwrites any existing destination file.

/P=pathName
Specifies the folder containing the source file or the folder into which the file is copied. pathName is the name of an existing symbolic path.

Both srcFileStr and destFileOrFolderStr must be either simple file or folder names, or paths relative to the folder specified by pathName.

/Q
Prevents printing results to an output file, text wave, History, or Clipboard. Use /Q to check for a match to regExprStr by testing the value of V_flag, V_value, S_value (/LIST), or W_Index (/INDEX) without generating any other matching line output.

Note: When using /Q neither destFileOrFolderStr nor destTextWaveName may be specified.

/S=saveMessageStr
Specifies the prompt message in any Save File dialog.
Line Termination

Line termination applies mostly to source and destination files. (The Clipboard and history area delimit lines with CR, and text waves have no line terminators.)

If /T is omitted, Grep will break file lines on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.)

Grep reads whichever of these terminator(s) appear in the source file and use them to write lines to any output file.

The terminator(s) are removed before the line is matched against the regular expression.

For lines that match regExprStr, terminator(s) in the input file are transferred to the output file unless the output is the Clipboard or history area, in which case the output terminator is always only CR (like LoadWave). This means you can transparently handle files that use CR, LF, CRLF, or LFCR as the terminator, and omitting /T will be suitable for most cases.

If you use the /T flag, then Grep will terminate line-from-file reads on the specified character only and will output the specified character into any output file.

“Lines” in One-dimensional Text Waves

Grep considers each row of srcTextWaveName or destTextWaveName to be a “line” of input or output.

When the destination is a file, the Clipboard, or the History area, Grep copies all of the text in a matching row of srcTextWaveName to the file and terminates the line. See Line Termination for the rules on line terminators.

When the destination is a destTextWaveName, Grep simply copies all the text in a matching row to a row in destTextWaveName, without adding or omitting any terminators.

“Lines” and Columns in Two-Dimensional Text Waves

Grep by default matches against only the first column (column 0) of each row of srcTextWaveName. You can use the /GCOL=grepCol flag to specify a different column to match against. Use /GCOL=-1 to match against any column of srcTextWaveName.

When the source is a text wave and the destination is a file, the Clipboard, or the History area, Grep by default copies only the first column (column 0) to the destination.

Use the /DCOL={colNum1, delimStr1, colNum2, delimStr2,...,colNumN} to print multiple columns (in any order) with delimiters after each column (the last column number need not be followed by a delimiter string). The output line is terminated with CR or termcharStr as described in Line Termination.

When both the source and destination are text waves and append (/A) is not specified, the destination text wave is redimensioned to have the same number of columns as the source text wave, and all columns of matching rows of srcTextWaveName are copied to destTextWaveName.

When both the source and destination are text waves and append /A is specified, then the number of columns in destTextWaveName is left unchanged, and each column of srcTextWaveName is copied to the corresponding column of destTextWaveName.
If the destination is a text wave and the source is a file or the Clipboard, each line (without the terminator) is copied to the first column of the destination text wave, or use /DCOL={destColNum} to put the text into a different column.

Output Variables
The Grep operation returns information in the following variables. When running in a user-defined function these are created as local variables. Otherwise they are created as global variables in the current data folder.

V_flag
0: Output successfully generated.
-1: User cancelled either the Open File or Save File dialogs.
Other: An error occurred, such as the specified file does not exist.

V_value
The number of input lines that matched the regular expression.

V_startParagraph
Zero-based line number into the file or Clipboard (or the row number of a source text wave) where the first regular expression was matched. Also see the /INDX flag.

S_fileName
Full path to the source file, the source text wave, or “Clipboard”. If an error occurred or if the user cancelled, it is an empty string.

S_path
Full path to the destination file or destination text wave.
"Clipboard": If destFileOrFolderStr was the Clipboard.
"History": If the output was printed to the history area of the window.
"": If an error occurred, if the user cancelled, or if /Q was specified.

S_value
Contains matching lines as a string list only if /LIST is specified.

Regular Expressions
A regular expression is a pattern that is matched against a subject string from left to right. Most characters stand for themselves in a pattern, and match the corresponding characters in the “subject”.

In the case of Grep, the “subject” is each line of the source file or Clipboard, or each row in the source text wave.

The regular expression syntax supported by Grep, GreplList, and GrepString is based on the “Perl-Compatible Regular Expression” (PCRE) library.

The syntax is similar to regular expressions supported by various UNIX and POSIX egrep(1) commands. See Regular Expressions on page IV-176 for more details.

As a trivial example, the pattern “Fred” as specified here:
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
matches lines that contain the string “Fred” anywhere on the line.

Character matching is case-sensitive by default, similar to strsearch. Prepend the Perl 5 modifier (?i) to match upper and lower-case versions of “Fred”:

// Copy lines that contain "Fred", "fred", "FRED", "fRED", etc
Grep/P=myPath/E="(?i)fred" "afile.txt" as "AnyFredFile.txt"

To copy lines that do not match the regular expression, set the /E flag’s reverse parameter:

// Copy lines that do NOT contain "Fred", "fred", "fRED", etc.
Grep/P=myPath/E="(?i)fred",1 "afile.txt" as "NotFredFile.txt"

Note: Igor doesn’t use the opening and closing regular expression delimiters that UNIX grep or Perl use: they would have used "/Fred/" and "/(?i)fred/".

Regular expressions in Igor support the expected metacharacters and character classes that make the whole grep paradigm so useful. For example:

// Copy lines that START with a space or tab character
Grep/P=myPath/E="^[ \t]" "afile.txt" as "LeadingTabsFile.txt"
Grep

For a complete description of regular expressions, see Regular Expressions on page IV-176, especially for a description of the many uses of the regular expression backslash character (see Backslash in Regular Expressions on page IV-179).

Note: Because Igor Pro also has special uses for backslash (see Escape Sequences in Strings on page IV-14), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes identifies a single backslash for the Grep command.

For example, to copy lines that contain "\z", the Perl pattern would be `\z`, but the equivalent Grep expression would be `/E="\\\\z"`.

See Backslash in Regular Expressions on page IV-179 for a more complete description of backslash behavior in Igor Pro.

Examples

// Copy lines in afile.txt containing "Fred" (case sensitive) // to an output file named "AnyFredFile.txt" in the same directory.
Grep/P=myPath/E="Fred" "afile.txt" as "AnyFredFile.txt"

// Copy lines in afile.txt containing "Fred" and "Wilma" (case-insensitive) // to a text wave (which must exist and is overwritten):
Make/O=N=0/T outputTextWave
Grep/P=myPath/E="(?i)fred"/E="(?i)wilma" "afile.txt" as outputTextWave

// Print lines in afile.txt containing "Fred" and "Wilma" (case-insensitive) // to the history area.
Make/O=N=0/T outputTextWave
Grep/P=myPath/E="(?i)fred"/E="(?i)wilma" "afile.txt"

// Test whether afile.txt contains the word "boondoggle", and if so, // on which line the first occurrence was found, WITHOUT creating any output. // // Note: the `\\b` sequences limit matches to a word boundary before and after // "boondoggle", so "boondoggles" and "aboondoggle" won't match.

References
The regular expression syntax supported by Grep, GrepString, and GrepList is based on the PCRE — Perl-Compatible Regular Expression Library by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.
Visit <http://pcre.org/> for more information about the PCRE library.

A helpful web site is: http://www.regular-expressions.info

See Also
Regular Expressions on page IV-176 and Symbolic Paths on page II-22.

Demo, CopyFile, PutScrapText, LoadWave operations. The GrepString, GrepList, StringMatch, and CmpStr functions.

GrepList

GrepList(listStr, regExprStr [, reverse [, listSepStr]])
The GrepList function returns each list item in listStr that matches the regular expression regExprStr.

ListStr should contain items separated by listSepStr which typically is ",".

regExprStr is a regular expression such as is used by the UNIX grep(1) command. It is much more powerful than the wildcard syntax used for ListMatch. See Regular Expressions on page IV-176 for regExprStr details.
GrepString

GrepString(string, regExprStr)

The GrepString function tests string for a match to the regular expression regExprStr. Returns 1 to indicate a match, or 0 for no match.

Details

regExprStr is a regular expression such as is used by the UNIX grep(1) command. It is much more powerful than the wildcard syntax used for StringMatch. See Regular Expressions on page IV-176 for regExprStr details.

Character matching is case-sensitive by default, similar to strsearch. Prepend the Perl 5 modifier "(?i)" to match upper and lower-case text

Examples

Test for truth that the string contains at least one digit:
if( GrepString(str,"[0-9]+") )

Test for truth that the string contains at least one “abc”, “Abc”, “ABC”, etc.:
if( GrepString(str,"(?i)abc") ) // case-insensitive test

See Also

Regular Expressions on page IV-176.

The StringMatch, CmpStr, strsearch, ListMatch, and ReplaceString functions and the Demo and sscanf operations.

GridStyle

GridStyle

GridStyle is a procedure subtype keyword that puts the name of the procedure in the Grid->Style Function submenu of the mover pop-up menu in the drawing tool palette. You can have Igor automatically create a grid style function for you by choosing Save Style Function from that submenu.

GroupBox

GroupBox [/Z] ctrlName [keyword = value [, keyword = value ...]]

The GroupBox operation creates a box to surround and group related controls.

For information about the state or status of the control, use the ControlInfo operation.

Parameters

ctrlName is the name of the GroupBox control to be created or changed.
The following keyword=value parameters are supported:

**align=alignment**
Sets the alignment mode of the control. The alignment mode controls the interpretation of the leftOrRight parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.
If alignment=0 (default), leftOrRight specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
If alignment=1, leftOrRight specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

**appearance={kind [, platform]}
Sets the appearance of the control. platform is optional. Both parameters are names, not strings.
kkind can be one of default, native, or os9.
platform can be one of Mac, Win, or All.
See DefaultGUIControls Default Fonts and Sizes for how enclosed controls are affected by native groupbox appearance.
See Button for more appearance details.

**disable=d**
Sets user editability of the control.
\(d=0:\) Normal.
\(d=1:\) Hide.
\(d=2:\) Draw in gray state.

**fColor=(r,g,b[,a])**
Sets color of the title text. \(r, g, b\), and \(a\) specify the color and optional opacity as RGBA Values.

**font=fontName**
Sets font used for the box title, e.g., font="Helvetica".

**frame=f**
Sets frame mode. If 1 (default), the frame has a 3D look. If 0, then a simple gray line is used. Generally, you should not use frame=0 with a title if you want to be in accordance with human interface guidelines.

**fsize=s**
Sets font size for box title.

**fstyle=fs**
Sets the font style of the title text. \(fs\) is a bitwise parameter with each bit controlling one aspect of the font style for the tick mark labels as follows:
Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

**help={helpStr}**
Sets the help for the control.
helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before). You can insert a line break by putting “\r” in a quoted string.

**labelBack=(r,g,b[,a]) or 0**
Sets fill color for the interior. \(r, g, b\), and \(a\) specify the color and optional opacity as RGBA Values.
If you do not set labelBack then the interior is transparent.
If an opaque fill color is used, drawing objects cannot be used because they will be covered up. Also, you will have to make sure the GroupBox is drawn before any interior controls.
The fidelity of the coloring is platform-dependent.
GuideInfo

pos=[leftOrRight,top] Sets the position in Control Panel Units of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+=[dx,dy] Offsets the position of the box in Control Panel Units.

size=[width,height] Sets box size in Control Panel Units.

userdata(UDName)=UDStr
Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create.

userdata(UDName)++=UDStr
Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr.

title=titleStr Sets title to titleStr. Use "" for no title.

win=winName Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags
/Z No error reporting.

Details
If no title is given and the width is less than 11 or height is specified as less than 6, then a vertical or horizontal separator line will be drawn rather than a box.

Note: Like TabControls, you need to click near the top of a GroupBox to select it.

See Also
Chapter III-14, Controls and Control Panels, for details about control panels and controls.

Control Panel Units on page III-444 for a discussion of the units used for controls.
The GetUserData function for retrieving named user data.
The ControlInfo operation for information about the control.

GuideInfo

GuideInfo(winNameStr, guideNameStr)
The GuidInfo function returns a string containing a semicolon-separated list of information about the named guide line in the named host window or subwindow.

Parameters
winNameStr can be "" to refer to the top host window.

When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

guideNameStr is the name of the guide line for which you want information.

Details
The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:
The following keywords will be present only for user-defined guides:

See Also
The GuideNameList, StringByKey and NumberByKey functions; the DefineGuide operation.
GuideNameList

GuideNameList(winNameStr, optionsStr)
The GuideNameList function returns a string containing a semicolon-separated list of guide names from the named host window or subwindow.

Parameters

winNameStr can be "" to refer to the top host window.

When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

optionsStr is used to further qualify the list of guides. It is a string containing keyword-value pairs separated by commas. Use "" to list all guides. Available options are:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>Name of the guide.</td>
</tr>
<tr>
<td>WIN</td>
<td>Name of the window or subwindow containing the guide.</td>
</tr>
<tr>
<td>TYPE</td>
<td>The value associated with this keyword is either User or Builtin. A User type denotes a guide created by the DefineGuide operation, equivalent to dragging a new guide from an existing one.</td>
</tr>
<tr>
<td>HORIZONTAL</td>
<td>Either 0 for a vertical guide, or 1 for a horizontal guide.</td>
</tr>
<tr>
<td>POSITION</td>
<td>The position of the guide in points. This is the actual position relative to the left or top edge of the window, not the relative position specified to DefineGuide.</td>
</tr>
<tr>
<td>GUIDE1</td>
<td>The guide is positioned relative to GUIDE1.</td>
</tr>
<tr>
<td>GUIDE2</td>
<td>In some cases, the guide is positioned at a fractional position between GUIDE1 and GUIDE2. If the guide does not use GUIDE2, the value will be &quot;&quot;.</td>
</tr>
<tr>
<td>RELPOSITION</td>
<td>The position relative to GUIDE1 (and GUIDE2 if applicable). This is the same as the val parameter in DefineGuide. The returned value is in units of points if only GUIDE1 is used, or a fractional value if both GUIDE1 and GUIDE2 are used.</td>
</tr>
</tbody>
</table>

Example

String list = GuideNameList("Graph0", "TYPE:Builtin,HORIZONTAL:1")

See Also
The DefineGuide operation and the GuideInfo function.

Hanning

Hanning waveName [ , waveName]...

Note: The WindowFunction operation has replaced the Hanning operation.

The Hanning operation multiplies the named waves by a Hanning window (which is a raised cosine function).

You can use Hanning in preparation for performing an FFT on a wave if the wave is not an integral number of cycles long.
The Hanning operation is not multidimensional aware. See Chapter II-6, *Multidimensional Waves*, particularly *Analysis on Multidimensional Waves* on page II-95 for details.

**See Also**
The WindowFunction operation implements the Hanning window as well as other forms such as Hamming, Parzen, and Bartlet (triangle).

**ImageWindow, DPSS**

**Hash**

`Hash(inputStr, method)`

The Hash function returns a cryptographic hash of the data in `inputStr`.

**Parameters**

`inputStr` is a string of length up to $2^{31}$ bytes. `inputStr` can contain binary or text data.

`method` is a number indicating the hash algorithm to use:

- 1: SHA-256 (SHA-2)
- 2: MD4
- 3: MD5
- 4: SHA-1
- 5: SHA-224 (SHA-2)
- 6: SHA-384 (SHA-2)
- 7: SHA-512 (SHA-2)

Prior to Igor Pro 7.00, only method 1 was supported.

**See Also**

WaveHash, StringCRC, WaveCRC

**HCluster**

`HCluster [ flags ] sourceWave`

The HCluster operation computes the information needed to create a cluster dendrogram using an agglomerative hierarchical clustering algorithm. "HCluster" stands for "hierarchical clustering". The HCluster operation was added in Igor Pro 9.00.

For background information, see *Hierarchical Clustering* on page III-162.

The input `sourceWave` represents either vectors in some data space or a square vector dissimilarity matrix (also called a "distance" matrix). You indicate which type of input you are providing using the `/ITYP` flag.

HCluster creates an output vector dissimilarity matrix wave or an output dendrogram wave or both, depending on the `/OTYP` flag. The output wave names default to `M_HCluster_Dissimilarity` and `M_HCluster_Dendrogram` but you can override the default using `/DEST`.

**Flags**

`/ITYP=it`

`it` is a keyword specifying the kind of data in `sourceWave`:

- `it=Vectors`: `sourceWave` rows represent data vectors (default).
- `it=DMATRIX`: `sourceWave` contains a square vector dissimilarity matrix.
/OTYP=ot

*ot* is a keyword specifying what type of output to be produced:

- **ot=DMatrix**: The output is a vector dissimilarity matrix. You can use /OTYP=DMatrix only if /ITYP=Vectors or if you omit /ITYP.
- **ot=Dendrogram**: The output is a multi-column wave describing the nodes in a dendrogram illustrating the way original data is joined into clusters. This is the default if you omit /OTYP.
- **ot=Both**: The output is both the vector dissimilarity matrix and a dendrogram.

See the /DEST flag for further discussion of the output wave or waves.

/LINK=linkMethod

*linkMethod* is a keyword specifying the method used to determine the dissimilarity between nodes in the dendrogram that represent more than one data vector. This is also referred to as the "linkage" method. Our definitions of node dissimilarities follow Python scipy.cluster.hierarchy.linkage.

The available keywordds for linkMethod are listed and described under HCluster Linkage Calculation Methods on page III-166.

If you omit /LINK, HCluster defaults to the average method.

/DISS=dm

*dm* is a keyword specifying the vector dissimilarity metric for calculating the dissimilarity between two data vectors. Our definitions of vector dissimilarity follow Python scipy.spatial.distance.pdist.

The available /DISS keywords are listed and described under HCluster Vector Dissimilarity Calculation Methods on page III-163.

If you omit /DISS, HCluster defaults to the Euclidean metric.

/P=pow

*pow* is the power for the Minkowski vector dissimilarity metric. The value of pow must be positive. The default is 2.0, equivalent to the Euclidean vector dissimilarity metric. Values that are too large can lead to floating-point overflow. Values less than 1.0 may give surprising results, as this can cause an inversion of the usual distance ordering. If the vector dissimilarity metric is not Minkowski this flag is ignored.

/VARW=varWave

Specifies the normalizing values Vj for use with the SEuclidean vector dissimilarity metric. Usually, the wave elements are variances of the vector elements over all the vectors. Thus, if you have a multi-column wave in which rows represent individual vectors, *varWave* should be filled with variances of the wave's columns. If your vectors have length of M, then *varWave* should be a 1D wave with M elements. This wave can be conveniently created using the MatrixOP operation, like this:

```
MatrixOp/O varWave = VarCols(rowVectorMatrix)^t
```

If the vector dissimilarity matrix is not SEuclidean, the /VARW flag is ignored.

/DEST=outWaveName

Specifies the output waves when you have specified /OTYP=DMatrix or /OTYP=Dendrogram.

If you specified /OTYP=DMatrix, *outWaveName* is the name of the output vector dissimilarity matrix wave to be created or overwritten, optionally preceded by a data folder path. If you omit /DEST, HCluster creates an output vector dissimilarity matrix named M_HCluster_Dissimilarity in the current data folder.

If you specified /OTYP=Dendrogram, *outWaveName* is the name of the output dendrogram wave to be created or overwritten, optionally preceded by a data folder path. If you omit /DEST, HCluster creates an output dendrogram named M_HCluster_Dendrogram in the current data folder.
/DEST={dMatrixName, dendrogramName}

Specifies the output waves when you have specified /OTYP=Both.
dMatrixName and dendrogramName are names of waves to be created or
overwritten, optionally preceded by data folder paths.

If you specify /OTYP=Both and omit /DEST, HCluster creates an output
vector dissimilarity matrix named M_HCluster_Dissimilarity and an output
dendrogram wave named M_HCluster_Dendrogram, both in the current
data folder.

/O

If present, allows the destination waves specified by the /DEST flag to
overwrite a pre-existing wave.

Parameter
If you specify /ITYP=Vectors or omit /ITYP, sourceWave is an N row x M column matrix containing N data
vectors of length M in the rows. HCluster creates a vector dissimilarity matrix from this input using the
distance calculation method specified by /LINK.

If you specify /ITYP=DMatrix, sourceWave is a square matrix of dissimilarities between data vectors. If you
choose this format, you are responsible for computing the dissimilarities between vectors. If none of the
vector dissimilarity metrics provided by the /DISS flag are suitable, or if you require more processing after
computing dissimilarities, you can use this format.

Dendrogram Output Wave
The HCluster operation optionally produces a dendrogram output wave that can be used to create a
dendrogram plot. See Dendrogram Wave Format on page III-167 for a description of the dendrogram
output wave format.

Reference
The HCluster operation is based on code developed by Daniel Müllner. This reference gives details of the
algorithm and the various distance and vector dissimilarity measures and node agglomeration methods:
Daniel Müllner, fastcluster: Fast Hierarchical, Agglomerative Clustering Routines for R and Python,

See Also
Hierarchical Clustering on page III-162

hcsr

hcsr(cursorName [, graphNameStr])
The hcsr function returns the horizontal coordinate of the named cursor (A through J) in the coordinate
system of the top (or named) graph’s X axis.

Parameters
cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on
forming the window hierarchy.

Details
The X axis used is the one that controls the trace on which the cursor is placed.

Examples
Variable xAxisValueAtCursorA = hcsr(A)        // not hcsr("A")
String str="A"
Variable xA= hcsr(str,"Graph0")             // $str is a name, too

The pcsr, qcsr, vcsr, xcsr, and zcsr functions.

Programming With Cursors on page II-321.
HDF5AttributeInfo

HDF5AttributeInfo(locationID, objectNameStr, objectType, attributeNameStr, options, di)

The HDF5AttributeInfo function stores information about the attribute such as its rank, dimension sizes and type in the HDF5DataInfo structure pointed to by di.

Documentation for the HDF5AttributeInfo function is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5AttributeInfo"

HDF5CloseFile

HDF5CloseFile [/A /Z] fileId

The HDF5CloseFile operation closes an HDF5 file previously opened by HDF5OpenFile or HDF5CreateFile.

Documentation for the HDF5CloseFile operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5CloseFile"

HDF5CloseGroup

HDF5CloseGroup [/Z] groupID

The HDF5CloseGroup operation closes an HDF5 group that you opened via HDFCreateGroup or HDF5OpenGroup.

Documentation for the HDF5CloseGroup operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5CloseGroup"

HDF5Control

HDF5Control [ keyword=value [, keyword=value] ]

The HDF5Control HDF5Control provides control of aspects of Igor’s use of the HDF5 file format.

Documentation for the HDF5CreateFile operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5Control"

HDF5CreateFile

HDF5CreateFile [/I /O /P=pathname /Z] fileId as fileNameStr

The HDF5CreateFile operation creates a new HDF5 file or overwrites an existing HDF5 file.

Documentation for the HDF5CreateFile operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5CreateFile"

HDF5CreateGroup

HDF5CreateGroup [/Z] locationID, nameStr, groupID

The HDF5CreateGroup operation creates an HDF5 group in the HDF5 file. It returns a group ID via groupID.

Documentation for the HDF5CreateGroup operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5CreateGroup"
HDF5CreateLink

HDF5CreateLink [ /EXT={pathName, filePath} /HARD=makeHardLink /Q /Z ]
  targetLocationID, targetName, linkLocationID, linkName

The HDF5CreateLink operation creates a new hard, soft or external link in an HDF5 file.

Documentation for the HDF5CreateLink operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5CreateLink"

HDF5DataInfo

The HDF5DataInfo structure is used with the HDF5DataInfo and HDF5AttributeInfo functions.

Documentation for the HDF5DataInfo structure is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5DataInfo"

HDF5DatasetInfo

HDF5DatasetInfo(locationID, datasetNameStr, options, di)

The HDF5DatasetInfo function stores information about the dataset such as its rank, dimension sizes and type in the HDF5DataInfo structure referenced by di.

Documentation for the HDF5DatasetInfo function is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5DatasetInfo"

HDF5DatatypeInfo

The HDF5DatatypeInfo structure is used with the HDF5TypeInfo function.

Documentation for the HDF5DatatypeInfo structure is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5DatatypeInfo"

HDF5DimensionScale

HDF5DimensionScale [ flags ] [ keyword=value [, keyword=value] ]

The HDF5DimensionScale operation supports the creation and querying of HDF5 dimension scales.

Documentation for the HDF5DimensionScale operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5DimensionScale"

HDF5Dump

HDF5Dump [ flags ] fileNameStr

The HDF5Dump operation dumps information about the specified HDF5 file.

Documentation for the HDF5Dump operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5Dump"

HDF5DumpErrors

HDF5DumpErrors [/CLR=clear /Q]

The HDF5DumpErrors operation dumps information about HDF5 library errors encountered by Igor.

Documentation for the HDF5DumpErrors operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5DumpErrors"
HDF5FlushFile

HDF5FlushFile [\A /Z] fileID
The HDF5FlushFile operation flushes an HDF5 file previously opened by HDF5OpenFile or HDF5CreateFile.

Documentation for the HDF5FlushFile operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5FlushFile"

HDF5LibraryInfo

HDF5LibraryInfo(options)
The HDF5LibraryInfo function returns information about the HDF5 library used by the currently-running version of Igor.

Documentation for the HDF5LibraryInfo function is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5LibraryInfo"

HDF5LinkInfo

HDF5LinkInfo(locationID, pathStr, options, li)
The HDF5LinkInfo function stores information about an HDF5 link in the HDF5LinkInfoStruct structure pointed to by li.

Documentation for the HDF5LinkInfo function is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5LinkInfo"

HDF5LinkInfoStruct

The HDF5LinkInfoStruct structure is used with the HDF5LinkInfo function.

Documentation for the HDF5LinkInfoStruct structure is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5LinkInfoStruct"

HDF5ListAttributes

HDF5ListAttributes [\TYPE=type /Z] locationID, nameStr
The HDF5ListAttributes operation returns a semicolon-separated list of attributes associated with the object specified by locationID and nameStr.

Documentation for the HDF5ListAttributes operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5ListAttributes"

HDF5ListGroup

HDF5ListGroup [flags] locationID, nameStr
The HDF5ListGroup operation returns a semicolon-separated list of the names of objects in the HDF5 file or group specified by locationID and nameStr.

Documentation for the HDF5ListGroup operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "HDF5ListGroup"
HDF5LoadData

HDF5LoadData [flags] locationID, nameStr
The HDF5LoadData operation loads a dataset or attribute from an HDF5 file.
Documentation for the HDF5LoadData operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "HDF5LoadData"

HDF5LoadGroup

HDF5LoadGroup [flags] dataFolderSpec, locationID, nameStr
The HDF5LoadGroup operation loads an HDF5 group and its datasets into an Igor Pro data folder.
Documentation for the HDF5LoadGroup operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "HDF5LoadGroup"

HDF5LoadImage

HDF5LoadImage [flags] locationID, nameStr
The HDF5LoadImage operation loads an image dataset and in some cases a palette dataset from an HDF5 file using the format specified in the HDF5 Image and Palette Specification version 1.2.
Documentation for the HDF5LoadImage operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "HDF5LoadImage"

HDF5OpenFile

HDF5OpenFile [/I /P=pathname /R /Z] fileId as fileNameStr
The HDF5OpenFile operation opens an existing HDF5 file for reading or for reading and writing.
Documentation for the HDF5OpenFile operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "HDF5OpenFile"

HDF5OpenGroup

HDF5OpenGroup [/Z] locationID, nameStr, groupID
The HDF5OpenGroup operation opens an existing HDF5 group in the HDF5 file.
Documentation for the HDF5OpenGroup operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "HDF5OpenGroup"

HDF5SaveData

HDF5SaveData [flags] wave, locationID [, nameStr]
The HDF5SaveData operation saves a single wave in an HDF5 file as a dataset or as an attribute if /A is present.
Documentation for the HDF5SaveData operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "HDF5SaveData"

HDF5SaveDataHookStruct

The HDF5SaveDataHookStruct structure is used with the HDF5SaveDataHook function.
Documentation for the HDF5DatatypeInfo structure is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "HDF5SaveDataHookStruct"
HDF5SaveGroup

**HDF5SaveGroup**

**HDF5SaveGroup** [flags] dataFolderSpec, locationID, nameStr

The HDF5SaveGroup operation saves the contents of an Igor data folder in an HDF5 file.

Documentation for the HDF5SaveGroup operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5SaveGroup"
```

HDF5SaveImage

**HDF5SaveImage** [flags] keyword [=value]

The HDF5SaveImage operation saves an image dataset and in some cases a palette dataset in an HDF5 file using the format specified in the HDF5 Image and Palette Specification version 1.2.

Documentation for the HDF5SaveImage operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5SaveImage"
```

HDF5TypeInfo

HDF5TypeInfo(locationID, datasetOrGroupNameStr, attributeNameStr, memberName, options, dti)

The HDF5TypeInfo function stores information about the datatype of a dataset or attribute in the HDF5DataTypeInfo structure referenced by dti.

Documentation for the HDF5TypeInfo function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5TypeInfo"
```

HDF5UnlinkObject

HDF5UnlinkObject [/Z] locationID, nameStr

The HDF5UnlinkObject operation unlinks the specified object (a group, dataset, datatype or link) from the HDF5 file.

Documentation for the HDF5UnlinkObject operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5UnlinkObject"
```

hermite

**hermite**

hermite(n, x)

The hermite function returns the Hermite polynomial of order n:

\[ H_n(x) = (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2). \]

The first few polynomials are:

1

2x

4x^2 - 2

8x^3 - 12x

See Also

The `hermiteGauss` function.
The hermiteGauss function returns the normalized Hermite polynomial of order \( n \):

\[
H_n(x) = \frac{1}{\sqrt{\pi 2^n n!}} (-1)^n \exp \left( x^2 \right) \frac{d^n}{dx^n} \exp \left( -x^2 \right).
\]

Here the normalization was chosen such that

\[
\int_{-\infty}^{\infty} e^{-x^2} H_n(x) H_m(x) dx = \delta_{nm},
\]

where \( \delta_{nm} \) is the Kronecker symbol.

You can verify the Hermite-Gauss normalization using the following functions:

```plaintext
Function TestNormalization(order)
    Variable order
    Variable/G theOrder = order
    // The integrand vanishes in double-precision outside [-30,30]
    Print/D Integrate1D(hermiteIntegrand,-30,30,2)
End

Function HermiteIntegrand(inX)
    Variable inX
    NVAR n = root:theOrder
    return HermiteGauss(n,inX)^2*exp(-inx*inx)
End
```

**See Also**
The `hermite` function.

---

**hide**

```
#pragma hide = value
```

The hide pragma allows you to make a procedure file invisible.

**See Also**
The The hide Pragma on page IV-54 and `#pragma`.

---

**HideIgorMenus**

```
HideIgorMenus [MenuNameStr [, MenuNameStr ]...]
```

The HideIgorMenus operation hides the named built-in menus or, if none are explicitly named, hides all built-in menus in the menu bar.

The effect of HideIgorMenus is lost when a new experiment is opened. The state of HideIgorMenus is saved with the experiment.

User-defined menus are not hidden by HideIgorMenus unless attached to built-in menus and the menu definition uses the hideable keyword.

**Parameters**

- `MenuNameStr` The name of an Igor menu, like “File”, “Data”, or “Graph”.

**Details**

The optional menu names are in English and not abbreviated. This ensures that code developed for a localized version of Igor will run on all versions.

The built-in menus that can be shown or hidden (the Help menu can be hidden only on Windows) are those that appear in the menu bar:
Hiding a built-in menu to which a user-defined menu is attached results in a built-in menu with only the user-defined items. For example, if this menu definition attaches items to the built-in Graph menu:

```plaintext
Menu "Graph"
   "Do My Graph Thing", ThingFunction()
End
```

Calling `HideIgorMenus "Graph"` will still leave a Graph menu showing (when a Graph is the top-most target window) with only the user-defined menu(s) in it: in this example the one “Do My Graph Thing” item.

Hiding the Macros menu hides menus created from Macro definitions like:

```plaintext
Macro MyMacro()
   Print "Hello, world."
End
```

but does not hide normal user-defined “Macros” definitions like:

```plaintext
Menu "Macros"
   "Macro 1", MyMacro(1)
End
```

You can set user-defined menus to hide and show along with built-in menus by adding the optional hideable keyword to the menu definition:

```plaintext
Menu "Graph", hideable
   "Do My Graph Thing", ThingFunction()
End
```

Then `HideIgorMenus "Graph"` will hide those items, too. If all user-defined Graph menu definitions use the hideable keyword, then no Graph menu will appear in the menu bar.

Some WaveMetrics procedures use the `hideable` keyword so that only customer-defined menus remain when `HideIgorMenus` is executed.

- `ShowIgorMenus`, `DoIgorMenu`, `SetIgorMenuMode`, Chapter IV-5, User-Defined Menus

## HideInfo

### HideInfo [/W=winName]

The `HideInfo` operation removes the info panel from a graph if it was previously shown by the `ShowInfo` operation.

**Flags**

- `/W=winName` Hides the info panel in the named window.

See Also
- The `ShowInfo` operation.
- Programming With Cursors on page II-321.

## HideProcedures

### HideProcedures

The `HideProcedures` operation hides all procedure windows without closing or killing them.

See Also
- The `DisplayProcedure` and `DoWindow` operations.

## HideTools

### HideTools [/A/W=winName]

The `HideTools` operation hides the tool palette in the top graph or control panel if it was previously shown by the `ShowTools` operation.
HilbertTransform

Flags

/V
Sizes the window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.

/W=winName
Hides the tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

winName must be either the name of a top-level window or a path leading to an exterior panel window (see Exterior Control Panels on page III-443).

See Also
The ShowTools operation.

HilbertTransform

The HilbertTransform operation computes the Hilbert transformation of srcWave, which is a real or complex (single or double precision) wave of 1-3 dimensions. The result of the HilbertTransform is stored in destWave, or in the wave W_Hilbert (1D) or M_Hilbert in the current data folder.

Flags

/DEST=destWave
Creates a real wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-72 for details.

/O
Overwrites srcWave with the transform.

/PAD={dim1 [, dim2, dim3, dim4]}
Converts srcWave into a padded wave of dimensions dim1, dim2,... The padded wave contains the original data at the start of the dimension and adds zero entries to each dimension up to the specified dimension size. The dim1... values must be greater than or equal to the corresponding dimension size of srcWave. If you need to pad just the lowest dimension(s) you can omit the remaining dimensions; for example, /PAD=dim1 will set dim2 and above to match the dimensions in srcWave.

This flag was added in Igor Pro 7.00.

/Z
No error reporting.

Details
The Hilbert transform of a function \( f(x) \) is defined by:

\[
F(t) = \frac{1}{\pi t} \int_{-\infty}^{\infty} \frac{f(x)dx}{x-t}.
\]

Theoretically, the integral is evaluated as a Cauchy principal value. Computationally one can write the Hilbert transform as the convolution:

\[
F(t) = \frac{-1}{\pi t} * f(t),
\]

which by the convolution theorem of Fourier transforms, may be evaluated as the product of the transform of \( f(x) \) with \(-i*\text{sgn}(x)\) where:

\[
\text{sgn}(x) = \begin{cases} 
-1 & x < 0 \\
0 & x = 0 \\
1 & x > 0 
\end{cases}
\]
Note that the Hilbert transform of a constant is zero. If you compute the Hilbert transform in more than one dimension and one of the dimensions does not vary (is a constant), the transform will be zero (or at least numerically close to zero).

There are various definitions for the extension of the Hilbert transform to more than one dimension. In two dimensions this operation computes the transform by multiplying the 2D Fourier transform of the input by the factor \((-i)\text{sgn}(x)\text{sgn}(y)\) and then computing the inverse Fourier Transform. A similar procedure is used when the input is 3D.

**Examples**

Extract the instantaneous amplitude and frequency of a narrow-band signal:

```plaintext
Make/O/N=1000 w0,amp,phase
SetScale/I x 0,50,**, w0,amp,phase
w0 = exp(-x/10)*cos(2*pi*x)
HilbertTransform /DEST=w0h w0 // w0+i*w0h is the "analytic signal", i=cmplx(0,1)
amp = sqrt(w0^2 + w0h^2) // extract the envelope
phase = atan2(-w0h,w0) // extract the phase [SIGN CONVENTION?]
Unwrap Z*pi, phase // eliminate the 2*pi phase jumps
Differentiate phase /D=freq // would have less noise if fit to a line
freq /= 2*pi // over interior points
Display w0,amp // original waveform and its envelope; note boundary effects
Display freq // instantaneous frequency estimate, with boundary effects
```

**See Also**
The FFT operation.

**References**

Compute the envelope of a signal:

```plaintext
Function calcEnvelope(Wave ddd)
HilbertTransform/dest=ht ddd
Matrixop/o sEnv=abs(cmplx(ddd,ht))
CopyScales ddd,sEnv
KillWaves/z ht
End
```

---

**Histogram**

```
Histogram [flags] srcWaveName, destWaveName
```

The Histogram operation generates a histogram of the data in `srcWaveName` and puts the result in `destWaveName` or in W_Histogram or in the wave specified by /DEST.

**Parameters**

- `srcWaveName` specifies the wave containing the data to be histogrammed.
- For historical reasons the meaning and use of `destWaveName` depend on the binning mode as specified by /B. See Histogram Destination Wave on page V-351 below for details.

**Flags**

- `/A` Accumulates the histogram result with the existing values in the destination wave instead of replacing the existing values with the result. Assumes /B=2 unless the /B flag is present.

  **Note:** The result will be incorrect if you also use /P.

</tbody>
</table>

/B=[binStart,binWidth,numBins]

Sets the histogram bins from these parameters rather than from destWaveName. Changes the X scaling and length of the destination wave.

/C

Sets the X scaling so that X values are in the centers of the bins, which is required when you do a curve fit to the histogram output. Ordinarily, wave scaling of the output wave is set with X values at the left bin edges.

/CUM

Requests a cumulative histogram in which each bin is the sum of bins to the left. The last bin will contain the total number of input data points, or, with /P, 1.0.

/CUM cannot be used with a weighted histogram (/W flag).

When used with /A, the destination wave must be the result of a histogram created with /CUM.

Note that if you use a binning mode (/B flag) that sets a bin range that does not include the entire range of the input data, then the output will not count all of input points and the last bin will not contain the total number of input points. Input points whose values fall below the left edge of the first bin or above the right edge of the last bin will not be counted.

/DEST=destWave

Saves the histogram output in a wave specified by destWave. The destination wave is created or overwritten if it already exists.

Creates a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-72 for details.

See Histogram Destination Wave on page V-351 below for further discussion.

The /DEST flag was added in Igor Pro 7.00.

/DP

Causes Histogram to create the destination wave as double-precision floating point instead of single-precision floating point. The /DP flag was added in Igor Pro 8.00.

Single-precision precisely represents integers up to 16,677,721 only. Double-precision precisely represents integers up to about 9 trillion.
For historical reasons there are multiple ways to specify the destination wave and the meaning and use of destWaveName depend on the binning mode as specified by /B. This section explains the details and then provides guidance and when to use which mode.

In binning modes 1 and 2 (/B=1 and /B=2, described above), the destination wave plays a role in determining the binning and destWaveName must be the name of an existing wave. If you omit /DEST then the output is written to destWaveName. If you provide /DEST then the output is written to the wave specified by /DEST.

In binning modes 3, 4 and 5 (/B=3, /B=4 and /B=5, described above), the destination wave plays no role in determining the binning. If you omit destWaveName and /DEST, Histogram stores its output in a wave named W_Histogram in the current data folder. If you omit /DEST and provide destWaveName, then

**/N**

Creates a wave named W_SqrtN containing the square root of the number of counts in each bin. This is an appropriate wave to use as a weighting wave when doing a curve fit to the histogram results. /N cannot be used with a weighted histogram (/W flag).

**/NLIN=binsWave**

Computes a non-linear histogram using the bins specified in the wave binsWave. This option is not compatible with the flags /A, /B, /C, /CUM, /N, /P, /W.

The bins must be contiguous and non-overlapping so that binsWave contains monotonically increasing values with no NaNs and INFs. For example, if you want the 3 bins [1,10),(10,100),(100,1000), execute:

Make/O/N=4 bins=[1,10,100,1000]

The upper end of each bin is open.

The /NLIN flag was added in Igor Pro 7.00.

**/P**

Normalizes the histogram as a probability distribution function, and shifts wave scaling so that data correspond to the bin centers.

When using the results with Integrate, you must use /METH=0 or /METH=2 to select rectangular integration methods.

**/R=(startX,endX)**

Specifies the range of X values of srcWaveName over which the histogram is to be computed.

**/R=[startP,endP]**

Specifies the range of points of srcWaveName over which the histogram is to be computed.

**/RMD=[firstRow,lastRow][firstColumn,lastColumn][firstLayer,lastLayer][firstChunk,lastChunk]**

Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 7.00.

You can include all higher dimensions by leaving off the corresponding brackets. For example:

/RMD=[firstRow,lastRow]

includes all available columns, layers and chunks.

You can use empty brackets to include all of a given dimension. For example:

/RMD=[][firstColumn,lastColumn]

means "all rows from column A to column B".

You can use a * to specify the end of any dimension. For example:

/RMD=[firstRow,*]

means "from firstRow through the last row".

**/W=weightWave**

Creates a “weighted” histogram. In this case, instead of adding a single count to the appropriate bin, the corresponding value from weightWave is added to the bin. weightWave may be any number type, and it may be complex. If it is complex, then the destination wave will be complex.

/W cannot be used with a cumulative histogram (/CUM flag).
destWaveName must name an existing wave to which the output is written. If you provide /DEST, you can omit destWaveName. If you provide both /DEST and destWaveName then destWaveName must name an existing wave but the operation ignores it.

Here is the recommended usage:

If you want to use specific binning that you have determined, use /B={binStart,binWidth,numBins}, use /DEST to specify the destination wave, and omit destWaveName.

If you want Igor to determine the binning, use /B=3, /B=4 or /B=5, use /DEST to specify the destination wave, and omit destWaveName.

For backward compatibility with Igor Pro 6, use /B=1, /B=2, /B=3, /B=4 or /B={binStart,binWidth,numBins}, create a destination wave, use it as destWaveName and omit /DEST.

Details

If you use /B={binStart,binWidth,numBins}, then the initial number of data points in the wave is immaterial since the Histogram operation changes the number of points.

Only one /B and only one /R flag is allowed.

If both /A and /B flags are missing, the bin range and number of bins is calculated as if /B=1 had been specified.

When accumulating multiple histograms in one output wave, typically you will want to use /B={binStart,binWidth,numBins} for the first histogram, and /A for successive histograms.

The Histogram operation works on single precision floating point destination waves. If necessary, Histogram redimensions the destination wave to be single precision floating point. However, Histogram/A requires that the destination wave already be single precision floating point.

For a weighted histogram, the destination wave will be double-precision.

If you specify the range as /R=(start), then the end of the range is taken as the end of srcWaveName.

In an ordinary histogram, input data is examined one data point at a time. The operation determines which bin a data value falls into and a single count is added to that bin. A weighted histogram works similarly, except that it adds to the bin a value from another wave in which each row corresponds to the same row in the input wave.
The Histogram operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details. In fact, the Histogram operation can be usefully applied to multidimensional waves, such as those that represent images. The /R flag will not work as expected, however.

Examples

// Create histogram of two sets of data.
Make/N=1000 data1=gnoise(1), data2=gnoise(1)
Make/N=1 histResult

// Sets bins, does histogram.
Histogram/B={-5,1,10} data1, histResult
Display histResult; ModifyGraph mode=5

// Accumulates into existing bins.
Histogram/A data2, histResult

---

**ICA**

**ICA [flags] srcWave**
The ICA operation performs independent component analysis using the FastICA algorithm. Input data is in the form of a 2D wave where each column represents the equivalent of a single data acquisition channel. The results of the operation are stored in the waves M_ICAComponents, M_ICAUnMix and M_matrixW in the current data folder.

The ICA operation was added in Igor Pro 7.00.

**Flags**

/A=alpha \(\alpha\) is a constant used as a factor in the argument of the logCosh function. It is not used with the exp function.

\(\alpha\) is in the range [1,2] and its default value is 1.

You will rarely need to change this value to affect the rate of convergence or the quality of the results.

/CF=num Specifies the contrast function, also called the non-quadratic function, used by ICA.

\(num=0:\) logCosh (default)
\(num=1:\) exp

/COLS Preconditions the input by subtracting the mean and then normalizing the input on a column-by-column basis. The algorithm appears to converge and produce better results when this flag is used.

As of Igor Pro 9.00, the input is preconditioned by default so /COLS is no longer required or recommended.

/DFLT Use the deflation/vector method where iterations solve for a single vector of the "unmixing" matrix at a time. By default the operation uses the matrix method which solves for the complete unmixing matrix at one time.
ICA

/PCA  Save the output of the "PCA" stage which is also the form of the data before the fastICA iterations. The SVD U matrix is saved in the wave M_PCA and the eigenvalues are saved in the wave W_PCAEV. Both are created in the current data folder.

/Q  Quiet mode; do not print anything in the history.

/TOL=tolerance  The tolerance value is used to determine when iterations converge.

/WINT=w  Provides an initial unmixing matrix W. If you do not provide this matrix the algorithm initializes using enoise.

/Z  No error reporting.

Details

srcWave is a 2D wave of nRows by nCols. It must be a single or double precision real-valued wave containing no NaNs or INFs. Each column of srcWave corresponds to a single data acquisition channel that is assumed to consist of a linear superposition of independent components. This can be expressed as a matrix product

\[ X = A (S^t) \]

where S is an nRows by nCols matrix of independent components, \(^t\) denotes the transpose, A is an nCols by nCols mixing matrix and X is the "mixed" input. The ICA operation attempts to find the independent components of S from the transformation

\[ S = W X \]

so that the mutual information between the resulting columns of S is minimized. Since mutual information is not affected by a multiplication of components by scalar constants, the resulting independent components can be specified up to a scalar factor.

The operation uses the FastICA algorithm to compute the independent components.

The algorithm has two available methods for computation. The default is to attempt to evaluate the full W matrix at once. The second method (/DFLT flag) also known as "deflation" computes one row of W at a time. The deflation method might have advantages in cases where there are fewer independent components than there are columns in the input.

Example

// Create the source
Make/O/N=(1000,3) ddd
ddd[][][0]=sin(2*pi*x/13)
ddd[][][1]=sin(2*pi*x/17)
ddd[][][2]=sin(2*pi*x/23)

// Create mixing matrix
Make/O/N=(3,3) AA
AA[0][0]= {0.291,0.6557,-0.5439}
AA[0][1]= {0.5572,0.3,-0.2}
AA[0][2]= {-0.1,-0.7,0.4}

// Do the mixing
MatrixOp/O xx=ddd x AA

// Try the ICA
ICA/DFLT/COLS xx
Display M_ICAComponents[][][0]
Display M_ICAComponents[][][1]
Display M_ICAComponents[][][2]
if-elseif-endif

if ( <expression1> )
   <TRUE part 1>
elseif ( <expression2> )
   <TRUE part 2>
[…]
[else
   <FALSE part>]
endif

In an if-elseif-endif conditional statement, when an expression first evaluates as TRUE (nonzero), then only code corresponding to the TRUE part of that expression is executed, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then FALSE part is executed when present. After executing code in any TRUE part or the FALSE part, execution will next continue with any code following the if-elseif-endif statement.

See Also
If-Elseif-Endif on page IV-40 for more usage details.

if-endif

if ( <expression> )
   <TRUE part>
[else
   <FALSE part>]
endif

An if-endif conditional statement evaluates expression. If expression is TRUE (nonzero) then the code in TRUE part is executed, or if FALSE (zero) then the optional FALSE part is executed.

See Also
If-Else-Endif on page IV-40 for more usage details.s

IFFT

IFFT [flags] srcWave

The IFFT operation calculates the Inverse Discrete Fourier Transform of srcWave using a multidimensional fast prime factor decomposition algorithm. This operation is the inverse of the FFT operation.

Output Wave Name

For compatibility with earlier versions of Igor, if you use IFFT without /ROWS or /COLS, the operation overwrites srcWave.

If you use the /ROWS flag, IFFT uses the default output wave name M_RowFFT and if you use the /COLS flag, IFFT uses the default output wave name M_ColFFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting srcWave.

Parameters

srcWave is a complex wave. The IFFT of srcWave is a either a real or complex wave, according to the length and flags.

Flags

/C Forces the result of the IFFT to be complex. Normally, the IFFT produces a real result unless certain special conditions are detected as described in Details.
The data type of srcWave must be complex and must not be an integer type. You should be aware that an IFFT on a number of points that is prime can be slow. By default, IFFT assumes you are performing an inverse transform on data that was originally real and therefore it produces a real result. However, for historical and compatibility reasons, IFFT detects the special conditions of a one-dimensional wave containing an integral power of 2 data points and automatically creates a complex result.

When the result is complex, the number of points (N) in the resulting wave will be of the same length. Otherwise the resulting wave will be real and of length (N-1)*2.

In either the complex or real case the X units of the output wave are changed to “s”. The X scaling also is changed appropriately, cancelling out the adjustments made by the FFT operation. When the data is multidimensional, the same considerations apply to the additional dimensions. The scaling description and IDFT equation below pretend that the IFFT is not performed in-place. After computing the IFFT values, the X scaling of waveOut is changed as if Igor had executed these commands:

Variable points // time-domain points, N_{timeDomain}
if( waveIn was complex wave )
    points= numpnts(waveIn)
else // waveIn was real wave
    points= (numpnts(waveIn) - 1) * 2
endif
Variable deltaT= 1 / (points*deltaX(waveIn)) // 1/(N_{timeDomain}dx)
SetScale/F waveOut 0,deltaT,"s"

The IDFT equation is:

$$waveOut[n] = \frac{1}{N} \sum_{k=0}^{N-1} waveIn[k] \exp \left( \frac{2\pi i kn}{N} \right), \quad \text{where} \quad i = \sqrt{-1}.$$
IgorInfo

**IgorInfo**

**IgorInfo**(selector)

The IgorInfo function returns information about the Igor application and the environment in which it is running.

**Details**

selector is a number from 0 to 13.

**Selector = 0**

If selector is 0, IgorInfo returns a collection of assorted information. The result string contains five kinds of information. Each group is prefaced by a keyword and a colon, and terminated with a semicolon.

<table>

</table>

**Selector = 1**

IgorInfo(1) returns the name of the current Igor experiment.

Use IgorInfo(12) to get the file name including the extension.
**Selector = 2**
IgorInfo(2) returns the name of the current platform: “Macintosh” or “Windows”.

**Selector = 3**
IgorInfo(3) returns a collection of more detailed information about the operating system, localization information, and the actual file version of the Igor executable. The keywords are OS, OSVERSION, LOCALE, and IGORFILEVERSION.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword For IgorInfo(3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGORFILEVERSION</td>
<td>The actual version number of the Igor application file.</td>
</tr>
<tr>
<td></td>

</tr>
</tbody>
</table>

**Selector = 4**
IgorInfo(4) returns the name of the current processor architecture. Currently this is always “Intel”.

**Selector = 5**
IgorInfo(5) returns, as a string, the serial number of the program if it is registered or “_none_” if it isn’t registered. Use str2num to store the result in a numeric variable. str2num returns NaN if the program isn’t registered.

**Selector = 6**
IgorInfo(6) returns, as a string, the version of the Qt library under which Igor is running, for example “5.9.4”. This selector value was added in Igor Pro 7.00.

**Selector = 7**
IgorInfo(7) returns, as a string, the name of the current user. This selector value was added in Igor Pro 7.00.

**Selector = 8**
IgorInfo(8) returns, as a string, the group of the current user on Macintosh. On Windows, an empty string is always returned. This selector value was added in Igor Pro 8.00.

**Selector = 9**
IgorInfo(9) returns “admin” if Igor’s process is being run as an administrator (Windows) or if the user that started Igor’s process is an administrator (Macintosh). Otherwise it returns “”. This selector value was added in Igor Pro 8.00.

**Selector = 10**
IgorInfo(10) returns a semicolon-separated list containing the names of activated XOPs. This selector value was added in Igor Pro 8.00.

**Selector = 11**
IgorInfo(11) returns a string specifying the type of the current experiment. This will be one of the following:
Selector = 12
IgorInfo(12) returns a string specifying the name of the current experiment file including the extension. If the experiment was never saved to a file, it returns "".
This selector value was added in Igor Pro 9.00.
Use IgorInfo(1) to get the file name without the extension.

Selector = 13
In Igor Pro 9.00 and later, IgorInfo(13) returns a collection of information about the autosave settings. See Autosave on page II-36 for background information.
This selector value was added in Igor Pro 9.00.

Selector = 14
IgorInfo(14) returns a collection of information about the HDF5 default compression settings. See HDF5 Default Compression on page II-214 for background information.
This selector value was added in Igor Pro 9.00.

The keywords are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword For IgorInfo(3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENABLED</td>
<td>0: Autosave is disabled</td>
</tr>
<tr>

<td>Bit 1: Autosave standalone procedure files</td>
</tr>
<tr>
<td></td>
<td>Bit 2: Autosave standalone plain text notebooks</td>
</tr>
<tr>
<td></td>
<td>Bit 3: Autosave standalone formatted text notebooks</td>
</tr>
</tbody>
</table>

See Setting Bit Parameters on page IV-12 for details about bit settings.

See Autosave on page II-36 for details.

Selector = 15
IgorInfo(15) returns a string specifying the default experiment file format.
This selector value was added in Igor Pro 9.00.
The returned value will be one of the following:

"Packed"          Default experiment file format is .pxp
"HDF5 packed"     Default experiment file format is .h5xp
"Unpacked"        Default experiment file format is .uxp
See Saving Experiments on page II-16 for a discussion of the various experiment file formats.

**Selector = 16**

IgorInfo(16) returns the total number of waves of all kinds (global, free, local) that currently exist. This selector value was added in Igor Pro 9.00.

IgorInfo(16) can help advanced Igor programmers detect wave leaks in their procedures. For details, see Detecting Wave Leaks on page IV-206.

**Examples**

Print NumberByKey("NSCREENS", IgorInfo(0)) // Number of active displays

Function RunningWindows()
    // Returns 0 if Macintosh, 1 if Windows
    String platform = UpperStr(IgorInfo(2))
    Variable pos = strsearch(platform,"WINDOWS",0)
    return pos >= 0
End

**IgorVersion**

#pragma IgorVersion = versNum

When a procedure file contains the directive, #pragma IgorVersion=versNum, an error will be generated if versNum is greater than the current Igor Pro version number. It prevents procedures that use new features added in later versions from running under older versions of Igor in which these features are missing. However, this version check is limited because it does not work with versions of Igor older than 4.0.

See Also
The The IgorVersion Pragma on page IV-54 and #pragma.

**IgorVersion**

The IgorVersion function returns version number of the Igor application as a floating point number. Igor Pro 8.00 returns 8.00, as does Igor Pro 8.00A.

**Details**

You can use IgorVersion in conditionally compile code expressions, which can be used to omit calls to new Igor features or to provide backwards compatibility code.

#if (IgorVersion() >= 8.00)
    [Code that compiles only on Igor Pro 8.00 or later]
#else
    [Code that compiles only on earlier versions of Igor]
#endif

If at all possible, it is better to require your users to use a later version of Igor rather than writing conditional code. Attempting this kind of backward-compatibility multiplies your testing requirements and the chances for bugs.

See Also
IgorInfo, Conditional Compilation on page IV-108, The IgorVersion Pragma on page IV-54

**ilim**

The ilim function returns the ending loop count for the inner most iterate loop Not to be used in a function. Iterate loops are archaic and should not be used.

**imag**

imag(z)

The imag function returns the imaginary component of the complex number z as a real (not complex) number.

See Also
The cmplx, conj, p2rect, r2polar, and real functions.
ImageAnalyzeParticles

ImageAnalyzeParticles [flags] keyword imageMatrix

The ImageAnalyzeParticles operation performs one of two particle analysis operations on a 2D or 3D source wave imageMatrix. The source image wave must be binary, i.e., an unsigned char format where the particles are designated by 0 and the background by 255 (the operation will produce erroneous results if your data uses the opposite designation). Note that all nonzero values in the source image will be considered part of the background. Grayscale images must be thresholded before invoking this operation (you may need to use the /I flag with the ImageThreshold operation).

Note: ImageAnalyzeParticles does not take into account wave scaling. All image metrics are in pixels and all pixels are assumed to be square.

Parameters

keyword is one of the following names:

mark Creates a masking image for a single particle, which is specified by an internal (seed) pixel using the /L flag. The masking image is stored in the wave M_ParticleMarker, which is an unsigned char wave. All points in M_ParticleMarker are set to 64 (image operations on binary waves use the value 64 to designate the equivalent of NaN) except points in the particle which are set to the 0. This wave is designed to be used as an overlay on the original image (using the explicit=1 mode of ModifyImage). This keyword is superseded by the ImageSeedFill operation.

stats Measures the particles in the image. See ImageAnalyzeParticles Stats on page V-365 for details.

Flags

/A=minArea Specifies a minimum area as a threshold that must be exceeded for a particle to be counted (e.g., use minArea=0 to find single pixel particles). The minimum area is measured in pixels; its default value is minArea=5.

When the source wave is 3D, minArea specifies the minimum number of voxels that constitute a particle.

/A has no effect when used with the mark method.

/B Erases a 1 pixel wide frame inset from the boundary. This insures that no particles will have boundary pixels (see /EBPC below) and all boundary waves will describe close contours.

/CIRC={minCircularity,maxCircularity} Use this flag to filter the output so that only particles in the range of the specified circularity are counted.

/D=dataWave Specify a wave from which the minimum, maximum, and total particle intensity are sampled when used with the stats keyword. dataWave must be of the same dimensions as the input binary image imageMatrix. It can be of any real numeric type. Results are returned in the waves W_IntMax, W_IntMin, and W_IntAvg.

/E Calculates an ellipse that best fits each particle. The equivalent ellipse is calculated by first finding the moments of the particle (i.e., average x-value, average y-value, average x^2, average y^2, and average x*y), and then requiring that the area of the ellipse be equal to that of the particle. The resulting ellipses are saved in the wave M_Moments. When imageMatrix is a 2D wave, the results returned in M_Moments are the columns: the X-center of the ellipse, the Y-center of the ellipse, the major axis, the minor axis, and the angle (radians) that the major axis makes with the X-direction. When imageMatrix is a 3D wave, the results in M_Moments include the sum of the X, Y, and Z components as well as all second order permutations of their products. They are arranged in the order: sumX, sumY, sumZ, sumXX, sumYY, sumZZ, sumXY, sumXZ, and sumYZ.
<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/EBPC</td>
<td>Use this flag to exclude from counting any particle that has one or more pixels on any boundary of the image.</td>
</tr>
<tr>
<td>/F</td>
<td>Fills 2D particles having internal holes and adjusts their area measure for the removal of holes. Internal boundaries around the holes are also eliminated. When the boundary of the particle consists of thin elements that cannot be traversed as a single closed path which passes each boundary pixel only once, the particle will not be filled. Note that filling particles may increase execution time considerably and on some images it may require large amount of memory. It is likely that a more efficient approach would be to preprocess the binary image and remove holes using morphology operations. This flag is not supported when <code>imageMatrix</code> is a 3D wave.</td>
</tr>
<tr>
<td>/FILL</td>
<td>Use /FILL to fill holes inside particles. The reported values of area and perimeter are computed as if there are no holes. The filling algorithm could fail if, for example, there is a closed contour of zeros around the particles. If you specify both /F and /FILL the operation used /FILL only. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>/L=(row,col)</td>
<td>Specifies a 2D particle location in connection with the mark method. (row, col) is a seed value corresponding to any pixel inside the particle. If the seed belongs to the particle boundary, the particle will not be filled. This flag is not supported when <code>imageMatrix</code> is a 3D wave.</td>
</tr>
</tbody>
</table>
| /M=markerVal | Use this flag with the stats mode for 2D images. See `stats` keyword for a full description of the following waves:  
  - `markerVal=0`: No marker waves.  
  - `markerVal=1`: M_ParticlePerimeter.  
  - `markerVal=2`: M_ParticleArea.  
  - `markerVal=3`: M_Particle.  
  This flag does not apply to 3D waves. |
| /MAXA=maxArea | Specifies an upper limit of the area of an acceptable particle when used with the stats keyword. The area is measured in pixels and the default value of `maxArea` is the number of pixels in the image. In 3D the maximum value applies to the number of voxels. |
| /NSW    | Creates the marker wave (see /M flag) but not the particle statistics waves when used with the stats keyword. This should reduce execution time in images containing many particles. |
| /P=plane | Specifies the plane when operating on a single layer of a 3D wave.                                                                                                                                           |
| /PADB   | Use this flag with the stats keyword to pad the image with a 1 pixel wide background. This has the effect that particles touching the image boundary are now interior particles with closed perimeter (that extend one pixel beyond the original image frame). In addition, entries in the wave `W_ObjPerimeter` will be longer for all boundary particles which will also affect other derived parameters such as circularity. /PADB is different from /B in that it takes into account all pixels belonging to the particle that lie on the boundary of the image. The two flags are mutually exclusive. /PADB was added in Igor Pro 7.00. |
| /PDLG   | Displays a progress dialog. /PDLG is useful when you are processing very large 3D images. The progress dialog provides feedback and allows the user to abort the operation. /PDLG was added in Igor Pro 9.00. |
| /Q      | Quiet flag, does not report the number of particles to the history area.                                                                                                                                 |
Particle analysis is accomplished by first converting the data from its original format into a binary representation where the particle is designated by zero and the background by any nonzero value. The algorithm searches for the first pixel or voxel that belongs to a particle and then grows the particle from that seed while keeping count of the area, perimeter and count of pixels or voxels in the particle. If you use additional flags, the algorithm must compute additional quantities for each pixel or voxel belonging to the particle.

If your goal is to mask only the particle, a more efficient approach is to use the `ImageSeedFill` operation, which similarly follows the particle but does not spend processing time on computing unrelated particle properties. `ImageSeedFill` also has the additional advantage of not requiring that the input wave be binary, which will save time on performing the initial threshold and, in fact, may produce much better results with the adaptive/fuzzy features that are not available in `ImageAnalyzeParticles`.

### ImageAnalyzeParticles Stats

The `ImageAnalyzeParticles` stats keyword measures the particles in the image. Results of the measurements are reported for all particles whose area exceeds the `minArea` specified by the `/A` flag. The results of the measurements are:

<table>
<thead>
<tr>
<th>Wave</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>V_NumParticles</td>
<td>Number of particles that exceed the <code>minArea</code> limit.</td>
</tr>
<tr>
<td>W_ImageObjArea</td>
<td>Area (in pixels) for each particle.</td>
</tr>
<tr>
<td>W_ImageObjPerimeter</td>
<td>Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.</td>
</tr>
<tr>
<td>W_circularity</td>
<td>Ratio of the square of the perimeter to $(4\pi \times \text{objectArea})$. This value approaches 1 for a perfect circle.</td>
</tr>
<tr>

<td>Ratio of the area of the particle to the area of the inscribing (nonrotated) rectangle. This ratio is $\pi/4$ for a perfectly circular object and unity for a nonrotated rectangle.</td>
</tr>
<tr>
<td>W_SpotX and W_SpotY</td>
<td>Contain a single x, y point from each object. There is one entry per particle and the entries follow the same order as all other waves created by this operation. Each (x,y) point from these waves can be used to define the position of a tag or annotation for a particle. Points can also be used as seed pixels for the associated <code>mark</code> method or for the <code>ImageSeedFill</code> operation.</td>
</tr>
</tbody>
</table>

**Details**

Particle analysis is accomplished by first converting the data from its original format into a binary representation where the particle is designated by zero and the background by any nonzero value. The algorithm searches for the first pixel or voxel that belongs to a particle and then grows the particle from that seed while keeping count of the area, perimeter and count of pixels or voxels in the particle. If you use additional flags, the algorithm must compute additional quantities for each pixel or voxel belonging to the particle.

If your goal is to mask only the particle, a more efficient approach is to use the `ImageSeedFill` operation, which similarly follows the particle but does not spend processing time on computing unrelated particle properties. `ImageSeedFill` also has the additional advantage of not requiring that the input wave be binary, which will save time on performing the initial threshold and, in fact, may produce much better results with the adaptive/fuzzy features that are not available in `ImageAnalyzeParticles`.

### ImageAnalyzeParticles Stats

The `ImageAnalyzeParticles` stats keyword measures the particles in the image. Results of the measurements are reported for all particles whose area exceeds the `minArea` specified by the `/A` flag. The results of the measurements are:

<table>
<thead>
<tr>
<th>Wave</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>V_NumParticles</td>
<td>Number of particles that exceed the <code>minArea</code> limit.</td>
</tr>
<tr>
<td>W_ImageObjArea</td>
<td>Area (in pixels) for each particle.</td>
</tr>
<tr>
<td>W_ImageObjPerimeter</td>
<td>Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.</td>
</tr>
<tr>
<td>W_circularity</td>
<td>Ratio of the square of the perimeter to $(4\pi \times \text{objectArea})$. This value approaches 1 for a perfect circle.</td>
</tr>
<tr>
<td>W_rectangularity</td>
<td>Ratio of the area of the particle to the area of the inscribing (nonrotated) rectangle. This ratio is $\pi/4$ for a perfectly circular object and unity for a nonrotated rectangle.</td>
</tr>
<tr>
<td>W_SpotX and W_SpotY</td>
<td>Contain a single x, y point from each object. There is one entry per particle and the entries follow the same order as all other waves created by this operation. Each (x,y) point from these waves can be used to define the position of a tag or annotation for a particle. Points can also be used as seed pixels for the associated <code>mark</code> method or for the <code>ImageSeedFill</code> operation.</td>
</tr>
</tbody>
</table>
One of the following waves can be created depending on the /M specification. The waves are designed to be used as an overlay on the original image (using the explicit=1 mode of ModifyImage). Note: the additional time required to create these waves is negligible compared with the time it takes to generate the stats data.

**M_ParticlePerimeter**  
Masking image of particle boundaries. It is an unsigned char wave that contains 0 values for the object boundaries and 64 for all other points.

**M_ParticleArea**  
Masking image of the area occupied by the particles. It is an unsigned char wave containing 0 values for the object boundaries and 64 for all other points. It is also different from the input image in that particles smaller than the minimum size, specified by /A, are absent.

**M_Particle**  
Image of both the area and the boundary of the particles. It is an unsigned char wave that contains the value 16 for object area, the value 18 for the object boundaries and the value 64 for all other points.

**M_rawMoments**  
Contains five columns. The first column is the raw sum of the x values for each particle, and the second column contains the sum of the y values. To obtain the average or “center” of a particle divide these values by the corresponding area. The third column contains the sum of x^2, the fourth column the sum of y^2, and the fifth column the sum of x*y. The entries of this wave are used in calculating a fit to an ellipse (using the /E flag).

When *imageMatrix* is a 3D wave, the different results are packed into a single 2D wave M_3DParticleInfo, which consists of one row and 11 columns for each particle. Columns are arranged in the following order: minRow, maxRow, minCol, maxCol, minLayer, maxLayer, xSeed, ySeed, zSeed, volume, and area. Use Edit M_3DParticleInfo.ld to display the results in a table with dimension labels describing the different columns.

### Examples

Convert a grayscale image (blobs) into a proper binary input:

```
ImageThreshold/M=4/Q/I blobs
```

Get the statistics on the thresholded image of blobs and create an image mask output wave for the perimeter of the particles:

```
ImageAnalyzeParticles/M=1 stats M_ImageThresh
```

Display an image of the blobs with a red overlay of the perimeter image:

```
NewImage/F blobs; AppendImage M_ParticlePerimeter
ModifyImage M_ParticlePerimeter explicit=1, eval={0,65000,0,0}
```

### See Also

The ImageThreshold, ImageGenerateROI Mask, ImageSeedFill, and ModifyImage operations. For more usage details see Particle Analysis on page III-375.

---

### ImageBlend

ImageBlend [/A=alpha /W=alphaWave] srcWaveA, srcWaveB [, destWave]  
The ImageBlend operation takes two RGB images (3D waves) in srcWaveA and srcWaveB and computes the alpha blending so that

\[ destWave = srcWaveA \times (1 - \alpha) + srcWaveB \times \alpha \]

for each color component. If destWave is not specified or does not already exist, the result is saved in the current data folder in the wave M_alphaBlend.

The source and destination waves must be of the same data types and the same dimensions. The alphaWave, if used, must be a single precision (SP) float wave and it must have the same number of rows and columns as the source waves.
ImageBoundaryToMask

ImageBoundaryToMask width=w, height=h, xwave=xwavename, ywave=ywavename [, scalingWave=scalingWaveName, [seedX=xVal, seedY=yVal]]

The ImageBoundaryToMask operation scan-converts a pair of XY waves into an ROI mask wave.

Parameters

- **height = h**: Specifies the mask height in pixels.
- **scalingWave = scalingWaveName**: 2D or 3D wave that provides scaling for the mask. If specified, the scaling of the first two dimensions of scalingWave are copied to M_ROIMask, and both the X and Y waves are assumed to describe pixels in the scaled domain.
- **seedX = xVal**: Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedY.
- **seedY = yVal**: Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedX.
- **width = w**: Specifies the mask width in pixels.
- **xwave = xwavename**: Name of X wave for mask region.
- **ywave = ywavename**: Name of Y wave for mask region.

Details

ImageBoundaryToMask generates an unsigned char 2D wave named M_ROIMask, of dimensions specified by width and height. The wave consists of a background pixels that are set to 0 and pixels representing the mask that are set to 1.

The x and y waves can be of any type. However, if the waves describe disjoint regions there must be at least one NaN entry in each wave corresponding to the discontinuity, which requires that you use either single or double precision waves. The values stored in the waves must correspond to zero-based integer pixel values.

If the x and y waves include a vertex that lies outside the mask rectangle, the offending vertex is moved to the boundary before the associated line segment is scan converted.

If you want to obtain a true ROI mask in which closed regions are filled, you can specify the seedX and seedY keywords. The ROI mask is set with zero outside the boundary of the domain and 1 everywhere inside the domain.

Examples

```make
Make/O/N=(100,200) src=gnoise(5) // create a test image
SetScale/P x 500,1,"", src;DelayUpdate // give it some funny scaling
SetScale/P y 600,1,"", src
Display; AppendImage src
Make/O/N=201 xxx,yyy // create boundary waves
xxx=550+25*sin(p*pi/100) // representing a close ellipse
yyy=700+35*cos(p*pi/100)
AppendToGraph yyy vs xxx
```

Now create a mask from the ellipse and scale it so that it will be appropriate for src:

```make
ImageBoundaryToMask ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src
```

V-367
To generate an ROI masked filled with 1 in a region defined by a seed value and the boundary curves:

\[
\text{ImageBoundaryToMask} \\
\text{yw} = y, x = x, \text{width} = 100, \text{height} = 200, \text{scaling} = \text{src}, \text{seed} = 550, \text{seedy} = 700
\]

**See Also**

The ImageAnalyzeParticles and ImageSeedFill operations. For another example see Converting Boundary to a Mask on page III-378.

---

**ImageComposite**

\[
\text{ImageComposite} \ [\text{/Z} \ /\text{FREE} \ /\text{DEST}=\text{destWave}] \ \text{srcImageA}, \ \text{srcImageB}
\]

The ImageComposite operation creates a new image by combining srcImageA and srcImageB subject to one of 12 Porter-Duff compositing modes.

The ImageComposite operation was added in Igor Pro 8.00.

**Flags**

- **/AALP=aWave**  Specifies a 2D single-precision wave as the alpha associated with srcImageA. Alpha values are in the range 0 (transparent) to 1 (opaque).
- **/ACON=a1**      Specifies a single alpha value for the whole srcImageA. a1 is in the range 0 (transparent) to 1 (opaque).
- **/BALP=aWave**    Specifies a 2D single-precision wave as the alpha associated with srcImageB. Alpha values are in the range 0 (transparent) to 1 (opaque).
- **/BCON=a1**      Specifies a single alpha value for the whole srcImageB. a1 is in the range 0 (transparent) to 1 (opaque).
- **/DEST=destWave** Specifies the wave to hold the composite image. If you omit /DEST the operation stores the image in the wave M_ImageComposite in the current data folder.
- **/FREE**         Creates output wave as free waves.
- **/Z**            No error reporting. The operation sets V_Flag to 0 if it succeeds or to an error code otherwise.

**Pre-multiplication**

An RGB value can be raw or pre-multiplied. "Pre-multiplied" means that the red, green, and blue values have been multiplied by normalized alpha values in the range 0 (transparent) to 1 (opaque).

ImageComposite operation is faster when working with pre-multiplicated values. ImageComposite assumes that your RGB values are pre-multiplied unless you specify otherwise using /PMA=0 and /PMB=0.

**Compositing Modes**

Here are the 12 compositing modes supported by ImageComposite:
ImageComposite computes an output RGB or RGBA image that result from compositing `srcImageA` and `srcImageB` using one of the Porter-Duff compositing modes shown in the table above. The waves `srcImageA` and `srcImageB` must have the same number of pixels and the same number type.

Supported number types are: unsigned char, unsigned short, unsigned int, single precision floating point and double precision floating point. When using integer waves expected alpha values are in the range $[0, 2^N - 1]$ where $N$ is the number of bits of the number type. Floating point waves should include alpha in the range $[0, 1]$.

There are three options to specify the alpha associated with each image:

1. The alpha can be expressed as the 4th layer in the wave.
2. The alpha can be specified by a single-precision wave that has the same number of pixels as the image using the `/AALP` and `/BALP` flags.
3. The alpha can be specified by a single number in the range $[0, 1]$ using the `/ACON` and `/BCON` flags.

Options 2 and 3 cannot override an alpha channel that is present in a source wave. To use these options you must delete the alpha channel in the source wave, if any.

**Example**

Function SetupImageCompositeDemo() // Setup - Create two sample images

```plaintext
Make/O/N=(128,128,4)/B/U imageA=0, imageB=0
imageA[0,64][0][0]=255
imageA[0,64][3][3]=128
NewImage/S=0/N=imageA imageA
imageB[0,64][1][1]=255
imageB[0,64][3][3]=128
NewImage/S=0/N=imageB imageB
AutoPositionWindow/M=0/R=imageA imageB
End
```

Function CompositeAOverB() // Composite A over B

```plaintext
Wave imageA, imageB
ImageComposite/PMA=0/PMB=0/DEST=M_Comp1/NMOD=4 imageA,imageB
NewImage/S=0/N=comp1 M_Comp1
AutoPositionWindow/M=0/R=imageB
End
```

Function CompositeAInB() // Composite A in B

```plaintext
Wave imageA, imageB
ImageComposite/PMA=0/PMB=0/DEST=M_Comp2/NMOD=6 imageA,imageB
NewImage/S=0/N=comp2 M_Comp2
```

**Details**

- `srcImageA`: Input image A.
- `srcImageB`: Input image B.
- `srcImageA` and `srcImageB` must have the same number of pixels and the same number type.
- Supported number types: unsigned char, unsigned short, unsigned int, single precision floating point, and double precision floating point.
- Integer waves assume alpha values in the range $[0, 2^N - 1]$ where $N$ is the number of bits of the number type.
- Floating point waves assume alpha in the range $[0, 1]$.

- Options 2 and 3 cannot override an existing alpha channel in the source wave. You must delete the alpha channel in the source wave if using these options.

**Example Code**

```plaintext
Function SetupImageCompositeDemo() // Setup - Create two sample images

Make/O/N=(128,128,4)/B/U imageA=0, imageB=0
imageA[0,64][0][0]=255
imageA[0,64][3][3]=128
NewImage/S=0/N=imageA imageA
imageB[0,64][1][1]=255
imageB[0,64][3][3]=128
NewImage/S=0/N=imageB imageB
AutoPositionWindow/M=0/R=imageA imageB
End

Function CompositeAOverB() // Composite A over B

Wave imageA, imageB
ImageComposite/PMA=0/PMB=0/DEST=M_Comp1/NMOD=4 imageA,imageB
NewImage/S=0/N=comp1 M_Comp1
AutoPositionWindow/M=0/R=imageB
End

Function CompositeAInB() // Composite A in B

Wave imageA, imageB
ImageComposite/PMA=0/PMB=0/DEST=M_Comp2/NMOD=6 imageA,imageB
NewImage/S=0/N=comp2 M_Comp2
```

**Porter-Duff Compositing Modes**

1. Clear
2. A
3. B
4. A over B
5. B over A
6. A in B
7. B in A
8. A out B
9. B out A
10. A atop B
11. B atop A
12. A xor B
ImageEdgeDetection

ImageEdgeDetection [flags] Method imageMatrix

The ImageEdgeDetection operation performs one of several standard image edge detection operations on the source wave imageMatrix.

Unless the /O flag is specified, the resulting image is saved in the wave M_ImageEdges.

The edge detection methods produce binary images on output; the background is set to 0 and the edges to 255. This is due, in most cases to a thresholding performed in the final stage.

Except for the case of marr and shen detectors, you can use the /M flag to specify a method for automatic thresholding; see the ImageThreshold /M flag.

Parameters
Method selects type of edge detection. Method is one of the following names:

- **canny**: Canny edge detector uses smoothing before edge detection and thresholding. You can optionally specify the threshold using the /T flag and the smoothing factor using /S.
- **frei**: Calculates the Frei-Chen edge operator (see Pratt p. 503) using only the row and column filters.
- **kirsch**: Kirsch edge detector (see Pratt p. 509). Performs convolution with 8 masks calculating gradients.
- **marr**: Marr-Hildreth edge detector. Performs two convolutions with Laplacian of Gaussian and then detects zero crossings. Use the /S flag to define the width of the convolution kernel.
- **prewitt**: Calculates the Prewitt compass gradient filters. Returns the result for the largest filter response.
- **roberts**: Calculates the square root of the magnitude squared of the convolution with the Robert’s row and column edge detectors.
- **shen**: Shen-Castan optimized edge detector. Supposed to be effective in the presence of noise. The flags that modify this operation are: /F for the threshold ratio (0.9 by default), /S for smoothness factor (0.9 by default), /W for window width (default is 10), /H for thinning factor which by default is 1.
- **sobel**: Sobel edge detector using convolutions with row and column edge gradient masks (see Pratt p. 501).

Flags

- **/F=fraction**: Determines the threshold value for the shen algorithm by starting from the histogram of the image and choosing a threshold such that fraction specifies the portion of the image pixels whose values are below the threshold. Valid values are in the interval (0 < fraction < 1).

- **/H=thinning**: Thins edges when used with shen edge detector. By default the thinning value is 1. Higher values produce thinner edges.

- **/I**: Inverts the output, i.e., sets the edges to 255 and the background to 0.

The ImageGenerateROIMask operation for creating ROIs and the ImageThreshold operation.

Edge Detectors on page III-365 for a number of examples.

References
ImageFileInfo

ImageFileInfo [P=pathname] fileNameStr
ImageFileInfo is no longer supported and always returns an error.
It is obsolete because it used QuickTime to obtain graphics file information and Apple is phasing out QuickTime.

ImageFilter

ImageFilter [flags] Method dataMatrix
The ImageFilter operation is identical to MatrixFilter, accepting the same parameters and flags, with the exception of the additional features described below.

Parameters
Method selects the filter type. Method is one of the following names:
- avg3d $n \times n \times n$ average filter for 3D waves.
- gauss3d $n \times n \times n$ gaussian filter for 3D waves.
- hybridmedian Implements ranking pixel values between two groups of pixels in a 5x5 neighborhood. The first group includes horizontal and vertical lines through the center, the second group includes diagonal lines through the center, and both groups include the center pixel itself. The resulting median value is the ranked median of both groups and the center pixel.
- max3d $n \times n \times n$ maximum rank filter for 3D waves.
- median3d $n \times n \times n$ median filter for 3D waves where $n$ must be of the form $3^r$ (integer $r$), e.g., 3x3x3, 9x9x9 etc. The filter does not change the value of the voxel it is centered on if any of the filter voxels lies outside the domain of the data.
- min3d $n \times n \times n$ minimum rank filter for 3D waves.
- point3d $n \times n \times n$ point finding filter using normalized $(n^3-1) \times \text{center-outer}$ for 3D waves.

Flags
/N=n Specifies the filter size. By default $n=3$. In most situations it will be useful to set $n$ to an odd number in order to preserve the symmetry in the filters.
/O Overwrites the source image with the output image. Used only with the hybridmedian filter, which does not automatically overwrite the source wave.

Details
You can operate on 3D waves using the 3D filters listed above. These filters are extensions of the 2D filters available under MatrixFilter. The avg3d, gauss3d, and point3d filters are implemented by a 3D convolution that uses an averaging compensation at the edges.
This operation does not support complex waves.

See Also
MatrixFilter for descriptions of the other available parameters and flags.
MatrixConvolve for information about convolving your own 3D kernels.

References
The ImageFocus operation creates in focus image(s) from a stack of images that contain in and out of focus regions. It computes the variance in a small neighborhood around each pixel and then takes the pixel value from the plane in which the highest variance is found.

Flags

/ED=edepth
Sets the effective depth in planes. For example, an effective depth of one means that it computes the best focus for each plane using a stack of three planes, which includes the current plane and any one adjacent plane above and below it. Does not affect the default method (/METH=0).

/METH=method
Specifies the calculation method.

method=0: Computes a single plane output for the stack (default).
method=1: Computes the best image for each plane using /ED.

/Q
Quiet mode; no output to history area.

/Z
No error reporting.

Chapter III-11, Image Processing contains links to and descriptions of other image operations.

ImageFromXYZ

ImageFromXYZ [flags] xyzWave, dataMatrix, countMatrix
ImageFromXYZ [flags] {xWave,yWave,zWave}, dataMatrix, countMatrix
ImageFromXYZ converts XYZ data to matrix form. You might use it, for example, to convert a "sparse matrix" to an actual matrix for easier display and processing.

You provide the input data in the XYZ triplet xyzWave or in 1D waves xWave, yWave, and zWave.
dataMatrix and countMatrix receive output data but you must create them prior to calling ImageFromXYZ.

For each XY location in the input data, ImageFromXYZ adds the corresponding Z value to an element of dataMatrix. The element is determined based on the input XY location and the X and Y scaling of dataMatrix.

For each XY location in the input data, ImageFromXYZ increments the corresponding element of countMatrix. This permits you to obtain an average Z value if multiple input values fall into a given element of dataMatrix.

Parameters

xyzWave is a triplet wave containing the input XYZ data.
xWave, yWave and zWave are 1D input waves containing XYZ data.

You specify either xyzWave by itself or xWave, yWave and zWave in braces.

dataMatrix is a 2D wave to which the Z values are added. It must be either single-precision or double-precision floating point. The X and Y scaling of dataMatrix determines how input values are mapped to output matrix elements.

countMatrix is a 2D wave the elements of which store the number of Z values added to each corresponding element of dataMatrix. ImageFromXYZ sets it to 32-bit integer if it is not already so.

Flags

/AS
If /AS (autoscale) is specified, ImageFromXYZ clears both dataMatrix and countMatrix and sets the X and Y scaling of dataMatrix based on the range of X and Y input values.

Details

For each point in the XYZ input data, ImageFromXYZ adds the Z value to the appropriate element of dataMatrix and increments the corresponding element of countMatrix. Normally you will clear dataMatrix and countMatrix before calling it.
You can combine multiple XYZ datasets in one matrix by calling ImageFromXYZ multiple times with different input data and the same dataMatrix and countMatrix. In this case you would clear dataMatrix and countMatrix before the first call to ImageFromXYZ only.

What you do with the output is up to you but one technique is to divide dataMatrix by countMatrix to get the average and then use MatrixFilter NanZapMedian to eliminate any NaN values that result from zero divided by zero.

Example

Make /N=1000 /O wx=enoise(2), wy=enoise(2), wz=exp(-(wx^2+wy^2))
Make /O /N=(100,100) dataMat=0
SetScale x,-2,2,dataMat
SetScale y,-2,2,dataMat
Duplicate /O dataMat,countMat
ImageFromXYZ /AS {wx,wy,wz}, dataMat, countMat

// Execute these one at a time
NewImage dataMat
dataMat /= countMat          // Replace cumulative z value with average
MatrixFilter NanZapMedian, dataMat    // Apply median filter, zapping NaNs

See Also
SetScale, Image X and Y Coordinates on page II-388.

ImageGenerateROIMask

The ImageGenerateROIMask operation creates a Region Of Interest (ROI) mask for use with other ImageXXX commands. It assumes the top (or /W specified) graph contains an image and that the user has drawn shapes using Igor’s drawing tools in a specific manner.

ImageGenerateROIMask creates an unsigned byte mask matrix with the same x and y dimensions and scaling as the specified image. The mask is initially filled with zeros. Then the drawing layer, progFront, in the graph is scanned for suitable fillable draw objects. The area inside each shape is filled with ones unless the fill mode for the shape is set to erase in which case the area is filled with zeros.

Flags

/E=e  Changes value used for the exterior from the default zero values to e.
/I=i  Changes value used for the interior from the default one values to i.
/W=winName  Looks for the named graph window or subwindow containing appropriate image masks drawn by the user. If /W is omitted, ImageGenerateROIMask uses the top graph window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

To generate an ROI wave for use with most image processing operations you need to set the values of interior pixels to zero and exterior pixels to one using /E=1/I=0.

Suitable objects are those that can be filled (rectangles, ovals, etc.) and which are plotted in axis coordinate mode specified using the same axes by which the specified image instance is displayed. Objects plotted in plot relative mode are also used, However, this is not recommended because it will give correct results only if the image exactly fills the plot rectangle. If you use axis coordinate mode then you can zoom in or out as desired and the resulting mask will still be correct.

Note that the shapes can have their fill mode set to none. This still results in a fill of ones. This is to allow the drawn ROI to be visible on the graph without obscuring the image. However cutouts (fills with erase mode) will obscure the image.

Note also that nonfill drawing objects are ignored. You can use this fact to create callouts and other annotations. In a future version of Igor, we may create a new drawing layer in graphs dedicated to ROIs.

The mask generated is named M_ROIMask and is generated in the current data folder.
Variable \( V_{flag} \) is set to 1 if the top graph contained draw objects in the correct layer and 0 if not. If 0 then the \( M\_ROI\_Mask \) wave was not generated.

**Examples**

Make/O/N=(200,400) jack=x*y; NewImage jack; ShowTools
SetDrawLayer ProgFront
SetDrawEnv linefgc=(65535,65535,0),fillpat=0,xcoord=top,ycoord=left,save
DrawRect 63.5,79.5,140.5,191.5
DrawRRect 61.5,206.5,141.5,280.5
SetDrawEnv fillpat= -1
DrawOval 80.5,169.5,126.5,226.5
ImageGenerateROIMask jack
NewImage M_ROIMask
AutoPositionWindow/E

**See Also**

For another example see *Generating ROI Masks* on page III-378.

### ImageGLCM

#### ImageGLCM \([flags] \ srcWave\)

The ImageGLCM operation calculates the gray-level co-occurrence matrix for an 8-bit grayscale image and optionally evaluates Haralick’s texture parameters.

The ImageGLCM operation was added in Igor Pro 7.00.

**Flags**

- **/D=distance**
  
  Sets the offset in pixels for which the co-occurrence matrix is calculated. The default value is 1.

- **/DEST=destGLCM**
  
  Specifies the wave to hold the co-occurrence matrix. If you omit /DEST the operation stores the matrix in the wave \( M\_GLCM \) in the current data folder.

- **/DETP=destParamWave**
  
  Specifies the wave to hold the computed texture parameters. If you omit /DETP the operation stores the texture parameters in the wave \( W\_TextureParams \) in the current data folder.

  If the destination wave already exists it is overwritten. Note that you must specify the /HTFP flag to compute the texture parameters.

- **/E=structureBits**

  \( structureBits \) is a bitwise setting that lets you control the combination of co-occurrences that you want to compute.

  Consider a wave displayed in a table and a pixel at position \( x \)

  \[
  \begin{array}{ccc}
  0 & 3 & 5 \\
  1 & x & 6 \\
  2 & 4 & 7 \\
  \end{array}
  \]

  The \( structureBits \) corresponding to co-occurrence between \( x \) and any direction is simply \( 2^\text{direction} \). By default the operation computes all combinations. This is equivalent to \( structureBits=255 \).

  Note that the \( structureBits \) only define directions. The combination of the distance (/D) and the \( structureBits \) define the full co-occurrence calculation.

  See *Setting Bit Parameters* on page IV-12 for details about bit settings.
ImageGLCM

/FREE

Creates output waves as free waves.

/FREE is permitted in user-defined functions only, not from the command line or in macros.

If you use /FREE then destGLCM and destParamWave must be simple names, not paths.

See Free Waves on page IV-91 for details on free waves.

/HTFP

Computes Haralick’s texture parameters. See the discussion in the Details section below for more information about the texture parameters.

/P=plane

If the image consists of more than one plane you can use this flag to determine which plane in srcWave is analysed. By default it is plane zero.

/Z

No error reporting.

Details

ImageGLCM computes the co-occurrence matrix for the image in srcWave and optionally evaluates Haralick’s texture parameters. The operation supports 8-bit grayscale images and generates a 256x256 single-precision floating point co-occurrence matrix.

The elements of the matrix $P[i][j]$ are defined as the normalized number of pixels that have a spatial relationship defined by the distance ($/D$) and the structure ($/E$) such that the first pixel has gray-level $i$ and the second pixel has gray-level $j$. The matrix is normalized so that the sum of all its elements is 1.

If you specify the /HTFP flag the operation computes the 13 Haralick texture parameters and stores them sequentially in the destination wave (see /DETP). The wave is saved with dimension labels defining each element. The expressions for the texture parameters are:

\[
\begin{align*}
  f_1 &= \sum_i \sum_j (p[i][j])^2, \\
  f_2 &= \sum_{n=0}^{254} n^2 \left\{ \sum_{i=0}^{255} \sum_{j=0}^{255} p[i][j] \right\}, \\
  f_3 &= \sum_i \sum_j \frac{(i - \mu_x)(j - \mu_y)p[i][j]}{\sigma_x \sigma_y}, \\
  f_4 &= \sum_i \sum_j (i - \mu)^2 p[i][j], \\
  f_5 &= \sum_i \sum_j \frac{1}{1 + (i - j)^2} p[i][j], \\
  f_6 &= \sum_i ip_{x+y}(i),
\end{align*}
\]
\[ f_7 = \sum_i (i - f_6)^2 p_{x+y}(i), \]

\[ f_8 = -\sum_i p_{x+y}(i) \log(p_{x+y}(i)), \]

\[ f_9 = -\sum_i \sum_j p[i][j] \log(p[i][j]), \]

\[ f_{10} = \text{Variance}(p_{x-y}), \]

\[ f_{11} = \sum_i p_{x-y}(i) \log(p_{x-y}(i)), \]

\[ f_{12} = \frac{f_9 - \text{HXY1}}{\max(HX, HY)}, \]

\[ f_{13} = \sqrt{1 - \exp(-2(\text{HXY2} - f9))}. \]

Here

\[ p_x(i) = \sum_j p[i][j], \quad p_y(j) = \sum_i p[i][j], \]

\[ \mu_x = \sum_i i p_x(i), \quad \mu_y = \sum_i i p_y(i), \quad \mu = (\mu_x + \mu_y)/2. \]

\[ \sigma_x = \sqrt{\sum_i (1 - \mu_x)^2 p_x(i)}, \quad \sigma_y = \sqrt{\sum_i (1 - \mu_y)^2 p_y(i)}, \]

\[ p_{x+y}(k) = \sum_i \sum_j p[i][j], \]

\[ p_{x-y}(k) = \sum_i \sum_{|i-j|=k} p[i][j], \]
There are at least two versions of f7 used in the literature and in software. We know of at least three versions of f14 so ImageGLCM does not compute it.

References

ImageHistModification

ImageHistModification [flags] imageMatrix

The ImageHistModification operation performs a modification of the image histogram and saves the results in the wave M_ImageHistEq. If /W is not specified, the operation is a simple histogram equalization of imageMatrix. If /W is specified, the operation attempts to produce an image with a histogram close to waveName. If /A is specified, the operation performs an adaptive histogram equalization. imageMatrix is a wave of any noncomplex numeric type. Adaptive histogram equalization applies only to 2D waves and the other parts apply to both 2D and 3D waves.

Flags

/A
Performs an adaptive histogram equalization by subdividing the image into a minimum of 4 rectangular domains and using interpolation to account for the boundaries between adjacent domains. When the /C flag is specified with contrast factor greater than 1, this operation amounts to contrast-limited adaptive histogram equalization. By default the operation divides the image into 8 horizontal and 8 vertical regions. See /H and /V.

/B=bins
Specifies the number of bins used with the /A flag. If not specified, this value defaults to 256.

/C=cFactor
Specifies a contrast factor (or clipping value) above which pixels are equally distributed over the whole range. cFactor must be greater than 1, in the limit as cFactor approaches 1 the operation is a regular adaptive histogram equalization. Note: this flag is used only with the /A flag.

/H=hRegions
Specifies the number of horizontal subdivisions to be used with the /A feature. Note, the number of image pixels in the horizontal direction must be an integer multiple of hRegions.

/I
Extends the standard histogram equalization by using $2^{16}$ bins instead of $2^8$ when calculating histogram equalization. This feature does not apply to the adaptive histogram equalization (/A flag).

/O
Overwrites the source image. If this flag is not specified, the resulting image is saved in the wave M_ImageHistEq.
ImageHistogram

ImageHistogram [flags] imageMatrix
The ImageHistogram operation calculates the histogram of imageMatrix. The results are saved in the wave W_ImageHist. If imageMatrix is an RGB image stored as a 3D wave, the resulting histograms for each color plane are saved in W_ImageHistR, W_ImageHistG, W_ImageHistB.

imageMatrix must be a real-valued numeric wave.

Flags

/I Calculates a histogram with 65536 bins evenly distributed between the minimum and maximum data values. The operation first finds the extrema and then calculates the bins and the resulting histogram. Data can be a 2D wave of any type including float or double.

/P=plane Restricts the calculation of the histogram to a specific plane when imageMatrix is a non RGB 3D wave.

See Also
The ImageGenerateROIMask and ImageTransform operations for creating ROIs. For examples see Histograms on page III-372 and Adaptive Histogram Equalization on page III-354.

ImageHistogram

flags

/R=roiSpec Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as imageMatrix. The ROI itself is defined by the entries whose values are 0. Regions outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape.

In general, the roiSpec has the form {roiWaveName, roiFlag}, where roiFlag can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.
roiFlag=1: Set pixels outside the ROI as in original image (default).
roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default roiFlag is set to 1 and it is then possible to use the /R flag with the abbreviated form /R=roiWave. When imageMatrix is a 3D wave, roiWave can be either a 2D wave (matching the number of rows and columns in imageMatrix) or it can be a 3D wave which must have the same number of rows, columns, and layers as imageMatrix. When using a 2D roiWave with a 3D imageMatrix, the ROI is understood to be defined by roiWave for each layer in the 3D wave.

See ImageGenerateROIMask for more information on creating ROI waves.

/V=vRegions Specifies the number of vertical subdivisions to be used with the /A flag. The number of image pixels in the horizontal direction must be an integer multiple of vRegions. If the image dimensions are not divisible by the number of regions that you want, you can pad the image using ImageTransform padImage.

/W=waveName Specifies a 256-point wave that provides the desired histogram. The operation will attempt to produce an image having approximately the desired histogram values. This flag does not apply to the adaptive histogram equalization (/A flag)
ImageInfo

/R=roiWave Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u) that has the same number of rows and columns as imageMatrix. The ROI itself is defined by the entries o pixels in the roiWave with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When imageMatrix is a 3D wave, roiWave can be either a 2D wave (matching the number of rows and columns in imageMatrix) or it can be a 3D wave that must have the same number of rows, columns and layers as imageMatrix. When using a 2D roiWave with a 3D imageMatrix the ROI is understood to be defined by roiWave for each layer in the 3D wave.

See ImageGenerateROIMask for more information on creating 2D ROI waves.

/S Computes the histogram for a whole 3D wave possibly subject to 2D or 3D ROI masking. The /S and /P flags are mutually exclusive.

Details
The ImageHistogram operation works on images, but it handles both 2D and 3D waves of any data type. Unless you use one of the special features of this operation (e.g., ROI or /P or /I) you could alternatively use the Histogram operation, which computes the histogram for the full wave and includes additional options for controlling the number of bins.

If the data type of imageMatrix is single byte, the histogram will have 256 bins from 0 to 255. Otherwise, the 256 bins will be distributed between the minimum and maximum values encountered in the data. Use the /I flag to increase the number of bins to 65536, which may be useful for unsigned short (/W/U) data.

See Also
ImageHistModification, ImageGenerateROIMask, JointHistogram, Histograms on page III-372

ImageInfo

ImageInfo(graphNameStr, imageWaveNameStr, instanceNumber)
The ImageInfo function returns a string containing a semicolon-separated list of information about the specified image in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

imageWaveNameStr contains either the name of a wave displayed as an image in the named graph, or an image instance name (wave name with "#n" appended to distinguish the nth image of the wave in the graph). You might get an image instance name from the ImageNameList function.

If imageWaveNameStr contains a wave name, instanceNumber identifies which instance you want information about. instanceNumber is usually 0 because there is normally only one instance of a wave displayed as an image in a graph. Set instanceNumber to 1 for information about the second image of the wave, etc. If imageWaveNameStr is "", then information is returned on the instanceNumberth image in the graph.

If imageWaveNameStr contains an instance name, and instanceNumber is zero, the instance is taken from imageWaveNameStr. If instanceNumber is greater than zero, the wave name is extracted from imageWaveNameStr, and information is returned concerning the instanceNumberth instance of the wave.
Details
The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon for ease of use with `StringByKey`. The keywords are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>AXISFLAGS</td>
<td>Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.</td>
</tr>
</tbody>
</table>
| COLORMODE | A number indicating how the image colors are derived:  
1: Color table (see Image Color Tables on page II-392).  
2: Scaled color index wave (see Indexed Color Details on page II-400).  
3: Point-scaled color index (See Example: Point-Scaled Color Index Wave on page II-401).  
4: Direct color (see Direct Color Details on page II-401).  
5: Explicit Mode (see ModifyImage explicit keyword).  
6: Color table wave (see Color Table Waves on page II-399). |
| RECREATION | Semicolon-separated list of `keyword=modifyParameters` commands for the ModifyImage command. |
| XAXIS     | X axis name. |
| XWAVE     | X wave name if any, else blank. |
| XWAVEDF   | The full path to the data folder containing the X wave or blank if there is no X wave. |
| YAXIS     | Y axis name. |
| YWAVE     | Y wave name if any, else blank. |
| YWAVEDF   | The full path to the data folder containing the Y wave or blank if there is no Y wave. |
| ZWAVE     | Name of wave containing Z data used to calculate the image plot. |
| ZWAVEDF   | The full path to the data folder containing the Z data wave. |

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “;”, prepend “ModifyImage “, replace the “x” with the name of a image plot (“data#1” for instance) and then Execute the resultant string as a command.

Example 1
This example gets the image information for the second image plot of the wave "jack" (which has an instance number of 1) and applies its ModifyImage settings to the first image plot.

```
#include <Graph Utility Procs>, version>=6.1 // For WMGetRECREATIONFromInfo

// Make two image plots of the same data on different left and right axes
Make/O/N=(20,20) jack=sin(x/5)+cos(y/4)
Display;AppendImage jack // bottom and left axes
AppendImage/R jack // bottom and right axes

// Put image plot jack#0 above jack#1
ModifyGraph axisEnab(left)={0.5,1},axisEnab(right)={0,0.5}

// Set jack#1 to use the Rainbow color table instead of the default Grays
ModifyImage jack#1 ctab={*,*,Rainbow,0}
```
Now we peek at some of the image information for the second image plot of the wave “jack” (which has an instance number of 1) displayed in the top graph:

```plaintext
Print ImageInfo("","jack",1)[69,148]  // Just the interesting stuff
;ZWAVE:jack;ZWADEF:root;:COLORMODE:1;RECREATION:ctab= {*,*},Rainbow,0;plane= 0;
// Apply the color table, etc from jack#1 to jack:
String info= WMGetRECREATIONFromInfo(ImageInfo("","jack",1))
info= RemoveEnding(info) // Remove trailing semicolon
// Use comma instead of semicolon separators
String text = ReplaceString(";", info, ",")
Execute "ModifyImage jack " + text
```

**Example 2**

This example gets the full path to the wave containing the Z data from which the first image plot in the top graph was calculated.

```plaintext
String info= ImageInfo("","");0) // 0 is index of first image plot
String pathToZ= StringByKey("ZWADEF",info)+StringByKey("ZWA",info)
Print pathToZ
root:jack
```

**Image Instance Names** on page II-403.

---

**ImageInterpolate**

**ImageInterpolate [flags] Method srcWave**

The ImageInterpolate operation interpolates the source srcWave and stores the results in the wave M_InterpolatedImage in the current data folder unless you specify a different destination wave using the /DEST flag.
Parameters

Method selects type of interpolation. Method is one of the following names:

**Affine2D**
Performs an affine transformation on srcWave using parameters specified by the /APRM flag. The transformation applies to a general combination of rotation, scaling, and translation represented by a 3x3 matrix

\[
M = \begin{bmatrix}
    r_{11} & r_{12} & t_x \\
    r_{21} & r_{22} & t_y \\
    0 & 0 & w
\end{bmatrix}
\]

The upper 2x2 matrix is a composite of rotation and scaling, \(tx\) and \(ty\) are composite translations and \(w\) is usually 1. It computes the dimensions of the output wave and then uses the inverse transformation and bilinear interpolation to compute the value of each output pixel. When an output pixel does not map back into the source domain it is set to the user-specified background value. It supports 2D and 3D input waves. If srcWave is a 3D wave it applies on a layer by layer basis.

The output is stored in the wave M_Affine in the current data folder.

**Bilinear**
Performs a bilinear interpolation subject to the specified flag. You can use either the /F or /S flag, but not both.

**Kriging**
Uses Kriging to generate an interpolated matrix from a sparse data set. Kriging calculates interpolated values for a rectangular domain specified by the /S flag. The Kriging parameters are specified via the /K flag.

Kriging is computed globally for a single user-selected variogram model. If there are significant spatial variances within the domain occupied by the data, you should consider subdividing the domain along natural boundaries and use a single variogram model in each subdivision.

If there are \(N\) data points, the algorithm first computes the NxN matrix containing the distances between the data and then inverts an associated matrix of similar size to compute the result for the selected variogram model. Because inversion of an NxN matrix can be computationally expensive, you should consider restricting the calculation to regions that are similar to the range implied by the variogram. Such an approach can also be justified in the sense that the local interpolation should not be affected by a remote datum.

**Note:** Kriging does not support data containing NaNs or INFs. Wave scaling has no effect.

**Pixelate**
Creates a lower resolution (pixelated) version of srcWave by averaging the pixels inside domain specified by /PXSZ flag. The results are saved in the wave M_PixelatedImage in the current data folder.

The computed wave has the same numeric type as srcWave so the averaging may be inaccurate in the case of integer waves.

When srcWave is a 3D wave you have the option of averaging only over data in each layer using /PXSZ=[nx,ny] or averaging over data in a rectangular cube using /PXSZ=[nx,ny,nz].

When not averaging over layers, the number of rows and columns of the new image are obtained by integer division of the original number by the respective size of the averaging rectangle and adding one more pixel for any remainder.

When averaging over layers the resulting rows and columns are obtained by truncated integer division ignoring remainders (if any).

See also **Multidimensional Decimation** on page II-98.
Resample
Computes a new image based on the selected interpolation function and transformation parameters. Set the interpolation function with the /FUNC flag. Use the /TRNS flag to specify transformation parameters for grayscale images, or /TRNR, /TRNG, and /TRNB for the red, green, and blue components, respectively, of RGB images. M_InterpolatedImage contains the output image in the current data folder.

There are currently two transformation functions: the first magnifies an image and the second applies a radial polynomial sampling. The radial polynomial affects pixels based on their position relative to the image center. A linear polynomial reproduces the same image. Any nonlinear terms contribute to distortion (or correction thereof).

Spline
Computes a 2D spline interpolation for 2D matrix data. The degree of the spline is specified by the /D flag.

Voronoi
Generates an interpolated matrix from a sparse data set (srcWave must be a triplet wave) using Voronoi polygons. It calculates interpolated values for a rectangular domain as specified by the /S or /RESL flags.

It first computes the Delaunay triangulation of X, Y locations in the Z=0 plane (assuming that X, Y positions occupy a convex domain in the plane). It then uses the Voronoi dual to interpolate the Z values for X and Y pairs from the grid defined by the /S flag. The computed grid may exceed the bounds of the convex domain defined by the triangulation. Interpolated values for points outside the convex domain are set to NaN or the value specified by the /E flag.

Use the /I flag to iterate to finer triangulation by subdividing the original triangles into smaller domains. Each iteration increases computation time by approximately a factor of two, but improves the smoothness of the interpolation.

If you have multiple sets of data in which X,Y locations are unchanged, you can use the /STW flag to store one triangulation and then use the /PTW flag to apply the precomputed triangulation to a new interpolation. To use this option you should use the Voronoi keyword first with a triplet wave for srcWave and set xn = x0 and yn = y0. The operation creates the wave W_TriangulationData that you use in the next triangulation with a 1D wave as srcWave.

Voronoi interpolation is similar to what can be accomplished with the ContourZ function except that it does not require an existing contour plot, it computes the whole output matrix in one call, and it has the option of controlling the subdivision iterations.

See Voronoi Interpolation Example below.

XYWaves
Performs bilinear interpolation on a matrix scaled using two X and Y 1D waves (specified by /W). The interpolation range is defined by /S. The data domain is defined between the centers of the first and last pixels (X in this example):

$$\text{xmin} = (xWave[0]+xWave[1])/2$$
$$\text{xmax} = (xWave[last]+xWave[last-1])/2$$

Values outside the domain of the data are set to NaN. The interpolation is contained in the M_InterpolatedImage wave, which is single precision floating point or double precision if srcWave is double precision.

Warp
Performs image warping interpolation using a two step algorithm with three optional interpolation methods. The operation warps the image based on the relative positions of source and destination grids. The warped image has the same size as the source image. The source and destination grids are each specified by a pair of 2D X and Y waves where the rows and columns correspond to the relative location of the source grid. The smallest supported dimensions of grid waves are 2x2. All grid waves must be double-precision floating point and must have the same number of points corresponding to pixel positions within the image. Grid waves must not contain NaNs or INFs. Wave scaling is ignored.

Flags

/APRM={r11,r12,tx,r21,r22,ty,w,background}

Sets elements of the affine transformation matrix and the background value.
/ATOL Allows ImageInterpolate to use a tolerance value if the result of the interpolation at any point is NaN. The algorithm returns the first non-NaN value it finds by adding or subtracting 1/10000th of the size of the X or Y interpolation step. At worst this algorithm is 5 times slower than the default algorithm if the interpolation is performed in a region which is completely outside the convex source domain.

/ATOL was added in Igor Pro 7.00.

/CMSH Use this flag in Voronoi interpolation to create a triangle mesh surface representing the input data. After triangulating the X, Y locations (in a plane z=const), the mesh is generated from a sequence of XYZ vertices of all the resulting triangles. The output is stored in the wave M_ScatterMesh in the current data folder. It is in the form of a triplet wave where every consecutive 3 rows represent a disjoint triangle.

If the input contains a NaN or INF in any column, the corresponding row is excluded from the triangulation.

If you want to generate this mesh without generating the interpolated matrix you can omit the /S flag.

/CMSH was added in Igor Pro 7.00.

/CSAF=factor In rare situations that usually involve spatial degeneracy, the Voronoi interpolation algorithm may need additional memory. You can use the /CSAF flag with an integer factor greater than 1 to increase the memory allocation.

/CSAF was added in Igor Pro 9.00.

/D=splineDeg Specifies the spline degree with the Spline method. The default spline degree is 2. Supported values are 2, 3, 4, and 5.

/DEST=destWave Specifies the wave to contain the output of the operation. If the specified wave already exists, it is overwritten.

Creates a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-72 for details.

/E=outerValue Assigns outerValue to all points outside the convex domain of the Delaunay triangulation. By default outerValue = NaN.

/F={fx,fy} Calculates a bilinear interpolation of all the source data. Here fx is the sampling factor for the X-direction and fy is the sampling factor in the Y-direction. The output number of points in a dimension is factor*(number of data intervals) +1. The number of data intervals is one less than the number of points in that dimension.

For example, if srcWave is a 2x2 matrix (you have a single data interval in each direction) and you use /F={2,2}, then the output wave is a 3x3 matrix (i.e., 2x2 intervals) which is a factor of 2 of the input. Sampling factors can be noninteger values.

/FDS Performs spline interpolation to a “local” cubic spline that depends only on the 2D neighboring data. The interpolation goes exactly through the original data and provides continuity of the function and its first derivative. The second derivative is set to vanish on the boundary. The implemented algorithm was provided by Francis Dalaudier. /FDS was added in Igor Pro 7.00.

/FEQS When performing Voronoi interpolation, forces the algorithm to use equal scaling for both axes. Normally the scaling for each axis is determined from its range. When the ranges of the two axes are different by an order of magnitude or more, it is helpful to force the larger range to be used for scaling both axes.
Specifies the interpolation function. `funcName` can be:

- **nn**: Nearest neighbor interpolation uses the value of the nearest neighbor without interpolation. This is the fastest function.
- **bilinear**: Bilinear interpolation uses the immediately surrounding pixels and computes a linear interpolation in each dimension. This is the second fastest function.
- **cubic**: Cubic polynomial (photoshop-like) uses a 4x4 neighborhood value to compute the sampled pixel value.
- **spline**: Spline smoothed sampled value uses a 4x4 neighborhood around the pixel.
- **sinc**: Slowest function using a 16x16 neighborhood.

Specifies the number of times the original triangulation is subdivided with the Voronoi interpolation method. By default the Voronoi interpolation computes the original triangulation without subdivision.

Specifies the variogram parameters for kriging using standard notation, models are expressed in terms of the nugget value $C_0$, sill value $C_0 + C_1$, and range $a$.

![Variogram Diagram]

- **model**: Selects the variogram model. Values and models are:
  1. Spherical. $\gamma(h) = C_0 + C_1 \cdot (3h/2a - 0.5 \cdot h^3/a^3)$
  2. Exponential. $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot h/a])$
  3. Gaussian. $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot (h/a)^2])$

- **nugget**: Specifies the lowest value in the variogram.
- **sill**: Specifies the maximum (plateau) value in the variogram range the characteristic length of the different variogram models.

Wave scaling has no effect on kriging calculations.

In Voronoi interpolation, controls the rectangular neighborhood about each datum position XY where the algorithm returns the original Z-value. The tolerance value $0 \leq tol < 1$ is tested separately in X and Y (i.e., it is not a geometric distance) when both X and Y are normalized to the range [0,1]. By default $tol=1e-15$.

Added in Igor Pro 7.00.

Uses a previous triangulation wave with Voronoi interpolation. `tWave` will be the wave saved by the `/STW` flag. You can’t use a triangulation wave that was computed and saved on a different computer platform.

See **PTW Flag Example** on page V-388.
/PXSZ={nx, ny} Specifies the size in pixels of the averaging rectangle used by the Pixelate operation. nx is the number of rows and ny is the number of columns that are averaged to yield a single output pixel. If srcWave is a 3D wave the resulting wave has the same number of layers as srcWave with pixelation computed on a layer-by-layer basis.

/PXSZ={nx, ny, nz} Specifies the size in pixels of the averaging rectangle used by the Pixelate operation. nx is the number of rows and ny is the number of columns and nz is the number of layers that are averaged to yield a single output pixel.

This form of the /PXSZ flag was added in Igor Pro 7.00.

/RESL={nx, ny} Specifies resampling the full input image to an output image having nx rows by ny columns.

/S={x0, dx, xn, y0, dy, yn} Calculates a bilinear interpolation of a subset of the source data. Here x0 is the starting point in the X-direction, dx is the sampling increment, xn is the end point in the X-direction and the corresponding values for the Y-direction. If you set x0 equal to xn the operation will compute the triangulation but not the interpolation.

/SPRT Skips the XY perturbation step. The perturbation step is designed to break degeneracies that originate when the XY data are sampled on a rectangular grid. If your data are not sampled on a rectangular grid you can skip the perturbation and get better accuracy in reproducing the Z-values at the sampled locations. See also ModifyContour with the keyword Perturbation.

Added in Igor Pro 7.00.

/STW Saves the triangulation information in the wave W_TriangulationData in the current data folder. W_TriangulationData can only be used on the computer platform where it was created.

/SV Saves the Voronoi interpolation in the 2D wave M_VoronoiEdges, which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle containing the convex domain.

/TRNS={transformFunc, p1, p2, p3, p4} Determines the mapping between a pixel in the destination image and the source pixel. transformFunc can be:

- scaleShift Sets image scaling which could be anamorphic if the X and Y scaling are different.
- radialPoly Corrects both color as well as barrel and pincushion distortion. In radialPoly the mapping from a destination pixel to a source pixel is a polynomial in the pixel’s radius relative to the center of the image.

A source pixel, sr, satisfies the equation:

\[ sr = ar + br^2 + cr^3 + dr^4, \]

where r is the radius of a destination pixel having an origin at the center of the destination image.

The corresponding parameters are:

<table>
<thead>
<tr>
<th>transformFunc</th>
<th>p1</th>
<th>p2</th>
<th>p3</th>
<th>p4</th>
</tr>
</thead>
<tbody>
<tr>
<td>scaleShift</td>
<td>xOffset</td>
<td>xScale</td>
<td>yOffset</td>
<td>yScale</td>
</tr>
<tr>
<td>radialPoly</td>
<td>a</td>
<td>b</td>
<td>c</td>
<td>d</td>
</tr>
</tbody>
</table>

/U=uniformScale Calculates a bilinear interpolation of all the source data as with the /F flag but with two exceptions: A single uniform scale factor applies in both dimensions, and the scale factor applies to the number of points — not the intervals of the data.
Flags for Warp

/W=xWave,yWave\] Provides the scaling waves for XYWaves interpolation. Both waves must be monotonic and must have one more point than the corresponding dimension in srcWave. The waves contain values corresponding to the edges of data points in srcWave, so that the X value at the first data point is equal to (xWave[0]+xWave[1])/2.

Details

When computing Bilinear or Spline interpolation srcWave can be a 2D or a 3D wave. When srcWave is a 3D wave the interpolation is computed on a layer by layer basis and the result is stored in a corresponding 3D wave. When the interpolation method is Kriging or Voronoi, srcWave is a 2D triplet wave (3-column wave) where each row specifies the X, Y, Z values of a datum. srcWave can be of any real data type. Results are stored in the wave M_InterpolatedImage. If srcWave is double precision so is M_InterpolatedImage; otherwise M_InterpolatedImage is a single precision wave.

Voronoi Interpolation Example

Function DemoVoronoiInterpolation()
Make/O/N=(100,3) sampleTriplet
sampleTriplet[[0]]=enoise(5)
sampleTriplet[[1]]=enoise(5)
sampleTriplet[[2]]=sqrt(sampleTriplet[p][0]^2+sampleTriplet[p][1]^2)

// Interpolate the data to a rectangular grid of 50x50 pixels
ImageInterpolate/RESL={50,50}/DEST=firstImage voronoi sampleTriplet

// Triangulate the XY locations and save the triangulation wave
ImageInterpolate/STW voronoi sampleTriplet

// Use the previous triangulation on the Z column of the sample
MatrixOp/O zData=col(sampleTriplet,2)
Wave W_TriangulationData
ImageInterpolate/PTW=W_TriangulationData/RESL={50,50}/DEST=secondImage voronoi zData
End

PTW Flag Example

Function DemoPTW()
// Create some random data
Make/O/N=(100,3) eee = enoise(5)

// Compute triangulation wave
ImageInterpolate/RESL={1,1}/STW voronoi eee
Wave W_TriangulationData

// Copy the Z-column to a 1D wave
MatrixOp/O e3 = col(eee,2)

// Use the previous triangulation with 1D wave
ImageInterpolate/PTW=W_TriangulationData/RESL={100,100} voronoi e3
Wave M_InterpolatedImage
Duplicate/O M_InterpolatedImage, oneD

// Direct computation for comparison
ImageInterpolate/RESL={100,100} voronoi eee
The ImageLineProfile operation provides sampling of a source image along an arbitrary path specified by the two waves: xWave and yWave. The arbitrary path is made of line segments between every two consecutive vertices of xWave and yWave. In each segment the profile is calculated at a number of points (profile points) equivalent to the sampling density of the original image (unless the /V flag is used). Both xWave and yWave should have the same scaling as srcWave. If srcWave does not have the same scaling in both dimensions you should remove the scaling to compute an accurate profile.

At each profile point, the profile value is calculated by averaging samples along the normal to the profile line segment. The number of samples in the average is determined by the keyword width. The operation actually averages the interpolated values at N equidistant points on the normal to profile line segment, with N=2(width+0.5). Samples outside the domain of the source image do not contribute to the profile value.

The profile values are stored in the wave W_Ima

gLineProfile. The actual locations of the profile points are stored in the waves W_LineProfileX and W_LineProfileY. The scaled distance measured along the path is stored in the wave W_LineProfileDisplacement.

When the averaging width is greater than zero, the operation can also calculate at each profile point the standard deviation of the values sampled for that point (see /S flag). The results are then stored in the wave W_LineProfileStdv. When using this operation on 3D RGB images, the profile values are stored in the 3 column waves M_Ima

gLineProfile and M_LineProfileStdv respectively.

Parameters

srcWave=srcWave

Specifies the image for which the line profile is evaluated. The image may be a 2D wave of any type or a 3D wave or RGB data.

xWave=xwave

Specifies the wave containing the x coordinate of the line segments along the path.

yWave=ywave

Specifies the wave containing the y coordinate of the line segments along the path.

width=value

Specifies the width (diameter) in pixels (need not be an integer value) in a direction perpendicular to the path over which the data is interpolated and averaged for each path point. If you do not specify width or use width=0, only the interpolated value at the path point is used.

widthWave=wWave

Specifies the width of the profile (see definition above) on a segment by segment basis. wWave should be a 1D wave that has the same number of entries as xWave and yWave. If you provide a widthWave any value assigned with the width keyword is ignored. All values in the wave must be positive and finite.
Flags

/IRAD=nRadIntervals

/IRAD was added in Igor Pro 9.00.

Use /IRAD to estimate the integrated intensity for an annular domain defined by the /RAD flag and the width parameter. For example, to integrate the intensity in the annular domain centered around Xc=50, Yc=50 for the radial range [24,25]:

```
Make/O/N=(100,100) ddd=sqrt((x-50)^2+(y-50)^2)
ImageLineProfile/RAD={50,50,24.5,.5,.001}/IRAD=100 srcWave=ddd
Print V_integral
```

/P=plane

Specifies which plane (layer) of a 3D wave is to be profiled. By default plane =-1 and the profiles are of either the single layer of a 2D wave or all three layers of a 3D RGB wave. Use plane =-2 if you want to profile all layers of a 3D wave.

/RAD={Xc, Yc, RADc, radWidth [, deltaAngle]}

/RAD was added in Igor Pro 9.00.

Use /RAD to compute a circular profile that is centered at (Xc,Yc) with a radius RADc. Xc, Yc, and RADc are expressed in terms of the scaled coordinates.

radWidth is in units of image pixels.

deltaAngle is the angle increment between samples in radians. If you omit it, the operation first computes the maximum radius (if width>0) and then computes the increment angle such that there are 5 (linearly interpolated) samples per path pixel. If your image data is relatively smooth you could reduce this sampling by specifying a large deltaAngle.

Here is an example using /RAD:

```
Make/O/N=(100,100) ddd=x*y // Default scaling
ImageLineProfile/RAD={50,50,24.5,0} srcWave=ddd
Display W_ImageLineProfile
```

/S

Calculates standard deviations for each profile point.

/SC

Saves W_LineProfileX and W_LineProfileY using the X and Y scaling of srcWave.

/V

Calculate profile points only at the vertices of xWave and yWave.

Examples

Make/N=(50, 50) sampleData
sampleData = sin((x-25) / 10) * cos((y-25) / 10)
NewImage sampleData
Make/n=2 xTrace={0,50} ,yTrace={20,20}
ImageLineProfile srcWave=sampleData, xWave=xTrace, yWave=yTrace
AppendtoGraph/T yTrace vs xTrace
Display W_ImageLineProfile

See Also

For additional examples see ImageLineProfile Operation on page III-372.

ImageLoad

ImageLoad [flags] [fileNameStr]

The ImageLoad operation loads an image file into an Igor wave. It can load PNG, JPEG, BMP, TIFF, and Sun Raster Files.

Parameters

The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.
If you use a full or partial path for `fileNameStr`, see Path Separators on page III-451 for details on forming the path.

If you want to force a dialog to select the file, omit the `fileNameStr` parameter or pass "" for it.

**Flags**

/AINF

Loads all of the image files in a disk folder into the current data folder. For example, if you have created an Igor symbolic path named `ImagePath` that points to a folder containing image files, you can execute:

```
ImageLoad/P=ImagePath/T=TIFF/AINF
```

When using /AINF, you must omit `fileNameStr` and you must include /T to specify the type of image file to be loaded.

This flag requires Igor Pro 7.03 or later.

/BIGT=mode

When mode is 1, ImageLoad uses the LibTIFF library to load TIFF files. This is the default if you omit /BIGT. The LibTIFF library supports the traditional TIFF file format and the Big TIFF file format, which supports file sizes greater than 4 GB and files containing compressed data.

When mode is 0, ImageLoad uses Igor’s internal TIFF code to load image data. This internal code does not support Big TIFF and is limited to file sizes less than 2 GB.

If you omit /BIGT, ImageLoad first attempts to load the file using LibTIFF. If an error occurs, it automatically attempts to load the file using Igor’s internal TIFF code.

The /SCNL, /STRP and /TILE flags require using LibTIFF. If you use any of these flags, /BIGT=1 is automatically in effect.

The /RAT and /RTIO flags require using Igor’s internal TIFF code. If you use these flags, /BIGT=0 is automatically in effect.

See Loading TIFF Files below for more information about supported data types.

/C=count

Specifies the number of images to load from a TIFF stack containing multiple images. The images are stored in individual waves if /LR3D is omitted or in a single 3D wave if /LR3D is present.

By default, it loads only a single image (i.e., /C=1). Use /C=-1 to load all images. Images must be either 8 bits, 16 bits, or 32 bits/pixel for this option.

To load a subset of the images in a TIFF stack, use /S to specify the starting image.

If you specify a count that exceeds the number of images in the file, ImageLoad loads all images beginning with the first image or the image specified by /S.

/G

Displays the loaded image in a new image plot window.

/LR3D

Specifies that the images in a TIFF stack are to be loaded into a 3D wave rather than into multiple 2D waves. This option works with grayscale images only, not with full color (e.g., RGB).

To load a subset of the images into the 3D wave, also use /S and /C.

/LTMD

Reads data stored in TIFF tags belonging to the main Image File Directory. /LTMD works only when you use /BIGT=1 and is ignored otherwise. It was added in Igor Pro 8.00.

/LTMD creates a data folder named "Tagn" for each loaded image. The name of the data folder has the numeric suffix n starting from zero.

The "Tagn" data folder contains a text wave named T_Tags where each row contains the metadata associated with a single tag. The order of the rows in the wave T_Tags is indeterminate.

If you need to parse the metadata, you can search for the tag descriptor which always appears at the start of the line and is followed by a colon and one space (": ").
ImageLoad

/N=baseName Stores the waves using baseName as the wave name. Only when baseName conflicts with an existing wave name will a numeric suffix be appended to the new wave names.

If you omit /N, ImageLoad uses the name of the file as the base name.

/O Overwrites an existing wave with the same name.

If you omit /O and there is an existing wave with the same name, a numeric suffix is appended to the image name to create a unique name.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/Q Quiet mode. Suppresses printing a description of the loaded data to the history area.

/RAT Read All Tags reads all of the tags in a TIFF file into one or more waves.

If you use /RAT, /BIGT=0 is automatically in effect. To load tags with /BIGT=1, use /LTMD instead of /RAT.

/RAT creates a data folder named “Tagn” with a numeric suffix, n, starting from zero for each loaded image. When reading multiple images from a stack TIFF file, /RAT creates a corresponding number of data folders.

Each data folder contains a text wave named T_Tags consisting of 5 columns. The first row contains the offset of the current Image File Directory (IFD) from the start of the file. The remaining rows describe the individual TIFF Tags as they appear in the IFD.

The first column contains the tag number, the second contains the tag description, the third contains the tag type, the fourth contains the tag length, and the fifth contains either the value of the tag or a statement identifying the name of the wave in which the data was stored. For example, a simple tag that contains a single value has the form:

<table>
<thead>
<tr>
<th>Num</th>
<th>Desc</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>256</td>
<td>IMAGEWIDTH</td>
<td>4</td>
<td>1</td>
<td>2560</td>
</tr>
</tbody>
</table>

A tag that contains more data, such as an array of values has the form:

<table>
<thead>
<tr>
<th>Num</th>
<th>Desc</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>273</td>
<td>STRIPOFFSETS</td>
<td>4</td>
<td>-120</td>
<td>tifTag273</td>
</tr>
</tbody>
</table>

Here the Length field is negative (-1*realLength) and the Value field contains the name of the wave tifTag273 which contains the array of strip offsets.

When the Value field consists of ASCII characters it is stored in the T_Tags wave itself. All other types are stored in a wave in the same Tag data folder.

Private tags are usually designated by negative tag numbers. If their data type is anything other than ASCII, they are saved in separate waves.

In Igor Pro 9.01 and later, /RAT sets the S_dataFolder output variable to the path to the data folder where the tag information is stored.

/RONI Stores the number of images in a TIFF stack file in the variable V_numImages. No images are loaded from the file. This file is not compatible with /BIGT=0. /RONI was added in Igor Pro 9.00.
ImageLoad

/RTIO  Reads tag information only from a TIFF file. /RTIO is similar to /RAT but it loads tag information only without loading any images.

If you use /RTIO, /BIGT=0 is automatically in effect. To load tags with /BIGT=1, use /LTMD instead of /RAT.

If you are loading a stack of images you can use the /C and /S flags to obtain tags from a specific range of images.

/S=start  Specifies the first image to load from a TIFF stack containing multiple images.

start is zero-based and defaults to 0.

Use /C to specify the number of images to load.

/SCNL=num  Reads the specified scanline from a TIFF file using LibTiff.

Added in Igor Pro 7.00.

/STRP=num  Reads the specified strip from a TIFF file using LibTiff.

Added in Igor Pro 7.00.

/T=type  Identifies what kind of image file to load. type is one of the following image file formats:

<table>
<thead>
<tr>
<th>type</th>
<th>Loads this Image Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>any</td>
<td>Any graphic file type</td>
</tr>
<tr>
<td>bmp</td>
<td>Windows bitmap file</td>
</tr>
<tr>
<td>jpeg</td>
<td>JPEG file</td>
</tr>
<tr>
<td>png</td>
<td>PNG file</td>
</tr>
<tr>
<td>rpng</td>
<td>Raw PNG file (see Details)</td>
</tr>
<tr>
<td>sunraster</td>
<td>Sun Raster file</td>
</tr>
<tr>
<td>tiff</td>
<td>TIFF file (see also Loading TIFF Files).</td>
</tr>
</tbody>
</table>

If you omit /T or specify /T=any, Igor makes a guess based on the file name extension. ImageLoad reports an error if it is unable to determine the image file type.

/T=any allows the user to choose any file, regardless of its file name extension, if ImageLoad displays an Open File dialog.

When loading TIFF, we recommend that you use /T=tiff. See Loading TIFF Files below for details.

/TILE=num  Reads the specified tile from a TIFF file using LibTiff.

Added in Igor Pro 7.00.

/Z  No error reporting.

Details

The name of the wave created by ImageLoad is based on the file name or on basename if you provide the /N=basename flag. In either case, if and only if there is a name conflict, ImageLoad appends a number to create a unique wave name.

If you use /P=pathname, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1.” or “C:\Folder1”. See Symbolic Paths on page II-22 for details.
Output Variables

ImageLoad sets the following variables:

\[ V_{\text{flag}} \]  Set to 1 if the image was successfully loaded or to 0 otherwise.

\[ S_{\text{fileName}} \]  Set to the name of the file that was loaded.

\[ S_{\text{path}} \]  Set to the file system path to the folder containing the file. S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

\[ V_{\text{numImages}} \]  Set to the number of images loaded. Applies to TIFF files only.
   Also set by /RONI flag.

\[ S_{\text{info}} \]  When using /BIGT=1, S_info contains the text stored in the IMAGEDESCRIPTION (270) TIFF tag. See /RAT and /LTMD above for other tag data.

\[ S_{\text{dataFolder}} \]  Set by the /RAT flag to the path to the data folder where the tag information is stored. Added in Igor Pro 9.01.

\[ S_{\text{waveNames}} \]  Set to a semicolon-separated list of the names of loaded waves.

Loading PNG Files

If you use /T=rpng ("raw PNG") or if you omit /T and the file as a .png extension, ImageLoad interprets the PNG file as raw data.

We recommend that you use /T=rpng and use /T=png only if /T=rpng does not produce the desired results.

/T=rpng creates an 8-bit or 16-bit unsigned integer wave with 1 to 4 layers.

PNG images with physical units produce waves with X and Y units of meters.

If a PNG image has a color table, ImageLoad creates two waves: a main image wave with one layer and a color table wave of the same name but with an ".pal" suffix. If the name is too long it creates a wave named PNG_pal instead.

Loading TIFF Files

ImageLoad/BIGT=0 supports 1-bit, 8-bit, 16-bit, 24-bit, and 32-bit TIFF files as well as floating point TIffs.

- 1-bit/pixel images are loaded into a unsigned byte waves
- 8-bit/pixel images are loaded into a unsigned byte waves
- 16-bit/pixel images are loaded into unsigned 16-bit waves
- 24-bit/pixel images and 32-bit/pixel images loaded into 3D RGB and RGBA waves respectively

ImageLoad/BIGT=1 supports the following data formats:

- 8-bit/sample signed or unsigned
- 12-bits/sample (packed into 16-bit unsigned)
- 16-bit/sample signed or unsigned
- 32-bit/sample IEEE single precision floating point, signed integer or unsigned integer
- 64-bit/sample IEEE double precision floating point, signed integer or unsigned integer

Loading a TIFF File With a Color Table

If your TIFF file includes a color table, ImageLoad/T=tiff/BIGT=0 loads the data into a 2D wave and loads the color table into a separate color table wave which can be used when creating an image plot.

If you want to load the TIFF file into a 3D RGB wave, use /T=tiff to load it into a 2D wave plus a color table and then use ImageTransform cmap2RGB to create the 3D RGB wave.

Loading TIFF Stacks

A TIFF stack is a TIFF file that contains multiple images. When loading a stack, you can:

- Load all images
- Load a range of images specified by /S (starting image) and /C (image count)

You can also load the images into:
• Separate 2D waves by omitting the /LR3D flag
• A single 3D wave by using the /LR3D flag

When you use /LR3D, ImageLoad stores each image from the TIFF file in a layer of the 3D output wave. This option works with grayscale images only, not with full color (e.g., RGB).

EXIF Metadata
Some applications embed metadata (information about the image) in EXIF format. In both JPEG and TIFF files, the metadata is stored using TIFF tags. To read the metadata, use the /RAT flag, even if you are loading a JPEG file.

Examples
// Load all images from a TIFF stack into separate 2D waves
ImageLoad /C=-1 /T=TIFF

// Load a single image from a TIFF stack into a 2D wave
ImageLoad/S=10/C=1/T=TIFF       // Load image 10 (zero based)

// Load all images from a TIFF stack into a single 3D wave
ImageLoad/LR3D/S=0/C=-1/T=TIFF

// Read all tags without loading any images
ImageLoad/C=-1/T=TIFF/RTIO

// Get the number of images in a TIFF stack
NewDataFolder/O/S tmp
ImageLoad/C=-1/T=TIFF/RTIO
Print V_numImages
KillDataFolder :

The ImageSave operation for saving waves as image files.

ImageMorphology

ImageMorphology [flags] Method imageMatrix

The ImageMorphology operation performs one of several standard image morphology operations on the source imageMatrix. Unless the /O flag is specified, the resulting image is saved in the wave M_ImageMorph. The operation applies only to waves of type unsigned byte. All ImageMorphology methods except for watershed use a structure element. The structure element may be one of the built-in elements (see /E flag) or a user specified element.

Erosion, Dilation, Opening, and Closing are the only methods supported for a 3D imageMatrix.

Parameters
Method is one of the following names:

- BinaryErosion: Erodes the source binary image using a built-in or user specified structure element (see /E and /S flags).
- BinaryDilation: Dilates the source binary image using a built-in or user specified structure element (see /E and /S flags).
- Closing: Performs the closing operation (dilation followed by erosion). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent, which means that there is no point of executing it more than once.
- Dilation: Performs a dilation of the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.
- Erosion: Erodes the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.
ImageMorphology

Opening  Performs an opening operation (erosion followed by dilation). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent which means that there is no point of executing it more than once.

TopHat  Calculates the difference between the eroded image and dilated image using the same structure element.

Watershed  Calculates the watershed regions for grayscale or binary image. Use the /N flag to mark all nonwatershed lines as NaNs. The /L flag switches from using 4 neighboring pixels (default) to 8 neighboring pixels.

Flags

/E=id  Uses a particular built in structure element. The following are the built-in structure elements; make sure to use the appropriate id for the dimensionality of imageMatrix:

<table>
<thead>
<tr>
<th>id</th>
<th>Element</th>
<th>Origin</th>
<th>Shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2x2</td>
<td>(0,0)</td>
<td>square (default)</td>
</tr>
<tr>
<td>2</td>
<td>1x3</td>
<td>(1,1)</td>
<td>row (in 3x3 square)</td>
</tr>
<tr>

<td>7x7x7</td>
<td>(3,3,3)</td>
<td>symmetric ball</td>
</tr>
</tbody>
</table>

Note that this flag has no effect on watershed calculations.

/I= iterations  Repeats the operation the specified number of iterations.

/L  Uses 8-connected neighbors instead of 4.
Examples
If you would like to apply a morphological operation to a wave whose data type is not an unsigned byte and you wish to retain the wave’s dynamic range, you can use the following approach:

```
Function ScaledErosion(inWave)
    Wave inWave
    WaveStats/Q inWave
    Variable nor=255/(V_max-V_min)
    MatrixOp/O tmp=nor*(inWave-V_min)
    Redimension/B/U tmp
    ImageMorphology/E=5 Erosion tmp
    Wave M_ImageMorph
    MatrixOp/O inWave=(M_ImageMorph/nor)+V_min
    KillWaves/Z tmp,M_ImageMorph
End
```

See Also
The ImageGenerateROIMask operation for creating ROIs. For details and usage examples see Morphological Operations on page III-368 and Particle Analysis on page III-375.

ImageNameList
```
ImageNameList(graphNameStr, separatorStr)
```
The ImageNameList function returns a string containing a list of image names in the graph window or subwindow identified by graphNameStr.
**ImageNameToWaveRef**

*Parameters*

`graphNameStr` can be "" to refer to the top graph window.

When identifying a subwindow with `graphNameStr`, see [Subwindow Syntax](page-III-92) for details on forming the window hierarchy.

`separatorStr` should contain a single ASCII character such as “,” or “;” to separate the names.

An image name is defined as the name of the 2D wave that defines the image with an optional #ddd suffix that distinguishes between two or more images that have the same wave name. Since the image name has to be parsed, it is quoted if necessary.

**Examples**

The following command lines create a very unlikely image display. If you did this, you would want to put each image on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack,'jack # 2';
Display;AppendImage jack
AppendImage/T/R jack
AppendImage 'jack # 2'
AppendImage/T/R 'jack # 2'
Print ImageNameList("",";"

prints jack;jack#1;'jack # 2';'jack # 2'#1;
```

**See Also**

Another command related to images and waves: ImageNameToWaveRef.

For commands referencing other waves in a graph: TraceNameList, WaveRefIndexed, XWaveRefFromTrace, TraceNameToWaveRef, CsrWaveRef, CsrXWaveRef, ContourNameList, and ContourNameToWaveRef.

**ImageNameToWaveRef**

*ImageNameToWaveRef*(`graphNameStr`, `imageNameStr`)  
The ImageNameToWaveRef function returns a wave reference to the 2D wave corresponding to the given image name in the graph window or subwindow named by `graphNameStr`.

*Parameters*

`graphNameStr` can be "" to refer to the top graph window.

When identifying a subwindow with `graphNameStr`, see [Subwindow Syntax](page-III-92) for details on forming the window hierarchy.

The image is identified by the string in `imageNameStr`, which could be a string determined using ImageNameList. Note that the same image name can refer to different waves in different graphs.

**See Also**

The ImageNameList function.

For a discussion of wave references, see Wave Reference Functions on page IV-197.

**ImageRegistration**

*ImageRegistration*  
`flags` [`testMask=testMaskWave`] [`refMask=refMaskWave`]  
`testWave=imageWave1, refWave=imageWave2`

The ImageRegistration operation adjusts the test image wave, `testWave`, to match the reference image wave, `refWave`, possibly subject to auxiliary mask waves. The registration may involve offset, rotation, scaling or skewing.

Image data may be in two or three dimensions.

ImageRegistration is designed to find accurate registration for relatively small variation on the order of a few degrees of rotation and a few pixels offset between the reference and test images.

All the input waves are expected to be single precision float (SP) so you may have to redimension your images before using ImageRegistration.
ImageRegistration does not tolerate NaNs or INFs; use the masks if you need to exclude pixels from the registration process.

**Parameters**

- **refMask=refMaskWave**: Specifies an optional ROI wave used to mask refWave. Omit refMask to use all of the refWave.
  - The wave must have the same dimensions as refWave. refMask is a single precision floating point wave with nonzero entries marking the “ON” state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.

- **refWave=imageWave2**: Specifies the name of the reference image wave used to adjust testWave.

- **testMask=testMaskWave**: Specifies an optional ROI wave used to mask testWave. Omit testMask to use all of the testWave.
  - The wave must have the same dimensions as refWave. testMask is a single precision floating point wave with nonzero entries marking the “ON” state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.

- **testWave=imageWave1**: Specifies the name of the image wave that will be adjusted to match refWave.

**testMaskWave** and **refMaskWave** are optional ROI waves. The waves must have the same dimensions as testWave and refWave respectively. They must be single precision floating point waves with nonzero entries marking the “ON” state. If you need to include the whole region described by testWave or the whole region described by refWave you can omit the respective mask wave.

**Flags**

- **/ASTP=val**
  - Sets the adaptation step for the Levenberg-Marquardt algorithm. Default value is 4.

- **/BVAL=val**
  - Enables clipping and sets the background values to which masked out voxels of the test data will be set.

- **/CONV=val**
  - Sets the convergence method.
    - **val=0**: Gravity, use if the difference between the images is only in translation. This option is frequently useful as a first step when the test and reference data are too far apart for accurate registration. The result of this registration is then passed to a subsequent ImageRegistration with /CONV=1.
    - **val=1**: Marquardt.

- **/CSNR=val**
  - Determines if the operation calculates the signal to noise ratio (SNR)
    - **val=0**: The SNR is not calculated.
    - **val=1**: The SNR is calculated (default).
  - Skipping the SNR calculation saves time and may be particularly useful when performing the registration on a stack of images.

- **/FLVL=val**
  - Specifies the finest level on which the optimization is to be performed.
    - If this is the same as /PRDL, then only the coarsest registration calculation is done.
    - If /FLVL=1 (default), then the full multiresolution pyramid is processed. You can use this flag to terminate the computation at a specified coarseness level greater than 1.

- **/GRYM**
  - Optimizes the gray level scaling factor.
    - It is sometimes dangerous to let the program adjust for gray levels because in some situations it might result in a null image.

- **/GGRYR**
  - Renders output using the gray scaling parameter. This is more meaningful if the operation computes the optimal gray scaling (see /GRYM).
Sets the three fields to the half-width of a Gaussian window that is used to smooth the data when computing the default masks. Defaults are \{1,1,1\}. See /REFM and /TSTM for more details.

Sets the interpolation method.

\begin{itemize}
  \item \textbf{val=0}: Nearest neighbor. Used when registering the center of gravity of the test and reference images.
  \item \textbf{val=1}: Trilinear.
  \item \textbf{val=2}: Tricubic (default).
\end{itemize}

Optimizes the isometric scaling. This option is inappropriate if voxels are not cubic.

Computes the multiresolution pyramid with isotropic size reduction. If the flag is not specified, the size reduction is in the XY plane only.

Sets the minimum gain at which the computations will stop. Default value is zero, but you can use a slightly larger value to stop the iterations earlier.

Sets mask combination value. During computation the masks for the test data and the mask for the reference data are also transformed. This flag determines how the two masks are to be combined. The registration criteria are computed for the combination of the two masks.

\begin{itemize}
  \item \textbf{val=0}: or.
  \item \textbf{val=1}: nor.
  \item \textbf{val=2}: and (default).
  \item \textbf{val=3}: nand.
  \item \textbf{val=4}: xor.
  \item \textbf{val=5}: nxor.
\end{itemize}

Specifies the depth of the multiresolution pyramid. The finest level is \textit{depth}=1. Each level of the pyramid decreases the resolution by a factor of 2. By default, the pyramid \textit{depth}=4, which corresponds to a resolution reduction by a factor of \(2^{(\text{depth}-1)}=8\).

The algorithm starts by computing the first registration on large scale features in the image (deepest level of the pyramid). It then makes small corrections to the registration at each consecutive pyramid level.

For best results, the coarsest representation the data should be between 30 and 60 pixels on a side. For example, for an image that is \(H\) by \(V\) pixels, you should choose the depth such that \(H/2^{(\text{depth}-1)} \approx 30\).

When performing registration of a stack of images, use this flag to apply the registration parameters of the previous layer as the initial guess for the registration of each layer after the first in the 3D stack.

Quiet mode; no messages printed in the history area.

Sets the reference mask.

\begin{itemize}
  \item \textbf{val=0}: To leave blank and then every pixel is taken into account.
  \item \textbf{val=1}: Value will be set if a valid reference mask is provided.
  \item \textbf{val=2}: The test mask is computed (default).
\end{itemize}

When computing the reference mask it is assumed that brighter features are more important. This is done by using a low pass filter on the data (using the parameters in /GWDT) which is then converted into a binary mask. Note that you do not need to specify /REFM=1 if you are providing a reference mask wave. See also /TSTM.
ImageRegistration will register images that have sufficiently similar features. It will not work if key features are too different. For example, ImageRegistration can handle two images that are rotated relative to each other by a few degrees, but cannot register images if the relative rotation is as large as 45 degrees. The algorithm is capable of subpixel resolution but it does not handle large variations between the test image and the reference image. If the centers of the two images are too far from each other, you should first try ImageRegistration using /CON=0 to remove the translation offset before proceeding with a finer registration of details.

The algorithm is based on an iterative processing that proceeds from coarse to fine detail. Optimization uses a modified Levenberg-Marquardt algorithm and produces an affine transformation for the relative rotation.

/SKEW={skewX,skewY,skewZ}

Determines if optimization will take into account skewness about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding skewness parameter. Defaults are {0,0,0}. Note that skewing and rotation or isometric scaling are mutually exclusive operations.

/STCK

Use /STCK to perform the registration between a 2D reference image and each of the layers in a 3D image. The number of rows and columns of the refWave must match exactly the number of rows and columns in testWave. The transformation parameters are saved in the wave M_RegParams where each column contains the parameters for the corresponding layer in testWave.

/STRT=val

Sets the first value of the adaptation parameter in the Levenberg-Marquardt algorithm. The default value of this parameter is 1.

/TRNS={transX,transY,transZ}

Determines if optimization will take into account translation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding translation parameter. Defaults are {1,1,0}, which are appropriate for finding the X and Y translations of an image.

/TSTM=val

Sets the test mask.

val=0: To leave blank and then every pixel is taken into account.
val=1: This value will be set if a valid reference mask is provided.
val=2: The reference mask is computed. This is the default value.

The test image mask is computed in the same way as the reference image mask (see /REFM) using the same set of smoothing parameters. Note that you do not need to specify /TSTM=1 if you are providing a test mask wave.

/USER=pWave

Provides a user transformation that will be applied to the input testWave in order to create the transformed image. pWave must be a double precision wave which contains the same number of rows as W_RegParams.

Note: If you use a previously created W_RegParams make sure to change its name as it is overwritten by the operation.

If pWave has only one column and testWave contains multiple layers, then the same transformation applies to all layers. If pWave contains more than one column, then each layer of testWave is processed with corresponding column. If there are more layers than columns the first column is used in place of the missing columns.

/ZMAN

Modifies the test and reference data by subtracting their mean values prior to optimization.

Details

ImageRegistration will register images that have sufficiently similar features. It will not work if key features are too different. For example, ImageRegistration can handle two images that are rotated relative to each other by a few degrees, but cannot register images if the relative rotation is as large as 45 degrees. The algorithm is capable of subpixel resolution but it does not handle large variations between the test image and the reference image. If the centers of the two images are too far from each other, you should first try ImageRegistration using /CON=0 to remove the translation offset before proceeding with a finer registration of details.

The algorithm is based on an iterative processing that proceeds from coarse to fine detail. Optimization uses a modified Levenberg-Marquardt algorithm and produces an affine transformation for the relative rotation.
ImageRegistration

and translation as well as for isometric scaling and contrast adjustment. The algorithm is most effective with square images where the center of rotation is not far from the center of the image.

When using gravity for convergence, skew parameters can’t be evaluated (only translation is supported). Skew and isoscaling are mutually exclusive options. Mask waves are defined to have zero entries for pixels outside the region of interest and nonzero entries otherwise. If a mask is not provided, every pixel is used.

ImageRegistration creates the waves M_RegOut and M_RegMaskOut, which are both single precision waves. In addition, the operation creates the wave W_RegParams which stores 20 double precision registration parameters. M_RegOut contains the transformed (registered) test image and M_RegMaskOut contains the transformed mask (which is not affected by mask combination). ImageRegistration ignores wave scaling; images are compared and registered based on pixel values only.

The results printed in the history include:

\[
dx, dy, dz \quad \text{translation offsets measured in pixels.}
\]

\[
a_{ij} \quad \text{Elements in the skewing transformation matrix.}
\]

\[
\phi \quad \text{Rotation angle in degrees about the X-axis. Zero for 2D waves.}
\]

\[
\theta \quad \text{Rotation angle in degrees about the Y-axis. Zero for 2D waves.}
\]

\[
\psi \quad \text{Rotation angle in degrees about the Z-axis.}
\]

\[
\text{det} \quad \text{Absolute value of determinant of the skewing matrix} (a_{ij}).
\]

\[
\text{err} \quad \text{Mean square error defined as}
\]

\[
\frac{1}{N} \sum (x_i - y_i)^2 ,
\]

where \(x_i\) is the original pixel value, \(y_i\) the computed value, and \(N\) is the number of pixels.

\[
\text{snr} \quad \text{Signal to noise ratio in dB. It is given by:}
\]

\[
10 \log \left( \frac{\sum x_i^2}{\sum (x_i - y_i)^2} \right).
\]

These parameters are stored in the wave W_RegParams (or M_RegParams in the case of registering a stack). Angles are in radians. Dimension labels are used to describe the contents of each row of the output wave. Each column of the wave consists of the following rows (also indicated by dimension labels):

<table>
<thead>
<tr>
<th>Point</th>
<th>Contents</th>

You can view the output waves with dimension labels by executing:

Edit W_RegParams.1d

See Also
The ImageInterpolate Warp operation.
ImageRemoveBackground

ImageRemoveBackground /R=roiWave [flags] srcWave
The ImageRemoveBackground operation removes a general background level, described by a polynomial of a specified order, from the image in srcWave. The result of the operation are stored in the wave M_RemovedBackground.

Flags
/F Computes only the background surface fit. Will only store the resulting fit in M_RemovedBackground. This will not subtract the fit from the image.
/O Overwrites the original wave.
/P=polynomial order Specifies the order of the polynomial fit to the background surface. If omitted, the order is assumed to be 1.
/R=roiWave Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/B/U), which has the same number of rows and columns as the image wave.

Details

The identification of the background is done via the ROI wave. Set the pixels that define the background region to 1. The remaining pixels can be any value other than 1. We recommend using 64 which Igor image processing operations often interpret as "blank" in unsigned byte image waves.

The ROI does not have to be contiguous.

See ImageGenerateROIMask for more information on creating ROI waves.

/W Specifies that polynomial coefficients are to be saved in the wave W_BackgroundCoeff.

Details

The identification of the background is done via the ROI wave. Set the pixels that define the background region to 1. The remaining pixels can be any value other than 1. We recommend using 64 which Igor image processing operations often interpret as "blank" in unsigned byte image waves.

The ROI does not have to be contiguous.

The operation first performs a polynomial fit to the points designated by the ROI wave using the specified polynomial order. A polynomial of order N corresponds to the function:

\[ F_N(x, y) = \sum_{m=0}^{N} \sum_{n=0}^{m} c_{nm} x^{m-n} y^n. \]

Using the polynomial fit, a surface corresponding to the polynomial is subtracted from the source wave and the result is saved in M_RemovedBackground, unless the /O flag is used, in which case the original wave is overwritten.

Use the /W flag if you want polynomial coefficients to be saved in the W_BackgroundCoeff wave. Coefficients are stored in the same order as the terms in the sums above.

If you do not specify the polynomial order using the /P flag, the default order is 1, which means that the operation subtracts a plane (fitted to the ROI data) from the source image.

Note, if the image is stored as a wave of unsigned byte, short, or long, you might consider converting it into single precision (using Redimension/S) before removing the background. To see why this is important, consider an image containing a region of pixels equal to zero and subtracting a background plane corresponding to a nonconstant value. After subtraction, at least some of the pixels in the zero region should become negative, but because they are stored as unsigned quantities, they appear incorrectly as large values.

Examples

See Background Removal on page III-379.
See Also
The ImageGenerateROIMask operation for creating ROIs.

ImageRestore
ImageRestore [flags] srcWave=wSrc, psfWave=wPSF [, relaxationGamma=h, startingImage=wRecon ]
The ImageRestore operation performs the Richardson-Lucy iterative image restoration.

Flags
/DEST=destWave Specifies the desired output wave.
   If /DEST is omitted, the output from the operation is stored in the wave M_Reconstructed in the current data folder.

/ITER=iterations Specifies the number of iterations. The default number of iterations is 100.
/Z Do not report errors.

Parameters
psfWave=wPSF Specifies a known point spread function. wPSF must be a 2D (square NxN) wave of the same numeric type as wSRC. N must be an odd number greater than 1.
relaxationGamma=h Specifies positive power gamma of in the relaxation mapping (see Details).
startingImage=wRecon Use this keyword to specify a starting image that could be for example the output from a previous call to this operation. wRecon must have the same dimensions as wSRC and the same numeric type.
   You must make sure that wRecon is not the user-specified or the default destination wave of the operation.

srcWave=wSrc Specifies the degraded image which must be a 2D single-precision or double-precision real wave.

Details
ImageRestore performs the Richardson-Lucy iteration solution to the deconvolution of an image. The input consists of the degraded image and point spread function as well as the desired number of iterations.
The operation allows you to apply additional iterations by setting the starting image to the restored output wave from a previous call to ImageRestore using the startingImage keyword. If startingImage is omitted, the starting image is created by ImageRestore with each pixel set to the value 1.
In the case of stellar images it may be useful to apply a relaxation step that involves scaling the correction evaluated at each iteration by

\[
\text{factor}(v) = \sin \left( \frac{\pi}{2} \frac{v - v_{\text{min}}}{v_{\text{max}} - v_{\text{min}}} \right)^\gamma,
\]

where \( v \) is pixel value, \( v_{\text{max}} \) and \( v_{\text{min}} \) are the maximum and minimum level pixels in the image and gamma is the user-specified relaxationGamma.

References
ImageRotate

**ImageRotate [flags] imageMatrix**

The ImageRotate operation rotates the image clockwise by *angle* (degrees) or counter-clockwise if /W is used.

The resulting image is saved in the wave M_RotatedImage unless the /O flag is specified. The size of the resulting image depends on the angle of rotation.

The portions of the image corresponding to points outside the domain of the original image are set to the default value 64 or the value specified by the /E flag.

You can apply ImageRotate to 2D and 3D waves of any data type.

**Flags**

/A=angle Specifies the rotation angle measured in degrees in the counter-clockwise direction. For rotations by exactly 90 degrees use /C or /W instead.

/C Specifies a counter-clockwise rotation by 90 degrees.

/E= val Specifies the value for pixels that are outside the domain of the original image. By default pixels are set to 64. If you specify /E=(NaN) and your data is of type char, short, or long, the operation sets the external values to 64.

/F Rotates image by 180 degrees.

/H Flip the image horizontally.

/O Overwrites the original image with the rotated image.

/Q Quiet mode. Without this flag the operation writes warnings in the history area.

/RGBA=[R, G, B [, A]] Specifies the RGB or RGBA values of pixels that lie outside the domain occupied by the original image. This flag was added in Igor Pro 7.00.

/S Uses source image wave scaling to preserve scaling and relative locations of objects in the image for rotation angles that are multiples of 90 degrees.

/V Flip the image vertically.

/W Specifies a clockwise rotation by 90 degrees.

/Z Ignore errors.

**See Also**

The MatrixTranspose operation.

ImageSave

**ImageSave [flags] waveName [[as] fileNameStr]**

The ImageSave operation saves the named wave as an image file.

Previously this operation used QuickTime to implement the saving of some file formats. As of Igor Pro 7.00, it no longer uses QuickTime. Consequently, some file formats re no longer supported and some flags have changed.

**Parameters**

The file to be written is specified by *fileNameStr* and /P=pathName where pathName is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from *fileNameStr* and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-451 for details on forming the path.
If you want to force a dialog to select the file, omit the `fileNameStr` parameter or specify "" for `fileNameStr` or use the /I flag. The "as" keyword before `fileNameStr` is optional.

In Igor Pro 7.00 or later, if you specify “Clipboard” for `fileNameStr` and the file type is JPEG or PNG, Igor writes the image to the clipboard.

In Igor Pro 7.00 or later, if the file type is PNG or JPEG you can write the image to the picture gallery using the magic path name _PictGallery_. For example

```
ImageSave/T=PNG/P=_PictGallery_ waveName
```

### Flags

**/ALPH=mode**

Sets the value used for the ExtraSamples tag (338) in the TIFF file format. This flag was added in Igor Pro 7.00.

The tag tells a TIFF file reader how to use the alpha values. Supported modes are 1 for premultiplied and 2 for unassociated alpha. Premultiplied means that the RGB components have already been multiplied by alpha. Unassociated means that the RGB components are raw.

By default, alpha is assumed to be premultiplied (`mode=1`).

**/BIGT**

Saves TIFF files in BigTIFF format, a newer TIFF standard that allows you to save large images (over 2GB) and provides support for several compression formats. Many applications that load TIFF files do not support BigTIFF.

The /BIGT flag was added in Igor Pro 9.00.

**/C=comp**

Specifies the compression to use when saving BigTIFF:

<table>
<thead>
<tr>
<th>comp</th>
<th>BigTIFF Compression</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>No compression (default)</td>
</tr>
<tr>
<td>2</td>
<td>CITTRUE</td>
</tr>
<tr>
<td>3</td>
<td>CCITTFFAX3</td>
</tr>
<tr>
<td>4</td>
<td>CCITTFAX4</td>
</tr>
<tr>
<td>5</td>
<td>LZW</td>
</tr>
<tr>

<td>ADOBE_DEFLATE</td>
</tr>
<tr>
<td>32773</td>
<td>PACKBITS</td>
</tr>
<tr>
<td>32946</td>
<td>DEFLATE</td>
</tr>
<tr>
<td>32947</td>
<td>DCS</td>
</tr>
<tr>
<td>34712</td>
<td>JP2000s</td>
</tr>
</tbody>
</table>

The /C flag was added in Igor Pro 9.00.

**/D=depth**

This flag is deprecated and should not be used in new code.

Specifies color depth in bits-per-pixel. Integer values of 1, 8, 16, 24, 32, and 40 are supported. A depth of 40 specifies 8-bit grayscale; a depth of 8 saves the file as 8-bits/pixel with a color lookup table. If /D is omitted, it acts like /D=8.

Saving with a color table may cause some loss of fidelity.

See also the discussion of saving TIFF files below.

**/DS=depth**

Saves TIFF data in depth bits/sample.

Values for depth of 8, 16, 32 and 64 are supported. The default is 8.

The total number of bits/pixel is: (bits/sample) * (samples/pixel).

When using 32 or 64 bits/sample, `srcWave` is saved without normalization.
Details

Image files are characterized by the number of color components per pixel and the bit-depth of each component. Igor displays images that consist of 1 component (gray-scale/false color), 3 components (RGB) or 4 components (RGBA) per pixel. You can display waves of all real numeric types as images, but wave data are assumed to be either in the range of \([0,255]\) for 8-bits/components or \([0,65535]\) for all other numeric types. For more information see Creating an Image Plot on page II-386.

When you save a numeric wave as image file your options depend on the number of components (layers) of your wave and its number type.

Saving as PNG

You can save an Igor wave as a PNG file with 24 bits per pixel or 32 bits per pixel. The following table describes how the wave's data type corresponds to the PNG pixel format.
Data normalization consists of finding the global (over all layers) minimum and maximum values of `srcWave` followed by scaling to the full range, e.g.,

\[
\text{minValue} = \text{WaveMin}(\text{srcWave}) \\
\text{maxValue} = \text{WaveMax}(\text{srcWave}) \\
\text{outValue}[i][j][k] = 255\times(\text{srcWave}[i][j][k]-\text{minValue})/(\text{maxValue}-\text{minValue})
\]

**Saving as Raw PNG**

The rpng image format requires a wave in 8- or 16-bit unsigned integer format with 1 to 4 layers. Use one layer for grayscale, 3 layers for rgb color, and the extra layer for an alpha channel. If X or Y scaling is not unity, they both must be valid and must be either inches per pixel or meters per pixel. If the units are not inches they are taken to be meters.

**Saving as TIFF**

ImageSave supports saving uncompressed TIFF images of 8, 16, 32 and 64 bits per color component with 1, 3 or 4 components per pixel.

Depending on the data type of your wave and the depth of the image file being created, ImageSave may save a "normalized" version of your data. The normalized version is scaled to fit in the range of the image file data type. For example, if you save a 16-bit Igor wave containing pixel values from -1000 to +1000 in an 8-bit grayscale TIFF file, ImageSave will map the wave values -1000 and +1000 to the file values 0 and 255 respectively. When saving an image file of 16-bits/component, Igor normalizes to 65535 as the full-scale value.

There is no normalization when you save in floating point (32 or 64 bits/component). Normalization is also not done when saving 8-bit wave data to an 8-bit image file. You can disable normalization with the /U flag. Saving in floating point can lead to large image files (e.g., 64-bit/component RGBA has 256 bits/pixel) which are not supported by many applications.

**Saving 3D or 4D Waves as a Stack of TIFF Images**

If your Igor data is a 3D wave other than an RGB wave or a 4D wave, you can save it as a stack of grayscale images without a color map.

Use /S to indicate that you want to save a stack of images rather than a single image from the first layer of the wave.

Use /D=8 to save as 8 bits. Normalization is done except if the wave data is 8 bits.

Use /D=16 to save as 16 bits with normalization.

Use /F to save as single-precision floating point without normalization. Many programs can not read this format.

Use /U to prevent normalization.

Stacked images are normalized on a layer by layer basis. If you want to have uniform scaling and normalization you should convert your wave to the file data type before executing ImageSave.

**See Also**

The ImageLoad operation for loading image files into waves.
The ImageSeedFill operation takes a seed pixel and fills a contiguous region with the target value, storing the result in the wave M_SeedFill. The filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). ImageSeedFill works on 2D and 3D waves.

**Parameters**

*keyword* is one of the following names:

- **adaptive=factor**
  Invokes the adaptive algorithm where a pixel or voxel is accepted if its value is between the specified minimum and maximum or its value satisfies:

  \[|val - avg| < factor * stdv.\]

  Here *val* is the value of the pixel or voxel in question, *avg* is the average value of the pixels or voxels in the neighborhood and *stdv* is the standard deviation of these values. By choosing a small *factor* you can constrain the acceptable values to be very close to the neighborhood average. A large *factor* allows for more deviation assuming that the *stdv* is greater than zero.

  This requirement means that a connected pixel has to be between the specified minimum and maximum value and satisfy the adaptive relationship. In most situations it is best to set wide limits on the minimum and maximum values and allow the adaptive parameter to control the local connectivity.

- **fillNumber=num**
  Specifies the number, in the range 1 to 26, of voxels in each 3x3x3 cube that belong to the set. If fillNumber is exceeded, the operation fills the remaining members of the cube. If you do not specify this keyword, the operation does not fill the cube. Used only in the fuzzy algorithm.

- **fuzzyCenter=fcVal**
  Specifies the center value for the fuzzy probability with the fuzzy algorithm (see Details). The default value is 0.25. Its standard range is 0 to 0.5, although interesting results might be obtained outside this range.

- **fuzzyProb=fpVal**
  Specifies a probability threshold that must be met by a voxel to be accepted to the seeded set. The value must be in the range 0 to 1. The default value is 0.75.

- **fuzzyScale=fsVal**
  Determines if a voxel is to be considered in a second stage using fuzzy probability. *fsVal* must be nonzero in order to invoke the fuzzy algorithm. The scale is used in comparing the value of the voxel to the value of the seed voxel. The scale should normally be in the range 0.5 to 2.0.

- **fuzzyWidth=fwVal**
  Defines the width of the fuzzy probability distribution with the fuzzy algorithm (see Details). In most situations you should not need to specify this parameter. The default value is 1.

- **min=minval**
  Specifies the minimum value that is accepted in the seeded set. Not needed when using fuzzy algorithm.

- **max=maxval**
  Specifies the maximum value that is accepted to the seeded set. Not needed when using the fuzzy algorithm.

- **seedP=row**
  Specifies the integer row location of the seed pixel or voxel. This avoids roundoff issues when srcWave has wave scaling. You must provide either seedP or seedX with all algorithms. It is sometimes convenient to use this with cursors e.g., seedP=pcsr(a).

- **seedQ=col**
  Specifies the integer column location of the seed pixel or voxel. This avoids roundoff difficulties when srcWave has wave scaling. You must provide either seedQ or seedY with all algorithms.
In two dimensions, the operation takes a seed pixel, optional minimum and maximum pixel values and optional adaptive coefficient. It then fills a contiguous region (in a copy of the source image) with the target value. There are two algorithms for 2D seed fill. In direct seed fill (only min, max, seedX and seedY are specified) the filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). In adaptive fill, there is an additional condition for the pixel or voxel to be selected, which requires that the pixel value must be within the standard deviation of the average in the 3x3 (2D) or 3x3x3 (3D) nearest neighbors. If you do not specify the minimum and maximum values then the operation selects only values identical to that of the seed pixel.

In 3D, there are three available algorithms. The direct seed fill algorithm uses the limits specified by the user to fill the seeded domain. In adaptive seed fill the algorithm requires the limits as well as the adaptive parameter. It fills the domain by accepting only voxels that lie within the adaptive factor times the standard deviation of the immediate voxel neighborhood. To invoke the third algorithm you must set fuzzyScale to a nonzero value. The fuzzy seed fill uses two steps to determine if a voxel should be in the filled domain. In the first step the value of the voxel is compared to the seed value using the fuzzy scale. If accepted, it passes to the second stage where a fuzzy probability is calculated based on the number of voxels in the 3x3x3 cell which passed the first step together with the user-specified probability center (fuzzyCenter) and width (fuzzyWidth). If the result is greater than fuzzyProb, the voxel is set to belong to the filled domain.

If the /O flag is not specified, the result is stored in the wave M_SeedFill.

If you specify a background value with the /B flag, the resulting image consists of the background value and the target value in the area corresponding to the seed fill. Although the wave is now bi-level, it retains the same number type as the source image.
ImageSeedFill returns a “bad seed pixel specification” if the seed pixel location derived from the various keywords above satisfies one or more of the following conditions:

- The computed integer pixel/voxel is outside the image.
- The value stored in the computed integer pixel/voxel location does not satisfy the min/max or fuzzy conditions. This is the most common condition when srcWave has wave scaling. To avoid this difficulty you should use the keywords seedP, seedQ, and seedR.

Examples
Using Cursor A position and value to supply parameter inputs for a 2D seedFill (Warning: command wrapped over two lines):
```
ImageSeedFill
  seedP=pcsr(a), seedQ=qcsr(a), min=zcsr(a), max=zcsr(a), target=0, srcwave=image0
```

Using the fuzzy algorithm for a 3D wave (Warning: command wrapped over two lines):
```
ImageSeedFill seedX=232, seedY=175, seedZ=42, target=1, fillNumber=10, fuzzyCenter=.25, fuzzyWidth=1, fuzzyScale=1, fuzzyProb=0.4, srcWave=ddd
```

See Also
For an additional example see Seed Fill on page III-377. To display the result of the operation for 3D waves it is useful to convert the 3D wave M_SeedFill into an array of quads. See ImageTransform vol2surf.

ImageSnake

ImageSnake [flags] srcWave

The ImageSnake operation creates or modifies an active contour/snake in the grayscale image srcWave. The operation iterates to find the “lowest total energy” snake. The energy is defined by a range of optional flags, each corresponding to an individual term in the total energy expression. Iterations terminate by reaching the maximum number of iterations, when the snake does not move between iterations or when the user aborts the operation.

Flags

- **/ALPH=alpha**: Sets the coefficient of the energy term arising from the “tightness” of the snake.
- **/BETA=beta**: Sets the coefficient of the energy term corresponding to curvature of the snake. A high value for beta makes the snake more rounded.
- **/DELT=delta**: Sets the coefficient of the repulsion energy. A high value of delta keeps nonconsecutive snake points far from each other.
- **/EPS=num**: Sets the maximum number of vertices which are allowed to move in one iteration. If the number of vertices which move during an iteration is smaller than num then iterations terminate.
- **/EXEF=eta**: Sets the coefficient of the optional external energy component. By default this value is set to zero and there is no external energy contribution to the snakes energy. Note, this component is referred to as “external” because it is completely up to the user to specify both its coefficient and the value associated with each pixel. It should not be confused with what is called external snake energy in the literature, which usually applies to energy proportional to the gradient image (see /GAMM and /GRDI).
- **/EXEN=wave**: Specify a wave that contains energy values that will be added to the snakes energy calculation. The wave must have the same dimensions as srcWave and must be single precision float. Each pixel value corresponds to user defined energy which will be multiplied by the /EXEF coefficient and added to the sum which the snake minimizes. Note that when /EXEF is set to zero this component is ignored. An external energy wave may be useful, for example, if you want to attract the snake to the picture boundaries. In that case you can set:
```
Duplicate/O srcWave,extWave
Redimension/S extWave
Variable rows=DimSize(srcWave,0)-1
Variable cols=DimSize(srcWave,1)-1
extWave=(p==0 || q==0 || p==rows || q==cols) ? 0:1
```
Details
A snake is a two-dimensional, usually closed, path drawn over an image. The snake is described by a pair of XY waves consisting of N vertices (sometimes called “snake elements” or “snaksels”). In this implementation it is assumed that the snake is closed so that the last point in the snake is connected to the first. Snakes are used in image segmentation, when you want to automatically select a contiguous portion of the plane based on some criteria. Unlike the classic contours, snakes do not have to follow a constant level. Their structure (or path) is found by associating the concept of energy with every snake configuration and attempting to find the configuration for which the associated energy is a minimum. The search for a
minimum energy configuration is usually time consuming and it strongly depends on the format of the energy function and the initial conditions (as defined by the starting snake). The operation computes the energy as a sum of the following 5 terms:

1. The coefficient alpha times a sum of absolute deviations from the average snake segment length. This term tends to distribute the vertices of the snake at even intervals.
2. The coefficient beta times a sum of energies associated with the curvature of the snake at each vertex.
3. The coefficient gamma times a sum of energies computed from the negative magnitude of the gradient of a Gaussian kernel convolved with the image. This term is usually referred to in the literature as the external energy and usually drives the snake to follow the direction of high image gradients.
4. The coefficient delta times a repulsion energy. Repulsion is computed as an inverse square law by adding contributions from all vertices except the two that are immediately connected to each vertex. This energy term is designed to make sure that the snake does not fold itself into “valleys”.
5. The coefficient eta times the sum of values corresponding to the positions of all snake vertices in the wave you provide in /EXEN.

The energy calculation skips all terms for which the coefficient is zero. In addition there is a built-in scan which adds a very high penalty for configurations in which the snake crosses itself.

ImageSkeleton3D

The ImageSkeleton3D operation computes the skeleton of a 3D binary object in srcWave by "thinning". Thinning is a layer-by-layer erosion until only the "skeleton" of an object remains. (See reference below.) It is used in neuroscience to trace neurons.

The ImageSkeleton3D operation was added in Igor Pro 7.00.

Parameters

srcWave is a 3D unsigned-byte wave where object voxels are set to 1 and the background is set to 0.

Flags

/DEST=destWave  Specifies the wave to contain the output of the operation. If the specified wave already exists, it is overwritten.

When used in a user-defined function, ImageSkeleton3D creates wave reference for destWave if it is a simple name. See Automatic Creation of WAVE References on page IV-72 for details.

If you omit /DEST the output wave is M_Skeleton in the current data folder.

/METH=m  Sets the method used to compute the skeleton.

   m=1: Uses elements of an algorithm by Kalman Palagyi (default).

This is currently the only supported method.

/Z  Do not report any errors.

Details

The output is stored in the wave M_Skeleton in the current data folder or in the wave specified by /DEST. Skeleton voxels are set to the value 1 and background voxels are set to 0.

Example

// Create a cube with orthogonal square holes
Make/B/U/N=(30,30,30) ddd=0
ddd[2,27][2,27][2,27]=1
ddd[2,27][10,20][10,20]=0
ddd[10,20][2,27][10,20]=0
ddd[10,20][10,20][2,27]=0
ImageSkeleton3D ddd

Chapter III-11, Image Processing, ImageMorphology, ImageSeedFill
ImageStats

The ImageStats operation calculates wave statistics for specified regions of interest in a real matrix wave. The operation applies to image pixels whose corresponding pixels in the ROI wave are set to zero. It does not print any results in the history area.

Flags

/BEAM Computes the average, minimum, and maximum pixel values in each layer of a 3D wave and 2D ROI. Output is to waves W_ISBeamAvg, W_ISBeamMax, and W_ISBeamMin in the current data folder. Use /RECT to improve efficiency for simple ROI domains. V_ variable results correspond to the last evaluated layer of the 3D wave. Do not use /G, /GS, or /P with this flag. Set /M=1 for maximum efficiency.

/BRXY={xWave, yWave}

Use this option with a 3D imageWave. It provides a more efficient method for computing average, minimum and maximum values when the set of points of interest is much smaller than the dimensions of an image.

Here xWave and yWave are 1D waves with the same number of points containing XY integer pixel locations specifying arbitrary pixels for which the statistics are calculated on a plane by plane basis as follows:

\[ W_{ISBeamAvg}[k] = \frac{1}{n} \sum_{i=1}^{n} Image[xWave[i]][yWave[i]]. \]

Pixel locations are zero-based; non-integer entries may produce unpredictable results.

The calculated statistics for each plane are stored in the current data folder in the waves W_ISBeamAvg, W_ISBeamMax and W_ISBeamMin.

Note: This flag is not compatible with any other flag except /BEAM.

/C=chunk

When imageWave is a 4D wave, /C specifies the chunk for which statistics are calculated. By default chunk = 0.

Added in Igor Pro 7.00.

/G={startP, endP, startQ, endQ}

Specifies the corners of a rectangular ROI. When this flag is used an ROI wave is not required. This flag requires that startP \leq endP and startQ \leq endQ. When the parameters extend beyond the image area, the command will not execute and V_flag will be set to -1. You should therefore verify that V_flag = 0 before using the results of this operation.

/GR={sMinRow, sMaxRow, sMinCol, sMaxCol}

Specifies a rectangular region of interest in terms of the scaled image coordinates. Each one of the 4 values will be translated to an integer pixel using truncation.

This flag, /G, and an ROI specification are mutually exclusive.

/M=val

Calculates the average and locates the minimum and the maximum in the ROI when /M=1. This will save you the computation time associated with the higher order statistical moments.

/P=planeNumber

Restricts the calculation to a particular layer of a 3D wave. By default, planeNumber= -1 and only the first layer of the wave is processed.
The image statistics are returned via the following variables:

- `V_adev`: Average deviation of pixel values.
- `V_avg`: Average of pixel values.
- `V_kurt`: Kurtosis of pixel values.
- `V_min`: Minimum pixel value.
- `V_minColLoc`: Specifies the location of the column in which the minimum pixel value was found or the first eligible column if no single column was found.
- `V_minRowLoc`: Specifies the location of the row in which the minimum pixel value was found or the first eligible row if no single minimum was found.
- `V_max`: Maximum pixel value.
- `V_maxColLoc`: Specifies the location of the column in which the maximum pixel value was found or the first eligible column if no single column was found.
- `V_maxRowLoc`: Specifies the location of the row in which the maximum pixel value was found or the first eligible row if no single maximum was found.
- `V_npnts`: Number of points in the ROI excluding NaNs.
- `V_rms`: Root mean squared of pixel values.
- `V_sdev`: Standard deviation of pixel values.
- `V_skew`: Skewness of pixel values.

Most of these statistical results are similarly defined as for the WaveStats operation. WaveStats will be more convenient to use when calculating statistics for an entire wave.

If `imageWave` is 4D it is often useful to use the reversible conversion

```
Redimension/N=(rows,cols,layers*chunks) ImageWave
```

which allows you to obtain the statistics for each layer and all chunks of the wave. To convert back to 4D, execute:

```
Redimension/N=(rows,cols,layers,chunks) ImageWave
```

See Also

**ImageThreshold**

```
ImageThreshold [flags] imageMatrix
```

The ImageThreshold operation converts a grayscale `imageMatrix` into a binary image. The operation supports all data types. However, the source wave must be a 2D matrix. If `imageMatrix` contains NaNs, the pixels corresponding to NaN values are mapped into the value 64. The values for the On and Off pixels are 255 and 0 respectively. The resulting image is stored in the wave `M_ImageThresh`. 
### ImageThreshold

#### Flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/C</td>
<td>Calculates the correlation coefficient between the original image and the image generated by the threshold operation. The correlation value is printed to the history area (unless the /Q flag is specified), it is also stored in the variable V_correlation.</td>
</tr>
<tr>
<td>/I</td>
<td>Inverts values written to the image, i.e., sets to zero all pixels above threshold.</td>
</tr>
<tr>
<td>/M=method</td>
<td>Specifies the thresholding method. The calculated value will be printed to the history area (unless /Q is specified) and stored in the variable V_threshold.</td>
</tr>
<tr>
<td>/N</td>
<td>Sets the background level to 64 (i.e., NaN).</td>
</tr>
<tr>
<td>/O</td>
<td>Overwrites the original image with the calculated threshold image.</td>
</tr>
<tr>
<td>/P=layer</td>
<td>When imageMatrix is a 3D wave /P selects a specific layer for which to compute the threshold. layer is the zero-based layer index.</td>
</tr>
<tr>
<td>/Q</td>
<td>Suppresses printing calculated correlation coefficients (/C) and calculated thresholds (/M) to the history area.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

<td>Automatically calculate a threshold value using an iterative method.</td>
</tr>
<tr>
<td>2</td>
<td>Image histogram is a simple bimodal distribution.</td>
</tr>
<tr>
<td>3</td>
<td>Adaptive thresholding. Evaluates threshold based on the last 8 pixels in each row, using alternating rows. The output wave M_ImageThresh has the same numeric type as the input wave. In particular, when the input is signed byte, the on and off pixel values are 127 and 0 respectively. Note that this method is not supported when used as part of the operation ImageEdgeDetection.</td>
</tr>
<tr>
<td>4</td>
<td>Fuzzy thresholding using entropy as the measure for “fuzziness”.</td>
</tr>
<tr>
<td>5</td>
<td>Fuzzy thresholding using a method that minimizes a “fuzziness” measure involving the mean gray level in the object and background.</td>
</tr>
<tr>
<td>6</td>
<td>Determines an ideal threshold by histograming the data and representing the image as a set of clusters that is iteratively reduced until there are two clusters left. The threshold value is then set to the highest level of the lower cluster. This method is based on a paper by A.Z. Arifin and A. Asano (see reference below) but modified for handling images with relatively flat histograms. If the image histogram results in less than two clusters, it is impossible to determine a threshold using this method and the threshold value is set to NaN. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>7</td>
<td>Determines the ideal threshold value by maximizing the total variance between the “object” and the “background”. See <a href="http://en.wikipedia.org/wiki/Otsu%27s_method">http://en.wikipedia.org/wiki/Otsu%27s_method</a>.</td>
</tr>
</tbody>
</table>

The /P flag was added in Igor Pro 7.00.
ImageTransform

ImageTransform [flags] Method imageMatrix

The ImageTransform operation performs one of a number of transformations on imageMatrix. The result of using most keywords is a new wave stored in the current data folder. Most flags in this operation are exclusive to the keywords in which they are mentioned.

Parameters

Method selects type of transform. It is one of the following names:

averageImage Computes an average image for a stack of images contained in 3D imageMatrix. The average image is stored in the wave M_AveImage and the standard deviation for each pixel is stored in the wave M_StdvImage in the current data folder. You can use this keyword together with the optional /R flag where a region of interest is defined by zero value points in a ROI wave. The operation sets to NaN the entries in M_AveImage and M_StdvImage that correspond to pixels outside the ROI. imageMatrix must have at least three layers.

averageRGBImage Computes an average image from a sequence of RGB images represented by a 4D wave. The average is computed separately for the R, G and B channels and the resulting RGB image is stored in the wave M_AverageRGBImage in the current data folder. The operation supports all real data types.

Added in Igor Pro 7.00.

For usage examples see Threshold Examples on page III-356. The ImageGenerateROIMask and ImageEdgeDetection operations.
backProjection
Reconstructs the source image from a projection slice and stores the result in the wave M_BackProjection. The projection slice should either be a wave produced by the projectionSlice keyword of this operation or a wave that would be similarly scaled. The input must be a single or double precision real 2D wave. Row scaling must range symmetrically about zero. For example, if the reconstructed image is expected to have 256 rows then the row scaling of the input should be from -128 to 127. Similarly, the column scaling of the input should range between zero and \( \pi \). An equivalent implementation as a user function is provided in the demo experiment. You can use this implementation as a starting point if you want to develop filtered back projection.

See the projectionSlice keyword and the RadonTransformDemo experiment. For algorithm details see the chapter “Reconstruction of cross-sections and the projection-slice theorem of computerized tomography” in Born and Wolf, 1999.

ccs subdivision
Performs a Catmull-Clark recursive generation of B-spline surfaces. There are two valid inputs: triangular meshes or quad meshes.

Quad meshes are assumed to be in the form of a 3D wave where the first plane contains the X-values, the second the Y-values and the third the Z-values.

Triangle meshes are much more complicated to convert into face-edge-vertex arrays so they are less desirable. They are stored in a three column (triplet) wave where the first column corresponds to the X coordinate, the second to the Y coordinate and the third to the Z coordinate. Each triangle is described by three rows in the wave and common vertices have to be repeated so that each sequential three rows in the triplet wave correspond to a single triangle. You can also associate a scalar value with each vertex and it will be suitably interpolated as new vertices are computed and old ones are shifted. In this case the input source wave contains one more column in the case of a triplet wave or one more plane in the case of a quad wave. The scalar value is added everywhere as an additional dimension to the spatial part of any point calculation.

You can specify the number of iterations using the /I flag. By default the operation executes a single iteration. The output is saved in a quad wave M_CCBSplines that consists of 4 columns. Each row corresponds to a Quad where the 3 planes contain the X, Y, and Z components. If you are using an optional scalar in the input, the scalar result is stored in the wave M_CCBScalar.

In some situations you may encounter spatial degeneracies when two or more parts of the surface meet at common vertices. This leads to one or more error messages in the history area of the command window. You can try to break a degeneracy yourself by adding a small perturbation to the input coordinates or you can use the /PRTF flag which adds a random perturbation on the order of 1e-10 times the extent of the data in each dimension. The perturbation does not affect the scalar.

cmap2rgb
Converts an image and its associated colormap wave (specified using the /C flag) into an RGB image stored in a 3D wave M_RGBOut.

CMYK2RGB
Converts a CMYK image, stored as 4 layer unsigned byte wave, into a 3 layer, standard RGB image wave. The output wave is M_CMYK2RGB that is stored in the current data folder.

compress
Compresses the data in the imageWave using a nonlossy algorithm and stores it in the wave W_Compressed in the current data folder. The compressed wave includes all data associated with imageWave including its units and wavenote. Use the decompress keyword to recover the original wave. The operation supports all numeric data types.

NOTE: The compression format for waves greater than 2GB in size was changed in version 6.30B02. If you compressed a wave greater than 2GB in IGOR64 6.30B01, you will need to decompress it using the same version. You can not decompress it in 6.30B02 or later.

convert2gray
Converts an arbitrary 2D wave into an 8-bit normalized 2D wave. The default output wave name is M_Image2Gray.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decompress</td>
<td>Decompresses a compressed wave. It saves a copy of the decompressed wave under the name W_DeCompressed in the current data folder.</td>
</tr>
<tr>
<td>NOTE:</td>
<td>The compression format for waves greater than 2GB in size was changed in version 6.30B02. If you compressed a wave greater than 2 GB in IGOR64 6.30B01, you will need to decompress it using the same version. You can not decompress it in 6.30B02 or later.</td>
</tr>
<tr>
<td>distance</td>
<td>Computes the distance transform, also called &quot;distance map&quot;, for the input image. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td></td>
<td>The distance transform/map is an image where every pixel belonging to the &quot;object&quot; is replaced by the shortest distance of that pixel from the background/boundary.</td>
</tr>
<tr>
<td>imageMatrix</td>
<td>must be a 2D wave of type unsigned byte (Make/B/U) where pixels corresponding to the object are set to zero and pixels corresponding to the background are set to 255. Such an image can be obtained, for example, using ImageThreshold.</td>
</tr>
<tr>
<td></td>
<td>The resulting distance map is stored in the wave M_DistanceMap in the current data folder. The operation supports three metrics (Manhattan, Euclidean, Euclidean + scaling) set via the /METR flag.</td>
</tr>
<tr>
<td>extractSurface</td>
<td>Extracts values corresponding to a plane that intersects a 3D volume wave (imageMatrix). You must specify the extraction parameters using the /X flag. The volume is defined by the wave scaling of the 3D wave. The result, obtained by trilinear interpolation, is stored in the wave M_ExtractedSurface and is of the type NT_FP64. Points in the plane that lie outside the volume are set to NaN.</td>
</tr>
<tr>
<td>fht</td>
<td>Performs a Fast Hartley Transform subject to the /T flag. The source wave must be a 2D real matrix with a power of 2 number of rows and columns. Default output is saved in the double-precision wave M_Hartley in the current data folder. If you use the /O flag the result overwrites imageMatrix without changing the numeric type. If imageMatrix is single-precision float the conversion is straightforward. All other numeric types are scaled. Single- and double-byte types are scaled to the full dynamic range. 32 bit integers are scaled to the range of the equivalent 16 bit types (i.e., unsigned int is scaled to unsigned short range etc.). It does not support wave scaling or NaN entries.</td>
</tr>
<tr>
<td>fillImage</td>
<td>Fills a 2D target image wave with data from a 1D image wave (specified using /D). Both waves must be the same data type, and the number of data points in the target wave must match the number of points in the data wave. There are four fill modes that are specified via the /M flag. The operation supports all noncomplex numeric data types.</td>
</tr>
<tr>
<td>findLakes</td>
<td>Originally intended to identify lakes in geographical data, this operation creates a mask for a 2D wave for all the contiguous points whose values are close to each other. You can determine the minimum number of pixels within a contiguous region using the /LARA=minPixels flag (default is 100). You can determine how close values must be in order to belong to a contiguous region using the /LTOL=tolerance flag (default is zero). You can also limit the search region using the /LRCT flag. Use the flag /LTAR=target to set the value of the masked regions. By default, the algorithm uses 4-connectivity when looking at adjacent pixels. You can set it to 8-connectivity using the /LCVT flag. The result of the operation is saved in the wave M_LakeFill. It has the same data type as the source wave and contains all the source values outside the masked pixels.</td>
</tr>
<tr>
<td>flipCols</td>
<td>Rearrange pixels by exchanging columns symmetrically about a center column or the center of the image (if the number of columns is even). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the /P flag to specify the plane that you want to operate on.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>flipRows</td>
<td>Rearrange pixels in the image by exchanging rows symmetrically about the middle row or the middle of the image (if the image has an even number of rows). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the /P flag to specify the plane that you want to operate on.</td>
</tr>
<tr>
<td>flipPlanes</td>
<td>Rearrange data in a 3D wave by exchanging planes symmetrically about the middle plane. The operation is performed in place and can be reverted by repeating the operation.</td>
</tr>
<tr>
<td>fuzzyClassify</td>
<td>Segments grayscale and color images using fuzzy logic. Iteration stops when it reaches convergence defined by /TOL or the maximum number of iterations specified by /I. It is a good practice to specify the tolerance and the number of iterations. If the number of classes is small, the operation prints the class values in the history. Use /Q to eliminate printing and increase performance. Use /CLAS to specify the number of classes and optionally use /CLAM to modify the fuzzy probability values. Use /SEG to generate the segmentation image. The classes are stored in the wave W_FuzzyClasses in the current data folder and it will be overwritten if it already exists. When imageMatrix is a grayscale image, each class is a single wave entry. When imageMatrix is a RGB image, classes are stored consecutively in the wave W_FuzzyClasses. If you request more classes than are present in imageMatrix, you will likely find a degeneracy where the space of a data class is spanned by more than one class. It is a good idea to compute the Euclidean distance between every possible pair of classes and eliminate degeneracies when the distance falls below some threshold. Any real data type is allowed but values in the range [0,255] are optimal. You can segment 3D waves of more than 3 layers in which a class will be a vector of dimensionality equal to the number of layers in imageMatrix. For examples see Examples/Imaging/fuzzyClassifyDemo.pxp.</td>
</tr>
<tr>
<td>getBeam</td>
<td>Extracts a beam from a 3D wave. A “beam” is a 1D array in the Z-direction. If a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension. The number of points in a beam is equal to the number of layers in imageWave. Specify the beam with the /BEAM={row,column} flag. It stores the result in the wave W_Beam in the current data folder. W_Beam has the same numeric type as imageWave. Use setBeam to set beam values. (See also, MatrixOp beam.)</td>
</tr>
<tr>
<td>getChunk</td>
<td>Extracts the chunk specified by chunk index /CHIX from imageMatrix and stores it in the wave M_Chunk in the current data folder. For example, if imageMatrix has the dimensions (10,20,3,10), the resulting M_Chunk has the dimensions (10,20,3). See also setChunk and insertChunk.</td>
</tr>
<tr>
<td>getCol</td>
<td>Extracts a 1D wave, named W_ExtractedCol, from any type of 2D or 3D wave. You specify the column using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. imageMatrix can be real or complex. (See also putCol keyword, MatrixOp col.)</td>
</tr>
<tr>
<td>getPlane</td>
<td>Creates a new wave, named M_ImagePlane, that contains data in the plane specified by the /P flag. The new wave is of the same data type as the source wave. You can specify the type of plane using the /PTYP flag. (See also setPlane keyword, MatrixOp.)</td>
</tr>
<tr>
<td>getRow</td>
<td>Extracts a 1D wave, named W_ExtractedRow, from any type of 2D or 3D wave. You specify the row using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. imageMatrix can be real or complex. (See also setRow keyword, MatrixOp row.)</td>
</tr>
</tbody>
</table>
### ImageTransform

| **Hough** | Performs the Hough transform of the input wave. The result is saved to a 2D wave M_Hough in which the columns correspond to angle and the rows correspond to the radial domain.

By default the output consists of 180 columns. Use the /F flag to modify the angular resolution.

If the input image has N rows and M columns then the number of rows in the M_Hough is set to $1 + \sqrt{N^2 + M^2}$. The output radius should be read relative to the center row.

It is assumed that the input wave has square pixels of unit size and that is binary (/B/0) where the background value is 0.

See also **Hough Transform** on page III-364.

| **hsl2rgb** | Transforms a 3-plane HSL wave into a 3-plane RGB wave. If the source wave for this operation is of any type other than byte or unsigned byte, the HSL values are expected to be between 0 and 65535. For all source wave types the resulting RGB wave is of type unsigned short. The result of the operation is the wave M_HSL2RGB (of type unsigned word), where the RGB values are in the range 0 to 65535.

| **hslSegment** | Creates a binary image of the same dimensions as the source image, in which all pixels that belong to all three of the specified Hue, Saturation, and Lightness ranges are set to 255 and the others to zero. You can specify the HSL ranges using the /H, /S, and /L flags. Each flag takes as an argument either a pair of values or a wave containing pairs of values. You must specify the /H flag but you can omit the /S and /L flags in which case the default values (corresponding to full range 0 to 1) are used. **imageMatrix** is assumed to be an RGB image.

| **imageToTexture** | Transforms a 2D or 3D image wave into a 1D wave of contiguous pixel components. The transformation is useful for creating an OpenGL texture (for Gizmo) or for saving a color image in a format requiring either RGB or RGBA sequences.

The /O flag does not apply to imageToTexture.

Use the /TEXT flag to specify the type of transformation. **imageMatrix** must be an unsigned byte wave. A 1D unsigned byte wave named W_Texture is created in the current data folder.

W_Texture's wave note is set to a semicolon-separated list of keyword -value pairs that can be parsed using **StringByKey** and **NumberByKey**:

<table>
<thead>
<tr>
<th><strong>Keyword</strong></th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>

<td>DimSize(imageMatrix,1) or truncated to nearest power of 2</td>
</tr>
<tr>
<td>LAYERS</td>
<td>DimSize(imageMatrix,2)</td>
</tr>
<tr>
<td>TEXTUREMODE</td>
<td>val parameter from /TEXT flag</td>
</tr>
<tr>
<td>SOURCEWAVE</td>
<td>GetWavesDataFolder(imageMatrix, 2)</td>
</tr>
</tbody>
</table>

| **indexWave** | Creates a 1D wave W_IndexedValues in the current data folder containing values from **imageMatrix** that are pointed to by the index wave (see /IWAV). Each row in the index wave corresponds to a single value of **imageMatrix**. If any row does not point to a valid index (within the dimensions of **imageMatrix**), the corresponding value is set to zero and the operation returns an error. Indices are zero based integers; the operation does not support interpolation and ignores wave scaling. |
**insertChunk**

Inserts a chunk (a 3D wave specified by the /D flag) into `imageMatrix` at chunk index specified by the /CHIX flag. The dimensions of the inserted chunk must match the first three dimensions of `imageMatrix`. The wave must also have the same numeric type. The 4th dimension of `imageMatrix` is incremented by 1 to accommodate the new data. See also `getChunk` and `setChunk`.

**insertImage**

Inserts the image specified by the flag /INSI into `imageMatrix` starting at the position specified by the flags /INSX and /INSY. If the `imageMatrix` is a 3D wave then it inserts the image in the layer specified by the /P flag. The inserted image and `imageMatrix` must be the same data type. The inserted data is clipped to the boundaries of `imageMatrix`.

**insertXplane**

Inserts a 2D wave as a new plane perpendicular to the X-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be cols x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 20x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.

**insertYplane**

Inserts a 2D wave as a new plane perpendicular to the Y-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.

**insertZplane**

Inserts a 2D wave as a new plane perpendicular to the Z-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x cols of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x20. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder. This keyword is included for completeness. You can accomplish the same task using InsertPoints.

**invert**

Converts pixel values using the formula `newValue=255-oldValue`. Works on waves of any dimension, but only on waves of type unsigned byte. The result is stored in the wave M_Inverted unless specifying the /O flag.

**matchPlanes**

Finds pixels that match test conditions in all layers of a 3D wave. It creates a 2D unsigned byte output wave, M_matchPlanes, that is set to the values 0 and 255. A value of 255 indicates that the corresponding pixel has satisfied test conditions in all layers of the wave for which conditions were provided. Otherwise the pixel value is 0.

Test conditions are entered as a 2D wave using the /D flag. The condition wave must be double precision and it must contain the same number of columns as the number of layers in the 3D source wave. A condition for layer j of the source wave is specified by two rows in column j of the condition wave. The first row entry, say A, and the second row entry, say B, imply a condition on pixels in layer j such that \( A \leq x < B \). You can have more than one condition for a given layer by adding pairs of rows to the condition wave. For example, if you add in consecutive rows the values C and D, this implies the test:

\[
(A \leq x \leq B) \land (C \leq x \leq D).
\]

If you do not have any conditions for some layer, set its corresponding condition column to NaN. Similarly, if you have two conditions for the first layer and one condition for the second layer, pad the bottom of column 1 in the condition wave with NaNs. See Examples for use of this keyword to perform hue/saturation segmentation.
offsetImage  Shifts an image in the XY plane by dx, dy pixels (specified by the /IOFF flag). Pixels outside the shifted image will be set to the specified background value. The operation works on 2D waves or on 3D waves with the optional /P flag. When shifting a 3D wave with no specified plane, it creates a 3D wave with all planes offset by the same amount. The wave M_OffsetImage contains the result in the current data folder.

The /O flag is not supported with offsetImage.

padImage  Resizes the source image. When enlarged, values from the last row and column fill in the new area. The /N flag specifies the new image size in terms of the rows and columns change. The /W flag specifies whether data should be wrapped when padding the image. Unless you use the /O flag, the result is stored in the wave M_PaddedImage in the current data folder.

projectionSlice  Computes a projection slice for a parallel fan of rays going through the image at various angles. For every ray in the fan the operation computes a line integral through the image (equivalent to the sum of the line profile along the ray). The operation computes the line integrals for multiple fans defined by the number and position of the rays as well as the angle that they make with the positive X-direction. Use the /PSL flag to specify the projection parameters. The projection slice itself is stored in a 2D wave M_ProjectionSlice where the rows correspond to the rays and the columns correspond to the selected range of angles. The operation does not support wave scaling. If the source wave is 3D the projection slice currently supports slices that are perpendicular to the z-axis and specified by their plane number.

See the backProjection keyword and the RadonTransformDemo experiment. For algorithm details see the chapter “Reconstruction of cross-sections and the projection-slice theorem of computerized tomography” in Born and Wolf, 1999.

putCol  Sets a column of imageMatrix to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number. See also getCol keyword.

putRow  Sets a row of imageMatrix to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number. See also getRow keyword.

removeXplane  Removes one or more planes perpendicular to the X-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.

removeYplane  Removes one or more planes perpendicular to the Y-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.

removeZplane  Removes one or more planes perpendicular to the Z-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.
**rgb2cmap**

Computes a default color map of 256 colors to represent the input RGB image. The colors are computed by clustering the input pixels in RGB space. The resulting color map is stored in the wave M_ColorIndex in the current data folder. The operation also saves the wave M_IndexImage which contains an index into the colormap that can be used to display the image using the commands:

```
NewImage M_IndexImage
ModifyImage M_IndexImage cindex= M_ColorIndex
```

To change the default number of colors use the /NCLR flag. When the number of colors are greater than 256, M_IndexImage will be a 16-bit unsigned integer or a 32 bit integer wave depending on the number. rgb2cmap supports input images in the form of 3D waves of type unsigned byte or single precision float. The floating point option may be used to input images in colorspaces that use signed numeric data.

**rgb2gray**

When the input *imageMatrix* is a 3D RGB wave, rgb2gray produces a 2D wave of type unsigned byte containing the grayscale representation of the input. By default, the operation stores the output in the wave M_RGB2Gray in the current data folder. The RGB values are converted into the luminance $Y$ of the YIQ standard using:

$$Y = 0.299R + 0.587G + 0.114B$$

When the input *imageMatrix* is a 4D wave containing multiple (3 layer) RGB chunks, the conversion produces a 3D wave where each layer corresponds to the grayscale conversion of the corresponding chunk in the input wave. In this case the numeric type of the output is the same as that of the input but the conversion formula is the same. The /O flag is not supported when transforming a 4D RGB wave.

**rgb2hsl**

Converts an RGB image stored in a 3D wave into another 3D wave in which the three planes correspond to Hue, Saturation and Lightness in the HSL color model. Values of all components are normalized to the range 0 to 255 unless the /U flag is used or if the source wave is not 8-bit, in which case the range is 0 to 65535. The default output wave name is M_RGB2HSL.

**rgb2i123**

Performs a colorspace conversion of an RGB image into the following quantities:

\[
\begin{align*}
  I_1 &= \frac{R - G}{D} \\
  I_2 &= \frac{R - B}{D} \quad \text{where} \quad D = \frac{255}{|R - G| + |R - B| + |G - B|} \\
  I_3 &= \frac{G - B}{D},
\end{align*}
\]

$I_1$, $I_2$, and $I_3$ are stored in the wave M_I123 (using the same data type as the original RGB wave) in the current data folder. $I_1$ is stored in the first layer, $I_2$ in the second and $I_3$ in the third. This color transformation is said to have useful applications in machine vision.

For more information see: Gevers and Smeulders (1999).

**rgb2xyz**

Converts a 3D RGB image wave into a 3D wave containing the XYZ color space equivalent. The conversion is based on the D65 white point and uses the following transformation:

\[
\begin{bmatrix}
  x \\
  y \\
  z
\end{bmatrix} = \begin{bmatrix}
  0.412453 & 0.357580 & 0.180423 \\
  0.212671 & 0.715160 & 0.072169 \\
  0.019334 & 0.119193 & 0.950227
\end{bmatrix} \begin{bmatrix}
  R \\
  G \\
  B
\end{bmatrix}.
\]

The XYZ values are stored in a wave named “M_RGB2XYZ” unless the /O flag is used, in which case the source image is overwritten and converted into single precision wave (NT_FP32).
<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roiTo1D</td>
<td>Copies all pixels in an ROI and saves them sequentially in a 1D wave. The ROI is specified by <code>/R</code>. The ROI wave must have the same dimensions as <code>imageMatrix</code>. If <code>imageMatrix</code> is a 3D wave, the ROI must have as many layers as <code>imageMatrix</code>. The wave <code>W_roi_to_1d</code> contains the output in the current data folder, has the same numeric type as <code>imageMatrix</code>, and contains the selected pixels in a column-major order.</td>
</tr>
<tr>
<td>rotateCols</td>
<td>Rotates rows in place. This operation is analogous to the <code>Rotate</code> operation except that it works on images and rotates an integer number of rows. The number of rows is specified by the <code>/G</code> flag.</td>
</tr>
<tr>
<td>rotateRows</td>
<td>Rotates columns in place. This operation is analogous to the <code>Rotate</code> operation except that it works on images and rotates an integer number of columns. The number of columns is specified by the <code>/G</code> flag.</td>
</tr>
<tr>
<td>scalePlanes</td>
<td>Scales each plane of the 3D wave, <code>imageMatrix</code>, by a constant taken from the corresponding entry in the 1D wave specified by the <code>/D</code> flag. The result is stored in the wave <code>M_ScaledPlanes</code> unless the <code>/O</code> flag is specified, in which case scaling is done in place.</td>
</tr>
<tr>
<td>selectColor</td>
<td>Creates a mask for the image in which pixel values depend on the proximity of the color of the image to a given central color. The central color, the tolerance and a grayscale indicator must be specified using the <code>/E</code> flag.</td>
</tr>
</tbody>
</table>

For example, `/E={174,187,75,10,1}` specifies an RGB of (174,187,75), a tolerance level of 10 and a requested grayscale output.

RGB values must be provided in a range appropriate for the source image. If the source wave type is not byte or unsigned byte, then the range of the RGB components should be 0 to 65535.

The color proximity is calculated in the nonuniform RGB space and the tolerance applies to the maximum component difference from the corresponding component of the central color.

The tolerance, just like the central color, should be appropriate to the type of the source wave.

The generated mask is stored in the wave `M_SelectColor` in the current data folder. If a wave by that name exists prior to the execution of this operation, it is overwritten. You can also use the `/R` flag with this operation to limit the color selection to pixels in the ROI wave whose value is zero.
setBeam | Sets the data of a particular beam in *imageMatrix*.

A “beam” is a 1D array in the Z-direction. If a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension.

Specify the beam with the /BEAM=[row,column] flag and the 1D beam data wave with the /D flag. The beam data wave must have the same number of elements as the number of layers and same numeric type as *imageMatrix*. Use **getBeam** to extract the beam.

setChunk | Overwrites the data in the wave *imageMatrix* at chunk index specified by /CHIX with the data contained in a 3D wave specified by the /D flag. The assigned data must be contained in a wave that matches the first three dimensions of *imageMatrix* and must have the same number type. See also **getChunk** and **insertChunk**.

setPlane | Sets a plane (given by the /P flag) in the designated image with the data in a wave specified by the /D flag. It is designed as a complement of the **getPlane** keyword to provide an easier (faster) way to create multiplane images. Note that the operation supports setting a plane when the source data is smaller than the destination plane in which case the source data is placed in memory contiguously starting from the corner pixel of the destination plane. If the source data is larger than the destination plane it is clipped to the appropriate rows and columns. If you are setting all planes in the destination wave using algorithmically named source waves you could use the **stackImages** keyword instead. See also **getPlane** keyword.

shading | Calculates relative reflectance of a surface for a light source position defined by the /A flag.

The operation estimates the slope of the surface and then computes a relative reflectance defined as the dot product of the direction of the light and the normal to the surface at the point of interest. Reflectivity is scaled using the expression:

\[ \text{outPixel} = \text{shadingA} \cdot (\text{sunDirection} \cdot \text{surfaceNormal}) + \text{shadingB} \]

By default shadingA=1, shadingB=0.

The result is stored in the wave *M_ShadedImage*, which has the same data type as the source wave.

If the source wave is any integer type, and the value of shadingA=1 the operation sets that value to 255.

The smallest supported wave size is 4x4 elements.

Values along the boundary (1 pixel wide) are arbitrary because there are no derivatives calculable for those pixels, so these pixels are filled with duplicates of the inner rows and columns.

shrinkBox | Shrinks 3D *imageMatrix* to include only the minimum three dimension rectangular range that contains all the voxels whose values are different from an outer value. The outer value is specified with the /F flag. This feature is useful in situations where ImageSeedFill has set the voxels around an object of interest to some outer value and it is desired to extract the smallest box that contains interesting data. The output is stored in the wave *M_shrunkBox*.

Added in Igor Pro 7.00.

shrinkRect | Shrinks *imageMatrix* to include only the minimum rectangle that contains all the pixels whose value is different from an outer value. The outer value is specified with the /F flag. This is useful in situations where ImageSeedFill has set the pixels around the object of interest to some outer value and it is desired to extract the smallest rectangle that contains interesting data. The output is stored in the wave *M_Shrunk*. 
stackImages  Creates a 3D or 4D stack from individual image waves in the current data folder. The waves should be of the form baseNameN, where N is a numeric suffix specifying the sequence order. imageMatrix should be the name of the first wave that you want to add to the stack. You can use the /NP flag to specify the number of waves that you want to add to the stack.

The result is a 3D or 4D wave named M_Stack, which overwrites any existing wave of that name in the current data folder.

With /K, it kills all waves copied into the stack.

sumAllCols  Creates a wave W_sumCols in which every entry is the sum of the pixels on the corresponding image column. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.

sumAllRows  Creates a wave W_sumRows in which every entry is the sum of the pixels on the corresponding image row. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.

sumCol  Stores in the variable V_value the sum of the elements in the column specified by /G flag and optionally the /P flag.

sumPlane  Stores in the variable V_value the sum of the elements in the plane specified by the /P flag.

sumPlanes  Creates a 2D wave M_SumPlanes which contains the same number of rows and columns as the 3D source wave. Each entry in M_SumPlanes is the sum of the corresponding pixels in all the planes of the source wave. M_SumPlanes is a double precision wave if the source wave is double precision. Otherwise it is a single precision wave.

sumRow  Stores in the variable V_value the sum of the elements of a row specified by /G flag and optionally the /P flag.

swap  Swaps image data following a 2D FFT. The transform swaps diagonal quadrants of the image in one or more planes. This keyword does not support any flags. The swapping is done in place and it overwrites the source wave.

swap3D  Swaps data following a 3D FFT. The transform swaps diagonal quadrants of the data. This keyword does not support any flags. The swapping is done in place and the source wave is overwritten.

transpose4D  Converts a 4D wave into a new 4D wave where the data are reordered by dimensions specified by the /TM4D flag. The results are stored in the wave M_4DTranspose in the current data folder. There is no option to overwrite the input wave so /O has no effect with transpose4D.

Added in Igor Pro 7.00.

transposeVol  Transposes a 3D wave. The transposed wave is stored in M_VolumeTranspose. The /O flag does not apply. The operation supports the following 5 transpose modes which are specified using the /G flag:

<table>
<thead>
<tr>
<th>mode</th>
<th>Equivalent Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>M_VolumeTranspose=imageMatrix[p][r][q]</td>
</tr>
<tr>
<td>2</td>
<td>M_VolumeTranspose=imageMatrix[r][p][q]</td>
</tr>
<tr>
<td>3</td>
<td>M_VolumeTranspose=imageMatrix[r][q][p]</td>
</tr>
<tr>
<td>4</td>
<td>M_VolumeTranspose=imageMatrix[q][r][p]</td>
</tr>
<tr>
<td>5</td>
<td>M_VolumeTranspose=imageMatrix[q][p][r]</td>
</tr>
</tbody>
</table>
vol2surf

Creates a quad-wave output (appropriate for display in Gizmo) that wraps around 3D "particles". A particle is defined as a region of nonzero value voxels in a 3D wave. The algorithm effectively computes a box at the resolution of the input wave which completely encloses the data. The output wave M_Boxy is a 2D single precision wave of 12 columns where each row corresponds to one disjoint quad and the columns provide the sequential X, Y, and Z coordinates of the quad vertices.

voronoi

Computes the voronoi tesselation of a convex domain defined by the X, Y positions of the input wave. imageMatrix must be a triplet wave where the first column contains the X-values, the second column contains the Y-values and the third column is an arbitrary (zero is recommended) constant. The result of the operation is stored in the two column wave M_VoronoiEdges which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle which contains the convex domain.

The operation creates two output waves:

M_Circles is a three column wave containing the center and radius of each natural neighborhood. The radius is correct only if equal scaling is applied.

M_DelaunayTriangles consists of 3 columns for the vertices of the triangles. Each triangle consists of 4 vertices. The 4th vertex is equal to the first. An extra row of NaNs used as a separator.

For an example, see Voronoi Tessellation Example below.

xProjection

Computes the projection in the X-direction and stores the result in the wave M_xProjection. See zProjection for more information.

xyz2rgb

Converts a 3D single precision XYZ color-space data into RGB based on the D65 white point. The transformation used is:

\[
\begin{bmatrix}
R \\
G \\
B
\end{bmatrix} = \begin{bmatrix}
3.240479 & -1.537150 & -0.498535 \\
0.969256 & 1.875992 & 0.041556 \\
0.055648 & -0.204043 & 1.057311
\end{bmatrix} \begin{bmatrix}
x \\
y \\
z
\end{bmatrix}.
\]

If you do not specify the /O flag, the results are saved in a single precision 3D wave (NT_FP32) “M_XYZ2RGB”.

Note that not all XYZ values map into positive RGB triplets (consider colors that reside outside the RGB triangle in the XYZ diagram). This operation gives you the following choices: by default, the output wave is a single precision wave that will include possible negative RGB values. If you specify the /U flag, for unsigned short output wave, the operation will set to zero all negative components and scale the remaining ones in the range 0 to 65535.

yProjection

Computes the projection in the Y-direction and stores the result in the wave M_yProjection. See zProjection for more information.

zDot

Computes the dot product of a beam in srcWave with a 1D zVector wave (specified with the /D flag). This will convert stacked images of spectral scans into RGB or XYZ depending on the scaling in zVector. The srcWave and zVector must be the same data type (float or double). The wave M_StackDot contains the result in the current data folder.

zProjection

Computes the projection in the Z-direction and stores the result in the wave M_zProjection. The source wave must be a 3D wave of arbitrary data type. The value of the projection depends on the method specified via the /METH flag.

Flags

/A={azimuth, elevation [, shadingA, shadingB]}
Specifies parameters for shade. Position of the light source is given by *azimuth* (measured in degrees counter-clockwise) and *elevation* (measured in degrees above the horizon).

The parameters *shadingA* and *shadingB* are optional. By default their values are 1 and 0, respectively.

/Beam={row,column} Designates a beam in a 3D wave; both *row* and *column* are zero based.

/Beam=[width, height] Specifies the backProjection parameters: *width* and *height* are the width and height of the reconstructed image and should be equal to the size of the original wave.

/C=CMapWave Specifies the colormap wave for cmap2rgb keyword. The CMapWave is expected to be a 2D wave consisting of three columns corresponding to the RGB entries.

/CHIX=chunkIndex Identifies the chunk index for getting, inserting or setting a chunk of data in a 4D wave. *chunkIndex* ranges from 0 to the number of chunks in *imageMatrix*.

/CLAM=fuzzy Sets the value used to compute the fuzzy probability in fuzzyClassify. It must satisfy *fuzzy* > 1 (default is 2).

/CLAS=num Sets the number of requested classes in fuzzyClassify. If you don’t know the number of expected classes and *num* is too high, fuzzyClassify will likely produce some degenerate classes.

/D=waveName Specifies a data wave. Check the appropriate keyword documentation for more information about this wave.

/F=value Increases the sampling in the angle domain when used with the Hough keyword. By default *value*=1 and the operation results in single degree increments in the interval 0 to 180, and if *value*=1.5 there will be 180*1.5 rows in the transform.

Specifies the outer pixel value surrounding the region of interest when used with shrinkRect keyword.

/FEQS When performing Voronoi tesselation, forces the algorithm to use equal scaling for both axes. Normally the scaling for each axis is determined from its range. When the ranges of the two axes are different by an order of magnitude or more, it is helpful to force the larger range to be used for scaling both axes.

/G=colNumber Specifies either the row or column number used in connection with getRow or getCol keywords. This flag also specifies the transpose mode with the transposeVol keyword.

/H={minHue, maxHue} Specifies the range of hue values for selecting pixels. The hue values are specified in degrees in the range 0 to 360. Hue intervals that contain the zero point should be specified with the higher value first, e.g., /H={330, 10}.

Use *hueWave* when you have more than one pair of hue values that bracket the pixels that you want to select.

See HSL Segmentation on page III-374 for an example.

/I=iterations Sets the number of iterations in ccsubdivision and in fuzzyClassify.

/INSI=imageWave Specifies the wave, *imageWave*, to be used with the insertImage keyword. *imageWave* is a 2D wave of the same numeric data type as *imageMatrix*.

/INSW=wave Specifies the 2D wave to be inserted into a 3D wave using the keywords: insertXplane, insertYplane, or insertZplane.

/INSW=xPos Specifies the pixel position at which the first row is inserted. Ignores wave scaling.

/INSW=yPos Specifies the pixel position at which the first column is inserted. Ignores wave scaling.
/IOFF\=[dx,dy, bgValue] Specifies the amount of positive or negative integer offset with \(dx\) and \(dy\) and the new background value, \(bgValue\), with the offsetImage keyword.

/IWAV=wave Specifies the wave which provides the indices when used with the keyword \texttt{indexWave}. The wave should have as many columns as the dimensions of \texttt{imageMatrix} (2, 3, or 4). For example, to specify indices for pixels in an image, the wave should have two columns. The first column corresponds to the row designation and the second to the column designation of the pixel. The wave can be of any number type (other than complex) and entries are assumed to be integer indices; there is no support for interpolation or for wave scaling.

/L=\{minLight, maxLight\} \texttt{L=lightnessWave}\] Specifies the range of lightness for selecting pixels. The lightness values are in the range 0-1. If you do not use the /L flag than the default full range is used.

/LARA=minPixels Specifies the minimum number of pixels required for an area to be masked by the \texttt{findLakes} keyword. If you do not specify this flag, the default value used is 100.

/LC\texttt{VT} Use 8-connectivity instead of 4-connectivity.

/LRCT=\{minX, minY, maxX, maxY\} Sets the rectangular region of interest for the \texttt{findLakes} keyword. The operation will not affect the original data outside the specified rectangle. The X and Y values are the scaled values (i.e., using wave scaling).

/LTAR=target Set the target value for the masked region in the \texttt{findLakes} keyword.

/LTOL=tol Specifies the tolerance for the \texttt{findLakes} keyword. By default the tolerance is zero. The tolerance must be a positive number. The operation uses the tolerance by requiring neighboring pixels to have a value between that of the current pixel \(V\) and \(V+tol\).

/M=n Specifies the method by which a 2D target image is filled with data from a 1D wave using the \texttt{fillImage} keyword.

\(n=0:\) Straight column fill, which you can also accomplish by a redimension operation.

\(n=1:\) Straight row fill.

\(n=2:\) Serpentine column fill. The points from the data wave are sequentially loaded onto the first column and continue from the last to the first point of the second column, and then sequentially through the third column, etc.

\(n=3:\) Serpentine row fill.

/METH=method Determines the values of the projected pixels for \texttt{xProjection}, \texttt{yProjection}, and \texttt{zProjection} keywords.

\texttt{method=1:}\ Pixel \((i,j)\) in \texttt{M_zProjection} is assigned the maximum value that \((i,j,*)\) takes among all layers of \texttt{imageMatrix} (default).

\texttt{method=2:}\ Pixel \((i,j)\) in \texttt{M_zProjection} is assigned the average value that \((i,j,*)\) takes among all layers of \texttt{imageMatrix}.

\texttt{method=3:}\ Pixel \((i,j)\) in \texttt{M_zProjection} is assigned the minimum value that \((i,j,*)\) takes among all layers of \texttt{imageMatrix}.
/METR=method

Sets the metric used by the distance transform. Added in Igor Pro 7.00.

method=0: Manhattan distance. Default.

method=1: Euclidean distance where the distance is measured between centers of pixels (assumed square).

method=2: Euclidean distance that also takes into account actual pixel size using the input’s wave scaling.

method=0 executes faster than the other methods. method=2 can be 2x slower especially if different scaling is applied along the two axes.

/N=[rowsToAdd, colsToAdd]

Creates an image that is larger or smaller by rowsToAdd, colsToAdd. The additional pixels are set by duplicating the values in the last row and the last column of the source image.

/NCLR=M

Specifies the maximum number of colors to find with the rgb2cmap keyword. M must be a positive number; the default value is 256 colors.

The result of the operation is saved in the wave M_paddedImage.

/NP=numPlanes

Specifies the number of planes to remove from a 3D wave when using the removeXplane, removeYplane, or removeZplane keywords. Specifies the number of waves to be added to the stack with the stackImages keyword.

/O

Overwrites the input wave with the result except in the cases of Hough transform and cmap2rgb. Does not apply to the transposeVol parameter.

/P=planeNum

Specifies the plane on which you want to operate with the rgb2gray or getPlane keywords. Also used for getRow or getCol if the source wave is 3D.

/PSL={xStart, dx, Nx, aStart, da, Na}

Specifies projection slice parameters. xStart is the first offset of the parallel rays measured from the center of the image. dx is the directed offset to the next ray in the fan and Nx is the number of rays in the fan. aStart is the first angle for which the projection is calculated. The angle is measured between the positive X-direction and the direction of the ray. da is the offset to the next angle at which the fan of rays is rotated and Na is the total number of angles for which the projection is computed.

/PTRF

Use /PTRF with the ccsubdivision keyword to apply small perturbation to the input coordinates in order to break spatial degeneracies that may occur when multiple facets meet at some point in space. See ccsubdivision above for details. /PTRF was added in Igor Pro 9.00.

/PTYP=num

Specifies the plane to use with the getPlane keyword.

num=0: XY plane.

num=1: XZ plane.

num=2: YZ plane.

/Q

Quiet flag. When used with the Hough transform, it suppresses report to the history of the angle corresponding to the maximum.

/R=roiWave

Specifies a region of interest (ROI) defined by roiWave. For use with the keywords: averageImage, scalePlanes and selectColor.

/S=[minSat, maxSat]
/S=saturationWave

Specifies the range of saturation values for selecting pixels. The saturation values are in the range 0 to 1. If you do not use the /S flag, the default value is the full saturation range.

Use saturationWave when you have more than one pair of saturation values. If you use a saturation wave you must also use a lightness wave (see /L). saturationWave should consist of pairs of values where the first point is the lower saturation value and the second point is the higher saturation value. There is no restriction on the order of pairs within the wave.

/SEG

Computes the segmentation image for fuzzyClassify. The image is stored in the 2D wave M_FuzzySegments. The value of each pixel is $255 \times \text{classIndex} / \text{number of classes}$. Here \text{classIndex} is the index of the class to which the pixel belongs with the highest probability.

/T=flag

Use one or more of the following flags.

1: Swaps the data so that the DC is at the center of the image.

2: Calculates the power defined as: $P(f) = 0.5 \cdot (H(f)^2 + H(-f)^2)$.

/TEXT=\text{val}

Specifies the type of texture to create with the imageToTexture keyword. \text{val} is a binary flag that can be a combination of the following values.

\begin{tabular}{|c|l|}
\hline
\text{val} & Texture \\
\hline
1 & Truncates each dimension to the nearest power of 2, which is required for OpenGL textures. \\
2 & Creates a 1D texture (all other textures are for 2D applications). \\
4 & Creates a single channel texture suitable for alpha or luminance channels. \\
8 & Creates a RGB texture from a 3 (or more) layer data. \\
16 & Creates a RGBA texture. If imageMatrix does not have a 4th layer, alpha is set to 255. \\
\hline
\end{tabular}

/TOL=tolerance

Sets the tolerance for iteration convergence with fuzzyClassify. Convergence is satisfied when the sum of the squared differences of all classes drops below tolerance, which must not be negative.

/TM4D=mode

Used with transpose4D to specify the format of the output wave. Here \text{mode} is a 4 digit integer that describes the mapping of the transformation. The digit 1 is used to represent the first dimension, 2 for the second, 4 for the third and 8 for the 4th dimension such that the original wave corresponds to mode=1248. All other modes are obtained by permuting one or more of the four digits and mode must consist of 4 distinct digits.

Added in Igor Pro 7.00.

/U

Creates an HSL wave of type unsigned short that contains values between 0 and 65535 when used with rgb2hsl.

/W

Pads the image by wrapping the data. If you are adding more rows or more columns than are available in the source wave, the operation cycles through the source data as many times as necessary.

/X={Nx,Ny,x1,y1,z1,x2,y2,z2,x3,y3,z3}

\text{Nx} and \text{Ny} are the rows and columns of the wave M_ExtractedSurface. The remaining parameters specify three 3D points on the extracted plane. The three points must be chosen at the vertices of the plane and entered in clock-wise order without skipping a vertex.

/Z

Ignores errors.
Examples
If you want to insert a 2D \((M \times N)\) wave, plane0, into plane number 0 of an \((M \times N \times 3)\) wave, rgbWave:

\[
\text{ImageTransform} \; /P=0/D=\text{plane0} \; \text{setPlane} \; \text{rgbWave}
\]

If your source wave is 100 rows by 100 columns and you want to create a montage of this image use:

\[
\text{ImageTransform} \; /W=N\{200,200\} \; \text{padImage} \; \text{srcWaveName}
\]

Hue and Saturation Segmentation Example

Function hueSatSegment(hslW, lowH, highH, lowS, highS)
- Wave hslW
- Variable lowH, highH, lowS, highS
- Make/D/O/N=(2,3) conditionW
- conditionW={\{lowH, highH\}, \{lowS, highS\}, \{NaN, NaN\}}
- ImageTransform/D=conditionW matchPlanes hslW
- KillWaves/Z conditionW
End

Voronoi Tesselation Example

Make/O/N=(33,3) ddd=gnoise(4)
ImageTransform voronoi ddd
Display ddd[1] vs ddd[0]
ModifyGraph mode=3, marker=19, msize=1, rgb=(0,0,65535)
AppendToGraph M_VoronoiEdges[1] vs M_VoronoiEdges[0]
SetAxis left -15,15
SetAxis bottom -5,10

Details about the rgb2i123 transform:

ImageUnwrapPhase

\[
\text{ImageUnwrapPhase} \; [\text{flags}] [\text{qualityWave}=\text{qWave},] \; \text{srcwave}=\text{waveName}
\]

The ImageUnwrapPhase operation unwraps the 2D phase in srcWave and stores the result in the wave M_UnwrappedPhase in the current data folder. srcWave must be a real valued wave of single or double precision. Phase is measured in cycles (units of \(2\pi\)).

Parameters
- qualityWave=qWave
  - Specifies a wave, qWave, containing numbers that rate the quality of the phase stored in the pixels. qWave is 2D wave of the same dimensions as srcWave that can be any real data type and values can have an arbitrary scale. If used with /M=1 the quality values determine the order of phase unwrapping subject to branch cuts, with higher quality unwrapped first. If used with /M=2 the unwrapping is guided by the quality values only. This wave must not contain any NaNs or INFs.

- srcwave=waveName
  - Specifies a real-valued SP or DP wave that may contain NaNs or INFs but is otherwise assumed to contain the phase modulo 1.

Flags
- /E
  - Eliminate dipoles. Only applies to Goldstein’s method (/M=1). Dipoles are a pair of a positive and negative residues that are side by side. They are eliminated from the unwrapping process by replacing them with a branch cut. The variable V_numResidues contains the number of residues remaining after removal of the dipoles.
ImageUnwrapPhase

/L
Saves the lookup table (LUT) used in the analysis with /M=1. This information may be useful in analyzing your results. The LUT is saved as a 2D unsigned byte wave M_PhaseLUT in the current data folder. Each entry consists of 8-bit fields:

bit=0: Positive residue.
bit=1: Negative residue.
bit=2: Branch cut.
bit=3: Image boundary exclusion.

Other bits are reserved and subject to change. See Setting Bit Parameters on page IV-12 for details about bit settings.

/M=method
Determines the method for computing the unwrapped phase:

method =0: Modified Itoh’s algorithm, which assumes that there are no residues in the phase. The phase is unwrapped in a contiguous way subject only to the ROI or singularities in the data (e.g., NaNs or INFs). You will get wrong results for the unwrapped phase if you use this method and your data contains residues.

method=1: Modified Goldstein’s algorithm. Creates the variables V_numResidues and V_numRegions. Optional qWave can determine order of unwrapping around the branch cuts.

method=2: Uses a quality map to decide the unwrapping path priority. The quality map is a 2D wave that has the same dimensions as the source wave but could have an arbitrary data type. The phase is unwrapped starting from the largest value in the quality map.

/REST = threshold
Sets the threshold value for evaluating a residue. The residue is evaluated by the equivalent of a closed path integral. If the path integral value exceeds the threshold value, the top-left corner of the quad is taken to be a positive residue. If the path integral is less than -threshold, it is a negative residue.

/REST = threshold
Saves the lookup table (LUT) used in the analysis with /M=1. This information may be useful in analyzing your results. The LUT is saved as a 2D unsigned byte wave M_PhaseLUT in the current data folder. Each entry consists of 8-bit fields:

Other bits are reserved and subject to change. See Setting Bit Parameters on page IV-12 for details about bit settings.

Details
Phase unwrapping in two dimensions is difficult because the result of the operation needs to be such that any path integral over a closed contour will vanish. In many practical situations, certain points in the plane have the property that a path integral around them is not zero. These nonzero points are residues. We use the definition that when a counterclockwise path integral leads to a positive value the residue is called a positive residue.

ImageUnwrapPhase uses the modified Itoh’s method by default. Phase is unwrapped with an offset equal to the first element that is allowed by the ROI starting at (0,0) and scanning by rows. If there are no residues or if you unwrap the phase using Itoh’s algorithm, then the phase is unwrapped only subject to the optional ROI using a seed-fill type algorithm that unwraps by growing a region outward from the seed pixel. Each time that the region growing is terminated by boundaries (external or due to the ROI), the algorithm returns to the row scanning to find a new starting point.

If there are residues and you choose Goldstein’s method, the residues are first mapped into a lookup table (LUT) and branch-cuts are determined between residues and boundaries. It is also possible to remove some residues (dipoles) using the /E flag. Phase is then unwrapped in regions bounded by branch cuts using a seed-fill type algorithm that does not cross branch cuts. With a quality wave, the algorithm follows the same seed-fill approach except that it gives priority to pixels with high quality level. The phase on the branch cuts themselves is subsequently calculated.
The output wave M_UnwrappedPhase has the same wave scaling and dimension units as srcWave. The unwrapped phase is units of cycles; you will have to multiply it by \(2\pi\) if you need the results in radians.

The operation creates two variables:

- **V_numResidues**: Number of residues encountered (if using /M=1).
- **V_numRegions**: Number of independent phase regions. In Goldstein’s method the regions are bounded by branch cuts, but in Itoh’s method they depend on the content of the ROI wave.

### Examples

```plaintext
// Unwrap the phase of a complex wave wCmplx
MatrixOP/O phaseWave=atan2(imag(wCmplx),real(wCmplx))/(2*pi)
ImageUnwrapPhase/M=1 srcWave=phaseWave

// Find the locations of positive residues in the phase
ImageUnwrapPhase/M=1/L srcWave=phaseWave
MatrixOP/O ee=greater(bitAnd(M_PhaseLUT,2),0)

// Find the branch cuts
MatrixOP/O bc=greater(bitAnd(M_PhaseLUT,8),0)
```

### See Also

The **Unwrap** operation and the **mod** function.

### References

The following reference is an excellent text containing in-depth theory and detailed explanation of many two-dimensional phase unwrapping algorithms:

The default output wave is created with the same data type as the source image. Therefore, if the source image is of type unsigned byte (/b/u) the result of using /I will be identically zero (except possibly for the middle-most pixel). If you keep in mind that you need to convert the source image to a wave type of single or double precision in order to perform the FFT, it is best if you convert your source image (e.g., Redimension/S srcImage) before using the ImageWindow operation.

The windowed output is in the M_WindowedImage wave unless the source is overwritten using the /O flag. The necessary normalization value (equals to the average squared window factor) is stored in V_value.

**ImageWindow Methods**

This section describes the supported keywords for the method parameter. In all equations, \( L \) is the array width and \( n \) is the pixel number.

**Hanning:**

\[
w(n) = \frac{1}{2} \left[ 1 - \cos \left( \frac{2\pi n}{L-1} \right) \right] \quad 0 \leq n \leq L-1
\]

**Hamming:**

\[
w(n) = 0.54 - 0.46 \cos \left( \frac{2\pi n}{L-1} \right) \quad 0 \leq n \leq L-1
\]

**Bartlet:**

Synonym for Bartlett.

**Bartlett:**

\[
w(n) =
\begin{cases} 
    \frac{2n}{L-1} & 0 \leq n \leq \frac{L-1}{2} \\
    2 - \frac{2n}{L-1} & \frac{L-1}{2} \leq n \leq L-1 
\end{cases}
\]

**Blackman:**

\[
w(n) = 0.42 - 0.5 \cos \left( \frac{2\pi n}{L-1} \right) + 0.08 \cos \left( \frac{4\pi n}{L-1} \right) \quad 0 \leq n \leq L-1
\]
IndependentModule

Examples
To see what one of the windowing filters looks like:

\[
I_0 \left( \omega_a \sqrt{\left( \frac{L-1}{2} \right)^2 - \left( n - \frac{L-1}{2} \right)^2} \right) / I_0 \left( \omega_a \left( \frac{L-1}{2} \right) \right) \quad 0 \leq n \leq L - 1
\]

where \( I_0(...) \) is the zeroth-order Bessel function of the first kind and \( \omega_a \) is the design parameter specified by /P=param.

\[
w(n) = \frac{I_0 \left( \frac{\pi \alpha}{2} \sqrt{1 - \left( \frac{n}{L/2} \right)^2} \right)}{I_0 \left( \frac{\pi \alpha}{2} \right)} \quad 0 \leq |n| \leq \frac{L}{2}
\]

KaiserBessel20: \( \alpha = 2.0 \)
KaiserBessel25: \( \alpha = 2.5 \)
KaiserBessel30: \( \alpha = 3.0 \)

\[
I_0(x) = \sum_{k=0}^{\infty} \left( \frac{x^2}{4} \right)^k \left( \frac{1}{k!} \right)^2
\]

IndependentModule

\#pragma IndependentModule = imName

The IndependentModule pragma designates groups of one or more procedure files that are compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows functioning control panels and menus to continue to work regardless of user programming errors.

See Also
Independent Modules on page IV-238, The IndependentModule Pragma on page IV-55 and #pragma.
IndependentModuleList

IndependentModuleList(listSepStr)
The IndependentModuleList function returns a string containing a list of independent module names separated by listSepStr.

Use StringFromList to access individual names.

Parameters
listSepStr contains the character, usually ";", to be used to separate the names in the returned list.

Details
In Igor6, only the first byte of listSepStr was used. In Igor7 and later, all bytes are used.
ProcGlobal is not in the returned list, and the order of returned names is not defined.

See Also
Independent Modules on page IV-238.
GetIndependentModuleName, StringFromList, FunctionList.

IndexedDir

IndexedDir(pathName, index, flags [, separatorStr])
The IndexedDir function returns a string containing the name of or the full path to the indexth folder in the folder referenced by pathName.

Parameters
pathName is the name of an Igor symbolic path pointing to the parent directory.
index is the index number of the directory (within the parent directory) of interest starting from 0. If index is -1, IndexedDir will return the name of all of the folders in the parent, separated by semicolons or by separatorStr if specified.
flags is a bitwise parameter:

Bit 0: Set if you want a full path. Cleared if you want just the directory name.

All other bits are reserved and should be cleared.

See Setting Bit Parameters on page IV-12 for details about bit settings.

separatorStr is an optional string argument used when index is -1. If you omit separatorStr, folder names are separated by ";". This parameter was added in Igor 9.01.

Details
You create the symbolic path identifying the parent directory using the NewPath operation or the New Path dialog (Misc menu).

Prior to Igor Pro 3.1, IndexedDir was an external function and took a string as the first parameter rather than a name. The pathName parameter can now be either a name or a string containing a name. Any of the following will work:

String str = "IGOR"
Print IndexedDir(IGOR, 0, 0) // First parameter is a name.
Print IndexedDir($str, 0, 0) // First parameter is a name.
Print IndexedDir("IGOR", 0, 0) // First parameter is a string.
Print IndexedDir(str, 0, 0) // First parameter is a string.

The acceptance of a string is for backward compatibility only. New code should be written using a name.
The returned path uses the native conventions of the OS under which Igor is running.

Examples

Example: Recursively Listing Directories and Files
Here is an example for heavy-duty Igor Pro programmers. It is an Igor Pro user-defined function that prints the paths of all of the files and folders in a given folder with or without recursion. You can rework this to do something with each file instead of just printing its path.
To try the function, copy and paste it into the Procedure window. Then execute the example shown in the comments.

// PrintFoldersAndFiles(pathName, extension, recurse, level)
// Shows how to recursively find all files in a folder and subfolders.
// pathName is the name of an Igor symbolic path that you created
// using NewPath or the Misc->New Path menu item.
// extension is a file name extension like ".txt" or "????" for all files.
// recurse is 1 to recurse or 0 to list just the top-level folder.
// level is the recursion level - pass 0 when calling PrintFoldersAndFiles.
// Example: PrintFoldersAndFiles("Igor", ".ihf", 1, 0)
Function PrintFoldersAndFiles(pathName, extension, recurse, level)
    String pathName // Name of symbolic path in which to look for folders and files.
    String extension // File name extension (e.g., ".txt") or "????" for all files.
    Variable recurse // True to recurse (do it for subfolders too).
    Variable level // Recursion level. Pass 0 for the top level.
    Variable folderIndex, fileIndex
    String prefix
    // Build a prefix (a number of tabs to indicate the folder level by indentation)
    prefix = ""
    folderIndex = 0
    do
        if (folderIndex >= level)
            break
        endif
        prefix += "\t" // Indent one more tab
        folderIndex += 1
        while(1)
    // Print folder
    String path
    PathInfo $pathName // Sets S_path
    path = S_path
    Printf "%s%s\r", prefix, path
    // Print files
    fileIndex = 0
    do
        String fileName
        fileName = IndexedFile($pathName, fileIndex, extension)
        if (strlen(fileName) == 0)
            break
        endif
        Printf "%s\t%s%s\r", prefix, path, fileName
        fileIndex += 1
        while(1)
        if (recurse) // Do we want to go into subfolder?
            folderIndex = 0
            do
                path = IndexedDir($pathName, folderIndex, 1)
                if (strlen(path) == 0)
                    break // No more folders
                endif
                Printf "%s\t\t%s\r", prefix, path
                fileIndex += 1
                while(1)
            endif
        endif
    End
Example: Fast Scan of Directories
Calling IndexedDir for each directory is an O(N^2) problem because to get the nth directory the OS routines underlying IndexedDir need to iterate through directories 0..n-1. This becomes an issue only if you are dealing with hundreds or thousands of directories.

This function illustrates a technique for converting this to an O(N) problem by getting a complete list of paths from IndexedDir in one call and storing them in a text wave. This approach could also be used with IndexedFile.

Function ScanDirectories(pathName, printDirNames)
  String pathName // Name of Igor symbolic path
  Variable printDirNames // True if you want to print the directory names

  Variable t0 = StopMSTimer(-2)
  String dirList = IndexedDir($pathName, -1, 0)
  Variable numDirs = ItemsInList(dirList)
  // Store directory list in a free text wave.
  // The free wave is automatically killed when the function returns.
  Make/N=(numDirs)/T/FREE dirs = StringFromList(p, dirList)

  String dirName
  Variable i
  for(i=0; i<numDirs; i+=1)
    dirName = dirs[i]
    Print i, dirName
  endfor

  Variable t1 = StopMSTimer(-2)
  Variable elapsed = (t1 - t0) / 1E6
  Printf "Took %g seconds\r", elapsed
End

IndexedFile

IndexedFile(pathName, index, fileTypeOrExtStr [, creatorStr, separatorStr])
If index is greater than or equal to zero, IndexedFile returns a string containing the name of the indexth file in the folder specified by pathName which matches the file type or extension specified by fileTypeOrExtStr.

If index is -1, IndexedFile returns a string list of all matching files separated by a semicolon, or by separatorStr if specified.

IndexedFile returns an empty string ("") if there is no such file.

Parameters

pathName is the name of an Igor symbolic path. It is not a string.

index normally starts from zero. However, if index is -1, IndexedFile returns a string containing a semicolon-separated list of the names of all files in the folder associated with the specified symbolic path which match fileTypeOrExtStr.

fileTypeOrExtStr is either:
- A string starting with ".", such as ".txt", ".bwav", or ".c". Only files with a matching file name extension are indexed. Set fileTypeOrExtStr to "." to index file names that end with "." such as "myFileNameEndsWithThisDot."
- A string containing exactly four ASCII characters, such as “TEXT” or “IGBW”. Only files of the specified Macintosh file type are indexed. However, if fileTypeOrExtStr is “????”, files of any type are indexed.
- On Windows, Igor considers files with ".txt" extensions to be of type TEXT. It does similar mappings for other extensions. See File Types and Extensions on page III-455 for details.

creatorStr is obsolete and should no longer be used unless you need to specify the separator in which case, use “????” for creatorStr.

separatorStr is an optional string argument used when index is -1. If you omit separatorStr, file names are separated by ";". This parameter was added in Igor 9.01.
Order of Files Returned By IndexedFile

The order in which files are returned by IndexedFile is determined by the operating system. If the order matters to you, you should explicitly sort the file names.

For example, assume you have files named "File1.txt", "File2.txt" and "File10.txt". An alphabetic order gives you: "File1.txt;File10.txt;File2.txt;". Often what you really want is a combination of alphabetic and numeric sorting returning "File1.txt;File2.txt;File10.txt;". Here is a function that does that:

Function DemoIndexedFile()
    String pathName = "Igor" // Refers to "Igor Pro Folder"
    // Get a semicolon-separated list of all files in the folder
    String list = IndexedFile(pathName, -1, ".txt")
    // Sort using combined alpha and numeric sort
    list = SortList(list, ";", 16)
    // Process the list
    Variable numItems = ItemsInList(list)
    Variable i
    for(i=0; i<numItems; i+=1)
        String fileName = StringFromList(i, list)
        Print i, fileName
    endfor
End

Treatment of Macintosh Dot-Underscore Files

IndexedFile ignores "dot-underscore" files unless fileTypeOrExtStr is "????".

A dot-underscore file is a file created by Macintosh when it writes to a non-HFS volume, for example, when it writes to a Windows volume via SMB file sharing. The dot-underscore file stores Macintosh HFS-specific data such as the file's type and creator codes, and the file's resource fork, if it has one.

For example, if a file named "wave0.ibw" is copied via SMB to a Windows volume, Mac OS X creates two files on the Windows volume: "wave0.ibw" and "._wave0.ibw". Mac OS X makes these two files appear as one to Macintosh applications. However, Windows does not do this. As a consequence, when a Windows program sees "._wave0.ibw", it expects it to be a valid .ibw file, but it is not. This causes problems.

By ignoring dot-underscore files, IndexedFile prevents this type of problem. However, if fileTypeOrExtStr is "????", IndexedFile will return dot-underscore files on Windows.

Examples

NewPath/O myPath "MyDisk:MyFolder:
Print IndexedFile(myPath,-1,"TEXT") // all text-type files
Print IndexedFile(myPath,0,"TEXT") // only the first text file
Print IndexedFile(myPath,-1,".dat") // *.dat
Print IndexedFile(myPath,-1,"TEXT","IGR0") // all Igor text files
Print IndexedFile(myPath,-1,"????") // all files, all creators
Print IndexedFile(myPath,-1,"????","????","\r") // CR separator

See IndexedDir for another example using IndexedFile and for a method for speeding up scanning of very large numbers of files.

See Also

The TextFile and IndexedDir functions.
IndexSort

IndexSort [ /DIML ] indexWaveName, sortedWaveName [, sortedWaveName]...

The IndexSort operation sorts the values in each sortedWaveName wave according to the Y values of indexWaveName.

Flags
/
DIML Moves the dimension labels with the values (keeps any row dimension label with the row’s value).

Details
indexWaveName can not be complex. indexWaveName is presumed to have been the destination of a previous MakeIndex operation.

This has the effect of putting the sortedWaveName waves in the same order as the wave from which the index values in indexWaveName was made.

All of the sortedWaveName waves must be of equal length.

See Also
Sorting on page III-132, MakeIndex and IndexSort on page III-134, Sort, MakeIndex

IndexToScale

IndexToScale(wave, index, dim)

The IndexToScale function returns the scaled coordinate value corresponding to wave element index in the specified dimension.

The IndexToScale function was added in Igor Pro 7.00.

Details
The function returns the expression:

\[ \text{DimOffset}(\text{wave}, \text{dim}) + \text{index} \times \text{DimDelta}(\text{wave}, \text{dim}) \]

index is an integer.

dim is 0 for rows, 1 for columns, 2 for layers or 3 for chunks.

The function returns NaN if dim is not a valid dimension or if index is greater than the number of elements in the specified dimension.

Examples

Make/N=(10,20,30,40) w4D
SetScale/P y 2,3, , , w4D
SetScale/P z 4,5, , , w4D
SetScale/P t 6,7, , , w4D
Print IndexToScale(w4D,1,0)
Print IndexToScale(w4D,1,1)
Print IndexToScale(w4D,1,2)
Print IndexToScale(w4D,1,3)
Print IndexToScale(w4D,-1,0)
Print IndexToScale(w4D,1,4)

See Also
ScaleToIndex, pnt2x, DimDelta, DimOffset

Waveform Model of Data on page II-62 for an explanation of wave scaling.

Inf

Inf

The Inf function returns the “infinity” value.
InsertPoints

InsertPoints [ /M=dim /V=value ] beforePoint, numPoints, waveName [, waveName]...

The InsertPoints operation inserts numPoints points in front of point beforePoint in each waveName. The new points have the value zero.

Flags

/M=dim Specifies the dimension into which elements are to be inserted. Values are 0 for rows, 1 for columns, 2 for layers, 3 for chunks. If /M is omitted, InsertPoints inserts in the rows dimension.

/V=value When used with numeric waves, value specifies the value for new elements. If you omit /V, new elements are set to zero. The /V flag was added in Igor Pro 8.00.

Details

Trying to insert points into any but the rows of a zero-point wave results in a zero-point wave. You must first make the number of rows nonzero before anything else has an effect.

See Also

Lists of Values on page II-78.

InstantFrequency

InstantFrequency [flags] srcWave [ (startX,endX) ]

The InstantFrequency operation computes the instantaneous frequency, and optionally the instantaneous amplitude, of srcWave. InstantFrequency was added in Igor Pro 9.00.

InstantFrequency creates an output wave whose name and location depends on the /DEST and /OUT flags as described under InstantFrequency Output Wave below.

Parameters

srcWave specifies the wave to be analyzed.

[startX,endX] is an optional subrange to analyze in point numbers.

(startX,endX) is an optional subrange to analyze in X values.

If you omit the subrange, startX defaults to the first point in srcWave and endX defaults to the last point in srcWave.

Flags for all Methods

/DEST=destWave Specifies the output wave created by the operation.

destWave can be a simple wave name, a data folder path plus wave name, or a wave reference to an existing wave.

It is an error to specify the same wave as both srcWave and destWave.

If you omit /DEST, the output wave name depends on /OUT.

When used in a function, the InstantFrequency operation by default creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-72 for details.

See InstantFrequency Output Wave below for further discussion.

/FREE Creates a free destination wave (see Free Waves on page IV-91).

/FREE is allowed only in functions and only if you include /DEST=destWave where destWave is a simple name or an valid wave reference.
### InstantFrequency

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/METH=method</td>
<td>Specifies the method by which the calculation is performed.</td>
</tr>
<tr>

<tr>
<td>mode=3</td>
<td>Frequency and amplitude</td>
</tr>
<tr>
<td>mode=4</td>
<td>Signed amplitude only</td>
</tr>
<tr>
<td>mode=5</td>
<td>Debugging output</td>
</tr>
</tbody>
</table>

If you omit /DEST, the output wave is created in the current data folder with a name determined by mode as follows:

- mode=1: W_InstantFrequency
- mode=2: W_InstantAmplitude
- mode=3: M_InstantFrequency
- mode=4: W_InstantAmplitude
- mode=5: M_InstantFrequency

### Flags for Spectrogram Method (/METH=2) Only

- /HOPS=hopSize: Specifies the offset in points between centers of consecutive source segments. By default hopSize is 1 and the transform is computed for segments that are offset by a single points from each other.
- /PAD=newSize: Converts each segment of srcWave into a padded array of length newSize. The padded array contains the original data at the center of the array with zeros elements on both sides.
- /SEGS=segSize: Sets the length of the segment sampled from srcWave in points. The segment is optionally padded to a larger dimension (see /PAD) and multiplied by a window function prior to FFT. segSize must be 32 or greater.

Defining $n$ as numpnts(srcWave), the default segment size, used if you omit /SEGS, is:

- $n/200$ if $n > 25600$
- $128$ if $130 <= n <= 25599$
- $n-2$ if $n <= 129$

- /WINF=windowKind: Premultiplies a data segment with the selected window function. The default window is Hanning. See Window Functions in the documentation for FFT for details.

### InstantFrequency Output Wave

- If you use the /FREE flag then the output wave is created as a free wave using the name or wave reference specified by /DEST=destWave.

- If you include the /DEST flag and omit /FREE then the output wave location and name is specified by the destWave parameter. destWave can be a simple wave name, a data folder path plus wave name, or a wave reference to an existing wave.
If you omit the /DEST and /FREE flags then the output wave is created in the current data folder with the default name W_InstantFrequency (/OUT=1), W_InstantAmplitude (/OUT=2 or 4), or M_InstantFrequency (/OUT=3 or 5), depending on the /OUT flag.

**Gabor Method (/METH=1)**

The Gabor method uses the Hilbert Transform to synthesize an "analytic" signal that is a copy of the source wave, shifted by 90 degrees, but with the constant ("DC") component removed.

A complex "phasor" wave is generated whose real part is the source wave, and the imaginary part is this analytic signal.

The phase at each time point is computed as \(\text{atan2}(\text{imag}(\text{phasor}[p]),\text{real}(\text{phasor}[p]))\). This phase calculation is affected by any constant component of the source wave. The derivative of this phase with respect to time is the instantaneous frequency.

The instantaneous amplitude is the magnitude of the phasor\([p]\).

See the [HilbertTransform](https://en.wikipedia.org/wiki/HilbertTransform) operation example for an equivalent implementation.

The /OUT=5 debugging output for the Gabor method is:

```plaintext
destWave[][0] // Instant frequency
destWave[][1] // Instant amplitude
destWave[][2] // Unwrapped phase wave
destWave[][3] // Trajectory Y wave (Hilbert transform of input wave)
```

**Osculating Circle Method (/METH=0)**

The primary drawback of the Gabor method is that any sizeable constant level distorts the phase such that it isn't always increasing, which results in negative frequencies being computed. The Osculating Circle Method does not have this problem.

The Osculating Circle method constructs the same analytic phasor as the Gabor method, but computes the phase and derivative differently in a way that eliminates the constant level distortion: at each point the phasor's previous, current, and next complex values (the "trajectory") are fit to a circle in the complex plane. That circle's origin is used to measure both the phase and amplitude at that point, instead of the origin at \((0+i0)\) that the Gabor method uses.

The /OUT=5 debugging output for the Osculating Circle method is:

```plaintext
destWave[][0] // Instant frequency
destWave[][1] // Signed instant amplitude
destWave[][2] // Unwrapped phase wave
destWave[][3] // Trajectory Y wave (Hilbert transform of input wave)
destWave[][4] // Trajectory dY wave
destWave[][5] // Trajectory ddY wave
destWave[][6] // Trajectory dX wave
destWave[][7] // Trajectory ddYX wave
destWave[][8] // Origin Y wave
destWave[][9] // Origin X wave
```

**Spectrogram (/METH=2 or 3)**

The Spectrogram method for determining instant frequency and amplitude is based on measuring the Short-Time Fourier Transform, the 2D time-frequency representation for a 1D array. The scaled magnitude of the transform is known as the "spectrogram" for time series or "sonogram" in the case of sound input. Methods 2 and 3 are comprised of the following steps:

1. Compute the Short-Time Fourier Transform according to the various spectrogram parameters. This results in a 2D wave, where the columns of each row comprise the scaled magnitude spectrum at one point in time.
2. For each spectrum determine where the dominant frequency lies, and its magnitude.

For /METH=2, the dominant frequency is found using the centerOfMass function.

For /METH=3, the dominant frequency is found by locating the maximum value.

The /OUT=5 debugging output for the Spectrogram method is the 2D spectrogram that would have been used as the output of step 1.

STFT, HilbertTransform, DSPPeriodogram

**Int**

`int localName`

In a user-defined function or structure, declares a local 32-bit integer in IGOR32, a local 64-bit integer in IGOR64.

Int is available in Igor Pro 7 and later. See **Integer Expressions** on page IV-38 for details.

See Also
Int64, UInt64

**Int64**

`int64 localName`

Declares a local 64-bit integer in a user-defined function or structure.

Int64 is available in Igor Pro 7 and later. See **Integer Expressions** on page IV-38 for details.

See Also
Int, UInt64

**Integrate**

The Integrate operation calculates the 1D numeric integral of a wave. X values may be supplied by the X-scaling of the source wave or by an optional X wave. Rectangular integration is used by default.

Integrate is multi-dimension-aware in the sense that it computes a 1D integration along the dimension specified by the /DIM flag or along the rows dimension if you omit /DIM.

Complex waves have their real and imaginary components integrated individually.

**Flags**

/DIM=d Specifies the wave dimension along which to integrate when `yWave` is multidimensional.

- d=1: Treats entire wave as 1D (default).
- d=0: Integrates along rows.
- d=1: Integrates along columns.
- d=2: Integrates along layers.
- d=3: Integrates along rows.

For example, for a 2D wave, /DIM=0 integrates each row and /DIM=1 integrates each column.

/METH=m Sets the integration method.

- m=0: Rectangular integration (default). Results at a point are stored at the same point (rather than at the next point as for /METH=2). This method keeps the dimension size the same.
- m=1: Trapezoidal integration.
- m=2: Rectangular integration. Results at a point are stored at the next point (rather than at the same point as for /METH=0). This method increases the dimension size by one to provide a place for the last bin.
Integrate

/V-447

Type Flags (used only in functions)
Integrate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See WAVE Reference Types on page IV-73 and WAVE Reference Type Flags on page IV-74 for a complete list of type flags and further details.

For example, when the input (and output) waves are complex, the output wave will be complex. To get the Igor compiler to create a complex output wave reference, use the /C type flag with /D=destwave:

Make/O/C cInput=cmplx(sin(p/8), cos(p/8))
Make/O/C/N=0 cOutput
Integrate/C cInput /D=cOutput

Wave Parameters

/Wave Parameters

Note: All wave parameters must follow yWave in the command. All wave parameter flags and type flags must appear immediately after the operation name (Integrate).

/D=destWave Specifies the name of the wave to hold the integrated data. It creates destWave if it does not already exist or overwrites it if it exists.

/X=xWave Specifies the name of corresponding X wave. For rectangular integration, the number of points in the X wave must be one greater than the number of elements in the Y wave dimension being integrated.

Details

The computation equation for rectangular integration using /METH=0 is:

\[ \text{waveOut}[p] = \sum_{i=0}^{p} \text{waveIn}[i] \cdot \Delta x. \]

The computation equation for rectangular integration using /METH=2 is:

\[ \text{waveOut}[0] = 0 \]

\[ \text{waveOut}[p + 1] = \sum_{i=0}^{p} (x_{i+1} - x_i) \text{waveIn}[i]. \]

The inverse of this rectangular integration is the backwards difference.

Trapezoidal integration (/METH=1) is a more accurate method of computing the integral than rectangular integration. The computation equation is:

\[ \text{waveOut}[0] = 0 \]

\[ \text{waveOut}[p] = \text{waveOut}[p - 1] + \frac{\Delta x}{2} (\text{waveIn}[p - 1] + \text{waveIn}[p]). \]

If the optional /D = destWave flag is omitted, then the wave is integrated in place overwriting the source wave.

When using an X wave, the X wave must be a 1D wave with data type matching the Y wave (excluding the complex type flag). Rectangular integration (/METH=0 or 2) requires an X wave having one more point than the number of elements in the dimension of the Y wave being integrated. X waves with number points plus one are allowed for rectangular integration with methods needing only the number of points. X waves are not used with integer source waves.
Although it is mathematically suspect, rectangular integration using /METH=0 would be correct if the X scaling of the output wave is offset by ΔX.

Differentiate/METH=1/EP=1 is the inverse of Integrate/METH=2, but Integrate/METH=2 is the inverse of Differentiate/METH=1/EP=1 only if the original first data point is added to the output wave. Integrate applied to an XY pair of waves does not check the ordering of the X values and doesn’t care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves first (see Sort).

Integrate1D

**Integrate1D(UserFunctionName, min_x, max_x [, options [, count [, pWave]]])**

The Integrate1D function performs numerical integration of a user function between the specified limits (min_x and max_x).

**Parameters**

UserFunctionName must have this format:

```
Function UserFunctionName(inX)
    Variable inX
    ... do something
    return result
End
```

However, if you supply the optional pWave parameter then it must have this format:

```
Function UserFunctionName(pWave, inX)
    Wave pWave
    Variable inX
    ... do something
    return result
End
```

options is one of the following:

0: Trapezoidal integration (default).
1: Romberg integration.
2: Gaussian Quadrature integration.

By default, options is 0 and the function performs trapezoidal integration. In this case Igor evaluates the integral iteratively. In each iteration the number of points where Igor evaluates the function increases by a factor of 2. The iterations terminate at convergence to tolerance or when the number of evaluations is $2^{23}$.

The count parameter specifies the number of subintervals in which the integral is evaluated. If you specify 0 or a negative number for count, the function performs an adaptive Gaussian Quadrature integration in which Igor bisects the interval and performs a recursive refining of the integration only in parts of the interval where the integral does not converge to tolerance.

pWave is an optional parameter that, if present, is passed to your function as the first parameter. It is intended for your private use, to pass one or more values to your function, and is not modified by Igor. The pWave parameter was added in Igor Pro 7.00.

**Details**

You can integrate complex-valued functions using a function with the format:

```
Function/C complexUserFunction(inX)
    Variable inX
    Variable/C result
    //... do something
    return result
End
```

The syntax used to invoke the function is:

```
Variable/C cIntegralResult=Integrate1D(complexUserFunction, min_x, max_x...)
```
You can also use Integrate1D to perform a higher dimensional integrals. For example, consider the function:
\[ F(x, y) = 2x + 3y + xy. \]

In this case, the integral
\[ h = \int dy \int f(x, y) dx \]
can be performed by establishing two user functions:

```plaintext
Function Do2dIntegration(xmin, xmax, ymin, ymax)
    Variable xmin, xmax, ymin, ymax
    Variable/G globalXmin=xmin
    Variable/G globalXmax=xmax
    Variable/G globalY
    return Integrate1d(userFunction2, ymin, ymax, 1) // Romberg integration
End

Function UserFunction1(inX)
    Variable inX
    NVAR globalY=globalY
    return (3*inX+2*globalY+inX*globalY)
End

Function UserFunction2(inY)
    Variable inY
    NVAR globalY=globalY
    globalY=inY
    NVAR globalXmin=globalXmin
    NVAR globalXmax=globalXmax
    // Romberg integration
    return Integrate1d(userFunction1, globalXmin, globalXmax, 1)
End
```

This method can be extended to higher dimensions.

If the integration fails to converge or if the integrand diverges, Integrate1D returns NaN. When a function fails to converge it is a good idea to try another integration method or to use a user-defined number of intervals (as specified by the count parameter). Note that the trapezoidal method is prone to convergence problems when the absolute value of the integral is very small.

Integrate2D

```
Integrate2D [flags] [keyword = value [, keyword = value ...]]
```

The Integrate2D operation calculates a two-dimensional numeric integral of a real-valued user-defined function or a wave. The result of the operation is stored in the variable V_value and the variable V_Flag is set to zero if there are no errors.

This operation was added in Igor Pro 7.00.

Flags

/OPTS=op  Sets the integration options. By default, both the x and the y integrations are performed using the adaptive trapezoidal method.
Integrate2D

\textit{op} is a bitwise parameter that you set to select the \textit{x} and \textit{y} integration methods. Set one bit for \textit{x} and one bit for \textit{y}:

- Bit 0: Trapezoidal in \textit{Y} (1)
- Bit 1: Romberg in \textit{Y} (2)
- Bit 2: Gaussian Quadrature in \textit{Y} (4)
- Bit 3: Trapezoidal in \textit{X} (8)
- Bit 4: Romberg in \textit{X} (16)
- Bit 5: Gaussian Quadrature in \textit{X} (32)

See \textit{Setting Bit Parameters} on page IV-12 for details about bit settings.

Using these constants you can specify, for example, Romberg integration in the \textit{Y} direction and Gaussian Quadrature in the \textit{X} direction using \texttt{/OPTS=(2 | 32)}.

- \texttt{/Q} Suppress printing to the history area.
- \texttt{/Z=zFlag} Set \textit{zFlag} to 1 to suppress error reporting.

\textbf{Keywords}

- \texttt{epsilon=ep} Specifies the convergence parameter. By default \textit{ep}=1e-5. Smaller values lead to more accurate integration result but the tradeoff is longer computation time.

- \texttt{integrand=uf} Specifies the user function to be integrated. See \textbf{The Integrand Function} below for details.

- \texttt{innerLowerLimit=y1} Specifies the lower limit of the inner integral if this limit is fixed, i.e., if it is not a function of \textit{x}. See the innerLowerFunc keyword if you need to specify a function for this limit.

- \texttt{innerUpperLimit=y2} Specifies the upper limit of the inner integral if this limit is fixed, i.e., if it is not a function of \textit{x}. See the innerUpperFunc keyword if you need to specify a function for this limit.

- \texttt{innerLowerFunc=y1Func} Specifies a user-defined function for the lower limit of the inner integral. See \textbf{The Limit Functions} below.

- \texttt{innerUpperFunc=y2Func} Specifies a user-defined function for the upper limit of the inner integral. See \textbf{The Limit Functions} below.

- \texttt{outerLowerLimit=x1} Specifies the lower limit of the outer integral.

- \texttt{outerUpperLimit=x2} Specifies the upper limit of the outer integral.

- \texttt{paramWave=pWave} Specifies a wave to be passed to the integrand and limit user-defined functions as the \textit{pWave} parameter. The wave may contain any number of values that you might need to evaluate the integrand or the integration limits.

  If you omit \texttt{paramWave} then the \textit{pWave} parameter to the functions will be NULL.

- \texttt{srcWave=mWave} If you need to perform 2D integration of some data, you can specify the data directly instead of providing a user-defined function that returns interpolated data. \textit{mWave} must be a 2D wave. Higher dimensional waves are accepted but only the first layer of the wave is used in the integration.

\textbf{The Integrand Function}

Integrate2D computes the general two-dimensional integral of a user-defined integrand function which you specify using the integrand keyword. The integrand function has this form:

\begin{verbatim}
Function integrandFunc(pWave,inX,inY)
    Wave/Z pWave
    Variable inX,inY
\end{verbatim}
... do something
return result
End

The function can have any name - integrandFunc is just an example. The function must take the parameters shown and must return a real numeric result. Returning a NaN terminates the integration.

pWave is a parameter wave that you specify using the paramWave keyword. The operation passes this wave on every call to the integrand function. If you omit paramWave when invoking Integrate2D then pWave will be NULL.

The Limit Functions
The limit functions provide lower and/or upper limits of integration for the inner integral if they are functions of x rather than fixed values. You specify a limit function using the innerLowerFunc and innerUpperFunc keywords. The form of the limit function is:

Function limitFunction(pWave,inX)
    Wave/Z pWave
    Variable inX
    ... do something
    return result
End

Details
The operation computes the general two-dimensional integral of the form

$$I = \int dx \int_{y_1(x)}^{y_2(x)} f(x,y)dy.$$  

Here \( y_1 \) and \( y_2 \) are in general functions of \( x \) but could also be simple constants, and \( f(x,y) \) is real valued function. The integral is evaluated by considering the "outer" integral

$$I = \int_{x_1}^{x_2} G(x)dx,$$

where \( G(x) \) is the "inner" integral

$$G(x) = \int_{y_1(x)}^{y_2(x)} f(x,y)dy.$$  

The operation allows you to specify different algorithms for integrating the inner and outer integrals. The simplest integration algorithm is the Trapezoidal method. You can typically improve on the accuracy of the calculation using Romberg integration and the performance of Gaussian quadrature depends significantly on the nature of the integrand.

Example 1: Integrating a 2D function over fixed limits
Suppose we wanted to check the normalization of the built-in two-dimensional Gauss function. The user-defined function would be:

Function myIntegrand1(pWave,inX,inY)
    Wave/Z pWave
    Variable inX,inY
    return Gauss(inX,50,10,inY,50,10)
End

To perform the integration, execute:

Integrate2D outerLowerLimit=0, outerUpperLimit=100, innerLowerLimit=0,
    innerUpperLimit=100, integrand=myIntegrand1
Print/D V_Value
Example 2: Integrating a 2D function using function limits

In this example we compute the volume of a sphere of radius 1. To do so we use symmetry and integrate the volume in one octant only. The limits of integration are \([0,1]\) in the x direction and \([0,\sqrt{1-x^2}]\) in the y direction. In this case we need to define two user-defined functions: one for the integrand and one for the upper limit of the inner integral:

```plaintext
Function myIntegrand2(pWave,inX,inY)
    Wave/Z pWave
    Variable inX, inY
    Variable r2 = inX^2 + inY^2
    if(r2 >= 1)
        return 0
    else
        return sqrt(1-r2)
    endif
End

Function y2Func(pWave,inX)
    Wave pWave
    Variable inX
    return sqrt(1-inX^2)
End
```

To perform the integration, execute:

```plaintext
Integrate2D outerLowerLimit=0, outerUpperLimit=1, innerLowerLimit=0, innerUpperLimit=y2Func, integrand=myIntegrand2
Print/D 4*pi/3 // Calculation error
```

Note that the integrand function tests that \(r^2\) does not exceed 1. This is because the \(\sqrt{\) function would return a NaN if \(r^2 > 1\) which can happen due to floating point rounding errors. Returning a NaN terminates the integration.

Example 3: Integrating a 2D wave using fixed limits

In this example we compute the volume between the surface defined by the wave my2DWave and the plane \(z=0\) with integration limits \([0,1]\) in the x-direction and \([0,2]\) in the y-direction. For simplicity we set the wave's value to be a constant (\(\pi\)).

```plaintext
Make/O/N=(5,9) my2DWave=pi
SetScale/P x 0,0.3,, my2DWave
SetScale/P y 0,0.4,, my2DWave
Integrate2D outerLowerLimit=0, outerUpperLimit=1, innerLowerLimit=0, innerUpperLimit=2, srcWave=my2DWave
Print/D 2*pi-V_Value // Calculation error
```

IntegrateODE

The IntegrateODE operation calculates a numerical solution to a set of coupled ordinary differential equations by integrating derivatives. The derivatives are user-specified via a user-defined function, derivFunc. The equations must be a set of first-order equations; a single second-order equation must be recast as two first-order equations, a third-order equation to three first order equations, etc. For more details on how to write the function, see Solving Differential Equations on page III-322.

IntegrateODE offers two ways to specify the values of the independent variable (commonly called X or t) at which output Y values are recorded. You can specify the X values or you can request a “free-run” mode.

The algorithms used by IntegrateODE calculate results at intervals that vary according to the characteristics of the ODE system and the required accuracy. You can set specific X values where you need output (see the /X flag below) and arrangements will be made to get values at those specific X values. In between those values, IntegrateODE will calculate whatever spacing is needed, but intermediate values will not be output to you.

If you specify free-run mode, IntegrateODE will simply output all steps taken regardless of the spacing of the X values that results.
IntegrateODE

### Parameters

- **cwaveName**: Name of wave containing constant coefficients to be passed to derivFunc.
- **derivFunc**: Name of user function that calculates derivatives. For details on the form of the function, see Solving Differential Equations on page III-322.
- **ywaveSpec**: Specifies a wave or waves to receive calculated results. The waves also contain initial conditions. The ywaveSpec can have either of two forms:
  - **ywaveName**: ywaveName is a single, multicolumn wave having one column for each equation in your equation set (if you have just one equation, the wave will be a simple 1D wave).
  - **{ywave0, ywave1, ...}**: The ywaveSpec is a list of 1D waves, one wave for each equation. The ordering is important — it must correspond to the elements of the y wave and dydx wave passed to derivFunc.

Unless you use the /R flag to alter the start point, the solution to the equations is calculated at each point in the waves, starting with row 1. You must store the initial conditions in row 0.

### Flags

/ CVOP={solver, jacobian, extendedErrors [, maxStep]}

Selects options that affect how the Adams-Moulton and BDF integration schemes operate. This flag applies only when using /M = 2 or /M = 3. These methods are based on the CVODE package, hence the flag letters “CV”.

The **solver** parameter selects a solver method for each step. The values of solver can be:

- **solver=0**: Select the default for the integration method. That is functional for /M=2 or Newton for /M=3.
- **solver=1**: Functional solver.
- **solver=2**: Newton solver.

The **jacobian** parameter selects the method used to approximate the jacobian matrix (matrix of \( \frac{df}{dy_i} \) where \( f \) is the derivative function).

- **jacobian=0**: Full jacobian matrix.
- **jacobian=1**: Diagonal approximation.

In both cases, the derivatives are approximated by finite differences.

In our experience, **jacobian = 1** causes the integration to proceed by much smaller steps. It might decrease overall integration time by reducing the computation required to approximate the jacobian matrix.

If the **extendedErrors** parameter is nonzero, extra error information will be printed to the history area in case of an error during integration using /M=2 or /M=3. This extra information is mostly of the sort that will be meaningful only to WaveMetrics software engineers, but may occasionally help you to solve problems. It is printed out as a bug message (BUG: ...) regardless of whether it is our bug or yours.

If **maxStep** is present and greater than zero, this option sets the maximum internal step size that the CVODE package is allowed to take. This is particularly useful with /M=3, as the BDF method is capable of taking extremely large steps if the derivatives don’t change much. Use of this option may be necessary to make sure that the CVODE package doesn’t step right over a brief excursion in, say, a forcing function. If you have something in your derivative function that may be step-like and brief, set **maxStep** to something smaller than the duration of the excursion.

If you want to set **maxStep** only, set the other three options to zero.
Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a fraction of a scaled number. The fraction is \( \varepsilon \). For instance, to achieve error less than one part in a thousand, set \( \varepsilon \) to 0.001. The number itself is set by a combination of the /F flag and possibly the wave specified with the /S flag. See Solving Differential Equations on page III-322 for details.

If you do not use the /E flag, \( \varepsilon \) is set to \( 10^{-6} \).

For details, see Error Monitoring on page III-332.

Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a scaled number. \( \text{errMethod} \) is a bitwise parameter that specifies what to include in that number:

- bit 0:  Add a constant from the error scaling wave set by the /S flag.
- bit 1:  Add the current value of the results.
- bit 2:  Add the current value of the derivatives.
- bit 3:  Multiply by the current step size (/M=0 or /M=1 only).

Each bit that you set of bits 0, 1, or 2 adds a term to the number; setting bit 3 multiplies the sum by the current step size to achieve a global error limit. Note that bit 3 has no effect if you use the Adams or BDF integrators (/M=2 or /M=3). See Setting Bit Parameters on page IV-12 for further details about bit settings.

If you don’t include the /F flag, a constant is used. Unless you use the /S flag, that constant is set to 1.0.

For details, see Error Monitoring on page III-332.

Specifies the method to use in calculating the solution.

- \( m=0 \): Fifth-order Runge-Kutta-Fehlberg (default).
- \( m=1 \): Bulirsch-Stoer method using Richardson extrapolation.
- \( m=2 \): Adams-Moulton method.
- \( m=3 \): BDF (Backwards Differentiation Formula, or Gear method). This method is the preferred method for stiff problems.

If you don’t specify a method, the default is the Runge-Kutta method (\( m=0 \)). Bulirsch-Stoer (\( m=1 \)) should be faster than Runge-Kutta for problems with smooth solutions, but we find that this is often not the case. Simple experiments indicate that Adams-Moulton (\( m=2 \)) may be fastest for nonstiff problems. BDF (\( m=3 \)) is definitely the preferred one for stiff problems. Runge-Kutta is a robust method that may work on problems that fail with other methods.

Sets quiet mode. In quiet mode, no messages are printed in the history, and errors do not cause macro abort. The variable \( \text{V}\_\text{flag} \) returns an error code. See Details for the meanings of the \( \text{V}\_\text{flag} \) error codes.

Specifies an X range of the waves in \( \text{ywaveSpec} \).

Specifies a point range in \( \text{ywaveSpec} \).

If you specify the range as /R=[startP,endP] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is evaluated. If you specify only the end point (/R=[endP]) the start point is taken as point 0.

You must store initial conditions in \( \text{startP} \). The first point is \( \text{startP}+1 \).
If you set bit 0 of *errMethod* using the /F flag, or if you don’t include the /F flag, a constant is required for scaling the estimated error for each differential equation. By default, the constants are simply set to 1.0.

You provide custom values of the constants via the /S flag and a wave. Make a wave having one element for each derivative, set a reasonable scale factor for the corresponding equation, and set *errScaleWaveName* to the name of that wave.

If you don’t use the /S flag, the constants are all set to 1.0.

*/STOP = {stopWave, mode}*  

Requests that IntegrateODE stop when certain conditions are met on either the solution values (Y values) or the derivatives.  
*stopWave* contains information that IntegrateODE uses to determine when to stop.  
*mode* controls the logical operations applied to the elements of *stopWave*:  

*mode=0:* OR mode. If *stopWave* contains more than one condition, any one condition will stop the integration when it is satisfied.  

*mode=1:* AND mode. If *stopWave* contains more than one condition, all conditions must be satisfied to cause the integration to stop.

See Details, below, for more information.

*/U=u*  

Update the display every *u* points. By default, it will update the display every 10 points. To disable updates, set *u* to a very large number.

*/X=xvaluespec*  

Specifies the values of the independent variable (commonly called x or t) at which values are to be calculated (see parameter *ywaveSpec*).  
You can provide a wave or *x0* and *deltaX*:

*/X = xWaveName*  

Use this form to provide a list of values for the independent variable. They can have arbitrary spacing and may increase or decrease, but should be monotonic.  
If you use the /XRUN flag to specify free-run mode, */X = xWaveName* is required. In this case, the X wave becomes an output wave and any contents are overwritten. See the description of /XRUN for details.

*/X = {x0, deltaX}*  

If you use this form, *x0* is the initial value of the independent variable. This is the value at which the initial conditions apply. It will calculate the first result at *x0+deltaX*, and subsequent results with spacing of *deltaX*.  
*deltaX* can be negative.

If you do not use the xValues keyword, it reads independent variable values from the X scaling of the results wave (see *ywaveSpec* parameter).
If \( dx0 \) is nonzero, the output is generated in a free-running mode. That is, the output values are generated at whatever values if the independent variable (\( x \) or \( t \)) the integration method requires to achieve the requested accuracy. Thus, you will get solution points at variably-spaced \( X \) values.

The parameter \( dx0 \) sets the step size for the first integration step. If this is smaller than necessary, the step size will increase rapidly. If it is too large for the requested accuracy, the integration method will decrease the step size as necessary.

If \( dx0 \) is set to zero, free-run mode is not used; this is the same as if the XRUN flag is not used.

When using free-run mode, you must provide an \( X \) wave using /\( X = xWaveName \). Set the first value of the wave (this is usually point zero, but may not be if you use the /R flag) to the initial value of \( X \).

As the integration proceeds, the \( X \) value reached for each output point is written into the \( X \) wave. The integration stops when the latest step taken goes beyond \( Xmax \) or when the output waves are filled.

**Details**

The various waves you may use with the IntegrateODE operation must meet certain criteria. The wave to receive the results (\( ywaveSpec \)), and which contains the initial conditions, must have exactly one column for each equation in your system of equations, or you must supply a list of waves containing one wave for each equation. Because IntegrateODE can’t determine how many equations there are from your function, it uses the number of columns or the number of waves in the list to determine the number of equations.

If you supply a list of waves for \( ywaveSpec \), all the waves must have the same number of rows. If you supply a wave containing values of the independent variable or to receive \( X \) values in free-run mode (using /\( X = xWaveName \)) the wave must have the same number of rows as the \( ywaveSpec \) waves.

The wave you provide for error scaling via the /\( S \) flag must have one point for each equation. That is, one point for each \( ywaveSpec \) wave, or one point for each column of a multicolumn \( ywaveSpec \).

By default, the display will update after each tenth point is calculated. If you display one of your \( ywaveSpec \) waves in a graph, you can watch the progress of the integration.

The display update may slow down the calculation considerably. Use the /U flag to change the interval between updates. To disable the updates entirely, set the update interval to a number larger than the length of the waves in \( ywaveSpec \).

In free-run mode, it is impossible to predict how many output values you will get. IntegrateODE will stop when either your waves are filled, or when the \( X \) value exceeds \( Xmax \) set in the /XRUN flag. The best strategy is to make the waves quite large; unused rows in the waves will not be touched. To avoid having “funny” traces on a graph, you can prefill your waves with NaN. Make sure that you don’t set the initial condition row and initial \( X \) value row to Nan!

**Stopping IntegrateODE**

In some circumstances it is useful to be able to stop the integration early, before the full number of output values has been computed. You can do this two ways: using the /STOP flag to put conditions on the solution, or by returning 1 from your derivative function.

When using /STOP={\( stopWave, mode \)}, \( stopWave \) must have one column for each equation in your system or, equivalently, a number of columns equal to the order of your system. Each column represents a condition on either the solution value or the derivatives for a given equation in your system.

Row 0 of \( stopWave \) contains a flag telling what sort of condition to apply to the solution values. If the flag is zero, that value is ignored. If the flag is 1, the integration is stopped if the solution value exceeds the value you put in row 1. If the flag is -1, integration is stopped when the solution value is less than the value in row 1.

Rows 2 and 3 work just like rows 0 and 1, but the conditions are applied to the derivatives rather than to the solution values.

If \( stopWave \) has two rows, only the solution values are checked. If \( stopWave \) has four rows, you can specify conditions on both solution values and derivatives.
You can set more than one flag value non-zero. If you do that, then mode determines how the multiple conditions are applied. If mode is 0, then any one condition can stop integration when it is satisfied. If mode is 1, all conditions with a non-zero flag value must be satisfied at the same time. If row 0 and row 2 have nothing but zeroes, then stopWave is ignored.

For further discussion, see Stopping IntegrateODE on a Condition on page III-335.

Output Variables
The IntegrateODE operation sets a variety of variables to give you information about the integration. These variables are updated at the same time as the display so you can monitor an integration in progress. They are:

- **V_ODEStepCompleted**: Point number of the last result calculated.
- **V_ODEStepSize**: Size of the last step in the calculation.
- **V_ODETotalSteps**: Total number of steps required to arrive at the current result. In free-run mode, this is the same as V_ODEStepCompleted.
- **V_ODEMinsStep**: Minimum step size used during the entire calculation.
- **V_ODEFunctionCalls**: The total number of calls made to your derivative function.
- **V_Flag**: Indicates why IntegrateODE stopped.

The values for V_Flag are:

0: Finished normally.
1: User aborted the integration.
2: Integration stopped because the step size became too small. That is, dX was so small that X + dX = X.
3: IntegrateODE ran out of memory.
4: In /M=2 or /M=3, the integrator received illegal inputs. Please report this to WaveMetrics (see Technical Support on page II-4 for contact details).
5: In /M=2 or /M=3, the integrator stopped with a failure in the step solver. The method chosen may not be suitable to the problem.
6: Indicates a bug in IntegrateODE. Please report this to WaveMetrics (see Technical Support on page II-4 for contact details).
7: An error scaling factor was zero (see /S and /F flags).
8: IntegrateODE stopped because the conditions specified by the /STOP flag were met.
9: IntegrateODE stopped because the derivative function returned a value requesting the stop.

Solving Differential Equations on page III-322 gives the form of the derivative function, details on the error specifications and what they mean, along with several examples.

References

The Adams-Moulton (/M=2) and BDF methods (/M=3) are based on the CVODE component of the SUNDIALS package developed at Lawrence Livermore National Laboratory:

DOI=http://dx.doi.org/10.1145/1089014.1089020

The CVODE package was derived in part from the VODE package. The parts used in Igor are described in this paper:

**interp**

\[
\text{interp}(x_1, x\text{waveName}, y\text{waveName})
\]

The interp function returns a linearly interpolated value at the location \( x = x_1 \) of a curve whose X components come from the Y values of \( x\text{waveName} \) and whose y components come from the Y values of \( y\text{waveName} \).

**Details**

interp returns nonsense if the waves are complex or if \( x\text{waveName} \) is not monotonic or if either wave contains NaNs.

The interp function is not multidimensional aware. See *Analysis on Multidimensional Waves* on page II-95 for details.

**Examples**

![Graph showing the interpolation process]

**See Also**

Interpolate2

The Loess, ImageInterpolate, Interpolate3D, and Interp3DPath operations. The Interp2D, Interp3D and ContourZ functions.

**Interp2D**

\[
\text{Interp2D}(src\text{WaveName}, xV, y)
\]

The Interp2D function returns a double precision number as the bilinear interpolation value at the specified coordinates of the source wave. It returns NaN if the point is outside the source wave domain or if the source wave is complex.

**Parameters**

- \( src\text{WaveName} \) is the name of a 2D wave which wave must be real.
- \( x \) is the X location of the interpolated point.
- \( y \) is the Y location of the interpolated point.

**See Also**

The ImageInterpolate operation. Interpolation on page III-114.

**Interp3D**

\[
\text{Interp3D}(src\text{Wave}, x, y, z \ [, \ triangulation\text{Wave}])
\]

The Interp3D function returns an interpolated value for location \( P=(x, y, z) \) in a 3D scalar distribution \( src\text{Wave} \).

If \( src\text{Wave} \) is a 3D wave containing a scalar distribution sampled on a regular lattice, the function returns a linearly interpolated value for any \( P=(x, y, z) \) location within the domain of \( src\text{Wave} \). If \( P \) is outside the domain, the function returns NaN.
To interpolate a 3D scalar distribution that is not sampled on a regular lattice, srcWave is a four column 2D wave where the columns correspond to \( x, y, z, f(z, y, z) \), respectively. You must also use a “triangulation” wave for srcWave (use Triangulate3D/OUT=1 to obtain the triangulation wave). If \( P \) falls within the convex domain defined by the tetrahedra in triangulationWave, the function returns the barycentric linear interpolation for \( P \) using the tetrahedron where \( P \) is found. If \( P \) is outside the convex domain the function returns NaN.

Examples
Make/O/N=(10,20,30) ddd=gnoise(10)
Print interp3D(ddd,1,0,0)
Print interp3D(ddd,1,1,1)

Make/O/N=(10,4) ddd=gnoise(10)
Triangulate3D/OUT=1 ddd
Print interp3D(ddd,1,0,0,M_3DVertexList)
Print interp3D(ddd,1,1,1,M_3DVertexList)

See Also
The Interpolate3D operation. Interpolation on page III-114.

Interp3DPath

Interp3DPath 3dWave tripletPathWave
The Interp3DPath operation computes the trilinear interpolated values of 3dWave for each position specified by a row of in tripletPathWave, which is a 3 column wave in which the first column represents the X coordinate, the second represents the Y coordinate and the third represents the Z coordinate. Interp3DPath stores the resulting interpolated values in the wave W_Interpolated. Interp3DPath is equivalent to calling the Interp3D() function for each row in tripletPathWave but it is computationally more efficient.

If the position specified by the tripletPathWave is outside the definition of the 3dWave or if it contains a NaN, the operation stores a NaN in the corresponding output entry.

Both 3dWave and tripletPathWave can be of any numeric type. W_Interpolated is always of type NT_FP64.

See Also
The ImageInterpolate operation and the Interp3D and interp functions. Interpolation on page III-114.

Interpolate2

Interpolate2 [flags] [xWave,] yWave
The Interpolate2 operation performs linear, cubic spline and smoothing cubic spline interpolation on 1D waveform or XY data. It produces output in the form of a waveform or an XY pair.

The cubic spline interpolation is based on a routine from "Numerical Recipes in C".

The smoothing spline is based on "Smoothing by Spline Functions", Christian H. Reinsch, Numerische Mathematic 10, 177-183 (1967).

For background information, see The Interpolate2 Operation on page III-115.

Parameters
xWave specifies the wave which supplies the X coordinates for the input curve. If you omit it, X coordinates are taken from the X values of yWave.

yWave specifies the wave which supplies the Y coordinates for the input curve.

Flags
/A=a Controls pre-averaging. Pre-averaging is deprecated - use the smoothing spline (/T=3) instead.

If a is zero, Interpolate2 does no pre-averaging. If a is greater than one, it specifies the number of nodes through which you want the output curve to go. Interpolate2 creates the nodes by averaging the raw input data.

Pre-averaging does not work correctly with the log-spaced output mode (/I=2). This is because the pre-averaging is done on linearly-spaced intervals but the input data is log-spaced.
Interpolate2

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| /E=e    | Controls how the end points are determined for cubic spline interpolation only. 
  e=1: Match first derivative (default) 
  e=2: Match second derivative (natural) |
| /F=f    | f is the smoothing factor used for the smoothing spline. 
  f=0 is nearly identical to the cubic spline. 
  f>0 gives increasing amounts of smoothing as f increases. 
  See Smoothing Spline Parameters on page III-119 for details. |
| /FREE   | Creates output waves as free waves (see Free Waves on page IV-91). 
  /FREE is allowed only in functions. If you use /FREE then the output waves specified by /X and /Y must be either simple names or valid wave references. 
  /FREE was added in Igor Pro 9.00. |
| /I=i    | Determines at what X coordinates the interpolation is done. 
  i=0: Gives output values at evenly-spaced X coordinates that span the X range of the input data. This is the default setting if /I is omitted. 
  i=1: Same as i=0 except that the X input values are included in the list of X coordinates at which to interpolate. This is rarely needed and is not available if no X destination wave is specified. /I is equivalent to /I=1. Both are not recommended. 
  i=2: Gives output values at X coordinates evenly-spaced on a logarithmic scale. Ignores any non-positive values in your input X data. 
  This mode is not recommended. See Interpolating Exponential Data on page III-118 for an alternative. 
  i=3: Gives output values at X coordinates that you specify by setting the X coordinates of the destination wave before calling Interpolate2. You must create your destination wave or waves before doing the If you omit /X=xDest then the X coordinates come from the X values of the output waveform designated by /Y=yDest. 
  If you include /X=xDest then the X coordinates come from the data values of the specified X output wave. 
  When using /I=3, the number of output points is determined by the destination wave and the /N flag is ignored. 
  See Destination X Coordinates from Destination Wave on page III-119 for further details. |
| /J=j    | Controls the use of end nodes with pre-averaging (/A). Pre-averaging is deprecated - use the smoothing spline (/T=3) instead. 
  j=0: Turns end nodes off. 
  j=1: Creates end nodes by cubic extrapolation. 
  j=2: Creates end nodes equal to the first and last data points of the input data set, not counting points that contain NaNs or INFs. |
| /N=n    | Controls the number of points in the output wave or waves. n defaults to the larger of 200 and the number of points in the source waves. This value is ignored if you /I=3 (X from dest mode). |
| /S=s    | s is the estimated standard deviation of the noise of the Y data. It is used for the smoothing spline only. s is used as the estimated standard deviation for all points in the Y data. 
  If neither /S nor /SWAV are present, Interpolate2 arbitrarily assumes an s equal to .05 times the amplitude of the Y data. |
| /SWAV=stdDevWave | |

V-460
Interpolate3D

\[ \text{Interpolate3D} \quad [/Z] \quad /\text{RNGX} = \{x_0, dx, nx\} /\text{RNGY} = \{y_0, dy, ny\} /\text{RNGZ} = \{z_0, dz, nz\} /\text{DEST} = \text{dataFolderAndName}, \text{triangulationWave} = t\text{Wave}, \text{srcWave} = s\text{Wave} \]

The Interpolate3D operation uses a precomputed triangulation of \( s\text{Wave} \) (see \text{Triangulate3D}) to calculate regularly spaced interpolated values from an irregularly spaced source. The interpolated values are calculated for a lattice defined by the range flags \( /\text{RNGX} \), \( /\text{RNGY} \), and \( /\text{RNGZ} \). \( s\text{Wave} \) is a 4 column wave where the first three columns contain the spatial coordinates and the fourth column contains the associated scalar value. Interpolate3D is essentially equivalent to calling the \text{Interp3D} function for each interpolated point in the range but it is much more efficient.

\[ \text{stdDevWave} \] is a wave containing the standard deviation of the noise of the Y data on a point-by-point basis. It is used for the smoothing spline only. \( \text{stdDevWave} \) must have the same number of points as the Y data wave.

If neither \( /S \) nor \( /SWAV \) are present, Interpolate2 arbitrarily assumes an \( s \) equal to .05 times the amplitude of the Y data.

\( /T=t \)

Controls the type of interpolation performed.

\( t=1: \) Linear interpolation
\( t=2: \) Cubic spline interpolation (default)
\( t=3: \) Smoothing spline interpolation

\( /X=xDest \)

Specifies the X destination wave.

If \( /X \) is present the output is an XY pair.

If \( /X \) is omitted the output is a waveform.

The X destination wave may or may not exist when Interpolate2 is called except for "X from dest" mode (\( /I=3 \)) when it must exist. Interpolate2 overwrites it if it exists.

\( /Y=yDest \)

Specifies the Y destination wave name.

If you omit \( /Y \), a default wave name is generated. The name of the default wave is the name of the source Y wave plus ".L" for linear interpolation, ".CS" for cubic spline or ".SS" for smoothing spline.

The Y destination wave may or may not exist when Interpolate2 is called. Interpolate2 overwrites it if it exists.

The Interpolate2 Operation on page III-115

Demos
Choose Files→Example Experiments→Feature Demos→Interpolate2 Log Demo.

References
"Numerical Recipes in C" for cubic spline.

Interpolate3D

**Parameters**

- **triangulationWave=tWave**
  Specifies a 2D index wave, tWave, in which each row corresponds to one tetrahedron and each column (tetrahedron vertex) is represented by an index of a row in sWave. Use Triangulate3D with /OUT=1 to obtain tWave.

- **srcWave=sWave**
  Specifies a real-valued 4 column 2D source wave, sWave, in which columns correspond to x, y, z, f(x, y, z). Requires that the domain occupied by the set of \{x, y, z\} be convex.

**Flags**

- **/DEST=**dataFolderAndName**
  Saves the result in the specified destination wave. The destination wave will be created or overwritten if it already exists. dataFolderAndName can include a full or partial path with the wave name.

- **/RNGX={x0,dx,nx}**
  Specifies the range along the X-axis. The interpolated values start at x0. There are nx equally spaced interpolated values where the last value is at x0+(nx-1)dx. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a YZ plane would have nx=1.

- **/RNGY={y0,dy,ny}**
  Specifies the range along the Y-axis. The interpolated values start at y0. There are ny equally spaced interpolated values where the last value is at y0+(ny-1)dy. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XZ plane would have ny=1.

- **/RNGZ={z0,dz,nz}**
  Specifies the range along the Z-axis. The interpolated values start at z0. There are nz equally spaced interpolated values where the last value is at z0+(nz-1)dz. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XY plane would have nz=1.

- **/Z**
  No error reporting.

**Details**

The triangulation wave defines a set of tetrahedra that spans the convex source domain. If the requested range consists of points outside the domain, the interpolated values will be set to NaN. The interpolation process for points inside the convex domain consists of first finding the tetrahedron in which the point resides and then linearly interpolating the scalar value using the barycentric coordinate of the interpolated point.

In some cases the interpolation may result in NaN values for points that are clearly inside the convex domain. This may happen when the preceding Triangulate3D results in tetrahedra that are too thin. You can try using Triangulate3D with the flag /OUT=4 to get more specific information about the triangulation. Alternatively you can introduce a slight random perturbation to the input source wave before the triangulation.

**Example**

```plaintext
Function Interpolate3DDemo()
Make/O/N=(50,4) ddd=gnoise(20) // First 3 columns store XYZ coordinates
ddd[[3]]=ddd[p][2] // Fourth column stores a scalar which is set to z
Triangulate3D ddd // Perform the triangulation
Wave M_3dVertexList
Interpolate3D /RNGX={-30,1,80}/RNGY={-40,1,80}/RNGZ={-40,1,80}
/DEST=W_Interp triangulationWave=M_3dVertexList,srcWave=ddd
End
```

**References**

inverseErf

inverseErf(x)
The inverseErf function returns the inverse of the error function.

Details
The function is calculated using rational approximations in several regions followed by one iteration of Halley’s algorithm.

See Also
The erf, erfc, dawson, and inverseErfc functions.

inverseErfc

inverseErfc(x)
The inverseErfc function returns the inverse of the complementary error function.

Details
The function is calculated using rational approximations in several regions followed by one iteration of Halley’s algorithm.

See Also
The erf, erfc, erfcw, dawson, and inverseErf functions.

ItemsInList

ItemsInList(listStr [, listSepStr])
The ItemsInList function returns the number of items in listStr. listStr should contain items separated by listSepStr which typically is ";".

Use ItemsInList to count the number of items in a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.

If listStr is "" then 0 is returned.
listSepStr is optional. If missing, listSepStr defaults to ";".

Details
listStr is searched for item strings bound by listSepStr on the left and right.

An item can be empty. The lists "abc;def;;ghi" and ";abc;def;;ghi;" have four items (the third item is ")
listStr is treated as if it ends with a listSepStr even if it doesn’t. The search is case-sensitive.
In Igor6, only the first byte of listSepStr was used. In Igor7 and later, all bytes are used.

Examples
Print ItemsInList("wave0;wave1;wave1#1;") // prints 3
Print ItemsInList("key1=val1,key2=val2", ",") // prints 2
Print ItemsInList("1 \t 2 \t", ",") // prints 2
Print ItemsInList(";" ) // prints 1
Print ItemsInList("; ;") // prints 2
Print ItemsInList(";a;") // prints 2
Print ItemsInList(";;;;") // prints 3

See Also
The AddListItem, StringFromList, FindListItem, RemoveListItem, RemoveFromList, WaveList, TraceNameList, StringList, VariableList, and FunctionList functions.

j

j
The j function returns the loop index of the 2nd innermost iterate loop in a macro. Not to be used in a function. Iterate loops are archaic and should not be used.
JCAMPLoadWave

JCAMPLoadWave [flags] [fileNameStr]
The JCAMPLoadWave operation loads data from the named JCAMP-DX file into waves.

Parameters
If fileNameStr is omitted or is "", or if the /I flag is used, JCAMPLoadWave presents an Open File dialog from which you can choose the file to load.
If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags

/A Automatically assigns arbitrary wave names using "wave" as the base name. Skips names already in use.
/A=baseName Same as /A but it automatically assigns wave names of the form baseName0, baseName1.
/D Creates double-precision waves. If omitted, JCAMPLoadWave creates single-precision waves.
/H Reads header information from JCAMP file. If you include /W, this information is stored in the wave note. If you include /V, it is stored in header variables.
/I Forces JCAMPLoadWave to display an Open File dialog even if the file is fully specified via /P and fileNameStr.
/N Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.
/N=baseName Same as /N except that it automatically assigns wave names of the form baseName0, baseName1.
/O Overwrite existing waves in case of a name conflict.
/P=pathName Specifies the folder to look in for fileNameStr. pathName is the name of an existing symbolic path.
/Q Suppresses the normal messages in the history area.
/R Reads data from file and creates Igor waves.
/V Set variables from header information if /H is also present
/W Stores header information in the wave note if /R and /H are also present.

Details
The /N flag instructs Igor to automatically name new waves "wave", or baseName if /N=baseName is used, plus a number. The number starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.
The /A flag is like /N except that Igor skips names already in use.

Output Variables
JCAMPLoadWave sets the following output variables:

V_flag Number of waves loaded or -1 if an error occurs during the file load.
S_fileName Name of the file being loaded.
S_path File system path to the folder containing the file.
S_waveNames Semicolon-separated list of the names of loaded waves.
S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

When JCAMPLoadWave presents an Open File dialog and the user cancels, V_flag is set to 0 and S_fileName is set to "".

In addition, if the /V flag is used, variables are created corresponding to JCAMP-DX labels in the header. See Variables Set By JCAMPLoadWave on page II-168 for details.

Example

Function LoadJCAMP(pathName, fileName)
    String pathName // Name of Igor symbolic path or ""
    String fileName // Full path, partial path or simple file name

    JCAMPLoadWave/P=$pathName fileName
    if (V_Flag == 0)
        Print "No waves were loaded"
        return -1
    endif

    NVAR VJC_NPOINTS
    Printf "Number of points: %d\r", VJC_NPOINTS

    SVAR SJC_YUNITS
    Printf "Y Units: %s\r", SJC_YUNITS

    return 0
End

See Also
Loading JCAMP Files on page II-168

**JacobiCn**

\[ \text{JacobiCn} \left(x, k\right) \]

The JacobiCn function returns the Jacobian elliptic function \( cn(x, k) \) for real \( x \) and modulus \( k \) with \( 0 < k^2 < 1 \).

The JacobiCn function was added in Igor Pro 7.00.

See Also
JacobiSn

Reference

**JacobiSn**

\[ \text{JacobiSn} \left(x, k\right) \]

The JacobiSn function returns the Jacobian elliptic function \( sn(x, k) \) for real \( x \) and modulus \( k \) with \( 0 < k^2 < 1 \).

The JacobiSn function was added in Igor Pro 7.00.

See Also
JacobiCn

Reference
The jlim function returns the ending loop count for the 2nd inner most iterate loop. Not to be used in a function. Iterate loops are archaic and should not be used.

JointHistogram

JointHistogram [flags] wave1, wave2 [, wave3, wave4]

The JointHistogram computes 2D, 3D and 4D joint histograms of data provided in the input waves. The input waves must be 1D real numeric waves having the same number of points. The result of the operation is stored in the multidimensional wave M_JointHistogram in the current data folder or in the wave specified via the /DEST flag.

This operation was added in Igor Pro 7.00.

Flags

/BINS=[nx, ny, nz, nt] Specifies the number of bins along each axis. Set the number of bins for unused axes to zero. If the number of bins is non-zero, then the flags /XBMT, /YBMT, /ZBMT, and /TBMT are overridden.

/C Sets the output wave scaling so that the values in each axis are centered in the bins. By default, wave scaling of the output wave is set with values at the left bin edges. This flag has no effect on axes where bins are specified by using /XBWV, /YBWV, /ZBWV or /TBWV.

/E Excludes outliers. This flag is relevant only if there are one or more bin waves specified by using /XBWV, /YBWV, /ZBWV or /TBWV. By default values that might fall below the first bin or above the last bin are folded into the first and last bin respectively. These values (outliers) are excluded from the joint histogram when you use /E. See /P below for the way outliers affect the probability calculation.

/DEST=destWave Specifies the output wave created by the operation. If you omit /DEST then the output wave is M_JointHistogram in the current data folder.

/W=weightWave Creates a weighted histogram. Instead of adding a single count to the appropriate bin, the corresponding value from weightWave is added to the bin. weightWave may be any real number type.

Methods

See JointHistogram Binning Methods below for details.
The input waves must be 1D real numeric waves. If one or more waves contain a non-finite value (a NaN or INF) the corresponding row of all waves are not counted in the joint histogram.

The optional waves that define user-specified bins must be real numeric waves and contain a monotonically increasing values. Using non-finite values in user-specified bin waves may lead to unpredictable results.

JointHistogram Binning Methods

The /XBMT, /YBMT, /ZBMT and /TBMT flags set the binning method for the X, Y, Z and T dimensions respectively.

These flags are overridden by /BINS if a non-zero value is specified for a given axis and by /XBWV, /YBWV, /ZBWV and /TBWV.

The method parameter is defined as follows:

- method=0: 128 equally spaced bins between the minimum and maximum of the input data. This is the default setting.
- method=1: The number of bins is computed using Sturges’ method where
  numBins=1+log2(N).
  N is the number of data points in each wave. The bins are distributed so that they include the minimum and maximum values.
- method=2: The number of bins is computed using Scott’s method where the optimal bin width is given by
  binWidth=3.49*σ*N−1/3.
  σ is the standard deviation of the distribution and N is the number of points. The bins are distributed so that they include the minimum and maximum values.
- method=3: Freedman-Diaconis method where
  binWidth=2*IQR*N−1/3,
  where IQR is the interquartile distance (see StatsQuantiles) and the bins are evenly distributed between the minimum and maximum values.

Bin selection methods are described at: http://en.wikipedia.org/wiki/Histogram

Example: 2D Joint Histogram

Histogram, ImageHistogram

JulianToDate

JulianToDate(julianDay, format)
The JulianToDate function returns a date string containing the day, month, and year. The input julianDay is truncated to an integer.

Parameters
julianDay is the Julian day to be converted.
format specifies the format of the returned date string.

<table>
<thead>
<tr>
<th>format</th>
<th>Date String</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>mm/dd/year</td>
</tr>
<tr>
<td>1</td>
<td>dd/mm/year</td>
</tr>
<tr>
<td>2</td>
<td>Tuesday November 15, 2002</td>
</tr>
<tr>
<td>3</td>
<td>year mm dd</td>
</tr>
<tr>
<td>4</td>
<td>year/mm/dd</td>
</tr>
</tbody>
</table>

See Also
The dateToJulian function.

For more information about the Julian calendar see:
<http://www.tondering.dk/claus/calendar.html>.

KillBackground

KillBackground
The KillBackground operation kills the unnamed background task.

KillBackground works only with the unnamed background task. New code should used named background tasks instead. See Background Tasks on page IV-319 for details.

Details
You can not call KillBackground from within the background function itself. However, if you return 1 from the background function, instead of the normal 0, Igor will terminate the background task.

See Also
The BackgroundInfo, CtrlBackground, CtrlNamedBackground, SetBackground, and SetProcessSleep operations; and Background Tasks on page IV-319.

KillControl

KillControl[/W=winName] controlName
The KillControl operation kills the named control in the top or specified graph or panel window or subwindow.
If the named control does not exist, KillControl does not complain.
KillDataFolder

The KillDataFolder operation kills the specified data folder and everything in it including other data folders. However, if `dataFolderSpec` is the name of a data folder reference variable that refers to a free data folder, the variable is cleared and the data folder is killed only if this is the last reference to that free data folder.

**Flags**

- `/Z` No error reporting (except for setting V_flag). Does not halt function execution.

**Parameters**

`dataFolderSpec` can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

**Details**

If specified data folder is the current data folder or contains the current data folder then Igor makes its parent the new current data folder.

For legacy reasons, a null data folder is taken to be the current data folder. This can happen when using a $ expression where the string might possibly evaluate to "".

It is legal to kill the root data folder. In this case the root data folder itself is not killed but everything in it is killed.

KillDataFolder generates an error if any of the waves involved are in use. In this case, nothing is killed.

Execution ceases unless `/Z` is specified.

The variable V_flag is set to 0 when there is no error, otherwise it is an error code.

**Examples**

- `KillDataFolder foo` // Kills foo in the current data folder.
- `KillDataFolder :bar:foo` // Kills foo in bar in current data folder.
- `String str= "root:foo"
  KillDataFolder $str` // Kills foo in the root data folder.

**See Also**

Chapter III-14, Controls and Control Panels, for details about control panels and controls.

---

KillFIFO

The KillFIFO operation discards the named FIFO.

**Details**

FIFOs are used for data acquisition.

If there is an output or review file associated with the FIFO, KillFIFO closes the file. If the FIFO is used by an XOP, you should call the XOP to release the FIFO before killing it.

**See Also**

See FIFOs and Charts on page IV-313 for information about FIFOs and data acquisition.
KillFreeAxis

**KillFreeAxis** [/W=winName] axisName

The KillFreeAxis operation removes a free axis specified by `axisName` from a graph window or subwindow.

**Flags**

/W=winName  
Kills the free axis in the named graph window or subwindow. If /W is omitted, it acts on the top graph window or subwindow.

When identifying a subwindow with `winName`, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

Only an axis created by **NewFreeAxis** can be killed and only if no traces or images are attached to the axis.

**See Also**

The **NewFreeAxis** operation.

KillPath

**KillPath** [/A/Z] pathName

The KillPath operation removes a path from the list of symbolic paths. KillPath is a newer name for the **RemovePath** operation.

**Flags**

/A  
Kills all symbolic paths in the experiment except for the built-in paths. Omit `pathName` if you use /A.

/Z  
Does not generate an error if a path to be killed is a built-in path or does not exist or is in use. To kill all paths in the experiment, use **KillPath/A/Z**.

**Details**

You can’t kill the built-in paths “home” and “Igor”.

A symbolic path is “in use” if the current experiment contains shared waves or notebooks loaded from the associated disk folder.

Prior to Igor Pro 9.00, the KillPath operation prevented killing a symbolic path used to load a shared wave if the shared wave file was in the current data folder. It now prevents killing a symbolic path used to load a shared wave in any data folder. Use the /Z flag to suppress error reporting if this change creates problems for you.

**See Also**

**Symbolic Paths** on page II-22, **NewPath**

KillPICTs

**KillPICTs** [/A/Z] [PICTName [, PICTName]...]

The KillPICTs operation removes one or more named pictures from the current Igor experiment.

**Flags**

/A  
Kills all pictures in the experiment.

/Z  
Does not generate an error if a picture to be killed is in use or does not exist. To kill all pictures in the experiment, use **KillPICTs/A/Z**.

**Details**

You can not kill a picture that is used in a graph or page layout.

**Warning:** You can kill a picture that is referenced from a graph or layout recreation macro. If you do, the graph or layout can not be completely recreated. Use the Find dialog (Edit menu) to locate references in the procedure window to a named picture you want to kill.

V-470
See Also
See Pictures on page III-509 for general information on how Igor handles pictures.

KillStrings

KillStrings [/A/Z] [stringName [, stringName]...]
The KillStrings operation discards the named global strings.

Flags

/A  Kills all global strings in the current data folder. If you use /A, omit stringName.
/Z  Does not generate an error if a global string to be killed does not exist. To kill all global strings in the current data folder, use KillStrings/A/Z.

KillVariables

KillVariables [/A/Z] [variableName [, variableName]...]
The KillVariables operation discards the named global numeric variables.

Flags

/A  Kills all global variables in the current data folder. If you use /A, omit variableName.
/Z  Does not generate an error if a global variable to be killed does not exist. To kill all global variables in the current data folder, use KillVariables/A/Z.

KillWaves

KillWaves [flags] waveName [, waveName]...
The KillWaves operation destroys the named waves.

Flags

/A  Kills all waves in the current data folder. If you use /A, omit waveNames.
/F  Deletes the Igor binary wave file from which waveName was loaded.
/Z  Does not generate an error if a wave to be killed is in use or does not exist.

Details
The memory the waves occupied becomes available for other uses. You can’t kill a wave used in a graph or table or which is reserved by an XOP.

XOPs reserve a wave by sending the OBJINUSE message.

For functions compiled with the obsolete rtGlobals=0 setting, you also can’t kill a wave referenced from a user-defined function.

Examples
KillWaves/A/Z    // kill waves not in use in current data folder

KillWindow

KillWindow [flags] winName
The KillWindow operation kills or closes a specified window or subwindow without saving a recreation macro.

Parameters
winName is the name of an existing window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
KMeans

Flags

/\Z  Does not generate an error if the specified window does not exist.

See Also

The DoWindow operation.

KMeans

KMeans [flags] populationWave

The KMeans operation analyzes the clustering of data in populationWave using an iterative algorithm. The result of KMeans is a specification of the classes which is saved in the wave M_KMClasses in the current data folder. Optional results include the distribution of class members (W_KMMembers) and the inter-class distances. populationWave is a 2D wave in which columns correspond to members of the population and rows contain the dimensional information.

Flags

/\CAN  Analyzes the clustering by computing Euclidean distances between the means of the resulting classes. The resulting distances are stored in an NxN square matrix where N is the number of classes. Self distances (along the diagonal) or distances involving classes that did not survive the iterations are filled with NaN. Also saves the wave W_KMDispersion, which contains the sum of the distances between the center of each class and all its members. Distances are evaluated using the method specified by /DIST.

/DEAD=method  Specifies how the algorithm should handle “dead” classes, which are those that lose all members in a given iteration.

method=1:   Remove the class if it looses all members.
method=2:   Default; keeps the last value of the mean vector in case the class might get new members in a subsequent iteration.
method=3:   Assigns the class a random mean vector.

/DIST=mode  Specifies how the class distances are evaluated.

mode=1:   Distance is evaluated as the sum of the absolute values (also known as Manhattan distance).
mode=2:   Default; distance is evaluated as Euclidean distance.

/INIT=method  Specifies the initialization method.

method=1:   Random assignment of members of the population to a class.
method=2:   User-specified mean values (/INW).
method=3:   Default; initialize classes using values of a random selection from the population.

/INW=iWave  Sets the initial classes. The number of rows of iWave equals the dimensionality of the class and the number of columns of iWave is the number of classes. For example, if we want to initialize 5 classes in a problem that involves position in two dimensions then iWave must have 2 rows and 5 columns. The number of rows must also match the number of rows in populationWave.

/NCLS=num  Sets the number of classes in the data. If the initialization method uses specific means (/INIT=2) then the number of columns of iWave (see /INW) must match num. The default number of classes is 2.
KMeans

Details
KMeans uses an iterative algorithm to analyze the clustering of data. The algorithm is not guaranteed to find a global optimum (maximum likelihood solution) so the operation provides various flags to control when the iterations terminate. You can determine if the operation iterates a fixed number of times or loops until at most a specified maximum number of elements change class membership in a single iteration. If you are computing KMeans in more than one dimension you should pay attention to the relative magnitudes of the data in each dimension. For example, if your data is distributed on the interval \([0,1]\) in the first dimension and on the interval \([0,1e7]\) in the second dimension, the operation will be biased by the much larger magnitude of values in the second dimension.

Examples
Create data with 3 classes:
```make
Make/O/N=(1,128) jack=4+gnoise(1)
jack[0][15,50]=10
jack[0][60,+]=20
```
Perform KMeans looking for 5 classes:
```make
KMeans/init=1/out=1/ter=1/dead=1/tern=1000/ncls=5 jack
Print M_KMClasses
```
```make
M_KMClasses[0][0] = {24.1439, 68}  
M_KMClasses[0][1] = {14.1026, 36}  
M_KMClasses[0][2] = {4.01537, 24}
```

See Also
The FPClustering function.
Label

Label \([/W=\text{winName}/Z]\) \text{axisName}, \text{labelStr}

The Label operation labels the named axis with \text{labelStr}.

Parameters

\text{axisName} is the name of an existing axis in the top graph. It is usually one of “left”, “right”, “top” or “bottom”, though it may also be the name of a free axis such as “VertCrossing”.

\text{labelStr} contains the text that labels the axis.

Flags

\(/W=\text{winName}\) Adds axis label in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with \text{winName}, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

\(/Z\) No errors generated if the named axis doesn’t exist. Used for style macros.

Details

\text{labelStr} can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-53 for details.

Some escape codes insert text based on axis properties. See Axis Label Escape Codes on page III-57 for details.

The characters “<??>” in an axis label indicate that you specified an invalid escape code or used a font that is not available.

See Also

See Annotation Escape Codes on page III-53. See the Legend operation about wave symbols.

Trace Names on page II-282, Programming With Trace Names on page IV-87.

laguerre

\text{laguerre}(n, x)

The \text{laguerre} function returns the Laguerre polynomial of degree \(n\) (positive integer) and argument \(x\). The polynomials satisfy the recurrence relation:

\[(n+1)\text{Laguerre}(n+1,x) = (2n+1-x)\text{Laguerre}(n,x) - n \text{Laguerre}(n-1,x),\]

with the initial conditions

\[\text{Laguerre}(0, x) = 1\]

and

\[\text{Laguerre}(1, x) = 1 - x.\]

See Also

The \text{laguerreA}, \text{laguerreGauss}, \text{chebyshev}, \text{chebyshevU}, \text{hermite}, \text{hermiteGauss}, and \text{legendreA} functions.
The laguerreA function returns the associated Laguerre polynomial of degree \( n \) (positive integer), index \( k \) (non-negative integer) and argument \( x \). The associated Laguerre polynomials are defined by

\[
L_n^k(x) = (-1)^k \frac{d^k}{dx^k} [L_{n+k}(x)],
\]

where \( L_{n+k}(x) \) is the Laguerre polynomial.

See Also
The laguerre and laguerreGauss functions.

References

The laguerreGauss function returns the normalized product of the associated Laguerre polynomials and a Gaussian. This function is typically encountered in solutions to physical problems where it represents the radial solution with an additional factor \( \exp(i m \phi) \) which is not included in this case. The LaguerreGauss is given by

\[
U_{pm}(r) = \frac{2p!}{\pi (m+p)!} \left( r\sqrt{2} \right)^m L_p^m \left( 2r^2 \right) \exp(-r^2).
\]

See Also
The laguerre, laguerreA, and hermiteGauss functions.

The LambertW function returns the complex value of Lambert’s W function for complex \( z \) and integer index \( branch \). The function can be defined through its inverse,

\[
z = w \exp(w).
\]

Since \( w \) is multivalued, the branch parameter is used to differentiate between solutions for the equation. The LambertW function was added in Igor Pro 7.00.

Details
IGOR’s LambertW uses complex input and output. You can use LambertW in real expressions but you must make sure that you are not calling the function in a range where its imaginary part is non-zero.

The average accuracy of the function defined by \( \text{cabs}(z-w^*\exp(w)) \) in the region \( |\text{real}(z)|<10, |\text{imag}(z)|<10 \) is 5e-14. In general the accuracy decreases with increasing \( |\text{branch}| \) and with increasing distance from the origin in the z-plane.

IGOR uses a hybrid algorithm to compute the function which requires longer computation times in the presence of numerical instabilities.

References
Layout

**Layout**  
*flags*  
*[objectSpec , , objectSpec]*  
*[as titleStr]*  
The Layout operation creates a page layout.

**Note:**  
The Layout operation is antiquated and cannot be used in user-defined functions. For new programming, use the **NewLayout** operation instead.

**Parameters**  
All of the parameters are optional.

Each *objectSpec* parameter identifies a graph, table, textbox or picture to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See **Details**.

titleStr is a string expression containing the layout's title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

**Flags**  
/A=*(rows,cols)*  
Specifies rows and columns for tiling or stacking.

/B=*(r,g,b[,a]*)  
Specifies the background color for the layout. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque white.

/C=colorOnScreen  
Obsolete. In ancient times, this flag switched the screen display of the layout between black and white and color. It is still accepted but has no effect.

/G=w  
Specifies grout, the spacing between tiled objects. Units are points unless /I, /M, or /R are specified.

/HIDE=h  
Hides (*h* = 1) or shows (*h* = 0, default) the window.

/I  
Specifies that coordinates are in inches. This affects subsequent /G, /W, and *objectSpec* coordinates. Coordinates are relative to the top/left corner of the paper.

/K=k  
Specifies window behavior when the user attempts to close it.

\[k=0: \text{Normal with dialog (default).} \]

\[k=1: \text{Kills with no dialog.} \]

\[k=2: \text{Disables killing.} \]

\[k=3: \text{Hides the window.} \]

If you use /K=2 or /K=3, you can still kill the window using the **KillWindow** operation.

/M  
Specifies that coordinates are in centimeters. This affects subsequent /G, /W, and *objectSpec* coordinates. Coordinates are relative to the top/left corner of the paper.

/P=orientation  
*orientation* is either Portrait or Landscape (*e.g.*, **Layout/P= Landscape**). This controls the orientation of the page in the layout. See **Details**.

If you use the /P flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as /T and /G.

/R  
Specifies that coordinates are in percent. This affects subsequent /G, /W, and *objectSpec* coordinates. For /W, coordinates are as a percent of the main screen. For /G and *objectSpec*, coordinates are relative to the top/left corner of the printing part of the page.

/S  
Stacks objects.

/T  
Tiles objects.

/W=*(left, top, right, bottom)*
When you create a new page layout window, if preferences are enabled, the page size is determined by the preferred page size as set via the Capture Layout Prefs dialog. If preferences are disabled, as is usually the case when executing a procedure, the page is set to the factory default size.

If you use the /P flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as /T and /G.

The form of an objectSpec is:

\[
\text{objectName} \left[ (\text{objLeft}, \text{objTop}, \text{objRight}, \text{objBottom}) \right] \left[ /O=\text{objType} \right] \left[ /F=\text{frame} \right] \left[ /T=\text{trans} \right] \left[ /D=\text{fidelity} \right]
\]

objectName can be the name of an existing graph, table or picture. It can also be the name of an object that does not yet exist. In this case it is called a “dummy object”.

objectSpec can be specified using a string by using the $ operator, but the entire objectSpec must be in the string.

Here are some examples of valid usage:

```
Layout Graph0
Layout/I Graph0(1, 1, 6, 5)/F=1
String s = "Graph0"
Layout/I $s
String s = "Graph0(1, 1, 6, 5)/F=1"
Layout/I $s // Entire object spec is in string.
```

The object’s coordinates are determined as follows:

- If objectName is followed by a coordinates specification in (objLeft, objTop, objRight, objBottom) form then this sets the object’s coordinates. The units for the coordinates are points unless the /I or /M flag was present in which case the units are inches or centimeters respectively.
- If the object coordinates are not specified explicitly but the Layout/S flag was present then the object is stacked. If the Layout/T flag was present then the object is tiled, and if the Layout/A=(rows,cols) flag is present, tiling is performed using that number of rows and columns.
- If the object’s coordinates are not determined by these rules then the object is set to a default size and is stacked.

Each object has a type (graph, table, textbox or picture) determined as follows:

\[
O=\text{objType}
\]

If the objectName/O=objectType flag is present then it determines the object’s type:

- objType=1: Graph.
- objType=2: Table.
- objType=8: Picture.
- objType=32: Textbox.

If there is no /O flag and objectName is the name of an existing graph, table or picture, then the object type is graph, table or picture.

If the object’s type is not determined by the above rules and objectName contains “Table”, “PICT”, or “TextBox”, then the object type is table, picture or textbox.

If the object’s type is not specified by any of the above rules, it is taken to be a graph type object.

The remaining flags have the following meanings:

\[
/D=\text{fidelity}
\]

Controls the drawing of the layout object:

- fidelity=0: Low fidelity display.
- fidelity=1: High fidelity display (default).

Layout

Layout is a procedure subtype keyword that identifies a macro as being a page layout recreation macro. It is automatically used when Igor creates a window recreation macro for a layout. See Procedure Subtypes on page IV-204 and Killing and Recreating a Layout on page II-477 for details.

See Also

LayoutInfo

LayoutInfo(winNameStr, itemNameStr)

The LayoutInfo function returns a string containing a semicolon-separated list of keywords and values that describe an object in the active page of a page layout or overall properties of the layout. The main purpose of LayoutInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges objects.

winNameStr is the name of an existing page layout window or "" to refer to the top layout.

itemNameStr is a string expression containing one of the following:

- The name (e.g., "Graph0") of a layout object in the active page to get information about that object.
- An object instance (e.g., "Graph0#0" or "Graph0#1") to get information about a particular instance of an object in the active page. This is of use only in the unusual situation when the same object appears in the active page multiple times. "Graph0#0" is equivalent to "Graph0". "Graph0#1" is the second occurrence of Graph0 in the active page.
- An integer object index starting from zero to get information about an object referenced by its position in the active page in the layout. Zero refers to the first object going from back to front in the page.
- The word "Layout" to get overall information about the layout.

Details

In cases 1, 2 and 3 above, where itemNameStr references an object, the returned string contains the following keywords, with a semicolon after each keyword-value pair.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIDELITY</td>
<td>Object fidelity expressed as a code usable in a ModifyLayout fidelity command.</td>
</tr>
<tr>
<td>FRAME</td>
<td>Object frame expressed as a code usable in a ModifyLayout frame command.</td>
</tr>
<tr>
<td>HEIGHT</td>
<td>Object height in points.</td>
</tr>
</tbody>
</table>

Controls the object frame:

frame=0: No frame.
frame=1: Single frame (default).
frame=2: Double frame.
frame=3: Triple frame.
frame=4: Shadow frame.

Controls the transparency of the layout object:

trans=0: Opaque (default).
trans=1: Transparent. For this to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. Pictures may have been created transparent or opaque, and Igor cannot make an inherently opaque picture transparent.

See Also

In case 4 above, where itemNameStr is “Layout”, the returned string contains the following keywords, with a semicolon after each keyword-value pair.

### LayoutInfo returns ”” in the following situations:
- winNameStr is ”” and there are no layout windows.
- winNameStr is a name but there are no layout windows with that name.
- itemNameStr is not "Layout" and is not the name or index of an existing object.

### Examples
This example sets the background color of all selected graphs in the active page of a particular page layout to the color specified by red, green, and blue, which are numbers from 0 to 65535.

```plaintext
Function SetLayoutGraphsBackgroundColor(layoutName, red, green, blue)
    String layoutName // Name of layout or ”” for top layout.
    Variable red, green, blue
    Variable index
    String info
    Variable selected
    String indexStr
    String objectTypeStr
    String graphNameStr
    ```
index = 0
do
  sprintf indexStr, "%d", index
  info = LayoutInfo(layoutName, indexStr)
  if (strlen(info) == 0)
    break     // No more objects
  endif
  selected = NumberByKey("SELECTED", info)
  if (selected)
    objectTypeStr = StringByKey("TYPE", info)
    if (CmpStr(objectTypeStr,"Graph") == 0)// This is a graph?
      graphNameStr = StringByKey("NAME", info)
      ModifyGraph/W=$graphNameStr wbRGB=(red,green,blue)
    endif
  endif
  index += 1
while(1)
End

See Also
The Layout operation. See Chapter II-18, Page Layouts.

LayoutMarquee

LayoutMarquee is a procedure subtype keyword that puts the name of the procedure in the layout Marquee menu. See Marquee Menu as Input Device on page IV-163 for details.

See Also
See Chapter II-18, Page Layouts.

LayoutPageAction

LayoutPageAction [/[W=winName] [keyword = value [, keyword = value ...]]] The LayoutPageAction operation adds, deletes, reorders, or adjusts the sizes of layout pages.
The LayoutPageAction operation was added in Igor Pro 7.00.

Parameters

appendPage  Appends a new page.
insertPage=page  Inserts a new page before page.
    Page numbers start from 1. Pass 0 for page to insert before the first page.
page=page  Makes page the active page.
    Page numbers start from 1.
deletePage=page  Deletes page. This action cannot be undone.
    Page numbers start from 1.
reorderPages={anchorPage, page1, ...}  Reorders the pages so that page1 and any others appear before anchorPage, in the same order as their appearance in the command.
    Page numbers start from 1.
size=(width, height)  Sets the global page dimensions for the layout to width and height, specified in units of points.
size(page)=(width, height)
LayoutSlideShow

Sets the dimensions of page to width and height, specified in units of points.
Using this keyword with page set to -1 modifies the global page dimensions for the layout.

margins=(leftMargin, topMargin, rightMargin, bottomMargin)

Sets the global page margins for the layout to the specified values, expressed in units of points.

margins(page)=(leftMargin, topMargin, rightMargin, bottomMargin)

Sets the margins of specified page to these values, expressed in units of points.
Page numbers start from 1.
Passing -1 for page sets the global margins for the layout.

Flags

/W=winName Modifies the named layout. When omitted, the actions affect the top layout.

Details

Page numbers start from 1. Use page=0 to refer to the active page.
The layout as a whole has a size and margins. These are called "global" dimensions and govern all pages by default. You can set the global dimensions using the size and margins keyword without specifying a particular page.
You can override the dimensions for a given page using size(page) and margins(page) to specify custom dimensions.
Use size(page)=(0,0) to revert the specified page to the global layout dimensions. This reverts both the page size and its margins.

See Also

Page Layouts on page II-475, NewLayout, ModifyLayout

LayoutSlideShow

LayoutSlideShow [/W=winName] [keyword = value [, keyword = value ...]]
The LayoutSlideShow operation starts, stops, or modifies a slideshow that displays the pages of a page layout.
The LayoutSlideShow operation was added in Igor Pro 7.00.

Parameters

autoMode=a Controls whether the presentation will advance between slides automatically (a=1) or manually (a=0). Use the delay keyword to control the delay between automatic transitions.
delay=d d is the number of seconds to wait between slide transitions when running in auto mode.
otherScreenContents=o

Controls what is displayed on any additional screens that may be connected.
o=0: Other screens show the presentation.
o=1: Other screens show a presenter's view with additional information. Use the presentersView keyword to control the contents of this view.
o=2: Other screens show a presenter's view with additional information. Use the presentersView keyword to control the contents of this view.
page=p Causes the slideshow to start from page p. p is a page number starting from 1. This keyword has no effect unless the start keyword is also present.
LayoutSlideShow

presentersView=p Controls what is displayed on the screens that show the presenter’s view.

p is a bitfield of flags:

- Bit 0: Show the next page.
- Bit 1: Show the current time.
- Bit 2: Show the elapsed time.

Setting Bit Parameters on page IV-12 for details about bit settings.

scaleMode=s Specifies how the pages are scaled to fit the screen.

- s=0: No scaling. Pages are drawn at actual size even if they are much larger or smaller than the screen size.
- s=1: All pages are individually scaled to the screen size.
- s=2: All pages are scaled by the same factor so that the largest page fits on the screen. This preserves the relative sizes of the pages.

screen=s Specifies the screen to be used for the main presentation. Use s=1 to use the primary screen. Use IgorInfo to determine the number of available screens.

start Starts the slideshow.

stop Stops the slideshow. You can also stop it by pressing the escape key.

wrapMode=w Controls what happens when the presentation reaches the last page in the slideshow.

- w=0: Advancing to the next page has no effect.
- w=1: Advancing to the next page causes the slideshow to wrap around to the first page.
- w=2: Advancing to the next page causes the slideshow to stop.

Flags

/W= winName winName is the name of the desired layout window. If /W is omitted or if winName is $"", the top layout window is used.

Details

A layout slide show can be used to present an Igor experiment to others, or to run an information kiosk. Any changes to the layout window during a slide show are automatically reflected in the slides. For example you could use a background task to update a graph so that the slides always show the latest data. You can control a running slide show by right-clicking on the slideshow. Alternatively, use the arrow keys or a mouse click to advance to the next slide.

Press the space bar to toggle between automatic and manual advancing of the slides. Press escape to end the slideshow.

Example

Function DemoSlideshow() // Press escape to end the slideshow
  NewLayout
  TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\2961"
  LayoutPageAction appendpage
  TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\2962"
  LayoutPageAction appendpage
  TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\2963"

LayoutStyle

LayoutStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Layout dialog and in the Layout Macros menu. See Page Layout Style Macros on page II-498 for details.

See Also
See Chapter II-18, Page Layouts and Page Layout Style Macros on page II-498.

leftx

leftx(waveName)
The leftx function returns the X value of point 0 (the first point) of the named 1D wave. The leftx function is not multidimensional aware. The multidimensional equivalent of this function is DimOffset.

Details
Point 0 contains a wave’s first value, which is usually the leftmost point when displayed in a graph. Leftx returns the value elsewhere called x0. The function DimOffset returns any of x0, y0, z0, or t0, for dimensions 0, 1, 2, or 3.

See Also
The deltax and rightx functions.
For multidimensional waves, see DimDelta, DimOffset, and DimSize.
For an explanation of waves and X scaling, see Changing Dimension and Data Scaling on page II-68.

Legend

Legend [flags] [legendStr]
The Legend operation puts a legend on a graph or page layout.

Parameters
legendStr contains the text that is printed in the legend.
If legendStr is missing or is an empty string (""), the text needed for a default legend is automatically generated. Legends are automatically updated when waves are appended to or removed from the graph or when you rename a wave in the graph.

legendStr can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-53 for details. However normally you leave it to Igor to automatically manage the legend.

See Legend Text on page III-42 for a discussion of what legendStr may contain.

Flags

/H=legendSymbolWidth
Sets the width in points of the area in which to draw the wave symbols. A value of 0 means “default”. This results in a width that is based on the text size in effect when the symbol is drawn. A value of 36 gives a 0.5 inch (36 points) width which is nice in most cases.

/H={[legendSymbolWidth, minThickness, maxThickness]}

leftx(waveName)
The leftx function returns the X value of point 0 (the first point) of the named 1D wave. The leftx function is not multidimensional aware. The multidimensional equivalent of this function is DimOffset.

Details
Point 0 contains a wave’s first value, which is usually the leftmost point when displayed in a graph. Leftx returns the value elsewhere called x0. The function DimOffset returns any of x0, y0, z0, or t0, for dimensions 0, 1, 2, or 3.

See Also
The deltax and rightx functions.
For multidimensional waves, see DimDelta, DimOffset, and DimSize.
For an explanation of waves and X scaling, see Changing Dimension and Data Scaling on page II-68.

Legend

Legend [flags] [legendStr]
The Legend operation puts a legend on a graph or page layout.

Parameters
legendStr contains the text that is printed in the legend.
If legendStr is missing or is an empty string (""), the text needed for a default legend is automatically generated. Legends are automatically updated when waves are appended to or removed from the graph or when you rename a wave in the graph.

legendStr can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-53 for details. However normally you leave it to Igor to automatically manage the legend.

See Legend Text on page III-42 for a discussion of what legendStr may contain.

Flags

/H=legendSymbolWidth
Sets the width in points of the area in which to draw the wave symbols. A value of 0 means “default”. This results in a width that is based on the text size in effect when the symbol is drawn. A value of 36 gives a 0.5 inch (36 points) width which is nice in most cases.

/H={[legendSymbolWidth, minThickness, maxThickness]}
This is an additional form of the /H flag. The legendSymbolWidth parameter works the same as described above.

The minThickness and maxThickness parameters allow you to create a legend whose line and marker thicknesses are different from the thicknesses of the associated traces in the graph. This can be handy to make the legend more readable when you use very thin lines or markers for the traces.

minThickness and maxThickness are values from 0.0 to 10.0. Also, setting minThickness to 0.0 and maxThickness to 0.0 (default) uses the same thicknesses for the legend symbols as for the traces.

/J Disables the default legend mechanism so that a default legend is not created even if legendStr is an empty string (""") or omitted.

Window recreation macros use /J in case legendStr is too long to fit on the same command line as the Legend operation itself. In this case, an AppendText command appears after the Legend command to append legendStr to the empty legend. For really long values of legendStr, there may be multiple AppendText commands.

/M[=sameSize] /M or /M=1 specifies that legend markers should be the same size as the marker in the graph.
/M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.

See the TextBox operation for documentation for all other flags.

Examples
The command Legend (with no parameters) creates a default legend. A default legend in a layout contains a line for each wave in each of the graphs in the layout, starting from the bottom graph and working toward the front.

The command:
Legend/C/N= name ""
changes the named existing legend to a default legend.

You can put a legend in a page layout with a command such as:
Legend "\s(Graph0.wave0) this is wave0"
This creates a legend in the layout that shows the symbol for wave0 in Graph0. The graph named in the command is usually in the layout but it doesn’t have to be.

TextBox, Tag, ColorScale, AnnotationInfo, AnnotationList.
Annotation Escape Codes on page III-53.
Legend Text on page III-42.
Trace Names on page II-282, Programming With Trace Names on page IV-87.
Color as f(z) Legend Example on page II-301 for a discussion of creating a legend whose symbols match the markers in a graph that uses color as f(z).

**legendreA**

The legendreA function returns the associated Legendre polynomial:

\[ P_n^m(x) \]

where \( n \) and \( m \) are integers such that \( 0 \leq m \leq n \) and \( |x| \leq 1 \).

References
The limit function returns num, limited to the range from low to high:

\[ \text{num if } \text{low} \leq \text{num} \leq \text{high}. \]

\[ \text{low if } \text{num} < \text{low}. \]

\[ \text{high if } \text{num} > \text{high}. \]

Since all comparisons with NaN return false, limit will not work as expected with NaNs. If a parameter may be NaN, use numtype to test it before calling limit.

LinearFeedbackShiftRegister

The LinearFeedbackShiftRegister operation implements a linear feedback shift register, or LFSR. A LFSR is a way to produce a sequence of very bad pseudorandom numbers, or a random bit stream (that is, a random sequence of zeroes of ones that over time are nearly equal in number).

If it produces bad random numbers, why would I want to use a LFSR? A properly-configured LFSR will create a “maximal-length sequence”: a LFSR of N bits will produce \(2^N-1\) numbers in a quasi-random sequence without repeating. That is, it will produce all the N-bit numbers except zero. This gives the sequence good spectral properties for certain applications, and, taking the least-significant bit as the output, it creates a pseudorandom bit stream with nearly equal numbers of zeroes and ones (nearly means one more one than zeroes).

The LinearFeedbackShiftRegister operation generates either a wave full of the sequential states of the shift register or a wave full of ones and zeroes representing the least significant bit of the shift register.

Linear Feedback Shift Registers

A LFSR is a shift register with taps. The tap bits are XOR’ed together and the result, after the register is shifted, becomes the new most significant bit. Here is a diagram of a 7-bit LFSR:

Each successive number is generated by shifting the contents of the register (boxes 1-7) to the right, while shifting in the output of the XOR node. The XOR node samples specified bits of the register contents, generating its output ready to be shifted in. Thus, the inputs of the XOR are bits sampled before a shift; the output of the XOR becomes the leading bit in the register after a shift.

In many applications the output of interest is the stream of bits that appear in the last position. This stream of bits is a pseudorandom sequence of ones and zeroes (or ones and minus ones, or whatever other binary sequence you need).

The bits fed into the XOR node are referred to as taps. The taps illustrated here would be specified with the tap list 7,6,4,1. As implemented in Igor Pro, the output tap (tap 7 in the illustration) is the least significant bit, so an alternate way to express the tap list is as the binary number 10010112 (7710).

With the right taps, a LFSR produces a maximal-length sequence. The list of sequential states in a maximal-length sequence has length \(2^N-1\) without repeating a state. That means that every possible N-bit nonzero number appears exactly once in the maximal-length sequence.

Maximal-length tap lists always have an even number of taps.

If you have a tap list that gives a maximal-length sequence, you can generate another tap list from it. If your tap list is \((n, A, B, C)\) the new tap list is \((n, n-C, n-B, n-A)\). This new tap list will generate a bit stream that is the mirror image in time of the bit stream produced by the first tap list.
LinearFeedbackShiftRegister

Flags

/DEST=wavename Specifies a wave to receive the generated sequence. With /MODE=0, the number type of the wave must have at least nbits bits for an integer wave, or at least an nbit mantissa if it is a floating-point wave. That is, /N=25 requires a double-precision wave or a 32-bit integer wave. /N=18 requires any floating-point wave or a 16- or 32-bit integer wave. If you use an integer wave, we recommend an unsigned integer wave for /N=8, 16, or 32.

If /MODE=1 is used, any number type is acceptable. See the Details for what happens if you don’t use /DEST.

If wavename doesn’t exist, a suitable integer wave will be made.

If wavename already exists, LinearFeedbackShiftRegister will use it as-is. The sequence length will be taken from the wave. If the number type of the wave is not suitable, an error is issued. If the sequence length is less than the number of points in your wave, it will be truncated to match.

/FREE In a user-defined function, makes a free wave. See Free Waves on page IV-91 for details.

/INIT=initialValue Sets the initial value of the shift register to initialValue. This will also be the first value in the output for /MODE=0, or the least-significant bit of initialValue will be the first output for /MODE=1. You can use this initial value to restart a very long sequence from the last state of a previous run.

Default is a single 1 bit in the first position (bit nbits-1 for /N=nbits).

/LEN=length Sets the length of sequence to generate. If the sequence repeats before length states are generated, the sequence is terminated early. If length is larger than the number of states in a maximal-length sequence, you will get a maximal-length sequence, or a shorter sequence if the initial value is seen again (that is, your sequence is not a maximal-length sequence).

You can specify length greater than the maximal-length sequence length, but it will be truncated to the maximal length.

/MAX=index An internal table of tap lists gives maximal-length sequences. This table has up to 32 tap lists for each value of nbits. You select a tap list by setting index to a number from 0 to 31. For values of nbits that do not have 32 maximal-length tap lists, the table repeats. Most nbits values have many more than 32 possible maximal-length sequences. For each tap list in the table, another tap list can be accessed using the /MROR flag.

/MODE=doBitStream Sets the output stream format.

doBitStream=0: Succession of bit register states (default).

doBitStream=1: Stream of ones and zeroes.

/MROR [=doMirror] Transforms the tap list into its complementary tap list, creating a mirror-image bit stream, when you use /MROR or doMirror=1. Specify the tap list using /TAPS, /TAPB, or /MAX.

/N=nbits Determines the number of bits in the shift register. A maximal-length sequence will have 2nbits-1 states. nbits must be in the range of 1-32. Note that nbits = 1 or 2 is not very interesting.

/STOP=stopValue Terminates the sequence when stopValue is the next shift register value. You can use this flag to generate long sequences using multiple calls to LinearFeedbackShiftRegister by storing the initial value of the first call, and setting stopValue to that initial value in subsequent calls.

/TAPB=tapbits An alternate way to express the tap list. tapbits is a number in which each bit represents a tap, with bit 0 representing the tap with tap number nbits.

/TAPS={t1, t2, …} Specifies the tap list. Tap numbers are in the range from 1 to nbits.
**Details**

If the /TAPS, /TAPB, or /MAX flags are absent, the maximal-length sequence corresponding to /MAX=0 is generated.

In you omit the /DEST flag, a wave named W_LFSR will be generated for you. W_LFSR is an unsigned integer wave with number type set to the minimum size for the shift register size and /MODE setting. Thus, if you set /N=10/MODE=0, W_LFSR will be an unsigned 16-bit integer wave.

Because W_LFSR is an unsigned integer wave, you will need to redimension the wave to a floating-point wave for many purposes. Use the Redimension operation or the Redimension Waves item in the Data menu.

Up to /N=18, W_LFSR will initially be created large enough to hold a maximal-length sequence, unless you request a shorter sequence using the /LEN flag. If the initial value is seen again before a maximal-length sequence is generated, it means that the tap list specified was not one that generates a maximal-length sequence, and generation is terminated. The wave is shortened to the generated sequence length.

If you set a register size greater than /N=18 and you do not use /LEN, the generated sequence will stop after 2^{18}-1 (262143) states. Note that beyond some N, it will be impossible to create a wave large enough to hold a maximal-length sequence.

Some tap lists do not generate maximal-length sequences but also do not repeat the initial value. In that case, the generated sequence will be of maximal length but will contain repeated subsequences. The V_flag variable will be set to 0 if the sequence was not a maximal-length sequence, or 1 if it was. If /LEN=length values were generated, V_flag is set to 2.

If you specify your own wave using /DEST, the sequence length will be the same as the length of your wave. Your wave will be resized if a shorter sequence is generated.

**Generating Long Sequences in Smaller Segments**

Very long maximal-length sequences will not fit in the largest wave you can make. It may also be more convenient to make multiple, small fragments of a longer sequence. You can do this using the /INIT, /STOP, and /LEN flags, along with the V_nextValue variable. Here is an example of making 1000-point subsequences from a 16-bit maximal-length sequence:

// Start with the first 1000 states, with initial value of 1
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=1
// /STOP=1 sets the stopping value to the first initial value
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_nextValue)/STOP=1
// Continue...
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_nextValue)/STOP=1

**Variables**

The LinearFeedbackShiftRegister operation returns information in the following variables:

- **V_flag**
  Set to zero when a nonmaximal-length sequence was detected. This occurs if the initial value is seen again before a maximal-length sequence was generated, or if a maximal-length sequence was generated but the final state was not the same as the initial state.

  Set to 1 when a maximal-length sequence was generated.

  Set to 2 when the sequence was limited by /LEN=length or by the default limit of 2^{18}-1 (262143) states.

- **V_tapValue**
  Set to the binary representation of the tap sequence used. That is, you can generate the same sequence using /TAPB=V_tapValue. If you use /MROR=1, V_tapValue reflects that setting. It will also give the actual tap value used when you specify the a maximal-length sequence using the /MAX flag.

- **V_nextValue**
  Set to the next value beyond the last generated register state. This can be used to restart a truncated sequence.

**Examples**

Generate a 16-bit maximal-length sequence and reprocess the output values to be centered on zero and normalized to a maximum value of 1:

```
LinearFeedbackShiftRegister/N=16
Redimension/D W_LFSR
```
Another way to do the same thing that avoids the Redimension operation, which could lead to fragmentation of memory:

```
Make/D/N=(2^16-1) LFSR_output
LinearFeedbackShiftRegister/N=16/DEST=LFSR_output
LFSR_output -= 2^15
LFSR_output /= 2^15-1
```

Make a bit stream with random +1 and -1 instead of 0 and 1:

```
LinearFeedbackShiftRegister/N=16/MODE=1
Redimension/B W_LFSR
W_LFSR = W_LFSR*2-1
```

**See Also**

If you really need random numbers, we provide high-quality RNG's that return random deviates from a number of distributions. See `enoise`, `gnoise`, and others.

**References**

A discussion of LFSR's can be found in “Generation of Random Bits” (Section 7.4) in Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992. They refer to “primitive polynomials modulo 2” and do not use the name Linear Feedback Shift Register, but it is the same thing. We use an implementation equivalent to their Method I.

---

**ListBox**

```
ListBox [/Z] ctrlName [keyword = value [, keyword = value ...]]
```

The ListBox operation creates or modifies the named control that displays, in the target window, a list from which the user can select any number of items.

For information about the state or status of the control, use the `ControlInfo` operation.

**Parameters**

`ctrlName` is the name of the ListBox control to be created or changed.

The following keyword=value parameters are supported:

- `align=alignment` Sets the alignment mode of the control. The alignment mode controls the interpretation of the `leftOrRight` parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.
  
  - If `alignment=0` (default), `leftOrRight` specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
  
  - If `alignment=1`, `leftOrRight` specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

- `appearance={kind [, platform]}`
  
  Sets the appearance of the control. `platform` is optional. Both parameters are names, not strings.
  
  - `kind` can be one of `default`, `native`, or `os9`.
  
  - `platform` can be one of `Mac`, `Win`, or `All`.
  
  See `Button` and `DefaultGUIControls` for more appearance details.

- `clickEventModifiers=modifierSelector`
Selects modifier keys to ignore when processing clicks to start editing a cell or
to change a checkbox. To prevent this, use this keyword.

**modifierSelector** is a bit pattern with a bit for each modifier key; sum these values
to get the desired combination of modifiers:

- `modifierSelector=1`: Control key (Macintosh only)
- `modifierSelector=2`: Option (Macintosh) or Alt (Windows)
- `modifierSelector=4`: Context click (right click on Windows, control-click on Macintosh)
- `modifierSelector=8`: Shift key
- `modifierSelector=16`: Cmd key (Macintosh) or Ctrl key (Windows)
- `modifierSelector=32`: Caps lock key

See [Setting Bit Parameters](#) on page IV-12 for details about bit settings.

**col=c**
Sets the left-most visible column (user scrolling will change this). The list is
scrolled horizontally as far as possible. Sometimes this won’t be far enough to
actually make column `c` the first column, but it will at least be visible. Use `c=1` to
put the left edge of column 1 (the second column) at the left edge of the list.

**colorWave=cw**
Specifies a 3-column (RGB) or 4-column (RGBA) numeric wave. Used in
conjunction with planes in selWave to define foreground and background colors
for individual cells. Values range from 65535 (full on) to 0.

**disable=d**
Sets user editability of the control.
- `d=0`: Normal.
- `d=1`: Hide.
- `d=2`: Draw in gray state; disable control action.

**editStyle=e**
Sets the style for cells designated as editable (see selWave, bit 1).
- `e=0`: Uses a light blue background (default).
- `e=1`: Draws a frame around the cell with a white background.
- `e=2`: Combines the frame with the blue background. The background in
  all cases can be overridden using the colorWave parameter.

**focusRing=fr**
Enables or disables the drawing of a rectangle indicating keyboard focus:
- `fr=0`: Focus rectangle will not be drawn.
- `fr=1`: Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have
enabled full keyboard access via the Shortcuts tab of the Keyboard system
preferences.

**font=fontName**
Sets the font used for the list box items, e.g., `font="Helvetica"`.

**frame=f**
Specifies the list box frame style.
- `f=0`: No frame.
- `f=1`: Simple rectangle.
- `f=2`: 3D well.
- `f=3`: 3D raised.
- `f=4`: Text well style.

**fsize=s**
Sets list box font size.
ListBox

fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:

Bit 0:   Bold
Bit 1:   Italic
Bit 2:   Underline
Bit 4:   Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

hScroll=h  Scrolls the list to the right by \(h\) pixels (user scrolling will change this). \(h\) is the total amount of horizontal scrolling, not an increment from the current scroll position: \(h\) will be the value returned in the V_horizScroll variable by ControlInfo.

help={helpStr}  Sets the help for the control.

helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).
You can insert a line break by putting “\r” in a quoted string.

helpWave=w  Text wave containing text for tooltips for individual listbox cells. See ListBox Help below. Added in Igor Pro 8.00.

keySelectCol=col  Sets scan column number \(col\) when doing keyboard selection. Default is to scan column zero.

listWave=w  A 1D or 2D text wave containing the list contents.

mode=m  List selection mode specifying how many list selections can be made at a time.

\(m=0\): No selection allowed.
\(m=1\): One or zero selection allowed.
\(m=2\): One and only one selection allowed.
\(m=3\): Multiple, but not disjoint, selections allowed.
\(m=4\): Multiple and disjoint selections allowed.

When multiple columns are used, you can enable individual cells to be selected using modes 5, 6, 7, and 8 in analogy to \(m=1-4\). When using \(m=3\) or 4 with multiple columns, only the first column of the selWave is used to indicate selections. Checkboxes and editing mode, however, use all cells even in modes 0-4.

Modes 9 and 10 are the same as modes 4 and 8 except they use different selection rules and require testing bit 3 as well as bit 0 in selWave. In modes 4 and 8, a shift click toggles individual cells or rows, but in modes 9 and 10, the Command (Macintosh) or Ctrl (Windows) key toggles individual cells or rows whereas Shift defines a rectangular selection. To determine if a cell is selected, perform a bitwise AND with 0x09.

proc=p  Set name of user function proc to be called upon certain events. See discussion below.

pos={leftOrRight,top}  Sets the position in Control Panel Units of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+=\{dx,dy\}  Offsets the position of the list box in Control Panel Units.

row=r  \(r\) is desired top row (user scrolling will change this). Use a value of -1 to scroll to the first selected cell (if any). Combine with selRow to select a row and to ensure it is visible (modes 1 and 2).

selCol=c  Defines the selected column when mode is 5 or 6 and no selWave is used. To read this value, use ControlInfo and the V_selCol variable.
ListBox

selRow=s
Defines the selected row when mode is 1 or 2; when no selWave is used, it is defined by modes 5 or 6. Use -1 for no selection.

To read this value, use ControlInfo and the V_value variable.

selWave=sw
sw is a numeric wave with the same dimensions as listWave. It is optional for modes 0-2, 5 and 6 and required in all other modes.

In modes greater than 2, sw indicates which cells are selected. In modes 1 and 2 use ControlInfo to find out which row is selected.

In all modes sw defines which cells are editable or function as checkboxes or disclosure controls.

Numeric values are treated as integers with individual bits defined as follows:

- Bit 0 (0x01): Cell is selected.
- Bit 1 (0x02): Cell is editable.
- Bit 2 (0x04): Cell editing requires a double click.
- Bit 3 (0x08): Current shift selection.
- Bit 4 (0x10): Current state of a checkbox cell.
- Bit 5 (0x20): Cell is a checkbox.
- Bit 6 (0x40): Cell is a disclosure cell. Drawn as a disclosure triangle (Macintosh) or a treeview expansion node (Windows).
- Bit 7 (0x80): Cell is disabled. Clicks on the cell are ignored and it is drawn with a grayed appearance. Added in Igor Pro 8.00. Because of technical issues, this bit currently does not prevent the selection of the cell using the arrow keys.

In modes 3 and 4 bit 0 is set only in column zero of a multicolumn listbox.

Other bits are reserved. Additional dimensions are used for color info. See the discussion for colorWave. selWave is not required for modes 5 and 6.

setEditCell={row,col,selStart,selEnd}

Initiates edit mode for the cell at row, col. An error is reported if row or col is less than zero. Nothing happens and no error is reported if row, col is beyond the limits of the listbox, or if the cell has not been made editable by setting bit 1 of selWave.

selStart and selEnd set the range of bytes that are selected when editing is initiated; 0 is the start of the text. If there are N bytes in the listbox cell, setting selStart or selEnd to N or greater moves the start or end of the selection to the point after the last character. Setting selStart and selEnd to the same value selects no characters and the insertion point is set to selStart. Setting selStart to -1 always causes all characters to be selected.

size={width, height}
Sets list box size in Control Panel Units.

special={kind, height, style}
**ListBox**

Specifies special cell formatting or contents.

- **kind=0:** Normal text but with specified `height` (if nonzero). Use a `style` of 1 to autocalculate widths based on the entire list contents. In this case, user widths are taken to be minimums and the last is not repeated.

- **kind=1:** Text taken to be the names of graphs or tables. Images of the graphs or tables are displayed in the cells. Use a `style` of 0 to display just the presentation portion of the graph or 1 to display it entirely. For tables, only the presentation portion is displayed.

- **kind=2:** Text taken to be the names of pictures. Images are displayed in the cells.

- **kind=3:** Displays a PNG, TIFF, or JPEG image. You can obtain binary picture data using `SavePICT`.

- **kind=4:** Displays raw text without any escape code processing. Added in Igor Pro 8.00 to allow display of LaTeX expressions which make heavy use of backslashes.

For **kind=1 or 2**, `height` may be zero to auto-set cell height to same as width or a specific value.

**titleWave=w**

Specifies a text wave containing titles for the listbox columns, instead of using the list wave dimension labels. Each row is the title for one column; if you have N columns you must have a wave with N rows.

**userColumnResize=u**

Enables resizing the list columns using the mouse.

- **u=0:** Columns are not resizable (default). The widths parameter still works, though.

- **u=1:** User can resize columns by dragging the column dividers.

  When resizing a column without Option, Alt, or Shift modifiers (a “normal” resizing), any width added to the column is subtracted from the following column (if any).

  When resizing while pressing Option (Macintosh) or Alt (Windows), only columns following the dragged divider will move (the same way table columns are resized).

  When pressing Shift, all columns are set to the same width as the column being resized. If the total widths of all columns is less than the width of the listbox, then each column expands to fill the available width.

**userdata=UDStr**

Sets the unnamed user data to `UDStr`.

**userdata(UDName)=UDStr**

Sets the named user data, `UDName`, to `UDStr`.

**userdata+=UDStr**

Appends `UDStr` to the current unnamed user data.

**userdata(UDName)+=UDStr**

Appends `UDStr` to the current named user data, `UDName`.

**widths={w1,w2,...}**

Optional list of minimum column widths in screen pixels. If more columns than widths, the last is repeated. If total of widths is greater than list box width then a horizontal scroll bar will appear. If total is less than available width then each expands proportionally.
ListBox

Flags

/Z No error reporting.

Details

If the list wave has column dimension labels (see SetDimLabel), then those will be used as column titles. Note that a 1D wave is subtly different from a 1 column 2D wave. The former does not have any columns and therefore no column dimension labels.

Alternately, use a text wave with the titleWave keyword to specify column titles.

Using escape codes you can change the font, size, style, and color of the title. See Annotation Escape Codes on page III-53 or details.

For instance, to make a title bold use the \f01 escape sequence:

SetDimLabel 1, columnNum, "\f01My Label", textWave

If you can’t fit title text within the 255 byte limit (styled text can be especially long), use the titleWave keyword with a text wave. The wave must have as many rows as the list wave has columns. When using a title wave, there are no restrictions on the number of bytes or on what characters you can use.

This example uses a title wave to add a red up-arrow graph marker to the end of a centered title:

Make/O/T/N=(numColumns) columnTitles
columnTitles[colNum]="\JCThis is the title\K(65535,0,0)\k(65535,0,0)\W523"
ListBox list0 titleWave=columnTitles

That’s a 51-byte title that results in 19 characters or symbols that you actually see. \JC requests centered text, \K sets the text color (which colors the inside of the graph marker), \k sets the marker stroke color, and \W523 inserts a down-pointing triangular graph marker.

When using modes that allow multiple selections, use Shift to extend or add to the selection.

You can specify individual cells as being editable by setting bit 1 (counting from zero on the right) in selWave. The user can start editing a cell by either clicking in it or, if the cell is selected, by pressing Enter (or Return). When finished, the user can press Enter to accept the changes or can press Escape to reject changes. The user may also press Up or Down Arrow to accept changes and begin editing the next editable cell in a column. Likewise, Tab and Shift-Tab moves to the next or previous column in a row. If bit 2 of selWave is set then a double click will be required rather than a single click. Note: in edit mode, Tab and Shift-Tab are used to move left and right because the Left and Right Arrow keys are used to move the text entry cursor left and right.

When the listbox has keyboard focus (either by tabbing to the list box or by clicking in the box), the keyboard arrow keys move a cell selection (or row depending on mode). When not in cell edit mode, Tab and Shift-Tab move the keyboard focus to other objects in the window. The Home, End, Page Up, and Page Down keys affect the vertical scroll bar.

When the listbox has focus, the user may type the first few chars of an entry in the list to select that entry. Only the first column is used. If a match is not found then nothing is done. The search is case insensitive.

ListBox Help

You can provide a text wave with help strings to show a tooltip for individual cells or rows of a listbox in place of the generic help string provided by the help keyword. In general, the string in helpWave[listbox row][listbox column] is used. If your help wave is a 1D wave, then the listbox column is ignored, and helpWave[listbox row] is used in all columns.
Note that a 1D wave (Make/N=rows) is not the same as a 2D wave with one column (Make/N=(rows,1)). A 2D wave with one column provides help for column 0 only and the generic help string is shown for column 1 and beyond. A 1D wave provides help for all columns.

If the help wave has an empty string for a given row and column then the generic help string is shown for the corresponding listbox cell. If the help wave has too few rows or columns, then the generic help string is shown for the cells outside the range of the help wave.

**Listbox Action Procedure**

The action procedure for a ListBox control takes a predefined structure `WMListboxAction` as a parameter to the function:

```plaintext
Function ActionProcName(LB_Struct) : ListboxControl
    STRUCT WMListboxAction &LB_Struct
    ...
    return 0
End
```

The `: ListboxControl` designation tells Igor to include this procedure in the Procedure pop-up menu in the List Box Control dialog.

See `WMListboxAction` for details on the WMListboxAction structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format listbox action procedure in old code:

```plaintext
Function MyListboxProc(ctrlName,row,col,event) : ListboxControl
    String ctrlName // name of this control
    Variable row // row if click in interior, -1 if click in title
    Variable col // column number
    Variable event // event code
    ...
    return 0 // other return values reserved
End
```

This old format should not be used in new code.

**Specifying Cell Color**

The background and foreground (text) color of individual cells may be defined by providing `colorWave` in conjunction with specific planes in `selWave`. The planes in `selWave` are taken to be integer indexes into `colorWave`. The planes are defined by specific dimension labels and not by specific plane numbers. To provide foreground colors, define a plane labeled “foreColors” that contains the desired index values. Likewise define and fill a plane labeled “backColors” for background colors. The value 0 is special and indicates that the default colors should be used. Note that if you have a one column list for which you want to supply colors, the `selWave` needs to be three dimensional but with just one column. Here is an example:

```plaintext
Make/T/N=(5,1) tw= "row "+num2str(p) // 5 row, 1 col text wave (2D)
Make/B/U/N=(5,1,2) sw // 5 row, 1 col, 2 plane byte wave
Make/O/W/U myColors={{0,0,0},{65535,0,0},{0,65535,0},{0,0,65535},{0,65535,65535}}
MatrixTranspose myColors // above was easier to enter as 3 rows, 5 cols

NewPanel
ListBox lb,mode=3,listWave= tw,selWave= sw,size={200,100},colorWave=myColors
sw[][][1]= p // arbitrary index values into plane 1
```

Now, execute the following commands one at a time and observe the results:

```plaintext
SetDimLabel 2,1,backColors,sw // define plane 1 as background colors
SetDimLabel 2,1,foreColors,sw // redefine plane 1 as foreground colors
sw[][][%foreColors]= 4-p // change the color index values
```

In the above example, the `selWave` was defined as unsigned byte. If you need more than 254 colors, you will have to use a larger number size.

The color wave may have four columns instead of three, with the fourth specifying transparency (65535=fully opaque, 0=fully transparent). Transparency of the background color is of limited utility as it just shows the white background color through the cell color, resulting in pastel shades. Transparency of the foreground color permits the cell background color to show through the text color.
Checkboxes in Cells
You can cause a cell to contain a checkbox by setting bit 5 in selWave. The title (if any) is taken from listWave and the results (selected/deselected) is bit 4 of selWave. If a checkbox cell is selected then the space bar will toggle the checkbox. (Clicking a checkbox cell does not select it — use the arrow keys.)

Errors
Your listbox may be drawn with a red X and an error code. The error codes are:

<table>
<thead>
<tr>
<th>Error</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>E1</td>
<td>The listbox is too small</td>
</tr>
<tr>
<td>E2</td>
<td>The listWave is invalid (missing, not text or no rows)</td>
</tr>
<tr>
<td>E3</td>
<td>The listWave and selWave do not match in dimensions</td>
</tr>
<tr>
<td>E4</td>
<td>Mode is greater than 2 but no selWave was specified</td>
</tr>
<tr>
<td>E5</td>
<td>The number of rows in titleWave does not match the number of columns in listWave</td>
</tr>
<tr>
<td>E6</td>
<td>The titleWave is not a textWave</td>
</tr>
</tbody>
</table>

Event Queue
It is possible for a single user action to produce more than one event. For instance, pressing the up arrow key while editing to select a cell that is not visible generates event codes 4, 8, and 6. Igor calls your action procedure separately for each code.

If your code tests for a nonzero value in eventCode2, and uses it only if it is nonzero, then the event queue method will not break your code. If you have determined empirically when you need to use eventCode2 and you do not test, your code will break.

Scroll Event Warnings
Events 8, 9, and 10 report to you that the listbox has been scrolled vertically or horizontally. These events are envisioned as allowing you to keep two listboxes synchronized (you may find other uses for these events). You might use an action procedure like this one to keep two listboxes (named list0 and list1) in sync:

Function ListBoxProc2(LB_Struct) : ListBoxControl
    STRUCT WMListboxAction &LB_Struct
    if (LB_Struct.eventCode == 8)
        String listname
        if (CmpStr(LB_Struct.ctrlName, "list1") == 0)
            listname = "list0"
        else
            listname = "list1"
        endif
        ControlInfo $listname
        if (V_startRow != LB_Struct.row)
            listbox $listname,row=LB_Struct.row
            ControlUpdate $listname
        endif
    endif
    return 0
End

It is very easy to create an infinite cascade of events feeding back between the two listboxes, especially if you use event 10. When this happens, you will see your listboxes jigging up and down endlessly. The test using ControlInfo is intended to make this unlikely.

The slow response of the old-style, nonstructure action procedure can defeat the ControlInfo test by delaying the action procedure execution. If you use events 8, 9, or 10, we recommended that you use the new-style action procedure.

Note on Keystroke Event
In a keystroke event passed to a listbox action procedure the eventCode is 12. A character code is stored in the row field of the WMListboxAction structure. This works only for ASCII characters and a few special
characters such as delete (8), forward delete (127) and escape (27). It does not work for non-ASCII characters such as accented characters which are represented as UTF-8 and require multiple bytes.

As explained below, many keystroke events are not sent to the listbox action procedure because they are consumed by the internal listbox code in Igor. For this reason the keystroke event for a listbox is of limited use.

The architecture of Igor controls is such that events are passed to an action procedure only after the control has used them. In the case of a keystroke event, that means that other uses of the keystroke may consume the event before the action procedure gets a chance at it. In particular, a listbox editable cell that is actively being edited consumes keystroke events, and the action procedure is not called. The only editing-related events your action procedure will get are event codes 6 and 7.

If an arrow key is pressed, and this results in the selected row or cell changing, your action procedure will not get a keystroke event. Instead, your action procedure will receive event code 4 or 5. If the arrow key causes scrolling to occur, the action procedure will also get event code 8 or 9.

Examples
Here is a simple Listbox example:

```
Make/O/T/N=30 tjack="this is row "+num2str(p)
Make/O/B/N=30 sjack=0
NewPanel /W=(19,61,319,261)
ListBox lb1, pos={42,9}, size={137,94}, listWave=tjack, selWave=sjack, mode=3
Edit/W=(367,61,724,306) tjack, sjack
ModifyTable width(tjack)=148
```

Make selections in the list and note changes in the table and vice versa. Edit one of the list text values in the table and note update of the list.

Here is an example using a titleWave and styled text in the title cells. Note that the last title isn’t very long when rendered, but requires a 63 byte specification.

```
Make/O/T/N=(4,3) ListWave="row "+num2str(p)+" col "+num2str(q)
Make/O/T/N=3 titles // three rows to match 3-column ListWave
titles[0] = "\f01Bold Title"
titles[1] = "title with semicolon;"
titles[2] = "Marker in Gray: \K(40000,40000,40000)\k(40000,40000,40000)\W517"
NewPanel /W=(515,542,1011,794)
ListBox list0, pos={1,2}, size={391,120}, listWave=ListWave
ListBox list0, titleWave=titles
```

It is often useful to be able to display a contextual menu in response to a click in a listbox cell. Here is a simple example:

```
Function ListBoxContextProc(lba) : ListBoxControl

    STRUCT WMListboxAction &lba

    Variable row = lba.row
    Variable col = lba.col
    WAVE/Z selWave = lba.selWave

    switch( lba.eventCode )
    // Always display the contextual menu on the mouse-down event
    // On Windows, the mouse-down is delivered only after the mouse is released
    case 1: // mouse down
        if (row >= 0 && row < DimSize(selWave, 0))// click must be in a cell
            if (col == 0) // click must be in the left column
                if (lba.eventMod & 16) // it's a contextual click
                    String menucontents = "Nothing;Checkbox;Disclosure;Disabled;Enabled;"
```

```
V_flag = 0

StrSwitch(S_selection) //

case "Nothing":
    SelWave[row][1] = 0
    break
case "Checkbox":
    SelWave[row][1] = 0x20
    break
case "Disclosure":
    SelWave[row][1] = 0x40
    break
case "Disabled":
    SelWave[row][1] =
    break
    case "Enabled":
    SelWave[row][1] =
    break
endswitch
endif
endif
endif
break
case 13: // checkbox clicked
    String msg
    // test the value of SelWave for the clicked cell to see what it is, and its state
    Variable isOn = (SelWave[row][1] & 0x10) ? 1 : 0
    if (SelWave[row][1] & 0x20)
        msg = "Checkbox was turned "
        if (isOn)
            msg += "on"
        else
            msg += "off"
        endif
    else
        msg = "Disclosure was "
        if (isOn)
            msg += "opened"
else
    msg += "closed"
endif
endif
DoAlert 0, msg
break
endswitch
return 0
End

Function ListBoxContextMenu()
    Make/N=(5,2)/T/O ListWaveContext
    ListWaveContext[[0] = "Column 1 should be:"
    ListWaveContext[[1] = "Row " + num2str(p)
    Make/N=(5,2)/O SelWaveContext
    SelWaveContext=0
    NewPanel /W=(150,53,450,253)
    ListBox list_w_context,pos=[50,30],size=[200,150],proc=ListBoxContextProc,widths=[3,1]
    ListBox list_w_context,listWave=root:ListWaveContext,selWave=root:SelWaveContext
EndMacro

Copy the code above to the Procedure window and compile. On the command line, invoke the function to build the panel:
ListBoxContextMenu()

In the listbox, right-clicking (Windows) or Ctrl-clicking (Macintosh) in the left column of the listbox will present a contextual menu with choices for what to do with the right column. If you choose Checkbox or Disclosure, and the cell is enabled, when you click on the cell in the right column, an alert is displayed telling you about what happened.

An example experiment that lets you easily experiment with ListBox settings is available in "Examples:Feature Demos 2:ListBox Demo.pxp".

ListBoxControl

ListBoxControl
ListBoxControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined listbox control. See Procedure Subtypes on page IV-204 for details. See ListBox for details on creating a listbox control.

ListMatch

ListMatch(listStr, matchStr [, listSepStr])
The ListMatch function returns each list item in listStr that matches matchStr.
ListStr should contain items separated by listSepStr which typically is ",".

V-498
You may include asterisks in `matchStr` as a wildcard character. Note that matching is case-insensitive. See `StringMatch` for wildcard details.

`ListSepStr` is optional. If omitted it defaults to `";"`.

**See Also**

The `GrepList`, `StringMatch`, `StringFromList`, and `WhichListItem` functions.

**ListToTextWave**

`ListToTextWave(listStr, separatorStr)`

The `ListToTextWave` function returns a free text wave containing the individual list items in `listStr`.

See [Free Waves](#) on page IV-91 for details on free waves.

The `ListToTextWave` function was added in Igor Pro 7.00.

**Parameters**

- `listStr` is a string that contains any number of substrings separated by a common string separator.
- `separatorStr` is the separator string that separates one item in the list from the next. It is usually a single semicolon character but can be any string.

**Details**

The `ListToTextWave` function returns a free wave so it can't be used on the command line or in a macro. If you need to convert the free wave to a global wave use `MoveWave`.

For lists with a large number of items, using `ListToTextWave` and then retrieving the substrings sequentially from the returned text wave is much faster than retrieving the substrings using `StringFromList`.

The reverse operation, converting the contents of a text wave into a string list, can be accomplished using `wfprintf` like this:

```
WAVE/T tw
String list
wfprintf list, "%s\r", tw // Carriage-return separated list
```

**Example**

```IGOR
Function Test(num, separator)
    Variable num
    String separator // Usually ";

    // Build a string list using separator
    String list = ""
    Variable i
    for(i=0; i<num; i+=1)
        list += "item_" + num2str(i) + separator
    endfor

    // Convert to a text wave and print its elements
    Wave/T w = ListToTextWave(list, separator)
    Print numpnts(w)
    for(i=0; i<num; i+=1)
        Print i, w[i]
    endfor
End
```

**See Also**

`ListToWaveRefWave`, `WaveRefWaveToList`, `wfprintf`

Using Strings as Lists on page IV-172, `StringFromList`, `MoveWave`, [Free Waves](#) on page IV-91

**ListToWaveRefWave**

`ListToWaveRefWave(stringList [, options])`

The `ListToWaveRefWave` function returns a free wave containing a wave reference for each entry in `stringList` that corresponds to an existing wave.

The `ListToWaveRefWave` function was added in Igor Pro 7.00.
Parameters

`stringList` is a semicolon-separated string list of waves specified using full paths or partial paths relative to the current data folder.

`options` is a bit field that is 0 by default. Set bit 0 to if you want the function to generate an error (see `GetRTError`) if any of the list elements does not specify an existing wave. Other bits are reserved for future use and must be cleared.

Example

```plaintext
Function Test()
    NewDataFolder/O/S root:TestDF // Create empty data folder as current DF
    Make/O aaa // aaa will be the first wave in list
    Make/O bbb
    String strList = WaveList("*", ";", ";")
    Wave/WAVE wr = ListToWaveRefWave(strList, 0) // Returns a free wave
    Wave w = wr[0]
    Print GetWavesDataFolder(w, 2)
    Wave w = wr[1]
    Print GetWavesDataFolder(w, 2)
End
```

`WaveRefWaveToList`, `ListToTextWave`, `Wave References` on page IV-71

**ln**

The `ln` function returns the natural logarithm of `num`, -INF if `num` is 0, or NaN if `num` is less than 0. In complex expressions, `num` is complex, and `ln(num)` returns a complex value.

To compute a logarithm base `n` use the formula:

\[ \log_n(x) = \frac{\log(x)}{\log(n)} \]

See Also

The `log` function.

**LoadData**

`LoadData [flags] fileOrFolderNameStr`

The `LoadData` operation loads data from the named file or folder. “Data” means Igor waves, numeric and string variables and data folders containing them. The specified file or folder must be an Igor packed experiment file or a folder containing Igor binary data, such as an Igor unpacked experiment folder or a folder in which you have stored Igor binary wave files.

In Igor Pro 9.00 or later, `LoadData` can load data from a standard packed experiment file (.pxp) or from an HDF5 packed experiment file (.h5xp). Previous versions support .pxp only. The term “packed experiment file” below refers to either .pxp or .h5xp.

`LoadData` loads data objects into memory and they become part of the current Igor experiment, disassociated from the file from which they were loaded.

If loading from a file-system folder, the data (waves, variables, strings) in the folder, including any subfolders if /R is specified, is loaded into the current Igor data folder.

If loading from a packed Igor experiment file, the data in the file, including any packed sub-data folders if /R is specified, is loaded into the current Igor data folder.

Use `LoadData` to load experiment data using Igor procedures. To load experiment data interactively, use the Data Browser (Data menu).

Parameters

If you use a full or partial path for `fileOrFolderNameStr`, see `Path Separators` on page III-451 for details on forming the path.
If `fileOrFolderNameStr` is omitted you get to locate the file (if `/D` is omitted) or the folder (if `/D` is present) via a dialog.

Flags

- `/D` If present, loads from a file-system folder (a directory). If omitted, `LoadData` loads from an Igor packed experiment file.

- `/GREP={regExpStr, grepMode, objectTypeMask, grepFlags}`
  Applies a regular expression to determine what objects are loaded. `/GREP` was added in Igor Pro 8.00.
  See **Using Regular Expressions With LoadData** on page V-503 for details.

- `/I` Interactive. Forces `LoadData` to present a dialog.

- `/J=objectNamesStr` Loads only the objects named in the semicolon-separated list of object names.

- `/L=loadFlags` Controls what kind of data objects are loaded with a bit for each data type:

<table>
<thead>
<tr>
<th>loadFlags</th>
<th>Bit Number</th>
<th>Loads this Object Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>Waves</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Numeric Variables</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>String Variables</td>
</tr>
</tbody>
</table>

To load multiple data types, sum the values shown in the table. For example, `/L=1` loads waves only, `/L=2` loads numeric variables only, and `/L=3` loads both waves and numeric variables. See **Setting Bit Parameters** on page IV-12 for further details about bit settings.

If no `/L` is specified, all object types are loaded. This is equivalent to `/L=7`. All other bits are reserved and should be set to zero.

- `/O[=overwriteMode]` If `/O` alone is used, overwrites existing data objects in case of a name conflict.
  `overwriteMode` is defined as follows:
  0: No overwrite, as if there were no `/O`.
  1: Normal overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory.
      Incoming data folders completely replace any conflicting data folders in memory.
  2: Mix-in overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory but nonconflicting objects in memory are left untouched.

  See **Details** for more about overwriting.

- `/P=pathName` Specifies folder to look in for the specified file or folder. `pathName` is the name of an existing Igor symbolic path. See **Symbolic Paths** on page II-22 for details.

- `/Q` Suppresses the normal messages in the history area.

- `/R` Recursively loads sub-data folders.

- `/S=subDataFolderStr` Specifies a sub-data folder within a packed experiment file to be loaded. See **Loading a Specific Data Folder from a Packed Experiment** on page V-502 for details.

- `/T=[topLevelName]` If `/T=topLevelName` is specified, it creates a new data folder in the current data folder with the specified name and places the loaded data in the new data folder.
  If just `/T` is specified, it creates a new data folder in the current data folder with a name derived from the name of the unpacked experiment folder, packed experiment file or packed sub-data folder being loaded.
LoadData

Details
If /T is present, LoadData loads the top level data folder and its contents. If /T is omitted, it loads just the contents of the top level data folder and not the data folder itself. This distinction has an analogy in the desktop. You can drag the contents of disk folder A into folder B or you can drag folder A itself into folder B.

Because LoadData can load from a complex packed Igor experiment file or from a complex hierarchy of file-system folders, it does not set the variables normally set by a file loader: S_path, S_fileName, and S_waveNames. The variable V_flag is set to the total number of objects loaded, or to -1 if the user cancelled the open file dialog. To find what objects were created by LoadData, you can use the CountObjects and GetIndexedObjName functions.

Overwriting Existing Data
If you do a load of a data folder, overwriting an existing data folder of the same name, the behavior of LoadData depends on whether you use /J. If you do not use /J, the entire data folder and all of its contents are replaced. If you do use /J, just the specified objects in the data folder are replaced, leaving any other preexisting objects in the data folder unchanged.

If you do not use the /O (overwrite) flag or if you use /O=0 and there is a conflict between objects or data folders in the current data folder and objects or data folders in the file or folder being loaded, LoadData presents a dialog to ask you if you want to replace the existing data. However, LoadData can not replace an object with an object of a different type and will refuse to do so.

You can overwrite an object that is in use, such as a wave that is displayed in a graph or table. You can also overwrite a data folder that contains objects that are in use. This is a powerful feature. Imagine that you define a data structure consisting of waves, variables and possibly sub-data folders. You can display the data in graphs and tables and you can display these in a layout. You can then overwrite the data with an analogous data structure from a packed experiment file and Igor will automatically update any graphs, tables or layouts that need to be updated.

Controlling Which Objects Are Loaded
LoadData provides several ways to control whether a given object is loaded or is skipped. These methods, which are described in the following sections, include:

- Using /L to control whether waves, numeric variables, and string variables are loaded
- Specifying a sub-data folder using /S
- Specifying object names using /J
- Applying a regular expression using /GREP. /GREP requires Igor Pro 8.00 or later.

You can use more than one of these flags. For example, if you use /S and /J, then LoadData loads only objects in the data folder specified by /S with names listed using /J. In most cases, if you use /GREP, you will not need to combine it with /S or /J.

Loading a Specific Data Folder from a Packed Experiment
If present, /S=subDataFolderStr specifies the sub-data folder within the packed experiment file from which the load is to start. For example:

LoadData/F=Path1/S="root:Folder A:Folder B" "aPackedExpFile.pxp"

This starts loading from data folder "root:Folder A:Folder B" in the packed experiment file. subDataFolderStr is the full data folder path to the desired data folder. A trailing semicolon is allowed but not required. Since this parameter is specified as a string, you must not use single quotes to quote liberal names.

Prior to Igor Pro 7.00, the "root:" part of the data folder path was implicit and you had to omit it from subDataFolderStr. Now you can provide the full path including "root:" and this is recommended for clarity. For backward compatibility, if subDataFolderStr does not start with "root:", LoadData automatically prepends it.

/\S has no effect if you are loading from an unpacked file system folder rather than from a packed experiment file.

Specifying /S="" acts like no /S at all.

Loading Specific Objects Based on Object Name
If /J=objectNamesStr is used, then only the objects named in objectNamesStr are loaded into the current experiment. For example, /J="wave0;wave1;" will load only the two named waves, ignoring any other data in the file or folder being loaded.
Assume that you have an experiment that contains 5 runs where each run, stored in a separate data folder in a packed experiment file, consists of data acquired from four channels from an ADC card. Using the /J flag, you can load just one specific channel from each run. You can use this to compare that channel's data from all runs without loading the other channels.

The list of object names used with /J must be semicolon-separated. A semicolon after the last object name in the list recommended but optional. Since objectNamesStr is specified as a string, you must not use single quotes to quote liberal names.

objectNamesStr is limited to 2000 bytes.

Specifying /J="" acts like no /J at all.

If you load a hierarchy of data folders, using the /R flag, with /J in effect, LoadData will create each data folder in the hierarchy even if it contains none of the named objects. This behavior is necessary to avoid loading a sub-data folder without loading its parent, as well as other such complications.

Using Regular Expressions With LoadData

If you include the /GREP={regExpStr,grepMode,objectTypeMask,grepFlags} flag, LoadData applies a regular expression (see Regular Expressions on page IV-176) to determine if a given object is to be loaded.

Before we get into the details, here are some simple examples. These examples assume that we are loading a packed experiment file named "Packed.pxp" and have an Igor symbolic path named Data.

// Load waves named wave1 from all data folders
LoadData/P=Data/Q/R/L=1/GREP="(?i)^wave1$",1,1,0) "Packed.pxp"

// Load root:DataFolder0B and all objects in it
LoadData/P=Data/Q/R/L=7/GREP="(?i)^root:DataFolder0B:$",3,8,0) "Packed.pxp"

// Load all data folders whose paths are of the form root:DataFolder<suffix>
LoadData/P=Data/Q/R/L=7/GREP="(?i)^root:DataFolder.+.*$",3,8,0) "Packed.pxp"

See the Examples on page V-504 for more examples.

regExpStr is the regular expression.

GREP is by default case-sensitive but Igor names are case-insensitive. For this reason, we recommend that you start regExpStr with "(?i)" which turns GREP's case-sensitivity off.

When looking for the appropriate value for regExpStr, you may find it helpful to test if a given name or path is matched by a given regular expression using GrepString. For example:

Print GrepString("root:DataFolder0A:str0", "(?i).*0$") // Prints 1 if path is matched

The grepMode parameter selects one of three modes of using the regular expression. If grepMode is 1, LoadData matches the name of each object of types specified by objectTypeMask against the specified regular expression. If there is a match, the object passes this test.

If grepMode is 2, LoadData matches the full data folder path to the object's parent data folder for objects of types specified by objectTypeMask against the regular expression. The full data folder path starts from "root:" and includes a trailing colon. If there is a match, the object passes this test. By definition, the parent of the root: data folder is "" (empty string) which can be expressed using the regular expression "^$".

If grepMode is 3, LoadData matches the full data folder path to the object against the regular expression. The full data folder path starts from "root:" and includes a trailing colon for data folder objects only. If there is a match, the object passes this test.

When loading unpacked data, modes 2 and 3 are not supported and are ignored. They apply when loading data from a packed experiment file only.

objectTypeMask is a bitwise parameter with each bit controlling whether the regular expression is applied to a given object type. Bits 0, 1, 2, and 3 control whether the regular expression is applied against waves, numeric variables, string variables and data folders respectively. You can apply a given regular expression to more than one type of object by setting more than one bit in objectTypeMask. See Setting Bit Parameters on page IV-12 for details about bit settings.

grepFlags is a bitwise parameter. Currently only bit 0 is used so its value must be 0 or 1. Normally, when grepFlags=0, objects that do not match the regular expression are skipped by LoadData. If grepFlags=1, the meaning of a match is reversed and objects that do match the regular expression are skipped by LoadData. For example:
LoadData

// Load all objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP="\{?i\}[2]$",1,7,0) "Packed.pxp" // Normal mode

// Load all objects except those whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP="\{?i\}[2]$",1,7,1) "Packed.pxp" // Reverse mode

It is often not necessary, but you can use /GREP more than once in a given LoadData command, each time
with a different combination of grepMode, object type, and reverse mode. A given object is loaded only if it
passes all tests as well as any tests specified by /L, /J and /S. For example:

// Load root:DataFolder0B and all objects in it, except objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP="\{?i\}:root:DataFolder0B:$",3,8,0|/GREP="\{?i\}[2]$",1,7,1) "Packed.pxp"

In this example, the first /GREP flag restricts which data folders are loaded and the second /GREP flag
restricts which waves and variables are loaded.

If no test is applied to a particular kind of object then all objects of that type are loaded. For example, this
command

LoadData/P=<pathName>/GREP="\{?i\}^wave1\$",1,1,0) <file name>

specifies that only waves named "wave1" should be loaded but it says nothing about numeric variables,
string variables, or data folders so they are all loaded regardless of name. If you want to exclude all numeric
and string variables, add the /L flag:

LoadData/P=<pathName>/L=1/GREP="\{?i\}^wave1\$",1,1,0) <file name>

As LoadData progresses through the data folders of the source, it has to create each data folder before it
applies regular expression tests to objects in that data folder and its descendants. Consequently, it would
be possible to end up with empty data folders because no data objects were loaded into them or their
descendants. To eliminate the clutter that this would create, if you use /GREP, after loading all of the data,
LoadData deletes any empty data folders that it created along the way. Data folders that existed before
LoadData ran are not deleted even if they are empty. For backward compatibility, this pruning of empty
data folders is done only if you use /GREP.

For each combination of grepMode, object type, and reverse mode, only one regular expression is applied. If
you specify, for example, /GREP="\{?i\}first",1,1,0) /GREP="\{?i\}second",1,1,0), the second /GREP flag
overrides the first because they both apply a name test (grepMode=1) to wave objects (objectTypeMask=1)
using normal mode (grepFlags=0). By contrast, /GREP="\{?i\}first",1,1,0) /GREP="\{?i\}second",1,2,0) results in
no overriding because the first /GREP flag applies to waves (objectTypeMask=1) while the second applies to
numeric variables (objectTypeMask=2). Similarly, /GREP="\{?i\}first",1,1,0) /GREP="\{?i\}second",1,1,1)
results in no overriding because the first /GREP flag uses normal mode (grepFlags=0) while the second uses
reverse mode (grepFlags=1).

Examples

These examples assume that we are loading a packed experiment file named "Packed.pxp" and have an Igor
symbolic path named Data. The file contains this data hierarchy:

```
root:
  wave0,wave1,wave2,var0,var1,var2,str0,str1,str2
DataFolder0A
  wave0,wave1,wave2,var0,var1,var2,str0,str1,str2
DataFolder0B
  wave0,wave1,wave2,var0,var1,var2,str0,str1,str2
```

// Load everything
LoadData/P=Data/Q/R "Packed.pxp"

// Load all objects named wave1
LoadData/P=Data/Q/R/J="wave1: " "Packed.pxp"

// Load all objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP="\{?i\}[2]$",1,7,0) "Packed.pxp"

// Load all numeric variables whose name starts with "var"
LoadData/P=Data/Q/R/L=2/GREP="\{?i\}^var\$",1,2,0) "Packed.pxp"

// Load all string variables whose name starts with "str" and ends with "2"
LoadData/P=Data/Q/R/L=4/GREP="\{?i\}^str.*2\$",1,4,0) "Packed.pxp"

// Load all objects whose path contains "DataFolder", case-insensitive
LoadData/P=Data/Q/R/L=7/GREP="\{?i\}DataFolder\$",2,7,0) "Packed.pxp"

// Load root:DataFolder0B and all objects in it using /S
LoadData/P=Data/Q/R/L=7/S="root:DataFolder0B"/T "Packed.pxp"
// Load root:DataFolder0B and all objects in it using /GREP
LoadData/P=Data/Q/R/L=7/GREP="(?i)\^root:DataFolder0B:\$",3,8,0} "Packed.pxp"

// Load all objects whose path contains "DataFolder" and whose name ends with "1"
LoadData/P=Data/Q/R/L=7/GREP="(?i)DataFolder\$",2,7,0}/GREP="(?i).*1\$",1,7,0} "Packed.pxp"

// Load all objects in root:DataFolder0B and whose name ends with "0"
LoadData/P=Data/Q/R/L=7/GREP="(?i)root:DataFolder0B:.*0\$",3,7,0} "Packed.pxp"

LoadPackagePreferences

LoadPackagePreferences [/[MIS=mismatch /P=pathName] packageName, prefsFileName, recordID, prefsStruct

The LoadPackagePreferences operation loads preference data previously stored on disk by the
SavePackagePreferences operation. The data is loaded into the specified structure.

Note: The package preferences structure must not use fields of type Variable, String, WAVE,
NVAR, SVAR or FUNCREF because these fields refer to data that may not exist when
LoadPackagePreferences is called.

The structure can use fields of type char, uchar, int16, uint16, int32, uint32, int64, uint64, float and double
as well as fixed-size arrays of these types and substructures with fields of these types.

If the /P flag is present then the location on disk of the preference file is determined by pathName and
prefsFileName. However in the usual case the /P flag will be omitted and the preference file is located in a file
named prefsFileName in a directory named packageName in the Packages directory in Igor’s preferences directory.

Note: You must choose a very distinctive name for packageName as this is the only thing
preventing collisions between your package and someone else’s package. If you use a
name longer than 31 bytes, your package will require Igor Pro 8.00 or later.

See Saving Package Preferences on page IV-251 for background information and examples.

Parameters

packageName is the name of your package of Igor procedures. It is limited to 255 bytes and must be a legal
name for a directory on disk. This name must be very distinctive as this is the only thing preventing
collisions between your package and someone else’s package. If you use a name longer than 31 bytes, your
package will require Igor Pro 8.00 or later.

prefsFileName is the name of a preference file to be loaded by LoadPackagePreferences. It should include an
extension, typically ".bin".

prefsStruct is the structure into which data from disk, if it exists, will be loaded.

recordID is a unique positive integer that you assign to each record that you store in the preferences file. If
you store more than one structure in the file, you would use distinct recordIDs to identify which structure
you want to load. In the simple case you will store just one structure in the preference file and you can use
0 (or any positive integer of your choice) as the recordID.

Flags

/MIS=mismatch Controls what happens if the number of bytes in the file does not match the size of
the structure:
0: Returns an error. Default behavior if /MIS is omitted.
1: Returns the smaller of the size of the structure and the number of
bytes in the file. Does not return an error. Use this if you want to
read and update old versions of a preferences structure.
LoadPICT

V_flag = Set to 0 if no error occurred or to a nonzero error code.
If the preference file does not exist, V_flag is set to zero so you must use V_bytesRead
to detect that case.

V_bytesRead = Set to the number of bytes read from the file. This will be zero if the preference file
does not exist.

V_structSize = Set to the size in bytes of prefsStruct. This may be useful in handling structure version
changes.

After calling LoadPackagePreferences if V_flag is nonzero or V_bytesRead is zero then you need to create
default preferences as illustrated by the example referenced below.

V_bytesRead, in conjunction with the /MIS flag, makes it possible to check for and deal with old versions
of a preferences structure as it loads the version field (typically the first field) of an older or newer version
structure. However in most cases it is sufficient to omit the /MIS flag and treat incompatible preference data
the same as missing preference data.

Example
See the example under Saving Package Preferences in a Special-Format Binary File on page IV-252.

See Also
SavePackagePreferences.

LoadPICT

LoadPICT [flags] [fileNameStr[, pictName]]
The LoadPICT operation loads a picture from a file or from the Clipboard into Igor. Once you have loaded
a picture, you can append it to graphs and page layouts.

Parameters
The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic
path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder
associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine
the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming
the path.

If you want to force a dialog to select the file, omit the fileNameStr parameter.

If fileNameStr is “Clipboard” and /P=pathName is omitted, LoadPICT loads its data from the Clipboard
rather than from a file.

pictName is the name that you want to give to the newly loaded picture. You can refer to the picture by its
name to append it to graphs and page layouts. LoadPICT generates an error if the name conflicts with some
other type of object (e.g., wave or variable) or if the name conflicts with a built-in name (e.g., the name of
an operation or function).

If you omit pictName, LoadPICT automatically names the picture as explained in Details.

Flags

/M=promptStr = Specifies a prompt to use if LoadPICT needs to put up a dialog to find the file.
LoadPICT

/O
   Overwrites an existing picture with the same name.
   If /O is omitted and there is an existing picture with the same name, LoadPICT displays a dialog in which you can resolve the name conflict.

/P=pathName
   Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/Q
   Quiet: suppresses the insertion of picture info into the history area.

/Z
   Doesn’t load the picture, just checks for its existence.

Details

If the picture file is not fully specified then LoadPICT presents a dialog from which you can select the file. “Fully specified” means that LoadPICT can determine the name of the file (from the fileNameStr parameter) and the folder containing the file (from the flag /P=pathName flag or from the fileNameStr parameter). If you want to force a dialog, omit the fileNameStr parameter.

If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-22 for details.

If you omit pictName, LoadPICT automatically names the picture as follows:

If the picture was loaded from a file, LoadPICT uses the file name. If necessary, it makes it into a legal name by replacing illegal characters or shortening it.
Otherwise, LoadPICT uses a name of the form “PICT_n”.

If the resulting name is in conflict with an existing picture name, Igor puts up a name conflict resolution dialog.
LoadPICT sets the variable V_flag to 1 if the picture exists and fits in available memory or to 0 otherwise. It also sets the string variable S_info to a semicolon-separated list of values:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>Name of the loaded PICT, often “PICT_0”, etc.</td>
</tr>
<tr>
<td>SOURCE</td>
<td>“Data fork” or “Clipboard”.</td>
</tr>
<tr>
<td>RESOURCENAME</td>
<td>Obsolete - always “”.</td>
</tr>
<tr>
<td>RESOURCEID</td>
<td>Obsolete - always 0.</td>
</tr>
<tr>
<td>TYPE</td>
<td>One of the following types: DIB Encapsulated PostScript Enhanced metafile JPEG PDF PNG SVG TIFF Windows bitmap Windows metafile Unknown type</td>
</tr>
<tr>
<td>BYTES</td>
<td>Amount of memory used by the picture.</td>
</tr>
<tr>
<td>WIDTH</td>
<td>Width of the picture in pixels.</td>
</tr>
</tbody>
</table>
LoadWave

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>HEIGHT</td>
<td>Height of the picture in pixels.</td>
</tr>
<tr>
<td>PHYSWIDTH</td>
<td>Physical width of the picture in points.</td>
</tr>
<tr>
<td>PHYSHEIGHT</td>
<td>Physical height of the picture in points.</td>
</tr>
</tbody>
</table>

See Pictures on page III-509 for general information on how Igor handles pictures.
The ImageLoad operation for loading PICT and other image file types into waves, and the PICTInfo function.

LoadWave

LoadWave [flags] [fileNameStr]
The LoadWave operation loads data from the named Igor binary, Igor text, delimited text, fixed field text, or general text file into waves. LoadWave can load 1D and 2D data from delimited text, fixed field text and general text files, or data of any dimensionality from Igor binary and Igor text files.

Parameters
The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If LoadWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

If fileNameStr is “Clipboard” and /P=pathName is omitted, LoadWave takes its data from the Clipboard rather than from a file. This is not implemented for binary loads.

If fileNameStr is omitted or is “”, or if the /I flag is used, LoadWave presents an Open File dialog from which you can choose the file to load.

Flags
/A “Auto-name and go” option (used with /G, /F or /J).
This skips the dialog in which you normally enter wave names. Instead it automatically assigns names of the form wave0, wave1, choosing names that are not already in use. When used with /W, it reads wave names from the file instead of automatically assigning names and /A just skips the wave name dialog. The /B flag can also override names specified by /A.

See LoadWave Generation of Wave Names on page II-142 for further discussion.

/A=baseName Same as /A but it automatically assigns wave names of the form baseName0, baseName1.

/B=columnInfoStr Specifies the name, format, numeric type, and field width for columns in the file. See Specifying Characteristics of Individual Columns on page II-145 for details.

/C This is used in experiment recreation commands generated by Igor to force experiment recreation to continue if an error occurs in loading a wave.

/D Creates double precision waves. (Used with /G, /F or /J.) The /B flag can override the numeric precision specified by the /D flag.

/E=editCmd Controls table creation:
editCmd=1: Makes a new table containing the loaded waves.
editCmd=2: Appends the loaded waves to the top table. If no table exists, a new table is created.
editCmd=0: Same as if /E had not been specified (loaded waves are not put in any table).
LoadWave

/ENCG=textEncoding
/ENCG={[textEncoding, tecOptions]}

Specifies the text encoding of the plain text file being loaded.
This flag was added in Igor Pro 7.00.
This flag is ignored when loading an Igor binary wave file.

See Text Encoding Names and Codes on page III-490 for a list of accepted values for textEncoding.
For most purposes the default value for tecOptions, 3, is fine and you can use /ENCG=textEncoding instead of /ENCG={[textEncoding, tecOptions]}.

/ENCG=[textEncoding, tecOptions] is an optional bitwise parameter that controls text encoding conversion. See Setting Bit Parameters on page IV-12 for details about bit settings.

/ENCG=textEncoding specifies the text encoding of the plain text file being loaded. This flag was added in Igor Pro 7.00. This flag is ignored when loading an Igor binary wave file. See Text Encoding Names and Codes on page III-490 for a list of accepted values for textEncoding.

For most purposes the default value for tecOptions, 3, is fine and you can use /ENCG=textEncoding instead of /ENCG={[textEncoding, tecOptions]}.

/ENCG=[textEncoding, tecOptions] is an optional bitwise parameter that controls text encoding conversion. See Setting Bit Parameters on page IV-12 for details about bit settings.

/ENCG=[textEncoding, tecOptions] is defined as follows:

- **Bit 0**: If cleared, the presence of null bytes causes LoadWave to consider the text invalid in all byte-oriented text encodings. This makes it easier for LoadWave to identify UTF-16 and UTF-32 text which usually contains null bytes.
  - If set (default), null bytes are allowed in byte-oriented text encodings.

- **Bit 1**: If cleared LoadWave does not validate text if the specified text encoding is UTF-8.
  - If set (default), LoadWave validates text even if the text encoding is UTF-8.

- **Bit 2**: If cleared (default) LoadWave validates the text in the specified text encoding except that validation for UTF-8 is skipped if bit 1 is cleared.
  - If set, LoadWave assumes that the text is valid in the specified text encoding and does not validate it. Setting this bit makes LoadWave slightly faster but it is usually inconsequential.

- **Bit 3**: If cleared (default), LoadWave presents the Choose Text Encoding dialog if the specified text encoding is not valid for the text in the file.
  - If set, LoadWave does not present the Choose Text Encoding dialog if the text is not valid in the specified text encoding and instead returns an error. Set this bit if you are running an automated procedure and do not want it interrupted by a dialog.

See LoadWave Text Encoding Issues on page II-149 for further discussion.

/F={numColumns, defaultFieldWidth, flags}

Indicates that the file uses the fixed field file format. Most FORTRAN programs generate files in this format.

- **numColumns** is the number of columns of data in the file.
- **defaultFieldWidth** is the default number of bytes in each column. If the columns do not all have the same number of bytes, you need to use the /B flag to provide more information to LoadWave.

- **flags** is a bitwise parameter that controls the conversion of text to values. The bits are defined as follows:
  - **Bit 0**: If set, any field that consists entirely of the digit “9” is taken to be blank. A field that consists entirely of the digit “9” except for a leading “+” or “-“ is also taken to be blank.

All other bits are reserved and must be cleared.

/G Indicates that the file uses the general text format.
LoadWave

/H Loads the wave into the current experiment and severs the connection between the wave and the file. When the experiment is saved, the wave copy will be saved as part of the experiment. For a packed experiment this means it is saved in the packed experiment file. For an unpacked experiment this means it is saved in the experiment’s home folder.

See Sharing Versus Copying Igor Binary Wave Files on page II-156.

/I Forces LoadWave to display an Open File dialog even if the file is fully specified via /P and fileNameStr.

/J Indicates that the file uses the delimited text format.

/K=k Controls how to determine whether a column in the file is numeric or text (only for delimited text and fixed field text files).

\[ k=0: \text{Deduces the nature of the column automatically.} \]

\[ k=1: \text{Treats all columns as numeric.} \]

\[ k=2: \text{Treats all columns as text.} \]

This flag as well as the ability to load text data into text waves were added in Igor Pro 3.0. The default for the LoadWave operation is /K=1, meaning that it will treat all columns as numeric. We did this so that existing procedures would behave the same in Igor Pro 3.0 as before. Use /K=0 when you want to load text columns into text waves. /K=2 may have use in a text-processing application.

For finer control, the /B flag specifies the format of each column in the file individually.

/L={nameLine, firstLine, numLines, firstColumn, numColumns}

Affects loading delimited text, fixed field text, and general text files only (/J, /F or /G). /L is accepted no matter what the load type but is ignored for Igor binary and Igor text loads. Line and column numbers start from 0.

nameLine is the number of the line containing column names. For general text loads, 0 means auto. See Loading General Text Files on page II-138 for details.

firstLine is the number of the first line to load into a wave. For general text loads, 0 means auto. See Loading General Text Files on page II-138 for details.

numLines is the number of lines that should be treated as data. 0 means auto which loads until the end of the file or until the end of the block of data in general text files. The numLines parameter can also be used to make loading very large files more efficient. See Loading Very Large Files on page II-150 for details.

firstColumn is the number of the first column to load into a wave. This is useful for skipping columns.

numColumns is the number of columns to load into a wave. 0 means auto, which loads all columns.

/M Loads data as matrix wave. If /M is used then it ignores the /W flag (read wave names) and follows the /U flags instead.

The wave is autonamed unless you provide a specific wave name using the /B flag.

The type of the wave (numeric or text) is determined by an assessment of the type of the first loaded column unless you override this using the /K flag or the /B flag.

See The Load Waves Dialog for Delimited Text — 2D on page II-133 for further information.

/N Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.

See LoadWave Generation of Wave Names on page II-142 for further discussion.
LoadWave

/N=baseName

Same as /N except that it automatically assigns wave names of the form baseName0, baseName1.

/NAME={namePrefix, nameSuffix, nameOptions}

The /NAME flag overrides or combines with the other flags (/A, /N, /W, and /B) that affect the names of waves loaded by LoadWave.

/NAME was added in Igor Pro 9.00. It applies to Load General Text (/G), Load Delimited Text (/J), and Load Fixed Field Text (/F), not when loading Igor binary files or Igor Text files.

The /NAME flag is primarily intended to provide an easy way to incorporate the file name in the wave names. For example, if you are loading a single wave from a file named File.txt, you can create a single wave named File and, if you are loading three waves from a file named File.txt, you can create three waves named File0, File1, and File2.

namePrefix is "" or text to be prepended to the final wave names.

nameSuffix is "" or text to be appended to the final wave names.

If both namePrefix and nameSuffix are "", it is as if the /NAME flag was omitted altogether.

In the construction of the final wave names, LoadWave replaces ".filename:" in namePrefix or nameSuffix with the name of the file being loaded without the file name extension.

nameOptions is a bitwise parameter. The bits are defined as follows:

Bit 0: Include normal name. If set, the "normal" wave name (the name that would be used if /NAME were omitted) is included in the final name between namePrefix and nameSuffix.

Bit 1: Include normal name. If set, the "normal" wave name (the name that would be used if /NAME were omitted) is included in the final name between namePrefix and nameSuffix.

Bit 2: Include suffix number when loading multiple waves. If multiple waves, a suffix number is appended unless suppressed by bit 3.

Bit 3: Include suffix number only if there is a name conflict. If set and there are no name conflicts, this overrides bits 1 and 2 and prevents appending suffix numbers.

Bit 4: Choose suffix number to create unique names. If set, LoadWave chooses suffix numbers to avoid conflicts with existing waves. If cleared suffix numbers start from 0 and increment by one for each loaded wave.

Bit 5: Allow liberal names (not recommended).

See Setting Bit Parameters on page IV-12 for details about bit settings.

See LoadWave Generation of Wave Names on page II-142 for further discussion.

/O Overwrite existing waves in case of a name conflict.

/P=pathName Specifies the folder to look in for fileNameStr. pathName is the name of an existing symbolic path.

/Q Suppresses the normal messages in the history area.

/R={languageName, yearFormat, monthFormat, dayOfMonthFormat, dayOfWeekFormat, layoutStr, pivotYear} Specifies a custom date format for dates in the file. If the /R flag is used, it overrides the date setting that is part of the /V flag.
*languageName* controls the language used for the alphabetic date components, namely the month and the day-of-week. *languageName* is one of the following:

Default

<table>
<thead>
<tr>
<th>Chinese</th>
<th>Chinese Simplified</th>
<th>Danish</th>
<th>Dutch</th>
</tr>
</thead>
<tbody>
<tr>
<td>English</td>
<td>Finnish</td>
<td>French</td>
<td>German</td>
</tr>
<tr>
<td>Italian</td>
<td>Japanese</td>
<td>Korean</td>
<td>Norwegian</td>
</tr>
<tr>
<td>Portuguese</td>
<td>Russian</td>
<td>Spanish</td>
<td>Swedish</td>
</tr>
</tbody>
</table>

Default means the system language on Macintosh or the user default language on Windows.

*yearFormat* is one of the following codes:

1: Two digit year.
2: Four digit year.

*monthFormat* is one of the following codes:

1: Numeric, no leading zero.
2: Numeric with leading zero.
3: Abbreviated alphabetic (e.g., Jan).
4: Full alphabetic (e.g., January).

*dayOfMonthFormat* is one of the following codes:

1: Numeric, no leading zero.
2: Numeric with leading zero.

*dayOfWeekFormat* is one of the following codes:

1: Abbreviated alphabetic (e.g., Mon).
2: Full alphabetic (e.g., Monday).

*layoutStr* describes which components appear in the date in what order and what separators are used. *layoutStr* is constructed as follows (but with no line break):

"<component keyword><separator>
<component keyword><separator>
<component keyword><separator>
<component keyword>"

where <component keyword> is one of the following:

Year
Month
DayOfMonth
DayOfWeek

and <separator> is a string of zero to 15 bytes.
Starting from the end, parts of the layout string must be omitted if they are not used. Extraneous spaces are not allowed in `layoutStr`. Each separator must be no longer than 15 bytes. No component can be used more than once. Some components may be used zero times.

`pivotYear` determines how LoadWave interprets two-digit years. If the year is specified using two digits, `yy`, and is less than `pivotYear` then the date is assumed to be `20yy`. If the two digit year is greater than or equal to `pivotYear` then the year is assumed to be `19yy`. `pivotYear` must be between 4 and 40.

See [Loading Custom Date Formats](#) on page II-144 for further discussion of date formats.

/T

Indicates that the file uses the Igor text format.

Although LoadWave is generally thread-safe, it is not thread-safe to load an Igor text file containing an Igor command (e.g., `X <command>`).

/U={readRowLabels, rowPositionAction, readColLabels, colPositionAction}

These parameters affect loading a matrix (/M) from a delimited text (/J) or a fixed field text (/F) file. They are accepted no matter what the load type is but are ignored when they don’t apply.

If `readRowLabels` is nonzero, it reads the first column of data in the file as the row labels for the matrix wave.

`rowPositionAction` has one of the following values:

- 0: The file has no row position column.
- 1: Uses the row position column to set the row scaling of the matrix wave.
- 2: Creates a 1D wave containing the values in the row position column. The name of the 1D wave will be the same as the matrix wave but with the prefix “RP_”.

The `readColLabels` and `colPositionAction` parameters have analogous meanings. The prefix used for the column position wave is “CP_”.

See Chapter II-9, [Importing and Exporting Data](#) for further details.

/N={delimsStr, skipCharsStr, numConversionFlags, loadFlags}

These parameters affect loading delimited text (/J) and fixed field text (/F) data and column names. They do not affect loading general text (/G). They are accepted no matter what the load type is but are ignored when they don’t apply. These parameters should rarely be needed.

`delimsStr` is a string expression containing the characters that should act as delimiters for delimited file loads. (When loading data as general text, the delimiters are always tab, comma and space.) The default is “\t,” for tab and comma. You can specify the space character as a delimiter, but it is always given the lowest priority behind any other delimiters contained in `delimsStr`. The low priority means that if a line of text contains any other delimiter besides the space character, then that delimiter is used rather than the space character.

`skipCharsStr` is a string expression containing characters that should always be treated as garbage and skipped when they appear before a number. The default is “$” for space and dollar sign. This parameter should rarely be needed.
numConversionFlags is a bitwise parameter that controls the conversion of text to numbers. The bits are defined as follows:

Bit 0: If set: dates are dd/mm/yy.
       If cleared: dates are mm/dd/yy.

Bit 1: If set: decimal character is comma.
       If cleared: it is period.

Bit 2: If set: thousands separators in numbers are ignored when loading delimited text only (LoadWave/J).

The thousands separator is the comma in 1,234 or, if comma is the decimal character, the dot in 1.234.

Most numeric data files do not use thousands separators and searching for them slows loading down so this bit should usually be 0.

This bit has no effect if the thousands separator (e.g., comma) is also a delimiter character as specified by delimsStr.

All other bits are reserved and must be cleared.

See Setting Bit Parameters on page IV-12 for details about bit settings.

If the /R flag is used to specify the date format, this overrides the setting of bit 0.

loadFlags is a bitwise parameter that controls the overall load. The bits are defined as follows:

Bit 0: If set, ignores blanks at the end of a column. This is appropriate if the file contains columns of unequal length. Set loadFlags = 1 to set bit 0.

Bit 1: If set, when the /W flag is specified and the line containing column labels starts with one or more space characters, the spaces are taken to be a blank column name. The resulting column will be named Blank. Use this if both the line containing column labels and the lines containing data start with leading spaces in a space-delimited file. Set loadFlags = 2 to set bit 1.

Bit 2: If set: Disables pre-counting of lines of data. See Loading Very Large Files on page II-150.

Bit 3: If set: Disables unescaping of backslash characters in text columns. See Escape Sequences on page II-150 below.

Bit 4: If set: Disables support for quoted strings.

Setting this bit improves compatibility with Igor7. It applies to delimited text only and should rarely be needed. See Quoted Strings in Delimited Text Files on page II-135 and Delimited Text Compatibility With Igor7 on page II-136 for background information.

/W  Looks for wave names in a file. (With /G, /F, and /J.)

LoadWave cleans up column names to create standard, not liberal, wave names. See Object Names on page III-501 and CleanupName for details.

Use /W/A to read wave names from the file and then continue the load without displaying the normal wave name dialog.

See LoadWave Generation of Wave Names on page II-142 for further discussion.

Details
Without the /G, /F, /J, or /T flags, LoadWave loads Igor binary wave files.

If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-22 for details.

When loading a general text file, the delimiters are always tab, comma and space.
Output Variables
LoadWave sets the following variables:

- **V_flag**: Number of waves loaded.
- **S_fileName**: Name of the file being loaded.
- **S_path**: File system path to the folder containing the file.
- **S_waveNames**: Semicolon-separated list of the names of loaded waves.

*S_path* uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon. If LoadWave is loading from the Clipboard, *S_path* is set to "".

When LoadWave presents an Open File dialog and the user cancels, *V_flag* is set to 0 and *S_fileName* is set to "".

---

**Loess**

\[
\text{Loess} \ [\text{flags}] \ srcWave = \ srcWaveName \ [, \ factors = \ factorWaveName1 \\
\hspace{1em} [, \ factorWaveName2 \ ... ]] 
\]

The Loess operation smooths *srcWaveName* using locally-weighted regression smoothing. This algorithm is sometimes classified as a “nonparametric regression” procedure. The regression can be constant, linear, or quadratic. A robust option that ignores outliers is available. See [Basic Algorithm](#), [Robust Algorithm](#), and [References](#) for additional details and terminology.

This implementation works with waveforms, XY pairs of waves, false-color images, matrix surfaces, and multivariate data (one dependent data wave with multiple independent variable data waves).

Unlike the [FilterFIR](#) operation, Loess discards any NaN input values and will not generate a result that is wholly NaN.

**Parameters**

*srcWaveName* is the input data to be smoothed. It may be a one-dimensional or a two-dimensional wave, and it may contain NaNs.

When no /DEST flag is specified, Loess will overwrite *srcWaveName* with the smoothed result.

If *srcWaveName* is one-dimensional and no factors are provided, X values are derived from the X scaling of *srcWaveName*.

If *srcWaveName* is two-dimensional, the factors keyword is not permitted and the X and Y values are derived from the X and Y scaling of *srcWaveName*.

Higher dimensions of *srcWaveName* are not supported.

The optional factors parameter(s) provide the independent variable value(s) that correspond to the observed value in *srcWaveName*.

**Note:** Cleveland et al. (1992) use the term “multiple factors” instead of “multivariate”, hence the keyword name “factors” is used to denote these waves.

Use one factors wave when *srcWaveName* is the one-dimensional Y wave of an XY data pair:

\[
srcWaveName[i] = \text{someFunction}(factorWaveName1[i]) 
\]
Use multiple factors waves when srcWaveName contains the values of a multivariate function. "Multivariate" means that srcWaveName contains the observed results of a process that combines multiple independent input variables:

\[ srcWaveName[i] = \text{someFunction}(factorWaveName1[i], factorWaveName2[i],...) \]

A maximum of 10 factors waves is supported.

All factors wave(s) must be numeric, noncomplex, one-dimensional and have the same number points as srcWaveName.

Any NaN values in srcWaveName[i], factorWaveName1[i], factorWaveName2[i], ... cause all corresponding values to be ignored. Factors waves may contain NaN values only when /DFCT is specified.

Loess does not support NaNs in any of destFactorWaveName1, destFactorWaveName2,.... and the results are undefined.

Flags

/CONF={confInt, ciPlusWaveName [,ciMinusWaveName]}

confInt specifies the confidence interval (a probability value from 0 to 1). ciPlusWaveName and the optional ciMinusWaveName are the names of new or overwritten output waves to hold the fitted value ± the confidence interval.

Note: /CONF uses large memory allocations, approximately N*N*8 bytes, where N is the number of points in srcWaveName (see Memory Details).

/DEST=destWaveName

Specifies the name of the wave to hold the smoothed data. It creates destWaveName if it does not already exist or overwrites it if it does. The x (and possibly y) scaling of destWave determines the independent (factor) coordinates unless /DFCT={destFactorWaveName1 [,destFactorWaveName2...]}. The y scaling of destWave determines the independent (factor) coordinates unless /DFCT is specified.

/DFCT

Specifies that the /DEST wave’s x (and possibly y) scaling determines the independent (factor) coordinates at which to compute the smoothed data.

/DFCT={destFactorWaveName1 [,destFactorWaveName2...]}]

Specifies the names of one-dimensional waves providing the independent coordinates at which to compute the smoothed data.

If /DFCT={...} is used, the same number of waves must be specified for /DFCT and for factors = {factorWaveName1 [, factorWaveName2...]}, though their lengths may (and usually will) be different. The length of destFactorWaveName waves must be the same as that of the destWaveName wave.

All destination factor waves must be numeric, noncomplex, and one-dimensional. The number of destination factor waves must match the number of source factor waves (if specified), or match the dimensionality of srcWaveName (one destination factor wave if srcWaveName is one-dimensional, two destination factors waves if srcWaveName is two-dimensional.)

The values in the destination factor waves may not be NaN.

/E=extrapolate

Set extrapolate to nonzero to use a slower fitting method that computes values beyond the domain defined by the source factors. This is the “surface” parameter named “direct” in Cleveland et al. (1992). The default is extrapolate = 0, which uses the “interpolate” surface parameter, instead.

/N=neighbors

Specifies the number of values in the smoothing window.

If neighbors is even, the next larger odd number is used. When neighbors is less than two, no smoothing is done.

The default is 0.5*numpnts(srcWaveName) rounded up to the next odd integer or 3, whichever is larger.

Use either /N or /SMTH, but not both.
Loess

Basic Algorithm

The basic locally-weighted regression algorithm fits a constant, line, or quadratic to each point of the source data, using data that falls within the given span of neighbors over the factor data. Data outside of the span

/NORM [=norm] Set norm to 0 when specifying multiple factors and they all have the same scale and meaning, for example multiple factors all in units of meters.

The default is norm = 1, which normalizes each factor independently when computing the weighting function. This is appropriate when the factors are not dimensionally related, for example one factor measures wavelength and another measures temperature.

/ORD=order Specifies the regression (fitting) order, the d parameter in Cleveland (1979):

order=0: Fits a constant to the locally-weighted neighbors around each point.

order=1: Fits a line to the locally-weighted neighbors around each point (Lowess smoothing).

order=2: Default; fits a quadratic (Loess smoothing).

/PASS=passes The number of iterations of local weighting and regression fitting performed. The minimum is 1 and the default is 4. The passes parameter corresponds to the t parameter in Cleveland (1979).

/R [=robust] Set robust to nonzero to use a robust fitting method that uses a bisquare weight function instead of the normal tricube weight function. This corresponds to the “symmetric” family in Cleveland et al. (1992). The robust method is less affected by outliers. The default is robust = 0, which is the “gaussian” family in Cleveland et al. (1992).

/SMTH=sf Another way to express the number of values in the smoothing window, 0 ≤ sf ≤ 1. The default is 0.5.

To compute neighbors from sf, use:

neighbors = 1+floor(sf*numpnts(srcWaveName)).

Use either /N or /SMTH, but not both.

/TIME=secs secs is the number of seconds allowed to complete the calculation before either warning (default) or stopping.

If the stop bit (4) of /V=verbose is set, the calculation stops after the allotted time. If the diagnostic bit of /V=verbose is also set, warnings about the calculation exceeding the allotted time are printed to the history area.

As an example, use /TIME=30/V=6 to abort calculations longer than 30 seconds and print the warning to the history area.

/V [=verbose] Controls how much information to print to the history area. verbose is a bitwise parameter with each bit controlling one aspect:

verbose=0: Prints nothing to the history area (default).

verbose=1: Prints the number of observations, equivalent number of parameters, and residual standard error.

verbose=2: Prints diagnostic information and error messages.

verbose=4 Use with /TIME. If this bit is set, calculations that exceed secs seconds are aborted.

Set verbose to 6 to both limit the time and print diagnostic and error messages.

/V alone is the same as /V=3, which prints all information.

S_info contains all the informational messages regardless of the value of

/Z=[z] Set z to nonzero to prevent an error from stopping execution. Use the V_flag variable to see if the smoothing succeeded.
is ignored (given a weight of zero), and data inside the span is given a weight that depends on the distance of the data from the point being evaluated: data closer to the point being evaluated have higher weights and have a greater affect on the fit.

The basic algorithm uses the “tricube” weighting function to emphasize near values and deemphasize far values. For the one-factor case (simple XY data), the weighting function can be expressed as:

$$w_i = \left(1 - \frac{x - x_i}{\text{max}_q (x - x_i)}\right)^3,$$

where $\text{max}_q (x - x_i)$ is the maximum Euclidean distance of the q factor values within the given span from the factor point (x) whose observation (y) value is being evaluated.

The weights are applied to the factor values in the span to compute the constant, linear, or quadratic regression at x.

When multiple factors are used, the Euclidean distance is computed using one dimension per factor. The default is to normalize each factor’s range by the standard deviation of that factor’s values before computing the Euclidean distances. When factors are dimensionally equal, use the /NORM=0 option to skip this normalization. (See /NORM, about “dimensionally equal”.)

**Robust Algorithm**

The robust algorithm adds to the basic algorithm a method to identify and remove outliers by rejecting values that exceed a threshold related to the “median absolute deviation” of the basic regression’s residuals. The remaining values are used to compute robust “bisquare” weighting values:

$$r_i = \begin{cases} 
\left(1 - \frac{e_i}{6 \cdot \text{median}(|e_i|)}\right)^2 & \text{for } 0 \leq |e_i| < 6 \cdot \text{median}(|e_i|) \\
0 & \text{for } |e_i| > 6 \cdot \text{median}(|e_i|) 
\end{cases}$$

where $e_i$ is the difference between the observed value and the regression’s fitted value, and $\text{median}(|e_i|)$ is evaluated for all the observed values.

These robust weighting values are multiplied with the original weighting values and a new regression (with new residuals) is computed. This process repeats 4 times by default. Use the /PASS flag to specify a different number of repetitions.

**Details**

Loess sets the variable V_flag to 0 if the smoothing was successful, or to an error code if not. Unlike other operations, the /Z flag allows execution to continue even if input parameters are in error.

Information printed to the history area when /V is set is always stored in the S_info string, even if /V=0 (the default). S_info also contains the error message text if V_flag is an error code.

The error messages are described in Cleveland et al. (1992). They are often more dire than they seem.

The error message “Span too small. Fewer data values than degrees of freedom” usually means that the /SMTH or /N values are too small. The error code returned in V_flag for this case is 1106.

The “Extrapolation not allowed with blending” (V_Flag = 1115) error usually means that the destination factors are trying to compute observations outside of the source factors domain without specifying /E=1. This happens if the /DEST destWaveName already exists and has X scaling that extends beyond the X scaling of srcWaveName. The solution is either kill the /DEST wave, limit the X scaling to the domain of the source wave, or use /E=1.
Memory Details
Loess requires a lot of memory, especially with the \(/CONF\) flag. Even without \(/CONF\), the memory allocations exceed this approximation:

Number of bytes allocated = number of points in \(srcWaveName\) * 216

With \(/CONF\), Loess can allocate large amounts of memory, approximately \(N^2 \times 8\) bytes, where \(N\) is the number of points in \(srcWaveName\). The 2GB memory limit of 32-bit addressing limits \(srcWaveName\) to approximately 10,000 points when using \(/CONF\).

More precisely, the memory allocation may be approximated by this function:

Function ComputeLoessMemory(srcPoints, numFactorsWaves, doConfidence)
  Variable srcPoints // number of points in srcWave, aka \(N\)
  Variable numFactorsWaves // 1 or number of factors (independent variables)
  Variable doConfidence // true if \(/CONF\) is specified
  Variable doubles= 9 * srcPoints // 9 allocated double arrays
  doubles += 5 * numFactorsWaves * srcPoints // 5 more arrays
  doubles += (1+numFactorsWaves) * srcPoints // another array
  doubles += (1+numFactorsWaves) * srcPoints // another array
  doubles += (4+5) * srcPoints // two more arrays
  if( doConfidence )
    doubles += srcPoints*srcPoints // one HUGE array
  endif
  Variable bytes= doubles * 8
  return bytes
End

\[ \log(n) \]

The log function returns the log base 10 of \( num \).
It returns -INF if \( num \) is 0, and returns NaN if \( num \) is less than 0.
To compute a logarithm base \( n \) use the formula:

\[ \log_n(x) = \frac{\log(x)}{\log(n)}. \]

See Also
The \( \ln \) function.
**logNormalNoise**

`logNormalNoise(m, s)`

The `logNormalNoise` function returns a pseudo-random value from the lognormal distribution function whose probability distribution function is

\[
    f(x, m, s) = \frac{1}{x s \sqrt{2\pi}} \exp\left\{ -\frac{\ln(x) - m}{2s^2} \right\},
\]

with a mean \( \exp\left( m + \frac{1}{2} s^2 \right) \),

and variance \( \exp(2m + s^2)[\exp(s^2) - 1] \).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use `SetRandomSeed`. The algorithm uses the Mersenne Twister random number generator.

**See Also**

The `SetRandomSeed` operation.

**Noise Functions** on page III-390.

Chapter III-12, **Statistics** for a function and operation overview.

**LombPeriodogram**

`LombPeriodogram [flags] srcTimeWave, srcAmpWave [, srcFreqWave ]`

The LombPeriodogram is used in spectral analysis of signal amplitudes specified by `srcAmpWave` which are sampled at possibly random sampling times given by `srcTimeWave`. The only assumption about the sampling times is that they are ordered from small to large time values. The periodogram is calculated for either a set of frequencies specified by `srcFreqWave` (slow method) or by the flags `/FR` and `/NF` (fast method). Unless you specify otherwise, the results of the operation are stored by default in `W_LombPeriodogram` and `W_LombProb` in the current data folder.

**Flags**

`/DESP=datafolderAndName`

Saves the computed P-values in a wave specified by `datafolderAndName`. The destination wave will be created or overwritten if it already exists. `dataFolderAndName` can include a full or partial path with the wave name.

Creates by default a wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-72 for details.

If this flag is not specified, the operation saves the P-values in the wave `W_LombProb` in the current data folder.

`/DEST=datafolderAndName`

Saves the computed periodogram in a wave specified by `datafolderAndName`. The destination wave will be created or overwritten if it already exists. `datafolderAndName` can include a full or partial path with the wave name `(/DEST=root:bar:destWave)`.

Creates by default a wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-72 for details.

If this wave is not specified the operation saves the resulting periodogram in the wave `W_LombPeriodogram` in the current data folder.
The Lomb-Scargle periodogram is useful in detecting periodicities in data. The main advantage of this approach over Fourier analysis is that the data are not required to be sampled at equal intervals. For an input consisting of N points this benefit comes at a cost of \(O(N^2)\) computations which becomes prohibitive for large data sets. The operation provides the option of computing the periodogram at equally spaced (output) frequencies using \(/FR\) and \(/NF\) or at completely arbitrary set of frequencies specified by \(\text{srcFreqWave}\). It turns out that when you use equally spaced output frequencies the calculation is more efficient because certain parts of the calculation can be factored.

The Lomb periodogram is given by

\[
LP(\omega) = \frac{1}{2\sigma^2} \left\{ \sum_{i=0}^{N-1} (y_i - \bar{y}) \cos[\omega(t_i - \tau)] \right\}^2 + \left\{ \sum_{i=0}^{N-1} (y_i - \bar{y}) \sin[\omega(t_i - \tau)] \right\}^2
\]

Here \(y_i\) is the \(i\)th point in \(\text{srcAmpWave}\), \(t_i\) is the corresponding point in \(\text{srcTimeWave}\),

\[
\bar{y} = \frac{1}{N} \sum_{i=0}^{N-1} y_i,
\]

\[
\tan(2\omega\tau) = \frac{\sum_{i=0}^{N-1} \sin(2\omega t_i)}{\sum_{i=0}^{N-1} \cos(2\omega t_i)}.
\]

and

\[
p = 1 - \left\{ 1 - \exp[LP(w)] \right\}^{N_{\text{ind}}},
\]

In the absence of a Nyquist limit, the number of independent frequencies that you can compute can be estimated using:

\[
N_{\text{ind}} = -6.362 + 1.193N + 0.00098N^2.
\]

This expression was given by Horne and Baliunas derived from least square fitting. \(N_{\text{ind}}\) is used to compute the P-values as:
\[ p = 1 - \left(1 - \exp[L_P(w)]\right)^{N_{ind}}. \]

Note that you can invert the last expression to determine the value of \(L_P(w)\) for any significance level.

**See Also**
The FFT and DSPPeriodogram operations.

**References**

**lorentzianNoise**

\( \text{lorentzianNoise}(a, b) \)

The function returns a pseudo-random value from a Lorentzian distribution

\[ f(x) = \frac{1}{\pi} \frac{(b/2)}{(x-a)^2 + (b/2)^2}. \]

Here \(a\) is the center and \(b\) is the full line width at half maximum (FWHM).

**See Also**
SetRandomSeed, enoise, gnoise.

**Noise Functions** on page III-390.

Chapter III-12, Statistics for a function and operation overview.

**LowerStr**

\( \text{LowerStr}(str) \)

The LowerStr function returns a string expression identical to \(str\) except that all upper-case ASCII characters are converted to lower-case.

**See Also**
The UpperStr function.

**Macro**

\( \text{Macro macroName([parameters]) [:macro type]} \)

The Macro keyword introduces a macro. The macro will appear in the Macros menu unless the procedure file has an explicit Macros menu definition. See Chapter IV-4, Macros and Macro Syntax on page IV-118 for further information.

**MacroInfo**

\( \text{MacroInfo(macroNameStr)} \)

The MacroInfo function returns a keyword-value pair list of information about the macro specified by \(macroNameStr\).

MacroInfo was added in Igor Pro 9.01.

In this section, "macro" includes all types of interpreted procedures, namely procedures introduced by the Macro, Proc and Window keywords.

**Parameters**

\(macroNameStr\) is a string expression containing the name of a macro.

If \(macroNameStr\) is "", MacroInfo returns information about the currently executing macro or "" if no macro is executing.
Details
Because macros exist only in the ProcGlobal context, macroNameStr must contain a simple name, not be a
double name in <module>#$<name> format.
The returned string contains several groups of information. Each group is prefaced by a keyword and colon,
and terminated with the semicolon. The keywords are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>The name of the macro. Same as contents of macroNameStr in most cases.</td>
</tr>
<tr>
<td>PROCWIN</td>
<td>Title of procedure window containing the macro definition.</td>
</tr>
<tr>
<td>PROCLINE</td>
<td>Line number within the procedure window of the macro definition.</td>
</tr>
<tr>
<td>MODULE</td>
<td>Module containing macro definition (see Regular Modules on page IV-236). Blank if the procedure window lacks a #pragma moduleName definition.</td>
</tr>
<tr>
<td>KIND</td>
<td>Macro, Proc or Window.</td>
</tr>
<tr>
<td>N_PARAMS</td>
<td>Number of parameters for this macro.</td>
</tr>
<tr>
<td>SUBTYPE</td>
<td>The macro subtype.</td>
</tr>
</tbody>
</table>

See Also
Macro, Proc, Window, MacroList, MacroPath, FunctionInfo, StringByKey, NumberByKey

MacroList

MacroList(matchStr, separatorStr, optionsStr)
The MacroList function returns a string containing a list of the names of user-defined procedures that start
with the Proc, Macro, or Window keywords that also satisfy certain criteria. Note that if the procedures
need to be compiled, then MacroList may not list all of the procedures.

Parameters
Only macros having names that match matchStr string are listed. See WaveList for examples.
separatorStr is appended to each macro name as the output string is generated. separatorStr is usually “;” for list
processing (See Processing Lists of Waves on page IV-198 for details on list processing).

optionsStr is used to further qualify the macros. It is a string containing keyword-value pairs separated by
commas. Available options are:

KIND: nk Determines the kind of procedure returned.
- nk=1: List Proc procedures.
- nk=2: List Macro procedures.
- nk=4: List Window procedures.

nk can be the sum of these values to match multiple procedure kinds. For example,
use 3 to list both Proc and Macro procedures.

NPARAMS: np Restricts the list to macros having exactly np parameters. Omitting this option lists
macros having any number of parameters.

SUBTYPE: typeStr Lists macros that have the type typeStr. That is, you could use ButtonControl as typeStr
to list only macros that are action procedures for buttons.

WIN: windowNameStr
Lists macros that are defined in the named procedure window. “Procedure” is the
name of the built-in procedure window.

Note: Because optionsStr keyword-value pairs are comma separated and procedure
window names can have commas in them, the WIN: keyword must be the last one
specified.
Examples
To list all Macros with three parameters:
Print MacroList("*",",""KIND:2,NPARAMS:3")
To list all Macro, Proc, and Window procedures in the main procedure window whose names start with b:
Print MacroList("b*",",""WIN:Procedure")

See Also
The DisplayProcedure operation and the FunctionList, OperationList, StringFromList, and WinList functions.
For details on procedure subtypes, see Procedure Subtypes on page IV-204, as well as Button, CheckBox, SetVariable, and PopupMenu.

MacroPath

MacroPath(macroNameStr)
The MacroPath function returns a path to the file containing the named macro.
MacroPath was added in Igor Pro 9.01.
In this section, "macro" includes all types of interpreted procedures, namely procedures introduced by the Macro, Proc and Window keywords.

Parameters
If macroNameStr is "", MacroPath returns the path to the currently executing macro or "" if no macro is executing.
Otherwise MacroPath returns the path to the named macro or "" if no macro by that name exists.

Details
MacroPath is useful in certain specialized cases, such as if a macro needs access to a lookup table of a large number of values.
The most likely use for this is to find the path to the file containing the currently running macro. This is done by passing "" for macroNameStr.
The returned path uses Macintosh syntax regardless of the current platform. See Path Separators on page III-451 for details.
If the procedure file is a normal standalone procedure file, the returned path will be a full path to the file.
If the macro resides in the built-in procedure window the returned path will be ":Procedure". If the macro resides in a packed procedure file, the returned path will be ":<packed procedure window title>".
If MacroPath is called when procedures are in an uncompiled state, it returns ":".

See Also
Macro, Proc, Window, MacroInfo, MacroList, FunctionPath

magsqr

magsqr(z)
The magsqr function returns the sum of the squares of the real and imaginary parts of the complex number z, that is, the magnitude squared.

Examples
Assume waveCmplx is complex and waveReal is real.
waveReal = sqrt(magsqr(waveCmplx))
sets each point of waveReal to the magnitude of the complex points in waveCmplx.
You may get unexpected results if the number of points in waveCmplx differs from the number of points in waveReal because of interpolation. See Mismatched Waves on page II-83 for details.

See Also
The cabs function.
WaveMetrics provides Igor Technical Note 006, "DSP Support Macros" which uses the magsqr function to compute the magnitude of FFT data, and Power Spectral Density with options such as windowing and segmenting. See the Technical Notes folder. Some of the techniques discussed there are available as Igor procedure files in the "WaveMetrics Procedures:Analysis:" folder.

Make

Make [flags] waveName [, waveName]...
Make [flags] waveName = {n0, n1, ...}]
Make [flags] waveName = {{n0, n1, ...}, {n0, n1, ...}, ...}...

The Make operation creates the named waves. Use braces to assign data values when creating the wave.

Flags

/B Makes 8-bit signed integer waves or unsigned waves if /U is present.
/C Makes complex waves.
/D Makes double precision waves.
/DF Wave holds data folder references.
See Data Folder References on page IV-78 for more discussion.
/FREE[=nm] Creates a free wave. Allowed only in functions and only if a simple name or wave reference structure field is specified.
See Free Waves on page IV-91 for further discussion. If nm is present and non-zero, then waveName is used as the name for the free wave, overriding the default name '_free_'. The ability to specify the name of a free wave was added in Igor Pro 9.00 as a debugging aid - see Free Wave Names on page IV-95 and Wave Tracking on page IV-207 for details.
/I Makes 32-bit signed integer waves or unsigned waves if /U is present.
/L Makes 64-bit signed integer waves or unsigned waves if /U is present. Requires Igor Pro 7.00 or later.
/N=n n is the number of points each wave will have. If n is an expression, it must be enclosed in parentheses: Make/N=(myVar+1) aNewWave
/N=(n1, n2, n3, n4)
n1, n2, n3, n4 specify the number of rows, columns, layers and chunks each wave will have. Trailing zeros can be omitted (e.g., /N=(n1, n2, 0, 0) can be abbreviated as /N=(n1, n2)).
/O Overwrites existing waves in case of a name conflict. After an overwrite, you cannot rely on the contents of the waves and you will need to reinitialize them or to assign appropriate values.
/R Makes real value waves (default).
/T Makes text waves.
/T=size Makes text waves with pre-allocated storage.
size is the number of bytes preallocated by Igor for each element in each text wave. The waves are not initialized - it is up to you to initialize them. Preallocation can dramatically speed up text wave assignment when the wave has a very large number of points but only when all strings assigned to the wave are exactly the same size as the preallocation size.
/U Makes unsigned Integer waves.
/W Makes 16-bit signed integer waves or unsigned waves if /U is present.
Wave Data Types
You can use /Y=(numType) to set the data type instead of the /B, /C, /D, /I, /L, /R, /T, /U, and /W data type flags. See WaveType function for numType values. The /Y flag overrides other type flags. You still need to use the explicit data type flags to control the automatic wave reference created by the compiler if you use the wave in an assignment statement in the same function; see WAVE Reference Types on page IV-73 for details.

Details
The maximum allowed number of elements (rows*columns*layers*chunks) in a wave depends on whether you are using the 64-bit version of Igor (max is 2,147,000,000) or the 32-bit version (max is 2,147,000,000).

Unless overridden by the flags, the created waves have the default length, type, precision, units and scaling. The factory defaults are:

**Note:** The preferred precision set by the Miscellaneous Settings dialog only presets the Make Waves dialog checkbox and determines the precision of imported waves. It does not affect the Make operation.

<table>
<thead>
<tr>
<th>Property</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of points</td>
<td>128</td>
</tr>
<tr>
<td>Precision</td>
<td>Single precision floating point</td>

</tr>
<tr>
<td>Data units</td>
<td>&quot; &quot; (blank)</td>
</tr>
</tbody>
</table>

The maximum allowed number of elements (rows*columns*layers*chunks) in a wave is 214,700,000,000.

See Also
The SetScale, Duplicate, and Redimension operations.

MakeIndex

**MakeIndex [/A/C/R] sortKeyWaves, indexWave**

The MakeIndex operation sets the data values of indexWave such that they give the ordering of sortKeyWaves.

For simple sorting problems, MakeIndex is not needed. Just use the Sort operation.

Parameters
sortKeyWaves is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.

indexWave must specify an existing numeric wave.

All waves must be of the same length and must not be complex.
MandelbrotPoint

Flags

/A Alphanumeric. When sortKeyWaves includes text waves, the normal sorting places “wave1” and “wave10” before “wave9”. Use /A to sort the number portion numerically, so that “wave9” is sorted before “wave10”.

/C Case-sensitive. When sortKeyWaves includes text waves, the ordering is case-insensitive unless you use the /C flag which makes it case-sensitive.

/LOC Performs a locale-aware sort.

When sortKeyWaves includes text waves, the text encoding of the text waves’ data is taken into account and sorting is done according to the sorting conventions of the current system locale. This flag is ignored if the text waves’ data encoding is unknown, binary, Symbol, or Dingbats. This flag cannot be used with the /A flag. See Details for more information.

The /LOC flag was added in Igor Pro 7.00.

/R Reverse the index so that ordering is from largest to smallest.

Details

MakIndex is used in preparation for a subsequent IndexSort operation. If /R is used the ordering is from largest to smallest. Otherwise it is from smallest to largest.

When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS specific text comparison routines based on the locale set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

When /LOC is omitted the sort is done on the raw text without regard to the waves’ text encoding.

See Also

Sorting on page III-132, MakeIndex and IndexSort on page III-134, Sort, IndexSort

MandelbrotPoint

MandelbrotPoint(x, y, maxIterations, algorithm)

The MandelbrotPoint function returns a value between 0 and maxIterations based on the Mandelbrot set complex quadratic recurrence relation z[n] = z[n-1]^2 + c where x is the real component of c, y is the imaginary component of c and z[0] = 0.

The returned value is the number of iterations the equation was evaluated before |z[n]| > 2 (the escape radius of the Mandelbrot set), or maxIterations, whichever is less.

Parameters

algorithm=0 The "Escape Time" algorithm returns the integer n which is the number of iterations until |z[n]| > 2.

algorithm=1 The "Renormalized Iteration Count Algorithm" algorithm returns a floating point value which is a refinement of the number of iterations n by adding the quantity:

5 - ln( ln( |z[n+4]| ) ) / ln(2)

(which requires four more iterations of the recurrence relation). The returned value is clipped to maxIterations.

The “MultiThread Mandelbrot Demo” experiment.

References

http://en.wikipedia.org/wiki/Mandelbrot_set
http://linas.org/art-gallery/escape/escape.html
The MarcumQ function returns the generalized Q-function defined by the integral

\[ Q_m(a,b) = \int_b^\infty \left( \frac{u^m}{2^m} \right) \exp \left( -\frac{(a^2 + u^2)}{2} \right) I_{m-1}(au) du \]

where \( I_k \) is the modified Bessel function of the first kind and order \( k \).

Its applications have been primarily in the fields of communication and detection theory. However, an interesting interpretation of its result with \( m=1 \) and appropriate parameter scaling is the fractional power of a two-dimensional circular Gaussian function within a displaced circular aperture.

Depending on the input arguments, the MarcumQ function may be computationally intensive but you can abort the calculation at any time.

References

**MarkPerfTestTime**

MarkPerfTestTime idval

Use the MarkPerfTestTime operation for performance testing of user-defined functions in conjunction with SetIgorOption DebugTimer. When used between SetIgorOption DebugTimer, Start and SetIgorOption DebugTimer, Stop, MarkPerfTestTime stores the ID value and the time of the call in a buffer. When SetIgorOption DebugTimer, Stop is called the contents of the buffer are dumped to a pair of waves: W_DebugTimerIDs will contain the ID values and W_DebugTimerVals will contain the corresponding times of the calls relative to the very first call. The timings use the same high precision mechanism as the StartMSTimer and StopMSTimer calls.

By default, SetIgorOption DebugTimer, Start allocates a buffer for up to 10000 entries. You can allocate a different sized buffer using SetIgorOption DebugTimer, Start=bufsize.

See Also
SetIgorOption, StartMSTimer, and StopMSTimer.

Additional documentation can be found in an example experiment, PerformanceTesting.pxp, and a WaveMetrics procedure file, PerformanceTestReport.ipf.

**MatrixBalance**

MatrixBalance [flags] srcWave

The MatrixBalance operation permutes and/or scales an NxN real or complex matrix to obtain a similar matrix that is more stable for subsequent calculations such as eigenvalues and eigenvectors. Balancing a matrix is useful when some matrix elements are much smaller than others.

MatrixBalance saves the resulting matrix in the wave specified by the /DSTM flag. It creates a secondary output wave specified by the /DSTS flag containing permutation and scaling information.

MatrixBalance was added in Igor Pro 9.00.

Parameters
srcWave must be single-precision or double-precision floating point, real or complex, and must contain no NaNs. MatrixBalance returns an error if these conditions are not met.

Flags
/DSTM=dest Specifies the destination wave for the balanced output matrix. If you omit /DSTM, the output is saved in M_Balanced in the current data folder.
MatrixBalance

/DEST=dest Specifies the destination wave for the scaling array. If you omit /DSTS, the scaling wave is saved as W_Scale in the current data folder.

/FREE Creates free destination waves when they are are specified via /DSTM or /DSTS.

/J=job job is one of the following letters:

N srcWave is not permuted or scaled.

P srcWave is permuted but not scaled.

S srcWave is scaled but not permuted. The scaling applies a diagonal similarity transformation to make the norms of the various columns close to each other.

B srcWave is both scaled and permuted (default).

/Z Do not report any errors. V_flag will be set to 0 if successful or to an error code. V_min and V_max will be set to NaN in case of an error.

Details

Matrix balancing is usually called internally by LAPACK routines when there is large variation in the magnitude of matrix elements. The /J flag supports the granularity of applying only permutation, only scaling or both.

After balancing there will be a block diagonal form that could typically be handled using Schur decomposition (see MatrixSchur). The rows/columns corresponding to this block diagonal are saved in zero based V_min and V_max. The scaling wave W_scale[i] (for i<V_min) contains the index of the row/column that was interchanged with row/col i. For i>=V_min the scaling wave contains the scaling factor use to balance row and column i.

When you balance srcWave using this operation the resulting eigenvectors belong to the balanced matrix. Use MatrixReverseBalance to obtain the eigenvectors of srcWave.

When solving for the Schur vectors of srcWave after using /J=P for permuting only, use MatrixReverseBalance to transform the vectors. If you are solving for the Schur vectors do not use either /J=S or /J=B because that balancing transformation is not orthogonal.

Output Variables

V_Flag Set to zero when the operation succeeds. Otherwise, when V_flag is positive the value is a standard error code. When V_flag is negative it is an indication of a wrong input parameter.

V_min Set to zero if /J=N or /J=S.

V_max Set to N-1 (where N is the number of rows or columns) if /J=N or /J=S.

// Check that W_Scale produces the correct balanced matrix
MatrixOP/O/FREE matProd=matDInv x srcWave x matD

// Compare with M_Balanced
MatrixOP/O/FREE/P=1 aa=sum(abs(M_Balanced-matProd))
End

Function DemoMatrixBalance2()
Make/O/N=(3,3) mat...
\[
\text{MatrixCondition}(\text{wave2D}, \text{mode})
\]

MatrixCondition returns the estimated reciprocal of the condition number of a 2D square matrix wave2D. The condition number is the product of the norm of the matrix with the norm of the inverse of the matrix (see details below). The type of norm is determined by the value of the mode parameter. 1-norm is used if mode is 1 and infinity-norm is used otherwise.

The MatrixCondition function was added in Igor Pro 7.00.

Details
The function uses LAPACK routines to estimate the reciprocal condition number by first obtaining the norm of the input matrix and then using LU decomposition to obtain the norm of the inverse of the matrix. The estimate returned is

\[
\text{reciprocalCon} = \frac{1}{\|\text{wave2D}\|_* \|\text{wave2D}^{-1}\|},
\]

where the norms are selected by the choice of the mode parameter. The 1-norm of matrix A with elements \(a_{ij}\) is defined as

\[
\|A\|_1 = \max_{1 \leq j \leq n} \sum_{i=1}^{n} |a_{ij}|,
\]
and the infinity-norm is defined by

\[ \|A\|_\infty = \max_{1 \leq i \leq m} \sum_{j=1}^{n} |a_{ij}|. \]

The function returns a NaN if there is any error in the input parameters.

References
http://en.wikipedia.org/wiki/Matrix_norm

See Also
MatrixSVD provides a condition number for L2 norm using the ratio of singular values.
The MatrixOp operation for more efficient matrix operations.
Matrix Math Operations on page III-138 for more about Igor’s matrix routines.

MatrixConvolve
MatrixConvolve [/R=roiWave] coefMatrix, dataMatrix
The MatrixConvolve operation convolves a small coefficient matrix coefMatrix into the destination dataMatrix.

Flags
/R=roiWave Modifies only data contained inside the region of interest. The ROI wave should be 8-bit unsigned with the same dimensions as dataMatrix. The interior of the ROI is defined by zeros and the exterior is any nonzero value.

Details
On input coefMatrix contains an NxM matrix of coefficients where N and M should be odd. Generally N and M will be equal. If N and M are greater than 13, it is more efficient to perform the convolution using the Fourier transform (see FFT).
The convolution is performed in place on the data matrix and is acausal, i.e., the output data is not shifted.
Edges are handled by replication of edge data.
When dataMatrix is an integer type, the results are clipped to limits of the given number type. For example, unsigned byte is clipped to 0 to 255.
MatrixConvolve works also when both coefMatrix and dataMatrix are 3D waves. In this case the convolution result is placed in the wave M_Convolution in the current data folder, and the optional /R=roiWave is required to be an unsigned byte wave that has the same dimensions as dataMatrix.
This operation does not support complex waves.

See Also
MatrixFilter and ImageFilter for filter convolutions.
Matrix Math Operations on page III-138 for more about Igor’s matrix routines.
The Loess operation.

MatrixCorr
MatrixCorr [/COV] [/DEGC] waveA [, waveB]
The MatrixCorr operation computes the correlation or covariance or degree of correlation matrix for the input 1D wave(s).
If we denote elements of waveA by \{x_i\} and elements of waveB by \{y_i\} then the correlation matrix for these waves is the vector product of the form:

\[ \begin{bmatrix} 1 & \rho_{xy} & \rho_{xz} \\ \rho_{xy} & 1 & \rho_{yz} \\ \rho_{xz} & \rho_{yz} & 1 \end{bmatrix} \]

where \( \rho_{xy} \) is the correlation coefficient between \( x \) and \( y \), and so on.
where * denotes complex conjugation. If you use the optional waveB then the matrix is the cross correlation matrix. waveB must have the same length of waveA but it does not have to be the same number type.

Flags
The flags are mutually exclusive; only one matrix can be generated at a time.

/COV Calculates the covariance matrix.

The covariance matrix for the same input is formed in a similar way after subtracting from each vector its mean value and then dividing the resulting matrix elements by (n-1) where n is the number of elements of waveA.

Results are stored in the M_Corr or M_Covar waves in the current data folder.

/DEGC Calculates the complex degree of correlation. The degree of correlation is defined by:

\[
\text{deg} C = \frac{\text{M\_Covar}}{\sqrt{\text{Var}(\text{waveA}) \cdot \text{Var}(\text{waveB})}},
\]

where M_Covar is the covariance matrix and Var(wave) is the variance of the wave.

The complex degree of correlation should satisfy: \(0 \leq \text{deg} C \leq 1\).

Examples
The covariance matrix calculation is equivalent to:

Variable N=1/(DimSize(waveA,0)-1)
Variable ma=mean(waveA,-inf,inf)
Variable mb=mean(waveB,-inf,inf)
waveA-=ma
waveB-=mb
MatrixTranspose/H waveB
MatrixMultiply waveA,waveB
M_product*=N

See Also
Matrix Math Operations on page III-138 for more about Igor’s matrix routines.

References

MatrixDet

\text{matrixDet(dataMatrix)}

The MatrixDet function returns the determinant of dataMatrix. The matrix wave must be a real, square matrix or else the returned value will be NaN.

Details
The function calculates the determinant using LU decomposition. If, following the decomposition, any one of the diagonal elements is either identically zero or equal to \(10^{-100}\), the return value of the function will be zero.
### MatrixDot

**MatrixDot**

**MatrixDot(waveA, waveB)**

The `MatrixDot` function calculates the inner (scalar) product for two 1D waves. A 1D wave `A` represents a vector in the sense:

\[ A = \sum \alpha_i \hat{e}_i, \quad \hat{e}_i \text{ is a unit vector.} \]

Given two such waves `A` and `B`, the inner product is defined as

\[ ip = \sum \alpha_i \beta_i. \]

When both `waveA` and `waveB` are complex and the result is assigned to a complex-valued number `MatrixDot` returns:

\[ ipc = \sum \alpha_i^* \beta_i. \]

If you prefer the definition where the second factor is the one that is conjugated, you can simply reverse the order of `waveA` and `waveB` in the function call.

If the result is assigned to a real number, `MatrixDot` returns:

\[ ip = \left| \sum \alpha_i \beta_i \right|. \]

If either `waveA` or `waveB` is complex and the result is assigned to a real-valued number, `MatrixDot` returns:

\[ ip = \left| \sum \alpha_i^* \beta_i \right|. \]

When the result is assigned to a complex-valued number `MatrixDot` returns:

\[ ipc = \sum \alpha_i \beta_i. \]

**See Also**

The `MatrixOp` operation for more efficient matrix operations.

**Matrix Math Operations** on page III-138 for more about Igor’s matrix routines.

### MatrixEigenV

**MatrixEigenV [flags] matrixA [, matrixB]**

`MatrixEigenV` computes the eigenvalues and eigenvectors of a square matrix using LAPACK routines.

**Flags for General Matrices**

`/C` Creates complex valued output for real valued input waves. This is equivalent to converting the input to complex, with zero imaginary component, prior to computing the eigenvalues and eigenvectors. The main benefit of this format is that the output has simple packing of eigenvalues and eigenvectors. See the example in the Details for General Matrices section below.

The `/C` flag was added in Igor Pro 7.00.
MatrixEigenV

/B=balance
Determines how the input matrix should be scaled and or permuted to improve the conditioning of the eigenvalues.

balance=0 (default), 1, 2, or 3, corresponding respectively to N, P, S, or B in the LAPACK routines. Applicable only with the /X flag.

0: Do not scale or permute.
1: Permute.
2: Do diagonal scaling.
3: Scale and permute.

/L
Calculates for left eigenvectors.

/O
Overwrites matrixWave, requiring less memory.

/R
Calculates for right eigenvectors.

/S=sense
Determines which reciprocal condition numbers are calculated.

sense=0 (default), 1, 2, or 3, corresponding respectively to N, E, V, or B in the LAPACK routines. Applicable only with the /X flag.

0: None.
1: Eigenvalues only.
2: Right eigenvectors.
3: Eigenvalues and right eigenvectors.

If sense is 1 or 3 you must compute both left and right eigenvectors.
NOTE: /S is applicable only with the /X flag or for the generalized eigenvalue problem.

/X
Uses LAPACK expert routines, which require additional parameters (see /B and /S flags). The operation creates additional waves:

The W_MatrixOpInfo wave contains in element 0 the ILO, in element 1 the IHI, and in element 2 the ABNRM from the LAPACK routines.

The wave W_MatrixRCONDE contains the reciprocal condition numbers for the eigenvalues.

The wave W_MatrixRCONDV contains the reciprocal condition number for the eigenvectors.

Flags for Symmetric Matrices

/SYM
Computes the eigenvalues of an NxN symmetric matrix and stores them in the wave W_eigenValues. You must specify this flag if you want to use the special routines for symmetric matrices. The number of eigenvalues is stored in the variable V_npnts. Because W_eigenValues has N points, only the first V_npnts will contain relevant eigenvalues.

When using this flag with complex input the matrix is assumed to be Hermitian.

/EVEC
Computes eigenvectors in addition to eigenvalues. Eigenvectors will be stored in the wave M_eigenVectors, which is of dimension NxN. The first V_npnts columns of the wave will contain the V_npnts eigenvectors corresponding to the eigenvalues in W_eigenValues. /EVEC must be preceded by /SYM.

/RNG=[method,low,high]
Flags for Generalized Eigenvalue Problem

These are the same flags as for general (non-symmetric) matrices above except for /O and /X which are not supported for the generalized eigenvalue solution.

Common Flags

/Z No error reporting (except for setting V_flag).

Details

There are three mutually exclusive branches for the operation. The first is designed for a square matrix input matrixA. The operation computes the solution to the problem

\[ Ax = \lambda x, \]

where \( A \) is the input matrix, \( x \) is an eigenvector and \( \lambda \) is an eigenvalue.

The second branch is designed for symmetric matrices \( A \), i.e., when

\( A = A^T, \)

where the superscript \( T \) denotes a transpose.

The third branch of the operation is designed to solve the generalized eigenvalue problem,

\[ Ax = \lambda Bx, \]

where \( A \) and \( B \) are square matrices, \( x \) is an eigenvector and \( \lambda \) is an eigenvalue.

Each branch of the operation supports its own set of flags as shown above. All branches support input of single and double precision in real or complex waves. If you specify both matrixA and matrixB then they must have the same number type.

Details for General Matrices

The eigenvalues are returned in the 1D complex wave W_eigenValues. The eigenvectors are returned in the 2D wave M_R_eigenVectors or M_L_eigenVectors.

The calculated eigenvectors are normalized to unit length.

Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

If the \( jth \) eigenvalue is real, then the corresponding eigenvector \( u(j)=M[[j]] \) is the \( jth \) column of M_L_eigenVectors or M_R_eigenVectors. If the \( jth \) and \((j+1)th\) eigenvalues form a complex conjugate pair, then \( u(j) = M[[j]] + i*M[[j+1]] \) and \( u(j+1) = M[[j]] - i*M[[j+1]] \).

Example

Function TestMatrixEigenVReal()
  Make/D/N=(2,2)/O eee={{0,1},{-1,0}}
  MatrixEigenV/R eee
  Wave W_eigenvalues, M_R_eigenVectors
  MatrixOP/O firstEV=cmplx(col(M_R_eigenVectors,0),col(M_R_eigenVectors,1))
  MatrixOP/O aa=eee x firstEV - W_eigenvalues[0]*firstEV
  Print aa
End

Function TestMatrixEigenVComplex()
  Make/D/N=(2,2)/O eee={{0,1},{-1,0}}
  MatrixEigenV/R/C eee
MatrixEigenV

Wave $W_{\text{eigenvalues}}$, $M_{\text{R eigenVectors}}$
MatrixOP/O $aa = eeee \times \text{col}(M_{\text{R eigenVectors}}, 0) - W_{\text{eigenValues}[0]} \times \text{col}(M_{\text{R eigenVectors}}, 0)$
Print $aa$
End

Details for Symmetric Matrices
The LAPACK routines that compute the eigenvalues and eigenvectors of symmetric matrices claim to use the Relatively Robust Representation whenever possible. If your matrix is symmetric you should use this branch of the operation (/SYM) for improved accuracy.

Details for Generalized Eigenvalue Problem
Here the right eigenvectors (/R) are solutions to the equation

$$Ax = \lambda Bx,$$

and the left eigenvectors (/L) are solutions to

$$x^H A = \lambda x^H B,$$

where the superscript $H$ denotes the conjugate transpose.

When both $matrixA$ and $matrixB$ are real valued, the operation creates the following waves in the current data folder:

- $W_{\text{alphaValues}}$ Contains the complex alpha values.
- $W_{\text{betaValues}}$ Contains the real-valued denominator such that the eigenvalues are given by $\lambda_j = \frac{\alpha_j}{\beta_j}$.
- $M_{\text{leftEigenVectors}}$ and $M_{\text{rightEigenVectors}}$ Real valued waves where columns correspond to eigenvectors of the equation.

Every point in the wave $W_{\text{alphaValues}}$ corresponds to an eigenvalue. When the imaginary part of $W_{\text{alphaValues}}[j]$ is zero, the eigenvalue is real and the corresponding eigenvector is also real e.g., $M_{\text{rightEigenVectors}}[[j]]$. When the imaginary part is positive then there are two eigenvalues that are complex-conjugates of each other with corresponding complex eigenvectors given by

$$\text{cmplx}(M_{\text{rightEigenVectors}}[[j]], M_{\text{rightEigenVectors}}[[j+1]])$$

and

$$\text{cmplx}(M_{\text{rightEigenVectors}}[[j]], -M_{\text{rightEigenVectors}}[[j+1]])$$

When both $matrixA$ and $matrixB$ are complex the operation creates the complex waves:

- $W_{\text{alphaValues}}$, $W_{\text{betaValues}}$, $M_{\text{leftEigenVectors}}$, $M_{\text{rightEigenVectors}}$

with the ratio $W_{\text{alphaValues}}[j]/W_{\text{betaValues}}[j]$ expressing the generalized eigenvalue. The corresponding $M_{\text{leftEigenVectors}}[[j]]$ and $M_{\text{rightEigenVectors}}[[j]]$ are the respective left and right eigenvectors. The simplicity of the complex case suggests that when $matrixA$ and $matrixB$ are real it is best to convert them to complex waves prior to executing matrixEigenV.

Depending on the choice of /S the operation also calculates the reciprocal condition number for the eigenvalues (stored in $W_{\text{reciprocalConditionE}}$) and the reciprocal condition number of the eigenvectors (stored in $W_{\text{reciprocalConditionV}}$). Note that a zero entry in $W_{\text{reciprocalConditionV}}$ implies that the eigenvalues could not be ordered.

See Also
Matrix Math Operations on page III-138 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.

Symmetric matrices can also be decomposed using the MatrixSchur operation and using MatrixOp chol.
MatrixFactor

MatrixFactor [ flags ] srcWave

The MatrixFactor operation computes two real-valued output matrices, conceptually called matA and matB, whose matrix product minimizes the Frobenius norm of:

\[ | srcWave - (matA \times matB) | \]

The MatrixFactor operation was added in Igor Pro 9.00.

Flags

/COMC=cCols
Sets the common dimension in the factorization so that, for srcWave with m rows and n columns, the factorization will be (m x cCols) matA and (cCols x n) matB. If you omit /COMC, cCols defaults to m/2.

/CORR=cRate
Sets the correction factor for the learning rate. The default value is 0.9.

/DSTA=wA
Specifies the output wave representing matA.

/DSTB=wB
Specifies the output wave representing matB.

/FREE
Creates output waves as free waves.

/INIA=iwA
Specifies an initial solution matrix for matA. The wave must have the same dimensions as matA and the same numeric type as srcWave.

/INIB=iwB
Specifies an initial solution matrix for matB. The wave must have the same dimensions as matB and the same numeric type as srcWave.

/ITER=nIters
Sets the maximum number of iterations. By default nIters is 1E7.

/LRNR=lRate
Sets the initial learning rate of the algorithm. The default value of lRate is 0.01.

/OUT=type
Sets restrictions on the output. The default value for type is 0 and there are no restrictions on the elements of the output. Set type=1 for non-negative output elements or type=2 for positive output elements.

/TOL=tolerance
Use /TOL to terminate iterations when the average Frobenius norm per input point falls below the tolerance value. By default tolerance is 1E-9 for single precision floating point input wave and 1E-15 for double precision input.

/Q
Quiet - do not print diagnostic information to the history area and do not display progress bar.

/Z
Errors are not fatal and do not abort procedure execution. Your procedure can inspect the V_flag variable to see if the operation succeeded. V_flag will be zero if it succeeded or nonzero if it failed.

Details

srcWave must be a single or double precision real wave.

If you specify the factorization output waves using /DSTA and /DSTB, they must have the same numeric type.

If you omit /DSTA or /DSTB, MatrixFactor produces output waves named factorAMat and factorBMat with the same numeric type as srcWave.

The algorithm produces a non-unique solution that may depend on the initialization of the two factors. The default initialization, used if you omit /INIA and /INIB, uses Igor's random number generator. If you want to investigate convergence you can generate your own initial values and specify them using the /INIA and /INIB flags. If you want to provide your own initial values you must provide them for both matA and matB via both /INIA and /INIB. You can run MatrixFactor once and use the outputs as initial values for a second run.

We recommend using double precision waves because the algorithm involves iterations where the Frobenius norm is computed. For large matrices or for a large number of iterations the calculation is strongly susceptible to roundoff errors which may cause it to fail to converge.
The algorithm iterates until either the tolerance is met or the number of iterations, specified by /ITER or the default value of 1E7, is exceeded. The algorithm also terminates if the the computed norm remains relatively constant:

\[(\text{prevIterationNorm} - \text{curIterationNorm}) / \text{prevIterationNorm} < 1e-16.\]

**Output Variables**
MatrixFactor sets these automatically created variables:

- **V_flag** Set to 0 if the operation succeeded or to a non-zero error code.
- **V_avg** The last average Frobenius norm (Frobenius sum divided by the number of points in srcWave).
- **V_iterations** The number of iterations executed before the algorithm terminated.

**Example**
Example

```plaintext
Function DemoMatrixFactor()
    Make/O/N=(10,8)/D matA0 = 1+abs(enoise(3))
    Make/O/N=(8,12)/D matB0 = 1+abs(enoise(3))
    MatrixOP/O matX0=matA0 x matB0
    MatrixFactor/COMC=8/DSTA = biMatA/DSTB=biMatB matX0
    MatrixOP/O/P=1 aa = sum(sq(matX0- biMatA x biMatB))/120 // Check norm
End
```

**References**

---

**MatrixFilter**

**MatrixFilter [flags] Method dataMatrix**

The MatrixFilter operation performs one of several standard image filter type operations on the destination dataMatrix.

**Note:** The parameters below are also available in ImageFilter. See ImageFilter for additional parameters.

**Parameters**

*Method* selects the filter type. *Method* is one of the following names:

- **avg** \(n \times n\) average filter.
- **FindEdges** 3x3 edge finding filter.
- **gauss** \(n \times n\) gaussian filter.
- **gradN, gradNW, gradW, gradSW, gradS, gradSE, gradE, gradNE** 3x3 North, NorthWest, West, … pointing gradient filter.
- **median** \(n \times n\) median filter. You can assign values other than the median by specifying the desired rank using the /M flag.
- **min** \(n \times n\) minimum rank filter.
- **max** \(n \times n\) maximum rank filter.
- **NanZapMedian** \(n \times n\) filter that only affects data points that are NaN. Replaces them with the median of the \(n \times n\) surrounding points. Unless /P is used, automatically cycles through matrix until all NaNs are gone or until cols*rows iterations.
- **point** 3x3 point finding filter 8*center-outer.
- **sharpen** 3x3 sharpening filter = (12*center-outer) / 4.
The MatrixGaussJ operation solves matrix expression $A \times x = b$ for column vector $x$ given matrix $A$ and column vector $b$. The operation can also be used to calculate the inverse of a matrix.

**Parameters**

- $matrixA$ is a $N \times N$ matrix of coefficients and $vectorsB$ is a $N \times M$ set of right-hand side vectors.

**Details**

On output, the array of solution vectors $x$ is placed in $M_x$ and the inverse of $A$ is placed in $M_{Inverse}$.

If the result is a singular matrix, $V_{flag}$ is set to 1 to indicate the error. All other errors result in an alert, and abort any calling procedure.

All output objects are created in the current data folder.

An error is generated if the dimensioning of the input arrays is invalid.

**See Also**

**References**

MatrixGLM

MatrixGLM [/Z] matrixA, matrixB, waveD
The MatrixGLM operation solves the general Gauss-Markov Linear Model problem (GLM) which minimizes the 2-norm of a vector y

\[ \min \|y\|_2 \quad subject \ to \quad d = Ax + By. \]

A is matrixA (an NxM wave), B is matrixB (an NxP wave), and d is provided by waveD which is a 1D wave of N rows. The vectors x and y are the results of the calculation; they are stored in output waves Mat_X and Mat_Y in the current data folder.

Flags
/Z In the event of an error, MatrixGLM will not return the error to Igor, which would cause procedure execute to abort. Your code should use the V_flag output variable to detect and handle errors.

Details
All input waves must have the same numeric type. Supported types are single-precision and double-precision floating point, both real and complex. The output waves Mat_X and Mat_Y have the same numeric type as the input.

The LAPACK algorithm assumes that M <= N <= M+P and

\[ \text{rank}(A) = M, \]
\[ \text{rank}(AB) = N. \]

Under these assumptions there is a unique solution x and a minimal 2-norm solution y, which are obtained using a generalized QR factorization of A and B. If the operation completes successfully the variable V_Flag is set to zero. Otherwise it contains a LAPACK error code.

Output Variables
V_flag Set to 0 if MatrixGLM succeeds or to a LAPACK error code.

See Also
Matrix Math Operations on page III-138 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.

MatrixInverse

MatrixInverse [flags] srcWave
The MatrixInverse operation calculates the inverse or the pseudo-inverse of a matrix. srcWave may be real or complex.

MatrixInverse saves the result in the wave M_Inverse in the current data folder.

This routine is provided for completeness only and is not recommended for general work (use LU decomposition — see MatrixLUD). MatrixGaussJ does calculate the inverse matrix but that is not generally needed either.
### MatrixLinearSolve

**Flags**

/D 
Creates the wave W_W that contains eigenvalues of the singular value decomposition (SVD) for the pseudo-inverse calculation. If one or more of the eigenvalues are small, the matrix may be close to singular.

/G 
Calculates only the direct inverse; does not affect calculation of pseudo-inverse. By default, it calculates the inverse of the matrix using LU decomposition. The inverse is calculated using Gauss-Jordan method. The only advantage in using Gauss-Jordan is that it is more likely to flag singular matrices than the LU method.

/O 
Overwrites the source with the result.

/P 
Calculates the pseudo-inverse of a matrix using the SVD algorithm. The calculated pseudo-inverse is a unique minimal solution to the problem:

$$\min_{X \in \mathbb{R}^{nm}} \|AX - I_m\|.$$  

**Examples**

- Make/O/N=(2,2) mat0 = {{2,3},{1,7}}  // Creates wave M_inverse
- MatrixInverse mat0 // Creates wave M_inverse
- MatrixOp/O/T=1 mat1 = M_inverse x mat0  // Check result
- Make/O/D/N=(4,6) mat1 = enoise(4)
- MatrixInverse/P mat1
- MatrixOp/O/T=1 aa = mat1 x M_Inverse
- MatrixOp/O/P=1 avgAbsErr = sum(abs(mat1 x M_Inverse - identity(4)))/12

### MatrixLinearSolve

MatrixLinearSolve [flags] matrixA matrixB

The MatrixLinearSolve operation solves the linear system matrixA *X=matrixB where matrixA is an N-by-N matrix and matrixB is an N-by-NRHS matrix of the same data type.
MatrixLinearSolveTD

Flags

/M=method  Determines the solution method which best suites input matrixA.

    method=1: Uses simple LU decomposition (default). See also LAPACK documentation for SGESV, CGESV, DGESV, and ZGESV.
    Creates the wave W_IPIV that contains the pivot indices that define the permutation matrix P. Row (i) if the matrix was interchanged with row ipiv(i).

    method=2: If matrixA is band diagonal, you also have to specify /D. See also LAPACK documentation for SGBSV, CGBSV, DGBSV, and ZGBSV.
    Creates the wave W_IPIV, which contains the pivot indices that define the permutation matrix P. Row (i) if the matrix was interchanged with row ipiv(i). Also note that if you are using the /O flag, the overwritten waves may have a different dimensions.

    method=4: For tridiagonal matrix; still expecting full matrix in matrixA, but it will ignore the data in the elements outside the 3 diagonals. See also LAPACK documentation for SGTSV, CGTSV, DTGSV, and ZGTSV.

    method=8: Symmetric/hermitian. See also LAPACK documentation for SPOSV, CPOSV, DPOSV, and ZPOSV.

    method=16: Complex symmetric (complex only). See also LAPACK documentation for CSYSV and ZSYSV.

/D={sub,super}  Specifies a band diagonal matrix. The subdiagonal (sub) and superdiagonal (super) size must be positive integers.

/L  Uses the lower triangle of matrixA. /L and /U are mutually exclusive flags.

/U  Uses the upper triangle of matrixA. /U is the default.

/O  Overwrites matrixA and matrixB with the results of the operation. This will save on the amount of memory needed.

/Z  No error reporting.

Details

If /O is not specified, the operation also creates the n-by-n wave M_A and the n-by-nrhs solution wave M_B.

The variable V_flag is created by the operation. If the operation completes successfully, V_flag is set to zero, otherwise it is set to the LAPACK error code.

See Also

Matrix Math Operations on page III-138 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.

MatrixLinearSolveTD

MatrixLinearSolveTD [ /Z ] upperW, mainW, lowerW, matrixB

The MatrixLinearSolveTD operation solves the linear system TDMatrix*X = matrixB. In the matrix product on the left hand side, TDMatrix is a tridiagonal matrix with upper diagonal upperW, main diagonal mainW, and lower diagonal lowerW. It solves for vector(s) X depending on the number of columns (NRHS) in matrixB.
MatrixLLS

Flags

/DSTC=solutionWave

Specifies the output wave when all input waves are complex. If you omit /DSTC then the output wave is M_TDLinearSolution in the current data folder. /DSTC was added in Igor Pro 9.00.

/DSTR=solutionWave

Specifies the output wave when all input waves are real. If you omit /DSTR then the output wave is M_TDLinearSolution in the current data folder. /DSTR was added in Igor Pro 9.00.

/FREE

Creates the solution wave as a free wave. /FREE is allowed only in functions and only if the solution wave, as specified by /DSTC or /DSTR, is a simple name or wave reference structure field. /DSTC was added in Igor Pro 9.00.

/Z

No error reporting.

Details

The input waves can be single or double precision (real or complex). Results are returned in the wave M_TDLinearSolution in the current data folder. The wave mainW determines the size of the main diagonal (N). All other waves must match it in size with upperW and mainW containing one less point and matrixB consisting of N-by-NRHS elements of the same data type.

MatrixLinearSolveTD should be more efficient than MatrixLinearSolve with respect to storage requirements.

MatrixLinearSolveTD creates the variable V_flag, which is zero when it finishes successfully.

See Also

Matrix Math Operations on page III-138; the MatrixLinearSolve and MatrixOp operations.

MatrixLLS

MatrixLLS [/O/Z/M=method] matrixA matrixB

The MatrixLLS operation solves overdetermined or underdetermined linear systems involving MxN matrixA, using either QR/LQ or SV decompositions. Both matrixA and matrixB must have the same number type. Supported types are real or complex single precision and double precision numbers.

Flags

/M=method

Specifies the decomposition method.

/method=0:  Decomposition is to QR or LQ (default). Creates the 2D wave M_A, which contains details of the QR/LQ factorization.

/method=1:  Singular value decomposition. Creates the 2D wave M_A, which contains the right singular vectors stored row-wise in the first min(m, n) rows. Creates the 1D wave M_SV, which contains the singular values of matrixA arranged in decreasing order.

/O

Overwrites matrixA with its decomposition and matrixB with the solution vectors. This requires less memory.

/Z

No error reporting.

Details

When the /O flag is not specified, the solution vectors are stored in the wave M_B, otherwise the solution vectors are stored in matrixB. Let matrixA be m rows by n columns and matrixB be an m by NRHS (if NRHS=1 it can be omitted). If m ≥ n, MatrixLLS solves the least squares solution to an overdetermined system:

\[ \text{Minimize} \| \text{matrixB} - \text{matrixA} \times \text{X} \|. \]
Here the first $n$ rows of $M_B$ contain the least squares solution vectors while the remaining rows can be squared and summed to obtain the residual sum of the squares. If you are not interested in the residual you can resize the wave using, for example:

Redimension/N=(n,NRHS) M_B

If $m < n$, MatrixLLS finds the minimum norm solution of the underdetermined system:

$$matrixA \times X = matrixB.$$ 

In this case, the first $m$ rows of $M_B$ contain the minimum norm solution vectors while the remaining rows can be squared and summed to obtain the residual sum of the squares for the solution. If you are not interested in the residual you can resize the wave using, for example:

Redimension/N=(m,NRHS) M_B

**Note:** Here $matrixB$ consists of one or more column vectors $B$ corresponding to one or more solution vectors $X$ that are computed simultaneously. If $matrixB$ consists of a single column, $M_B$ is a 2D matrix wave that contains a single solution column.

The variable $V\_flag$ is set to 0 when there is no error; otherwise it contains the LAPACK error code.

**Examples**

```c
// Construct matrixA as a 4x4 matrix
Make/O/D/N=(4,4) matrixA
matrixA[0][0] = {-54,-27,-9,-38}  
matrixA[0][1] = {13,60,-42,-26}  
matrixA[0][2] = {-80,17,44,-35}  
matrixA[0][3] = {98,-8,-72,7}  

// Construct matrixB as a single column (1D wave)  
Make/O/D/N=4 matrixB={-20,77,-79,-33}  

// Solve for matrixA x vectorX = matrixB  
MatrixLLS matrixA, matrixB// Output stored in M_B 

// Verify the solution  
MatrixOP/O/P=1 aa=sum(abs(matrixA x col(M_B,0) - matrixB))  
aa={9.947598300641403e-14}  

// Compute multiple solutions at once  
// Construct matrixB as two columns (2D wave)  
Redimension/N=(4,2) matrixB  
matrixB[0][0] = {-20,77,-79,-33}  
matrixB[0][1] = {-94,61,29,68}  

// Perform the calculation  
MatrixLLS matrixA, matrixB  

// Verify the solutions  
MatrixOP/O/P=1 aa=sum(abs(matrixA x col(M_B,0) - col(matrixB,0)))  
aa={9.947598300641403e-14}  
MatrixOP/O/P=1 aa=sum(abs(matrixA x col(M_B,1) - col(matrixB,1)))  
aa={1.989519660128281e-13}  

// See if we have an overdetermined system ...  
Make/O/D/N=(5,4) matrixA  
matrixA[0][0] = {-7,-62,-47,-54,-80}  
matrixA[0][1] = {43,15,-9,-94,57}  
matrixA[0][2] = {22,61,-95,-95,51}  
matrixA[0][3] = {-54,88,81,-51,54}  
Make/O/D/N=(5) matrixB  
matrixB[0] = {-28,-75,-74,35,86}  

// Perform the calculation  
MatrixLLS matrixA, matrixB  

// Remove the extra rows from M_B  
Redimension/N=4 M_B  

// M_B is only the least squares solution so there is no point in attempting  
// to verify the solution as in the example above.
```
MatrixLUBkSub

See Also
Matrix Math Operations on page III-138 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.

MatrixLUBkSub
MatrixLUBkSub matrixL, matrixU, index, vectorB
The MatrixLUBkSub operation provides back substitution for LU decomposition.

Details
This operation is used to solve the matrix equation $Ax=b$ after you have performed LU decomposition (see MatrixLUD). Feed this routine M_Lower, M_Upper and W_LUPermutation from MatrixLUD along with your right-hand-side vector b. The solution vector x is returned as M_x. The array b can be a matrix containing a number of b vectors and the M_x will contain a corresponding set of solution vectors.

Generates an error if the dimensions of the input matrices are not appropriate.

See Also
Matrix Math Operations on page III-138 for more about Igor’s matrix routines.

MatrixLUD
MatrixLUD [flags] matrixA
The MatrixLUD operation computes the LU factorization of a matrix. The general form of the factorization/decomposition is expressed in terms of matrix products:

$M_{Pt} \times srcWave = M_{Lower} \times M_{Upper}$

$M_{Pt}, M_{Lower}$ and $M_{Upper}$ are outputs created by MatrixLUD.

$M_{Pt}$ is the transpose of the permutation matrix, $M_{Lower}$ is a lower triangular matrix with 1’s on the main diagonal and $M_{Upper}$ is an upper triangular (or trapezoidal) matrix.

The MatrixLUD operation was substantially changed in Igor Pro 7.00. See the /B flag for information about backward compatibility.

Flags
/B
This flag is provided for backward compatibility only; it is not compatible with any other flag. /B makes MatrixLUD behave as it did in Igor Pro 6. This flag is deprecated and will be removed in a future version of Igor.

The input is restricted to a 2D real valued, single or double precision square matrix. The outputs (all double precision) are stored in the waves M_Upper, M_Lower and W_LUPermutation in the current data folder.

The $W_{LUPermutation}$ output wave was needed for solving a linear system of equations using the back substitution routine, MatrixLUBkSub. For better computation methods see MatrixLinearSolve, MatrixLinearSolveTD and MatrixLLS.

/CMF
Uses Combined Matrix Format where the upper and lower matrix factors are combined into a single matrix saved in the wave $M_{LUFactors}$ in the current data folder. The upper matrix factor is constructed from the main and from the upper diagonals of $M_{LUFactors}$. The lower matrix factor is constructed from the lower diagonals of $M_{LUFactors}$ and setting the main diagonal to 1.

/MIND
Finds the minimum magnitude diagonal element of $M_{Upper}$ and store it in $V_{min}$. This is useful for investigating the behavior of the determinant of the matrix when it is close to being singular.

/PMAT
Saves the transpose of the permutation matrix in a double precision wave $M_{Pt}$ in the current data folder. Note that the permutation matrix is orthogonal and so the inverse of the matrix is equal to its transpose.

/SUMP
Computes the sum of the phases of the elements on the main diagonal of $M_{Upper}$ and store in the variable V_Sum. V_Sum is initialized to NaN and is set only if /SUMP is specified and $M_{Upper}$ is complex.
Details
The input matrix srcWave is an MxN real or complex wave of single or double precision. Use MatrixLUDTD if your input is tri-diagonal.

The main results of the factorization are stored in the waves M_Lower, M_Upper and M_Pt. Alternatively the lower and upper factors can be combined and stored in the wave M_LUFactors (see /CMF). The waves M_Lower, M_Upper and M_LUFactors have the same data type as the input wave. M_Pt is always double precision.

When the input matrix srcWave is square (NxN), the resulting matrices have the same dimensions (NxN). You can reconstruct the input using the MatrixOp expression:

```
MatrixOp/O rA=(M_Pt^t) x (M_Lower x M_Upper)
```

If the input matrix is rectangular (NxM) the reconstruction depends on the size of N and M.

If N<M:

```
MatrixOp/O rA=(M_Pt^t) x (subRange(M_lower,0,N-1,0,N-1) x M_Upper)
```

If N>M:

```
MatrixOp/O rA=(M_Pt^t) x M_lower x subRange(M_Upper,0,M-1,0,M-1)
```

The variable V_flag is set to zero if the operation succeeds and to 1 otherwise (e.g., if the input is singular). When you use the /B flag the polarity of the matrix is returned in the variable V_LUPolarity. The variables V_Sum and V_min are also set by some of the flag options above.

Matrix Math Operations on page III-138 for more about Igor's matrix routines.

MatrixLUDTD

MatrixLUDTD [flags] srcMain, srcUpper, srcLower

The MatrixLUDTD operation computes the LU factorization of a tri-diagonal matrix. The general form of the factorization/decomposition is expressed in terms of matrix products:

```
M_Pt x triDiagonalMat = M_Lower x M_Upper
```

triDiagonalMat is the matrix defined by the main diagonal specified by srcMain, the upper diagonal specified by srcUpper, and the lower diagonal specified by srcLower.

M_Pt is an output wave created when the /PMAT flag is present. M_Lower and M_Upper are output waves created when the /FM flag is present. M_Pt is the transpose of the permutation matrix, M_Lower is a lower triangular matrix with 1's on the main diagonal and M_Upper is an upper triangular (or trapezoidal) matrix.

Flags

/ MIND  Finds the minimum magnitude diagonal element of M_Upper and stores it in V_min. This feature is useful if you want to investigate the behaviour of the determinant of the matrix when it is close to being singular.

/ PMAT  Saves the transpose of the permutation matrix in the wave M_Pt in the current data folder. Note that the permutation matrix is orthogonal and so the inverse of the matrix is equal to its transpose.

/ SUMP  Computes the sum of the phases of the elements on the main diagonal of M_Upper and store in the variable V_Sum. Note that the variable is initialized to NaN and that it is not set unless this flag is specified and M_Upper is complex.

/ FM  The full matrix output is stored in the waves M_Lower and M_Upper in the current data folder.

Details
You specify the tridiagonal matrix using three 1D waves of the same data type (single or double precision real or complex).

If /FM is present the output of the operation consists of two 2D waves and one 1D wave:

```
M_Lower is a lower triangular matrix with 1's on the main diagonal.
```
MatrixMultiply

M_Upper is an upper triangular (or trapezoidal) matrix.
W_PIV is 1D wave containing pivot indices.
See code example below for implementation details.

If /FM is omitted the output of the operation consists of five 1D waves:
W_Diagonal is the main diagonal of matrixU.
W_UDiagonal is the first upper diagonal of M_Upper.
W_U2Diagonal is the second diagonal of M_Upper.
W_LDiagonal is the first lower diagonal of M_Lower.
W_PIV is a vector of pivot indices.

In this case M_Lower can be constructed (see below) from W_LDiagonal and the pivot index wave W_PIV.

If you are working with tridiagonal matrices you can take advantage of MatrixOp functionality to
reconstruct your outputs. For example:

MatrixOp/O M_Upper=Diagonal(W_diagonal)
MatrixOp/O M_Upper=setOffDiag(M_Upper,1,W_UDiagonal)
MatrixOp/O M_Upper=setOffDiag(M_Upper,2,W_U2Diagonal)

These commands can be combined into a single command line.

The construction of M_Lower is a bit more complicated and can be accomplished for real data using the
following code:

Function MakeLTMatrix(W_diagonal,W_LDiagonal,W_PIV)
  Wave W_diagonal,W_LDiagonal,W_PIV
  Variable i,N=DimSize(W_diagonal,0)
  MatrixOp/O M_Lower=setOffDiag(ZeroMat(N,N,4),-1,W_LDiagonal)
  M_Lower=p==q ? 1:M_Lower[p][q] // Set the main diagonal to 1's
  MatrixOp/O index=W_PIV-1 // Convert from 1-based array
  for(i=1;i<=N-2;i+=1)
    if(index[i]!=i)
      variable j,tmp
      for(j=0;j<i-1;j+=1)
        tmp=M_Lower[i][j]
        M_Lower[i][j]=M_Lower[i+1][j]
        M_Lower[i+1][j]=tmp
      endfor
    endif
  endfor
End

This code is provided for illustration only. In practice you could use the /FM flag so that the operation
creates the full lower and upper matrices for you.

The variable V_flag is set to zero if the operation succeeds and to 1 otherwise (e.g., if the input is singular).
The variables V_Sum and V_min are also set by some of the flag options above.

MatrixLUD, MatrixOp, Matrix Math Operations on page III-138 for more about Igor’s matrix routines.

MatrixMultiply

MatrixMultiply matrixA [/T], matrixB [/T] [, additional matrices]
The MatrixMultiply operation calculates matrix expression matrixA*matrixB and puts the result in a matrix
wave named M_product generated in the current data folder. The /T flag can be included to indicate that
the transpose of the specified matrix should be used.

If any of the source matrices are complex, then the result is complex.

Parameters
If matrixA is an NxP matrix then matrixB must be a PxM matrix and the product is an NxM matrix. Up to 10
matrices can be specified although it is unlikely you will need more than three. The inner dimensions must
be the same. Multiplication is performed from right to left.

It is legal for M_product to be one of the input matrices. Thus MatrixMultiply A,B,C could also be done as:
MatrixMultiplyAdd

Details
Supports multiplication of complex matrices.
An error is generated if the dimensioning of the input arrays is invalid.

See Also
MatrixOp and MatrixMultiplyAdd for more efficient matrix operations.
Matrix Math Operations on page III-138 for more about Igor’s matrix routines.
FastOp for additional efficient non-matrix operations.

MatrixMultiplyAdd

MatrixMultiplyAdd [/ZC or /DC] [/A=alpha] [/B=beta] matA[/T], matB[/T] matC

The MatrixMultiplyAdd operation calculates the matrix expression:
matC = alpha*matA x matB + beta*matC

where * indicates scalar multiplication and x indicates matrix multiplication.
MatrixMultiplyAdd uses the LAPACK library for fast computation. It was added in Igor Pro 9.00.
Use /B=0 for just matrix multiply with no addition. In this case, the beta*matC term is not evaluated.

Parameters
matA, matB and matC must be of the same number type and must be single or double precision real or complex.
If matA is an NxP matrix then matB must be a PxM matrix and the product is an NxM matrix. If these conditions are violated MatrixMultiplyAdd generates an error.
Include the /T flag after matA and/or matB to indicate that the transpose of matA and/or matB should be used.
If matC is a NULL wave reference, then a free wave is created and a reference to it is stored in the wave reference matC.

Flags

/A=alpha  alpha is the scalar value multiplied with matA. It defaults to 1.
/B=beta  beta is the scalar value multiplied with matB. It defaults to 1. Use /B=0 to omit the beta*matC term.
/DC  Duplicates the wave referenced by matC as a free wave, performs the calculation with the duplicate as the destination, and stores a reference to the free wave in matC.
/DC is allowed only when calling MatrixMultiplyAdd from a user-defined function. It is an error to use /DC from the command line or in a macro.
/T  Used after matA and/or matB, /T indicates tells MatrixMultiplyAdd to use the transform of matA and/or matB in the calculation.
/ZC  Clears the input wave reference matC. This guarantees that matC is NULL which causes MatrixMultiplyAdd to create a free output wave and store a reference to it in matC.
When using MatrixMultiplyAdd in a loop, use /ZC to clear the input wave reference to ensure that a new free wave is created each time through the loop rather than re-using the same output wave.
/ZC is allowed only when calling MatrixMultiplyAdd from a user-defined function. It is an error to use /ZC from the command line or in a macro.

Details
matA and matB must exist but, when running in a user-defined function, matC may or may not exist. If it does not exist, MatrixMultiplyAdd creates a free output wave, creates a wave reference named matC, and stores a reference to the free output wave in matC.
Both \textit{alpha} and \textit{beta} must be real and default to 1.

Use /B=0 to omit the \textit{beta*matC} term.

**Example**

Function Demo() // Demonstrates various ways to call MatrixMultiplyAdd
// Create input waves
Make/O/N=(3,3) matA = p + 10\*q
Make/O/N=(3,3) matB = p == q

Print "=== matC = matA x matB ==="
Make/O/N=(3,3) matC = 0
MatrixMultiplyAdd /B=0 matA, matB, matC
Print matC

Print "=== matC = 2*matA x matB ==="
Make/O/N=(3,3) matC = 0
MatrixMultiplyAdd /A=2 /B=0 matA, matB, matC
Print matC

Print "=== Free Wave Using WaveClear = matA x matB ==="
Make/O/N=(3,3) matC = 0 // matC wave ref is cleared by WaveClear
WaveClear matC // MatrixMultiplyAdd creates a free output wave
MatrixMultiplyAdd /B=0 matA, matB, matC
Print matC

Print "=== Free Wave Using /ZC = matA x matB ==="
Make/O/N=(3,3) matC = 0 // matC wave ref is cleared by /ZC
MatrixMultiplyAdd /B=0 /ZC matA, matB, matC
Print matC

Print "=== Create dest wave using string variable ==="
String dest = "matDest1"
Make/O/N=(3,3) $dest = 0
WAVE destWave = $dest
MatrixMultiplyAdd /B=0 matA, matB, destWave
Print destWave
End

**See Also**
MatrixOp and MatrixMultiply for more efficient matrix operations.
Matrix Math Operations on page III-138 for more about Igor’s matrix routines.
FastOp for additional efficient non-matrix operations.

**MatrixOp**

\texttt{MatrixOp [/C /FREE /NTHR=n /O /S] destwave = expression}

The MatrixOp operation evaluates \textit{expression} and stores the result in \textit{destWave}.

\textit{expression} may include literal numbers, numeric variables, numeric waves, and the set of operators and functions described below. MatrixOp does not support text waves, strings or structures.

MatrixOp is faster and in some case more readable than standard Igor waveform assignments and matrix operations.

## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destWave</td>
<td>Specifies a destination wave for the assignment expression. destWave is created at runtime. If it already exists, you must use the /O flag to overwrite it or the operation returns an error. When the operation is completed, destWave has the dimensions and data type implied by expression. In particular, it may be complex if expression evaluates to a complex quantity. If expression evaluates to a scalar, destWave is a 1x1 wave. If you include the /FREE flag then destWave is created as a free wave. By default the data type of destWave depends on the data types of the operands and the nature of the operations on the right-hand side of the assignment. If expression references integer waves only, destWave may be an integer wave too but most operations with a scalars convert destWave into a double precision wave. See MatrixOp Data Promotion Policy on page III-145 for further discussion. Even if destWave exists before the operation, MatrixOp may change its data type and dimensionality as implied by expression. You can force the number type using MatrixOp functions such as uint16 and fp32.</td>
</tr>
<tr>
<td>expression</td>
<td>expression is a mathematical expression referencing waves, local variables, global variables and literal numbers together with MatrixOp functions and MatrixOp operators as listed in the following sections. You can use any combination of data types for operands. In particular, you can mix real and complex types in expression. MatrixOp determines data types of inputs and the appropriate output data type at runtime without regard to any type declaration such as Wave/C.</td>
</tr>
</tbody>
</table>
Operators

+ Addition between scalars, matrix addition or addition of a scalar (real or complex) to each element of a matrix.

- Subtraction of one scalar from another, matrix subtraction, or subtracting a scalar from each element of a matrix. Subtraction of a matrix from a scalar is not defined.

* Multiplication between two scalars, multiplication of a matrix by a scalar, or element-by-element multiplication of two waves of the same dimensions.

/ Division of two scalars, division of a matrix by a scalar, or element-by-element division between two waves of the same dimensions.

Division of a scalar by a matrix is not supported but you can use the rec function with multiplication instead.

x Matrix multiplication (lower case x symbol only).

This operator must be preceded and followed by a space. Matrix multiplication requires that the number of columns in the matrix on the left side be equal to the number of rows in the matrix on the right.

. Generalized form of a dot product. In an expression $a.b$ it is expected that $a$ and $b$ have the same number of points although they may be of arbitrary numeric type. The operator returns the sum of the products of the sequential elements as if both $a$ and $b$ were 1D arrays.

For complex binary operand waves $a$ and $b$, this operator returns the MatrixOp equivalent of $\text{sum}(a^\ast\text{conj}(b))$. The MatrixDot function returns $\text{sum}(b^\ast\text{conj}(a))$.

^t Matrix transpose. This is a postfix operator meaning that $^t$ appears after the name of a matrix wave.

^h Hermitian transpose. This is a postfix operator meaning that $^h$ appears after the name of a matrix wave.

&& Logical AND operator supports all real data types and results in a signed byte numeric token with the value of either 0 or 1. The operation acts on an element by element basis and is performed for each element of the operand waves.

|| Logical OR operator supports all real data types and results in a signed byte numeric token with the value of either 0 or 1. The operation acts on an element by element basis and is performed for each element of the operand waves.

MatrixOp does not support operator combinations such as $+=$. This table shows the precedence of MatrixOp operators:

<table>
<thead>
<tr>
<th>MatrixOp Operator</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>^h</td>
<td>^t</td>
</tr>
<tr>
<td>x</td>
<td>.</td>
</tr>
<tr>
<td>*</td>
<td>/</td>
</tr>
<tr>
<td>+</td>
<td>-</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td></td>
</tr>
</tbody>
</table>

You can use parentheses to force evaluation order.

Operators that have the same precedence associate from right to left. This means that $a * b / c$ is equivalent to $a * (b / c)$.

Functions

These functions are available for use with MatrixOp.

abs($w$) Absolute value of a real number or the magnitude of a complex number.
acos(w)  Arc cosine of w.

acosh(w)  Inverse hyperbolic cosine of w. Added in Igor Pro 7.00.

addCols(w, dc)  Returns a matrix where elements of the 1D wave dc are added to the corresponding column in w:
    out = w + dc[q]
    Added in Igor Pro 9.00.

addRows(w, dr)  Returns a matrix where elements of the 1D wave dr are added to the corresponding row in w:
    out = w + dr[p]
    Added in Igor Pro 9.00.

asin(w)  Arc sine of w.

asinh(w)  Inverse hyperbolic sine of w. Added in Igor Pro 7.00.

asyncCorrelation(w)  Asynchronous spectrum correlation matrix for a real valued input matrix wave w. See syncCorrelation for details.

atan(w)  Arc tangent (inverse tangent) of w.

atan2(y, x)  Arc tangent (inverse tangent) of real y/x.

atanh(w)  Inverse hyperbolic tangent of w. Added in Igor Pro 7.00.

averageCols(w)  Returns a (1xcolumns) wave containing the averages of the columns of matrix w. This is equivalent to sumCols(w)/numRows(w).
    Added in Igor Pro 7.00.

axisToQuat(ax)  See Functions Using Quaternions on page V-573.

backwardSub(U, c)  Returns a column vector solution for the matrix equation Ux=c, where U is an (NxN) wave representing an upper triangular matrix and c is a column vector of N rows. If c has additional columns they are ignored. Ideally, U and c should be either SP or DP waves (real or complex). Other numeric data types are supported with a slight performance penalty.

This function is typically used in solving linear equations following a matrix decomposition into lower and upper triangular matrices (e.g., Cholesky), with an expression of the form:

\[
\text{MatrixOp/O solVector=backwardSub(U,forwardSub(L,b))}
\]

where U and L are the upper and lower triangular factors.
    Added in Igor Pro 7.00.

beam(w, row, col)  When w is a 3D wave the beam function returns a 1D array corresponding to the data in the beam defined by \[ [row][col] \]. In other words, it returns a 1D array consisting of all elements in the specified row and column from all layers. See also ImageTransform getBeam.

When w is a 4D wave it returns a 2D array containing \[ [row][col][][] \]. In other words, it returns a matrix consisting of all elements in the specified row and column from all layers and all chunks.

The beam function belongs to a special class in that it does not operate on a layer by layer basis. It therefore does not permit compound expressions in place of any of its parameters.

The beam function has the highest precedence.
MatrixOp

- **bitAnd(w1, w2)**: Returns an array of the same dimensions and number type as \( w1 \) where each element corresponds to the bitwise AND operation between \( w1 \) and \( w2 \). \( w2 \) can be either a single number or a matrix of the same dimensions as \( w1 \). Both \( w1 \) and \( w2 \) must be real integer numeric types.
  - Added in Igor Pro 7.00.

- **bitOr(w1, w2)**: Returns an array of the same dimensions and number type as \( w1 \) where each element corresponds to the bitwise OR operation between \( w1 \) and \( w2 \). \( w2 \) can be either a single number or a matrix of the same dimensions as \( w1 \). Both \( w1 \) and \( w2 \) must be real integer numeric types.
  - Added in Igor Pro 7.00.

- **bitReverseCol(w, c, order)**: Returns the matrix \( w \) with the entries of column \( c \) reordered.
  - bitReverseCol was added in Igor Pro 9.00.
  - \( order \) is one of the following values:
    - 0: Direct binary reversal of the index
    - 1: Hadamard order
    - 2: Dyadic/Paley/Gray order
    - 3: Unchanged order
  - bitReverseCol can be used for changing the order of entries in fast transform algorithms such as FFT and the fast Walsh-Hadamard transform. The number of rows in \( w \) must be a power of 2.
  - See Examples below for an example using bitReverseCol.

- **bitShift(w1, w2)**: Returns an array of the same dimensions and number type as \( w1 \) shifted by the amount specified in \( w2 \). When \( w2 \) is positive the shifting is to the left. When it is negative the shifting is to the right.
  - \( w2 \) can be either a single number or a matrix of the same dimensions as \( w1 \). Both \( w1 \) and \( w2 \) must be real integer numeric types.
  - Added in Igor Pro 7.00.

- **bitXor(w1, w2)**: Returns an array of the same dimensions and number type as \( w1 \) where each element corresponds to the bitwise XOR operation between \( w1 \) and \( w2 \).
  - \( w2 \) can be either a single number or a matrix of the same dimensions as \( w1 \). Both \( w1 \) and \( w2 \) must be real integer numeric types.
  - Added in Igor Pro 7.00.

- **bitNot(w)**: Returns an array of the same dimensions and number type as \( w \) where each element is the bitwise complement of the corresponding element in \( w \).
  - Added in Igor Pro 7.00.

- **catCols(w1, w2)**: Concatenates the columns of \( w2 \) to those of \( w1 \). \( w1 \) and \( w2 \) must have the same number of rows and the same number type.
  - Added in Igor Pro 7.00.

- **catRows(w1, w2)**: Concatenates the rows of \( w2 \) to those of \( w1 \). \( w1 \) and \( w2 \) must have the same number of columns and the same number type.
  - Added in Igor Pro 7.00.

- **cbrt(w)**: Returns the cube root of the elements of \( w \). When \( w \) is complex \( cbrt \) returns the principal cube root (the root with a positive imaginary number).
  - Added in Igor Pro 8.00.
MatrixOp

\[ \text{ceil}(z) \] Smallest integer larger than \( z \).

\[ \text{chirpZ}(data, A, W, M) \] Chirp Z Transform of the 1D wave data calculated for the contour defined by
\[ z_k = AW^{-k}, \]
\[ k = 0,1,\ldots,M - 1. \]

Here both \( A \) and \( W \) are complex and the standard \( z \) transform for a sequence \( \{x(n)\} \) is defined by
\[ X(z) = \sum_{k=0}^{N-1} x(n)z^{-k}. \]

The phase of the output is inverted to match the result of the ChirpZ transform on the unit circle with that of the FFT.

\[ \text{chirpZf}(data, f1, f2, df) \] Chirp Z Transform except that the transform parameters are specified by real-valued starting frequency \( f1 \), end frequency \( f2 \) and frequency resolution \( df \). The transform is confined to the unit circle because both \( A \) and \( W \) have unit magnitude.

\[ \text{chol}(w) \] Returns the Cholesky decomposition \( U \) of a positive definite symmetric matrix \( w \) such that \( w=U^t \times U \). Note that only the upper triangle of \( w \) is actually used in the computation.

\[ \text{chunk}(w, n) \] Returns chunk \( n \) from 4D wave \( w \).

Added in Igor Pro 7.00.

\[ \text{clip}(w, low, high) \] Returns the values in the wave \( w \) clipped between the \( low \) and the \( high \) parameters. If \( w \) contains NaN or INF values, they are not modified. The result retains the same number type as the input wave \( w \) irrespective of the range of the \( low \) and \( high \) input parameters.

\[ \text{cmplx}(re, im) \] Returns a complex token from two real tokens. \( re \) and \( im \) must have the same dimensionality.

Added in Igor Pro 7.00.

\[ \text{col}(w, c) \] Returns column \( c \) from matrix wave \( w \).

\[ \text{colRepeat}(w, n) \] Returns a matrix that consists of \( n \) identical columns containing the data in the wave \( w \). If \( w \) is a 2D wave, it is treated as if it were a single column containing all the data. Higher dimensions are supported on a layer-by-layer basis. MatrixOp returns an error if \( n<2 \).

Added in Igor Pro 7.00.

\[ \text{conj}(\text{matrixWave}) \] Complex conjugate of the input expression.

\[ \text{const}(r, c, val) \] Returns an \((r \times c)\) matrix where all elements are equal to \( val \). The data type of the returned matrix is the same as that of \( val \). See also \text{zeroMat} below.

Added in Igor Pro 7.00.
**MatrixOp**

**convolve(w1, w2, opt)**  
Convolution of w1 with w2 subject to options opt. The dimensions of the result are determined by the largest dimensions of w1 and w2 with the number of rows padded (if necessary) so that they are even. Supported options include opt=0 for circular convolution and opt=4 for acausal convolution.

For fast 2D convolutions where where w1 is an image and w2 is a square kernel of the same numeric type, you can use opt=-1 or opt=-2. When opt=-1 the convolution at the boundaries is evaluated using zero padding. When opt=-2 the padding is a reflection of w1 about the boundaries. When working with integer waves the kernel is internally normalized by the sum of its elements. The kernel for floating point waves remain unchanged.

To convolve an image in w1 with a smaller point spread function in w2 you can use:

- opt=-1 if you want to pad the image boundaries with zeros or
- opt=-2 if you want to pad the boundaries by reflecting image values about each boundary.

The negative options are designed for a very optimized convolution calculation which requires that w1 and w2 have the same numeric type. If the size of the point spread function is larger than about 13x13 it may become more efficient to compute the convolution using the positive options.

**correlate(w1, w2, opt)**  
Correlation of w1 with w2 subject to options opt. The dimensions of the result are determined by the largest dimensions of w1 and w2 with the number of rows padded (if necessary) so that they are even. Supported options include opt=0 for circular correlation and opt=4 for acausal correlation.

**cos(w)**  
Cosine of w.

**cosh(w)**  
Hyperbolic cosine of w. Added in Igor Pro 7.00.

**covariance(w)**  
Returns the sample covariance matrix. Added in Igor Pro 8.00.

If w is a rows x cols real matrix then the returned value is the cols x cols matrix Q with elements

\[ q_{ij} = \frac{1}{rows-1} \sum_{i=0}^{rows-1} (w_{ij} - \bar{w}_j)(w_{ik} - \bar{w}_k), \]

where

\[ \bar{w}_k = \frac{1}{rows} \sum_{i=0}^{rows-1} w_{ik}. \]

**crossCovar(w1, w2, opt)**  
Returns the cross-covariance for 1D waves w1 and w2. The options parameter opt can be set to 0 for the raw cross-covariance or to 1 if you want the results to be normalized to 1 at zero offset. If w1 has N rows and w2 has M rows then the returned vector is of length N+M-1. The cross-covariance is computed by subtracting the mean of each input followed by correlation and optional normalization. See also **Correlate** with the /NODC flag.
decimateMinMax\( (w, N) \) Decimates the matrix \( w \) on a column by column basis. Each column is divided into \( N \) bins and each bin is represented by its minimum and maximum values.

For an \( R \times C \) real valued input \( w \), the output is an array of dimensions \( 2N \times C \) and the extrema are ordered as in \( \{\text{min}0, \text{max}0, \text{min}1, \text{max}1, \ldots\} \).

Because of roundoff, sequential bins may not represent the same number of elements when \( R \) is not an integer multiple of \( N \). In this case you not count on the exact form of the bin size roundoff.

The decimateMinMax keyword was added in Igor Pro 9.00.

det(\( w \)) Returns a scalar corresponding to the determinant of matrix \( w \), which must be real.

diagonal(\( w \)) Creates a square matrix that has the same number of rows as \( w \). All elements are zero except for the diagonal elements which are taken from the first column in \( w \). Use DiagRC if the input is not an existing wave (such as a result from another function).

diagRC(\( w, rows, cols \)) 2D matrix of dimensions \( rows \) by \( cols \). All matrix elements are set to zero except those of the diagonal which are filled sequentially from elements of \( w \). The dimensionality of \( w \) is unimportant. If the total number of elements in \( w \) is less than the number of elements on the diagonal then all elements will be used and the remaining diagonal elements will be set to zero.

e Returns the base of the natural logarithm.

equal(\( w1, w2 \)) Returns unsigned byte result with 1 for equality and zero otherwise. The dimensionality of the result matches the dimensionality of the largest parameter.

Either or both \( w1 \) and \( w2 \) can be constants (i.e., one row by one column).

If \( w1 \) and \( w2 \) are not constants, they must have the same number of rows and columns. If \( w1 \) or \( w2 \) have multiple layers, they must either have the same number of layers or one of them must have a single layer.

Both parameters can be either real or complex. A comparison of a real with a complex parameter returns zero.

erf(\( w \)) Returns the error function (see erf) for real values in \( w \).

Added in Igor Pro 7.00.

erfc(\( w \)) Returns the complementary error function (see erfc) for real values in \( w \).

Added in Igor Pro 7.00.

exp(\( w \)) Exponential function for \( w \) which can be real or complex, scalar or a matrix.

expIntegralE1(\( w \)) Returns the exponential integral for real arguments \( w \). See also ExpIntegralE1. Added in Igor Pro 9.00.

expm(\( w \)) Returns the matrix exponential of a real-valued square matrix \( w \). Added in Igor Pro 9.00.

FCT(\( w, dir \)) See Trignometric Transform Functions on page V-571.

fft(\( w, options \)) FFT of \( w \).

\( w \) must have an even number of rows.

\( options \) contains a binary field flag. Set bit 1 to 1 if you want to disable the zero centering (see /Z flag in the FFT operation). Other bits are reserved.

MatrixOp does not support wave scaling and therefore it does not produce the same wave scaling changes as the FFT operation.

</table>
| forwardSub(L, b)    | Returns a column vector solution for the matrix equation Lx=b, where L is an (N×N) wave representing a lower triangular matrix and b is a column vector of N rows. If b has additional columns they are ignored.  
Ideauxly, L and b should be either SP or DP waves (real or complex). Other numeric data types are supported with a slight performance penalty.  
This function is typically used in solving linear equations following a matrix decomposition into lower and upper triangular matrices (e.g., Cholesky), with an expression of the form:  
MatrixOp/O solVector=backwardSub(U,forwardSub(L,b))  
where U and L are the upper and lower triangular factors. | Igor Pro 7.00     |
| fp32(w)             | Converts w to 32-bit single precision floating point representation. See also the /NPRM flag below for more information.                                                                                     | Igor Pro 7.00     |
| fp64(w)             | Converts w to 64-bit single precision floating point representation. See also the /NPRM flag below for more information.                                                                                     | Igor Pro 7.00     |
| Frobenius(w)        | Returns the Frobenius norm of a matrix defined as the square root of the sum of the squared absolute values of all elements.                                                                            | Igor Pro 7.00     |
| FST(w, dir)         | See Trignometric Transform Functions on page V-571.                                                                                                                                                        |                   |
| FSST(w, dir)        | See Trignometric Transform Functions on page V-571.                                                                                                                                                       |                   |
| FSCT(w, dir)        | See Trignometric Transform Functions on page V-571.                                                                                                                                                       |                   |
| FSST2(w, dir)       | See Trignometric Transform Functions on page V-571.                                                                                                                                                       |                   |

| gamma(w)            | Returns the gamma function for real arguments w. See also gamma. Added in Igor Pro 9.00.                                                                                                                 | Igor Pro 9.00     |
| gammaln(w)          | Returns the natural log of the gamma function for real arguments w. See also gammaln. Added in Igor Pro 9.00.                                                                                             | Igor Pro 9.00     |
| getDiag(w2d, d)     | Returns a 1D wave that contains diagonal d of w2d. d=0 is the main diagonal, d>0 correspond to upper diagonals and d<0 to lower diagonals.                                                              | Igor Pro 7.00     |
| greater(a, b)       | Returns an unsigned byte for the truth of a > b. Both a and b must be real but one or both can be constants (see equal() above). The dimensionality of the result matches the dimensionality of the largest parameter. |                   |
| greaterOrEqual(a, b)| Returns an unsigned byte for the truth of a >= b. Both a and b must be real but one or both can be constants (see equal() above). The dimensionality of the result matches the dimensionality of the largest parameter.        | Igor Pro 9.00     |
| hypot(w1, w2)       | Returns the square root of the sum of the squares of w1 and w2.                                                                                                                                           | Igor Pro 7.00     |
**ifft**(*w*, *options*)  
**IFFT of** *w*.  
*options* is a bitwise parameter defined as follows:  
Bit 0: Forces the result to be real, like the **IFFT** operation /C flag.  
Bit 1: Disables center-zero.  
Bit 2: Swaps the results.  

See **Setting Bit Parameters** on page IV-12 for details about bit settings.  
MatrixOp does not support wave scaling and therefore it does not produce the same wave scaling changes as the **IFFT** operation.

**identity**(n, m)  
**Create**s a computational object that is an identity matrix. If you use a single argument *n*, the identity created is an (*nxn*) square matrix with 1’s for diagonal elements (the remaining elements are set to zero). If you use both arguments, the function creates an (*nxm*) zero matrix and fills its diagonal elements with 1’s. Note that the identity is created at runtime and persists only for the purpose of the specific operation.

**imag**(*w*)  
Returns the imaginary part of *w*.

**indexCols**(*w*)  
Returns a token of the same dimensions as *w* where each element is equal to its column index. This is the MatrixOp equivalent of q used on righthand side of a standard wave assignment statement. The returned token is unsigned 32-bit integer if the number of columns in *w* is less than 2^32 or double-precision floating point otherwise.  
Added in Igor Pro 8.00.

**indexRows**(*w*)  
Returns a token of the same dimensions as *w* where each element is equal to its row index. This is the MatrixOp equivalent of p used on righthand side of a standard wave assignment statement. The returned token is unsigned 32-bit integer if the number of rows in *w* is less than 2^32 or double-precision floating point otherwise.  
Added in Igor Pro 8.00.

**inf**()  
Returns INF.  
Added in Igor Pro 7.00.

**int8**(*w*)  
Converts *w* to 8-bit signed integer representation. See also the /NPRM flag below for more information.  
Added in Igor Pro 7.00.

**int16**(*w*)  
Converts *w* to 16-bit signed integer representation. See also the /NPRM flag below for more information.  
Added in Igor Pro 7.00.

**int32**(*w*)  
Converts *w* to 32-bit signed integer representation. See also the /NPRM flag below for more information.  
Added in Igor Pro 7.00.

**integrate**(*w*, *opt*)  
Returns a running sum of *w*.  
If *opt*=0 the sum runs over the entire input wave treating the columns of 2D waves as if they were part of one big column.  
If *opt*=1 the running sum is computed separately for each column of a 2D wave.  
Added in Igor Pro 7.00.
intMatrix(\(w\)) Returns a double-precision matrix of the same dimensions as \(w\).
Each element of the returned matrix is the sum of all the corresponding elements of \(w\) that are above and to the left of it, i.e.,

\[
out_{ij} = \sum_{m=0}^{i} \sum_{n=0}^{j} w_{mn}.
\]

The utility of this function is apparent in the following relationship:

\[
\sum_{i=x_1}^{x_2} \sum_{j=y_1}^{y_2} w_{ij} = out[x_2, y_2] - out[x_2, y_1 - 1] - out[x_1 - 1, y_2] + out[x_1 - 1, y_1 - 1].
\]

intMatrix was added in Igor Pro 7.00.

inv(\(w\)) Returns the inverse of the square matrix \(w\).
If \(w\) is not invertible, the operation returns a matrix of the same dimensions where all elements are set to NaN.

inverseErf(\(w\)) Returns the inverse error function (see inverseErf) for the real values in \(w\).
Added in Igor Pro 7.00.

inverseErfc(\(w\)) Returns the inverse complementary error function (see inverseErfc) for the real values in \(w\).
Added in Igor Pro 7.00.

kronProd(\(u, v\)) Returns the Kronecker product of matrices \(u\) and \(v\).
kronProd was added in Igor Pro 9.00.
If \(u\) has dimensions \(M \times N\) and \(v\) has dimensions \(P \times Q\) then the returned block matrix has dimensions \(M^*P \times N^*Q\). It is given by

\[
u \otimes v = \begin{bmatrix}
u_{11} v_{11} & u_{11} v_{12} & \cdots & u_{11} v_{1q} & \cdots & \cdots & u_{1n} v_{11} & u_{1n} v_{12} & \cdots & u_{1n} v_{1q} \\
u_{11} v_{21} & u_{11} v_{22} & \cdots & u_{11} v_{2q} & \cdots & \cdots & u_{1n} v_{21} & u_{1n} v_{22} & \cdots & u_{1n} v_{2q} \\
\vdots & \vdots & \ddots & \vdots & \cdots & \cdots & \vdots & \vdots & \ddots & \vdots \\
u_{11} v_{p1} & u_{11} v_{p2} & \cdots & u_{11} v_{pq} & \cdots & \cdots & u_{1n} v_{p1} & u_{1n} v_{p2} & \cdots & u_{1n} v_{pq} \\
\vdots & \vdots & \ddots & \vdots & \cdots & \cdots & \vdots & \vdots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \vdots & \cdots & \cdots & \vdots & \vdots & \ddots & \vdots \\
u_{m1} v_{11} & u_{m1} v_{12} & \cdots & u_{m1} v_{1q} & \cdots & \cdots & u_{mn} v_{11} & u_{mn} v_{12} & \cdots & u_{mn} v_{1q} \\
u_{m1} v_{21} & u_{m1} v_{22} & \cdots & u_{m1} v_{2q} & \cdots & \cdots & u_{mn} v_{21} & u_{mn} v_{22} & \cdots & u_{mn} v_{2q} \\
\vdots & \vdots & \ddots & \vdots & \cdots & \cdots & \vdots & \vdots & \ddots & \vdots \\
u_{m1} v_{p1} & u_{m1} v_{p2} & \cdots & u_{m1} v_{pq} & \cdots & \cdots & u_{mn} v_{p1} & u_{mn} v_{p2} & \cdots & u_{mn} v_{pq}
\end{bmatrix}
\]

See Examples below for an example using kronProd.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>layer(w, n, chunk)</code></td>
<td>Returns a layer of a 3D or 4D wave.</td>
</tr>
<tr>
<td></td>
<td>The layer function was added in Igor Pro 7.00.</td>
</tr>
<tr>
<td></td>
<td>The optional <code>chunk</code> parameter was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td></td>
<td>If you omit <code>chunk</code> and <code>w</code> is a 3D wave, the layer function returns layer <code>n</code> from <code>w</code>.</td>
</tr>
<tr>
<td></td>
<td>If you omit <code>chunk</code> and <code>w</code> is a 4D wave, the layer function returns layer <code>n</code> of chunk 0 from <code>w</code>.</td>
</tr>
<tr>
<td></td>
<td>If you include <code>chunk</code>, <code>w</code> must be a 4D wave and the layer function returns layer <code>n</code> of the specified chunk from <code>w</code>.</td>
</tr>
<tr>
<td></td>
<td>In all cases <code>w</code> must be an actual wave and not an expression.</td>
</tr>
<tr>
<td><code>layerStack(w, n)</code></td>
<td>The <code>layerStack</code> function takes a 4D input wave <code>w</code> and a layer number <code>n</code> and returns a 3D wave (stack) that contains sequentially the data in layer <code>n</code> of each chunk of <code>w</code>. <code>w</code> must be a wave and not a derived token.</td>
</tr>
<tr>
<td></td>
<td><code>layerStack</code> was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>// Create 3D stack from red channel of 4D RGB movie wave</td>
</tr>
<tr>
<td></td>
<td>MatrixOP/O redChannelStack=layerStack(myRGBMovie, 0)</td>
</tr>
<tr>
<td><code>limitProduct(w1, w2)</code></td>
<td>Returns a partial element-by-element multiplication of waves <code>w1</code> and <code>w2</code>.</td>
</tr>
<tr>
<td></td>
<td>It is assumed that the dimensions of <code>w1</code> are greater or equal to that of <code>w2</code>. If <code>w2</code> is of dimensions <code>NxM</code> then the function returns a matrix of the same dimensions as <code>w1</code> with the first <code>NxM</code> elements contain the product of the corresponding elements in <code>w1</code> and <code>w2</code> and the remaining elements set to zero.</td>
</tr>
<tr>
<td></td>
<td>The function is designed to be used in filtering applications where the size of the kernel <code>w2</code> is much smaller than the size of the input <code>w1</code>.</td>
</tr>
<tr>
<td></td>
<td>Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td><code>log(w)</code></td>
<td>Returns the log base 10 of a token <code>w</code> which can be real or complex, scalar or a matrix.</td>
</tr>
<tr>
<td><code>log2(w)</code></td>
<td>Returns the log base 2 of a token <code>w</code> which can be real or complex, scalar or a matrix. <code>log2</code> was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td><code>ln(w)</code></td>
<td>Returns the natural logarithm of a token <code>w</code> which can be real or complex, scalar or a matrix.</td>
</tr>
<tr>
<td><code>mag(w)</code></td>
<td>Returns a real valued wave containing the magnitude of each element of <code>w</code>. This is equivalent to the <code>abs</code> function.</td>
</tr>
<tr>
<td><code>magSqr(w)</code></td>
<td>Returns a real value wave containing the square of a real <code>w</code> or the squared magnitude of complex <code>w</code>.</td>
</tr>
<tr>
<td><code>maxAB(a, b)</code></td>
<td>Returns the larger of the two real numbers <code>a</code> and <code>b</code>.</td>
</tr>
<tr>
<td></td>
<td><code>maxAB</code> does not support NaN or complex inputs.</td>
</tr>
<tr>
<td></td>
<td>Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td><code>maxMagAB(a, b)</code></td>
<td>For each data point in the tokens <code>a</code> and <code>b</code>, <code>maxMagAB</code> returns the one with the larger absolute value.</td>
</tr>
<tr>
<td></td>
<td><code>maxMagAB</code> does not support complex numbers.</td>
</tr>
<tr>
<td></td>
<td>Added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>maxCols(w)</td>
<td>Returns a 1D wave containing the maximum value of each column in the wave w. If w is complex the output contains the maximum magnitude of each column of w. maxCols does not support NaN.</td>
</tr>
<tr>
<td>maxRows(w)</td>
<td>Returns a 1D wave containing the maximum value of each row in the wave w. If w is complex the output contains the maximum magnitude of each row of w. maxRows does not support NaN.</td>
</tr>
<tr>
<td>maxVal(w)</td>
<td>Returns the maximum value of the wave w. If w is complex it returns the maximum magnitude of w. When w is real, the returned number type is the same as w's. When w is complex, the result is real and represents the maximum of the magnitudes of the elements of w. If w is double precision, then the result is double precision; otherwise it is single precision. When w is a 3D or 4D wave, maxVal returns a (1 x 1 x layers x chunks) data token. maxVal does not support NaN values.</td>
</tr>
<tr>
<td>mean(w)</td>
<td>Returns the mean value w.</td>
</tr>
<tr>
<td>minAB(a, b)</td>
<td>Returns the smaller of the two real numbers a and b. minAB does not support NaN or complex inputs.</td>
</tr>
<tr>
<td>minMagAB(a, b)</td>
<td>For each data point in the tokens a and b, minMagAB returns the one with the smaller absolute value. minMagAB does not support complex numbers.</td>
</tr>
<tr>
<td>minCols(w)</td>
<td>Returns a 1D wave containing the minimum value of each column in the wave w. If w is complex the output contains the minimum magnitude of each column of w. minCols does not support NaN.</td>
</tr>
<tr>
<td>minRows(w)</td>
<td>Returns a 1D wave containing the minimum value of each row in the wave w. If w is complex the output contains the minimum magnitude of each row of w. minRows does not support NaN.</td>
</tr>
<tr>
<td>minVal(w)</td>
<td>Returns the minimum value of the wave w. If w is complex the function returns the minimum magnitude of w. When w is real, the returned number type is the same as w's. When w is complex, the result is real and represents the minimum of the magnitudes of the elements of w. If w is double precision, then the result is double precision; otherwise it is single precision. When w is a 3D or 4D wave, minVal returns a (1 x 1 x layers x chunks) data token. minVal does not support NaN values.</td>
</tr>
</tbody>
</table>
MatrixOp

\[ \text{mod}(w, b) \]

Returns the remainder after dividing \( w \) by \( b \). \( b \) can be a scalar or a matrix of the same dimensions as \( w \).

Added in Igor Pro 7.00.

\[ \text{nan}() \]

Returns NaN.

Added in Igor Pro 7.00.

\[ \text{normalize}(w) \]

Normalized version of a vector or a matrix. Normalization is such that the returned token should have a unity magnitude except if all elements are zero, in which case output is unchanged.

\[ \text{normalizeCols}(w) \]

Divides each column of the real wave \( w \) by the square root of the sum of the squares of all elements of the column.

\[ \text{normalizeRows}(w) \]

Divides each row of the real wave \( w \) by the square root of the sum of the squares of all the elements in that row.

\[ \text{normP}(w, pn) \]

Returns the \( p \)-norm of matrix \( w \) defined by

\[
\|w\|_p = \left( \sum_{j=0}^{\text{cols}} \sum_{i=0}^{\text{rows}} |w[i][j]|^p \right)^{1/p}.
\]

The case of \( pn=2 \) is equivalent to the MatrixOp Frobenius function.

Added in Igor Pro 9.00.

\[ \text{numCols}(w) \]

Returns the number of columns in the wave \( w \). When \( w \) is 1D the function returns 1.

\[ \text{numPoints}(w) \]

Returns the number of points in a layer of \( w \).

\[ \text{numRows}(w) \]

Returns the number of rows in \( w \).

\[ \text{numType}(w) \]

Number the number type of \( w \):

0: \( w \) is a normal number

1: \( w \) is +/- INF

2: \( w \) is NaN

\[ \text{oneNorm}(w) \]

Returns the 1-norm of matrix \( w \) defined as the maximum absolute column sum

\[
\|w\|_1 = \max_{0 \leq j < \text{cols}} \left( \sum_{i=0}^{\text{rows}} |w[i][j]| \right).
\]

Added in Igor Pro 9.00.

\[ \text{outerProduct}(w1, w2) \]

For a 1D wave \( w1 \) containing \( M \) points and a 1D wave \( w2 \) containing \( N \) points, \( \text{outerProduct} \) returns an \( M \) by \( N \) matrix where the \((i,j)\) element is:

\[
\text{out}[i,j] = w1[i] \times \text{conj}(w2[j])
\]

Added in Igor Pro 8.00.

\[ \text{p2Rect}(w) \]

Converts each element of \( w \) from polar to rectangular representation.

\[ \text{phase}(w) \]

Returns a real valued wave containing the phase of each element of \( w \) calculated using \( \text{phase} = \text{atan2}(y,x) \).

\( \pi \)

Returns \( \pi \).

\[ \text{powC}(w1, w2) \]

Complex valued \( w1^{w2} \) where \( w1 \) and \( w2 \) can be real or complex.

\[ \text{powR}(x, y) \]

Returns \( x^y \) for real \( x \) and \( y \).
MatrixOp

**productCol(\(w, c\))**

Returns the (1 x 1) wave containing the product of the elements in column \(c\) of wave \(w\). The output is double precision real or complex.

Added in Igor Pro 7.00.

**productCols(\(w\))**

Returns a (1 x cols) wave where each entry is the product of all the elements in the corresponding column. The output is double precision real or complex.

Added in Igor Pro 7.00.

**productDiagonal(\(w, d\))**

Returns a (1 x 1) wave containing the product of the elements on the specified diagonal of wave \(w\). \(d=0\) is the main diagonal, \(d>0\) correspond to upper diagonals and \(d<0\) to lower diagonals. The output is double precision real or complex.

Added in Igor Pro 7.00.

**productRow(\(w, r\))**

Returns the a (1 x 1) wave containing the product of the elements in row \(r\) of wave \(w\). The output is double precision real or complex.

Added in Igor Pro 7.00.

**productRows(\(w\))**

Returns a (1 x rows) wave where each entry is the product of all the elements in the corresponding row. The output is double precision real or complex.

Added in Igor Pro 7.00.

**quat(\(arg\))**

See Functions Using Quaternions on page V-573.

**quatToAxis(\(qIn\))**

See Functions Using Quaternions on page V-573.

**quatToEuler(\(qIn, mode\))**

See Functions Using Quaternions on page V-573.

**quatToMatrix(\(qIn\))**

See Functions Using Quaternions on page V-573.

**r2Polar(\(w\))**

Performs the equivalent of the \(r2polar\) function on each element of \(w\), i.e., each complex number \((x+iy)\) is converted into the polar representation \(r, \theta\) with \(x+iy=r\exp(i\theta)\)

**real(\(w\))**

Returns the real part of \(w\).

**rec(\(w\))**

Returns the reciprocal of each element in \(w\).

**redimension(\(w, nr, nc\))**

Returns an (\(nr \times nc\)) matrix from the data in the wave \(w\). The data in \(w\) are moved contiguously (column by column regardless of dimensionality) into the output. If the output size is larger than \(w\) the remaining points are set to zero. If \(w\) contains more than one layer the new dimensions apply on a layer by layer basis. For example:

\[
\text{Make/N=(10,20,30) ddd = p + 10*q + 100*r} \\
\text{MatrixOp/O aa = redimension(ddd,25,1)}
\]

creates a wave \(aa\) with dimensions (25,1,30).

Added in Igor Pro 7.00.

**replace(\(w, findVal, replacementVal\))**

Replace in wave \(w\) every occurrence of \(findVal\) with \(replacementVal\). The wave \(w\) retains its dimensionality and number type. \(replacementVal\) is converted to the same number type as \(w\) which may cause truncation.

**replaceNaNs(\(w, replacementVal\))**

Replaces every occurrence of NaN in the wave \(w\) with \(replacementVal\). The wave \(w\) retains its dimensionality. \(replacementVal\) is converted to the same number type as \(w\) which may cause truncation.
MatrixOp

reverseCol(w, c)  
Returns array w with column c in reverse order.  
Added in Igor Pro 7.00.

reverseCols(w)  
Returns array w with all columns in reverse order.  
Added in Igor Pro 7.00.

reverseRow(w, r)  
Returns array w with row r in reverse order.  
Added in Igor Pro 7.00.

reverseRows(w)  
Returns array w with all rows in reverse order.  
Added in Igor Pro 7.00.

rotateChunks(w, n)  
Returns a matrix where the last n chunks of w are moved to chunks [0, n-1].  
If n is negative then the first abs(n) chunks are moved to the end of the data.  
It is an error to pass NaN for n.  
Added in Igor Pro 7.00.

rotateCols(w, nc)  
Rotates the columns of a 2D wave w so that the last nc columns are moved to columns [0,nc -1] of the data.  
If nc is negative the first abs(nc) columns are moved to columns [n-1-nc,n-1-1]. Here n is the total number of columns.  
It is an error to pass NaN for nc.  
If nc is greater than the number of columns then the effective rotation is mod(nc,actualCols).  
Added in Igor Pro 7.00.

rotateLayers(w, n)  
Returns a matrix where the last n layers of w are moved to layers [0, n-1].  
If n is negative then the first abs(n) layers are moved to the end of the data.  
It is an error to pass NaN for n.  
Added in Igor Pro 7.00.

rotateRows(w, nr)  
Rotates the rows of a 2D wave w so that the last nr rows are moved to rows [0,nr -1] of the data.  
If nr is negative the first abs(nr) rows are moved to rows [n-1-nr,n-1-1] where n is the total number of rows.  
It is an error to pass NaN for nr.  
If nr is greater than the number of rows then the effective rotation is mod(nr,actualRows).  
Added in Igor Pro 7.00.

round(z)  
Rounds z to the nearest integer. The rounding method is “away from zero”.  

row(w, r)  
Returns row r from matrix wave w. The returned row is a (1xC) wave where C is the number of columns in w.  
To convert it to a 1D wave use Redimension/N=(C).  
See also ImageTransform getRow.  

rowRepeat(w, n)  
Returns a matrix that consists of n identical rows containing the data in the wave w.  
If w is a 2D wave, it is treated as if it were a single column containing all the data.  
Higher dimensions are supported on a layer-by-layer basis.  
MatrixOp returns an error if n<2.  
Added in Igor Pro 7.00.

scale(w, low, high)  
Returns the values in the wave w scaled between the low and the high parameters.  
If w contains NaN or INF values, they are not modified. The result retains the same number type as that of w irrespective of the range of the low and high input parameters.  

scaleCols(w1, w2)  
Returns a matrix of the same dimensions as w1 where each column of w1 is scaled by the value in the corresponding row of the 1D wave w2. The number of rows in w2 must equal the number of columns in w1.  
Added in Igor Pro 7.00.

scaleRows(w1, w2)  
Returns a matrix of the same dimensions as w1 where each row of w1 is scaled by the value in the corresponding row of the 1D wave w2. The number of rows in w2 must equal the number of rows in w1.  
Added in Igor Pro 7.00.
**MatrixOp**

```plaintext
select(w,sr,sc)  Returns a matrix consisting of the elements of matrix w for which the row index satisfies (p%sr)==0 and the column index satisfies (q%sc)==0. The first row and column are always selected.

  sr and sc must be real, finite, and non-negative.

  Added in Igor Pro 9.00.

setCol(w2d,c,w1d)  Returns the data in the w2d with the contents of w1d stored in column c.

  w1d must have at least as many elements as the number of rows of w2d. w2d and w1d must be either both real or both complex.

  Added in Igor Pro 7.00.

setColsRange(w,low,high)  Returns a matrix in which each column of w is scaled to the range [low,high].

  w must be real-valued.

  setColsRange was added in Igor Pro 9.00.

setNaNs(w,mask)  Returns the data in the wave w with NaNs stored where the mask wave is non-zero. The wave w can be of any numeric type.

  mask must have the same dimensions as w and must be real. It is usually the result of another expression. For example, to set all values in the destination to NaN where w is greater than 5:

  MatrixOp/o ou = setNaNs(w,greater(w,5))

  Added in Igor Pro 7.00.

setOffDiag(w,d,w1)  Returns the data in the w with the contents of w1 stored in diagonal d.

  d=0 is the main diagonal of w, d>0 correspond to upper diagonals and d<0 to lower diagonals. w and w1 can either be both real or both complex.

  Added in Igor Pro 7.00.

setRow(w2d, r, w1d)  Returns the data in the w2d with the contents of w1d stored in row r.

  w1d must have at least as many elements as the number of columns in w2d. w2d and w1d must be either both real or both complex.

  Added in Igor Pro 7.00.

sgn(w)  Returns the sign of each element in w. It returns -1 for negative numbers and 1 otherwise. It does not accept complex numbers.

sin(z)  Sine of z.

sinh(z)  Hyperbolic sine of z. Added in Igor Pro 7.00.

slerp(qIn1,qIn2,frac)  See Functions Using Quaternions on page V-573.

spliceCols(w,c,d,ic)  Returns a matrix where ic columns from matrix d are spliced into matrix w starting at column c of w. Matrix d must have the same number of rows as matrix w and they must both have the same number type. ic must be non-negative integer. If ic is greater than the number of columns in the matrix d, the function repeats as many columns of d as necessary.

  Added in Igor Pro 9.00.

sq(w)  Returns the square of each element of the matrix w.

  For complex elements z the returned value is z*z, not magsqr(z).

  Added in Igor Pro 9.00.
```
sqrt(z)  
Square root of z.

subRange(w,rs,re/cs,ce)  
Returns a contiguous subset of the wave w from starting row rs through ending row re and from starting column cs through ending column ce. This is similar to Duplicate/R except that dimension scaling and labels not preserved.
Added in Igor Pro 7.00.

subtractMean(w,opt)  
Computes the mean of the real wave w and returns the values of the wave minus the mean value (opt=0). Computes the mean of each column and subtracts it from that column (opt=1). Subtracts the mean of each row from row values (opt=2).

subWaveC(w,r,c,count[,stride])  
Returns a subset of the data that is sampled along columns of the wave w, containing count elements starting with the element at row r and column c. By default stride=1 and the sampling is continuous.
You can specify a negative stride to sample backwards from the starting element.
The operation returns an error if the sampling would exceed the array bounds in either direction.
For example:
Make/O/N=(22,33) ddd=x  
MatrixOP/O/P=1 aa=subWaveC(ddd,4,5,10,2)  
// aa={4,6,8,10,12,14,16,18,20,0}  
MatrixOP/O/P=1 aa=subWaveC(ddd,4,5,5,-4)  
// aa={4,0,18,14,10}

subWaveR(w,r,c,count[,stride])  
Returns a subset of the data that is sampled along rows of the wave w, containing count elements starting with the element at row r and column c. By default stride=1 and the sampling is continuous.
You can specify a negative stride to sample backwards from the starting element.
The operation returns an error if the sampling would exceed the array bounds in either direction.
Examples:
Make/O/N=(10,20) ddd=y  
// Forward sampling across right boundary  
MatrixOP/O/P=1 aa=subWaveR(ddd,4,15,6,2)  
// aa={15,17,19,1,3,5}  
// Reverse sampling across left boundary  
MatrixOP/O/P=1 aa=subWaveR(ddd,2,3,5,-1)  
// aa={3,2,1,0,19}

sum(z)  
Returns the sum of all the elements in expression z.
**MatrixOp**

**sumBeams(w)**  Returns an \((n \times m)\) matrix containing the sum over all layers of all the beams of the 3D wave \(w\):

\[
out_{ij} = \sum_{k=0}^{nLayers-1} w_{ijk}.
\]

A beam is a 1D array in the Z-direction.

sumBeams is a non-layered function which requires that \(w\) be a proper 3D wave and not the result of another expression.

**sumCols(w)**  Returns a \((1 \times m)\) matrix containing the sums of the \(m\) columns in the \(n \times m\) input wave \(w\):

\[
out_j = \sum_{i=0}^{nRows-1} w_{ij}.
\]

**sumND(w)**  Returns a 1-point wave containing the sum of the token \(w\) regardless of its dimensionality.

sumND was added in Igor Pro 9.00.

This example illustrates the difference between sumND and the sum function which operates on a layer-by-layer basis:

```
Make/O/N=(5,6,3) w3D = z
MatrixOP/O/P=1 sumOut=sum(w3D) // Prints 3 layer sums
MatrixOP/O/P=1 sumNDOut=sumND(w3D) // Prints single sum
```

**sumRows(w)**  Returns an \((n \times 1)\) matrix containing the sums of the \(n\) rows in the \(n \times m\) input wave \(w\):

\[
out_i = \sum_{j=0}^{nCols-1} w_{ij}.
\]

**sumSqr(w)**  Sum of the squared magnitude of all elements in \(w\).

**syncCorrelation(w)**  Synchronous spectrum correlation matrix for a real valued input matrix wave \(w\). See also asyncCorrelation.

The correlation matrix is computed by subtracting from each column of \(w\) its mean value, multiplying the resulting matrix by its transpose, and finally dividing all elements by \((nrows-1)\) where nrows is the number of rows in \(w\).

**tan(w)**  Tangent of \(w\).

**tanh(w)**  Hyperbolic tangent of \(w\). Added in Igor Pro 7.00.

**tensorProduct(w1,w2)**  Returns a 2D matrix that is the tensor product of the 2D matrices \(w1\) and \(w2\). For example, the tensor product of two \((2 \times 2)\) matrices is given by:

\[
\begin{pmatrix}
  a_{11} & a_{12} \\
  a_{21} & a_{22}
\end{pmatrix}
\otimes
\begin{pmatrix}
  b_{11} & b_{12} \\
  b_{21} & b_{22}
\end{pmatrix}
= 
\begin{pmatrix}
  a_{11}b_{11} & a_{11}b_{12} & a_{12}b_{11} & a_{12}b_{12} \\
  a_{11}b_{21} & a_{11}b_{22} & a_{12}b_{21} & a_{12}b_{22} \\
  a_{21}b_{11} & a_{21}b_{12} & a_{22}b_{11} & a_{22}b_{12} \\
  a_{21}b_{21} & a_{21}b_{22} & a_{22}b_{21} & a_{22}b_{22}
\end{pmatrix}
\]

Added in Igor Pro 7.00.
Trace\((w)\)
Returns a real or complex scalar which is the sum of the diagonal elements of \(w\). If \(w\) is not a square matrix, the sum is over the elements for which the row and column indices are the same.

transposeVol\((w, mode)\)
For 3D wave \(w\), transposeVol returns a transposed 3D wave depending on the value of the \(mode\) parameter:

- \(mode=1\): \(output=w[p][r][q]\)
- \(mode=2\): \(output=w[r][p][q]\)
- \(mode=3\): \(output=w[r][q][p]\)
- \(mode=4\): \(output=w[q][r][p]\)
- \(mode=5\): \(output=w[q][p][r]\)

transposeVol is a non-layered function which requires that \(w\) be a proper 3D wave and not the result of another expression.

triDiag\((w1, w2, w3)\)
Returns a tri-diagonal matrix where \(w1\) is the upper diagonal, \(w2\) the main diagonal and \(w3\) the lower diagonal. If \(w2\) has \(n\) points then \(w1\) and \(w3\) are expected to have \(n-1\) points. The waves can be of any numeric type and the returned wave has a numeric type that accommodates the input.

uint8\((w)\)
Converts \(w\) to 8-bit unsigned integer representation. See also the /NPRM flag below for more information. Added in Igor Pro 7.00.

uint16\((w)\)
Converts \(w\) to 16-bit unsigned integer representation. See also the /NPRM flag below for more information. Added in Igor Pro 7.00.

uint32\((w)\)
Converts \(w\) to 32-bit unsigned integer representation. See also the /NPRM flag below for more information. Added in Igor Pro 7.00.

varBeams\((w)\)
Returns a matrix containing the variances of the beams of the real-valued 3D wave \(w\).

varBeams was added in Igor Pro 9.00.

varBeams is a non-layered function which requires that \(w\) be a proper 3D wave and not the result of another expression.

When \(w\) consists of a single layer the returned variances are all NaN.

varCols\((w)\)
Returns a \((1 \times cols)\) wave where each element contains the variance of the corresponding column in \(w\).

waveX\((w)\)
For pure wave argument \(w\), waveX returns the X value for each point as determined by the wave's X scaling.

Added in Igor Pro 9.00.

waveY\((w)\)
For pure wave argument \(w\), waveY returns the Y value for each point as determined by the wave's Y scaling.

Added in Igor Pro 9.00.

waveZ\((w)\)
For pure wave argument \(w\), waveZ returns the Z value for each point as determined by the wave's Z scaling.

Added in Igor Pro 9.00.

waveT\((w)\)
For pure wave argument \(w\), waveT returns the T value for each point as determined by the wave's T scaling.

Added in Igor Pro 9.00.

waveIndexSet\((w1, w2, w3)\)
MatrixOp

Returns a matrix of the same dimensions as \( w_1 \) with values taken either from \( w_1 \) or from \( w_3 \) depending on values in \( w_2 \) using:

\[
\text{out}[i][j] = \begin{cases} 
  w_1[i][j] & \text{if } w_2[i][j] < 0 \\
  w_3[w_2[i][j]] & \text{otherwise}
\end{cases}
\]

\( w_1 \) and \( w_2 \) must have the same number of rows and columns. \( w_1 \) and \( w_3 \) must match in number type. \( w_2 \) cannot be unsigned.

Values from \( w_2 \) are used as point number indices into \( w_3 \) which is treated like a 1D wave regardless of its actual dimensionality.

An index value from \( w_2 \) is out-of-bounds if it is greater than or equal to the number of points in \( w_3 \). In this case, the output value is taken from \( w_1 \) as if the index value were negative.

\text{waveMap}(\text{w1},\text{w2}) \quad \text{returns an array of the same dimensions as } \text{w2} \text{ containing the values } \text{w1}[\text{w2}[i][j]]. \text{The data type of the output is the same as that of } \text{w1}. \text{Values of } \text{w2} \text{ are taken as 1D integer indices into the } \text{w1} \text{ array. See also } \text{IndexSort}.

\text{waveChunks}(\text{w}) \quad \text{returns the number of chunks in the wave } \text{w}. \text{Added in Igor Pro 7.00.}

\text{waveLayers}(\text{w}) \quad \text{returns the number of layers in the wave } \text{w}. \text{Added in Igor Pro 7.00.}

\text{wavePoints}(\text{w}) \quad \text{returns the number of points in the wave } \text{w}. \text{Added in Igor Pro 7.00.}

\text{within}(\text{w},\text{low},\text{high}) \quad \text{returns an array of the same dimensions as } \text{w} \text{ with the value 1 where the corresponding element of } \text{w} \text{ is between low and high (low} <= \text{w}[i][j] < \text{high). Added in Igor Pro 7.00.}

All parameters must be real. It is an error to pass a NaN as either \text{low} or \text{high}. It is also an error if \text{low} >= \text{high}. If \text{w} contains NaNs, the corresponding outputs are 0.

\text{zapINFs}(\text{w}) \quad \text{returns a one-column wave containing the sequential data of } \text{w} \text{ with all INF elements removed. The input } \text{w} \text{ can be 1D or 2D but higher dimensions are not supported. Added in Igor Pro 9.00.}

\text{zapNaNs}(\text{w}) \quad \text{returns a one-column wave containing the sequential data of } \text{w} \text{ with all NaN elements removed. The input } \text{w} \text{ can be 1D or 2D but higher dimensions are not supported. Added in Igor Pro 9.00.}

\text{zeroMat}(r,c,nt) \quad \text{returns an } (r \times c) \text{ matrix of number type } nt \text{ where all entries are set to zero. See } \text{WaveType} \text{ for supported types. See also } \text{const} \text{ above. Added in Igor Pro 7.00.}
Trigonometric Transform Functions

**FCT(w, dir)**
Computes the fast, real to real cosine transform on 1D wave \( w \).
Added in Igor Pro 8.00.
The forward transform (\( dir=1 \)) is defined by:

\[
F(k) = \frac{1}{n} \left[ f(0) + f(n) \cos(k\pi) \right] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos\left(\frac{ik\pi}{n}\right), \quad k = 0,\ldots,n
\]

The number of intervals is \( n=numpnts(w)-1 \).
The inverse transform (\( dir=-1 \)) is defined by:

\[
f(i) = \frac{1}{2} \left[ F(0) + F(n) \cos(i\pi) \right] + \sum_{k=1}^{n-1} F(k) \cos\left(\frac{ik\pi}{n}\right), \quad i = 0,\ldots,n
\]

See Trigonometric Transforms on page V-576 below for more information.

**FST(w, dir)**
Computes the fast, real to real sine transform on 1D wave \( w \).
Added in Igor Pro 8.00.
The forward transform (\( dir=1 \)) is defined by:

\[
F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin\left(\frac{ik\pi}{n}\right), \quad k = 1,\ldots,n-1
\]

where \( n=numpnts(w) \).
The inverse transform (\( dir=-1 \)) is defined by:

\[
f(i) = \sum_{k=1}^{n-1} F(k) \sin\left(\frac{ik\pi}{n}\right), \quad i = 1,\ldots,n-1
\]

See Trigonometric Transforms on page V-576 below for more information.

**FSST(w, dir)**
Computes the fast, real to real staggered sine transform on 1D wave \( w \).
Added in Igor Pro 8.00.
The forward direction (\( dir=1 \)) is defined by:

\[
F(k) = \frac{1}{n} \sin\left(\frac{(2k-1)\pi}{2}\right) f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin\left(\frac{i(2k-1)\pi}{2n}\right), \quad k = 1,\ldots,n
\]

where \( n=numpnts(w) \).
The inverse transform (\( dir=-1 \)) is defined by:

\[
f(i) = \sum_{k=1}^{n} F(k) \sin\left(\frac{i(2k-1)\pi}{2n}\right), \quad i = 1,\ldots,n
\]

See Trigonometric Transforms on page V-576 below for more information.
MatrixOp

FSCT\((w, \text{dir})\) Computes the fast, real to real, staggered cosine transform on 1D wave \(w\).

Added in Igor Pro 8.00.

The forward direction \((\text{dir}=1)\) is defined by:

\[
F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{j=1}^{n-1} f(j) \cos\left(\frac{j\pi(2k+1)}{2n}\right), \quad k = 0, \ldots, n-1
\]

The inverse transform \((\text{dir}=-1)\) is defined by:

\[
f(i) = \sum_{k=0}^{n-1} F(k) \cos\left(\frac{(2k+1)i\pi}{2n}\right), \quad i = 0, \ldots, n-1
\]

See Trigonometric Transforms on page V-576 below for more information.

FSST2\((w, \text{dir})\) Computes the fast, real to real, staggered2 sine transform on 1D wave \(w\).

Added in Igor Pro 8.00.

The forward direction \((\text{dir}=1)\) is defined by:

\[
F(k) = \frac{2}{n} \sum_{i=1}^{n} f(i) \sin\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), \quad k = 1, \ldots, n
\]

The inverse transform \((\text{dir}=-1)\) is defined by:

\[
f(i) = \sum_{k=1}^{n} F(k) \cos\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), \quad i = 1, \ldots, n
\]

See Trigonometric Transforms on page V-576 below for more information.

FSCT2\((w, \text{dir})\) Computes the fast, real to real, staggered2 cosine transform on 1D wave \(w\).

Added in Igor Pro 8.00.

The forward direction \((\text{dir}=1)\) is defined by:

\[
F(k) = \frac{2}{n} \sum_{i=1}^{n} f(i) \cos\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), \quad k = 1, \ldots, n
\]

The inverse transform \((\text{dir}=-1)\) is defined by:

\[
f(i) = \sum_{k=1}^{n} F(k) \cos\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), \quad i = 1, \ldots, n
\]

See Trigonometric Transforms on page V-576 below for more information.
Functions Using Quaternions
These functions create and manipulate quaternion tokens or return quaternion results. They were added in Igor Pro 8.00. See MatrixOp Quaternion Data Tokens on page III-146 for background information on quaternions in MatrixOp.

\[ \text{quat}(\text{arg}) \]
Converts arg into a quaternion token.

\[ \text{arg} \]
can be:
- A scalar which is converted to a real quaternion
- A 1x3 or 3x1 wave which is converted to a pure imaginary quaternion
- The output from another quat call

Arithmetic on quaternion tokens obeys quaternion arithmetic rules.
\[ \text{arg} \]
must not be complex. The resulting quaternion token is not normalized by the quat function.
See MatrixOp Quaternion Data Tokens on page III-146 for details.

\[ \text{quatToMatrix}(\text{qIn}) \]
Converts qIn into a quaternion token, if not already a quaternion token, normalizes it, and returns the equivalent 4x4 homogeneous rotation matrix.

\[ \text{quatToAxis}(\text{qIn}) \]
Converts qIn into a quaternion token, if not already a quaternion token, normalizes it, and returns the equivalent axis of rotation and rotation angle. The result is a 4-element wave in which the first three elements define the rotation axis and the last element is the rotation angle in radians.

\[ \text{quatToEuler}(\text{qIn}, \text{mode}) \]
Converts qIn into a quaternion token, if not already a quaternion token, and returns a 3x1 wave containing equivalent Euler angles expressed in radians.

The returned Euler angles are are phi (rotation about the X axis), theta (rotation about the Y axis), and psi (rotation about the Z axis).

The \text{mode} parameter defines the rotation sequence. The supported modes are: 121, 123, 131, 132, 212, 213, 231, 232, 312, 313, 321 and 323. 1 designates the X axis, 2 the Y axis and 3 the Z axis. See, for example:
https://www.euclideanspace.com/maths/geometry/rotations/conversions/quaternionToEuler/quat_2_euler_paper_ver2-1.pdf

\[ \text{axisToQuat}(\text{ax}) \]
ax is a 4-element wave with the axis of rotation in the first 3 elements and the rotation angle in radians as the last element. Returns a 4-element wave containing the quaternion components representing this rotation.

\[ \text{slerp}(\text{qIn1, qIn2, frac}) \]
Performs spherical linear interpolation between quaternion qIn1 and quaternion qIn2. frac is a value between 0 and 1 representing the amount of desired rotation from qIn1 to qIn2.

The function returns a 4-element wave containing the quaternion components that represent the rotated quaternion. This is useful, for example, in animating a sequence of rotations.

Wave Parameters
MatrixOp was designed to work with 2D waves (matrices) but also works with 1D, 3D and 4D waves. A 1D wave is treated like a 1-column matrix. 3D and 4D waves are treated on a layer-by-layer basis, as if each layer were a matrix>
You can reference subsets of waves in expression. Only two types of subsets are supported: those that evaluation to a single element, which are treated as scalars, and those that evaluate to one or more layers. For example:

- `wave1d[a]` Scalar
- `wave2d[a][b]` Scalar
- `wave3d[a][b][c]` Scalar
- `wave3d[][][a]` Layer $a$ from 3D wave
- `wave3d[][a,b]` Layers $a$ through $b$ from 3D wave
- `wave3d[][a,b,c]` Layers $a$ through $b$ stepping by $c$ from 3D wave

You can pass waves of any dimensions as parameters to MatrixOp functions. For example:

```plaintext
Make/O/N=128 wave1d = x
MatrixOp/O outWave = powR(wave1d, 2)
```

MatrixOp does not allow using the same 3D wave on both sides of the assignment:

```plaintext
MatrixOp/O wave3D = wave3D + 3  // Not allowed
```

See MatrixOp Wave Data Tokens on page III-141 for further discussion.

**Flags**

- `/AT=allocationType`
  - `/AT` lets you control the method used to allocate memory in MatrixOP. It was added in Igor Pro 9.00.
  - Use `allocationType=0` for generic memory allocation.
  - Use `allocationType=1` for Intel scalable allocation.
  - Use `allocationType=2` for Intel scalable and aligned allocation.
  - By default MatrixOP uses scalable and aligned allocation.

- `/C`
  - Provides a complex wave reference for `destWave`. If omitted, MatrixOp creates a real wave reference for `destWave`. The wave reference allows you to refer to the output wave in a subsequent statement of a user-defined function.

- `/FREE`
  - Creates `destWave` as a free wave. Allowed only in functions and only if a simple name or wave reference structure field is specified.
  - Requires Igor Pro 6.1 or later. For advanced programmers only.

  See Free Waves on page IV-91 for more discussion.

- `/NTHR=n`
  - Sets the number of threads used to compute the results for 3D waves. Each thread computes the results for a single layer of the input.
  - By default (/NTHR omitted) the calculations are performed by the main thread only.
  - If $n=0$ the operation uses as many threads you have processors on your computer.
  - If $n>0$, $n$ specifies the number of threads to use. More threads may or may not improve performance.
MatrixOp

/NPRM Use /NPRM to restrict the automatic promotion of numeric data types in MatrixOp expressions.

By default, MatrixOp promotes numeric data types so that operations result in reasonable accuracy. In some situations you may want to keep the results as a particular data type even at the risk of truncation or overflow. If you include the /NPRM flag, MatrixOp creates the destination wave using the highest precision data type in the expression. For example, an expression A=B+C where B is 16-bit wave and C is an 8-bit wave results in a 16-bit wave A.

Unsigned number types can result only when all operands are unsigned.

/NPRM is ignored when data promotion is required. For example:

Make/B/U wave2
MatrixOp/O/NPRM wave1 = -wave2

You can use MatrixOp functions such as int8, int16, etc., to precisely control the number type of any token.

/NV=mode Controls use of Intel MKL vectorized functions. /NV was added in Igor Pro 9.00.

By default, mode=1, which uses vectorized functions where possible.

Set mode to 0 to request non-vectorized execution. This may improve speed when MatrixOP is called in a preemptive thread by preventing spawning additional threads.

/O Overwrites destWave if it already exists.

/P=printMode Controls printing of the result of the MatrixOp evaluation. /P was added in Igor Pro 8.00.

/P is ignored if MatrixOp is not running in the main thread.

printMode is a value between 0 and 2:

0: No printing is done (default).
1: Prints the result from evaluating expression in layer-by-layer order to the history area of the command window and stores the result in the destination wave.
2: Prints the result from evaluating expression in layer-by-layer order to the history area of the command window but does create or store the resulting values in the destination wave. If the destination wave may already exist, you must include the /O flag, even though the destination wave is not changed by the operation.

Use /P=1 if you want MatrixOp to work normally and then to print the destination wave.

Use /P=2 if you want MatrixOp to print its result without creating or affecting any waves.

Values are printed sequentially using 16-digit precision. Output is not formatted to represent rows and columns.

When the operation’s result is a 3D or 4D wave, the results are printed on a layer-by-layer basis.

See MatrixOp Printing Examples on page V-577 below.

/S Preserves the dimension scaling, units and wave note of a pre-existing destination wave in a MatrixOp/O command.

/T=k Displays results in a table. k specifies the behavior when the user attempts to close it.

0: Normal with dialog (default).
1: Kills with no dialog.
2: Disables killing.

Details
MatrixOp has the general form:

MatrixOp [flags] destWave = expression
MatrixOp

destWave specifies the wave created by MatrixOp or overwritten by MatrixOp/O.

From the command line, destWave can be a simple wave name, a partial data folder path or a full data folder path. In a user-defined function it can be a simple wave name or, if /O is present, a wave reference pointing to an existing wave.

expression is a mathematical expression that consists of one or more data tokens combined with the built-in MatrixOp functions and MatrixOp operators listed above. MatrixOp does not support the p, q, r, s, or x, y, z, t symbols that are used in waveform assignment statements.

Data tokens include waves, variables and literal numbers.

You can use any combination of data types for operands. In particular, you can mix real and complex types in expression. MatrixOp determines data types of inputs and the appropriate output data type at runtime without regard to any type declaration such as Wave/C.

See Using MatrixOp on page III-140 for more information.

Trigonometric Transforms

The trigonometric transform functions were added in Igor Pro 8.00.

FST, FCT, FSST, FSCT, FSST2 and FSCT2 are implemented using INTEL MKL library functions. The transforms may automatically execute in multiple threads.

In MatrixOP’s implementation, all input and output arrays are zero based. This is illustrated by the following example for the staggered2 cosine:

Function DoStaggered2Cosine(inWave)
    Wave inWave
    Variable n = dimsize(inWave,0)
    Make/O/N=(n)/D outStaggered2CosTransform=0
    Variable i, k, theSum, frontFactor=2/n
    for(k=1; k<=n; k+=1)
        theSum=0
        for(i=1; i<=n; i+=1)
            theSum += inWave[i-1] * cos((2*k-1) * (2*i-1) * pi/(4*n))
        endfor
        outStaggered2CosTransform[k-1] = frontFactor * theSum
    endfor
End

Examples

In addition to these examples, see MatrixOp Optimization Examples on page III-148.

The following matrices are used in these examples:

Make/O/N=(3,3) r1=x, r2=y

Matrix addition and matrix multiplication by a scalar:

MatrixOp/O outWave = r1+r2-3*r1

Using the matrix Identity function:

MatrixOp/O outWave = Identity(3) x r1

Create a persisting identity matrix for another calculation:

MatrixOp/O id4 = Identity(4)

Using the Trace function:

MatrixOp/O outWave = (Trace(r1)*identity(3) x r1)-3*r1

Using matrix inverse function Inv() with matrix multiplication:

MatrixOp/O outWave = Inv(r2) x r2

Using the determinant function Det():

MatrixOp/O outWave = Det(r1)+Det(r2)

Using the Transpose postfix operator:

MatrixOp/O outWave = r1^t+(r2-r1)^t-r2^t

Using a mix of real and complex data:
Variable/C complexVar = cmplx(1,2)
MatrixOp/O outWave = complexVar*r2 - Cmplx(2,4)*r1

Hermitian transpose operator:
MatrixOp/O outWave = Trace(complexVar*r2)^h -Trace(cmplx(2,4)*r1)^h

In-place operation and conversion to complex:
MatrixOp/O r1 = r1*cmplx(1,2)

Image filtering using 2D spatial filter filterWave:
MatrixOp/O filteredImage=IFFT(FFT(srcImage,2)*filterWave,3)

Positive shift:
Make/O w={0,1,2,3,4,5,6}
MatrixOp/O w=shiftVector(w,2,77)
Print w
  // w[0]= {77,77,0,1,2,3,4}

Negative shift:
Make/O w={0,1,2,3,4,5,6}
MatrixOp/O w=shiftVector(w,(-2),77)
Print w
  // w[0]= {2,3,4,5,6,77,77}

// Using KronProd function to generate Hadamard matrices
Function HadamardMatrix(int N) // N must be >= 2
Make/FREE/N=(2,2) H2={1,1},{1,-1}
Duplicate/FREE H2, tmp
int i
for(i=2; i<N; i+=1)
  MatrixOP/O/FREE tmp=KronProd(H2,tmp)
endfor
Duplicate/O tmp, Hadamard
End

// bitReverseCol
Make/N=8 index = p
MatrixOP/O/P=1 out = bitReverseCol(index,0,0) // Direct binary reversal
  // Prints: out = {0,4,2,6,1,5,3,7}
MatrixOP/O/P=1 out = bitReverseCol(index,0,1) // Hadamard order
  // Prints: out = {0,4,6,2,3,7,5,1}
MatrixOP/O/P=1 out = bitReverseCol(index,0,2) // Dyadic/Paley/Gray order
  // Prints: out = {0,1,3,2,6,7,5,4}

MatrixOp Printing Examples
// Print a single-valued result
Make/O/N=(10,5) m2D=(p+1)*(q+1)
MatrixOP/O/P=1 aa=sum(m2D)
  aa={825}

// Print a real 2D result
Make/O/N=(1,4) ddd=enoise(3)
MatrixOp/O/P=1 aa=ddd
  aa={-2.273916482925415,-2.327789783477783,1.286988377571106,-0.8658701777458191}

// Print higher-dimension result layer-by-layer
Make/O/N=(3,4,3) ddd=ez+1
MatrixOP/O/P=1 aa=mean(ddd)
  aa={1} // Each layer results in a 1x1 value
  aa={2}
  aa={3}

FastOp

MatrixRank

\texttt{matrixRank(matrixWaveA [, conditionNumberA])}

The matrixRank function returns the rank of \texttt{matrixWaveA} subject to the specified condition number. The matrix is not considered to have full rank if its condition number exceeds the specified \texttt{conditionNumberA}.

If the optional parameter \texttt{conditionNumberA} is not specified, Igor Pro uses the value \(10^{20}\).

\texttt{matrixRank} supports real and complex single precision and double precision numeric wave data types. The value of \texttt{conditionNumberA} should be large enough but taking into account the accuracy of the numerical representation given the numeric data type.

If there are any errors the function returns NaN.

See Also
Matrix Math Operations on page III-138 for more about Igor’s matrix routines.

MatrixReverseBalance

\texttt{MatrixReverseBalance [flags] scaleWave, eigenvectorsWave}

\texttt{MatrixReverseBalance} inverse-transforms left or right eigenvectors contained in \texttt{eigenvectorsWave} that were computed for a matrix that was balanced using \texttt{MatrixBalance}. The results are the eigenvectors of the pre-balanced matrix. \texttt{scaleWave} is \texttt{W_scale} as returned by \texttt{MatrixReverseBalance}.

\texttt{MatrixBalance} was added in Igor Pro 9.00.

Parameters
\texttt{eigenvectorsWave} must be single-precision or double-precision floating point, real or complex, and must contain no NaNs. \texttt{MatrixReverseBalance} returns an error if these conditions are not met.

Flags

\texttt{/DSTM=dest} Specifies the destination wave for the inverse-transformed eigenvectors. If you omit \texttt{/DSTM}, the output is saved in M\_RBEigenvectors in the current data folder.

\texttt{/FREE} Create free destination wave when it is specified via \texttt{/DSTM}.

\texttt{/J=job} \texttt{job} is the type of backward transformation required. It is one of the following letters:

\texttt{N} \texttt{srcWave} is not permuted or scaled.
\texttt{P} \texttt{srcWave} is permuted but not scaled.
\texttt{S} \texttt{srcWave} is scaled but not permuted. The scaling applies a diagonal similarity transformation to make the norms of the various columns close to each other.
\texttt{B} \texttt{srcWave} is both scaled and permuted (default).

You should use the same value for \texttt{job} as was used in the original balancing.

\texttt{/LH={low,high}} Specifies the zero-based low and high indices that were returned by \texttt{MatrixBalance} in \texttt{V_min} and \texttt{V_max} respectively.

\texttt{/Z} Suppresses error reporting. If you use \texttt{/Z}, check the \texttt{V\_Flag} output variable to see if the operation succeeded.
Details
Matrix balancing is usually called internally by LAPACK routines when there is large variation in the magnitude of matrix elements. Following matrix balancing the computed eigenvalues are expected to be more accurate but the resulting eigenvectors are not the correct eigenvectors of the original pre-balanced matrix. MatrixReverseBalance is then applied to the balanced eigenvectors in order to obtain the eigenvectors of the original matrix.

The operation uses outputs from MatrixBalance as inputs. Pass the W_scale output from MatrixBalance as the scaleWave parameter. Pass the V_min and V_max outputs from MatrixBalance as the /LH low and high parameters. See MatrixBalance for an example.

Output Variables

V_Flag Set to zero when the operation succeeds. Otherwise, when V_flag is positive the value is a standard Igor error code. When V_flag is negative it is an indication of an invalid input parameter.

References
The operation uses the following LAPACK routines: sgebak, dgebak, cgebak, and zgebak.

See Also
MatrixBalance

MatrixSchur

MatrixSchur [/Z] srcMatrix
The MatrixSchur operation computes for an NxN nonsymmetric srcMatrix, the eigenvalues, the real Schur form A and the matrix of Schur vectors V.

The Schur factorization has the form: S = V x A x (V^T), where V^T is the transpose (use V^H if S is complex) and x denotes matrix multiplication.

Flags

/Z No error reporting.

Details
The operation creates:

M_A Upper triangular matrix containing the Schur form A.
M_V Unitary matrix containing the orthogonal matrix V of the Schur vectors.
W_REigenValues Waves containing the real and imaginary parts of the eigenvalues when srcMatrix is a real wave. If srcMatrix is complex, the eigenvalues are stored in W_eigenValues.
W_IEigenValues

The variable V_flag is set to 0 when there is no error; otherwise it contains the LAPACK error code.

Examples
You can test this operation for an N-by-N source matrix:
Make/D/C/N=(5,5) M_S=complex(enoise(1),enoise(1))
MatrixSchur M_S
MatrixOp/O unitary=(M_V^h) x M_V // Check unitary
MatrixOp/O diff=abs(M_S-M_V x M_A x (M_V^H)) // Check decomposition

See Also
Matrix Math Operations on page III-138 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.

MatrixSolve

MatrixSolve method, matrixA, vectorB
The MatrixSolve operation was superseded by MatrixLLS and is included for backward compatibility only. Used to solve matrix equation Ax=b using the method of your choice. Choices for method are:
**MatrixSparse**

<table>
<thead>
<tr>
<th>method</th>
<th>Solution Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>GJ</td>
<td>Gauss Jordan.</td>
</tr>
<tr>
<td>LU</td>
<td>LU decomposition.</td>
</tr>
<tr>
<td>SV</td>
<td>Singular Value decomposition.</td>
</tr>
</tbody>
</table>

**Details**

The array b can be a matrix containing a number of b vectors and the output matrix M_x will contain a corresponding set of solution vectors.

V_flag is set to zero if success, 1 if singular matrix using GJ or LU and 1 if SV fails to converge.

For normal problems you should use LU. GJ is provided only for completeness and has no practical use.

When using SV, singular values smaller than $10^{-6}$ times the largest singular value are set to zero before back substitution.

Generates an error if the dimensions of the input matrices are not appropriate.

**See Also**

The MatrixLLS operation. Matrix Math Operations on page III-138 for more about Igor’s matrix routines.

## MatrixSparse

**MatrixSparse** [flags] keyword=value

The MatrixSparse operation provides support for basic matrix operations on sparse matrices. The MatrixSparse operation was added in Igor Pro 9.00.

The following sections use terms and concepts explained under Sparse Matrices. You will need to understand those terms and concepts to understand the following material.

**Flags**

/LM     Limited memory hint. Specifies that the operation can allocate limited memory proportional to vector size. If this flag is omitted, the operation allocates memory aggressively up to the size of the sparse matrix.

/Q      Quiet - do not print diagnostic information to the history area.

/Z      Errors are not fatal and do not abort procedure execution. Your procedure can inspect the V_flag variable to see if the operation succeeded. V_flag will be zero if it succeeded or nonzero if it failed.

**Keywords**

alpha=value Specifies the real part of the alpha value for the MM, MV, and TRSV operations. The default value is 1.

alphai=value Specifies the imaginary part of the alpha value for the MM, MV, and TRSV operations on complex matrices. The default value is 0.

alpha should be specified only when operating on complex matrices.

beta=value Specifies the real part of the beta value for the MM and MV operations. The default value is 0.

betai=value Specifies the imaginary part of the beta value for the MM and MV operations. The default value is 0.

beta should be specified only when operating on complex matrices.

colsA=nCols Specifies the number of columns of the sparse matrix A.

colsA is a required keyword for all MatrixSparse commands even in the rare cases where neither cooA, cscA, nor csrA are used.
colsG=nCols  
Specifies the number of columns of the sparse matrix G.  
(colsG is a required keyword for operations involving sparse matrix G.)

cooA={valuesWave, rowsWave, colsWave}

Specifies sparse matrix A in COO format using three 1D waves. See Sparse Matrix Formats on page III-151 for background information on cooA format.

The COO format is used only for conversion operations, not for math operations which always use CSR format.

(valuesWave is an array of length nnz (number of non-zero values) containing the non-zero values of A. The array must be single or double precision real or complex and must not contain any NaNs or INFs.  
(rowsWave and colsWave are 64-bit integer 1D waves created with Make/L that contain nnz row and column indices respectively.  
When using cooA, you must also specify the rowsA and colsA keywords.

cscA={valuesWave, rowsWave, ptrWave}

Specifies sparse matrix A in CSC format using three 1D waves. See Sparse Matrix Formats on page III-151 for background information on cscA format.

The CSC format is used only for conversion operations, not for math operations which always use CSR format.

(valuesWave is an array of length nnz (number of non-zero values) containing the non-zero values of A. The array must be single or double precision real or complex and must not contain any NaNs or INFs.  
(rowsWave and ptrWave are 64-bit integer 1D waves created with Make/L.  
(rowsWave consists of nnz entries that specify the zero-based row index of each entry in valuesWave.  
(ptrWave contains nCols or nCols+1 entries the first of which must be zero. ptrWave[i] gives the index in valuesWave of the first non-zero value in column i. The optional longer version of ptrWave stores nnz in the last wave point.  
When using cscA, you must also specify the rowsA and colsA keywords.

csrA={valuesWave, colsWave, ptrWave}

Specifies sparse matrix A in CSR format using three 1D waves. See Sparse Matrix Formats on page III-151 for background information on csrA format.

The CSR format is used for conversion operations and for math operations.

(valuesWave is an array of length nnz (number of non-zero values) containing the non-zero values of A. The array must be single or double precision real or complex and must not contain any NaNs or INFs.  
colsWave and ptrWave are 64-bit integer 1D waves created with Make/L.  
colsWave consists of nnz entries that specify the zero-based column index of each entry in valuesWave.  
(ptrWave contains nRows or nRows+1 entries the first of which must be zero. ptrWave[i] gives the index in valuesWave of the first non-zero value in row i. The optional longer version of ptrWave stores nnz in the last wave point.  
When using csrA, you must also specify the rowsA and colsA keywords.

cooG={valuesWave, rowsWave, colsWave}

Similar to cooA but applies to sparse matrix G.

cscG={valuesWave, rowsWave, ptrWave}

Similar to cscA but applies to sparse matrix G.
MatrixSparse

csrG={valuesWave, colsWave, ptrWave}

Similar to csrA but applies to sparse matrix G.

matrixB=wb

Designates the 2D wave wb as matrix B for the MM operation.
The wave wb must be of the same data type as sparse matrix A and must not contain INFs or NaNs.

matrixC=wc

Designates the 2D wave wc as matrix C for the MM operation.
The wave wc must be of the same data type as sparse matrix A and must not contain INFs or NaNs.

opA=opName

Specifies a transformation that is applied to sparse matrix A. opName is a single letter:
T: Transpose
H: Hermitian
N: No transformation (default)
See MatrixSparse Transformations on page III-156 for details.

opG=opName

Specifies a transformation that is applied to sparse matrix G. opName is a single letter:
T: Transpose
H: Hermitian
N: No transformation (default)
See MatrixSparse Transformations on page III-156 for details.

operation=opN

Specifies the operation name. This is a required keyword.
opN is one of the following:
ADD Adds sparse matrices. See MatrixSparse ADD on page III-157 for details.
MM Computes the product of a sparse matrix and a dense matrix. See MatrixSparse MM on page III-157 for details.
MV Computes the product of a sparse matrix and a vector. See MatrixSparse MV on page III-158 for details.
SMSM Computes the product of two sparse matrices. See MatrixSparse SMSM on page III-158 for details.
TOCOO Creates a sparse matrix in COO format from a sparse matrix or dense matrix. See MatrixSparse TOCOO on page III-159 for details.
TOCSC Creates a sparse matrix in CSC format from a sparse matrix or dense matrix. See MatrixSparse TOCSC on page III-159 for details.
TOCSR Creates a sparse matrix in CSR format from a sparse matrix or dense matrix. See MatrixSparse TOCSR on page III-160 for details.
TODENSE Creates a dense matrix from a sparse matrix. See MatrixSparse TODENSE on page III-160 for details.
TRSV Solves a system of linear equations for a triangular sparse matrix. See MatrixSparse TRSV on page III-161 for details.

rowsA=nRows

Specifies the number of rows of the sparse matrix A.
rowsA is a required keyword for all MatrixSparse commands even in the rare cases where neither cooA, cscA, nor csrA are used.

rowsG=nRows

Specifies the number of rows of the sparse matrix G.
rowsG is a required keyword for operations involving sparse matrix G.
MatrixSVBkSub

**sparseMatrixType=**\{smType, smMode, smDiag\}

Provides optional information to describe both sparse matrix A and sparse matrix G. All of the parameters are keywords.

- **smType**: GENERAL, SYMMETRIC, HERMITIAN, TRIANGULAR, DIAGONAL, BLOCK_TRIANGULAR, or BLOCK_DIAGONAL.
- **smMode**: LOWER or UPPER.
- **smDiag**: DIAG or NON_DIAG.

See [Optional Sparse Matrix Information](#) on page III-156 for details.

**vectorX=**\{wx\}

Designates the 1D wave *wx* as vector X for the MV and TRSV operations.

The wave *wx* must be of the same data type as the sparse matrix data and it must not contain INFs or NaNs.

**vectorY=**\{wy\}

Designates the 1D wave *wy* as vector Y for the MV operation.

The wave *wy* must be of the same data type as the sparse matrix data and it must not contain any INFs or NaNs.

**Details**

MatrixSparse supports data waves with single-precision and double-precision floating point real and complex data types. See [MatrixSparse Operation Data Type](#) on page III-155 for details.

Index waves must be signed 64-bit integer. See [MatrixSparse Index Data Type](#) on page III-156 for details.

MatrixSparse does not support waves containing NaNs or INFs.

MatrixSparse math operations (ADD, MV, MM, SMSM, TRSV) require that input sparse matrices be in CSR format. The math operations that return sparse matrices (ADD, SMSM) create output sparse matrices in CSR format.

The conversion operations (TOCOO, TOCSC, TOCSR, TODENSE) accept inputs in COO, CSC, CSR, or dense formats.

**Output Variables**

MatrixSparse sets these automatically created variables:

- **V_flag**
  
  Set to 0 if the operation succeeded or to a non-zero error code.

**Examples**

You can find examples using MatrixSparse under [MatrixSparse Operations](#) on page III-156.

**See Also**

- [Sparse Matrices](#) on page III-151 for background information about Igor’s sparse matrix support.
- [MatrixSparse Operations](#) on page III-156 for details on each supported operation and examples.

**MatrixSVBkSub**

**MatrixSVBkSub** *matrixU, vectorW, matrixV, vectorB*

The MatrixSVBkSub operation does back substitution for SV decomposition.

**Details**

Used to solve matrix equation \(Ax=b\) after you have performed an SV decomposition.

Feed this routine the \(M_U, W_W\) and \(M_V\) waves from [MatrixSVD](#) along with your right-hand-side vector \(b\). The solution vector \(x\) is returned as \(M_x\).

The array \(b\) can be a matrix containing a number of \(b\) vectors and the \(M_x\) will contain a corresponding set of solution vectors.

Generates an error if the dimensions of the input matrices are not appropriate.
MatrixSVD

See Also

Matrix Math Operations on page III-138 for more about Igor’s matrix routines.

MatrixSVD

MatrixSVD [flags] matrixWave

The MatrixSVD operation uses the singular value decomposition algorithm to decompose an MxN matrixWave into a product of three matrices. The default decomposition is into MxM wave M_U, min(M,N) wave W_W and NxN wave M_VT.

Flags

/B
Use this flag for backwards compatibility with Igor Pro 3. This option applies only to real valued input waves. Note that no other flag can be combined with /B. Here the decomposition is such that:

\[ U^*W^*V^T = matrixWave \]

U: MxN column-orthonormal matrix.
W: NxN diagonal matrix of positive singular values.
V: NxN orthonormal matrix.

/DACA
Replaces the standard LAPACK algorithm with one that is based on a divide and conquer approach. For a typical 1000x1000 matrix this provides a 6x speed improvement.

Added in Igor Pro 7.00.

/INVW
Saves the inverse of the elements in W_W. The results are then stored in wave W_InvW.

/O
Overwrites matrixWave with the first columns of U. Use this flag to if you need to conserve memory. See also related settings of /U and /V.

/PART = nVals
Performs a partial SVD computing only nVals singular values (stored in W_W) and the associated vectors in the matrix M_U and M_V. If you use this flag the operation ignores all other flags except /PDEL. The partial SVD is computed using the Power method of Nash and Shlien.

The /PART flag was added in Igor Pro 7.00.

/PDEL = del
Sets the convergence threshold which defaults to 1e-6. Larger positive values result in faster execution but may lead to less accurate results.

The /PDEL flag was added in Igor Pro 7.00.

/U = UMatrixOptions
UMatrixOptions can have the following values:

0: All columns of U are returned in the wave M_U (default).
1: The first min(m,n) columns of U are returned in the wave M_U.
2: The first min(m,n) columns of U overwrite matrixWave (/O must be specified).
3: No columns of U are computed.

/V = VMatrixOptions
VMatrixOptions can have the following values:

0: All rows of V^T are returned in the wave M_VT (default).
1: The first min(m,n) rows of V^T are returned in the wave M_VT.
2: The first min(m,n) rows of V^T are overwritten on matrixWave (/O must be specified).
3: No rows of V^T are computed.

/Z
No error reporting.
Details
The singular value decomposition is computed using LAPACK routines. The diagonal elements of matrix W are returned as a 1D wave named W_W. If /B is used W_W will have N elements. Otherwise the number of elements in W_W is min(M,N).

The matrix V is returned in a matrix wave named M_V if /B is used otherwise the transpose V^T is returned in the wave M_VT.

All output objects are created in the current data folder.

The variable V_flag is set to zero if the operation succeeds. It is set to 1 if the algorithm fails to converge.

The variable V_SVConditionNumber is set to the condition number of the input matrix. The condition number is the ratio of the largest singular value to the smallest.

Example
Make/O/D/N=(10,20) A=gnoise(10)
MatrixSVD A
MatrixOp/O diff=abs(A-(M_U x DiagRC(W_W,10,20) x M_VT))
Print sum(diff,-inf,inf)

References

See Also
The MatrixOp operation for more efficient matrix operations.

Matrix Math Operations on page III-138 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.

MatrixTrace
matrixTrace(dataMatrix)
The matrixTrace function calculates the trace (sum of diagonal elements) of a square matrix. dataMatrix can be of any numeric data type.

If the matrix is complex, it returns the sum of the magnitudes of the diagonal elements.

See Also
Matrix Math Operations on page III-138 for more about Igor’s matrix routines.

MatrixTranspose
MatrixTranspose [/H] matrix
The MatrixTranspose operation Swaps rows and columns in matrix.

Does not take complex conjugate if data are complex. You can do that as a follow-on step.

Swaps row and column labels, units and scaling.

This works with text as well as numeric waves. If the matrix has zero data points, it just swaps the row and column scaling.

Flags
/H Compiles the Hermitian conjugate of a complex wave.

See Also
The MatrixOp operation for more efficient matrix operations.

Matrix Math Operations on page III-138 for more about Igor’s matrix routines.
The max function returns the greatest value of num1, num2, ... num200. If any parameter is NaN, the result is NaN.

Details
In Igor7 or later, you can pass up to 200 parameters. Previously max was limited to two parameters.

See Also
min, limit, WaveMin, WaveMax, WaveMinAndMax

mean
mean(waveName [, x1, x2])
The mean function returns the arithmetic mean of the wave for points from x=x1 to x=x2.

Details
If x1 and x2 are not specified, they default to -∞ and +∞, respectively.
The wave values from x1 to x2 are summed, and the result divided by the number of points in the range.
The X scaling of the wave is used only to locate the points nearest to x=x1 and x=x2. To use point indexing, replace x1 with pnt2x(waveName, pointNumber1), and a similar expression for x2.
If the points nearest to x1 or x2 are not within the point range of 0 to numpnts(waveName)-1, mean limits them to the nearest of point 0 or point numpnts(waveName)-1.
If any values in the point range are NaN, mean returns NaN.
The function returns NaN if the input wave has zero points.
Unlike the area function, reversing the order of x1 and x2 does not change the sign of the returned value.
The mean function is not multidimensional aware. See Chapter II-6, Multidimensional Waves, particularly Chapter II-6, Analysis on Multidimensional Waves for details.

Examples
Make/O/N=100 data; SetScale/I x 0,Pi,data
data=sin(x)
Print mean(data,0,Pi) // the entire point range, and no more
Print mean(data) // same as -infinity to +infinity
Print mean(data,Inf,-Inf) // +infinity to -infinity

The following is printed to the history area:
Print mean(data,0,Pi) // the entire point range, and no more
0.630201
Print mean(data) // same as -infinity to +infinity

The figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the Details section of the faverage function.

median
median(waveName [, x1, x2])
The median function returns the median value of the wave for points from x=x1 to x=x2.
The median function was added in Igor Pro 7.00.

Details
If you omit x1 and x2, they default to -INF and +INF, respectively.
The X scaling of the wave is used only to locate the points nearest to \( x=x_1 \) and \( x=x_2 \). To use point indexing, replace \( x_1 \) with “pnt2x(waveName,pointNumber1 )”, and a similar expression for \( x_2 \).

If the points nearest to \( x_1 \) or \( x_2 \) are outside the point range of 0 to numpnts(waveName)-1, median limits them to the nearest of point 0 or point numpnts(waveName)-1.

If the wave contains NaNs they are skipped.

The function returns NaN if the input wave has zero non-NaN points.

MeasureStyledText

MeasureStyledText  [/W=winName /A=axisName /B=baselineMode /F=fontName
 /SIZE=fontSize /STYL=fontStyle]  [styledTextStr]

The MeasureStyledText operation takes as input a string optionally containing style codes such as are used in graph annotations and the DrawText operation. It sets various variables with information about the dimensions of the string.

In Igor Pro 9.00, the styledTextStr parameter was made optional, the /B flag was added, and several output variables (all but V_width and V_height) were added.

Flags

/W=winName  Takes default text information from the window winName.
If you omit /W, MeasureStyledText works on the top graph window.

/A=axisName  Takes default text information from the axis named axisName in the top graph or in the window specified by /W.

/B=baselineMode  Selects which baseline offset is returned in V_baseline if the text contains multiple lines (separated by carriage returns).
If you omit /B or specify /B=0, V_baseline is set to the offset to the last line of the text.
If you specify /B=1, V_baseline is set to the offset to the first line of the text.
The /B flag was added in Igor Pro 9.00.

/F=fontNameStr  The name of the default font.
In Igor Pro 9.00 and later, /F=“default” and /F=”” are the same as omitting /F in which case the default font is defined by /W, /A, or by the overall default font specified by the DefaultFont operation.

/SIZE=size  Sets default font size.

/STYL=fontStyle  Sets default font style:
Bit 0:  Bold
Bit 1:  Italic
Bit 2:  Underline
Bit 4:  Strikethrough

/STYLE=0 specifies plain text.
See Setting Bit Parameters on page IV-12 for details about bit settings.

Parameters

styledTextStr  is the styled text to be measured.
In Igor Pro 9.00 and later, styledTextStr  is an optional parameter. Previously it was required.
If you include styledTextStr, the default font and styled text output variables are set.
If you omit styledTextStr, only the default font output variables are set.
V-588

MeasureStyledText

See Default Font Output Variables and Styled Text Output Variables below.

styledTextStr can contain escape codes to set the font, size, style, color and other properties. See Annotation Escape Codes on page III-53 for details. The text may contain multiple lines separated with carriage returns (“\r”).

Details

In the absence of formatting codes within the text that set the font, font size and font style, some mechanism must be provided that sets them.

The /W flag tells MeasureStyledText to get the default font name and font size from the specified window. If /W is omitted, defaults come from the top graph window.

The /A flag specifies that the default font name and font size come from the specified axis in the graph window specified by /W or in the top graph if /W is omitted.

The /F, /SIZE and /STYL flags set defaults that override any defaults from a window or axis. If you don't use any flags, the defaults are Igor's overall defaults.

If you omit all flags, the font specified by the DefaultFont operation is used, the default font size is 12 points, and the style is plain.

Default Font Output Variables

In the descriptions of these variables, "default font" refers to the font, size, and style defined by /W, /A, /SIZE, and /STYLE, and not any escape codes in styledTextStr.

MeasureStyledText returns information about the default font via the following output variables:

- **S_font** The name of the default font (before escape codes in styledTextStr take effect). If a substitute font would be used, the name of the substitute font is returned.
- **V_ascent** Height above the baseline of the default font. This will include some blank space above even the tallest characters.
- **V_descent** Height below the baseline of the default font.
- **V_fontSize** The default font size in points.
- **V_fontStyle** The default font style.
- **V_subscriptExtraHeight** Extra height needed to accommodate any subscript when using the default font.
- **V_superscriptExtraHeight** Extra height needed to accommodate any superscript when using the default font.

Styled Text Output Variables

The MeasureStyledText operation returns information in the following variables:

- **V_width** The width in points of the text.
- **V_height** The height in points of the text.
- **V_baseline** The offset to the baseline of the styled text in points, as measured from the bottom of the text.

  If you omit /B or specify /B=0, this is is the offset to the last line's baseline.

  If you specify /B=1, this is is the offset to the first line's baseline.

MeasureStyledText Diagrams

These diagrams illustrate the meanings of the various output variables:
Example
See the Example section of the documentation for MeasureStyledText in the Igor Reference help file.

See Also
Annotation Escape Codes on page III-53 for a list of text formatting codes.

DefaultFont

Menu

Menu menuNameStr [, hideable, dynamic, contextualmenu]
The Menu keyword introduces a menu definition. You can use this to create your own menu, or to add
items to a built-in Igor menu.
Use the optional hideable keyword to make the menu hideable using HidelgorMenus.
Use the optional dynamic keyword to cause Igor to re-evaluate the menu definition when the menu is used.
This is helpful when the menu item text is provided by a user-defined function. See Dynamic Menu Items
on page IV-129.
Use the optional contextualmenu keyword for menus invoked by PopupContextualMenu/N.
See Chapter IV-5, User-Defined Menus for further information.

min

min(num1, num2 [, num3, ..., num200])
The min function returns the least value of num1, num2, ..., num200.
If any parameter is NaN, the result is NaN.

Details
In Igor7 or later, you can pass up to 200 parameters. Previously min was limited to two parameters.

See Also
max, limit, WaveMin, WaveMax, WaveMinAndMax

MLLoadWave

MLLoadWave [flags] fileNameStr
The MLLoadWave operation loads data from the named Matlab MAT file into single 1D waves (vectors),
multidimensional waves (matrices), numeric variables or string variables.
For background information, including configuration instructions, see Loading Matlab MAT Files on page
II-163.

Parameters
The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor
symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative
to the folder associated with pathName, or the name of a file in the folder associated with pathName. If
LoadWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog
allowing you to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming
the path.
If fileNameStr is omitted or is "" or the /I flag is used, MLLoadWave displays an Open File dialog in which
you locate the file to be loaded.
### Flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/A[=name]</code></td>
<td>Assign wave names using &quot;wave&quot; or <code>name</code>, if present, as the name or base name. Skips names already in use.</td>
</tr>
<tr>
<td><code>/B</code></td>
<td>This flag is obsolete and is ignored. Previously it was required to tell MLLoadWave the byte order of the data in the file. MLLoadWave now determines the byte order automatically.</td>
</tr>
<tr>
<td><code>/C</code></td>
<td>Loads columns from a Matlab matrix into an Igor 1D wave. Use <code>/R</code> to load rows.</td>
</tr>
<tr>
<td><code>/E</code></td>
<td>Skips empty Matlab matrices.</td>
</tr>
<tr>
<td><code>/G</code></td>
<td>Tells Igor to make numeric and string variables global when called from a macro. When called from a user-defined function or from the command line, variables are always created as globals.</td>
</tr>
<tr>
<td><code>/I</code></td>
<td>Interactive. Displays the Open File dialog to get the path to the file.</td>
</tr>
</tbody>
</table>
| `/M=m` | `m=1`: Loads an entire Matlab matrix into an Igor 1D wave. This is the default if you omit `/M`.  
`m=2`: Loads an entire Matlab matrix into an Igor multidimensional wave.  
`m=3`: Loads an entire Matlab matrix into a transposed Igor multidimensional wave.  
`/M` by itself is equivalent to `/M=1`. |
| `/N[=name]` | Assign wave names using "wave" or `name`, if present, as the name or base name. Overwrites existing waves if the name is already in use. |
| `/O` | Overwrites existing waves and variables in case of a name conflict. If `/O` is omitted, MLLoadWave chooses names that don’t conflict with existing objects. |
| `/P=pathName` | Specifies the folder to look in for the specified file or folder. `pathName` is the name of an existing Igor symbolic path. |
| `/Q` | Be quiet. Suppresses normal diagnostic messages. |
| `/R` | Loads rows from a Matlab matrix into an Igor 1D wave. Use `/C` to load columns. |
| `/S=s` | Controls how Matlab string data is loaded:  
`s=1` Skips Matlab string matrices.  
`s=2` Loads Matlab string matrices into Igor string variables. This is the default if `/S` is omitted.  
`s=3` Loads Matlab string matrices into Igor text waves.  
`/S` by itself is equivalent to `/S=1`. |
| `/T` | Displays the loaded waves in a new table. |
| `/V` | Skips Matlab numeric variables (numeric matrices with one element). |

Starting with Igor Pro 8.00, after loading a matrix that results in an Mx1 2D wave, MLLoadWave automatically redimensions the wave as an M-row 1D wave.
MLLoadWave

/Y=y  Specifies the number type of the numeric waves to be created. The allowed codes for y are:
2:  Single-precision floating point
4:  Double-precision floating point
32: 32-bit signed integer
16: 16-bit signed integer
8:  8-bit signed integer
96: 32-bit signed integer
80: 16-bit signed integer
72:  8-bit signed integer

/Z  Interactive load. Displays a dialog presenting options for each Matlab matrix in the file.

MLLoadWave Wave Naming
If neither /A, /A[name], /N, or N[name] is used then the waves names are taken from the matrix name, as stored in the Matlab file.

When loading 1D waves, the /N flag instructs MLLoadWave to automatically name new waves "wave" (or baseName if /N=baseName is used) plus a number. The number starts from zero and increments by one for each wave loaded from the file. When loading multidimensional waves, name is used without an appended number.

The /A flag is like /N except that MLLoadWave skips names already in use.

If you specify /M=2 (load matrix into matrix) or /M=3 (load matrix into transposed matrix), MLLoadWave uses the name without appending any digits. For example, if you have a 5x3 matrix in a file and you tell MLLoadWave to load it as a matrix using the name "mat", MLLoadWave will name the matrix "mat". However, if you tell MLLoadWave to load the matrix as 3 1D waves, it will use "mat0", "mat1" and "mat2".

If the name that MLLoadWave would use when creating a wave or variable is in use for an object of the same type and if you use the overwrite flag, then it will overwrite the existing object. If you do not tell MLLoadWave to overwrite, it will choose a non-conflicting name. If the conflict is with an object of a different type or with an operation or function, MLLoadWave will also choose a non-conflicting name.

Loading Strings from Matlab Files
When loading Matlab strings into Igor, you can tell MLLoadWave to create Igor string variables or Igor text waves. For example, if you have a 2x8 string matrix, MLLoadWave can create two string variables (/S=2) or one text wave (/S=3) containing two elements.

When loading Matlab string data into an Igor wave, the Igor wave will be of dimension one less than the Matlab data set. This is because each element in a Matlab string data set is a single byte whereas each element in an Igor string wave is a string (any number of bytes).

Loading Numeric Variables from Matlab Files
MLLoadWave loads numeric matrices with one element into Igor numeric variables. It loads all other numeric matrices into Igor waves.

When called from a macro, MLLoadWave creates local numeric and string variables unless you use the /G flag which tells it to create global variables. When called from the command line or from a user-defined function, MLLoadWave always creates global variables. Macros should be avoided in new programming.

Automatic Redimensioning from 2D to 1D
Starting with Igor Pro 8.00, after loading a matrix that results in an Mx1 2D wave, MLLoadWave automatically redimensions the wave as an M-row 1D wave.

This automatic redimensioning not affect the naming of the wave. It is still named using the 2D rules explained above under MLLoadWave Wave Naming.

Loading 3D and 4D Data from Matlab Files
For a discussion of how MLLoadWave handles 3D and 4D Matlab data, see Numeric Data Loading Modes.
Specifying Loading Options for Each Matlab Matrix
The /Z flag instructs MLLoadWave to load each Matlab object (matrix, vector, variable, string) step by step. MLLoadWave presents a dialog for each Matlab object in the file. You can choose to load or skip the object. If you omit the /Z flag, MLLoadWave will load all objects in the file without presenting any dialogs.

Output Variables
MLLoadWave sets the following output variables:

- **S_path**
  File system path to the folder containing the file.
  This is a system file path (e.g., "hd:FolderA:FolderB:"), not an Igor symbolic path. The path uses Macintosh path syntax, even on Windows, and has a trailing colon.

- **S_fileName**
  Name of the loaded file.

- **V_flag**
  Number of waves created.

- **V_flag1**
  Number of Matlab data sets (2D, 3D, or 4D) loaded.

- **V_flag2**
  Number of waves created.

- **V_flag3**
  Number of numeric variables created.

- **V_flag4**
  Number of string variables created.

- **S_waveNames**
  Semicolon-separated list of the names of loaded waves.

Prior to MLLoadWave 5.50, the variables V_Flag1, V_Flag2, V_Flag3 and V_Flag4 were named V1_Flag, V2_Flag, V3_Flag and V4_Flag.

- Symbolic Paths on page II-22
- See Loading Matlab MAT Files on page II-163 for background information, including configuration instructions.

mod

mod(num, div)
The mod function returns the remainder when num is divided by div.

The mod function may give unexpected results when num or div is fractional because most fractional numbers can not be precisely represented by a finite-precision floating point value.

See Also
- trunc, gcd

ModDate

ModDate(waveName)
The ModDate function returns the modification date/time of the wave.

Details
The returned value is a double precision Igor date/time value, which is the number of seconds from 1/1/1904. It returns zero for waves created by versions of Igor prior to 1.2, for which no modification date/time is available.

See Also
- WaveModCount, Secs2Date, Secs2Time
Modify

Modify
We recommend that you use **ModifyGraph**, **ModifyTable**, **ModifyLayout**, or **ModifyPanel** rather than Modify. When interpreting a command, Igor treats the Modify operation as ModifyGraph, ModifyTable, ModifyLayout or ModifyPanel, depending on the target window. This does not work when executing a user-defined function.

ModifyBoxPlot

ModifyBoxPlot [/W=winName] [keyword=value, keyword=value, ...]
The ModifyBoxPlot operation modifies a box plot trace in the target or named graph. To create a box plot trace, see **AppendBoxPlot**. For a detailed discussion of box plots and the parts of a box plot, see **Box Plots** on page II-331.

ModifyBoxPlot was added in Igor Pro 8.00.

Parameters
ModifyBoxPlot parameters consist of keyword=value pairs. The trace keyword specifies the trace targeted by the subsequent keywords. For example, the command:

ModifyBoxPlot trace=trace0, boxFill=(49151,60031,65535) // Light blue
sets the box fill for all datasets of the trace0 trace to light blue.

As of Igor Pro 9.00, you can modify a setting for a specific dataset of a specific trace by adding a zero-based dataset index in square brackets after the keyword. For example:

ModifyBoxPlot trace=trace0, boxFill[1]=(49151,65535,49151) // Light green
This sets the box fill for the second dataset (index=1) to light green leaving the box fill for other datasets unchanged.

General Parameters

**trace=traceName**
Specifies the name of a box plot trace to be modified. An error results if the named trace is not a box plot trace. Without the trace keyword, ModifyBoxPlot uses the first trace in the graph, whether it is a box plot trace or not. But, see the instance keyword for an exception.

**instance=instanceNum**
The combination of trace and instance works the same as (traceName#instanceNum) for a ModifyGraph keyword.

The instance keyword without trace keyword accesses the instanceNum'th trace in the graph, just like [traceNum] used with a ModifyGraph keyword. See **Trace Names** on page II-282 and **Object Indexing** on page IV-20.

**medianIsMarker[v]**
If v is omitted or is non-zero, the median is shown using a marker instead of with a line across the box part of the box plot.

**notched[n]**
If n omitted or is non-zero, a notched box plot is drawn. The notches represent the 95 percent confidence limits of the median value.

**outlierMethod=m**
outlierMethod={m, p1, p2, p3, p4}
When the raw data values are drawn on the box plot, they are classified as normal data points, outliers and far outliers. There are four methods for categorizing the values. Method 0 and 1 require no parameters and can use the `outlierMethod=m` format. Method 2 and 3 require extra parameters and require the extended format that uses curly braces:

- **m=0**: Tukey’s method (default): outliers are values outside of the inner fences and far outliers are values outside the outer fences. For details including the definition of the fences, see Box Plots on page II-331.
- **m=1**: Outliers are any data values beyond the ends of the whiskers. With this method, there are no far outliers.
- **m=2**: Outliers are values beyond the mean ± factor1*SD. Far outliers are values beyond the mean ± factor2*SD, where SD is the standard deviation. The factor1 is given by `p1` and factor2 is given by `p2`. The parameters `p3` and `p4` are not used.
- **m=3**: Outliers and far outliers are completely specified by the parameters. `p1` sets the boundary for lower far outliers, `p2` for lower outliers, `p3` for upper outliers, and `p4` for upper far outliers. All four parameters are required.

The `outlierMethod` keyword was added in Igor Pro 9.00.

**quartileMethod=m** Selects the method to be used in computing the quartiles (top and bottom of the boxes):

- **m=0**: Tukey’s method (default)
- **m=1**: Minitab method
- **m=2**: Moore and McCabe method
- **m=3**: Mendenhall and Sincich method

See the discussion of `StatsQuantiles /QM flag` for details.

**showData=whatData** Selects a subset of the raw data for each box plot in a trace to be displayed using markers. The value of `whatData` is a name:

- **All**: Show all data points (default)
- **None**: Show no data points
- **Outliers**: Show only outliers and far outliers
- **FarOutliers**: Show only far outliers

See Box Plots on page II-331 for more information about outliers.

By default, the marker for normal data points is a hollow circle 0.7 times the size of a normal trace marker, outliers are shown by a full-size filled circle, and far outliers are shown using a full-size filled box.

**showFences=[v]** If `v` is omitted or non-zero, the fences are shown as dotted lines the same width as the boxes. See Box Plots on page II-331 for a discussion of fences. `v` defaults to 0.

**showMean=[v]** If `v` is omitted or non-zero, the mean of the data is shown as a marker. `v` defaults to 0.

**whiskerMethod=m**

**whiskerMethod={m [, p1, p2]}**
The whiskers are drawn from the quartiles (top and bottom of the box) to some extreme value, as determined by whiskerMethod. Methods 0-5 do not take extra parameters, and can be specified using the whiskerMethod=m format. Methods 6 and 7 take extra parameters and require the extended format with curly braces.

The extended format was added in Igor Pro 9.00.

m=0: The extreme data values (default)
m=1: The inner fences
m=2: The “adjacent” points - the last data points inside the inner fences
m=3: One standard deviation away from the mean value
m=4: The 9th and 91st percentiles
m=5: The 2nd and 98th percentiles
m=6: The lower whisker is drawn from the box to a percentile given by p1. The upper whisker is drawn from the box to a percentile given by p2. This method requires both p1 and p2. Added in Igor Pro 9.00.
m=7: Whisker ends are at values given by mean data value + a factor times the standard deviation. The factor is given by p1. p2 is not used for this method. Added in Igor Pro 9.00.

See Box Plots on page II-331 for a discussion of fences and percentiles.

Appearance Parameters

boxWidth=w For a non-category X axis, boxWidth sets the width of the box showing the quartiles. If w is between zero and one, it is taken to be a fraction of the width of the plot rectangle. If w is greater than one, it is in points.

If the box plot is displayed using a category X axis, boxWidth is ignored. The box width is set the same as a category plot box and is affected by ModifyGraph barGap and catGap.

A new non-category box plot has box width set as boxWidth=1/(2*n) where n is the number of datasets (the number of boxes) on the trace.

capWidth=w The whiskers may optionally be terminated with a horizontal line of width controlled by the capWidth keyword. If w is between zero and one, it is a fraction of the box width. If w is greater than one, it is in points. If w is zero (default), no cap is drawn.

jitter=j Applies a horizontal offset to each displayed data point in order to make it easier to see dense datasets. j controls the maximum offset applied to any data point, expressed as a fraction of the box width. The value of j may be greater than 1, but in general values less than 1 look better. The default is 0.7.

lineStyles=[boxStyle, whiskerStyle, medianStyle[, capStyle]]

Set the line style used to draw the box, the whiskers, the median line, and optionally the whisker caps. See Dashed Lines on page III-496 for a description of line styles.

A line style of -1 uses the line style set by ModifyGraph lstyle.

All parameters default to -1.

lineThickness=[boxThickness, whiskerThickness, medianThickness[, capThickness]]
Sets the line thickness used to draw the box, the whiskers, the median line, and optionally the whisker caps. A thickness less than zero uses the thickness set by the ModifyGraph lsize keyword. A zero thickness hides the corresponding element of the box plot.

All parameters default to -1.

\[\text{markers=\{dataMarker, outlierMarker, farOutlierMarker[\}, medianMarker, meanMarker\]}\]

Sets the marker number to be used for ordinary data points, outliers, far outliers, the median value if the medianIsMarker keyword was specified and the mean value if the showMean keyword was specified. See Markers on page II-291 for a complete list.

These parameters default to markers=[8, 19, 16, 26, 27] (hollow circle, filled circle, filled square, X, horizontal diamond). Setting any of the parameters to -1 uses the corresponding default marker.

\[\text{markersOnTop=\{dataOnTop, medianOnTop, meanOnTop\}}\]

By default, the data markers, median marker if enabled by medianIsMarker, and mean marker if enabled by showMean, are drawn below the box and whisker lines so that they don’t obscure the lines. But some special effects require the markers to be on top.

Setting dataOnTop to 1 causes all raw data points (normal data points, outliers and far outliers) to be drawn above the box and whisker lines. medianOnTop and meanOnTop similarly control the drawing of median and mean markers.

The markersOnTop keyword was added in Igor Pro 9.00.

\[\text{markSizes=\{dataSize, outlierSize, farOutlierSize[\}, medianSize, meanSize\}}\]

Sets the marker size for ordinary data points, outliers, far outliers, the median value if the medianIsMarker keyword has been specified and the mean value if the showMean keyword has been specified. A marker size of zero uses the marker size set by ModifyGraph msize times a scaling factor: the scaling factor is 2/3 for non-outlier points, 1 for outliers and the median and mean markers, and 4/3 for far outliers.

All parameters default to 0.

\[\text{opaqueMarkers=\{opaqueData, opaqueOutliers, opaqueFarOutliers, opaqueMedian, opaqueMean\}}\]

Causes the interior of hollow markers to be drawn opaque, covering up items underneath. This keyword has a separate settings for normal data points, outliers, far outliers, the median marker (if medianIsMarker is enabled) and the mean marker (if showMean is enabled). Markers of a given type are opaque if the corresponding parameter is set to 1.

The opaqueMarkers keyword was added in Igor Pro 9.00.

**Color Parameters**

All colors are specified as \((r, g, b[, a])\) **RGBA Values**. Specify color=(0,0,0,0) to use the color set by ModifyGraph rgb.

\[\text{boxColor=(r, g, b[, a])}\]

Sets the outline color of the box part. The default color is black.

\[\text{boxFill=(r, g, b[, a])}\]

Sets the fill color of the box.

\[\text{capColor=(r, g, b[, a])}\]

Sets the color of the cap line, if present. The default color is black.

\[\text{dataColor=(r, g, b[, a])}\]

Sets the color of non-outlier data points. The default color is the trace color.
### Box Plot Per-Data-Point Marker Settings

You can override the basic settings for data point marker color, marker style and marker size using marker settings waves containing per-data-point settings. This feature was added in Igor Pro 9.00.

You can apply per-data-point marker settings to an entire trace (to all datasets comprising a trace) or to a specific dataset of a trace. For example:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataStrokeColor=(r,g,b[a])</td>
<td>Sets the stroke color of non-outlier data points. The default color is black. The dataStrokeColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>dataFillColor=(r,g,b[a])</td>
<td>Sets the fill color of non-outlier data points when the markers are hollow. The default color is white. The dataFillColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>farOutlierColor=(r,g,b[a])</td>
<td>Sets the color of far outlier points. The default color is the trace color. The farOutlierColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>farOutlierStrokeColor=(r,g,b[a])</td>
<td>Sets the stroke color of far outlier data points. The default color is black. The farOutlierStrokeColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>farOutlierFillColor=(r,g,b[a])</td>
<td>Sets the fill color of far outlier data points when the markers are hollow. The default color is white. The farOutlierFillColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>meanColor=(r,g,b[a])</td>
<td>Sets the color of the mean marker. The default color is the trace color. The meanColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>meanStrokeColor=(r,g,b[a])</td>
<td>Sets the stroke color of the mean marker, if showMean is enabled. The default color is black. The meanStrokeColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>meanFillColor=(r,g,b[a])</td>
<td>Sets the fill color of the mean marker, if showMean is enabled. Applies when the marker is hollow. The default color is white. The meanFillColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>medianLineColor=(r,g,b[a])</td>
<td>Sets the color of the median line. You can see the effect only if medianIsMarker is not set. The default color is black.</td>
</tr>
<tr>
<td>medianMarkerColor=(r,g,b[a])</td>
<td>Sets the color of the median marker. You can see the effect only if medianIsMarker is set. The default color is the trace color.</td>
</tr>
<tr>
<td>medianStrokeColor=(r,g,b[a])</td>
<td>Sets the stroke color of the median marker which is displayed if medianIsMarker is enabled. The default color is black. The medianStrokeColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>medianFillColor=(r,g,b[a])</td>
<td>Sets the fill color of the median marker which is displayed if medianIsMarker is enabled. Applies when the marker is hollow. The default color is white. The medianFillColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>outlierColor=(r,g,b[a])</td>
<td>Sets the color of the markers for normal outliers. The default color is the trace color.</td>
</tr>
<tr>
<td>outlierStrokeColor=(r,g,b[a])</td>
<td>Sets the stroke color of outlier data points. The default color is black. The outlierStrokeColor keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>outlierFillColor=(r,g,b[a])</td>
<td>Sets the fill color of outlier data points when the markers are hollow. The default color is white. The outlierFillColor keyword was added in Igor Pro 9.00.</td>

<tr>
<td>whiskerColor=(r,g,b[a])</td>
<td>Sets the color the whisker lines. The default color is black.</td>
</tr>
</tbody>
</table>
Function DemoBoxPlotPerPointMarkerSettings()
     Make/O box0={1,2,3,4,5}, box1={2,3,4,5,6}, box2={3,4,5,6,7}
     String title = "Box Plot Per Point Marker Settings"
     Display/W=(557,99,948,310)N=BoxPlotPerPointPlot as title
     // Create a trace named trace0 with three datasets: box0, box1, box2
     AppendBoxPlot/TN=trace0 box0,box1,box2
     // Set the marker and marker size for all datasets of trace trace0
     ModifyBoxPlot trace=trace0, markers={18,-1,-1} // 18=Diamond
     ModifyBoxPlot trace=trace0, markerSizes={5,5,5}
     // Set the per-data-point marker for all datasets of trace0
     Make/O boxMarkers = {15,16,17,18,19}
     ModifyBoxPlot trace=trace0, dataMarkerWave=boxMarkers
     // Set the per-data-point marker for dataset box1 only
     Make/O boxMarkersForBox1 = {32,33,34,35,36}
     ModifyBoxPlot trace=trace0, dataMarkerWave[1]=boxMarkersForBox1
End

Usually a marker settings wave will have the same number of rows as there are data points in a given
dataset, but that is not required. If there are fewer rows in the settings wave than in the dataset, the extra
data points retain their basic settings. If there are more rows in the settings wave than in the dataset, the
extra settings wave points are not used.

See Making Each Data Point Look Different on page II-343 for more information and examples.

dataColorWave [=colorWave] Sets colorWave to override data point marker color on a point-by-
point basis. The wave must be a 3 or 4 column wave containing red,
green, blue and optionally alpha values.

If you omit "=colorWave", any previous marker color wave setting is cleared.

The dataColorWave keyword was added in Igor Pro 9.00.

dataMarkerWave [=markerWave] Sets markerWave to override data point markers on a point-by-point
basis. The values in markerWave are standard graph marker
numbers. See Markers on page II-291 for a table of the markers and
the associated marker numbers. The marker numbers are clipped
to a valid range.

If you omit "=markerWave", any previous marker wave setting is cleared.

The dataMarkerWave keyword was added in Igor Pro 9.00.

dataSizeWave [=markerSizeWave] Sets markerSizeWave to override data point marker size on a point-
by-point basis. The values in markerSizeWave are clipped to the range [0,200].

If you omit "=markerSizeWave", any previous marker size wave
setting is cleared.

The dataSizeWave keyword was added in Igor Pro 9.00.

Example

Make/O/N=(25,3) multicol // A three-column wave with 25 rows
SetRandomSeed(.4) // For reproducible "randomness"
multicol = gnoise(1) // Three normally-distributed datasets
multicol[20][1] = 5 // A "far" outlier
multicol[13][2] = -4 // An outlier
Display; AppendBoxPlot multicol
ModifyGraph lSize=2
ModifyBoxPlot markers={8,19,19}
ModifyBoxPlot markerSizes={3,5,9}
ModifyBoxPlot capWidth=0.5
ModifyBoxPlot boxColor=(0,0,65535)
ModifyBoxPlot medianLineColor=(0,0,65535)
ModifyBoxPlot whiskerColor=(40000,40000,65535)
ModifyBoxPlot capColor=(40000,40000,65535)
ModifyBoxPlot boxFill=(0,0,65535,20000)
ModifyBoxPlot dataColor=(0,0,0)
ModifyBoxPlot outlierColor=(0,0,0)
ModifyBoxPlot farOutlierColor=(0,0,0)
ModifyBoxPlot jitter=0.75

ModifyBoxPlot trace=multicol,markerThick={1,0,0},markersFilled={1,0,0,0}
ModifyBoxPlot trace=multicol,markerThick={1,0,0},dataFillColor=(2,39321,1)

ModifyBoxPlot trace=multicol,dataFillColor[1]=(0,65535,0)

Box Plots on page II-331
ModifyBrowser

ModifyBrowser [/M] [keyword = value [, keyword = value ...]]

The ModifyBrowser operation modifies the state of the Data Browser according to the specified keywords.

Documentation for the ModifyBrowser operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "ModifyBrowser"

ModifyCamera

ModifyCamera [flags] [keywords]

The ModifyCamera operation modifies the properties of a camera window.

Documentation for the ModifyCamera operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "ModifyCamera"

ModifyContour

ModifyContour [/W=winName] contourInstanceName, keyword=value

[, keyword=value...]  

The ModifyContour operation modifies the number, Z value and appearance of the contour level traces associated with contourInstanceName.

contourInstanceName is a name derived from the name of the wave that provides the Z data values. It is usually just the name of the wave, but may have #1, #2, etc. added to it in the unlikely event that the same Z wave is contoured more than once in the same graph.

contourInstanceName can also take the form of a null name and instance number to affect the instance of a contour plot. That is,

ModifyContour ''#1

modifies the appearance of the second contour plot in the top graph, no matter what the contour plot names are. Note: Two single quotes, not a double quote.

The number of contour level traces and their Z values are set by the autoLevels, manLevels, and moreLevels keywords, described in the Parameters section. Normally, you will use either autoLevels or manLevels, and then optionally generate additional levels using moreLevels.

Parameters

Each parameter has the syntax

keyword = value

and is applied to all of the contour level traces associated with contourInstanceName.

To modify an individual contour level trace, use ModifyGraph.

allocationFactor= factor

In rare situations that usually involve spatial degeneracy, the Voronoi interpolation algorithm may need additional memory. You can use the allocationFactor keyword with an integer factor greater than 1 to increase the memory allocation.

allocationFactor was added in Igor Pro 9.00.

autoLevels= {minLevel, maxLevel, numLevels}
ModifyContour

Controls automatic determination of contour levels.

If numLevels is zero, no automatic levels are generated. If it is nonzero, it specifies
the desired number of automatic contour levels.

minLevel specifies the minimum contour level and maxLevel specifies the
maximum contour level. The values that you specify are an approximate guide
for Igor to use in determining the actual levels.

However, if minLevel or maxLevel is * (asterisk symbol), Igor uses the minimum or
maximum value of the Z data for the corresponding contour level.

Using the autoLevels keyword cancels the effect of any previous autoLevels or
manLevels keyword.

When you first append a contour plot to a graph, default contour levels are
generated by the default setting autoLevels={*,*,11}.

boundary=b

Draws an outline around the XY domain of the contour data. For a matrix, this
draws a rectangle showing the minimum and maximum X and Y values. For
XYZ triples, the outline is a polygon enclosing the outside edges of the
Delaunay Triangulation. Like the contour lines, the boundary is drawn using
a graph trace, whose name is usually something like
"contourInstanceName = boundary".

b=0: Hides the data boundary (default).
b=1: Shows the data boundary.

clIndexFill= matrixWave

Sets contour fills to use a color index wave when automatic fill is on (see the fill
keyword).
clIndexFill works the same as the clIndexLines keyword which controls the colors
of the contour level traces.

See Contour Fills on page II-373 for more information.
clIndexFill was added in Igor Pro 7.00.

cIndexLines= matrixWave

Sets the Z value mapping mode such that contour line colors are determined by
doing a lookup in the specified matrix wave.

matrixWave is a 3 column wave that contains red, green, and blue values from 0
to 65535. (The matrix can actually have more than three columns. Any extra
columns are ignored.)

The color for a the contour line at Z=z is determined by finding the RGB values in
the row of matrixWave whose scaled X index is z. In other words, the red value is
matrixWave(z)[0], the green value is matrixWave(z)[1] and the blue value is
matrixWave(z)[2].

If matrixWave has default X scaling, where the scaled X index equals the point
number, then row 0 contains the color for Z=0, row 1 contains the color for Z=1,
etc.

If you use cIndexLines, you must not use ctabLines or rgbLines in the same
command.

cTabFill= {zMin, zMax, ctName, mode}

Sets contour fills to use a color table when automatic fill is on (see the fill
keyword).

cTabFill works the same as the ctabLines keyword which controls the colors of the
contour level traces.

See Contour Fills on page II-373 for more information.
cTabFill was added in Igor Pro 7.00.
ctabLines=[zMin, zMax, ctName, mode]

Sets the Z value mapping mode such that contour line colors are determined by doing a lookup in the specified color table. \( zMin \) is mapped to the first color in the color table. \( zMax \) is mapped to the last color. Z values between the min and max are linearly mapped to the colors between the first and last in the color table.

You can enter * (an asterisk) for \( zMin \) and \( zMax \), which uses the minimum and maximum Z values of the data. The default is [*,*,Rainbow].

Set parameter \( \text{mode} \) to 1 to reverse the color table; zero or missing does not reverse the color table.

\( \text{ctName} \) can be any color table name returned by the CTabList function, such as Grays or Rainbow (see Image Color Tables on page II-392) or the name of a 3 column or 4 column color table wave (see Color Table Waves on page II-399).

A color table wave name supplied to ctabLines must not be the name of a built-in color table (see CTabList). A 3 column or 4 column color table wave must have values that range between 0 and 65535. Column 0 is red, 1 is green, and 2 is blue. In column 3 a value of 65535 is opaque, and 0 is fully transparent.

If you use ctabLines, you must not use cIndexLines or rgbLines in the same command.

equalVoronoisDistances=e

Normally the x range and y range of the data are each normalized to a 0-1 range separately to generate the Voronoi triangulation. Voronoi triangulation is a distance-based ("nearest neighbor") algorithm that may benefit from scaling the X and Y ranges together to avoid numerical problems that occur when the triangles become very thin because of widely differing x and y ranges.

e=0: The x and y ranges are scaled individually to the 0-1 range (default).

e=1: The x and y ranges are scaled so that that maximum range of x or y is scaled to the 0-1 range, and the other is proportionally smaller. For example, if yMax-yMin = 1000 and xMax-xMin = 5, then the y range is scaled to 0-1 and the y range is scaled to 5/1000 = 0 - 0.005.

The equalVoronoisDistances keyword is allowed only for XYZ contour plots.

fill=f

Controls the automatic filling of contour levels.

f=0: Turns automatic fill off. Default.

f=1: Turns automatic fill on.

See Contour Fills on page II-373 for more information.

fill was added in Igor Pro 7.00.
XYZ contours can be interpolated to increase the apparent resolution, resulting in smoother contour lines.

This keyword is allowed only for XYZ contours, created by `AppendXYZContour`.

\( i \): Linear interpolation (default). This means that only the original Delaunay triangulation generates contour lines.

\( i=1 \): Four times the resolution generates a smoother set of contour lines.

\( i=2 \): Sixteen times the resolution generates a much smoother set of contour lines. This is rather slow.

The interpolate parameter can be up to 8. Each time you increase \( i \) by one, you quadruple the apparent resolution and get smoother contour lines at the expense of computation time. Values of \( i \) greater than two are impractical because of the computation time required.

Controls the background color of contour labels.

\( b=0 \): Uses each label’s individual background color, as set via the Modify Annotation dialog.

\( b=1 \): Makes all contour level labels transparent.

\( b=2 \): Uses the plot area background color as the label background color (default).

\( b=3 \): Uses the window background color as the label background color.

\( d \) is the number of digits after the decimal point when using `labelFormat=3` or `labelFormat=5`.

Default; specifies the font to use for contour level labels. If you pass "" for `fontName`, it will use the graph font (set via the Modify Graph dialog) for contour labels.

Controls the formatting of contour labels. See the printf operation for a discussion of formatting.

\( l=0 \): Uses general format that is suitable for most data. This is equivalent to \"%<sigDigits>g\".

\( l=1 \): Uses integer format, equivalent to \"%<sigDigits>d\". This rounds fractional values.

\( l=3 \): Uses fixed point format, equivalent to \"%<decimalDigits>f\".

\( l=5 \): Uses exponential format, equivalent to \"%<decimalDigits>e\".

Specifies the font size of contour labels in points. For example, use `labelSize=12` for 12 point type. The default value is 0, which chooses the size automatically based on the size of the graph.

\( n \) is a bitwise parameter with each bit controlling one aspect of the font style for the contour level labels. The default is 0, plain text.

Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.
ModifyContour

labelHV=\(hv\)  
Specifies the contour label orientation.
If \(hv\) is 3, 4, 5, or 6, the contour label’s text rotates whenever it is redrawn, usually when the underlying contour data changes, the graph is resized, or the label is reattached to a new contour trace point.
\(hv = 0\): Horizontal contour level labels.
\(hv = 1\): Vertical contour level labels.
\(hv = 2\): Horizontal or vertical contour level labels, depending on the slope of the contour line.
\(hv = 3\): Tangent to the contour line.
\(hv = 4\): Tangent to the contour line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal (default).
\(hv = 5\): Perpendicular to the contour line.
\(hv = 6\): Perpendicular to the contour line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.

labelRGB=(r,g,b[,a])  
Sets the text color for all contour level labels. \(r, g, b,\) and \(a\) specify the color and optional opacity as RGBA Values. The default is opaque black.

labels=l  
Controls the display of contour labels.
\(l = 0\): Hides contour level labels.
\(l = 1\): Leaves any contour level labels in place but stops updating them and stops generation of new labels.
\(l = 2\): Generates or updates labels for the existing contour levels and window size when the command executes, but disables further updating of labels when window size or contour plot changes. This is the recommended setting if updating the labels takes long enough to annoy you.
\(l = 3\): Default; generates labels for all contour levels whenever the contoured data changes but not when the window size changes. If you resize the graph, the labels may overlap or be too sparse.
\(l = 4\): Generates labels for all contour levels whenever the contoured data, contour levels, axis range, or the graph size changes. (Actually, there are too many causes to list here. If all this update annoys you, use labels=2 “update once, now”.)

labelSigDigits=d  
\(d\) is the number of significant digits when labelFormat=0 is used.

logLines= 1 or 0  
0 sets the default linearly-spaced contour line colors.
1 turns on logarithmically-spaced line colors. This requires that the contour levels values be greater than 0 to display correctly.

Affects line color only when the cIndexLines or ctabLines parameter is used.
logLines does not affect the contour levels. To assign logarithmically-spaced contour levels, use the moreLevels parameter and disable autoLevels, for example:
```plaintext
ModifyContour "'#0, autoLevels={*,*,0} // No auto levels
ModifyContour "'#0, moreLevels=0
ModifyContour "'#0, moreLevels={1e-07,1e-06,1e-05,1e-04}
```

manLevels= \{firstLevel, increment, numLevels\}  
Explicitly specifies contour levels. ModifyContour will generate numLevels contour levels, evenly spaced starting from firstLevel and stepping by increment.
manLevels cancels the effect of any previous manLevels or autoLevels settings.

manLevels= manLevelsWave
ModifyContour

Explicitly specifies contour levels. ModifyContour will generate contour levels at the values in \textit{manLevelsWave}.

\texttt{manLevels} cancels the effect of any previous \texttt{manLevels} or \texttt{autoLevels} settings.

\texttt{moreLevels=\{level, level …\}}

Explicitly specifies contour levels. ModifyContour will generate a contour trace for each of the listed levels. The maximum number of levels that you can specify in a single command is the 50. However, you can concatenate any number of ModifyContour \texttt{moreLevels} commands. \texttt{moreLevels} adds levels in addition to any specified by \texttt{manLevels} or \texttt{autoLevels}. It does not override other parameters.

\texttt{moreLevels=0}: Removes all levels generated by previous \texttt{moreLevels} settings.

\texttt{nullValue=zValue}

This keyword only affects the behavior of the \textit{ContourZ} function. It is allowed only for XYZ contours, created by \texttt{AppendXYZContour}.

By default, \textit{ContourZ} treats data outside the domain of the contour as NaN and so returns NaN if you ask for a contour value outside that domain.

The nullValue keyword allows you to change the default behavior to make \textit{ContourZ} treat values outside the domain as the specified \texttt{zValue}.

\texttt{nullValueAuto}

This keyword only affects the behavior of the \textit{ContourZ} function. It is allowed only for XYZ contours, created by \texttt{AppendXYZContour}.

\texttt{nullValueAuto} acts like \texttt{nullValue=zValue} with \texttt{zValue} automatically set to the minimum value in the \textit{Z} wave minus 1.

See the \texttt{nullValue} keyword for details.

To turn \texttt{nullValueAuto} off and return the contour to the default state, execute:

\texttt{ModifyContour <contourInstanceName>, nullValue=NaN}

\texttt{perturbation=p}

Enable or disable perturbation (alteration) of the x and y values by a miniscule amount to improve the natural neighbor triangulation of XYZ contours.

\texttt{p=0}: Disables perturbation, preserving the original x and y values unchanged.

\texttt{p=1}: Enables x/y perturbation (default). The values are shifted by random values less than +/-0.000005 times the x and y domain extents.

You can observe the perturbed x/y coordinates in the triangulation trace added by ModifyContour \texttt{triangulation=1}.

The perturbation keyword is allowed only for XYZ contour plots.

\texttt{rgbFill=(r,g,b[,a])}

Specifies red, green, and blue values for all contour fills. \texttt{r, g, b,} and \texttt{a} specify the color and optional opacity as RGBA Values.

If you use \texttt{rgbFill}, you must not use \texttt{cIndexFill} or \texttt{ctabFill} in the same command.

\texttt{rgbLines=(r,g,b[,a])}

Specifies red, green, and blue values for all contour lines. \texttt{r, g, b,} and \texttt{a} specify the color and optional opacity as RGBA Values.

If you use \texttt{rgbLines}, you must not use \texttt{cIndexLines} or \texttt{ctabLines} in the same command.

\texttt{triangulation=t}

Draws the Delaunay Triangulation. As part of the XYZ contouring algorithm, the XY domain is subdivided into triangles in a process called Delaunay Triangulation. Like the contour lines, the triangulation is drawn using a graph trace, whose name is usually something like “contourInstanceName =triangulation”.

The \texttt{triangulation} keyword is allowed only for XYZ contours, created by \texttt{AppendXYZContour}.

\texttt{t=0}: Hides the Delaunay triangulation (default).

\texttt{t=1}: Shows the Delaunay triangulation.

**Flags**

/W=winName

Applies to contours in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**See Also**

AppendMatrixContour and AppendXYZContour.

**References**

---

**ModifyControl**

\[/Z\] ctrlName \[ keyword = value [, keyword = value ...] \]

The ModifyControl operation modifies the named control. ModifyControl works on any kind of existing control. To modify multiple controls, use **ModifyControlList**.

**Parameters**

ctrlName specifies the name of the control to be created or changed. The control must exist.

**Keywords**

The following keyword=value parameters are supported:

activate, align, appearance, bodywidth, disable, fColor, focusRing, font, fSize, fStyle, help, labelBack, noproc, pos, proc, rename, size, title, userdata, valueBackColor, valueColor, win

Coordinates are in **Control Panel Units**.

For details on these keywords, see the documentation for **SetVariable** on page V-854.

The following keywords are not supported:
ModifyControl

Flags
/Z No error reporting.

Details
Use ModifyControl to move, hide, disable, or change the appearance of a control without regard to its kind.

Example
Here is a TabControl procedure that shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are.

The “trick” here is that all controls that are to be shown within particular tab \( n \) have been assigned names that end with \( "\_\text{tab}n" \) such as \( "\_\text{tab}0" \) and \( "\_\text{tab}1" \):

Function TabProc(ctrlName, tabNum) : TabControl
    String ctrlName
    Variable tabNum

    String curTabMatch= "*_tab"+num2istr(tabNum)
    String controls= ControlNameList(""
    Variable i, n= ItemsInList(controls)
    for(i=0; i<n; i+=1)
        String control= StringFromList(i, controls)
        Variable isInATab= stringmatch(control,"*_tab")
        if( isInATab )
            Variable show= stringmatch(control,curTabMatch)
            ControlInfo $control // gets V_disable
            if( show )
                V_disable= V_disable & ~0x1 // clear the hide bit
            else
                V_disable= V_disable | 0x1 // set the hide bit
            endif
            ModifyControl $control disable=V_disable
        endif
    endfor
    return 0
End

// Action procedures which enable or disable the buttons
Function Tab1CheckProc(ctrlName, enableButton) : CheckBoxControl
    String ctrlName
    Variable enableButton

    ModifyControl button_tab1, disable=(enableButton ? 0 : 2 )
End

Function Tab0CheckProc(ctrlName, enableButton) : CheckBoxControl
    String ctrlName
    Variable enableButton

    ModifyControl button_tab0, disable=(enableButton ? 0 : 2 )
End

// Panel macro that creates a TabControl using TabProc
Window TabbedPanel() : Panel
    PauseUpdate; Silent 1 // building window...
    NewPanel /W=(381,121,614,237) as "Tab Demo"
    TabControl tab, pos={12,9}, size={205,91}, proc=TabProc, tabLabel(0)="Tab 0"
    TabControl tab, tabLabel(1)="Tab 1", value= 0
    Button button_tab0, pos={54,39}, size={110,20}, disable=2
    Button button_tab0, title="Button in Tab 0"
    Button button_tab1, pos={54,63}, size={110,20}, disable=1
    Button button_tab1, title="Button in Tab 1"
    CheckBox check1_tab1, pos={51,41}, size={117,14}, disable=1, value= 1
    CheckBox check1_tab1, proc=Tab1CheckProc, title="Enable Button in Tab 1"
    CheckBox check0_tab0, pos={51,73}, size={117,14}, proc=Tab0CheckProc
    CheckBox check0_tab0, value= 0, title="Enable Button in Tab 0"
EndMacro

Run TabbedPanel to create the panel. Then click on “Tab 0” and “Tab 1” to run TabProc.
ModifyControlList

See Also
Chapter III-14, Controls and Control Panels, for details about control panels and controls.

Control Panel Units on page III-444 for a discussion of the units used for controls.

Related functions ModifyControlList and ControlNameList.

The Button, Chart, CheckBox, GroupBox, ListBox, PopupMenu, SetVariable, Slider, TabControl, TitleBox, and ValDisplay controls.

ModifyControlList

ModifyControlList [ /Z ] listStr [, keyword = value] ...

The ModifyControlList operation modifies the controls named in the listStr string expression.
ModifyControlList works on any kind of existing control.

Parameters
listStr is a semicolon-separated list of names in a string expression. The expression can be an explicit list of control names such as "button0;checkbox1;" or it can be any string expression such as a call to the ControlNameList string function:
ModifyControlList ControlNameList("",";","*_tab0") disable=1

The controls must exist.

Keywords
The following keyword=value parameters are supported:

activate align appearance bodywidth disable fColor
focusRing font fSize fStyle help labelBack
noproc pos proc rename size title
userdata valueBackColor valueColor win

Coordinates are in Control Panel Units.
For details on these keywords, see the documentation for SetVariable on page V-854.
The following keywords are not supported:

mod popmatch popvalue value variable

Flags

/Z No error reporting.

Details
Use ModifyControlList to move, hide, disable, or change the appearance of multiple controls without regard to their kind.

If listStr contains the name of a nonexistent control, an error is generated.

if listStr is "" (or any list element in listStr is ""), it is ignored and no error is generated.

Example
Here is the TabControl procedure example from ModifyControl rewritten to use ModifyControlList. It shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are, but the code is simpler. This method does not, however, preserve the enable bit when a control is hidden.
The “trick” here is that all controls that are to be shown within particular tab n have been assigned names that end with "_tabn" such as "_tab0" and "_tab1":

// Action procedure
Function TabProc2(ctrlName,tabNum) : TabControl
    String ctrlName
    Variable tabNum

    String controlsInATab= ControlNameList("",";","*_tab*")
String curTabMatch= "*_tab"+num2istr(tabNum)
String controlsInCurTab= ListMatch(controlsInATab, curTabMatch)
String controlsInOtherTabs= ListMatch(controlsInATab,"!"+curTabMatch)
ModifyControlList controlsInOtherTabs disable=1 // hide
ModifyControlList controlsInCurTab disable=0 // show
return 0
End

// Panel macro that creates a TabControl using TabProc2():
Window TabbedPanel2() : Panel
PauseUpdate; Silent 1 // building window…
NewPanel /W=(35,208,266,374) as "Tab Demo"
TabControl tab,pos={12,9},size={205,140},proc=TabProc2
TabControl tab,tabLabel(0)="Tab 0"
TabControl tab,tabLabel(1)="Tab 1",value= 0
Button button_tab0,pos={26,43},size={110,20},title="Button in Tab0"

The Button, Chart, CheckBox, GroupBox, ListBox, PopupMenu, SetVariable, Slider, TabControl, TitleBox, and ValDisplay controls.

ModifyFreeAxis

ModifyFreeAxis [\W=winName] axisName, master=mastName
[\, hook=funcName]
The ModifyFreeAxis operation designates the free axis (created with NewFreeAxis) to follow a controlling axis from which it gets axis range and units information. The free axis updates whenever the controlling axis changes. The axis limits and units can be modified by a user hook function.

Parameters
axisName is the name of the free axis (which must have been created by NewFreeAxis).
masterName is the name of the master axis controlling axisName.
funcName is the name of the user function that modifies the limits and units properties of the axis. If funcName is $"$", the named hook function is removed.

Flags
\W=winName Modifies axisName in the named graph window or subwindow. If /W is omitted the command affects the top graph window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
The free axis can also be designated to call a user-defined hook function that can modify limits and units properties of the axis. The hook function must be of the following form:

Function MyAxisHook(info)
  STRUCT WMAxisHookStruct &info
    <code to modify graph units or limits>
  return 0
End
ModifyFreeAxis

where WMAxisHookStruct is a built-in structure with the following members:

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>char win[MAX_WIN_PATH+1]</td>
<td>Host (sub)window</td>
</tr>
<tr>
<td>char axName[MAX_OBJ_NAME+1]</td>
<td>Name of the axis</td>
</tr>
<tr>
<td>char mastName[MAX_OBJ_NAME+1]</td>
<td>Name of controlling axis or &quot;&quot;</td>
</tr>
<tr>
<td>char units[MAX_UNITS+1]</td>
<td>Axis units</td>
</tr>
<tr>
<td>double min, max</td>
<td>Axis range minimum and maximum values</td>
</tr>
</tbody>
</table>

The constants used to size the char arrays are internal to Igor and are subject to change in future versions.

The hook function is called when refreshing axis range information (generally early in the update of a graph). Your hook must never kill a graph or an axis.

Example

This example demonstrates how to program a free axis hook function, whose most important task is to change the values of info.min and info.max to alter the axis range of the free axis. The example free axis displays Fahrenheit values for data in Celsius.

Function CentigradeAndFahrenheit()

Make/O/N=20 temperatures = -2+p/3+gnoise(0.5) // sample data
Display temperatures// default left axis will indicate data's centigrade range
String graphName = S_name
Label/W=$graphName left "°C"
ModifyGraph/W=$graphName zero(left)=1
Legend/W=$graphName

// make a right axis whose range will be Fahrenheit
NewFreeAxis/R/O/W=$graphName fahrenheit
ModifyGraph/W=$graphName freePos(fahrenheit)={0,kwFraction},lblPos(fahrenheit)=43
Label/W=$graphName fahrenheit "°F"
ModifyFreeAxis/W=$graphName fahrenheit, master=left, hook=CtoF_FreeAxisHook
// NOTE master=left part which makes the "free" axis
// actually a "slave" to the left ("master") axis.
End

Function CtoF_FreeAxisHook(info)

STRUCT WMAxisHookStruct &info

GetAxis/Q/W=$info.win $info.mastName // get master axis range in V_min, V_Max
Variable minF = V_min*9/5+32
Variable maxF = V_max*9/5+32

// SetAxis/W=$info.win $info.axName, minF, maxF
// SetAxis here is fruitless. These values get overwritten by Igor
// after reading info.min and info.max, which we now set:
info.min = minF // new min for free axis
info.max = maxF // new max for free axis
return 0
End

See Also

The SetAxis, KillFreeAxis, and NewFreeAxis operations.

The ModifyGraph (axes) operation for changing other aspects of a free axis.
ModifyGizmo

ModifyGizmo [flags] keyword [=value]
The ModifyGizmo operation changes Gizmo properties.

Documentation for the ModifyGizmo operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "ModifyGizmo"

ModifyGraph  (general)

ModifyGraph [/W=winName/Z] key=value [, key=value]...
The ModifyGraph operation modifies the target or named graph. This section of ModifyGraph relates to general graph window settings.

Parameters

expand=e
Specifies the onscreen expansion (or magnification) factor of a graph. e may be zero or 0.125 to 8 times expansion.

Graph magnification affects only base graphs (not subwindowed graphs), and it affects only the onscreen display; it has no effect on graph exporting or printing.

When magnification changes, the graph window will automatically resize except for negative values, which are used in recreation macros where the size is already correct.

frameInset= i
Specifies the number of pixels by which to inset the frame of the graph subwindow.

frameStyle= f
Specifies the frame style for a graph subwindow.

f=0:   None.
f=1:   Single.
f=2:   Double.
f=3:   Triple.
f=4:   Shadow.
f=5:   Indented.
f=6:   Raised.
f=7:   Text well.

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the graph itself is a light shade of gray.

gfMult= f
Multiplies font and marker size by f percent. Clipped to between 25% and 400%; it is applied after all other font and marker size calculations.

gFont=fontStr
Specifies the name of the default font for the graph, overriding the normal default font. The normal default font for a subgraph is obtained from its parent while a base graph uses the value set by the DefaultFont operation.

gfSize=gfs
Sets the default size for text in the graph. Normally, the default size for text is proportional to the graph size; gfSize will override that calculation as will the gfRelSize method. Use a value of -1 to make a subgraph get its default font size from its parent.

gfRelSize=pct
Specifies the percentage of the graph size to use in calculating a default size for text in the graph. This overrides the normal method for setting default font size as a function of graph size. When used, the default marker size is set to one third the font size. Use a value of 0 to revert to the default method.

gmSize=gms
Sets the default size for markers in the graph. Use a value of -1 to make a subgraph get its default marker size from its parent.

height=heightSpec
Sets the height for the graph area. See the Examples.
ModifyGraph (general)

**swapXY=s**  
Sets the orientation of the X and Y axes.  
\(s=0\): Normal orientation of X and Y axes.  
\(s=1\): Swap X and Y values to plot Y coordinates versus the horizontal axes and X coordinates versus the vertical axes. The effect is similar to mirroring the graph about the lower-left to upper-right diagonal.

**useComma=uc**  
Controls the decimal separator used in tick mark labels.  
\(uc=0\): Use period as decimal separator and comma as thousands separator (default) when displaying numbers in graph labels and annotations.  
\(uc=1\): Use comma as decimal separator and period as the thousands separator. This does not alter the presentation of numbers in \{expression\} constructs in annotations.

**UIControl=f**  
Disables certain aspects of the user interface for graphs. The UIControl keyword, added in Igor Pro 7.00, is for use by advanced Igor programmers who want to disable user actions.  
This is a bitwise setting. Setting Bit Parameters on page IV-12 for details about bit settings.  
\(f\) is defined as follows:  
Bit 0: Disable axis click. Prevents moving or otherwise modifying an axis.  
Bit 1: Disable cursor click. Prevents moving a graph cursor.  
Bit 2: Disable trace drag. Prohibits the click-and-hold action to offset a trace on the graph.  
Bit 3: Disable marquee. When set, you can’t make a marquee on the graph, which in turn prevents changing the range of the graph using the marquee.  
Bit 4: Disable draw mode.  
Bit 5: Disable double click. Prohibits any double-click action. In general, double-clicks in a graph bring up dialogs to modify the graph’s appearance.  
Bit 6: Disable clicks on annotations. Prevents modification of annotations.  
Bit 7: Disable tool tips.  
Bit 8: Disable contextual menus.  
Bit 9: Disable marquee menu. With this set, you can still have a marquee and use it for, i.e., selecting some portion of the graph, but you can’t use the marquee menu to change the graph’s range. Note that if bit 3 is set, this bit is moot.  
Bit 10: Disable mouse wheel events. This will prevent axis scaling using the mouse wheel.  
Bit 11: Disable option-drag. Prevents offsetting the graph by holding down the option (Macintosh) or Alt (Windows) key and then dragging in the plot area.

To disable items in the Graph menu use **SetIgorMenuMode**.

**useDotForX=u**  
In the display of axis labels, if \(u=1\) then, in instances of exponential notation such as \(5\times10^3\), the normal “x” is replaced with a dot giving \(5\times10^3\). useDotForX was added in Igor Pro 9.00.

**useLongMinus=m**  
Uses a normal (\(m=0\); default) or long dash (\(m=1\)) for the minus sign.

**width=widthSpec**  
Sets the width of the graph area. See the examples.
Flags

/W=winName  Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z  Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

Examples

The following code creates a graph where all the text expands and contracts directly in relation to the window size:

Make jack=sin(x/8);display jack
ModifyGraph mode=4,marker=8,gfRelSize=5.0
TextBox/N=text0/A=MC "Some \Zr200big\\0 and \Zr050small\\0\text"

The widthSpec and heightSpecs set the width and height mode for the top graph. The following examples illustrate how to specify the various modes.

ModifyGraph width=0, height=0  Set to auto height, width mode. The width, height of horizontal and vertical axes are automatically determined based on the overall size of the graph and other factors such as axis offset setting and effect of exterior textboxes. This is the normal, default mode.

Variable n=72*5
ModifyGraph width=n  Five inches as points absolute width mode, horizontal axis width constrained to n points.

ModifyGraph height=n  Absolute height mode, n is in points. The height of the vertical axes is constrained to n points.

Variable n=2
ModifyGraph width=perUnit,n,bottom  Per unit width mode. The width of the horizontal axes is n points times the range of the bottom axis.

ModifyGraph height={Aspect,n}  Aspect height mode, n = aspect ratio. The height of the vertical axes is n times the width of the horizontal axes.

ModifyGraph width={Plan,n,bottom,left}  Plan width mode. The width of the horizontal axes is n times the height of the vertical axes times range of the bottom axis divided by the range of the left axis.

ModifyGraph  (traces)

ModifyGraph [/W=winName/Z] key [ (traceName) ] = value 
    [ , key [ (traceName) ] = value ]...

This section of ModifyGraph relates to modifying the appearance of wave “traces” in a graph. A trace is a representation of the data in a wave, usually connected line segments.

Parameters

Each key parameter may take an optional traceName enclosed in parentheses. Usually traceName is simply the name of a wave displayed in the graph, as in “mode (myWave)=4”. If “(traceName)” is omitted, all traces in the graph are affected. For instance, “ModifyGraph lSize=0.5” sets the lines size of all traces to 0.5 points.

For multiple trace instances, traceName is followed by the “#” character and instance number. For example, “mode (myWave#1)=4”. See Instance Notation on page IV-20.

A string containing a trace name can be used with the $ operator to specify traceName. For example, String MyTrace="myWave#1"; mode ($MyTrace)=4.

Though not shown in the syntax, the optional “(traceName)” may be replaced with “[traceIndex]”, where traceIndex is zero or a positive integer denoting the trace to be modified. “[0]” denotes the first trace appended to the graph, “[1]” denotes the second trace, etc. This syntax is used for style macros, in conjunction with the /Z flag.
For certain modes and certain properties, you can set the conditions at a specific point on a trace by appending the point number in square brackets after the trace name. For more information, see the Customize at Point on page V-625.

The parameter descriptions below omit the optional "(traceName)". When using ModifyGraph from a user-defined function, be careful not to pass wave references to ModifyGraph. ModifyGraph expects trace names, not wave references. See Trace Name Parameters on page IV-88 for details.

arrowMarker=0

```
arrowMarker=[aWave, lineThick, headLen, headFat, posMode [, barbSharp=b, barbSide=s, frameThick=f]]
```

Draws arrows instead of conventional markers at each data point in a wave. Arrows are not clipped to the plot area and will be drawn wherever a data point is within the plot area.

\(aWave\) contains arrow information for each data point. It is a two (or more) column wave containing arrow line lengths (in points) in column 0 and angles (in radians measured counterclockwise) in column 1. Zero angle is a horizontal arrow pointing to the right. If an arrow is below the minimum length of 4 points, a default marker is drawn.

You can change arrow markers into standard meteorological wind barbs by adding a column to \(aWave\) and giving it a column label of windBarb. Values are integers from 0 to 40 representing wind speeds up to 4 flags. Use positive integers for clockwise barbs and negative for the reverse. Use NaN to suppress the drawing. See Wind Barb Plots on page II-329 for an example.

Additional columns may be supplied in \(aWave\) to control parameters on a point by point basis. These optional columns are specified by dimension label and not by specific column numbers. The labels are lineThick, headLen, and headFat that correspond to the same parameters listed above.

\(lineThick\) is the line thickness in points.

\(headLen\) is the arrow head length in points.

\(headFat\) controls the arrow fatness. It is the width of the arrow head divided by the length.

\(posMode\) specifies the arrow location relative to the data point.

- **posMode=0**: Start at point.
- **posMode=1**: Middle on point.
- **posMode=2**: End at point.

In addition to the wave specification, \(aWave\) can also be the literal _inline_ to draw lines and arrows between points on the trace (see Examples). If \(aWave\) is _inline_, \(posMode\) values are:

- **posMode=0**: Arrow at start.
- **posMode=1**: Arrow in middle.
- **posMode=2**: Arrow at end.
- **posMode=3**: Arrow in middle pointing backwards.

You can also enable inline mode even if \(aWave\) is not _inline_ by setting posMode to values between 4 and 7. These are the same as modes 0-3 above.

Optional parameters must be specified using keyword = value syntax and can only be appended after posMode in any order.

\(barbSharp\) is the continuously variable barb sharpness between -1.0 and 1.0:

- **barbSharp=1**: No barb; lines only.
- **barbSharp=0**: Blunt (default).
- **barbSharp=-1**: Diamond.
barbSide specifies which side of the line has barbs relative to a right-facing arrow:

- barbSide=0: None.
- barbSide=1: Top.
- barbSide=2: Bottom.
- barbSide=3: Both (default).

frameThick specifies the stroke outline thickness of the arrow in points. The default is frameThick = 0 for solid fill.

aWave can contain columns with data for each optional parameter using matching column names.

barStrokeRGB=(r,g,b[,a])

Specifies a separate color for bar strokes (outlines) if useBarStrokeRGB is 1. r, g, b, and a specify the color and optional opacity as RGBA Values. The default is opaque black.

Applies only to Histogram Bars drawing mode (mode=5).

The bar fill color continues to be set with the rgb=(r,g,b[,a]), zColor={...}, usePlusRGB, plusRGB=(r,g,b[,a]), useNegRGB, and negRGB=(r,g,b[,a]) parameters.

Use barStrokeRGB and useBarStrokeRGB to put a differently-colored outline around Histogram Bars:

![useBarStrokeRGB=0](image1.png) ![useBarStrokeRGB=1](image2.png)

cmplxMode=c

Display method for complex waves.

- c=0: Default mode displays both real and imaginary parts (imaginary part offset by dx/2).
- c=1: Real part only.
- c=2: Imaginary part only.
- c=3: Magnitude.
- c=4: Phase (radians).

cmplxMode=0 does not work when the trace is a subrange of a multidimensional wave.

column=n

Changes the displayed column from a matrix. Out of bounds values are clipped.

gaps=g

Controls treatment of NaNs:

- g=0: No gaps (ignores NaNs).
- g=1: Gaps (shows NaNs as gaps).

gradient

See Gradient Fills on page III-498 for details.

gradientExtra

See Gradient Fills on page III-498 for details.

hBarNegFill=n

Fill kind for negative areas if useNegPat is true. n is the same as for the hbFill keyword.
**hbFill=\( n \)**
Sets the fill pattern.
- \( n=0 \): No fill.
- \( n=1 \): Erase.
- \( n=2 \): Solid black.
- \( n=3 \): 75% gray.
- \( n=4 \): 50% gray.
- \( n=5 \): 25% gray.
- \( n\geq 6 \): See **Fill Patterns** on page III-498.

\( \text{hideTrace=} h \)
Removes a trace from the graph display.
- \( h=0 \): Shows the trace if it is hidden.
- \( h=1 \): Hides the trace and removes it from autoscale calculations.
- \( h=2 \): Hides the trace.

When using \( h=1 \) to hide a graph trace, the hidden trace symbol and following text in annotations are also hidden. The amount of hidden text is the lesser of: the remaining text on the same line or the text up to but not including another trace symbol "\( \backslash s(\text{traceName}) \) ".

\( \text{lHair=} lh \)
Sets the hairline factor for traces printed on a PostScript® printer.

\( \text{lineJoin=}\{j, \, ml\} \)
Sets the line join style and miter limit.
- **Line join:**
  - \( j=0 \): Miter joins
  - \( j=1 \): Round joins
  - \( j=2 \): Bevel joins (default)
- **Miter limit:**
  - \( ml \geq 1 \): Sets miter limit to \( ml \)
  - \( ml = \text{INF} \): Sets miter limit to unlimited
  - \( ml = 0 \): Leaves miter limit unchanged
  - \( ml = -1 \): Sets miter limit to default (10)

The miter limit applies only to miter joins \( (j=0) \) and is ignored otherwise.

See **Line Join and End Cap Styles** on page III-496 for further information.

The lineJoin keyword was added in Igor Pro 8.00.

\( \text{live=lv} \)
\( lv \) is a bitwise parameter defined as follows:
- **Bit 0:** Live mode (see Live Mode below)
- **Bit 1:** Fast line drawing (see Fast Line Drawing)

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

\( \text{logZColor=lzc} \)
Controls the interpretation of the zColor parameter.
- \( lzc=0 \): Sets the default linearly-spaced zColors.
- \( lzc=1 \): Turns on logarithmically-spaced zColors. This requires that the zWave values be greater than 0 to display correctly.

Affects trace line color only when the zColor parameter is used with a color table or color index wave - it has no effect if \( \text{rgb=(}r,g,b\text{)} \) parameter or \( \text{zColor=}\{\ldots,\text{directRGB}\} \) are used.
ModifyGraph (traces)

lOptions=cap
Sets the line end cap style:

cap=0: Flat caps

cap=1: Round caps

cap=2: Square caps (default)

See Line Join and End Cap Styles on page III-496 for further information.

lSize=l
Sets the line thickness, which can be fractional or zero, which hides the line.

lSmooth=ls
Sets the smoothing factor for traces printed on a PostScript® printer.

lStyle=s
Sets trace line style or dash pattern.

s=0 for solid lines. s=1 to s=17 for various dashed line styles.

<table>
<thead>
<tr>
<th>Value</th>
<th>Dash Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solid</td>
</tr>
<tr>

</tbody>
</table>

marker=n
n =0 to 62 designates various markers if mode=3 or 4.

You can also create custom markers. See the SetWindow markerHook keyword. See Markers on page II-291 for a table of marker values.

mask=({maskWave, mode, value} or 0

Specifies individual points for display by comparing values in maskWave with value as specified by mode.

mode=0: Exclude if equal.
mode=1: Include if equal.
mode=2: Include if bitwise AND is true.
mode=3: Include if bitwise AND is false.

maskWave can be specified using subrange notation. The length of maskWave (or subrange) must match the size of specified trace’s wave (or subrange.) Bitwise modes should be used with integer waves with the intent of using one mask wave with multiple traces. See Examples.

mode=m
Sets trace display mode.

m=0: Lines between points.

m=1: Sticks to zero.

m=2: Dots at points.

m=3: Markers.

m=4: Lines and markers.

m=5: Histogram bars.

m=6: Cityscape.

m=7: Fill to zero.

m=8: Sticks and markers.

mrkFillRGB=(r,g,b[,a])
Sets the background fill color for hollow markers. \( r, g, b, \text{ and } a \) specify the color and optional opacity as RGBA Values.

This setting takes effect only if opaque is set to non-zero. See the opaque keyword below.

The mrkFillRGB keyword was added in Igor Pro 9.00.

\[
\text{mrkStrokeRGB}=(r,g,b[,a])
\]

Specifies the color for marker stroked lines if useMrkStrokeRGB = 1. \( r, g, b, \text{ and } a \) specify the color and optional opacity as RGBA Values. The default is opaque black.

The marker fill color continues to be set with the rgb=(r,g,b[,...]) or zColor={...} parameters.

Applies only to the nontext and nonarrow marker modes.

Use mrkStrokeRGB and useMrkStrokeRGB to put a colored outline around filled markers, such as marker=19:

![Example images of filled markers with and without a stroke](image1.png)

**Note:** The stroke color of unfilled markers such as marker 8 is also affected by mrkStrokeRGB, but their fill color is only affected by the opaque parameter (and the opaque fill color is always white, so if you want a color-filled marker, don’t use unfilled markers).

\[
\text{mrkThick}=t
\]

Sets the thickness of markers in points, which can be fractional.

\[
\text{msize}=m
\]

Specifies the marker size in points.

- \( m=0 \): Autosize markers.
- \( m>0 \): Sets marker size.

\( m \) can be fractional, which will only make a difference when the graph is printed because fractional points can not be displayed on the screen.

\[
\text{mskip}=n
\]

Puts a marker on only every \( n \)th data point in Lines and Markers mode (mode=4). Useful for displaying many data points when you want to identify the traces with markers. The maximum value for \( n \) is 32767.

\[
\text{m standoff}=s
\]

Prevents lines from touching markers in lines and markers mode if \( s \) is greater than zero. \( s \) is in units of points. This feature was added in Igor Pro 8.00.

\[
\text{muloffset}=(mx,my)
\]

Sets the display multiplier for X (\( mx \)) and Y (\( my \)). The effective value for a given X or Y data point then becomes \( \text{muloffset} \times \text{data+offset} \). A value of zero means “no multiplier” — not multiply by zero.

\[
\text{negRGB}=(r,g,b[,...])
\]

Specifies the color for negative values represented by the trace if useNegRGB is 1. \( r, g, b, \text{ and } a \) specify the color and optional opacity as RGBA Values.

\[
\text{offset}=[x,y]
\]

Sets the display offset in horizontal (X) and vertical (Y) axis units.

\[
\text{opaque}=o
\]

Displays transparent (\( o=0 \)) or opaque (\( o=1 \)) markers.

If \( o \) is zero (default) hollow markers such as unfilled circles and boxes have transparent backgrounds. If \( o \) is non-zero, the background is filled with color. The color defaults to white, but you can change it using the mrkFillRGB keyword.

\[
\text{patBkgColor}=0, 1, 2 \text{ or } (r,g,b[,a])
\]
Specifies the background color for fill patterns.  
0, the default, is white, 1 is graph background, 2 is transparent.  
Use \( (r,g,b,a) \) for a specific RGB color.  \( r, g, b \), and \( a \) specify the color and optional opacity as RGBA Values.

\[ \text{plotClip} = p \]  
p = 1 clips the trace by the operating system (not by Igor) to the plot rectangle. This trims overhanging markers and thick lines. On Windows, this may not be supported for certain printers or by certain applications when importing.

\[ \text{plusRGB} = (r,g,b[,a]) \]  
Specifies the color for positive values represented by the trace if usePlusRGB is 1.  \( r, g, b \), and \( a \) specify the color and optional opacity as RGBA Values.

\[ \text{quickdrag} = q \]  
Controls dragging of traces.  
\( q=0 \): Normal traces.  
\( q=1 \): Traces that can be instantly dragged without the normal one second delay. See the Quickdrag section below.  
\( q=2 \): Causes the mouse cursor to change to 4 arrows when over the trace and a reduced search is used.

\[ \text{removeCustom} = r \]  
Removes per-point trace customizations. See Customize at Point on page II-306 for background information. The removeCustom keyword was added in Igor Pro 9.00.  
The parameter \( r \) is required by the ModifyGraph syntax, but its value is immaterial. We recommend using 1 for \( r \) but any number will work.  
These examples show how to use the removeCustom keyword given a graph with a trace named wave0:

\[
// \text{Remove customizations for point 3 of trace wave0} 
\text{ModifyGraph removeCustom(wave0[3])} = 1
\]

\[
// \text{Remove customizations for all points of trace wave0} 
\text{ModifyGraph removeCustom(wave0)} = 1
\]

\[
// \text{Remove customizations for all points of all traces} 
\text{ModifyGraph removeCustom = 1}
\]

\[ \text{rgb} = (r,g,b[,a]) \]  
Specifies the color of the trace.  \( r, g, b \), and \( a \) specify the color and optional opacity as RGBA Values.

\[ \text{textMarker} = \{ <\text{char or wave}>, font, style, rot, just, xOffset, yOffset \} \text{ or 0} \]  
Uses the specified character or text from the specified wave in place of the marker for each point in the trace.  
If the first parameter is a quoted string or a string expression of the form 
\("+\\text{strexpr}\) in a user function, ModifyGraph uses the first three bytes of the string as the marker for all points. Three bytes are supported mainly for non-ASCII characters but can be used for 3 separate single-byte characters. Otherwise, it interprets the first parameter as the name of a wave. If the wave is a text wave, it uses the value of each point in the text wave as the marker for the corresponding point in the trace. If the wave is a numeric wave, the value for each point is converted into text and the result is used as the marker for the corresponding point in the trace.

\( \text{xOffset} \) and \( \text{yOffset} \) are offsets in fractional points. Each marker will be drawn offset from the location of the corresponding point in the trace by these amounts.

\text{style} is a font style code as used with the ModifyGraph fstyle keyword.

\text{rot} is a text rotation between -360 and 360 degrees.

\text{just} is a justification code as used in the DrawText operation except the X and Y codes are combined as \( y*4+x \). Use 5 for centered.

The font size is \( 3*\text{marker size} \). Note that marker size and color can be dynamically set via the zColor and zmrkSize keywords.
ModifyGraph (traces)

**toMode=t**

Modifies the behavior of the display modes as determined by the mode parameter.

- **t=0**: Fill to zero.
- **t=1**: Fill to next trace. Applies to Sticks to zero (mode=1), histogram bars (mode=5), and fill to zero (mode=7).
- **t=2**: Add the current trace’s Y values to the next trace’s Y values. Works with all display modes.
- **t=3**: Stack on next and is the same as t=2 except that the added value is clipped to zero. Works with all display modes.
- **t=-1**: This mode is used only with category plots and means "keep with next" (i.e., put in the same subcategory as the next trace). It is used for special effects only.

For modes 1, 2 and 3, both Y-waves must have the same number of points and must use the same X values. Igor uses the X values from the first wave for both Y-

**traceName=name**

Sets, changes, or removes a custom trace name.

The traceName keyword was added in Igor Pro 9.00.

By default Igor assigns trace names based on the name of the displayed wave. You can assign a custom trace name when appending a wave to a graph using the /TN flag with the Display and AppendToGraph operations. See Trace Names on page II-282 for details.

The traceName keyword allows you to change the name of a trace after it has been added to a graph. For example:

```plaintext
Make/O wave0; Display wave0  
ModifyGraph traceName(wave0)=Custom0
```

Use "$" for name to remove the custom name and revert to the default trace name:

```plaintext
ModifyGraph traceName(Custom0)="$"
```

Renaming a trace can change the names of other traces in the graph from the same wave. For example, if you display two instances of wave0 in one graph, the first trace name is wave0 and the second is wave0#1. If you now rename trace wave0, the name of the second instance of wave0 changes from wave0#1 to wave0. See Instance Notation on page IV-20 for further discussion.

**useBarStrokeRGB=u**

If u=1 then bar stroked lines use the color specified by the barStrokeRGB keyword. Applies only to Histogram Bars drawing mode (mode=5).

The bar fill color continues to be set with the rgb, zColor, usePlusRGB, plusRGB, useNegRGB, and negRGB keywords.

If u=0 then the bar stroked line colors are set with the rgb=(r,g,b[,a]) or zColor={…} parameters, just like the bar fill color.

**useMrkStrokeRGB=u**

If u=1 then marker stroked lines use the color specified by the mrkStrokeRGB keyword. The marker fill color continues to be set with the rgb=(r,g,b[,a]) or zColor={…} parameters.

Applies only to the nontext and nonnarrow marker modes.

If u=0 then the marker stroked line colors are set with the rgb=(r,g,b[,a]) or zColor={…} parameters, just like the marker fill color.

**useNegPat=u**

If u=1, negative fills use the mode specified by the hBarNegFill keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.

**useNegRGB=u**

If u=1, negative fills use the color specified by the negRGB keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.
usePlusRGB = u

If u = 1, positive fills use the color specified by the plusRGB keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.

userData = {udName, doAppend, data}

Attaches arbitrary data to a trace. You should specify a trace name (userData(<traceName>)={...}). Otherwise copies of the data will be attached to every trace, which is most likely not what you intend.

Use the GetUserData function to retrieve the data, with the trace name as the object ID.

 UDName: The name of your user data. Use "$" for unnamed user data.
 DoAppend=0: Do not append. Any pre-existing data is replaced.
 DoAppend=1: Append the data. Data is added to the end of any pre-existing data.
 Data: A string expression containing the data you wish to attach to the trace.

zColor = {zWave, zMin, zMax, ctName [reverseMode [, cWave]]} or 0

Dynamically sets color based on the values in zWave and color table name or mode specified by ctName.

zWave may be a subrange expression such as myZWave[2, 9] when zWave has more points than the trace, in which case myZWave[2] provides the Z value for the first point of the trace, and autoscaled zMin or zMax is determined over only the zWave subrange.

If a value in the zWave is NaN then a gap or missing marker will be observed. If a value is out of range it will be replaced with the nearest valid value. See also the zColorMax and zColorMin keywords.

cName can be the name of a built-in color table such as returned by the CTabList function, such as Grays or Rainbow, for color table mode, ctableRGB for color table wave mode, cindexRGB for color index wave mode, or directRGB for direct color wave mode.

zColor for Built-in Color Table Mode

This mode uses zWave to select a color from a built-in color table specified by ctName. See Image Color Tables on page II-392 for details.

zWave contains values that are used to select a color from the built-in color table specified by ctName.

zMin is the zWave value that maps to the first entry in the color table. Use * for zMin to autoscale it to the smallest value in zWave.

zMax is the zWave value that maps to the last entry in the color table. Use * for zMax to autoscale it to the largest value in zWave.

ctName is the name of a built-in color table such as Grays or Rainbow. See the CTabList function for a list of built-in color tables.

Set reverseMode to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit reverseMode or specify -1, the reverse mode is unchanged.

cWave must be omitted.

Normally the colors from the color table are linearly distributed between zMin and zMax. Use logzColor=1 to distribute them logarithmically.

// Example zColor command using built-in color table
ModifyGraph zColor(data)={zWave, *, *, Rainbow}
**zColor for Color Table Wave Mode**

This mode is like Built-in Color Table except that the colors are stored in a color table wave that you have created. A color table wave can be a 3 column RGB wave or a 4 column RGBA wave. See Color Table Waves on page II-399 for details.

- \( z\text{Wave} \) contains values that are used to select a color from the color table wave specified by \( c\text{Wave} \).
- \( z\text{Min} \) is the \( z\text{Wave} \) value that maps to the first entry in the color table wave. Use * for \( z\text{Min} \) to autoscale it to the smallest value in \( z\text{Wave} \).
- \( z\text{Max} \) is the \( z\text{Wave} \) value that maps to the last entry in the color table wave. Use * for \( z\text{Max} \) to autoscale it to the largest value in \( z\text{Wave} \).
- \( ct\text{Name} \) is \( \text{ctableRGB} \).

Set \( reverse\text{Mode} \) to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit \( reverse\text{Mode} \) or specify -1, the reverse mode is unchanged.

\( c\text{Wave} \) is a reference to your color table wave.

Normally the colors from the color table are linearly distributed between \( z\text{Min} \) and \( z\text{Max} \). Use \( \log\text{ZColor}=1 \) to distribute them logarithmically.

**Example ctableRGB zColor command:**

```cpp
ColorTab2Wave Rainbow // Creates M_Colors wave
Rename M_Colors, MyColorTableWave
ModifyGraph zColor(data)={zWave,*,*,ctableRGB,0,MyColorTableWave}
```

**zColor for Color Index Wave Mode**

This mode is like Color Table Wave except that the values in \( z\text{Wave} \) represent X indices with respect to \( c\text{Wave} \). You must create the RGB or RGBA color index wave and set its X scaling appropriately. See Color Index Wave on page II-372 for details.

- \( z\text{Wave} \) contains values that are used to select a color from the color index wave specified by \( c\text{Wave} \).
- \( z\text{Min} \) and \( z\text{Max} \) are not used and should be set to *.
- \( ct\text{Name} \) is \( \text{cindexRGB} \).

Set \( reverse\text{Mode} \) to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit \( reverse\text{Mode} \) or specify -1, the reverse mode is unchanged. Normally the \( z\text{Wave} \) values select the color from the row of \( c\text{Wave} \) whose X value is closest to the \( z\text{Wave} \) value. \( reverse\text{Mode}=1 \) reverses the colors.

\( c\text{Wave} \) is a reference to your color index wave.

Normally the colors from the color index wave are linearly distributed between the minimum and maximum X values of the color index wave. Use \( \log\text{ZColor}=1 \) to distribute them logarithmically.

**Example cindexRGB zColor command**

```cpp
zColor(data)={myZWave,*,*,cindexRGB,0,M_colors}
// M_colors is generated by ColorTab2Wave
```
zColor for Direct Color Wave Mode

In direct color mode, zWave is an RGB or RGBA wave that directly specifies the color for each point in the trace. If zWave is 8-bit unsigned integer, then color component values range from 0 to 255. For other numeric types, color component values range from 0 to 65535. See ColorTab2Wave, which generates RGB waves, and Direct Color Details on page II-401.

zWave is an RGB or RGBA wave that directly specifies the color for each point of the trace.

zMin and zMax are not used and should be set to *.

cName is directRGB.

reverseMode is not applicable and should be omitted or set to 0.

cWave must be omitted.

// Example directRGB zColor command
zColor(data)={zWaveRGB,*,*,directRGB}

Turning zColor Off

zColor = 0 turns the zColor modes off.

zColorMax=(red, green, blue)

Sets the color of the trace for zColor=[zWave, …] values greater than the zColor’s zMax. Also turns on zColorMax mode.

The red, green, and blue color values are in the range of 0 to 65535.

zColorMax=1, 0, or NaN

Turns zColorMax mode off, on, or transparent. These modes affect the color of zColor=[zWave, …] values greater than the zColor’s zMax.

1: Turns on zColorMax mode. The color of the affected trace pixels is black or the last color set by zColorMax=(red, green, blue).

0: Turns off zColorMax mode (default). The color of the affected trace pixels is the last color in the zColor’s ctname color table.

NaN: Transparent zColorMax mode. Affected trace pixels are not drawn.

zColorMin=(red, green, blue)

Sets the color of the trace for zColor=[zWave, …] values less than the zColor’s zMin. Also turns zColorMin mode on.

The red, green, and blue color values are in the range of 0 to 65535.

zColorMin=1, 0, or NaN

Turns zColorMin mode off, on, or transparent. These modes affect the color of zColor=[zWave, …] values less than the zColor’s zMin.

1: Turns on zColorMin mode. The color of the affected image pixels is black or the last color set by zColorMin=(red, green, blue).

0: Turns off zColorMin mode (default). The color of the affected trace pixels is the first color in the zColor’s ctname color table.

NaN: Transparent zColorMin mode. Affected trace pixels are not drawn.

zmrkNum=[zWave] or 0
Dynamically sets the marker number for each point to the corresponding value in \textit{zWave}. The values in \textit{zWave} are the marker numbers (as used with the marker keyword). If a value in the \textit{zWave} is NaN then no marker will be drawn at the corresponding point. If a value is out of range it will be replaced with the nearest valid value.

\texttt{zmrkNum=0} turns this mode off.

\texttt{zmrkSize=[zWave,zMin,zMax,\textit{mrkMin} ,\textit{mrkMax},[axis]]} or 0

Dynamically sets marker size based on values in \textit{zWave}. See \textbf{Marker Size as f(z)} on page II-299 for background information.

\texttt{zmrkSize = 0} turns this mode off.

Use * or a missing parameter for \textit{zMin} and \textit{zMax} to autoscale. \textit{mrkMin} and \textit{mrkMax} can be fractional.

\textit{mrkMin} is the marker size to use when \textit{z} equals \textit{zMin} and \textit{mrkMax} is the marker size to use when \textit{z} equals \textit{zMax}. \textit{mrkMin} and \textit{mrkMax} are not limits; they just control the linear mapping of \textit{z} values to marker size.

If a value in the \textit{zWave} is NaN then the corresponding marker is not drawn.

The marker size is clipped to 400 on the high end and to 1 point on the low end.

\textit{axis} is an optional parameter specifying an existing axis on the graph. It is supported in Igor Pro 9.00 and later. Passing \$\text{""}" for \textit{axis} is the same as omitting it.

If \textit{axis} is specified, the values in \textit{zWave} are interpreted as in units of the specified axis and specify the half-width of the marker to be drawn. For a circle marker, this is the radius of the marker.

If \textit{axis} is specified, the \textit{zMin}, \textit{zMax}, \textit{mrkMin}, and \textit{mrkMax} parameters have no impact on the marker size unless you remove the specified axis in which case those parameters control the trace's marker sizes.

See \textbf{Marker Size as f(z) in Axis Units} on page II-300 for further information.

\texttt{zpatNum=[zWave]} or 0

Dynamically sets the positive fill type/pattern number for each point to the corresponding value in \textit{zWave}. The values in \textit{zWave} are the pattern numbers (as used with the \texttt{hbFill} keyword). If a value in the \textit{zWave} is NaN then the corresponding point will not be drawn. If a value is out of range it will be replaced with the nearest valid value.

\texttt{zpatNum=0} turns this mode off.

Flags

\texttt{/W=winName} Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the Command Line.

When identifying a subwindow with \textit{winName}, see \textbf{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.

\texttt{/Z} Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

Details

Waves supplied with \texttt{zmrkSize}, \texttt{zmrkNum}, and \texttt{zColor} may use \textbf{Subrange Display Syntax} on page II-321.

Live Mode

Bit 0 of \texttt{live=lv} controls live mode. Live mode improves graph update performance when one or more of the waves displayed in the graph is frequently modified, for example, if the waves are being acquired from a data acquisition system. Live Mode traces do not autoscale axes.
Fast Line Drawing

Bit 1 of live=lv controls fast line drawing. When enabled, Igor draws traces in lines-between-points mode using custom fast code instead of the normal system drawing code. The result is not as esthetically pleasing but can be much faster and may be critical in data acquisition applications. The custom code is used only for drawing to the screen, not for exporting graphics.

Fast line drawing was added in Igor Pro 8.00.

Quickdrag

Quick drag mode (quickdrag=1) is a special purpose mode for creating cross hair cursors using a package of Igor procedures. (See the Cross Hair Demo example experiment.) Normally you would have to click and hold on a trace for one second before entering drag mode. When quickdrag is in effect, there is no delay. If a trace is in quickdrag mode it should also be set to live mode. With this combination you can click a trace and immediately drag it to a new XY offset. In addition to quick drag mode, the cross hair package relies on Igor to store information about the drag in a string variable if certain conditions are in effect. The string variable name (that you have to create) is $\_TraceOffsetInfo, which must reside in a data folder that has the same name as the graph (not title!) which in turn must reside in root:WinGlobals:. If these conditions are met, then after a trace is dragged, information will be stored in the string using the following key-value format:

```
GRAPH:<name of graph>;XOFFSET:<x offset value>;YOFFSET:<y offset value>;TNAME:<trace name>
```

Customize at Point

You can customize the appearance of individual points on a trace in a graph for bar, marker, dot and lines to zero modes using key(tracename[pnt])=value syntax. The point number must be a literal number and the trace name is required.

To remove a customization, use key(tracename[-pnt-1])=value where value is not important but must match the syntax for the keyword. The offset of -1 is needed because point numbers start from zero.

You can also remove customizations using the removeCustom keyword described above.

Although the syntax is allowed for all trace modifiers, it has meaning only for the following: rgb, marker, msize, mrkThick, opaque, mrkFillRGB, mrkStrokeRGB, barStrokeRGB, hbFillRGB, patBkgColor and lSize.

Note that useBarStrokeRGB and useMrkStrokeRGB are not needed. The act of using barStrokeRGB or mrkStrokeRGB is enough to customize the point. But as a convenience, since these are generated by the modify graph dialog, they are ignored if used with [pnt] syntax.

Also note that legend symbols can use [pnt] syntax like so:

```
\$<tracename>[pnt])
```

Automatically generated legends automatically include symbols for customized points.

For example:

```
Make/O/N=10 jack=sin(x); Display jack
ModifyGraph mode=5,hbFill=6,rgb=(0,0,0)
ModifyGraph hbFill(jack[2])={7,rgb(jack[2]=0,65535,0)
ModifyGraph rgb(jack[3])=(65535,0,0)
Legend/C/N=text1/F=0/A=MC
```

Examples

Arrow markers.

```
Make/N=10 wavel= x; Display wavel
Make/N=(10,2) awave
awave[0][0]= p*5 // length
awave[0][1]= pi*p/9 // angle
ModifyGraph mode=3,arrowMarker(wavel)=awave(1,10,0.3,0)
// Now add an optional column to control headLen
Redimension/N=(-1,3) awave
awave[2][2]= 7+p // will be head length
// Note: nothing changes until the following is executed
SetDimLabel 1,2,headLen,awave
```

Create meteorological wind barb symbols.

```
Make/O/N=50 jack= floor(x/10),jackx= mod(x,10)
Display jack vs jackx
Make/O/N=(50,3) jackbarb
```
ModifyGraph (axes)

jackbarb[0]= 40 // length of stem
jackbarb[1]= 45*pi/180 // angle (45deg)
SetDimLabel 1,2,windBarb,jackbarb
ModifyGraph mode=3,arrowMarker(jack)=jackbarb,1,10,0.5,0
ModifyGraph margin(top)=62,margin(right)=84

See also Wind Barb Plots on page II-329.

Inline arrows and barb sharpness.
Make/O/N=20 wavex=cos(x/3),wavey=sin(x)
Display wavey vs wavex
ModifyGraph mode=3,arrowMarker={_inline_,1,20,.5,0,barbSharp= 0.2}

Use direct color mode to individually color each point in a trace:
Make jack=sin(x/8)
Make/N=(128,3)/B/U jackrgb
Display jack
ModifyGraph mode=3,marker=19
jackrgb= enoise(128)+128
ModifyGraph zColor(jack)={jackrgb,*,*,directRGB}

Use masking.
Make/N=100 jack= (p&1) ? sin(x/8) : cos(x/8)
Display jack
Make/N=100 mjack= (p&1) ? 0 : NaN // just to show NaN can be used
ModifyGraph mask(jack)={mjack,0,NaN}
// now switch which points are shown
mjack= (p&1) ? NaN : 0

See Also
Trace Names on page II-282, Programming With Trace Names on page IV-87.

ModifyGraph (axes)

modifygraph [/W=winName/Z] key [(axisName)] = value
[, key [(axisName)] = value]…

This section of ModifyGraph relates to modifying the appearance of axes in a graph.

Parameters
Each key parameter may take an optional axisName enclosed in parentheses.
axisName is “left”, “right”, “top”, “bottom” or the name of a free axis such as “vertCrossing”. For instance, “ModifyGraph axThick(left)=0.5” sets the axis thickness for only the left axis.

If “(axisName)” is omitted, all axes in the graph are affected. For instance, “ModifyGraph standoff=0” disables axis standoff for all axes in the graph.

The parameter descriptions below omit the optional “(axisName)”.

axisClip= c
    Specifies one of three clipping modes for traces.
    c=0: Clips traces to a plot rectangle as defined by the pair of axes used by a given trace (default).
    c=1: Plots traces on an axis with a restricted range (as set by axisEnab) to extend to the full range of the normal plot rectangle.
    c=2: Traces extend outside the normal plot rectangle to the full extent of the graph area.

axisEnab=[lowFrac,highFrac]

Restricts the length of an axis to a subrange of normal. The axis is drawn from lowFrac to highFrac of graph area height (vertical axis) or width (horizontal axis). For instance, {0.1,0.75} specifies that the axis is drawn from 10% to 75% of the graph area height/width, instead of the normal 0% to 100%. AxisEnab is discussed in Creating Split Axes on page II-347 and Creating Stacked Plots on page II-324.
axisOnTop=t

Specifies drawing level of axis and associated grid lines.

t=0: Draws axis before traces and images (default).

t=1: Draws the axis after all traces and images.

axOffset=a

Specifies the distance from default axis position to actual axis position in units of the width of a zero character (0) in a tick mark label. Unlike margin, axOffset adjusts to changes in the size of the graph.

axThick=t

Specifies the axis thickness in points.

barGap=fraction

Sets the fraction of the width available for bars to be used as gap between bars.

barGap sets the gap between bars within a single category while catGap sets the gap between categories.

btLen=p

Sets the length of major ("big") tick marks to p points. If p is zero, it uses the default length. p may be fractional.

btThick=p

Sets the thickness of major ("big") tick marks to p points. If p is zero, it uses the default thickness. p may be fractional.

catGap=fraction

The value for catGap is the fraction of the category width to be used as gap. The gap is divided equally between the start and end of the category width. A value of 0.2 would use 20% of the available space for the gap and leave 80% of the available space for the bars.

catGap sets the gap between categories while barGap sets the gap between bars within a single category.

dateFormat={languageName, yearFormat, monthFormat, dayOfMonthFormat, dayOfWeekFormat, layoutStr, commonFormat}

Sets the custom date format used in the active graph.

Note: Use a custom date format only if you turn it on via a ModifyGraph dateInfo command. The last parameter to the ModifyGraph dateInfo command must be -1 to turn on the custom date format.

Parameters are the same as for the LoadWave/R flag except for the last one.

commonFormat selects the common date format to use in the Modify Axis dialog. The legal values correspond to the choices in the Common Format pop-up menu of the Modify Axis dialog. They are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Date Format</th>
<th>Value</th>
<th>Date Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>mm/dd/yy</td>
<td>16</td>
<td>mm/yy</td>
</tr>
<tr>
<td>2</td>
<td>mm-dd-yy</td>
<td>17</td>
<td>mm.yy</td>
</tr>
<tr>
<td>3</td>
<td>mm.dd.yy</td>
<td>18</td>
<td>Abbreviated month and year</td>
</tr>
<tr>
<td>4</td>
<td>mm/ddyy</td>
<td>19</td>
<td>Full month and year</td>
</tr>
<tr>
<td>6</td>
<td>dd/mm/yy</td>
<td>21</td>
<td>mm/dd</td>
</tr>
<tr>
<td>7</td>
<td>dd-mm-yy</td>
<td>22</td>
<td>dd.mm</td>
</tr>
<tr>
<td>8</td>
<td>dd.mm.yy</td>
<td>23</td>
<td>Abbreviated month and day</td>
</tr>
<tr>
<td>9</td>
<td>ddmmyy</td>
<td>24</td>
<td>Full month and day</td>
</tr>
<tr>
<td>11</td>
<td>yy/mm/dd</td>
<td>26</td>
<td>Abbreviated date without day of week</td>
</tr>
<tr>
<td>12</td>
<td>yy-mm-dd</td>
<td>27</td>
<td>Abbreviated date with day of week</td>
</tr>
<tr>
<td>13</td>
<td>yy.mm.dd</td>
<td>28</td>
<td>Full date without day of week</td>
</tr>
<tr>
<td>14</td>
<td>yymmdd</td>
<td>29</td>
<td>Full date with day of week</td>
</tr>
</tbody>
</table>
If the `commonFormat` parameter is negative, then it will select the Use Custom Format radio button in the Modify Axis dialog rather than Use Common Format and will then use the absolute value of `commonFormat` to determine which item to select in the Common Format pop-up menu.

dateInfo=[sd,tm,dt]  
Controls formatting of date/time axes.

- `sd=0`: Show date in the date&time format.
  The date is always suppressed if `tm=2` (elapsed time).
  The time is always suppressed if there are fewer than one ticks per day and `tm=0` (12-hour time) or `tm=1` (24-hour time).

- `sd=1`: Suppress date.
  The date is always suppressed if `tm=2` (elapsed time).

- `sd=2`: Suppress time.
  The time is always shown if `tm=2` (elapsed time).
  `sd=2` requires Igor Pro 9.00 or later.

- `tm=0`: 12 hour (AM/PM) time.

- `tm=1`: 24 hour (military) time.

- `tm=2`: Elapsed time.

- `dt=1`: Custom date as specified via the dateFormat keyword.

- `dt=0`: Short dates (2/22/90).

font="fontName"  
Sets the axis label font, e.g., `font(left)="Helvetica"`.

freePos(freeAxName)=p  
Sets the position of the `free` axis relative to the edge of the plot area to which the axis is anchored. `p` is in points. i.e., if the axis was made via `/R=axName` then the axis is placed `p` points from the right edge of the plot area. Positive is away from the central plot area. `freeAxName` may not be any of the standard axes: “left”, “bottom”, “right” or “top”.

freePos(freeAxName)=[crossAxVal,crossAxName]  
Positions the `free` axis so it will cross the perpendicular axis `crossAxName` where it has a value of `crossAxVal`. `freeAxName` may not be any of the standard axis names “left”, “bottom”, “right”, or “top”, though `crossAxName` may.

You can position a `free` axis as a fraction of the distance across the plot area by using `kwFraction` for `crossAxName`. `crossAxVal` then be between 0 and 1; any values outside this range are clipped to valid values.

fsize=s  
Autosizes (s=0) tick mark labels and axis labels.

If `s` is between 3 and 99 then the labels are fixed at `s` points.
fstyle=f  
*f is a bitwise parameter with each bit controlling one aspect of the font style for the axis and tick mark labels as follows:

Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

ftLen=p  
Sets the length of 5th (or emphasized minor) tick marks to p points. If p is zero, it uses the default length. p may be fractional.

ftThick=p  
Sets the thickness of 5th (or emphasized minor) tick marks to p points (fractional). If p is zero, it uses the default thickness.

grid=g  
Controls grid lines.

g=0: Grid off.

g=1: Grid on.

g=2: Grid on major ticks only.

gridEnab=[lowFrac,highFrac]  
Resticts the length of axis grid lines to a subrange of normal. The grid is drawn from lowFrac to highFrac of graph area height (if axis is horizontal) or width (if axis is vertical).

gridHair=h  
Sets the grid hairline thickness (h =0 to 3; 0 for thicker lines, 3 for thinner; default is 2). If h=0, the thickness of grid lines on major tick marks is the same as the axis thickness, half for a minor tick and one tenth for a subminor tick (log axis only). As h increases these thicknesses decrease by a factor of $2^h$. If you want to see the effect of different values of gridHair, you will need to print a sample graph because you generally can’t see the effect of thin lines on the screen. Also see the example experiment “Examples:Graphing Techniques:Graph Grid Demo”.

gridStyle=g  
Sets the grid style to various combinations of solid and dashed lines. In the following discussion, major, minor and subminor refer to grid lines the corresponding tick marks. Subminor ticks are used only on log axes when there is a small range and sufficient room (they correspond to hundredths of a decade). The different grid styes are solid, dotted, dashed, and blank. The possible grids are as follows:

g=0: Same as mode 1 if graph background is white else uses mode 5.

g=1: Major dotted, minor and subminor dashed.

g=2: All dotted.

g=3: Major solid, minor dotted, subminor blank.

g=4: Major and minor solid, subminor dotted.

g=5: All solid.

Also see the example experiment “Examples:Graphing Techniques:Graph Grid Demo”.

highTrip=h  
If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation.

lblLatPos=p  
Sets a lateral offset for the axis label. This is an offset parallel to the corresponding axis. p is in points. Positive is down for vertical axes and to the right for horizontal axes.

lblLineSpacing=linespace
ModifyGraph (axes)

Specifies an adjustment to the normal line spacing for multi-line axis labels. linespace is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.

lblLineSpacing affects all lines of the axis label. See also the \sa and \sb line spacing escape codes described under General Escape Codes on page III-54. They can be used to affect the spacing between individual lines.

lblMargin=l Specifies the distance from the edge of graph to a label in points.

lblPos=p Sets the distance from an axis to the corresponding axis label in points. If p=0, it automatically picks an appropriate distance.

This setting is used only if the given graph edge has at least one free axis. Otherwise, the lblMargin setting is used to position the axis label.

lblPosMode= m Affects the meaning and usage of lblPos, lblLatPos, and lblMargin parameters. Mainly for use when you have multiple axes on a side and you need axis labels to be properly positioned even as you make graph windows dramatically larger or smaller.

m=0: Default compatibility mode (Margin or Axis absolute depending on presence of free axis).

m=1: Margin absolute.

m=2: Margin scaled.

m=3: Axis absolute.

m=4: Axis scaled.

The absolute modes are measured in points whereas scaled modes have similar values but automatically expand or contract as the axis font height changes. Mode 0 is the default and results in no change relative to previous versions of Igor Pro that used lblMargin unless a given side used a free axis in which case it used lblPos in absolute mode. The margin modes measure relative to an edge of the graph while the axis modes measure relative to the position of the axis. When using stacked axes, use either margin modes. With multiple nonstacked axes, use Axis scaled if the graph edge is not using a fixed margin or use axis absolute if it is.

lblRot=r Rotates the axis label by r degrees. r is a value from -360 to 360. Rotation is counterclockwise and starts from the label’s normal orientation.

linTkLabel=tl tI=1 attaches the data units with any exponent or prefix to each tick label on a normal axis. tI=0 removes them.

In Igor Pro 9.00 and later, tI=2 suppresses the space character normally displayed before units.

log=l Controls axis log mode.

g=0: Normal axis.

g=1: Log base 10.

g=2: Log base 2.

logHTrip= h Same as highTrip but for log axes.

logLabel=l Sets the maximum number of decades in a log axis before minor tick labels are suppressed.

logLTripl Same as lowTrip but for log axes.

loglinear=l Switches to a linear tick method (l=1) on a log axis if the number of decades of ranges is less than 2. It switches to a linear tick exponent method if the number of decades is greater than five.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logmtlOffset=0</td>
<td>Offsets the minor tick mark labels on a log axis by ( o ) fractional points relative to the default tick mark label position. Positive is away from the axis. Added in Igor Pro 9.00.</td>
</tr>
<tr>
<td>logTicks=t</td>
<td>Sets the maximum number of decades in log axis before minor ticks are suppressed.</td>
</tr>
<tr>
<td>lowTrip=l</td>
<td>If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation.</td>
</tr>
<tr>
<td>manminor={number, emphasizeEvery}</td>
<td>Specifies how to draw minor ticks in manual tick mode. There will be ( number ) ticks between each major (labeled) tick. You will usually want to set this to 4 to make 5 divisions, or 9 to make 10 divisions. A medium-sized tick (an emphasized minor tick) will be drawn every ( emphasizeEvery ) minor tick.</td>
</tr>
<tr>
<td>manTick=[cantick, tickinc, exp, digitsrt [, timeUnit]]</td>
<td>Turns on manual tick mode. The tick from which all other ticks are calculated is the cononic tick (( cantick )). The numerical spacing between ticks is set by ( tickinc ). ( cantick ) and ( tickinc ) are multiplied by ( 10^{exp} ). The number of digits to the right of the decimal point displayed in the tick labels is set by ( digitsrt ). The optional parameter ( timeUnit ) is used with Date/Time axes to specify the units of tickinc. In this case, tickinc must be an integer. The value of ( timeUnit ) is one of the following keywords: second, minute, hour, day, week, month, year On a date/time axis, the ( exp ) and ( digitsrt ) keywords are ignored, but must be present. You can set them to zero.</td>
</tr>
<tr>
<td>manTick=0</td>
<td>Turns off manual tick mode.</td>
</tr>
<tr>
<td>margin=m</td>
<td>Sets a fixed margin from the edge of the window to the axis in points. Used principally to make axes of multiple graphs on a page line up when “stacked”. You can use the left, right, bottom, and top axis names (even if an axis with that name doesn’t exist) to adjust the graph plot area. See Types of Axes on page II-279. ( m=0 ): Sets “automatic” margin size (dependent on the length and height of tick marks and labels). ( m=-1 ): Sets the margin to “none”, or 0. The axis is drawn at the graph window’s edge.</td>
</tr>
<tr>
<td>minor=m</td>
<td>Disables ( (m=0) ) or enables ( (m=1) ) minor ticks.</td>
</tr>
<tr>
<td>mirror=m</td>
<td>Controls axis mirroring. ( m=1 ): Right axis mirroring left or top mirroring bottom. ( m=2 ): Mirror axis without tick marks. ( m=3 ): Mirror axis with tick marks and tick labels. ( m=0 ): No mirroring.</td>
</tr>
<tr>
<td>mirrorPos=pos</td>
<td>Specifies the position of the mirror axis relative to the normal position. ( pos ) is a value between 0 and 1.</td>
</tr>
<tr>
<td>noLabel=n</td>
<td>Controls axis labeling. ( n=0 ): Normal labels. ( n=1 ): Suppresses tick mark labels. ( n=2 ): Suppresses tick mark labels and axis labels.</td>
</tr>
</tbody>
</table>
### ModifyGraph (axes)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>notation=n</td>
<td>Uses engineering ((n=0)) or scientific ((n=1)) notation for tick mark labels. Affects tick mark labels displayed exponentially. See highTrip and lowTrip. Does not affect log axes.</td>
</tr>
<tr>
<td>nticks=n</td>
<td>Specifies the approximate number of ticks marks ((n)) on axis.</td>
</tr>
<tr>
<td>prescaleExp=exp</td>
<td>Multiplies axis range by (10^{\text{exp}}) for tick labeling and exp is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. (This affects the display only, not the source data.)</td>
</tr>
<tr>
<td>sep=s</td>
<td>Specifies the minimum number of screen points ((s)) between minor ticks.</td>
</tr>
<tr>
<td>standoff=s</td>
<td>Suppresses ((s=0)) or enables ((s=1)) axis standoff. Axis standoff prevents waves or markers from covering the axis.</td>
</tr>
<tr>
<td>stLen=p</td>
<td>Sets the length of minor (“small”) tick marks to (p) points. If (p) is zero, it uses the default length. (p) may be fractional.</td>
</tr>
<tr>
<td>stThick=p</td>
<td>Sets the thickness of minor (“small”) tick marks to (p) points. If (p) is zero, it uses the default thickness. (p) may be fractional.</td>
</tr>
<tr>
<td>tick=t</td>
<td>Sets tick position.</td>
</tr>
<tr>
<td></td>
<td>(t=0:) Outside axis.</td>
</tr>
<tr>
<td></td>
<td>(t=1:) Crossing axis.</td>
</tr>
<tr>
<td></td>
<td>(t=2:) Inside axis.</td>
</tr>
<tr>
<td></td>
<td>(t=3:) None.</td>
</tr>
</tbody>
</table>

In a category plot, adding 4 to the usual values for the tick keyword will place the tick marks in the center of each category rather than at the edges.

In a normal (non-category) plot specifying \(t=4\) or \(t=5\) replaces tick marks and axis lines with rectangular regions with alternating fills. This feature, which was added in Igor Pro 8.00, is used for cartographic plots. \(t=4\) gives even fills and \(t=5\) gives odd fills. The btLen keyword determines the thickness of the fill area.

It is recommended that you use mirror axes and axisOnTop=1 as shown in this example:

```
Make jack=sin(x/8)
Display jack
ModifyGraph axisOnTop=1
ModifyGraph mirror=1
ModifyGraph standoff=0
ModifyGraph tick=4
```

<p>| tickEnab={lowTick,highTick} | Restricts axis ticking to a subrange of normal. Ticks are drawn and labelled only if they fall within this inclusive numerical range. |
| tickExp=te      | (te=1) forces tick labels to exponential notation when labels have units with a prefix. (te=0) turns this off. |
| tickUnit=tu     | Suppresses ((tu =1)) or turns on ((tu =0)) units labels attached to tick marks. |
| tickZap={v1,v2,v3} | Suppresses drawing of the tick mark label for values given in the list. This is useful when you have crossing axes to prevent tick mark labels from overlapping. The list may contain zero, one, two or three values. The values must be exact to suppress the label. |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tkLblRot=r</td>
<td>Rotates the tick mark labels by ( r ) degrees. ( r ) is a value from -360 to 360. Rotation is counterclockwise and starts from the label's normal orientation.</td>
</tr>
<tr>
<td>tOffset=o</td>
<td>Offsets the tick mark labels by ( o ) fractional points relative to the default tick mark label position. Positive is away from the axis.</td>
</tr>
<tr>
<td>ttLen=p</td>
<td>Sets the length of subminor (&quot;tiny&quot;) tick marks to ( p ) points. If ( p ) is zero, it uses the default length. ( p ) may be fractional. Subminor ticks are used only in log axes.</td>
</tr>
<tr>
<td>ttThick=p</td>
<td>Sets the thickness of subminor (&quot;tiny&quot;) tick marks to ( p ) points. If ( p ) is zero, it uses the default thickness. ( p ) may be fractional.</td>
</tr>
<tr>
<td>userticks={tickPosWave, tickLabelWave}</td>
<td>Draws axes with purely user-defined tick mark positions and labels, overriding other settings. ( \text{tickPosWave} ) is a numeric wave containing the desired positions of the tick marks, and ( \text{tickLabelWave} ) is a text wave containing the labels. See User Ticks from Waves on page II-313 for an example. The tick mark labels can be multiline and use styled text. For more details, see Fancy Tick Mark Labels on page II-358. ( \text{tickPosWave} ) need not be monotonic. Igor will plot a tick if a value is in the range of the axis. Both linear and log axes are supported. Graph margins will adjust to accommodate tick labels. This will not prevent overlap between labels, which you will need fix yourself.</td>
</tr>
</tbody>
</table>

\| userticks=0 \| Removes the userticks setting returning the axis to the previously-set mode. |
\| useTSep=t \| \( t=1 \) displays a thousand’s separator character between every group of three digits in the tick mark label (e.g., "1,000" instead of "1000"). The default is \( t=0 \). |
\| zapLZ=t \| Removes \( (t=1) \) leading zeros from tick mark labels. For example 0.5 becomes .5 and -0.5 becomes -.5. Default is \( t=0 \). |
\| zapTZ=t \| Removes \( (t=1) \) trailing zeros from tick mark labels. The the radix point will also be removed if all digits are zero. Default is \( t=0 \). |
\| zero=z \| Controls the zero line. \( z=0 \): A zero line at \( x=0 \) or \( y=0 \). The line style is set to \( z-1 \). See ModifyGraph (traces) on page V-613, lStyle keyword, for details on line styles. \( z=1 \): No zero line. |
\| zeroThick=zt \| Sets the thickness of the zero line in points, from 0.0 to 5.0 points. \( zt=0.0 \) means the zero line thickness automatically follows the thickness of the axis; this is the default. You can use 0.1 for a thin zero line thickness. |
\| ZisZ=t \| \( t=1 \) uses the single digit 0 as the zero tick mark label (if any) regardless of the number of digits used for other labels. Default is \( t=0 \). |
ModifyGraph (colors)

Flags

/W=winName    Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z    Does not generate an error if the named axis does not exist in a style macro.

Details

With the prescaleExp parameter, you can force tick and axis label scaling to values different from the defaults. For example, if you have data whose X scaling ranges from 9pA to 120pA and you display this on a log axis, the tick marks will be labelled 10pA and 100pA. But if you really want the tick marks labeled 10 and 100 with pA in the axis label, you can set the prescaleExp to 12. To see this, execute the following commands:

Make/O jack=x
Display jack
SetScale x,9e-12,120e-12,"A",jack
ModifyGraph log(bottom)=1

then execute:

ModifyGraph prescaleExp(bottom)=12

The tickExp parameter applies to units that do not traditionally use SI prefix characters. For example, one usually speaks of 10^-3 Torr and not mTorr. To see how this feature works, execute the following example commands:

Make/O jack=x
Display jack
SetScale x,1E-7,1E-5,"Torr",jack
ModifyGraph log(bottom)=1

then execute:

ModifyGraph tickExp(bottom)=1

at this point, the tick mark labels have Torr in them. If you want to eliminate the units from the tick marks, execute:

ModifyGraph tickUnit(bottom)=1

and if you now want Torr in the label string, use the \U escape in the label string:

Label bottom \"\U"

To see the effect of linTkLabel, execute these commands:

Make/O jack=x
Display jack
SetScale x,1E-7,1E-5,"Torr",jack

then execute:

ModifyGraph linTkLabel(bottom)=1

and then try:

ModifyGraph tickExp(bottom)=1

and finally:

ModifyGraph tickUnit(bottom)=1

ModifyGraph (colors)

ModifyGraph [ /W=winName/Z ] key [ (axisName)]=[r,g,b,[a]]
    [, key [(axisName)]=[r,g,b[,a]]]...

This section of ModifyGraph relates to modifying the use of colors in a graph.

Parameters

Most of the key parameters may take an optional axisName enclosed in parentheses. axisName is “left”, “right”, “top”, “bottom” or the name of an free axis such as “vertCrossing”.

Where the parameter descriptions indicate an “(axisName)”, it may be omitted to change all axes in the graph. r, g, b, and a specify the color and optional opacity as RGBA Values. (0, 0, 0) specifies opaque black and (65535, 65535, 65535) specifies opaque white.
On Windows, use maximum white to set the control bar background color to track the 3D Objects color in the Appearance Tab of the Display Properties control panel:

```
ModifyGraph cbRGB=(65535,65535,65535)
```

See Also

See **Instance Notation** on page IV-20.

## ModifyImage

```
ModifyImage [/W=winName] imageInstance, keyword = value
         [, keyword = value]...
```

The ModifyImage operation changes properties of the given image in the top graph (or the specified graph if /W is used). `imageInstance` is the name of the image to be altered. This name is usually simply the name of the matrix wave containing the image data. If the same matrix wave is displayed more than once, you must append #0, #1 etc. to the name to distinguish which is which.

`imageInstance` can also take the form of a null name with an instance number to affect the instanceth image. That is,

```
ModifyImage ''#1
```

modifies the appearance of the second image that was appended to the top graph, no matter what the image names are. Note: two single quotes are used, not a double quote.
Parameters

Here are the keyword-value pairs. These apply to false color images in which the data in the matrix is used as an index into a color table. They do not apply to direct color images in which the data in the matrix specifies the color directly.

\texttt{cindex=matrixWave} \texttt{ Sets the Z value mapping mode such that image colors are determined by doing a lookup in the specified matrix wave.}

\textit{matrixWave} is a 3 column wave that contains red, green, and blue values from 0 to 65535. (The matrix can actually have more than three columns. It ignores any extra columns.)

The color at \(Z=z\) is determined by finding the RGB values in the row of \textit{matrixWave} whose scaled X index is \(z\). In other words, the red value is \textit{matrixWave}(z)[0], the green value is \textit{matrixWave}(z)[1] and the blue value is \textit{matrixWave}(z)[2].

If \textit{matrixWave} has default X scaling, where the scaled X index equals the point number, then row 0 contains the color for \(Z=0\), row 1 contains the color for \(Z=1\), etc.

If you use \texttt{cindex}, you should not use \texttt{ctab} in the same command.

\texttt{ctab=[zMin, zMax, ctName, reverse]} \texttt{ Sets the z mapping mode by which values in the matrix are mapped linearly into the color table specified by \texttt{ctName}.}

\texttt{zMin} and \texttt{zMax} set the range of \(z\) values to map. Omit \texttt{zMin} or \texttt{zMax} to leave as is or use * to autoscale.

The color table name can be missing if you want to leave it as is.

\texttt{ctName} can be any color table name returned by the CTabList function, such as Grays or Rainbow (see \textbf{Image Color Tables} on page II-392) or the name of a 3 column or 4 column color table wave (\textbf{Color Table Waves} on page II-399).

A color table wave name supplied to \texttt{ctab} must not be the name of a built-in color table (see \texttt{CTabList}). A 3 column or 4 column color table wave must have values that range between 0 and 65535. Column 0 is red, 1 is green, and 2 is blue. In column 3 a value of 65535 is opaque, and 0 is fully transparent.

Set \texttt{reverse} to 1 to reverse the color table. Setting it to 0 or omitting it leaves the color table unreversed.

\texttt{ctabAutoscale=autoBits} \texttt{ Sets the range of data used for autoscaling \texttt{ctab} * values.}

\begin{itemize}
  \item Bit 0: Autoscales only the XY subset being displayed.
  \item Bit 1: Autoscales only the current plane being displayed.
\end{itemize}

If neither bit is set (if \texttt{autoBits} = 0, the default), then all of the data in the image wave is used to autoscale the *'d \texttt{zMin}, \texttt{zMax} values for \texttt{ctab}.

\texttt{eval=[value, red, green, blue, [alpha]]} \texttt{ If the red, green, and blue values are in the valid range for a color value (0 to 65535) the explicit value-color pair is added (or updated if value already exists). If the color values are out of range (-1 is suggested) then the value is removed from the list if it is present (no error if it is not).}

\texttt{alpha} is optional: a value of 65535 is opaque, and 0 is fully transparent.
### ModifyImage

<table>
<thead>

<tr>
<td></td>
<td><code>alpha</code> is optional: a value of 65535 is opaque, and 0 is fully transparent.</td>
</tr>
<tr>
<td>maxRGB=1 or 0 or NaN</td>
<td></td>
</tr>
</tbody>
</table>
ModifiesImage

Sets the color of image values less than the ctab zMin or less than the cindex of the matrixWave minimum X scaling value. Also turns min color mode on.

The red, green, and blue color values are in the range of 0 to 65535.
alpha is optional: a value of 65535 is opaque, and 0 is fully transparent.

minRGB=(red, green, blue, [alpha])

Sets the color of image values less than the ctab zMin or less than the cindex of the matrixWave minimum X scaling value. Also turns min color mode on.

The red, green, and blue color values are in the range of 0 to 65535.
alpha is optional: a value of 65535 is opaque, and 0 is fully transparent.

minRGB=1 or 0 or NaN

Turns min color mode off, on, or transparent. These modes affect the display of image values less than the ctab zMin or less than the cindex of the matrixWave minimum X scaling value.

1: Turns on min color mode. The color of the affected image pixels is black or the last color set by minRGB=(red, green, blue).
0: Turns off min color mode (default). The color of the affected image pixels is the first color table or color index color.
NaN: Transparent min color mode. The affected image pixels are not drawn.

plane=p

Determines which part of a 3D or 4D image wave to display.
The meaning of p depends on the nature of the image wave. If the size of the layer dimension of the image wave is exactly three then the wave is treated as RGB data with R, G, and B data in the three layers. If the size of the layer dimension is exactly four, then the wave is treated as RGBA data, with A in the fourth layer. Otherwise each layer of the wave is treated as a separate grayscale image.

Plane=p With RGB Data
If the wave is 3D, plane=p has no effect.
If the wave is 4D, each chunk contains a different set of R, G and B layers and p selects which chunk to display.

Plane=p With Grayscale Data
If the wave is 3D, p selects which layer to display.
If the wave is 4D, plane=p acts as if all of the chunks were combined into a virtual 3D wave and p selects which layer of this virtual 3D wave to display.

rgbMult=m

If m is non-zero, direct color values in a 3-plane RGB or 4-plane RGBA image are multiplied by m. (Alpha values are not multiplied.) This would typically be used for 10, 12 or 14 bit integers in a 16 bit word. For example, if your image data is 14 bits, use rgbMult=4.
ModifyLayout

ModifyLayout [flags] key [(objectName)] =value [, key [(objectName)] =value]...

The ModifyLayout operation modifies objects in the top layout or in the layout specified by the /W flag.

Parameters

Each key parameter may take an optional objectName enclosed in parentheses. If "(objectName)" is omitted, all objects in the layout are affected.

Though not shown in the syntax, the optional "(objectName)" may be replaced with "[objectIndex]", where objectIndex is zero or a positive integer denoting the object to be modified. "[0]" denotes the first object appended to the layout, "[1]" denotes the second object, etc. This syntax is used for style macros, in conjunction with the /Z flag.

The parameter descriptions below omit the optional "(objectName)".

The “units”, “mag” and “bgRGB” keywords apply to the layout as a whole, not to a specific object and do not accept an objectName.

bgRGB=(r,g,b[a]) Specifies the background color for the layout. r, g, b, and a specify the color and optional opacity as RGBA Values.

columns=c Specifies the number of columns for a table object.

fidelity=f Controls the drawing of layout objects.

frame=f Specifies the type of frame enclosing the object.

gradient See Gradient Fills on page III-498 for details.

gradientExtra See Gradient Fills on page III-498 for details.

height=h Sets the height of the object.

left=l l is the horizontal coordinate of the left edge of the object relative to the left edge of the paper.

mag=m Sets the on screen layout magnification where m is a value between 0.5 and 10. m=1 corresponds to 100%.

Factors of two, such as m=.25, m=.5, m=1, m=2, tend to produce the best on screen graphics.

rows=r Specifies the number of rows for table object.

top=t t is the vertical coordinate of the top edge of the object relative to the top edge of the paper.

Flags

/W=winName Directs action to a specific window or subwindow rather than the top graph window. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

</table>

### Flags

- **/I**: Dimensions in inches.
- **/M**: Dimensions in centimeters.
- **/W=winName**: `winName` is the name of the page layout window to be modified. If `/W` is omitted or if `winName` is `""`, the top page layout is modified.
- **/Z**: Does not generate an error if the indexed or named object does not exist in a style macro.

The `/I` and `/M` flags affect the units of the parameters for the left, top, width and height keywords only. If neither `/I` nor `/M` is present then the parameters for the left, top, width and height keywords are points.

### Details

Note that the units keyword affects only the units used in the layout info panel and in the Modify Objects dialog. It has nothing to do with the units used for the left, top, width and height keywords. Those units are points unless the `/I` or `/M` flags is present.

### See Also

- `NewLayout`
- `AppendLayoutObject`
- `RemoveLayoutObjects`
- `LayoutPageAction`

### ModifyPanel

ModifyPanel  
```plaintext
[/W=winName] keyword = value [, keyword = value ...]
```

The ModifyPanel operation modifies properties of the top or named control panel window or subwindow.

### Parameters

- **`keyword`** is one of the following:
  - **cbRGB=(r,g,b,a)**: Specifies the background color of the entire control panel or the graph’s control bar area. `r`, `g`, `b`, and `a` specify the color and optional opacity as RGBA Values.
  - **drawInOrder=d**: Determines the drawing order of controls in the control panel.
    - `d=0`: Draw tab controls before any other controls (default).
    - `d=1`: Draw all controls in the order in which they appear in the recreation macro, which is also the creation order.

The `drawInOrder` keyword was added in Igor Pro 8.00.

Prior to Igor Pro 8.00 tab controls (see `TabControl`) were always drawn before all other controls. This prevented placing a tab control inside a groupbox with a colored interior. `drawInOrder=1` forces Igor to draw controls in creation order, which is the same as the order in which they appear in a recreation macro.
ModifyPanel

expand=\(e\) Sets the expansion factor of the panel. \(e\) is a number between 0.25 to 8.0. Values of \(e\) greater than 1.0 make the panel, its controls, and its subwindows, appear larger than normal.

Though rarely needed, using the expand keyword, you can set the expansion of panel subwindows independent of the main panel window’s expansion.

When you change the expansion of a top-level control panel window, the panel window automatically resizes itself.

The expand keyword was added in Igor Pro 9.00.

See Control Panel Expansion on page III-443 for further discussion.

fixedSize=\(f\) Controls the resizing of the panel window.

\(f=0\): Panel can be resized (default).
\(f=1\): Panel cannot be resized by adjusting the size box or frame (nor maximized on Windows), but the window can be minimized (on Windows) and the MoveWindow operation can still change the size.

The fixedSize keyword overrides any previous size limit set using the SetWindow sizeLimit command. If you try to use SetWindow sizeLimit on a window with fixedSize=1, Igor generates an error.

frameInset= \(i\) Specifies the number of pixels by which to inset the frame of the panel subwindow. Mostly useful for overlaying panels in graphs to give a fake 3D frame a better appearance.

frameStyle= \(f\) Specifies the frame style for a panel subwindow.

\(f=0\): None.
\(f=1\): Single.
\(f=2\): Indented.
\(f=3\): Raised.
\(f=4\): Text well.

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the panel itself is a light shade of gray.

noEdit= \(e\) Sets the editability of the panel.

\(e=0\): Editable (default).
\(e=1\): Not editable. For a panel window, the Panel menu item is not present and the ShowTools command is ignored. For a panel subwindow, it can not be activated by clicking.

Flags

/W= winName Modifies the control panel in the named graph or control panel window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

On Windows, set \(r\), \(g\), and \(b\) to 65535 (maximum white) to set the background color of the control panel to track the 3D Objects color in the Appearance Tab of the Display Properties control panel.

See Also

The NewPanel operation.

Controls in Graphs on page III-441.
**ModifyProcedure**

ModifyProcedure \[/A[=all] /W=procWinTitleListStr\] /Z[=z]

[procedure=functionOrMacroNameStr, hide=h, lock=ro, writeProtect=wp, userCanOverride=ovr]

The ModifyProcedure operation modifies one or more procedure windows, depending on the /A and /W flags and on the procedure keyword.

The ModifyProcedure operation was added in Igor 8.03.

Use /W="Procedure" to modify the built-in procedure window.

Use /W=procWinTitleListStr to modify a procedure window specified by its title, such as /W="MyProc" for packed procedure files or /W="MyProc.ipf" for standalone procedure files.

Use procedure=functionOrMacroNameStr to modify a procedure window containing a particular function.

See Specifying Which Procedure Windows to Modify below for other usages.

If the procedure window is associated with a standalone file, as opposed to being packed, the file's read-only setting may be set or cleared, as described below for the lock and writeProtect keywords.

**Parameters**

procedure=functionOrMacroNameStr

_funcOrMacroNameStr_ is a string containing the name of a function or macro in the procedure window to modify.

_funcOrMacroNameStr_ may be a simple name or may include independent module and/or module name prefixes to designate static functions. For use with independent modules, see Using ModifyProcedure With Independent Modules below.

lock=ro

Sets or clears the read-only state of the targeted procedure windows.

ro=-2: Clears the read-only state, like _ro_=0.

In addition, if the procedure window is associated with a standalone file, as opposed to being packed, the file's read-only setting is set to unlocked, as with SetFileFolderInfo/RO=0.

ro=-1: The read-only state is not changed.

ro=0: Clears the read-only state. This allows the user to change the text if the procedure window is also not write-protected.

ro=1: Sets the read-only state. The procedure window shows a lock icon in the lower left corner.

ro=-2: Sets the read-only state, like _ro_=1.

In addition, if the procedure window is associated with a standalone file, as opposed to being packed, the file's read-only setting is set to locked, as with SetFileFolderInfo/RO=1.

hide=h

Hides or shows the targeted procedure windows. Added in Igor 9.00.

h=-1: The procedure window visibility is not changed.

h=0: Shows the procedure window.

h=1: Hides the procedure window.
ModifyProcedure

writeProtect=wp  Sets or clears the write-protect state of the targeted procedure windows.

wp=-2:  Clears the write-protect state, like wp=0.
In addition, if the procedure window is associated with a standalone file, as opposed to being packed, the file’s read-only setting is set to unlocked, as with SetFileFolderInfo/RO=0.

wp=-1:  The write-protect state is not changed.

wp=0:  Clears the write-protect state. The user can change the text if the procedure window is also not locked.

wp=1:  Sets the write-protect state. The procedure window shows a write-protect icon (a pencil with a red circle-and-line indicator).

wp=2:  Sets the write-protect state, like wp=1.
In addition, if the procedure window is associated with a standalone file, as opposed to being packed, the file’s read-only setting is set to locked, as with SetFileFolderInfo/RO=1.

userCanOverride=ovr  Controls the ability of the user to change the write-protect state of the targeted procedure windows.

ovr=0:  Prevents the user from changing the write-protect state by clicking the write-protect icon.

ovr=1:  Allows the user to change the write-protect state by clicking the write-protect icon.

Flags

/A[=all]  Specifies all procedure windows as the targets of the ModifyProcedure operation. Use /A=1 to target all procedure windows in the ProcGlobal module. /A alone is the same as /A=1.

Use /A=2 to target all procedure windows in independent modules. See Using ModifyProcedure With Independent Modules for details.

/W=procWinTitleListStr  Specifies a particular procedure window or a list of procedure windows as the targets of the ModifyProcedure operation.
If procWinTitleListStr is the title of a single procedure window, this specifies that procedure window as the single target.
If procWinTitleListStr contains a semicolon-separated list of procedure window titles, this specifies those procedure windows as targets.
See Specifying Which Procedure Windows to Modify below for details.

/Z[=z]  Prevents procedure execution from aborting if an error occurs. Use /Z or /Z=1 if you want to handle errors from ModifyProcedure in your procedures rather than having execution abort.

Details

When changing the lock or write-protect states for a standalone file (lock=+/2 or writeProtect=+/2), there are scenarios where the file's locked state can’t be changed. This would occur, for example, if the file is open in another program or if you do not have sufficient privileges to modify the file.

Specifying Which Procedure Windows to Modify

The simplest way to modify one procedure window whose title you know is to use /W:

ModifyProcedure/W="My Procedure.ipf" writeProtect=2  // 2 for standalone file
ModifyProcedure/W="Procedure" writeProtect=1       // Modifies built-in procedure window

Use /A=1 to target all procedure windows in the ProcGlobal module:

ModifyProcedure/A=1 writeProtect=1
Don’t specify both /A and /W as this is ambiguous and generates an error.

Use procedure=\textit{functionOrMacroNameStr} to modify all procedure windows in the ProcGlobal module containing a procedure with the specified name:

\begin{verbatim}
ModifyProcedure procedure=MyFunction, writeProtect=1
\end{verbatim}

If you omit procedure=\textit{functionOrMacroNameStr}, /A, and /W then the built-in procedure window is modified.

Use \textit{functionOrMacroNameStr} only when you are not certain which procedure window contains the function or macro. If a procedure window has syntax errors that prevent Igor from determining where functions and macros start and end, then \texttt{ModifyProcedure} may not be able to locate the correct procedure window in which case it returns an error.

You can use /W and procedure=\textit{functionOrMacroNameStr} to search for a function or macro in one or more procedure windows. This is useful when \textit{functionOrMacroNameStr} is the name of a static function in a procedure window that uses \#pragma moduleName.

\section*{Using \texttt{ModifyProcedure} With Independent Modules}

To work with independent modules, you must enable independent module development. This is for advanced programmers only. See Independent Modules on page IV-238 for details. The material in this section assumes that independent module development is enabled.

\texttt{/W=\textit{procWinTitleListStr}} can be a list of procedure window titles each followed by a space and an independent module name in brackets. Then \texttt{procedure=\textit{functionOrMacroNameStr}} applies to the specified procedure windows and independent modules.

For example, if any procedure file contains these statements:

\begin{verbatim}
#pragma IndependentModule=myIM
#include <Axis Utilities>
\end{verbatim}

then the commands

\begin{verbatim}
ModifyProcedure/W="Axis Utilities.ipf [myIM]" procedure="HVAxisList"
Print S_windowList, V_isReadOnly, V_writeProtect
\end{verbatim}

report the title, read-only state, and write-protect state of the procedure window that contains the HVAxisList function, which is in the "Axis Utilities.ipf" file and the independent module myIM.

Similarly, \texttt{procedure=\textit{functionOrMacroNameStr}} may also specify an independent module prefix followed by the # character. The preceding \texttt{ModifyProcedure} command can be rewritten as:

\begin{verbatim}
ModifyProcedure/W="Axis Utilities.ipf" procedure="myIM#HVAxisList"
\end{verbatim}

or simply:

\begin{verbatim}
ModifyProcedure procedure="myIM#HVAxisList"
\end{verbatim}

You can use the same syntax to modify the procedure window containing a static function in a non-independent module procedure file using a module name instead of, or in addition to, the independent module name.

\texttt{procWinTitleListStr} can also be just an independent module name in brackets to target all procedure windows that belong to the named independent module containing the specified function:

\begin{verbatim}
ModifyProcedure/W=[myIM]" procedure="HVAxisList", writeProtect=0
\end{verbatim}

\section*{Output Variables}

The \texttt{ModifyProcedure} operation returns information in the following variables for the last procedure window targeted by the parameters. The information returned reflects the state of affairs after the \texttt{ModifyProcedure} command performs any requested modifications except for \texttt{V_wasHidden}.

\begin{itemize}
  \item \texttt{V_wasHidden} If the procedure window was previously hidden, \texttt{V_wasHidden} is set to 1, otherwise to 0.
  \item \texttt{V_isReadOnly} If the procedure's lock icon is showing, \texttt{V_isReadOnly} is set to 1, otherwise to 0.
  \item \texttt{V_writeProtect} If the pencil with the red line icon is showing, \texttt{V_writeProtect} is set to 1, otherwise to 0.
  \item \texttt{V_userCanOverride} Set to 1 (the default) if the user can change the write-protect state to writable.
\end{itemize}
You can obtain the information provided by the output variables without modifying any procedure windows by omitting the lock, writeProtect, and userCanOverride keywords.

Examples

// Completely unlock main Procedure window
ModifyProcedure lock=0, writeProtect=0, userCanOverride=1; Print S_windowList

// Completely unlock the procedure window containing the function named MyFunction
ModifyProcedure procedure="MyFunction", lock=0, writeProtect=0, userCanOverride=1
Print S_windowList  // Print procedure window title

// Lock all procedure windows in the myIM independent module, even those included into it, // and print the titles of the matching procedure windows
Execute "SetIgorOption IndependentModuleDev=1"
ModifyProcedure/W="[myIM]" lock=1, writeProtect=1, userCanOverride=0; Print S_windowList

// Unlock all procedure windows in the ProcGlobal module
ModifyProcedure/A=1 lock=0, writeProtect=0, userCanOverride=1

// Hide all procedures in ProcGlobal and all independent modules
ModifyProcedure/A=2 hide=1  // Equivalent to HideProcedures

See Also
Independent Modules on page IV-238
HideProcedures, DisplayProcedure, ProcedureText, ProcedureVersion
DoWindow, WinList
MacroList, FunctionList

ModifyTable

ModifyTable [/[W=winName/Z] key [(columnSpec)] =value [, key [(columnSpec)] =value]...}

The ModifyTable operation modifies the appearance the top or named table window or subwindow.

Parameters

Many of the parameter keywords take an optional columnSpec enclosed in parentheses. Usually columnSpec is simply the name of a wave displayed in the table. All table columns are affected when you omit (columnSpec).

More precisely, column specifications are wave names for waves in the current data folder or data folder paths leading to waves in any data folder optionally followed by the suffixes .i, .l, .d, .id or .ld to specify dimension indices, dimension labels, data values, dimension indices and data values, or dimension labels and data values of the wave. For example, ModifyTable font (myWave.i)="Helvetica". If the wave is complex, the column specification may be followed by .real or .imag suffixes.

One additional columnSpec is Point, which refers to the first column containing the dimension index numbers. If multidimensional waves are displayed in the table, this column may have the title “Row”, “Column”, “Layer”, “Chunk” or “Element”, but the columnSpec for this column is always Point. See Column Names on page II-241 for details.

Though not shown in the syntax, the optional (columnSpec) may be replaced with [columnIndex], where columnIndex is zero or a positive integer denoting the column to be modified. [0] denotes the Point column, [1] denotes the first column appended to the table, [2] denotes the second appended column, etc. This syntax is used for style macros, in conjunction with the /Z flag.

You can use a range of column numbers instead of just a single column number, for example [0,3].
The parameter descriptions below omit the optional (columnSpec).

alignment=a
Sets the alignment of table cell text.

a=0: Left aligned.
a=1: Center aligned.
a=2: Right aligned.

autosize=(mode, options, padding, perColumnMaxSeconds, totalMaxSeconds)
Autosizes the specified column or columns.

mode=0: Sets width of each data column from a given multidimensional wave individually.
mode=1: Sets width of all data columns from a given multidimensional wave the same.

options is a bitwise parameter. Usually 0 is the best choice.

Bit 0: Ignores column names.
Bit 1: Ignores horizontal indices.
Bit 2: Ignores data cells.

All other bits are reserved and must be set to zero.
See Setting Bit Parameters on page IV-12 for details about bit settings.

padding specifies extra padding for each column in points. Use -1 to get the default amount of padding (16 points).

perColumnMaxSeconds specifies the maximum amount of time to spend autosizing a single column. Use 0 to get the default amount of time (one second).

totalMaxSeconds specifies the maximum amount of time for autosizing the entire table. Use 0 to get the default amount of time (ten seconds).

digits=d
Specifies the number of digits after decimal point or, for hexadecimal and octal columns, the number of total digits.

elements=(row, col, layer, chunk)
Selects the view of a multidimensional wave in the table. The values given to row, col, layer, and chunk specify how to change the view.

-1: No change from current view.
-1: Display this dimension vertically.
-3: Display this dimension horizontally.
≥0: For waves with 3 or 4 dimensions, display this element of the other dimensions.

See ModifyTable Elements Command on page II-263 for a detailed discussion of

entryMode=m
Queries or sets the table’s entry line mode.

m=0: Just queries.
m=1: Accepts any entry that was started if possible.
m=2: Cancels any entry that was started if possible.

If m is 0 then the entry line state is not changed but is returned via V_flag as follows:

0: No entry is in progress.
-1: An entry is in progress and is valid.
Other: An entry is in progress and is invalid.

In Igor Pro 8.03 and later, S_value is set to contain the text showing in the entry line.
ModifyTable

If \( m \) is 1 then the entry is accepted if it is valid and its state is returned via \( V \_flag \) as follows:
\begin{align*}
0: & \quad \text{No entry is in progress.} \\
-1: & \quad \text{The entry was accepted.}
\end{align*}
Other: \quad \text{The entry is invalid and was not accepted.}

In Igor Pro 8.03 and later, \( S \_value \) is set to contain the text showing in the entry line whether or not an entry was in progress and whether or not \( i \) was accepted.

If \( m \) is 2 then the entry is cancelled if possible and its state is returned via \( V \_flag \) as follows:
\begin{align*}
0: & \quad \text{No entry is in progress.} \\
-1: & \quad \text{The entry was cancelled.}
\end{align*}

In Igor Pro 8.03 and later, \( S \_value \) is set to contain the text showing in the entry line after the entry was cancelled.

\textbf{font=\"fontName\"} \quad \text{Sets font used in the table, e.g., font=\"Helvetica\".}

\textbf{format=f} \quad \text{Sets the data format for the table.}
\begin{align*}
f=0: & \quad \text{General.} \\
f=1: & \quad \text{Integer.} \\
f=2: & \quad \text{Integer with thousands (e.g., "1,234").} \\
f=3: & \quad \text{Fixed point (e.g., "1234.56").} \\
f=4: & \quad \text{Fixed point with thousands (e.g., "1,234.56").} \\
f=5: & \quad \text{Exponential (scientific only).} \\
f=6: & \quad \text{Date format.} \\
f=7: & \quad \text{Time format (always 24 hour time).} \\
f=8: & \quad \text{Date\&time format (date followed by time).} \\
f=9: & \quad \text{Octal.} \\
f=10: & \quad \text{Hexadecimal.}
\end{align*}

You cannot apply date or date\&time formats to a wave that is not double-precision (see \textbf{Date, Time, and Date\&Time Units} on page II-69). To avoid this error, use \textbf{Redimension} to change the wave to double-precision.

\textbf{frameInset= i} \quad \text{Specifies the number of pixels by which to inset the frame of the table subwindow.}

\textbf{frameStyle= f} \quad \text{Specifies the frame style for a table subwindow.}
\begin{align*}
f=0: & \quad \text{None.} \\
f=1: & \quad \text{Single.} \\
f=2: & \quad \text{Double.} \\
f=3: & \quad \text{Triple.} \\
f=4: & \quad \text{Shadow.} \\
f=5: & \quad \text{Indented.} \\
f=6: & \quad \text{Raised.} \\
f=7: & \quad \text{Text well.}
\end{align*}

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the table itself is a light shade of gray.
**horizontalIndex**=h

Controls what is displayed in the horizontal index row when multidimensional waves are displayed.

- **h=0:** Displays dimension labels if the multidimensional wave’s label column is displayed, otherwise displays numeric indices (default).
- **h=1:** Always displays numeric indices for multidimensional waves.
- **h=2:** Always displays dimension labels for multidimensional waves.

The horizontal index row appears below the row of column names if the table contains a multidimensional wave. Use horizontalIndex to override the default behavior in order to display labels for the horizontal dimension while displaying numeric indices for the vertical dimension or vice versa.

The horizontalIndex keyword controls the horizontal index row only. To control what is displayed vertically, use **AppendToTable** to append a numeric index or dimension label column.

**rgb**=(r,g,b[a])

Sets color of text. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque black.

**selection**=(firstRow, firstCol, lastRow, lastCol, targetRow, targetCol)

Sets the selected cells in the table.

If any of the parameters have the value -1 then the corresponding part of the selection is not changed.

Otherwise they set the first and last selected cell and the target cell. Row and column values are 0 or greater. The Point column can not be selected.

The proposed parameters are clipped to avoid invalid combinations, such as the last selected row being before the first selected row.

With one exception, it does not support selecting unused cells. Therefore the proposed selection is clipped to prevent this. The exception is that, if the parameters call for selecting the first cell in the first unused column, then this is permitted.

**showFracSeconds**=s

Shows (s=1) or hides (s=0; default) fractional seconds.

**showParts**=parts

Specifies what elements of the table should be visible. Other elements are hidden.

*parts* is a bitwise parameter specifying what to show.

- **bit 0:** Entry line and other top line controls.
- **bit 1:** Name row.
- **bit 2:** Horizontal index row.
- **bit 3:** Point column.
- **bit 4:** Horizontal scroll bar.
- **bit 5:** Vertical scroll bar.
- **bit 6:** Insertion cells.
- **bit 7:** Insertion cells.

All other bits are reserved and must be set to zero except that you can pass -1 to indicate that you want to show all parts of the table.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

Presentation tables in subwindows in graphs and page layouts do not have an entry line or scroll bars and therefore never show these items.

See **Parts of a Table** on page II-235 and **Showing and Hiding Parts of a Table** on page II-237 for further information.

**sigdigits**=d

*d* is the number of significant digits when the numeric format is general.

**size**=s

Font size, e.g., *size*=14.
ModifyViolinPlot

style=n  

n is a bitwise parameter with each bit controlling one aspect of the column’s font style as follows:

- Bit 0: Bold
- Bit 1: Italic
- Bit 2: Underline
- Bit 4: Strikethrough

For example, bold underlined is $2^0 + 2^2 = 1 + 4 = 5$. See Setting Bit Parameters on page IV-12 for details about bit settings.

title="title"  

Sets the title of a column to title.

topLeftCell=(row, column)  

Scrolls the table contents so that the cell identified by (row, column) is the top left visible data cell, or as close as possible.

If row is -1 then the table’s vertical scrolling is not changed. If column is -1 then the table’s horizontal scrolling is not changed.

If they are positive, row and column are zero-based numbers which are clipped to valid values before being used. row=0 refers to the first row of data in the table, column=0 refers to the first column of data.

The Point column can not be scrolled horizontally.

trailingZeros=t  

$t=1$ shows trailing zeros. This affects the general numeric format only.

viewSelection  

Scrolls the table contents so that the target cell and selection are maximally in view. The target cell will always be visible. The selection may overflow the visible area.

See also the topLeftCell and selection keywords.

viewSelection was added in Igor Pro 9.00.

width=w  

Sets column width to w points.

You will not always get the exact number of points that you request. This is because a column must have an even number of screen pixels, so that grid lines look good. Igor will modify your requested number of points to meet this requirement.

Flags

/W= winName  

Modifies the named table window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z  

No errors generated if the indexed or specified column does not exist in a style macro.

Examples

ModifyTable size(myWave)=14 // change font size of myWave column  
ModifyTable width(Point)=0 // hide Point column  
ModifyTable style(complxWave.imag)=32 // condensed= bit 5 = 2^5 = 32

See Also

See Column Names on page II-241 and ModifyTable Elements Command on page II-263.

ModifyViolinPlot

ModifyViolinPlot [/W=winName] [keyword=value, keyword=value, ...]  

The ModifyViolinPlot operation modifies a violin plot trace in the target or named graph.

ModifyViolinPlot was added in Igor Pro 8.00.

For a detailed discussion of violin plots and the parts of a violin plot, see Violin Plots on page II-337.
ModifyViolinPlot parameters consist of keyword=value pairs. The trace keyword specifies the trace targeted by the subsequent keywords. For example, the command:

```
ModifyViolinPlot trace=trace0, markerSize=5
```

sets the marker size for all datasets of the trace0 trace.

As of Igor Pro 9.00, you can modify a setting for a specific dataset of a specific trace by adding a zero-based dataset index in square brackets after the keyword. For example:

```
ModifyViolinPlot trace=trace0, markerSize[1]=7
```

This sets the marker size for the second dataset (index=1) to 7 leaving the marker size for other datasets unchanged.

### General Parameters

- **trace=traceName**
  Specifies the name of a violin plot trace to be modified. An error results if the named trace is not a violin plot trace. Without the trace keyword, ModifyViolinPlot uses the first trace in the graph, whether it is a violin plot trace or not but see the instance keyword for an exception.

- **instance=instanceNum**
  The combination of trace and instance works the same as \((traceName#instanceNum)\) for a ModifyGraph keyword.

  The instance keyword without trace keyword accesses the \(instanceNum\)'th trace in the graph, just like \([traceNum]\) used with a ModifyGraph keyword. See Trace Names on page II-282 and Object Indexing on page IV-20.

- **bandwidth[(ds)]=bw**
  Sets the bandwidth used in computing the KDE curves. If you include \(ds\), the bandwidth is set to \(bw\) for dataset \(ds\). If you omit \(ds\), the bandwidth is set for all datasets. \(bw\) must be greater than or equal to 0. 0 uses the bandwidth estimated by the method set by the bandwidthMethod keyword.

- **bandwidthMethod=m**
  Sets the method used to estimate the appropriate bandwidth used in computing the KDE curves. The methods are

  - \(m=0\): Silverman
  - \(m=1\): Scott (default)
  - \(m=2\): Bowman and Azzalini

  See StatsKDE for details.

  You can override the estimated bandwidth using the bandwidth keyword.

- **boxWidth=w**
  For a non-category X axis, boxWidth sets the width of the space reserved for displaying the KDE curves. If \(w\) is between zero and one, it is taken to be a fraction of the width of the plot rectangle. If \(w\) is greater than one, it is in points.

  All the KDE curves are normalized such that the maximum density value of the KDEs over all datasets fills the box width so only one of the violin plots will be as wide as \(w\). You can control the normalization using the maxDensity keyword.

  If the violin plot is displayed using a category X axis, boxWidth is ignored. The space reserved for each dataset is controlled by the category axis and is affected by ModifyGraph barGap and catGap.

  A new non-category violin plot has box width set as \(boxWidth=1/(2^n)\) where \(n\) is the number of datasets (the number of violin plots) on the trace.

- **closeOutline=[close]**
  If \(close\) is 1 or omitted, the ends of the KDE curves are connected by a straight line. Closed curves are more visible if side=1 or side=2 in which case the KDE curves are closed by a straight line at the midline between the curves.
<table>

<tr>
<td><code>curveExtension=ext</code></td>
<td>Sets the range of the KDE curves. The KDE curves are computed for a range of $y=\minData-ext$ to $y=\maxData+ext$, where $ext$ is in units of bandwidth. $ext$ defaults to 1.</td>
</tr>
<tr>
<td><code>dataMarker=marker</code></td>
<td>Sets the marker number used to display the raw data. If marker is -1, the marker as set by ModifyGraph marker is used. The default is 8 (hollow circle).</td>
</tr>
<tr>
<td><code>jitter=j</code></td>
<td>In order to separate closely-spaced raw data points, the data points can be displaced horizontally. $j$ controls the maximum offset applied to any data point, expressed as a fraction of the box width. The value of $j$ may be greater than 1, but in general values less than 1 look better. The default value is 0.5.</td>
</tr>
<tr>
<td><code>kernel=k</code></td>
<td>Sets the kernel function to be used in computing the KDE curves. Supported values are $k=1$: Epanechnikov, $k=2$: Bi-weight, $k=3$: Tri-weight, $k=4$: Triangular, $k=5$: Gaussian (default), $k=6$: Rectangular.</td>
</tr>
</tbody>
</table>

It is unusual for a violin plot to use anything other than Gaussian, which is the default. See StatsKDE for details.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>lineStyle=style</code></td>
<td>Sets the line style used to draw the KDE curves. See Dashed Lines on page III-496 for a description of line styles. A line style of -1 uses the line style set by ModifyGraph istyle. $style$ defaults to -1.</td>
</tr>
<tr>
<td><code>lineThickness=thick</code></td>
<td>Sets the thickness of the line used to plot the KDE curves. A thickness less than zero uses the line width set by the ModifyGraph lsize keyword. $thick=0$ hides the KDE curve. The default value is -1.</td>
</tr>
<tr>
<td><code>markerSize=size</code></td>
<td>Sets the size of the marker used to display the raw data. A marker size of zero uses one-half of the marker size as set by ModifyGraph msize. $size$ defaults to zero.</td>
</tr>
<tr>
<td><code>markerThick=t</code></td>
<td>Sets the thickness in points of the strokes of markers used to display the raw data. The markerThick keyword was added in Igor Pro 9.00.</td>
</tr>
<tr>
<td><code>maxDensity=d</code></td>
<td>Sets the normalization for the width of the KDE curves to $d$. All the KDE curves are normalized such that the maximum density value of all KDEs fills the box width. The width of each curve gives an indication of the relative maximum density. maxDensity allows you to set the same normalization for multiple violin plots so that the width for all is relative to the same value.</td>
</tr>
<tr>
<td><code>plotSide=side</code></td>
<td>By default, a violin plot is symmetrical with the KDE curve plotted twice in mirror image. You can control which side is plotted: $side=0$: Both sides in mirror image (default) $side=1$: The left side $side=2$: The right side</td>
</tr>
</tbody>
</table>

Using 1 or 2 allows you to combine two violin plots in an asymmetric plot.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>showData[=sd]</code></td>
<td>Shows or hides the raw data points. $sd$ is 0 or 1. showData by itself is equivalent to showData=1. The default is 1.</td>
</tr>
</tbody>
</table>

**Mean and Median Parameters**
You can display markers showing the mean and the median of each dataset using the keywords documented in this section. See **Markers** on page II-291 for a list of available markers. For both mean and median, a marker size of zero uses the marker size set by ModifyGraph msize.

**showMean[=show]**
- Shows or hides the marker representing the mean value. `show` is 0 or 1.
- `showMean` by itself is equivalent to `showMean=1`. The default is 0.
- Sets the marker to use for the mean value. The default for the mean marker is 27 (hollow horizontal diamond with dot).
- Sets the size of the marker used to display the mean value. A value of zero uses the trace marker size as set by ModifyGraph msize, or the normal trace default marker size. The default is zero.
- Sets the thickness in points of the stroke of markers used to display the mean value if `showMean` is enabled.
- The `meanMarkerThick` keyword was added in Igor Pro 9.00.

**showMedian[=show]**
- Shows or hides the marker representing the median value. `show` is 0 or 1.
- `showMedian` by itself is equivalent to `showMedian=1`. The default is 0.
- Sets the marker to use for the median value. The default for the median marker is 26 (filled horizontal diamond).
- Sets the size of the marker used to display the median value. A value of zero uses the trace marker size as set by ModifyGraph msize, or the normal trace default marker size. The default is zero.
- Sets the thickness in points of the stroke of markers used to display the median value if `showMedian` is enabled.
- The `medianMarkerThick` keyword was added in Igor Pro 9.00.

**Color Parameters**

All colors are specified as \((r,g,b,[a])\) RGBA Values.

**fillColor=(r,g,b,[a])**
- Fills the area between the distribution curves with the specified color.
- Specifying `fillColor=(0,0,0,0)` removes the fill. If `side=1` or `side=2`, the fill is between the curve and the mid line.

**lineColor=(r,g,b,[a])**
- Sets the color of the KDE curves.
- Specify `lineColor=(0,0,0,0)` to use the trace color set using ModifyGraph rgb as the line color. The default is black.

**markerColor=(r,g,b,[a])**
- Sets the color of markers used to display the raw data.
- Specify `markerColor=(0,0,0,0)` to use the trace color set using ModifyGraph rgb as the marker color. This is the default behavior.

**markerStrokeColor=(r,g,b,[a])**
- Sets the color of the strokes of markers used to display the raw data.
- Specify `markerStrokeColor=(0,0,0,0)` to use the to use the trace color set using ModifyGraph rgb as the marker color. This is the default behavior.
- The `markerStrokeColor` keyword was added in Igor Pro 9.00.

**markerFilled=f**
- If `f` is non-zero, markers are filled with color. Normally, hollow markers have transparent fill. Default fill color is white. Applies only to hollow markers such as marker 8, the hollow circle marker.
- The `markerFilled` keyword was added in Igor Pro 9.00.

**markerFillColor=(r,g,b,[a])**
- Sets the fill color of markers used to display the raw data. Applies only to hollow markers such as marker 8, the hollow circle marker.
- The `markerFillColor` keyword was added in Igor Pro 9.00.
Violin Plot Per-Data-Point Marker Settings

You can override the basic settings for data point marker color, marker style and marker size using marker settings waves containing per-data-point settings.

You can apply per-data-point marker settings to an entire trace (to all datasets comprising a trace) or to a specific dataset of a trace. For example:

```
Function DemoViolinPlotPerPointMarkerSettings()
    Make/O violin0={1,2,3,4,5}, violin1={2,3,4,5,6}, violin2={3,4,5,6,7}
    String title = "Violin Plot Per Point Marker Settings"
    Display/W=(557,99,948,310)/N=ViolinPlotPerPointPlot as title

    // Create a trace named trace0 with three datasets: violin0, violin1, violin2
    AppendViolinPlot/TN=trace0 violin0,violin1,violin2
```

<table>
<thead>
<tr>
<th>Setting Name</th>

</tr>
</thead>
<tbody>
<tr>
<td>meanMarkerColor</td>
<td>Sets the color of markers used to display the mean value. Specify meanMarkerColor=(0,0,0,0) to use the trace color set using ModifyGraph rgb as the mean marker color. This is the default behavior.</td>
</tr>
<tr>
<td>meanMarkerStrokeColor</td>
<td>Sets the color of the strokes of markers used to display the mean of the data if showMean is enabled. Specify meanMarkerStrokeColor=(0,0,0,0) to use the trace color set using ModifyGraph rgb as the marker color. This is the default behavior.</td>
</tr>
<tr>
<td>meanMarkerFilled</td>
<td>If f is non-zero, the mean value marker is filled with color. Normally, hollow markers have transparent fill. Default fill color is white. Applies only to hollow markers such as marker 8, the hollow circle marker.</td>
</tr>
<tr>
<td>meanMarkerFillColor</td>
<td>Sets the fill color of markers used to display the mean value if showMean is enabled. Applies only to hollow markers such as marker 8, the hollow circle marker.</td>
</tr>
<tr>
<td>medianMarkerColor</td>
<td>Sets the color of markers used to display the median value. Specify medianMarkerColor=(0,0,0,0) to use the trace color set using ModifyGraph rgb as the median marker color. This is the default behavior.</td>
</tr>
<tr>
<td>medianMarkerStrokeColor</td>
<td>Sets the color of the strokes of markers used to display the mean of the data if showMedian is enabled. Specify medianMarkerStrokeColor=(0,0,0,0) to use the trace color set using ModifyGraph rgb as the marker color. This is the default behavior.</td>
</tr>
<tr>
<td>medianMarkerFilled</td>
<td>If f is non-zero, the median value marker is filled with color. Normally, hollow markers have transparent fill. Default fill color is white. Applies only to hollow markers such as marker 8, the hollow circle marker.</td>
</tr>
<tr>
<td>medianMarkerFillColor</td>
<td>Sets the fill color of markers used to display the median value if showMedian is enabled. Applies only to hollow markers such as marker 8, the hollow circle marker.</td>
</tr>
</tbody>
</table>
// Set the marker and marker size for all datasets of trace trace0
ModifyViolinPlot trace=trace0, dataMarker=18  // 18=Diamond
ModifyViolinPlot trace=trace0, markerSize=5

// Set the per-data-point marker for all datasets of trace trace0
Make/O violinMarkers = {15,16,17,18,19}
ModifyViolinPlot trace=trace0, dataMarkerWave=violinMarkers

// Set the per-data-point marker for dataset violin1 only
Make/O violinMarkersForViolin1 = {32,33,34,35,36}
ModifyViolinPlot trace=trace0, dataMarkerWave[1]=violinMarkersForViolin1
End

Usually a marker settings wave will have the same number of rows as there are data points in a given
dataset, but that is not required. If there are fewer rows in the settings wave than in the dataset, the extra
data points retain their basic settings. If there are more rows in the settings wave than in the dataset, the
extra settings wave points are not used.

See Making Each Data Point Look Different on page II-343 for more information and examples.

dataColorWave ["=colorWave"] Sets colorWave to override data point marker color on a point-by-
point basis. The wave must be a 3 or 4 column wave containing red, green, blue and optionally alpha values.

If you omit "=colorWave", any previous marker color wave setting is cleared.

The dataColorWave keyword was added in Igor Pro 9.00.

dataMarkerWave ["=markerWave"] Sets markerWave to override data point markers on a point-by-point
basis. The values in markerWave are standard graph marker
numbers. See Markers on page II-291 for a table of the markers and
the associated marker numbers. The marker numbers are clipped
to a valid range.

If you omit "=markerWave", any previous marker wave setting is cleared.

The dataMarkerWave keyword was added in Igor Pro 9.00.

dataSizeWave ["=markerSizeWave"] Sets markerSizeWave to override data point marker size on a point-by-
point basis. The values in markerSizeWave are clipped to the
range [0,200].

If you omit "=markerSizeWave", any previous marker size wave
setting is cleared.

The dataSizeWave keyword was added in Igor Pro 9.00.

Examples
A violin plot with transparent marker color used to give a visual indication of the density of data points.

// Create a violin plot with transparent marker color used to give a visual
// indication of the density of data points
Make/O/N=(25,3) multicol  // A three-column wave with 25 rows
SetRandomSeed(.4)  // For reproducible "randomness"
multicol = gnoise(1)  // Three normally-distributed datasets
multicol[20][1] = 5  // A "far" outlier
multicol[13][2] = -4  // An outlier
Display; AppendViolinPlot multicol
ModifyViolinPlot lineColor=(0,0,65535)
ModifyViolinPlot fillColor=(0,0,65535,19661)
ModifyViolinPlot jitter=0
ModifyViolinPlot showData=1
ModifyViolinPlot dataMarker=19
ModifyViolinPlot markerSize=6
ModifyViolinPlot markerColor=(0,0,65535,6554)
ModifyViolinPlot fillColor[1]=(0,65535,0,19661) // Second dataset transparent green

ModifyViolinPlot fillColor[1]=(0,65535,0,19661) // Second dataset transparent green

ModifyViolinPlot trace=multicol, Jitter=0.7
ModifyViolinPlot trace=multicol, DataMarker=42, MarkerSize=5
// Add jitter, choose the circle-with-plus marker
ModifyViolinPlot trace=multicol, MarkerColor=(16385,16388,65535)
ModifyViolinPlot trace=multicol, MarkerThick=1
// Set marker color to blue with a one-point outline
ModifyViolinPlot trace=multicol, MarkerFilled=1, MarkerFillColor=(3,52428,1)
// Set the marker to filled with dark green fill color
ModifyViolinPlot trace=multicol, MarkerFilled=1, MarkerFillColor=(3,52428,1)

// Set a marker size wave for dataset 0 (the first dataset)
Make/N=25/O sizeWave = enoise(5)+7
ModifyViolinPlot DataSizeWave[0] = sizeWave
ModifyViolinPlot

// Create a violin plot with asymmetric curves plotted on a category axis
Make/O/N=(25,3) ds1, ds2
SetRandomSeed(.4)  // For reproducible "randomness"
  ds1 = gnoise(1)
  ds2 = gnoise(2)+q

// We need a text wave to make a category plot
Make/N=3/T/O labels={"treatment 1", "treatment 2", "treatment 3"}
Display
AppendViolinPlot ds1 vs labels
AppendViolinPlot ds2 vs labels

// Keep plots together in a single category space
ModifyGraph toMode(ds1)=-1
  // Display ds1 on the left, ds2 on the right
ModifyViolinPlot trace=ds1,plotSide=1
ModifyViolinPlot trace=ds2,plotSide=2

// Extend the KDE curves
ModifyViolinPlot trace=ds1,CurveExtension=2
ModifyViolinPlot trace=ds2,CurveExtension=2

// Close the curves with line at the midline
ModifyViolinPlot trace=ds1,closeOutline=1
ModifyViolinPlot trace=ds2,closeOutline=1

// Use the same normalization for both curves
ModifyViolinPlot trace=ds1,maxDensity=0.36
ModifyViolinPlot trace=ds2,maxDensity=0.36

// Apply jitter to the data points
ModifyViolinPlot trace=ds1,jitter=0.5
ModifyViolinPlot trace=ds2,jitter=0.5

// Set markers and colors
ModifyViolinPlot trace=ds1,showData=1,dataMarker=16,markerColor=(2,39321,1),lineColor=(2,39321,1)
ModifyViolinPlot trace=ds2,showData=1,dataMarker=19,markerColor=(0,0,65535),lineColor=(0,0,65535)
ModifyViolinPlot trace=ds1,fillColor=(2,39321,1,19661)
ModifyViolinPlot trace=ds2,fillColor=(0,0,65535,19661)
ModifyWaterfall

ModifyWaterfall \([/W=\text{winName}] \ keyword = \ value \ [, \ keyword = \ value \ ...]\)

The ModifyWaterfall operation modifies the properties of the waterfall plot in the top or named graph.

Parameters

\(\keyword\) is one of the following:

- \(\text{angle}=a\)  Angle in degrees from horizontal of the angled Y axis (\(a=10\) to \(90\)).
- \(\text{axlen}=\text{len}\)  Relative length of angled Y axis. \(\text{len}\) is a fraction between \(0.1\) and \(0.9\).
- \(\text{hidden}=h\)  Controls the hidden line algorithm.
  - \(h=0\):  Turns hidden lines off.
  - \(h=1\):  Uses painter’s algorithm.
  - \(h=2\):  True hidden.
  - \(h=3\):  Hides lines with bottom removed.
  - \(h=4\):  Hides lines using a different color for the bottom. When specified, the top color is the normal color for lines and the bottom color is set using \(\text{ModifyGraph negRGB}=(r,g,b[,a])\).

Hidden lines are active only when the mode is lines between points.

Flags

\(/W=\text{winName}\)  Modifies waterfall plot in the named graph window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with \(\text{winName}\), see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

Painter’s algorithm draws the traces from back to front and erases hidden lines while modes 2, 3 and 4 detect which line segments are hidden and suppresses the drawing of these segments.

See Also

Waterfall Plots on page II-326.

The NewWaterfall and ModifyGraph operations.
ModuleName

Pragma ModuleName = modName

The ModuleName pragma assigns a name, which must be unique among all procedure files, to a procedure file so that you can use static functions and Proc Pictures in a global context, such as in the action procedure of a control or on the Command Line.

Using the ModuleName pragma involves at least two steps. First, within the procedure file assign it a name using #pragma ModuleName=modName, and then access objects in the named file by preceding the object name with the name of the module and the # character, such as or example: ModName#StatFuncName().

See Also
The Regular Modules on page IV-236, Static, Picture, and #pragma.

MoveDataFolder

MoveDataFolder [ /O=options /Z ] sourceDataFolderSpec, destDataFolderPath

The MoveDataFolder operation removes the source data folder (and everything it contains) and places it at the specified location with the original name.

Parameters
sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Flags
/O=options Overwrites the destination data folder if it already exists.

The /O flag was added in Igor Pro 8.00.

options=1: Completely overwrites the destination data folder. If the destination data folder exists, MoveDataFolder first deletes it if possible. If it can not be deleted, for example because it contains a wave that is in use, MoveDataFolder generates an error. If the deletion succeeds, MoveDataFolder then copies the source to the destination. Then the source data folder is deleted.

options=2: Merges the source data folder into the destination data folder. If an item in the source data folder exists in the destination data folder, MoveDataFolder overwrites it. Otherwise it copies it. Items in the destination data folder that do not exist in the source data folder remain in the destination data folder. Then the source data folder is deleted.

options=3: Merges the source data folder into the destination data folder and then deletes items that are not in the source data folder if possible. If an item in the source data folder does not exist in the destination data folder, MoveDataFolder attempts to delete it from the destination data folder. If it can not be deleted because it is in use, no error is generated. Then the source data folder is deleted.

/Z Errors are not fatal - if an error occurs, procedure execution continues. You can check the V_flag output variable to see if an error occurred.

Details
MoveDataFolder generates an error if a data folder of the same name already exists at the destination unless the /O flag is used. When the /O flag is non-zero and the destination data folder already exists, MoveDataFolder is equivalent to DuplicateDataFolder followed by a KillDataFolder on the source.

Output Variables
MoveDataFolder sets the following output variable:

V_flag 0 if the operation succeeded or a non-zero error code. The V_flag output variable was added in Igor Pro 8.00.
MoveFile

Examples
MoveDataFolder root:DF0, root:archive // Move DF0 into archive

See Also
See the DuplicateDataFolder operation. Chapter II-8, Data Folders.

MoveFile
MoveFile [flags] [srcFileStr] [as destFileOrFolderStr]
The MoveFile operation moves or renames a file on disk. A file is renamed by “moving” it to the same folder it is already in using a different name.

Parameters
srcFileStr can be a full path to the file to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from srcFileStr and pathName, it displays an Open File dialog allowing you to specify the source file.
destFileOrFolderStr is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.

If destFileOrFolderStr is a partial path, it is relative to the folder associated with pathName.

If /D is specified, the source file is moved inside the folder using the source file’s name.

If Igor can not determine the location of the destination file from pathName, srcFileStr, and destFileOrFolderStr, it displays a Save File dialog allowing you to specify the destination file (and folder).

If you use a full or partial path for either srcFileStr or destFileOrFolderStr, see Path Separators on page III-451 for details on forming the path.

Folder paths should not end with single Path Separators. See the Details section for MoveFolder.

Flags
/D           Interprets destFileOrFolderStr as the name of (or path to) an existing folder (or directory). Without /D, destFileOrFolderStr is the name of (or path to) a file.
If destFileOrFolderStr is not a full path to a folder, it is relative to the folder associated with pathName.

/I [=i]     Specifies the level of interactivity with the user.
/I=0:       Interactive only if srcFileStr or destFileOrFolderStr is not specified or if the source file is missing. (Same as if /I was not specified.)
/I=1:       Interactive even if srcFileStr is specified and the source file exists.
/I=2:       Interactive even if destFileOrFolderStr is specified.
/I=3:       Interactive even if srcFileStr is specified and the source file exists. Same as /I only.

/M=messageStr Specifies the prompt message in the Open File dialog. If /S is not specified, then messageStr will be used for both Open File and for Save File dialogs.
/O           Overwrite existing destination file, if any. Without /O, the user is asked if replacing the existing file is to be allowed.

/P=pathName Specifies the folder to look in for the source file, and the folder into which the file is copied. pathName is the name of an existing symbolic path.
Using /P means that both srcFileStr and destFileOrFolderStr must be either simple file or folder names, or paths relative to the folder specified by pathName.

/S=saveMessageStr Specifies the prompt message in the Save File dialog.
MoveFile

/Z=[=z] Prevents procedure execution from aborting if it attempts to move a file that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

/Z=0: Same as no /Z.
/Z=1: Moves a file only if it exists. /Z alone is equivalent to /Z=1.
/Z=2: Moves a file if it exists or displays a dialog if it does not exist.

Variables
The MoveFile operation returns information in the following variables:

V_flag Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.

S_fileName Stores the full path to where the file was moved from. If an error occurred or if the user cancelled, it is set to an empty string.

S_path Stores the full path where the file was moved to. If an error occurred or if the user cancelled, it is set to an empty string.

Examples
Rename a file, using full paths:
MoveFile "HD:folder:aFile.txt" as "HD:folder:bFile.txt"

Rename a file, using a symbolic path:
MoveFile/P=myPath "aFile.txt" as "bFile.txt"

Move a file into a subfolder (the subfolder must exist):
MoveFile/D "Macintosh HD:folder:aFile.txt" as ":subfolder"

Move a file into an unrelated folder (the subfolder must exist):
MoveFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"

Move a file from one folder to another and rename it:

Move user-selected file into a particular folder:
MoveFile/D as "C:My Data:Selected Files Folder"

Move user-selected file in any folder as bFile.txt in same folder:
MoveFile as "bFile.txt"

Move user-selected file in any folder as bFile.txt in any folder:
MoveFile/I=2 as "bFile.txt"

See Also
The Open, MoveFolder, CopyFolder, NewPath, and CreateAliasShortcut operations. The IndexedFile function. Symbolic Paths on page II-22.
The MoveFolder operation moves or renames a folder on disk. A folder is renamed by “moving” it into the same folder it is already in, but with a different name.

**Warning:** The MoveFolder command can destroy data by overwriting another folder and its contents!

If you overwrite an existing folder on disk, MoveFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog’s Misc category.

If permission is denied, the folder will not be moved and V_Flag will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the /Z flag is specified.

**Parameters**

`srcFolderStr` can be a full path to the folder to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with `pathName`, or the name of a folder within the folder associated with `pathName`.

If the location of the source folder cannot be determined from `srcFolderStr` and `pathName`, it displays a Select Folder dialog allowing you to specify the source.

If `/P=pathName` is given, but `srcFolderStr` is not, then the folder associated with `pathName` is moved or renamed. `destFolderStr` specifies the final location of the folder or, if /D is used, the parent of the final location of the folder.

`destFolderStr` can be a full path to the output (destination) folder (in which case /P is not needed), or a partial path relative to the folder associated with `pathName`.

If the location of the destination folder cannot be determined from `destFolderStr` and `pathName`, it displays a Save Folder dialog allowing you to specify the destination.

If you use a full or partial path for either file, see Path Separators on page III-451 for details on forming the path.

**Flags**

/D  Interprets `destFolderStr` as the name of (or path to) an existing folder (or “directory”) to move the source folder into. Without /D, it interprets `destFolderStr` as the name of (or path to) the moved folder.

If `destFolderStr` is not a full path to a folder, it is relative to the source folder.

/I [=i]  Specifies the level of interactivity with the user.

/I=0:    Interactive only if `srcFolderStr` or `destFolderStr` is not specified or if the source folder is missing. (Same as if /I was not specified.)
/I=1:    Interactive even if `srcFolderStr` is specified and the source folder exists.
/I=2:    Interactive even if `destFolderStr` is specified.
/I=3:    Interactive even if `srcFolderStr` is specified and the source folder exists. Same as /I only.

/M=messageStr  Specifies the prompt message in the Open File dialog. If /S is not used, then `messageStr` will be used for both Open File and for Save File dialogs.

/O  Overwrite existing destination folder, if any. This deletes the existing destination folder. When /O is specified, the source folder can’t be moved into an existing folder without specifying the name of the moved folder in `destFolderStr`.

/P=pathName  Specifies the folder for relative paths in `srcFolderStr` and `destFolderStr`. `pathName` is the name of an existing symbolic path.

If `srcFolderStr` is omitted, the folder associated with `pathName` is moved. If `destFolderStr` is omitted, the source folder is moved into the folder associated with `pathName`.

Using /P means that `srcFolderStr` (if specified) and `destFolderStr` must be either simple folder names or paths relative to the folder specified by `pathName`. 
MoveFolder

<table>
<thead>
<tr>
<th>Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>V_flag</strong></td>
<td>Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.</td>
</tr>
<tr>
<td><strong>S_fileName</strong></td>
<td>Stores the full path to the folder that was moved, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.</td>
</tr>
<tr>
<td><strong>S_path</strong></td>
<td>Stores the full path of the moved folder, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.</td>
</tr>
</tbody>
</table>

**Details**

You can use only `/P=pathName` (omitting `srcFolderStr`) to specify the source folder to be moved.

A folder path should not end with single Path Separators. For example:

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder:"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder:"
```

will do weird, unexpected things (and probably damaging things when /O is also used). Instead, use:

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"
```

Beware of PathInfo and other command which return paths with an ending path separator. (They can be removed with the RemoveEnding function.)

A folder may not be moved into one of its own subfolders.

Conversely, the command:

```
MoveFolder/O/P=myPath "afolder"
```

which attempts to overwrite the folder associated with myPath with a folder that is inside it (namely “afolder”) is not allowed. Instead, use:

```
MoveFolder/O/P=myPath ":afolder"
```

On Windows, renaming or moving a folder never updates the value of any Igor Symbolic Paths that point to a moved folder:

```
// Create a folder
NewPath/O/C myPath "C:\My Data\My Work"

// Move the folder
MoveFolder/P=myPath as "C:\My Data\Move"

// Display the path's value
PathInfo myPath // (or use the Path Status dialog)
Print S_path    // C:My Data:My Work
```

You can use PathInfo to determine if a folder referred to by an Igor symbolic path exists and where it is on the disk. Use NewPath/O to reset the path’s value.

On the Macintosh, however, renaming or moving a folder on the same volume does alter the value of symbolic path. This is because MoveFolder uses a Mac OS alias to keep track of the folder. A folder renamed or moved on the same volume retains the original “volume refnum” and “directory ID” stored in the alias mechanism, so that the alias (and hence Igor’s symbolic path) remains pointing to the moved folder. After moving the folder, using the unchanged volume refnum and directory ID (in PathInfo or when you use `/P=pathName`) returns the updated path.
Moving the folder to a different volume actually creates a new folder with new volume refnum and directory IDs, and symbolic paths pointing to or into the moved folder aren’t updated. They will be pointing at a deleted folder (they’re probably invalid).

**Examples**

Rename a folder (“move” it to the same folder):

MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"

Rename a folder referred to by only a path:

NewPath/O myPath "Macintosh HD:folder"
MoveFolder/P=myPath as "::Renamed Folder"

Move a folder from one volume to another. This moves “Macintosh HD:My Folder” inside “Server:My Folder” if “Server:My Folder” already exists:

MoveFolder "Macintosh HD:My Folder" as "Server:My Folder"

Move a folder from one volume to another. This overwrites “Server:My Folder” (if it existed) with the moved “Macintosh HD:My Folder”:

MoveFolder/O "Macintosh HD:My Folder" as "Server:My Folder"

Move user-selected folder in any folder as “Renamed Folder” into a user-selected folder (possibly the same one):

MoveFolder as "Renamed Folder"

Move user-selected file in any folder as “Moved Folder” in any folder:

MoveFolder/1=3 as "Moved Folder"

**See Also**

MoveFile, CopyFolder, DeleteFolder, IndexedDir, PathInfo, and RemoveEnding, Symbolic Paths on page II-22.

**MoveString**

MoveString *sourceString*, destDataFolderPath [*newname*]

The MoveString operation removes the source string variable and places it in the specified location optionally with a new name.

**Parameters**

*sourceString* can be just the name of a string variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.

*destDataFolderPath* can be a partial path (relative to the current data folder) or an absolute path (starting from root).

**Details**

An error is issued if a variable or wave of the same name already exists at the destination.

**Examples**

MoveString :foo:s1,:bar: // Move string s1 into data folder bar
MoveString :foo:s1,:bar:ss1 // Move string s1 into bar with new name ss1

**See Also**

The MoveVariable, MoveWave, and Rename operations; and Chapter II-8, Data Folders.

**MoveSubwindow**

MoveSubwindow [/W=winName] *key* = (values)[, *key* = (values)]...

The MoveSubwindow operation moves the active or named subwindow to a new location within the host window. This command is primarily for use by recreation macros; users should use layout mode for repositioning subwindows.

**Parameters**

fguide=(gLeft, gTop, gRight, gBottom)
MoveSubwindow

Specifies the frame guide name(s) to which the outer frame of the subwindow is attached inside the host window.

The frame guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.

When the host is a graph, additional standard guides are available for the outer graph rectangle and the inner plot rectangle (where traces are plotted).

See Details for standard guide names.

\[ \text{fnum}= (\text{left}, \text{top}, \text{right}, \text{bottom}) \]

Specifies the new location of the subwindow. The location coordinates of the subwindow sides can have one of two possible meanings:

When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.

When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or Control Panel Units for control panel hosts, relative to the top left corner of the host frame.

\[ \text{pguide}= (g\text{Left}, g\text{Top}, g\text{Right}, g\text{Bottom}) \]

Specifies the guide name(s) to which the plot rectangle of the graph subwindow is attached inside the host window.

Guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.

See Details for standard guide names.

Flags

\[ /W= \text{winName} \]

Moves the subwindow in the named window or subwindow. When omitted, action will affect the active subwindow.

When identifying a subwindow with \text{winName}, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

When moving an exterior subwindow, only the fnum keyword may be used. The values are the same as the NewPanel /W flag for exterior subwindows.

The names for the built-in guides are as defined in the following table:

<table>
<thead>
<tr>
<th>Guide Type</th>
<th>Left</th>
<th>Right</th>
<th>Top</th>
<th>Bottom</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subwindow Frame</td>
<td>FL</td>
<td>FR</td>
<td>FT</td>
<td>FB</td>
</tr>
<tr>
<td>Outer Graph Rectangle</td>
<td>GL</td>
<td>GR</td>
<td>GT</td>
<td>GB</td>
</tr>
<tr>
<td>Inner Plot Rectangle</td>
<td>PL</td>
<td>PR</td>
<td>PT</td>
<td>PB</td>
</tr>
</tbody>
</table>

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows.

See Also

The MoveWindow operation. Chapter III-4, Embedding and Subwindows for further details and discussion.
MoveVariable

MoveVariable sourceVar, destDataFolderPath [newname]
The MoveVariable operation removes the source numeric variable and places it in the specified location optionally with a new name.

Parameters
sourceVar can be just the name of a numeric variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.
destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details
An error is issued if a variable or wave of the same name already exists at the destination.

Examples
MoveVariable :foo:v1,:bar: // Move v1 into data folder bar
MoveVariable :foo:v1,:bar:vv1 // Move v1 into bar with new name vv1

See Also
The MoveString, MoveWave, and Rename operations; and Chapter II-8, Data Folders.

MoveWave

MoveWave sourceWave,[destDataFolderPath:][newName]
The MoveWave operation removes the source wave and places it in the specified location optionally with a new name.

If you want to rename a wave without moving it, use Rename instead.

Parameters
sourceWave can be just the name of a wave in the current data folder, a partial path (relative to the current data folder) and wave name, an absolute path (starting from root) and wave name, or a wave reference variable in a user-defined function.
destDataFolderPath can be a partial path (relative to the current data folder), an absolute path (starting from root), or a data folder reference (DFREF) in a user-defined function. If the destination is a null DFREF, the wave is moved to the current data folder.

Details
An error is issued if a variable or wave of the same name already exists at the destination.

MoveWave Destination
Depending on the syntax you use, MoveWave may move sourceWave to another data folder, rename sourceWave, or both. To explain this, we show examples below which call this setup function:

Function Setup()
  SetDataFolder root:
  KillDataFolder root: // clear out any previous stuff
  NewDataFolder/O root:DF0
  Make/O root:wave0
End

The Setup function gives you a data hierarchy like this:
root (<- current data folder)
  wave0
  DF0

// 1. Simple dest name: Renames wave0 as wave1
Function Demo1()
  Setup()
  Wave w = root:wave0
  MoveWave w, wave1 // Use Rename instead
End

// 2. Dest path with trailing colon: Moves wave0 without renaming
Function Demo2()
  Setup()
MoveWindow

Wave w = root:wave0
MoveWave w, root:DF0:
End

// 3. Dest path with trailing colon and name: Moves wave0 and renames as wavel
Function Demo3()
    Setup()
    Wave w = root:wave0
    MoveWave w, root:DF0:wavel
End

// 4. DFREF dest without trailing colon: Moves wave0 without renaming
Function Demo4()
    Setup()
    Wave w = root:wave0
    DFREF dfr = root:DF0
    MoveWave w, dfr
End

// 5. DFREF dest with trailing colon: Generates error
Function Demo5()
    Setup()
    Wave w = root:wave0
    DFREF dfr = root:DF0
    MoveWave w, dfr:// Error - trailing colon not allowed
End

// 6. Dest path with trailing colon and name: Moves wave0 and renames as wavel
Function Demo6()
    Setup()
    Wave w = root:wave0
    DFREF dfr = root:DF0
    MoveWave w, dfr:wavel
End

// 7. Null DFREF as destination; moves to current data folder
Function Demo7()
    Setup()
    Wave w = root:wave0
    SetDataFolder root:DF0 // make DF0 the current data folder
    DFREF noDF = "$\text{Doesnotexist}$
    MoveWave w, noDF // moves to current DF
end

// 8. Use MoveWave to make a wave free (move it to no data folder)
Function Demo8()
    Setup()
    Wave w = root:wave0
    // Doesn't do it:
    //DFREF noDF = "$\text{Doesnotexist}$" //MoveWave w, noDF // moves to current DF
    DFREF freedf = NewFreeDataFolder()
    MoveWave w, freedf
    KillDataFolder freedf
    // as long as wave reference w remains, // the wave will continue to exist, and is a free wave
end

See Also
The MoveString, MoveVariable, and Rename operations; and Chapter II-8, Data Folders.

MoveWindow

MoveWindow [flags] left, top, right, bottom
The MoveWindow operation moves the target or specified window to the given coordinates.

Flags
/C        Moves Command window instead of the target window.
/F        Windows: Moves the Igor Pro application “frame” and the frame is then adjusted so that no part is offscreen.
        Macintosh: Moves nothing.
Details
Note that neither winName nor procedureTitleAsName is a string but is the actual window name or procedure window title. If the procedure window’s title (procedure windows don’t have names) has a space in it, use $ and quotes:

MoveWindow/F=$"Log Histogram" 0,0,600,400

If /W, /F, /C, and /P are omitted, MoveWindow moves the target window.

The coordinates are in points if neither /I nor /M is used.

In Igor Pro 7.00 or later, to move the window without changing its size, pass -1 for both right and bottom.

You can use the MoveWindow operation to minimize, restore, or maximize a window by specifying 0, 1, or 2 for all of the coordinates, respectively, as follows:

MoveWindow 0, 0, 0, 0 // Minimize target window.
MoveWindow 1, 1, 1, 1 // Restore target window.
MoveWindow 2, 2, 2, 2 // Maximize target window.

On Macintosh, “maximize” means to move and resize the window so that it fills the screen.
“Minimize” means to minimize to the dock.

If the window size has been constrained by SetWindow sizeLimit, those limits are silently applied to the size set by MoveWindow.

See Also
The MoveSubwindow and DoWindow operations.

MPFXEMGPeak

The MPFXEMGPeak function implements a single exponentially modified Gaussian peak with no Y offset in the format of an all-at-once fitting function. The exponentially modified Gaussian peak shape is a convolution of an exponential and a Gaussian peak.
Parameters

- **cw**: Coefficient wave, which must be a double-precision wave.
  - The Gaussian peak shape is defined by the coefficients as follows:
    - **cw[0]**: Peak location. This is actually the location of the underlying Gaussian peak. There is no analytic expression for the actual peak location.
    - **cw[1]**: Standard deviation of the Gaussian portion.
    - **cw[2]**: Amplitude-related parameter.
    - **cw[3]**: Decay constant of the exponential portion.
  - **cw** must be a double precision wave.

- **yw**: Y wave into which values are stored.
  - **yw** may be either double precision or single precision.

- **xw**: X wave containing the X values at which the peak function is to be evaluated.
  - **xw** may be either double precision or single precision.

Details

There is no analytic expression for peak parameters of common interest like the amplitude, location and width. The Multipeak Fitting package uses numerical techniques to get approximations.

This function is primarily intended to support the Multipeak Fitting package.

To use MPFXEMGPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

```lisp
Function FitVoigtPeak(Wave cw, Wave yw, Wave xw) : FitFunc
    Variable dummy = MPFXEMGPeak(cw, yw, xw)
End
```

The assignment to "dummy" is required because you must explicitly do something with the return value of a built-in function.

The implementation of this function involves the **erfcx** function.

If the waves do not satisfy the number type requirements, the function returns NaN. A successful invocation returns zero.

See Also

All-At-Once Fitting Functions on page III-256

**MPFXExpConvExpPeak**

**MPFXExpConvExpPeak (cw, yw, xw)**

The MPFXExpConvExpPeak function implements a single peak with no Y offset in the format of an all-at-once fitting function. The peak shape is that of an exponential convolved with another exponential.

MPFXExpConvExpPeak is similar to the MPFXEMGPeak, but it has a sharp onset. It fills the wave **yw** with peak values as if a simple wave assignment was executed.
Parameters

$cw$ Coefficient wave. The Gaussian peak shape is defined by the coefficients as follows:

$cw[0]$: Peak location.
$cw[3]$: Inverse of the decay constant of the other exponential.

$cw$ must be a double precision wave.

$yw$ Y wave into which values are stored.
$yw$ may be either double precision or single precision.

$xw$ X wave containing the X values at which the peak function is to be evaluated.
$xw$ may be either double precision or single precision.

Details

The following equations and discussion use these definitions:

c_0 = cw[0], c_1 = cw[1], c_2 = cw[2], c_3 = cw[3]

The peak location given by $c_0$ is not the actual peak location; it is simply a parameter that offsets the peak in the X direction. The actual location is given by

$$loc = \frac{\ln\left(\frac{c_2}{c_3}\right)}{c_2 - c_3} + c_0$$

The actual peak height is given by

$$h = \frac{c_1 \cdot c_2 \left\{ \left(\frac{c_2}{c_3}\right) - \frac{c_2}{c_2-c_3} - \left(\frac{c_2}{c_3}\right) - \frac{c_3}{c_2-c_3} \right\}}{c_3 - c_2}$$

The peak area is given by $c_1/c_3$.

We are not aware of an analytic expression for the full width at half maximum (FWHM).

This function is primarily intended to support the Multi-peak Fitting package.

To use MPFXExpConvExpPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

Function FitVoigtPeak(Wave cw, Wave yw, Wave xw) : FitFunc
    Variable dummy = MPFXExpConvExpPeak(cw, yw, xw)
End

The assignment to “dummy” is required because you must explicitly do something with the return value of a built-in function.

If the waves do not satisfy the number type requirements, the function returns NaN. A successful invocation returns zero.

See Also

All-At-Once Fitting Functions on page III-256

MPFXGaussPeak

MPFXGaussPeak(cw, yw, xw)

The MPFXGaussPeak function implements a single Gaussian peak with no Y offset in the format of an all-at-once fitting function. It fills the wave $yw$ with values defined by a Gaussian peak as if this wave assignment statement was executed:

$yw = cw[2] \cdot \exp\left(-((xw - cw[0]) / cw[1])^2\right)$
MPFXLorentzianPeak

Parameters

cw  Coefficient wave. The Lorentzian peak shape is defined by the coefficients as follows:
    cw[0]:  Peak location.
    cw[1]:  Peak width as full width at half maximum.
    cw[2]:  Peak area.

cw must be a double precision wave.

yw  Y wave into which values are stored.
    yw may be either double precision or single precision.

xw  X wave containing the X values at which the peak function is to be evaluated.
    xw may be either double precision or single precision.

Details

This function is primarily intended to support the Multipeak Fitting package. To use MPFXLorentzianPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

Function FitLorentzianPeak(Wave cw, Wave yw, Wave xw) : FitFunc
    Variable dummy = MPFXLorentzianPeak(cw, yw, xw)
End

The assignment to "dummy" is required because you must explicitly do something with the return value of a built-in function.

If the waves do not satisfy the number type requirements, the function returns NaN. A successful invocation returns zero.

See Also

All-At-Once Fitting Functions on page III-256

MPFXLorentzianPeak

MPFXLorentzianPeak(cw, yw, xw)

The MPFXLorentzianPeak function implements a single Lorentzian peak with no Y offset in the format of an all-at-once fitting function. It fills the wave yw with values defined by a Lorentzian peak as if this wave assignment statement was executed:

yw = 2*cw[2]/pi * cw[1]/(4*(xw-cw[0])^2 + cw[1]^2)

Parameters

cw  Coefficient wave. The Lorentzian peak shape is defined by the coefficients as follows:
    cw[0]:  Peak location.
    cw[1]:  Peak width as full width at half maximum.
    cw[2]:  Peak area.

cw must be a double precision wave.

yw  Y wave into which values are stored.
    yw may be either double precision or single precision.

xw  X wave containing the X values at which the peak function is to be evaluated.
    xw may be either double precision or single precision.

Details

This function is primarily intended to support the Multipeak Fitting package. To use MPFXLorentzianPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

Function FitLorentzianPeak(Wave cw, Wave yw, Wave xw) : FitFunc
    Variable dummy = MPFXLorentzianPeak(cw, yw, xw)
End
The assignment to "dummy" is required because you must explicitly do something with the return value of a built-in function. If the waves do not satisfy the number type requirements, the function returns NaN. A successful invocation returns zero.

**See Also**
*All-At-Once Fitting Functions* on page III-256

### MPFXVoigtPeak

**MPFXVoigtPeak**(cw, yw, xw)

The MPFXVoigtPeak function implements a single Voigt peak with no Y offset in the format of an all-at-once fitting function. It fills the wave yw with values defined by a Voigt peak as if this wave assignment statement was executed:

```
yw = cw[2]*VoigtFunc(cw[1]*(xw-cw[0]), cw[3])
```

The *VoigtFunc* function here is a basic Voigt peak shape, a convolution of a Gaussian and Lorentzian peak shapes. The first parameter of *VoigtFunc* controls the shape. A value of zero results in a peak shape that is 100% Gaussian. As the first parameter approaches infinity the shape transitions to 100% Lorentzian. At a value of $\sqrt{\ln(2)} \approx 0.832555$ the mix is 50/50.

**Parameters**

- **cw** Coefficient wave. The Gaussian peak shape is defined by the coefficients as follows:
  - *cw[0]*: Peak location.
  - *cw[1]*: Affects the width; the actual width is a complicated function of *cw[1]*, *cw[2]*, and *cw[3]*
  - *cw[2]*: Amplitude factor; the actual amplitude is affected by the other parameters.
  - *cw[3]*: Shape factor. Zero results in pure Gaussian, infinity results in pure Lorentzian, one is 50% Gaussian and 50% Lorentzian.

  *cw* must be a double precision wave.

- **yw** Y wave into which values are stored. 
  *yw* may be either double precision or single precision.

- **xw** X wave containing the X values at which the peak function is to be evaluated.
  *xw* may be either double precision or single precision.

**Details**

This function is primarily intended to support the MultiPeak Fitting package. For other purposes we recommend the *VoigtPeak* function which has more convenient parameters.

To use MPFXVoigtPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

```
Function FitVoigtPeak(Wave cw, Wave yw, Wave xw) : FitFunc
    Variable dummy = MPFXVoigtPeak(cw, yw, xw)
End
```

The assignment to "dummy" is required because you must explicitly do something with the return value of a built-in function. If the waves do not satisfy the number type requirements, the function returns NaN. A successful invocation returns zero.

**References**

The code used to compute VoigtPeak was written by Steven G. Johnson of MIT. You can learn more about it at http://ab-initio.mit.edu/Faddeeva.

**See Also**
*All-At-Once Fitting Functions* on page III-256, *VoigtPeak*, *VoigtFunc*
MultiTaperPSD operation estimates the power spectral density of `srcWave` using Slepian (DPSS) tapers. The MultiTaperPSD operation was added in Igor Pro 7.00.

Flags

/A Uses Thomson’s adaptive algorithm. In this case the operation also creates the wave `W_MultiTaperDF` that contains the effective degrees of freedom. For each frequency of the PSD the algorithm is expected to converge within few iterations. When it fails to converge, the operation prints in the history the total number of frequencies where it did not converge while the actual output contains the last iteration estimate.

/DB Scale the PSD results as $10 \times \log_{10}(\text{spectralEst}(f))$.

/DBF=$f_0$ Scale the PSD results as $10 \times \log_{10}(\text{spectralEst}(f)/\text{spectralEst}(f_0))$ where $f_0$ must be in the range $[0,0.5/\text{DimDelta}(\text{srcWave},0)]$.

/DEST=destWave Saves the PSD estimate in a wave specified by `destWave`. The destination wave is created or overwritten if it already exists.

Creates a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-72 for details.

If you omit /DEST the operation saves the resulting spectral estimate in the wave `W_MultiTaperPSD` in the current data folder.

/F Computes F-test statistic for each output frequency. The results are stored in the wave `W_MultiTaperF`.

If /DEST is also used then the F-test results are stored in the same data folder as `destWave`. Otherwise `W_MultiTaperF` is created in the current data folder.

The statistic is a variance ratio, of the background and the power at the specific frequency. Since the PSDs of the background and the line are assumed to be distributed as Chi-squared with 2 and $2*nTapers-2$ degrees of freedom respectively, the relevant critical value for computing confidence intervals can be obtained from:

`StatsInvFCdf(percentSignificance/100,2,2*nTapers-2)`

/NOR=N Sets the normalization factor that is used to multiply each element of the output. For example, if you want to normalize the output such that the sum of the PSD estimate matches the variance of the input use /NOR=2/(np*np) where `np` is the number of points in `srcWave`.

/NTPR=nTapers Specifies the number of Slepian tapers to be used. If you do not specify a number of tapers, the operation uses $2*nw$ (twice the time-bandwidth product).

/NW=nw Specifies the time-bandwidth product. This value should typically be in the range $[2,6]$. Given a time-bandwidth product `nw` it is recommended to use no more than $2*nw$ tapers in order to maximize variance efficiency.

/Q Quiet mode; suppresses printing in the history area.

/R=[startPoint,endPoint] Calculates the PSD estimate for a specified input range. `startPoint` and `endPoint` are expressed in terms of point numbers of the source wave.

/R=(startX,endX) Calculates the PSD estimate for a specified input range. `startX` and `endX` are expressed in terms of X values. Note that this option converts your X specifications to point numbers and some roundoff may occur.

/Z Do not report errors.
Details
The MultiTaperPSD operation estimates the PSD of srcWave by computing a set of discrete prolate spheroidal functions (Slepian DPSS) and using them as optimal window functions. The window functions/tapers are applied to the input signal and squares of the resulting Fourier transforms are weighted together to produce the PSD estimate.

csrcWave must be a real-valued numeric wave of single or double precision and must not contain any INFs or NaNs.
The mean value of the input is subtracted prior to multiplication by the tapers. Like DSPPeriodogram, the MultiTaperPSD operation leaves the normalization to the user.
The default PSD estimate is calculated by combining the Fourier transforms of the tapered signal with weights from the DPSS calculation. You can use the /A flag to improve the PSD estimate for increasing tapers. Thomson’s adaptive algorithm is reasonably efficient and also provides an estimate of the effective degrees of freedom as a function of frequency.
The operation sets the variable V_Flag to zero if successful or to a -1 if it encounters an error. If you are using Thomson’s adaptive algorithm (/A) V_Flag is set to the number of frequencies at which the algorithm failed to converge.

Demos
See the “MultiTaperPSD Demo” example experiment.

References

MultiThread

MultiThread [ /N=numThreads ] wave = expression
In user-defined functions, the MultiThread keyword can be inserted in front of wave assignment statements to speed up execution on multiprocessor computer systems.

Warning: Misuse of this keyword can result in a performance penalty or even a crash. Be sure to read Automatic Parallel Processing with MultiThread on page IV-323 before using MultiThread.

The expression must be thread-safe. This means that if it calls a function, the function must be thread-safe. This goes for both built-in and user-defined functions.

Not all built-in functions are thread-safe. Use the Command Help tab in the Igor Help Browser to see which functions are thread-safe.

User-defined functions are thread-safe if they are defined using the ThreadSafe keyword. See ThreadSafe Functions on page IV-106 for details.

You can specify the number of threads using the /NT flag. The default value, which takes effect if you omit /NT or specify /NT=0, uses the number returned by ThreadProcessorCount. /NT=1 specifies a single thread and is equivalent to omitting the MultiThread keyword; you might want to turn off threading to avoid its overhead when the wave has few points. numThreads values greater than one specify the desired number of threads to be used. Igor may use fewer threads depending on how it is able to partition the task. The /NT flag was added in Igor Pro 8.00.

Automatic Parallel Processing with MultiThread on page IV-323.
Waveform Arithmetic and Assignments on page II-74.
The “MultiThread Mandelbrot Demo” experiment.

MultiThreadingControl

**MultiThreadingControl** keyword [=value]
The MultiThreadingControl operation allows you to control how automatic multithreading works with those IGOR operations that support it. Automatic multithreading is described below under Details.

For most purposes you will not need to use this operation.
The MultiThreadingControl operation was added in Igor Pro 7.00.

**Keywords**

**getMode**
Writes the current mode value into the variable V_autoMultiThread.

**getThresholds**
Creates the wave W_MultiThreadingArraySizes in the current data folder. See **Automatic Multithreading Thresholds** below for details.

**setMode=m**
Sets the mode for automatic multithreading. The mode controls the circumstances in which automatic multithreading is enabled.

- **m=0**: Disables automatic multithreading unconditionally.
- **m=1**: Enables automatic multithreading based on operation-specific thresholds for operations called from the main thread only. This is the default setting.
- **m=4**: Enables automatic multithreading based on operation-specific thresholds for operations called from the main thread and from user-created explicit threads.
- **m=8**: Enables automatic multithreading unconditionally - regardless of thresholds or the type of the calling thread.

You can not combine modes by ORing. The only valid values for m are those shown above.

**setThresholds=tWave**
Sets the thresholds for automatic multithreading. See **Automatic Multithreading Thresholds** below for details.

**Details**
Some IGOR operations and functions have internal code that can execute calculations in parallel using multiple threads. These operations are marked as "Automatically Multithreaded" in the Command Help pane of the Igor Help Browser.

Running on multiple threads reduces the time required for number-crunching tasks on multi-processor machines when the benefit of using multiple processors exceeds the overhead of running in multiple threads. This is usually the case only for large-scale jobs.

By default Igor uses automatic multithreading in operations that support it when the number of calculations exceeds a threshold value. This is called "automatic multithreading" to distinguish it from the explicit multithreading that you can instruct Igor to do. Explicit multithreading is described under **ThreadSafe Functions and Multitasking** on page IV-329. You don't need to do anything to benefit from automatic multithreading.

By default automatic multithreading is enabled for operations called from the main thread and disabled for operations called from explicit threads that you create (mode=1). You can change this using the setMode keyword described above.

The state of automatic multithreading is not saved with the experiment. It is initialized to mode=1 with default thresholds every time you start IGOR.

**Automatic Multithreading Thresholds**
Executing these commands

```
MultiThreadingControl getThresholds
Edit W_MultiThreadingArraySizes.ld
```
creates a wave named W_MultiThreadingArraySizes and displays it in a table. This shows you the current threshold for each operation that supports automatic multithreading. The wave includes dimension labels so you can see which row represents which operation’s threshold.

The meaning of a given threshold value depends on the operation. For most operations the threshold is in terms of the number of points in the input wave. For some operations the threshold depends on the complexity of the calculation. For example, the threshold for the CurveFit operation takes the complexity of the fitting function into account.

You can change the threshold for a given operation by setting the data for the appropriate row of W_MultiThreadingArraySizes and passing it back to the MultiThreadingControl operation using the setThresholds keyword. For example:

```
W_MultiThreadingArraySizes[%ICA]=5000 // Set the ICA threshold
MultiThreadingControl setThresholds=W_MultiThreadingArraySizes // Apply
```

You should not change any aspect of the wave other than the threshold values.

**Multithreading and Roundoff Error**

Every floating point operation can potentially lead to roundoff error. Normally, if you run the exact same code on the exact same data, you get the exact same roundoff error and the exact same result.

This is not necessarily the case with multithreaded calculations. Because the partitioning of work among threads depends on circumstances, such as how many threads are free, different calculation runs on the same data may partition work differently. This can lead to differences in roundoff error and therefore differences in results.

You can obtain reproducibility at the expense of performance by turning off automatic multithreading:

```
MultiThreadingControl setMode=0
```

Although this provides reproducibility, it does not necessarily reduce the size of roundoff error.

**Examples**

```
MultiThreadingControl setMode=0 // Disable automatic multithreading
MultiThreadingControl setMode=8 // Always multithread regardless of wave size
```

ThreadSafe Functions on page IV-106, ThreadSafe Functions and Multitasking on page IV-329

**NameOfWave**

**NameOfWave (wave)**

The NameOfWave function returns a string containing the name of the specified wave.

In a user-defined function that has a parameter or local variable of type WAVE, NameOfWave returns the actual name of the wave identified by the WAVE reference. It can also be used with wave reference functions such as WaveRefIndexedDFR.

NameOfWave does not return the full data folder path to the wave. Use GetWavesDataFolder for this information.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using WaveRefIndexedDFR in a loop to act on all waves in a data folder, and the loop has incremented beyond the highest valid index.

**Examples**

```
Function ZeroWave(w)
    Wave w
    w = 0
    Print "Zeroed the contents of", NameOfWave(w)
End
```

See Also

See WAVE; the GetWavesDataFolder and WaveRefIndexed functions; and Wave Reference Functions on page IV-197.
**NaN**

The NaN function returns the “Not a Number” value according to the IEEE standards. Comparison operators do not work with NaN parameters because, by definition, NaN compared to anything, even another NaN, is false. Use **numtype** to test if a value is NaN.

**NeuralNetworkRun**

```
NeuralNetworkRun [/Q/Z] Input=testWave, WeightsWave1=w1, WeightsWave2=w2
```

The NeuralNetworkRun operation uses the interconnection weights generated by NeuralNetworkTrain, and saved in the waves M_Weights1 and M_Weights2, to execute the network for a given input. The input can contain a single run represented by a 1D wave or M runs represented by M columns of a 2D wave. The output of the calculation is saved in the wave W_NNResults or M_NNResults depending on the dimensionality of the input wave. The structure of the network is completely specified by the two weights waves and must match the number of rows in the input wave.

**Flags**

- `/Q` Suppresses printing information in the History area.
- `/Z` No error reporting.

**Parameters**

- `Input=testWave` Specifies the input to the neural network. `testWave` must be a single or double precision wave containing entries in the range [0,1] and have the correct number of rows to match the weights. Execute the network for multiple runs by using a 2D input wave where each column corresponds to a single run. For a 2D input, the result will be stored in M_NNResults with a corresponding column structure.
- `WeightsWave1=w1` Specifies the interconnection weights between the input and the hidden layer.
- `WeightsWave2=w2` Specifies the interconnection weights between the hidden layer and the output.

**See Also**
The **NeuralNetworkTrain** operation.

**NeuralNetworkTrain**

```
NeuralNetworkTrain [/Q/Z] [keyword = value]...
```

The NeuralNetworkTrain operation trains a three-layer neural network. The training produces two 2D waves that store the interconnection weights between the network neurodes. Once you obtain the weights, you can use them with NeuralNetworkRun.

**Flags**

- `/Q` Suppresses printing information in the History area.
- `/Z` No error reporting.

**Parameters**

`keyword` is one of the following:

- `Input=inWave` Specifies the input patterns for training. `inWave` is a 2D wave where each row corresponds to a single training event and each column corresponds to the input values. The number of rows in `inWave` (the number of training sets) and in the output wave must be equal. `inWave` must be single or double precision and all entries must be in the range [0,1].
- `Iterations=num` Specifies the number of iterations. Default is 10000.
- `MinError=val` Terminates training when the total error drops below `val` (default is 1e-8). The total error is normalized, and is defined as the sum of the squared errors divided by the number of training sets times outputs.
NeuralNetworkTrain is the first half of the implementation of a three-layer neural network in which both inputs and outputs are taken as normalized quantities in the range $[0,1]$. Network training is based on back-propagation to iteratively minimize the error between the output and the expected output for any given training set. Training creates in two 2D waves that contain the interconnection weights between the neurodes. $M_{Weights1}$ contains the weights between the input layer and the hidden layer and $M_{Weights2}$ contains the weights between the hidden layer and the output layer. During the iteration stage, global error information can be printed in the history area.

The algorithm computes the output of the $k$th neurode by

$$V_k = \left[ 1 + \exp \left( -\sum_{i=1}^{n} w_i s_i \right) \right]^{-1},$$

where $w_i$ is the weight corresponding to input $i$, $s_i$ is the signal corresponding to that input, and $n$ is the number of inputs connected to the neurode.

The total error is defined as the sum (over all training sets and all outputs) of the squared differences between the network outputs and the expected values. The sum is normalized by the product of the number of training sets and the number of outputs. The history reports (see NReport parameter) the square root of the total error (RMS error). The square root of the error computed at the end of the last iteration is stored in the variable $V_{rms}$.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Momentum=val</td>
<td>Specifies a coefficient for the back-propagation algorithm. This coefficient adds to the change in a particular weight a contribution proportional to the error in a previous iteration. Default momentum is 0.075.</td>
</tr>
<tr>
<td>NHidden=num</td>
<td>Specifies the number of hidden neurodes. You do not need to use the Structure keyword with NHidden because the network is completely specified by the training waves and NHidden.</td>
</tr>
<tr>
<td>NReport=num</td>
<td>Specifies over how many iterations (default is 1000) to print the global RMS error to the history area. Ignored with /Q.</td>
</tr>
<tr>
<td>Output=outWave</td>
<td>Specifies the expected outputs corresponding to the entries in the input wave. The number of rows in outWave (the number of training sets) and in the input wave must be equal. outWave must be single or double precision and all entries must be in the range $[0,1]$.</td>
</tr>
<tr>
<td>LearningRate=val</td>
<td>Sets the network learning rate, which is used in the backpropagation calculation. Default is 0.15.</td>
</tr>
<tr>
<td>Restart</td>
<td>Allows specification of your own set of weights as the starting values. Use this to run the training and feed the output weights of one training session as the input for the next.</td>
</tr>
<tr>
<td>Structure=[Ni, Nh, No]</td>
<td>Specifies the structure of the network. $Ni$ is the number of neurodes at the input, $Nh$ is the number of hidden neurodes, and $No$ is the number of output neurodes. Structure is unnecessary when using NHidden is because the remaining numbers are determined by the sizes of the input and output waves.</td>
</tr>
<tr>
<td>WeightsWave1=w1</td>
<td>Specifies the weights for propagation from the first layer to the second. The 2D wave must be double precision and the dimensions must match the specified neurodes with the same numbers of rows and inputs and with matching numbers of columns and hidden neurodes.</td>
</tr>
<tr>
<td>WeightsWave2=w2</td>
<td>Specifies the weights for propagation from the second to the third layer. The 2D wave must be double precision and the dimensions must match the specified neurodes with the same numbers of rows and hidden neurodes and with matching numbers of columns and outputs.</td>
</tr>
</tbody>
</table>
See Also
The NeuralNetworkRun operation.

NewCamera

NewCamera [flags] [keywords]
The NewCamera operation creates a new camera window.

Documentation for the NewCamera operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "NewCamera"

NewDataFolder

NewDataFolder [/O/S] dataFolderSpec
The NewDataFolder operation creates a new data folder of the given name.

Parameters
dataFolderSpec can be just a data folder name, a partial path (relative to the current data folder) with name
or a full path (starting from root) with name. If just a data folder name is used then the new data folder is
created in the current data folder. If a full or partial path is used, all data folders except for the last in the
path must already exist.

Flags
/O No error if a data folder of the same name already exists.
/S Sets the current data folder to dataFolderSpec after creating the data folder.

Examples
NewDataFolder foo // Creates foo in the current data folder
NewDataFolder :bar:foo // Creates foo in bar in current data folder
NewDataFolder root:foo // Creates foo in the root data folder

See Also
Chapter II-8, Data Folders.

NewFIFO

NewFIFO FIFOName
The NewFIFO operation creates a new FIFO.

Details
Useless until channel info is added with NewFIFOChan.

An error is generated if a FIFO of same name already exists. FIFOName needs to be unique only among
FIFOs. You can not overwrite a FIFO.

See Also
FIFOs are used for data acquisition. See FIFOs and Charts on page IV-313 and the NewFIFOChan
operation for more information.

NewFIFOChan

NewFIFOChan [flags] FIFOName, channelName, offset, gain, minusFS, plusFS,
unitsStr [, vectPnts]
The NewFIFOChan operation creates a new channel for the named FIFO.

Parameters
channelName must be unique for the specified FIFO.

The offset, gain, plusFS, minusFS and unitsStr parameters are used when the channel’s data is displayed in a
chart or transferred to a wave. If given, vectPnts must be between 1 and 65535.
Flags
The flags define the type of data to be stored in the FIFO channel:

- /B 8-bit signed integer. Unsigned if /U is present.
- /C Complex.
- /D Double precision IEEE floating point.
- /I 32-bit signed integer. Unsigned if /U is present.
- /S Single precision IEEE floating point (default).
- /U Unsigned integer data.
- /W 16-bit signed integer. Unsigned if /U is present.
- /Y=type Specifies wave data type. See details below.

Wave Data Types
As a replacement for the above number type flags you can use /Y=numType to set the number type as an integer code. See the WaveType function for code values. Do not use /Y in combination with other type flags.

Details
You can not invoke NewFIFOChan while the named FIFO is running.

If you provide a value for vectPnts, you will create a channel capable of holding a vector of data rather than just a single data value. When such a channel is used in a Chart, it is displayed as an image using one of the built-in color tables.

Igor scales values in the FIFO channel before displaying them in a chart or transferring them to a wave as follows:

\[ \text{scaled\_value} = (\text{FIFO\_value} - \text{offset}) \times \text{gain} \]

Igor uses the plusFS and minusFS parameters (plus and minus full scale) to set the default display scaling for charts.

The unitsStr parameter is limited to a maximum of three bytes.

When you transfer a channel's data to a wave, using the FIFO2Wave operation, Igor stores the plusFS and minusFS values and the unitsStr in the wave’s Y scaling.

See Also
FIFOs are used for data acquisition. See FIFOs and Charts on page IV-313 and the NewFIFO and FIFO2Wave operations for more information.

The Chart operation for displaying FIFO data.

NewFreeAxis

NewFreeAxis [flags] axisName
The NewFreeAxis operation creates a new free axis that has no controlling wave.

Parameters
axisName is the name for the new free axis.
NewFreeDataFolder

**Flags**

/L/R/B/T  Specifies whether to attach the free axis to the Left, Right, Bottom, or Top plot edge, respectively. The Left edge is used by default.

/O  Replaces axisName if it already exists, which means any existing axis is marked as truly free.

/W=winName  Draws in the named graph window. winName may also be the name of a subwindow. winName must not conflict with other axis names except when using the /O flag. If /W is omitted, it creates a new axis in the active graph window or subwindow.

**Details**

A truly free axis does not use any scaling or units information from any associated waves (which need not exist.) You can set the properties of a free axis using SetAxis or ModifyFreeAxis.

**Example**

Copy this function to your Procedure window and compile:

```plaintext
Function axhook(s)
  STRUCT WMAxisHookStruct &s
  Variable t = s.max
  s.max = s.min
  s.min = t
  return 0
End
```

Now execute this code on the Command line:

```
Make jack=x
Display jack
NewFreeAxis fred
ModifyFreeAxis fred, master=left, hook=axhook
```

**See Also**

The SetAxis, KillFreeAxis, and ModifyFreeAxis operations.

NewFreeDataFolder

NewFreeDataFolder()

The NewFreeDataFolder function creates a free data folder and then returns its data folder reference. Recommended for advanced programmers only.

**Details**

Free data folders are those that are not a part of the normal data folder hierarchy and can not be located by name.

**See Also**

Chapter II-8, Data Folders, Free Data Folders on page IV-96 and Data Folder References on page IV-78.

NewFreeWave

NewFreeWave(type, numPoints [, nameStr])

The NewFreeWave function creates a free 1D wave of the given type and number of points and then returns its wave reference. Recommended for advanced programmers only.

**Details**

By default, NewFreeWave creates a free wave named '_free_'. You can specify another name via the optional nameStr input. The ability to specify the name of a free wave was added in Igor Pro 9.00 as a debugging aid - see Free Wave Names on page IV-95 and Wave Tracking on page IV-207 for details.

You can also create free waves using Make/FREE and Duplicate/FREE. These are preferable for creating multidimensional free waves and also fine for general use.
The type parameter can be either a code as documented for WaveType or can be 0x100 to create a data folder reference wave or 0x200 to create a wave reference wave.

You can redimension free waves as desired but, for maximum efficiency, you should create the wave with the desired type and total number of points and then use the /E=1 flag with Redimension to simply reshape without moving data.

A free wave is automatically discarded when the last reference to it disappears.

See Also
Free Waves on page IV-91, Make, Duplicate.

NewGizmo

NewGizmo [flags]
The NewGizmo operation creates a new Gizmo display window.

Documentation for the NewGizmo operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "NewGizmo"

NewImage

NewImage [flags] matrix
The NewImage operation creates a new image graph much like “Display;AppendImage matrix” except the graph is prepared using a style more appropriate for images. Rather than using preferences, NewImage provides several discrete styles to choose from.

Parameters
matrix is usually an MxN matrix containing image data. See AppendImage for details.

Flags

/F By default, the image is flipped vertically to correspond to normal image orientation. if /F is present then the image is not flipped.

/G=g Controls treatment of three-plane images as direct (RGB) color.

  g=1: Suppresses the autodetection of three-plane images as direct (RGB) color.

  g=1: Same as no /G flag (default).

/HIDE=h Hides (h = 1) or shows (h = 0, default) the window.

/HOST=hcSpec Embeds the new image plot in the host window or subwindow specified by hcSpec.

When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/K=k Specifies window behavior when the user attempts to close it.

  k=0: Normal with dialog (default).

  k=1: Kills with no dialog.

  k=2: Disables killing.

  k=3: Hides the window.

If you use /K=2 or /K=3, you can still kill the window using the KillWindow operation.

/N=name Requests that the created graph have this name, if it is not in use. If it is in use, then name0, name1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen graph name.
The graph is sized to make the image pixels a multiple of the screen pixels with the graph size constrained to be not too small and not too large.

If `matrix` appears to fit Igor's standard monochrome category, then explicit mode is set (See `ModifyImage` explicit). To be considered monochrome the wave must be unsigned byte and contain only values of 0, 64 or 255.

Once the graph is created it is a normal graph and has no special properties other than the settings it was created with. Specifically, it will not autosize itself if the dimensions of `matrix` are changed. NewImage is just a shortcut for creating a graph window with a style appropriate for images.

This operation is limited in scope by design. If you need to specify the position, size or title, then use the operations Display and AppendImage.

If the styles provided are not what you desire, touch up an image graph to meet your needs and then use `Capture Graph Prefs` from the Graphs menu. Then use "Display; AppendImage" rather than NewImage.

See Also
The Display, DoWindow, AppendImage, and ModifyImage operations.

NewLayout

```
NewLayout [flags] [as titleStr]
```

The NewLayout operation creates a page layout.

Unlike the Layout operation, NewLayout can be used in user-defined functions. Therefore, NewLayout should be used in new programming instead of Layout.

NewLayout just creates the layout window. Use `AppendLayoutObject` to add objects to the window.

Parameters
The optional `titleStr` parameter is a string expression containing the layout's title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

Flags
```
/B=(r,g,b[a])    Specifies the background color for the layout. r, g, b, and a specify the color and optional opacity as RGBA Values. The default is opaque white.
/C=colorOnScreen Obsolete. In ancient times, this flag switched the screen display of the layout between black and white and color. It is still accepted but has no effect.
/HIDE=h        Hides (h = 1) or shows (h = 0, default) the window.
/K=k          Specifies window behavior when the user attempts to close it.
               k=0:Normal with dialog (default).
               k=1:Kills with no dialog.
               k=2:Disables killing.
               k=3:Hides the window.
```

If you use `/K=2` or `/K=3`, you can still kill the window using the KillWindow operation.
When you create a new page layout window, if preferences are enabled, the page size is determined by the preferred page size as set via the Capture Layout Prefs dialog. If preferences are disabled, as is usually the case when executing a procedure, the page is set to the factory default size.

See Also
AppendLayoutObject, DoWindow, RemoveLayoutObjects, and ModifyLayout.

NewMovie

NewMovie [flags] [as fileNameStr]
The NewMovie operation opens a movie file in preparation for adding frames.

By default, NewMovie creates MP4 movies on both Macintosh and Windows. Prior to Igor Pro 8, it created QuickTime movies on Macintosh and AVI movies on Windows. That older technology is still available using the /A flag on Windows, but it is deprecated and may not be available in future operating systems. QuickTime is no longer available as of Mac OS 10.15 (Catalina) and the /A flag results in an error in Igor Pro 9 on all Mac operating system versions.

Parameters
The file to be opened is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If NewMovie can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags

/CF= factor Specifies a compression factor relative to the theoretical uncompressed value. The default compression factor of 200 is used if you omit /CF. /CF was added in Igor Pro 8.00. It is ignored if you use the /A flag.

/CTYPE=typeStr Specifies the compression codec to use.

Windows: typeStr can be "WMV3" to create .wmv files or "mp4v" to create MP4 files (default).

Macintosh: /CTYP is ignored and an MP4 file is created.

/F=frameRate Frames per second between 1 and 60. frameRate defaults to 30.

/I Obsolete.
### NewNotebook

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/L=flatten</td>
<td>Obsolete.</td>
</tr>
<tr>
<td>/O</td>
<td>Overwrite existing file, if any.</td>
</tr>
<tr>
<td>/P=pathName</td>
<td>Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.</td>
</tr>
<tr>
<td>/PICT=pictName</td>
<td>Uses the specified picture (see Pictures on page III-509) rather than the top graph.</td>
</tr>
<tr>
<td>/S=soundWave</td>
<td>Adding a sound track is not currently supported. If you would like this feature, let us know.</td>
</tr>
<tr>
<td>/Z</td>
<td>No error reporting; an error is indicated by nonzero value of the output variable V_flag. If the user clicks the cancel button in the Save File dialog, V_flag is set to -1.</td>
</tr>
</tbody>
</table>

**Details**

If either the path or the file name is omitted then NewMovie displays a Save File dialog to let you create a movie file. If both are present, NewMovie creates the file automatically.

If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-22 for details. There can be only one open movie at a time.

The target window at the time you invoke NewMovie must be a graph, page layout or Gizmo plot unless the /PICT flag is present. The window size should remain constant while adding frames to the movie. The window and optional sound wave are used to determine the size and sound properties only; they do not specify the first frame.

In Igor7 or later, the target window at the time you call NewMovie is remembered and is used by AddMovieFrame even if it is not the target window when you call AddMovieFrame.

The /PICT flag allows you to create a movie from a page layout in conjunction with the SavePICT/P=_PictGallery_ method. See SavePICT on page V-826. This allows creation of a movie from a source other than a graph, page layout or Gizmo window, but is rarely needed.

**See Also**

Movies on page IV-245.

The AddMovieFrame, AddMovieAudio, CloseMovie, PlayMovie, PlayMovieAction and SavePICT operations.

### NewNotebook

NewNotebook [flags] [as titleStr]

The NewNotebook operation creates a new notebook document.

**Parameters**

The optional titleStr is a string containing the title of the notebook window.

**Flags**

/FG=(gLeft, gTop, gRight, gBottom)

Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.

Guides may override the numeric positioning set by /W.
/HOST=hcSpec

Embeds the new notebook in the host window or subwindow specified by hcSpec. The host window or subwindow must be a control panel. Graphs and page layouts are not supported as hosts for notebook subwindows.

When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Notebooks as Subwindows in Control Panels on page III-91 for more information.

/ENCG=textEncoding

textEncoding specifies the text encoding for the new notebook. This determines the text encoding used for later saving the notebook to a file.

See Text Encoding Names and Codes on page III-490 for a list of accepted values for textEncoding.

This flag was added in Igor Pro 7.00.

This flag is relevant for plain text notebooks only and has no effect for formatted notebooks because formatted text notebooks can contain multiple text encodings. See Plain Text File Text Encodings on page III-466 and Formatted Text Notebook File Text Encodings on page III-472 for details.

If you omit /ENCG or pass 0 (unknown) for textEncoding, the notebook’s text encoding is determined by the default text encoding - see The Default Text Encoding on page III-465 for details.

For most purposes, UTF-8 (textEncoding=1) is recommended. Other values are available for compatibility with software that requires a specific text encoding. This includes Igor Pro 6 which uses MacRoman (textEncoding=2), Windows-1252 (textEncoding=3) or Shift-JIS (textEncoding=4) depending on the operating system and localization.

This flag has an optional form that allows you to control whether the byte order mark is written when the notebook is later saved to disk. It applies to Unicode text encodings also. The form is:

/ENCG = {textEncoding, writeBOM }

If you use the simpler form or omit /ENCG entirely, the notebook’s writeBOM property defaults to 1.

See Byte Order Marks on page III-471 for background information.

/F=format

Specifies the format of the notebook:

format=0: Plain text.
format=1: Formatted text.
format=-1: Displays a dialog in which the user can choose plain text or formatted text (default).

/K=k

Specifies window behavior when the user attempts to close it.

k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.
k=3: Hides the window.

If you use /K=2 or /K=3, you can still kill the window using the KillWindow operation.

/N=winName

Sets the notebook’s window name to winName.
A notebook has a file name, a window name, and a window title. In the simplest case these will all be the same. The file name is the name by which the operating system identifies the notebook once it is saved to disk. When you initially create a notebook, it is not associated with any file. However it still has a file name. This is the name that will be used when the file is saved to disk.

The window name is the name by which Igor identifies the window and therefore the name you specify in operations that act on the notebook.

The window title is what appears in the window’s title bar. If you omit the title, NewNotebook uses a default title that is the same as the window name.

If you specify the window name and the notebook format and omit the window title, this is the simplest case. NewNotebook creates the document with no user interaction. The file name, window name and window title will all be the same. For example:

```
NewNotebook/N=Notebook1/F=0
```

If you omit the window name, NewNotebook chooses a default name (e.g., “Notebook0”) and presents the standard New Notebook dialog.

If you omit the format or specify a format of -1 (either plain or formatted text), NewNotebook presents the standard New Notebook dialog. For example:

```
NewNotebook/N=Notebook1 // no format specified
```

### Details

A notebook has a file name, a window name, and a window title. In the simplest case these will all be the same. The file name is the name by which the operating system identifies the notebook once it is saved to disk. When you initially create a notebook, it is not associated with any file. However it still has a file name. This is the name that will be used when the file is saved to disk.

The window name is the name by which Igor identifies the window and therefore the name you specify in operations that act on the notebook.

The window title is what appears in the window’s title bar. If you omit the title, NewNotebook uses a default title that is the same as the window name.

If you specify the window name and the notebook format and omit the window title, this is the simplest case. NewNotebook creates the document with no user interaction. The file name, window name and window title will all be the same. For example:

```
NewNotebook/N=Notebook1/F=0
```

If you omit the window name, NewNotebook chooses a default name (e.g., “Notebook0”) and presents the standard New Notebook dialog.

If you omit the format or specify a format of -1 (either plain or formatted text), NewNotebook presents the standard New Notebook dialog. For example:

```
NewNotebook/N=Notebook1 // no format specified
```

### See Also

The [Notebook](#) and [OpenNotebook](#) operations, and Chapter III-1, [Notebooks](#).

[Notebooks as Subwindows in Control Panels](#) on page III-91.
**NewPanel**

NewPanel [flags] [as titleStr]

The NewPanel operation creates a control panel window or subwindow, which may contain Igor controls and drawing objects.

**Flags**

/EXP=e

Sets the expansion of the panel. e is a number between 0.25 to 8.0. Values of e greater than 1.0 make the panel, its controls, and its subwindows, appear larger than normal.

The expansion factor affects the size of the window specified by /W.

If you omit /EXP or specify /EXP=0, the expansion defaults to the value set in the Panel section of the Miscellaneous Settings dialog.

To change the expansion after the panel is created, use ModifyPanel expand=e or the Expansion submenu of the Panel menu.

The /EXP flag was added in Igor Pro 9.00.

See Control Panel Expansion on page III-443 for further discussion.

/EXT=e

Creates an exterior subwindow in combination with /HOST. e specifies the host window side location:

- e=0: Right.
- e=1: Left.
- e=2: Bottom.
- e=3: Top.

/FG=(gLeft, gTop, gRight, gBottom)

Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.

Guides may override the numeric positioning set by /W.

/FLT[f]

/FLT or /FLT=1 makes the panel a floating panel.

/FLT=2 makes it a floating panel with no close box.

/FLT=0 is the same as omitting /FLT and creates a regular (non-floating) control panel.

You must execute the following after the NewPanel command:

SetActiveSubwindow _endfloat_

See Floating Panels below for further information.

/FLTH=h

Selects whether a floating panel is automatically hidden when Igor is deactivated.

- h=0: The panel is not automatically hidden.
- h=1: The panel is automatically hidden.

The default is platform specific and matches the behavior prior to Igor Pro 9. On Macintosh floating panels are hidden when Igor is deactivated. On Windows they are not hidden when Igor is deactivated.

/HIDE=h

Hides (h = 1) or shows (h = 0, default) the window.

/HOST=hcSpec

Embeds the new control panel in the host window or subwindow specified by hcSpec.

When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/I

Sets coordinates to inches.
Details
If /N is not used, NewPanel automatically assigns to the panel a window name of the form “Paneln”, where n is some integer. In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the panel from a procedure. Use the RenameWindow operation to rename the panel.

On Windows there are special considerations relating to screen resolution and control panels. See Control Panel Resolution on Windows on page III-456 for details.

Floating Panels
Floating control panels float above all other windows except dialogs. Because floating panels cover up other windows, you should use them sparingly and you should take care to make them small and unobtrusive.

Floating panels are not resizable by default. To allow panel resizing use

ModifyPanel fixedSize=0

Because floating panels always act as if they are on top, the standard rules for target windows and keyboard focus do not apply.

Normally, a floating panel is never the target window and control procedures will need to explicitly designate the target. But a newly-created floating panel is the default target and will remain so until you execute

SetActiveSubwindow _endfloat_
It also becomes the default target when the tools are showing and in any non-Operate mode. Similarly, a floating panel with tools not in Operate mode has keyboard focus. To avoid confusion, do not attempt to work on other windows when a floating panel is the default target.

When working with a floating panel, you can show or hide tools or create a recreation macro by Control-clicking (Macintosh) or right-clicking (Windows) in the panel.

A floating panel does not have keyboard focus. However, a floating panel gains keyboard focus when a control that needs focus is clicked. Focus remains until you press Enter or Escape for a text entry in a setvariable, press Tab until no control has the focus, or until you click outside a focussable control.

On Macintosh, if a floating panel has focus and you activate another window, focus will leave the panel. However on Windows, if a floating panel has focus and you activate another window, the activate sequence will be fouled up leaving the windows in an indeterminant state. Consequently, it is important that you always finish any keyboard interaction started in a floating panel before moving on to other windows. If this can cause confusion, you should not use controls such as SetVariable and ListBox in a floating panel.

On Macintosh, floating panels are hidden when dialogs are up or when Igor Pro is not the front application.

Exterior Subwindows

Exterior subwindows are automatically positioned along the designated side of a host window. The host window can be a graph, table, panel or Gizmo plot. You can designate fixed sizes or automatic size with minima. Subwindows are stacked beside the designated side in their creation order with the first one closest.

Subwindow dimensions have various meanings depending on their location. Interior values are taken to be additional grout, exterior values are taken to be sizes. For left or right panels, top is taken to be the minimum height and bottom, if not zero, is height. For top and bottom, left is taken to be the minimum width and right, if not zero, is width. Zero values default to 50 for width and height or size of host.

Exterior subwindows are nonresizable by default. Use ModifyPanel fixedSize=0 to allow manual resizing. If you resize a panel, the original window dimensions are lost. You can also use MoveSubwindow to resizze the subwindow.

Unlike normal subwindows, exterior subwindows have a tools palette. Click in the window and then choose the Show Tools or Hide Tools menu item.

Exterior subwindows have hook functions independent of the host window.

Examples

In a new experiment, execute these commands on the command line to create two exterior subwindows:

```
Display
// Create panel on right with min height of 200 points, width of 100.
NewPanel/HOST=Graph0/EXT=0/W=(0,200,100,0)
// Create another panel on right with grout of 10 and height= width= 100.
NewPanel/HOST=Graph0/EXT=0/W=(10,0,100,100)
```

Now try resizing and moving the graph.

For a demonstration of how the various exterior panels work, copy the following code to the procedure window in a new experiment:

```
Function bpNewExSw(ba) : ButtonControl
    STRUCT WMButtonAction &ba

    switch( ba.eventCode )
    case 2: // mouse up
        ControlInfo/W=$ba.win ckUseRect
        Variable useR= V_Value
        ControlInfo/W=$ba.win popSide
        Variable side= V_Value-1
        ControlInfo/W=$ba.win ckResizeable
        Variable resizeable= V_Value
        WAVE w=root:epsizes
        if( useR )
            NewPanel/HOST=$ba.win/EXT=(side)/W=(w[0],w[1],w[2],w[3])
        else
            NewPanel/HOST=$ba.win/EXT=(side)
        endif
        if( resizeable )
            ModifyPanel fixedSize=0 // default is 1 for floating and exterior sw
```

V-689
NewPath

```plaintext
endif
break
endswitch
return 0
End
Window ExSwTest() : Graph
    PauseUpdate; Silent 1 // building window...
    Display /W=(803,377,1158,591)
    Button bNewSw,pos={35,21},size={181,30},proc=bpNewExSw,title="Exterior Subwindow"
    SetVariable svLeft,pos={118,82},size={96,15},title="left"
    SetVariable svTop,pos={0,100,1},value= epsizes[0],bodyWidth= 76
    SetVariable svTop,pos={120,97},size={94,15},title="top"
    SetVariable svTop,pos={0,100,1},value= epsizes[1],bodyWidth= 76
    SetVariable svRight,pos={112,113},size={102,15},title="right"
    SetVariable svTop,pos={120,97},size={94,15},title="top"
    SetVariable svRight,pos={0,100,1},value= epsizes[1],bodyWidth= 76
    SetVariable svBottom,pos={103,129},size={111,15},title="bottom"
    SetVariable svTop,pos={120,97},size={94,15},title="top"
    CheckBox ckUseRect,pos={70,62},size={61,14},title="Use Rect:",value= 0
    PopupMenu popSide,pos={73,149},size={78,20},title="Side"
    CheckBox ckResizeable,pos={76,176},size={65,14},title="Resizeable",value= 0
EndMacro

Function test()
    Make/O/N=4 epsizes=0
    Execute "ExSwTest()"
End
```

After compiling the procedures, execute `test()` on the command line. You can now experiment with different sides and size values.

See Also

Chapter III-14, Controls and Control Panels, for details about control panels and controls.

Interpretation of NewPanel Coordinates on page III-444 for a discussion of the units used with NewPanel /W.

The ModifyPanel operation.

NewPath

`NewPath [flags] pathName [, pathToFolderStr]`

The NewPath operation creates a new symbolic path name that can be used as a shortcut to refer to a folder on disk.

Parameters

`pathToFolderStr` is a string containing the path to the folder for which you want to make a symbolic path. `pathToFolderStr` can also point to an alias (Macintosh) or shortcut (Windows) for a folder.

If you use a full path for `pathToFolderStr`, see Path Separators on page III-451 for details on forming the path.

If you use a partial path or just a simple name for `pathToFolderStr`, and you use the /C flag, a new folder is created relative to the Igor Pro folder. No dialog is presented.

If you omit `pathToFolderStr`, you get a chance to select a folder or create a new folder from a dialog.

Flags

/C Create the folder specified by `pathToFolderStr` if it does not already exist.

/M=messageStr Specifies the prompt message in the dialog.

/O Overwrites the symbolic path if it exists.

/Q Suppresses printing path information in the history.

/Z Doesn’t generate an error if the folder does not exist.

Details

Symbolic paths help to isolate your experiments from specific file system paths that contain files created or used by Igor. By using a symbolic path, if the actual location or name of the folder changes, you won’t need
to change all of your commands. Instead, you need only to change the symbolic path so that it points to the
changed folder location.

NewPath sets the variable V_flag to zero if the operation succeeded or to nonzero if it failed. The main use
for this is to determine if the user clicked Cancel when you use NewPath to display a choose-folder dialog.
On the Macintosh, pressing Command-Option as the Choose Folder dialog comes up will allow you to
choose package folders and folders inside packages.

**Examples**

```plaintext
NewPath Path1, "hd:IgorStuff:Test 1"       // Macintosh
NewPath Path1, "C:IgorStuff:Test 1"       // Windows
```

creates the symbolic path named Path1 which refers to the specified folder (the path’s “value”). You can
then refer to this folder in many Igor operations and dialogs by using the symbolic path name Path1.

**Windows Note:**

You can use either the colon or the backslash character to separate folders. However, the
backslash character is Igor’s escape character in strings. This means that you have to
double each backslash to get one backslash like so:

```plaintext
NewPath stuff, "C:\IgorStuff\Test 1"
```

Because of this complication, it is recommended that you use Macintosh path syntax
even on Windows. See **Path Separators** on page III-451 for details.

**See Also**
The **PathInfo** operation; especially if you need to preset a starting path for the dialog.

**KillPath**

**NewWaterfall**

```plaintext
NewWaterfall [flags] matrixWave [vs {xWave, yWave}]
```

The NewWaterfall operation creates a new waterfall plot window or subwindow using each column in the
2D matrix wave as a waterfall trace.

You can manually set x and z scaling by specifying `xWave` and `yWave` to override the default scalings. Either
`xWave` or `yWave` may be omitted by using a “*”.

**Flags**

```plaintext
/FG=(gLeft, gTop, gRight, gBottom)
```

- Specifies the frame guide to which the outer frame of the subwindow is attached
  inside the host window.

- The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and
  bottom frame guides, respectively, or user-defined guide names as defined by the
  host. Use * to specify a default guide name.

- Guides may override the numeric positioning set by `/W`.

```plaintext
/HIDE=h
```

- Hides (h = 1) or shows (h = 0, default) the window.

```plaintext
/HOST=hcSpec
```

- Embeds the new waterfall plot in the host window or subwindow specified by `hcSpec`.

- When identifying a subwindow with `hcSpec`, see **Subwindow Syntax** on page III-92
  for details on forming the window hierarchy.

```plaintext
/I
```

- Sets window coordinates to inches.
The X and Z axes are always at the bottom and left, whereas the Y axis runs at a default 45 degrees along the right-hand side. The angle and length of the Y axis can be changed using the ModifyWaterfall operation. Other features of the graph can be changed using normal graph operations.

Each column from matrixWave is plotted in, and clipped by, a rectangle defined by the X and Z axes with the rectangle displaced along the angled Y axis as a function of the Y value.

Except when hidden lines are active, the traces are drawn from back to front.

To modify certain properties of a waterfall plot, you need to use the ModifyWaterfall operation. For other properties, use the usual axis and trace dialogs.

See Also
Waterfall Plots on page II-326.
The ModifyWaterfall and ModifyGraph operations.

norm

norm(srcWave)
The norm function evaluate the norm of srcWave. It returns:
This function does not support text waves.

See Also
MatrixOp

NormalizeUnicode

 NormalizeUnicode(sourceTextStr, normalizationForm[, options])

The NormalizeUnicode function normalizes the UTF-8-encoded text in sourceTextStr using the specified normalization form. The output text encoding is UTF-8.

NormalizeUnicode was added in Igor Pro 7.00. Most users will have no need for this function and can ignore it.

As explained under Details, in Unicode there are sometimes multiple ways to spell what appears visually to be the same word. This can cause problems when comparing text. Two strings that appear to represent the same word and which you consider equivalent may be spelled differently, causing a comparison operation to indicate that they are unequal. The NormalizeUnicode function converts sourceTextStr to a normalized form, which aides comparison.

Parameters

sourceTextStr is the text that you want to normalize. It must be encoded as UTF-8.

normalizationForm specifies the normalization form to use. These forms are described at http://unicode.org/reports/tr15/#Norm_Forms. The allowed values are:

0: NFD (Canonical Decomposition)
1: NFC (Canonical Decomposition, followed by Canonical Composition)
2: NFKD (Compatibility Decomposition)
3: NFKC (Compatibility Decomposition, followed by Canonical Composition)

options is a bitwise parameter, with the bits defined as follows:

Bit 0: If cleared, in the event of an error, a null string is returned and an error is generated. Use this if you want to abort procedure execution if an error occurs.

If set, in the event of an error, a null string is returned but no error is generated. Use this if you want to detect and handle an error yourself. You can test for null using strlen as shown in String Variable Text Encoding Error Example on page III-479.

All other bits are reserved and must be cleared.

Details

The Unicode standard specifies that some sequences of code points represent essentially the same character. There are two types of equivalence: canonical equivalence and compatibility.

Sequences of code points defined as canonically equivalent are assumed to have the same appearance and meaning when printed or displayed. For example, the code point U+006E (LATIN SMALL LETTER N) followed by U+0303 (COMBINING TILDE) is defined by Unicode to be canonically equivalent to the single code point U+00F1 (LATIN SMALL LETTER N WITH TILDE). The former is called "decomposed" while the later is called "precomposed".

Sequences that are defined as compatible are assumed to have possibly distinct appearances, but the same meaning in some contexts. Thus, for example, the code point U+FB00 (LATIN SMALL LIGATURE FF) is defined to be compatible, but not canonically equivalent, to the sequence U+0066 U+0066 (two Latin "f" letters). Sequences that are canonically equivalent are also compatible, but the opposite is not necessarily true.
Text searching and sorting routines in Igor do not do any form of Unicode normalization. As a consequence, searching for the precomposed form of small letter n with tilde (U+00F1) in a string that contains the decomposed form (U+006E U+0303) will not result in a match. To get the desired result, you would need to first pass both the target string and the string to be searched through NormalizeUnicode using the same value for the normalizationForm parameter.

Example

Function TestNormalizeUnicode()
    String precomposed = "Ni" + "\u00F1" + "o"
    String decomposed = "Ni" + "\u006E\u0303" + "o"
    String decomposedTarget = "\u006E\u0303"
    Variable foundPos
    // SUCCESSFUL TESTS
    // Searching the precomposed string for the precomposed target is successful.
    foundPos = strsearch(precomposed, precomposedTarget, 0)
    Print foundPos // Prints 2

    // Likewise, searching the decomposed string for the decomposed target is successful.
    foundPos = strsearch(decomposed, decomposedTarget, 0)
    Print foundPos // Prints 2

    // UNSUCCESSFUL TESTS
    // Searching the precomposed string for the decomposed target fails.
    foundPos = strsearch(precomposed, decomposedTarget, 0)
    Print foundPos // Prints -1

    // Likewise, searching the decomposed string for the precomposed target fails.
    foundPos = strsearch(decomposed, precomposedTarget, 0)
    Print foundPos // Prints -1

    // USING NormalizeUnicode() FUNCTION
    Variable normForm = 2 // Could use 0-3 and the results would be the same.
    String precomposedNorm = NormalizeUnicode(precomposed, normForm)
    String decomposedNorm = NormalizeUnicode(decomposed, normForm)
    String precomposedTargetNorm = NormalizeUnicode(precomposedTarget, normForm)
    String decomposedTargetNorm = NormalizeUnicode(decomposedTarget, normForm)
    // Now, searching either precomposedNorm or decomposedNorm for either
    // precomposedTargetNorm or decomposedTargetNorm will give a match.
    Print strsearch(decomposedNorm, precomposedTargetNorm, 0) // Prints 2
    Print strsearch(precomposedNorm, precomposedTargetNorm, 0) // Prints 2
    Print strsearch(precomposedNorm, decomposedTargetNorm, 0) // Prints 2
    Print strsearch(decomposedNorm, decomposedTargetNorm, 0) // Prints 2

End

Text Encodings on page III-459, String Variable Text Encoding Error Example on page III-479
http://unicode.org/reports/tr15/#Norm_Forms

Note

The note function returns a string containing the note associated with the specified wave.

See Also
To create a wave note, use the Note operation.

Note [/K/NOCR] waveName [, str]
The Note operation appends str to the wave note for the named wave.

Parameters
str is a string expression.
Flags

/K  Kills existing note for specified wave.
/NOCR  Appends note without a preceding carriage return (\r character). No effect when used with /K.

Examples

Note/K wave0 // remove existing note
Note wave0, "This is the first line of the note"
Note wave0, "This is the second line of the note"
Note/K wave0, "This is now the only line of the note"

See Also
To get the contents of a wave note, use the note function.

Notebook

Notebook winName, keyword=value [, keyword=value]...

The Notebook operation sets various properties of the named notebook window. Notebook also inserts text and graphics. See Chapter III-1, Notebooks, for general information on notebooks.

Notebook returns an error if the notebook is open for read-only. Keywords that don't materially change the notebook, including findText, findPicture, selection, visible, magnification, userKillMode, showRuler and rulerUnits, are still permitted. See Notebook Read/Write Properties on page III-10 for further information.

Parameters

winName is either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.

If winName is an hcSpec, the host window or subwindow must be a control panel. Graphs and page layouts are not supported as hosts for notebook subwindows.

The parameters to the Notebook operation are of the form keyword=value where keyword says what to do and value is a parameter or list of parameters. Igor limits the parameters that you specify to legal values before applying them to the notebook.

The parameters are classified into related groups of keywords.

See Also
To create or modify a notebook action special character, see NotebookAction.

To create a notebook subwindow in a control panel, see Notebooks as Subwindows in Control Panels on page III-91.
Notebook document property parameters
This section of Notebook relates to setting the document properties of the notebook.

adopt=a
Adopts a notebook if it is a file saved to disk. Adopting a notebook makes it part of the packed experiment file, which becomes more self-contained; if you send the experiment to a colleague you will not need to send a notebook file.

a=0: Checks only whether the notebook is adoptable. Sets V_flag to 0 if the notebook is already adopted or to 1 if it is adoptable.
a=1: Checks only whether the notebook is adoptable. Sets V_flag to 0 if the notebook is already adopted or to 1 if it is adoptable.

backRGB=(r,g,b[,a]) Sets background color. r, g, b, and a specify the color and optional opacity as RGBA Values. Alpha (a) is accepted but ignored.

dechangeableByCommandOnly=c
This changeableByCommandOnly property is used to prevent manual modifications to the notebook but allow modifications using commands.
c=0: Turn changeableByCommandOnly off.
c=1: Turn changeableByCommandOnly on.

See Notebook Read/Write Properties on page III-10 for details.

defaultTab=dtwp
dtwp is the default tab width in points.
The defaultTab keyword sets the default tab mode to 1 meaning that the default tab width for all paragraphs is specified in units of points. See the defaultTab2 keyword for further discussion.

defaultTab2={mode,dtwp,dtws}
Controls the width of default tab stops.
The defaultTab2 keyword was added in Igor Pro 9.00.
mode is defined as follows:
mode=1: Points mode: The default tab width for all paragraphs is specified in units of points by dtwp.
mode=2: Spaces mode: The default tab width for all paragraphs is specified in units of spaces by dtws.
mode=3: Mixed mode: The default tab width for paragraphs controlled by proportional fonts is specified in units of points by dtwp. The default tab width for paragraphs controlled by monospace fonts is specified in units of spaces by dtws.

Specify -1 for mode to leave the mode unchanged.
The space character unit used in mode 2 and in mode 3 for monospace fonts is the width of a space character in the ruler font for a given paragraph. Plain text notebooks have only one ruler so the space character width is the same for all paragraphs. Formatted text notebooks can have many rulers and each has an associated space character width.
dtwp is the default tab width in points. It is used in mode 1 and in mode 3 for proportional fonts. Specify -1 for dtwp to leave the default tab width in points unchanged.
dtws is the default tab width in spaces. It is used in mode 2 and in mode 3 for monospace fonts. Specify -1 for dtws to leave the default tab width in spaces unchanged.

See Notebook Default Tabs on page III-6 for further discussion.
magnification=$m$

Specifies the desired magnification in percent (between 25 and 500). Otherwise, $m$ can be one of these special values:

$m=1$: Default magnification.
$m=2$: Default magnification.
$m=3$: Default magnification.

In Igor Pro 6 this specified the no-longer-supported Fit Width mode.
In Igor Pro 6 this specified the no-longer-supported Fit Page mode.

<table>
<thead>
<tr>
<th>pageMargins=[left, top, right, bottom]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets page margins in points. left, top, right, and bottom are distances from the respective edges of the physical page.</td>
</tr>
<tr>
<td>This setting overrides the margins set via the the page setup dialog and the PrintSettings operation margins keyword.</td>
</tr>
</tbody>
</table>

rulerUnits=$r$

Sets the units for the ruler:

$r=0$: Points.
$r=1$: Inches.
$r=2$: Centimeters.

showRuler=$s$

Hides ($s=0$) or shows ($s=1$) the ruler.

startPage=$sp$

Sets the starting page number for printing.

statusWidth=$sw$

As of Igor7, because of changes to the layout of notebook windows, this keyword does nothing.
In Igor6 it set the width in points of the status area on the left of the horizontal scroll bar.

userKillMode=$k$

Specifies window behavior when the user attempts to close it.

$k=0$: Normal with dialog (default).
$k=1$: Clicking the close button kills the notebook with no dialog.
$k=2$: Clicking the close button does nothing.
$k=3$: Clicking the close button hides the notebook with no dialog.

writeBOM=$w$

Sets the document’s writeBOM property which determines if Igor writes a byte order mark when saving the notebook. This applies to plain text notebooks only and is ignored for formatted text notebooks.

$w=1$: Does not change writeBOM flag.
$w=0$: Sets writeBOM to false.
$w=1$: Sets writeBOM to true.

See **Byte Order Marks** on page III-471 for details.
This keyword was added in Igor Pro 7.00.

writeProtect=$wp$

The write-protect property is used to prevent inadvertent manual changes to the notebook.

$wp=0$: Turn write-protect off.
$wp=1$: Turn write-protect on.

See **Notebook Read/Write Properties** on page III-10 for details.
Notebook (Headers and Footers)

Notebook headers and footers
You can turn headers and footers on and off and position headers and footers using the keywords in this section.

There is currently no way to set the content of headers and footers except manually through the Document Settings dialog. You may be able to use stationery files to create files with specific headers and footers.

`footerControl=[defaultFooter, firstFooter, evenOddFooter]`
- `defaultFooter` is 1 to turn the default footer on, 0 to turn it off.
- `firstFooter` is 1 to turn the first page footer on, 0 to turn it off.
- `evenOddFooter` is 1 to turn different footers for even and odd pages on, 0 to use the same footer for even and odd pages.

`footerPos=pos`  
`pos` is the position of the footer relative to the bottom of the page in points.

`headerControl=[defaultHeader, firstHeader, evenOddHeader]`
- `defaultHeader` is 1 to turn the default header on, 0 to turn it off.
- `firstHeader` is 1 to turn the first page header on, 0 to turn it off.
- `evenOddHeader` is 1 to turn different headers for even and odd pages on, 0 to use the same header for even and odd pages.

`headerPos=pos`  
`pos` is the position of the header relative to the top of the page in points.

Notebook (Miscellaneous)

Notebook miscellaneous parameters
This section of Notebook relates to setting miscellaneous properties of the notebook.

`autoSave=v`  
Controls auto-save mode.
- `v=0`: Notebook subwindow contents will not be saved in recreation macros.
- `v=1`: Notebook subwindow contents will be saved in recreation macros (default).

This affects notebook subwindows in control panels only. Use `autoSave=0` if you do not want the notebook’s contents to be saved and restored when the control panel is recreates. Otherwise the notebook subwindow’s contents will be restored when recreated.

`frameInset=i`  
Specifies the number of pixels by which to inset the frame of a notebook subwindow. Does not affect a normal notebook window.

This keyword was added in Igor Pro 7.00.
**frameStyle= f**  
Specifies the frame style for a notebook subwindow. Does not affect a normal notebook window.  
- f=0: None.  
- f=1: Single.  
- f=2: Double.  
- f=3: Triple.  
- f=4: Shadow.  
- f=5: Indented.  
- f=6: Raised.  
- f=7: Text well.  

The last three styles are fake 3D and will look best if the background color behind the subwindow is a light shade of gray.  
This keyword was added in Igor Pro 7.00.

**status={messageStr, flags}**  
Sets the message in the status area at the bottom left of the notebook window.  
*flags* is interpreted bitwise. Message is erased when:  
- Bit 0: Selection changes.  
- Bit 1: Window is activated.  
- Bit 2: Window is deactivated.  
- Bit 3: Document is modified.  

If all bits are zero, the message stays until a new message comes along. All other bits are reserved for future use and should be zero. See *Setting Bit Parameters* on page IV-12 for details about bit settings.

**updating={flags, r}**  
Sets parameters related to the updating of special characters.  
*flags* is interpreted bitwise:  
- Bit 0: Suppress automatic periodic updating of date and time special characters. By default this bit is set so date and time special characters are updated only when the user explicitly requests it or during printing when they appear in headers and footers.  
- Bit 1: Allow manual updating of special characters via the specialUpdate keyword or via the Special menu. By default this is cleared so manual updating is not allowed.  

All other bits are reserved for future use and should be zero. See *Setting Bit Parameters* on page IV-12 for details about bit settings.  
*r* is the update rate in seconds for updating date and time special characters.  

These settings have no effect on the updating of special characters in headers or footers. These characters are always automatically updated when the document is printed.  
We recommend that you leave automatic updating off (set bit 0 of the *flags* parameter to 1) so that updating occurs only via the specialUpdate keyword or via the Special menu.

**visible=v**  
Sets notebook visibility.  
- v=0: Hides notebook.  
- v=1: Shows notebook but does not make it top window.  
- v=2: Shows notebook and makes it top window.
Notebook (Paragraph Properties)

Notebook paragraph property parameters
This section of Notebook relates to setting the paragraph properties of the current selection in the notebook.

The margins, spacing, justification, tabs and rulerDefaults keywords provide control over paragraph properties which are governed by rulers. These keywords, in conjunction with the ruler and newRuler keywords, allow you to set paragraph properties. They are allowed for formatted text notebooks only, not for plain text notebooks.

The ruler keywords are described in detail below. Before we get to the detail, you should understand the different things you can do with rulers.

There are four things you can do with a ruler:

modify it  (analogous to manually adjusting a ruler).
redefine it  (analogous to the Redefine Ruler dialog).
create it  (analogous to the Define New Ruler dialog).
apply it  (analogous to selecting a ruler name from Ruler pop-up menu).

Igor’s behavior in response to ruler keywords depends on the order in which the keywords appear.

To modify the ruler(s) for the selected paragraph(s), use the margins, spacing, justification, tabs and rulerDefaults keywords without using the newRuler or ruler keywords. For example:

Notebook Notebook0 tabs={36,144,288}, justification=1

To redefine an existing ruler, invoke the ruler=rulerName keyword before any other keywords. For example:

Notebook Notebook0 ruler=Ruler1, tabs={36,144,288}, justification=1

Unlike redefining the ruler manually, when you redefine an existing ruler using ruler=rulerName, it does not apply the ruler to the selected text. However, it does update any text governed by the redefined ruler.

To create a new ruler, invoke the newRuler=rulerName keyword before any other keywords. For example:

Notebook Notebook0 newRuler=Ruler1, tabs={36,144,288}, justification=1

Unlike creating it manually, when you create a new ruler using newRuler=rulerName, it does not apply the new ruler to the selected text. If you do not set a particular ruler property when creating a new ruler, the property will be the same as for the Normal ruler. If the specified ruler already exists, newRuler=rulerName overwrites the existing ruler.

To apply an existing ruler to the selected text, invoke the ruler=rulerName keyword without any other keywords. For example:

Notebook Notebook0 ruler=ruler1

You and Igor will get confused if you mix ruler keywords with other types of keywords in the same command. It is alright, however to put a selection keyword at the start of the command. Mixing will not cause a crash or any drastic problem but it will likely produce results that you don’t understand.

To keep things clear, follow these rules:
• If you use ruler=rulerName or newRuler=rulerName, put them before any other ruler keywords.
• Do not mix ruler keywords with other kinds, except that it is alright to use the selection keyword at the start of the command.

justification=j  Sets text justification:
  j=0: Left aligned.
  j=1: Center aligned.
  j=2: Right aligned.
  j=3: Fully justified.

margins={indent,left,right}
indent sets the indentation of first line from left page margin.
left sets the paragraph’s left margin in points measured from the left page margin.
right sets the paragraph’s right margin in points measured from the left page margin.

newRuler=ru lerName

Creates a new ruler with the specified name. If a ruler with this name already exists, it is overwritten.

ruler=ru lerName

Applies the named ruler to the selected text or to redefine the named ruler, as explained above.

ru lerDefaults={"fontName", fSize, fStyle, (r,g,b,a)}

"fontName" sets the ruler’s text font, e.g., "Helvetica".
fSize sets the ruler’s text size.
fStyle sets the ruler’s text style.
(r,g,b,a]) sets the ruler’s text color. r, g, b, and a specify the color and optional opacity as RGBA Values. The default is opaque white.

You can use rulerDefaults only if you are redefining an existing ruler using ruler=ru lerName or you are creating a new ruler using newRuler=ru lerName.

spacing={spaceBefore,spaceAfter,lineSpace}

spaceBefore sets the extra space before paragraph in points.
spaceAfter sets the extra space after paragraph in points.
lineSpace sets the extra space between lines of a paragraph in points.

tabs={tabSpec}

tabSpec is list of tab stops in points added to special values that change the tab stop type.

Tab stops have two parts: the tab stop position and the tab type. Each integer in the list of tabs encodes both of these parts as follows:
The low 11 bits contains the tab stop position in points.
The next two bits are reserved for future use and must be zero.
The high three bits are used to contain the tab type as follows:
left tab 0 add 1*8192 to tab stop position.
center tab 1 add 2*8192 to tab stop position.
right tab 2 add 3*8192 to tab stop position.
decimal tab 3 add 4*8192 to tab stop position.
comma tab 4 add 5*8192 to tab stop position.

Tabs Example
The following puts a left tab at 1 inch, a center tab at 3 inches and a decimal tab at 5 inches:

Notebook Notebook1 tabs=(1*72, 3*72 + 8192, 5*72 + 3*8192)
Notebook (Selection)

Notebook selection parameters
This section of Notebook relates to selecting a range of the content of the notebook.

findPicture={graphicNameStr, flags}

Searches for the picture containing the named graphic (Macintosh only) or the next picture if you pass "". Sets V_flag to 1 if the picture was found or to 0 if not found.

flags is a bitwise parameter interpreted as follows:
  Bit 0: Show selection after the find.

All other bits are reserved for future use. Set bit 0 by setting flags = 1.

The search is always forward from the end of the current selection to the end of the document.

findSpecialCharacter={specialCharacterNameStr, flags}

Searches for the special character with the specified name or the next special character if you pass "". Selects the special character if it is found.

Sets V_flag to 1 if the special character was found or to 0 if not. Sets S_name to the name of the found special character or to "" if it was not found.

flags is a bitwise parameter interpreted as follows:
  Bit 0: Show selection after the find.

All other bits are reserved for future use. Set bit 0 by setting flags = 1.

If specialCharacterNameStr is empty (""), the search proceeds from the end of the current selection to the end of the document. Otherwise the search always covers the entire document.

findText={textToFindStr, flags}

Searches for the specified text. Sets V_flag to 1 if the text was found or to 0 if not found.

textToFindStr is a string expression for the text you want to find. If the text contains a carriage return, Igor considers only the part of the text before the carriage return.

flags is a bitwise parameter interpreted as follows:
  Bit 0: Show selection after the find.
  Bit 1: Do case-sensitive search.
  Bit 2: Search for whole words.
  Bit 3: Wrap around.
  Bit 4: Search backward.

All other bits are reserved and must be set to zero.

To set bit 0 and bit 3, use \(2^0 \times 2^3 = 9\) for flags. See Setting Bit Parameters on page IV-12 for details about bit settings.

If you are searching forward, the search starts from the end of the current selection. If you are searching backward, the search starts from the start of the current selection.

If you specify "" as the text to search for, it “finds” the current selection. This displays the current selection using findText="", 1).

selection={selStart, selEnd}
selStart and selEnd are locations within the document. You can specify these
document locations by using the following expressions:

(paragraph, pos)  \hspace{1cm} \texttt{paragraph} and \texttt{pos} are numeric expressions.
\hspace{1cm} \texttt{paragraph} is a paragraph number from 0 to \( n-1 \) where \( n \) is
\hspace{1cm} the number of paragraphs in the document.
\hspace{1cm} \texttt{pos} is a byte position from 0 to \( n \) where \( n \) is the number
\hspace{1cm} of bytes in the paragraph. Position 0 is to the left of the
\hspace{1cm} first character in the paragraph. Position \( n \) is to the right
\hspace{1cm} of the last character in the paragraph.
startOfFile \hspace{1cm} \text{Start of the document.}
endOfFile \hspace{1cm} \text{End of the document.}
startOfParagraph \hspace{1cm} \text{Start of current selStart paragraph.}
endOfParagraph \hspace{1cm} \text{End of current selStart paragraph.}
startOfNextParagraph \hspace{1cm} \text{Start of paragraph after current selStart paragraph.}
endOfNextParagraph \hspace{1cm} \text{End of paragraph after current selStart paragraph.}
startOfPrevParagraph \hspace{1cm} \text{Start of paragraph before current selStart paragraph.}
endOfPrevParagraph \hspace{1cm} \text{End of paragraph before current selStart paragraph.}
endOfChars \hspace{1cm} \text{Just before the carriage return of current selStart paragraph.}
startOfPrevChar \hspace{1cm} \text{Start of the character before the character at the current}
\hspace{1cm} \text{selection start or selection end. This moves the selection}
\hspace{1cm} \text{start or selection end like pressing the left arrow key.}
\hspace{1cm} \text{Added in Igor Pro 7.00.}
startOfNextChar \hspace{1cm} \text{Start of the character after the character at the current}
\hspace{1cm} \text{selection start or selection end. This moves the selection}
\hspace{1cm} \text{like pressing the right arrow key.}
\hspace{1cm} \text{Added in Igor Pro 7.00.}

Igor clips the specified locations to legal values. It also sets the \texttt{V\_flag} variable to 0 if
the \texttt{selStart} location that you specified was valid, to 1 if the start paragraph was out of
bounds and to 2 if the start position was out of bounds. You can use the
startOfNextParagraph keyword to step through the document one paragraph at a
time. When \texttt{V\_flag} is nonzero, you are at the end of the document.

The terms next and prev are relative to the paragraph containing the start of the
selected text before the selection keyword was invoked.

The selection keyword just sets the selection. If you also want to scroll the selected text
into view you must also use the \texttt{findText} keyword as shown in the examples.

Selection Examples
Following are some examples of setting the selection:

// select all text in notebook
Notebook Notebook1 selection={startOfFile, endOfFile}

// move selection to the start of the notebook and display the selection
Notebook Notebook1 selection={startOfFile, startOfFile}, findText="",1

// move selection to the end of the notebook and display the selection
Notebook Notebook1 selection={endOfFile, endOfFile}, findText="",1

// select all of paragraph 3
Notebook Notebook1 selection={(3,0), (4,0)}

// select all of paragraph 3 and display the selection
Notebook Notebook1 selection={(3,0), (4,0)}, findText="",1

// select all of current paragraph except for trailing CR, if any
Notebook Notebook1 selection={startOfParagraph, endOfChars}
// select the first occurrence of "Hello" in the document and display the selection
Notebook Notebook1 selection=(startOfFile,startOfFile), findText="Hello",1

// select the first picture in the document
Notebook Notebook1 selection=(startOfFile,startOfFile), findPicture="",1

See Also
The GetSelection operation to “copy” the selection.
Notebook  (Text Properties)

Notebook text property parameters
This section of Notebook relates to setting the text properties of the current selection in the notebook.

font=fontName  "fontName" is the name of the font. Use "default" to specify the paragraph’s ruler font.
If you specify an unavailable font, it does nothing. This is so that, when you share procedures with a colleague, using a font that the colleague does not have will not cause your procedures to fail. The downside of this behavior is that if you misspell a font name you will get no error message.

fSize=fontSize  Text size from 3 to 32000 points.
Use -1 to specify the paragraph’s ruler size.

fStyle=fontStyle  A binary coded integer with each bit controlling one aspect of the text style as follows:
- Bit 0: Bold
- Bit 1: Italic
- Bit 2: Underline
- Bit 4: Strikethrough

Use -1 to specify the paragraph’s ruler style. To set bit 0 and bit 1 (bold italic), use $2^0+2^1 = 3$ for fontStyle. See Setting Bit Parameters on page IV-12 for details about bit settings.

syntaxColorSelection=n  Use $n=1$ to syntax-color the selected text in the notebook. This is the equivalent of selecting Notebook → Syntax Color Selection. Other values of $n$ are reserved for future use.
To remove syntax coloring, use the textRGB keyword to set the selected text to a specified color.
The syntaxColorSelection keyword was added in Igor Pro 9.00.

textRGB=(r,g,b[,a])  Specifies text color. $r$, $g$, $b$, and $a$ specify the color and optional opacity as RGBA Values. The default is opaque black.

vOffset=v  Sets the vertical offset in points (positive offset is down, negative is up). Use this to create subscripts and superscripts. vOffset is allowed for formatted text files only, not for plain text files.

Notebook  (Writing Graphics)

Writing notebook graphics parameters
This section of Notebook relates to inserting graphics at the current selection in the notebook.
These graphics keywords are allowed for formatted text files only, not for plain text files.

convertToPNG=x  Converts all pictures in the current selection to cross-platform PNG format. If the picture is already PNG, it does nothing.
$x$ is the resolution expansion factor, an integer from 1 to 16 times screen resolution. $x$ is clipped to legal limits.
frame=f

Sets the frame used for the picture and insertPicture keywords.

f=0: No frame (default).

f=1: Single frame.

f=2: Double frame.

f=3: Triple frame.

f=4: Shadow frame.

insertPicture={pictureName, pathName, filePath, options}

Inserts a picture from a file specified by pathName and filePath. The supported graphics file formats are listed under Inserting Pictures on page III-13.

pictureName is the special character name (see Special Character Names on page III-14) to use for the inserted notebook picture or "$" to automatically assign a name.

pathName is the name of an Igor symbolic path created via NewPath or "$" to use no path.

filePath is a full path to the file to be loaded or a partial path or simple file name relative to the specified symbolic path.

If pathName and filePath do not fully specify a file, an Open File dialog is displayed from which the user can choose the file to be inserted.

options is a bitwise parameter interpreted as follows:

Bit 0: If set, an Open File dialog is displayed even if the file is fully specified by pathName and filePath.

Bit 1: Determines what to do in the event of a name conflict. If set, the existing special character with the conflicting name is overwritten. If cleared, a unique name is created and used as the special character name for the inserted picture.

All other bits are reserved and must be set to zero.

See Setting Bit Parameters on page IV-12 for details about bit settings.

The variable V_flag is set to 1 if the picture was inserted or to 0 otherwise, for example, if the user canceled from the Open File dialog.

The string variable S_name is set to the special character name of the picture that was inserted or to "" if no picture was inserted.

The string variable S_fileName is set to the full path of the file that was inserted or to "" if no picture was inserted.

picture={objectSpec, mode, flags [, expansion]}

Inserts a picture based on the specified object.

objectSpec is usually just an object name, which is the name of a graph, table, page layout, Gizmo plot, or picture from Igor’s picture gallery (Misc->Pictures). See further discussion below.

mode controls what happens when you insert a picture of a graph, table or page layout window. It does not affect insertions of pictures from the picture gallery.
*mode* specifies the format of the picture as follows:

<table>
<thead>
<tr>
<th>mode</th>
<th>Macintosh</th>
<th>Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>-9</td>
<td>SVG</td>
<td>SVG</td>
</tr>
<tr>
<td>-8</td>
<td>Igor PDF</td>
<td>Igor PDF</td>
</tr>
<tr>
<td>-7</td>
<td>TIFF</td>
<td>TIFF</td>
</tr>
<tr>
<td>-6</td>
<td>JPEG</td>
<td>JPEG</td>
</tr>
<tr>
<td>-5</td>
<td>PNG</td>
<td>PNG</td>
</tr>
<tr>
<td>-4</td>
<td>4X PNG</td>
<td>Device-independent bitmap</td>
</tr>
<tr>
<td>-2</td>
<td>8X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>-1</td>
<td>8X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>0</td>
<td>8X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>1</td>
<td>1X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>2</td>
<td>2X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>4</td>
<td>4X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>8</td>
<td>8X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
</tbody>
</table>

Modes -6, -7, -8, and -9 require Igor Pro 7.00 or later.

In Igor 7 and 8, mode=-8 produced PDF on Macintosh and EMF on Windows. As of Igor Pro 9.00, it produces PDF on both Macintosh and Windows. If you were using -8 for EMF on Windows, change your code to use -2.

Mode -2 (PDF on Macintosh, EMF on Windows) is recommended for platform-specific graphics. Mode -5 (PNG) is recommended for platform-independent bitmap graphics. Mode -8 (PDF) is recommended for platform-independent vector graphics but see the note above about -8 on Windows.

If *objectSpec* names a Gizmo window, only modes -5, -6, or -7 are allowed.

Modes -2 through 8 are supported for backward compatibility. In previous versions of Igor, they selected other formats that are now obsolete.

*flags* is a bitwise parameter interpreted as follows:

Bit 0: 0 for black and white, 1 for color.

All other bits are reserved and must be set to zero.

For color, set $flags = 2^0 = 1$.

See *Setting Bit Parameters* on page IV-12 for details about bit settings.

*expansion* is optional and requires Igor Pro 7.00 or later. It affects only modes -5, -6, and -7.

*expansion* sets the expansion factor over screen resolution. *expansion* must be an integer between 1 and 8 and is usually 1, 2, 4 or 8. The default value is 1.

$scaling=[h, v]$  
Sets the horizontal ($h$) and vertical ($v$) scaling for the selected picture or the picture and insertPicture keywords. $h$ and $v$ are in percent.

When using the picture keyword, you may include a coordinate specification after the object name in *objectSpec*. For example:

Notebook Notebook1 picture={Layout0(100, 50, 500, 700), 1, 1}

The coordinates are in points. A coordinate specification of (0, 0, 0, 0) behaves the same as no coordinate specification at all.
If the object is a graph, the coordinate specification determines the width and height of the graph. If you omit the coordinate specification, Igor takes the width and height from the graph window.

If the object is a layout, the coordinate specification identifies a section of the layout. If you omit the coordinate specification, Igor selects a section of the layout that includes all objects in the layout plus a small margin.

For any other kind of object, Igor ignores the coordinate specification if it is present.

The scaling and frame keywords affect the selected picture, if any. If no picture is selected, they affect the insertion of a picture using the picture or insertPicture keywords. For example, this command inserts a picture of Graph0 with 50% scaling and a double frame:

```plaintext
Notebook Test1 scaling={50, 50}, frame=2, picture={Graph0, 1, 1}
```

If no picture is selected and no picture is inserted, scaling and frame have no effect.

### InsertPicture Example

```plaintext
Function InsertPictureFromFile(nb)
    String nb // Notebook name or "" for top notebook
    if (strlen(nb) == 0)
        nb = WinName(0, 16, 1)
    endif
    if (strlen(nb) == 0)
        Abort "There are no notebooks"
    endif
    // Display Open File dialog to get the file to be inserted
    Variable refNum // Required for Open but not really used
    String fileFilter = "Graphics Files:.eps,.jpg,.png;All Files:.*;"
    Open /D /R /F=fileFilter refNum
    String filePath = S_fileName
    if (strlen(filePath) == 0)
        Print "You cancelled"
        return -1
    endif
    Notebook $nb, insertPicture={$"", $"", filePath, 0}
    if (V_flag)
        Print "Picture inserted"
    else
        Print "No picture inserted"
    endif
    return 0
End
```

### Save notebook pictures to files

The savePicture keyword is allowed for formatted text files only, not for plain text files.

```plaintext
savePicture={pictureName, pathName, filePath, options}
```

Saves a picture from a formatted text notebook to a file specified by `pathName` and `filePath`.

- `pictureName` is the special character name (see Special Character Names on page III-14) of the picture to be saved or "$" to save the selected picture in which case one picture and one picture only must be selected in the notebook.

- `pathName` is the name of an Igor symbolic path created via NewPath or "$" to use no path.

- `filePath` is a full path to the file to be written or a partial path or simple file name relative to the specified symbolic path.

If `pathName` and `filePath` do not fully specify a file, a Save File dialog is displayed in which the user can specify the file to be written.
Writing special character parameters

This section of Notebook relates to inserting special characters at the current selection in the notebook. To insert a notebook action, see NotebookAction.

The special characters are page break, short date, long date, abbreviated date and time. They act in some respects like a single character but have special properties. You can insert the special characters using the specialChar keyword.

The specialChar keyword is allowed for formatted text files only, not for plain text files.

Other special characters are allowed in headers and footers only and you can not insert them in a document using the specialChar keyword. These are window title, page number and total pages.

The special characters other than page break character are dynamic and update periodically.

specialChar={type, flags, optionsStr}

\textit{type} is the special character type as follows:

1: Page break.
2: Short date.
3: Long date.
4: Abbreviated date.
5: Time.

\textit{flags} is reserved for future use. You should pass 0 for \textit{flags}.

\textit{optionsStr} is reserved for future use. You should pass "" for \textit{optionsStr}.

specialUpdate=flags

Updates special characters in the notebook.

\textit{flags} is interpreted bitwise:

Bit 0: 0 to update all special characters.
Bit 1: 1 to update special characters in the selected text.

If 1, updates regardless of whether updating is enabled or not.

All other bits are reserved and must be set to zero.

See Setting Bit Parameters on page IV-12 for details about bit settings.
The specialUpdate keyword can update pictures of graphs, tables, and page layouts that were created from windows in the current experiment.

See Also
Chapter III-1, Notebooks. The NewNotebook, NotebookAction, and OpenNotebook operations; the SpecialCharacterInfo and SpecialCharacterList functions.

Notebook (Accessing Contents)

**Accessing Notebook Contents**

**getData**\(=\)\(mode\)

Causes Igor to return the contents of the notebook in the \(S\)\_value variable. The contents are binary data in a private Igor format encoded as text. The only use for this keyword is to transfer data from one notebook to another by calling getData followed by setData.

Causes Igor to return the contents of the notebook in the \(S\)\_value variable. The contents are binary data in a private Igor format encoded as text. The only use for this keyword is to transfer data from one notebook to another by calling getData followed by setData.

\(mode=1\): Stores in \(S\)\_value plain text or formatted text data, depending on the type of the notebook, from the entire notebook.

\(mode=2\): Stores in \(S\)\_value plain text data, regardless of the type of the notebook, from the entire notebook.

\(mode=3\): Stores in \(S\)\_value plain text or formatted text data, depending on the type of the notebook, from the notebook selection only.

\(mode=4\): Stores in \(S\)\_value plain text data, regardless of the type of the notebook, from the notebook selection only.

See the Notebook In Panel example experiment for examples using getData and setData.
Writing notebook text parameters
This section of Notebook relates to inserting text at the current selection in the notebook.

- **text=textStr**
  - Inserts the text at the current selection.
  - Before the text is inserted, Igor converts escape sequences in textStr as described in Escape Sequences in Strings on page IV-14.
  - Then, it checks for illegal characters. The only character code that is illegal is zero (ASCII NUL character). If it finds an illegal character, Igor generates an error and does not insert the text.

- **setData=dataStr**
  - Inserts the data at the current selection.
  - dataStr is either a regular string expression or the result returned by Notebook getData.

- **zData=dataStr**
  - This keyword is used by Igor during the recreation of a notebook subwindow in a control panel. dataStr is encoded binary data created by Igor when the recreation macro was generated. It represents the contents of the notebook subwindow in a format private to Igor.

- **zDataEnd=1**
  - This keyword is used by Igor during the recreation of a notebook subwindow in a control panel. It marks the end of encoded binary data created by Igor when the recreation macro was generated.

**NotebookAction**

- **NotebookAction [/W=winName] keyword = value [, keyword = value ...]**
  - The NotebookAction operation creates or modifies an “action” in a notebook. A notebook action is an object that executes commands when clicked.
  - See Chapter III-1, Notebooks, for general information about notebooks.
  - NotebookAction returns an error if the notebook is open for read-only. See Notebook Read/Write Properties on page III-10 for further information.

**Parameters**

- The parameters are in keyword =value format. Parameters are automatically limited to legal values before being applied to the notebook.

  - **bgRGB=(r, g, b)**
    - Specifies the action background color. r, g, and b specify the amount of red, green, and blue as integers from 0 to 65535.
  
  - **commands=str**
    - Specifies the command string to be executed when clicking the action. For multiline commands, add a carriage return (\r) between lines.
  
  - **enableBGRGB=enable**
    - Uses the background color specified by bgRGB (enable=1). Background color is ignored for enable=0.
  
  - **frame=f**
    - Specifies the frame enclosing the action.
      - f=0: No frame.
      - f=1: Single frame (default).
      - f=2: Double frame.
      - f=3: Triple frame.
      - f=4: Shadow frame.

  - **helpText=helpTextStr**
**NotebookAction**

Specifies the help string for the action. The text is limited to 255 bytes. On Macintosh, help appears when the cursor is over the action after choosing Help→Show Igor Tips. On Windows, help appears in the status line when the cursor is over the action.

`ignoreErrors=ignore`

Controls whether an error dialog will appear (`ignore=0`) or not (`ignore` is nonzero) if an error occurs while executing the action commands.

`linkStyle=linkStyle`

Controls the action title text style. If `linkStyle=1`, the style is the same as a help link (blue underlined). If `linkStyle=0`, the style properties are the same as the preceding text.

`name=name`

Specifies the name of the new or modified notebook action. This is a standard Igor name. See **Standard Object Names** on page III-501 for details.

`padding=[leftPadding, rightPadding, topPadding, bottomPadding, internalPadding]`

Sets the padding in points. `internalPadding` sets the padding between the title and the picture when both elements are present.

`picture=name`

Specifies a picture for the action icon. `name` is the name of a picture in the picture gallery (see **Pictures** on page III-509). If `name` is null (`""`), it clears the picture parameter.

`procPICTName=name`

Specifies a Proc Picture for the action icon (see **Proc Pictures** on page IV-56). `name` is the name of a Proc Picture or null (`""`) to clear it. This will be a name like `ProcGlobal#myPictName` or `MyModuleName#myPictName`. If you use a module name, the Proc Picture must be declared static.

If you specify both picture and procPICTName, picture will be used.

`quiet=quiet`

Displays action commands in the history area (`quiet=0`), otherwise (`quiet=1`) no commands will be recorded.

`scaling=[h, v]`

Scales the picture in percent horizontally, `h`, and vertically, `v`.

`showMode=mode`

Determines if the title or picture are displayed.

`mode=1`: Title only.

`mode=2`: Picture only.

`mode=3`: Picture below title.

`mode=4`: Picture above title.

`mode=5`: Picture to left of title.

`mode=6`: Picture to right of title.

Without a picture specification, the action will use title mode regardless of what you specify.

`title=titleStr`

Sets the action title to `titleStr`, which is limited to 255 bytes.

**Flags**

`/W=winName`

Specifies the notebook window of interest.

`winName` is either `kwTopWin` for the top notebook window, the name of a notebook window or a host-child specification (an `hcSpec`) such as `Panel0#nb0`. See **Subwindow Syntax** on page III-92 for details on host-child specifications.

If `/W` is omitted, NotebookAction acts on the top notebook window.

**Examples**

```plaintext
String nb = WinName(0, 16, 1)   // Top visible notebook
NotebookAction name=Action0, title="Beep", commands="Beep"   // Create action
NotebookAction name=Action0, enableBGRGB=1, padding={4,4,4,4,4}
```
num2char

num2char(num [, options])

The num2char function returns a string containing a character.

The options parameter was added in Igor Pro 7.00 and defaults to 0.

As of Igor7, Igor represents text internally as UTF-8, a form of Unicode. Previously it represented text as system text encoding. Because of this change, the behavior of num2char is complicated.

Recommended use of num2char in Igor7 or later

If num is a Unicode code point, pass 0 for options and num2char will return a UTF-8 string containing the character for the Unicode code point represented by num.

If you want a string containing a single byte, even though it may not be a valid UTF-8 string, pass 1 for options and num2char will return a string containing the single byte whose value is num, provided that num is between 0 and 255.

Detailed description of num2char in Igor7 or later

If num is between 0 and 127, num2char returns a string containing a single byte whose value is num. This represents an ASCII character.

If num is between 128 and 255 and options is 1, num2char returns a string containing a single byte whose value is num. This is not valid UTF-8 text, but it is consistent with the behavior of num2char in Igor6.

If num is between 128 and 255 and options is 0 or omitted, num2char returns the UTF-8 representation of the character for the Unicode code point represented by num.

If num is greater than 255, num2char returns the UTF-8 representation of the character for the Unicode code point represented by num regardless of the value of options.

If you provide the options parameter, it must be either 0 or 1. Other values may be used for other purposes in the future.

Examples

Print num2char(65)  // Prints A
Print num2char(97)  // Prints a
Print num2char(0xF7)  // Prints division sign
Print num2char(0xF7, 0)  // Prints division sign
Print num2char(0xF7, 1)  // Prints missing character symbol
Print num2char(0x0127)  // Prints small letter h with stroke (h-bar)
Print num2char(0x0127, 0)  // Prints small letter h with stroke (h-bar)
Print num2char(0x0127, 1)  // Prints small letter h with stroke (h-bar)

// In the case of num2char(0xF7, 1), num2char returns a string containing a single byte whose value is 0xF7. This is not a valid UTF-8 string.

See Also

The char2num, str2num and num2str functions.

Text Encodings on page III-459.

num2istr

num2istr(num)

The num2istr function returns a string representing num after rounding to the nearest integer.
num2str

num2str(num [, formatStr])
The num2str function returns a string representing the number num.
The optional formatStr parameter was added in Igor Pro 9.00.
If you omit formatStr, the precision of the output string is limited to only five decimal places. This can cause unexpected and confusing results. For this reason, we recommend that you specify a larger precision with formatStr or use num2istr or sprintf for more control of the format and precision of the number conversion.

Parameters
num
The value to be converted to string representation.
formatStr
Controls the format of the output string. See printf for details on format strings.
formatStr is optional and requires Igor Pro 9.00 or later.
If you omit formatStr, the format used is "%.5g". For more precision use something like "%.15g".

See Also
printf, sprintf, str2num, char2num, num2char

NumberByKey

NumberByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]]])
The NumberByKey function returns a numeric value extracted from kwListStr based on the specified key contained in keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "KEY:value1;KEY2:value2", depending on the values for keySepStr and listSepStr.
Use NumberByKey to extract a numeric value from a strings containing "key1=value1;key2=value2;" style lists such as those returned by functions like AxisInfo or TraceInfo.
If the key is not found or if any of the arguments is '"' or if the conversion to a number fails then it returns NaN. keySepStr, listSepStr, and matchCase are optional; their defaults are '"', ';', and 0 respectively.

Details
kwListStr is searched for an instance of the key string bound by listSepStr on the left and a keySepStr on the right. The text up to the next listSepStr is converted to the returned number.
kwListStr is treated as if it ends with a listSepStr even if it doesn’t.
Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional matchCase parameter to 1 makes the comparisons case sensitive.
In Igor6, only the first byte of keySepStr and listSepStr was used. In Igor7 and later, all bytes are used.
If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

Examples
Print NumberByKey("AKEY", "AKEY:123;") // prints 123
Print NumberByKey("BKEY", "AKEY=123;Bkey=456;", ";") // prints 456
Print NumberByKey("KEYZ", "KEY1=123,KEY2=999;", ";", ";// prints 999
Print NumberByKey("ckey", "CKEY=123;ckey=456;", ";") // prints 123
Print NumberByKey("ckey", "CKEY=123;ckey=456;", ";", ";", 1) // prints 456

See Also
The StringByKey, RemoveByKey, ReplaceNumberByKey, ReplaceStringByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

numpnts

numpnts(waveName)
The numpnts function returns the total number of data points in the named wave. To find the number of elements in a dimension of a multidimensional wave, use the DimSize function.
Do not use numpnts to test if a wave reference is null as this causes a runtime error. Use WaveExists.

**numtype**

`numtype (num)`
The numtype function returns a number which indicates what kind of value `num` contains.

**Details**
If `num` is a real number, numtype returns a real number whose value is:

0: If `num` contains a normal number.
1: If `num` contains +/-INF.
2: If `num` contains NaN.

If `num` is a complex number, numtype returns a complex number in which the real part is the number type of the real part of `num` and the imaginary part is the number type of the imaginary part of `num`.

**NumVarOrDefault**

`NumVarOrDefault (pathStr, defVal)`
The NumVarOrDefault function checks to see if the `pathStr` points to a numeric variable. If the numeric variable exists, NumVarOrDefault returns its value. If the numeric variable does not exist, it returns `defVal` instead.

**Details**
NumVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. String variables use the corresponding numeric function, StrVarOrDefault.

**Examples**
Function DemoNumVarOrDefault()
  Variable nVal = NumVarOrDefault("root:Packages:MyPackage:gNVal",2)
  String sVal = StrVarOrDefault("root:Packages:MyPackage:gSVal","Hello")
  Print nval, sval
  // Store values in package data folder for next time
  // Create package data folder if it does not yet exist
  NewDataFolder/O root:Packages
  NewDataFolder/O root:Packages:MyPackage
  DFREF dfr = root:Packages:MyPackage // Get reference to package data folder
  // Create or overwrite globals in package data folder
  Variable/G dfr:gNVal = nVal
  String/G dfr:gSVal = sVal
  
  NVAR gNVal = dfr:gNVal
  gNVal += 1
  SVAR gSVal = dfr:gSVal
  gSVal += "!
End

**NVAR**

`NVAR [/C] [/Z] [/SDFR=defr] localName [= pathToVar] [, localName1 [= pathToVar1]] ...`

NVAR is a declaration that creates a local reference to a global numeric variable accessed in a user-defined function.

The NVAR declaration is required when you access a global numeric variable in a function. At compile time, the NVAR statement specifies the local name referencing a global numeric variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global numeric variable must exist when the NVAR statement is executed.
When `localName` is the same as the global numeric variable name and you want to reference a global variable in the current data folder, you can omit `pathToVar`.

`pathToVar` can be a full literal path (e.g., `root:FolderA:var0`), a partial literal path (e.g., `:FolderA:var0`) or `$` followed by string variable containing a computed path (see Converting a String into a Reference Using $ on page IV-62).

You can also use a data folder reference or the `/SDFR` flag to specify the location of the numeric variable if it is not in the current data folder. See Data Folder References on page IV-78 and The /SDFR Flag on page IV-80 for details.

If the global variable may not exist at runtime, use the `/Z` flag and call `NVAR_Exists` before accessing the variable. The `/Z` flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:

```igor
NVAR/Z nv=<pathToPossiblyMissingNumericVariable>
if( NVAR_Exists(nv) )
  <do something with nv>
endif
```

Note that to create a global numeric variable, you use the `Variable/G` operation.

### Flags

- `/C` Variable is complex.
- `/SDFR=dfr` Specifies the source data folder. See The /SDFR Flag on page IV-80 for details.
- `/Z` Ignores variable reference checking failures.

### See Also

- `NVAR_Exists` function.
- Accessing Global Variables and Waves on page IV-65.
- Converting a String into a Reference Using $ on page IV-62.

---

### Open

`Open [flags] refNum [as fileNameStr]`

The `Open` operation can, depending on the flags passed to it:

- Open an existing file to read data from (/R flag without /D).
- Open a to append results to (/A flag without /D).
- Create a new file or overwrite an existing file to write results to (no /D, /R or /A flags).
- Display an Open File dialog (/D/R or /D/A flags with or without /MULT).
- Display a Save File dialog (/D flag without /R or /A).

#### Parameters

`refNum` is the name of a numeric variable to receive the file reference number. `refNum` is set by Open if Open actually opens a file for reading or writing (cases 1, 2 and 3). You use `refNum` with the `FReadLine`, `FStatus`, `FGetPos`, `FSetPos`, `FBinWrite`, `FBinRead`, `fprintf`, and `wfprintf` operations to read from or write to the file. When you're finished, use pass `refNum` to the `Close` operation to close the file.
Open does not set the file reference number when the /D flag is used (cases 4 and 5) but you must still supply a refNum parameter.

The following discussion of the pathName and fileNameStr parameters applies when you are attempting to open a file for reading or writing (cases 2, 3, and 5 above).

The targeted file is specified by a combination of the pathName parameter and the fileNameStr parameter. There are three ways to specify the targeted file:

<table>
<thead>
<tr>
<th>Method</th>
<th>How To Use It</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symbolic path and</td>
<td>Use /P=pathname and fileNameStr, where pathname is the name of an Igor</td>
</tr>
<tr>
<td>simple file name</td>
<td>symbolic path (see Symbolic Paths on page II-22) that points to the folder</td>
</tr>
<tr>
<td></td>
<td>containing the file and fileNameStr is the name of the file.</td>
</tr>
<tr>
<td>Symbolic path and</td>
<td>Use /P=pathname and fileNameStrs, where pathname is the name of an Igor</td>
</tr>
<tr>
<td>partial path</td>
<td>symbolic path that points to the folder containing the file and fileNameStr is</td>
</tr>
<tr>
<td></td>
<td>a partial path starting from the folder and leading to the file.</td>
</tr>
<tr>
<td>Full path</td>
<td>Use just fileNameStr, where fileNameStr is a full path to the file.</td>
</tr>
</tbody>
</table>

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

The targeted file is fully specified if fileNameStr is a full path or if both pathName and fileNameStr are present and not empty strings.

The targeted file is not fully specified in any of these cases:

- as fileNameStr is omitted
- fileNameStr is an empty string
- fileNameStr is not a full path and no symbolic path is specified

Opening an Existing File For Reading Only
This covers cases 1 (/R without /D).

If the file is fully-specified but does not exist, an error is generated. If you want to detect and handle the error yourself, use the /Z flag.

If the file is not fully-specified, Open displays an Open File dialog.

If a file is opened, refNum is set to the file reference number.

Opening an Existing File For Appending
This covers cases 1 (/R without /D) and 2 (/A without /D).

If the file is fully-specified and exists, it is opened for read/write and the current file position is moved to the end of the file.

If the file is fully-specified but does not exist, the file is created and opened for read/write.

If the file is not fully-specified, Open displays an Open File dialog.

If a file is opened, refNum is set to the file reference number.

Opening a File For Write
This covers case 3 (no /R, /A or /D).

If the targeted file exists, it is overwritten.

If the targeted file does not exist and it is fully-specified and targets a valid path, a new file is created.

If the file is fully-specified and targets an invalid path, an error is generated. If you want to detect and handle the error yourself, use the /Z flag.

If the file is not fully-specified, Open displays a Save File dialog.

If a file is opened, refNum is set to the file reference number.

Displaying an Open File Dialog To Select a Single File
This covers cases 4 (/D with /R or /A).
Open

Open does not actually open the file but just displays the Open File dialog.

If the user chooses a file in the Open File dialog, the \texttt{S\_fileName} output string variable is set to a full path to the file. You can use this in subsequent commands. If the user cancels, \texttt{S\_fileName} is set to "".

See the documentation for the /D, /F and /M flags and then read \textbf{Displaying an Open File Dialog} on page IV-148 for details.

\textit{refNum} is left unchanged.

\textbf{Displaying an Open File Dialog To Select Multiple Files}

This covers cases 4 (/D with /R or /A) with the /MULT=1 flag.

Open does not actually open the file but just displays the Open File dialog.

If the user chooses one or more files in the Open File dialog, the \texttt{S\_fileName} output string variable is set to a carriage-return-delimited list of full paths to one or more files. You can use this in subsequent commands. If the user cancels, \texttt{S\_fileName} is set to "".

See the documentation for the /D, /F, /M and /MULT flags and then read \textbf{Displaying a Multi-Selection Open File Dialog} on page IV-149 for details.

\textit{refNum} is left unchanged.

\textbf{Displaying a Save File Dialog}

This covers cases 5 (/D without /R or /A).

Open does not actually open the file but just displays the Save File dialog.

If the user chooses a file in the Save File dialog, the \texttt{S\_fileName} output string variable is set to a full path to the file. You can use this in subsequent commands. If the user cancels, \texttt{S\_fileName} is set to "".

See the documentation for the /D, /F and /M flags and then read \textbf{Displaying a Save File Dialog} on page IV-150 for details.

\textit{refNum} is left unchanged.

\textbf{Flags}

\texttt{/A} \hfill \textbf{Opens an existing file for appending or, if the file does not exist, creates a new file and opens it for appending.}

\texttt{/C=creatorStr} \hfill \textbf{Specifies the file creator code. This is meaningful on Macintosh only and is ignored on Windows. For opening an existing file, creator defaults to "???" which means "any creator". For creating a new file, \textit{creatorStr} defaults to "IGR0" which is Igor's creator code.}

\texttt{/D[=mode]} \hfill \textbf{Specifies dialog-only mode.}

\texttt{/D:} \hfill A dialog is always displayed.

\texttt{/D=1:} \hfill Same as /D.

\texttt{/D=2:} \hfill A dialog is displayed only if \textit{pathName} and \textit{fileNameStr} do not specify a valid file.

Use this mode to allow the user to choose a file to be opened by a subsequent operation, such as \textbf{LoadWave}.

With /D or /D=1, open presents a dialog from which the user can select a file but does not actually open the file. Instead, Open puts the full path to the file into the string variable \texttt{S\_fileName}.

\texttt{/D=2} does the same thing except that it skips the dialog if \textit{pathName} and \textit{fileNameStr} specify a valid file. In this case, if \textit{pathName} and \textit{fileNameStr} refer to an alias (Macintosh) or shortcut (Windows), the target of the alias or shortcut is returned.

If the user clicks the Cancel button, \texttt{S\_fileName} is set to an empty string.
Use Open/D/R to bring up an Open File dialog. See Displaying an Open File Dialog on page IV-148 for details.

Use Open/D/R/MULT=1 to bring up an Open File dialog to select multiple files. See Displaying a Multi-Selection Open File Dialog on page IV-149 for details.

Use Open/D to bring up a Save File dialog. See Displaying a Save File Dialog on page IV-150 for details.

See Using Open in a Utility Routine on page IV-151 for an example using /D=2.

Do not use /Z with /D.

/F=fileFilterStr /F provides control over the file filter menu in the Open File dialog. See Open File Dialog File Filters on page IV-149 and Save File Dialog File Filters on page IV-151 for details.

/M=messageStr Prompt message text in the dialog used to select the file, if any.

/MULT=m Use /D/R/MULT=1 to display a multi-selection Open File dialog.

/D/R/MULT=0 or just /D/R displays a single-selection Open File dialog.

/MULT=1 is allowed only if /D or /D=1 and /R are specified.

See Displaying a Multi-Selection Open File Dialog on page IV-149 for details.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/R The file is opened read only.

/T=typeStr When creating a new file on Macintosh (/A and /R flag omitted), /T sets the Macintosh file type property for the file if it does not already exist. For example, /T="BINA" sets the Macintosh file type to 'BINA'. If /T is omitted the Macintosh file type will be 'TEXT'. Apple has deemphasized Macintosh file types in favor of file name extensions.

For new code, /F is recommended instead of /T.

When opening an existing file (/A or /R flag used), /T provides control over the file filter menu in the Open File dialog. See Open File Dialog File Filters on page IV-149 for details.

When creating a new file (/A and /R flag omitted), /T provides control over the file filter menu in the Save File dialog. See Save File Dialog File Filters on page IV-151 for details.

/Z[=z] Prevents aborting of procedure execution if an error occurs, for example if the procedure tries to open a file that does not exist for reading. Use /Z if you want to handle this case in your procedures rather than having execution abort.

When using /Z, /Z=1, or /Z=2, V_flag is set to 0 if no error occurred or to a nonzero value if an error did occur.

Do not use /Z with /D.

/Z=0: Same as no /Z.

/Z=1: Suppresses normal error reporting. When used with /R, it opens the file if it exists. /Z alone has the same effect as /Z=1.

/Z=2: Suppresses normal error reporting. When used with /R, it opens the file if it exists or displays a dialog if it does not exist.

Details

When Open returns, if a file was actually opened, the refNum parameter will contain a file reference number that you can pass to other operations to read or write data. If the file was not opened because of an error or because the user canceled or because /D was used, refNum will be unchanged.

If you use /R (open for read), Open opens an existing file for reading only.
If you use /A, Open opens an existing file for appending. If the file does not exist, it is created and then opened for appending.

If both /R and /A are omitted then Open creates and opens a file. If the specified file does not already exist, Open creates it and opens it for writing. If the file does already exist then Open opens it and sets the current file position to the start of the file. The current file position determines where in the file data will be written. Thus, you will be overwriting existing data in the file.

**Warning**: If you open an existing file for writing (you do not use /R) then you will overwrite or truncate existing data in the file. To avoid this, open for read (use /R) or open for append (use /A).

**Output Variables**
The Open operation returns information in the following variables:

- **V_flag**: Set only when the /Z flag is used.
  - V_flag is set to zero if the file was opened, to -1 if Open displayed a dialog (because the file was not fully-specified) and the user canceled, and to some nonzero value if an error occurred.

- **S_fileName**: Stores the full path to the file that was opened.
  - If /MULT=1 is used, S_fileName is a carriage-return-separated list of full paths to one or more files.
  - If an error occurred or if the user canceled, S_fileName is set to an empty string.

When using /D, the value of V_flag is undefined. Do not use /Z with /D. Use S_fileName to determine if the user selected a file or canceled.

**Examples**
This example function illustrates using Open to open a text file from which data will be read. The function takes two parameters: an Igor symbolic path name and a file name. If either of these parameters is an empty string, the Open operation will display a dialog allowing the user to choose the file. Otherwise, the Open operation will open the file without displaying a dialog.

```igor
Function DemoOpen(pathName, fileName)
    String pathName  // Name of symbolic path or "" for dialog.
    String fileName  // File name, partial path, full path or "" for dialog.
    Variable refNum
    String str

    // Open file for read.
    Open/R/Z=2/P=$pathName refNum as fileName

    // Store results from Open in a safe place.
    Variable err = V_flag
    String fullPath = $S_fileName

    if (err == -1)
        Print "DemoOpen canceled by user."
        return -1
    endif

    if (err != 0)
        DoAlert 0, "Error in DemoOpen"
        return err
    endif

    Printf "Reading from file \"%s\". First line is:\r", fullPath
    FReadLine refNum, str  // Read first line into string variable
    Print str
    Close refNum
    return 0
End
```

**See Also**

- Close, FBinRead, FBinWrite, FReadLine
OpenHelp

OpenHelp [flags] fileNameStr
The OpenHelp operation opens the specified help file.

The OpenHelp operation was added in Igor Pro 7.00.

Parameters
The help file to be opened is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If OpenHelp can not determine the location of the file from fileNameStr and pathName, it returns an error.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags

/INT=interactive Controls whether opening the help file is interactive or not.
/INT=1: If the help file being opened needs to be compiled, OpenHelp presents a dialog asking the user whether the file should be compiled. During the compile, a progress dialog is displayed. Any errors are presented to the user in an error dialog. This is the default behavior if /INT is omitted.
/INT=0: If the help file being opened needs to be compiled, OpenHelp compiles it without presenting a dialog. Compilation errors are not presented to the user but are reflected in the V_Flag output variable.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing Igor symbolic path.

/PICT Scans the compiled help file for pictures and stores information about all pictures in a semicolon separated list into the S_pictureInfo output string. If the help file needs to be compiled but compilation fails, S_pictureInfo is set to "".

/V=visible Controls help window visibility.
visible=0: The help window will be initially hidden.
visible=1: The help window will be initially visible. This is the default if /V is omitted.

/W=(left,top,right,bottom) Specifies window size and position. Coordinates are in points.

Displaying an Open File Dialog on page IV-148, Displaying a Multi-Selection Open File Dialog on page IV-149, Open File Dialog File Filters on page IV-149

Displaying a Save File Dialog on page IV-150, Save File Dialog File Filters on page IV-151

Using Open in a Utility Routine on page IV-151
OpenNotebook

/Z[=z] Controls error reporting.
/Z=0: Report errors normally. /Z=0 is the same as omitting /Z altogether.
   This is the default behavior if /Z is omitted.
/Z=1: Suppresses normal error reporting.
   /Z alone has the same effect as /Z=1.
/Z=1 prevents aborting procedure execution if an error occurs, for example if the file
does not exist or if there is a compilation error. Use /Z=1 if you want to handle errors
in your procedures rather than having execution abort.
When using /Z or /Z=1, check V_Flag to see if an error occurred.

Details
If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a
file system path like "hd:Folder1:" or "C:\\Folder1\". See Symbolic Paths on page II-22 for details.
If the specified file is already open but not as a help window (for example as a notebook), OpenHelp returns
an error.
If the /W or /V flag is used, or both, the window size and position and visibility are set as specified even if
the file itself is already open, so long as the file is already opened as a help window.

Output Variables
The OpenHelp operation returns information in the following variables:

V_Flag Set to a non-zero value if an error occurred and to zero if no error occurred.
V_alreadyOpen Set to 1 if the specified help file was already open as a help file or to zero otherwise.
S_pictureInfo Scans the compiled help file for pictures and stores information about all pictures in
a semicolon separated list into the S_pictureInfo output string. If the help file needs to
be compiled but compilation fails, S_pictureInfo is set to "".

See Also
CloseHelp

OpenNotebook

OpenNotebook [flags] [fileNameStr]
The OpenNotebook operation opens a file for reading or writing as an Igor notebook.
Unlike the Open operation, OpenNotebook will not create a file if the specified file does not exist. To create
a new notebook, use the NewNotebook operation.

Parameters
The file to be opened is specified by fileNameStr and /P=pathName where pathName is the name of an Igor
symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative
to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor
can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you
to specify the file.
If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming
the path.
Flags

/A Moves the notebook’s selection to the end of the notebook.

/ENCG=textEncoding

Specifies the text encoding of the plain text file to be opened as a notebook.

This flag was added in Igor Pro 7.00.

This is relevant for plain text notebooks only and is ignored for formatted notebooks because they can contain multiple text encodings. See Plain Text File Text Encodings on page III-466 and Formatted Text Notebook File Text Encodings on page III-472 for details.

OpenNotebook uses the text encoding specified by /ENCG and the rules described under Determining the Text Encoding for a Plain Text File on page III-467 to determine the source text encoding for conversion to UTF-8.

Passing 0 for textEncoding acts as if /ENCG were omitted.

See Text Encoding Names and Codes on page III-490 for a list of accepted values for textEncoding.

/K=k Specifies window behavior when the user attempts to close it.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

k=3: Hides the window.

If you use /K=2 or /K=3, you can still kill the window using the KillWindow operation.

/M=messageStr Prompt message text in the dialog used to find the file, if any.

/N=winName Specifies the window name to be assigned to the new notebook. If omitted, it assigns a name like “Notebook0”.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/R Opens the file as read only.

/T=typeStr Specifies the type or types of files that can be opened.

/V=visible Hides (visible= 0) or shows (visible= 1; default) the notebook.

/W=(left,top,right,bottom) Specifies window size and position. Coordinates are in points.

/Z Suppresses error generation. Use this to check if a file exists. If you use /Z, OpenNotebook sets the variable V_flag to 0 if the notebook was opened or to nonzero if there was an error, usually because the specified file does not exist.

Details

The /A (append) flag has no effect other than to move the selection to the end of the notebook after it is opened.

If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\\Folder1\\”. See Symbolic Paths on page II-22 for details.

The /T=typeStr flag affects only the dialog that OpenNotebook presents if you do not specify a path and filename. The dialog presents only those files whose type is specified by /T=typeStr. There are two file types that are allowed for notebooks: ‘TEXT’ which is a plain text file and ‘WMT0’ which is a WaveMetrics formatted text file. Therefore, the file type, if you use it, should be either “TEXT” or “WMT0”. If /T=typeStr is missing, it defaults to “TEXTWMT0”. This opens either type of notebook file. On Windows, Igor considers files with “.txt” extensions to be of type TEXT and considers files with “.ifn” to be of type WMT0. See File Types and Extensions on page III-455 for details.
OpenProc

See Also
The Notebook and NewNotebook operations, and Chapter III-1, Notebooks.

OpenProc

OpenProc [flags] [fileNameStr]

The OpenProc operation opens a file as an Igor procedure file.

Note: This operation is used automatically to open procedure files when you open an Igor experiment. You can invoke OpenProc only from the command line. Do not invoke it from a procedure. To open procedure files from a procedure or from a menu definition, use the Execute/P operation.

Parameters

The file to be opened is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags

/A Moves the procedure window’s selection to the end of the window.

/ENCG=textEncoding

Specifies the text encoding of the plain text file to be opened as a procedure file.
This flag was added in Igor Pro 7.00.
OpenProc uses the text encoding specified by /ENCG and the rules described under Determining the Text Encoding for a Plain Text File on page III-467 to determine the source text encoding for conversion to UTF-8.
Passing 0 for textEncoding acts as if /ENCG were omitted.
See Text Encoding Names and Codes on page III-490 for a list of accepted values for textEncoding.

/M=messageStr Prompt message text in the dialog used to find the file, if any.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/R The file is opened read only.

/T=typeStr Specifies the type or types of files that can be opened.

/V=visible Hides (visible=0) or shows (visible=1; default) the procedure window.

/Z Suppresses error generation if the specified file does not exist.

Details

The /A (append) flag has no effect other than to move the selection to the end of the procedure file after it is opened.
If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\". See Symbolic Paths on page II-22 for details.
OpenProc automatically opens procedure files when you open an Igor experiment. Normally, you will have no use for it. You can not open a procedure file while procedures are executing. Thus, you can’t invoke OpenProc from within a procedure. You can only invoke it from the command line or from a user menu definition (actually, you may get away with it in a macro, but it’s not recommend).

See Also
Chapter III-13, Procedure Windows, Execute, CloseProc
The Execute operation.

OperationList

OperationList(matchStr, separatorStr, optionsStr)
The OperationList function returns a string containing a list of internal (built-in) or external operation names corresponding to matchStr.

Parameters
Only operation names that match matchStr string are listed. Use "*" to match all names. See WaveList for examples.

separatorStr is appended to each operation name as the output string is generated. separatorStr is usually ":" for list processing (See Processing Lists of Waves on page IV-198 for details).

Use optionsStr to further qualify the list of operations. optionsStr is a (case-insensitive) string containing one of these values:

"internal"    Restrictions the list to built-in operations.
"external"    Restrictions the list to external operations (see Igor Extensions on page III-511).

Any other value for optionsStr ("all" is recommended) will return both internal and external operations.

See Also
The DisplayProcedure operation and the FunctionList, MacroList, StringFromList, and WinList functions.

Optimize

Optimize [flags] funcSpec, pWave
The Optimize operation determines extrema (minima or maxima) of a specified nonlinear function. The function must be defined in the form of an Igor user function.

Use the first form for univariate functions (one dimensional functions; functions taking just one variable). Use the second form with multivariate functions (functions in more than one dimension; functions of more than one variable).

Optimize uses Brent’s method for univariate functions. For multivariate functions you can choose several variations of quasi-Newton methods or simulated annealing.

Flags

/A [findMax]    Finds a maximum (/A=1 or /A) or minimum (/A=0 or no flag).
/D=nDigits     Specifies the number of good digits returned (default is 15) by the function being optimized. If you use /X=xWave with a single-precision wave, the default is seven. Ignored with simulated annealing (/M={3,0}).
/DSA=destWave  Sets a wave to track the current best model only found with simulated annealing (/M={3,0}). destWave must have the same number of points as the X vector.
/F=trustRegion Sets the initial trust region when /M={1 or 2, …} with multivariate functions. The value is a scaled step size (see Multivariate Details). After the first iteration the trust region is adjusted according to conditions. Ignored with simulated annealing (/M={3,0}).
/H=highBracket Find the extrema of a univariate function. lowBracket and highBracket are X values on either side of the extreme point. An extreme point is found between the bracketing values.
/L=lowBracket  If lowBracket and highBracket are equal, Optimize adds 1.0 to highBracket before looking for an extreme point.

Default values for lowBracket and highBracket are zero. Thus, if neither lowBracket nor highBracket is present, this is the same as /L=0/H=1.

Ignored with simulated annealing (/M={3,0}).
Optimize

/I=\textit{maxIters} \quad \text{Sets the maximum number of iterations in searching for an extreme point to } \textit{maxIters}. Default is 100 for \textit{stepMethod} (/M flag) 0-2, 10000 for \textit{stepMethod} = 3 (simulated annealing).

If you use this form of the /I flag with simulated annealing, \textit{maxItersAtT} is set to \textit{maxIters}/2 and \textit{maxAcceptances} is set to \textit{maxIters}/10.

/I=[\textit{maxIters}, \textit{maxItersAtT}, \textit{maxAcceptances}] \quad \text{Specifies the number of iterations for simulated annealing. The maximum number of iterations is set by } \textit{maxIters}, \textit{maxItersAtT} \text{ sets the maximum number of iterations at a given temperature in the cooling schedule, and } \textit{maxAcceptances} \text{ sets the total number of accepted changes in the X vector (whether they increase or decrease the function) at a given temperature.}

If you use this form of the flag with any \textit{stepMethod} (/M flag) other than 3, \textit{maxItersAtT} and \textit{maxAcceptances} are ignored.

Defaults for \textit{stepMethod} = 3 are \{10000, 5000, 500\}.

/M=[\textit{stepMethod}, \textit{hessMethod}] \quad \text{Specifies the method used for selecting the next step (\textit{stepMethod}) and the method for calculating the Hessian (matrix of second derivatives) with multivariate functions.}

\begin{tabular}{|c|l|c|}
\hline
\textit{stepMethod} & \text{Method} & \textit{hessMethod} & \text{Method} \\
\hline
0 & Line Search & 0 & \text{secant (BFGS)} \\
1 & Dogleg & 1 & \text{finite differences} \\
2 & More-Hebdon & & \\
3 & Simulated Annealing & & \\
\hline
\end{tabular}

Default values are \{0,0\}. The \textit{hessMethod} variable is ignored if you select \textit{stepMethod} = 3.

/Q \quad \text{Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.}

/R=[\textit{typX1, typX2, \ldots}] \quad \text{Specifies the expected size of X values with multivariate functions. These values are used to scale X values. If the X values you expect are very different from one, you will get more accurate results if you can give a reasonable estimate. Optimize will use } \textit{typXi} \text{ to scale } X_i \text{ to reduce floating-point truncation error.}

You must provide the same number of values in either a wave or a list of values as you provide to the /X flag.

Ignored with simulated annealing (/M=[3,0]).

/S=\textit{stepMax} \quad \text{Limits the largest scaled step size allowed with multivariate functions. Optimize will stop if five consecutive steps exceed } \textit{stepMax}.

Ignored with simulated annealing (/M=[3,0]).

/SSA=\textit{stepWave} \quad \text{Name of a 3-column wave having number of rows equal to the length of the X vector only when used with simulated annealing (/M=[3,0]). } \textit{stepWave} \text{ sets information about the step size used to generate new X vectors. The step sizes are in terms of normalized X values. The normalization is such that the } X_i \text{ ranges from -1 to 1 based on the ranges set by the /XSA flag.}

Column zero sets the step size used when creating new trial X vectors. Default is 1.0.

Column one sets the minimum step size. Default is 0.001.

Column two sets the maximum step size. Default is 1.0.
### Parameters

**func** specifies the name of your user-defined function that will be optimized.

**pwave** gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified by Igor. It is intended for your private use to pass adjustable constants to your function.

### Function Format

Finding extreme points of a nonlinear function requires that you realize the function as an Igor user function of a certain form. See Finding Minima and Maxima of Functions on page III-343 for detailed examples.

Your function must look like this:

```plaintext
Function myFunc(w, x1, x2, ...)
  Wave w
  Variable x1, x2
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>func</strong></td>
<td>Specifies the name of your user-defined function that will be optimized.</td>
</tr>
<tr>
<td><strong>pwave</strong></td>
<td>Gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified by Igor. It is intended for your private use to pass adjustable constants to your function.</td>
</tr>
</tbody>
</table>

### Function Format Details

**Finding extreme points of a nonlinear function requires that you realize the function as an Igor user function of a certain form.**

Consider the function format:

```plaintext
Function myFunc(w, x1, x2, ...)
  Wave w
  Variable x1, x2
```

In this format:

- **func** specifies the name of your user-defined function that will be optimized.
- **pwave** gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified by Igor. It is intended for your private use to pass adjustable constants to your function.

### Finding Extreme Points

To find extreme points, optimize will attempt to find a minimum within ± `tol`.

When this form is used with a multivariate function, `gradTol` is set to `tol` and `stepTol` is set to `gradTol^2`.

### Stopping Criteria

- **/T=tol**
  - Sets the stopping criterion with univariate functions. Optimize will attempt to find a minimum within ± `tol`.

- **/T=gradTol, stepTol**
  - Sets the stopping criteria for multivariate functions. Iterations stop if a point is found with estimated scaled gradient less than `gradTol`, or if an iteration takes a scaled step shorter than `stepTol`. Default values are [8.53618x10^-6, 7.28664x10^-11]. These values are (6.022x10^{-16})^{1/3} and (6.022x10^{-16})^{2/3} as suggested by Dennis and Schnabel. 6.022x10^{-16} is the smallest double precision floating point number that, when added to 1, is different from 1.

### Additional Parameters

- **/TSA=InitialTemp, CoolingRate**
  - Used only with simulated annealing (/M={3,0}).
  - **InitialTemp** sets the initial temperature. If `InitialTemp` is set to zero, Optimize calls your function 100 times to estimate the best initial temperature. This is the recommended setting unless your function is very expensive to evaluate (in which case, you may not want to use simulated annealing at all).
  - **CoolingRate** sets the factor by which the temperature is decreased.

- **/X=xWave**
  - Sets the starting point for searching for an extreme point with multivariate functions or with simulated annealing (/M={3,0}). The starting point can be specified with a wave having as many points as the number of independent variables, or you can write out a list of X values in braces. If you are finding extreme points of a univariate function, use /L and /H instead unless you are using the simulated annealing method. If you specify a wave, this wave is also used to receive the result of the extreme point search.

- **/XSA=XLimitWave**
  - Name of a 2-column wave having number of rows equal to the length of the X vector only when used with simulated annealing (/M={3,0}).
  - Column zero sets the minimum value allowed for each element of the X vector.
  - Column one sets the maximum value allowed for each element of the X vector.
  - Default is ±X_i*10 if X_i is nonzero, or ±1 if X_i is zero. While a default is provided, it is highly recommended that you provide an `XLimitWave`.

- **/Y=funcSize**
  - Specifies expected sizes of function values with multivariate functions. If you expect your function will return values very different from one, you should set `funcSize` to the expected size. Optimize will use this value to scale the function results to reduce floating-point truncation error.
return f(x1, x2, ...) // an expression ...
End

A univariate function would have only one X variable.

A multivariate function can use a wave to pass in the X values:
Function myFunc(w,xw)
  Wave w
  Wave xw
  return f(xw) // an expression ...
End

Replace “f(…)” with an appropriate numerical expression.

**Univariate Details**
The method used by Optimize to find extreme points of univariate functions requires that the point be bracketed before starting. If you don’t use /L and /H to specify the bracketing X values, the defaults are zero and one. Optimize first attempts to find the requested extreme point using the bracketing values (or the default). If that is unsuccessful, it attempts to bracket an extreme point by expanding the bracketing interval. If a suitable interval is found (the search is by no means perfectly reliable), then the search for an extreme point is made again.

Optimize uses Brent’s method for univariate functions, which requires no derivatives. This combines a quadratic extrapolation with checking for wild results. In the case of wild results (points beyond the best current bracketing values) the method reverts to a golden section bisection algorithm. For well-behaved functions, the quadratic extrapolation converges superlinearly. The golden section bisection algorithm converges more slowly but features global convergence, that is, if an extremum is there, it will be found.

The stopping criterion is

\[
\left| x + \frac{a+b}{2} \right| + \frac{a-b}{2} \leq \frac{2}{3} \text{tol}.
\]

In this expression, \(a\) and \(b\) are the current bracketing values, and \(x\) is the best estimate of the extreme point within the bracketing interval.

The left side of this expression works out to being simply the distance from the current solution to the boundary of the bracketing interval.

**Note:** Optimizing a univariate function with the simulated annealing method (/M={3,0}) works like a multivariate function, and this section does not apply. See the sections devoted to simulated annealing.

**Multivariate Details**
With multivariate functions, Optimize scales certain quantities to reduce floating point truncation error. You enter scaling factors using the /R and /Y flags. The /R flag specifies the expected magnitude of X values; Optimize then uses \(X_i/\text{typ}X_i\) in all calculations. Likewise, /Y specifies the expected magnitude of function values.

This scaling can be important for maintaining accuracy if your X’s or Y’s are very different from one, and especially if your X’s have values spanning orders of magnitude.

The Optimize operation uses a quasi-Newton method with derivatives estimated numerically. The function gradient is calculated using finite differences. For estimation of the Hessian (second derivative matrix) you can use either a secant method (\(\text{hessMethod} = 0\)) or finite differences (\(\text{hessMethod} = 1\)). The finite difference method gives a more accurate estimate and may succeed with difficult functions but requires more function evaluations per iteration. The finite difference method’s greater accuracy may reduce the total number of iterations required, so the overall number of function evaluations depends on details of the problem being solved. Usually the secant method requires fewer function evaluations and is preferred for functions that are expensive to evaluate.

Once a Newton step is calculated, there are three choices for the method used to find the best next value-line search along the Newton direction (\(\text{stepMethod} = 0\)), double dogleg (\(\text{stepMethod} = 1\)), or More-Hebdon (\(\text{stepMethod} = 2\)). The best method can be found only by experimentation. See Dennis and Schnabel (cited in References) for details.

The /F=trustRegion, /S=stepMax and /T={…, stepTol} all refer to scaled step sizes. That is,
The Optimize operation presumes that an extreme point has been found when either the gradient at the latest point is less than $gradTol$ or when the last step taken was smaller than $stepTol$. These criteria both refer to scaled quantities:

$$\max_{1 \leq i \leq n} \left\{ \left| g_i \right| \frac{\max(|x|,typX_i)}{\max(|y|,funcSize)} \right\} \leq gradTol,$$

or

$$\max_{1 \leq i \leq n} \left\{ \left| \frac{\Delta x_i}{\text{max}(|x|,\text{typX}_i)} \right| \right\} \leq stepTol.$$

**Simulated Annealing Introduction**

The simulated annealing or Metropolis algorithm optimizes a function using a random search of the $X$ vector space. It does not use derivatives to guide the search, making it a good choice if the function to be optimized is in some way poorly behaved. For instance, it is a good method for functions with discontinuities in the function value or in the derivatives.

Simulated annealing also has a good chance of finding a global minimum or maximum of a function having multiple local minima or maxima.

Because simulated annealing uses a random search method, it may require a large number of function evaluations to find a minimum, and it is not guaranteed that it will stop at an actual minimum. For these reasons, it is best to use one of the other methods unless those methods have failed.

The simulated annealing method generates new trial solutions by adding a random vector to the current $X$ vector. The elements of the random vector are set to $\text{stepsize}_i R_i$ where $R_i$ is a random number in the interval (-1, 1). As the solution progresses, the $\text{stepsize}$ is gradually decreased.

Bad trials, that is, those that change the function value in the wrong direction are accepted with a probability that depends on the simulated temperature. It is this aspect that allows simulated annealing to find a global minimum.

Function values are generated and accepted or rejected for some number of iterations at a given temperature, then the temperature is reduced. The probability of a bad iteration being accepted decreases with decreasing temperature. A too-fast cooling rate can freeze in a bad solution.

**Simulated Annealing Details**

It is highly recommended that you use the XSA flag to specify $XLimitWave$. This wave sets bounds on the values of the elements of the $X$ vector during the random search. The defaults may be adequate but are totally ad hoc. You are better off to specify bounds that make sense to the problem you are solving.

The values of $XLimitWave$ in addition to bounding the search space also scale the $X$ vector during computations of probabilities, temperatures, etc. Consequently, the $X$ limits can affect the performance of the algorithm.

A large number of iterations is required to have a good probability of finding a reasonable solution.

It is recommended that you set the initial temperature to zero so that Optimize can estimate a good initial temperature. If you can’t afford the 100 function evaluations required, you probably shouldn’t be using simulated annealing.

Optimize uses an exponential cooling schedule in which $T_{i+1} = \text{CoolingRate}^i T_i$ (see the /TSA flag). $\text{CoolingRate}$ must be in the range 0 to 1. A fast cooling rate (small value of $\text{CoolingRate}$) can cause simulated quenching; that is, a bad solution can be frozen in. Very slow cooling will result in slow convergence.

When simulated annealing is selected, the optimization is treated as multivariate even if your function has only a single $X$ input. That is, the output variables and waves are the ones listed under multivariate functions.

$\text{stepXi} = \frac{\Delta x_i}{\text{max}(|x|,\text{typX}_i)}$. 

$$\max_{1 \leq i \leq n} \left\{ \left| g_i \right| \frac{\max(|x|,\text{typX}_i)}{\max(|y|,\text{funcSize})} \right\} \leq gradTol,$$

$$\max_{1 \leq i \leq n} \left\{ \left| \frac{\Delta x_i}{\text{max}(|x|,\text{typX}_i)} \right| \right\} \leq stepTol.$$
Variables and Waves for Output
The Optimize operation reports success or failure via the V_flag variable. A nonzero value is an error code.

Variables for a univariate function:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>V_flag</td>
<td>0</td>
<td>Search for an extreme point was successful.</td>
</tr>
<tr>
<td></td>
<td>57</td>
<td>User abort.</td>
</tr>
<tr>
<td></td>
<td>785</td>
<td>Function returned NaN.</td>
</tr>
<tr>
<td></td>
<td>786</td>
<td>Unable to find bracketing values for an extreme point.</td>
</tr>
</tbody>
</table>

If you searched for a minimum:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>V_minloc</td>
<td>X value at the minimum.</td>
</tr>
<tr>
<td>V_min</td>
<td>Function value (Y) at the minimum.</td>
</tr>
</tbody>
</table>

If you searched for a maximum:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>V_maxloc</td>
<td>X value at the maximum.</td>
</tr>
<tr>
<td>V_max</td>
<td>Function value (Y) at the maximum.</td>
</tr>
</tbody>
</table>

For simulated annealing only:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>V_SANumIncreases</td>
<td>Number of “bad” iterations accepted.</td>
</tr>
<tr>
<td>V_SANumReductions</td>
<td>Number of iterations resulting in a better solution.</td>
</tr>
</tbody>
</table>

Variables for a multivariate function:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>V_flag</td>
<td>0</td>
<td>Search for an extreme point was successful.</td>
</tr>
<tr>
<td></td>
<td>57</td>
<td>User abort.</td>
</tr>
<tr>
<td></td>
<td>788</td>
<td>Iteration limit was exceeded.</td>
</tr>
<tr>
<td></td>
<td>789</td>
<td>Maximum step size was exceeded in five consecutive iterations.</td>
</tr>
<tr>
<td></td>
<td>790</td>
<td>The number of points in the typical X size wave specified by /R does not match the number of X values specified by the /X flag</td>
</tr>
<tr>
<td></td>
<td>791</td>
<td>Gradient nearly zero and no iterations taken. This means the starting point is very nearly a critical point. It could be a solution, or it could be so close to a saddle point or a maximum (when searching for a minimum) that the gradient has no useful information. Try a slightly different starting point.</td>
</tr>
</tbody>
</table>

V_OptTermCode Indicates why Optimize stopped. This may be useful information even if V_flag is zero. Values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Gradient tolerance was satisfied.</td>
</tr>
<tr>
<td>2</td>
<td>Step size tolerance was satisfied.</td>
</tr>
<tr>
<td>3</td>
<td>No step was found that was better than the last iteration. This could be because the current step is a solution, or your function may be too nonlinear for Optimize to solve, or your tolerances may be too large (or too small), or finite difference gradients are not sufficiently accurate for this problem.</td>
</tr>
<tr>
<td>4</td>
<td>Iteration limit was exceeded.</td>
</tr>
</tbody>
</table>
If you searched for a minimum:

\[ V_{\text{min}} \text{ Function value (Y) at the minimum.} \]

If you searched for a maximum:

\[ V_{\text{max}} \text{ Function value (Y) at the maximum.} \]

**Variables for all functions:**

- \( V_{\text{OptNumIters}} \) Number of iterations taken before Optimize terminated.
- \( V_{\text{OptNumFunctionCalls}} \) Number of times your function was called before Optimize terminated.

**Waves for a multivariate function:**

- \( W_{\text{extremum}} \) Solution if you didn’t use /X=<xWave>. Otherwise the solution is returned in your X wave.
- \( W_{\text{OptGradient}} \) Estimated gradient of your function at the solution.

**See Also**

- **Finding Minima and Maxima of Functions** on page III-343 for further details and examples.

**References**

The Optimize operation uses Brent’s method for univariate functions. *Numerical Recipes* has an excellent discussion (see section 10.2) of this method (but we didn’t use their code):

For multivariate functions Optimize uses code based on Dennis and Schnabel. To truly understand what Optimize does, read their book:

**Override**

Override constant objectName = newVal
Override strconstant objectName = newVal
Override Function funcName()

The Override keyword redefines a constant, strconstant, or user function. The objectName or funcName must be the same as the name of the original object or function that is being redefined. The override must be defined before the target object appears in the compile sequence.

**See Also**

- **Function Overrides** on page IV-106 and **Constants** on page IV-51 for further details.

**p**

The \( p \) function returns the row number of the current row of the destination wave when used in a wave assignment statement. The row number is the same as the point number for a 1D wave.
p2rect

Details
Outside of a wave assignment statement p acts like a normal variable. That is, you can assign a value to it and use it in an expression.

See Also
Waveform Arithmetic and Assignments on page II-74.

For other dimensions, the q, r, and s functions.
For scaled dimension indices, the x, y, z, and t functions.

p2rect

\( p2rect(z) \)
The \( p2rect \) function returns a complex value in rectangular coordinates derived from the complex value \( z \) which is assumed to be in polar coordinates (magnitude is stored in the real part and the angle, in radians, in the imaginary part of \( z \)).

Examples
Assume \( \text{waveIn} \) and \( \text{waveOut} \) are complex, then:

\[ \text{waveOut} = p2rect(\text{waveIn}) \]

sets each point of \( \text{waveOut} \) to the rectangular coordinates based on the magnitude in the real part and the angle (in radians) in the imaginary part of the points in \( \text{waveIn} \).

You may get unexpected results if the number of points in \( \text{waveIn} \) differs from the number of points in \( \text{waveOut} \).

See Also
The functions \( \text{cmplx, conj, imag, r2polar, and real.} \)

PadString

\( \text{PadString}(\text{str, finalLength, padValue}) \)
The PadString function returns a string identical to \( \text{str} \) except that it has been extended to a total length of \( \text{finalLength} \) using bytes of \( \text{padValue} \). Use zero to create a C-language style string or use 0x20 to pad with spaces (FORTRAN style). This is useful when reading or writing binary files using \( \text{FBinRead} \) and \( \text{FBinWrite} \).

UnPadString, ReplaceString, ReplicateString

Panel

Panel
Panel is a procedure subtype keyword that identifies a macro as being a control panel recreation macro. It is automatically used when Igor creates a window recreation macro for a control panel. See Procedure Subtypes on page IV-204 and Saving a Window as a Recreation Macro on page II-47 for details.

PanelResolution

\( \text{PanelResolution}(\text{wName}) \)
The PanelResolution function returns the current resolution of the specified window in pixels per inch.

If \( \text{wName} \) is empty, it returns the current global setting for panel resolution in pixels per inch which is controlled by \( \text{SetIgorOption PanelResolution} \) (see page III-456).

If \( \text{wName} \) is the name of a graph window, it returns the resolution for the ControlBar area in pixels per inch.
\( \text{wName} \) can be a subwindow specification.
The PanelResolution function was added in Igor Pro 7.00.
In general, PanelResolution and ScreenResolution return the same thing. However, on Windows when the screen resolution is 96 DPI, which is typical for normal-resolution screens, panels can use 72 DPI for compatibility with Igor Pro 6 and earlier.
ParamIsDefault

`ParamIsDefault(pName)`

The ParamIsDefault function determines if an optional user function parameter `pName` was specified during the function call. It returns 1 when `pName` is default (not specified) or it returns 0 when it was specified.

**Details**

ParamIsDefault works only in the body of a user function and only with optional parameters. The variable `pName` must be valid at compile time; you can not defer lookup to runtime with $.

**See Also**

Optional Parameters on page IV-33 and Using Optional Parameters on page IV-60.

ParseFilePath

`ParseFilePath(mode, pathInStr, separatorStr, whichEnd, whichElement)`

The ParseFilePath function provides the ability to manipulate file paths and to extract sections of file paths.

**Parameters**

The meaning of the parameters returned depends on `mode`.

<table>
<thead>
<tr>
<th><code>mode</code></th>
<th>Information Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Returns the element specified by <code>whichEnd</code> and <code>whichElement</code>. <code>&lt;whichEnd&gt;</code> is 0 to select an element relative to the beginning of <code>pathInStr</code>, 1 to select an element relative to the end. <code>&lt;whichElement&gt;</code> is zero-based. Pass <code>:</code> if <code>pathInStr</code> is a Macintosh HFS path, <code>\</code> if it is a Windows path. See Path Separators on page III-451 for details about Macintosh versus Windows paths.</td>
</tr>
<tr>
<td>1</td>
<td>Returns the entire <code>pathInStr</code>, up to but not including the element specified by <code>whichEnd</code> and <code>whichElement</code>. <code>&lt;whichEnd&gt;</code> is 0 to select an element relative to the beginning of <code>pathInStr</code>, 1 to select an element relative to the end. <code>&lt;whichElement&gt;</code> is zero-based. Pass <code>:</code> if <code>pathInStr</code> is a Macintosh HFS path, <code>\</code> if it is a Windows path. See Path Separators on page III-451 for details about Macintosh versus Windows paths.</td>
</tr>
<tr>
<td>2</td>
<td>Returns the entire <code>pathInStr</code> with a trailing separator added if it is not already there. This is useful when you have a path to a folder and want to tack on a file name. Pass <code>:</code> if <code>pathInStr</code> is a Macintosh HFS path, <code>\</code> if it is a Windows path. See Path Separators on page III-451 for details about Macintosh versus Windows paths. <code>&lt;whichEnd&gt;</code> and <code>&lt;whichElement&gt;</code> are ignored. Pass 0 for them.</td>
</tr>
<tr>
<td>3</td>
<td>Returns the last element of <code>pathInStr</code> with the extension, if any, removed. The extension is anything after the last dot in <code>pathInStr</code>. <code>&lt;whichEnd&gt;</code> and <code>&lt;whichElement&gt;</code> are ignored. Pass 0 for them.</td>
</tr>
<tr>
<td>4</td>
<td>Returns the extension in <code>pathInStr</code> or <code>&quot;&quot;</code> if there is no extension. The extension is anything after the last dot in <code>pathInStr</code>. Pass <code>:</code> if <code>pathInStr</code> is a Macintosh HFS path, <code>\</code> if it is a Windows path. See Path Separators on page III-451 for details about Macintosh versus Windows paths. <code>&lt;whichEnd&gt;</code> and <code>&lt;whichElement&gt;</code> are ignored. Pass 0 for them.</td>
</tr>
<tr>
<td>5</td>
<td>Returns the entire <code>pathInStr</code> but converts it to a format determined by <code>separatorStr</code>.</td>
</tr>
</tbody>
</table>
ParseFilePath

<table>
<thead>
<tr>
<th>mode</th>
<th>Information Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>separatorStr = &quot;&quot;:&quot; Converts the path to Macintosh HFS style if it is Windows style. Does nothing to a Macintosh HFS path. separatorStr = &quot;&quot;</td>
<td>Converts the path to Windows style if it is Macintosh style. Does nothing to a Windows path. separatorStr = &quot;&quot;</td>
</tr>
</tbody>
</table>
When dealing with Windows paths, you need to be aware that Igor treats the backslash character as an escape character. When you want to put a backslash in a literal string, you need to use two backslashes. See Escape Sequences in Strings on page IV-14 and Path Separators on page III-451 for details.

On Windows two types of file paths are used: drive-letter paths and UNC (“Universal Naming Convention”) paths. For example:

// This is a drive-letter path.
C:\Program Files\WaveMetrics\Igor Pro Folder\WaveMetrics Procedures

// This is a UNC path.
\\BigServer\SharedApps\WaveMetrics\Igor Pro Folder\WaveMetrics Procedures

In this example, ParseFilePath considers the volume name to be C: in the first case and \\BigServer\SharedApps in the second. The volume name is treated as one element by ParseFilePath, except for modes 7 and 8 which permit you to extract the components of the UNC volume name.

Except for the leading backslashes in a UNC path, ParseFilePath modes 0 and 1 internally strip any leading or trailing separator (as defined by the separatorStr parameter) from pathInStr before it starts parsing. So if you pass ":Igor Pro Folder:WaveMetrics Procedures:", it is the same as if you had passed "Igor Pro Folder:WaveMetrics Procedures".

If there is no element corresponding to whichElement and mode is 0, ParseFilePath returns ""
If there is no element corresponding to whichElement and mode is 1, ParseFilePath returns the entire pathInStr.

### mode Information Returned

<table>
<thead>
<tr>
<th>mode</th>
<th>Information Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>UNC share name (“Share” from \ \ Server\Share”) if pathIn starts with a UNC volume name or &quot;&quot; if not. Pass &quot;&quot;&quot;&quot; for separatorStr. whichEnd and whichElement are ignored. Pass 0 for them.</td>
</tr>
<tr>
<td>9</td>
<td>Macintosh only. On Windows this mode returns an error. Returns a Posix version of pathInStr which must be a full HFS path pointing to an existing volume, directory or file. This is the same as mode 5 except that separatorStr must be &quot;*&quot;. whichEnd and whichElement are ignored. Pass 0 for them. You would typically use this mode when you are about to execute a Unix command, which requires Posix paths, via ExecuteScriptText. This mode was created in Igor Pro 7.00 to provide an alternative to the obsolete HFSToPosix function provided by the HSFAndPosix XOP. With HFSToPosix, if the input path referred to a directory, the output always ended with a slash. With ParseFilePath(9), the output will end with a slash only if the input path ends with a colon.</td>
</tr>
<tr>
<td>10</td>
<td>Macintosh only. On Windows this mode returns an error. Returns the HFS path corresponding to the Posix path in pathInStr. pathInStr must be a full Posix path starting with a slash character. It does not need to point to an existing directory or file. The returned path may or may not refer to an existing volume, folder or file, depending on pathInStr. Pass &quot;*&quot; for separatorStr. whichEnd and whichElement are ignored. Pass 0 for them. You would typically use this mode when you receive a Posix path from a Unix command executed via ExecuteScriptText and you want to use that path in Igor. This mode was created in Igor Pro 7.00 to provide an alternative to the obsolete PosixToHFS function provided by the HSFAndPosix XOP.</td>
</tr>
</tbody>
</table>

**Details**

When dealing with Windows paths, you need to be aware that Igor treats the backslash character as an escape character. When you want to put a backslash in a literal string, you need to use two backslashes. See Escape Sequences in Strings on page IV-14 and Path Separators on page III-451 for details.
ParseOperationTemplate

Examples

String pathIn, pathOut
// Full path
pathIn= "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf"

// Extract first element.
Print ParseFilePath(0, pathIn, ":", 0, 0) // Prints "hd"

// Extract second element.
Print ParseFilePath(0, pathIn, ":", 0, 1) // Prints "Igor Pro Folder"

// Extract last element.
Print ParseFilePath(0, pathIn, ":", 1, 0) // Prints "Wave Lists.ipf"

// Extract next to last element.
Print ParseFilePath(0, pathIn, ":", 1, 1) // Prints "Waves"

// Get path to folder containing the file.
Print ParseFilePath(1, pathIn, ":", 1, 0)

// Extract the file name without extension.
Print ParseFilePath(3, pathIn, ":", 0, 0) // Prints "Wave Lists"

// Extract the extension.
Print ParseFilePath(4, pathIn, ":", 0, 0) // Prints "ipf"

// Make sure the given path ends with a colon and concatenate file name.
String path = <routine that returns a Macintosh-style path to a folder>
path = ParseFilePath(2, path, ":", 0, 0)
path += "AFile.txt"

See Also

ParseOperationTemplate

ParseOperationTemplate [flags] cmdTemplate

The ParseOperationTemplate operation helps XOP programmers and WaveMetrics programmers write code to implement Igor operations. If you are not an XOP programmer nor a WaveMetrics programmer, it will be of no interest.

ParseOperationTemplate generates starter code for programmers who are creating Igor operations. The starter code is copied to the clipboard, overwriting any previous clipboard contents.

Flags

/C=c
If c is nonzero, ParseOperationTemplate stores code for your ExecuteOperation and RegisterOperation functions in the clipboard.

c=0: Do not generate code

c=1: Generate simplified C code - not recommended

c=2: Generate C code

c=6: Generate C++ code

The only difference between /C=6 and /C=2 is that the ExecuteOperation function is declared as extern "C" instead of static. C++ files that use static work fine although extern "C" is correct.
PathInfo

\( /S \) = Stores a definition of your runtime parameter structure in the clipboard if \( s \) is nonzero.

\( s=0 \): Do not generate the runtime parameter structure
\( s=1 \): Use your mnemonic names - recommended
\( s=2 \): Automatically generate mnemonic names - not recommended

We recommend that you use \( /S=1 \) and provide unique mnemonic parameter names in your template. ParseOperationTemplate then uses your parameter names as structure field names.

If you use \( /S=2 \), ParseOperationTemplate creates unique field names by concatenating flag or keyword text and your mnemonic names. This is left over from the early days of Operation Handler and is not recommended.

\( /T \) = Stores a comment listing your command template in the clipboard.

\( /TS \) = Identifies a ThreadSafe operation by adding an extra field to the runtime parameter structure. This is only of use to WaveMetrics programmers.

**Parameters**

\( cmdTemplate \) is the template that describes the syntax for your operation. See the *Igor XOP Toolkit Reference Manual* for details.

**Details**

ParseOperationTemplate parses your command template, generating structures that embody the syntax of your operation. It then uses these structures to generate code that can serve as a starting point for implementing your operation. The starter code is stored in the clipboard.

For most uses, the recommended flags are:

\( /T/S=1/C=2 \) // For non-threadsafe operations
\( /T/S=1/C=2/TS \) // For threadsafe operations

ParseOperationTemplate sets the following output variable, but only when called from a function or macro:

\( V\_flag \):

0: \( cmdTemplate \) was successfully parsed.

-1: \( cmdTemplate \) was not successfully parsed.

If \( V\_flag \) is nonzero, this indicates that your \( cmdTemplate \) syntax is incorrect. See the *Igor XOP Toolkit Reference Manual* for details.

**Examples**

Function Test()

String cmdTemplate

\( cmdTemplate = "MyTest" \)
\( cmdTemplate += " /A={number:aNum1,string:aStrH}" \)
\( cmdTemplate += " /B=wave:bWaveH" \)
\( cmdTemplate += " key1={name:k1N1[,wave:k1WaveH,name:k1N2,string[2]:k1StrHArray]}" \)

// If your XOP is C instead of C++, use /C=2 instead of /C=6
TestOperationParser/T/S=1/C=6 cmdTemplate
Print V_flag, S_value

End

**See Also**

Igor Extensions on page III-511.

PathInfo

**PathInfo** \( [/S ] /SHOW \) \( pathName \)

The PathInfo operation stores information about the named symbolic path in the following variables:

\( V\_flag \):

0 if the symbolic path does not exist, 1 if it does exist.

\( S\_path \):

The full path (e.g., "hd:This:That:").
The path returned is a colon-separated path which can be used on Macintosh or Windows. See Path Separators on page III-451 for details.

Flags

/S Presets the next otherwise undirected open or save file dialog to the given disk folder. This flag is ignored when PathInfo is called from a preemptive thread.

/SHOW Shows the folder, if it exists, in the Finder (Mac OS X) or Windows Explorer (Windows). This flag is ignored when PathInfo is called from a preemptive thread.

Details

The use of PathInfo in a preemptive thread requires Igor Pro 8.00 or later.

Examples

// The following lines perform equivalent actions:
PathInfo/S myPath;Open refNum
Open/P=myPath refNum

// Show Igor's Preferences folder in the Finder/Windows Explorer.
String fullpath= SpecialDirPath("Preferences",0,0,0)
NewPath/O/Q tempPathName, fullpath
PathInfo/SHOW tempPathName

See Also

Symbolic Paths on page II-22.

The NewPath, GetFileFolderInfo, ParseFilePath and SpecialDirPath operations.

PathList

PathList(matchStr, separatorStr, optionsStr)
The PathList function returns a string containing a list of symbolic paths selected based on the matchStr parameter.

Details

For a path name to appear in the output string, it must match matchStr. separatorStr is appended to each path name as the output string is generated.

PathList works like the WaveList function, except that the optionsStr parameter is reserved for future use. Pass "" for it.

Examples

When a new experiment is created there is only one path:
Print PathList("*",";","")
Prints the following in the history area:
Igor;

See Also

The WaveList function for an explanation of the matchStr and separatorStr parameters and for examples. See also Symbolic Paths on page II-22 for an explanation of symbolic paths.

PauseForUser

PauseForUser [/C] mainWindowName [, targetWindowName]
The PauseForUser operation pauses function execution to allow the user to manually interact with a window. For example, you can call PauseForUser from a loop to allow the user to move the cursors on a graph. In this scenario, targetWindowName would be the name of the graph and mainWindowName would be the name of a control panel containing a message telling the user to adjust the cursors and then click, for example, the Continue button.

If targetWindowName is omitted then mainWindowName plays the role of target window.

PauseForUser works with graph, table, and panel windows only.
PauseForUser

Flags

/C  Tells PauseForUser to return immediately after handling any pending events. See Details.

Details
During execution of PauseForUser, only mouse and keyboard activity directed toward either 
mainWindowName or targetWindowName is allowed.

While waiting for user action, PauseForUser disables double-clicks and any contextual menus that can lead
to dialogs in order to prevent changes on the command line. It also disables killing windows by clicking the
close icon in the title bar unless the window was originally created with the /K=1 flag (kill with no dialog).
If /C is omitted, PauseForUser returns only when the main window has been killed.

If /C is present, PauseForUser handles any pending events, sets V_Flag to the truth the target window still
exists, and then returns control to the calling user-defined function. Use PauseForUser/C in a loop if you
need to do something while waiting for the user to finish interacting with the target window, such as
updating a progress indicator.

As of Igor Pro 8.00, the PauseForUser operation is allowed only in user-defined functions. It returns an error
if called from a macro or from the command line.

See Also
Pause For User on page IV-152 for examples and further discussion.

PauseUpdate

PauseUpdate
The PauseUpdate operation delays the updating of graphs and tables until you invoke a corresponding
ResumeUpdate command.

Details
PauseUpdate is useful in a macro that changes a number of things relating to the appearance of a graph. It
prevents the graph from being updated after each change. Its effect ends when the macro in which it occurs
ends. It also affects updating of tables.

This operation is not allowed from the command line. It is allowed but has no effect in user-defined
functions. During execution of a user-defined function, windows update only when you explicitly call the
DoUpdate operation.

See Also
The DelayUpdate, DoUpdate, ResumeUpdate, and Silent operations.

PCA

PCA [flags] [wave0, wave1,... wave99]
The PCA operation performs principal component analysis. Input data can be in the form of a list of 1D
waves, a single 2D wave, or a string containing a list of 1D waves. The operation can produce multiple
output waves depending on the specified flags.

Flags

/ALL  Shortcut for the combination of commonly used flags: /CVAR, /SL, /NF, /IND, /IE, and
       /RMS.

/COV  Calculates the input wave(s) covariance matrix, which as the input for the remainder of
       the analysis. The covariance matrix is computed by first creating a matrix copying each
       input 1D wave into sequential columns and then multiplying that matrix by its transpose.

/CVAR Computes the cumulative percent variance defined as 100 * sum of first m eigenvalues
divided by the sum of all eigenvalues. The results are stored in the wave
       W_CumulativeVAR in the current data folder. See also /VAR.
/IE Computes the imbedded error. Returns errors in the wave W_IE in the current data folder. The wave is scaled using SetScale/P x 1,1,"", W_IE. The imbedded error is a function of the number of factors, the number of rows and columns and the sum of the eigenvectors not included in the significant factors. The behavior of IE determines the number of significant factors.

/IND Computes the factor indicator function. Note that if you specify /IND the residual standard deviation will also be calculated. Returns results in the wave W_IND in the current data folder. The wave is scaled using SetScale/P x 1,1,"", W_IND.

/LEIV Limits eigenvalues so that the SVD calculation does not require too much memory. The limit is set to the minimum of the number of rows or columns of the input.

/NF Finds the number of significant factors and stores it in the variable V_npnts. You must use /IND in order to compute the significant factors.

/O Overwrites input waves.

/Q Suppresses printing of factors in the history area.

/RSD[=rsdMode] Computes the Residual Standard Deviation (RSD) and returns the RSD in the wave W_RSD in the current data folder. The first element in W_RSD is NaN and all remaining wave elements correspond to the number of significant factors.

\[ rsdMode = 0: \text{Covariance about the origin.} \]
\[ rsdMode = 1: \text{Correlation about the origin.} \]

/RMS Computes the RMS error. Returns results in the wave W_RMS in the current data folder. The wave is scaled using SetScale/P x 1,1,"", W_RMS.

/SCMT Saves C matrix after the singular value decomposition (SVD) in the wave M_C in the current data folder.

/SCR Converts the individual wave input into standard scores. Does not work when the input is a single 2D wave. It is an error to convert to standard scores when one or more entries in the waves are NaN or INF. If you use this feature make sure to use the appropriate form of the RSD calculation.

/SDM Saves a copy of the data matrix at the end of the calculation. This is useful if your input consists of individual waves or if you want to save the computed standard scores. If the input is a 2D matrix, you will get a copy of the input matrix in the wave M_D.

/SEVC Saves the eigenvalue vector in the wave W_Eigen, which are the raw eigenvalues generated by the SVD, in the current data folder. Normally, if the SVD was applied to a raw data matrix, i.e., not covariance or correlation matrix, you must square each element of the wave to obtain the PCA eigenvalues. Note that this wave has default wave scaling.

/SL Computes percent significance level and stores it in the wave W_PSL in the current data folder.

/SQEV Does not square SVD eigenvalues. If you specify /COV there is no need to use this flag. Use only if your input is already a covariance matrix. In this case the results of the SVD are the eigenvalues not their square roots.

/SRMT Saves R matrix after the SVD in the wave M_R in the current data folder.

/U Leaves the input waves unchanged only when the input is a 2D wave. Note that covariance calculations will not be made even if the appropriate flag is used.

/VAR Computes the variance associated with each eigenvalue. The variance is defined as the ratio of the eigenvalue to the sum of all eigenvalues. The results are stored in the wave W_VAR in the current data folder. See also /CVAR above.

/WSTR=waveListStr
Semicolon-separated string list of the names of all input waves.

/Z No error reporting.

Details
The input is either via /WSTR=waveListStr or a list of up to 100 1D waves or a single 2D wave following the last flag.

waveListStr is string containing a semicolon-separated list of 1D waves to be used for the data matrix. waveListStr can include any legal path to a wave. Liberal names can be quoted or not quoted. It is assumed that all waves are of the same numerical type (either single or double precision) and that all waves have the same number of points.

Regardless of the inputs, the operation expects that the number of rows in the resulting matrix is greater than or equal to the number of columns.

The operation starts by creating the data matrix from the input wave(s). If you provide a list of 1D waves they become the columns of the data matrix. You can choose to use the covariance matrix (/COV) as the data matrix and you can also choose to normalize each column of the data matrix to convert it into standard scores. This involves computing the average and standard deviation of each column and then setting the new values to be:

\[ newValue = \frac{oldValue - colAverage}{colStdv} \]

You can pre-process the input data using MatrixOp with the SubtractMean, NormalizeRows, and NormalizeCols functions.

After creating the data matrix the operation computes the singular value decomposition (SVD) of the data matrix. Results of the SVD can be saved or processed further. Save the C and R matrices using /SCMT and /SRMT. These are related to the input data matrix through: \[ D = R \cdot C \].

The remainder of the operation lets you compute various statistical quantities defined by Malinowski (see References). Use the flags to determine which ones are computed.

The operation generates a number of output waves. All waves are stored in the current data folder. You can save the input matrix D in the wave M_D, the optional SVD results are stored in the waves M_C that contains the column matrix C, M_R that contains the row matrix R, and W_Eigen that contains the eigenvalues of the data matrix. Note that these can be the eigenvalues or the square of the eigenvalues depending on the input matrix being a covariance matrix or not (see /SQEV).

The optional 1D output waves (W_RSD, W_RMS, W_IE, W_IND, W_PSL) are saved with wave scaling to make it easier to display the wave as a function of the number of factors.

ICA

pcsr

\texttt{pcsr(cursorName [, graphNameStr])}

The pcsr function returns the point number of the point which the specified cursor (A through J) is on in the top (or named) graph. When used with cursors on images or waterfall plots, pcsr returns the row number, and when used with a free cursor, it returns the relative X coordinate.

Parameters
cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.
When identifying a subwindow with \textit{graphNameStr}, see \textit{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.

\textbf{Details}

The pcsr result is not affected by any X axis.

\textbf{See Also}

The \texttt{hcsr}, \texttt{qcsr}, \texttt{vcsr}, \texttt{xcsr}, and \texttt{zcsr} functions.

\textit{Programming With Cursors} on page II-321.

\textbf{Pi}

\texttt{Pi}

The \texttt{Pi} function returns $\pi$ (3.141592...).

\textbf{PICTInfo}

\texttt{PICTInfo(pictNameStr)}

The \texttt{PICTInfo} function returns a string containing a semicolon-separated list of information about the named picture. If the named picture does not exist, then "" is returned. Valid picture names can be found in the Pictures dialog.

\textbf{Details}

The string contains six pieces of information, each prefaced by a keyword and colon and terminated with a semicolon.

\begin{tabular}{|l|l|}
\hline
\textbf{Keyword} & \textbf{Information Following Keyword} \\
\hline
\texttt{BYTES} & Amount of memory used by the picture. \\
\texttt{WIDTH} & Width of the picture in pixels. \\
\texttt{HEIGHT} & Height of the picture in pixels. \\
\texttt{PHYSWIDTH} & Physical width of the picture in points. \\
\texttt{PHYSHEIGHT} & Physical height of the picture in points. \\
\hline
\end{tabular}

\textbf{Examples}

Print \texttt{PICTInfo("PICT_0")}

will print the following in the history area:

\texttt{TYPE:PICT;BYTES:55734;WIDTH:468;HEIGHT:340;PHYSWIDTH:468;PHYSHEIGHT:340;}

\textbf{See Also}

The \texttt{ImageLoad} operation for loading PICT and other image file types into waves, and the \texttt{PICTList} function. The \texttt{StringFromList} operation for parsing the information string.

See \textit{Pictures} on page III-509 and \textit{Pictures Dialog} on page III-510 for general information on picture handling.

\textbf{PICTList}

\texttt{PICTList(matchStr, separatorStr, optionsStr)}

The \texttt{PICTList} function returns a string containing a list of pictures based on \texttt{matchStr} and \texttt{optionsStr} parameters. See \textit{Details} for information on listing pictures in graphs, panels, layouts, and the picture gallery.

\textbf{Details}

For a picture name to appear in the output string, it must match \texttt{matchStr} and also must fit the requirements of \texttt{optionsStr}. \texttt{separatorStr} is appended to each picture name as the output string is generated.
The name of each picture is compared to \textit{matchStr}, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

- "*" Matches all picture names.
- "xyz" Matches picture name xyz only.
- "*xyz" Matches picture names which end with xyz.
- "xyz*" Matches picture names which begin with xyz.
- "*xyz*" Matches picture names which contain xyz.
- "abc*xyz" Matches picture names which begin with abc and end with xyz.

\textit{matchStr} may begin with the ! character to return items that do not match the rest of \textit{matchStr}. For example:

- "!*xyz" Matches picture names which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of \textit{matchStr}.

\textit{optionsStr} is used to further qualify the picture.

Use "" accept all pictures in the Pictures Dialog that are permitted by \textit{matchStr}.

Use the WIN: keyword to limit the pictures to the named or target window:

- "WIN:" Match all pictures displayed in the top graph, panel, or layout.
- "WIN:windowName" Match all pictures displayed in the named graph, panel, or layout window.

\textbf{Examples}

\begin{verbatim}
PICTList("*", ";", "")
PICTList("*", ";", "WIN:")
PICTList("*_bkg", ";", "WIN:Layout0")
\end{verbatim}

Returs a list of all pictures in the Pictures Dialog.

Returs a list of all pictures displayed in the top panel, graph, or layout.

Returns a list of pictures whose names end in "_bkg" and which are displayed in Layout0.

\textbf{See Also}

The \texttt{ImageLoad} operation for loading PICT and other image file types into waves, and the \texttt{PICTInfo} function. Also the \texttt{StringFromList} function for retrieving items from lists.

See \texttt{Pictures} on page III-509 and \texttt{Pictures Dialog} on page III-510 for general information on picture handling.

\section*{Picture}

\textbf{Picture pictureName}

The Picture keyword introduces an ASCII code picture definition of binary image data.

\textbf{See Also}

Proc Pictures on page IV-56 for further information.

\section*{PixelFromAxisVal}

\begin{verbatim}
PixelFromAxisVal(graphNameStr, axNameStr, val)
\end{verbatim}

The PixelFromAxisVal function returns the local graph pixel coordinate corresponding to the axis value in the graph window or subwindow.

\textbf{Parameters}

\textit{graphNameStr} can be "" to refer to the top graph window.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

If the specified axis is not found and if the name is “left” or “bottom” then the first vertical or horizontal axis will be used.

If graphNameStr references a subwindow, the returned pixel value is relative to top left corner of base window, not the subwindow.

Axis ranges and other graph properties are computed when the graph is redrawn. Since automatic screen updates are suppressed while a user-defined function is running, if the graph was recently created or modified, you must call DoUpdate to redraw the graph so you get accurate axis information.

See Also
The AxisValFromPixel and TraceFromPixel functions.

PlayMovie

PlayMovie [flags] [as fileNameStr]

The PlayMovie operation opens a movie file in a window and plays it.

Parameters

The file to be opened is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details.

The file is passed to the operating system to be opened with the default program for the given filename extension and the /W flag is ignored.

On Macintosh, prior to Mac OS 10.15 (Catalina,) QuickTime could be used to play a movie in an Igor window and could be controlled using PlayMovieAction. Since QuickTime is no longer available, movies no longer open in Igor windows on any operating system and PlayMovieAction after PlayMovie is no longer of use.

Flags

/I This flag is obsolete and is ignored.

/M This flag is obsolete and is ignored.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/W=(left,top,right,bottom) This flag is obsolete and is ignored.

/Z No error reporting; an error is indicated by nonzero value of the variable V_flag. If the user clicks the cancel button in the Open File dialog, V_flag is set to -1.

Details

If the movie file to be played is not fully specified by /P and fileNameStr, PlayMovie displays an Open File dialog to let you choose a movie file. See Symbolic Paths on page II-22 and Path Separators on page III-451 for details.

See Also
Movies on page IV-245.

The PlayMovieAction operation.
PlayMovieAction

`PlayMovieAction [ /A/Z ] keyword [=value] [, keyword [=value]]`

The PlayMovieAction operation is used to extract frames from a movie file.

**Flags**

/A  Macintosh: /A is ignored.

Windows: Uses alternate deprecated technology, AVI instead of MMF.

/Z  Errors do not stop procedure execution. Use V_Flag to see if an error occurred.

**Keywords**

`extract`  Extracts current frame into an 8-bit RGB image wave named M_MovieFrame. (Can be combined with frame=e.)

`extract=e`  Extracts e frames into a single multiframe wave, M_MovieChunk. This wave will have 3 planes for RGB and will have e chunks.

e=1 is the same as plain extract.

For e>1, the current time is automatically updated.

`frame=f`  Moves to specified movie frame.

`getID`  Returns top movie ID number in V_Value. Do not use in same call with getTime.

`getTime`  Reads current movie time into variable V_value (in seconds).

`gotoBeginning`  Goes to beginning of movie.

`gotoEnd`  Closes the movie opened using the open keyword movie file.

`kill`  Closes open movie.

`loop=mode`  On Macintosh only, mode chooses between two extraction methods. The default, equivalent to loop=0, is fast but can not back up; an attempt to extract a frame previous to the last one extracted results in an error. The alternate method, loop=1, provides random access but can be very slow when reading sequential frames.

The loop keyword was added in Igor Pro 8.00. It is ignored on Windows.

`open=fullPath`  Opens the specified movie file to enable frame extraction. V_Flag is set to zero if no error occurred and V_Value is set to the file reference number.

`ref=refNum`  The ref keyword is used with all PlayMovieAction commands after using the open keyword to access a movie file. refNum must be the file reference number returned in V_Value in the open step.

The ref keyword is needed only if multiple files or windows are open. You can also use setFrontMovie to set the active movie.

`setFrontMovie= id`  Sets the movie with given id as the active movie file.

Do not use setFrontMovie and getID in same call to PlayMovieAction.

`start`  Obsolete. Movie windows are no longer supported in Igor itself.

`step=s`  Moves by s frames into movie (0 is same as 1, negative values move backwards).

`stop`  Obsolete. Movie windows are no longer supported in Igor itself.

**Details**

Operations are performed in the following order: kill, gotoBeginning, gotoEnd, frame, step, getTime, extract. kill overrides all other parameters.

If you want to extract a grayscale image, you can convert the RGB image into grayscale using the ImageTransform command as follows:
When you are finished extracting frames, use the kill keyword to close the file.

To get a full path for use with the open keyword, use the PathInfo or Open /D/R commands.

**Examples**

These commands show to determine the number of frames in a simple movie:

```plaintext
PlayMovieAction open = <full path to movie file>
PlayMovieAction gotoEnd,getTime
Variable tend= V_value
PlayMovieAction Step=-1,getTime
Print "frames= ",tend/(tend-V_value)
PlayMovieAction kill
```

Movies on page IV-245.

The PlayMovie operation.

---

### PlaySnd

**PlaySnd [flags] fileNameStr**

*Note:* PlaySnd is obsolete. Use PlaySound instead.

Available only on the Macintosh.

The PlaySnd operation plays a sound from the file’s data fork, or from an `snd` resource.

**Parameters**

The file containing the sound is specified by `fileNameStr` and `/P=pathName` where `pathName` is the name of an Igor symbolic path. `fileNameStr` can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with `pathName`, or the name of a file in the folder associated with `pathName`. If Igor can not determine the location of the file from `fileNameStr` and `pathName`, it displays a dialog allowing you to specify the file.

If you use a full or partial path for `fileNameStr`, see Path Separators on page III-451 for details on forming the path.

**Flags**

- `/I=resourceIndex` Specifies the `snd` resource to load by resource index, starting from 1.
- `/M=promptStr` Specifies a prompt if PlaySnd needs to put up a dialog to find the file.
- `/N=resNameStr` Specifies the resource to load by resource name.
- `/P=pathName` Specifies the folder to look in for the file. `pathName` is the name of an existing symbolic path.
- `/Q` Quiet: suppresses the insertion of `snd` info into the history area.
- `/R=resourceID` Specifies the `snd` resource to load by resource ID.
- `/Z` Does not play the sound, just checks for its existence.

**Details**

If none of `/I`, `/N` or `/R` are specified, PlaySnd tries to play a sound stored in the data fork of the file. If the file dialog is used, only files of type `sfil` are shown.

If any of `/I`, `/N` or `/R` are specified, PlaySnd tries to play a sound from an `snd` resource. Most programs store sounds in `snd` resources. If the file dialog is used, files of all types are shown.

If `/P=pathName` is omitted, then `fileNameStr` can take on three special values:

- "Clipboard" Loads data from Clipboard.
- "System" Loads data from System file.
“Igor” Loads data from Igor Pro application.

If you specify /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\\”. See Symbolic Paths on page II-22 for details.

There are no sounds in the Igor Pro application file.

If the file is not fully specified and fileNameStr is not one of these special values, then PlaySnd presents a dialog from which you can select a file. “Fully specified” means that Igor can determine the name of the file (from the fileNameStr parameter) and the folder containing the file (from the /P=pathName flag or from the fileNameStr parameter).

PlaySnd sets the variable V_flag to 1 if the sound exists and fits in available memory or to 0 otherwise.

If the sound exists, PlaySnd also sets the string variable S_Info to:

"SOURCE:sourceName;RESOURCENAME:resourceName;RESOURCEID:resourceID"

If the sound is not a resource then resourceName is "" and resourceID is 0. sourceName will be the name of the file that was loaded or “Clipboard”, “System” or “Igor”.

Examples

PlaySnd/I=1/P=mySnds/Z "Wild Eep"
If (V_flag) // Any 'snd ' in the "Wild Eep" file?
   Print S_info // Yes, print resource number, etc.
Endif

This prints the following into the history area:

SOURCE:resource fork;RESOURCENAME:Wild Eep;RESOURCEID:8;

PlaySound

PlaySound [/A=a] /BITS=bits /C] soundWave
PlaySound /A=a] /BITS=bits {soundWave1, soundWave2 [, soundWaveN…]}

The PlaySound operation plays the audio samples in the named wave. The various sound output parameters — number of samples, sample rate, number of channels, and number of bits of resolution — are determined by the corresponding parameters of the wave.

Flags

/A=[a] Plays sounds asynchronously so that sounds will continue to play after the command itself has executed.
   /A=0: Same as no /A flag.
   /A=1: Plays sounds asynchronously; same as /A.
   /A=2: Stop playing any current sound before starting this one.
   /A=3: Return with user abort error if output buffers are full (rather than waiting.)
     Use GetRTError(1) to detect and clear the error condition.

/BITS=bits Controls the number of bits used for each sound sample sent to the sound output hardware.

Use /BITS=24 with a 32-bit integer wave for 24-bit sound data capable of representing values from -8,388,608 to +8,388,607.

If you omit /BITS or use /BITS=0, PlaySound uses the wave’s data type and size to determine how many bits are used for each sound sample.

The /BITS flag was added in Igor Pro 9.00.

/C Obsolete - do not use.

On Windows /C causes sound wave data greater than 16-bits to be converted to 16-bit integer. Such data should range from -32768 to +32767.

On Macintosh /C is ignored.
Details
The wave’s time per point, as determined by its X scaling, must be a valid sampling rate. A value of 1/44100 (CD standard) is typical.

Sound waves can be 8, 16, or 32-bit signed integer waves, or single-precision floating point waves:

- 8-bit integer waves support a sample range of -128 to +127.
- 16-bit inter waves support a sample range of -32768 to +32767.
- 32-bit integer waves are used to hold both 24-bit and 32-bit audio. Use /BITS=24 to tell PlaySound that the wave contains 24-bit instead of 32-bit values.
- 32-bit floating point waves support a range of -1 to +1.

Do not use complex waves with PlaySound.

To play a stereo sound, provide a 2 column wave with the left channel in column 0. Actually, the software will attempt to play as many channels as there are columns in the wave. You can also use multiple 1D waves with the /A flag. To use this method, enclose the list of 1D waves in braces.

With the /A flag, the sound plays asynchronously (i.e., the command returns before the sound is finished). If another command is issued before the sound is finished then the new command will wait until the last sound finishes. A PlaySound without the /A flag can play on top of the current sound. The transition between sounds should be seamless on Macintosh but may be slightly delayed on Windows.

It is OK to kill the sound wave immediately after PlaySound returns even if the /A flag is used.

Examples
Under Windows, support for sound is somewhat idiosyncratic so these sound examples may not work correctly with your particular hardware configuration.

```
Make/B/O/N=1000 sineSound // 8 bit samples
SetScale/P x,0,1e-4,sineSound  // Set sample rate to 10Khz
sineSound= 100*sin(2*Pi*1000*x) // Create 1Khz sinewave tone
PlaySound sineSound
```

The following example will create a rising pitch in the left channel and a falling pitch in the right channel:

```
Make/W/O/N=(20000,2) stereoSineSound  // 16 bit data
SetScale/P x,0,1e-4, stereoSineSound  // Set sample rate to 10Khz
stereoSineSound= 20000*sin(2*Pi*(1000 + (1-2*q)*150*x)*x)
PlaySound/A stereoSineSound  // 16 bit, asynchronous
```

Multichannel sounds as in the previous example but from multiple 1D waves:

```
Make/W/O/N=20000 stereoSineSoundL,stereoSineSoundR // 16 bit data
SetScale/P x,0,1e-4, stereoSineSoundL, stereoSineSoundR // Set sample rate to 10Khz
stereoSineSoundL= 20000*sin(2*Pi*(1000 + 150*x)*x)  // rising pitch in left
stereoSineSoundR= 20000*sin(2*Pi*(1000 - 150*x)*x)  // falling in right
PlaySound/A {stereoSineSoundL, stereoSineSoundR} // two 1D waves
```

See Also
SoundLoadWave, SoundSaveWave

pnt2x

```
pnt2x(waveName, pointNum)
```

The pnt2x function returns the X value of the named wave at the point pointNum. The point number is truncated to an integer before use.

For higher dimensions, use IndexToScale.

Details
The result is derived from the wave’s X scaling, not any X axis of a graph it may be displayed in.

If you would like to convert a fractional point number to an X value you can use:

```
leftx(waveName) + deltax(waveName) * pointNum.
```

See Also
DimDelta, DimOffset, x2pnt, IndexToScale

Waveform Model of Data on page II-62 and Changing Dimension and Data Scaling on page II-68 for an explanation of waves and dimension scaling.
**Point**

The Point structure is used as a substructure usually to store the location of the mouse on the screen.

```cpp
Structure Point
  Int16 v
  Int16 h
EndStructure
```

**PointF**

The PointF structure is the same as Point but with floating point fields.

```cpp
Structure PointF
  Float v
  Float h
EndStructure
```

**poissonNoise**

```cpp
poissonNoise(num)
```

The poissonNoise function returns a pseudo-random value from the Poisson distribution whose probability distribution function is

\[
f(x; \lambda) = \frac{e^{-\lambda} \lambda^x}{x!}, \quad \lambda > 0, \quad x = 0, 1, 2, ...
\]

with mean and variance equal to \( \text{num} = \lambda \).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use `SetRandomSeed`. The algorithm uses the Mersenne Twister random number generator.

**See Also**

The `SetRandomSeed` operation.

**Noise Functions** on page III-390.

Chapter III-12, **Statistics** for a function and operation overview.

**poly**

```cpp
poly(coefsWaveName, x1)
```

The `poly` function returns the value of a polynomial function at \( x = x1 \).

`coefsWaveName` is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial.

If you use `poly` in a real expression, \( x1 \) must be real and `poly` returns a real value. The wave containing the coefficients can be real or complex. Complex coefficients are interpreted as `real(coef)`.

If you use `poly` in a complex expression, \( x1 \) must complex and `poly` returns a complex value. The wave containing the coefficients can be real or complex. Real coefficients are interpreted as `cmplx(coef, 0)`.

Support for complex expressions was added in Igor Pro 9.00.

**Examples**

```cpp
// Fill wave0 with 100 points containing the polynomial 1 + 2*x + 3*x^2 + 4*x^3
// evaluated over the range from x = -1 to x = 1
Make coefs = {1, 2, 3, 4} // f(x) = 1 + 2*x + 3*x^2 + 4*x^3
Make/N=100/O wave0; SetScale/I x, -1, 1, wave0
wave0 = poly(coefs, x)
Display wave0
```

**poly2D**

```cpp
poly2D(coefsWaveName, x1, y1)
```

The `poly2D` function returns the value of a 2D polynomial function at \( x = x1, y = y1 \).
The coefficients wave contains polynomial coefficients for low degree terms first. All coefficients for terms of a given degree must be present, even if they are zero. Among coefficients for a given degree, those for terms having higher powers of \( x \) are first. Thus, \texttt{poly2D} returns, for a coefficient wave \( \text{cw} \):

\[
\text{f}(x,y) = \text{cw}[0] + \text{cw}[1]*x + \text{cw}[2]*y + \text{cw}[3]*x^2 + \text{cw}[4]*x*y + \text{cw}[5]*y^2 + \ldots
\]

A 2D polynomial of degree \( N \) has \((N+1)(N+2)/2\) terms.

**Poly2D Example 1**

Fill \( \text{mat1} \) with the polynomial \( 1 + 2*x + 2.5*y + 3*x^2 + 3.5*x*y + 4*y^2 \) evaluated over the range \( x = (-1, 1) \) and \( y = (-1, 1) \):

```plaintext
Function Poly2DExample1()
    Make/O coefs1 = {1, 2, 2.5, 3, 3.5, 4}
    Make/N=(20,20)/O mat1
    SetScale/I x, -1, 1, mat1
    SetScale/I y, -1, 1, mat1
    mat1 = poly2D(coefs1, x, y)
    Display; AppendMatrixContour mat1
End
```

The polynomial is second degree, so the first command above made the wave \( \text{coefs} \) with six elements because \((2+1)(2+2)/2 = 6\).

**Poly2D Example 2**

Fill \( \text{mat2} \) with the polynomial \( 1 + 2*x + 3*y + 4*x^2 + 4*y^2 + 5*x^3 + 6*y^3 \) evaluated over the range \( x = (-1, 1) \) and \( y = (-1, 1) \). The first zero eliminates the second-order cross term \( x*y \) and the second and third zeros eliminate the third-order cross terms \( x^2*y \) and \( x*y^2 \):

```plaintext
Function Poly2DExample2()
    Make/O coefs2 = {1, 2, 3, 4, 0, 4, 5, 0, 0, 6}
    Make/N=(20,20)/O mat2
    SetScale/I x, -1, 1, mat2
    SetScale/I y, -1, 1, mat2
    mat2 = poly2D(coefs2, x, y)
    Display; AppendMatrixContour mat2
End
```

**Poly2D Example 3**

This example illustrates using \texttt{poly2D} in a complex expression:

```plaintext
Function Poly2DExample3()
    Make/N=(200,200)/C/O cMat3 // Complex-valued matrix
    SetScale/I x -pi,pi,cMat3
    SetScale/I y -pi,pi,cMat3
    Make/D/O coefs3={1,1.5,2,2.5,3,3.5}
    cMat3 = poly2d(coefs3, cmplx(sin(x),cos(y)), cmplx(cos(x),sin(y)))
    Display; Appendimage cMat3
    ModifyImage cMat3 ctab= {*,*,Rainbow256,0}
    ModifyImage cMat3 imCmplxMode=3 // Display the complex phase
End
```

**PolygonArea**

The \texttt{PolygonArea} function returns the area of a simple, closed, convex or nonconvex planar polygon described by consecutive vertices in \( x\text{Wave} \) and \( y\text{Wave} \).

A simple polygon has no internal “holes” and its boundary curve does not intersect itself. Both \( x\text{Wave} \) and \( y\text{Wave} \) must be 1D, real, numerical waves of the same dimensions. The minimum number of vertices is 3. The function uses the shoelace algorithm to compute the area (see theorem 1.3.3 in the reference below). If there is any error in the input, the function returns NaN.
Example

Function estimatePi(num)
  Variable num
  Make/O/N=(num+1) xxx,yyy
  xxx=sin(2*pi*x/num)
  yyy=cos(2*pi*x/num)
  Printf "Relative Error=%g\r",(pi-PolygonArea(xxx,yyy))/pi
End

areaXY, faverageXY, PolygonOp

References

PolygonOp

*PolygonOp [flags] [keyword=***value***]*

The PolygonOp operation performs operations on planar polygons. Polygons and polygon paths are represented by XY pairs of waves with NaNs separating closed polygons.

The operation performed is specified using the operation keyword. The resulting polygon is returned as an XY pair of waves as specified by the /DSTX and /DSTY flags.

PolygonOp uses the clipper library by Angus Johnson. It was added in Igor Pro 9.00.

Flags

/ADDR=**addingRule**

*addingRule* determines how the primary and secondary polygons are added to the primary and secondary paths. The interior of the polygon is defined as the region that would be "filled" using one of the standard fill rules. The even-odd rule applies to scan lines while the other rules are based on winding counts.

*addingRule* is one of the following:

0: Even-odd (default). All odd numbered sub-regions are filled, while even numbered sub-regions are not filled.
1: Non-zero. All non-zero winding subregions are filled.
2: Positive. All sub-regions with winding counts>0 are filled.
3: Negative. All sub-regions with winding counts<0 are filled.

/NCFP

Disables closing the resulting polygons by connecting the last vertex to the first vertex of each output path.

/DIST=**dist**

Specifies the distance in scaled units (see the /SM flag) below which vertices are stripped. The default value is approximately sqrt(2).

/DSTX=**destX**

Specifies the X destination wave. The output is corrected for any scaling (see /SM below).

In a user-defined function, if **destX** is a simple wave name, PolygonOp automatically creates a real wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-72 for details.

If you omit /DSTX, the X destination wave defaults to polyOpWaveX in the current data folder.

If **destX** is a simple name and you include /FREE, the X destination is created as a free wave.
PolygonOp

/DSTY=destY Specifies the Y destination wave. The output is corrected for any scaling (see /SM below).

In a user-defined function, if destY is a simple wave name, PolygonOp automatically creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-72 for details.

If you omit /DSTY, the Y destination wave defaults to polyOpWaveX in the current data folder.

If destY is a simple name and you include /FREE, the Y destination is created as a free wave.

/FA Computes the final area of the resulting polygon and stores it in V_area. This is an algebraic (signed) area in contrast to the area returned by PolygonArea which is always non-negative.

/FREE Creates the output waves specified by /DSTX and /DSTY as free waves.

/JTYP=jointType Specifies the joint type used when offsetting a polygon. The following joint types are supported:

0: Square joint
1: Round joint
2: Miter joint

Square and round joints may give rise to additional vertices along the path.

/MLMT=miterLimit When the path consists of two edges connected at an acute angle, the offset could give rise to very long spikes. The miter limit sets the maximum distance in multiples of the offset that vertices can be offset from their original positions before a square joint (see /JTYP) is used. The default value for miterLimit is 2. The miterLimit parameter is scaled by /SM scaleFactor.

/OFST=offset Applies an offset to the final polygon. For example, if the polygon represents a rectangle, a positive offset creates an inscribing rectangle while a negative offset creates an inscribed rectangle. If the command includes a binary operation between primary and secondary polygon paths then the offset applies to the result of the binary operation. The offset parameter is scaled by /SM scaleFactor.

/Q Quiet mode. Do not print any information in the history area of the command window.

/RPRC=rPrecision The rounding precision rPrecision specifies the maximum distance in scaled units that a line segment can deviate from the exact arc. This applies only when /JTYP=1 and when offsetting a polygon. The rPrecision parameter is scaled by /SM scaleFactor.

/SM=[scaleMethod [,scaleFactor]]
Specifies a scaling method and a scaling factor used when converting the input data into the internal integer representation employed by the algorithm.

scaleMethod is one of the following:
0: No scaling. Floating point vertex locations are converted to integers by simple truncation:
\[ V_c = \text{trunc}(V_{in}) \]
1: Multiplication by scaleFactor followed by truncation to integer:
\[ V_c = \text{trunc}(V_{in} \times \text{scaleFactor}) \]
2: Scaling followed by rounding to integer:
\[ V_c = \text{round}(V_{in} \times \text{scaleFactor}) \]

scaleFactor must be a finite positive number and defaults to 1.0. All scaling is reversed on output using multiplication by the reciprocal of scaleFactor. Depending on the range of your data you may be able to use a scale factor which improves the resolution of the calculation. For example, if your data are \( O(1) \) and you use a scale factor of 10 or 100 the resulting conversion into integers will be more accurate. On the other hand, if your data are \( O(2^{30}) \) a scale factor greater than 1 is not ideal.

/SPT=(testPointX, testPointY)
Specifies a single point for testing if the point is inside the primary path polygon. The coordinates of point are scaled using the same scaling as the primary waves. The result of the test is stored in V_value as 0 if that the point is outside the polygon, 1 if that the point is inside the polygon, and 2 if the point is on the boundary of the polygon.

/Z Suppresses error reporting. If you use /Z, check the V_Flag output variable to see if the operation succeeded.
Keywords

operation=op

You can omit the operation=op pair when you are applying an offset to the primary polygon or when testing for pointsInPoly. Otherwise, op is one of the following:

opN is one of the following:

**Intersection**

Computes the intersection of the region defined by the primary path or paths and the region defined by the secondary path or paths.

**Union**

Computes the union between the region defined by the primary path or paths and the region defined by the secondary path or paths.

**Difference**

Computes the difference between the region defined by the primary path or paths and the region defined by the secondary path or paths.

**XOR**

Computes the exclusive OR between the regions defined by the primary path or paths and the regions defined by the secondary path or paths. This includes all regions where either the primary or secondary polygons are filled but not where both are filled.

**PointInPoly**

Tests if the points specified by pointsWaves are inside the target polygon. The results are stored in the unsigned byte wave W_inPoly in the current data folder: 0 for a point outside, 1 for a point inside, and 2 for a point on the boundary.

The target polygon is defined by primaryWaves. The tested points are internally scaled with the same scaling method (/SM) that applies to primary waves. You can perform this test on a target polygon that is a result of any binary polygon operation if you only specify the pointsWaves, for example:

```
PolygonOp operation=union,
primaryWaves={wx,wy}, secondarywaves={sx,sy},
pointsWaves={px,py}
```

**Area**

Computes the polygon area and stores it in V_area when

**CleanPolygon**

Removes vertices from the primary paths that satisfy one of the following conditions:

1. The vertices lie on a co-linear edge. For every three vertices the middle vertex is removed if it lies close enough (see /DIST above) to the edge connecting the vertices on both of its sides.

2. The vertices are situated below a critical distance from an adjacent vertex (see /DIST above).

See also the Simplify operation.

**MinkowskiDiff**

If the primary and secondary paths represent sets of vectors, the Minkowski difference of the two sets is defined as the set formed by subtracting each vector in the primary set from each vector in the secondary set.

**MinkowskiSum**

If the primary and secondary paths represent sets of vectors, the Minkowski sum of the two sets is defined as the set formed by adding each vector in the primary set to each vector in the secondary set.

**Simplify**

Removes self-intersections from the input polygons. In case of touching vertices the resulting polygon is split into two polygons.

**Reverse**

Reverses the polygon paths.

pointsWaves=[pointsXWave, pointsYWave]
PolygonOp performs various operations on polygon paths that are defined by pairs of 1D real numeric waves. A path is defined by an XY pair of waves that may describe one or more closed polygons. Consecutive polygons are separated by a NaN value in both path waves.

You must always specify the primary path waves. You must specify the secondary waves if you need to perform a binary polygon operation.

To simplify the computation the input waves are internally mapped into 32-bit signed integer arrays so that vertices correspond to discrete integer pairs (pixels).

To support a broad range of inputs, the operation allows you to specify how the input waves are scaled into integers. Scaling is isotropic; there is currently no support for anamorphic scaling. The scaling factor determines the number of significant figures that remain after conversion to integers. In extreme cases it is advisable to preprocess the polygon waves, e.g., by removing a mean offset and/or applying anamorphic scaling. On output, an inverse scaling is applied with no compensation for the initial truncation or rounding. The inverse scaling is also applied to area calculations.

**Output Variables**

PolygonOp sets the following output variables:

- **V_flag**: Zero if the operation succeeds or to a non-zero error code.
- **V_value**: The pointInPolyResult result for a single point specified using /SPT.
- **V_area**: The area of the resulting polygon corrected for scaling.
- **S_waveNames**: Semicolon separated list of the names of the waves created by the operation.

DrawPoly, FindPointsInPoly, PolygonArea

Demos

Choose Files→Example Experiments→Feature Demos 2→PolygonOp Demo.

**popup**

The popup keyword is used with Prompt statements in Functions and Macros. It indicates that you want a pop-up menu instead of the normal text entry item in a DoPrompt simple input dialog (or a Macro’s missing parameter dialog (archaic)). menuList is a string expression containing a list of items, separated by semicolons, that are to appear in the pop-up menu.

Pop-up menus accept both numeric and string parameters. For numeric parameters, the number of the item selected is placed in the variable. Numbering starts from one. For string parameters, the selected item’s text is placed in the string variable.
PopupContextualMenu

Pop-up items support all of the special characters available for user-defined menu definitions (see Special Characters in Menu Item Strings on page IV-133) with the exception that items in pop-up menus are limited to 50 bytes, keyboard shortcuts are not supported, and special characters must be enabled.

See Also
Prompt, DoPrompt, and Pop-Up Menus in Simple Dialogs on page IV-145.

See WaveList, TraceNameList, ContourNameList, ImageNameList, FontList, MacroList, FunctionList, StringList, and VariableList for functions useful in generating lists of Igor objects.

Chapter III-14, Controls and Control Panels for details about control panels and controls.

PopupContextualMenu

PopupContextualMenu [ /C=(xpix, ypix) /N /ASYN[=func] ] popupStr

The PopupContextualMenu operation displays a pop-up menu.

The menu appears at the current mouse position or at the location specified by the /C flag.

The content of the menu is specified by popupStr as a semicolon-separated list of items or, if you include the /N flag, by a user-defined menu definition referred to by the name contained in popupStr.

If you omit the /ASYN flag, the menu is tracked and the operation does not return until the user makes a selection or cancels the menu by clicking outside of its window.

If you include /ASYN, the menu is displayed and the operation returns immediately. When the user makes a selection, then the result is sent to the specified function or to the user-defined menu’s execution text. You can use /ASYN to allow a background task to continue while a contextual menu is popped up. /ASYN requires Igor Pro 7.00 or later.

Parameters
If popupStr specifies the pop-up menu’s items (/N is not specified), then popupStr is a semicolon-separated list of items such as “yes;no;maybe;”, or a string expression that returns such a list, such as TraceNameList.

The menu items can be formatted and checkmarked, like user-defined menus can. See Special Characters in Menu Item Strings on page IV-133.

If /N is specified, popupStr must be the name of a user-defined menu that also has the popupcontextualmenu keyword. See Example 3.
Flags

/ASYN
When used with /N: The user-defined menu is displayed and operation returns immediately. The result of menu selection is handled by the user-defined menu’s execution text. See User-Defined Menus on page IV-125.

/ASYN=func
When used without /N: The user-defined menu is displayed and operation returns immediately. The result of menu selection or cancellation is handled by calling the named function, which must have the following format:

```
Function func(popupStr, selectedText, menuItemNum)
    String popupStr
    String selectedText
    Variable menuItemNum
```

In Igor Pro 8.05 and later, if the user cancels the menu selection, selectedText will be "" and menuItemNum will be 0.

/C=(xpix, ypix)
Sets the coordinates of the menu’s top left corner.
Units are in pixels relative to the top-most window or the window specified by /W, like the MOUSEX and MOUSEY values passed to a window hook. See the window hook example, below and SetWindow.

If /C is not specified, the menu’s top left corner appears at the current mouse position.

/N
Indicates that popupStr contains the name of a menu definition instead of containing a list of menu items.

/W=winName
The /C coordinates are relative to the top/left corner of the named window or subwindow. If you omit /W, /C uses the top-most window having focus.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/W was added in Igor Pro 7.00.

Details

If you omit /N and /ASYN, PopupContextualMenu sets the following variables:

V_flag=0
User cancelled the menu without selecting an item, or there was an error such as an empty popupStr.

V_flag=1
1 if the first menu item was selected, 2 for the second, etc.

S_selection
"" if the user cancelled or error, else the text of the selected menu item.
If you include /N and omit /ASYN, PopupContextualMenu sets the following variables in a manner similar to GetLastUserMenuInfo:

V_kind  The kind of menu that was selected:

<table>
<thead>
<tr>
<th>V_kind</th>
<th>Menu Kind</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal text menu item, including Optional Menu Items (see page IV-130) and Multiple Menu Items (see page IV-131).</td>
</tr>
<tr>
<td>3</td>
<td>&quot;<em>FONT</em>&quot;</td>
</tr>
<tr>
<td>6</td>
<td>&quot;<em>LINESTYLEPOP</em>&quot;</td>
</tr>
<tr>
<td>7</td>
<td>&quot;<em>PATTERNPOP</em>&quot;</td>
</tr>
<tr>
<td>8</td>
<td>&quot;<em>MARKERPOP</em>&quot;</td>
</tr>
<tr>
<td>9</td>
<td>&quot;<em>CHARACTER</em>&quot;</td>
</tr>
<tr>
<td>10</td>
<td>&quot;<em>COLORPOP</em>&quot;</td>
</tr>
<tr>
<td>13</td>
<td>&quot;<em>COLORTABLEPOP</em>&quot;</td>
</tr>
</tbody>
</table>

See Specialized Menu Item Definitions on page IV-132 for details about these special user-defined menus.

V_flag -1 if the user didn't select any item, otherwise V_flag returns a value which depends on the kind of menu the item was selected from:

<table>
<thead>
<tr>
<th>V_kind</th>
<th>V_flag Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Text menu item number (the first menu item is number 1).</td>
</tr>
<tr>
<td>3</td>
<td>Font menu item number (use S_selection, instead).</td>
</tr>
<tr>
<td>6</td>
<td>Line style number (0 is solid line)</td>
</tr>
<tr>
<td>7</td>
<td>Pattern number (1 is the first selection, a SW-NE light diagonal).</td>
</tr>
<tr>
<td>8</td>
<td>Marker number (1 is the first selection, the X marker).</td>
</tr>
<tr>
<td>9</td>
<td>Character as an integer, = char2num(S_selection). Use S_selection instead.</td>
</tr>
<tr>
<td>10</td>
<td>Color menu item (use V_Red, V_Green, V_Blue, and V_Alpha instead).</td>
</tr>
<tr>
<td>13</td>
<td>Color table list menu item (use S_selection instead).</td>
</tr>
</tbody>
</table>

S_selection The menu item text, depending on the kind of menu it was selected from:

<table>
<thead>
<tr>
<th>V_kind</th>
<th>S_selection Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Text menu item text.</td>
</tr>
<tr>
<td>3</td>
<td>Font name or &quot;default&quot;.</td>
</tr>
<tr>
<td>6</td>
<td>Name of the line style menu or submenu.</td>
</tr>
<tr>
<td>7</td>
<td>Name of the pattern menu or submenu.</td>
</tr>
<tr>
<td>8</td>
<td>Name of the marker menu or submenu.</td>
</tr>
<tr>
<td>9</td>
<td>Character as string.</td>
</tr>
<tr>
<td>10</td>
<td>Name of the color menu or submenu.</td>
</tr>
<tr>
<td>13</td>
<td>Color table name.</td>
</tr>
</tbody>
</table>
In the case of **Specialized Menu Item Definitions** (see page IV-132), `S_selection` will be the title of the menu or submenu, etc.

**V_Red, V_Green, V_Blue, V_Alpha**

If a user-defined color menu ("COLORPOP" menu item) was selected then these values hold the red, green, and blue values of the chosen color. The values range from 0 to 65535 - see **RGBA Values**.

Will be 0 if the last user-defined menu selection was not a color menu selection.

If you include /N and /ASYN, `PopupContextualMenu` sets the following variables:

V_flag=0
There was an error such as an empty `popupStr` or `popupStr` did not name a compiled user-defined menu.

V_flag=-1
No error. The named user menu was valid and no item was selected yet.

S_selection    

If you include /N and omit /ASYN, `PopupContextualMenu` sets the following variables:

V_flag=0
There was an error such as an empty `popupStr`.

V_flag=-1
No error. `popupStr` was valid and no item was selected yet.

S_selection    

**Examples**

**Example 1 - `popupStr` contains a list of menu items**

// Menu formatting example

String checked= "\M0!:" + num2char(18) + ":"   // checkmark code
String items= "first;\M1-;"+checked+"third;"    // 2nd is divider, 3rd is checked

`PopupContextualMenu` items

switch( V_Flag )
  case 1:
    // do something because first item was chosen
    break;
  case 3:
    // do something because first item was chosen
    break;
endswitch

**Example 2 - `popupStr` contains a list of menu items**

// Window hook example

SetWindow kwTopWin hook=TableHook, hookevents=1     // mouse down events
Function TableHook(infoStr)
  String infoStr
  Variable handledEvent=0
  String event= StringByKey("EVENT",infoStr)
  strswitch(event)
    case "mousedown":
      Variable isContextualMenu= NumberByKey("MODIFIERS",infoStr) & 0x10
      if( isContextualMenu )
        Variable xpix= NumberByKey("MOUSEX",infoStr)
        Variable ypix= NumberByKey("MOUSEY",infoStr)
        `PopupContextualMenu/C=(xpix,ypix) "yes;no;maybe;"` strswitch(S_selection)
          case "yes":
            // do something because "yes" was chosen
            break
          case "no":
            break
          case "maybe":
            // do something because "maybe" was chosen
            break
  endswitch
Example 3 - popupStr contains the name of a user-defined menu

// User-defined contextual menu example
// dynamic menu (to keep WaveList items updated), otherwise not required.
// contextualmenu keyword is required, and implies /Q for all menu items.
//
// NOTE: Actions here are accomplished by the menu definition's
// execution text, such as DoSomethingWithColor.
// See Example 4 for another approach.
//
Menu "ForContext", contextualmenu, dynamic
 "Hello", Beep
 Submenu "Color"
 "*COLORPOP*", DoSomethingWithColor()
 End
 Submenu "Waves"
 WaveList("*",";",""), /Q, DoSomethingWithWave()
 End

Function DoSomethingWithColor()
 GetLastUserMenuInfo
 Print V_Red, V_Green, V_Blue, V_Alpha
 End

Function DoSomethingWithWave()
 GetLastUserMenuInfo
 WAVE w = $S_value
 Print "User selected "+GetWavesDataFolder(w,2)
 End

// Use this code in a function or macro:
PopupContextualMenu/N "ForContext"
if( V_flag < 0 )
 Print "User did not select anything"
endif

Example 4 - popupStr contains the name of a user-defined menu

// User-defined contextual menu example

Menu "JustColorPop", contextualmenu
 "*COLORPOP*(65535,0,0)", ;// initially red, empty execution text
 End

// Use this code in a function or macro
PopupContextualMenu/C=(xpix, ypix)/N "JustColorPop"
if( V_flag < 0 )
 Print "User did not select anything"
else
 Print V_Red, V_Green, V_Blue, V_Alpha
endif

Example 5 - popupStr contains a list of menu items, asynchronous popup result

Function YourFunction()
 // Use this code in a function or macro:
 PopupContextualMenu/ASYN=Callback "first;second;third;"
 (YourFunction continues...)
 End

// Routine called when/if popup menu item is selected. selectedItem=1 is the first item.
Function Callback(String list, String selectedText, Variable selectedItem)
PopupMenu

PopupMenu \([/Z] \) \textit{ctrlName} \([\textit{keyword} = \textit{value} [, \textit{keyword} = \textit{value} ...]]\)

The PopupMenu operation creates or modifies a pop-up menu control in the target or named window. For information about the state or status of the control, use the \texttt{ControlInfo} operation.

**Parameters**

- \textit{ctrlName} is the name of the PopupMenu control to be created or changed.

The following keyword=value parameters are supported:

- **align**=alignment  
  Sets the alignment mode of the control. The alignment mode controls the interpretation of the \textit{leftOrRight} parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

  If \textit{alignment}=0 (default), \textit{leftOrRight} specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

  If \textit{alignment}=1, \textit{leftOrRight} specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

- **appearance**={kind \[, platform\]}  
  Sets the appearance of the control. \textit{platform} is optional. Both parameters are names, not strings.

  \textit{kind} can be one of \texttt{default}, \texttt{native}, or \texttt{os9}.

  \textit{platform} can be one of \texttt{Mac}, \texttt{Win}, or \texttt{All}.

  See \texttt{Button} and \texttt{DefaultGUIControls} for more appearance details.

- **bodyWidth**=width  
  Specifies an explicit size for the body (nontitle) portion of a PopupMenu control. By default (bodyWidth=0), the body portion autosizes depending on the current text. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.

- **disable**=d  
  Sets user editability of the control.

  \(d=0\): Normal.

  \(d=1\): Hide.

  \(d=2\): Draw in gray state; disable control action.

---

Example 6 - popupStr contains the name of a user-defined menu, asynchronous popup result

Function YourFunction()
  PopupContextualMenu/ASYN/N "ForContext"
  (YourFunction continues...)
End

// Selection result is handled in "ForContext" menu's execution texts, as in Example 4

Creating a Contextual Menu on page IV-162, User-Defined Menus on page IV-125.

Special Characters in Menu Item Strings on page IV-133.

Chapter III-14, Controls and Control Panels, for details about control panels and controls.

The \texttt{SetWindow} and \texttt{PopupMenu} operations.
**PopupMenu**

**fColor**(r,g,b[,a])  Sets the initial color of the title.  r, g, b, and a specify the color and optional opacity as RGBA Values. The default is opaque black.

To further change the color of the title text, use escape sequences as described for title=titleStr.

**focusRing**=fr Enables or disables the drawing of a rectangle indicating keyboard focus:

fr=0: Focus rectangle will not be drawn.
fr=1: Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

**font**="fontName"  Sets the font used for the pop-up title, e.g., font="Helvetica".

**fs** Sets the font size for the pop-up title.

**fstyle**=fs  fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:

Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

**help**=helpStr  Sets the help for the control.

dlhelpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).

You can insert a line break by putting “\r” in a quoted string.

**mode**=m  Specifies the pop-up title location.

m=0: Title is in pop-up menu.

m=1: Title is to the left of pop-up menu, the chosen menu item appears in the pop-up menu, and menu item number m is initially selected.

**noproc**  Specifies that no procedure is to execute when choosing in the pop-up menu.

**popColor**(r,g,b[,a])  Specifies the color initially chosen in the color pop-up palette.  r, g, b, and a specify the color and optional opacity as RGBA Values. See the Colors, Color Tables, Line Styles, Markers, and Patterns section.

**popmatch**=matchStr  Sets mode to the enabled menu item that matches matchStr. matchStr may be a "wildcard" expression. See StringMatch. If no item is matched, mode is unchanged.

**popvalue**=valueStr  Sets the string displayed by the menu when first created, if mode is not zero. See Popvalue Keyword section.

**pos**=[leftOrRight,top]  Sets the position in Control Panel Units of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

**pos+=**=[dx,dy]  Offsets the position of the pop-up in Control Panel Units.

**proc**=procName  Specifies the procedure to execute when the pop-up menu is clicked. See Pop-up Menu Action Procedure below.

**rename**=newName  Gives pop-up menu a new name.

**size**=[width,height]  Sets pop-up menu size in Control Panel Units.
PopupMenu

| title=titleStr | Sets title of pop-up menu to the specified string expression. Defaults to "" (no title). Using escape codes you can change the font, size, style, and color of the title. See Annotation Escape Codes on page III-53 or details. |
| userdata(UDName)=UDStr | Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create. You can retrieve the data using GetUserData. |
| userdata(UDName)++=UDStr | Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr. |
| value=itemListSpec | Specifies the pop-up menu's items. itemListSpec can take several forms as described below under Setting The Popup Menu Items. |
| win=winName | Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy. |

Flags
/Z No error reporting.

Details
The target window, or the window named with the win=winName keyword, must be a graph or panel.

Pop-up Menu Action Procedure
The action procedure for a pop-up menu control takes a predefined WMPopupAction structure as a parameter to the function:

Function PopupMenuAction(PU_Struct) : PopupMenuControl
    STRUCT WMPopupAction &PU_Struct
    ...
    return 0
End

The ": PopupMenuControl" designation tells Igor to include this procedure in the list of available popup menu action procedures in the PopupMenu Control dialog used to create a popup menu.

See WMPopupAction for details on the WMPopupAction structure.
Although the return value is not currently used, action procedures should always return zero.

You may see an old format pop-up menu action procedure in old code:

Function PopupMenuAction (ctrlName,popNum,popStr) : PopupMenuControl
    String ctrlName
    Variable popNum // which item is currently selected (1-based)
    String popStr // contents of current popup item as string
    ...
    return 0
End

This old format should not be used in new code.

Setting The Popup Menu Items
This section discusses popup menus containing lists of text items. The next section discusses popup menus for choosing colors, line styles, markers and patterns.

The items in the popup menu are determined by the itemListSpec parameter used with the value keyword. itemListSpec can take several different forms from simple to complex.

No matter what the form, Igor winds up storing an expression that returns a string in the popup menu's internal structure. This expression may be a literal string ("Red;Green;Blue;"), a call to a built-in or user-defined function that returns a string, or the path to a global string variable. Igor evaluates this expression
when the popup menu is first created and again each time the user clicks on the menu. You can see the string expression for a given popup menu using the PopupMenu Control dialog.

The right form for `itemListSpec` depends on your application. Here is a guide to choosing the right form with the simpler forms first.

**A literal string expression**

Use this if you know the items you want in your popup menu when you write the PopupMenu call. For example:

```math
Function PopupDemo1() // Literal string
    NewPanel
    PopupMenu popup0, value="Red;Green;Blue;"
End
```

This method is limited to 2500 bytes of menu item text.

**A function call**

Use this if you need to compute the popup menu item list when the user clicks the popup menu. The function must return a string containing a semicolon-separated list of menu items. This example creates a popup menu which displays the name of each wave in the current data folder at the time the menu is clicked:

```math
Function PopupDemo2() // Built-in function
    NewPanel
    PopupMenu popup0, value=WaveList("*", ";", ")
End
```

You can also use a user-defined function. This example shows how to list waves from other than the current data folder:

```math
Function/S MyPopupWaveList()
    DFREF saveDF
    // Create some waves for demo purposes
    saveDF = GetDataFolderDFR()
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S PopupMenuDemo
    Make/O demo0, demo1, demo2
    SetDataFolder saveDF
    saveDF = GetDataFolderDFR()
    SetDataFolder root:Packages:PopupMenuDemo
    String list = WaveList("*", ";", ")
    SetDataFolder saveDF
    return list
End
```

```math
Function PopupDemo3() // User-defined function
    NewPanel
    PopupMenu popup0, value=MyPopupWaveList()
End
```

**# followed by a local string variable specifying items**

Use this when the popup menu item list is not known when you write the code but you can compute it at runtime. For example:

```math
Function PopupDemo4() // Local string variable specifying items
    NewPanel
    String quote = \"\"
    String list
    if (CmpStr(IgorInfo(2),\"Windows\") == 0)
        list = quote + \"Windows XP; Windows VISTA;\" + quote
    else
        list = quote + \"Mac OS X 10.4; Mac OS X 10.5;\" + quote
    endif
    PopupMenu popup0, value=#list
End
```

The strange-looking use of the quote string variable is necessary because the parameter passed to the `value=#` keyword is evaluated once when the PopupMenu command executes and the result of that
PopupMenu evaluation is evaluated again when the PopupMenu is created or clicked. The result of the first evaluation must be a legal string expression.

This method is limited to 2500 bytes of menu item text.

# followed by a local string variable specifying a function

Use this when you need to compute the popup menu item list at click time and you need to select the function which computes the list when the popup menu is created. For example:

Function/S WindowsItemList()
  String list
  list = "Windows XP; Windows VISTA;"
  return list
End

Function/S MacItemList()
  String list
  list = "Mac OS X 10.4;Mac OS X 10.5;"
  return list
End

Function PopupDemo5() // Local string variable specifying function
  String listFunc
  if (CmpStr(IgorInfo(2),"Windows") == 0)
    listFunc = "WindowsItemList()"
  else
    listFunc = "MacItemList()"
  endif
  NewPanel
  PopupMenu popup0, value=#listFunc
End

This form is useful when you create a control panel in an independent module. Since the control panel runs in the global name space, you must specify the independent module name in the invocation of the function that provides the popup menu items. For example:

// Calling a non-static function in an independent module from #included code
#pragma IndependentModuleName=IM
.
String listFunc= GetIndependentModuleName()+"#PublicFunctionInIndepMod()"
PopupMenu popup0, value=#listFunc

// Calling a static function in an independent module from #included code
#pragma IndependentModuleName=IM
#pragma ModuleName=ModName
.
String listFunc= GetIndependentModuleName()+"#ModName#StaticFunctionInIndepMod()"
PopupMenu popup0, value=#listFunc

We use GetIndependentModuleName rather than hard-coding the name of the independent module so that the code will continue to work if the name of the independent module is changed. Also, because this code does not depend on the specific name of the independent module, it can be added to an independent module via a #included procedure file.

Also see GetIndependentModuleName and Independent Modules and Popup Menus on page IV-241.

# followed by a quoted literal path to a global string variable

Use this if you want to compute the popup menu item list before it is clicked, not each time it is clicked. This would be advantageous if it takes a long time to compute the item list, and the list changes only at well-defined times when you can set the global string variable.

The global string variable must exist when the PopupMenu command executes and when the menu is clicked. In this example, the gPopupMenuItems global string variable is created and initialized when the popup menu is created but can be changed to a different value later before the menu is clicked:

Function PopupDemo6() // Global string variable containing list
  NewDataFolder/O root:Packages
  NewDataFolder/O root:Packages:PopupMenuDemo
  String/G root:Packages:PopupMenuDemo:gPopupMenuItems = "Red;Green;Blue;"
  NewPanel
  PopupMenu popup0, value="root:Packages:PopupMenuDemo:gPopupMenuItems"
End
PopupMenu

# followed by a local string variable containing a path to a global string variable
Use this when the popup menu item list contents will be stored in a global string variable whose location
is not known until the popup menu is created. For example:

Function PopupDemo7() // Local string containing path to global string
    String graphName = WinName(0, 1, 1)// Name of top graph
    if (strlen(graphName) == 0)
        Print "There are no graphs."
        return -1
    endif
    NewDataFolder/O root:Packages
    NewDataFolder/O root:Packages:PopupMenuDemo
    // Create data folder for graph
    NewDataFolder/O root:Packages:PopupMenuDemo:$\{graphName\}
    String list = "Red;Green;Blue;";
    String/G root:Packages:PopupMenuDemo:$\{graphName\}:gPopupMenuItems = list
    NewPanel
    String path // Local string containing path to global string
    path = "root:Packages:PopupMenuDemo:" + graphName + ":gPopupMenuItems"
    PopupMenu popup0, value=#path
    return 0
End

Colors, Color Tables, Line Styles, Markers, and Patterns
You can create PopupMenu controls for color, color tables, line style (dash modes), markers, and patterns.
To do so, simply specify the itemListSpec parameter to the value keyword as one of "*COLORPOP*",
"*COLORTABLEPOP*", "*COLORTABLEPOPNAMES*", "*LINESTYLEPOP*", "*MARKERPOP*", or
"*PATTERNPOP*". In these modes the body of the control will contain a color box, a color table (gradient),
a line style sample, a marker, or a pattern sample.

For these special pop-up menus, mode=0 ("Title in Box" checked) is not used.

For a line style pop-up menu, the mode value is the line style number plus one. Thus line style 0 (a solid
line) is mode=1.

For a marker pop-up, the mode value is the marker number plus one, and marker 0 (the + marker) is mode=1.

For a pattern pop-up, the mode value is the SetDrawEnv fillPat number minus 4, so mode=1 corresponds
to fillPat=5, the SW-NE lines fill pattern shown above.

For a color table pop-up, the mode value is the CTabList() index plus 1, so mode=1 corresponds to the first
item in the list returned by CTabList, which is “Grays”:

ControlInfo $ctrlName // Sets V_Value
Print StringFromList(V_Value-1,CTabList()) // Prints "Grays"

ControlInfo also returns the color table name in S_Value.

To set the pop-up to a given color table name, you can use code like this:

Variable m = 1 + WhichListItem(ctabName, CTabList())
PopupMenu $ctrlName mode=m

For color pop-up menus, you set the current value using the popColor=(r,g,b|a) keyword. On output
(via the popStr parameter of your action procedure or via the S_value output from ControlInfo) the color
is encoded as "(r,g,b)" or "(r,g,b,a)". To get these numerical values, you can extract them from the string
using the MyRGBStrToRGB function below or use ControlInfo which sets V_Red, V_Green, V_Blue and
V_Alpha.

The following example demonstrates the line style and color pop-up menus. To run the example, copy the
following code to the procedure window of a new experiment and then run the panel macro.

Window Panel0() : Panel
    PauseUpdate; Silent 1 // building window ...
    NewPanel /W=(150,50,400,182)
    PopupMenu popup0,pos={74,31},size={96,20},proc=ColorPopMenuProc,title="colors"
    PopupMenu popup0,pos={9,68},size={221,20},mode=1,popColor= (0,65535,65535),value= "*COLORPOP*"
    "*COLORPOP*"
PopupMenu popup1, title="line styles", mode=1, value="*LINESTYLEPOP*"
EndMacro

Function ColorPopMenuProc(ctrlName, popNum, popStr) : PopupMenuControl
    String ctrlName
    Variable popNum
    String popStr
    Variable r, g, b, a
    MyRGBStrToRGB(popStr, r, g, b, a)  // One way to get r, g, b
    print popStr, " gives: ", r, g, b, a
    ControlInfo $ctrlName  // Another way: Sets V_Red, V_Green, V_Blue, V_Alpha
    Printf "ControlInfo returned (%d,%d,%d,%d)\r", V_Red, V_Green, V_Blue, V_Alpha
    return 0
End

Function MyRGBStrToRGB(rgbStr, r, g, b, a)
    String rgbStr
    Variable &r, &g, &b, &a
    if (CmpStr(rgbStr[0], ")") == 0)
        rgbStr = rgbStr[1, inf]
    endif
    r = str2num(StringFromList(0, rgbStr, ","))
    g = str2num(StringFromList(1, rgbStr, ","))
    b = str2num(StringFromList(2, rgbStr, ","))
    a = 65535
    if (itemsinList(rgbStr) > 3)
        a = str2num(StringFromList(3, rgbStr, ","))
    endif
End

Function LStylePopMenuProc(ctrlName, popNum, popStr) : PopupMenuControl
    String ctrlName
    Variable popNum
    String popStr
    Print "style:", popNum - 1
    return 0
End

**Popvalue Keyword**

There are times when the displayed value cannot be determined and saved such that it can be displayed when the pop-up menu is recreated. For instance, because window recreation macros are evaluated in the root folder, a pop-up menu of waves may not contain the correct list when a panel is recreated. That is, the intention may be to have the menu show a particular wave from a data folder other than root. When the panel recreation macro runs, the function that lists waves will list waves in the root data folder. The desired selection may be wrong or nonexistent.

Similarly, a pop-up menu of fonts may need to display a particular font upon recreation on a different computer having a different list of fonts. The mode=\_m\_ keyword probably won’t pick the correct font from the new list.

The solution to these problems is to save the correct selection with the popvalue=valueStr keyword. The list function will not be executed when the menu is first created. If the menu is popped, the list function will be evaluated, and the correct list will be displayed then.

It is a good idea to set the mode=m keyword to the correct number, if it is known. That way, when the menu is popped the correct item is chosen.

Normally you can let Igor redraw the pop-up menu when it redraws the graph or control panel containing it. However, there are situations in which you may want to force the pop-up menu to be redrawn. This can be done using the **ControlUpdate** operation.

**See Also**

Chapter III-14, *Controls and Control Panels*, for details about control panels and controls.

**Control Panel Units** on page III-444 for a discussion of the units used for controls.

The GetUserData function for retrieving named user data.

The ControlInfo operation for information about the control.
PopupMenuControl

The ControlUpdate, WaveList, and TraceNameList operations.

Special Characters in Menu Item Strings on page IV-133.

PopupMenuControl

PopupMenuControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined pop-up menu control. See Procedure Subtypes on page IV-204 for details. See PopupMenu for details on creating a popup menu control.

PossiblyQuoteName

PossiblyQuoteName(nameStr)
The PossiblyQuoteName function returns the input name string if it conforms to the rules of standard wave or Data Folder names. If it does not, then the name is returned in single quotes. This is used when generating a command string that you will pass to the Execute command. You might get the input name string from a function such as NameOfWave or CsrXWave.

Examples

Print PossiblyQuoteName("wave0") // prints wave0
Print PossiblyQuoteName("wave 0") // prints 'wave 0'

Details

See Programming with Liberal Names on page IV-168 for an example.

Preferences

Preferences [/Q] [newPrefsState]
The Preferences operation sets or displays the state of user preferences.

User preferences affect the creation of new graphs, panels, tables, layouts, notebooks, procedure windows, and the command window. They also affect the appearance of waves appended to graphs and tables, and objects appended to layouts.

Parameters

If newPrefsState is present, it sets the state of user preferences as follows:

newPrefsState=0: Preferences off (use factory defaults).
newPrefsState=1: Preferences on.

If newPrefsState is omitted, the state of user preferences is printed in the history area.

Flags

/Q Disables printing to the history.

Details

The Preferences operation sets the variable V_flag to the state of user preferences that were in effect before the Preferences command executed: 1 for on, 0 for off.

You can also set the state of Preferences with the Misc menu.

Under most circumstances we want procedures to be independent of preferences so that a particular procedure will do the same thing regardless of the state of preferences. To achieve this, preferences are automatically off when you initiate procedure execution. When execution is complete, the state of preferences is restored to what it was before.

If you want preferences to be in effect during procedure execution, you must turn it on with the Preferences operation.

If the preferences setting is changed by a procedure, the effect of the call is propagated down the calling chain. If a macro changes the preferences setting, that change is undone when the macro returns. If a function changes the preferences setting, the change persists after the function returns. However, even with a function, the changed preferences state does not persist when Igor regains control.
Examples

Function Test()
  Variable oldPrefState
  Preferences 1; oldPrefState=V_flag // remember prefs setting
  Make wave0=x
  Display wave0 // Display uses preferences
  Preferences oldPrefState // put prefs back, like a macro would
End

See Also
Chapter III-18, Preferences.

PrimeFactors

PrimeFactors [/Q] inNumber
PrimeFactors calculates the prime factors of inNumber. By default factors are printed in the history and are also stored in the wave W_PrimeFactors in the current data folder.

Flags

/Q  Suppresses printing of factors in the history area.

Details
The largest number that this operation can handle is $2^{32}-1$.

See Also
gcd, RatioFromNumber

Print

Print [flags] expression [, expression]...
The Print operation prints the evaluated expressions in the history area.

Parameters
An expression can be a wave, a numeric expression (e.g., $3*\pi/4$), a string expression (e.g., "Today is " + date()), or a individual structure element or an entire structure variable.

Flags

/C  Evaluates all numeric expressions as complex.
/D  Prints a greater number of digits.
/F  Prints numeric wave data (1D and 2D waves only) using “nice,” easily readable formatting.
/LEN=len  Sets the string break length to len number of bytes. The default is 200 and len is clipped to between 200 and 2500.
/S  Obsolete. Numeric results are printed with a moderate number of digits whether you use /S or not. To print more digits, use /D.
/SR  Prints a wave subrange for expressions that start as “waveName[]”. Without /SR, such an expression is taken as the start of a numeric expression such as wave[3]-wave[2]. (You can still use wave[pnt] but only if it does not start the numeric expression.)
Wave subrange printing is not done with /F.
You can specify a single row or column using [r] syntax. For example, to print column 4 of a matrix, use:
Print mymat[][4]

Details
Numeric expressions are always evaluated in double precision. The /D flag just controls the number of digits displayed.
printf

Print determines if an expression is real, complex, or string from the first symbol in the expression. Usually this works fine, but occasionally Print guesses wrong and you may have to rearrange your expression. For example:

Print 1+cmplx(1,2)

will give an error because the first symbol, “1”, is real but the expression should be complex. Changing this to

Print cmplx(1,2)+1

will work.

Printing numeric or string expressions involving structure elements must not start with the structure element. Instead an appropriate numeric or string literal must appear first so that Igor can determine what kind of expression to compile. For example rather than

Print astruct.astring + "hello"

use

Print "" + astruct.astring + "hello"

Print breaks long strings into multiple lines. If there are no natural breaks (carriage returns or semicolons) within a default length, then it breaks the string arbitrarily.

The default line length is 200 bytes. You can override this using the /LEN flag. The maximum number of bytes that can be printed on a line in the history area is 2500.

When printing waves, you can use either formatted (specified by /F) or unformatted (default) methods. Unformatted output is in an executable syntax for each printed line: wave={}. 

Note: Executing lines printed from floating point waves will not exactly reproduce the source data due to roundoff or insufficient digits in the printed output.

Printing formatted wave data gives easily (human) readable output, and works best for small 1D and 2D waves. If the data are too large or in an unsupported format (3D or greater, or the wave is text), then the output will be unformatted. Formatting is done using spaces, so the output will look best in a fixed-width font.

Printed wave data, both formatted and unformatted, are limited to no more than 100 lines of output. When the line limit is exceeded a warning message will be printed at the end of the truncated output. For text waves, output is limited to 50 bytes of each string element, and there is no warning when a string is truncated.

See Also

The printf operation.

The PrintGraphs, PrintTable, PrintLayout and PrintNotebook operations.

printf

printf formatStr [, parameter [, parameter]...] 

The printf operation prints formatted output to the history area.

Parameters

formatStr is a string which specifies the formatting of the output.

The type of the parameter, string or numeric, must agree with the corresponding conversion specification in formatStr, or else the results will be indeterminate.

The printf parameters can be numeric or string expressions. Numeric and string structure fields are allowed except that complex structure fields and non-numeric (e.g., WAVE, FUNCREF) structure fields are not allowed.

Details

The formatStr contains literal text and conversion specifications.

A conversion specification starts with the % character and ends with a conversion character (for example, g, e, f, d, or s as illustrated below). In between the % and the conversion character you may include one or more flag characters, a field width specifier, and a precision specifier. The first % corresponds to the first parameter, the second % corresponds to the second parameter, etc. If formatStr contains no % characters, no parameters are expected.

Here are some simple examples. numVar is a numeric variable and strVar is a string variable.
printf "The answer is: %g\r", numVar
printf "Created wave %s\r", strVar
printf "Created wave %s, %d points\r", strVar, numVar

%g is a general-purpose format (floating point or scientific notation) that represents the value of numVar.
%d is an integer format that represents the value of numVar. %s specifies that the corresponding parameter (strVar) is a string.

The "\r" in these examples appends a carriage return to the end of the printed text.

Here is a complex example using all of these elements of a conversion specification:
printf "%+015.4f\r", 1e6*PI

This prints:
The answer is: +003141592.6536

"+" is a flag character that tells printf to put a + or - sign in front of the number.

"015" is a field width specifier that tells printf to print the number in a field of at least 15 bytes, padded with leading zeros. Using "15" instead of "015" would cause printf to pad with spaces before the + sign instead of zeros after it.

".4" is a precision specifier that tells printf to print four digits after the decimal point.

"f" tells printf to use a floating point format.

The most common conversions characters are “f” for floating point, “g” for general, “d” for decimal, and “s” for string. They are interpreted as for the printf() function in the C programming language.

The escape codes \t and \r represent the tab and return characters respectively. See Escape Sequences in Strings on page IV-14 for more information.

Printf Flag Characters
The supported flag characters and their meanings are as follows:
- Left align the result in the field.
+ Put a plus or minus sign before the number.
<space> Put a space before a positive number.
# Specifies alternate form for e, f, g, and x formats.

The meaning of the precision specifier depends on the numeric format (%g, %e, %f, %d, etc.) being used:
e, E, f Precision specifies number of digits after decimal point.
g, G Precision specifies maximum number of significant digits.
d, o, u, x, X Precision specifies minimum number of digits.

You can replace both the field width and precision specifiers with an asterisk. This gets the field width or precision specifier from a parameter. For example:
printf "%.*f\r", 4, 3, 1e6*PI
means that the field width is 4 and the precision is 3. You could use numeric expressions instead of the literal numbers to control the field width and precision algorithmically.

Printf Conversion Characters
Here is a complete list of the conversion characters supported by printf:
To include a literal percent character, use two consecutive % characters, like this:

Variable percentage = 37.3
printf "%.1f%% of participants had prior medical conditions", percentage

Igor also supports a non-C, WaveMetrics extension to the conversion characters recognized by printf. This conversion specification starts with “%W”. It is followed by a flag digit and a format character. For example,
printf "%W0Ps", 12.345E-6
printf

<table>
<thead>
<tr>
<th>Conversion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
<td>Converts a numeric parameter as [-]ddd.ddd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If the # flag is present, a decimal point will be used even if there are no digits to the right of it. This conversion character uses the “round-to-half-even” rule, also known as “banker’s rounding”. When the truncated digits are exactly 0.5000..., the quantity is rounded to an even number. For example:</td>
</tr>
<tr>
<td>e, E</td>
<td>Converts a numeric parameter as [-]d.ddde+/−dd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If you use “E” instead of “e” then printf uses a capital “E” in the number. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.</td>
</tr>
<tr>
<td>g, G</td>
<td>Converts a numeric parameter using “f” or “e” style conversion depending on the magnitude of the number. “e” is used if the exponent is less than -4 or greater than the precision. “G” uses “f” or “E” style conversion. If the # flag is present, a decimal point will be used even if there are no digits to the right of it and trailing zeros will not be removed.</td>
</tr>
<tr>
<td>d, o, u</td>
<td>Converts a numeric parameter as a signed decimal integer, unsigned octal integer or unsigned decimal integer. The precision defaults to one and specifies the minimum number of digits to print. These conversion characters use the “round-away-from-zero” rule, like Igor’s round function. For example:</td>
</tr>
<tr>
<td>x, X</td>
<td>Converts a numeric parameter as an unsigned hexadecimal integer, rounding floating point values. Also supports integer data up to 64 bits. The “x” style uses lower case for the hexadecimal numerals “abcdef” where the “X” style uses upper case. The precision defaults to one and specifies the minimum number of digits to print. If the # flag is present, the string “0x” or “0X” is prepended to the number if it is not zero.</td>
</tr>
<tr>
<td>s</td>
<td>Converts a string parameter. If a precision is specified, it sets the maximum number of bytes from the string parameter to be printed. As of Igor Pro 9.00, there is no limit to the length of the string parameter. It was limited to 2400 bytes in Igor Pro 8 and to 1000 bytes before that.</td>
</tr>
<tr>
<td>b</td>
<td>WaveMetrics extension. Converts a numeric parameter to binary.</td>
</tr>
<tr>
<td>c</td>
<td>Converts a numeric parameter to a single ASCII character.</td>
</tr>
<tr>
<td>%</td>
<td>Prints a % sign. No parameter is used.</td>
</tr>
<tr>
<td>%W</td>
<td>WaveMetrics extension. See description below.</td>
</tr>
</tbody>
</table>

prints 12.345000µs. In this example, the “%W0” introduces the WaveMetrics conversion specification. The “0” (zero) following the “W” is the flag digit. The “P” that follows is the format specifier character, which prints the number using a prefix, in this case, “µ”. There is only one WaveMetrics format specifier character, “P”, which prints using a prefix such as µ, m, k, or M. It recognizes two flag-digits, “0” or “1”. Option “0” prints with no space between the numeric part and the prefix character while flag “1” prints with 1 space. Numbers greater than tera or less than femto print using a power of ten notation. Here are a few examples:  

printf’%.2W0PHz”, 12.342E6     // prints 12.34MHz
printf’%.2W1PHz”, 12.342E6     // prints 12.34 MHz
printf’%.0W0Ps”, 12.342E-6     // prints 12µs
printf’%.0W1Ps”, 12.342E-9     // prints 12 ns
PrintGraphs

PrintGraphs [flags] graphSpec [, graphSpec]...

The PrintGraphs operation prints one or more graphs.

PrintGraphs prints one or more graphs on a single page from the command line or from a procedure. The graphs can be overlaid or positioned any way you want.

Parameters

The graphSpec specifies the name of a graph to print, the position of the graph on the page and some other options.

Flags

/C=num Renders graphs in black and white (num=0) or in color (num=1; default).
/D Disables high resolution printing. This flag is of use only on Macintosh. It has no effect on Windows.
/G=grout Specifies grout, the spacing between objects, for tiling in prevailing units.
/I Coordinates are in inches.
/M Coordinates are in centimeters.
/R Coordinates are in percent of page size (see Examples).
/PD[=d] Displays print dialog. This allows the user to use Print Preview or to print to a file.
   If present the /PD flag must be the first flag.
   d=0: Default. Prints without displaying the Print dialog.
   d=1: Displays the Print dialog. /PD is equivalent to /PD=1.
   d=2: Displays the Print Preview dialog. Requires Igor Pro 7.00 or later.
/S Stacks graphs.
/T Tiles graphs.

Details

Graph coordinates are in inches (/I) or centimeters (/M) relative to the top left corner of the physical page. If none of these options is present, coordinates are assumed to be in points.

The form of a graphSpec is:

graphName [(left, top, right, bottom)] [/F=f] [/T]

Here are some examples:

// Take size and position from window size and position.
PrintGraphs Graph0, Graph1

// Specify size and position explicitly.
PrintGraphs/I Graph0(1, 1, 6, 5)/F=1, Graph1(1, 6, 6, 10)/F=1

If the coordinates are missing and the /T or /S flags are present before graphSpec then the graphs are tiled or stacked. If the coordinates are missing but no /T or /S flags are present then the graph is sized and positioned based on its position on the desktop.
Finally there are these `graphSpec` options, which appear after the graph name:

/F=f  Specifies a frame around the graph.
  f=0: No frame (default).
  f=1: Single frame.
  f=2: Double frame.
  f=3: Triple frame.
  f=4: Shadow frame.

/T  Graph is transparent. This allows special effects when graphs are overlaid.

For this to be effective, the graph and its contents must also be transparent. Graphs are transparent only if their backgrounds are white. Annotations have their own transparent/opaque settings. PICTs may have been created transparent or opaque; an opaque PICT cannot be made transparent.

**Examples**

You can put an entire `graphSpec` into a string variable and use the string variable in its place. In this case the name of the string variable must be preceded by the $ character. This is handy for printing from a procedure and also keeps the `PrintGraphs` command down to a reasonable number of characters. For example:

```latex
String spec0, spec1, spec2
spec0 = "Graph0(1, 1, 6, 5)/F=1"
spec1 = "Graph1(1, 6, 6, 10)/F=1"
spec2 = "" // PrintGraphs will ignore spec2.
PrintGraphs/I $spec0, $spec1, $spec2
```

If you use a string for a `graphSpec` and that string contains no characters then `PrintGraphs` will ignore that `graphSpec`.

**See Also**

The `PrintSettings`, `PrintTable`, `PrintLayout` and `PrintNotebook` operations.

---

**PrintLayout**

```
PrintLayout [/C=num /D] winName
```

The `PrintLayout` operation prints the named page layout window.

**Parameters**

`winName` is the window name of the page layout to print.

**Flags**

/C=num  Renders graphs, tables, and annotations in black-and-white (`num=0`) or in color (`num=1`; default). It has no effect on pictures, which are colored independently.

/D  Prints the layout at the default resolution of the output device. Otherwise it is printed at the highest resolution. This flag is of use only on Macintosh. It has no effect on Windows.

**Details**

Normally page layouts are printed at the highest available resolution of the output device (printer, plotter, or whatever). On Macintosh, it may not work properly at high resolution with some unusual output devices. If this happens, you can try using the /D flag to see if it works properly at the default resolution.

**See Also**

The `PrintSettings`, `PrintGraphs`, `PrintTable` and `PrintNotebook` operations.
PrintNotebook

PrintNotebook [flags] notebookName
The PrintNotebook operation prints the named notebook window.

Parameters

notebookName is either kwTopWin for the top notebook window, the name of a notebook window or a host-
child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on
host-child specifications.

Flags

/B=hiResMethod        Macintosh only; this flag has no effect on Windows.
    hiResMethod=1:   Print HiRes PICTs using high resolution bitmaps.
    hiResMethod=0:   Don’t print HiRes PICTs using high resolution
                     bitmaps.
    hiResMethod=-1:  Print using the default method. Prints HiRes PICTs
                     using high resolution bitmaps and is the same as
                     method 1.

/P=startPage,endPage  Specifies a page range to print. 1 is the first page.

/S=selection          Controls what is printed.
    selection=0:     Print entire notebook (default).
    selection=1:     Print selection only.

Details

If no /B flag is given, the default method of handling HiRes PICTs is used (/B=1). Printing of HiRes PICTs is
not well supported on the Macintosh, so by default it prints them using temporary high resolution bitmaps.
If a future version of the Mac OS improves in this respect, we will change the default method to print directly.

See Also

Chapter III-1, Notebooks.

The PrintSettings, PrintGraphs, PrintTable and PrintLayout operations.

PrintSettings

PrintSettings [/I /M /W=winName] [copySource=source, orientation=o,
    margins={left, top, right, bottom}, scale=s, colorMode=m,
    getPrinter, setPrinter=printerNameStr, getPageSettings,
    getPageDimensions]       
The PrintSettings operation gets or sets parameters associated with printing, such as a list of available
printers or page setup information for a particular window.

An exception is the graphMode and graphSize keyword pair which affect printing of all graphs. This pair
was added in Igor Pro 7.00.

Prior to Igor Pro 7.00, PrintSettings applied to a page layout affected the size and orientation of the layout
page. In Igor Pro 7.00 and later, the size and orientation of the layout page are independent of print settings.
See Page Layout Page Sizes on page II-478 for details.

When getting or setting page setup information, PrintSettings acts on a particular window called the
destination window. The destination window is the top graph, table, page layout, or notebook window or
the window specified by the /W flag.

PrintSettings can not act on page setup records associated with the command window, procedure
windows, help windows, control panel, XOP windows, or any type of window other than graphs, tables,
page layouts, and notebooks.

The PrintSettings operation services the keywords in the order shown above, not in the order in which they
appear in the command. Thus, for example, the getPageSettings and getPageDimensions keywords report
the settings after all other keywords are executed.
PrintSettings

Flags

/I Measurements are in inches. If both /I and /M are omitted, measurements are in points.

/M Measurements are in centimeters. If both /I and /M are omitted, measurements are in points.

/W=winName Acts on the page setup record of the graph, table, page layout, or notebook window identified by winName. If winName is omitted or if winName is "", then it used the page setup for the top window.

Keywords

colorMode=m Sets the color mode for the page setup to monochrome (m=0) or to color (m=1).
This keyword does nothing on Macintosh because it is not supported by Mac OS X.

copySource=source Copies page setup settings from the specified source to the destination window. source can be the name of a graph, table, page layout, or notebook window or it can be one of the following special keywords:

Default_Settings: Sets the page setup record to the default for the associated printer as specified by the printer driver.

Factory_Settings: Sets the page setup record to the WaveMetrics factory default. This is the page setup you get when creating a new window with user preferences turned off.

Preferred_Settings: Sets the page setup record to the user preferred page setup. This is the page setup you get when creating a new window with user preferences turned on. Because there is only one page setup for all graphs and one page setup for all tables, this has no effect when the destination window is a graph or table. It does work for layouts and notebooks.

ggetPageDimensions Returns page dimensions via the string variable $S_{value}$, which contains keyword-value pairs that can be extracted using NumberByKey and StringByKey. See Details for keyword-value pair descriptions.

ggetPageSettings Returns page setup settings in the string variable $S_{value}$, which contains keyword-value pairs that can be extracted using NumberByKey and StringByKey. See Details for keyword-value pair descriptions.

getPrinter Returns the name of the selected printer for the destination window in the string variable $S_{value}$. On Macintosh the returned value will be "" if the setPrinter keyword was never used on the destination window. This means that the window will use the operating system’s “current printer”.

getPrinterList Returns a semicolon-separated list of printer names in the string variable $S_{value}$.

Mac OS X: Returns a list of printers added through Print Center.

Windows: Returns the names of any local printers and names of network printers to which the user has made previous connections.

graphMode=g Sets the printing mode for graphs:

1: Fill page
2: Same size
3: Same aspect ratio
4: Custom size as set by graphSize keyword
5: Same size or shrink to fit page (default)

The graphMode keyword was added in Igor Pro 7.00.

graphSize=[left, top, width, height]
PrintSettings

Sets the custom graph size used when graphMode is 4. Parameters are in points unless /I or /M is used.

Invoking the graphSize keyword automatically sets the graphMode to 4. left and top are clipped so that they are no smaller than the minimum allowed by the printer driver. width and height are not clipped.

This setting is not saved and is set to a default value when Igor starts.

The graphSize keyword was added in Igor Pro 7.00.

margins={left, top, right, bottom}

Sets the page margins. Dimensions are in points unless /I or /M is used.

This setting is ignored for notebook windows. Use the Notebook operation pageMargins keyword instead.

The margins are clipped so that they are no smaller than the minimum allowed by the printer driver and no larger than one-half the size of the paper.

The terms left, top, right, and bottom refer to the sides of the page after possible rotation for landscape orientation.

Passing zero for all four margins sets the margins to the minimum margin allowed by the printer.

On Macintosh only, passing -1 for all four margins sets the margins to whatever minimum margin is allowed by the printer, even if the printer is changed later. This is how Igor Pro behaved on Macintosh prior to the creation of the PrintSettings operation, when the minimum printer margins were always used.

orientation=0

Sets the paper orientation to portrait (o=0) or to landscape (o=nonzero).

scale=s

In Igor Pro 7 and later, the scale keyword returns an “unimplemented” error, unless s=100, because it is currently not supported. Let us know if this feature is important to you. Though s=100 does not generate an error, it does nothing. You can still set the scaling manually using the Page Setup dialog.

setPrinter=printerNameStr

Sets the selected printer for the destination window.

SetPrinter attempts to preserve orientation, margins, scale, and color mode but other settings may revert to the default state.

printerNameStr is a name as returned by the getPrinterList keyword and may not be identical to the name displayed in various dialogs. For example, on Mac OS X, the printer name “DESKJET 840C” is returned by getPrinterList as “DESKJET_840C”. The latter is the “Queue Name” displayed by the Mac OS X Print Center or Printer Setup Utility programs.

If printerNameStr is “”, the printer for the destination window is set to the default state. This means different things depending on the operating system:

Mac OS X: The destination window will use the operating system’s “current printer”, as if the setPrinter keyword had never been used.

Windows: The destination window will use the system default printer.

If you receive an error when using setPrinter, use the getPrinterList keyword to verify that the printer name you are using is correct. Verify that the printer is connected and turned on.

Windows printer names are sometimes UNC names of the form “\ \Server\Printer”. You must double-up backslashes when using a UNC name in a literal string. See UNC Paths on page III-451 for details.
PrintSettings

Details
All graphs in the current experiment share a single page setup record so if you change the page setup for one graph, you change it for all graphs.
All tables in the current experiment share a single page setup record.
Each page layout window has its own page setup record.
Each notebook window has its own page setup record.
The keyword-value pairs for the getPageSettings keyword are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORIENTATION:</td>
<td>0 if the page is in portrait orientation, 1 if it is in landscape orientation.</td>
</tr>
<tr>
<td>MARGINS:</td>
<td>The left, top, right, and bottom margins in points, separated by commas. These margins are ignored for notebook windows. Use the Notebook operation pageMargins keyword instead.</td>
</tr>
<tr>
<td>SCALE:</td>
<td>The page scaling expressed in percent. 50 means that the graphics are drawn at 50% of their normal size.</td>
</tr>
<tr>
<td>COLORMODE:</td>
<td>0 for black&amp;white, 1 for color. This is not supported on Macintosh and always returns 1.</td>
</tr>
</tbody>
</table>

The keyword-value pairs for the getPageDimensions keyword are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPER:</td>
<td>The left, top, right, and bottom coordinates of the paper in points, separated by commas. The top and left are negative numbers so that the page can start at (0,0).</td>
</tr>
<tr>
<td>PAGE:</td>
<td>The left, top, right, and bottom coordinates of the page in points, separated by commas. The term page refers to the part of the paper inside the margins. The top/left corner of the page is always at (0,0).</td>
</tr>
<tr>
<td>PRINTAREA:</td>
<td>The left, top, right, and bottom coordinates of the page in points, separated by commas. The print area is the part of the paper on which printing can occur, as determined by the printer. This is equal to the paper inset by the minimum supported margins. The top and left are negative numbers so that the page can start at (0,0).</td>
</tr>
</tbody>
</table>

Examples
For an example using the PrintSettings operation, see the PrintSettings Tests example experiment file in the “Igor Pro Folder:Examples:Testing” folder.
Here are some simple examples showing how you can use the PrintSettings operation.

Function GetOrientation(name)  // Returns 0 (portrait) or 1 (landscape)
    String name  // Name of graph, table, layout or notebook
    PrintSettings/W=$name getPageSettings
    Variable orientation = NumberByKey("ORIENTATION", S_value)
    return orientation
End

Function SetOrientationToLandscape(name)
    String name  // Name of graph, table, layout or notebook
    PrintSettings/W=$name orientation=1
End

Function/S GetPrinterList()
    PrintSettings getPrinterList
    return S_value
End

Function SetPrinter(destWinName, printerName)
    String destWinName, printerName
    PrintSettings/W=$destWinName setPrinter=printerName
    return 0
End
See Also
The PrintGraphs, PrintTable, PrintLayout and PrintNotebook operations.

PrintTable
PrintTable [/P=(startPage,endPage) /S=selection] winName
The PrintTable operation prints the named table window.

Parameters
winName is the window name of the table to print.

Flags
/P=(startPage,endPage) Specifies a page range to print. 1 is the first page.
If /P is omitted all pages are printed unless /S is used.
/S=selection Controls what is printed.
selection=0: Print entire table (default).
selection=1: Print selection only.

See Also
Chapter II-12, Tables.
The PrintSettings, PrintGraphs, PrintLayout and PrintNotebook operations.

Proc
Proc macroName([parameters]) [:macro type]
The Proc keyword introduces a macro that does not appear in any menu. Otherwise, it works the same as Macro. See Macro Syntax on page IV-118 for further information.

ProcedureText
ProcedureText(macroOrFunctionNameStr [, linesOfContext [, procedureWinTitleStr]])
The ProcedureText function returns a string containing the text of the named macro or function as it exists in some procedure file, optionally with additional lines that are before and after to provide context or to collect documenting comments.
Alternatively, all of the text in the specified procedure window can be returned.

Parameters
macroOrFunctionNameStr identifies the macro or function. It may be just the name of a global (nonstatic) procedure, or it may include a module name, such as "myModule#myFunction" to specify the static function myFunction in a procedure window that contains a #pragma ModuleName=myModule statement.
If macroOrFunctionNameStr is set to "", and procedureWinTitleStr specifies the title of a single procedure window, then all of the text in the procedure window is returned.
linesOfContext optionally specifies the number of lines around the function to include in the returned string. The default is 0 (no additional contextual lines of text are returned). This parameter is ignored if macroOrFunctionNameStr is "" and procedureWinTitleStr specifies the title of a single procedure window.
Setting linesOfContext to a positive number returns that many lines before the procedure and after the procedure. Blank lines are not omitted.
Setting linesOfContext to -1 returns lines before the procedure that are not part of the preceding macro or function. Usually these lines are comment lines describing the named procedure. Blank lines are omitted.
Setting linesOfContext to -n, where n>1, returns at most n lines before the procedure that are not part of the preceding macro or function. Blank lines are not omitted in this case. n can be -inf, which acts the same as -1 but includes blank lines.
The optional procedureWinTitleStr can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf"). The text of the named macro or function in the specified procedure window is returned.
You can use `procedureWinTitleStr` to select one of several static functions with identical names among different procedure windows, even if they do not use a `#pragma moduleName=myModule` statement.

**Advanced Parameters**

If `SetIgorOption IndependentModuleDev=1`, `procedureWinTitleStr` can also be a title followed by a space and, in brackets, an independent module name. In such cases `ProcedureText` retrieves function text from the specified procedure window and independent module. (See **Independent Modules** on page IV-238 for independent module details.)

For example, in a procedure file containing:

```plaintext
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

A call to `ProcedureText` like this:

```plaintext
String text=ProcedureText("HVAxisList",0,"Axis Utilities.ipf [myIM]"
```

will return the text of the `HVAxisList` function located in the `Axis Utilities.ipf` procedure window, which is normally a hidden part of the `myIM` independent module.

You can see procedure window titles in this format in the Windows→Procedure Windows menu when `SetIgorOption IndependentModuleDev=1` and when an experiment contains procedure windows that comprise an independent module, as does `#include <New Polar Graphs>`.

`procedureWinTitleStr` can also be just an independent module name in brackets to retrieve function text from any procedure window that belongs to the named independent module:

```plaintext
String text=ProcedureText("HVAxisList",0,"[myIM]"
```

**See Also**

Regular Modules on page IV-236 and Independent Modules on page IV-238.

The `WinRecreation` and `FunctionList` functions.

### ProcedureVersion

`ProcedureVersion(macroOrFunctionNameStr [, procedureWinTitleStr ])`

The `ProcedureVersion` function returns the version number as specified by the first `#pragma version=versionNum` in the procedure file containing the named macro, function. Alternatively it can return the version number of a specified procedure window.

The `ProcedureVersion` function was added in Igor Pro 9.01.

**Parameters**

`macroOrFunctionNameStr` identifies the macro or function. It may be just the name of a global (nonstatic) procedure, or it may include a module name, such as "MyModule#MyFunction" to specify the static function MyFunction in a procedure window that contains a `#pragma ModuleName=MyModule` statement.

If `macroOrFunctionNameStr` is "" and `procedureWinTitleStr` is not specified then the value of the first `#pragma version` statement in the procedure window containing the currently running macro or function is returned.

If `macroOrFunctionNameStr` is "" and `procedureWinTitleStr` is specified then the value of the first `#pragma version` statement in that procedure window is returned.

**Details**

The return value is rounded to a multiple of 0.001.

The returned value is 0 if the `#pragma version` statement is absent or the procedure window is "invisible" because the function is an independent module but `SetIgorOption IndependentModule=0`.

**Example**

```plaintext
#pragma version=1.2345 // 1 more digit than recommended
...
Function Test()
    Variable version = ProcedureVersion("") // Version of procedure file containing test
    Print version // 1.234
End
```

**See Also**

`ProcedureText`, `FunctionList`, `MacroList`
ProcGlobal

ProcGlobal#procPictureName
The ProcGlobal keyword is used with Proc Pictures to avoid possible naming conflicts with any other global pictures in the experiment. When you add a picture to an experiment using the Pictures dialog, such a picture is global in scope and may potentially have the same name as a Proc Picture. When a Proc Picture is global (and only then), you should use the ProcGlobal keyword to make sure that the Proc Picture is used with your code and to avoid confusion with pictures in the Pictures dialog.

See Also

Project

Project [ /C={long, lat} /M=method /P={p1, p2, ...} ] longitudeWave, latitudeWave
The Project operation calculates projections of XY data, which most often are longitude and latitude waves of geographic coordinates. The output waves are W_XProjection and W_YProjection. Longitude and Latitude are in degrees.

Parameters

longitudeWave is the name of the wave supplying the longitude or equivalent coordinates. latitudeWave is the name of the wave supplying the latitude or equivalent coordinates.

Flags

/C={long, lat} Specifies longitude and latitude center of projection. By default long=0 and lat=90.

/M=method Indicates the type of projection. method can be one of the following:
0: Orthographic (default).
1: Stereographic.
2: Gnomonic.
3: General perspective.
4: Lambert equal area.
5: Equidistant.
6: Mercator.
7: Transverse Mercator.
8: Albers Equal Area conic.
9: Eckert IV (Igor Pro 9.00 or later)
10: Winkel III (Igor Pro 9.00 or later)

/P={p1,p2,...} One or more parameters required by a particular projection. See the following sections for parameters required by the various projections.

Gnomonic
Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that cos(c) in Eq. (5-3) of Snyder is greater than the specified parameter:

/P={cos(c)}
The actual transformation uses Eqs. (22-4) and (22-5) of Snyder with k’ given by (22-3).

General Perspective
Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that cos(c) in Eq. (5-3) of Snyder is greater than the specified parameter.
The actual transformation uses Eqs. (22-4) and (22-5) with k’ given by (22-3). Here we specify the height H is units of sphere radius. The tilt of the plane is specified by omega and gamma following the notation of Snyder page 175.

The parameters actually specified by the command are:

\[ /P = \{ H, \omega, \gamma, \delta x, \delta y \} \]

H is the height (in radii) above the surface of the earth, \( \gamma \) is the azimuth east of north of the Y axis, and \( \omega \) is the tilt angle or the angle between the projection plane and the tangent plane. The x output will be limited to \( \pm \delta x \) and the y output will be limited to the range \( \pm \delta y \).

**Mercator**

This projection requires the following parameters:

\[ /P = \{ \text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat} \} \]

If /P is not specified, the default is \{0,360,-90,90\}

Note that this projection flips the sign of y when \( \cos(\text{longitude-long}_0) \) changes sign. If you are plotting a continuous path in which consecutive points exhibit the sign change, you should add a NaN entry in the wave so that the path does not wrap.

**Albers Equal Area Conic**

This projection requires:

\[ /P = \{ \text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}, \Phi_1, \Phi_2 \} \]

\( \Phi_1 \) and \( \Phi_2 \) are the specification of the two standard parallels, the other four parameters determine the boundary of the map area for display.

**References**

“Transforming Data into a Common Spatial Reference” in the “IgorGIS Help” file.

---

**Prompt**

**Prompt** \textit{variableName, titleStr [, popup, menuListStr]}\textit{ }

The Prompt command is used in functions for the simple input dialog and in macros for the missing parameter dialog. Prompt supplies text to describe \textit{variableName} to the user, and optionally provides a pop-up menu of choices for the value of \textit{variableName}.

**Parameters**

\textit{variableName} is the name of a macro input parameter or function variable.

\textit{titleStr} is a string or string expression containing the text to present in the dialog to describe what \textit{variableName} is. \textit{titleStr} is limited to 255 bytes.

The optional keyword \textit{popup} is used to provide a pop-up list of choices for the values of \textit{variableName}. If \textit{popup} is used, then \textit{menuListStr} is required.

\textit{menuListStr} is a string or string expression that contains a semicolon-separated list of choices for the value of \textit{variableName}. It \textit{variableName} is a string, choosing from this list will set the string to the selection. If it is a numeric variable, then it is set to the item number of the selection (if the first item is selected, the numeric variable is set to 1, etc.).

**Details**

In macros, there must be a blank line after the set of input parameter declarations and prompt statements and there must not be any blank lines within the set.

In user-defined functions, Prompt may be used anywhere within the body of the function, but must precede any DoPrompt that uses the Prompt variable.

\textit{menuListStr} may be continued on succeeding lines only in macros, as long as no comment is appended to the Prompt line. The additional lines should start with a semicolon, and are appended to the \textit{menuListStrs} on preceding lines.
See Also
For use in user-defined functions, see The Simple Input Dialog on page IV-144.
For use in macros, see The Missing Parameter Dialog on page IV-121.
For use in functions and macros, see the DoPrompt and popup keywords.

PulseStats

PulseStats \([flags]\) waveName

The PulseStats operation produces simple statistics on a region of the named wave that is expected to contain three edges as shown below. If more than three edges exist, PulseStats works on the first three edges it finds.

Cases and flags:

**Case 1:** 3 edges.
- There is no point 3

**Case 2:** 2 edges.
- There is no point 3

**Case 3:** 1 edge.
- There is no point 2 or 3

**Flags**

- `/A=n` Determines `startLevel` and `endLevel` automatically by averaging `n` points centered at `startX` and `endX`. This does not work in case 2, which requires that you use the `/L` flag. Default is `/A=1`.

- `/B=box` Sets box size for sliding average. This should be an odd number. If `/B=box` is omitted or `box` equals 1, no averaging is done.

- `/F=f` Specifies levels 1, 2, and 3 as a fraction of `(endLevel-startLevel)`:
  \[
  level1 = level2 = level3 = f \times (endLevel-startLevel) + startLevel
  \]
  `f` must be between 0 and 1. The default value is 0.5 which sets the levels to midway between the base levels.

- `/L=(startLevel, endLevel)` Sets `startLevel` and `endLevel` explicitly.

- `/M=dx` Sets minimum edge width. Once an edge is found, the search for the next edge starts `dx` units beyond the found edge. Default `dx` is 0.

- `/P` Output edge locations (see Details) are set in terms of point number. If `/P` is omitted, edge locations are set in terms of X values.

- `/Q` Prevents results from being printed in history and prevents error if edge is not found.
PulseStats

/R=(startX,endX) Specifies an X range of the wave to search. You may exchange startX and endX to reverse the search direction.

/R=[startP,endP] Specifies a point range of the wave to search. You may exchange startP and endP to reverse the search direction.

If you specify the range as /R=[startP] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is searched.

/T=dx Forces search in two directions for a possibly more accurate result. dx controls where the second search starts.

Details

The /B=box, /T=dx, /P and /Q flags behave the same as for the FindLevel operation.

PulseStats considers a region of the input wave between two X locations, called startX and endX. startX and endX are set by the /R=(startX,endX) flag. If this flag is missing, startX and endX default to the start and end of the entire wave.

The startLevel and endLevel values define the base levels of the pulse. You can explicitly set these levels with the /L=(startLevel, endLevel) flag or you can let PulseStats find the base levels for you by using the /A=n flag. With this flag, PulseStats determines startLevel and endLevel by averaging n points centered at startX and at endX. In case 2, you must use /L=(startLevel, endLevel) since startLevel is not at point 0.

Given startLevel and endLevel and an f value (which you can set with the /F=f flag), PulseStats computes level1, level2 and level3 which are always equal. With the default f value of 0.5, level1 is midway between startLevel and endLevel.

With these levels defined, PulseStats searches the wave from startX to endX looking for one, two or three level crossings. PulseStats sets the following variables:

V_flag
0: All three level crossings were found.
1: One or two level crossings were found.
2: No level crossings were found.

V_PulseLoc1 X location where level1 was found.
V_PulseLoc2 X location where level2 was found.
V_PulseLoc3 X location where level3 was found.
V_PulseLvl0 startLevel value.
V_PulseLvl123 Level1 value that is the same as level2 and level3.
V_PulseLvl14 endLevel value.
V_PulseAmp4_0 Pulse amplitude (endLevel - startLevel).
V_PulseWidth2_1 Left pulse width (x distance between point 2 and point 1).
V_PulseWidth3_2 Right pulse width (x distance between point 3 and point 2).
V_PulseWidth3_1 Pulse period (x distance between point 3 and point 1).
V_PulsePolarity Trend of the edge at point 1 (-1 if decreasing, +1 if increasing).

X locations and distances are in terms of the X scaling of the source wave, unless you use the /P flag in which case they are in terms of point number.

If any level crossings are missing then PulseStats sets the associated variables to NaN (Not a Number). If one crossing is missing, variables depending on point 3 are set to NaN. If two crossings are missing, variables depending on points 2 and 3 are set to NaN. If all crossings are missing, variables depending on points 1, 2, and 3 are set to NaN. You can use the numtype function to test a variable to see if it is NaN.

The PulseStats operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.
See Also
The FindLevel operation about the /B=box, /T=dx, /P and /Q flags, EdgeStats and the numtype function.

PutScrapText

PutScrapText textStr
The PutScrapText operation places textStr on the Clipboard (aka “scrap”). This text will be used when the user subsequently chooses Paste from the Edit menu.

Details
All contents of the Clipboard (including pictures) are cleared before the text is placed there.

Examples
Put two lines of text into the Clipboard:
String text = "This is the first line.\rAnd this is the second."
PutScrapText text
Empty the Clipboard:
PutScrapText ""

See Also
The GetScrapText function and the SavePICT operation.

pwd

cwd
The pwd operation prints the full path of the current data folder to the history area. It is equivalent to Print GetDataFolder(1).

pwd is named after the UNIX "print working directory" command.

See Also
GetDataFolder, cd, Dir, Data Folders on page II-107

q

q
The q function returns the current column index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled column index is available as the y function.

Details
Unlike p, outside of a wave assignment statement, q does not act like a normal variable.

See Also
Waveform Arithmetic and Assignments on page II-74.
For other dimensions, the p, r, and s functions.
For scaled dimension indices, the x, y, z and t functions.

qcsr

qcsr(curs

qcsr(cursorName [, , graphNameStr])
The qcsr function can be used with cursors on images or waterfall plots to return the column number. It can also be used with free cursors to return the relative Y coordinate.

Parameters
cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
Quit

See Also
The hcsr, pcsr, vcsr, xcsr, and zcsr functions.

Programming With Cursors on page II-321.

Quit

Quit [/N/Y]
The Quit operation quits Igor Pro.

Flags
/N Quits without saving changes and without dialog.
/Y Saves current experiment before quitting without putting up dialog unless current experiment is “Untitled”.

r

r
The r function returns the current layer index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled layer index is available as the z function.

Details
Unlike p, outside of a wave assignment statement, r does not act like a normal variable.

See Also
Waveform Arithmetic and Assignments on page II-74. For other dimensions, the p, q, s, and t functions. For scaled dimension indices, the x, y, z, and t functions.

r2polar

r2polar(z)
The r2polar function returns a complex value in polar coordinates derived from the complex value z, which is assumed to be in rectangular coordinates. The magnitude is stored in the real part and the angle (in radians) is stored in the imaginary part of the returned complex value.

Examples
Assume waveIn and waveOut are complex.
waveOut= r2polar(waveIn)
sets each point of waveOut to the polar coordinates derived from the real and imaginary parts of waveIn.
You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.

See Also
The functions cmplx, conj, imag, p2rect, and real.

RatioFromNumber

RatioFromNumber [flags] num
The RatioFromNumber operation computes two integers whose ratio is equal to num ± maxError (/MERR flag). The ratio is returned in V_numerator and V_denominator.

Parameters
num is the number to approximate by V_numerator/V_denominator.

Flags
/MERR=maxError Specifies the maximum tolerable error. The computed ratio differs from num by no more than maxError (default value is num*1e-6). maxError must be a value between 0 and num. See Details about setting maxError to 0.
Rect

/MITS = maxIterations  Keeps returned values small by specifying a small number for maxIterations. maxIterations must be a value between 1 and 32767 (default is 100).

/V[v]

Prints output variables to history.
v=1: Prints variables (same as /V).
v=0: Nothing printed (same as no /V).

Details
The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking \( \text{num} - (V_{\text{numerator}}/V_{\text{denominator}}) \) against /MERR.

Setting maxError = 0 computes a maximally accurate ratio. The returned values can be surprisingly large:

\[
\text{RatioFromNumber /V/MERR=0 (1/1666)}
\begin{align*}
V_{\text{numerator}} &= 4398046511104; \\
V_{\text{denominator}} &= 7.3271454874993e+15; \\
\text{ratio} &= 0.00060024009603842; \\
\text{V_difference} &= 0;
\end{align*}
\]

Using the default /MERR returns the expected 1 and 1666. The difference is attributable to floating-point roundoff errors.

The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking \( \text{num} - (V_{\text{numerator}}/V_{\text{denominator}}) \) against /MERR.

Output Variables
RatioFromNumber sets the following output variables:

- \( V_{\text{difference}} \)  \( V_{\text{numerator}}/V_{\text{denominator}} - \text{num} \) (positive if the approximation is too big).
- \( V_{\text{flag}} \)  0: \( V_{\text{difference}} \) less than or equal to /MERR.
  1: \( V_{\text{difference}} \) greater than /MERR.
- \( V_{\text{numerator}}, V_{\text{denominator}} \)  Values for the numerator and denominator. The ratio of \( V_{\text{numerator}}/V_{\text{denominator}} \) approximates \( \text{num} \).
- \( V_{\text{iterations}} \)  The number of iterations actually used.

RatioFromNumber prints the output variables if you specify /V or /V=1 but only when running in the main thread.

Examples
RatioFromNumber /V pi
\begin{align*}
V_{\text{numerator}} &= 355; \\
V_{\text{denominator}} &= 113; \\
\text{ratio} &= 3.141592920354; \\
\text{V_difference} &= 2.6676418940497e-07; \\
\text{V_iterations} &= 3;
\end{align*}

RatioFromNumber /V/MITS=2 pi
\begin{align*}
V_{\text{numerator}} &= 22; \\
V_{\text{denominator}} &= 7; \\
\text{ratio} &= 3.1428571428571; \\
\text{V_difference} &= 0.0012644892673497; \\
\text{V_iterations} &= 1;
\end{align*}

See Also
gcd, trunc, PrimeFactors

Rect
The Rect structure is used as a substructure usually to store the coordinates of a window or control.

Structure Rect
\begin{verbatim}
Int16 top
Int16 left
Int16 bottom
Int16 right
EndStructure
\end{verbatim}

RectF
The RectF structure is the same as Rect but with floating point fields.
The `ReadVariables` operation reads variables into an experiment.

The `real(z)` function returns the real component of the complex value `z`.

See Also
The functions `cmplx`, `conj`, `imag`, `p2rect`, and `r2polar`.

The `Redimension` operation remakes the named waves, preserving their contents as much as possible.

Flags
- `/B` Converts waves to 8-bit signed integer or unsigned integer if `/U` is present.
- `/C` Converts real waves to complex.
- `/D` Converts single precision waves to double precision.
- `/E=e` Controls the redimension mode:
  - `e=0`: No special action (default).
  - `e=1`: Force reshape without converting or moving data.
  - `e=2`: Perform endian swap. See `FBinRead` for a discussion of endian byte ordering.
- `/I` Converts waves to 32-bit signed integer or unsigned integer if `/U` is present.
- `/L` Converts waves to 64-bit signed integer or unsigned integer if `/U` is present. Requires Igor Pro 7.00 or later.
- `/N=n` `n` is the new number of points each wave will have. Multidimensional waves are converted to 1 dimension. If `n=-1`, the wave is converted to a 1-dimensional wave with the original number of rows.
- `/N=(n1, n2, n3, n4)`
  - `n1`, `n2`, `n3`, `n4` specify the number of rows, columns, layers, and chunks each wave will have. Trailing zeros can be omitted (e.g., `/N=(n1, n2, 0, 0)` can be abbreviated as `/N=(n1, n2)`). If any dimension size is to remain unchanged, pass -1 for that dimension.
- `/R` Converts complex waves to real by discarding the imaginary part.
- `/S` Converts double precision waves to single precision.
- `/U` Converts integer waves to unsigned.
- `/W` Converts waves to 16-bit integer (unsigned integer if `/U` is present).
- `/Y=type` Specifies wave data type. See details below.
Wave Data Types
As a replacement for the above number type flags you can use /Y=numType to set the number type as an integer code. See the WaveType function for code values. Do not use /Y in combination with other type flags. This technique cannot be used to change the number type without changing the real/complex setting.

Details
The waves must already exist. New points in waves that are extended are zeroed.

In general, Redimension does not move data from one dimension to another. For instance, if you have a 6x6 matrix wave, and you would like it to be 3x12, the rows have been shortened and the data for the last three rows is lost.

As a special case, if converting to or from a 1D wave, Redimension will leave the data in place while changing the dimensionality of the wave. For example, you can use Redimension to convert a 36-element 1D wave into a 6x6 matrix in which the elements in the first column (column 0) are the first 6 elements of the 1D wave, the elements of the second column are the next 6, etc. When redimensioning from a 1D wave, columns are filled first, then layers, followed by chunks.

Examples
Reshaping a 1D wave having 4 elements to make a 2x2 matrix:
Make/N=4 vector=x
Redimension/N=(2,2) vector

See Also
Make, DeletePoints, InsertPoints, Concatenate, SplitWave

Remez
Remez [\[N=\text{num} \ /Q=\text{iter} \ ]] frWave, wtWave, gridWave, coefsWave
The Remez operation calculates the coefficients for digital filters given a desired frequency response as input.

Remez is primarily used for the MPR filter feature of the Igor Filter Design Laboratory (IFDL) package.

Parameters
frWave contains the desired response.
wtWave contains the weight function array. For a differentiator, the weight function is inversely proportional to frequency.
gridWave contains the frequencies corresponding to each point in frWave and wtWave. Its values range from 0 to 0.5 with gaps where the band edges occur.
coefsWave receives the resulting coefficients. Its length defines the number of coefficients (nfilt in the IEEE program referenced below).

Flags
/N=mode
mode=0: Selects multiple passband/stopband filter (default).
mode=1: Selects differentiator or Hilbert transform filter.
/Q=iter
Determines if execution stops if the filter doesn’t converge.
If you omit /Q, execution stops if the filter doesn’t converge.
If you specify /Q or /Q=0, execution continues if the filter doesn’t converge, regardless of the number of iterations.
For iter>=1, execution stops if the filter fails to converge in iter iterations or less. If the filter does converge after iter iterations, execution does stop.
Use /Q=3 to stop execution for serious errors (after only 1, 2, or 3 iterations) but not for minor errors (after 4 or more iterations).

Details
Remez returns symmetrical coefficients suitable for use with FilterFIR in coefsWave.
The algorithm is based upon the McClellan-Parks-Rabiner Fortran program as found in the IEEE and Elliot references cited below.

If the filter converged, Remez sets \( V\_\text{Flag} \) to 0. Otherwise it sets it to the number of iterations before it failed.

**Example**

This example specifies a length 41 lowpass filter with passband 0 to 0.14 \( \times \) fs and stopband 0.18 \( \times \) fs to 0.5 \( \times \) fs. The passband weight is equal to the stopband weight.

```
Make/O/N=41 coefs = NaN
Make/O/N=(41*16) fr, wt, grid
grid = 0.5*p/numpnts(grid) ; Frequencies where fr and wt define desire response
wt = 1
fr[0,0.14*numpnts(fr)] = 1 ; Low pass from 0 to 0.14 \( \times \) fs

// Remove transition frequencies
DeletePoints 0.14*numpnts(fr), 0.04*numpnts(fr), fr, wt, grid

// Compute filter coefs
Remez fr, wt, grid, coefs

// Analyze the filter's frequency response
FFT/OUT=3/PAD={256}/DEST=coefs_FFT coefs

// Display filter response for 1Hz sample rate
Display coefs_FFT
```

**References**

**See Also**

FMaxFlat, FilterFIR

**Remove**

When interpreting a command, Igor treats the Remove operation as **RemoveFromGraph**, **RemoveFromTable**, or **See Also**, depending on the target window. This does not work when executing a user-defined function. Therefore, we recommend that you use **RemoveFromGraph**, **RemoveFromTable**, or **RemoveLayoutObjects** rather than Remove.

**RemoveByKey**

```
RemoveByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]])
```

The RemoveByKey function returns `kwListStr` after removing the keyword-value pair specified by `keyStr`. `kwListStr` should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for `keySepStr` and `listSepStr`.

Use RemoveByKey to remove information from a string containing a "key1:value1;key2:value2;" or "key1=value1, key2=value2, " style list such as those returned by functions like `AxisInfo` or `TraceInfo`.

If `keyStr` is not found then `kwListStr` is returned unchanged.

`keySepStr`, `listSepStr`, and `matchCase` are optional; their defaults are ":", ";", and 0 respectively.

**Details**

`kwListStr` is searched for an instance of the key string bound by `listSepStr` on the left and a `keySepStr` on the right. The key, the `keySepStr`, and the text up to and including the next `listSepStr` (if any) are removed from the returned string.

If the resulting string contains only `listSepStr` characters, then an empty string ("" ) is returned.
**RemoveContour**

RemoveContour is treated as if it ends with a listSepStr even if it doesn’t.

Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional matchCase parameter to 1 makes the comparisons case sensitive.

In Igor6, only the first byte of keySepStr and listSepStr was used. In Igor7 and later, all bytes are used.

If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

**Examples**

```
Print RemoveByKey("AKEY", "AKEY:123;BKEY:val")    // prints "BKEY:val"
Print RemoveByKey("AKEY", "akey=1;BK=b;", ";")     // prints "BK=b;"
Print RemoveByKey("ckey","CKEY:1;BKEY:2")          // prints "BKEY:2"
Print RemoveByKey("ckey","CKEY:1;BKEY:2",";",",",1) // prints "CKEY:1;BKEY:2"
```

**See Also**

The NumberByKey, StringByKey, ReplaceNumberByKey, ReplaceStringByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

**RemoveContour**

RemoveContour [/W=winName] contourInstanceName [, contourInstanceName]...

The RemoveContour operation removes the traces, and releases memory associated with the contour plot of contourInstanceName in the target or named graph.

**Parameters**

contourInstanceName is usually simply the name of a wave. More precisely, contourInstanceName is a wave name, optionally followed by the $ character and an instance number to identify which contour plot of a given wave is to be removed.

**Flags**

/ALL

Removes all contour plots from the graph. Any contour name parameters listed are ignored. /ALL was added in Igor Pro 9.00.

/W=winName

Removes contours from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

**Details**

If the axes used by the contour plot are no longer in use, they will also be removed.

A contour instance name in a string can be used with the $ operator to specify contourInstance.

**Examples**

```
Display;AppendMatrixContour zw    //new graph, contour of zw matrix
AppendMatrixContour zw           //two contours of zw
RemoveContour zw#1              //remove the second contour
```

**See Also**

The AppendMatrixContour and AppendXYZContour operations.
RemoveEnding

RemoveEnding(str [, endingStr])
The RemoveEnding function removes one character from the end of str, or it removes the endingStr from the end of str.

The RemoveEnding function returns str with endingStr removed from the end. If you omit endingStr, it returns str with one grapheme removed from the end.

Details
If you specify endingStr, RemoveEnding compares it to the end of str using case-insensitive comparison. If there is a match, RemoveEnding returns the contents of str up to endingStr. If there is no match, RemoveEnding returns the entirety of str.

If you omit endingStr, RemoveEnding returns str with the last grapheme removed. A grapheme is whatever visually appears to be one character even if it consists of more than one character. In "ABÇ", the last grapheme is "Ç" which is also the last character. In "ABÇ", "Ç" consists of two characters: a C character and a "combining cedilla" character; RemoveEnding removes "Ç" which is the last grapheme.

Examples
Print RemoveEnding("123")       // Prints "12"
Print RemoveEnding("ABC")        // Prints "AB"
Print RemoveEnding("no semi" , ";") // Prints "no semi"
Print RemoveEnding("trailing semi;" , ";") // Prints "trailing semi"
Print RemoveEnding("file.txt" , ".TXT") // Prints "file"

See Also
The CmpStr and ParseFilePath functions.

RemoveFromGizmo

RemoveFromGizmo [flags]
The RemoveFromGizmo operation removes the specified object from the specified list and optionally performs an update.

Documentation for the RemoveFromGizmo operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "RemoveFromGizmo"

RemoveFromGraph

RemoveFromGraph [/W=winName/Z] traceName [, traceName]...
The RemoveFromGraph operation removes the specified wave traces from the target or named graph. A trace is a representation of the data in a wave, usually connected line segments.

Parameters
traceName is usually just the name of a wave.

More generally, traceName is a wave name, optionally followed by the # character and an instance number - for example, wave0#1. See Instance Notation on page IV-20 for details.
RemoveFromLayout

Flags

/ALL  Removes all non-contour traces from the graph. Any trace name parameters listed are ignored. /ALL was added in Igor Pro 9.00.

/W=winName  Removes traces from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z  Suppresses errors if specified trace or image is not on the graph.

Details

Up to 100 traceNames may be specified, subject to the 2500 byte command length limit.

If the axes used by the given trace are not in use after removing the trace, they will also be removed.

A string containing a trace name can be used with the $ operator to specify traceName.

Specifying "$#0" for traceName removes the first trace in the graph. "$#1" removes the second trace in the graph, and so on. "$" is equivalent to "$#0".

Note that removing all the contour traces from a contour plot is not the same as removing the contour plot itself. Use the RemoveContour operation.

Examples

The command:

Display myWave,myWave;Modify mode(myWave#1)=6

appends two instances of myWave to the graph. The first/backmost instance of myWave is instance 0, and its trace name is just myWave as a synonym for myWave#0. The second or frontmost instance of myWave is myWave#1 and it is displayed with the cityscape mode.

To remove the second instance from the graph requires the command:

RemoveFromGraph myWave#1

or

String MyTraceName="myWave#1"
RemoveFromGraph $MyTraceName

See Also

Trace Names on page II-282, Programming With Trace Names on page IV-87.

RemoveFromList

RemoveFromList itemOrListStr, listStr [, listSepStr [, matchCase]]

The RemoveFromList function returns listStr after removing the item or items specified by itemOrListStr. listStr should contain items separated by listSepStr which typically is ";".

If itemOrListStr contains multiple items, they should be separated by the listSepStr character, too.
Use RemoveFromList to remove item(s) from a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.

If all items in itemOrListStr are not found or if any of the arguments is "" then listStr is returned unchanged (unless listStr contains only list separators, in which case an empty string is returned).

listSepStr and matchCase are optional; their defaults are ";" and 1 respectively.

Details
itemStr may have any length.

listStr is searched for an instance of the item string(s) bound by listSepStr on the left and right. All instances of the item(s) and any trailing listSepStr (if any) are removed from the returned string.

If the resulting string contains only listSepStr characters, then an empty string (""") is returned.

listStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for listSepStr are case-sensitive. Searches for items in itemOrListStr are usually case-sensitive.

Setting the optional matchCase parameter to 0 makes the comparisons case insensitive.

In Igor6, only the first byte of listSepStr was used. In Igor7 and later, all bytes are used.

If matchCase is specified, then listStr must also be specified.

Examples
Print RemoveFromList("wave1", "wave0;wave1;") // prints "wave0;"
Print RemoveFromList("wave1", ";wave0;wave1;") // prints ""
Print RemoveFromList("KEY=joy", ",AX=3,KEY=joy,"",") // prints "AX=3;"
Print RemoveFromList("fred;barney", "fred\twilma","\c") // prints "wilma"
Print RemoveFromList("fred;barney", "fred;wilma;barney") // prints "wilma;"
Print "X"+RemoveFromList("",";";")+"Y" // prints "XY"
Print RemoveFromList("FRED", "fred\twilma") // prints "fred\twilma"
Print RemoveFromList("FRED", "fred\twilma", ";", 0) // prints "wilma"

See Also
The FindListItem, FunctionList, ItemsInList, RemoveByKey, RemoveListItem, StringFromList, StringList, TraceNameList, UpperStr, VariableList, and WaveList functions.

RemoveFromTable

RemoveFromTable [/W=winName] columnSpec [, columnSpec]...
The RemoveFromTable operation removes the specified columns from the top table.

Parameters
columnSpecs are the same as for the Edit operation; usually they are just the names of waves.

Flags
/W=winName Removes columns from the named table window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also
Edit about columnSpecs, and AppendToTable.

RemoveImage

RemoveImage [/W=winName/Z] imageInstance [, imageInstance]...
The RemoveImage operation removes the given image from the target or named graph.

Parameters
imageInstance is usually simply the name of a wave. More precisely, imageInstance is a wave name, optionally followed by the # character and an instance number to identify which image of a given wave is to be removed.
RemoveLayoutObjects

Flags

/ALL
Removes all image plots from the graph. Any image name parameters listed are ignored. /ALL was added in Igor Pro 9.00.

/W=winName
Removes an image from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. Must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z
Suppresses errors if specified image is not on the graph.

Details
If the axes used by the given image are not in use after removing the image, they will also be removed.

An image name in a string can be used with the $ operator to specify imageInstance.

See Also
The AppendImage operation.

RemoveLayoutObjects

RemoveLayoutObjects[/PAGE=page/W=winName/Z] objectSpec [, objectSpec]

The RemoveLayoutObjects operation removes the specified object or objects from the top page layout, or from the layout specified by the /W flag. It targets the active page or the page specified by the /PAGE flag.

Unlike the RemoveFromLayout operation, RemoveLayoutObjects can be used in user-defined functions. Therefore, RemoveLayoutObjects should be used in new programming.

Parameters
objectSpec is either an object name (e.g., Graph0) or an objectName with an instance (e.g., Graph0#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0#0 and Graph0#1 refers to the second instance of Graph0 in the layout.

Flags

/PAGE=page
Removes the object from the specified page.
Page numbers start from 1. To target the active page, omit /PAGE or use page=0.
The /PAGE flag was added in Igor Pro 7.00.

/W=winName
winName is the name of the page layout window from which the object is to be removed. If /W is omitted or if winName is $"", the top page layout is used.

/Z
Does not report errors if the specified layout object does not exist.

See Also
NewLayout, AppendLayoutObject, ModifyLayout, LayoutPageAction

RemoveListItem

RemoveListItem(index, listStr [, listSepStr [, offset]])

The RemoveListItem function returns listStr after removing the item specified by the list index index.

RemoveListItem removes an item from a string containing a list of items separated by a separator, such as strings returned by functions like TraceNameList and AnnotationList.

Parameters

index is the zero-based index of the list item that you want to remove.
listStr contains a series of text items separated by listSepStr. The trailing separator is optional though recommended.
listSepStr is optional. If omitted it defaults to ";". Prior to Igor Pro 7.00, only the first byte of listSepStr was used. Now all bytes are used.
RemovePath

Offset

RemoveList: is optional and requires Igor Pro 7.0 or later. If omitted it defaults to 0. The search begins offset bytes into listStr. When iterating through lists containing large numbers of items, using the offset parameter provides dramatically faster execution. For an example using the offset parameter, see StringFromList.

Details

RemoveList differs from RemoveFromList in that it specifies the item to be removed by index and removes only that item, while RemoveFromList specifies the item to be removed by value, and removes all matching items.

If index less than 0 or greater than ItemsInList(listStr) - 1, or if listSepStr is "", then listStr is returned unchanged (unless listStr contains only list separators, in which case an empty string is returned).

If the resulting string contains only listSepStr characters, then an empty string ("") is returned.

Examples

Print RemoveList(1, "wave0;wave1;w2;") // Prints "wave0;w2;"

See Also

The AddList, FindList, FunctionList, ItemsInList, RemoveByKey, RemoveFromList, StringFromList, StringList, TraceNameList, VariableList, WaveList, and WhichList functions.

RemovePath

RemovePath [/A/Z] pathName

The RemovePath operation removes a path from the list of symbolic paths. RemovePath is an old name for the new KillPath operation, which we recommend you use instead.

Rename

Rename oldName, newName

The Rename operation renames waves, strings, or numeric variables from oldName to newName.

Parameters

oldName may be a simple object name or a data folder path and name. newName must be a simple object name.

Details

You can not rename an object using a name that already exists. The following will result in an error:

Make wave0, wave1
// Rename wave0 and overwrite wave1.
Rename wave0, wave1 // This will not work.

However, you can achieve the desired effect as follows:

Make wave0, wave1
Duplicate/O wave0, wave1, wave1; KillWaves wave0

See Also

The Duplicate operation.

RenameDataFolder

RenameDataFolder sourceDataFolderSpec, newName

The RenameDataFolder operation changes the name of the source data folder to the new name.

sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

newName is just the new name for the data folder, without any path.

Details

RenameDataFolder generates an error if the new name is already in use as a data folder contained within the source data folder.

Examples

RenameDataFolder root:foo,foo2 // Change name of foo to foo2
See Also
Chapter II-8, Data Folders.

**RenamePath**

**RenamePath** *oldName, newName*

The RenamePath operation renames an existing symbolic path from *oldName* to *newName*.

See Also
Symbolic Paths on page II-22

**RenamePICT**

**RenamePICT** *oldName, newName*

The RenamePICT operation renames an existing picture to from *oldName* to *newName*.

See Also
Pictures on page III-509.

**RenameWindow**

**RenameWindow** *oldName, newName*

The RenameWindow operation renames an existing window or subwindow from *oldName* to *newName*.

Parameters

*oldName* is the name of an existing window or subwindow.

When identifying a subwindow with *oldName*, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also
The DoWindow operation.

**ReorderImages**

**ReorderImages** [/W=*winName*] *anchorImage, {imageA, imageB, ...}*

The ReorderImages operation changes the ordering of graph images to that specified in the braces.

Flags

/W=*winName* Reorders images in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

Igor keeps a list of images in a graph and draws the images in the listed order. The first image drawn is consequently at the bottom. All other images are drawn on top of it. The last image is the top one; no other image obscures it.

ReorderImages works by removing the images in the braces from the list and then reinserting them at the location specified by *anchorImage*. If *anchorImage* is not in the braces, the images in braces are placed before *anchorImage*.

If the list of images is A, B, C, D, E, F, G and you execute the command

ReorderImages F, {B,C} images B and C are placed just before F: A, D, E, B, C, F, G.

The result of

ReorderImages E, {D,E,C} is to reorder C, D and E and put them where E was. Starting from the initial ordering this gives A, B, D, E, C, F, G.
ReorderTraces generates an error if the same trace is in the list twice.

In Igor7 or later, anchorImage can be _front_ or _back_. To move A to the front, you can write:
ReorderImage _front_, {A}

See Also
The ReorderTraces operation.

ReorderTraces

ReorderTraces [] /W=winName /L[axisName] /R[axisName] anchorTrace, {traceA, traceB, ...}

The ReorderTraces operation changes the ordering of graph traces to that specified in the braces.

Flags

/W=winName Reorders traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/L[axisName] Moves traces to a new or existing axis. This feature was added in Igor Pro 8.00.

/R[axisName] To reference the built-in left or right axes, you can use /L or /R without specifying the axis name. To reference a free axis, you must specify the axis name.

If the specified axis does not already exist, a new axis is created by cloning the axis controlling traceA.

If the move results in no traces assigned to an axis, then that axis is deleted.

Reordering is optional. Specify _none_ for anchorTrace for no reordering.

You can move a trace manually by right-clicking a trace and choosing Move to Opposite Axis.

Details

Igor keeps a list of traces in a graph and draws the traces in the listed order. The first trace drawn is consequently at the bottom. All other traces are drawn on top of it. The last trace is the top one; no other trace obscures it.

ReorderTraces works by removing the traces in the braces from the list and then reinserting them at the location specified by anchorTrace. If anchorTrace is not in the braces, the traces in braces are placed before anchorTrace.

If the list of traces is A, B, C, D, E, F, G and you execute the command
ReorderTraces F, {B,C}

traces B and C are placed just before F: A, D, E, B, C, F, G.

The result of
ReorderTraces E, {D,E,C}
is to reorder C, D and E and put them where E was. Starting from the initial ordering results in A, B, D, E, C, F, G.

ReorderTraces generates an error if the same trace is in the list twice.

In Igor7 or later, anchorImage can be _front_ or _back_. To move A to the front, you can write:
ReorderImages _front_, {A}

See Also
Trace Names on page II-282, Programming With Trace Names on page IV-87.

The ReorderImages operation.
ReplaceNumberByKey

ReplaceNumberByKey(keyStr, kwListStr, newNum [, keySepStr [, listSepStr [, case]]])

The ReplaceNumberByKey function returns kwListStr after replacing the numeric value of the keyword-value pair specified by keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "key:value1;KEY2:value2", depending on the values for keySepStr and listSepStr.

Use ReplaceNumberByKey to add or modify numeric information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like AxisInfo or TraceInfo.

If keyStr is not found in kwListStr, then the key and the value are appended to the end of the returned string. keySepStr, listSepStr, and case are optional; their defaults are ":", ";", and 0 respectively.

Details

The actual string appended is:

[listSepStr] keyStr keySepStr newNum listSepStr

The optional leading list separator listSepStr is added only if kwListStr does not already end with a list separator. kwListStr is searched for an instance of the key string bound by listSepStr on the left and a keySepStr on the right. The text up to the next ";" is replaced by newNum after conversion to text using the %.15g format (see printf for format conversion specifications).

kwListStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional case parameter to 0 makes the comparisons case sensitive.

In Igor6, only the first byte of keySepStr and listSepStr was used. In Igor7 and later, all bytes are used.

If listSepStr is specified, then keySepStr must also be specified. If case is specified, keySepStr and listSepStr must be specified.

Examples

Print ReplaceNumberByKey("K1", "K1:7;", 4) // prints "K1:4;"
Print ReplaceNumberByKey("K2", "K2=8;", 5, ";") // prints "K2=5;"
Print ReplaceNumberByKey("K3", "K3:9;", 6, ",", ",") // prints "K3:6;"  
Print ReplaceNumberByKey("K4", "K4:9;", 6, ",", ",") // prints "K4:6;"
Print ReplaceNumberByKey("K5", "K5:9;", 6, ",", ",", 1) // prints "K5:9,k5:6;"

See Also

The ReplaceStringByKey, NumberByKey, StringByKey, RemoveByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

ReplaceString

ReplaceString(replaceThisStr, inStr, withThisStr [, caseSense [, maxReplace]])

The ReplaceString function returns inStr after replacing any instance of replaceThisStr with withThisStr. The comparison of replaceThisStr to the contents of inStr is case-insensitive. Setting the optional caseSense parameter to nonzero makes the comparison case-sensitive.

Usually all instances of replaceThisStr are replaced. Setting the optional maxReplace parameter limits the replacements to that number.

Details

If replaceThisStr is not found, inStr is returned unchanged.

If maxReplace is less than 1, then no replacements are made. Setting maxReplace = Inf is the same as omitting it.

Examples

Print ReplaceString("hello", "say hello", "goodbye")// prints "say goodbye"
Print ReplaceString("\r\n", "line1\r\nline2", ") // prints "linelline2"
Print ReplaceString("A", "an Ack-Ack", "a", 1) // prints "an ack-ack"
Print ReplaceString("A", "an Ack-Ack", "a", 1, 1) // prints "an ack-Ack"
Print ReplaceString("", "input", "whatever") // prints "input" (no change)

V-799
ReplaceStringByKey

ReplaceStringByKey(keyStr, kwListStr, newTextStr [, keySepStr [, listSepStr [, matchCase]]])

The ReplaceStringByKey function returns kwListStr after replacing the text value of the keyword-value pair specified by keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for keySepStr and listSepStr.

Use ReplaceStringByKey to add or modify text information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like AxisInfo or TraceInfo.

If keyStr is not found in kwListStr, then the key and the value are appended to the end of the returned string. keySepStr, listSepStr, and matchCase are optional; their defaults are ";", ";", and 0 respectively.

Details
The actual string appended is:
[listSepStr]keyStr keySepStr newTextStr listSepStr

The optional leading list separator listSepStr is added only if kwListStr does not already end with a list separator.
kwListStr is searched for an instance of the key string bound by a "" on the left and a "" on the right. The text up to the next "" is replaced by newTextStr.

If newTextStr is ",", any existing value is deleted, but the key, the key separator, and the list separator are retained. To remove a keyword-value pair, use the RemoveByKey function.

kwListStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are case-insensitive. Setting the optional matchCase parameter to 1 makes the comparisons case-sensitive.

In Igor6, only the first byte of keySepStr and listSepStr was used. In Igor7 and later, all bytes are used.

If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

Examples
Print ReplaceStringByKey("KY", "KY:a;KZ:c", "b")  // prints "KY:b;KZ:c"
Print ReplaceStringByKey("KY", "ky:a;", "b", "c")   // prints "ky=b;"
Print ReplaceStringByKey("KY", "KY:a;", "b", ";", ",")// prints "KY:b,"
Print ReplaceStringByKey("ky", "ZZ:a;", "b", ";", ",")// prints "ZZ:a,ky:b,"
Print ReplaceStringByKey("kz", "KZ:a;", "b", ";", ",")// prints "KZ:b,"
Print ReplaceStringByKey("kz", "KZ:a;", "b", ";", ",", 1)  // prints "KZ:a,kz:b,"

See Also
The ReplaceString, ReplaceNumberByKey, NumberByKey, StringByKey, ItemsInList, RemoveByKey, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.
ReplaceText

ReplaceText [/W=winName/N=name] textStr
The ReplaceText operation replaces the text in the most recently created or changed annotation or in the
annotation specified by /W=winName and /N=name.

Parameters
textStr can contain escape codes to set the font, size, style, color and other properties. See Annotation
Escape Codes on page III-53 for details.

If the annotation is a color scale, this command replaces the text of the color scale's main axis label.

Flags
/N=name Replaces the text of the named tag or textbox.
/W=winName Replaces text in the named graph window or subwindow. When omitted, action will
affect the active window or subwindow. This must be the first flag specified when
used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92
for details on forming the window hierarchy.

See Also
Tag, TextBox, ColorScale, Legend, AppendText, Annotation Escape Codes on page III-53.

ReplaceWave

ReplaceWave [/W=winName] allinCDF
ReplaceWave [/X/W=winName] trace=traceName, waveName
ReplaceWave [/X/Y/W=winName] image=imageName, waveName
ReplaceWave [/X/Y/W=winName] contour=contourName, waveName

The ReplaceWave operation replaces waves displayed in a graph with other waves. The waves to be
replaced, and the replacement waves are chosen by the flags, the keyword and the wave names on the
command line.

Flags
/W=winName Replaces the wave in the named graph window or subwindow. When omitted, action will
affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92
for details on forming the window hierarchy.

/X Replaces the wave supplying X coordinates.

If the trace represents a category plot, the wave must be either a text wave or the
special keyword '_labels_' to use dimension labels from the Y wave controlling the
axis.

/Y Replaces the wave supplying Y data.

Keywords
allinCDF Searches the current data folder for waves with the same names as waves used in
the graph. If found and if the waves are of the correct type, they replace the
existing waves. Thus, if you have several data folders with identically-named
waves containing data from different experimental runs, you can browse through
the runs by moving from one data folder to another, using ReplaceWave
allinCDF to update the graph.

contour=contourName Replaces the wave supplying the Z data for contourName. If /X or /Y is used,
replaces the wave used to set the X or Y data spacing (if the Z data are in a matrix)
or the wave used to supply the X or Y positions if XYZ triplets were specified with
three separate waves.
ReplicateString

ReplicateString(str, totalNumCopies)

The ReplicateString function returns a string containing str repeated totalNumCopies times.

The ReplicateString function was added in Igor Pro 9.00.

Example

String in = "αβγ"
String out = ReplicateString(in, 3) // Returns "αβγαβγαβγ"

See Also
PadString, ReplaceString
The Resample operation resamples `waveName` by interpolating or up-sampling (set by `/UP=upSample`), lowpass filtering, and decimating or down-sampling (set by `/DOWN=downSample`).

Lowpass filtering is specified with `/N` and `/WINF` or with `/COEF=coefsWaveName`.

The sampling frequency (1/DimDelta) of a resampled output wave `waveName` is changed by the ratio of `upSample/downSample`. For example, if `upSample=4` and `downSample=3`, then the final sampling rate is 4/3 of the original value.

Straight interpolation can be accomplished by setting `upSample` to the interpolation factor and `downSample=1`, in which case the sample rate is multiplied by `upSample`. Deltax(`waveName`) will be proportionally smaller.

Linear interpolation is accomplished by setting `numReconstructionSamples=3` and `windowKind=None`.

For decimation only, set `upSample=1` and `downSample` to the decimation factor. The sample rate is divided by `downSample`, and Deltax(`waveName`) will be proportionally larger.

Use `RatioFromNumber` to choose appropriate values for `upSample` and `downSample`, or use `/SAME=sWaveName` or `/RATE=sampRate`. See Resampling Rates Example for details.

When using `/COEF=coefsWaveName`, the filter coefficients should implement a low-pass filter appropriate for the `upSample` and `downSample` values or aliasing (filtering errors) will result. See Advanced Externally-Supplied Low Pass Filter Example for details.

Resampling Rates Flags

The `upSample` and `downSample` values define how much interpolation and decimation to perform. They can be set directly with `/UP` and `/DOWN` or indirectly with `/SAME` or `/RATE`.

- `/DOWN=downSample` Down-samples or decimates the filtered result by this integer factor after up-sampling and lowpass filtering. The default is 1 (no down-sampling).
  - For example, `/DOWN=3` places only every third value in the output wave.
  - Down-sampling divides the sampling rate of the filtered data by a factor of `downSample`. The DimDelta(`waveName, dim`) value is multiplied by the same factor.

- `/RATE=sampRate` Converts the output `waveName` to the specified sampling rate frequency (normally Hz).
  - The necessary `upSample` and `downSample` values for each `waveName` are computed internally as if you had executed:
    - `RatioFromNumber (deltax(waveName)*sampRate)`
    - `upSample = V_numerator`
    - `downSample = V_denominator`
  - `/RATE` returns `V_numerator` and `V_denominator` set to these automatically-determined values for the last `waveName`.

- `/SAME=sWaveName` Converts the output `waveName` to the same sampling rate as `sWaveName`, 1/DimDelta(`sWaveName, dim`). The necessary `upSample` and `downSample` values are computed internally as if you had executed:
  - `Variable dd = DimDelta(waveName,dim)`
  - `RatioFromNumber dd/DimDelta(sWaveName, dim)`
  - `upSample = V_numerator`
  - `downSample = V_denominator`
  - `/SAME` returns `V_numerator` and `V_denominator` set to these automatically-determined values for the last `waveName`. 

Resample

/UP=upSample

Up-samples or interpolates the input by this integer factor. The default is 1 (no up-sampling).

For example, /UP=4 inserts three extra points between each input point (producing 4 times as many values) before the lowpass filtering and downsampling occurs.

Up-sampling multiplies the sampling rate of the input data by a factor of upSample, though no additional signal information is created. The DimDelta(waveName, dim) value is divided by the same factor.

Internal Sinc Reconstruction Filter Flags

If /COEF=coefsWaveName is not specified, Resample computes a windowed sinc filter from /N, /DOWN, /UP, and /WINF flag values.

If /COEF=coefsWaveName is specified, then coefsWaveName supplies the filter, and /N and /WINF are ignored. See Externally-Supplied Low Pass Filter Flags.

/COEF

Replaces the first waveName with coefficients generated by downSample, upSample, numReconstructionSamples, and windowKind, a windowed sinc impulse response.

When resampling multiple waveNames with different filters (because /RATE or /SAME were specified and the multiple waveNames had different sampling rates), the filter used to resample the last waveName is returned.

/N=numReconstructionSamples

Specifies the number of input values used to created the up-sampled values (default is 21).

The value of numReconstructionSamples must be odd.

The size of the computed filter is (numReconstructionSamples-1) * upSample + 1.

Bigger is better: 15 is usually on the low side for yielding reasonably accurate results, and although 101 will nearly always give very good results, it will be slow.

Use /COEF to output the impulse response, and the FFT to display the frequency response of the interpolator:

Make/O coefs
Variable numReconstructionSamples= 51, upSample= 5
Resample/COEF/N=(numReconstructionSamples)/UP=(upSample) coefs
Variable evenNum= 2*floor((numpnts(coefs)+1)/2)
FFT/OUT=3/PAD={evenNum}/DEST=coefs_FFT coefs
Display coefs_FFT

Bigger is also slower: the filtering is computed in the time-domain, and execution time is linearly related to upSample/downSample * numReconstructionSamples.

/WINF=windowKind

Applies the window, windowKind, to the computed filter coefficients. If /WINF is omitted, the Hanning window is used. For no coefficient windowing, use /WINF=None, though this is discouraged unless you want linear interpolation, in which case it should be paired with /N=3.

Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when numReconstructionSamples is large.

Choices for windowKind are:

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, Riemann and None.

See FFT for window equations and details.
Externally-Supplied Low Pass Filter Flags

/COEF = coefsWaveName

Identifies the wave, coefsWaveName, containing filter coefficients that implement a low-pass filter with a cutoff frequency of the lesser of 0.5/upSample and 0.5/downSample, where 0.5 corresponds to the Nyquist frequency of the up-sampled data.

For example, if upSample=2, then the filter must contain the classic “half-band” filter, which stops the higher half of the frequencies and passes the lower half. If upSample=10, then the filter must pass only the lowest 1/10th of the frequencies.

For downSample > upSample, the low-pass filter’s cutoff frequency must be 0.5/downSample. This prevents the decimation from introducing aliasing to the resampled data.

To avoid shifting the output with respect to the input, coefsWaveName must have an odd length with the “center” coefficient in the middle of the wave.

The length of coefsWaveName must be 1+upSample*n, where n is any even integer.

Note: Instead of using /N=numReconstructionSamples with /COEF=coefsWaveName, numReconstructionSamples is computed from upSample and the number of points in coefsWaveName:

numReconstructionSamples=1+(numpnts(coefsWaveName)-1)/upSample.

Coefficients are usually symmetrical about the middle point, but this is not enforced. coefsWaveName must not be a destination waveName.

coefsWaveName must be single- or double-precision numeric and one-dimensional.

Data Range Flags

/DIM=d

Specifies the wave dimension to resample.

For d=0,1,..., resampling is along rows, columns, etc.

The default is /DIM=0, which resamples each individual column (each one a channel, say left and right) in a multidimensional waveName where each row comprises all sound samples at a particular time.

To resample in multiple dimensions, execute the command once for each dimension. For example, use /DIM=0 followed by another command with /DIM=1 to resample a two-dimensional wave in each direction.

E=endEffect

Determines how to handle the ends of the resampled wave(s) (w) when fabricating missing neighbor values.

endEffect=0: Bounce method. Uses w[i] in place of the missing w[-i] and w[n-i] in place of the missing w[n+i].

endEffect=1: Wrap method. Uses w[n-i] in place of the missing w[-i] and vice versa.

endEffect=2: Zero method (default). Uses 0 for any missing value.

endEffect=3: Repeat method. Uses w[0] in place of the missing w[-i] and w[n] in place of the missing w[n+i].

Parameters

waveName can be a wave with any number of dimensions. Only one dimension is resampled. Use multiple Resample calls to resample across multiple dimensions.

Without /DIM, resampling is done along the row (first) dimension for each column. That is, each column is resampled as if it were a separate one-dimensional wave. This allows multichannel audio to be resampled to another frequency.

If /DIM=1, then resampling proceeds across all the columns of each row.
If `/COEF` is specified without `coefsWaveName`, then the first `waveName` is overwritten by the filter coefficients instead of being resampled.

**Details**

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length (/N or the length of `coefsWaveName`) should be small in comparison to the resampled waves.

Resample should not be used on data that contains NaNs; use Smooth/M=NaN to replace NaN values with a local median, or use MatrixOp zapNaNs to remove them.

Resample assumes that the middle point of `coefsWaveName corresponds to the delay=0 point. The “middle” point number = trunc((numpnts(coefsWaveName)-1)/2). `coefsWaveName` usually contains the two-sided impulse response of a filter, an odd number of points, and implements a low-pass filter whose cutoff frequency is the lesser of 0.5/`upSample` and 0.5/`downSample` (0.5 corresponds to the Nyquist frequency = 1/2 sampling frequency).

When `/COEF` creates a coefficients wave it sets the wave’s X scaling deltax property to the deltax of the input wave multiplied by the /DOWN factor and divided by the /UP factor. It also sets the x0 property so that the zero-phase (center) coefficient is located at x=0.

**Simple Examples**

// Interpolation by factor of 4, default filter
Resample/UP=4 data

// Interpolation by factor of 7, linear interpolation
Resample/UP=7/N=3/WINF=None data

// Decimation by factor of 3, default filter
Resample/DOWN=3 data

// Match sampling rates, default filter
Resample/SAME=dataAtDesiredRate dataAtWrongRate1, dataAtWrongRate2,...

// Resample waves to 10 KHz sampling rate
Resample/RATE=10e3 dataAtWrongRate1, dataAtWrongRate2,...

// Interpolate an image by a factor of 2
Resample/UP=2 image // default is /DIM=0, resample rows
Resample/UP=2/DIM=1 image // resample across columns

**Note:** Interpolating by a factor of two does not produce an image with twice as many rows and columns. The new number of rows = (original rows-1)*`upSample` +1, and a similar computation applies to columns.

**Resampling Rates Example**

Suppose we have an audio wave sampled at 44,100 Hz and we wish to resample it to a higher 192,000 Hz frequency.

We can use `/RATE= 192000` and let Resample determine the correct values (provided `waveName` has its X scaling set properly to reflect sampling at 44100 Hz), but let’s compute `upSample` and `downSample` ourselves.

Because the sampling rate = 1/deltax(`wave`), we can recast the /SAME formula to RatioFromNumber (desiredSamplingRate/currentSamplingRate):

```
•RatioFromNumber/V (192000 / 44100)
  V_numerator= 640; V_denominator= 147;
  ratio= 4.3537414965986;
  V_difference= 0;
```

Then `upSample`=640 and `downSample`=147.

The 44100 Hz input data will be interpolated by 640 to 28,224,000 Hz.

The result is low-pass filtered with a “cutoff frequency” of 1/640th of the interpolated Nyquist frequency = (28224000/2)/640 = 22,050 Hz, the same as the input signal’s original Nyquist frequency.
The result will be decimated by 147 to 192,000 Hz, which is the desired output sampling frequency.

**Note:** If `downSample` had been greater than `upSample`, then the low-pass filter’s cutoff frequency would have been 1/downSample of the interpolated Nyquist frequency = (28224000/2)/downSample. This prevents the decimation from introducing aliasing to the resampled data.

Resample/UP=640/DOWN=147 sound // convert 44.1 KHz to 192 KHz

**Advanced Externally-Supplied Low Pass Filter Example**
You can generate an appropriate filter by executing commands like these:

```
// Compute a filter for after the input is upsampled
// to restore the frequency content to the original range.
Variable fc = min(0.5 / upSample, 0.5 * upSample / downSample)
// Transition width, small widths need big n
Variable tw = fc/10
// Set end of pass band
Variable fl = fc-tw/2
// Set start of stop band
Variable f2 = fc+tw/2
// Use bigger values of n to make the filter smoother
Variable nReconstruct= 31
Variable n = (nReconstruct-1)*upSample+1 // odd = no phase shift
// Create a wave to hold the coefficients; it gets resized to n
Make/O/N=0 coefsWaveName
FilterFIR/COEF/{fl,f2,n} coefsWaveName
```

However, FilterFIR does not create windowed sinc lowpass filters that have the endearing property that the original input values are unaltered in the filtered output, though only if `upSample` > `downSample`. This is called a “Nyquist filter” or “Kth-band filter” in the literature.

If `upSample` > `downSample`, you can enforce the Nyquist criterion by “zeroizing” the designed filter by setting every `upSample`th value to 0 except the center one.

```
// coefsWaveName length must be 1+upSample*n, where n is any even integer
Function Zeroize(w, upSample)
    Wave w // coefsWaveName
    Variable upSample // upSample value
    Variable n= DimSize(w,0)
    Variable centerP= floor((n-1)/2) // if n=101, centerP= 50
    Variable i
    for (i=0; i<n; i+=upSample)
        if( i != centerP )
            w[i] = 0
        endif
    endfor
End
```

Resample zeroizes the internally-generated low pass filter when `upSample` > `downSample`.

Additionally, the FilterFIR command generates a low-pass filter whose gain needs to be multiplied by `upsample`: `coefsWaveName *= upSample`

When designing an externally supplied filter, you should also consider the filter’s “polyphase” nature; `coefsWaveName` is actually a set of `upSample` interleaved filters, each with its own response. It makes sense to adjust these filters to produce consistent responses. If you don’t, the results will contain ringing with a period of `upSample/downSample`. This is most apparent when `downSample` is 1.

Using the filter we’ve designed so far with `upSample=4`, here’s the output of a constant-input wave:

```
Make/O constantData= 1
Resample/COEF=coefsWaveName/UP=4 constantData
```
The graph shows that the filter response at 0 Hz for the first of 4 filters is 1.0010, the second and fourth filter’s responses are very close to 1.0, and the third filter’s response at 0 Hz is a little less than 1.0.

These variations can be eliminated by normalizing the sum of each polyphase filter to 1.0:

```
Function PolyphaseNormalize(w, upSample)
    Wave w  // coefsWaveName
    Variable upSample  // upSample value

    Variable n= DimSize(w,0)
    Variable filt
    // for each filter (0..upSample-1)
    for (filt=0; filt<upSample; filt+=1)
        Variable total=0
        Variable pt
        // compute total for this filter
        for (pt=filt; pt<n; pt+=upSample)
            total += w[pt]
        endfor
        // divide by total to normalize total to 1
        for (pt=filt; pt<n; pt+=upSample)
            w[pt] /= total
        endfor
    endfor
End
```

Now the filter is ready to be used to filter data:

```
Resample/COEF=coefsWaveName/UP=(upSample)/DOWN=(downSample) dataWave
```

You can see that designing an externally-supplied lowpass filter is much more complicated than using the internal sinc reconstruction filter, which does all this zeroizing, scaling, and polyphase normalization for you.

ResumeUpdate

ResumeUpdate

The ResumeUpdate operation cancels the corresponding PauseUpdate.

This operation is of use in macros. It is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the DoUpdate operation.

See Also
The DelayUpdate, DoUpdate, and PauseUpdate operations.

return

return [expression]

The return flow control keyword immediately stops execution of the current procedure. If called by another procedure, it returns expression and control to the calling procedure.

Functions can return only a single value directly to the calling procedure with a return statement. The return value must be compatible with the function type. A function may contain any number of return statements; only the first one encountered during procedure execution is evaluated.

A macro has no return value, so return simply quits the macro.

See Also
The Return Statement on page IV-35.

Reverse

The Reverse operation reverses data in a wave in a specified dimension. It does not accept text waves.

Flags

/DIM=d	 specifying the wave dimension to reverse.  
  d= -1: Treats entire wave as 1D (default).  
  For d=0, 1, … , operates along rows, columns, etc.

/P	 suppresses adjustment of dimension scaling. Without /P the scaled dimension value of reversed points remains the same.

Type Flags (used only in functions)

Reverse also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it is needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See WAVE Reference Types on page IV-73 and WAVE Reference Type Flags on page IV-74 for a complete list of type flags and further details.

Wave Parameters

Note: All wave parameters must follow wave in the command. All wave parameter flags and type flags must appear immediately after the operation name (Reverse).

/D=destWave	 specifies the name of the wave to hold the reversed data. It creates destWave if it does not already exist or overwrites it if it exists.

Details

If the optional /D = destWave flag is omitted, then the wave is reversed in place.

See Also
Sorting on page III-132, Sort, SortColumns
The RGBColor structure is used as a substructure usually to store various color settings.

```
Structure RGBColor
    UInt16 red
    UInt16 green
    UInt16 blue
EndStructure
```

The RGBAColor structure is the same as RGBColor but with an alpha field to represent translucency.

```
Structure RGBAColor
    UInt16 red
    UInt16 green
    UInt16 blue
    UInt16 alpha
EndStructure
```

The rightx function returns the X value corresponding to point N of the named 1D wave of length N.

```
rightx(waveName)
```

**Details**

Note that the point numbers in a wave run from 0 to N-1 so there is no point with this X value. To get the X value of the last point in a wave (point N-1), use the following:

```
pnt2x(waveName, numpnts(waveName) - 1) // N = numpnts(waveName)
```

which is more accurate than:

```
rightx(waveName) - deltax(waveName)
```

The rightx function is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details. The equivalent information for any dimension can be calculated this way:

```
IndexN = DimSize(wave, dim) * DimDelta(wave, dim) + DimOffset(wave, dim)
```

Here IndexN is the value of the scaled dimension index corresponding to element N of the dimension dim in a named wave that has N elements in that dimension.

**See Also**

The deltax and leftx functions, also the pnt2x and numpnts functions.

For an explanation of waves and dimension scaling, see Changing Dimension and Data Scaling on page II-68. For multidimensional waves, see DimDelta, DimOffset, and DimSize.

```
root[:dataFolderName[:...]][:objectName]
```

Igor’s data folder hierarchy starts with the root folder as its basis. The root data folder always exists and it contains all other objects (waves, variables, strings, and data folders). By default, the root data folder is the current data folder in a new experiment. In commands, root is used as part of a path specifying the location of a data object in the folder hierarchy.

**See Also**

Chapter II-8, Data Folders.

The Rotate operation rotates the Y values of waves in wavelist by rotPoints points.

```
Rotate rotPoints, waveName [, waveName]...
```

**Parameters**

If rotPoints is positive then values are rotated from the start of the wave toward the end and rotPoints values from the end of a wave wrap around to the start of the wave.
If `rotPoints` is negative then values are rotated from the end of the wave toward the start and `rotPoints` values from the start of a wave wrap around to the end of the wave.

**Details**
The X scaling of the named waves is changed so that the X values for the Y values remains the same except for the points that wrap around.

The Rotate operation is not multidimensional aware. To rotate rows or columns of 2D waves, see the `rotateRows`, `rotateCols`, `rotateLayers` and `rotateChunks` keywords for `MatrixOp` and the `rotateRows` and `rotateCols` keywords for `ImageTransform`.

For general information about multidimensional analysis, see Analysis on Multidimensional Waves on page II-95.

**See Also**
The shift parameter of the `WaveTransform` operation.

### round

`round(num)`
The round function returns the integer value closest to `num`.

The rounding method is “away from zero”.

The result for INF and NAN is undefined.

**See Also**
The `ceil`, `floor`, and `trunc` functions.

### rtGlobals

`#pragma rtGlobals = 0, 1, 2, or 3`
`#pragma rtglobals=<n>` is a compiler directive that controls compiler and runtime behaviors for the procedure file in which it appears.

This statement must be flush against the left edge of the procedure file with no indentation. It is usually placed at the top of the file.

`#pragma rtglobals=0` turns off runtime creation of globals. This is obsolete.

`#pragma rtglobals=1` is a directive that turns on runtime lookup of globals. This is the default behavior if `#pragma rtGlobals` is omitted from a given procedure file.

`#pragma rtGlobals=2` turns off compatibility mode. This is mostly obsolete. See Legacy Code Issues on page IV-113 for details.

`#pragma rtglobals=3` turns on runtime lookup of globals, strict wave reference mode and wave index bounds checking.

rtGlobals=3 is recommended.

See The rtGlobals Pragma on page IV-52 for a detailed explanation of rtGlobals.

### s

The `s` function returns the current chunk index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled chunk index is available as the `t` function.

**Details**
Unlike `p`, outside of a wave assignment statement, `s` does not act like a normal variable.

**See Also**
Waveform Arithmetic and Assignments on page II-74.

For other dimensions, the `p`, `r`, and `q` functions.

For scaled dimension indices, the `x`, `y`, `z` and `t` functions.
Save [flags] waveList [as fileNameStr]

The Save operation saves the named waves to disk as text (/F, /G or /J) or as Igor binary.

Parameters

waveList is either a list of wave names or, if the /B flag is present, a string list of references to waves. For example, the following commands are equivalent, assuming that the waves in question are in the root data folder and root is the current data folder:

Save/J wave0,wave1 as "Test.dat"
Save/J root:wave0,root:wave1 as "Test.dat"
Save/J/B "wave0;wave1;" as "Test.dat"
String list="root:wave0;root:wave1;"; Save/J/B list as "Test.dat"

The form using the /B flag and a string containing a list of references to waves saves a very large number of waves using one command. This is not possible using a list of wave names because of the 2500 byte command line length limit. When using this form, the string must contain semicolon-separated wave names or data folder paths leading to waves. Liberal names in the string may be quoted or unquoted.

The file to be written is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If it cannot determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags

/A=[a]  
Appends to the file rather than overwriting it (with /T, /G or /J).

a=0:  
Does not append.
a=1:  
Appends to the file with a blank line before the appended data (same as /A only).
a=2:  
Appends to the file with no blank line before the appended data.

/B  
The waveList parameter is a string containing a list of references to waves instead of a literal list of waves.

/C  
Saves a copy of the wave when saving as Igor binary.

/DELIM=delimStr  
Specifies the string to use as a column delimiter. This flag affects general text saves (/G) and delimited text saves (/J) only.

delimStr defaults to tab. It can consist of multiple characters.

If you choose a delimiter that also appears in the data you are saving, for example if you choose to save text waves containing commas using comma as the separator, the resulting file is likely to be misinterpreted by any software loading it.

/DELIM was added in Igor Pro 7.00.

/DSYM=dsStr  
Specifies a string containing the character to use as the decimal symbol for all numbers (default is a period). If dsStr is empty (""), then the decimal symbol is as defined in system preferences as of when Igor was launched.

/E=useEscapeCodes  
Determines whether to use escape sequences for special characters.

/E=1:  
Converts carriage-return, linefeed, tab, and backslash characters to escape sequences when writing general or delimited text files (default; same as no /E).

/E=0:  
No escape sequences used in general or delimited text files. When saving text waves containing backslashes (such as Windows paths) in a file intended for another program, you probably should use /E=0.
Save

/F  Writes delimited and general text files with numeric formatting as it appears in the top table. Has no effect if there is no top table or if the wave being saved does not appear in the top table.

Note: The text written to the file is exactly as displayed in the table. Set the table to display as many digits of precision as you want in the file.

Note: Fractional and out-of-range floating point wave data cannot be formatted as octal or hex. See Octal Numeric Formats on page II-257 and Hexadecimal Numeric Formats on page II-257 for details.

Note: When saving a multi-column wave (1D complex wave or multidimensional wave), all columns of the wave are saved using the table format for the first table column from the wave.

/G  Saves waves in general text format.

/H  "Adopts" the waves specified by waveList.

"Adopt" means that any connection between the waves and external files is severed. The waves become part of the current experiment. When the experiment is next saved, the waves are saved in the experiment file (for a packed experiment) or in the experiment folder (for an unpacked experiment).

When you use the /H flag, all other flags and the fileNameStr parameter are ignored. The wave is not actually saved but rather is marked for saving as part of the current experiment.

You would normally do this to make an experiment more self-contained which makes it easier to send to other people. See Sharing Versus Copying Igor Binary Wave Files on page II-156 and the LoadWave /H flag.

/I  Presents a dialog from which you can specify file name and folder.

/J  Saves waves in delimited text format.

The delimiter defaults to tab unless you specify another delimiter using /DLIM.

/M=termStr  Specifies the terminator character or characters to use at the end of each line of text. The default is /M="\r", which uses a carriage return character. This is the Macintosh convention. To use the Windows convention, carriage return plus line feed, specify /M="\r\n". To use the Unix convention, just a line feed, specify /M="\n".

/O  Overwrites file if it exists already.

/P=pathName  Specifies the folder to store the file in. pathName is the name of an existing symbolic path.

/T  Saves waves in Igor Text format.

/U=[writeRowLabels, rowPositionAction, writeColLabels, colPositionAction]

These parameters affect the saving of a matrix (2D wave) to a delimited text (/J) or general text (/G) file. They are accepted no matter what the save type is but are ignored when they don’t apply.

If writeRowLabels is nonzero, Save writes the row labels of the matrix as the first column of data in the file.

rowPositionAction has one of the following values:

0:  Don’t write a row position column.
1:  Writes a row position column based on the row scaling of the matrix wave.
2:  Writes a row position column based on the contents of the row position wave for the matrix. The row position wave is an optional 1D wave whose name is the same as the matrix wave but with the prefix "RP_".
Details

The Save operation saves only the named waves; it does not save the entire experiment.

Waves saved in Igor binary format are saved one wave per file. If you are saving more than one wave, you must not specify a fileNameStr. Save will give each file a name which consists of the wave name concatenated with ".ibw".

When you save a wave as Igor binary, unless you use the /C flag to save a copy, the current experiment subsequently references the file to which the wave was saved. See References to Files and Folders on page II-24 for details.

In a general text file (/G), waves with different numbers of points are saved in different groups. Waves with different precisions and number types are saved in same group if they have the same number of points.

In a delimited text file (/J), all waves are saved in one group whether or not they have the same number of points.

If you save multiple 2D waves, the blocks of data are written one after the other.

If you save 3D waves, the data for each wave is written as a contiguous block having as many columns as there are columns in the wave, and R*L rows, where R is the number of rows in the multidimensional wave and L is the number of layers. All rows for layer 0 are saved followed by all rows for layer 1, and so on.

If you save 4D waves, the data for each wave is written as a contiguous block having R*L*C rows, where R is the number of rows, L is the number of layers and C is the number of chunks. Igor writes all data for chunk 0 followed by all data for chunk 1, and so on.

The Save operation will always present a save dialog if you try to save to an existing file without using the overwrite flag.

Here are some details about saving an Igor binary wave file.

If you omit the path or the file name, the Save operation will normally present a save dialog. However, if the wave has already been saved to a stand-alone file and if you use the overwrite flag, it will save the wave to the same file without a dialog. Also, if the wave has never been saved and the current experiment is an unpacked experiment, it will save to the home folder without a dialog.

If you use /P=pathname, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-22 for details.

Examples

This function uses the string list of references to waves to save some or all of the waves in the current data folder:

Function SaveWavesFromCurrentDF(matchStr)
    String matchStr // As for the WaveList function.
    String list // As for the WaveList function.
    list = WaveList(matchStr, ";", ":")
    Save/O/J/W/I/B list
End

For example, to save all of the waves in the current data folder, execute:

SaveWavesFromCurrentDF("*")

To save those waves in the current data folder whose name starts with “wave”, execute:

SaveWavesFromCurrentDF("wave*")

This function saves all of the waves used in a particular graph:

Function SaveWavesFromGraph(graphName) // Saves all waves in graph.
    String graphName // "" for top graph.
    String list, traceList, traceName
    Variable index = 0
    list = ""
    traceList = TraceNameList(graphName, ";", 1)
do
    traceName = StringFromList(index, traceList, ";")
    if (strlen(traceName) == 0)
        break
    endif
    Wave w = TraceNameToWaveRef(graphName, traceName)
    list += GetWavesDataFolder(w, 2) + ";"
    index += 1
while(1)
    if (strlen(list) > 0)
        Save/O/J/W/I/B list
    endif
End

See Also
Exporting Data on page II-177.

SaveData

SaveData [flags] fileOrFolderNameStr

The SaveData operation writes data from the current data folder of the current experiment to a packed experiment file on disk or to a file system folder. “Data” means Igor waves, numeric and string variables, and data folders containing them. The data is written as a packed experiment file or as unpacked Igor binary wave files in a file-system folder.

Warning: If you make a mistake using SaveData, it is possible to overwrite critical data, even entire folders containing critical data. It is your responsibility to make sure that any file or folder that you cannot afford to lose is backed up. If you provide procedures for use by other people, you should warn them as well.

SaveData provides a way to save data for archival storage or unload data from memory during a lengthy process like data acquisition. The file or files that SaveData writes are disassociated from the current experiment.

Use SaveData to save experiment data using Igor procedures. To save experiment data interactively, use the Save Copy button in the Data Browser (Data menu).

Parameters

fileOrFolderNameStr specifies the packed experiment file (if /D is omitted) or the file system folder (if /D is present) in which the data is to be saved. The documentation below refers to this file or folder as the “target”.

If you use a full or partial path for fileOrFolderNameStr, see Path Separators on page III-451 for details on forming the path.

If fileOrFolderNameStr is omitted or is empty (""), SaveData displays a dialog from which you can select the target. You also get a dialog if the target is not fully specified by fileOrFolderNameStr or the /P=pathName flag.

If you are saving to a packed experiment file (/D omitted or /D=0), SaveData writes an HDF5 packed experiment file if the file name extension is ".h5xp". Otherwise it writes a standard packed experiment file (.pxp format). The .h5xp format requires Igor Pro 9 or later.

Flags

/COMP={minWaveElements, gzipLevel, shuffle}

Specifies that compression is to be applied to numeric waves saved when saving as an HDF5 packed experiment file. The /COMP flag was added in Igor Pro 9.00.

minWaveElements is the minimum number of elements that a numeric wave must have to be eligible for compression. Waves with fewer than this many total elements are not compressed.

gzipLevel is a value from 0 to 9. 0 means no GZIP compression.

shuffle is 0 to turn shuffle off or 1 to turn shuffle on.

When compression is applied by SaveData, the entire wave is saved in one chunk. See HDF5 Layout Chunk Size on page II-214 for background information and SaveExperiment Compression on page II-214 for details.
SaveData

/D [=d]  Writes to a file-system folder (a directory). If omitted, SaveData writes to an Igor packed experiment file.

   d=1: If the target folder already exists, the new data is “mixed-in” with the data already there (same as /D).
   d=2: If the target folder already exists, it is completely deleted before the writing of data starts.

If in doubt, use /D=1. See Details below.

/I  Presents a dialog in which you can interactively choose the target.

/J=objectNamesStr  Saves only the objects named in the semicolon-separated list of object names.

When saving as an HDF5 packed experiment file (.h5xp), /J is not supported and returns an error if you use it and provide a non-empty string as objectNamesStr.

See Saving Specific Objects below for further discussion of /J.

/L=saveFlags  Controls what kind of data objects are saved with a bit for each data type:

<table>
<thead>
<tr>
<th>saveFlags</th>
<th>Bit Number</th>
<th>Saves this Type of Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>Waves</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Numeric variables</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>String variables</td>
</tr>
</tbody>
</table>

To save multiple data types, sum the values shown in the saveFlags column. For example, /L=1 saves waves only, /L=2 saves numeric variables only and /L=3 saves both waves and numeric variables.

If /L is not specified, all of these object types are saved. This is equivalent to /L=7. All other bits are reserved and must be set to zero. See Setting Bit Parameters on page IV-12 for details.

/M=modDateTime  Saves waves modified on or after the specified modification date/time. Waves modified before modDateTime will not be saved. Applies to waves only (not variables or strings).

modDateTime is in standard Igor time format — seconds since 1/1/1904. If modDateTime is zero, all waves will be saved, as if there were no /M flag at all.

/O  Overwrites existing files or folders on disk.

Warning: If you use the /O flag and if the target already exists, it will be overwritten without any warning. If you use /O with /D=2, you will completely overwrite the target folder and all of its contents, including subfolders. Do not use /O with /D unless you are absolutely sure you know what your doing.

/P=pathName  Specifies the folder in which to save the specified file or folder.

pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:Folder1:" or "C:\\Folder1". See Symbolic Paths on page II-22 for details.

When used with the /D flag, if /P=pathName is present and fileOrFolderNameStr is ":", the target is the directory specified by /P=pathName.

/Q  Suppresses normal messages in the history area.

/R  Recursively saves subdata folders.
SaveData

/T [=topLevelName] Creates an enclosing data folder in the target with the specified name, topLevelName, and writes the data to the new data folder.

If just /T is specified, it creates an enclosing data folder in the target using the name of the data folder being saved. However, if the data folder being saved is the root data folder, the name Data is used instead of root. In packed experiment files and unpacked experiment folders, the root data folder is implicit.

If /T is omitted, the contents of the current data folder are saved with no enclosing data folder.

Saving Specific Objects
If /J=objectNamesStr is used, then only the objects named in objectNamesStr are saved. For example, specifying /J="wave0;wave1;" will save only the two named waves, ignoring any other data in all data folders.

The list of object names used with /J must be semicolon-separated. A semicolon after the last object name in the list is optional. The object names must not be quoted even if they are liberal. The list is limited to 1000 characters.

Using /J="" acts like no /J at all.

When saving as an HDF5 packed experiment file (.h5xp), /J is not supported and returns an error if you use it and provide a non-empty string as objectNamesStr.

Details
The /M=modDateTime flag can be used in data acquisition projects to save only those waves modified since the previous save. For example, assume that we have a global variable in the root data folder named gLastWaveSaveDateTime. Then this function will write out only those waves modified since the previous save:

Function SaveModifiedWaves(savePath)
String savePath // Symbolic path pointing to output directory
NVAR lastSave = root:gLastWaveSaveDateTime
SaveData/O/P=$savePath/D=1/L=1/M=(lastSave) ":"
lastSave = datetime
End

Because the datetime function and the wave modification date have a coarse resolution (one second), this function may sometimes save the same wave twice.

The /M flag makes sense only in conjunction with the /D=1 flag because /D=1 is the only way to mix-in new data with existing data.

Writing to a Packed Experiment File
When writing to a packed file, SaveData creates a standard packed Igor experiment file which you can open as an experiment, browse using the Data Browser, or access using the LoadData operation.

If you do not use the /O (overwrite) flag and the packed file already exists on disk, SaveData will present a dialog to confirm which file you want to write to. If you use the /O flag, SaveData will overwrite without presenting a dialog. When writing a packed file, SaveData always completely overwrites the preexisting packed file.

Appending to a packed experiment file is not supported because dealing with the possibility of name conflicts (e.g., two waves with the same name in the same data folder in the packed experiment file) would be technically difficult, very slow and errors would result in corrupted files.

Writing to a File-System Folder
When saving to a folder on disk, SaveData writes wave files, variables files, and subfolders. This resembles the experiment folder of an unpacked experiment, but it does not contain other unpacked experiment files, such as history or procedures. You can browse the folder using the Data Browser or access it using the LoadData operation.

If the target directory does not exist, SaveData creates it.

If you do not use the /O (overwrite) flag and the target folder already exists on disk, SaveData will present a dialog to confirm that you want to write to it. SaveData checks for the existence of the top file system folder only. For example, if you write data to hd:Data:Run1, SaveData will display a dialog if hd:Data:Run1 exists. But SaveData will not display a dialog for any folders inside hd:Data:Run1.

If you use the /O flag, SaveData will write without presenting a dialog.
SaveData

When writing to a directory, SaveData can operate in one of two modes. If you use /D=1 or just /D, SaveData operates in “mix-in” mode. If you use /D=2, SaveData operates in “delete” mode.

**Warning:** If the target directory exists and delete mode is used, SaveData deletes the target directory and all of its contents. Then SaveData creates the target directory and writes the data to it. This is a complete overwrite operation.

If the target directory exists and mix-in mode is used, SaveData does not do any explicit deletion. It writes data to the target directory and any subdirectories. Conflicting files in any directory are overwritten but other files are left intact.

To prevent you from inadvertently deleting an entire volume, SaveData will not permit you to target the root directory of any volume. You must target a subdirectory.

The /J flag will not work as expected when writing numeric and string variables in mix-in mode. Instead of mixing-in the specified variables, SaveData will overwrite all variables already in the target. This is because all numeric and string variables in a particular data folder are stored in a single file-system folder (named “variables”), so it is not possible to mix-in. Since waves are written one-to-a-file, /J will work as expected for waves.

When SaveData writes a wave to a file-system folder, the file name for the wave is the same as the wave name, with the extension “.ibw” added. This is true even if the wave in the experiment was loaded from a file with a different name.

**Limitations of SaveData**

SaveData does not save free waves, free data folders, wave waves or DFREF waves all of which are ignored by SaveData.

When saving as HDF5 packed (.h5xp), the entire experiment must use UTF-8 text encoding. If the experiment uses non-UTF8 text encoding, SaveData displays an alert directing you to Misc→Text Encoding→Convert to UTF-8 Text Encoding and returns an error.

When saving as HDF5 packed (.h5xp), the /J flag is not supported and returns an error if you use it and provide a non-empty string as objectNamesStr.

**Outputs**

SaveData sets the variable V_flag to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel during an interactive save. This would occur if you use the /I flag or if you omit /O and the target already exists. V_flag will also be nonzero if an error occurs during the save.

SaveData sets the string variable S_path to the full file system path to the file or folder that was written. S_path uses Macintosh path syntax (e.g., “hd:FolderA:FolderB:"), even on Windows. When saving unpacked, S_path includes a trailing colon.

**Examples**

Write the contents of the current data folder and all subdata folders to a packed experiment file:

```vbscript
Function SaveDataInPackedFile(pathName, fileName)
    String pathName // Name of symbolic path
    String fileName // Name of packed file to be written
    SaveData/R/P=$pathName fileName
End
```

Write the contents of the current data folder and all subdata folders to an unpacked file-system folder:

```vbscript
Function SaveDataInUnpackedFolder(pathName, folderName)
    String pathName // Name of symbolic path
    String folderName // Name of file-system folder
    SaveData/D=1/R/P=$pathName folderName
End
```

Copy the contents of an unpacked file-system folder to a packed experiment file:

```vbscript
Function TransferUnpackedToPacked(path1, folderName, path2, fileName)
    String path1 // Points to parent of unpacked folder
    String folderName // Name of folder containing unpacked data
    String path2 // Points to folder where file is to be written
    String fileName // Name of packed file to be written
End
```

**Warning:** If the target directory exists and delete mode is used, SaveData deletes the target directory and all of its contents. Then SaveData creates the target directory and writes the data to it. This is a complete overwrite operation.
SaveExperiment

SaveExperiment [flags] [as fileName]
The SaveExperiment operation saves the current experiment.

Warning: SaveExperiment overwrites any previously-existing file named fileName.

Parameters
The optional fileName string contains the name of the experiment to be saved. fileName can be the currently open experiment, in which case it overwrites the experiment file.

If fileName and pathName are omitted and the experiment is Untitled, you will need to locate where the experiment file will be saved interactively via a dialog.

If you use a full or partial path for pathName, see Path Separators on page III-451 for details on forming the path.

Flags

/C Saves an experiment copy (valid only when fileName or pathName is provided or both if experiment is Untitled).

/COMP={minWaveElements, gzipLevel, shuffle}

Specifies that compression is to be applied to numeric waves saved when saving as an HDF5 packed experiment file. The /COMP flag was added in Igor Pro 9.00.

minWaveElements is the minimum number of elements that a numeric wave must have to be eligible for compression. Waves with fewer than this many total elements are not compressed.

gzipLevel is a value from 0 to 9. 0 means no GZIP compression.

shuffle is 0 to turn shuffle off or 1 to turn shuffle on.

When compression is applied by SaveExperiment, the entire wave is saved in one chunk. See HDF5 Layout Chunk Size on page II-214 for background information and SaveExperiment Compression on page II-214 for details.

/F={format, unpackedExpFolderNameStr, unpackedExpFolderMode}

Specifies the experiment file format.

See Experiment File Format below for details.

/P=pathName

Specifies folder in which to save the experiment. pathName is the name of an existing symbolic path.

Details
SaveExperiment acts like the Save menu command in the File menu. If the experiment is associated with an already saved file, then SaveExperiment with no parameters will simply save the current experiment. If the experiment resides only in memory and has not yet been saved, then a dialog will be presented unless the path and file name are specified.
SaveExperiment

If you use a full path in the name you will not need the /P flag. If instead you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-22 for details.

Experiment File Format
For background information on experiment file formats, see Experiments on page II-16.

The /F flag provides control of the file format of a previously-unsaved experiment independent of the user's preferences as set in the Experiment Settings section of the Miscellaneous Settings dialog. It also allows you to save a previously-saved experiment using a different experiment file format.

If you just want to save the current experiment in its current format, you don't need to use /F.

If you use /F, you must fully-specify the location of the experiment file through the /P flag and the fileName parameter or through fileName alone if it contains a full path.

The format parameter controls the experiment file format used by SaveExperiment:

- format = -1: Default format
- format = 0: Unpacked experiment file
- format = 1: Packed experiment file
- format = 2: HDF5 packed experiment file

If /F is omitted or if format is -1 then the experiment is saved in its current format or, if it was never saved to disk, as a packed experiment file (.pxp).

If format = 0, the experiment is saved in unpacked experiment file format. fileName must end with ".uxp" or ".uxt".

If format = 1, the experiment is saved in packed experiment file format. fileName must end with ".pxp" or ".pxt".

If format = 2, the experiment is saved in HDF5 packed experiment file format. fileName must end with ".h5xp" or ".h5xt". This format requires Igor Pro 9.00 or later.

Unpacked Experiment Folder
The unpacked experiment folder is the folder in which wave files, the history file, the variables file, and other experiment files are stored for an unpacked experiment. See Saving as an Unpacked Experiment File on page II-17 for details.

The /F unpackedExpFolderNameStr parameter specifies the name of the experiment folder for an unpacked experiment. It contains a folder name, not a full or partial path. It is ignored unless saving in unpacked experiment format.

The unpacked experiment folder is created in the same directory as the experiment file.

If /F=0 is used and unpackedExpFolderNameStr is "" then the experiment folder name is the same as the experiment file name with the extension removed and a space and "Folder" added.

If the specified unpacked experiment folder already exists and is the current experiment's unpacked experiment folder, it is reused. "Reuse" means that SaveExperiment saves files in the unpacked experiment folder, possibly overwriting files already in it, but does not delete any files or folders already in it.

The unpackedExpFolderMode parameter controls what happens if the folder to be used as the unpacked experiment folder already exists and is not the current experiment's unpacked experiment folder:

- unpackedExpFolderMode=0: SaveExperiment returns an error.
- unpackedExpFolderMode=1: SaveExperiment displays a dialog asking the user if it is OK to reuse the folder. If the user answers yes, the operation proceeds. Otherwise, it returns an error.
- unpackedExpFolderMode=2: SaveExperiment reuses the folder without asking the user.

Warning: If you pass 2 for unpackedExpFolderMode, files and folders in the unpacked experiment folder may be overwritten without the user's express permission.
SaveGizmoCopy

**SaveGizmoCopy**  
`SaveGizmoCopy [flags] [as fileNameStr]`

The `SaveGizmoCopy` operation saves a Gizmo window and its waves in an Igor packed experiment file. `SaveGizmoCopy` was added in Igor Pro 8.00.

**Parameters**

The file to be written is specified by `fileNameStr` and `/P=pathName` where `pathName` is the name of an Igor symbolic path. `fileNameStr` can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with `pathName`, or the name of a file in the folder associated with `pathName`. If Igor can not determine the location of the file from `fileNameStr` and `pathName`, it displays a dialog allowing you to specify the file.

If you use a full or partial path for `fileNameStr`, see **Path Separators** on page III-451 for details on forming the path.

**Flags**

- `/I`  
  Presents a dialog from which you can specify file name and folder.

- `/O`  
  Overwrites file if it exists already.

- `/P=pathName`  
  Specifies the folder to store the file in. `pathName` is the name of an existing symbolic path.

- `/T=saveType`  
  Specifies the file format of the saved file.
  
  `saveType=0`: Packed experiment file.
  
  `saveType=1`: HDF5 packed experiment file. If `fileNameStr` is specified the file name extension must be ".h5xp".

  The `/T` flag was added in Igor Pro 9.00.

- `/W=winName`  
  `winName` is the name of the Gizmo window to be saved. If `/W` is omitted or if `winName` is ".", the top Gizmo window is saved.

- `/Z`  
  Errors are not fatal and error dialogs are suppressed. See Details.

**Details**

The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the Gizmo window starting from the root data folder. Only the Gizmo window, its waves as well as the objects on Gizmo's object list and attribute list are saved in the packed experiment file. Associated procedures including hook functions are not saved.

`SaveGizmoCopy` does not know about dependencies. If a Gizmo window contains a wave, `wave0`, that is dependent on another wave, `wave1` which is not used in the Gizmo window, `SaveGizmoCopy` will save `wave0` but not `wave1`. When the saved experiment is open, there will be a broken dependency.

`SaveGizmoCopy` sets the variable `V_flag` to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the `/Z` flag and check `V_flag` after calling `SaveGizmoCopy`.

**See Also**

`SaveGraphCopy`, `SaveTableCopy`, `SaveData`, **Merging Experiments** on page II-19

SaveGraphCopy

**SaveGraphCopy**  
`SaveGraphCopy [flags] [as fileNameStr]`

The `SaveGraphCopy` operation saves a graph and its waves in an Igor packed experiment file.
SaveGraphCopy

Parameters
The file to be written is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor cannot determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags
/I Present a dialog from which you can specify file name and folder.
/O Overwrites file if it exists already.
/P=pathName Specifies the folder to store the file in. pathName is the name of an existing symbolic path.
/T=saveType Specifies the file format of the saved file.
   saveType=0: Packed experiment file.
   saveType=1: HDF5 packed experiment file. If fileNameStr is specified the file name extension must be ".h5xp".

The /T flag was added in Igor Pro 9.00.

/W= winName winName is the name of the graph to be saved. If /W is omitted or if winName is "", the top graph is saved.
/Z Errors are not fatal and error dialogs are suppressed. See Details.

Details
The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see Merging Experiments on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the graph starting from the “top” data folder, which is the data folder that encloses all waves displayed in the graph. The top data folder becomes the root data folder of the resulting experiment file. Only the graph, its waves, dashed line settings, and any pictures used in the graph are saved in the packed experiment file, not procedures, variables, strings or any other objects in the experiment.

SaveGraphCopy does not work well with graphs containing controls. First, the controls may depend on waves, variables or FIFOs (for chart controls) that SaveGraphCopy will not save. Second, controls typically rely on procedures which are not saved by SaveGraphCopy.

SaveGraphCopy does not know about dependencies. If a graph contains a wave, wave0, that is dependent on another wave, wave1 which is not in the graph, SaveGraphCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

SaveGraphCopy sets the variable V_flag to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check V_flag after calling SaveGraphCopy.

The SaveData operation also has the ability to save data from a graph to a packed experiment file. SaveData is more complex but a bit more flexible than SaveGraphCopy.

Examples
This function saves all graphs in the experiment to individual packed experiment files.

Function SaveAllGraphsToPackedFiles(pathName)
   String pathName       // Name of an Igor symbolic path.
   String graphName
   Variable index
   index = 0
   do
      graphName = WinName(index, 1)
      if (strlen(graphName) == 0)
         break
   end

V-822
SaveNotebook

SaveNotebook [flags] notebookName [as fileNameStr]

The SaveNotebook operation saves the named notebook.

Parameters

`notebookName` is either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.

If `notebookName` is an host-child specification, /S must be used and `saveType` must be 3 or higher.

The file to be written is specified by `fileNameStr` and /P=`pathName` where `pathName` is the name of an Igor symbolic path. `fileNameStr` can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with `pathName`, or the name of a file in the folder associated with `pathName`. If Igor can not determine the location of the file from `fileNameStr` and `pathName`, it displays a dialog allowing you to specify the file.

If you use a full or partial path for `fileNameStr`, see Path Separators on page III-451 for details on forming the path.

Flags

/ENCG=textEncoding

Specifies text encoding in which the notebook is to be saved.

This flag was added in Igor Pro 7.00.

This is relevant for plain text notebooks only and is ignored for formatted notebooks because they can contain multiple text encodings. See Plain Text File Text Encodings on page III-466 and Formatted Text Notebook File Text Encodings on page III-472 for details.

If omitted, the file is saved in its original text encoding. Normally you should omit /ENCG. Use it only if you have some reason to change the file's text encoding.

Passing 0 for `textEncoding` acts as if /ENCG were omitted.

See Text Encoding Names and Codes on page III-490 for a list of accepted values for `textEncoding`.

This flag does not affect HTML export. Use /H instead.

/H={encodingName, writeParagraphProperties, writeCharacterProperties, PNGOrJPEG, quality, bitDepth}

Controls the creation of an HTML file.

`encodingName` specifies the HTML file text encoding. The recommended value is "UTF-8".

See Also
SaveTableCopy, SaveGizmoCopy, SaveData, Merging Experiments on page II-19
SaveNotebook

`writeParagraphProperties` determines what paragraph properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

- Bit 0: Write paragraph alignment.
- Bit 1: Write first indent.
- Bit 2: Write minimum line spacing.
- Bit 3: Write space-before and space-after paragraph.

All other bits are reserved for future use and should be set to zero.

`writeCharacterProperties` determines what character properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

- Bit 0: Write font families.
- Bit 1: Write font sizes.
- Bit 2: Write font styles.
- Bit 3: Write text colors.
- Bit 4: Write text vertical offsets.

All other bits are reserved for future use and should be set to zero.

If you set bit 2, SaveNotebook exports only the bold, underline, and italic styles because other character styles are not supported by HTML.

`PNGOrJPEG` determines whether SaveNotebook will write picture files as PNG or JPEG:

- 0: PNG (default).
- 1: JPEG.
- 2: JPEG.

In Igor7 and later, there is no difference between `PNGOrJPEG=1` and `PNGOrJPEG=2`. See Details for more on HTML picture files.

`quality` specifies the degree of compression or image quality when writing pictures as JPEG files. Legal values are in the range 0.0 to 1.0.

In Igor7 or later, the quality used is 0.9 regardless of what you pass for this parameter.

`bitDepth` specifies the color depth when writing pictures as JPEG files. Legal values are legal: 1, 8, 16, 24, and 32.

In Igor7 or later, the bit depth used is 32 regardless of what you pass for this parameter.

/I Saves interactively. A dialog is displayed.

/M=messageStr Specifies prompt message used in save dialog.

/O Overwrites existing file without asking permission.

/P=pathName Specifies the folder to store the file in. `pathName` is the name of an existing symbolic path.

/S=saveType Controls the type of save.

- `saveType=1`: Normal save (default).
- `saveType=2`: Save-as.
- `saveType=3`: Save-a-copy.
- `saveType=4`: Export as RTF (Rich Text Format).
- `saveType=5`: Export as HTML (Hypertext Markup Language).
- `saveType=6`: Export as plain text.
- `saveType=7`: Export as formatted notebook.
- `saveType=8`: Export as plain text with line breaks.

Details

Interactive (/I) means that Igor displays the Save, Save As, or Save a Copy dialog.
The save will be interactive under the following conditions:

- You include the /I flag and the \textit{saveType} is 2, 3, 4, 5, 6, 7 or 8.
- \textit{saveType} is 2, 3, 4, 5, 6, 7 or 8 and you do not specify the path or filename.

If the \textit{saveType} is normal and the notebook has previously been saved to a file then the /I flag, the path and file name that you specify, if any, are ignored and the notebook is saved to its associated file without user intervention.

The full path to the saved file is stored in the string \texttt{S_path}. If the save was unsuccessful, \texttt{S_path} will be "".

If you use /P=pathname, note that it is the name of an Igor symbolic path, created via \texttt{NewPath}. It is not a file system path like "hd:Folder1:" or "C:\Folder1\". \texttt{See Symbolic Paths} on page II-22 for details.

\textit{saveType}=8 applies to formatted notebooks only. It exports the notebook as plain text with line breaks where text wraps in the formatted notebook. This feature was added in Igor Pro 8.00. Special characters such as pictures are skipped. If the notebook is plain text then \textit{saveType}=8 acts like \textit{saveType}=6.

**Exporting as RTF**

For background information on writing RTF files, see \texttt{Import and Export Via Rich Text Format Files} on page III-20.

**Exporting as HTML**

For background information on writing HTML files, see \texttt{Exporting a Notebook as HTML} on page III-21.

You can pass “UTF-8” or “UTF-2” for the \texttt{encodingName} parameter. In virtually all cases, you should use “UTF-8”.

When creating an HTML file, \texttt{SaveNotebook} can write pictures using the PNG or JPEG graphics formats. PNG is recommended because it is lossless.

**See Also**

Chapter III-1, \texttt{Notebooks}.

\texttt{Setting Bit Parameters} on page IV-12 for further details about bit settings.

**SavePackagePreferences**

\texttt{SavePackagePreferences} [/FLSH=flush /KILL /P=pathname] \texttt{packageName, prefsFileName, recordID, prefsStruct}

The \texttt{SavePackagePreferences} operation saves preference data in the specified structure so that it can be accessed later via the \texttt{LoadPackagePreferences} operation.

**Note:** The package preferences structure must not use fields of type \texttt{Variable}, \texttt{String}, \texttt{WAVE}, \texttt{NVAR}, \texttt{SVAR} or \texttt{FUNCREF} because these fields refer to data that may not exist when \texttt{LoadPackagePreferences} is called.

The structure can use fields of type char, uchar, int16, uint16, int32, uint32, int64, uint64, float and double as well as fixed-size arrays of these types and substructures with fields of these types.

The data is stored in memory and by default flushed to disk when the current experiment is saved or closed and when Igor quits.

If the /P flag is present then the location on disk of the preference file is determined by \texttt{pathname} and \texttt{prefsFileName}. However in the usual case the /P flag will be omitted and the preference file is located in a file named \texttt{prefsFileName} in a directory named \texttt{packageName} in the Packages directory in Igor’s preferences directory.

**Note:** You must choose a very distinctive name for \texttt{packageName} as this is the only thing preventing collisions between your package and someone else’s package.

See \texttt{Saving Package Preferences} on page IV-251 for background information and examples.

**Parameters**

\texttt{packageName} is the name of your package of Igor procedures. It is limited to 31 bytes and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else’s package.
SavePICT

*prefsFileName* is the name of a preference file to be saved by `SavePackagePreferences`. It should include an extension, typically `.bin`.

*prefsStruct* is the structure containing the data to be saved in the preference file on disk.

*recordID* is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct *recordIDs* to identify which structure you want to save. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the *recordID*.

**Flags**

- **/FLSH=flush** Controls when the data is actually written to the preference file:
  - flush=0: The data will be flushed to disk when the current experiment is saved, reverted or closed or when Igor quits. This is the default behavior used when `/FLSH` is omitted and is recommended for most purposes.
  - flush=1: The data is flushed to disk immediately.

- **/KILL** Instead of saving *prefsStruct* under the specified record ID, that record is deleted from the package’s preference if it exists. If it does not exist, nothing is done and no error is returned.

- **/P=pathName** Specifies the directory in which to save the file specified by *prefsFileName*.
  - *pathName* is the name of an existing symbolic path. See [Symbolic Paths](#) on page II-22 for details.
  - `/P=$<empty string variable>` acts as if the `/P` flag were omitted.

**Details**

`SavePackagePreferences` sets the following output variables:

- **V_flag**
  - Set to 0 if preferences were successfully saved or to a nonzero error code if they were not saved. The latter case is unlikely and would indicate some kind of corruption such as if Igor’s preferences directory were deleted.

- **V_structSize**
  - Set to the size in bytes of *prefsStruct*. This may be useful in handling structure version changes.

**Example**

See the example under [Saving Package Preferences in a Special-Format Binary File](#) on page IV-252.

**See Also**

`LoadPackagePreferences`.

**SavePICT**

`SavePICT [flags] [as fileNameStr]`

The `SavePICT` operation creates a picture file representing the top graph, table or layout. The picture file can be opened by many word processing, drawing, and page layout programs.

**Parameters**

The file to be written is specified by *fileNameStr* and `/P=pathName` where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see [Path Separators](#) on page III-451 for details on forming the path.
If you omit `fileNameStr` but include `/P=pathName`, SavePICT writes the file using a default file name. The default file name is the window name followed by an extension, such as "_.png", "_.emf" or "_.svg", that depends on the graphic format being exported.

If you specify the file name as "Clipboard", and do not specify a `/P=pathName`, Igor copies the picture to the Clipboard, rather than to a file. EPS is a file-only format and can not be stored in the clipboard.

If you specify the file name as "_string_" the output will be saved into a string variable named S_Value, which is used with the ListBox binary bitmap display mode.

If you use the special name _PictGallery_ with the /P flag, then the picture will be stored in Igor's picture gallery (see Pictures on page III-509) with the name you provide via `fileNameStr`. This feature was added in support of making movies using the /PICT flag with NewMovie.

Flags

- **/B=dpi**: Controls image resolution in dots-per-inch (dpi). The legal values for dpi are n*72 where n can be from 1 to 8. The actual image dpi is not used. Igor calculates n from your value of dpi and then multiplies n by your computer's screen resolution. This is because bitmap images that are not an integer multiple of the screen resolution look quite bad.
  
  Also see the /RES flag.

- **/C=c**: Specifies color mode.
  
  - c=0: Black and white.
  
  - c=1: RGB color (default).
  
  - c=2: CMYK color (EPS and native TIFF only).

- **/D=d**: Obsolete in Igor Pro 7 or later.

- **/E=e**: Sets graphics format used when exporting a graphic. See Details for formats. See also Chapter III-5, Exporting Graphics (Macintosh), or Chapter III-6, Exporting Graphics (Windows), for a description of these modes and when to use them.

- **/EF= e**: Sets font embedding.
  
  - e=0: No font embedding. Not honored in Igor Pro 7 or later.
  
  - e=1: Embed nonstandard fonts.
  
  - e=2: Embed all fonts.

- **/I**: Specifies that /W coordinates are inches.

- **/M**: Specifies that /W coordinates are centimeters.

- **/N=winSpec**: /N is antiquated but still supported. Use /WIN instead.

- **/O**: Overwrites file if it exists.

- **/P=pathName**: Saves file into a folder specified by pathName, which is the name of an existing symbolic path.

- **/PGR=(firstPage, lastPage)**: Controls which pages in a multi-page layout are saved.

  - firstPage and lastPage are one-based page numbers. All pages from firstPage to lastPage are saved if the file format supports it.

  - The special value 0 refers to the current page and -1 refers to the last page in the layout.

  - Currently only the PDF formats support saving multiple pages. Other file formats save only firstPage and ignore the value of lastPage.

  - /PGR was added in Igor Pro 7.00.

- **/PICT=pict**: Saves specified named picture rather than the target window. Native format of the picture is used and all format flags are ignored.
SavePICT

/PLL=\p Specifies Postscript language level when used in conjunction with EPS export.
\p=1: For very old Postscript printers.
\p=2: For all other uses (default).

/Q=\q Sets quality factor (0.0 is lowest, 1.0 is highest). Default is dependent on individual format. Used only by lossy formats such as JPEG.

/R=\resID Obsolete in Igor Pro 7 or later.

/RES=\dpi Controls the resolution of image formats in dots-per-inch. Unlike the similar /B flag, the value for /RES is the actual output resolution and is useful when your publisher demands a specific resolution.

/S Suppresses the preview that is normally included with an EPS file.
Obsolete in Igor Pro 7 or later.

/SNAP=\s Saves a snapshot (screen dump) of a graph or panel window.
\s=1: Include all controls in capture.
\s=2: Capture only window data content.

/SNAP=\s

Snapshot mode is available only for graphs and panels and only for bitmap export formats PNG, JPEG, and TIFF at screen resolution. When using /W to specify the size of a graph, the capture is sized to fit within the specified rectangle while maintaining the window aspect ratio. Coordinates used with /W are in pixels.

/T=\t Obsolete QuickTime export type. Not supported in Igor Pro 7 or later.

/TRAN=[1 or 0] Makes white background areas transparent using an RGBA type PNG when used with native PNG export of graphs or page layouts.

/W=(left,top,right,bottom) Specifies the size of the picture when exporting a graph. If /W is omitted, it uses the graph window size.

When exporting a page layout, specifies the part of the page to export. Only objects that fall completely within the specified area are exported. If /W is omitted, the area of the layout containing objects is exported.

When exporting a page layout in Igor Pro 7.00 or later, you can specify /W=(0,0,0,0) to use the full page size.

Coordinates for /W are in points unless /I or /M are specified before /W.

/WIN=\winSpec Saves the named window or subwindow. \winSpec can be just a window name, or a window name following by a “#” character and the name of the subwindow, as in /WIN=Panel0#G0.

/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details
SavePICT sets the variable V_flag to 0 if the operation succeeds or to a nonzero error code if it fails.

If you specify a path using the /P=\pathName flag, then Igor saves the file in the folder identified by the path. Note that \pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-22 for details. Otherwise, with no path specified, Igor presents a standard save dialog to let you specify where the file is to be saved.

Graphics formats, specified via /E, are as follows:

<table>
<thead>
<tr>
<th>/E Value</th>
<th>Macintosh File Format</th>
<th>Windows File Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>-9</td>
<td>SVG file.</td>
<td>SVG file.</td>
</tr>
<tr>
<td>-8</td>
<td>PDF file.</td>
<td>PDF file.</td>
</tr>
</tbody>
</table>
SaveTableCopy

The low resolution PDF formats on Macintosh are probably not useful and are just placeholders for compatibility with old procedures.

See Also
The ImageSave operation for saving waves as PICTs and other image file formats. The LoadPICT operation.
See Chapter III-5, Exporting Graphics (Macintosh), or Chapter III-6, Exporting Graphics (Windows), for a description of the /E modes.

SaveTableCopy

\text{SaveTableCopy} \ [\text{flags}] \ [\text{as fileNameStr}]

The SaveTableCopy operation saves a copy of the data displayed in a table on disk. The saved file can be an Igor packed experiment file, a tab-delimited text file, or a comma-separated values text file.

When saving as text, by default the data format matches the format shown in the table. This causes truncation if the underlying data has more precision than shown in the table. If you specify /F=1, SaveTableCopy uses as many digits as needed to represent the data with full precision.

The point column is never saved.

To save data as text with full precision, use the Save operation.

When saving 3D and 4D waves as text, only the visible layer is saved. To save the entirety of a 3D or 4D wave, use the Save operation.

Parameters

The file to be written is specified by \text{fileNameStr} and /P=pathName where pathName is the name of an Igor symbolic path. \text{fileNameStr} can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor

<table>
<thead>
<tr>
<th>/E Value</th>
<th>Macintosh File Format</th>
<th>Windows File Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>-7</td>
<td>TIFF file. Lossless but larger file than PNG; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. You can specify the resolution with the /B or /RES flag. Cross-platform compatible.</td>
<td></td>
</tr>
<tr>
<td>-6</td>
<td>JPEG file. Lossy compression; best used for grayscale and color images with smooth tones. The /Q flag specifies compression quality and the /B or /RES flag sets the resolution. Cross-platform compatible. PNG is a better choice for scientific graphics.</td>
<td></td>
</tr>
<tr>
<td>-5</td>
<td>PNG (Portable Network Graphics) file. Lossless compression; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. Specify the resolution with /B or /RES. Cross-platform compatible.</td>
<td></td>
</tr>
<tr>
<td>-4</td>
<td>High resolution bitmap PICT file. Default resolution is 288 dpi. Specify the resolution with /B or /RES.</td>

<td></td>
</tr>
<tr>
<td>4</td>
<td>Low resolution Quartz PDF at 4x normal size. High-resolution Enhanced Metafile (EMF).</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>Low resolution Quartz PDF at 8x normal size. High-resolution Enhanced Metafile (EMF).</td>
<td></td>
</tr>
</tbody>
</table>
can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags

/A=a  Appsends data to the file rather than overwriting.
    a=0:  Does not append.
    a=1:  Appends to the file with a blank line before the appended data.
    a=2:  Appends to the file with no blank line before the appended data.
    /A applies when saving text files and is ignored when saving packed experiment files.
    If the file does not exist, a new file is created and /A has no effect.

/F=f  Controls the precision of saved numeric data.
    f=0:  Numeric data is written exactly as shown in the table. This may cause truncation. This is the default behavior if /F is omitted.
    f=1:  Numeric data is written with as many digits as needed to represent the data with full precision.
    The /F flag was added in Igor Pro 7.00

/I  Presents a dialog from which you can specify file name and folder.

/M=termStr  Specifies the terminator character or characters to use at the end of each line of text. The default is /M="\r" on Macintosh and /M="\r\n" on Windows; it is used when /M is omitted. To use the Unix convention, just a linefeed, specify /M="\n".

/N=n  Specifies whether to use column names, titles, or dimension labels.

    n is a bitwise parameter with the bits defined as follows:
    Bit 0: Include column names or titles. The column title is included if it is not empty. If it is empty, the column name is included.
    Bit 1: Include horizontal dimension labels if they are showing in the table.

    The default setting for n is 1. All other bits are reserved and must be zero.

/O  Overwrites file if it exists already.

/P=pathName  Specifies the folder to store the file in. pathName is the name of an existing symbolic path.

/S=s  Saves all of the data in the table (s=0; default) or the selection only (s=1).

    /S applies when saving text files and is ignored when saving packed experiment files.

/T=saveType  Specifies the file format of the saved file.

    saveType=0:  Packed experiment file.
    saveType=1:  Tab-delimited text file.
    saveType=2:  Comma-separated values text file.
    saveType=3:  Space-delimited values text file.
    saveType=4:  HDF5 packed experiment file (requires Igor Pro 9 or later). If fileNameStr is specified the file name extension must be ".h5xp".

/W= winName  winName is the name of the table to be saved. If /W is omitted or if winName is ",", the top table is saved.

/Z  Errors are not fatal and error dialogs are suppressed. See Details.
Details
The main uses for saving a table as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see Merging Experiments on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the table starting from the “top” data folder, which is the data folder that encloses all waves displayed in the table. The top data folder becomes the root data folder of the resulting experiment file. Only the table and its waves are saved in the packed experiment file, not variables or strings or any other objects in the experiment.

SaveTableCopy does not know about dependencies. If a table contains a wave, wave0, that is dependent on another wave, wave1 which is not in the table, SaveTableCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

The main use for saving as a tab or comma-delimited text file is for exporting data to another program.

When calling SaveTableCopy from a procedure, you should call DoUpdate before calling SaveTableCopy. This insures that the table is up-to-date if your procedure has redimensioned or otherwise changed the number of points in the waves in the table.

SaveTableCopy sets the variable V_flag to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check V_flag after calling SaveTableCopy.

The SaveData operation also has the ability to save a table to a packed experiment file. SaveData is more complex but a bit more flexible than SaveTableCopy.

Examples
This function saves all tables to a single tab-delimited text file.

Function SaveAllTablesToTextFile(pathName, fileName)
  String pathName  // Name of an Igor symbolic path.
  String fileName
  String tableName
  Variable index
  index = 0
  do
    tableName = WinName(index, 2)
    if (strlen(tableName) == 0)
      break
    endif
    SaveTableCopy/P=$pathName/W=$tableName/T=1/A=1 as fileName
    index += 1
  while(1)
End

See Also
SaveGraphCopy, SaveGizmoCopy, SaveData, Merging Experiments on page II-19

sawtooth

The sawtooth function returns \((num + n2\pi \mod 2\pi)/2\pi\) where n is used to correct if num is negative. Sawtooth is used to create arbitrary periodic waveforms like sine and cosine.

Examples
wave1 = sawtooth(x)
creates a sawtooth in wave1 whose Y values range from 0 to 1 as its X values go through \(2\pi\) units.
wave1 = exp(sawtooth(x))
creates a series of exponentials in wave1 of amplitude \(\exp(1)\) and period \(2\pi\).
You can also use sawtooth to create periodic repetitions of a given part of a wave:
wave1 = wave2(sawtooth(x))
creates a periodic repetition of wave2 in wave1 given the correct X scaling for the waves.
ScaleToIndex

ScaleToIndex(wave, coordValue, dim)
The ScaleToIndex function returns the number of the element in the requested dimension whose scaled index value is closest to coordValue.

The ScaleToIndex function was added in Igor Pro 7.00.

Parameters
dim is a dimension number: 0 for rows, 1 for columns, 2 for layers, 3 for chunks.
coordValue is a scaled index in that dimension.

Details
The ScaleToIndex function returns the value of the expression:
\[ \text{round}((\text{coordValue} - \text{DimOffset}(\text{wave}, \text{dim})) / \text{DimDelta}(\text{wave}, \text{dim})) \]

With dim=0, ScaleToIndex is equivalent to x2pnt.

If coordValue is NaN or +/-INF, ScaleToIndex returns NaN. Otherwise, the result is computed based on the DimOffset and DimDelta of the specified dimension of the wave. The result is not clipped to a valid element number for the wave dimension.

See Also
IndexToScale, x2pnt, DimDelta, DimOffset

Waveform Model of Data on page II-62 for an explanation of wave scaling.

ScreenResolution

ScreenResolution
The ScreenResolution function returns the logical resolution of your video display screen in dots per inch (dpi). On Macintosh this is always 72. On Windows it is usually 96 (small fonts) or 120 (large fonts).

Examples
// 72 is the number of points in an inch which is constant.
Variable pixels = numPoints * (ScreenResolution/72) // Convert points to pixels
Variable points = numPixels * (72/ScreenResolution) // Convert pixels to points

See Also
PanelResolution

sec

sec(angle)
The sec function returns the secant of angle which is in radians:

\[ \sec(x) = \frac{1}{\cos(x)} \]

In complex expressions, angle is complex, and sec(angle) returns a complex value.

See Also
sin, cos, tan, csc, cot

sech

sech(x)
The sech function returns the hyperbolic secant of x.

\[ \text{csch}(x) = \frac{1}{\cosh(x)} = \frac{2}{e^x + e^{-x}} \]
In complex expressions, \( x \) is complex, and \( \text{sech}(x) \) returns a complex value.

**See Also**
cosh, tanh, coth, csch

**Secs2Date**

**Secs2Date**\( (\text{seconds}, \text{format} [, \text{sep}]) \)

The Secs2Date function returns a string containing a date.

With \( \text{format} \) values 0, 1, and 2, the formatting of dates depends on operating system settings entered in the Language & Region control panel (Macintosh) or the Region control panel (Windows). These date formats do not work with dates before 0001-01-01 in which case Date2Secs returns an empty string.

If \( \text{format} \) is -1, the format is independent of operating system settings. The fixed-length format is “day/month/year (dayOfWeekNum)”, where \( \text{dayOfWeekNum} \) is 1 for Sunday, 2 for Monday… and 7 for Saturday.

If \( \text{format} \) is -2, the format is YYYY-MM-DD.

The optional \( \text{sep} \) parameter affects format -2 only. If \( \text{sep} \) is omitted, the separator character is “-”. Otherwise, \( \text{sep} \) specifies the separator character.

**Parameters**

- \( \text{seconds} \) is the number of seconds from 1/1/1904 to the date to be returned.
- \( \text{format} \) is a number between -2 and 2 which specifies how the date is to be constructed.

**Examples**

Print Secs2Date(DateTime,-2) // 1993-03-14
Print Secs2Date(DateTime,-2,"/") // 1993/03/14
Print Secs2Date(DateTime,-1) // 15/03/1993 (2)
Print Secs2Date(DateTime,0) // 3/15/93 (depends on system settings)
Print Secs2Date(DateTime,1) // Monday, March 15, 1993 (depends on system settings)
Print Secs2Date(DateTime,2) // Mon, Mar 15, 1993 (depends on system settings)

**See Also**

For further discussion of how Igor represents dates, see Date/Time Waves on page II-85.
The date, date2secs and DateTime functions.

**Secs2Time**

**Secs2Time**\( (\text{seconds}, \text{format}, [\text{fracDigits}]) \)

The Secs2Time function returns a string containing a time.

**Parameters**

- \( \text{seconds} \) is the number of seconds from 1/1/1904 to the time to be returned.
- \( \text{format} \) is a number between 0 and 5 that specifies how the time is to be constructed. It is interpreted as follows:
  0: Normal time, no seconds.
  1: Normal time, with seconds.
  2: Military time, no seconds.
  3: Military time, with seconds and optional fractional seconds.
  4: Elapsed time, no seconds.
  5: Elapsed time, with seconds and optional fractional seconds.

“Normal” formats (0 and 1) follow the preferred formatting of the short time format as set in the International control panel (Macintosh) or in the Regional and Language Options control panel (Windows).

“Military” means that the hour is a number from 0 to 23. Hours greater than 23 are wrapped.
“Elapsed” means that the hour is a number from -9999 to 9999. The result for hours outside that range is undefined.

The fracDigits parameter is optional and specifies the number of digits of fractional seconds. The default value is 0. The fracDigits parameter is ignored for format=0, 1, 2, and 4.

**Examples**

```
Print Secs2Time(DateTime,0)      // prints 1:07 PM
Print Secs2Time(DateTime,1)      // prints 1:07:28 PM
Print Secs2Time(DateTime,2)      // prints 13:07
Print Secs2Time(DateTime,3)      // prints 13:07:29
Print Secs2Time(30*60*60+45*60+55,4) // Prints 30:45
Print Secs2Time(30*60*60+45*60+55,5) // Prints 30:45:55
```

**See Also**

For a discussion of how Igor represents dates, see *Date/Time Waves* on page II-85.

The Secs2Date, date, date2secs and DateTime functions. Also, *Operators* on page IV-6 for ?: details.

**SelectNumber**

The `SelectNumber` function returns one of `val1`, `val2`, or (optionally) `val3` based on the value of `whichOne`.

```
SelectNumber(whichOne, val1, val2 [, val3])
```

- `SelectNumber(whichOne, val1, val2)` returns `val1` if `whichOne` is zero, else it returns `val2`.
- `SelectNumber(whichOne, val1, val2, val3)` returns `val1` if `whichOne` is negative, `val2` if `whichOne` is zero, or `val3` if `whichOne` is positive.

**Details**

SelectNumber works with complex (or real) `val1`, `val2`, and `val3` when the result is assigned to a complex wave or variable. (Print expects a real result, see the “causes error” example, below).

If `whichOne` is NaN, then NaN is returned.

- `whichOne` must always be a real value.

Unlike the `? :` conditional operator, SelectNumber always evaluates all of the numeric expression parameters `val1`, `val2`, ...

SelectNumber works in a macro, whereas the conditional operator does not.

**Examples**

```
Print SelectNumber(0,1,2)          // prints 1
Print SelectNumber(0,1,2,3)        // prints 2
wv=SelectNumber(numtype(wv[p])==2,wv[p],0) // replace NaNs with zeros
```

// chooses among complex values

```
Variable/C cx= SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))
```

// causes error because Print expects a real value (not complex)

```
Print SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))
```

// The real function expects a complex result

```
Print real(SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1)))
```

**See Also**

The `SelectString` and *limit* functions, and *Waveform Arithmetic and Assignments* on page II-74. Also, *Operators* on page IV-6 for details about the `?:` operator.

**SelectString**

The `SelectString` function returns one of `str1`, `str2`, or (optionally) `str3` based on the value of `whichOne`.

```
SelectString(whichOne, str1, str2 [, str3])
```

- `SelectString(whichOne, str1, str2)` returns `str1` if `whichOne` is zero, else it returns `str2`.
- `SelectString(whichOne, str1, str2, str3)` returns `str1` if `whichOne` is negative, `str2` if `whichOne` is zero, or `str3` if `whichOne` is positive.
SetActiveSubwindow

Details
If `whichOne` is NaN, then "" is returned.

`whichOne` must always be a real value.

Unlike the `? :` conditional operator, SelectString always evaluates all of the string expression parameters `str1, str2, ...`

SelectString works in a macro, whereas the conditional operator does not.

Examples
```plaintext
Print SelectString(0, "hello", "there") // prints "hello"
Print SelectString(1, "hello", "there") // prints "hello"
Print SelectString(-3, "hello", "there", "jack") // prints "hello"
Print SelectString(0, "hello", "there", "jack") // prints "there"
Print SelectString(100, "hello", "there", "jack") // prints "jack"
```

See Also
The `SelectNumber` function and String Expressions on page IV-13. Also, Operators on page IV-6 for details about the `? :` operator.

SetActiveSubwindow

`SetActiveSubwindow subWinSpec`

The SetActiveSubwindow operation specifies the subwindow that is to be activated. This operation is mainly for use by recreation macros.

Parameters
`subWinSpec` specifies an existing subwindow. See Subwindow Syntax on page III-92 for details on subwindow specifications.

Use `_endfloat_` for `subWinSpec` to make a newly-created floating panel not be the default target.

See Also
GetWindow with the activeSW keyword.

SetAxis

`SetAxis [flags] axisName [, num1, num2]`

The SetAxis operation sets the extent (or “range”) of the named axis.

Parameters
`axisName` is usually “left”, “right”, “top” or “bottom”, but it can also be the name of a free axis, such as “vertCrossing”.

If `axisName` is a vertical axis such as “left” or “right” then `num1` sets the bottom end of the axis and `num2` sets the top end of the axis.

If `axisName` is a horizontal axis such as “top” or “bottom” then `num1` sets the left end of the axis and `num2` sets the right end of the axis.

You can flip the graph by reversing `num1` and `num2` (or by using `/A/R`). This is particularly useful for images, because Igor plots an image inverted.

If you pass * (asterisk) for `num1` and/or `num2` then the corresponding end of the axis will be autoscaled.

Flags

/`A`=a] Autoscale axis (when used, `num1, num2` should be omitted).

`a=0`: No autoscale. Same as no `/A` flag.

`a=1`: Normal autoscale. Same as `/A`.

`a=2`: Autoscale Y axis to a subset of the data defined by the current X axis range.
**SetBackground**

The `SetBackground numericExpression` operation sets `numericExpression` as the current unnamed background task. New code should use named background tasks instead. See Background Tasks on page IV-319 for details.

The background task runs while Igor is not busy with other things. Normally, there won’t be a background task. The most common use for the background task is to monitor or drive a continuous data acquisition process.

**Parameters**

`numericExpression` is a single precision numeric expression that Igor executes when it isn’t doing anything else.

**Details**

`numericExpression` is expected to return one of three numeric values:

- **0:** Background task executed normally.
- **1:** Background task wants to stop.
- **2:** Background task encountered error and wants to stop.

Usually the expression will be a call to a user-defined numeric function or external function to drive or monitor data acquisition. The expression should be designed to execute very quickly and it should not present a dialog to the user nor should it create or destroy windows. Generally, it should do nothing more than store data into waves or variables. You can use Igor’s dependency mechanism to perform more extensive tasks.

SetBackground designates the background task but you must use CtrlBackground to start it. You can also use KillBackground to stop it. You cannot call SetBackground from the background function itself.

**See Also**

The `BackgroundInfo`, `CtrlBackground`, `CtrlNamedBackground`, `KillBackground`, and `SetProcessSleep` operations, and Background Tasks on page IV-319.

</table>
SetDashPattern

SetDashPattern dashNumber, \{d1, s1 [, d2, s2]…\}

The SetDashPattern operation defines a dashed-line pattern for a user-defined dashed line. These dashed lines are used by the drawing tools and the Modify Waves Appearance dialog, and are elsewhere referred to as “line styles”.

Parameters

dashNumber specifies which dash pattern is to be set. It must be between 1 and 17. Dash pattern 0 is reserved for a solid line.

\{d1,s1 [, d2, s2]…\} defines the dash pattern. The dash pattern consists of 1 to 8 “dash,skip” pairs. Each pair consists of the number of drawn points followed by the number of skipped points.

d1 specifies the number of drawn points and s1 specifies the number of skipped points in the first “dash,skip” pair. d2 and s2 specify the number of drawn and skipped points in the second pair and so on. Each draw or skip value must be between 1 and 127.

Details

SetDashPattern updates all graphs, panels and layouts so that any dashed lines will be updated with the new pattern. If you repeatedly call SetDashPattern from within a macro, you should precede the commands with the PauseUpdate operation to prevent multiple updates (which would be slow).

Dashed lines may also be redefined by the Dashed Lines dialog which you can choose from the Misc menu.

The dashed line patterns are saved as part of the experiment. When a new experiment is opened, the preferred dash patterns are restored.

Some programs and printer drivers do not properly render dashed lines with many “dash,skip” pairs.

Examples

Make test; Display test
SetDashPattern 17, \{20,3,15,8\} // sets last dashed line pattern
ModifyGraph lstyle(test)=17 // apply pattern to trace

See Also

PauseUpdate and ResumeUpdate operations, and Dashed Lines on page III-496.

SetDataFolder

SetDataFolder dataFolderSpec

The SetDataFolder operation sets the current data folder to the specified data folder.

Parameters

dataFolderSpec can be a simple name (MyDataFolder), a path (root:MyDataFolder) or a string expression containing a name or path. It can also be a data folder reference created by the DFREF keyword or returned by GetDataFolderDFR.

If dataFolderSpec is a path it can be a partial path relative to the current data folder (:MyDataFolder) or an absolute path starting from root (root:MyDataFolder).

Examples

SetDataFolder foo // Sets CDF to foo in the current data folder
SetDataFolder :bar:foo // Sets CDF to foo in bar current data folder
SetDataFolder root:foo // Sets CDF to foo in the root data folder
DFREF savedDF= GetDataFolderDFR() // Remember current data folder
NewDataFolder/O/S root:MyDataFolder // Set CDF to a new data folder
Variable/G newVariable=1       // Do work in the new data folder
SetDataFolder savedDF        // Restore current data folder

See Also
Chapter II-8, Data Folders and Data Folder References on page IV-78.

SetDimLabel

SetDimLabel dimNumber, dimIndex, label, wavelist
The SetDimLabel operation sets the dimension label or dimension element label to the specified label.

Parameters
Use dimNumber=0 for rows, 1 for columns, 2 for layers and 3 for chunks.
If dimIndex is -1, it sets the label for the entire dimension. For dimIndex ≥ 0, it sets the dimension label for that element of the dimension.

label is a name (e.g., time), not a string (e.g., "time").
label is limited to 255 bytes. If you use more than 31 bytes, your wave will require Igor Pro 8.00 or later.

Details
Dimension labels can contain up to 255 bytes and may contain spaces and other normally-illegal characters allowed in liberal names if you surround the name in single quotes or if you use the $ operator to convert a string expression to a name.
Dimension labels have the same characteristics as object names. See Object Names on page III-501 for a discussion of object names in general.
Prior to Igor Pro 9.00, Igor allowed you to create dimension labels containing illegal characters (double-quotes, single-quotes, colon, semicolon, and control characters). This is now flagged as an error. Existing experiments containing dimension labels with illegal names can still be loaded without error.

See Also
GetDimLabel, FindDimLabel, CopyDimLabels
Dimension Labels on page II-93 and Example: Wave Assignment and Indexing Using Labels on page II-82 for further usage details and examples.

SetDrawEnv

SetDrawEnv [/W=winName] keyword [=value] [, keyword [=value]] ...
The SetDrawEnv operation sets properties of the drawing environment.
If one or more draw objects are selected in the top window then the SetDrawEnv command will apply only to those objects.
If no objects are selected and if the keyword save is not used then the command applies only to the next object drawn.
If no objects are selected and if the keyword “save” is used then the command sets the environment for all following objects.
Each draw layer has its own draw environment settings.

Parameters
SetDrawEnv can accept multiple keyword=value parameters on one line.
arrow=arr Specifies the arrow head position on lines.
arrow=0: No arrowhead (default).
arrow=1: Arrowhead at end.
arrow=2: Arrowhead at start.
arrow=3: Arrowhead at start and end.
arrowfat=afat Sets ratio of arrowhead width to length (default is 0.5).
arrowlen=alen Sets length of arrowhead in points (default is 10).
**SetDrawEnv**

<td>Sets text size, default is 12 points.</td>
</tr>
</tbody>
</table>
SetDrawEnv

fstyle=fs  
fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:
- Bit 0: Bold
- Bit 1: Italic
- Bit 2: Underline
- Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

gedit=flag  
Supplies optional edit flag for a group of objects. Use with gstart.
- flag=0: Select entire group, moveable (default).
- flag=1: Individual components editable as if not grouped. Allows objects to be grouped by name but still be editable.

gname=name  
Supplies optional name for an object group. Use with gstart.

gstart  
Marks the start of a group of objects.

gstop  
Marks the end of a group of objects.

gradient  
See Gradient Fills on page III-498 for details.

gradientExtra  
See Gradient Fills on page III-498 for details.

linebgc=(r,g,b[,a])  
Specifies line background color. r, g, b, and a specify the color and optional opacity as RGBA Values. The default is the window’s background color.

linecap=cap  
Sets the line end cap style:
- cap=0: Flat caps (default)
- cap=1: Round caps
- cap=2: Square caps

See Line Join and End Cap Styles on page III-496 for further information.

linecap was added in Igor Pro 8.00.

linefgc=(r,g,b[,a])  
Specifies line foreground color. r, g, b, and a specify the color and optional opacity as RGBA Values. The default is opaque black.

linejoin=j  
Sets the line join style:
- j=0: Miter joins
- j=1: Round joins (default)
- j=2: Bevel joins (default)

For a miter join, you can also set the miter limit using the lineMiterLimit keyword.

See Line Join and End Cap Styles on page III-496 for further information.

linejoin was added in Igor Pro 8.00.

lineMiterLimit=ml  
Applies only to a miter line join style. See the linejoin keyword.
- ml >= 1: Sets miter limit to ml
- ml = INF: Sets miter limit to unlimited
- ml = 0: Leaves miter limit unchanged
- ml = -1: Sets miter limit to default (10)

See Line Join and End Cap Styles on page III-496 for further information.

lineMiterLimit was added in Igor Pro 8.00.

linethick=thick  
thick is a line thickness ≥ 0, default is 1 point.
origin= x0,y0  Moves coordinate system origin to x0,y0. Unlike translate, rotate, and scale, this survives a change in coordinate system and is most useful that way. See Coordinate Transformation.

pop  Pops a draw environment from the stack. Pops should always match pushes.

push  Pushes the current draw environment onto a stack (limited to 10).

rotate= deg  Rotates coordinate system by deg degrees. Only makes sense if X and Y coordinate systems are the same. See Coordinate Transformation.

rounding=rnd  Radius for rounded rectangles in points, default is 10.

rsabout  Redefines coordinate system rotation or scaling to occur at the translation point instead of the current origin. To use, combine rotate or scale with translate and rsabout parameters.

save  Stores the current drawing environment as the default environment.

scale= sx,sy  Scales coordinate system by sx and sy. Affects only coordinates — not line thickness or arrow head sizes. See Coordinate Transformation.

subpaths=sp  Controls the way polygon and Bezier curve segments separated by NaN values are drawn:

sp=0: Each segment is drawn as a separate polygon or Bezier curve, and any arrows are added to each segment as if they are separate polygons or Bezier curves. This is the default if you omit the subpaths keyword.

sp=1: The segments are treated as subpaths within a single polygon or Bezier curve, making it possible to define a shape with holes. Any arrows are added only to the first or last points in the entire shape.

The subpaths keyword applies only to polygons created with DrawPoly and DrawBezier, not to those created manually.

Also see the fillRule keyword.

The subpaths keyword was added in Igor Pro 9.00.

textrgb=(r,g,b[,a])  Specifies text color. r, g, b, and a specify the color and optional opacity as RGBA Values. The default is opaque black.

textrot=rot  Text rotation in degrees.

rot is a value from -360 to 360.

0 is normal (default) horizontal left-to-right text,
90 is vertical bottom-to-top text, etc.

textxjust=xj  Sets horizontal text alignment.

xj=0: Left aligned text (default).

xj=1: Center aligned text.

xj=2: Right aligned text.

textyjust=yj  Sets vertical text alignment.

yj=0: Bottom aligned text (default).

yj=1: Middle aligned text.

yj=2: Top aligned text.

translate= dx,dy  Shifts coordinate system by dx and dy. Units are in the current coordinate system. See Coordinate Transformation.

</tbody>
</table>
Flags

/W=winName   Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

   When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Coordinate Transformation
The execution order for the translate, rotate, scale, and origin parameters is important. Translation followed by rotation is different than rotation followed by translation. When using multiple keywords in one SetDrawEnv operation, the order in which they are applied is origin, translate, rotate followed by scale regardless of the command order (with the exception of the rsabout parameter). Before using origin with the save keyword, you should use push to save the current draw environment and then use pop after drawing objects using the new origin.

Examples
Following is a simple example of arrow markers:

NewPanel
SetDrawEnv arrow= 1,arrowlen= 30,save
SetDrawEnv arrowsharp= 0.3
DrawLine 61,67,177,31
SetDrawEnv arrowsharp= 1
DrawLine 65,95,181,59
SetDrawEnv astyle= 1
DrawLine 69,123,185,87
SetDrawEnv arrowframe= 1
DrawLine 73,151,189,115

   You can position objects in one coordinate system and then draw them in another with the origin keyword. In the following coordinate transformation example, we position arrows in axis units but size them in absolute units.

   Make/O jack=sin(x/8)
   Display jack
SetDrawEnv xcoord=bottom,ycoord=left,save
SetDrawEnv push
SetDrawEnv origin=50,0
SetDrawEnv xcoord=abs,ycoord=abs,arrow=1,arrowlen=20,arrowsharp=0.2,save
DrawLine 0,0,50,0 // arrow 50 points long pointing to the right
DrawLine 0,0,0,50 // arrow 50 points long pointing down
// now let's move over, rotate a bit and draw the same arrows:
SetDrawEnv translate=100,0
SetDrawEnv rotate=30,save
DrawLine 0,0,50,0
DrawLine 0,0,0,50
SetDrawEnv pop

Now try zooming in on the graph. You will see that the first pair of arrows always starts at 50 on the bottom axis and 0 on the left axis whereas the second pair is 100 points to the right of the first.

See Also
Chapter III-3, Drawing, and DrawAction.
SetDrawLayer

**SetDrawLayer [ /K=W=winName ] layerName**
The SetDrawLayer operation makes all future drawing operations use the named layer.

**Parameters**
Valid *layerNames* for graphs:

- ProgBack
- UserBack
- ProgAxes
- UserAxes
- ProgFront
- UserFront
- Overlay

Valid *layerNames* for page layouts:

- ProgBack
- UserBack
- ProgFront
- UserFront
- Overlay

Valid *layerNames* for control panels:

- ProgBack
- UserBack
- ProgFront
- UserFront
- Overlay

There are really only three layers for control panels. ProgFront is treated as an alias for ProgBack and UserFront is treated as an alias for UserBack.

**Flags**

- **/K** Kills (erases) the given layer.
- **/W=winName** Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

  When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**
The Overlay layer is drawn above all else. It is not included when printing or exporting graphics and is provided for programmers who wish to add user-interface drawing elements without disturbing graphics drawing elements. Overlay was added in Igor Pro 7.00.

The back-to-front order of the layers is shown by the layer pop-up menu obtained by clicking the Layer icon in the drawing palette: ![Layer Icon]. A checkmark indicates the current layer. Non-drawing layers are indicated with gray text.

**Output Variables**

SetDrawLayer sets S_Name to the name of the previously-selected drawing layer. You can use this to restore the active drawing layer after programmatic drawing.

**See Also**
Drawing Layers on page III-68 and the DrawAction operation.

SetEnvironmentVariable

**SetEnvironmentVariable( varName, varValue )**
The SetEnvironmentVariable function creates an environment variable in Igor’s process and sets its value to *varValue*. If a variable named *varName* already exists, its value is set to *varValue*.

The function returns 0 if it succeeds or a nonzero value if it fails.

The SetEnvironmentVariable function was added in Igor Pro 7.00.
The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables. Any child process created by calling ExecuteScriptText inherits the environment variables of Igor's process.

SetEnvironmentVariable changes the environment variables present in Igor's process and any future process created by ExecuteScriptText but does not affect any other processes already created.

On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

Examples

Variable result
result = SetEnvironmentVariable("SOME_VARIABLE", "15")
result = SetEnvironmentVariable("SOME_OTHER_VARIABLE", "string value")

See Also
GetEnvironmentVariable, UnsetEnvironmentVariable

SetFileFolderInfo

The SetFileFolderInfo operation changes the properties of a file or folder.

Parameters

fileOrFolderNameStr specifies the file or folder to be changed.

If you use a full or partial path for fileOrFolderNameStr, see Path Separators on page III-451 for details on forming the path.

Folder paths should not end with single Path Separators. See the MoveFolder Details section.

If Igor can not determine the location of the file or folder from fileOrFolderNameStr and /P=pathName, it displays a dialog allowing you to specify the file to be deleted. Use /D to select a folder in this event, otherwise Igor prompts your for a file.

Flags

At least one of the seven following flags is required, or nothing is actually accomplished:

/CDAT=cdate Specifies the number of seconds since midnight January 1, 1904 when the file or folder was first created. cDate is interpreted as local time or UTC depending on the /UTC flag.

/INV[=inv] Sets the visibility of a file.

inv=0: File is visible.
inv=1: Default; file is invisible (Macintosh) or Hidden (Windows).

/MDAT=mdate Specifies the number of seconds since midnight January 1, 1904 when the file or folder was modified most recently. mDate is interpreted as local time or UTC depending on the /UTC flag.

/RO[=ro] Sets the read/write state of a file or folder.

ro=0: File or folder is writable.
ro=1: File or folder is locked (default).
On Macintosh, locking the file or folder is equivalent to setting the locked property manually using the Get Info window in the Finder.

On Windows, locking the file or folder is equivalent to setting the read-only property manually using the Properties window in Windows Explorer.

If fileOrFolderNameStr refers to a file (not a folder), SetFileFolderInfo updates the file properties to reflect values given with the following keywords:

/CRE8=creatorStr  Sets the four-character creator code string, such as 'IGR0' (Igor Pro creator code). Ignored on Windows, where files have no “creator code”; instead file extensions are “registered” or “owned” by one, and only one, application. You cannot change that ownership from Igor Pro.

/FTYP=fTypeStr  Sets the four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment). Ignored on Windows. Use MoveFile to change the file extension.

/STA[=st]  Specifies whether the file is a stationery file or not.

st=1: Stationery file (default).
st=0: Normal file.

Ignored on Windows. Use MoveFile to change the file extension.

Optional Flags

/D  Uses the Select Folder dialog rather than Open File dialog when pathName and fileOrFolderNameStr do not specify an existing file or folder.

/P=pathName  Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/R[=r]  Recursively applies change(s) to all files or folders in the folder specified by /P=pathName or fileOrFolderNameStr, and the folder itself:

r=0: No recursion. Same as no /R.
r=1: Recursively apply changes to files.
r=2: Recursively apply changes to folders, including the folder specified by pathName or fileOrFolderNameStr.
r=3: Recursively apply changes to both files and folders (default).

/R requires /D and a folder specification.

/UTC[=u]  If you include /UTC or /UTC=1, SetFileFolderInfo interprets the creation and modification dates as UTC (coordinated universal time). If you omit /UTC or specify /UTC=0, SetFileFolderInfo interprets the creation and modification dates as local time.

The default, used if you omit /UTC, is local time.

The /UTC flag was added in Igor Pro 9.00.

/Z[=z]  Prevents procedure execution from aborting if SetFileFolderInfo tries to set information about a file or folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

/Z=0: Same as no /Z at all.
/Z=1: Used for setting information for a file or folder only if it exists. /Z alone has the same effect as /Z=1.
/Z=2: Used for setting information for a file or folder if it exists and displaying a dialog if it does not exist.

Variables
SetFileFolderInfo returns information about the file or folder in the following variables:

- **V_flag**: 0: File or folder was found.  
  -1: User cancelled the Open File dialog.  
  >0: An error occurred, such as the specified file or folder does not exist.
- **S_path**: File system path of the selected file or folder.

**Examples**

Change the file creator code; no complaint if it doesn’t exist:

```
SetFileFolderInfo/Z /CRE8="CWIE", "Macintosh HD:folder:afile.txt"
```

Set the file modification date:

Variable `mDate= Date2Secs(2000,12,25) + hrs*3600+mins*60+secs`

```
SetFileFolderInfo/P=myPath/MDAT=(mDate), "afile.txt"
```

Remove read-only property from a folder and everything within it:

```
SetFileFolderInfo/P=myPath/D/R/RO=0
```

**See Also**
The SetFileFolderInfo, MoveFile, and FStatus operations. The IndexedFile, date2secs, and ParseFilePath functions.

**SetFormula**

```
SetFormula waveName, expressionStr
SetFormula variableName, expressionStr
```

The SetFormula operation binds the named wave, numeric or string variable to the expression or, if the expression is "", unbinds it from any previous expression. In user functions, SetFormula must be used to create dependencies.

**Parameters**

- **expressionStr** is a string containing a numeric or string expression, depending on the type of the bound object.

Pass an empty string (" ") for **expressionStr** to clear any previous dependency expression associated with the wave or variable.

**Details**

The dependent object (the wave or variable) will depend on the objects referenced in the string expression. The expression will be reevaluated any time an object referred to in the expression is modified.

Besides being set from a string expression this differs from just typing:

```
name := expression
```

in that syntax errors in **expressionStr** are not reported and are not fatal. You end up with a dependency assignment that is marked as needing to be recompiled. The recompilation will be attempted every time an object is created or when the procedure window is recompiled.

Use the Object Status dialog in the Misc menu to check up on dependent objects.

**Examples**

This command makes the variable `v_sally` dependent on the user-defined function `anotherFunction`, waves `wave_fred` and `wave_sue`, and the system variable `K2`:

```
SetFormula v_sally, "anotherFunction(wave_fred[1]) + wave_sue[0] + K2"
```

This is equivalent to:

```
v_sally := anotherFunction(wave_fred[1]) + wave_sue[0] + K2
```

except that no error will be generated for the SetFormula if, for instance, `wave_fred` does not exist.

A string variable dependency can be created by a command such as:

```
SetFormula myStringVar, "note(wave_joe)"
```

observe that **expressionStr** is a string containing a string expression, and that:

```
SetFormula myStringVar,note(wave_joe)
```
SetIdlePeriod is not the same thing. In this case the note of wave_joe would contain the expression that myStringVar would depend on! Also, wave_joe would have to exist for Igor to understand the statement.

See Also
Chapter IV-9, Dependencies, and the GetFormula function.

SetIdlePeriod

SetIdlePeriod operation changes and reports the period of Igor’s main idle loop. The units of period are milliseconds. Setting period to zero does not change the period.

SetIdlePeriod was added in Igor Pro 8.00.

The default idle period is 20 milliseconds. Setting the period higher may make a slight improvement in the performance of some computation-heavy tasks.

Setting the period lower can make some parts of Igor more responsive. In particular, background tasks can be made to run more often, as the minimum period between runs of a background task is determined by Igor’s idle period. Reducing the period too far increases the likelihood that your background task will run too long. Setting the period to very low values can make Igor very sluggish.

Output Variables
SetIdlePeriod creates the output variable V_value and sets it to the idle period before the call was made. Yu can use this value to restore the idle period after temporarily changing it. If period is zero, the idle period is not changed, but the current value is returned in V_value.

Background Tasks on page IV-319

SetIgorHook

SetIgorHook [K/L] [hookType = [procName]]

The SetIgorHook operation tells Igor to call a user-defined "hook" function at the following times:

• After procedures have been successfully compiled (AfterCompiledHook)
• After a file is opened (AfterFileOpenHook)
• After the MDI frame window is resized on Windows (AfterMDIFrameSizedHook)
• After a window is created (AfterWindowCreatedHook)
• Before the debugger is opened (BeforeDebuggerOpensHook)
• Before an experiment is saved (BeforeExperimentSaveHook)
• Before a file is opened (BeforeFileOpenHook)
• Before a new experiment is opened (IgorBeforeNewHook)
• Before Igor quits (IgorBeforeQuitHook)
• When a menu item is selected (IgorMenuHook)
• During Igor’s quit processing (IgorQuitHook)
• When Igor starts or a new experiment is created (IgorStartOrNewHook)

The term “hook” is used as in the phrase “to hook into”, meaning to intercept or to attach.

Hook functions are typically used by a sophisticated procedure package to make sure that the package’s private data is consistent.

In addition to using SetIgorHook, you can designate hook functions using fixed function names (see User-Defined Hook Functions on page IV-280). The advantage of using SetIgorHook over fixed hook names is that you don’t have to worry about name conflicts.

You can designate hook functions for specific windows using window hooks (see SetWindow on page V-865).
SetIgorHook

**Flags**

/K  Removes procName from the list of functions called for the hookType events.
    If procName is not specified all hookType functions are removed.
    If hookType is not specified all functions are removed for all hookType events, returning Igor to
    the pre-SetIgorHook state.

/L  Executes procName last. Without /L, a newly added hook function runs before previously
    registered hook functions.
    A function that has been previously registered with SetIgorHook can be moved from being
called first to being called last by calling SetIgorHook again with /L.
    To move a function from being called last to being called first requires removing the hook
function with /K and then calling SetIgorHook without /L.

**Parameters**

hookType  Specifies one of the fixed-name hook function names:

- AfterCompiledHook
- AfterFileOpenHook
- AfterMDIFrameSizedHook
- AfterWindowCreatedHook
- BeforeDebuggerOpensHook
- BeforeExperimentSaveHook
- BeforeFileOpenHook
- IgorBeforeNewHook
- IgorBeforeQuitHook
- IgorMenuHook
- IgorQuitHook
- IgorStartOrNewHook

See the note below about these hookType names.

hookType is required except with /K.

procName  Names the user-defined hook function that is called for the hookType event.

**Details**

The parameters and return type of the user-defined function procName varies depending on the hookType it
is registered for.

For example, a function registered for the AfterFileOpenHook type must have the same parameters and
return type as the shown for the AfterFileOpenHook on page IV-282.

The procName function is called after any window-specific hook for these hookTypes, and the procName
function is called before any other hook functions previously registered by calling SetIgorHook unless the /L
flag is given, in which case it still runs after window-specific hook functions, but also after all other
previously registered hook functions.

The procName function should return a nonzero value (1 is typical) to prevent later functions from being
called. Returning 0 allows successive functions to be called.

SetIgorHook does not work at Igor start or new experiment time, so SetIgorHook IgorStartOrNewHook is
disallowed. Define a global or static fixed-name IgorStartOrNewHook function (see page IV-292).

The saved Igor experiment file remembers the SetIgorHooks that are in effect when the experiment is saved:
SetIgorHook

Hook Function Interactions
After all the SetIgorHook functions registered for hookType have run (and all have returned 0), any static fixed-name hook functions are called and then the (only) fixed-name user-defined hook function, if any, is called. As an example, when a menu event occurs, Igor handles the event by calling routines in this order:

1. The top window’s hook function as set by SetWindow
2. Any SetIgorHook-registered hook functions
3. Any static fixed-named IgorMenuHook functions (in any independent module)
4. The one-and-only non-static fixed-named IgorMenuHook function (in only the ProcGlobal independent module)

<table>
<thead>
<tr>
<th>1. SetWindow event (called first)</th>
<th>2. SetIgorHook hookType (called second)</th>
<th>3. User-defined Hook Function(s) (called last)</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableMenu</td>
<td>IgorMenuHook</td>
<td>IgorMenuHook</td>
</tr>
<tr>
<td>menu</td>
<td>IgorMenuHook</td>
<td>IgorMenuHook</td>
</tr>
</tbody>
</table>

Note: Although you can technically use one of the fixed-name functions, as described in User-Defined Hook Functions on page IV-280, for procName, the result would be that the function will be called twice: once as a registered named hook function and once as the fixed-named hook function. That is, don’t use SetIgorHook this way:

```
SetIgorHook AfterFileOpenHook=AfterFileOpenHook // NO
```

Variables
SetIgorHook returns information in the following variables:

- S_info: Semicolon-separated list of all current hook functions associated with hookType, listed in the order in which they are called. S_info includes the full independent module paths (e.g., /ProcGlobal#MyMenuHook;MyIM#MyModule#MyMenuHook;).

Examples
This hook function invokes the Export Graphics menu item when Command-C (Macintosh) or Ctrl+C (Windows) is selected for a graph, preventing the usual Copy.

```
SetIgorHook IgorMenuHook=CopyIsExportHook

Function CopyIsExportHook(isSelection,menuName,itemName,itemNo,win,wType)
  Variable isSelection
  String menuName,itemName
  Variable itemNo
  String win
  Variable wType
  Variable handledIt= 0
  if( isSelection && wType==1 ) // menu was selected, window is graph
    if( Cmpstr(menuName,"Edit")==0 && CmpStr(itemName,"Copy")==0 )
      DoIgorMenu "Edit", "Export Graphics" // dialog instead
      handledIt= 1 // don't call other IgorMenuHook functions.
    endif
  endif
return handledIt
End
```

To unregister CopyIsExportHook as a hook procedure:

```
SetIgorHook/K IgorMenuHook=CopyIsExportHook // unregister CopyIsExportHook
```

To discover which functions are associated with a hookType, use a command such as:

```
SetIgorHook IgorMenuHook // inquire about names registered for IgorMenuHook
Print S_info // list of functions
```

To remove (or “unregister”) named hooks:

```
SetIgorHook/K // removes all hook functions for all hookTypes
SetIgorHook/K IgorMenuHook // removes all IgorMenuHook functions
SetIgorHook/K IgorMenuHook=CopyIsExportHook// removes only this hook function
```
The `SetIgorMenuMode` operation allows an Igor programmer to disable or enable Igor’s built-in menus and menu items. This is useful for building applications that will be used by end-users who shouldn’t have access to all Igor’s extensive and confusing functionality.

**Parameters**

- **MenuNameStr**: The name of an Igor menu, like “File”, “Graph”, or “Load Waves”.
- **MenuItemStr**: The text of an Igor menu item, like “Copy” (in the Edit menu) or “New Graph” (in the Windows menu). For menu items in submenus, such as the “Load Waves” submenu in the “Data” menu, **MenuItemStr** is the name of the submenu.
- **Action**: One of DisableItem, EnableItem, DisableAllItems, or EnableAllItems.

*DisableItem* and *EnableItem* disable or enable just the single item named by **MenuNameStr** and **MenuItemStr**. If **MenuItemStr** is “”, then the menu itself is disabled. *DisableAllItems* and *EnableAllItems* disable and enable all the items in the menu named by **MenuNameStr**.

**Details**

All menu names and menu item text are in English. This ensures that code developed for a localized version of Igor will run on all versions. Note that no trailing “…” is used in **MenuItemStr**.

The `SetIgorMenuModeProc.ipf` procedure file includes procedures and commands that disable or enable every menu and item possible. It is in your Igor Pro folder, in WaveMetrics Procedures:Utilities. It is not intended to be used as-is. You should make a copy and edit the copy to include just the parts you need.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the **MenuItemStr** parameter. Use “Save Window”, “Save Window As”, “Save Window Copy”, “Adopt Window” and “Revert Window” instead of “Save Notebook” or “Save Procedure”, etc. Use “Page Setup” instead of “Page Setup For All Graphs”, etc. Use “Print” instead of “Print Graph”, etc.

The Edit → Insert File menu item was previously named Insert Text. For compatibility reasons, you can specify either “Insert File” or “Insert Text” as **MenuItemStr** to modify this item.

**See Also**

- `DoIgorMenu`
- `ShowIgorMenus`
- `HideIgorMenus`

The `SetIgorMenuModeProc.ipf` WaveMetrics procedure file contains `SetIgorMenuMode` commands for every menu and menu item. You can load it using

```
#include <SetIgorMenuModeProc>
```

---

The `SetIgorOption` operation makes unusual and temporary changes to Igor Pro’s behavior. The behavior changes are of interest to advanced users only and last only until you end the Igor session.

The details of the syntax depend on the keyword and are documented where the alternate behaviors are described.

`SetIgorOption` is not compilable. To use it in a user-defined function, you need to use `Execute`.

In most cases the current value of a setting can be read using the `keyword=`? syntax.

For example, the `IndependentModuleDev` keyword is used to enable editing of procedure files that implement independent modules:
SetMarquee

SetIgorOption IndependentModuleDev=?; Print V_Flag // Query
SetIgorOption IndependentModuleDev=1 // Set

Most SetIgorOption keywords are obscure and rarely of use. Here are some of the more commonly-used SetIgorOption keywords:

IndependentModuleDev  See SetIgorOption IndependentModuleDev=1 on page IV-239
PoundDefine  See Conditional Compilation on page IV-108
GraphicsTechnology  See Graphics Technology on page III-506
PanelResolution  See SetIgorOption PanelResolution on page III-456
DisableThreadSafe  See Debugging ThreadSafe Code on page IV-225

It is rarely necessary, but you can find the more obscure applications using Help→Search Igor Files to search for "SetIgorOption".

SetMarquee

SetMarquee [ /HAX=hAxisName /VAX=vAxisName /W=winName] left, top, right, bottom

The SetMarquee operation creates a marquee on the target graph or layout window or the specified window or subwindow.

Parameters

The left, top, right, and bottom coordinates are in units of points unless you specify /HAX or /VAX in which case they are in axis units. Axis units are allowed for graphs only, not for layouts.

If the coordinates are all 0, the marquee, if it exists, is killed.

Flags

/HAX=hAxisName  Specifies that the left and right parameters are in units of the axis named by hAxisName. The /HAX flag was added in Igor Pro 9.00.
/VAX=vAxisName  Specifies that the top and bottom parameters are in units of the axis named by vAxisName. The /VAX flag was added in Igor Pro 9.00.
/W=winName  Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

Igor stores marquee coordinates internally as integers in units of points. If you specify coordinates in axis units, there will be some roundoff error when Igor converts to integer points. This results in a small discrepancy between the coordinates you set using /HAX or /VAX and the coordinates returned by GetMarquee.

See Also

GetMarquee

SetProcessSleep

SetProcessSleep sleepTicks

The SetProcessSleep operation is obsolete and does nothing as of Igor Pro 7.00. It is documented here in case you come across it in old Igor procedure code. Do not use it in new code.

The SetProcessSleep operation determines how much time Igor will give to background tasks or other Macintosh applications executing in the background. This operation does nothing on Windows.

Parameters

sleepTicks is the amount of time given to background tasks in sixtieths of a second. sleepTicks values between 0 and 60 are valid.
Details
Igor starts up with sleepTicks = 1. Use 0 to give Igor maximum time, use a larger number to give other applications more time.

Background tasks are used mainly by data acquisition programs.

See Also
Background Tasks on page IV-319 and the SetBackground operation.

SetRandomSeed

SetRandomSeed seed
The SetRandomSeed operation seeds the random number generator used for the noise functions listed under Noise Functions on page III-390.

Use SetRandomSeed if you need “random” numbers that are reproducible. If you don’t use SetRandomSeed, the random number generator is initialized using the system clock when Igor starts. This almost guarantees that you will never get the same sequence twice unless you use SetRandomSeed.

Flags
/BETR[=better] If better is absent or non-zero, a better method is used for seeding the Mersenne Twister random number generator. /BETR is ignored for all other random generators.

Parameters
seed should be a number in the interval (0, 1]. For any given seed, enoise or gnoise or any of the other random-number generator functions generates a particular sequence of pseudorandom numbers. Calling SetRandomSeed with the same seed restarts and repeats the sequence.

Details
Igor’s noise functions are listed under Noise Functions on page III-390. The enoise and gnoise functions allow you to choose a random number generator. The other functions always use the Mersenne Twister generator.

How the seed is used internally depends on the generator. For the Linear Congruential Generator the seed is scaled to a 32-bit signed integer. For the Mersenne Twister the seed is scaled to a 32-bit unsigned integer. Both only use the lower 16-bits of the so scaled value for historic reasons.

The Xoshiro256** generator uses all available bits and scales it to an unsigned 64-bit integer.

All generators use the scaled seed value when initializing their internal state tables.

See Also
The enoise and gnoise functions. Noise Functions on page III-390.

SetScale

SetScale [I/P] dim, num1, num2 [, unitsStr], waveName [, waveName]…
SetScale d, num1, num2 [, unitsStr], waveName [, waveName]…

The SetScale operation sets the dimension scaling or the data full scale for the named waves.

Parameters
The first parameter dim must be one of the following:

<table>
<thead>
<tr>
<th>Character</th>
<th>Signifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Data full scale.</td>
</tr>
<tr>
<td>t</td>
<td>Scaling of the chunks dimension (t scaling).</td>
</tr>
<tr>
<td>x</td>
<td>Scaling of the rows dimension (x scaling).</td>
</tr>
<tr>
<td>y</td>
<td>Scaling of the columns dimension (y scaling).</td>
</tr>
<tr>
<td>z</td>
<td>Scaling of the layers dimension (z scaling).</td>
</tr>
</tbody>
</table>
If setting the scaling of any dimension (x, y, z, or t), \textit{num1} is the starting index value — the scaled index for the first point in the dimension. The meaning of \textit{num2} changes depending on the /I and /P flags. If you use /P, then \textit{num2} is the delta value — the difference in the scaled index from one point to the next. If you use /I, \textit{num2} is the “ending value” — the index value for the last element in the dimension. If you use neither flag, \textit{num2} is the “right value” — the index value that the element after the last element in the dimension would have.

These three methods are just three different ways to specify the two scaling values, the starting value and the delta value, that are stored for each dimension of each wave.

If setting the data full scale (d), then \textit{num1} is the nominal minimum and \textit{num2} is the nominal maximum data value for the waves. The data full scale values are not used. They serve only to document the minimum and maximum values the waves are expected to attain. No flags are used when setting the data full scale.

The \textit{unitsStr} parameter is a string that identifies the natural units for the x, y, z, t, or data values of the named waves. Igor will use this to automatically label graph axes. This string must be one to 49 bytes such as “m” for meters, “g” for grams or “s” for seconds. If the waves have no natural units you can pass "" for this parameter.

Setting \textit{unitsStr} to "dat" (case-sensitive) tells Igor that the wave is a date/time wave containing data in Igor date/time format (seconds since midnight on January 1, 1904). Date/time waves must be double-precision.

Flags

At most one flag is allowed, and then only if dimension scaling (not data full scale) is being set:

\begin{itemize}
  \item /I Inclusive scaling. \textit{num2} is the ending index — the index value for the very last element in the dimension.
  \item /P Per-point scaling. \textit{num2} is the delta index value — the difference in scaled index value from one element to the next.
\end{itemize}

Details

\textit{SetScale} will not allow the delta scaling value to be zero. If you execute a \textit{SetScale} command with a delta value of zero, it will set the delta value to 1.0.

If you do not use the /P flag, \textit{SetScale} converts \textit{num1} and \textit{num2} into a starting index value and a delta index value. If you call \textit{SetScale} on a dimension with fewer than two elements, it does this conversion as if the dimension had two elements.

Prior to Igor Pro 3.0, Igor supported only 1D waves. “\textit{SetScale x}” was used to set the scaling for the rows dimensions and “\textit{SetScale y}” was used to set the data full scale. With the addition of multidimensional waves, “\textit{SetScale y}” is now used to set the scaling of the columns dimension and “\textit{SetScale d}” is used to set the data full scale. For backward compatibility, “\textit{SetScale y}” on a 1D wave sets the data full scale.

When setting the dimension scaling of a numeric wave, you can omit the \textit{unitsStr} parameter. Igor will set the wave’s scaling but not change its units. However, when setting the dimension scaling of a text wave, you must supply a \textit{unitsStr} parameter (use "" if the wave has no units). If you don’t, Igor will think that the text wave is the start of a string expression and will attempt to treat it as the \textit{unitsStr}.

See Also

\textbf{CopyScales, DimDelta, DimOffset, DimSize, WaveUnits}

For an explanation of waves and dimension scaling, see \textbf{Changing Dimension and Data Scaling} on page II-68.

For further discussion of how Igor represents dates, see \textbf{Date/Time Waves} on page II-85.

\textbf{SetVariable}

\texttt{SetVariable [/Z] ctrlName [ keyword = value [, keyword = value ...] ]}

The \texttt{SetVariable} operation creates or modifies a \texttt{SetVariable} control in the target window.

A \texttt{SetVariable} control sets the value of a global numeric or string variable or a point in a wave when you type or click in the control. A \texttt{SetVariable} can also hold its own value without the need for a global or wave. For information about the state or status of the control, use the \texttt{ControlInfo} operation.
**Parameters**

`ctrlName` is the name of the SetVariable control to be created or changed.

The following keyword=value parameters are supported:

- **activate**
  Activates the control and selects the text that sets the value. Use `ControlUpdate` to deactivate the control and deselect the text.

- **align=alignment**
  Sets the alignment mode of the control. The alignment mode controls the interpretation of the `leftOrRight` parameter to the `pos` keyword. The `align` keyword was added in Igor Pro 8.00.
  
  If `alignment=0` (default), `leftOrRight` specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

  If `alignment=1`, `leftOrRight` specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

- **appearance={kind [, platform]}

  Sets the appearance of the control. `platform` is optional. Both parameters are names, not strings.

  `kind` can be one of `default`, `native`, or `os9`.

  `platform` can be one of `Mac`, `Win`, or `All`.

  See `Button` and `DefaultGUIControls` for more appearance details.

- **bodyWidth=width**
  Specifies an explicit size for the body (nontitle) portion of a SetVariable control. By default (bodyWidth=0), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size or text of the title changes, then the body portion may grow or shrink. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.

- **disable=d**
  Sets user editability of the control.

  `d=0`: Normal.

  `d=1`: Hide.

  `d=2`: No user input.

- **fColor=(r,g,b[,a])**
  Sets the initial color of the title. `r, g, b`, and `a` specify the color and optional opacity as RGBA Values. The default is opaque black.

  To further change the color of the title text, use escape sequences as described for `title=`.

- **focusRing=fr**
  Enables or disables the drawing of a rectangle indicating keyboard focus:

  `fr=0`: Focus rectangle will not be drawn.

  `fr=1`: Focus rectangle will be drawn (default).

  On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

- **font=fontName**
  Sets the font used to display the value of the variable, e.g., `font=“Helvetica”`.

- **format=formatStr**
  Sets the numeric format of the displayed value, e.g., `format=“%g”`. Not used with string variables. Never use leading text or the “%W” formats, because Igor reads the value back without interpreting the units. For a description of `formatStr`, see the `printf` operation.
SetVariable

frame=f  
Sets the frame for the value readout.  
\( f = 0 \): Value unframed.  
\( f = 1 \): Value framed (default).

fsize=s  
Sets the size of the type used to display the variable’s value.

fstyle=fs  
\( fs \) is a bitwise parameter with each bit controlling one aspect of the font style as follows:  
Bit 0: Bold  
Bit 1: Italic  
Bit 2: Underline  
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

help={helpStr}  
Sets the help for the control.  
helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).  
You can insert a line break by putting “\r” in a quoted string.

labelBack=(\( r, g, b [ , a ] \)) or 0  
Specifies the background fill color for labels.  \( r, g, b \), and  \( a \) specify the color and optional opacity as RGBA Values.  The default is 0, which uses the window’s background color.

limits={low,high,inc}  
Sets the limits of the allowable values (\( low \) and \( high \)) for the variable.  \( inc \) sets the amount by which the variable is incremented if you click the control’s up/down arrows.  This applies to numeric variables, not to string variables.  If \( inc \) is zero then the up/down arrows will not be drawn.

live=l  
Determines when the readout is updated.  
\( l = 0 \): Update only after variable changes (default).  
\( l = 1 \): Update as variable changes.

noedit=val  
noedit=1 prevents the user from clicking (or tabbing into) a SetVariable control to directly edit its value.  This is useful when you want to make a string read-only or when you want to restrict a numeric setting to those available only via the control’s up or down arrow buttons.  
noedit=0 reactivates user editing.  
noedit=2 is deprecated as of Igor Pro 6.34 but still supported.  It allows the use of formatting escape codes described under Annotation Escape Codes.  Use styledText=1, instead.

noproc  
No procedure is to execute when the control’s value is changed.

pos={leftOrRight,top}  
Sets the position in Control Panel Units of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1.  See the align keyword above for details.

pos+=\{dx,dy\}  
Offsets the position of the control in Control Panel Units.

proc=procName  
Sets the procedure to execute when the control’s value is changed.

rename=newName  
Gives control a new name.

styledText=val  
styledText=1 allows the use of formatting escape codes described under Annotation Escape Codes on page III-53.  This works for string SetVariable controls only, not for numeric controls.

For example:  
SetVariable sv0 value=_STR:"\J(65535,0,0)Centered Red Text"
styledText=0 treats escape codes as plain text.

The styledText keyword was added in Igor Pro 6.34. For compatibility with earlier versions of Igor, the combination of noedit=1 and styledText=1 is recorded as noedit=2 in recreation macros.

\[\text{size=\{width,\text{height}\}}\] Set width of control in \textbf{Control Panel Units. height is ignored.}

textAlign=t

Sets the alignment of the text displayed in the body of the control.

\[
\begin{align*}
t & = 0: & \text{Left (default)} \\
& = 1: & \text{Center} \\
& = 2: & \text{Right}
\end{align*}
\]

The textAlign keyword was added in Igor Pro 9.00.

title=titleStr

Sets the title of the control to the specified string expression. The title is displayed to the left of the control. If titleStr is empty (""), the name of the controlled variable is displayed as the title. Use title="" (put a space within the quotation marks) to create a "blank" title.

Using escape codes you can change the font, size, style, and color of the title. See \textbf{Annotation Escape Codes} on page III-53 or details.

\[\text{userdata(UDName)=UDStr}\]

Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create.

\[\text{userdata(UDName)+=UDStr}\]

Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr.

value=varOrWaveName

Sets the numeric or string variable or wave element to be controlled.

If varOrWaveName references a wave, the point is specified using standard bracket notation with either a numeric point number or a row label, for example: value=awave[4] or value=awave[%alabel].

You may also use a 2D, 3D, or 4D wave and specify a column, layer, and chunk index or dimension label in addition to the row index.

You can have the control store the value internally rather than in a global variable. In place of varName, use \_STR:str or \_NUM:num. For example:

\[\text{NewPanel; SetVariable sv1, value=NUM:123}\]

valueColor=(r,g,b[,a])

Sets the color of the value text. \(r, g, b, a\) specify the color and optional opacity as \textbf{RGBA Values}. The default is opaque black.

valueBackColor=(r,g,b[,a])

Sets the background color under the value text. \(r, g, b, a\) specify the color and optional opacity as \textbf{RGBA Values}.

valueBackColor=0

Sets the background color under the value text to the default color, the standard document background color used on the current operating system, which is usually white.

win=winName

Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with winName, see \textbf{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.
SetVariableControl

Flags

/Z No error reporting.

Details
The target window must be a graph or panel.

SetVariable Action Procedure
The action procedure for a SetVariable control takes a predefined WMSetVariableAction structure as a parameter to the function:

Function ActionProcName(SV_Struct) : SetVariableControl
    STRUCT WMSetVariableAction &SV_Struct
    ...
    return 0
End

The “: SetVariableControl” designation tells Igor to include this procedure in the Procedure pop-up menu in the SetVariable Control dialog.

See WMSetVariableAction for details on the WMSetVariableAction structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format SetVariable action procedure in old code:

Function procName(ctrlName,varNum,varStr,varName) : SetVariableControl
    String ctrlName
    Variable varNum // value of variable as number
    String varStr // value of variable as string
    String varName // name of variable
    ...
    return 0
End

This old format should not be used in new code.

Examples
Executing the commands:

Variable/G globalVar=99
SetVariable setvar0 size={120,20}
SetVariable setvar0 font="Helvetica", value=globalVar

creates a SetVariable control that displays the value of globalVar.

See Also
The printf operation for an explanation of formatStr, and SetVariable on page III-417.

Chapter III-14, Controls and Control Panels, for details about control panels and controls.

Control Panel Units on page III-444 for a discussion of the units used for controls.

The GetUserData function for retrieving named user data.

The ControlInfo operation for information about the control.

SetVariableControl

SetVariableControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined SetVariable control. See Procedure Subtypes on page IV-204 for details. See SetVariable for details on creating a SetVariable control.

SetWaveLock

SetWaveLock lockVal, waveList
The SetWaveLock operation locks a wave or waves and protects them from modification. Such protection is not absolute, but it should prevent most common attempts to change or kill a wave.

Parameters
lockVal can be 0, to unlock, or 1, to lock the wave(s).
waveList is a list of waves or it can be allInCDF to act on all waves in the current data folder.

See Also
WaveInfo to check if a wave is locked.

SetWaveTextEncoding

SetWaveTextEncoding [flags] newTextEncoding, elements, [wave, wave, ...]
The SetWaveTextEncoding operation changes the text encoding of the specified waves and/or the text encoding of all waves in the specified data folder.

Wave text encodings are mostly an issue in dealing with pre-Igor Pro 7 experiments containing non-ASCII text. Most users will have no need to worry about or change them. You should not use this operation unless you have a thorough understanding of text encoding issues or are instructed to use it by someone who has a thorough understanding.

See Wave Text Encodings on page III-472 for essential background information.

SetWaveTextEncoding can work on a list of specific waves or on all of the waves in a data folder (/DF flag). When working on a data folder, it can work on just the data folder itself or recursively on sub-data folders as well.

If /CONV is present, SetTextWaveEncoding actually converts the text to a different text encoding. You would use this, for example, to convert text stored as Shift JIS (Japanese non-Unicode) into UTF-8 (Unicode).

If /CONV is omitted, SetTextWaveEncoding merely causes Igor to reinterpret text. You would do this to tell Igor what text encoding is used for a wave created by Igor Pro 6 if Igor gets it wrong.

Conversion does not change the characters that make up text - it merely changes the numeric codes used to represent those characters. Reinterpretation does not change the numeric codes but does change the characters by changing the interpretation of the numeric codes.

In some cases it may be necessary to fix text encoding issues in Igor Pro 6.3x before opening an experiment in later versions.

Parameters

newTextEncoding specifies the text encoding to set the wave element to. See Text Encoding Names and Codes on page III-490 for a list of codes.

newTextEncoding can be the special value 255 which marks a text wave’s content as really containing binary data, not text. See Text Waves Containing Binary Data on page III-475 below for details.

elements is a bitwise parameter that specifies one or more elements of a wave, as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Wave name</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Wave units</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Wave note</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
<td>Wave dimension labels</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>Text wave content</td>
</tr>
</tbody>
</table>

See Setting Bit Parameters on page IV-12 for details about bit settings.

wave, wave, ... is a list of the targeted waves. The list is optional and typically should be omitted if you use the /DF flag. However, if you specify a data folder via /DF and you also list specific waves, SetWaveTextEncoding works on all waves in the data folder as well as the specifically listed waves.

Flags

/BINA=[markAsBinary, diagnosticsFlags]
If `markAsBinary` is 1, `SetWaveTextEncoding` marks the content of any text wave as binary if the data contains control characters (codes less than 32) other than carriage return (13), linefeed (10), and tab (9). The number of waves so marked is returned via `V_numMarkedAsBinary`.

If `markAsBinary` is 0, `SetWaveTextEncoding` acts as if `/BINA` were omitted. `diagnosticsFlags` is optional and defaults to 1. If you omit it you can also omit the braces (`/BINA=1`).

diagnosticsFlags is a bitwise parameter defined as follows:

- Bit 0: Emit diagnostic message for each wave marked as binary.

All other bits are reserved for future use.

See Setting Bit Parameters on page IV-12 for details about bit settings.

The `/BINA=1` flag works with with the content of text waves only. It skips non-text waves. It is also independent of the `elements` parameter. That is, it marks the text wave content and only the text wave content as binary even if `elements` is something other than 16.

If you pass 255 for `newTextEncoding` when using the `/BINA` flag, this tells `SetWaveTextEncoding` to stop processing after marking binary waves. No further conversion or reinterpretation is done.

See Text Waves Containing Binary Data on page III-475 for further discussion.

`/CONV={errorMode [, defaultTextEncoding, diagnosticsFlags, conversionFlags]}`

Causes the text data to be converted to the specified text encoding. If `/CONV` is present, `SetTextWaveEncoding` actually converts the text. If it is omitted, `SetTextWaveEncoding` merely causes Igor to reinterpret it.

defaultTextEncoding, diagnosticsFlags and conversionFlags are optional and are further discussed below. If you omit them you can also omit the braces (`/CONV=1`).

If `/CONV` is specified and the original text encoding is binary (255) then `SetWaveTextEncoding` does nothing, because all conversions involving binary are NOPs.

If `/CONV` is specified and `newTextEncoding` is binary (255) then no conversion is done, because all conversions involving binary are NOPs, but the wave is marked as binary. Thus this amounts to the same thing as reinterpreting the wave's text data as binary.

If `/CONV` is specified, `defaultTextEncoding` is omitted or is -1, and the original text encoding is unknown (0) then `SetWaveTextEncoding` does nothing. That is, it does no reinterpretation or conversion.

diagnosticMode determines how `SetWaveTextEncoding` behaves if the conversion can not be done because the text can not be mapped to the specified text encoding. This will occur if the text contains characters that can not be represented in the specified text encoding or if Igor's notion of the original text encoding is wrong. In the latter case, call `SetWaveTextEncoding` without `/CONV` to correct Igor's interpretation of the text and then call `SetWaveTextEncoding` with `/CONV` to do the conversion.
errorMode takes one of these values:

1: Generate error. SetWaveTextEncoding returns an error to Igor.

2: Use a substitute character for any unmappable characters. The substitute character for Unicode is the Unicode replacement character, U+FFFD. For most non-Unicode text encodings it is either control-Z or a question mark.

3: Skip unmappable input characters. Any unmappable characters will be missing in the output.

4: Use escape sequences representing any unmappable characters or invalid source text.

   If the source text is valid in the source text encoding but can not be represented in the destination text encoding, unmappable characters are replaced with \uxXXX where XXXX specifies the UTF-16 code point of the unmappable character in hexadecimal.

   If the conversion can not be done because the source text is not valid in the source text encoding, invalid bytes are replaced with \xXX where XX specifies the value of the invalid byte in hexadecimal.

defaultTextEncoding is optional. If it is present, not -1, and if the wave text element’s original encoding is unknown (0), then the wave text element is treated as if it were the specified defaultTextEncoding. This allows you to convert the text of Igor Pro 6 waves that are set to unknown when you know that they are really some other text encoding. For example, if you know a wave’s text data text encoding is Shift JIS, you can convert it to UTF-8 in one step, like this:

SetWaveTextEncoding /CONV={1,4} 1, 16, textWave0

Without the defaultTextEncoding, you would have to do two steps - the first to tell Igor what the real text encoding is and the second to do the conversion:

   // Text encoding is Shift JIS
   SetWaveTextEncoding 4, 16, textWave0
   // Convert to UTF-8
   SetWaveTextEncoding /CONV=1 1, 16, textWave0

Passing -1 for defaultTextEncoding acts the same as omitting it.

diagnosticsFlags is an optional bitwise parameter defined as follows:

Bit 0: Emit diagnostic message if text conversion succeeds.

Bit 1: Emit diagnostic message if text conversion fails.

Bit 2: Emit diagnostic message if text conversion is skipped.

Bit 3: Emit summary diagnostic message.

All other bits are reserved for future use and must be 0.

See Setting Bit Parameters on page IV-12 for details about bit settings.

diagnosticsFlags defaults to 2 (bits 1 set) if the /DF flag is not present and to 10 (bits 1 and 3 set) if the /DF flag is present.

Text conversion may be skipped because the wave element is marked as unknown text encoding, because it is marked as binary, because of the /ONLY or /SKIP flags, or because newTextEncoding is the same as the wave element’s original text encoding.
SetWaveTextEncoding

conversionFlags is an optional bitwise parameter defined as follows:

Bit 0: Do a dry run only.

All other bits are reserved for future use and must be 0.

See Setting Bit Parameters on page IV-12 for details about bit settings.

The conversionFlags parameter was added in Igor Pro 9.00.

conversionFlags defaults to 0. If conversionFlags is 1, SetWaveTextEncoding goes through the entire conversion process but does not actually do any conversions. This feature was added to provide a way to determine if conversions are needed to create a pure UTF-8 experiment. For most purposes you can omit the conversionFlags parameter.

/DF=[dfr, recurse, excludedDFR]

dfr is a reference to a data folder. SetWaveTextEncoding operate on all waves in the specified data folder. If dfr is null (""), SetWaveTextEncoding acts as if /DF was omitted.

If recurse is 1, SetWaveTextEncoding works recursively on all sub-data folders. Otherwise it affects only the data folder referenced by dfr.

excludedDFR is an optional reference to a data folder to be skipped by SetWaveTextEncoding. For example, this command sets the text encoding of text wave data for all waves in all data folders except for root:Packages and its sub-data folders:

SetWaveTextEncoding /DF={root:,1,root:Packages} 1, 16

If excludedDFR is null (""), SetWaveTextEncoding acts as if excludedDFR was omitted and no data folders are excluded.

/KIND=kind

SetWaveTextEncoding changes only waves of the specified kind. kind is:

1: Home waves only
2: Shared waves only
3: Home and shared waves (default)

A "home wave" is a wave that is stored in the experiment file for packed experiment or in the disk folder corresponding to the wave's data folder for an unpacked experiment.

A "shared wave" is a wave that is stored in a standalone file for packed experiment or in a standalone file outside the disk folder corresponding to the wave's data folder for an unpacked experiment.

See References to Files and Folders on page II-24 for an explanation of shared versus home waves.

/ONLY=targetedTextEncoding

SetWaveTextEncoding changes only wave elements that are currently set to targetedTextEncoding. For example, this command converts the content of all waves that are currently set to unknown text encoding (0) to UTF-8 (1), treating the waves originally marked as unknown as Shift JIS (4) waves:

SetWaveTextEncoding /DF={root:,1} /ONLY=0 /CONV={1,4} 1, 16

Passing -1 for targetedTextEncoding acts as if you omitted /ONLY altogether.

/Skip=skipTextEncoding
SetWaveTextEncoding skips all wave elements that are currently set to skipTextEncoding. For example, this command converts the content of all waves to UTF-8 (1) except those that are set to Japanese (4):

```
SetWaveTextEncoding /DF={root:,1} /SKIP=4 /CONV=1 1, 16
```

As explained under /CONV, binary (255) wave elements are always skipped and unknown (0) wave elements are skipped if the /CONV defaultTextEncoding parameter is omitted.

Passing -1 for skipTextEncoding acts as if you omitted /SKIP altogether.

```
/TYPEx=type
```

SetWaveTextEncoding changes only waves of the specified type.

type is:

1: Text waves only
2: Non-text waves only
3: All waves (default)

```
/Z=x
```

Prevents procedure execution from aborting if SetWaveTextEncoding generates an error. Use /Z or the equivalent, /Z=1, if you want to handle errors in your procedures rather than having execution abort.

/Z does not suppress invalid parameter errors. It suppresses only errors in doing text encoding reinterpretation or conversion.

Details

Because SetWaveTextEncoding is intended for use by experts or by users instructed by experts, it does not respect the lock state of waves. That is, it will change waves even if they are locked using SetWaveLock.

For background information on wave text encodings, see Wave Text Encodings on page III-472.

A wave’s text wave content text encoding can also be set to the special value 255. This marks a text wave as really containing binary data, not text. See Text Waves Containing Binary Data on page III-475 for details.

Using SetWaveTextEncoding

One of the main uses for SetWaveTextEncoding is to set the encoding settings to some value other than 0 (unknown) so that Igor’s idea of the text encoding used for the items accurately reflects the actual text encoding. We call this “reinterpreting” the item. It does not change the numeric codes representing the text but rather just changes the setting that controls Igor’s idea of how the text is encoded. This does change the meaning of the underlying numeric codes. In other words, it changes the characters represented by the text.

You would do reinterpretation if you load an Igor6 experiment and Igor interprets the waves using the wrong text encoding. For example, if you load an experiment that you know uses Shift JIS encoding but Igor interprets it as Windows-1252, you get garbage for Japanese text. Reinterpreting it as Shift JIS fixes this. An example is provided below.

The other use for SetWaveTextEncoding is to actually change the numeric codes representing the text - i.e., to convert the content to a different text encoding. For example, if you have text waves from Igor Pro 6 that are encoded in Japanese (Shift JIS), you may want to convert the text to UTF-8 (a form of Unicode) so that you can combine Japanese and non-Japanese characters or use other features that require Unicode. This also applies to western text containing non-ASCII characters encoded as MacRoman or Windows-1252. Converting changes the underlying numeric codes but does not change the characters represented by the text.

The main use for converting text is to convert Igor Pro 6 waves from whatever encoding they use, which typically will be MacRoman, Windows-1252, or Shift JIS, to UTF-8 (a form of Unicode) which is a more modern representation but is not backward compatible with Igor Pro 6.

If the /CONV flag is omitted SetWaveTextEncoding does reinterpretation. If the /CONV flag is present then SetWaveTextEncoding does text conversion except if the original text encoding is unknown (0) or binary (255) in which case it does nothing.

If a wave has mistakenly been marked as containing binary, use SetTextWaveEncoding without /CONV to set it to the correct text encoding.
If a wave’s text encoding is set to unknown (0) but you know that it really contains text in some specific encoding, you can use `SetWaveTextEncoding` without /CONV to set it to the correct text encoding and then use `SetWaveTextEncoding` with /CONV to convert it to the desired final text encoding. Alternately you can combine these two steps by using /CONV and providing a value for the optional `defaultTextEncoding` parameter.

**Output Variables**
The `SetWaveTextEncoding` operation returns information in the following variables:

- **V_numConversionsSucceeded**: Set only when the /CONV flag is used. Zero otherwise.
  - `V_numConversionsSucceeded` is set to the number of successful text element conversions.

- **V_numConversionsFailed**: Set only when the /CONV flag is used. Zero otherwise.
  - `V_numConversionsFailed` is set to the number of unsuccessful text conversions. Because `SetWaveTextEncoding` quits when any error occurs, `V_numConversionsFailed` will be either 0 or 1.

- **V_numConversionsSkipped**: Set only when the /CONV flag is used. Zero otherwise.
  - `V_numConversionsSkipped` does not count waves skipped because of the /TYPE flag.

- **V_numMarkedAsBinary**: Set only when the /BINA flag is used. Zero otherwise.
  - `V_numMarkedAsBinary` is set to the number of text waves whose text wave content was marked as binary.

  - `V_numMarkedAsBinary` was added in Igor Pro 9.00.

- **V_numWavesAffected**: `V_numWavesAffected` is set to the number of waves modified in any way, whether through reinterpretation, conversion of one or more elements, or marking as binary.
  - `V_numWavesAffected` was added in Igor Pro 9.00.

**Examples**

// Keep in mind that, if /CONV is present, `SetWaveTextEncoding` does nothing
// for wave text elements currently set to binary (255).
// Also, if /CONV is present, `SetWaveTextEncoding` does nothing
// for wave text elements currently set to unknown (0) if the /CONV
// optional defaultTextEncoding parameter is omitted.
// In the following examples 1 means UTF-8, 4 means Shift JIS, and 16
// means text wave content.

// Reinterpret specific text waves as Shift JIS if they are currently set to unknown
`SetWaveTextEncoding` /ONLY=0 4, 16, textWave0, textWave1

// Convert specific waves' content to UTF-8
`SetWaveTextEncoding` /CONV=1 1, 16, textWave0, textWave1

// Reinterpret all text waves as Shift JIS if they are currently set to unknown
`SetWaveTextEncoding` /DF={root:,1} /ONLY=0 4, 16

// Convert all waves' content to UTF-8
`SetWaveTextEncoding` /DF={root:,1} /CONV=1 1, 16

// Convert all text waves' content from Shift JIS to UTF-8
// if it is currently set to unknown
`SetWaveTextEncoding` /DF={root:,1} /ONLY=0 /TYPE=1 /CONV={1,4} 1, 16

// Same as before but exclude the root:Packages data folder
SetWaveTextEncoding /DF={root:,1,root:Packages} /ONLY=0 /TYPE=1 /CONV={1,4} 1, 16
// Mark a text wave as really containing binary data
SetWaveTextEncoding 255, 16, textWaveContainingBinaryData
// This example illustrates how to do a conversion based on criteria
// that require inspecting each wave.
Function ConvertCJKToUTF8(dfr, recurse)
  DFREF dfr
  Variable recurse
  Variable index = 0
  do
    Wave/Z w = WaveRefIndexedDFR(dfr, index)
    if (!WaveExists(w))
      break
    endif
    if (WaveType(w) == 0) // Text wave?
      Variable currentEncoding = WaveTextEncoding(w,5)// Wave content current
        encoding
        switch(currentEncoding)
          case 4: // Japanese (Shift JIS)
          case 5: // Traditional Chinese (Big5)
          case 6: // Simplified Chinese (ISO-2022-CN)
          case 7: // Macintosh Korean (EUC-KR)
          case 8: // Windows Korean (Windows-949)
            SetWaveTextEncoding /CONV=1 1, 16, w
            break
        endswitch

      ConvertCJKToUTF8(childDFR, 1)
    endfor
  endif
  SetDataFolder saveDFR
End

See Also
Text Encodings on page III-459, Wave Text Encodings on page III-472, Text Encoding Names and Codes
on page III-490, Text Waves Containing Binary Data on page III-475

SetWindow

SetWindow winName [, keyword = value]...
The SetWindow operation sets the window note and user data for the named window or subwindow.
SetWindow can also set hook functions for a base window or exterior subwindow (interior subwindows
not supported).

Parameters
winName can be the name of any target window (graph, table, page layout, notebook, control panel, Gizmo,
camera, or XOP target window). It can also be the keyword kwTopWin to specify the topmost target
window.
When identifying a subwindow with `winName`, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**activeChildFrame**

Determines if the frame indicating the active subwindow in the named window or subwindow is drawn.

- `f=1`: Default. Recursively check ancestors of this window. If one is found with a value of either 0 or 1, use that value. If the topmost window has a value of -1, then the frame is drawn.
- `f=1`: If this subwindow or one of its descendants becomes active, then the frame is drawn.
- `f=0`: If this subwindow or one of its descendants becomes active, then the frame is not drawn.

**doScroll**

Controls scrolling mode for top-level graph and panel windows only. The `doScroll` keyword was added in Igor Pro 9.00.

- `mode=1`: Turns scrolling mode on for the graph or panel.
  
  When scrolling mode is on, the size of the content area of the graph or panel is fixed and the window no longer grows or shrinks when you resize the window. If you shrink the window smaller than the size of the content area, scroll bars appear which allow you to view different parts of the content area.
  
  When scrolling mode is on, you can change the size of the content area of the graph or panel window using `doScroll=(width, height)`.

- `mode=0`: Turns scrolling mode off for the graph or panel.
  
  When scrolling mode is off, scroll bars are not shown and the size of the content area of the graph or panel grows or shrinks when you resize the window.

**graphicsTech**

Sets the graphics technology used to draw the window. This flag may be useful in rare cases to work around graphics limitations. See **Graphics Technology** (see page III-506) for background information.

- `t=0`: Default: The graphics technology specified in Miscellaneous Settings dialog, Miscellaneous category. This is Qt Graphics by default.
- `t=1`: Native: Core Graphics on Macintosh, GDI+ on Windows.
- `t=2`: Old: Core Graphics on Macintosh, GDI on Windows.

**hide**

Hides or unhides widows or subwindows.

- `h=0`: Unhides a subwindow or base window.
- `h=1`: Hides a subwindow or base window.
- `h=2`: Unhides without restoring minimized windows (Windows only).

When unhiding subwindows, you should combine with `needUpdate=1` if conditions require the subwindow to be redrawn since the window was hidden.

**hook**

Sets the window hook function that Igor will call when certain events happen. Use `SetWindow hook=""` to specify no hook function.

See **Unnamed Window Hook Functions** on page IV-305 for further details.
SetWindow

Defines a named window hook hName and sets the function that Igor will call when certain events happen. hName can be any legal name. Named hooks are called before any unnamed hooks.

Use "$" " for procName to specify no hook.

See Named Window Hook Functions on page IV-295 for further details.

To hook a subwindow, see Window Hooks and Subwindows on page IV-294.

hookcursor=number
Sets the mouse cursor. This keyword is antiquated. See Setting the Mouse Cursor on page IV-302 for the preferred technique.

hookevents=flags
Bitfield of flags to enable certain events for the unnamed hook function:

Bit 0: Mouse button clicks.
Bit 1: Mouse moved events.
Bit 2: Cursor moved events.

To set bit 0 and bit 1 (mouse clicks and mouse moved), use $2^0+2^1 = 1+2 = 3$ for flags.
Use 7 to also enable cursor moved events. See Setting Bit Parameters on page IV-12 for details about bit settings.

This keyword applies to the unnamed hook function only. It does not affect named hook functions which always receive all events.

markerHook= {hookFuncName, start, end}
Specifies a user function and marker number range for custom markers. The marker range can be any positive integers less than 1000 and can overlap built-in marker numbers. See Custom Marker Hook Functions on page IV-308 for details.

Use "$" for hookFuncName to specify no hook.

needUpdate= n
Marks a window as needing an update (n=1) or takes no action (n=0).

note=noteStr
Sets the window note to noteStr, replacing any existing note.

note+=noteStr
Appends noteStr to current contents of the window note.

sizeLimit= {minWidth, minHeight, maxWidth, maxHeight}
SetWindow

Imposes limits on a window’s size when resized with the mouse or by calling MoveWindow. The units of the limits are the same as those returned by GetWindow wsize.

The sizeLimit keyword was added in Igor Pro 7.00.

To allow the window width to grow essentially without bound, pass INF for maxWidth.

To allow the window height to grow essentially without bound, pass INF for maxHeight.

If minWidth > maxWidth or minHeight > maxHeight, the maximum dimensions are set to the minimum, effectively fixing the size of the window in that dimension. For control panels, it is better to use ModifyPanel fixedSize=1.

Combining these limits with ModifyGraph width and height modes leads to unexpected results and is discouraged.

If you first use sizeLimit and then execute ModifyPanel fixedSize=1 on the same window, the fixedSize command takes precedence. If you execute SetWindow sizeLimit on a control panel that has fixedSize=1, Igor generates an error.

Igor includes a SetWindow sizeLimit command in a window recreation macro if necessary. Igor6 does not support SetWindow sizeLimit so this causes an error when recreating the window in Igor6. If you never set the sizeLimit property for a window, or if the minimum dimensions are very small and maximum dimensions are INF, then no SetWindow command is generated.

tooltipHook(hName)=procName

A tooltip hook function is like a window hook function (see Named Window Hook Functions on page IV-295), except that it allows you to alter the text of a tooltip in a graph or table. At present, a tooltip hook function is called for a graph when the mouse hovers over a trace or image, and for a table when the mouse hovers over the data for a wave.

Unlike a window hook function, a tooltip hook function can be set for either a top-level window or a subwindow.

For details, see Tooltip Hook Functions on page IV-310.

userdata=UDStr
userdata(UDName)=UDStr

Sets the window or subwindow user data to UDStr. Use the optional (UDName) to specify a named user data to create.

userdata+=UDStr
userdata(UDName)+=UDStr

Appends UDStr to the current window or subwindow user data. Use the optional (UDName) to append to the named user data.

Details
For details on named window hooks, see Window Hook Functions on page IV-293.

Unnamed window hook functions are supported for backward compatibility only. New code should use named window hook functions. For details on unnamed window hooks, see Unnamed Window Hook Functions on page IV-305.

For details on marker hooks, see Custom Marker Hook Functions on page IV-308.

You can also attach user data to traces in graphs using the userData keyword of the ModifyGraph operation and to controls using the userData keyword of the various control operations.
See Also
The `GetWindow`, `SetIgorHook`, and `SetIgorMenuMode` operations and `AxisValFromPixel`, `NumberByKey`, `PopupContextualMenu`, and `TraceFromPixel` functions. The `GetUserData` operation for retrieving named user data.

ShowIgorMenus

`ShowIgorMenus [MenuNameStr [, MenuNameStr] ...`  
The `ShowIgorMenus` operation shows the named built-in menus or, if none are explicitly named, shows all built-in menus in the menu bar.
User-defined menus attached to built-in menus are also affected by this operation.

Parameters

`MenuNameStr`  
The name of an Igor menu, like “File”, “Data”, or “Graph”.

Details

See `HideIgorMenus` for details.

See Also

`HideIgorMenus`, `DoIgorMenu`, `SetIgorMenuMode`, User-Defined Menus on page IV-125

ShowInfo

`ShowInfo [/CP=num /W=winName]`  
The `ShowInfo` operation puts an information panel on the target or named graph. The information panel contains cursors and readouts of values associated with waves in the graph.

Flags

`/CP=num`  
Selects a cursor pair to display in the info panel.

`num=0`: Selects cursor A and cursor B.
`num=1`: Selects cursor C and cursor D.
`num=2`: Selects cursor E and cursor F.
`num=3`: Selects cursor G and cursor H.
`num=4`: Selects cursor I and cursor J.

`/CP={n1,n2,...}`  
Allows you to select multiple cursor pairs to be displayed in the info panel. The numbers n1, n2, etc., are the same as the single-pair version of this flag.
This form of `/CP` was added in Igor Pro 7.00.

`/SIDE=side`  
Selects the side of the host window where the info panel should be attached:

`side = 0`: right side
`side = 1`: left side
`side = 2`: bottom side (default)
`side = 3`: top side

`/V=num`  
If num is non-zero, selects a vertical layout for the info panel. Most appropriate when `/SIDE=0 or 1.`

`/W=winName`  
Displays info panel in the named window.

See Also

Info Panel and Cursors on page II-319.
The `HideInfo` operation.

Programming With Cursors on page II-321.
ShowTools

ShowTools [/A/W=winName] [toolName]
The ShowTools operation puts a tool palette for drawing along the left hand side of the target or named graph or control panel, and optionally activates the named tool.

Flags
/A
Sizes window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.

/W=winName
Shows tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

/winName must be either the name of a top-level window or a path leading to an exterior panel window (see Exterior Control Panels on page III-443).

Parameters
If you specify a toolName (which can be one of: normal, arrow, text, line, rect, rrect, oval, or poly) the named tool is activated. Specifying the "normal" tool has the same effect as issuing the GraphNormal command for a graph that has the drawing tools selected.

Details
The activated tool is not highlighted until the top graph or control panel becomes the topmost (activated) window. Use DoWindow/F to bring a window to the top (or “front”).

See Also
The DoWindow, GraphNormal, GraphWaveDraw, GraphWaveEdit, and HideTools operations.

SinIntegral

SinIntegral(z)
The SinIntegral(z) function returns the sine integral of z.

If z is real, a real value is returned. If z is complex then a complex value is returned.

The SinIntegral function was added in Igor Pro 7.00.

Details
The sine integral is defined by

\[
Si(z) = \int_0^z \frac{\sin(t)}{t} \, dt.
\]

IGOR computes the SinIntegral using the expression:

\[
Si(z) = z \, _2F_1 \left(1; \frac{3}{2}, \frac{3}{2}; -\frac{z^2}{4} \right).
\]

References

See Also
CosIntegral, ExpIntegralE1, hyperGPFQ

sign

sign(num)
The sign function returns -1 if num is negative or 1 if it is not negative.
Silent

**Silent**

*Silent num*

The Silent operation is largely obsolete. Only very obscure uses remain and most users can ignore this operation.

Prior to Igor Pro 7, Silent was used to enable or disable the display of macro commands in the command line as they were executed. It was also used to enable compatibility modes for very old experiments.

**Parameters**

If *num* is 2, commands issued by AppleEvents or ActiveX Automation are not shown in the history are of the command window. Use 3 to re-enable.

If *num* is 100, 101 or 102, all procedures are recompiled. For 102, the time to recompile is displayed in the history.

**sin**

*<code>sin(angle)</code>*

The sin function returns the sine of *angle* which is in radians.

In complex expressions, *angle* is complex, and *sin(angle)* returns a complex value:

\[ \sin(x + iy) = \sin(x) \cosh(y) + i \cos(x) \sinh(y). \]

**See Also**

asin, cos, tan, sec, csc, cot

**sinc**

*<code>sinc(num)</code>*

The sinc function returns \( \sin(num)/num \). The sinc function returns 1.0 when *num* is zero. *num* must be real.

**sinh**

*<code>sinh(num)</code>*

The sinh function returns the hyperbolic sine of *num*:

\[ \sinh(x) = \frac{e^x - e^{-x}}{2}. \]

In complex expressions, *num* is complex, and sinh(*num*) returns a complex value.

**See Also**

cosh, tanh, coth

**Sleep**

*<code>Sleep [flags] timeSpec</code>*

The Sleep operation puts Igor to sleep for a while. After the while is up, Igor continues execution.

You could use Sleep, for example, to give an instrument time to perform an action or to allow a user to admire a graph before proceeding.

More advanced programmers may prefer to use a background task as an alternative. See **Background Tasks** on page IV-319.

**Parameters**

The format of *timeSpec* depends on which flags, if any, are present.

If no flags are present, then *timeSpec* is in **hh:mm:ss** format and specifies the number of elapsed hours, minutes and seconds to sleep.
The Sleep operation does not let the user choose menus, move cursors, run procedures, draw in graphs, or do any other interactive task.

Normally \textit{timeSpec} specifies an amount of elapsed time. If the /A flag is present, then \textit{timeSpec} is an absolute time when sleep is to end. If the specified absolute time has already passed, no sleep occurs unless you also use /W, which makes it wait until tomorrow.

If you specify time in hh:mm:ss format, you can also specify the time indirectly through a string variable. See the examples.
You can end sleep by pressing the User Abort Key Combinations. Normally when you do this, it aborts any procedure that is running. However, if you use the /Q flag, the procedure continues running normally.

Displacing a Progress Dialog
When you specify /C=6 or if you use the /PROG flag, Sleep displays a progress dialog with a progress bar showing how much of the sleep time has passed. The dialog displays a prompt which you can control using the /M flag.

If you use /PROG, then /Q and /B are ignored.

If you use /C=6, then /Q and /B have special meanings:

/C=6 Progress dialog with Cancel button which aborts running procedures.
The Abort key combinations abort running user procedures.

/C=6/B Progress dialog with Abort button which aborts running procedures.
The Abort key combinations abort running user procedures.

/C=6/Q Progress dialog with Continue button which terminates the current sleep operation but allows procedures to continue.
Abort key combinations allow running procedures to continue.

/C=6/B/Q Progress dialog with Continue and Abort buttons. The Continue button terminates the current sleep operation but allows procedures to continue. The Abort button aborts running procedures.
Abort key combinations allow running procedures to continue.

If you use the /PROG flag, you can provide your own titles for the Cancel and Continue buttons.

Examples
These examples assume the current time is 4 PM:

Sleep 00:01:30 // sleeps for 1 minute, 30 seconds
Sleep/A 23:30:00 // sleeps until 11:30 PM
Sleep/A 03:00:00 // doesn't sleep at all because time is past
Sleep/A/W 03:00:00 // sleeps until 3 AM tomorrow
String str1= "03:00:00" // put wakeup call time in string
Sleep/A/W $str1 // sleeps until 3 AM tomorrow
Sleep/B/C=2/S/Q 60 // sleep 60 seconds, or until user clicks,
// and keep going (don't abort)

The following function creates a graph and then periodically updates the displayed data. By default, it sleeps for a number of seconds specified by the sleepTime parameter.

Function SleepDemo(sleepTime, displayProgressDialog)
  Variable sleepTime // In seconds
  Variable displayProgressDialog // 1 for progress dialog

  Make/N=200/0 junk
  SetScale/I x 0, 2*pi, junk
  junk=sin(x)
  DoWindow/F SleepDemoGraph
  if (V_Flag == 0)
    Display/N=SleepDemoGraph junk
  endif
  DoUpdate

  try
    Variable i
    for (i = 0; i < 10; i+=1)
      if (displayProgressDialog)
        // Because the abortMode is 0, pressing the user abort key combinations
        // or pressing the Done button generates an abort instead of merely
        // terminating the current Sleep call.
        int abortMode = 0
        Sleep/S/PROG={"Done", "Continue", abortMode} sleepTime
      else
        // /B makes Sleep terminate if the user clicks.
      endif
    endfor
  endtry
Because the /Q flag is omitted, pressing the user abort key combinations or pressing Igor's Abort button generates an abort instead of merely terminating the current Sleep call.

```plaintext
Sleep/S/C=2/B sleepTime
endif
junk = sin(x*(i+2))
DoUpdate
endfor
```

catch
Printf "An abort occurred with V_abortCode=%d\r", V_abortCode
endtry
End

Slider operation creates or modifies a Slider control in the target window.

A Slider control sets or displays a single numeric value. The user can adjust the value by dragging a thumb along the length of the Slider.

For information about the state or status of the control, use the ControlInfo operation.

**Parameters**

- `ctrlName` is the name of the Slider control to be created or changed.

The following keyword=value parameters are supported:

- `align=alignment` Sets the alignment mode of the control. The alignment mode controls the interpretation of the `leftOrRight` parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.
  - If `alignment=0` (default), `leftOrRight` specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
  - If `alignment=1`, `leftOrRight` specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

- `appearance={kind [, platform]}` Sets the appearance of the control. `platform` is optional. Both parameters are names, not strings.
  - `kind` can be one of `default`, `native`, or `os9`.
  - `platform` can be one of `Mac`, `Win`, or `All`.

  **Note:** The Slider control reverts to `os9` appearance on Macintosh if `thumbColor` isn’t the default blue (0,0,65535).

  See Button and DefaultGUIControls for more appearance details.

- `disable=d` Sets user editability of the control.
  - `d=0`: Normal.
  - `d=1`: Hide.
  - `d=2`: Draw in gray state; disable control action.

- `fColor=(r,g,b[,a])` Sets the color of the tick marks. `r`, `g`, `b`, and `a` specify the color and optional opacity as RGBA Values. The default is opaque black.

- `focusRing=fr` Enables or disables the drawing of a rectangle indicating keyboard focus:
  - `fr=0`: Focus rectangle will not be drawn.
  - `fr=1`: Focus rectangle will be drawn (default).

  On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

- `font="fontName"` Sets the font used to display the tick labels, e.g., `font="Helvetica"`.

<td>Sets width or height of control in <em>Control Panel Units</em>. <em>height</em> is ignored if (vert=0) and (width) is ignored if (vert=1).</td>
</tr>
<tr>
<td>thumbColor=(r,g,b,{a})</td>
<td>If appearance={os9} is in effect, sets dominant foreground color of thumb. <em>r</em>, <em>g</em>, <em>b</em>, and <em>a</em> specify the color and optional opacity as <em>RGBA Values</em>. Alpha <em>(a)</em> is accepted but ignored.</td>
</tr>
</tbody>
</table>
Slider Action Procedure

The action procedure for a Slider control takes a predefined `WMSliderAction` structure as a parameter to the function:

```igor
Function ActionProcName(S_Struct) : SliderControl
    STRUCT WMSliderAction &S_Struct
    
    return 0
End
```

The "`: SliderControl`" designation tells Igor to include this procedure in the Procedure pop-up menu in the Slider Control dialog.

Flags

/\z No error reporting.

Details

The target window must be a graph or panel.

If you use negative ticks to suppress automatic labeling, you can label tick marks using drawing tools (panels only).

Slider Action Procedure

The action procedure for a Slider control takes a predefined `WMSliderAction` structure as a parameter to the function:

```igor
Function ActionProcName(S_Struct) : SliderControl
    STRUCT WMSliderAction &S_Struct
    
    return 0
End
```

The "`: SliderControl`" designation tells Igor to include this procedure in the Procedure pop-up menu in the Slider Control dialog.

Flags

/\z No error reporting.

Details

The target window must be a graph or panel.

If you use negative ticks to suppress automatic labeling, you can label tick marks using drawing tools (panels only).

Slider Action Procedure

The action procedure for a Slider control takes a predefined `WMSliderAction` structure as a parameter to the function:

```igor
Function ActionProcName(S_Struct) : SliderControl
    STRUCT WMSliderAction &S_Struct
    
    return 0
End
```

The "`: SliderControl`" designation tells Igor to include this procedure in the Procedure pop-up menu in the Slider Control dialog.
See WMSliderAction for details on the WMSliderAction structure.

See Handling Slider Events on page III-430 for a demonstration of slider event handling.

Although the return value is not currently used, action procedures should always return zero.

This old format for a slider action procedure should not be used in new code:

```plaintext
Function MySliderProc(name, value, event) : SliderControl
    String name // name of this slider control
    Variable value  // value of slider
    Variable event  // bit field: bit 0: value set; 1: mouse down,
                     //  2: mouse up, 3: mouse moved
    return 0 // other return values reserved
End
```

Repeating Sliders

A repeating slider calls your action procedure periodically while the user is clicking the thumb. See Repeating Sliders on page III-418 for an overview.

When the repeat style is set to 2, the call rate is proportional to the slider value. See the Slider reference documentation in the online help for the formula.

Whereas the rate can be set as high as 1000 calls per second, if your action procedure takes more time to execute than the period of the slider repeat, you will simply lose repeats. It is unlikely that a rate of more than about 50 calls per second can realistically be achieved.

Examples

```plaintext
Function SliderExample()
    NewPanel /W=(150,50,501,285)
    Variable/G var1
    Execute "ModifyPanel cbRGB=(56797,56797,56797)"
    SetVariable setvar0,pos=[141,18],size=[122,17],limits=[-Inf,Inf,1],value=var1
    Slider foo2, pos=[26,31], size=[62,143], limits=[-5,10,1], variable=var1
    Slider foo2, limits=[-5,10,1], variable=var1, vert=0, thumbColor=(0,1000,0)
    Slider foo3, pos=[80,31], size=[62,143]
    Slider foo3, limits=[-5,10,1], variable=var1, side=2, thumbColor=(1000,1000,0)
    Slider foo4, limits=[-5,10,1], variable=var1, side=0, vert=0
    Slider foo4, thumbColor=(1000,1000,1000)
    Slider foo5, pos=[173,90], size=[150,53]
    Slider foo5, limits=[-5,10,1], variable=var1, side=2, vert=0
    Slider foo5, ticks=5, thumbColor=(500,1000,1000)
End
```

Demos

Choose File→Example Experiments→Feature Demos 2→Slider Labels.

Choose File→Example Experiments→Feature Demos 2→Slider Repeat Demo.

SliderControl

SliderControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined slider control. See Procedure Subtypes on page IV-204 for details. See Slider for details on creating a slider control.

Slow

Slow ticks

The Slow operation is obsolete. Prior to Igor Pro 7 it slowed down execution of macros for debugging purposes. It now does nothing.
Smooth

Smooth  

The Smooth operation smooths the named waves using binomial (Gaussian) smoothing, boxcar (sliding average) smoothing, Savitzky-Golay (polynomial) smoothing, or running-median filtering.

Parameters

num is the number of smoothing operations to be applied for binomial smoothing or the integer number of points in the smoothing window for boxcar, Savitzky-Golay, and running-median smoothing, or, if you use /BLPF, the low-pass cutoff frequency.

Each wave, which may be floating point or integer, is smoothed in-place, overwriting the values with the smoothed result.

If an input wave is complex, the real and imaginary parts are smoothed independently.

If an input wave contains NaNs, smoothing results are unsatisfactory unless running-median (/M) filtering is used with a median of 3 or more. The Loess operation can fill in NaNs and the Interpolate2 operation ignores NaNs and INFs.
### Flags

/b [b]  
Invokes boxcar smoothing algorithm. If given, b specifies the number of passes to use when smoothing the data with smoothing factor num (box width). The number of passes can be any value between 1 and 32767.

/blpf=roundMode  
Calculates the integer number of smoothing operations to be applied for binomial smoothing based on interpreting the num parameter as the low-pass cutoff frequency and then performs the smoothing. /blpf was added in Igor Pro 8.00.

The calculated number of smoothing operations is returned in V_iterations:

\[
V_{\text{iterations}} = \ln(\sqrt{2}) \left( \frac{1}{\left( \left( \pi f_{cn} \right)^2 - \frac{1}{6} \right)} \right)
\]

where \( f_{cn} = \text{num} \times \text{DimDelta(wave0, dim)} \)

If roundMode is 1, \( V_{\text{iterations}} \) is rounded down to an integer value. This is the default if you use /blpf by itself without roundMode.

If roundMode is 2, \( V_{\text{iterations}} \) is rounded up to an integer value.

\( f_{cn} \) is the Nyquist-normalized cutoff frequency and should be ≤ 0.182028, which results in \( V_{\text{iterations}} = 1 \).

The cutoff frequency, also known as the "half power point", is the frequency at which the magnitude response of the smoothing filter declines to \( 1/\sqrt{2} \approx 0.707107 \).

/dim=dim  
Specifies the wave dimension to smooth.

\( \text{dim}=1 \): Treats entire wave as 1D (default)  
\( \text{dim}=0 \): Operates along rows  
\( \text{dim}=1 \): Operates along columns  
\( \text{dim}=2 \): Operates along layers  
\( \text{dim}=3 \): Operates along chunks

/e=endEffect  
Determines how to handle the ends of the wave (w) when fabricating missing neighbor values.

\( \text{endEffect}=0 \): Bounce method (default). Uses \( w[i] \) in place of the missing \( w[-i] \) and \( w[n+i] \) in place of the missing \( w[n-i] \).

\( \text{endEffect}=1 \): Wrap method. Uses \( w[n-i] \) in place of the missing \( w[-i] \) and vice versa.

\( \text{endEffect}=2 \): Zero method. Uses 0 for any missing value.

\( \text{endEffect}=3 \): Repeat method. Uses \( w[0] \) in place of the missing \( w[-i] \) and \( w[n] \) in place of the missing \( w[n+i] \).

/even [=evenAllowed]  
Specifies the smoothing increment for boxcar smoothing (/b). Values are:

0: Increments even values of \( \text{num} \) to the next odd value. Default when /even omitted.

1: Uses even values of \( \text{num} \) for boxcar smoothing despite the half-sample shifting this introduces in the smoothed output (prior to version 6, this shift was prevented). Same as /even alone.

/f [=f]  
Selects the boxcar or multipass binomial smoothing method:

\( f=0 \): Slow, but accurate, method (default).

\( f=1 \): Fast method. Same as /f alone.
Smooth

/\text{M=\text{threshold}}\quad \text{Invokes running-median smoothing and specifies an absolute numeric threshold used to optionally replace “outliers”. Points that differ from the central median by an amount exceeding \text{threshold} are replaced, either with the \text{replacement} value specified by /R, or otherwise with the median value.}

Special threshold values are:

- 0: Replace all values with running-median values or the replacement value.
- (NaN): Replace only NaN input values with running-median values or the replacement value.

The smoothing factor \(num\) is the number of points in the smoothing window used to compute each median.

/\text{MPCT=\text{percentile}}\quad \text{Used with /M to compute a smoothed value that is a different percentile than the median. /M must be present if /MPCT is used.}

\text{percentile} is a value from 0 to 100.

Roughly speaking, the smoothed value returned is the smallest value in the smoothing window that is greater than the smallest \text{percentile} \% of the values. See "Median and Percentile Smoothing Details", below.

- \text{percentile}=0: The smoothed value is the minimum value in the smoothing window.
- \text{percentile}=50: The smoothed value is the median of the values in the smoothing window. This is the default if /MPCT is omitted.
- \text{percentile}=100: The smoothed value is the maximum value in the smoothing window.

/\text{R=\text{replacement}}\quad \text{Specifies the value that replaces input values that exceed the central median by threshold (requires /M). replacement can be any value (including NaN or ±Inf if \text{waveName} is floating point).}

/\text{S=\text{sgOrder}}\quad \text{Invokes Savitzky-Golay smoothing algorithm and specifies the smoothing order. sgOrder must be either 2 or 4.}

Binomial Smoothing Details

For binomial smoothing, use no flags other than /BLPF, /DIM, /E, and /F.

If you are not using /BLPR, \(num\) is the number of smoothing operations between 1 and 32767.

If you are using /BLPF, \(num\) is the low-pass cutoff frequency which must be less than 0.182028 times the sampling frequency of \text{wave0}. The computed smoothing factor is returned in \text{V_iterations}. Very small values of fcn (≈ 0.0007 or less) will fail with errors due to excessive number of smoothing operations or to insufficient range (too few wave points).

In Igor Pro 6 and later, the binomial smooth algorithm automatically switches to a nearly-equivalent but much faster multipass box smooth when \(num \geq 50\). You can prevent the switch to box smoothing by setting this global variable:

\text{Variable/G root:V_doOrigBinomSmooth=1}

The binomial smoothing algorithm does not detect and ignore NaNs in the input data. Use Loess or Interpolate2 to fill in NaNs.

Boxcar Smoothing Details

For boxcar smoothing, use the /B flag and a \(num\) value from 1 to 32767.

For \(num < 2\), no smoothing is done.

If \(num\) is even and /EVEN is not specified, \(num\) is incremented to the next (odd) integer.

If \(num\) is even and /EVEN is specified, each smoothed output is formed from one more previous value than future values.
The fast boxcar smoothing (/F) algorithm creates small errors when the data has a large offset. For some data sets you may want to subtract the mean of the data before smoothing and add it back in afterwards.

The boxcar smoothing algorithm detects and ignores NaNs in the input data. If num is less than the number of NaNs near the output point, then the result is NaN. Otherwise the average of the non-NaN neighboring points is used to compute the smoothed result.

Savitzky-Golay Smoothing Details

For Savitzky-Golay smoothing, use the /S flag and an odd num value from 5 to 25. An even value for num returns an error. If sgOrder=4, then num=5 gives no smoothing at all so num should be at least 7.

The Savitzky-Golay smoothing algorithm does not detect and ignore NaNs in the input data.

Median and Percentile Smoothing Details

For running-median smoothing, use the /M flag and a num value from 1 to 32767. When num is 1, no smoothing is done.

If num is even, the median is the average of the two middle values.

For example, the median of 6 values around data[i] is the median of data[i-3], data[i-2], data[i-1], data[i], data[i+1], and data[i+2], and if these values were already sorted, the median would be the average of data[i-1] and data[i].

Use /M=0 to replace all values with the median over the smoothing window or use /M=threshold/R=(NaN) to replace outliers with NaNs.

Use /M=(NaN) to replace only NaN input values with the running-median values or the replacement value.

The running-median smoothing algorithm detects and ignores NaNs in the input data. If num is less than the number of NaNs near the output point, then the result is NaN. Otherwise the median of the non-NaN neighboring points is used to compute the smoothed result.

The running-median is a special case of running-percentile, with percentile=50.

The /M and /MPCT algorithm uses an interpolated rank to compute the value of percentiles other than 0 and 100.

Using Example 1 from <http://cnx.org/content/m10805/latest/> (“A Third Definition”), the 25th percentile (/MPCT=25) of the 8 values:

\[
\text{Make/O sortedData} = \{3, 5, 7, 8, 9, 11, 13, 15\} \quad // \text{Already sorted, rank 1 to 8}
\]

The first step is to compute the rank (R) of the 25th percentile. This is done using the following formula: \( R = (\text{percentile}/100) \times (\text{num}+1) \), where percentile is 25 and num is 8, so here \( R = 2.25 \).

If R were an integer, the Pth percentile would be the number with rank R; if R were 2 the result would be the 2nd value = 5.

Since R is not an integer, we compute the Pth percentile by interpolation as follows:

1. Define IR as the integer portion of R (the number to the left of the decimal point). For this example, IR=2.
2. Define FR as the fractional portion of R. For this example, FR=0.25
3. Find the values with Rank IR and with Rank IR+1. For this example, this means the values with Rank 2 and the score with Rank 3. The values are 5 and 7.
4. Interpolate by multiplying the difference between the values by FR and add the result to the lower values. For these data, this is 0.25(7-5)+5=5.5

Therefore, the 25th percentile is 5.5:

\[
\text{Smooth/M=0/MPCT=(percentile) 8, sortedData} \quad // \text{8-point smoothing window}
\]

Print sortedData[3] // prints 5.5, the 25th percentile of all 8 values

Smoothing Window and End Effects Details

These smoothing algorithms compute the output value for a given point using each point’s neighbors. Except for running-median smoothing, each algorithm combines neighboring points before and after the point being smoothed. At the start or end of a wave some points will not have enough neighbors so some method for fabricating neighbor values must be implemented. The /E flag specifies the method.

The running-median filter, however, ignores /E. At each end of the data fewer values are included in the median calculation, so that values “beyond” the end of data are not needed.
The first output value is the median of \( \text{wave}[0, \lfloor (\text{num}-1)/2 \rfloor] \). For example, if \( \text{num} = 7 \), then the first output value is the median of \( \text{wave}[0], \text{wave}[1], \text{wave}[2], \) and \( \text{wave}[3] \). Because that is an even number of points, the median is the average of the two middle values. Continuing the example, if the values were 3, 1, 7, and 5, the two middle values are 3 and 5. The computed median would be \((3+5)/2=4\).

Examples

Box smoothing example:

Make/O=N=100 \( \text{wv} \); Display \( \text{wv} \)
\( \text{wv}=\text{gnoise}(1) \)
Smooth/B/E=3,3,\( \text{wv} \)  // output[\( p \)] = average of \( \text{wv}[p-1], \text{wv}[p] \) and \( \text{wv}[p+1] \)
// /E=3 causes \( \text{wv}[0] = (\text{w}[0]+\text{w}[0]+\text{w}[1])/3 \)
// and \( \text{wv}[\text{num-1}] = (\text{w}[\text{num-2}]+\text{w}[\text{num-1}]+\text{w}[\text{num-1}])/3 \)

Demonstrate the impulse response of Savitzky-Golay Smoothing:

Make/O/N=100 \( \text{wv} \)
\( \text{wv}= \quad \text{p==50} \quad // 1 \text{ at center of wave, 0 elsewhere; an impulse} \)
SetScale/P x, 0, 1/1000, "s", \( \text{wv} \)  // 1000 Hz sampling rate
Smooth/S=2 5,\( \text{wv} \)
Display \( \text{wv} \)
ModifyGraph mode=8,marker=19
FFT/MAG/DEST=fftMag \( \text{wv} \)
Display fftMag

Replace NaN with median:

Make/O/N=100 \( \text{data} = \text{enoise}(1)>.9 \ ? \text{NaN} : \text{sin}(x/8) \quad // \text{signal}\) with NaNs
Duplicate/O \( \text{data}, \text{dataMedian} \)
Smooth/M=(NaN) 5,\( \text{dataMedian} \)  // replace (only) NaNs with 5-point median

Binomial Smoothing References

Savitzky-Golay Smoothing References

Percentile References

<http://en.wikipedia.org/wiki/Percentile>
<http://cnx.org/content/m10805/latest/>
SmoothCustom

SmoothCustom [/E=endEffect] coefsWaveName, waveName [, waveName]...

Note: SmoothCustom is obsolete. Use the FilterFIR operation instead. For multidimensional data use the MatrixConvolve or MatrixFilter operations.

Parameters
coefsWaveName must be single or double floating point, must not be one of the destination waveNames, must not be complex.
waveName is a numeric destination wave that is overwritten by the convolution of itself and coefsWaveName.

Flags
/E=endEffect End effect method, a value between 0 and 3. See the Smooth operation for a description of the /E flag.

Details
The convolution is in the time domain. That is, the FFT is not employed. For this reason the length of coefsWaveName should be small or small in comparison to the destination waves.

SmoothCustom presumes that the middle point of coefsWaveName corresponds to the delay = 0 point. The “middle” point number = trunc(numpnts(coefsWaveName)-1)/2. coefsWaveName usually contains the two-sided impulse response of a filter, and contains an odd number of points. This is the type of wave created by FilterFIR.

SmoothCustom ignores the X scaling of all the waves.

The SmoothCustom operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-95 for details.

Sort
Sort [ /A /DIML /C /R ] sortKeyWaves, sortedWaveName [, sortedWaveName]...

The Sort operation sorts the sortedWaveNames by rearranging their Y values to put the data values of sortKeyWaves in order.

Parameters
sortKeyWaves is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.

All waves must be of the same length.

The sortKeyWaves must not be complex.

Flags
/A=[a] Alphanumeric sort. When sortKeyWaves includes text waves, the normal sorting places “wave1” and “wave10” before “wave9”.

The optional a parameter requires Igor Pro 7.00 or later.

Use /A or /A=1 to sort the number portion numerically, so that “wave9” is sorted before “wave10”.

Use /A=2 to ignore + and - characters in the text so that “Text-09” sorts before “Text-10”.

See Also
See the Loess, MatrixConvolve, and MatrixFilter operations for true 2D smoothing.

FilterFIR, FilterIIR, Loess, Interpolate2

Also see the “Smooth Operation Responses” example experiment.
SortColumns

/C Case-sensitive sort. When sortKeyWaves includes text waves, the sort is case-insensitive unless you use the /C flag to make it case-sensitive.

/DIML Moves the dimension labels with the values (keeps any row dimension label with the row’s value).

/LOC Performs a locale-aware sort.

When sortKeyWaves includes text waves, the text encoding of the text waves’ data is taken into account and sorting is done according to the sorting conventions of the current system locale. This flag is ignored if the text waves’ data encoding is unknown, binary, Symbol, or Dingbats. This flag cannot be used with the /A flag. See Details for more information.

The /LOC flag was added in Igor Pro 7.00.

/R Reversed sort; sort from largest to smallest.

Details

sortKeyWaves are not actually sorted unless they also appear in the list of destination waves.

The sort algorithm does not maintain the relative position of items with the same key value.

When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS specific text comparison routines based on the locale set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

When /LOC is omitted the sort is done on the raw text without regard to the waves’ text encoding.

Examples

Sort/R myWave,myWave // sorts myWave in decreasing order
Sort xWave,xWave,yWave // sorts x wave in increasing order,
// corresponding yWave values follow.
Make/O/T myWave={"1st","2nd","3rd","4th"}
Make/O key1={2,1,1,1} // places 2nd, 3rd, 4th before 1st.
Make/O key2={0,1,3,2} // arranges 2nd, 3rd, 4th as 2nd, 4th, 3rd.
Sort {key1,key2},myWave // sorts myWave in increasing order by key1.
// For equal key1 values, sorted by key2.
// Result is myWave={"2nd","4th","3rd","1st"}
Make/O/T tw={"w1","w10","w9","w-2.1"}
Sort/A tw,tw // sorts tw in increasing number-aware order:
// Result is tw={"w-2.1","w1","w9","w10"}

MakeIndex, IndexSort, Reverse, SortColumns, SortList

FindDuplicates, TextHistogram

SortColumns

SortColumns [flags] keyWaves={waveList}, sortWaves={waveList}

The SortColumns operation rearranges data in columns of the sortWaves using the data movements that would sort the values of the keyWaves if they were sorted.

The SortColumns operation was added in Igor Pro 7.00.

Parameters

keyWaves is a lists of 1 or more wave references in braces separated by commas. The first listed wave is the primary sort key, the second is the secondary sort key, and so on. The keyWaves list can contain a maximum of 10 waves. The key waves can be either text or real numeric waves but all key waves must be of the same type and have the same number of points. Complex waves, wave reference waves and data folder reference waves can not be used as key waves.

sortWaves is a lists of one or more wave references in braces separated by commas. The sortWaves list can contain a maximum of 100 waves.
SortColumns

Flags

/A Alphanumeric sort.

When keyWaves includes text waves, or the /KNDX flag is used and the first wave in the sortWaves list is a text wave, the normal sorting places "wave1" and "wave10" before "wave9". Use /A to sort the number portion numerically, so that "wave9" is sorted before "wave10". /A cannot be used with the /LOC flag.

/C Case-sensitive sort. When keyWaves includes text waves, or the /KNDX flag is used and the first wave in the sortWaves list is a text wave, the sort is case-insensitive unless you use the /C flag to make it case-sensitive.

/DIML Moves the row dimension labels with the data values. Column dimension labels remain unchanged.

/KNDX=[c0, c1, ... c9]

Specifies up to 10 columns of the first wave in the sortWaves list to use as the sort keys. This flag and the keyWaves keyword are mutually exclusive. If this flag is used then the first wave in the sortWaves list must be either a real numeric or text wave.

/LOC Locale aware sort.

When keyWaves includes text waves, or the /KNDX flag is used and the first wave in the sortWaves list is a text wave, the text encoding of the text waves' data is taken into account and sorting is done according to the sorting conventions of the current system locale.

/LOC is ignored if the text waves' data encoding is unknown, binary, Symbol, or Dingbats.

/LOC can not be used with the /A flag.

See Details for more information.

/R Reverses the sort, sorting from largest to smallest.

Details

Waves in the keyWaves list are not actually sorted unless they also appear in the sortWaves list.

All waves must have the same number of rows but can have different numbers of columns, layers and chunks.

keyWaves, or the first wave in the sortWaves list when /KNDX is used, must be either numeric or text waves.

When the sortWaves list includes 3D or 4D waves, the operation sorts all columns of all layers/chunks.

The sorting algorithm used does not maintain the relative position of rows with the same key value.

When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS-specific text comparison routines based on the current locale as set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

Examples

// Define a function that creates sample data
Function CreateSampleData()
Make/O key1=[3,1,0,2]
Make/O/T text1=\"Jack",\"Fred\",\"Robin\",\"Bob\"
Make/O w1=[[1,2,3,4],[11,12,13,14]]
End

// Create sample data and display in a table
CreateSampleData()
Edit key1,text1,w1

// Sort based on a numeric key
SortColumns keyWaves=key1,sortWaves=w1
// Revert the data
CreateSampleData()

// Sort based on text key
SortColumns keyWaves=text1,sortWaves=w1

// Revert the data
CreateSampleData()

// Sort using key index
SortColumns/kndx=0 sortWaves={text1,w1}

See Also
Sorting on page III-132, Sort, Reverse, SortList

SortList

SortList(listStr [, listSepStr [, options]])
The SortList function returns listStr after sorting it according to the default or listSepStr and options parameters. listStr should contain items separated by listSepStr, such as "the first item;second item;".

Use SortList to sort the items in a string containing a list of items separated by a string, such as those returned by functions like TraceNameList or WaveList, or a line of text from a delimited text file, where listSepStr can be "\r" or "\r\n".

listSepStr and options are optional; their defaults are ";" and 0 (ascending alphabetic sort), respectively.

Details
listStr is treated as if it ends with a listSepStr even if it doesn’t. The returned list will always have an ending listSepStr string.

In Igor6, SortList used only the first byte of listSepStr. As of Igor7, it uses the whole string.

options controls the sorting method, as follows:

0: Default sort (ascending case-sensitive alphabetic ASCII sort).
1: Descending sort.
2: Numeric sort.
4: Case-insensitive sort.
8: Case-sensitive alphanumeric sort.
16: Case-insensitive alphanumeric sort that sorts wave0 and wave9 before wave10.
32: Unique sort in which duplicates are removed. Added in Igor Pro 7.00.
64: Ignore + and - in the alphanumeric sort so that “Text-09” sorts before “Text-10”. Set options to 80 or 81. Added in Igor Pro 7.00.

options may also be a bitwise combination of these values with the following restriction: only one of 2, 4, 8, or 16 may be specified. Thus the legal values are thus 0, 1, 2, 3, 4, 5, 8, 9, 16, 17, 32, 33, 34, 35, 36, 40, 41, 48, 49, 80 or 81. Other values will produce undefined sorting.

In a case-insensitive, unique sort (options=4+32), if two items differ only in case, which one is retained is not specified.

Examples

// Alphabetic sorts
Print SortList("c;a;a;b") // prints "a;a;b;c;"
Print SortList("you,me,More", ",", 0) // prints "More,me,you,"
Print SortList("you,me,More", ",", 4) // prints "me,More,you,"
Print SortList("9,93,91,33,15,3", ",", 4) // prints "15,3,33,9,91,93,"
Print SortList("Zx;abc;All;", ",", 0) // prints "All;Zx;abc;"
Print SortList("Zx;abc;All;", ",", 8) // prints "abc;All;Zx;"
Print SortList("w9;w10;w02;", ",", 16) // prints "w02;w9;w10;"

// Unique sort
Print SortList("b;c;a;a;", ",", 32) // prints "a;b;c;"
SoundInRecord

Print SortList("b;c;a;A;a;", ",", 4+32)  // prints "A;b;c;"
Print SortList("b;c;a;A;", ",", 4+32)  // prints "a;b;c;"

// Numeric sorts
Print SortList("9,93,91,33,15,3", ",",2)  // prints "3,9,15,33,91,93,"
Print SortList("9,93,91,33,15,3", ",",3)  // prints "93,91,33,15,9,3,"

See Also
Sort, StringFromList, WaveList, RemoveEnding
See Setting Bit Parameters on page IV-12 for details about bit settings.

SoundInRecord

SoundInRecord [/BITS=bits /Z] wave
The SoundInRecord operation records audio input at the sample rate obtained from the wave's X scaling
and for the number of points determined by the length of the wave. The recording is done synchronously.
The number type of the wave must be a type supported by the sound input hardware as reported by the
SoundInStatus operation. Use SoundInStatus with the format keyword to check if a particular format is
supported.
On Windows 8-bit or 16-bit integer are typically supported. On Macintosh, 16-bit integer or 32-bit floating
point (the Mac OS native type for sound) are typically supported.
To record in stereo, provide a 2 column wave. (The software is designed to handle any number of channels
but has not been tested on more than 2.)

Flags

/BITS=bits Controls the number of bits used for each recorded sound sample.
Use /BITS=24 with a 32-bit integer wave for 24-bit sound data capable of representing
values from -8,388,608 to +8,388,607.
If you omit /BITS or use /BITS=0, SoundInRecord uses the wave's data type and size
to determine how many bits are recorded for each sound sample.
The /BITS flag was added in Igor Pro 9.00.
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details
SoundInRecord requires a computer with sound inputs. Several sample experiments using sound input can
be found in your Igor Pro Folder in the Examples folder.

See Also
SoundInSet, SoundInStartChart, SoundInStatus

SoundInSet

SoundInSet [/Z] [gain=g, agc=a]
The SoundInSet operation is used to setup the input device for recording.

Parameters
SoundInSet can accept multiple keyword =value parameters on one line.

agc=a Turns automatic gain control mode on (a=1) or off (a=0). Will generate an error if device does
not support setting agc. Use SoundInStatus to check or use /Z flag to make errors nonfatal.
Windows: This is not supported and V_SoundInAGC from the SoundInStatus command
always returns -1.

gain=g Sets input gain, 0 is lowest gain and 1 is highest. Will generate an error if device does not
support setting gain. Use SoundInStatus to check or use /Z flag to make errors nonfatal.
SoundInStartChart

Windows: SoundInSet attempts to adjust the master gain of the sound input device but not all sound cards have a master gain. If V_SoundInGain from the SoundInStatus command returns -1, you will have to use your sound card software to adjust the input gain for the particular input source your are using. On some cards there are separate line-in and microphone-in sources.

Flags
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details
SoundInSet requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

See Also
The SoundInRecord, SoundInStartChart, and SoundInStatus operations.

SoundInStartChart

SoundInStartChart \[/Z\] \texttt{buffersize, destFIFOname}

The SoundInStartChart operation starts audio data acquisition into the given FIFO.

Parameters\n\texttt{buffersize} is the number of bytes to allocate for the interrupt time buffer which then feeds into the given Igor named FIFO \texttt{destFIFOname}. The FIFO must be set up with the correct number of channels and number type - use SoundInStatus to find legal values. The sample rate is read from the FIFO also, so that also needs to be correct.

Flags
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details
SoundInStartChart requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

On systems where 32-bit floating point data is supported, you can use NewFIFOChan with no flags and a range of -1 to 1.

See Also
The SoundInRecord, SoundInSet, SoundInStatus and SoundInStopChart operations, and FIFOs and Charts on page IV-313.

SoundInStatus

SoundInStatus \[\text{format}=(\text{intOrFloat}, \text{channels}, \text{bits}, \text{frequency})]\]

The SoundInStatus operation creates and sets a set of variables and strings with information about the current sound input device.

Keywords
\text{format}=(\text{intOrFloat, channels, bits, frequency})
SoundInStopChart

Checks if a specific sound input format is supported. This is useful because it is often the case that more sound input formats are supported than are reported via the V_SoundInSampSize and W_SoundInRates outputs.

V_Flag is set to 0 if the specified format is supported by the input device or to a non-zero error code otherwise.

The format keyword was added in Igor Pro 9.00.

intOrFloat is a keyword (unquoted), either int or float.

channels is 1 for mono, 2 for stereo. Additional channels may also work with some sound hardware.

bits may be any value between 8 and 64, though 8, 16, 24, and 32 are most likely to be supported by the operating system. CD audio samples use 16 bits.

frequency is the sampling rate in Hertz, with a minimum of 4800. CD audio is sampled at 44100 Hz. A practical upper limit is 192000.

Outputs

V_Flag
Set to 0 if the device is available or to a non-zero error code.
Also, if you use the format keyword and the specified format is not supported then V_Flag is set to a non-zero error code.
If V_Flag is non-zero then none of the following outputs are valid.

S_SoundInName
String with name of device.

V_SoundInAGC
Automatic gain control on or off (1 or 0). This is an optional item and if the current device does not support AGC then V_SoundInAGC will be set to -1.

V_SoundInChansAv
Available number of channels (e.g., 1 for mono, 2 for stereo).

V_SoundInGain
Current input gain. Ranges from 0 (lowest) to 1. This is an optional item and if the current device does not support gain then V_SoundInGain will be set to -1.

V_SoundInSampSize
Bits set depending on number of bits available in a sample.
Bit 0: Set if 8-bit integer is supported.
Bit 1: Set if 16-bit integer is supported.
Bit 2: Set if 32-bit integer is supported.
Bit 3: Set if 32-bit floating point is supported (range is -1 to 1).
Bit 4: Set if 64-bit floating point is supported (range is -1 to 1).

W_SoundInRates
Wave containing sample rate information: If point 0 contains 0 then points 1 and 2 contain the lower and upper limits of a continuous range; otherwise point 0 contains the number of discrete rates which follow in the wave. The usual rates are 44100 Hz and 4800 Hz.

See Also
SoundInSet, SoundInRecord, SoundInStartChart

SoundInStopChart

SoundInStopChart [/Z]
The SoundInStopChart operation stops audio data acquisition started by SoundInStartChart.

Flags

/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details
SoundInStopChart requires a computer equipped with sound input hardware.
Audio data acquisition also stops automatically when an experiment is closed.

See Also
The SoundInStartChart and SoundInStatus operations.

SoundLoadWave

SoundLoadWave [flags] waveName [ ,fileNameStr ]

The SoundLoadWave operation loads sound data from the named file into a wave. Mono, stereo, surround-sound, and high-resolution sound formats are supported.
The SoundLoadWave operation was added in Igor Pro 7.00.

Parameters

waveName is the name of the wave to load the sound into.

If fileNameStr is omitted or is "", SoundLoadWave displays an Open File dialog.

The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If SoundLoadWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to choose the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags

/I [=filterStr] Force interactive mode. Use optional filter string to limit allowable file extensions. See Open File Dialog File Filters on page IV-149.

/O Overwrite existing waves in case of a name conflict.

/P=pathName Specifies the folder to load the file from. pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:Folder1:" or "C:\Folder1". See Symbolic Paths on page II-22 for details.

/Q Quiet: Doesn't print message to history area, and doesn't abort, if the sound can not be loaded. V_Error is set to the returned error code, which will be zero if there was no error.

/S=(startT,endT) Load a subrange of the sound resource. startT and endT are in seconds, clipped to the duration of the loaded sound.

/TMOT= timeOut Aborts load if timeOut, in seconds, is exceeded.

Details

SoundLoadWave uses Core Audio on Macintosh and Qt framework calls on Windows. Note that some files can not be loaded due to digital rights managment issues even though they can be played.

If waveName specifies a wave that does not exist, it is created. The wave is redimensioned to a wave type that maintains the numeric precision of the sound data. If the wave can not be created or resized to fit the loaded data then SoundLoadWave returns an error.

If waveName does exist, the wave is overwritten only if the /O flag is specified. Without the /O flag SoundLoadWave returns an error.

Multi-channel audio is loaded into sequential columns of the destination wave.

On Macintosh, Igor uses Core Audio to produce 32-bit or 64-bit floating point waves. The BITS value in S_info, described below, may be zero for some formats.

On Windows, SoundLoadWave uses the smallest Igor wave data type that preserves the number of bits in the audio. Igor doesn't have a 24-bit data type, so these values are stored in a 32-bit integer wave.
Output Variables

SoundLoadWave sets these output variables:

- **V_flag**: Set to 1 if a sound is loaded and fits into available memory, 0 otherwise.
- **V_Error**: Set if /Q is specified. V_Error is set to a non-zero error code if something went wrong or to zero on success. Negative returned codes are system-dependent, positive are Igor-defined errors. 
  
  V_Error = 1 means there wasn’t enough memory to load the (uncompressed) sound.
- **S_path**: Set to the full file path of the loaded file, not including the file name.
- **S_fileName**: Set to the name of the loaded file.
- **S_waveNames**: Set to the name of loaded wave.
- **S_info**: Information about the loaded sound.

If the sound file exists, SoundLoadWave sets the string variable S_info to:

"FILE:nameOfFile;FORMAT:soundFileFormat;CHANNELS:numChannels;CHANNEL_LAYOUT:channelLayoutDescription;CHANNEL_ORDER:channelsList;BITS:numBits;SAMPLES:numSamples;RATE:samplesPerSec;"

The `soundFileFormat` and `channelLayoutDescription` values are text descriptions of the sound data in the file, and are written in the localized language. This information is available only on Macintosh and may or may not be present in a given sound file.

The `channelsList` value is a comma-separated list of channel names, always in English abbreviations, such as "L,R" or "L,R,C,LFE,Ls,Rs". The meaning of the abbreviations:

<table>
<thead>
<tr>
<th>channelList Abbreviation</th>
<th>Channel or Speaker Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>L</td>
<td>Front Left</td>

SoundSaveWave

Examples

// Display an Open File dialog and load the chosen file.
// Use file's name for wave, overwrite any pre-existing wave, print information to history
SoundLoadWave/O myDestWave

// SoundLoadWave stores following in S_Info and prints it to the history area
FILE:<file name>;FORMAT:MPEG Layer 3;CHANNELS:2;BITS:0;SAMPLES:524416;RATE:44100;

// Rename the wave to a cleaned up version of the file name
Rename myDestWave, $CleanupName(S_fileName,1)

See Also
SoundSaveWave, PlaySound

SoundSaveWave

SoundSaveWave [flags] typeStr, waveName [ , fileNameStr ]

The SoundSaveWave operation saves the named wave on disk as an Audio Interchange File Format (AIFF-C) or Microsoft WAVE sound file. AIFF-C is primarily used on Macintosh.

Parameters

typeStr must be either "AIFC" or "WAVE".

fileNameStr contains the name of the file in which the named wave is saved. If you omit fileNameStr, SoundSaveWave uses the wave name with the appropriate extension.

The file to be written is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If SoundSaveWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

Flags

/BITS=bits Controls the number of bits used for each sound sample written to the file.

Use /BITS=24 with a 32-bit integer wave to save 24-bit sound data capable of representing values from -8,388,608 to +8,388,607.

If you omit /BITS or use /BITS=0, SoundSaveWave uses the wave’s data type and size to determine how many bits are written for each sound sample.

The /BITS flag was added in Igor Pro 9.00.

/I Presents a Save File dialog in which you can specify the file to be saved.

/O Overwrites the file if it already exists.

If you omit /O and the file exists, SoundSaveWave displays a Save File dialog.

/P=pathName Specifies the folder to store the file in. pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\". See Symbolic Paths on page II-22 for details.

/Q Suppresses the normal messages in the history area of the command window. At present nothing is written to the history even if /Q is omitted.

Details

The sound file is always an uncompressed AIFF-C or WAVE file, with as many channels as the wave contains columns.

The sound file format is determined by the wave’s data type, typeStr, and the /BITS flag. Signed 8-, 16- and 24-bit integers are supported as are 32-bit and 64-bit floating point. When writing floating point waves, the wave data should be scaled to +/- 1.0 as full scale.
The SoundSaveWave operation was added in Igor Pro 7.00. 24-bit integer and 64-bit floating point support were added in Igor Pro 9.00.

Output Variables
SoundSaveWave sets these automatically created variables:

- **V_flag**: Set to 0 if the wave was successfully saved to the file or to a non-zero error code.
- **S_fileName**: Set to the name of the saved file.
- **S_path**: Set to the full path to the file's directory.

Examples

// Create a simple sound (1000 Hz tone burst)
Make/O/N=10000 mySound // Single-precision wave, 10,000 values
SetScale/P x, 0, 1/8000, "" mySound // 8000 Hz sampling frequency (1.25 seconds)
mySound= sin(2*pi*1000*x) // 1000 Hz tone
Hanning mySound // Fade in and out

// Save it to a file, chosen from the Save File dialog
SoundSaveWave "AIFC", mySound, "my sound.aif"

// Create a floating point stereo frequency sweep
Make/O/N=(20000,2) stereoSineSoundF32 // 32-bit float data
SetScale/P x,0,1e-4, stereoSineSoundF32 // Set sample rate to 10KHz
stereoSineSoundF32= sin(2*Pi*(1000 + (1-2*q)*150*x)*x) // Create a symbolic path via dialog
NewPath sound // Create a symbolic path via dialog
SoundSaveWave/P=sound/O "WAVE", stereoSineSoundF32

SoundLoadWave, PlaySound, WaveType, WaveInfo

SpecialCharacterInfo

**SpecialCharacterInfo(notebookNameStr, specialCharacterNameStr, whichStr)**

The SpecialCharacterInfo function returns a string containing information about the named special character in the named notebook window.

Parameters

If `notebookNameStr` is "", the top visible notebook is used. Otherwise `notebookNameStr` contains either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.

`specialCharacterNameStr` is the name of a special character in the notebook.

If `specialCharacterNameStr` is "" and if exactly one special character is selected, the selected special character is used. If other than exactly one special character is selected, an error is returned.

`whichStr` identifies the information item you want. Because SpecialCharacterInfo can return several items that may contain semicolons, it does not return a semicolon-separated keyword-value list like other info functions. Instead it returns just one item as specified by `whichStr`.

Details

Here are the supported values for `whichStr`.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Returned Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>The name of the special character.</td>
</tr>
<tr>
<td>FRAME</td>
<td>0: None&lt;br&gt;1: Single&lt;br&gt;2: Double&lt;br&gt;3: Triple&lt;br&gt;4: Shadow</td>
</tr>
</tbody>
</table>
SpecialCharacterInfo

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Returned Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOC</td>
<td>Paragraph and character position (e.g., 1,3).</td>
</tr>
<tr>
<td>SCALING</td>
<td>Horizontal and vertical scaling in units of one tenth of a percent (e.g., 1000,1000).</td>
</tr>
<tr>
<td>TYPE</td>
<td>Special character type is: Picture, Graph, Table, Layout, Action, ShortDate, LongDate, AbbreviatedDate, Time, Page, TotalPages, or WindowTitle.</td>
</tr>
</tbody>
</table>

These keywords apply to Igor-object pictures only. If the specified character is not an Igor-object picture, "" is returned.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Returned Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>WINTYPE</td>
<td>1 for graphs, 2 for tables, 3 for layouts.</td>
</tr>
<tr>
<td>OBJECTNAME</td>
<td>The name of the window with which the special character is associated.</td>
</tr>
</tbody>
</table>

The remaining keywords apply to notebook action characters only. If the specified special character is not a notebook action character, "" is returned.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Returned Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>BGRGB</td>
<td>Background color in RGB format (e.g., 65535,65534,49151).</td>
</tr>
<tr>
<td>COMMANDS</td>
<td>Command string.</td>
</tr>
<tr>
<td>ENABLEBGRGB</td>
<td>1 if the action’s background color is enabled, 0 if not.</td>
</tr>
<tr>
<td>HELPTEXT</td>
<td>Help text string.</td>
</tr>
<tr>
<td>IGNOREERRORS</td>
<td>0 or 1.</td>
</tr>
<tr>
<td>LINKSTYLE</td>
<td>0 or 1.</td>
</tr>
<tr>
<td>PADDING</td>
<td>The value of the left, right, top, bottom and internal padding properties, in that order (e.g, 4,4,4,4,8).</td>
</tr>
<tr>
<td>PICTURE</td>
<td>1 if the action has a picture, 0 if not.</td>
</tr>
<tr>
<td>PROCPICTNAME</td>
<td>The name of the action Proc Picture or &quot;&quot; if none.</td>
</tr>
<tr>
<td>QUIET</td>
<td>0 or 1.</td>
</tr>
<tr>
<td>SHOWMODE</td>
<td>1: Title only&lt;br&gt;2: Picture only&lt;br&gt;3: Picture below title&lt;br&gt;4: Picture above title&lt;br&gt;5: Picture to the left of title&lt;br&gt;6: Picture to the right of title</td>
</tr>
<tr>
<td>TITLE</td>
<td>Title string.</td>
</tr>
</tbody>
</table>

If whichStr is an unknown keyword, SpecialCharacterInfo returns "" but does not generate an error.

Examples

Function PrintSpecialCharacterInfo(notebookName, specialCharacterName)
  String notebookName, specialCharacterName
  String typeStr=SpecialCharacterInfo(notebookName, specialCharacterName, "TYPE")
  String locStr=SpecialCharacterInfo(notebookName, specialCharacterName, "LOC")
  Printf "TYPE: %s\r", typeStr
  Printf "LOC: %s\r", locStr
End

See Also

The Notebook and NotebookAction operations; the SpecialCharacterList function; Using Igor-Object Pictures on page III-18.
SpecialCharacterList

SpecialCharacterList(notebookNameStr, separatorStr, mask, flags)
The SpecialCharacterList function returns a string containing a list of names of special characters in a formatted text notebook.

Parameters
If notebookNameStr is "", the top visible notebook is used. Otherwise notebookNameStr contains either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.

separatorStr should contain a single ASCII character, usually semicolon, to separate the names.

mask determines which types of special characters are included. mask is a bitwise parameter with values:

1: Pictures including graphs, tables and layouts.
2: Notebook actions.
4: All other special characters such as dates and times.

or a bitwise combination of the above for more than one type. See Setting Bit Parameters on page IV-12 for details about bit settings.

flags is a bitwise parameter. Pass 0 to include all special characters or 1 to include only selected special characters. All other bits are reserved and should be passed as zero.

Details
Only formatted text notebooks have special characters. When called for a plain text notebook, SpecialCharacterList always returns "".

Examples
Print a list of all special characters in the top notebook:
Print SpecialCharacterList("", ";", -1, 0)
Print a list of notebook action characters in Notebook0:
Print SpecialCharacterList("Notebook0", ";", 2, 0)
Print a list of selected notebook action characters in Notebook0:
Print SpecialCharacterList("Notebook0", ";", 2, 1)

See Also
The Notebook and NotebookAction operations; the SpecialCharacterInfo function.

SpecialDirPath

SpecialDirPath(dirIDStr, domain, flags, createDir)
The SpecialDirPath function returns a full path to a file system directory specified by dirIDStr and domain. It provides a programmer with a way to access directories of special interest, such as the preferences directory and the desktop directory.

The path returned always ends with a separator character which may be a colon, backslash, or forward slash depending on the operating system and the flags parameter.

SpecialDirPath depends on operating system behavior. The exact path returned depends on the locale, the operating system, the specific installation, the current user, and possibly other factors.

Parameters
dirIDStr is one of the following strings:

"Packages" Place for advanced programmers to put preferences for their procedure packages.
"Documents" The OS-defined place for users to put documents.
"Preferences" The OS-defined place for applications to put preferences.
"Desktop" The desktop.
"Temporary" The OS-defined place for applications to put temporary files.

"Igor Application" The Igor installation folder. This is typically:
/Applications/Igor Pro X Folder (Macintosh) or
C:\Program Files\WaveMetrics\Igor Pro X Folder (Windows)
where “X” is the major version number.
Use only with domain = 0 (the current user).

"Igor Executable" The folder containing the current Igor executable. On Macintosh, this is the path to the executable itself, not to the application bundle.
Use only with domain = 0 (the current user).
Requires Igor Pro 7.00 or later.

"Igor Preferences" The folder in which Igor's own preference files are stored.

"Igor Pro User Files" A guaranteed-writable folder for the user to store their own Igor files, and to activate extensions, help, and procedure files by creating shortcuts or aliases in the appropriate subfolders. Use only with domain = 0 (the current user).
This is the folder opened using the Show Igor Pro User Files menu item in the Help menu.

domain permits discriminating between, for example, the preferences folder for all users versus the preferences folder for the current user. It is supported only for certain dirIDStrs. It is one of the following:

0: The current user (recommended value for most purposes).
1: All users (may generate an error or return the same path as 0).
2: System (may generate an error or return the same path as 1).

flags a bitwise parameter:

Bit 0: If set, the returned path is a native path (Macintosh-style on Mac OS 9, Unix-style on Mac OS X, Windows-style on Windows). If cleared, the returned path is a Macintosh-style path regardless of the current platform. In most cases you should set this bit to zero since Igor accepts Macintosh-style paths on all operating systems. You must set this bit to one if you are going to pass the path to an external script.

All other bits are reserved and must be set to zero.

See Setting Bit Parameters on page IV-12 for details about bit settings.

createDir is 1 if you want the directory to be created if it does not exist or 0 if you do not want it to be created. This flag will not work if the current user does not have sufficient privileges to create the specified directory. In almost all cases it is not needed, you can't count on it, and you should pass 0.

Details
The domain parameter has no effect in most cases. In almost all cases you should pass 0 (current user) for this parameter. For values other than 0, SpecialDirPath might return an error which you must be prepared to handle.

In the event of an error, SpecialDirPath returns a NULL string and sets a runtime error code. You can check for an error like this:

String fullPath = SpecialDirPath("Packages", 0, 0, 0)
Variable len = strlen(fullPath) // strlen(NULL) returns NaN
if (numtype(len) == 2) // fullPath is NULL?
      Print "SpecialDirPath returned error."
endif

Here is sample output from SpecialDirPath("Packages",0,0,0):

Mac OS X
      hd:Users<user>:Library:Preferences:WaveMetrics:Igor Pro X:Packages:
sphericalBessJ

sphericalBessJ(n, x [, accuracy])

The sphericalBessJ function returns the spherical Bessel function of the first kind and order n.

\[ j_n(x) = \sqrt{\frac{\pi}{2x}} J_{n+1/2}(x). \]

For example:

\[ j_0(x) = \frac{\sin(x)}{x}, \]
\[ j_1(x) = \frac{\sin(x)}{x^2} - \frac{\cos(x)}{x}, \]
\[ j_2(x) = \left( \frac{3}{x^2} - \frac{1}{x} \right) \sin(x) - \frac{3}{x^2} \cos(x). \]

SphericalInterpolate

**SphericalInterpolate** \(\text{triangulationDataWave}, \text{dataPointsWave}, \text{newLocationsWave}\)

The SphericalInterpolate operation works in conjunction with the SphericalTriangulate operation to calculate interpolated values on a surface of a sphere. Given a set of \([x_i, y_i, z_i]\) points on the surface of a sphere with their associated values \([v_i]\), the SphericalTriangulate operation performs the Delaunay triangulation and creates an output that is used by the SphericalInterpolate operation to calculate values at any other point on the surface of a sphere. The interpolation calculation uses Voronoi polygons to weigh the contribution of the nearest neighbors to any given location on the sphere.

**Parameters**

- \(\text{triangulationDataWave}\) is a 13 column wave that was created by the SphericalTriangulate operation.
- \(\text{dataPoints}\) is a 4 column wave. The first 3 columns are the \([x_i, y_i, z_i]\) locations that were used to create the triangulation, and the last column corresponds to the \([v_i]\) values at the triangulation locations.
- \(\text{newLocationsWave}\) is a 3 column wave that specifies the \(x, y, z\) locations on the sphere at which the interpolated values are calculated. Note that internally, each triplet is normalized to a point on the unit sphere before it is used in the interpolation.

**Details**

You will always need to use the SphericalTriangulate operation first to generate the \(\text{triangulationDataWave}\) input for this operation.

The result of the operation are put in the wave \(W_{\text{SphericalInterpolation}}\).

**See Also**

- SphericalTriangulate, Triangulate3D, ImageInterpolate with keyword Voronoi

**Demo**

Choose File → Example Experiments → Analysis → SphericalTriangulationDemo.

SphericalTriangulate

**SphericalTriangulate** \(\[/Z\] \(\text{tripletWaveName}\)

The SphericalTriangulate operation triangulates an arbitrary XYZ triplet wave on a surface of a sphere.

It starts by normalizing the data to make sure that \(\sqrt{x^2+y^2+z^2}=1\), and then proceeds to calculate the Delaunay triangulation.

**Flags**

- \(/Z\) No error reporting.

**Details**

The result of the triangulation is the wave \(M_{\text{SphericalTriangulation}}\). This 13 column wave is used in SphericalInterpolate to obtain the interpolated values.

**Example**

// Generates output waves that can be used in Gizmo to display the triangulation.
// \(\text{triangulationData}\) is the \(M_{\text{TriangulationData}}\) output from SphericalTriangulate.
// \(\text{tripletWave}\) is the source wave input to SphericalTriangulation.
// Output wave \(\text{sphereTrianglesPath}\) can be used to display the triangulation as a path.
// Output wave \(\text{sphereTrianglesSurf}\) can be used to display the triangulation as a surface.
Function BuildTriangleWaves(triangulationData,tripletWave)
Wave triangulationData, tripletWave
// Extract 3 columns from triangulationData that contain the index of the row.
Duplicate/O/FREE/r=[1,3] triangulationData,triIndices
Variable finalNumTriangles=dimSize(triIndices,0),i,j,k
// Initialize both waves to NaN so any unassigned point would appear as a hole.
Make/O/N=(5*finalNumTriangles,3) sphereTrianglesPath=NaN
Make/O/N=(3*finalNumTriangles,3) sphereTrianglesSurf=NaN
// Assign the values of the vertices to the two waves:
Variable rowIndex,rowIndex0,outRowCount=0,outcount2=0
for(i=1;i<finalNumTriangles;i+=1)
for(j=0;j<3;j+=1)
    rowIndex=triIndices[i][j]
for(k=0;k<3;k+=1)
    sphereTrianglesPath[outRowCount][k]=tripletWave[rowIndex][k]
sphereTrianglesSurf[outcount2][k]=tripletWave[rowIndex][k]
endfor
outRowCount+=1
outcount2+=1
endfor
    // Close the triangle path by returning to the first vertex:
    rowIndex0=triIndices[i][0]
sphereTrianglesPath[outRowCount][0]=tripletWave[rowIndex0][0]
sphereTrianglesPath[outRowCount][1]=tripletWave[rowIndex0][1]
sphereTrianglesPath[outRowCount][2]=tripletWave[rowIndex0][2]
outRowCount+=2    // Increment row count and skip the NaN
endfor
End

Choose File→Example Experiments→Analysis→SphericalTriangulationDemo.

SplitString

SplitString /E=regExprStr str [, substring1 [, substring2,... substringN]]
The SplitString operation uses the regular expression regExprStr to split str into subpatterns. See Subpatterns on page IV-186 for details. Each matched subpattern is returned sequentially in the corresponding substring parameter.

Parameters
str is the input string to be split into subpatterns.

The substring1...substringN output parameters must be the names of existing string variables if you need to use the matched subpatterns. The first matched subpattern is returned in substring1, the second in substring2, etc.

Flags
/E=regExprStr Specifies the Perl-compatible regular expression string containing subpattern definition(s).

Details
regExprStr is a regular expression with successive subpattern definitions, such as shown in the examples. (Subpatterns are regular expressions within parentheses.)

For unmatched subpatterns, the corresponding substring is set to "". If you specify more substring parameters than subpatterns, the extra parameters are also set to "".

The number of matched subpatterns is returned in V_flag.
The part of str that matches regExprStr (often all of str) is stored in S_value.

Examples
// Split the output of the date() function:
Print date()
  Mon, May 2, 2005
String expr="([^[:alpha:]]+)\s*,\s*([^[:alpha:]]+)\s*,\s*([^[:digit:]]+),\s*([^[:digit:]]+)"
String dayOfWeek, monthName, dayNumStr, yearStr
SplitString/E=(expr) date(), dayOfWeek, monthName, dayNumStr, yearStr
Print V_flag
  4
Print dayOfWeek
  Mon
Print monthName
  May
Print dayNumStr
  2
Print yearStr

V-900
SplitWave

The SplitWave operation creates new waves containing subsets of the data in srcWave which must be 2D or greater.

The newly generated waves have lower dimensionality than srcWave. The operation is ideal for splitting 2D waves into constituent columns, 3D waves into their layers, etc.

Added in Igor Pro 7.00.

**Flags**

- **/DDF=destDataFolder** Specifies the data folder where the generated waves are created. If the data folder does not exist the operation creates it. If the /DDF flag is not used, output goes into the current data folder.

- **/FREE** Generates free output waves. The /OREF flag must also be used when the /FREE flag is used. When you use this flag there is no need to use either /N or /NAME.

- **/N=baseName** Provides the base name for all output waves. The waves will be named sequentially, i.e., baseName0, baseName1...

- **/NAME=straList** strList is a semicolon-separated list of wave names to be used as the names of the output waves.

  If strList contains fewer names than the number needed, the operation terminates and returns an error.

  If the output data folder is the data folder containing srcWave then strList must not contain the name of srcWave.

  Only simple names, not full paths, are allowed in strList.

- **/NOTE** Copies the wave note, if any, from srcWave to the output waves. The /NOTE flag was added in Igor Pro 8.00.

- **/O** Permits overwriting of existing destination waves. Overwriting srcWave is not permitted.

- **/OREF=waveRefWave** waveRefWave is a wave reference wave. SplitWave stores a wave reference for each of the output waves in waveRefWave.

  If the specified waveRefWave already exists it is overwritten and its size is changed as appropriate. If it does not already exist, it is created by the operation.

- **/SDIM=n** Specifies the dimensionality of the output waves. By default this is 1 less than the dimensionality of srcWave. The minimum value is n=1 which results in 1D output waves.

- **/Z=[z]** /Z or /Z=1 prevents procedure execution from aborting if there is an error. Use /Z if you want to handle this case in your procedures rather than having execution abort.

  /Z=0: Same as no /Z at all. This is the default.

  /Z=1: Same as /Z alone.

Regular Expressions on page IV-176 and Subpatterns on page IV-186.

sscanf, Grep, strsearch, str2num, RemoveEnding, TrimString
**Details**

The SplitWave operation is in some ways the inverse of the Concatenate operation. `srcWave` is decomposed into waves of lower dimensionality.

Splitting a 2D 10x15 wave results in 15 waves of 10 rows each.

Splitting a 3D 10x15x4 using `/SDIM=2` results in 4 2D waves of dimension 10x15.

Splitting a 3D 10x15x4 using `/SDIM=1` results in 60 1D waves of 10 rows each.

The SplitWave operation works on all wave types. `srcWave` must be 2D or greater.

The operation creates the string variable `S_waveNames` which contains a semicolon separated list of the names of the output waves. However if you use `/FREE` then `S_waveNames` will be empty as free waves can not be accessed by name; use `/OREF` to access the created waves.

**Examples**

```plaintext
// Create sample input
Make/N=(5,4,3,2) wave1 = p + 10*q + 100*r + 1000*s

// Split chunks into 2 3D waves and store them in data folder Chunks
SplitWave/DDF=Chunks/N=chunk wave1

// Split layers into 6 2D waves and store them in data folder Layers
SplitWave/DDF=Layers/N=Layers/SDIM=2 wave1

// Split into 24 1D waves and store them in data folder Columns
SplitWave/DDF=Columns/N=Columns/SDIM=1 wave1
```

---

**sprintf**

```plaintext
sprintf stringName, formatStr [, parameter]...
```

The sprintf operation is the same as printf except it prints the formatted output to the string variable `stringName` rather than to the history area.

**Parameters**

- `formatStr` See printf.
- `parameter` See printf.
- `stringName` Results are “printed” into the named string variable.

**See Also**

The printf operation for complete format and parameter descriptions and **Creating Formatted Text** on page IV-259.

---

**sqrt**

```plaintext
sqrt(num)
```

The sqrt function returns the square root of `num` or NaN if `num` is negative.

In complex expressions, `num` is complex, and sqrt(`num`) returns the complex value `x + iy`.

---

**sscanf**

```plaintext
sscanf scanStr, formatStr, var [, var]
```

The sscanf operation is useful for parsing text that contains numeric or string data. It is based on the C sscanf function and provides a subset of the features available in C.

Here is a trivial example:

```plaintext
Variable v1
sscanf "Value= 1.234", "Value= %f", v1
```

This skips the text “Value=” and the following space and then converts the text “1.234” (or whatever number appeared there) into a number and stores it in the local variable `v1`. 
The sscanf operation sets the variable V_flag to the number of values read. You can use this as an initial check to see if the scanStr is consistent with your expectations.

**Note:** The sscanf operation is supported in user functions only. It is not available using the command line, using a macro, or using the Execute operation.

**Parameters**

```
scanStr contains the text to be parsed.
```

```formatStr``` is a format string which describes how the parsing is to be done.

```formatStr``` is followed by the names of one or more local numeric or string variables or NVARs (references to global numeric variables) or SVARs (references to global string variables), which are represented by ```var``` above.

sscanf can handle a maximum of 100 ```var``` parameters.

**Details**

The format string consists of the following:

- Normal text, which is anything other than a percent sign ("%") or white space.
- White space (spaces, tabs, linefeed, carriage returns).
- A percent ("%") character, which is the start of a conversion specification.

The trivial example illustrates all three of these components.

```
Variable v1
sscanf "Value= 1.234", "Value= %f", v1
```

sscanf attempts to match normal text in the format string to the identical normal text in the scan string. In the example, the text "Value=" in the format string skips the identical text in the scan string.

sscanf matches a single white space character in the format string to 0 or more white space characters in the scan string. In the example, the single space skips the single space in the scan string.

When sscanf encounters a percent character in the format string, it attempts to convert the corresponding text in the scan string into a number or string, depending on the conversion character following the percent, and stores the resulting number or string in the corresponding variable in the parameter list. In the example, "%f" converts the text "1.234" into a number which it stores in the local variable v1.

A conversion specification consists of:

- A percent character ("%").
- An optional "*", which is a conversion suppression character.
- An optional number, which is a maximum field width.
- A conversion character, which specifies how to interpret text in the scan string.

Don't worry about the suppression character and the maximum width specification for now. They will be explained later.

The sscanf operation supports a subset of the conversion characters supported by the C sscanf operation. The supported conversion characters, which are case-sensitive, are:

- d Converts text representing a decimal number into an integer numeric value.
- i Converts text representing a decimal, octal or hexadecimal number into an integer value. If the text starts with "0x" (zero-x), it is interpreted as hexadecimal. Otherwise, if it starts with "0" (zero), it is interpreted as octal. Otherwise it is interpreted as decimal.
- o Converts text representing an octal number into an integer numeric value.
- u Converts text representing an unsigned decimal number into an integer numeric value.
- x Converts text representing a hexadecimal number into an integer numeric value.
- c Converts a single character into an integer value which is the ASCII code representing that character.
- e Converts text representing a decimal number into a floating point numeric value.
- f Same as e.
Here are some simplified examples to illustrate each of these conversions.

Variable v1
String s1

Convert text representing a decimal number to an integer value:

```c
sscanf "1234", "%d", v1
```

Convert text representing a decimal, octal, or hexadecimal number:

```c
sscanf "1.234", "%i", v1 // Convert from decimal.
sscanf "01234", "%i", v1 // Convert from octal.
sscanf "0x123", "%i", v1 // Convert from hex.
```

Convert text representing an octal number:

```c
sscanf "1234", "%o", v1
```

Convert text representing an unsigned decimal number:

```c
sscanf "1234", "%u", v1
```

Convert text representing a hexadecimal number:

```c
sscanf "1FB9", "%x", v1
```

Convert a single ASCII character:

```c
sscanf "A", "%c", v1
```

Convert text representing a decimal number to a floating point value:

```c
sscanf "1.234", "%e", v1
sscanf "1.234", "%f", v1
sscanf "1.234", "%g", v1
```

Copy a string of text up to the first white space:

```c
sscanf "Hello There", "%s", s1
```

Copy a string of text matching the specified characters:

```c
sscanf "+4.27", "%[+-]", s1
```

In a C program, you will sometimes see the letters "l" (ell) or "h" between the percent and the conversion character. For example, you may see "%lf" or "%hd". These extra letters are not needed or tolerated by Igor’s sscanf operation.

When sscanf matches the format string to the scan string, it reads from the scan string until a character that would be inappropriate for the section of the format string that sscanf is trying to match. In the following example, sscanf stops reading characters to be converted into a number when it hits the first character that is not appropriate for a number.

Variable v1
String s1, s2

```c
sscanf "1234Volts DC", "%d%s %s", v1, s1, s2
```

sscanf stops matching text for "%d" when it hits "V" and stores the converted number in v1. It stops matching text for the first "%s" when it hits white space and stores the matched text in s1. It then skips the space in the scan string because of the corresponding space in the format string. Finally, it matches the remaining text to the second "%s" and stores the text in s2.

The maximum field width must appear just before the conversion character ("d" in this case).

Variable v1, v2

```c
sscanf "12349876", "%4d%4d", v1, v2
```

The suppression character ("\") is used in a conversion specification to skip values in the scan string. It parses the value, but sscanf does not store the value in any variable. In the following example, we read one
number into local variable v1, skip a colon, and read another number into local variable v2, skip a colon, and read another number into local variable v3.

```plaintext
Variable v1, v2, v3
sscanf "12:30:45", "%d%*:]:%d%*:]:%d", v1, v2, v3
```

Here "%*:]:" means “read a colon character but don’t store it anywhere”. The “*” character must appear immediately after the percent. Note that there is nothing in the parameter list corresponding to the suppressed strings.

If the text in the scan string is not consistent with the text in the format string, sscanf may not read all of the values that you expected. You can check for this using the V_flag variable, which is set to the number of values read. This kind of inconsistency does not cause sscanf to return an error to Igor, which would cause procedure execution to abort. It is a situation that you can deal with in your procedure code.

The sscanf operation returns the following kinds of errors:

- Out-of-memory.
- The number of parameters implied by `formatStr` does not match the number of parameters in the `var` list.
- `formatStr` calls for a numeric variable but the parameter list expects a string variable.
- `formatStr` calls for a string variable but the parameter list expects a numeric variable.
- `formatStr` includes an unsupported, unknown or incorrectly constructed conversion specification.
- The `var` list references a global variable that does not exist.

Examples

Here is a simple example to give you the general idea:

```plaintext
Function SimpleExample()
    Variable v1, valuesRead
    sscanf "Value=1.234", "Value=%g", v1
    valuesRead = V_flag
    if (valuesRead != 1)
        Printf "Error: Expected 1 value, got %d values\r", valuesRead
    else
        Printf "Value read = %g\r", v1
    endif
End
```

For an example that uses sscanf to load data from a text file, choose File→Example Experiments→Programming→Load File Demo.

StartMSTimer

StartMSTimer
The StartMSTimer function creates a new microsecond timer and returns a timer reference number.

Details
You can create up to ten different microsecond timers using StartMSTimer. A valid timer reference number
is a number between 0 and 9. If StartMSTimer returns -1, there are no free timers available. StartMSTimer
works in conjunction with StopMSTimer.

See Also
StopMSTimer, ticks, DateTime

Static

Static constant objectName = value
Static strconstant objectName = value
Static Function funcName()
Static Structure structureName
Static Picture pictName
The Static keyword specifies that a constant, user-defined function, structure, or Proc Picture is local to the
procedure file in which it appears. Static objects can only be used by other functions; they cannot be
accessed from macros; they cannot be accessed from other procedure files or from the command line.

See Also
Static Functions on page IV-105, Proc Pictures on page IV-56, and Constants on page IV-51.

StatsAngularDistanceTest

StatsAngularDistanceTest [flags] [srcWave1, srcWave2, srcWave3...]
The StatsAngularDistanceTest operation performs nonparametric tests on the angular distance between sample
data and reference directions for two or more samples in individual waves. The angular distance is the shortest
distance between two points on a circle (in radians). Specify the sample waves using /WSTR or by listing them
following the flags. Set reference directions with /ANG, /ANGW, or the sample mean direction.

Flags

/ALPH=val Sets the significance level (default 0.05).
/ANG={d1, d2} Sets reference directions (in radians) for two samples; for more than two samples use
/ANGW.
/ANGM Computes the mean direction of each sample and uses it as the reference direction.
/ANGW=dWave Sets reference directions (in radians) for more than two samples using directions in
dWave, which must be single or double precision.
/APRX=m Controls the approximation method for computing the P-value in the case of two
samples (Mann-Whitney Wilcoxon). See StatsWilcoxonRankTest for more details.
The default value is 0, which may require long computation times if your sample size
is large. Use /APRX=1 if you have a large sample and you expect ties in the data.
/Q No results printed in the history area.
/T=k Displays results in a table. k specifies the table behavior when it is closed.
k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.
The inputs for StatsAngularDistanceTest are two or more waves each corresponding to individual sample. The waves must be single or double precision expressing the angles in radians. There is no restriction on the number of points or dimensionality of the waves but the data should not contain NaNs or INFs. We recommend that you use double precision waves, especially if there are ties in the data. The reference directions should also be in radians. For two samples, StatsAngularDistanceTest computes the angular distances between the input data and the reference directions and then uses the Mann-Whitney-Wilcoxon test (StatsWilcoxonRankTest). Results are stored in the W_WilcoxonTest wave and in the corresponding table. For more than two samples, StatsAngularDistanceTest uses the Kruskal-Wallis test, storing results in the wave W_KWTestResults wave in the current data folder.

V_flag will be set to -1 for any error and to zero otherwise.

References
See, in particular, Chapter 27 of:

Chapter III-12, *Statistics* for a function and operation overview; StatsWilcoxonRankTest and StatsKWTest.

StatsANOVA1Test

StatsANOVA1Test flags [wave1, wave2, ... wave100]

The StatsANOVA1Test operation performs a one-way ANOVA test (fixed-effect model). The standard ANOVA test results are stored in the M_ANOVA1 wave in the current data folder.

Flags

/ALPH=val Sets the significance level (default 0.05).

/BF Performs the Brown and Forsythe test computing F'' and degrees of freedom. The W_ANOVA1BnF wave in the current data folder contains the output.

/Q No results printed in the history area.

/T=k Displays results in a table; additional tables are created with /BF and /W.

k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

/W Performs the Welch test F' and computes degrees of freedom. The W_ANOVA1Welch wave in the current data folder contains the output.
Details
Inputs to StatsANOVA1Test are two or more 1D numerical waves containing (one wave for each group of samples). Use NaN for missing entries or use waves with different numbers of points. The standard ANOVA results are in the M_ANOVA1 wave with corresponding row and column labels. Use /T to display the results in a table. In each case you will get the two degrees of freedom values, the F value, the critical value Fc for the choice of alpha and the degrees of freedom, and the P-value for the result. V_flag will be set to -1 for any error and to zero otherwise.

In some cases the ANOVA test may not be appropriate. For example, if groups do not exhibit sufficient homogeneity of variances. Although this may not be fatal for the ANOVA test, you may get more insight by performing the variances test in StatsVariancesTest.

If there are only two groups this test should be equivalent to StatsTTest.

You can evaluate the power of an ANOVA test for a given set of degrees of freedom and noncentrality parameter using:

\[
power = 1 - \text{StatsNCFCDF}(\text{StatsInvFCDF}((1-\alpha), n_1, n_2), n_1, n_2, \delta)
\]

Here \( n_1 \) is the Groups' degrees of freedom, \( n_2 \) is the Error degrees of freedom, and \( \delta \) is the noncentrality parameter. For more information see ANOVA Power Calculations Panel and the associated example experiment.

References

See Also
Chapter III-12, Statistics for a function and operation overview; StatsVariancesTest, StatsTTest, StatsNCFCDF, and StatsInvFCDF.

StatsANOVA2NRTest
The StatsANOVA2NRTest operation performs a two-factor analysis of variance (ANOVA) on the data that has no replication where there is only a single datum for every factor level. srcWave is a 2D wave of any numeric type. Output is to the M_ANOVA2NRResults wave in the current data folder or optionally to a table.

Flags

/ALPH=\text{val}
Sets the significance level (default 0.05).

/FOMD
Estimates one missing value. You will also have to use a single or double precision wave for srcWave and designate the single missing value as NaN. The estimated value is printed to the history as well as the bias used to correct the sum of the squares of factor A.

/INT=\text{val}
Sets the degree of interactivity.

Sets the degree of interactivity.

\text{val}=0: \quad \text{No interaction between the factors (default).}
\text{val}=1: \quad \text{Significant interaction effect between factors.}

Combination with /MODL determines which factors to test:

\[
\begin{array}{ccc}
\text{val} & \text{Model 1} & \text{Model 2} & \text{Model 3} \\
1 & A&B & A \\
0 & A&B & A&B \\
\end{array}
\]
StatsANOVA2RMTest

As indicated in the table, factor B is not tested for significant interaction under Model 3 and neither factor A nor factor B are tested for Model 1. If you are willing to accept an increase in Type II error you can obtain the relevant values by specifying Model 2. None of the models support a test for interaction A x B.

/MODL=m
Sets the model number.

m=1: Factor A and factor B are fixed.
m=2: Both factors are random.
m=3: Factor A is fixed and factor B is random (default).

/Q
No results printed in the history area.

/T=k
Displays results in a table. k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
Input to StatsANOVA2NRTest is a 2D wave in which the Factor A corresponds to rows and Factor B corresponds to columns. H0 provides that there is no difference in the means of the respective populations, i.e., if H0 is rejected for Factor A but accepted for Factor B that means that there is no difference in the means of the columns but the means of the rows are different.

NaN and INF entries are not supported although you may use a single NaN value in combination with the /FOMD flag. If srcWave contains dimension labels they will be used to designate the two factors in the output.

The contents of the M_ANOVA2NRResults output wave columns are as follows:

Column 0 Sum of the squares (SS) values
Column 1 Degrees of freedom (DF)
Column 2 Mean square (MS) values
Column 3 Computed F value for this test
Column 4 Critical F value (Fc) for the specified alpha
Column 5 Conclusion with 0 to reject H0 or 1 to accept it

The variable V_flag is set to zero if the operation succeeds or to -1 otherwise.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test and StatsANOVA2Test.

StatsANOVA2RMTest

StatsANOVA2RMTest [flags] srcWave
The StatsANOVA2RMTest operation performs analysis of variance (ANOVA) on srcWave where replicates consist of multiple measurements on the same subject (repeated measures). srcWave is a 2D wave of any numeric type. Output is to the M_ANOVA2RMResults wave in the current data folder or optionally to a table.

Flags

/ALPH=val
Sets the significance level (default 0.05).

/Q
No results printed in the history area.
Details
Input to StatsANOVA2Test is the single or double precision 3D `srcWave` in which the factor A levels are columns, the factor B levels are rows, and the replicates are layers. If `srcWave` contains dimension labels they will be used to designate the factors in the output.

Flags
/ALPH=\(val\) Sets the significance level (default 0.05).
/FAKE=\(num\) Specifies the number of points in `srcWave` obtained by “estimation”. \(num\) is subtracted from the total and error degrees of freedom.
/MODL=\(m\) Sets the model number.
\(m=1\): Factor A and factor B are fixed.
\(m=2\): Both factors are random.
\(m=3\): Factor A is fixed and factor B is random (default).
/Q No results printed in the history area.
/T=\(k\) Displays results in a table. \(k\) specifies the table behavior when it is closed.
\(k=0\): Normal with dialog (default).
\(k=1\): Kills with no dialog.
\(k=2\): Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsANOVA2NRTest and StatsANOVA2Test.
Ideally, the number of replicates must be equal for each factor and each level. StatsANOVA2Test supports both equal replication and proportional replication. Proportional replication allows for different number of data in each cell with missing data represented as NaN and the number of points in each cell is given by 

\[ N_{ij} = \frac{\text{sum of data in row } i \times \text{sum of data in column } j}{\text{number of samples}}. \]

If you have no replicates (a single datum per cell) use StatsANOVA2NRTest instead. If the number of replicates in your data does not satisfy these conditions you may be able to “estimate” additional replicates using various methods. In that case use the /FAKE flag so that the operation can account for the estimated data by reducing the total and error degrees of freedom. /FAKE only accounts for the number of estimates being used. You must provide an appropriate number of estimated values.

The contents of the M_ANOVA2Results output wave columns are: the first contains the sum of the squares (SS) values, the second the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the computed F value for this test, the fifth contains the critical Fc value for the specified alpha and degrees of freedom, and the last contains the conclusion with 0 to reject \( H_0 \) or 1 to accept it. In each case \( H_0 \) corresponds to the mean level, which is the same for all populations.

\( V \_\text{flag} \) will be set to -1 for any error and to zero otherwise.

Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test and StatsANOVA2NRTest.

**StatsBetaCDF**

\[ \text{StatsBetaCDF}(x, p, q [, a, b]) \]

The StatsBetaCDF function returns the beta cumulative distribution function

\[
F(x; p, q, a, b) = \frac{1}{B(p,q)} \int_{0}^{\frac{x-a}{b-a}} t^{p-1}(1-t)^{q-1} dt, \quad p, q > 0, \quad a \leq x \leq b
\]

where \( B(p,q) \) is the beta function

\[
B(p,q) = \int_{0}^{1} t^{p-1}(1-t)^{q-1} dt.
\]

The defaults (\( a=0 \) and \( b=1 \)) correspond to the standard beta distribution were \( a \) is the location parameter, \( (b-a) \) is the scale parameter, and \( p \) and \( q \) are shape parameters.

**References**

**See Also**

Chapter III-12, Statistics for a function and operation overview; StatsBetaPDF and StatsInvBetaCDF.

**StatsBetaPDF**

\[ \text{StatsBetaPDF}(x, p, q [, a, b]) \]

The StatsBetaPDF function returns the beta probability distribution function

\[
f(x; p, q, a, b) = \frac{(x-a)^{p-1}(b-x)^{q-1}}{B(p,q)(b-a)^{p+q-1}}, \quad a \leq x \leq b, \quad p, q > 0
\]

where \( B(p,q) \) is the beta function

\[
B(p,q) = \int_{0}^{1} t^{p-1}(1-t)^{q-1} dt.
\]
The defaults \((a=0 \text{ and } b=1)\) correspond to the standard beta distribution were \(a\) is the location parameter, \((b-a)\) is the scale parameter, and \(p\) and \(q\) are shape parameters. When \(p<1\), \(f(x=a)\) returns Inf.

**StatsCauchyCDF**

**StatsCauchyCDF** \((x, \mu, \sigma)\)
The StatsCauchyCDF function returns the Cauchy-Lorentz cumulative distribution function

\[
F(x; \mu, \sigma) = \frac{1}{2} + \frac{1}{\pi} \tan^{-1}\left(\frac{x-\mu}{\sigma}\right).
\]

See Also
Chapter III-12, *Statistics* for a function and operation overview; *StatsCauchyCDF* and *StatsCauchyPDF*. 
StatsCauchyPDF

StatsCauchyPDF(\(x, \mu, \sigma\))
The StatsCauchyPDF function returns the Cauchy-Lorentz probability distribution function

\[
f(x; \mu, \sigma) = \frac{1}{\sigma \pi \left(1 + \left(\frac{x - \mu}{\sigma}\right)^2\right)},
\]

where \(\mu\) is the location parameter and \(\sigma\) is the scale parameter. Use \(\mu=0\) and \(\sigma=1\) for the standard form of the Cauchy-Lorentz distribution.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsCauchyCDF and StatsInvCauchyCDF.

StatsChiCDF

StatsChiCDF(\(x, n\))
The StatsChiCDF function returns the chi-squared cumulative distribution function for the specified value and degrees of freedom \(n\).

\[
F(x; n) = \frac{\gamma\left(\frac{n}{2}, \frac{x}{2}\right)}{\Gamma\left(\frac{n}{2}\right)}.
\]

where is \(\gamma(a,b)\) the incomplete gamma function. The distribution can also be expressed as

\[
F(x; n) = 1 - \text{gammq}\left(\frac{n}{2}, \frac{x^2}{2}\right).
\]

See Also
Chapter III-12, Statistics for a function and operation overview; StatsChiPDF, StatsInvChiCDF, and gammq.

StatsChiPDF

StatsChiPDF(\(x, n\))
The StatsChiPDF function returns the chi-squared probability distribution function for the specified value and degrees of freedom as

\[
f(x; n) = \frac{\exp\left(-\frac{x^2}{2}\right) x^{n-1}}{2^{\frac{n}{2}} \Gamma\left(\frac{n}{2}\right)}.
\]

See Also
Chapter III-12, Statistics for a function and operation overview; StatsChiCDF and StatsChiPDF.

StatsChiTest

StatsChiTest [flags] srcWave1, srcWave2
The StatsChiTest operation computes a \(\chi^2\) statistic for comparing two distributions or a \(\chi^2\) statistic for comparing a sample distribution with its expected values. In both cases the comparison is made on a bin-by-bin basis. Output is to the W_StatsChiTest wave in the current data folder or optionally to a table.
**StatsCircularCorrelationTest**

### Flags

- **/ALZR**  
  Allows zero entries in source waves. If you are using /S zero entries in srcWave2 are skipped.

- **/NCON=nCon**  
  Specifies the number of constraints (0 by default), which reduces the number degrees of freedom and the critical value by nCon.

- **/S**  
  Sets the calculation mode to a single distribution where srcWave1 represents an array of binned measurements and srcWave2 represents the corresponding expected values.

- **/T=k**  
  Displays results in a table. k specifies the table behavior when it is closed.
  
  - k=0: Normal with dialog (default).
  - k=1: Kills with no dialog.
  - k=2: Disables killing.

- **/Z**  
  Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

### Details

The source waves, srcWave1 and srcWave2, must have the same number of points and can be any real numeric data type. Any nonpositive values (including NaN) in either wave removes the entry in both waves from consideration and reduces the degrees of freedom by one. The number degrees of freedom is initially the number of points in srcWave1-1-nCon. By default it is assumed that srcWave1 and srcWave2 represent two distributions of binned data.

When you specify /S, srcWave1 must consist of binned values of measured data and srcWave2 must contain the corresponding expected values. The calculation is:

\[
\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_i - V_i)^2}{V_i}
\]

Here \(Y_i\) is the sample point from srcWave1, \(V_i\) is the expected value of \(Y_i\) based on an assumed distribution (srcWave2), and \(n\) is the number of points in the each wave. If you do not use /S, it calculates:

\[
\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_{1i} - Y_{2i})^2}{Y_{1i} + Y_{2i}}
\]

where \(Y_{1i}\) and \(Y_{2i}\) are taken from srcWave1 and srcWave2 respectively.

V_flag will be set to -1 for any error and to zero otherwise.

---

**StatsCircularCorrelationTest [flags] waveA, waveB**

The StatsCircularTwoSampleTest operation performs a number of tests for two samples of circular data. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data expressed in radians and an optional second column contains associated vector lengths. The waves must be either single or double precision floating point. Results are stored in the W_StatsCircularCorrelationTest wave in the current data folder and optionally displayed in a table. Some flags generate additional outputs, described below.

### Flags

- **/ALPH=val**  
  Sets the significance level (default 0.05).

- **/NAA**  
  Performs a nonparametric angular-angular correlation test.
The nonparametric test (/NAA) follows Fisher and Lee’s modification of Mardia’s statistic, which is an analogue of Spearman’s rank correlation. The test ranks the angles of each sample and computes the quantities $r'$ and $r''$ as follows:

$$r' = \frac{1}{n^2} \left\{ \sum_{i=0}^{n-1} \cos \left[ \frac{2\pi}{n} (r_{ai} - r_{bi}) \right] \right\}^2 + \left\{ \sum_{i=0}^{n-1} \sin \left[ \frac{2\pi}{n} (r_{ai} - r_{bi}) \right] \right\}^2,$$

$$r'' = \frac{1}{n^2} \left\{ \sum_{i=0}^{n-1} \cos \left[ \frac{2\pi}{n} (r_{ai} + r_{bi}) \right] \right\}^2 + \left\{ \sum_{i=0}^{n-1} \sin \left[ \frac{2\pi}{n} (r_{ai} + r_{bi}) \right] \right\}^2.$$

Here $n$ is the number of data pairs and $r_{ai}$ and $r_{bi}$ are the ranks of the $i$th member in the first and second samples respectively.

The test statistic is $(n-1)(r'-r'')$, which is compared with the critical value (for one and two tails). The CDF of the statistic is a highly irregular function. The critical value is computed by a different methods according to $n$. For $3 \leq n \leq 8$, a built-in table of CDF transitions gives a “conservative” estimate of the critical value. For $9 \leq n \leq 30$, the CDF is approximated by a 7th order polynomial in the region $x > 0$. For $n \geq 30$, the CDF is from the asymptotic expression. For $3 \leq n \leq 30$, CDF values are obtained by Monte-Carlo simulations using 1e6 random samples for each $n$.

The parametric test for angular-angular correlation (/PAA) involves computation of a correlation coefficient $r_{aa}$ and then evaluating the mean $r_{aa}$ and variance $s_{aa}^2$ of equivalent correlation coefficients computed from the same data but by deleting a different pair of angles each time. The mean and variance are then used to compute confidence limits L1 and L2:

$$L1 = nr_{aa} - (n-1) \bar{r}_{aa} - Z_{\alpha(2)} \sqrt{\frac{s_{aa}^2}{n}},$$

$$L2 = nr_{aa} - (n-1) \bar{r}_{aa} + Z_{\alpha(2)} \sqrt{\frac{s_{aa}^2}{n}}.$$

where $Z_{\alpha(2)}$ is the normal distribution two-tail critical value at the a level of significance. $H_0$ (corresponding to no correlation) is rejected if zero is not contained in the interval $[L1,L2]$.

The parametric test for angular-linear correlation (/PAL) involves computation of the correlation coefficient $r_{al}$ which is then compared with a critical value from $\chi^2$ for alpha significance and two degrees of freedom.
StatsCircularMeans

\[ r_{al} = \sqrt{\frac{r_{xc}^2 + r_{xs}^2 - 2r_{xc}r_{xs}}{1 - r_{cs}^2}}, \]

where:

\[ r_{xc} = \frac{\sum_{i=0}^{n-1} X_i \cos(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \cos(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left(\sum_{i=0}^{n-1} X_i\right)^2\right)\left(\sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \cos(a_i)\right)^2\right)}}. \]

\[ r_{xs} = \frac{\sum_{i=0}^{n-1} X_i \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \sin(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left(\sum_{i=0}^{n-1} X_i\right)^2\right)\left(\sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \sin(a_i)\right)^2\right)}}. \]

\[ r_{cs} = \frac{\sum_{i=0}^{n-1} \cos(a_i) \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} \sin(a_i) \sum_{i=0}^{n-1} \cos(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \sin(a_i)\right)^2\right)\left(\sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \cos(a_i)\right)^2\right)}}. \]

StatsCircularMeans

StatsCircularMeans [flags] srcWave

The StatsCircularMeans operation calculates the mean of a number of circular means, returning the mean angle (grand mean), the length of the mean vector, and optionally confidence interval around the mean angle. Output is to the history area and to the W_CircularMeans wave in the current data folder.

Flags

/ALPH=val Sets the significance level (default 0.05).

/CI Calculates the confidence interval (labeled CI_t1 and CI_t2) around the mean angle.

/NSOA Performs nonparametric second order analysis according to Moore’s version of Rayleigh’s test where H_0 corresponds to uniform distribution around the circle. Moore’s test ranks entries by the lengths of the mean radii (second column of the input) from smallest (rank 1) to largest (rank n) and then computes the statistic:
The `srcWave` input to StatsCircularMeans must be a single or double precision two column wave containing in each row a mean angle (radians) and the length of a mean radius (the first column contains mean angles and the second column contains mean vector lengths). `srcWave` must not contain any NaNs or INFs. The confidence interval calculation follows the procedure outlined by Batschelet.

V_flag will be set to -1 for any error and to zero otherwise.

Details

V_flag will be set to -1 for any error and to zero otherwise.
StatsCircularMoments

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; StatsCircularMoments, StatsInvMooreCDF, and StatsInvFCD.

StatsCircularMoments

**StatsCircularMoments** \([flags]\) *srcWave*

The StatsCircularMoments operation computes circular statistical moments and optionally performs angular uniformity tests for the data in *srcWave*. The extent of the calculation is determined by the requested moment. The default results are stored in the W_CircularStats wave in the current data folder and are optionally displayed in a table. Additional results are listed under the corresponding flags.

**Flags**

/ALPH=alpha  Sets an alpha value for computing confidence intervals (default is 0.05).

/AXD=p  Designates the input as p-axial data. For example, if the input represents undirected lines then \(p = 2\) and the operation multiplies the angles by a factor \(p\) (after shifting /ORGN and accounting for /CYCL). It does not back-transform the mean or median axis.

/CYCL=cycle  Specifies the length of the data cycle. You do not need to do so if you are using one of the built-in modes, but this is still a useful option, as for setting the length of a particular month when using /MODE=5.

/GRPD=\{start, delta\}  Computes circular statistics for grouped data. In this case *srcWave* contains frequencies or the number of events that belong to a particular angle group. There are as many groups as there are elements in *srcWave*. The first group is centered at \(start\) radians and each consecutive group is centered \(delta\) radians away. You must set both the \(start\) and \(delta\) to sensible values. *srcWave* may contain NaNs but it is an error if all values are NaN. The only other flags that work in combination with this flag are /Q, /T, and /Z.

/KUPR=\[k\]  Tests the uniformity of a circular distribution of ungrouped data using the Kuiper statistic. The data are converted into a set \(\{x_i\}\) by normalizing the input angles to the range \([0,1]\), ranking the results then using the two quantities \(D_+\) and \(D_-\) to compute the Kuiper statistic. Use \(k=0\) for Fisher’s version:

\[
V = \left( D_+ + D_- \right) \left( \frac{\sqrt{n} + 0.155 + 0.24}{\sqrt{n}} \right),
\]

Use \(k=1\), added in Igor Pro 8.00, for the more common definition of the Kuiper statistic:

\[
V = \left( D_+ + D_- \right).
\]

Here

\[
D_+ = \text{Max of: } \frac{1}{n} \cdot \frac{2}{n} \cdot \ldots \cdot 1 - x_n, \quad x_1, \ldots, x_n
\]

\[
D_- = \text{Max of: } x_1, \ldots, x_1 - \frac{1}{n}, \ldots, x_n - \frac{n-1}{n}
\]

and \(n\) is the number of valid points in *srcWave*. You can find the results in the wave W_CircularStats under row label “Kuiper V” and “Kuiper CDF(V)”. See Fisher and Press *et al.* for more information.
Computes Linear Order Statistics by sorting the angle values from small to large, dividing each angle by $2\pi$ and shifting the origin so that the output range is $[0,1]$. The results are stored in the wave `W_LinearOrderStats` in the current data folder. The X scaling of the wave is set so that the offset and the delta are $1/(n+1)$ where $n$ is the number of non-NaN points in the input.

Computes specified moments. By default, it computes the second order moments as well as skewness, kurtosis, median, and mean deviation. Use `/M=1` for the first moment. For higher moments, both the specified moment and all the default quantities are computed.

Handles special types of data.

<table>
<thead>
<tr>
<th>mode</th>
<th>Data in srcWave</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Angles in radians $[0,2\pi]$</td>
</tr>
<tr>
<td>1</td>
<td>Angles in radians $[-\pi, \pi]$</td>
</tr>
<tr>
<td>2</td>
<td>Angles in degrees $[0,360]$</td>
</tr>
<tr>
<td>3</td>
<td>Angles in degrees $[-180,180]$</td>
</tr>
<tr>
<td>4</td>
<td>Igor date format for one year cycles.</td>
</tr>
<tr>
<td>5</td>
<td>Igor date format for one month cycles.</td>
</tr>
<tr>
<td>6</td>
<td>Igor date format for one week cycles.</td>
</tr>
<tr>
<td>7</td>
<td>Igor date format for one day cycles.</td>
</tr>
<tr>
<td>8</td>
<td>Igor date format for one hour cycles.</td>
</tr>
</tbody>
</table>

Specifies the origin of the data (the value corresponding to an angle of zero degrees). For example, if you are using Igor date format and you want the origin to be the first second in year YYYY, use `/ORGN=(date2secs(YYYY,1,1))`.

No results printed in the history area.

Performs the Rayleigh test for uniformity. If the "alternative" mean direction is specified (in radians), the test computes

$$r0Bar=rBar \cos(tBar-meanDirection)$$

and then computes the significance probability of $r0Bar$. The null hypothesis $H_0$ corresponds to uniformity. It is rejected when $r0Bar$ is too large. If the mean direction is not specified then $r0Bar$ is $rBar$ which is always calculated as part of the first moments so the operation only computes the relevant significance probability (P-Value). The critical values for both cases are computed according to Durand and Greenwood.

Saves the translated angle data in the wave `W_AngleWave` in the current data folder.

Displays results in a table. $k$ specifies the table behavior when it is closed.

- $k=0$: Normal with dialog (default).
- $k=1$: Kills with no dialog.
- $k=2$: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists, but does not display the output wave from the current data folder, the table is renamed and a new table is created.

Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.
StatsCircularMoments

Details
StatsCircularMoments is equivalent to WaveStats but it applies to circular data, which are distributed on the perimeter of a circle representing some period or cycle. If your data are not described by one of the built-in modes, you can specify the value of the origin (/ORGN), which is mapped to zero degrees and the size of a cycle or period.

When you use Igor date formats with the built-in modes for dates, the default origin is set to zero. The default cycle in the case of Mode 4 is 366. This is done in order to handle both leap and nonleap years. Similarly, Mode 5 uses a cycle of 31 days. Note that the internal conversion from Igor date to (year, month, day) is independent of the cycle specification and is therefore not affected by this choice. You should use the /CYCL flag if you use one of these modes with a fixed size of year or month.

The parameters listed below are computed and displayed (see row labels) in the table. Here $N$ is the number of valid (non-NaN) angles $\{\theta_i\}$

$$C = \sum_{i=1}^{n} \cos \theta_i$$

$$S = \sum_{i=1}^{n} \sin \theta_i$$

$$R = \sqrt{C^2 + S^2}$$

$$cBar = \bar{C} = \frac{C}{n}$$

$$sBar = \bar{S} = \frac{S}{n}$$

$$rBar = \bar{R} = \frac{R}{n}$$

$$tBar = \bar{\theta} = \begin{cases} \ \text{atan}(S/C) & S > 0, C > 0 \\ \ \text{atan}(S/C) + \pi & C < 0 \\ \ \text{atan}(S/C) + 2\pi & S < 0, C > 0 \end{cases}$$

$$V = 1 - \bar{R}$$

$$v = \sqrt{-2 \ln(1 - V)}$$

median is the value which minimizes

$$d(\theta) = \pi - \frac{1}{n} \sum_{i=1}^{n} \pi - |\theta_i - \bar{\theta}|$$

mean deviation = The minimum of the last equation when $\theta \to \text{median}$.

Higher order moments are denoted with the moment number such that $t3Bar$ is the uncentered third moment of the angle while primed quantities are relative to mean direction $tBar$. Using this notation

$$\tilde{\rho}_2 = \frac{1}{n} \sum_{i=1}^{n} \cos 2(\theta_i - \bar{\theta})$$

$$\text{circular dispersion} = \frac{1 - \tilde{\rho}_2^2}{2\bar{R}}$$
skewness = \frac{\widehat{\rho}_2 \sin (\widehat{\mu}' - 2\widehat{\theta})}{\left(1 - \overline{R}\right)^{3/2}}

kurtosis = \frac{\widehat{\rho}_2 \cos (\widehat{\mu}' - 2\widehat{\theta}) - \overline{R}^4}{\left(1 - \overline{R}\right)^2}

where

\[ \hat{\mu}' = \begin{cases} 
  \tan^{-1}\left(\frac{S_p}{C_p}\right) & S_p > 0, C_p > 0 \\
  \tan^{-1}\left(\frac{S_p}{C_p}\right) + \pi & C_p < 0 \\
  \tan^{-1}\left(\frac{S_p}{C_p}\right) + 2\pi & S_p < 0, C_p > 0
\end{cases} \]

and

\[ C_p = \frac{1}{n} \sum_{i=1}^{n} \cos p\theta_i, \quad S_p = \frac{1}{n} \sum_{i=1}^{n} \sin p\theta_i. \]

*WaveStats*, *StatsAngularDistanceTest*, *StatsCircularCorrelationTest*, *StatsCircularMeans*, *StatsHodgesAjneTest*, *StatsWatsonUSquaredTest*, *StatsWatsonWilliamsTest*, and *StatsWheelerWatsonTest*.

**StatsCircularTwoSampleTest**

*StatsCircularTwoSampleTest* [flags] *waveA*, *waveB*

The StatsCircularTwoSampleTest operation performs second order analysis of angles. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data (mean angles) expressed in radians and an optional second column that contains associated vector lengths. The waves must be either single or double precision. Results are stored in the W_StatsCircularTwoSamples wave in the current data folder and optionally displayed in a table. Some of the tests may have additional outputs.

**Flags**

- **/ALPH = val** Sets the significance level (default val=0.05).
- **/NPR** Performs nonparametric paired-sample test (Moore). The input waves must contain paired angular data so both must have single column and the same number of points.
- **/NSOA** Perform nonparametric second order two-sample test. Input waves must each contain two columns.
- **/PPR** Performs parametric paired-sample test. Input waves must contain paired data and must have the same number of points.
Details

The nonparametric paired-sample test (/NPR) is Moore’s test for paired angles applied in second order analysis. The input can consist of one or two column waves. When both waves contain a single column the operation proceeds as if all the vector length were identically 1. The Moore statistic (H_0 → pair equality) is computed and compared to the critical value from the Moore distribution (see StatsInvMooreCDF).

The nonparametric second-order two-sample test (/NSOA) consists of pre-processing where the grand mean is subtracted from the two inputs followed by application of Watson’s U^2 test (StatsWatsonUSquaredTest) with H_0 implying that the two samples came from the same population. The results of this test are stored in the wave W_WatsonUtest.

The parametric paired-sample test (/PPR) is due to Hotelling. In this test the input should consist of both angular and vector length data. The test statistic is compared with a critical value from the F distribution (StatsInvFCDF).

The parametric second order two-sample test (/PSOA) is an extension of Hotelling one-sample test to second order analysis where an F-like statistic is computed corresponding to H_0 of equal mean angles.

StatsCMSSDCDF

StatsCMSSDCDF(C, n)
The StatsCMSSDCDF function returns the cumulative distribution function of the C distribution (mean square successive difference), which is

\[ f(C,n) = \frac{\Gamma(2m + 2)}{a^{2m+1}[\Gamma(m+1)]^2} \left( 1 - \frac{C^2}{a^2} \right)^m, \]

where

\[ a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^3 - 13n + 24)}, \]

\[ m = \frac{(n^4 - n^3 - 13n^2 + 37n - 60)}{2(n^3 - 13n + 24)}. \]

The distribution (C>0) can then be expressed as
where $2\text{F}_1$ is the hypergeometric function $\text{hyperG2F1}$.

**References**

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; *StatsCMSSDCDF* and *StatsSRTest*.

**StatsCochranTest**

**StatsCochranTest [flags] [wave1, wave2, ... wave100]**

The StatsCochranTest operation performs Cochran’s (Q) test on a randomized block or repeated measures dichotomous data. Output is to the M_CochranTestResults wave in the current data folder or optionally to a table.

**Flags**

- `/ALPH = val` 
  Sets the significance level (default $val=0.05$).
- `/Q` 
  No results printed in the history area.
- `/T = k` 
  Displays results in a table. $k$ specifies the table behavior when it is closed.
  - $k=0$: Normal with dialog (default).
  - $k=1$: Kills with no dialog.
  - $k=2$: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

- `/WSTR = waveListString` 
  Specifies a string containing a semicolon-separated list of waves that contain sample data. Use `waveListString` instead of listing each wave after the flags.
- `/Z` 
  Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

**Details**

StatsCochranTest computes Cochran’s statistic and compares it to a critical value from a Chi-squared distribution, which depends only of the significance level and the number of groups (columns). The null hypothesis for the test is that all columns represent the same proportion of the effect represented by a non-zero data.

The Chi-square distribution is appropriate when there are at least 4 columns and at least 24 total data points.

Dichotomous data are presumed to consist of two values 0 and 1, thus StatsCochranTest distinguishes only between zero and any nonzero value, which is considered to be 1; it does not allow NaNs or INFs. Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with `/WSTR`. In the standard terminology, data rows represent blocks and data columns represent groups. $H_0$ corresponds to the assumption that all groups have the same proportion of 1’s.

With the `/T` flag, it displays the results in a table that contains the number of rows, the number of columns, the Cochran statistic, the critical value, and the conclusion (1 to accept $H_0$ and 0 to reject it). V_flag will be set to -1 for any error and to zero otherwise.

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; *StatsFriedmanTest*.
The StatsContingencyTable operation performs contingency table analysis on 2D and 3D tables. Output is to the W_ContingencyTableResults wave in the current data folder or optionally to a table or the history area.

Flags

/ALPH = val  
Sets the significance level (default $val=0.05$).

/COR=mode  
Sets the correction type for 2x2 tables. By default there is no correction. Use $mode=1$ for Yates and $mode=2$ for Haber correction.

/FEXT=[row, col]  
Computes Fisher’s Exact P-value with 2x2 contingency tables. $row$ and $col$ are zero-based indices of the table entry where it computes the probability of getting the results in the table or more extreme values. Without the /Q flag, it prints the probabilities of each individual table in the history.

Given the contingency table:

<table>
<thead>
<tr>
<th></th>
<th>Succeeded</th>
<th>Failed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group1</td>
<td>11</td>
<td>8</td>
</tr>
<tr>
<td>Group2</td>
<td>4</td>
<td>9</td>
</tr>
</tbody>
</table>

Example 1: When you use /FEXT={0, 0} the P-value represents the sum of the probabilities of the first group having in the Succeeded column 11 or more extreme values, i.e., 12, 13, 14, and 15. In each case the remaining table elements are adjusted so that row and column sums remain constant.

Example 2: When you needed to evaluate the sum of the probabilities of Group2 having 4 counts or less in the Succeeded column, then the appropriate flag is /FEXT={1, 1}, which effectively computes the equivalent of having 9, 10, 11, 12, and 13 Failed counts. In each case it computes the upper, the lower, and the two-tail probabilities.

/HTRG  
Tests for heterogeneity between tables stored as layers of 3D wave.

/LLIK  
Computes log likelihood statistic.

/Q  
No results printed in the history area.

/T=k  
Displays results in a table. $k$ specifies the table behavior when it is closed.

$k=0$: Normal with dialog (default).

$k=1$: Kills with no dialog.

$k=2$: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

/Z  
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

StatsContingencyTable supports 2D waves representing single contingency tables or 3D waves representing multiple 2D tables (where each table is a layer) or a single 3D table. Each entry in the wave must contain a frequency value and must be a positive number; it does not support 0’s, NaNs, or INFs. In the special case of 2x2 tables, use the /COR flag to compute the statistic using either the Yates or Haber corrections. Except for the heterogeneity option you can also compute the log likelihood statistic. In all the tests, $H_0$ corresponds to independence between the tested variables.

For 3D tables StatsContingencyTable provides Chi-squared, degrees of freedom, the critical value, and optionally the log likelihood G statistic (/LLIK flag) for each of the following cases:
StatsCorrelation

- Mutual independence by testing if all three variables are independent of each other.
- Partial dependence (rows) by testing if rows independent of columns and layers.
- Partial dependence (columns) by testing if columns independent of rows and layers.
- Partial dependence (layers) by testing if layers independent of rows and columns.

In each case you should compare the statistic with the critical value and reject $H_0$ if the statistic exceeds or equals the critical value.

You should examine the table entries to determine if the Chi-square statistic is appropriate (if the frequency is smaller than 6 for /ALPH=0.05 you should consider computing the Fisher exact test).

$V_{\text{flag}}$ will be set to -1 for any error and to zero otherwise.

**See Also**
Chapter III-12, *Statistics* for a function and operation overview; *StatsInvChiCDF*.

**StatsCorrelation**

$\text{StatsCorrelation}(\text{waveA}[, \text{waveB}])$

The *StatsCorrelation* function computes Pearson’s correlation coefficient between two real valued arrays of data of the same length. Pearson $r$ is given by:

$$r = \frac{\sum_{i=0}^{n-1} (\text{waveA}[i] - A)(\text{waveB}[i] - B)}{\sqrt{\sum_{i=0}^{n-1} (\text{waveA}[i] - A)^2 \sum_{i=0}^{n-1} (\text{waveB}[i] - B)^2}}$$

Here $A$ is the average of the elements in *waveA*, $B$ is the average of the elements of *waveB* and the sum is over all wave elements.

**Details**

If you use both *waveA* and *waveB* then the two waves must have the same number of points but they could be of different number type. If you use only the *waveA* parameter then *waveA* must be a 2D wave. In this case *StatsCorrelation* will return 0 and create a 2D wave M_Pearson where the $(i,j)$ element is Pearson’s $r$ corresponding to columns $i$ and $j$.

Fisher’s $z$ transformation converts Person’s $r$ above to a normally distributed variable $z$:

$$z = \frac{1}{2} \ln \left( \frac{1+r}{1-r} \right),$$

with a standard error

$$\sigma_z = \frac{1}{\sqrt{n-3}}.$$

You can convert between the two representations using the following functions:

Function *pearsonToFisher*(inr)
- Variable inr
  - return $0.5 \times (\ln(1+\text{inr}) - \ln(1-\text{inr}))$
End

Function *fisherToPearson*(inz)
- Variable inz
  - return $\tanh(\text{inz})$
End

**See Also**
*Correlate*, *StatsLinearCorrelationTest*, and *StatsCircularCorrelationTest*. 
StatsDExpCDF

\textbf{StatsDExpCDF}(x, m, s)

The StatsDExpCDF function returns the double-exponential cumulative distribution function

\[ F(x; \mu, \sigma) = \begin{cases} 
\exp\left(\frac{x - \mu}{\sigma}\right) & \text{when } x < \mu \\
1 - \frac{1}{2} \exp\left(-\frac{x - \mu}{\sigma}\right) & \text{when } x \geq \mu 
\end{cases} \]

for \( \sigma > 0 \). It returns NaN when \( \sigma = 0 \).

\textbf{See Also}

Chapter III-12, \textit{Statistics} for a function and operation overview; \textit{StatsDExpPDF} and \textit{StatsInvDExpCDF}.

StatsDExpPDF

\textbf{StatsDExpPdf}(x, m, s)

The StatsDExpPdf function returns the double-exponential probability distribution function

\[ f(x; \mu, \sigma) = \frac{1}{2\sigma} \exp\left[-\frac{|x - \mu|}{\sigma}\right], \]

where \( \mu \) is the location parameter and \( \sigma > 0 \) is the scale parameter. Use \( \mu = 0 \) and \( \sigma = 1 \) for the standard form of the double exponential distribution. It returns NaN when \( \sigma = 0 \).

\textbf{See Also}

Chapter III-12, \textit{Statistics} for a function and operation overview; \textit{StatsDExpCDF} and \textit{StatsInvDExpCDF}.

StatsDIPTest

\textbf{StatsDIPTest} [/Z] srcWave

The StatsDIPTest operation performs Hartigan test for unimodality.

\textbf{Flags}

/Z 

Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

\textbf{Details}

The input to the operation \textit{srcWave} is any real numeric wave. Outputs are: V_Value contains the dip statistic; V_min is the lower end of the modal interval; and V_max is the higher end of the modal interval. Percentage points or critical values for the dip statistic can be obtained from simulations using an identical sample size as in this example:

Function getCriticalValue(sampleSize, alpha)
Variable sampleSize, alpha
Make/O/N=(sampleSize) dataWave
Make/O/N=100000 dipResults
Variable i
for(i=0;i<100000;i+=1)
dataWave=enoise(100)
StatsDipTest dataWave
dipResults[i]=V_Value
endfor
Histogram/P/B=4 dipResults // Compute the PDF.
Wave W_Histogram
Integrate/METH=1 W_Histogram/D=W_INT // Compute the CDF.
Findlevel/Q W_int,(1-alpha) // Find the critical value.
return V_LevelX
End
StatsDunnettTest

StatsDunnettTest \([flags]\) \([wave1, wave2, \ldots wave100]\)

The StatsDunnettTest operation performs the Dunnett test by comparing multiple groups to a control group. Output is to the M_DunnettTestResults wave in the current data folder or optionally to a table. StatsDunnettTest usually follows StatsANOVA1Test.

Flags

- /ALPH = val: Sets the significance level (default val=0.05).
- /CIDX=cIndex: Specifies the (zero based) index of the input wave corresponding to the control group. The default is zero (the first wave corresponds to the control group).
- /Q: No results printed in the history area.
- /SWN: Creates a text wave, T_DunnettDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
- /TAIL=tc: Specifies H0.
  - tc=1: One tailed test \((\mu_c \leq \mu_a)\)
  - tc=2: One tailed test \((\mu_c \geq \mu_a)\)
  - tc=4: Two tailed test \((\mu_c = \mu_a)\) (default)
  Code combinations are not allowed.
- /WSTR=waveListString: Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
- /Z: Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

StatsDunnettTest inputs are two or more 1D numeric waves (one wave for each group of samples). The input waves may contain different number of points, but they must contain two or more valid entries per wave.

For output to a table (using /T), each labelled row represents the results of the test for comparing the means of one group to the control group, and rows are ordered so that all comparisons are computed sequentially starting with the group having the smallest mean. The contents of the labeled columns are:

- First: The difference between the group means
- Second: SE (which is computed for possibly unequal number of points)
- Third: The q statistic for the pair which may be positive or negative

StatsErlangCDF

$\text{StatsErlangCDF}(x, b, c)$

The StatsErlangCDF function returns the Erlang cumulative distribution function

$$F(x; b, c) = 1 - \frac{\Gamma \left( \frac{x}{c,b} \right)}{\Gamma(c)}.$$  

where $b>0$ (also as $\lambda=1/b$) is the scale parameter, $c>0$ the shape parameter, $\Gamma(x)$ the gamma function, and $\Gamma(a,x)$ the incomplete gamma function gammaInc.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsErlangPDF.

StatsErlangPDF

$\text{StatsErlangPDF}(x, b, c)$

The StatsErlangPDF function returns the Erlang probability distribution function

$$f(x; b, c) = \frac{\left( \frac{x}{b} \right)^{c-1} \exp\left( -\frac{x}{b} \right)}{b(c-1)!}.$$  

where $b>0$ (also as $\lambda=1/b$) is the scale parameter and $c>0$ the shape parameter.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsErlangCDF.

StatsErrorPDF

$\text{StatsErrorPDF}(x, a, b, c)$

The StatsErrorPDF function returns the error probability distribution function or the exponential power distribution

$$f(x; a, b, c) = \frac{\exp \left[ -\frac{1}{2} \left( \frac{|x-a|}{b} \right)^2 \right]}{b 2^{c-1} \Gamma \left( 1 + \frac{c}{2} \right)}.$$  

where $a$ is the location parameter, $b>0$ is the scale parameter, $c>0$ is the shape parameter, and $\Gamma(x)$ is the gamma function.
StatsEValueCDF

**StatsEValueCDF**

StatsEValueCDF(x, μ, σ)

The StatsEValueCDF function returns the extreme-value (type I, Gumbel) cumulative distribution function

\[ F(x; \mu, \sigma) = 1 - \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right), \]

where \( \sigma > 0 \). This is also known as the “minimum” form or distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of \( \sigma \).

**See Also**

Chapter III-12, **Statistics** for a function and operation overview.

StatsEValuePDF, StatsInvEValueCDF, StatsGEVCDF, StatsGEVPDF

StatsEValuePDF

**StatsEValuePDF**

StatsEValuePDF(x, μ, σ)

The StatsEValuePDF function returns the extreme-value (type I, Gumbel) probability distribution function

\[ f(x; \mu, \sigma) = \frac{1}{\sigma} \exp\left(-\frac{x - \mu}{\sigma}\right), \]

where \( \mu \) is the location parameter and \( \sigma > 0 \) is the scale parameter. Use \( \mu = 0 \) and \( \sigma = 1 \) for the standard form of the exponential distribution. It returns NaN for \( \sigma = 0 \).

**See Also**

Chapter III-12, **Statistics** for a function and operation overview.

StatsEValueCDF, StatsInvEValueCDF, StatsGEVCDF, StatsGEVPDF

StatsExpCDF

**StatsExpCDF**

StatsExpCDF(x, μ, σ)

The StatsExpCDF function returns the exponential cumulative distribution function

\[ F(x; \mu, \sigma) = 1 - \exp\left(-\frac{x - \mu}{\sigma}\right), \]

where \( x \geq \mu \) and \( \sigma > 0 \). It returns NaN for \( \sigma = 0 \).

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; StatsExpPDF and StatsInvExpCDF.
StatsFCDF

StatsFCDF\( (x, n1, n2) \)
The StatsFCDF function returns the cumulative distribution function for the F distribution with shape parameters \( n1 \) and \( n2 \)

\[
F(x; n1, n2) = 1 - \text{Betai} \left( \frac{n2}{2}, \frac{n1}{2}, \frac{n2}{n1 + n2 x} \right),
\]

where \( \text{Betai} \) is the incomplete beta function.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsExpCDF and StatsInvExpCDF.

StatsFPDF

StatsFPDF\( (x, n1, n2) \)
The StatsFPDF function returns the probability distribution function for the F distribution with shape parameters \( n1 \) and \( n2 \)

\[
f(x; n1, n2) = \frac{\Gamma \left( \frac{n1 + n2}{2} \right) \left( \frac{n1}{n2} \right)^{n1/2} x^{n1/2 - 1}}{\Gamma \left( \frac{n1}{2} \right) \Gamma \left( \frac{n2}{2} \right) \left( 1 + \frac{n1 x}{n2} \right)^{n1 + n2/2}}.
\]

See Also
Chapter III-12, Statistics for a function and operation overview; StatsFCDF and StatsInvFCDF.

StatsFriedmanCDF

StatsFriedmanCDF\( (x, n, m, \text{method}, \text{useTable}) \)
The StatsFriedmanCDF function returns the cumulative probability distribution of the Friedman distribution with \( m \) rows and \( n \) columns. The exact Friedman distribution is computationally intensive, taking on the order of \( (n!)^m \) iterations. You may use a range of precomputed exact values by passing a nonzero value for \( \text{useTable} \), which will use \text{method} only if the value is not in the table. For large \( m \), consider using the Chi-squared or the Monte-Carlo approximations. To abort execution, press the User Abort Key Combinations.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsInvFriedmanCDF and StatsFriedmanTest.
StatsFriedmanTest

StatsFriedmanTest [flags] [wave1, wave2,... wave100]

The StatsFriedmanTest operation performs Friedman's test on a randomized block of data. It is a nonparametric analysis of data contained in either individual 1D waves or in a single 2D wave. Output is to the M_FriedmanTestResults wave in the current data folder or optionally to a table.

Flags

/ALPH = val Sets the significance level (default val=0.05).
/Q No results printed in the history area.
/RW Saves the ranking wave M_FriedmanRanks, which contains the rank values corresponding to each input datum.
/T=k Displays results in a table. k specifies the table behavior when it is closed.
  k=0: Normal with dialog (default).
  k=1: Kills with no dialog.
  k=2: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.

/WSTR=waveListString

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The Friedman test ranks the input data on a row-by-row basis, sums the ranks for each column, and computes the Friedman statistic, which is proportional to the sum of the squares of the ranks.

Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with /WSTR. All 1D waves must have the same number of points. A 2D wave must not contain any NaNs.

The critical value for the Friedman distribution is fairly difficult to compute when the number of rows and columns is large because it requires a number of permutations on the order of (numColumns!)^numRows. A certain range of these critical values are supported by precomputed tables. When the exact critical value is not available you can use one of the two approximations that are always computed: the Chi-squared approximation or the Iman and Davenport approximation, which converts the Friedman statistic is converted to a new value Ff then compares it with critical values from the F distribution using weighted degrees of freedom.

With the /T flag, it displays the results in a table that contains the number of rows, the number of columns, the Friedman statistic, the exact critical value (if available), the Chi-squared approximation, the Iman and Davenport approximation, and the conclusion (1 to accept H0 and 0 to reject it).

V_flag will be set to -1 for any error and to zero otherwise.

References

Chapter III-12, Statistics for a function and operation overview; StatsFriedmanCDF and StatsInvFriedmanCDF.

StatsFTest

StatsFTest [flags] wave1, wave2

The StatsFTest operation performs the F-test on the two distributions in wave1 and wave2, which can be any real numeric type, must contain at least two data points each, and can have an arbitrary number of dimensions. Output is to the W_StatsFTest wave in the current data folder or optionally to a table.
The F statistic is the ratio of the variance of wave1 to the variance of wave2. We assume the waves have equal wave variances and that H0 is sigma1=sigma2. For the upper one-tail test we reject H0 if F is greater than the upper critical value or if F is smaller than the lower critical value in the lower one-tail test. In the two-tailed test we reject H0 if F is either greater than the upper critical value or smaller than the lower critical value. The critical values are computed by numerically solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

\[ F(x, n_1, n_2) = 1 - betai \left( \frac{n_2 - 1}{2}, \frac{n_1 - 1}{n_2 + n_1} \right) \]

where the degrees of freedom n1 and n2 equal the number of valid (non-NaN) points in each wave -1, and betai is the incomplete beta function. To get the critical value for the upper one-tail test we solve F(x)=1-alpha. For the lower one-tail test we solve F(x)=alpha. In the two-tailed test the lower critical value is a solution for F(x)=alpha/2 and the upper critical value is a solution for F(x)=1-alpha/2.

The F-test requires that the two samples are from normally distributed populations.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsVariancesTest, StatsFCDF, and betai.

StatsGammaCDF

The StatsGammaCDF function returns the gamma cumulative distribution function

\[ F(x; \mu, \sigma, \gamma) = \frac{\Gamma_{inc} \left( \gamma, \frac{x - \mu}{\sigma} \right)}{\Gamma(\gamma)} \cdot \frac{1}{\sigma}, \gamma > 0, x \geq \mu \]

where \( \Gamma_{inc} \) is the incomplete gamma function and \( \Gamma(\gamma) \) is the gamma function. See Also
Chapter III-12, Statistics for a function and operation overview; StatsGammaPDF and StatsInvGammaCDF.
StatsGammaPDF

StatsGammaPDF(x, μ, σ, γ)
The StatsGammaPDF function returns the gamma probability distribution function

\[ f(x; \mu, \sigma, \gamma) = \frac{(x - \mu)^{\gamma-1} \exp\left(-\frac{x - \mu}{\sigma}\right)}{\sigma^\gamma \Gamma(\gamma)}. \quad x \geq \mu, \sigma, \gamma > 0 \]

where \(\mu\) is the location parameter, \(\sigma\) is the scale parameter, \(\gamma\) is the shape parameter, and \(\Gamma\) is the gamma function.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGammaCDF and StatsInvGammaCDF.

StatsGeometricCDF

StatsGeometricCDF(x, p)
The StatsGeometricCDF function returns the geometric cumulative distribution function

\[ F(x, p) = 1 - (1 - p)^{x+1}. \]

where \(p\) is the probability of success in a single trial and \(x\) is the number of trials for \(x \geq 0\).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGeometricPDF and StatsInvGeometricCDF.

StatsGeometricPDF

StatsGeometricPDF(x, p)
The StatsGeometricPDF function returns the geometric probability distribution function

\[ f(x, p) = p(1 - p)^x, \]

where the \(p\) is the probability of success in a single trial and \(x\) is the number of trials \(x \geq 0\).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGeometricCDF and StatsInvGeometricCDF.

StatsHodgesAjneTest

StatsHodgesAjneTest [flags] srcWave
The StatsHodgesAjneTest operation performs the Hodges-Ajne nonparametric test for uniform distribution around a circle. Output is to the W_HodgesAjne wave in the current data folder or optionally to a table.

Flags

/ALPH = val \hspace{1cm} \text{Sets the significance level (default val=0.05).}
/Q \hspace{1cm} \text{No results printed in the history area.}
/SA=specAngle \hspace{1cm} \text{Uses the Batschelet modification of the Hodges-Ajne test to test for uniformity against the alternative of concentration around the specified angle. specAngle must be expressed in radians modulus 2\pi.}
The input `srcWave` must contain angles in radians, can be any number of dimensions, can be single or double precision, and should not contain NaNs or INFs.

StatsHodgesAjneTest performs the standard Hodges-Ajne test, which simply tests for uniformity against the hypothesis that the population is not uniformly distributed around the circle. This test finds a diameter that divides the circle into two halves such that one contains the least number of data points, the test statistic. Use `/SA` to perform the modified (Batschelet) test, which tests against the alternative that the population is concentrated somehow about the specified angle. The modified test counts the number of points in 90-degree neighborhoods around the specified angle. The test statistic is given by \( C = n - m' \) where \( n \) is the number of points in the wave. The critical value is computed from the binomial probability density.

In both cases \( H_0 \) is rejected if the statistic is smaller than the critical value. \( V_{\text{flag}} \) will be set to -1 for any error and to zero otherwise.

\[ F(x, \mu, \sigma, \xi) \]

The StatsGEVPDF function returns the generalized extreme value probability distribution function.

V-934
The StatsHyperGCDF function returns the hypergeometric cumulative distribution function, which is the probability of getting \(x\) marked items when drawing (without replacement) \(k\) items out of a population of \(m\) items when \(n\) out of the \(m\) are marked.

**Details**

The hypergeometric distribution is

\[
f(x, \mu, \sigma, \xi) = \frac{1}{\sigma} \left[ 1 + \xi \left( \frac{x - \mu}{\sigma} \right) \right]^{-1/\xi} \exp \left\{ - \left[ 1 + \xi \left( \frac{x - \mu}{\sigma} \right) \right]^{-1/\xi} \right\},
\]

where

\[
1 + \xi \left( \frac{x - \mu}{\sigma} \right) > 0,
\]

and \(\sigma > 0\).

**See Also**
Chapter III-12, *Statistics* for a function and operation overview.

StatsGEVCDF, StatsEValuePDF, StatsEValueCDF, StatsInvEValueCDF

### StatsHyperGCDF

**StatsHyperGCDF\((x, m, n, k)\)**

The StatsHyperGCDF function returns the hypergeometric cumulative distribution function, which is the probability of getting \(x\) marked items when drawing (without replacement) \(k\) items out of a population of \(m\) items when \(n\) out of the \(m\) are marked.

**Details**

The hypergeometric distribution is

\[
F(x; m, n, k) = \sum_{L=0}^{x} \binom{n}{L} \binom{m-L}{k-L} \binom{m}{k},
\]

where \(\binom{a}{b}\) is the binomial function. All parameters must be positive integers and must have \(m>n\) and \(x<k\); otherwise it returns NaN.

Chapter III-12, *Statistics* for a function and operation overview; StatsHyperGPDF.

### StatsHyperGPDF

**StatsHyperGPDF\((x, m, n, k)\)**

The StatsHyperGPDF function returns the hypergeometric probability distribution function, which is the probability of getting \(x\) marked items when drawing without replacement \(k\) items out of a population of \(m\) items where \(n\) out of the \(m\) are marked.

**Details**

The hypergeometric distribution is
StatsInvBetaCDF

\[ f(x;m,n,k) = \binom{n}{x} \binom{m-n}{k-x} \frac{k}{m}, \]

where \( \binom{a}{b} \) is the binomial function. All parameters must be positive integers and must have \( m>n \) and \( x<k \).

Klotz, J.H., Computational Approach to Statistics.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsHyperGCDF.

StatsInvBetaCDF

StatsInvBetaCDF(cdf, p, q [ , a, b ])
The StatsInvBetaCDF function returns the inverse of the beta cumulative distribution function. There is no closed form expression for the inverse beta CDF; it is evaluated numerically.
The defaults (\( a=0 \) and \( b=1 \)) correspond to the standard beta distribution.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsBetaCDF and StatsBetaPDF.

StatsInvBinomialCDF

StatsInvBinomialCDF(cdf, p, N)
The StatsInvBinomialCDF function returns the inverse of the binomial cumulative distribution function.
The inverse function returns the value at which the binomial CDF with probability \( p \) and total elements \( N \) has the value 0.95. There is no closed form expression for the inverse binomial CDF; it is evaluated numerically.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsBinomialCDF and StatsBinomialPDF.

StatsInvCauchyCDF

StatsInvCauchyCDF(cdf, \( \mu, \sigma \))
The StatsInvCauchyCDF function returns the inverse of the Cauchy-Lorentz cumulative distribution function

\[ x = \mu + \frac{\sigma}{\pi} \tan^{-1} \left( \frac{cdf - 1/2}{\sigma} \right). \]

It returns NaN for \( cdf < 0 \) or \( cdf > 1 \).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsCauchyCDF and StatsCauchyPDF.

StatsInvChiCDF

StatsInvChiCDF(x, n)
The StatsInvChiCDF function returns the inverse of the chi-squared distribution of \( x \) and shape parameter \( n \). The inverse of the distribution is also known as the percent point function.
StatsInvCMSSDCDF

**StatsInvCMSSDCDF**

**StatsInvCMSSDCDF**(*cdf*, *n*)

The StatsInvCMSSDCDF function returns the critical values of the C distribution (mean square successive difference distribution), which is given by

\[
f(C,n) = \frac{\Gamma(2m+2)}{a^{2m+1} \Gamma(m+1)} \left( 1 - \frac{C^2}{a^2} \right)^m,
\]

where

\[
a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^3 - 13n + 24)},
\]

\[
m = \frac{(n^4 - n^3 - 13n^2 + 37n - 60)}{2(n^3 - 13n + 24)}.
\]

Critical values are computed from the integral of the probability distribution function.

**References**

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; StatsCMSSDCDF and StatsSRTest.

StatsInvDExpCDF

**StatsInvDExpCDF**(*cdf*, *μ*, *σ*)

The StatsInvDExpCDF function returns the inverse of the double-exponential cumulative distribution function

\[
x = \begin{cases} 
\mu + \sigma \ln(2cdf) & \text{when } cdf < 0.5 \\
\mu - \sigma \ln\left(2(1-cdf)\right) & \text{when } cdf \geq 0.5 
\end{cases}
\]

It returns NaN for *cdf* < 0 or *cdf* > 1.

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; StatsDExpCDF and StatsDExpPDF.

StatsInvEValueCDF

**StatsInvEValueCDF**(*cdf*, *μ*, *σ*)

The StatsInvEValueCDF function returns the inverse of the extreme-value (type I, Gumbel) cumulative distribution function

\[
x = \mu - \sigma \ln(1 - cdf)
\]

where \(\sigma > 0\). It returns NaN for *cdf* < 0 or *cdf* > 1. This inverse applies to the "minimum" form of the distribution. Reverse the sign of \(\sigma\) to obtain the inverse distribution of the maximum form.

**See Also**

Chapter III-12, *Statistics* for a function and operation overview.
StatsInvExpCDF

StatsInvExpCDF

\texttt{StatsInvExpCDF(cdf, \mu, \sigma)}

The \texttt{StatsInvExpCDF} function returns the inverse of the exponential cumulative distribution function

\[ x = \mu - \sigma \ln(1 - cdf). \]

It returns NaN for \( cdf < 0 \) or \( cdf > 1. \)

See Also

Chapter III-12, \textit{Statistics} for a function and operation overview; \texttt{StatsExpCDF} and \texttt{StatsExpPDF}.

StatsInvFCDF

\texttt{StatsInvFCDF(x, n1, n2)}

The \texttt{StatsInvFCDF} function returns the inverse of the F distribution cumulative distribution function for \( x \) and shape parameters \( n1 \) and \( n2 \). The inverse is also known as the percent point function.

See Also

Chapter III-12, \textit{Statistics} for a function and operation overview; \texttt{StatsFCDF} and \texttt{StatsFPDF}.

StatsInvFriedmanCDF

\texttt{StatsInvFriedmanCDF(cdf, n, m, method, useTable)}

The \texttt{StatsInvFriedmanCDF} function returns the inverse of the Friedman distribution cumulative distribution function of \( cdf \) with \( m \) rows and \( n \) columns. Use this typically to compute the critical values of the distribution

\texttt{Print StatsInvFriedmanCDF(1-alpha,n,m,0,1)}

where alpha is the significance level of the associated test.

The complexity of the computation of Friedman CDF is on the order of \((n!)^m\). For nonzero values of \texttt{useTable}, searches are limited to the built-in table for distribution values. If \( n \) and \( m \) are not in the table the calculation may still proceed according to the \texttt{method}.

\begin{tabular}{ll}
\textit{method} & \textit{What It Does} \\
0 & Exact computation (slow, not recommended). \\
1 & Chi-square approximation. \\
2 & Monte-Carlo approximation (slow). \\
3 & Use built-in table only and return a NaN if not in table. \\
\end{tabular}

For large \( m \) and \( n \), consider using the Chi-squared or the Iman and Davenport approximations. To abort execution, press the \textbf{User Abort Key Combinations}.

\textbf{Note:} Table values are different from computed values for both methods. Table values use more conservative criteria than computed values. Table values are more consistent with published values because the Friedman distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the X value of the next vertical transition to the one on which the specified P is found.

Precomputed tables use these values:

\begin{tabular}{ll}
\textbf{\( n \)} & \textbf{\( m \)} \\
3 & 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16 \\
4 & 2, 3, 4, 5, 6, 7, 8, 9 \\
5 & 2, 3, 4, 5, 6 \\
\end{tabular}
StatsInvGammaCDF

StatsInvGammaCDF(\(cdf\), \(\mu\), \(\sigma\), \(\gamma\))
The StatsInvGammaCDF function returns the inverse of the gamma cumulative distribution function. There is no closed form expression for the inverse gamma distribution; it is evaluated numerically.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGammaCDF and StatsGammaPDF.

StatsInvGeometricCDF

StatsInvGeometricCDF(\(cdf\), \(p\))
The StatsInvGeometricCDF function returns the inverse of the geometric cumulative distribution function where \(p\) is the probability of success in a single trial and \(x\) is the number of trials.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGeometricCDF and StatsGeometricPDF.

StatsInvKuiperCDF

StatsInvKuiperCDF(\(cdf\))
The StatsInvKuiperCDF function returns the inverse of Kuiper cumulative distribution function. There is no closed form expression. It is mapped to the range of 0.4 to 4, with accuracy of 1e-10.

References
See in particular Section 14.3 of

See Also
Chapter III-12, Statistics for a function and operation overview; StatsKuiperCDF.

StatsInvLogisticCDF

StatsInvLogisticCDF(\(cdf\), \(a\), \(b\))
The StatsInvLogisticCDF function returns the inverse of the logistic cumulative distribution function
StatsInvLogNormalCDF

\[ x = a + b \log \left( \frac{cdf}{1 - cdf} \right). \]

where the scale parameter \( b > 0 \) and the shape parameter is \( a \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogisticCDF and StatsLogisticPDF functions.

StatsInvLogNormalCDF

StatsInvLogNormalCDF(cdf, sigma, theta, mu)
The StatsInvLogNormalCDF function returns the numerically evaluated inverse of the lognormal cumulative distribution function.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogNormalCDF and StatsLogNormalPDF functions.

StatsInvMaxwellCDF

StatsInvMaxwellCDF(cdf, k)
The StatsInvMaxwellCDF function returns the evaluated numerically inverse of the Maxwell cumulative distribution function. There is no closed form expression.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsMaxwellCDF and StatsMaxwellPDF functions.

StatsInvMooreCDF

StatsInvMooreCDF(cdf, N)
The StatsInvMooreCDF function returns the inverse cumulative distribution function for Moore’s R*, which is used as a critical value in nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range \( 3 \leq N \leq 120 \) and does not change appreciably for \( N > 120 \).
The inverse distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

References

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsCircularMeans function.

StatsInvNBinomialCDF

StatsInvNBinomialCDF(cdf, k, p)
The StatsInvNBinomialCDF function returns the numerically evaluated inverse of the negative binomial cumulative distribution function. There is no closed form expression.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNBinomialCDF and StatsNBinomialPDF functions.

StatsInvNCChiCDF

StatsInvNCChiCDF(cdf, n, d)
The StatsInvNCChiCDF function returns the inverse of the noncenteral chi-squared cumulative distribution function. It is computationally intensive because the inverse is computed numerically and involves multiple evaluations of the noncentral distribution, which is evaluated from a series expansion.
StatsInvNCFCDF

StatsInvNCFCDF(cdf, n1, n2, d)
The StatsInvNCFCDF function returns the numerically evaluated inverse of the cumulative distribution function of the noncentral F distribution. n1 and n2 are the shape parameters and d is the noncentrality measure. There is no closed form expression for the inverse.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNCFCDF and StatsNCFPDF functions.

StatsInvNormalCDF

StatsInvNormalCDF(cdf, m, s)
The StatsInvNormalCDF function returns the numerically computed inverse of the normal cumulative distribution function. There is no closed form expression.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNormalCDF and StatsNormalPDF functions.

StatsInvParetoCDF

StatsInvParetoCDF(cdf, a, c)
The StatsInvParetoCDF function returns the inverse of the Pareto cumulative distribution function

\[ x = \frac{a}{(1 - cdf)^{1/c}} \]

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsParetoCDF and StatsParetoPDF functions.

StatsInvPoissonCDF

StatsInvPoissonCDF(cdf, \lambda)
The StatsInvPoissonCDF function returns the numerically evaluated inverse of the Poisson cumulative distribution function. There is no closed form expression for the inverse Poisson distribution.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPoissonCDF and StatsPoissonPDF functions.

StatsInvPowerCDF

StatsInvPowerCDF(cdf, b, c)
The StatsInvPowerCDF function returns the inverse of the Power Function cumulative distribution function

\[ x = \frac{b}{cdf^{1/c}} \]

where the scale parameter b and the shape parameter c satisfy b,c>0.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPowerCDF, StatsPowerPDF and StatsPowerNoise functions.
StatsInvQCDF

StatsInvQCDF(cdf, r, c, df)
The StatsInvQCDF function returns the critical value of the Q cumulative distribution function for r the number of groups, c the number of treatments, and df the error degrees of freedom (df=r*c*(n-1) with sample size n).

Details
The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use r=1.

Examples
The critical value for a Tukey test comparing 5 treatments with 6 samples and 0.05 significance is:
Print StatsInvQCDF(1-0.05,1,5,5*(6-1))

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsTukeyTest function.

StatsInvQpCDF

StatsInvQpCDF(ng, nt, df, alpha, side, sSizeWave)
The StatsInvQpCDF function returns the critical value of the Q’ cumulative distribution function for ng the number of groups, nt the number of treatments, and df the error degrees of freedom. side=1 for upper-tail or side=2 for two-tailed critical values.
sSizeWave is an integer wave of ng columns and nt rows specifying the number of samples in each treatment. If sSizeWave is a null wave ("" ) StatsInvQpCDF computes the number of samples from df=ng*nt*(n-1) with n truncated to an integer.

Details
StatsInvQpCDF is a modified Q distribution typically used with Dunnett’s test, which compares the various means with the mean of the control group or treatment.
StatsInvQpCDF differs from other StatsInvXXX functions in that you do not specify a cdf value for the inverse (usually 1-alpha for the critical value). Here alpha selects one- or two-tailed critical values.
It is computationally intensive, taking longer to execute for smaller alpha values.

Examples
The critical value for a Dunnett test comparing 4 treatments with 4 samples and (upper tail) 0.05 significance is:
// n=4 because 12=1*4*(4-1).
Print StatsInvQpCDF(1,4,12,0.05,1,""")
2.28734

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsDunnettTest and StatsInvQCDF functions.

StatsInvRayleighCDF

StatsInvRayleighCDF(cdf [, s [, m]])
The StatsInvRayleighCDF function returns the inverse of the Rayleigh cumulative distribution function given by
\[ x = \mu + \sigma \sqrt{-2 \ln (1 - cdf)} \],
with defaults s=1 and m=0. It returns NaN for s \leq 0 and zero for x \leq m.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRayleighCDF and StatsRayleighPDF functions.
StatsInvRectangularCDF

\[ \text{StatsInvRectangularCDF}(cdf, a, b) \]

The StatsInvRectangularCDF function returns the inverse of the rectangular (uniform) cumulative distribution function

\[ x = a + cdf(b - a), \quad a < b. \]

where \( a < b \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRectangularCDF and StatsRectangularPDF functions.

StatsInvSpearmanCDF

\[ \text{StatsInvSpearmanCDF}(cdf, N) \]

The StatsInvSpearmanCDF function returns the inverse cumulative distribution function for Spearman’s \( r \), which is used as a critical value in rank correlation tests.

The inverse distribution is computed by finding the value of \( r \) for which it attains the \( cdf \) value. The result is usually lower than in published tables, which are more conservative when the first derivative of the distribution is discontinuous.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRankCorrelationTest, StatsSpearmanRhoCDF, and StatsKendallTauTest functions.

StatsInvStudentCDF

\[ \text{StatsInvStudentCDF}(cdf, n) \]

The StatsInvStudentCDF function returns the numerically evaluated inverse of Student cumulative distribution function. There is no closed form expression.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsStudentCDF and StatsStudentPDF functions.

StatsInvTopDownCDF

\[ \text{StatsInvTopDownCDF}(cdf, N) \]

The StatsInvTopDownCDF function returns the inverse cumulative distribution function for the top-down distribution. For \( 3 \leq N \leq 7 \) it uses a lookup table CDF and returns the next higher value of \( r \) for which the distribution value is larger than \( cdf \). For \( 8 \leq N \leq 50 \) it returns the nearest value for which the built-in distribution returns \( cdf \). For \( N > 50 \) it returns the scaled normal approximation.

Tabulated values are from Iman and Conover who pick as the critical value the very first transition of the distribution following the specified \( cdf \) value. These tabulated values tend to be slightly higher than calculated values for \( 7 < N < 15 \).

References

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRankCorrelationTest and StatsTopDownCDF functions.

StatsInvTriangularCDF

\[ \text{StatsInvTriangularCDF}(cdf, a, b, c) \]

The StatsInvTriangularCDF function returns the inverse of the triangular cumulative distribution function
StatsInvUSquaredCDF

\[
x = \begin{cases} 
  a + \sqrt{\text{cdf}(b-a)(c-a)} & 0 \leq \text{cdf} \leq \frac{c-a}{b-a} \\
  b - \sqrt{(1-\text{cdf})(b-a)(b-c)} & \frac{c-a}{b-a} \leq \text{cdf} \leq 1 
\end{cases}
\]

where \(a < c < b\).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsTriangularCDF and StatsTriangularPDF functions.

StatsInvUSquaredCDF

StatsInvUSquaredCDF(cdf, n, m, method, useTable)

The StatsInvUSquaredCDF function returns the inverse of Watson’s \(U^2\) cumulative distribution function integer sample sizes \(n\) and \(m\). Use a nonzero value for useTable to search a built-in table of values. If \(n\) and \(m\) cannot be found in the table, it will proceed according to method:

<table>
<thead>
<tr>
<th>method</th>
<th>What It Does</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exact computation using Burr algorithm (could be slow).</td>
</tr>
<tr>
<td>1</td>
<td>Tiku approximation using chi-squared.</td>
</tr>
<tr>
<td>2</td>
<td>Use built-in table only and return a NaN if not in table.</td>
</tr>
</tbody>
</table>

For large \(n\) and \(m\), consider using the Tiku approximation. To abort execution, press the User Abort Key Combinations. Because \(n\) and \(m\) are interchangeable, \(n\) should always be the smaller value. For \(n\geq8\) the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with \(m\) values exceeding these limits.

The inverse is obtained from precomputed tables of Watson’s \(U^2\) (see StatsUSquaredCDF).

Note: Table values are different from computed values. These values use more conservative criteria than computed values. Table values are more consistent with published values because the \(U^2\) distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the X value of the next vertical transition to the one on which the specified P is found. See StatsInvFriedmanCDF.

References

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsWatsonUSquaredTest and StatsUSquaredCDF functions.

StatsInvVonMisesCDF

StatsInvVonMisesCDF(cdf, a, b)

The StatsInvVonMisesCDF function returns the numerically evaluated inverse of the von Mises cumulative distribution function where the value of the integral of the distribution matches cdf. Parameters are as for StatsVonMisesCDF.

References

V-944
StatsInvWeibullCDF

StatsInvWeibullCDF(cdf, m, s, g)
The StatsInvWeibullCDF function returns the inverse of the Weibull cumulative distribution function

\[ x = \mu + \sigma \left[-\ln(1 - cdf)\right]^{1/\gamma}. \]

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsVonMisesPDF and StatsVonMisesNoise functions.

StatsJBTest

StatsJBTest [flags] srcWave
The StatsJBTest operation performs the Jarque-Bera test on srcWave. Output is to the W_JBResults wave in the current data folder.

Flags
/ALPH = val Sets the significance level (default val=0.05).
/Q No results printed in the history area.
/T=k Displays results in a table. k specifies the table behavior when it is closed.
  \( k=0: \) Normal with dialog (default).
  \( k=1: \) Kills with no dialog.
  \( k=2: \) Disables killing.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
StatsJBTest computes the Jarque-Bera statistic

\[ JB = \frac{n}{6} \left(S^2 + \frac{K^2}{4}\right), \]

where \( S \) is the skewness, \( K \) is the kurtosis, and \( n \) is the number of points in the input wave. We can express \( S \) and \( K \) terms of the \( j \)th moment of the distribution for \( n \) samples \( X_i \)

\[ \mu_j = \frac{1}{n} \sum_{i=1}^{n} (X_i - \bar{X})^j \]

as

\[ S = \frac{\mu_3}{\left(\mu_2\right)^{3/2}}, \]

and
The Jarque-Bera statistic is asymptotically distributed as a Chi-squared with two degrees of freedom. For values of \( n \) in the range \([7,2000]\) the operation provides critical values obtained from Monte-Carlo simulations. For further details or if you would like to run your own simulation to obtain critical values for other values of \( n \), use the JarqueBeraSimulation example experiment.

StatsJBTest reports the number of finite data points, skewness, kurtosis, Jarque-Bera statistic, asymptotic critical value, and the critical value obtained from Monte-Carlo calculations as appropriate; it ignores NaNs and INFs.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; *StatsKSTest*, *WaveStats*, and *StatsCircularMoments*.

StatsKDE

StatsKDE [flags] srcWave
StatsKDE can be used to estimate a PDF from original data distribution. Unlike histograms, this method produces a smooth result as it constructs the PDF from a normalized superposition of kernel functions. The StatsKDE operation was added in Igor Pro 7.00.

Flags

/BWM=m Sets the bandwidth selection method.

\( m = 0 \): User-specified via /H flag

\( m = 1 \): Silverman

\( m = 2 \): Scott

\( m = 3 \): Bowmann and Azzalini

/DEST=destWave Specifies the output destination. Creates a real wave reference for the destination wave in a user function. See *Automatic Creation of WAVE References* on page IV-72 for details.

/FREE Makes the destination wave (specified by /DEST) a free wave.

/H=bw Specifies a fixed user-defined bandwidth.

/KT=kernel Specifies the kernel type.

\( kernel = 1 \): Epanechnikov

\( kernel = 2 \): Bi-weight

\( kernel = 3 \): Tri-weight

\( kernel = 4 \): Triangular

\( kernel = 5 \): Gaussian

\( kernel = 6 \): Rectangular

/Q No results printed in the history area. In the case of univariate KDE this flags suppresses the printing of the bandwidth value.

\( S = [x0,dx,xn] \) Specifies the range of the output starting from \( x = x0 \) to \( x = xn \) in increments of \( dx \).
Details
StatsKDE estimates the PDF of a distribution of values using a smoothing kernel and a bandwidth parameter which affects the degree of smoothing.
Theory suggests that the Epanechnikov kernel is the most efficient but many expressions for the optimal bandwidth are derived for the Gaussian kernel. If srcWave contains N points and the requested output (/S flag) has M points then the computational complexity is O(NM). For large problems it may be beneficial to use the Gaussian kernel via the FastGaussTransform operation.

References

See Also
Statistics on page III-383, Histogram, FastGaussTransform

StatsKendallTauTest
\[\text{StatsKendallTauTest} \ [\text{flags}] \ [\text{wave1}] \ [, \ \text{wave2}]\]
The StatsKendallTauTest operation performs the nonparametric Mann-Kendall test, which computes a correlation coefficient \( \tau \) (similar to Spearman’s correlation) from the relative order of the ranks of the data. Output is to the W_StatsKendallTauTest wave in the current data folder.

Flags
\[\text{/Q}\]
No results printed in the history area.
\[\text{/T=k}\]
Displays results in a table. \( k \) specifies the table behavior when it is closed.
\( k=0: \) Normal with dialog (default).
\( k=1: \) Kills with no dialog.
\( k=2: \) Disables killing.
\[\text{/Z}\]
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
Inputs may be a pair of XY (1D) waves of any real numeric type or a single 1D wave, which is equivalent to using a pair of XY waves where the X wave is monotonically increasing function of the point number. StatsKendallTauTest ignores wave scaling.
Kendall’s \( \tau \) is 1 for a monotonically increasing input and -1 for monotonically decreasing input. The significance of the test is computed from the normal approximation

\[\text{Var}(\tau) = \frac{4n + 10}{9n(n-1)},\]

where \( n \) is the number of data points in each wave. The significance is expressed as a P-value for the null hypothesis of no correlation.

References

See Also
Chapter III-12, Statistics for a function and operation overview; StatsRankCorrelationTest.
For small values of \( n \) you can compute the exact probability using the procedure WM_KendallSProbability().

/V-947
StatsKSTest

**StatsKSTest [flags] srcWave [, distWave]**

The StatsKSTest operation performs the Kolmogorov-Smirnov (KS) goodness-of-fit test for two continuous distributions. The first distribution is `srcWave` and the second distribution can be expressed either as the optional `wave distWave` or as a user function with `/CDFF`. Output is to the W_KSResults wave in the current data folder.

**Flags**

/ALPH = val  
Sets the significance level (default val=0.05).

/CDFF=func  
Specifies a user function expressing the cumulative distribution function. See Details.

/Q  
No results printed in the history area.

/T=k  
Displays results in a table. k specifies the table behavior when it is closed.
  
k=0: Normal with dialog (default).
  k=1: Kills with no dialog.
  k=2: Disables killing.

/Z  
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

**Details**

The Kolmogorov-Smirnov (KS) goodness-of-fit test applies only to continuous distributions and cases where the compared distribution (expressed as a user function) is completely specified without estimating parameters from the data. It compares the cumulative distribution function (CDF) of two distributions and sets the test statistic D to the largest difference between the CDFs. Because CDFs are in the range [0,1], D is also bound by this range.

When specifying the distributions with two waves, StatsKSTest first sorts the data in the waves and then computes the CDFs and D. You can also specify one of the distributions with a user function. For example, the following function tests if the data in `srcWave` is normally distributed with zero mean and stdv=5:

```plaintext
Function GetUserCDF(inX) : CDFFunc
    Variable inX
    return StatsNormalCDF(inX,0,5)
End
```

The " : CDFFunc" designation, which requires Igor7 or later, tells Igor to make the function accessible from the Kolmogorov-Smirnov Test dialog.

Outputs are the number of elements, the KS statistic D, and the critical value. When both distributions are specified by waves, the number of elements is the weighted value (n1*n2)/(n1+n2).

**References**

Critical values are based on:

A statistically more powerful modification of the classic KS test can be found in:

StatsKSTest implements the original KS test. The difficulty in implementing the modified tests for all the cases defined by Stephens is in obtaining the critical values which have to be derived by time consuming Monte-Carlo simulations.

Critiques can be found in:

See Also
Chapter III-12, Statistics for a function and operation overview; StatsJBTest, WaveStats, and StatsCircularMoments.

StatsKuiperCDF

StatsKuiperCDF(V)
The StatsKuiperCDF function returns the Kuiper cumulative distribution function

\[ F(V) = 1 - 2 \sum_{j=1}^{\infty} \left( 4^{j}V^{2} - 1 \right) \exp\left( -2^{j}V^{2} \right) . \]

Accuracy is on the order of 1e-15. It returns 0 for values of \( V < 0.4 \) or 1 for \( V > 3.1 \).

References
See in particular Section 14.3 of

See Also
Chapter III-12, Statistics for a function and operation overview; StatsInvKuiperCDF.

StatsKWTest

StatsKWTest [flags] [wave1, wave2,… wave100]
The StatsKWTest operation performs the nonparametric Kruskal-Wallis test which tests variances using the ranks of the data. Output is to the W_KWTestResults wave in the current data folder.

Flags

/ALPH = val Sets the significance level (default \( \text{val}=0.05 \)).

/E Computes the exact P-value using the Klotz and Teng algorithm, which may require long computation times for large data sets. You can stop the calculation by pressing the User Abort Key Combinations after which all remaining results remain valid and the exact P-value is set to NaN.

/Q No results printed in the history area.

/T=k Displays results in a table. \( k \) specifies the table behavior when it is closed.

k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.

/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z Ignores errors. \( V \_\text{flag} \) will be set to -1 for any error and to zero otherwise.

Details

Inputs are two or more 1D numerical waves (one for each group of samples). Use NaNs for missing data or use waves with different number of points.

StatsKWTest always computes the critical values using both the Chi-squared and Wallace approximations. If appropriate (small enough data set) you can also use /E to obtain the exact P value. When the calculation involves many waves or many data points the calculation of the exact critical value can be very lengthy. All the results are saved in the wave W_KWTestResults in the current data folder and are optionally displayed in a table (/T). The wave contains the following information:

\( H_{0} \) for the Kruskal-Wallis test is that all input waves are the same. If the test fails and the input consisted of more than two waves, there is no indication for possible agreement between some of the waves. See StatsNPMCTest for further analysis.
StatsLinearCorrelationTest

**References**

**See Also**
Chapter III-12, *Statistics* for a function and operation overview; *StatsWilcoxonRankTest*, *StatsNPMCTest*, and *StatsAngularDistanceTest*.

**StatsLinearCorrelationTest**

`StatsLinearCorrelationTest [flags] waveA, waveB`

The StatsLinearCorrelationTest operation performs correlation tests on waveA and waveB, which must be real valued numeric waves and must have the same number of points. Output is to the W_StatsLinearCorrelationTest wave in the current data folder or optionally to a table.

**Flags**

- `/ALPH = val` Sets the significance level (default `val`=0.05).
- `/CI` Computes confidence intervals for the correlation coefficient.
- `/Q` No results printed in the history area.
- `/RHO=rhoValue` Tests hypothesis that the correlation has a nonzero value |r| ≤ 1.
- `/T=k` Displays results in a table. k specifies the table behavior when it is closed.
  - k=0: Normal with dialog (default).
  - k=1: Kills with no dialog.
  - k=2: Disables killing.
- `/Z` Ignores errors.

**Details**

The linear correlation tests start by computing the linear correlation coefficient for the n elements of both waves:
Next it computes the standard error of the correlation coefficient

\[ sr = \sqrt{\frac{1 - r^2}{n - 2}} \]

The basic test is for hypothesis \( H_0 \): the correlation coefficient is zero, in which case \( t \) and \( F \) statistics are applicable. It computes the statistics:

\[ t = \frac{r}{sr} \]

and

\[ F = \frac{1 + |r|}{1 - |r|}, \]

and then the critical values for one and two tailed hypotheses (designated by \( t_{c1}, t_{c2}, F_{c1}, \) and \( F_{c2} \) respectively). Critical value for \( r \) are computed using

\[ r_{ci} = \sqrt{\frac{t_c^2}{t_c^2 + n}} \]

where \( i \) takes the values 1 or 2 for one and two tailed hypotheses. Finally, it computes the power of the test at the alpha significance level for both one and two tails (\( \text{Power1} \) and \( \text{Power2} \)).

If you use /RHO it uses the Fisher transformation to compute

\[ \text{FisherZ} = \frac{1}{2} \ln \left( \frac{1 + r}{1 - r} \right) \]

\[ \zeta = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right) \]

the standard error approximation

\[ \sigma_Z = \frac{1}{\sqrt{n - 3}} \]

\[ Z\text{statistic} = \frac{\text{FisherZ} - \zeta}{\sigma_Z} \]

and the critical values from the normal distribution \( Z_{ci} \).
The confidence intervals are calculated differently depending on the hypothesis for the value of the correlation coefficient. If /RHO is not used the confidence intervals are computed using the critical value $F_{c,2}$, otherwise they are computed using the critical $Z_{c,2}$ and sigmaZ.

References

See Also
Chapter III-12, Statistics for a function and operation overview; StatsCircularCorrelationTest, StatsMultiCorrelationTest, and StatsRankCorrelationTest.

StatsLinearRegression

StatsLinearRegression [flags] [wave0, wave1,...]
The StatsLinearRegression operation performs regression analysis on the input wave(s). Output is to the W_StatsLinearRegression wave in the current data folder or optionally to a table. Additionally, the M_DunnettMCElevations, M_TukeyMCSlopes, and M_TukeyMCElevations waves may be created as specified.

Flags
/ALPH = val Sets the significance level (default val=0.05).
/B=beta0 Tests the hypothesis that the slope $b=beta0$ (default is 0). The results are expressed by the t-statistic, which can be compared with the tc value for the two-tailed test. Get the critical value for a one-tailed test using StatsStudentCDF(1-alpha,N-2). It does not work with /MYVW.

/BCIW Computes two confidence interval waves for the high side and the low side of the confidence interval. The new waves are named with _CH and _CL suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.

/BPIW=mAdditional Computes prediction interval waves for the high side and the low side of the confidence interval on a single additional measurement (default). Use mAdditional to specify additional measurements. The new waves are named with _PH and _PL suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.

/DET=controlIndex Performs Dunnett’s multicomparison test for the elevations. The test requires more than two Y waves for regression, the test for the slopes should not reject the equal slope hypothesis, and the test for the elevations should reject the equal elevation hypothesis. controlIndex is the zero-based index of the Y wave representing the control (X waves do not count in the index specification). The test compares the elevation of every Y wave with the specified control.

Output is to the M_DunnettMCElevations wave in the current data folder or optionally to a table. For every Y wave and control Y wave combination, the results include SE, q, q’ (shown as qp), and the conclusion with 1 to accept the hypothesis of equal elevations or 0 to reject it. Use /TAIL to determine the critical value and the sense of the test. If you use /TUK you will also get the Tukey test for the set of elevations.

/MYVW={xWave, yWave}
Specifies that the input consists of multiple Y values for each X value. It ignores all other inputs and the results are appropriate only for multiple Y values at each X point. yWave is a 2D wave of values arranged in columns. Use NaNs for padding where rows do not have the same number of entries as others. It will use the X scaling of yWave when xWave is null, /MYVW={*, yWave}.
It first tests the hypothesis \( H_0 \) that the population regression is linear in an analysis of variance calculation. It generates results 1-7 (see Details) as well as: Among Groups SS, Among Groups DF, Within Groups SS, Within Groups DF, Deviations from Linearity SS, Deviations from Linearity DF, F statistic defined by the ratio of Deviation from Linearity MS to Within Groups MS, and the critical value Fc.

Next, it tests the hypothesis that the slope beta=0. If the original \( H_0 \) was accepted, the new F statistic=regressionMS/residualMS. Otherwise the with the critical F=regressionMS/WithinGroupsMS with a corresponding critical value. Finally, it reports the values of the coefficient of determination \( r^2 \) and the standard error of the estimate \( syx \).

/PAIR Specifies that the input waves are XY pairs, where each pair must be an X wave followed by a Y wave.

/Q No results printed in the history area.

/RTO Reflects the regression through the origin.

/T=k Displays results in a table. \( k \) specifies the table behavior when it is closed.

/k=0: Normal with dialog (default).

/k=1: Kills with no dialog.

/k=2: Disables killing.

/TAIL=tCode Sets the sense of the test when applying Dunnett’s test (see /DET). \( tCode \) is 1 or 2 for a one-tail critical value and 4 for a two-tail critical value.

/TUK Performs a Tukey-type test on multiple regressions on two or more Y waves. There are two possible Tukey-type tests: The first is performed if the hypothesis of equal slopes is rejected. It compares all combinations of two Y waves to identify if some of the waves have equal slopes. Output is to the M_TukeyMCSlopes wave in the current data folder or optionally to a table. For every Y wave pair, the results include the difference between slopes (absolute value), \( q \), the critical value \( qc \), and the conclusion set to 1 for accepting the equality of the pair of slopes or 0 for rejecting the hypothesis.

The second Tukey-type test is performed if all the slopes are the same but the elevations are not. The test (see /DET) compares all possible pairs of elevations to determine which satisfy the hypothesis of equality. Output is to the M_TukeyMCElevations wave in the current data folder.

/WSTR=waveListString Specifies a string containing a semicolon-separated list of waves that contain sample data. Use \( waveListString \) instead of listing each wave after the flags.

/Z Ignores errors.

Details

Inputs may consist of Y waves or XY wave pairs. If X data are not used, the X values are inferred from the Y wave scaling. For multiple waves where only some have pairs, use the /PAIR flag and enter * in each place where the X values should be computed.

For each input StatsLinearRegression calculates:
1. Least squares regression line \( y = a + bx \).
2. Mean value of \( X \): xBar.
3. Mean value of \( Y \): yBar.
4. Sum of the squares \( (x_i - \text{xBar})^2 \).
5. Sum of the squares \( (y_i - \text{yBar})^2 \).
6. Sum of the product \( (x_iy_i - \text{xyBar}) \).
7. Standard error of the estimate \( s^2 = \frac{\sum (y_i - \hat{y})^2}{n-2} \).
8. F statistic for the hypothesis \( \beta = 0 \).
9. Critical F value \( F_c \).
10. Coefficient of determination \( r^2 \).
11. Standard error of the regression coefficient \( S_b \).
12. t-statistic for the hypothesis \( \beta = \beta_0 \), NaN if \( /B \) is not specified.
13. Critical value \( t_c \) for the t-statistic above (used to calculate \( L_1 \) and \( L_2 \)).
14. Lower confidence interval boundary \( L_1 \) for the regression coefficient.
15. Upper confidence interval boundary \( L_2 \) for the regression coefficient.

For two \( Y \) waves with the same slope, it computes a common slope \( \beta_c \) and then tests the equality of the elevations \( \Delta \). In both cases it computes a t-statistic and compares it with a critical value. If the elevations are also the same then it computes the common elevation \( \Delta_c \) and the pooled means of \( X \) and \( Y \) in \( (X_p) \) and \( (Y_p) \).

For more than two \( Y \) waves it computes:

\[
A_c = \sum_{j=1}^{W} A_j; \quad A_j = \sum_{i=0}^{n_j-1} x_i^2 = \sum_{i=0}^{n_j-1} X_j^2 - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} X_i \right)^2
\]

\[
B_c = \sum_{j=1}^{W} B_j; \quad B_j = \sum_{i=0}^{n_j-1} x_i y_i = \sum_{i=0}^{n_j-1} X_i Y_i - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} X_i \right) \left( \sum_{i=0}^{n_j-1} Y_i \right)
\]

\[
C_c = \sum_{j=1}^{W} C_j; \quad C_j = \sum_{i=0}^{n_j-1} y_i^2 = \sum_{i=0}^{n_j-1} Y_i^2 - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} Y_i \right)^2
\]

\[
SS_p = \sum_{j=1}^{W} C_j - \frac{B_j^2}{A_j}
\]

\[
SS_c = C_c - \frac{B_c^2}{A_c^2}
\]

\[
SS_t = \sum_{j=1}^{W} \sum_{i=0}^{n_i} Y_{ji}^2 - \frac{1}{N} \left( \sum_{j=1}^{W} \sum_{i=0}^{n_i} X_{ji} \right)^2 = \left( \frac{\sum_{j=1}^{W} \sum_{i=0}^{n_i} X_{ji} Y_{ji} - \frac{1}{N} \left( \sum_{j=1}^{W} \sum_{i=0}^{n_i} X_{ji} \right) \left( \sum_{j=1}^{W} \sum_{i=0}^{n_i} Y_{ji} \right)}{N} \right)^2 \left( \frac{\sum_{j=1}^{W} \sum_{i=0}^{n_i} X_{ji}^2 - \frac{1}{N} \left( \sum_{j=1}^{W} \sum_{i=0}^{n_i} X_{ji} \right)^2}{N} \right)
\]
Here \( W \) is the number of Y-waves and \( N = \sum_{j=1}^{w} n_j \) is the total number of data points in all Y-waves.

The test statistic \( F \) for equality of slopes is given by:

\[
F = \left( \frac{SSc - SSP}{numWaves - 1} \right) \cdot \frac{SSP}{DFp}.
\]

\( Fc \) is the corresponding critical value. Output is to the \( W \_ \)LinearRegressionMC wave in the current data folder. \( V \_flag \) is set to -1 for any error and to zero otherwise. \( S \_waveNames \) is set to a semicolon-separated list of the names of the waves created by the operation.

Chapter III-12, Statistics for a function and operation overview; curvefit.

**StatsLogisticCDF**

**StatsLogisticCDF(\( x \), \( a \), \( b \))**
The StatsLogisticCDF function returns the logistic cumulative distribution function

\[
F(x; a, b) = \frac{1}{1 + \exp\left(-\frac{x - a}{b}\right)}
\]

where the scale parameter \( b>0 \) and the shape parameter is \( a \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogisticPDF and StatsInvLogisticCDF functions.

**StatsLogisticPDF**

**StatsLogisticPDF(\( x \), \( a \), \( b \))**
The StatsLogisticPDF function returns the logistic probability distribution function

\[
f(x; a, b) = \frac{\exp\left(-\frac{x - a}{b}\right)}{b\left[1 + \exp\left(-\frac{x - a}{b}\right)\right]^2},
\]
where the scale parameter \( b > 0 \) and the shape parameter is \( a \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogisticCDF and StatsInvLogisticCDF functions.

StatsLogNormalCDF

\( \text{StatsLogNormalCDF}(x, \sigma, \theta, \mu) \)

The StatsLogNormalCDF function returns the lognormal cumulative distribution function

\[
F(x; \sigma, \theta, \mu) = \frac{1}{\sigma \sqrt{2\pi}} \int_{0}^{x} \frac{1}{t-\theta} \exp \left\{ - \frac{\left[ \ln \left( \frac{t-\theta}{\mu} \right) \right]^2}{2\sigma^2} \right\} dt,
\]

for \( x > 0 \) and \( \sigma, \mu > 0 \). The standard lognormal distribution is for \( \theta = 0 \) and \( \mu = 1 \), which are the optional parameter defaults.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogNormalPDF and StatsInvLogNormalCDF functions.

StatsLogNormalPDF

\( \text{StatsLogNormalPDF}(x, \sigma, \theta, \mu) \)

The StatsLogNormalPDF function returns the lognormal probability distribution function

\[
f(x; \sigma, \theta, \mu) = \frac{1}{\sigma \sqrt{2\pi}} \frac{1}{x-\theta} \exp \left\{ - \frac{\left[ \ln \left( \frac{x-\theta}{\mu} \right) \right]^2}{2\sigma^2} \right\} ,
\]

for \( x > 0 \) and \( \sigma, \mu > 0 \), where \( \theta \) is the location parameter, \( \mu \) is the scale parameter and, \( \sigma \) is the shape parameter. The standard lognormal distribution is for \( \theta = 0 \) and \( \mu = 1 \), which are the optional parameter defaults.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogNormalCDF and StatsInvLogNormalCDF functions.

Reference
The expression for the PDF follows the NIST definition at: https://www.itl.nist.gov/div898/handbook/eda/section3/eda3669.htm. Note that alternate definitions use \( \mu \) differently.

StatsMaxwellCDF

\( \text{StatsMaxwellCDF}(x, k) \)

The StatsMaxwellCDF function returns the Maxwell cumulative distribution function

\[
F(x; k) = \text{gammp} \left( \frac{3}{2}, \frac{kx^2}{2} \right), \quad x > 0.
\]

where \( \text{gammp} \) is the regularized incomplete gamma function.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsMaxwellPDF and StatsInvMaxwellCDF functions.
StatsMaxwellPDF

\texttt{StatsMaxwellPDF(x, k)}

The StatsMaxwellPDF function returns Maxwell’s probability distribution function

\[ f(x; k) = \sqrt{\frac{2}{\pi}} k^{3/2} x^2 \exp\left(-\frac{kx^2}{2}\right), \quad x > 0. \]

The Maxwell distribution describes, for example, the speed distribution of molecules in an ideal gas.

See Also
Chapter III-12, Statistics for a function and operation overview; the \texttt{StatsMaxwellCDF} and \texttt{StatsInvMaxwellCDF} functions.

StatsMedian

\texttt{StatsMedian(waveName)}

The StatsMedian function returns the median value of a numeric wave \texttt{waveName}, which must not contain NaNs.

Example

Make/N=5 sample1={1,2,3,4,5}
Print StatsMedian(sample1)
3
Make/N=6 sample2={1,2,3,4,5,6}
Print StatsMedian(sample2)
3.5

See Also
Chapter III-12, Statistics for a function and operation overview
\texttt{median}, \texttt{WaveStats}, \texttt{StatsQuantiles}

StatsMooreCDF

\texttt{StatsMooreCDF(x, N)}

The StatsMooreCDF function returns the cumulative distribution function for Moore’s R*, which is used in a nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range \( 3 \leq N \leq 120 \) and does not change appreciably for \( N > 120 \).

The distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

References

See Also
Chapter III-12, Statistics for a function and operation overview; the \texttt{StatsCircularMeans} function.

StatsMultiCorrelationTest

\texttt{StatsMultiCorrelationTest [flags] corrWave, sizeWave}

The StatsMultiCorrelationTest operation performs various tests on multiple correlation coefficients. Inputs are two 1D waves: \texttt{corrWave}, containing correlation coefficients, and \texttt{sizeWave}, containing the size (number of elements) of the corresponding samples. Although you can do all the tests at the same time, it rarely makes sense to do so.

Flags

/ALPH = val \hspace{1cm} \text{Sets the significance level (default \texttt{val}=0.05).}

/CON=[controlRow,tails]
StatsMultiCorrelationTest

Performs a multiple comparison test using the controlRow element of corrWave as a control. It is one- or twoailed test according to the tails parameter. Output is to the M_ControlCorrTestResults wave in the current data folder.

/CONT=cWave

Performs a multiple contrasts test on the correlation coefficients. The contrasts wave, cWave, contains the contrast factor, c_i, entry for each of the n correlation coefficients r_i in corrWave, and satisfying the condition that the sum of the entries in cWave is zero. H_0 corresponds to

\[ \sum_{i=0}^{n-1} c_i r_i = 0. \]

The test statistic S is

\[ S = \frac{1}{\sqrt{\sum_{i=0}^{n-1} c_i^2}} \left[ \sum_{i=0}^{n-1} c_i z_i \right] \sqrt{n_i - 3}, \]

where z_i is the Fisher z transform of the correlation coefficient r_i:

\[ z_i = \frac{1}{2} \ln \left( \frac{1 + r_i}{1 - r_i} \right). \]

It produces the SE value, the contrast statistic S, and the critical value, which are labeled ContrastSE, ContrastS, and Contrast_Critical, respectively, in the W_StatsMultiCorrelationTest wave.

/Q

No results printed in the history area.

/T=k

Displays results in a table. k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

/TUK

Performs a Tukey-type multi comparison testing between the correlation coefficients by comparing every possible combination of pairs of correlation coefficients, computing the difference in their z-transforms, the SE, and the q statistic:

\[ q = \sqrt{\frac{\left| z_j - z_i \right|^2}{\frac{1}{n_i - 3} + \frac{1}{n_j - 3}}}. \]

The critical value is computed from the q CDF (StatsInvQCDF) with degrees of freedom numWaves and infinity. Output is to the M_TukeyCorrTestResults wave in the current data folder or optionally to a table.

/Z

Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Without any flags, StatsMultiCorrelationTest computes \( \chi^2 \) for the correlation coefficients and compares it with the critical value.
where $z_i$ is the Fisher’s z transform of the correlation coefficients and $n_i$ is the corresponding sample size. It computes the common correlation coefficient $r_w$ and its transform $z_w$.

\[
z_w = \frac{\sum_{i=0}^{n-1} z_i (n_i - 3)}{\sum_{i=0}^{n-1} (n_i - 3)}
\]

These values are calculated even when not appropriate, such as when $\chi^2$ exceeds the critical value and $H_0$ (all samples came from populations of identical correlation coefficients) is rejected.

The operation also computes ChiSquaredP (due to S.R. Paul), a different variant of $\chi^2$ that is corrected for bias and should be compared with the same critical value. Output is to the W_StatsMultiCorrelationTest wave in the current data folder or optionally to a table.

*StatsLinearCorrelationTest, StatsCircularCorrelationTest, StatsDunnettTest, StatsTukeyTest, StatsInvQCDF, and StatsScheffeTest.*

### StatsNBinomialCDF

**StatsNBinomialCDF**($x$, $k$, $p$)
The StatsNBinomialCDF function returns the negative binomial cumulative distribution function

\[
F(x;k,p) = \text{Beta}(k,x+1;p),
\]

where \text{beta} is the regularized incomplete beta function.

See Also
Chapter III-12, *Statistics* for a function and operation overview; the *StatsNBinomialPDF* and *StatsInvNBinomialCDF* functions.

### StatsNBinomialPDF

**StatsNBinomialPDF**($x$, $k$, $p$)
The StatsNBinomialPDF function returns the negative binomial probability distribution function

\[
f(x;k,p) = \binom{x+k-1}{k-1} p^k (1-p)^x, \quad x = 0,1,2...
\]

where \( \binom{a}{b} \) is the \text{binomial} function.

The binomial distribution expresses the probability of the kth success in the $x+k$ trial for two mutually exclusive results (success and failure) and $p$ the probability of success in a single trial.
StatsNCChiCDF

StatsNCChiCDF(\(x, n, d\))
The StatsNCChiCDF function returns the noncentral chi-squared cumulative distribution function

\[
F(x; n, d) = \sum_{i=1}^{\infty} \exp(d/2) \frac{(d/2)^i}{i!} F_c(x; n + 2i),
\]

where \(n > 0\) corresponds to degrees of freedom, \(d \geq 0\) is the noncentrality parameter, and \(F_c\) is the central chi-squared distribution.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; the StatsChiCDF, StatsNCChiPDF, and StatsChiPDF functions.

StatsNCChiPDF

StatsNCChiPDF(\(x, n, d\))
The StatsNCChiPDF function returns the noncentral chi-squared probability distribution function

\[
f(x; n, d) = \sqrt{d} \exp\left(-\frac{x + d}{2}\right) x^{(n-1)/2} \frac{I_{n/2-1}(\sqrt{d}x)}{2(dx)^{n/4}}.
\]

where \(n > 0\) is the degrees of freedom, \(d \geq 0\) is the noncentrality parameter, and \(I_n(x)\) is the modified Bessel function of the first kind, *bessI*.

See Also
Chapter III-12, *Statistics* for a function and operation overview; the StatsNCChiCDF, StatsInvNCChiCDF, StatsChiCDF, and StatsChiPDF functions.

StatsNCFCDF

StatsNCFCDF(\(x, n1, n2, d\))
The StatsNCFCDF function returns the cumulative distribution function of the noncentral F distribution. \(n1\) and \(n2\) are the shape parameters and \(d\) is the noncentrality measure. There is no closed form expression for the distribution.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; the StatsNCFPDF and StatsInvNCFCDF functions.

StatsNCFPDF

StatsNCFPDF(\(x, n1, n2, d\))
The StatsNCFPDF function returns the probability distribution function of the noncentral F distribution
\[ f(x; n_1, n_2, d) = \frac{\exp\left(-d/2\right)}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)} x^{n_1/2-1} \left(x n_1 + n_2\right)^\left(-\left(n_1+n_2\right)/2\right) \frac{n_1}{2}^{n_1/2} n_2^{n_2/2} \, _1F_1\left(\frac{n_1+n_2}{2}, \frac{n_1}{2}, \frac{xdn_1}{x n_1 + n_2}\right), \]

where \(B()\) is the beta function and \(_1F_1()\) is the hypergeometric function \(\text{hyperG1F1}\).

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; the StatsNCFCDF and StatsInvNCFCDF functions.

**StatsNCTCDF**

\(\text{StatsNCTCDF}(x, df, d)\)

The StatsNCTCDF function returns the cumulative distribution function of the noncentral Student-T distribution. \(df\) is the degrees of freedom (positive integer) and \(d\) is the noncentrality measure. There is no closed form expression for the distribution.

**References**

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; the StatsStudentCDF, StatsStudentPDF, and StatsNCTPDF functions.

**StatsNCTPDF**

\(\text{StatsNCTPDF}(x, df, d)\)

The StatsNCTPDF function returns the probability distribution function of the noncentral Student-T distribution. \(df\) is the degrees of freedom (positive integer) and \(d\) is the noncentrality measure.

\[ f(x; n, \delta) = \frac{n^{n/2} n!}{2^n e^{\delta^2/2} (n + x^2)^{n/2} \Gamma\left(n/2\right)} \sqrt{2} \delta x_1 \frac{1}{2\Gamma\left(n/2\right)} \left\{ \frac{\left(n + l + 1 \cdot \frac{3}{2} \cdot \frac{\delta^2 x^2}{2(n + x^2)}\right)}{\left(n + l + 1\right) \Gamma\left(n/2\right)} + \frac{\left(1 + \frac{1}{2} \cdot \frac{\delta^2 x^2}{2(n + x^2)}\right)}{\sqrt{(n + l + 1)} \Gamma\left(n/2 + 1\right)} \right\} + \frac{\left(\frac{n + l + 1}{2} \cdot \frac{\delta^2 x^2}{2(n + x^2)}\right)}{\sqrt{(n + l + 1)} \Gamma\left(n/2 + 1\right)} \right\}. \]

**References**

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; the StatsStudentPDF, StatsStudentCDF, and StatsNCTCDF functions.

**StatsNormalCDF**

\(\text{StatsNormalCDF}(x, m, s)\)

The StatsNormalCDF function returns the normal cumulative distribution function

\[ F(x, \mu, \sigma) = \frac{1}{2} + \frac{1}{2} \text{erf}\left(\frac{x - \mu}{\sigma \sqrt{2}}\right), \]
StatsNormalPDF

where \( \text{erf} \) is the error function.

See Also
Chapter III-12, Statistics for a function and operation overview; the \( \text{erf} \), \text{StatsNormalPDF} and \text{StatsInvNormalCDF} functions.

\[
f(x, \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp \left( -\frac{(x - \mu)^2}{2\sigma^2} \right).
\]

See Also
Chapter III-12, Statistics for a function and operation overview; the \text{StatsNormalCDF} and \text{StatsInvNormalCDF} functions.

StatsNPMCTest

\[
\text{StatsNPMCTest} \quad \text{[flags]} \quad \text{[wave1, wave2, ... wave100]}
\]

The StatsNPMCTest operation performs a number of nonparametric multiple comparison tests. Output waves are saved in the current data folder according to the test(s) performed. Some tests are only appropriate when you have the same number of samples in all groups. StatsNPMCTest usually follows \text{StatsANOVA1Test} or \text{StatsKWTest}.

Flags

/ALPH = val \quad \text{Sets the significance level (default val=0.05).}

/CIDX=controlIndex \quad \text{Performs nonparametric multiple comparisons on a control group specified by the zero-based controlIndex wave in the input list. Output is to the M_NPCCResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the rank sums of the control and each of the other waves; the second contains the standard error (SE); the third contains the statistic q, defined as the ratio of the difference in rank sums to SE; the fourth contains the critical value which also depends on the tails specification (see /TAIL); and the fifth contains the conclusion with 0 to reject \( H_0 \) and 1 to accept it. One version of this test applies when all inputs contain the same number of samples. When that is not the case, it uses the Dunn-Hollander-Wolfe approach to compute an appropriate SE and to handle possible ties.}

/CONW=cWave \quad \text{Performs a nonparametric multiple contrasts tests. cWave has one point for each input wave. The cWave value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave.}

The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If \( cWave=[0,1,1,1,2] \), then the contrast is computed as

\[
\text{contrast} = \frac{1}{3} R_{w1} + R_{w2} + R_{w3} - R_{w4}
\]

where \( R_{wi} \) is the normalized rank sum of the samples from the corresponding input wave. Note the significance of allowing zeros in the contrast wave because the actual ranking is performed on the pool of all the samples.
Output is to the M_NPMConResults wave in the current data folder or optionally to a table. The output column contents are: the first is the contrast value; the second is the standard error (SE); the third is the statistic S, which is the ratio of the absolute value of the contrast to SE; the fourth is the critical value (from $\chi^2$ the approximation); and the fifth is the conclusion with 0 to reject $H_0$ and 1 indicating acceptance.

This test supports input waves with different number of samples and can also handle tied ranks. Note that the contrast wave used here is structured differently than for StatsMultiCorrelationTest.

/DHW
Performs the Dunn-Holland-Wolfe test, which supports unequal number of samples and accounts for ties in the rank sums. Output is to the M_NPMCDHWResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the means of the rank sums (rank sums divided by the number of samples in the group), the second contains the standard error (SE), the third contains the DHW statistic Q, the fourth contains the critical value, and the fifth contains the conclusion (0 to reject $H_0$ and 1 to accept).

/Q
No results printed in the history area.

/SWN
Creates a text wave containing wave names corresponding to each row of the comparison table. Depending on your choice of tests, the following wave names are created:

/CIDX test: T_NPCCResultsDescriptors
/DHW test: T_NPMCDHWDescriptors
/SNK test: T_NPMCSNKResultsDescriptors
/TUK test: T_NPMCTukeyDescriptors

/T=k
Displays results in a table. $k$ specifies the table behavior when it is closed.

$k=0$: Normal with dialog (default).
$k=1$: Kills with no dialog.
$k=2$: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.

/TAIL=tC
Specifies $H_0$ with /CIDX.

$tC=1$: One tailed test ($\mu_c \leq \mu_a$).
$tC=2$: One tailed test ($\mu_c \geq \mu_a$).
$tC=4$: Default; two tailed test ($\mu_c = \mu_a$).

Code combinations are not allowed.

/SNK
Performs a nonparametric variation on the Student-Newman-Keuls test where the standard error SE is a function of $p$ (the rank difference). This test requires equal numbers of samples in all groups; use /DHW for unequal sizes.

Output is to the M_NPMCSNKResults wave in the current data folder. The output column contents are: the first contains the difference between rank sums, the second contains the standard error (SE), the third contains the $p$ value (rank difference), the fourth the statistic, the fifth contains the critical value, and the sixth contains the conclusion (0 to reject $H_0$ and 1 to accept). This test is more sensitive to differences than the Tukey test (/TUK).
StatsNPNominalSRTest

/TUK Perform a Tukey-type (Nemenyi) multiple comparison test using the difference between the rank sums. This is the default that is performed if you do not specify any of the test flags. This test requires equal numbers of points in all waves; use /DHW for unequal sizes.

Output is to the M_NPMCTukeyResults wave in the current data folder. The output column contents are: the first contains the difference between the rank sums, the second contains the SE values, the third contains the statistic q, the fourth contains the critical value for this specific alpha and the number of groups; and the last contains a conclusion flag with 0 indicating a rejection of H₀ and 1 indicating acceptance. H₀ postulates that the paired means are the same.

/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z Ignores errors.

Details
Inputs to StatsNPMCTest are two or more 1D numerical waves (one wave for each group of samples) containing two or more valid entries. The waves must have the same number of points for the use /SNK and /TUK tests, otherwise, for waves of differing lengths you must use the Dunn-Hollander-Wolfe test (/DHW).

V_flag will be set to zero for no execution errors. Individual tests may fail if, for example, there are different number of samples in the input waves for a test that requires an equal number of points. StatsNPMCTest skips failed tests and V_flag will be a binary combination identifying the failed test(s):

- V_flag & 1 Tukey method failed (/TUK).
- V_flag & 2 Student-Newman-Keuls failed (/SNK).

V_flag will be set to -1 for any other errors.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test and StatsKWTest.
For multiple comparisons in parametric tests see: StatsDunnettTest and StatsScheffeTest.

StatsNPNominalSRTest

StatsNPNominalSRTest [flags] [srcWave]

The StatsNPNominalSRTest operation performs a nonparametric serial randomness test for nominal data consisting of two types. The null hypothesis is that the data are randomly distributed. Output is to the W_StatsNPSRTest wave in the current data folder.

Flags

/ALPH = val Sets the significance level (default val=0.05).
/Q No results printed in the history area.
/P=[m,n,u] Provides a summary of the data instead of providing the nominal series. m is the number of elements of the first type, n is the number of elements of the second type, and u is the number of runs or contiguous sequences of each type. Do not use srcWave with /P.
/T=k Displays results in a table. k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.
/Z Ignores errors.
StatsParetoCDF

The StatsParetoCDF function returns the Pareto cumulative distribution function

\[ F(x; a, c) = 1 - \left( \frac{a}{x} \right)^c. \]

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsParetoPDF and StatsInvParetoCDF functions.

StatsParetoPDF

The StatsParetoPDF function returns the Pareto probability distribution function

\[ f(x; a, c) = \begin{cases} \frac{c}{x} \left( \frac{a}{x} \right)^c, & a, c > 0 \\ x \geq a. \end{cases} \]

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsParetoCDF and StatsInvParetoCDF functions.

StatsPermute

The StatsPermute function permutes elements in waveA based on the lexicographic order of waveB and the direction dir. It returns 1 if a permutation is possible and returns 0 otherwise. Use dir=1 for the next permutation and dir=-1 for a previous permutation.

Details
Both waveA and waveB must be numeric. The lexicographic order of elements in the index wave is set so that permutations start with the index wave waveB in ascending order and end in descending order. Elements of waveA are permuted in place according to the order of the indices in waveB which are clipped (after permutation) to the valid range of entries in waveA. waveB is also permuted in place in order to allow you to obtain sequential permutations. If waveA consists of real numbers you can permute them using the lexicographic value of the entries directly. To do so pass "" for waveB. Whenever it returns 0, neither waveA and waveB are changed.
StatsPoissonCDF

Examples
Function AllPermutations(num)
    Variable num
    Variable i,nf=factorial(num)
    Make/O/N=(num) wave0=p+1,waveA,waveB=p
    Print wave0
    for(i=0;i<nf;i+=1)
        waveA=wave0
        if(statsPermute(waveA,waveB,1)==0)
            break
        endif
        print waveA
    endfor
end
Executing AllPermutations(3) prints:
wave0[0] = {1,2,3}
wwaveA[0] = {1,3,2}
wwaveA[0] = {2,1,3}
wwaveA[0] = {2,3,1}
wwaveA[0] = {3,1,2}
wwaveA[0] = {3,2,1}

See Also
Chapter III-12, Statistics for a function and operation overview.

StatsPoissonCDF
StatsPoissonCDF(x, λ)
The StatsPoissonCDF function returns the Poisson cumulative distribution function

\[ F(x; \lambda) = \sum_{i=0}^{x} \frac{\exp(-\lambda) \lambda^i}{i!}, \quad x = 0,1,2... \]

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPoissonPDF and StatsInvPoissonCDF functions.

StatsPoissonPDF
StatsPoissonPDF(x, λ)
The StatsPoissonPDF function returns the Poisson probability distribution function

\[ f(x; \lambda) = \frac{\exp(-\lambda) \lambda^x}{x!}, \quad x = 0,1,2... \]

where \( \lambda \) is the shape parameter.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPoissonCDF and StatsInvPoissonCDF functions.

StatsPowerCDF
StatsPowerCDF(x, b, c)
The StatsPowerCDF function returns the Power Function cumulative distribution function

\[ F(x; b, c) = \left( \frac{x}{b} \right)^c \]

where the scale parameter \( b \) and the shape parameter \( c \) satisfy \( b,c > 0 \) and \( b \geq x \geq 0 \).
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPowerPDF, StatsInvPowerCDF and StatsPowerNoise functions.

StatsPowerNoise
StatsPowerNoise(b, c)
The StatsPowerNoise function returns a pseudorandom value from the power distribution function with probability distribution:

\[ f(x; b, c) = \frac{c x^c}{b^c} \cdot \]

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

See Also
The SetRandomSeed operation.
The StatsPowerPDF StatsInvPowerCDF and StatsInvPowerCDF functions.
Noise Functions on page III-390.
Chapter III-12, Statistics for a function and operation overview.

StatsPowerPDF
StatsPowerPDF(x, b, c)
The StatsPowerPDF function returns the Power Function probability distribution function

\[ f(x, b, c) = \frac{c x^c}{x^b} \cdot \]

where b is a scale parameter and c is a shape parameter.
For b,c > 0, x is drawn from b >= x >= 0.
For b>0, c<0, x is drawn from x>b.
For b<0, c>0, x is drawn from -b <= x <= 0.
For b<0, c<0, x is drawn from x<-b.
Note that for -1<c<0 the average diverges and the magnitude of a mean calculated from N samples will increase indefinitely with N.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPowerCDF, StatsInvPowerCDF and StatsPowerNoise functions.

StatsQCDF
StatsQCDF(q, r, c, df)
The StatsQCDF function returns the value of the Q cumulative distribution function for r the number of groups, c the number of treatments, and df the error degrees of freedom (f=rc(n-1) with sample size n).

Details
The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use r=1.

References
StatsQpCDF

**StatsQpCDF**

*StatsQpCDF*(q, nr, nt, dt, side, sSizeWave)

The `StatsQpCDF` function returns the Q' cumulative distribution function associated with Dunnett's test.

Here `nr` is the number of groups (should be set to 1), `nt` is the number of treatments, `df` is the error degrees of freedom.

Set `side`=1 for upper-tail or `side`=2 for two-tailed CDF.

`sSizeWave` is an integer wave of `nt` rows specifying the number of samples in each treatment.

**Details**

`StatsQpCDF` is a modified Q distribution typically used with Dunnett's test, which compares the various means with the mean of the control group or treatment.

**References**

**See Also**

Chapter III-12, Statistics for a function and operation overview; the `StatsDunnettTest`, `StatsInvQpCDF`, and `StatsInvQCDF` functions.

StatsQuantiles

*StatsQuantiles* `[flags] srcWave

The `StatsQuantiles` operation computes quantiles and elementary univariate statistics for a set of data in `srcWave`.

**Flags**

/ALL Invokes all flags except /Q, /QM, and /Z.

/BOX Computes parameters necessary to construct a box plot.

/iNaN Ignores NaNs, which are sorted to the end of the array by default.

/IW Creates an index wave W_QuantilesIndex. W_QuantilesIndex[i] corresponds to the position of srcWave[i] when sorted from minimum to maximum.

/Q No information printed in the history area.

/QM=qMethod Specifies the method for computing quartiles. qMethod has one of these values:

0: Tukey (default).

1: Minitab.

2: Moore and McCabe.

3: Mendenhall and Sincich.

See Details for more information.

/QW Creates a single precision wave W_QuantileValues containing the quantile value corresponding to each entry in srcWave.

/STBL Uses a stable sort, which may require significant computation time for multiple entries with the same value.
StatsQuantiles produces quick five-number summaries or more detailed results for univariate data. Values are returned in the wave W_StatsQuantiles and in the variables:

- V_min Minimum value.
- V_max Maximum value.
- V_Median Median value.
- V_Q25 Lower quartile.
- V_Q75 Upper quartile.
- V_IQR Inter-quartile range V_Q75-VQ25, which is also known as the H-spread.
- V_MAD Median absolute deviation.
- V_mode The most frequent value.
  - If there is a tie and several values have the highest frequency then the lowest value among them is returned as the mode.
  - If all values in srcWave are unique or if the number of points in srcWave is less than 3, V_mode is set to NaN.

This output was added in Igor Pro 7.00.

Entries in the wave W_StatsQuantiles depend on your choice of flags. Each row has a row label explicitly defining its value. If you use the /ALL flag, W_StatsQuantiles will contain the following row labels:

- minValue
- maxValue
- Median
- Q25
- Q75
- IQR
- MedianAbsoluteDeviation

Otherwise, W_StatsQuantiles will contain the first five entries and any additionally requested value. You should always access values using the dimension labels (see Dimension Labels on page II-93).

There is frequently some confusion in comparing statistical results computed by different programs because each may use a different definition of quartiles. You can specify the method of computing the quartiles as you prefer with the /QM flag. If you neglect to choose a method, StatsQuantiles uses Tukey’s method, which computes quartiles (also called hinges) as the lower and upper median values between the
median of the data and the edges of the array. The Moore and McCabe method is similar to Tukey’s method except you do not include the median itself in computing the quartiles. Mendenhall and Sincich compute the quartiles using 1/4 and 3/4 of (numDataPoints+1) and round to the nearest integer (if the fraction part is exactly 0.5 they round up for the lower quartile and down for the upper quartile). Minitab uses the same expressions but instead of rounding it uses linear interpolation.

StatsQuantiles uses a stable index sorting routine so that
\[ \text{IndexSort } W_{\text{QuantilesIndex}}, \text{srcWave} \]
is a monotonically increasing wave.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; WaveStats, StatsMedian, Sort, and MakeIndex.

StatsRankCorrelationTest

StatsRankCorrelationTest \([flags]\) waveA, waveB

The StatsRankCorrelationTest operation performs Spearman’s rank correlation test on \(waveA\) and \(waveB\), 1D waves containing the same number of points. Output is to the \(W_{\text{StatsRankCorrelationTest}}\) wave in the current data folder.

Flags

/ALPH = val  Sets the significance level (default \(val=0.05\)).
/P=method  Controls the computation of the P-value.

The /P flag was added in Igor Pro 9.00.

\(method=0\): If the number of data points is less than or equal to 6 then an exact calculation is made. This is the default if /P is omitted.

\(method=1\): The P-value is computed using the Edgeworth approximation.

\(method=2\): The P-value is computed using the Student-T approximation.

This is appropriate when the number of data points is large.

/Q  No results printed in the history area.

/T=k  Displays results in a table. \(k\) specifies the table behavior when it is closed.

\(k=0\): Normal with dialog (default).

\(k=1\): Kills with no dialog.

\(k=2\): Disables killing.

/Z  Ignores errors.

Details
StatsRankCorrelationTest ranks \(waveA\) and \(waveB\) and then computes the sum of the squared differences of ranks for all rows. Ties are assigned an average rank and the corrected Spearman rank correlation coefficient is computed with ties. It reports the sum of the squared ranks (\(\text{sumDi2}\)), the sums of the ties coefficients (\(\text{sumTx} \) and \(\text{sumTy}\) respectively), the Spearman rank correlation coefficient (in the range \([-1,1]\)), and the critical value. \(H_0\) corresponds to zero correlation against the alternative of nonzero correlation. The critical value is usually lower than the one in published tables. When the first derivative of the CDF is discontinuous, tables tend to use a more conservative value by choosing the next transition of the CDF as the critical value. StatsRankCorrelationTest is not as powerful as StatsLinearCorrelationTest.

See Also
Chapter III-12, *Statistics* for a function and operation overview.
StatsRayleighCDF

StatsRayleighCDF(x [, s [, m]])
The StatsRayleighCDF function returns the Rayleigh cumulative distribution function

\[ F(x; \sigma, \mu) = 1 - \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right), \quad \sigma > 0, x > \mu. \]

with defaults \( s=1 \) and \( m=0 \). It returns NaN for \( s \leq 0 \) and zero for \( x \leq m \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRayleighPDF and StatsInvRayleighCDF functions.

StatsRayleighPDF

StatsRayleighPDF(x [, s [, m]])
The StatsRayleighPDF function returns the Rayleigh probability distribution function

\[ f(x; \sigma, \mu) = \frac{x - \mu}{\sigma^2} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right), \quad \sigma > 0, x > \mu. \]

with defaults \( s=1 \) and \( m=0 \). It returns NaN for \( s \leq 0 \) and zero for \( x \leq m \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRayleighCDF and StatsInvRayleighCDF functions.

StatsRectangularCDF

StatsRectangularCDF(x, a, b)
The StatsRectangularCDF function returns the rectangular (uniform) cumulative distribution function

\[
F(x, a, b) = \begin{cases} 
0 & x \leq a \\
\frac{x - a}{b - a} & a \leq x \leq b \\
1 & x \geq b
\end{cases}
\]

where \( a < b \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRectangularPDF and StatsInvRectangularCDF functions.

StatsRectangularPDF

StatsRectangularPDF(x, a, b)
The StatsRectangularPDF function returns the rectangular (uniform) probability distribution function

\[
f(x; a, b) = \begin{cases} 
\frac{1}{b - a} & a \leq x \leq b \\
0 & otherwise
\end{cases}
\]
where \(a < b\).

**See Also**
Chapter III-12, *Statistics* for a function and operation overview; the *StatsRectangularCDF* and *StatsInvRectangularCDF* functions.

### StatsResample

**StatsResample**

**StatsResample /N=numPoints** [flags] **srcWave**

The StatsResample operation resamples `srcWave` by drawing (with replacement) `numPoints` values from `srcWave` and storing them in the wave W_Resampled or M_Resampled if /MC is used. You can iterate the process and compute various statistics on the data samples.

**Flags**

/ITER=n 
 Repeats the resampling for \(n\) iterations, which is useful only when combined with /WS or /SQ.

The /ITER flag is ignored by the Jack-Knife analysis (/JCKN).

/JCKN=ufunc 
 Performs Jack-Knife analysis. Here ufunc is a user function of the format:

```
Function ufunc(inWave)
  wave inWave
  ... compute some statistic for inWave
  return someValue
End
```

The results are stored in the wave W_JackKnifeStats in the current data folder. Use Edit W_JackKnifeStats.ld to display the wave with dimension labels.

In the Jack-Knife method the operation runs \(N\) iterations where \(N\) is the number of points in `srcWave`. In each iteration the operation calls the user-defined function `ufunc(inWave)` passing it an internal wave which contains (\(N-1\)) samples from `srcWave`. The function computes some user-defined statistic, say "\(Z\)", and stores it in `inWave`. At the end of iterations the operation uses the \(Z\) values in `inWave` to compute various Jack-Knife estimates. The standard estimator is defined as:

\[
Z = ufunc(srcWave).
\]

The Jack-Knife estimator is simply:

\[
\hat{z} = \frac{1}{n} \sum_{i=1}^{n} z_i.
\]

The Jack-Knife t-estimator is slightly less biased. It is given by:

\[
t = nZ - (n - 1)\hat{z},
\]

The estimate of the standard error is given by:

\[
\hat{\sigma}_\hat{z} = \sqrt{\frac{n-1}{n} \sum_{i=1}^{n} (z_i - \hat{z})^2}.
\]

The Jack-Knife analysis ignores the /N and /ITER flags. The number of points and the number of iterations are determined by the number of points in `srcWave`. 

V-972
StatsResample can perform Bootstrap Analysis, permutations tests, and Monte-Carlo simulations. It draws the specified number of data points (with replacement) from `srcWave` and places them in a destination wave `W_Resampled`.

Specify `/WS` or `/SQ` to use the WaveStats or StatsQuantiles operations, respectively, to compute results directly from the data. StatsResample normally creates the wave `W_Resampled` and, optionally, the `M_WaveStats` and `W_StatsQuantiles` waves. Both options also create various V_variables described below. If you use more than one iteration, StatsResample creates instead the waves `M_WaveStatsSamples` and `M_StatsQuantilesSamples` for the results.

M_WaveStatsSamples (with `/WS`) contains a column for each iteration. Each column is equivalent to the contents of `M_WaveStats` for that iteration. You can use the command

```plaintext
Edit M_WaveStatsSamples.ld
```

to display the results in a table using row labels, and, for example, to display a graph of the rms of the samples as a function of iteration number execute:

```plaintext
Display M_WaveStatsSamples[5][]
```

M_StatsQuantilesSamples (with `/SQ`) contains a column for each iteration. Each column consists of the contents of W_StatsQuantiles for the corresponding data. Here again you can execute the command

```plaintext
Edit M_StatsQuantilesSamples.ld
```

to display the wave in a table using row labels. To display a graph of the median as a function of iteration execute:

```plaintext
Display M_statsQuantilesSamples[2][]
```

Output Variables

StatsResample creates the following variables: V_Median, V_Q25, V_Q75, V_IQR, V_min, V_max, V_numNaNs, V_numINFs, V_avg, V_sdev, V_rms, V_adev, V_skew, V_kurt, and V_Sum.

These variables are valid only if you use either `/SQ` or `/WS`, but not both, and only if you do not use `/ITER`. Unused variables are set to NaN.
StatsSample

If you use /SQ the operation sets V_Median, V_Q25, V_Q75, V_IQR, V_min, and V_max.
If you use /WS the operation sets V_min, V_max, V_numNaNs, V_numINFs, V_avg, V_sdev, V_rms, V_ae, V_skew, V_kurt, and V_Sum.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsSample, WaveStats and StatsQuantiles.

StatsSample

StatsSample /N=numPoints [flags] srcWave
StatsSample creates a random, non-repeating sample from srcWave.
It samples srcWave by drawing without replacement numPoints values from srcWave and storing them in the output wave W_Sampled or M_Sampled if /MC or /MR are used.
The /N flag is required.

Flags

/ACMB Creates a wave containing all unique combinations of numPoints values from srcWave. It is assumed that srcWave is a 1D numeric wave containing more than numPoints elements. The results are stored in the wave M_Combinations in the current data folder. Each row in the result wave corresponds to a unique combination of samples.
Added in Igor Pro 7.00.

/CMPL Stores all data elements from srcWave that were excluded from the random sample in the wave W_CompWave or M_CompWave in the current data folder. /CMPL was added in Igor Pro 8.00.

/N=numPoints Specifies the number of points sampled from srcWave. When combined with /MC, numPoints is the number of sampled rows and when combined with /MR, it is the number of sampled columns.

/MC Use /MC (multi-column) to randomly sample full rows from srcWave, i.e., the output consists of all columns of each selected row. /MC and /MR are mutually exclusive flags.

/MR Use /MR (multi-row) to randomly sample full columns from srcWave, i.e., the output consists of all rows of each of the selected columns. /MC and /MR are mutually exclusive flags.

/Z Ignores errors.

Details
If you omit /MC and /MR, the output is a 1D wave named W_Sampled where the samples are chosen from srcWave without regard to its dimensionality.
If you use either /MC or /MR the output is a 2D wave named M_Sampled which will have either the same number of columns (/MC) as srcWave or the same number of rows (/MR) as srcWave.

See Also
Chapter III-12, Statistics, StatsResample

StatsRunsCDF

StatsRunsCDF(n, r)
The StatsRunsCDF function returns the cumulative distribution function for the up and down runs distribution for total number of runs r in a random linear arrangement of n unequal elements. There is no closed form expression. It is computed numerically from the recursion of the probability density
StatsScheffeTest

\[ f(r, n) = \frac{rf(r, n-1) + 2f(r-1, n-1) + (n-r)f(r-2, n-1)}{n}, \]

with the initial condition
\[ f(1, n) = \frac{2}{n!}. \]

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; the StatsSRTTest function.

StatsScheffeTest

*StatsScheffeTest [flags] [wave1, wave2,... wave100]*

The StatsScheffeTest operation performs Scheffe’s test for the equality of the means. It supports two basic modes: the default tests all possible combinations of pairs of waves; the second tests a single combination where the precise form of \( H_0 \) is determined by the coefficients of a contrast wave (see /CONT). Output is to the M_ScheffeTestResults wave in the current data folder.

Flags
/ALPH=val
Sets the significance level (default 0.05).

/CONW=cWave
Performs a multiple contrasts test. cWave has one point for each input wave. The cWave value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave.

The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If cWave={0,1,1,1,2}, then the contrast hypothesis \( H_0 \) corresponds to:

\[ \frac{X_1 + X_2 + X_3}{3} - \overline{X}_4 = 0. \]

For each pair of waves \((i, j)\) with \( i \neq j \), it computes

\[ SE_{ij} = \sqrt{s^2 \left( \frac{1}{n_j} + \frac{1}{n_i} \right)}, \]

\[ s^2 = \sum_{i=1}^{w} \sum_{j=0}^{n_i-1} X_j^2 - \sum_{i=1}^{w} \left( \sum_{j=0}^{n_i-1} X_j \right)^2 / n_j, \]

the statistic

\[ S = \frac{\sum_{i=0}^{n-1} c_i \overline{X}_i}{SE}, \]
The Shapiro-Wilk tests the null hypothesis that the population is normally distributed. If the P-value is less than the selected alpha then the null hypothesis, normality, is rejected.

The test is valid only for waves containing 3 to 5000 data points. The operation ignores any NaNs or INFs in `srcWave`.

**Example**

```plaintext
// Test normally distributed data
Make/O/N=(200) ggg=gnoise(5)
StatsShapiroWilkTest ggg
W=0.995697 p=0.846139 // p>alpha so accept normality
```
StatsSignTest

StatsSignTest [flags] wave1, wave2
The StatsSignTest operation performs the sign test for paired-sample data contained in wave1 and wave2.

Flags

/ALPH=val Sets the significance level (default 0.05).
/Q No results printed in the history area.
/T=k Displays results in a table. k specifies the table behavior when it is closed.
   k=0: Normal with dialog (default).
   k=1: Kills with no dialog.
   k=2: Disables killing.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
The input waves must be the equal length, real numeric waves and must not contain any NaNs or INFs. Results are saved in the wave W_SignTest and are optionally displayed in a table. StatsSignTest computes the differences in each pair and counts the total number of entries with positive and negative differences, and tests the results using a binomial distribution. When the number of data pairs exceeds 1024 it uses a normal approximation to the binomials for calculating the probabilities and the power of the test.

References

Chapter III-12, *Statistics* for a function and operation overview.

StatsWilcoxonRankTest

StatsSpearmanRhoCDF

StatsSpearmanRhoCDF(r, N)
The StatsSpearmanRhoCDF function returns the cumulative distribution function for Spearman’s r, which is used in rank correlation test. It is valid for N>1 and -1 ≤ r ≤ 1. The distribution is mostly computed using the Edgeworth series expansion.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; the StatsRankCorrelationTest, StatsInvSpearmanCDF, and StatsKendallTauTest functions.

StatsSRTTest

StatsSRTTest [flags] srcWave
The StatsSRTTest operation performs a parametric or nonparametric serial randomness test on srcWave, which must contain finite numerical data. The null hypothesis of the test is that the data are randomly distributed. Output is to the W_S StatsSRTTest wave in the current data folder.
The parametric test for serial randomness is according to Young. \( C \) is given by

\[
C = 1 - \frac{\sum_{i=0}^{n-2} (X_i - X_{i+1})^2}{2 \sum_{j=0}^{n-1} (X_j - \bar{X})^2},
\]

where \( \bar{X} \) is the mean and \( n \) is the number of points in \( srcWave \). The critical value is obtained from mean square successive difference distribution \( \text{StatsInvCMSSDCDF} \). For more than 150 points, \( \text{StatsSRTest} \) uses the normal approximation and provides the critical values from the normal distribution. For samples from a normal distribution, \( C \) is symmetrically distributed about 0 with positive values indicating positive correlation between successive entries and negative values corresponding to negative correlation.

The nonparametric test consists of counting the number of runs that are successive positive or successive negative differences between sequential data. If two sequential data are the same it computes two numbers of runs by considering the two possibilities where the equality is replaced with either a positive or a negative difference. The results of the operation include the number of runs up and down, the number of unchanged values (the number of places with no difference between consecutive entries), the size of the longest run and its associated probability, the number of converted equalities, and the probability that the number of runs is less than or equal to the reported number (\( \text{StatsRunsCDF} \)). When equalities are encountered the operation computes the probabilities that the computed number of runs or less can be found in an equivalent random sequence.

Converted equalities are those with the same sign on both sides so that when we replace the equality by the opposite sign we increase the number of runs. The equalities that are not converted are found between two different signs and therefore regardless of the sign that we give them they do not affect the total number of runs. We implicitly assume that the data does not contain more than one sequential equalities.

The longest run is determined without taking into account equalities or their conversions. The probability of the longest run is computed from Equation 6 of Olmstead, which is accurate within 0.001 when the...
number of runs is 5 or more. This probability applies to either positive or negative differences and should be divided by two if a specific sign is selected.

Chapter III-12, *Statistics* for a function and operation overview; *StatsNPNominalSRTTest* and *StatsRunsCDF*.

**StatsStudentCDF**

**StatsStudentCDF**(*t*, *n*)
The StatsStudentCDF function returns the Student (uniform) cumulative distribution function

\[
F(t,n) = \begin{cases} 
\frac{1}{2} \left[ 1 + I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) \right] - I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+1} \right) & t > 0 \\
\frac{1}{2} \left[ 1 + I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) \right] - I \left( \frac{n}{2}, \frac{1}{2}; \frac{1}{n+1} \right) & t < 0 \\
\frac{1}{2} & t = 0
\end{cases}
\]

where *n*>0 is degrees of freedom and is the incomplete beta function \( \text{betal} \).

See Also
Chapter III-12, *Statistics* for a function and operation overview; the *StatsStudentPDF* and *StatsInvStudentCDF* functions.

**StatsStudentPDF**

**StatsStudentPDF**(*t*, *n*)
The StatsStudentPDF function returns the Student (uniform) probability distribution function

\[
f(t,n) = \frac{n}{n+t^2}^{(n+1)/2} \sqrt{n B \left( \frac{n}{2}, \frac{1}{2} \right)}
\]

where *n*>0 is degrees of freedom and \( B() \) is the \( \text{beta} \) function.

See Also
Chapter III-12, *Statistics* for a function and operation overview; the *StatsStudentCDF* and *StatsInvStudentCDF* functions.
StatsTopDownCDF

\textbf{StatsTopDownCDF}(x, N)

The StatsTopDownCDF function returns the cumulative distribution function for the top-down correlation coefficient. It is computationally intensive because it must evaluate many permutations \(O((n!)^2)\). It exactly calculates the distribution for \(3 \leq N \leq 7\); outside this range it uses Monte-Carlo estimation for \(8 \leq N \leq 50\) and asymptotic Normal approximation for \(N > 50\). The Monte-Carlo estimate uses 1e6 random permutations fitted with two 9-order polynomials for the range \([-1,0]\) and \([0,1]\). The results are within 0.2% of exact values where known.

\textbf{See Also}

Chapter III-12, \textit{Statistics} for a function and operation overview; the \texttt{StatsRankCorrelationTest} and \texttt{StatsInvTopDownCDF} functions.

\textbf{StatsTriangularCDF}

\textbf{StatsTriangularCDF}(x, a, b, c)

The StatsTriangularCDF function returns the triangular cumulative distribution function

\[
F(x; a, b, c) = \begin{cases} 
0 & x \leq a \\
\frac{(x-a)^2}{(b-a)(c-a)} & a < x \leq c \\
1-\frac{(b-x)^2}{(b-a)(b-c)} & c < x < b \\
1 & x \geq b 
\end{cases}
\]

where \(a < c < b\).

\textbf{See Also}

Chapter III-12, \textit{Statistics} for a function and operation overview; the \texttt{StatsTriangularPDF} and \texttt{StatsInvTriangularCDF} functions.

\textbf{StatsTriangularPDF}

\textbf{StatsTriangularPDF}(x, a, b, c)

The StatsTriangularPDF function returns the triangular probability distribution function

\[
f(x; a, b, c) = \begin{cases} 
\frac{2(x-a)}{(b-a)(c-a)} & a \leq x < c \\
\frac{2(b-x)}{(b-a)(b-c)} & c < x \leq b \\
0 & \text{Otherwise}
\end{cases}
\]

where \(a < c < b\).

\textbf{See Also}

Chapter III-12, \textit{Statistics} for a function and operation overview; the \texttt{StatsTriangularCDF} and \texttt{StatsInvTriangularCDF} functions.
StatsTrimmedMean

**StatsTrimmedMean**(waveName, trimValue)

The StatsTrimmedMean function returns the mean of the wave waveName after removing trimValue fraction of the values from both tails of the distribution. trimValue is a number in the range [0, 0.5]. waveName can be any real numeric type.

**See Also**

Chapter III-12, Statistics for a function and operation overview; StatsQuantiles and mean.

StatsTTest

**StatsTTest**(flags) wave1[, wave2]

The StatsTTest operation performs two kinds of T-tests: the first compares the mean of a distribution with a specified mean value (/MEAN) and the second compares the means of the two distributions contained in wave1 and wave2, which must contain at least two data points, can be any real numeric type, and can have an arbitrary number of dimensions. Output is to the W_StatsTTest wave in the current data folder or optionally to a table.

**Flags**

/ALPH = val  Sets the significance level (default val=0.05).

/CI  Computes the confidence intervals for the mean(s).

/DFM=m  Specifies method for calculating the degrees of freedom.

  m=0: Default; computes equivalent degrees of freedom accounting for possibly different variances.

  m=1: Computes equivalent degrees of freedom but truncates to a smaller integer.

  m=2: Computes degrees of freedom by DF=n1+n2-2, where n is the sum of points in the wave. Appropriate when variances are equal.

/MEAN=meanV  Compares meanV with the mean of the distribution in wave1. Outputs are the number of points in the wave, the degrees of freedom (accounting for any NaNs), the average, standard deviation (σ),

\[ s_x = \frac{\sigma}{\sqrt{DF + 1}}, \]

the statistic

\[ t = \frac{\bar{X} - meanV}{s_x}, \]

and the critical value, which depends on /TAIL.

/PAIR  Specifies that the input waves are pairs and computes the difference of each pair of data to get the average difference \( \bar{d} \) and the standard error of the difference \( s_d \). The t statistic is the ratio of the two

\[ t = \frac{\bar{d}}{s_d}. \]

In this case H₀ is that the difference \( \bar{d} \) is zero.

This mode does not support /CI and /DFM.

/Q  No results printed in the history area.
When comparing the mean of a single distribution with a hypothesized mean value, you should use /MEAN and only one wave (wave1). If you use two waves StatsTTest performs the T-test for the means of the corresponding distributions (which is incompatible with /MEAN).

When comparing the means of two distributions, the default t-statistic is computed from Welch’s approximate t:

\[
t' = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}},
\]

where \( s_i^2 \) are variances, \( n_i \) the number of samples, and \( \bar{x}_i \) the averages of the respective waves. This expression is appropriate when the number of points and the variances of the two waves are different. If you want to compute the t-statistic using pooled variance you can use the /AEVR flag. In this case the pooled variance is given by

\[
s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2},
\]

and the t-statistic is

\[
t = \frac{\bar{x}_1 - \bar{x}_2}{s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}},
\]

The different test are:

/\text{T}=k

Displays results in a table. \( k \) specifies the table behavior when it is closed.

- \( k=0 \): Normal with dialog (default).
- \( k=1 \): Kills with no dialog.
- \( k=2 \): Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/TAIL=tailCode

Specifies \( H_0 \).

- \( \text{tailCode}=1 \): One tailed test (\( \mu_1 \leq \mu_2 \)).
- \( \text{tailCode}=2 \): One tailed test (\( \mu_1 \geq \mu_2 \)).
- \( \text{tailCode}=4 \): Default; two tailed test (\( \mu_1 = \mu_2 \)).

When performing paired tests using /PAIR:

- \( \text{tailCode}=1 \): One tailed test (\( \mu_d \leq 0 \)).
- \( \text{tailCode}=2 \): One tailed test (\( \mu_d \geq 0 \)).
- \( \text{tailCode}=4 \): Default; two tailed test (\( \mu_d = 0 \)).

Here \( \mu_d \) is the mean of the difference population.

/Z

Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

When comparing the mean of a single distribution with a hypothesized mean value, you should use /MEAN and only one wave (wave1). If you use two waves StatsTTest performs the T-test for the means of the corresponding distributions (which is incompatible with /MEAN).

When comparing the means of two distributions, the default t-statistic is computed from Welch’s approximate t:
StatsTukeyTest

<table>
<thead>
<tr>
<th>$H_0$</th>
<th>Rejection Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\mu_1 = \mu_2$</td>
<td>$</td>
</tr>
<tr>
<td>$\mu_1 &gt; \mu_2$</td>
<td>$t \leq Tc(\alpha, v)$</td>
</tr>
<tr>
<td>$\mu_1 &lt; \mu_2$</td>
<td>$t \geq Tc(\alpha, v)$</td>
</tr>
</tbody>
</table>

$Tc$ is the critical value and $v$ is the effective number of degrees of freedom (see /DFM flag). When accounting for possibly unequal variances, $v$ is given by

$$v = \frac{\left(\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}\right)^2}{\frac{s_1^2}{n_1 - 1} + \frac{s_2^2}{n_2 - 1}}.$$ 

The critical values ($Tc$) are computed by numerically by solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

$$F(x) = \begin{cases} 
\frac{1}{2} \text{betai} \left( \frac{v}{2}, 2, \frac{v}{v + x^2} \right) & x < 0 \\
1 - \frac{1}{2} \text{betai} \left( \frac{v}{2}, 2, \frac{v}{v + x^2} \right) & x \geq 0.
\end{cases}$$

To get the critical value for the upper one-tail test we solve $F(x)=1-\alpha$. For the lower one-tail test we solve for $x$ the equation $F(x)=\alpha$. In the two-tailed test the lower critical value is a solution for $F(x)=\alpha/2$ and the upper critical value is a solution for $F(x)=1-\alpha/2$.

The T-test assumes both samples are randomly taken from normal population distributions.

References

StatsTukeyTest

StatsTukeyTest [flags] [wave1, wave2, ... wave100]

The StatsTukeyTest operation performs multiple comparison Tukey (HSD) test and optionally the Newman-Keuls test. Output is to the M_TukeyTestResults wave in the current data folder. StatsTukeyTest usually follows StatsANOVA1Test.

Flags

/ALPH = val  Sets the significance level (default val=0.05).
/NK  Computes the Newman-Keuls test.
/Q  No results printed in the history area.
/SWN  Creates a text wave, T_TukeyDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
Details

Inputs to StatsTukeyTest are two or more 1D numeric waves (one wave for each group of samples) containing any numbers of points but with at least two or more valid entries.

The contents of the M_TukeyTestResults columns are: the first contains the difference between the group means, \( \bar{X}_i - \bar{X}_j \), the second contains SE (supports unequal number of points), the third contains the q statistic for the pair, and the fourth contains the critical q value, the fifth contains the conclusion with 0 to reject \( H_0 \) (\( \mu_i = \mu_j \)) or 1 to accept \( H_0 \), with /NK, the sixth contains the p values

\[ p = \text{rank}[\bar{X}_i] - \text{rank}[\bar{X}_j] + 1, \]

the seventh contains the critical values, and the eighth contains the Newman-Keuls conclusion (with 0 to reject and 1 to accept \( H_0 \)). The order of the rows is such that all possible comparisons are computed sequentially starting with the comparison of the group having the largest mean with the group having the smallest mean.

V_flag will be set to -1 for any error and to zero otherwise.

Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test, StatsScheffeTest, and StatsDunnettTest.

StatsUSquaredCDF

**StatsUSquaredCDF**

**StatsUSquaredCDF(u2, n, m, method, useTable)**

The StatsUSquaredCDF function returns the cumulative distribution function for Watson’s U² with parameters u² (U² statistic) and integer sample sizes n and m. The calculation is computationally intensive, on the order of binomial\((n+m, m)\). Use a nonzero value for useTable to search a built-in table of values. If n and m cannot be found in the table, it will proceed according to method:

<table>
<thead>
<tr>
<th>method</th>
<th>What It Does</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exact computation using Burr algorithm (could be slow).</td>
</tr>
<tr>
<td>1</td>
<td>Tiku approximation using chi-squared.</td>
</tr>
<tr>
<td>2</td>
<td>Use built-in table only and return a NaN if not in table.</td>
</tr>
</tbody>
</table>

For large n and m, consider using the Tiku approximation. To abort execution, press the User Abort Key Combinations.

Precomputed tables, using the algorithm described by Burr, contain these values:

<table>
<thead>
<tr>
<th>n</th>
<th>m</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>4-30</td>
</tr>
<tr>
<td>5</td>
<td>5-30</td>
</tr>
<tr>
<td>6</td>
<td>6-30</td>
</tr>
<tr>
<td>7</td>
<td>7-30</td>
</tr>
</tbody>
</table>
Because \( n \) and \( m \) are interchangeable, \( n \) should always be the smaller value. For \( n > 8 \) the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with \( m \) values exceeding these limits.

**StatsVariancesTest**

The *StatsVariancesTest* operation performs Bartlett’s or Levene’s test to determine if wave variances are equal. Output is to the \( W_{\text{StatsVariancesTest}} \) wave in the current data folder or optionally to a table.

**Flags**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ALPH=( val )</td>
<td>Sets the significance level (default ( val=0.05 )).</td>
</tr>
<tr>
<td>/METH=( m )</td>
<td>Specifies the test type. ( m=0 ): Bartlett test (default). ( m=1 ): Levene’s test using the mean. ( m=2 ): Modified Levene’s test using the median. ( m=3 ): Modified Levene’s test using the 10% trimmed mean.</td>
</tr>
<tr>
<td>/Q</td>
<td>No results printed in the history area.</td>
</tr>
<tr>
<td>/T=( k )</td>
<td>Displays results in a table. ( k ) specifies the table behavior when it is closed. ( k=0 ): Normal with dialog (default). ( k=1 ): Kills with no dialog. ( k=2 ): Disables killing. The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.</td>
</tr>
<tr>
<td>/WSTR=( \text{waveListString} )</td>
<td>Specifies a string containing a semicolon-separated list of waves that contain sample data. Use ( \text{waveListString} ) instead of listing each wave after the flags.</td>
</tr>
<tr>
<td>/Z</td>
<td>Ignores errors. ( V_{\text{flag}} ) will be set to -1 for any error and to zero otherwise.</td>
</tr>
</tbody>
</table>

**Details**
All tests define the null hypothesis by
StatsVariancesTest

$H_0: \quad \sigma_i^2 = \sigma_j^2 = \ldots = \sigma_k^2,$

against the alternative

$H_a: \quad \sigma_i^2 \neq \sigma_j^2 \text{ for at least one } i \neq j.$

Bartlett’s test computes:

$$T = \frac{(n - k) \ln(\sigma_w^2) - \sum_{i=1}^{k} (n_i - 1) \ln(\sigma_i^2)}{1 + \frac{1}{3(k - 1)} \left[ \sum_{i=1}^{k} \frac{1}{n_i - 1} - \frac{1}{N - k} \right]}.$$  

Here $\sigma_i^2$ is the variance of the $i$th wave, $N$ is the sum of the points of all the waves, $n_i$ is the number of points in wave $i$, and $k$ is the number of waves. The weighted variance is given by

$$\sigma_w^2 = \frac{\sum_{i=1}^{k} (n_i - 1) \sigma_i^2}{N - k}.$$  

$H_0$ is rejected if $T$ is greater than the critical value taken from the $\chi^2$ distribution computed by solving for $x$:

$$1 - \alpha = 1 - \text{gammq}\left(\frac{k - 1}{2}, \frac{x}{2}\right).$$

Levene’s test computes:

$$W = \frac{(N - k) \sum_{i=1}^{k} n_i (\bar{Z}_i - \bar{Z})^2}{(k - 1) \sum_{i=1}^{k} \sum_{j=1}^{k} (Z_{ij} - \bar{Z}_i)^2},$$

where

$$Z_{ij} = |Y_{ij} - \bar{Y}_i|,$$

$$\bar{Z}_i = \frac{1}{n_i} \sum_{j=1}^{k} Z_{ij},$$

$$\bar{Z} = \frac{1}{N} \sum_{i=1}^{k} \sum_{j=1}^{k} Z_{ij},$$

$Y_i$ depends on /METH.

$H_0$ is rejected if $W$ is greater than the critical value from the F distribution computed by solving for $x$:

$$1 - \alpha = 1 - \text{betai}\left(\frac{V_2}{2}, \frac{V_1}{2}, \frac{V_2}{V_2 + V_1 x}\right).$$
StatsVonMisesCDF

StatsVonMisesCDF(x, a, b)
The StatsVonMisesCDF function returns the von Mises cumulative distribution function

\[ F(\theta; a, b) = \frac{1}{2\pi I_0(b)} \int_0^\theta \exp\left( b \cos(x - a) \right) dx. \]

where \( I_0(b) \) is the modified Bessel function of the first kind \( \text{bessI} \), and

\[ 0 < \theta \leq 2\pi \]
\[ 0 < a \leq 2\pi \]
\[ b > 0. \]

</tbody>
</table>
StatsWatsonWilliamsTest

**Details**
The input waves, srcWave1 and srcWave2, each must contain at least two angles in radians (mod 2\(\pi\)), can have any number of dimensions, and can be single or double precision. They must not contain any NaNs or INFs.

The Watson U² H₀ postulates that the two samples came from the same population against the different populations alternative. In the calculation, StatsWatsonUSquaredTest ranks the two inputs, accounts for possible ties, computes the test statistic U², and compares it with the critical value. Because of the difficulty of computing the critical values, it always computes first the approximation due to Tiku and if possible it computes the exact critical value using the method outlined by Burr. You can evaluate the U² CDF to get more information about the critical region.

V_flag will be set to -1 for any error and to zero otherwise.

**References**
We have found that this method leads to slightly different results depending on the compiler and the system on which it is implemented:

**See Also**
Chapter III-12, *Statistics* for a function and operation overview; StatsWatsonWilliamsTest, StatsWheelerWatsonTest, StatsUSquaredCDF, and StatsInvUSquaredCDF.

StatsWatsonWilliamsTest

The StatsWatsonWilliamsTest operation performs the Watson-Williams test for two or more sample means. Output is to the W_WatsonWilliams wave in the current data folder or optionally to a table.

**Flags**

- `/ALPH = val` Sets the significance level (default val=0.05).
- `/Q` No results printed in the history area.
- `/T=k` Displays results in a table. k specifies the table behavior when it is closed.
  - k=0: Normal with dialog (default).
  - k=1: Kills with no dialog.
  - k=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

- `/WSTR=waveListString` Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
- `/Z` Ignores errors.

**Details**
The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians, can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Watson-Williams H₀ postulates the equality of the means from all samples against the simple inequality alternative. The test computes the sums of the sines and cosines from which it obtains a weighted r value (rw). According to Mardia, you should use different statistics depending on the size of rw: for rw>0.95 use the simple F statistic, but for 0.95>rw>0.7 you should use the F-statistic with the K correction factor. Otherwise you should use the t-statistic. StatsWatsonWilliamsTest computes both the (corrected) F-statistic and the t-statistic as well as their corresponding critical values.

V_flag will be set to -1 for any error and to zero otherwise.

Chapter III-12, *Statistics* for a function and operation overview; the StatsWeibullCDF and StatsInvWeibullCDF functions.

StatsWheelerWatsonTest

**StatsWheelerWatsonTest** *(flags) [srcWave1, srcWave2, srcWave3,...]*
The StatsWheelerWatsonTest operation performs the nonparametric Wheeler-Watson test for two or more samples. Output is to the W_WheelerWatson wave in the current data folder or optionally to a table.

Flags

/ALPH=val \hspace{1cm} Sets the significance level (default val=0.05).
/Q \hspace{1cm} No results printed in the history area.
/T=k \hspace{1cm} Displays results in a table. \( k \) specifies the table behavior when it is closed.

Displays results in a table. \( k \) specifies the table behavior when it is closed.

\( k=0: \) Normal with dialog (default).
\( k=1: \) Kills with no dialog.
\( k=2: \) Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
StatsWilcoxonRankTest

/WSTR=waveListString
   Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z
   Ignores errors.

Details
The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians (mod 2\pi), can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Wheeler-Watson H0 postulates that the samples came from the same population. The extension of the test to more than two samples is due to Mardia. The Wheeler-Watson test is not valid for data with ties, in which case you should use Watson's U2 test.

V_flag will be set to -1 for any error and to zero otherwise.

References

See, in particular, Chapter 27 of:

See Also
Chapter III-12, *Statistics* for a function and operation overview; StatsWatsonUSquaredTest and StatsWheelerWatsonTest.

StatsWilcoxonRankTest

StatsWilcoxonRankTest [flags] waveA, waveB
The StatsWilcoxonRankTest operation performs the nonparametric Wilcoxon-Mann-Whitney two-sample rank test or the Wilcoxon Signed Rank test (for paired data) on waveA and waveB. Output is to the W_WilcoxonTest wave in the current data folder or optionally to a table.

waveA and waveB must not contain NaNs or INFs.

Flags

/ALPH = val
   Sets the significance level (default val=0.05).

/APRX=m
   Sets the approximation method. It computes an exact critical value by default.
   m=1: Standard normal approximation with ties (Zar P. 151).
   m=2: Improved normal approximation (Zar P. 152).

Approximations may be appropriate for large sample sizes when computation may take a long time.

/Q
   No results printed in the history area.

/T=k
   Displays results in a table. k specifies the table behavior when it is closed.
   k=0: Normal with dialog (default).
   k=1: Kills with no dialog.
   k=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/TAIL=tail
   tail is a bitwise parameter that specifies the tails tested.
   Bit 0: Lower tail.
   Bit 1: Upper tail (default).
   Bit 2: Two tail.
The Wilcoxon-Mann-Whitney test combines the two samples and ranks them to compute the statistic \( U \). If \( \text{wave}A \) has \( m \) points and \( \text{wave}B \) has \( n \) points, then \( U \) is given by

\[
U = mn + \frac{m(m+1)}{2} - R_i,
\]

with the corresponding statistic \( U' \) given by

\[
U' = nm + \frac{n(n+1)}{2} - R2.
\]

where \( R_i \) is the ranks of data in the \( i \)th wave (ranked in ascending order).

The distribution of \( U \) is difficult to compute, requiring the number of possible permutations of \( m \) elements of \( \text{wave}A \) and \( n \) elements of \( \text{wave}B \) that give rise to \( U \) values that do not exceed the one computed. The distribution is computed according to the algorithm developed by Klotz. With increasing sample size one can avoid the time consuming distribution computation and use a normal approximation instead. Klotz recommends this approximation for \( N=m+n \geq 100 \).

Use /APRX=2 for the best approximation. The two approximations are discussed by Zar.

The Wilcoxon Signed Rank Test, or Wilcoxon Paired-Sample Test, ranks the difference between pairs of values and computes the sums of the positive ranks (\( Tp \)) and the negative ranks (\( Tm \)). It calculates \( Tp \) and \( Tm \) and P-values for all tail combinations. The P-values are:

- \( P_{\text{lower\_tail}} = P(Wp<=Tp) \)
- \( P_{\text{upper\_tail}} = P(Wp>=Tp) \)
- \( P_{\text{two\_tail}} = 2*\text{Min}(P_{\text{lower\_tail}},P_{\text{upper\_tail}}) \)

\( Wp \) is the generic symbol for the sum of positive ranks for the given number of pairs.

\( V \) flag will be set to -1 for any error and to zero otherwise.

In both Wilcoxon-Mann-Whitney two-sample rank test and the Wilcoxon Signed Rank test \( H_0 \) is that the data in the two input waves are statistically the same.

References

StatsWRCorrelationTest

**StatsWRCorrelationTest [flags] waveA, waveB**

The StatsWRCorrelationTest operation performs a Weighted Rank Correlation test on `waveA` and `waveB`, which contain the ranks of sequential factors. The waves are 1-based, integer ranks of factors in the range 1-2^31.

StatsWRCorrelationTest computes a top-down correlation coefficient using Savage sums as well as the critical and P-values. Output is to the \( \hat{W}_\text{StatsWRCorrelationTest} \) wave in the current data folder or optionally to a table.

**Flags**

- **/ALPH = val** Sets the significance level (default `val`=0.05).
- **/Q** No results printed in the history area.
- **/T=k** Displays results in a table. \( k \) specifies the table behavior when it is closed.
  - \( k=0 \): Normal with dialog (default).
  - \( k=1 \): Kills with no dialog.
  - \( k=2 \): Disables killing.

  The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

- **/Z** Ignores errors.

**Details**

The StatsWRCorrelationTest input waves must be one-dimensional and have the same length. The waves are 1-based, integer ranks of factors corresponding to the point number. Ranks may have ties in which case you should repeat the rank value. For example, if the second and third entries have the same rank you should enter \{1,2,2,4\}. \( H_0 \) stipulates that the same factors are most important in both groups represented by `waveA` and `waveB`.

The top-down correlation is the sum of the product of Savage sums for each row:

\[
\hat{r}_{TD} = \frac{\sum_{i=1}^{n} S_{iA}S_{iB} - n}{n - S_i},
\]

where \( n \) is the number of rows and the Savage sum \( S_i \) is

\[
S_i = \sum_{j=1}^{n} \frac{1}{j},
\]

and \( S_{iA} \) corresponds to the \( S_i \) value of the rank of the data in row \((i-1)\) of `waveA`.

STFT

STFT [flags] srcWave
The STFT operation computes the Short-Time Fourier Transform of srcWave. STFT was added in Igor Pro 8.00.

Output is stored in the wave M_STFT in the current data folder or in a wave specified by the /DEST flag.

Flags

/DB=dbMode  
*dbMode* determines if output is scaled in decibels:
* 0: No dB scaling (default)
* 1: Scale the output to standard dB using $20 \log(wave)$
* 2: Compute dBFS (dB relative to full scale where 0 is the maximum value)

/DEST=destWave  
Specifies the output wave created by the FFT operation.
It is an error to attempt specify the same wave as both srcWave and destWave.
The default output wave name M_STFT is used if you omit /DEST.
When used in a function, the STFT operation by default creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-72 for details.

/HOPS=hopSize  
Specifies the offset in points between centers of consecutive source segments. By default this value is 1 and the transform is computed for segments that are offset by a single points from each other.

/OUT=mode  
Sets the output wave format.
* mode=1: Complex output (default)
* mode=2: Real output
* mode=3: Magnitude
* mode=4: Magnitude square
* mode=5: Phase
* mode=6: Scaled magnitude
* mode=7: Scaled magnitude squared

The scaled quantities apply to transforms of real valued inputs where the output is normally folded in the first dimension (because of symmetry). The scaling applies a factor of 2 to the squared magnitude of all components except the DC. The scaled transforms should be used whenever Parseval's relation is expected to hold.

/PAD=newSize  
Converts each segment of srcWave into a padded array of length newSize. The padded array contains the original data at the center of the array with zeros elements on both sides.

/RP=[startPoint, endPoint]  
Specifies the range of srcWave from which data are sampled in point numbers. startPoint is the first point at which segments are centered. Wave data from points preceding startPoint are used as needed for the left parts of beginning segments.

/RX=(startX, endX)  
Specifies the range of srcWave from which data are sampled in X values. The operation expects startX<endX. startX corresponds to the first point at which segments are centered. Data from points preceding startX are used as necessary to fill left parts of the beginning segments.

/SEGS=segSize  
Sets the length of the segment sampled from srcWave in points. The segment is optionally padded to a larger dimension (see /PAD) and multiplied by a window function prior to FFT. The default segment size is 128 when the number of points in srcWave is greater than 128. Otherwise it is set to one less than the number of points in the srcWave. The operation requires that segSize is at least 32 points.
Details
The Short-Time Fourier Transform is a time-frequency representation for a 1D array. The squared magnitude of the transform is known as the "spectrogram" for time series or "sonogram" in the case of sound input. The operation comprises the following steps:

1. Sampling the data.
   A segment of size specified by /SEGS is sampled from srcWave centered about the first point in the wave or as specified by /RX or /RP flags. When the first point is at the beginning of the wave the centering implies that the first half of the segment is set to zero. If the first point is somewhere else the operation uses as many points as are available in the wave and sets the rest to zero. End effects are mitigated by scaling the result by a factor that accounts for the actual number of source data used in the segment. Subsequent segments are each centered at hopSize points from the previous center.

2. Apply windowing.
   The selected segment is multiplied by the specified window function.

3. Apply padding.
   If padding is specified the windowed data are centered onto a zero padded array. Padding may be used to simulate longer arrays for improved spectral resolution.

4. Compute the FFT.
   Initial complex transform may be further processed according to the /OUT flag.

StopMSTimer
StopMSTimer(timerRefNum)
The StopMSTimer function frees up the timer associated with the timerRefNum and returns the number of elapsed microseconds since StartMSTimer was called for this timer.

Parameters
timerRefNum is the value returned by StartMSTimer or the special values -1 or -2. If timerRefNum is not valid then StopMSTimer returns 0.

On Windows, passing -1 returns the clock frequency of the timer and. On Macintosh, it returns NaN.
Passing -2 returns the time in microseconds since the computer was started.

Details
If you want to make sure that all timers are free, call StopMSTimer ten times with timerRefNum equal to 0 through 9. It is OK to stop a timer that you never started.

The function result may exclude the time the system has spent in sleep states. As of this writing this applies to Macintosh only, but this behavior may change in the future since it is determined by the operating system.

Examples
How long does an empty loop take on your computer?

Function TestMSTimer()
  Variable timerRefNum
  Variable microSeconds
  Variable n
timerRefNum = StartMSTimer
if (timerRefNum == -1)
    Abort "All timers are in use"
endif
n=10000
do
    n -= 1
while (n > 0)
    microSeconds = StopMSTimer(timerRefNum)
    Print microSeconds/10000, "microseconds per iteration"
End

See Also
StartMSTimer, ticks, DateTime

str2num
str2num(str)
The str2num function returns a number represented by the string expression str.

Details
str2num returns NaN if str does not contain the text for a number.
str2num skips leading spaces and tabs and then reads up to the first non-numeric character.

See Also
The char2num, num2char and num2str functions.
The sscanf operation for more complex parsing jobs.

StrConstant
StrConstant ksName="literal string"
The StrConstant declaration defines the string literal string under the name ksName for use by other code, such as in a switch construct.

See Also
The Constant keyword for numeric types, Constants on page IV-51, and Switch Statements on page IV-43.

String
String [/G] strName[/N=name] [=strExpr] [, strName[/N=name] [=strExpr] ...]
The String operation creates string variables and gives them the specified names.

Flags
/G Creates a global string. Overwrites any existing string with the same name.
/N=name Specifies a local name for the global string variable. /N was added in Igor Pro 8.00 and is available in user-defined functions only. See SVAR Creation below for details.

Details
The string variable is initialized when it is created if you supply the =strExpr initializer. However, when String is used to declare a function parameter, it is an error to attempt to initialize it.
You can create more than one string variable at a time by separating the names and optional initializers with commas.
If used in a procedure, the new string is local to that procedure unless the /G flag is used. If used on the command line, String is equivalent to String/G.
strName can optionally include a data folder path.

SVAR Creation
In a user-defined function, you need a local SVAR reference to access a global string variable. If you use a simple name rather than a path, Igor automatically creates an SVAR:

String/G sVar1              // Creates an SVAR named sVar1
If you use a path or a $ expression, Igor does not create an automatic SVAR reference. You can explicitly create SVARs like this:

```plaintext
String/G root:sVar2
SVAR sVar2 = root:sVar2 // Creates an SVAR named sVar2

String path = "root:sVar3"
String/G $path
SVAR sVar3 = $path // Creates an SVAR named sVar3
```

In Igor Pro 8.00 and later, you can explicitly create an SVAR reference in a user-defined function using the /N flag, like this:

```plaintext
String/G sVar4/N=sVar4 // Creates an SVAR named sVar4
String/G root:sVar5/N=sVar5 // Creates an SVAR named sVar5
String path = "root:sVar6"
String/G $path/N=sVar6 // Creates an SVAR named sVar6
```

The name used for the SVAR does not need to be the same as the name of the global variable:

```plaintext
String/G sVar7/N=sv7 // Creates an SVAR named sv7
String/G root:sVar8/N=sv8 // Creates an SVAR named sv8
String path = "root:sVar9"
String/G $path/N=sv9 // Creates an SVAR named sv9
```

### See Also

[String Variables](#) on page II-105, [Working With Strings](#) on page IV-13, [Accessing Global Variables and Waves](#) on page IV-65

### StringByKey

```plaintext
StringByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]])
```

The StringByKey function returns a substring extracted from `kwListStr` based on the specified key contained in `keyStr`. `kwListStr` should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "KEY:valuE1;KEY2:valuE2", depending on the values for `keySepStr` and `listSepStr`.

Use StringByKey to extract a string value from a string containing a "key1:value1;key2: value2;" style list such as those returned by functions like `AxisInfo` or `TraceInfo`.

If the key is not found or if any of the arguments is "" then a zero-length string is returned.

`keySepStr`, `listSepStr`, and `matchCase` are optional; their defaults are ":", ";", and 0 respectively.

#### Details

- `kwListStr` is searched for an instance of the key string bound by `listSepStr` on the left and a `keySepStr` on the right. The text up to the next `listSepStr` is returned.
- `kwListStr` is treated as if it ends with a `listSepStr` even if it doesn’t.
- Searches for `keySepStr` and `listSepStr` are always case-sensitive. Searches for `keyStr` in `kwListStr` are usually case-insensitive. Setting the optional `matchCase` parameter to 1 makes the comparisons case sensitive.
- In Igor6, only the first byte of `keySepStr` and `listSepStr` was used. In Igor7 and later, all bytes are used.
- If `listSepStr` is specified, then `keySepStr` must also be specified. If `matchCase` is specified, `keySepStr` and `listSepStr` must be specified.

#### Examples

```plaintext
Print StringByKey("BKEY", "AKEY:hello;BKEY:nok-nok") // prints "nok-nok"
Print StringByKey("KY", "XX=1;KY:hello", ";"=") // prints "hello"
Print StringByKey("KY", "XX:1,KY:joey," ",";",") // prints "joey"
Print StringByKey("kz", "KZ:1st,kz:2nd"," ",",") // prints "1st"
Print StringByKey("kz", "KZ:1st,kz:2nd"," ",",",1) // prints "2nd"
```

#### See Also

The `NumberByKey`, `RemoveByKey`, `ReplaceNumberByKey`, `ReplaceStringByKey`, `ItemsInList`, `AxisInfo`, `IgorInfo`, `SetWindow`, and `TraceInfo` functions.
StringCRC

StringCRC\((inCRC, str)\)
The StringCRC function returns a 32-bit cyclic redundancy check value of bytes in \textit{str} starting with \textit{inCRC}.

Pass 0 for \textit{inCRC} the first time you call StringCRC for a particular stream of bytes as represented by the string data.

Pass the last-returned value from StringCRC for \textit{inCRC} if you are creating a CRC value for a given stream of bytes through multiple calls to StringCRC.

\textbf{Details}

Polynomial used is:
\[x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^{8}+x^{7}+x^{5}+x^{4}+x^{2}+x+1\]

See crc32.c in the public domain source code for zlib for more information.

\textbf{See Also}
Hash, WaveHash, WaveCRC

StringFromList

StringFromList\((index, listStr [, listSepStr] [, offset])\)
The StringFromList function returns the \textit{index}th substring extracted from \textit{listStr} starting \textit{offset} bytes into \textit{listStr}. \textit{listStr} should contain items separated by \textit{listSepStr} which typically is ";".

Use StringFromList to extract an item from a string such as those returned by functions like \texttt{TraceNameList} and \texttt{AnnotationList}.

\textbf{Parameters}

- \textit{index} is the zero-based index of the list item that you want to get. If \textit{index} < 0, or \textit{index} \geq the number of items in list, or if \textit{listStr} or \textit{listSepStr} is "", then a zero-length string is returned.

- \textit{listStr} contains a series of text items separated by \textit{listSepStr}. The trailing separator is optional though recommended. For example, these are both valid lists:

"First;Second;"
"First;Second"

- \textit{listSepStr} is optional. If omitted it defaults to ";". Prior to Igor Pro 7.00, only the first byte of \textit{listSepStr} was used. Now all bytes are used.

- \textit{offset} is optional and requires Igor Pro 7.00 or later. If omitted it defaults to 0. The search begins \textit{offset} bytes into \textit{listStr}. When iterating through lists containing large numbers of items, using the \textit{offset} parameter provides dramatically faster execution.

\textbf{Details}

For optimal performance, especially with lists larger than 100 items, provide the \textit{separatorStr} and \textit{offset} parameters as shown in the DemoStringFromList example below. When using this technique, the \textit{index} parameter must be 0 and the \textit{offset} parameter controls which list item is returned.

\textbf{Examples}

Print StringFromList(0, "wave0;wave1;") // Prints "wave0"
Print StringFromList(2, "wave0;wave1;") // Prints ""
Print StringFromList(1, "wave0;;wave2") // Prints ""

// Iterate quickly over a list using the offset parameter
Function DemoQuickStringFromList(list)
    String list // A semicolon-separated string list
    String separator = ";;"
    Variable separatorLen = strlen(separator)
    Variable numItems = ItemsInList(list, separator)
    Variable offset = 0
    Variable i
    for(i=0; i<numItems; i+=1)
        // When using offset, the index parameter is always 0
        String item = StringFromList(0, list, separator, offset)
StringList

StringList(matchStr, separatorStr [, dfr ])

The StringList function returns a string containing a list of global string variables selected based on the matchStr parameter. The string variables listed are all in the current data folder or the data folder specified by dfr.

Details

For a string variable name to appear in the output string, it must match matchStr. separatorStr is appended to each string variable name as the output string is generated.

The name of each string variable is compared to matchStr, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

- "*" Matches all string variable names
- "xyz" Matches name xyz only
- "*xyz" Matches names which end with xyz
- "xyz*" Matches names which begin with xyz
- "*xyz*" Matches names which contain xyz
- "abc*xyz" Matches names which begin with abc and end with xyz

The returned list contains names only, without data folder paths. Thus, they are not suitable for accessing string variables outside the current or specified data folder.

matchStr may begin with the ! character to return items that do not match the rest of matchStr. For example:

- "!*xyz" Matches variable names which do not end with xyz

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.

dfr is an optional data folder reference: a data folder name, an absolute or relative data folder path, or a reference returned by, for example, GetDataFolderDFR. The dfr parameter requires Igor Pro 9.00 or later.

Examples

StringList("**",";") Returns a list of all string variables in the current data folder.
StringList("S_*",";") Returns a list of all string variables in the current data folder whose names begin with "S_".

See Also

VariableList, WaveList, DataFolderList
StringMatch

StringMatch(string, matchStr)
The StringMatch function tests string for a match to matchStr. You may include asterisks in matchStr as a wildcard character.

StringMatch returns 1 to indicate a match, 0 for no match or NaN if it ran out of memory.

Details
matchStr is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*" Matches any string.
"xyz" Matches the string “xyz” only.
"*xyz" Matches strings ending with “xyz”, for instance “abcxyz”.
"xyz*" Matches strings beginning with xyz, for instance “xyzpqr”.
"*xyz*" Matches strings containing xyz, for instance “abcxyzpqr”.
"abc*xyz" Matches strings beginning with abc and ending with xyz, for instance “abcpqxyxyz”.

If matchStr begins with the ! character, a match is indicated if string does not match matchStr. For example:

"!*xyz" Matches strings which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else.

Note that matching is case-insensitive, so “xyz” also matches “XYZ” or “Xyz”.

Also note that it is impossible to match an asterisk in string: use GrepString instead.

Among other uses, the StringMatch function can be used to build your own versions of the WaveList function, using NameOfWave and stringmatch to qualify names of waves found by WaveRefIndexedDFR.

See Also
The GrepString, CmpStr, strsearch, Demo, ListMatch, and ReplaceString functions and the sscanf operation.

StringToUnsignedByteWave

StringToUnsignedByteWave(str)
The StringToUnsignedByteWave function returns a free unsigned byte wave containing the contents of str.

If str is an empty string, a zero point wave is returned. If str is null, a null wave reference is returned.

The StringToUnsignedByteWave function was added in Igor Pro 9.00.

Parameters
str is a string.

Details
The StringToUnsignedByteWave function returns a free wave so it can't be used on the command line or in a macro. If you need to convert the free wave to a global wave use MoveWave.

Using StringToUnsignedByteWave makes it possible to use commands that work on waves to manipulate the data originally stored in a string. This can be faster and more convenient than manipulating the data directly in the string. If necessary, you can create a string containing the manipulated data using WaveDataToString.

StringToUnsignedByteWave stores each byte of str in an element of the output wave. It does not do ASCII-to-binary conversion. For example, if str contains "123", it returns an unsigned binary wave containing three elements with values 49, 50, and 51 (0x31, 0x32, and 0x33). It does not return the numeric value 123.

Example
Function DemoStringToUnsignedByteWave()
String theStr = "123"
// This requires Igor 9.00
WAVE/B/U w1 = StringToUnsignedByteWave(theStr)
Print w1

// This works in older versions of Igor
Variable len = strlen(theStr)
Make/B/U/FREE/N=(len) w1
w1 = char2num(theStr[p])
Print w1
End

See Also
WaveDataToString, MoveWave, Free Waves on page IV-91, Working With Binary String Data on page IV-175

strlen

strlen(str)
The strlen function returns the number of bytes in the string expression str.
strlen returns NaN if the str is NULL. A local string variable or a string field in a structure that has never been set is NULL. NULL is not the same as zero length. Use numtype to test if the result from strlen is NaN.

Examples
String zeroLength = ""
String neverSet
Print strlen(zeroLength), strlen(neverSet)

// Test if a string is null
Variable len = strlen(neverSet) // NaN if neverSet is null
if (numtype(len) == 2) // strlen returned NaN?
    Print "neverSet is null"
endif

See Also
Characters Versus Bytes on page III-483, Character-by-Character Operations on page IV-173

strsearch

strsearch(str, findThisStr[, start[, options]])
The strsearch function returns the byte position of the string expression findThisStr in the string expression str.

Details
strsearch performs a case-sensitive search.
strsearch returns -1 if findThisStr does not occur in str.
The search starts from the byte position in str specified by start; 0 references the start of str.
strsearch clips start to one less than the length of str in bytes, so it is useful to use Inf for start when searching backwards to ensure that the search is from the end of str.

options is an optional bitwise parameter specifying the search options:
1: Search backwards from start.
2: Ignore case.
3: Search backwards and ignore case.

Examples
String str="This is a test isn't it?"
Print strsearch(str,"test",0) // prints 10
Print strsearch(str,"TEST",0) // prints -1
Print strsearch(UpperStr(str),"TEST",0) // prints 10
Print strsearch(str,"TEST",0,2) // prints 10
Print strsearch(str,"is",0) // prints 2
**strswitch-case-endswitch**

```plaintext
Print strsearch(str,"is",3) // prints 5
Print strsearch(str,"is",Inf,1) // prints 15
```

See Also

`sscanf`, `FindListItem`, `ReplaceString`, Character-by-Character Operations

See Setting Bit Parameters on page IV-12 for details about bit settings.

**strswitch-case-endswitch**

```
strswitch(<string expression>)
  case <literal><constant>:
    <code>
    [break]
  [default:
    <code>]
endswitch
```

A `strswitch-case-endswitch` statement evaluates a string expression and compares the result to the case labels using a case-insensitive comparison. If a case label matches `string expression`, then execution proceeds with `code` following the matching case label. When none of the cases match, execution will continue at the default label, if it is present, or otherwise the strswitch will be exited with no action taken. Note that although the `break` statement is optional, in almost all case statements it will be required for the strswitch to work correctly.

See Also

Switch Statements on page IV-43, `default` and `break` for more usage details.

**STRUCT**

```
STRUCT structureName localName
```

`STRUCT` is a reference that creates a local reference to a Structure accessed in a user-defined function. When a Structure is passed to a user function, it can only be passed by reference, so in the declaration within the function you must use `&localStructName` to define the function input parameter.

See Also

Structures in Functions on page IV-99 for further information.

See the `Structure` keyword for creating a Structure definition.

**StructFill**

```
StructFill [ /AC=createFlags /SDFR=dfr ] structVar
```

StructFill is a programmer-convenience operation that initializes NVAR, SVAR and WAVE fields in a structure. At run time, it scans through the fields in the specified structure and attempts to set all null NVAR, SVAR and WAVE fields by looking up corresponding same-named globals in the current data folder or in the specified data folder.

StructFill was added in Igor Pro 8.00.

Parameters

`structVar` is the name of a STRUCT variable.
StructGet

Flags

/AC=createFlags Enables auto-creation of globals.

Bit 0 enables creation of numeric and string global variables which are set to 0 and "" respectively. Variables are auto-created only if they do not already exist.

Bit 1 enables creation of waves which are created with zero points. Waves are auto-created only if they do not already exist.

/SDFR=dfr Specifies a data folder. If you omit /SDFR, the current data folder used.

See The /SDFR Flag on page IV-80 for details.

Output Variables
StructFill sets the following output variables:

V_Flag The number of NVAR, SVAR and WAVE fields that were successfully initialized.

V_Error The number of NVAR, SVAR and WAVE fields that could not be initialized.

If auto-creation is off, a field can not be initialized if the corresponding global variable, string variable, or wave does not exist. If auto-creation is on, a field can not be initialized if there was an error creating the global variable or wave.

When using auto-creation, errors are not reported other than via V_Error.

If you unexpectedly get non-zero for V_Error, you can print the structure to see which fields were left null.

See Also
Structures in Functions on page IV-99

StructGet

StructGet [/B=b] structVar, waveStruct[[colNum]]

StructGet /S [/B=b] structVar, strStruct

The StructGet operation reads binary numeric data from a specified column of a wave or from a string variable and copies the data into the designated structure variable. The source wave or string will have been filled beforehand by StructPut.

Parameters

structVar is the name of an existing structure that is to be filled with new data values.

waveStruct is the name of a wave containing binary numeric data that will be used to fill structVar. Use the optional colNum parameter to specify a column from the structure wave. The contents of waveStruct are created beforehand using StructPut.

strStruct is the name of a string variable containing binary numeric data. The contents of strStruct are created beforehand using StructPut.

Flags

/B=b Sets the byte ordering for reading of structure data.

b=0: Reads in native byte order.

b=1: Reads bytes in reversed order.

b=2: Default; reads data in big-endian, high-byte-first order (Motorola).

b=3: Reads data in little-endian, low-byte-first order (Intel).

/S Reads binary data from a string variable, which was set previously with StructPut.

Details

The data that are stored in waveStruct and strStruct are in binary format so you can not directly view a meaningful representation of their contents by printing them or viewing the wave in a table. To view the contents of waveStruct or strStruct you must use StructGet to export them back into a structure and then retrieve the members.
If \( \text{colNum} \) is out of bounds it will be clipped to valid values and an error reported. If the row dimension does not match the structure size, as much data as possible will be copied to the structure.

By default, data are read in big-endian, high-byte order (Motorola). This allows data written on one platform to be read on the other.

**See Also**
The StructPut operation for writing structure data to waves or strings.

### StructPut

**StructPut**

**/B=b**  \( \text{structVar}, \text{waveStruct} \)[[\text{colNum}]]

**StructPut /S**  \( /B=b \) \( \text{structVar}, \text{strStruct} \)

The StructPut operation copies the binary numeric data in a structure variable to a specified column in a wave or to a string variable. The data in the wave or string can be read out into another structure using StructGet.

**Parameters**

- **structVar** is the name of a structure from which data will be exported.
- **waveStruct** is the name of an existing wave to which data will be exported. Use the optional **colNum** parameter to specify a column in **waveStruct** to contain the data. The first column of **waveStruct** will be filled if **colNum** is omitted.
- **strStruct** is the name of an existing string variable to which data will be exported.

**Flags**

- **/B=b**  Sets the byte ordering for writing of structure data.
  - \( b=0 \): Writes in native byte order.
  - \( b=1 \): Writes bytes in reversed order.
  - \( b=2 \): Default; writes data in big-endian, high-byte-first order (Motorola).
  - \( b=3 \): Writes data in little-endian, low-byte-first order (Intel).

- **/S**  Writes binary data to a string variable.

**Details**

The structure fields to be exported must contain only numeric data in either integer, floating point, or double precision format. If the structure contains any objects such as String, NVAR, WAVE, etc., then only the numeric data at the end of the structure is copied. If there is no suitable data at the end, an error is generated at compile time. Prior to Igor Pro 8, the presence of any illegal field would result in an error.

If needed, StructPut will redimension **waveStruct** to unsigned byte format, will set the number of rows to equal the size of the structure, and set the column dimension large enough to accommodate the size specified by **colNum**. You can think of **waveStruct** as a one-dimensional array of structure contents indexed by **colNum** although the wave is actually two-dimensional with each column containing a copy of a separate structure.

By default, data are written in big-endian, high-byte order (Motorola). This allows data written on one platform to be read on the other.

After you have exported the structure data to **waveStruct** or **strStruct** they will contain binary data that you cannot inspect directly. To view the contents of **waveStruct** or **strStruct**, you must use the original structure or use StructGet to export them into another structure.

**See Also**
The StructGet operation for reading structure data from waves or strings.
Structure

Structure structureName
   memType memName [arraySize] [, memName [arraySize]]

... EndStructure

The Structure keyword introduces a structure definition in a user function. Within the body of the structure you declare the member type (memType) and the corresponding member name(s) (memName). Each memName may be declared with an optional array size.

Details

Structure member types (memType) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, DFREF, FUNCREF, or STRUCT.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

<table>
<thead>
<tr>
<th>Igor Member Type</th>
<th>C Equivalent</th>
<th>Size</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>signed 8-bit int</td>
<td>1 byte</td>
<td></td>
</tr>
<tr>
<td>uchar</td>
<td>unsigned 8-bit int</td>
<td>1 byte</td>
<td></td>
</tr>
<tr>
<td>int16</td>
<td>signed 16-bit int</td>
<td>2 bytes</td>
<td></td>
</tr>
<tr>
<td>uint16</td>
<td>unsigned 16-bit int</td>
<td>2 bytes</td>
<td></td>
</tr>
<tr>
<td>int32</td>
<td>signed 32-bit int</td>
<td>4 bytes</td>
<td></td>
</tr>
<tr>
<td>uint32</td>
<td>unsigned 32-bit int</td>
<td>4 bytes</td>
<td></td>
</tr>
<tr>
<td>int64</td>
<td>signed 64-bit int</td>
<td>8 bytes</td>
<td>Requires Igor Pro 7.00 or later</td>
</tr>
<tr>
<td>uint64</td>
<td>unsigned 64-bit int</td>
<td>8 bytes</td>
<td>Requires Igor Pro 7.00 or later</td>
</tr>
<tr>
<td>float</td>
<td>float</td>
<td>4 bytes</td>
<td></td>
</tr>
<tr>
<td>double</td>
<td>double</td>
<td>8 bytes</td>
<td></td>
</tr>
</tbody>
</table>

The Variable and double types are identical although Variable can be also specified as complex (using the /C flag).

Each structure member may have an optional arraySize specification, which gives the number of elements contained by the structure member. The array size is an integer number from 1 to 400 except for members of type STRUCT for which the upper limit is 100.

See Also

Structures in Functions on page IV-99 for further information.

See the STRUCT declaration for creating a local reference to a Structure.

StrVarOrDefault

StrVarOrDefault(pathStr, defStrVal)

The StrVarOrDefault function checks to see if pathStr points to a string variable and if so, it returns its value. If the string variable does not exist, returns defStrVal instead.

Details

StrVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. Numeric variables use the corresponding numeric function, NumVarOrDefault.

Examples

Macro foo(nval, sval)
   Variable nval=NumVarOrDefault("root:Packages:mypack:nvalSav",2)
   String sval=StrVarOrDefault("root:Packages:mypack:svalSav","Hi")
   DFREF dfSav= GetDataFolderDFR() 
   NewDataFolder/O/S root:Packages
NewDataFolder/O/S mypack
Variable/G nvalSav= nval
String/G svalSav= sval
SetDataFolder dfSav
End

**StudentA**

**StudentA( t, DegFree)**

*Note:* This function is deprecated. New code should use the more accurate **StatsStudentCDF**.

The StudentA function returns the area from -t to t under the Student’s T distribution having *DegFree* degrees of freedom. That is, it returns the probability that a random sample from Student’s T is between -t and t.

Note that this is the bi-tail result. That is, it gives the area from -t to t, rather than the cumulative area from -∞ to t. It is this latter number that is commonly tabulated - StudentA returns the probability 1-α where the area from -∞ to t is the probability 1-α/2.

StudentA tests whether a normally-distributed statistic is significantly different from a certain value. You could use it to test whether an intercept from a line fit is significantly different from zero:

Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
CurveFit line Data /D
Print "Prob = ", StudentA(W_coef[0]/W_sigma[0], V_npnts-2)

Because the noise is random, the results will differ slightly each time this is tried. When we did it, the result was:

Prob = 0.999898

which indicates that the intercept of the line fit was different from zero with 99.99 per cent probability.

See Also
StatsStudentCDF, StatsStudentPDF, StatsInvStudentCDF

**StudentT**

**StudentT( Prob, DegFree)**

*Note:* This function is deprecated. New code should use the more accurate **StatsInvStudentCDF**.

The StudentT function returns the t value corresponding to an area *Prob* under the Student’s T distribution from -t to t for *DegFree* degrees of freedom.

Note that this is a bi-tail result, which is what is usually desired. Tabulated values of the Student’s T distribution are commonly the one-sided result.

StudentT calculates confidence intervals from standard deviations for normally-distributed statistics. For instance, you can use it to calculate a confidence interval for the coefficients from a curve fit:

Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
CurveFit line Data /D
print "intercept = ", W_coef[0], "±", W_sigma[0]*StudentT(0.95, V_npnts-2)
print "slope = ", W_coef[1], "±", W_sigma[1]*StudentT(0.95, V_npnts-2)

See Also
StatsStudentCDF, StatsStudentPDF, StatsInvStudentCDF

**Submenu**

**Submenu menuNameStr**

The Submenu keyword introduces a submenu definition. It is used inside a Menu definition. See Chapter IV-5, **User-Defined Menus** for further information.
sum

\[ \text{sum(waveName [, x1, x2])} \]

The sum function returns the sum of the wave elements for points from \( x=x1 \) to \( x=x2 \).

Details

The X scaling of the wave is used only to locate the points nearest to \( x=x1 \) and \( x=x2 \). To use point indexing, replace \( x1 \) with \( \text{pnt2x(waveName, pointNumber1)} \), and a similar expression for \( x2 \).

If \( x1 \) and \( x2 \) are not specified, they default to \(-\infty\) and \( +\infty \), respectively.

If the points nearest to \( x1 \) or \( x2 \) are not within the point range of \( 0 \) to \( \text{numpnts(waveName)}-1 \), sum limits them to the nearest of point \( 0 \) or point \( \text{numpnts(waveName)}-1 \).

If any values in the point range are NaN, sum returns NaN.

Examples

Make/O/N=100 data; SetScale/I x 0,Pi,data
data=sin(x)
Print sum(data,0,Pi)  // the entire point range, and no more
Print sum(data)        // same as -infinity to +infinity
Print sum(data,Inf,-Inf)  // +infinity to -infinity

The following is printed to the history area:

Print sum(data,0,Pi)  // the entire point range, and no more
63.0201
Print sum(data)        // same as -infinity to +infinity
63.0201
Print sum(data,Inf,-Inf)  // +infinity to -infinity
63.0201

See Also

mean, area, SumSeries, SumDimension

SumDimension

\text{SumDimension [flags] srcWave}

The SumDimension operation sums values in \( srcWave \) along the specified dimension.

The SumDimension operation was added in Igor Pro 7.00.

Flags

/\text{D=dimension} \quad \text{Specifies a zero-based dimension number.}
\quad \text{\emph{dimension}0: Rows}
\quad \text{\emph{dimension}1: Columns}
\quad \text{\emph{dimension}2: Layers}
\quad \text{\emph{dimension}3: Chunks}

If you omit /\text{D} the operation sums the highest dimension in the wave.

/\text{DEST=destWave} \quad \text{Specifies the output wave created by the operation. If \text{destWave} already exists it is overwriten by the new results.}

If you omit /\text{DEST} the operation saves the data in W_SumDimension if the output wave is 1D or M_SumDimension otherwise.

/\text{Y=type} \quad \text{Specifies the data type of the output wave. See \text{WaveType} for the supported values of type.}

If you omit /\text{Y}, the output wave is double precision.

Pass -1 for type to force the output wave to have the same data type as \( srcWave \).

Details

The operation sums one dimension of an N dimensional wave producing an output wave with N-1 dimensions except if \( srcWave \) is 1D wave in which case SumDimension produces a single point 1D output wave. For example, given a 4D wave of dimensions \( \text{dim0 x dim1 x dim2 x dim3} \) and the command:
SumSeries

SumDimension/D=1/DEST=wout wave4d
creates a wave wout that satisfies

\[ wout[i][j][k][l] = \sum_{j=0}^{\text{dim 1}-1} \text{wave4d}[i][j][k][l], \]

and wout has dimensions \( \text{dim 0} \times \text{dim 2} \times \text{dim 3} \).
If any values in srcWave are NaN, the corresponding sum element will be NaN.

See Also
sum
MatrixOp keywords sumRows, sumCols, sumBeams
ImageTransform keywords sumAllCols, sumAllRows, sumPlane, sumPlanes

SumSeries

SumSeries [flags] keyword=value
The SumSeries operation computes the sum of the results returned from a user-defined function for input values between two specified index limits.
SumSeries was added in Igor Pro 7.00.

Flags
/CCNT=nc When summing with one or two infinite limits you can use this flag to specify the minimum number of calls to the summand function which, when added to the sum, produce a change that is less than the tolerance. By default \( n_c=10 \).
If you are summing a well-behaved monotonic series it is sufficient to set \( n_c=1 \). In some pathological cases it is useful to check that the sum remains effectively unchanged even after many terms are added to the series.

/INAN Ignore NaNs returned from the user function. In the case of a complex valued summand, a NaN in either the real or imaginary components excludes the contribution of the term to the sum.

/Q Quiet mode; do not print in the history.

/Z[=z] /Z or /Z=1 prevents reporting any errors. If the operation encounters an error it sets V_Flag to the error code.

Keywords
lowerLimit=n1 Specifies the starting index at which the summand is evaluated. \( n1 \) must be either an integer -INF.

series=userFunc Specifies the name of the user function that returns the summand (i.e., a single term in the sum that corresponds to the input index). See The SumSeries Summand Function below for details.

upperLimit=n2 Specifies the last value at which the summand is evaluated. \( n2 \) must be either an integer INF.

tolerance=tol Specifies a tolerance value used when one or both of the limits are infinite. By default, the tolerance value is 1e-10. \( tol \) must be finite. If both limits are finite this keyword is ignored.

paramWave=pw \( pw \) is a single-precision or double-precision wave that is passed to the summand function. This is useful if you need to provide the summand function external/global data.
If you omit the paramWave keyword then the summand function receives a null wave as the parameter wave.
The SumSeries Summand Function
You specify the summand function using the series keyword. The form of the user-defined summand function is:

```plaintext
Function summandReal(inW,index)
  Wave inW
  Variable index
  ... compute something
  return result
End
```

The index changes by 1 for each successive call to the summand.

You can also define a complex summand function:

```plaintext
Function/C summandComplex(inW,index)
  Wave inW
  Variable index
  ... compute something
  Variable/C result
  return result
End
```

Details
The SumSeries operation is primarily intended for use with one or two infinite limits. If both limits are finite the operation performs the straightforward sum by calling the summand function once for every index from lowerLimit to upperLimit, inclusive.

If one limit is infinite the sum is evaluated by starting from the finite limit and proceeding in the direction of the infinite limit index until convergence is reached. Convergence in this context is defined as multiple (nc) consecutive calls to the summand which do not change the value of the sum by more than the tolerance value. By default nc=10 but you can change it using the /CCNT flag.

When both limits are infinite the operation first computes the sum for indices 0 to INF and then the sum from -1 to -INF. The two calculations are independent and require that the same convergence condition is met independently in each case. When the summand function is complex the convergence condition must hold for the real and imaginary components independently.

The operation does not perform any test on the summand function to estimate its rate of convergence. If you provide a non-converging summand function the operation can run indefinitely. You can abort it by pressing the User Abort Key Combinations or by clicking the Abort button.

The result of the sum is stored in V_resultR and, if the summand function returns a complex result, V_resultI.

If the calculation completes without error V_Flag is set to 0. Otherwise it contains an error code.

Examples
A simple test case is the geometric series for powers of 1/2. The sum of xi for i=0 to i=INF where 0<x<1 is given by 1/(1-x). For x=1/2, this sum is 2.

```plaintext
Function s1(paramWave, index)
  Wave/Z paramWave // Not used
  Variable index
  return 0.5^index
End
```

// Execute:
SumSeries series=s1,lowerLimit=0,upperLimit=INF
Print V_resultR

In the next example we use the series expansion of cosine and sine to evaluate exp(i*pi).

```plaintext
Function/C s2(paramWave, index)
  Wave/Z paramWave // Not used
  Variable index
  Variable n2=2*index
  Variable xx=pi^n2
  Variable sn=((-1)^index
  Variable fn=Factorial(n2)
```
SVAR

    return cmplx(sn*xx/fn,sn*xx*pi/(fn*(n2+1)))
End

// Execute:
SumSeries series=s2,lowerLimit=0,upperLimit=INF
Print V_resultR,V_resultI

In the next example we sum 18 terms in the series for exp(x) using a parameter wave to pass the value of x.

Function fex(paramWave, index)
    Wave/Z paramWave // Contains x value at which to evaluate exp(x)
    Variable index

    Variable xx = paramWave[0]
    if (index == 0)
        return 1
    endif
    return (xx^index) / factorial(index)
End

// Execute:
Make/D/O exponent = {-1} // The value of x at which to evaluate exp(x)
SumSeries series=fex, lowerLimit=0, upperLimit=17, paramWave=exponent
Print/D V_resultR - exp(-1) // Compare with built-in exp function

See Also
Integrate1D, sum

SVAR

SVAR [/Z] [/SDFR=dfr] localName [= pathToStr] [, localName1 [= pathToStr1]]...

SVAR is a declaration that creates a local reference to a global string variable accessed in a user-defined function.

The SVAR reference is required when you access a global string variable in a function. At compile time, the SVAR statement specifies a local name referencing a global string variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global string variable must exist when the SVAR statement is executed.

When localName is the same as the global string variable name and you want to reference a global variable in the current data folder, you can omit pathToStr.

pathToStr can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or $ followed by string variable containing a computed path (see Converting a String into a Reference Using $ on page IV-62).

You can also use a data folder reference or the /SDFR flag to specify the location of the string variable if it is not in the current data folder. See Data Folder References on page IV-78 and The /SDFR Flag on page IV-80 for details.

If the global variable may not exist at runtime, use the /Z flag and call SVAR_Exists before accessing the variable. The /Z flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:

SVAR/Z nv=<pathToPossiblyMissingStringVariable>
if( SVAR_Exists(sv) )
    <do something with sv>
endif

Note that to create a global string variable, you use the String/G operation.

Flags

/SDFR=dfr Specifies the source data folder. See The /SDFR Flag on page IV-80 for details.
/Z An SVAR reference to a null string variable does not cause an error or a debugger break.

See Also
SVAR_Exists function.

Accessing Global Variables and Waves on page IV-65.
SVAR_Exists

SVAR_Exists(name)
The SVAR_Exists function returns 1 if the specified SVAR reference is valid or 0 if not. It can be used only in user-defined functions.

For example, in a user function you can test if a global string variable exists like this:

```
SVAR /Z str1 = gStr1 // /Z prevents debugger from flagging bad SVAR
if (!SVAR_Exists(str1)) // No such global string variable?
    String/G gStr1 = "" // Create and initialize it
endif
```

See Also
WaveExists, NVAR_Exists, and Accessing Global Variables and Waves on page IV-65.

switch-case-endswitch

```
switch(<numeric_expression>)
    case <literal><constant>:
        <code>
        [break]
    [default:
        <code>]
endswitch
```

A switch-case-endswitch statement evaluates the numeric expression and rounds the result to the nearest integer. If a case label matches numerical expression, then execution proceeds with code following the matching case label. When no cases match, execution continues at the default label, if present, or otherwise the switch exits with no action taken. Although the break statement is optional, in almost all case statements it is required for the switch to work correctly.

Literal numbers used as case labels are required by the compiler to be integers. Numeric constants used as case labels are rounded by the compiler to the nearest integers.

See Also
Switch Statements on page IV-43, default and break for more usage details.

t

t
The t function returns the T value for the current chunk of the destination wave when used in a multidimensional wave assignment statement. T is the scaled chunk index while s is the chunk index itself.

Details
Unlike x, outside of a wave assignment statement, t does not act like a normal variable.

See Also
Waveform Arithmetic and Assignments on page II-74.

For other dimensions, the p, q, r, and s functions.

For scaled dimension indices, the x, y, and z functions.

TabControl

TabControl [/Z] ctrlName [keyword = value [, keyword = value ...]]
The TabControl operation creates tab panels for controls.

For information about the state or status of the control, use the ControlInfo operation.

Parameters
ctrlName is the name of the TabControl to be created or changed.
TabControl

The following keyword=value parameters are supported:

align=alignment
Sets the alignment mode of the control. The alignment mode controls the interpretation of the leftOrRight parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

If alignment=0 (default), leftOrRight specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If alignment=1, leftOrRight specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

appearance={kind [, platform]}
Sets the appearance of the control. platform is optional. Both parameters are names, not strings.

kind can be one of default, native, or os9.
platform can be one of Mac, Win, or All.

See DefaultGUIControls Default Fonts and Sizes for how enclosed controls are affected by native TabControl appearance.
See Button for more appearance details.

disable=d
Sets user editability of the control.

d=0: Normal.
d=1: Hide.
d=2: Draw in gray state; disable control action.

dColor=(r,g,b[,a])
Sets the initial color of the tab labels. r, g, b, and a specify the color and optional opacity as RGBA Values. Use of transparency is discouraged. The default is opaque black.

To further change the color of the tab labels text, use escape sequences in the text specified by the tabLabel keyword.

focusRing=fr
Enables or disables the drawing of a rectangle indicating keyboard focus:

fr=0: Focus rectangle will not be drawn.
fr=1: Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

font= "fontName"
Sets the font used for tabs, e.g., font="Helvetica".

fsize= s
Sets the font size for tabs.

fstyle=fs
fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:

Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

help={helpStr}
Sets the help for the control.

helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).
You can insert a line break by putting "\n" in a quoted string.
TabControl

**Flags**

_/Z_ No error reporting.

**TabControl Action Procedure**

The action procedure for a TabControl takes a predefined `WMTabControlAction` structure as a parameter to the function:

```plaintext
Function ActionProcName(TC_Struct) : TabControl
    STRUCT WMTabControlAction &TC_Struct
    --
    return 0
End
```

The ": TabControl" designation tells Igor to include this procedure in the Procedure pop-up menu in the Tab Control dialog.

See `WMTabControlAction` for details on the `WMTabControlAction` structure.

Although the return value is not currently used, action procedures should always return zero.

When clicking a TabControl with the selector arrow, click in the title region. The control is not selected if you click in the body. This is to make it easier to select controls in the body rather than the TabControl itself.

---

**labelBack**

Sets fill color for current tab and the interior. _r, g, b_, and _a_ specify the color and optional opacity as **RGBA Values**.

If not set, then interior is transparent and the current tab is filled with the window background, though this style is platform-dependent.

If you use an opaque fill color, drawing objects will not be seen because they will be covered up.

**noproc**

Specifies that no function is to run when clicking a tab.

**pos={leftOrRight,top}**

Sets the position in **Control Panel Units** of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

**pos+={dx,dy}**

Offsets the position of the control in **Control Panel Units**.

**proc=procName**

Specifies the function to run when the tab is pressed. Your function must hide and show other controls as desired. The TabControl does not do this automatically.

**size={width,height}**

Sets TabControl size in **Control Panel Units**.

**tabLabel(n)=lbl**

Sets _n_th tab label to _lbl_.

Set the label of the last tab to "" to remove the last tab.

Using escape codes you can change the font, size, style, and color of the label. See **Annotation Escape Codes** on page III-53 or details.

**userdata(UDName)=UDStr**

Sets the unnamed user data to _UDStr_. Use the optional (UDName) to specify a named user data to create.

**userdata(UDName)+=UDStr**

Appends _UDStr_ to the current unnamed user data. Use the optional (UDName) to append to the named _UDStr_.

**value=v**

Sets current tab number. Tabs count from 0.

**win=winName**

Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with **winName**, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
Example
Designing a TabControl with all the accompanying interior controls can be somewhat difficult. Here is a suggested technique:

First, create and set the size and label for one tab. Then create the various controls for this first tab. Before starting on the second tab, create the TabControl’s procedure so that it can be used to hide the first set of controls. Then add the second tab, click it to run your procedure and start adding controls for this new tab. When done, update your procedure so the new controls are hidden when you start on the third tab.

Here is an example:

1. Create a panel and a TabControl:
   
   NewPanel /W=(150,50,478,250)
   ShowTools
   TabControl MyTabControl,pos={29,38},size={241,142},tabLabel(0)="First Tab",value=0

2. Add a few controls to the interior of the TabControl:
   
   Button button0,pos={52,72},size={80,20},title="First"
   CheckBox check0,pos={52,105},size={102,15},title="Check first",value=0

3. Write an action procedure:
   
   Function TabActionProc(tc) : TabControl
   STRUCT WMTabControlAction& tc
   switch(tc.eventCode)
     case 2: // Mouse up
       Button button0, disable=(tc.tab!=0)
       CheckBox check0, disable=(tc.tab!=0)
     break
   endswitch
   End

4. Set the action procedure and add a new tab:
   
   TabControl MyTabControl,proc=TabActionProc,tabLabel(1)="Second Tab"

5. Click the second tab, which hides the first tab’s controls, and then add new controls like this:
   
   Button button1,pos={58,73},size={80,20},title="Second"
   CheckBox check1,pos={60,105},size={114,15},title="Check second",value= 0

6. Finally, change the action procedure by adding these lines at the end:
   
   Button button1,disable=(tc.tab!=1)
   CheckBox check1,disable=(tc.tab!=1)

See Also
Chapter III-14, Controls and Control Panels, for details about control panels and controls.
Control Panel Units on page III-444 for a discussion of the units used for controls.
The GetUserData function for retrieving named user data.
The ControlInfo operation for information about the control.
The ModifyControl and ModifyControlList operations.

TabControl

TabControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined tab control. See Procedure Subtypes on page IV-204 for details. See TabControl for details on creating a tab control.

Table

Table is a procedure subtype keyword that identifies a macro as being a table recreation macro. It is automatically used when Igor creates a window recreation macro for a table. See Procedure Subtypes on page IV-204 and Killing and Recreating a Table on page II-241 for details.
TableStyle

TableStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Table dialog and in the Table Macros menu. See Table Style Macros on page II-272 for details.

TableInfo

TableInfo(winNameStr, itemIndex)

The TableInfo function returns a string containing a semicolon-separated list of keywords and values that describe a column in a table or overall properties of the table. The main purpose of TableInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges a table or which manipulates the table selection.

Parameters

winNameStr is the name of an existing table window or "" to refer to the top table.

itemIndex is one of the following:

<table>
<thead>
<tr>
<th>itemIndex Value</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>Information about the table as a whole.</td>
</tr>
<tr>
<td>-1</td>
<td>Information about the Point column</td>
</tr>
<tr>
<td>≥0</td>
<td>Information about a column other than the Point column. 0 refers to the first column after the Point column, 1 refers to the second column after the Point column, and so on.</td>
</tr>
</tbody>
</table>

TableInfo returns "" in the following situations:

• winNameStr is "" and there are no table windows.
• winNameStr is a name but there are no table windows with that name.
• itemIndex not -2 and is out of range for an existing column.

Details

If itemIndex is -2, the returned string describes the table as a whole and contains the following keywords, with a semicolon after each keyword-value pair.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLENAME</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>HOST</td>
<td>The host specification of the table’s host window if it is a subwindow or &quot;&quot; if it is a top-level table window.</td>
</tr>
<tr>
<td>ROWS</td>
<td>Number of used rows in the table.</td>
</tr>
<tr>
<td>COLUMNS</td>
<td>Number of used columns in the table including the Point column.</td>
</tr>
<tr>
<td>SELECTION</td>
<td>A description of the table selection as you would specify it when invoking the ModifyTable operation’s selection keyword.</td>
</tr>
<tr>
<td>FIRSTCELL</td>
<td>An identification of the first visible data cell in the top/left corner of the table in row-column format. The first data cell is at location 0, 0.</td>
</tr>
<tr>
<td>LASTCELL</td>
<td>An identification of the last visible data cell in the bottom/right corner of the table in row-column format.</td>
</tr>
</tbody>
</table>
If itemIndex is -1 up to but not including the number of used columns to the right of the Point column, the returned string describes the specified column and contains the following keywords, with a semicolon after each keyword-value pair.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>TARGETCELL</td>
<td>An identification of the target (highlighted) data cell in row-column format.</td>
</tr>
<tr>
<td>ENTERING</td>
<td>1 if an entry has been started in the entry line, 0 if not.</td>
</tr>
<tr>
<td>ENTRYTEXT</td>
<td>The text displayed in the entry line. If the user is editing the text in the entry line, this is the text as edited so far. If the user is not editing, it is the value of the first selected cell, as text.</td>
</tr>
<tr>
<td></td>
<td>The ENTRYTEXT keyword is the last keyword-value pair in the returned string. It is not terminated with a trailing &quot;;&quot; character unless the entry line text itself ends with &quot;;&quot;.</td>
</tr>
<tr>
<td></td>
<td>The ENTRYTEXT keyword was added in Igor Pro 9.00.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLENAME</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>HOST</td>
<td>The host specification of the table’s host window if it is a subwindow or &quot;&quot; if it is a top-level table window.</td>
</tr>
<tr>
<td>COLUMNNAME</td>
<td>Name of the column as you would specify it to the Edit operation if you were creating a table showing just the column of interest.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Column’s type which will be one of the following: Unused, Point, Index, Label, Data, RealData, ImagData. “Index” identifies a index column such as the X values of a wave. “Label” identifies a column of dimension labels. “Data” identifies a data column of a scalar wave. RealData and ImagData identify a real or imaginary column of a complex wave.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Column’s position. -1 refers to the Point column, 0 to the first data column, and so on.</td>
</tr>
<tr>
<td>DATATYPE</td>
<td>Numeric data type of the wave or zero for text waves. See WaveType for a definition of data type codes.</td>
</tr>
<tr>
<td>WAVE</td>
<td>A full data folder path to the wave displayed in the column or &quot;&quot; for the Point column.</td>
</tr>
<tr>
<td>COLUMNS</td>
<td>The total number of columns in the table from the wave for the column for which you are getting information. This can be used to skip over all of the columns of a multidimensional wave.</td>
</tr>
<tr>
<td>HDIM</td>
<td>The wave dimension displayed horizontally as you move from one column to the next. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.</td>
</tr>
<tr>
<td>VDIM</td>
<td>The wave dimension displayed vertically in the column. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.</td>
</tr>
<tr>
<td>TITLE</td>
<td>As specified for the ModifyTable operation’s title keyword.</td>
</tr>
<tr>
<td>WIDTH</td>
<td>Column’s width in points.</td>
</tr>
<tr>
<td>FORMAT</td>
<td>As specified for the ModifyTable operation’s format keyword.</td>
</tr>
<tr>
<td>DIGITS</td>
<td>As specified for the ModifyTable operation’s digits keyword.</td>
</tr>
<tr>
<td>SIGDIGITS</td>
<td>As specified for the ModifyTable operation’s sigDigits keyword.</td>
</tr>
<tr>
<td>TRAILINGZEROS</td>
<td>As specified for the ModifyTable operation’s trailingZeros keyword.</td>
</tr>
<tr>
<td>SHOWFRACSECONDS</td>
<td>As specified for the ModifyTable operation’s showFracSeconds keyword.</td>
</tr>
</tbody>
</table>
Examples
This example makes the table’s target cell advance by one position within the range of selected cells each time it is called. To try it, create a table, select a range of cells and then run the function using the Macros menu.

Menu "Macros"
"Test/1", /Q, AdvanceTargetCell("")
End

Function AdvanceTargetCell(tableName)
    String tableName // Name of table or "" for top table.
    String info = TableInfo(tableName, -2)
    if (strlen(info) == 0)
        return -1 // No such table
    endif
    String selectionInfo
    selectionInfo = StringByKey("SELECTION", info)
    Variable fRow, fCol, lRow, lCol, tRow, tCol
    sscanf selectionInfo, "%d,%d,%d,%d,%d,%d", fRow, fCol, lRow, lCol, tRow, tCol
    tCol += 1
    if (tCol > lCol)
        tCol = fCol
        tRow += 1
        if (tRow > lRow)
            tRow = fRow
        endif
    endif
    ModifyTable selection=(-1, -1, -1, -1, tRow, tCol)
End

The ModifyTable operation.

Tag
Tag [flags] [taggedObjectName, xAttach [, textStr]]
The Tag operation puts a tag on the target or named graph window or subwindow. A tag is an annotation that is attached to a particular point on a trace, image, waterfall plot, or axis in a graph.

The Tag operation can be invoked in several ways as illustrated by these examples:

// Make a wave and a graph
Make wave0 = sin(x/8); Display wave0

// Tag command with all optional parameters included
Tag/N=tag0 wave0, 0, "Point 0 on wave0" // Add a tag to a trace

// Tag command with all optional parameters omitted
Tag/C=N=tag0/F=0 // Change frame using /F flag

// Tag command with optional text parameter omitted
Tag/C/N=tag0 wave0, 50 // Change the tagged point
taggedObjectName and xAttach can be omitted only when changing an existing tag using Tag/C/N=<tagName>. 
textStr can be included only if taggedObjectName and xAttach are included.

Parameters

taggedObjectName is a trace, image or axis name which identifies the object to which the tag is to be attached. The name can be optionally followed by the # character and an instance number to distinguish multiple trace or image instances of the same wave. An axis name can be one of the standard axis names (bottom, top, left, or right) or a user-defined free axis name.

The taggedObjectName parameter is a name so, if you have a string variable containing the name, you must precede the string variable name with the $ operator.

xAttach identifies the point on the trace, image, or axis, to which the tag is to be attached. See xAttach Parameter below for details.

textStr is the text that is to appear in the tag.

xAttach Parameter

xAttach identifies the point on the trace, image, or axis, to which the tag is to be attached.

For a trace tag, xAttach is the X wave scaling value of the attachment point.

For an image tag, xAttach is the X index in terms of the image wave's X scaling of the wave element to be tagged treating the wave as if it were 1D.

For a horizontal axis tag, xAttach is the X axis value of the point on the axis to which the tag is to be attached. Specifying NaN for xAttach centers the tag on the axis.

For a vertical axis tag, xAttach is the Y axis value of the point on the axis to which the tag is to be attached. Specifying NaN for xAttach centers the tag on the axis.

Flags

/A=anchorCode

Specifies position of tag anchor point. anchorCode is a literal, not a string.

LT left top
LC left center
LB left bottom
MT middle top
MC middle center (default)
MB middle bottom
RT right top
RC right center
RB right bottom

The anchor point is on the tag itself. Any line or arrow drawn from the tag to the wave starts at the tag’s anchor point. The anchor point also determines the precise spot on the tag which represents its position.

/AM=a0

Sets the text’s auto-orientation mode. A non-zero a0 value overrides the /O value.

/AM is for trace tags only. Setting /AM for any other kind of annotation has no effect.

An auto-oriented tag’s text rotates whenever it is redrawn, usually when the underlying data changes, the graph is resized, or when the tag is attached to a new point.
The values for $ao$ are:
- $ao=0$: No auto-orientation. Use the /O value (default).
- $ao=1$: Tangent to the trace line at the attachment point.
- $ao=2$: Tangent to the trace line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.
- $ao=3$: Perpendicular to the trace line.
- $ao=4$: Perpendicular to the trace line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.

/AXS[/isAxisTag] Specifies that $taggedObjectName$ is to be interpreted as an axis name. This is useful when the axis name is the same as one of the graph’s trace or image instance names. /AXS is the same as /AXS=1. The /AXS flag was added in Igor Pro 9.00.

/B=(r,g,b[,a]) Sets color of the tag’s background. $r$, $g$, $b$, and $a$ specify the color and optional opacity as RGBA Values.

/B=b Controls the tag background.
- $b=0$: Opaque background.
- $b=1$: Transparent background.
- $b=2$: Same background as the graph plot area background.
- $b=3$: Same background as the window background.

/C Changes the existing tag.

/F=frame Controls the tag frame.
- $frame=0$: No frame.
- $frame=1$: Underline frame.
- $frame=2$: Box frame.

/G=(r,g,b[,a]) Sets color of the text in the tag. $r$, $g$, $b$, and $a$ specify the color and optional opacity as RGBA Values.

/H=legendSymbolWidth $legendSymbolWidth$ sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.

/I=i Controls the tag visibility.
- $i=1$: Tag will be invisible if it is “off screen”. “Off screen” means that its attachment point or any part of the tag’s text is off screen. This is esthetically pleasing but gives you nothing to grab if you want to drag the tag back on screen.
- $i=0$: Tag will always be visible. If it is “off screen”, it appears at the extreme edge of the graph.

/IMG[/isAxisTag] Specifies that $taggedObjectName$ is to be interpreted as an image instance name. This is useful when the image instance name is the same as one of the graph’s trace instance names or one of the axis names. /IMG is the same as /IMG=1. The /IMG flag was added in Igor Pro 9.00.

/K Kills existing tag.

/L=line Controls the line attaching the tag to the tagged point.
- $line=0$: No line from tag to attachment point.
- $line=1$: Line connecting tag to attachment point.
- $line=2$: Line with arrow pointing from tag to attachment point.
- $line=3$: Line with arrow pointing from attachment point to tag.
- $line=4$: Line with arrows at both ends.
<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/LS= linespace</td>
<td>Specifies a tweak to the normal line spacing where linespace is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.</td>
</tr>
<tr>
<td>/M[=sameSize]</td>
<td>/M or /M=1 specifies that legend markers should be the same size as the marker in the graph. /M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.</td>
</tr>
<tr>
<td>/N=name</td>
<td>Specifies name of the tag to create or change.</td>
</tr>
<tr>
<td>/O=rot</td>
<td>Sets the text’s rotation. rot is in (integer) degrees, counterclockwise and must be a number from -360 to 360. 0 is normal horizontal left-to-right text, 90 is vertical bottom-to-top text. If the tag is attached to a trace (not an image or axis), any non-zero /AO value will overwrite this rotation value.</td>
</tr>
<tr>
<td>/P=tipOffset</td>
<td>Sets the offset from the tip of a tag’s line or arrow to the point on the wave that it is tagging. tipOffset is a positive number from 0 to 200 in points. If tipOffset=0 (default), it automatically chooses an appropriate offset.</td>
</tr>
<tr>
<td>/Q[=contourInstance]</td>
<td>Associates a tag with a particular contour level trace in a graph recreation macro. Of interest mainly to hard-core programmers. When “=contourInstance” is present, /Q associates the tag with the contour wave. Igor will feel free to change or delete the tag, as appropriate, when it recalculates the contour (because you changed the contour data or appearance, the graph size or the axis range). contourInstance is a contour instance name, such as zWave or zWave#1 if you have the same wave contoured twice in the graph. /Q by itself, with “=contourInstance” not present, disassociates the tag from the contour wave. Igor will no longer modify or delete the tag (unless the contour level to which it is attached is deleted). If you manually tweak a contour label, using the Modify Annotation dialog, Igor uses this flag.</td>
</tr>
<tr>
<td>/R=newName</td>
<td>Renames the tag.</td>
</tr>
<tr>
<td>/S=style</td>
<td>Controls the tag frame style. style=0: Single frame. style=1: Double frame. style=2: Triple frame. style=3: Shadow frame.</td>
</tr>
<tr>
<td>/T=tabSpec</td>
<td>tabSpec is a single number in points, such as /T=72, for evenly spaced tabs or a list of tab stops in points such as /T={50, 150, 225}.</td>
</tr>
<tr>
<td>/TL=extLineSpec</td>
<td>Specifies extended tag line parameters similar to the SetDrawEnv arrow settings. extLineSpec = {keyword = value,...} or zero to turn off all extended specifications.</td>
</tr>
</tbody>
</table>
Valid keyword-value pairs are:

- **len=l**  
  Length of arrow head in points (l=0 for auto).
- **fat=f**  
  Width to length ratio of arrow head (default is 0.5 same as f=0).
- **style=s**  
  Sets barb side mode (see SetDrawEnv astyle for values).
- **shar =s**  
  Sets sharpness between -1 and 1 (default is 0; blunt).
- **frame=f**  
  Sets frame thickness in outline mode.
- **lThick=l**  
  Sets line thickness in points (default is 0.5 for l=0).
- **lineRGB=(r,g,b[a])**  
  Sets color for lines. r, g, b, and a specify the color and optional opacity as RGBA Values. The default is opaque black.
- **dash=d**  
  Specifies dash pattern number between 0 and 17 (see SetDashPattern for patterns).

/W=winName  
Operates on the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/V=vis  
Controls annotation visibility.

- **vis=0:** Invisible annotation; not selectable. The annotation is still listed in AnnotationList.
- **vis=1:** Visible annotation (default).

/X=xOffset  
Distance from point to tag as percentage of graph width. For axis tags, the offsets are proportional to the size of the text used for the axis labels.

/Y=yOffset  
Distance from point to tag as percentage of graph height. For axis tags, the offsets are proportional to the size of the text used for the axis labels.

/Z=freeze  
Controls freezing of tag position.

- **freeze=1:** Freezes tag position (you can’t move it with the mouse).
- **freeze=0:** Unfreezes it.

Details

If the /C flag is used, it must be the first flag in the command and must be followed immediately by the /N=name flag.

If the /K flag is used, it must be the first flag in the command and must be followed immediately by the /N=name flag with no further flags or parameters.

taggedObjectName and xAttach can be omitted only when changing an existing tag using Tag/C/N=<tag name>. textStr can be included only if taggedObjectName and xAttach are included. This syntax allows changes to the tag to be made through the flags parameters without needing to respecify the other parameters. Similarly, the tag’s attachment point can be changed without needing to respecify the textStr parameter.

A tag can have at most 100 lines.

textStr can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-53 for details.

"\r" inserts a carriage-return character which starts a new line of text in the annotation.

Some escape codes insert text based on the wave point or axis to which a tag is attached. See Tag Escape Codes on page III-55 and Axis Label Escape Codes on page III-57 for details.
The characters "<??>" in a tag indicate that you specified an invalid escape code or used a font that is not available.

Examples
Following is an example of various ways in which axis tags can be used:

Make/O jack=sin(x/8)
SetScale x,0,14e9,"y" jack
Display jack
Label bottom "\\u#2" // turn off default axis label
ModifyGraph axOffset(bottom)=1.16667 // make room for tag (manual adjustment)
Tag/N=axisTag0/F=0/A=MT/X=0.20/Y=-4.29/L=0 bottom, Nan, "\\JCTime (\\U)\\r2nd line"

// Now tag a few important points
Tag/N=axisTag1/F=0/A=LB/X=1.20/Y=3.00 bottom, 0, "Big Bang"
Tag/N=axisTag2/F=0/A=MB/X=0.00/Y=2.86 bottom, 8000000000, "Earth formed"
Tag/N=axisTag3/F=0/A=RB/X=-0.80/Y=4.71 bottom, 13040000000, "Dinosaurs ruled"

TagVal, TagWaveRef

Annotation Escape Codes on page III-53
Label, Axis Labels on page II-318
Trace Names on page II-282, Programming With Trace Names on page IV-87

TagVal

TagVal(code)

TagVal is a very specialized function that is only valid when called from within the text of a tag as part of a \{} dynamic text escape sequence. It returns a number reflecting some property of the tag and helps you to display information about the tagged wave. The property is selected by the code parameter:

code | Return Value
---|---
0 | Similar to \OP, returns the tag attach point number.
1 | Similar to \OX, returns the X coordinate of tag attachment in the graph. When a tag is attached to an XY pair of traces, the X coordinate will most likely be different than the tag’s X scaling attachment value specified in the Tag command.
2 | Similar to \OY, returns the Y coordinate of tag attachment in the graph or the Y axis value in a Waterfall plot.
3 | Similar to \OZ, returns the Z coordinate of tag attachment in a contour, image, or Waterfall plot.
4 | Similar to \Ox, returns the trace x offset.
5 | Similar to \Oy, returns the trace y offset.
6 | Returns the X muloffset (with the not set value 0 translated to 1).
7 | Returns the Y muloffset (with the not set value 0 translated to 1).

Because TagVal returns a numeric value, the result can be formatted any way you wish using the printf formatting codes. In contrast, the \O codes insert preformatted text, and you don’t have control over the format.

TagVal is sometimes used in conjunction with the TagWaveRef function. For example, you might write a user-defined function that calculates a value as a function of a wave and a point number.

Examples

Tag wave0, 0, "Y value is \\"%g\",TagVal(2)"
Tag wave0, 0, "Y value is \\"%g\",TagWaveRef() [TagVal(0)]"
Tag wave0, 0, "Y value is \\"%g\"

These examples all produce identical results.
TagWaveRef

TagWaveRef ()
TagWaveRef is a very specialized function that is only valid when called from within the text of a tag as part of a \{} dynamic text escape sequence. It returns a wave reference to the wave that the tag is on and helps you to display information about the tagged wave. It is often used in conjunction with the TagVal function. You can pass the result of TagWaveRef to any function that takes a Wave parameter.

Examples
Show the name of the data folder containing the tagged wave:
Tag wave0, 0,"\ON is in \{{"s"},GetWavesDataFolder(TagWaveRef(),0)}"

See Also
The Tag operation, the TagVal function
For a discussion of wave references, see Wave Reference Functions on page IV-197.

tan

tan(angle)
The tan function returns the tangent of angle which is in radians.
In complex expressions, angle is complex, and tan(angle) returns a complex value:
\[
\tan(x + iy) = \frac{\sin(x + iy)}{\cos(x + iy)} = \frac{\sin(2x) + i \sinh(2y)}{\cos(2x) + \cosh(2y)}.
\]

See Also
atan, atan2, sin, cos, sec, csc, cot

tanh

tanh(num)
The tanh function returns the hyperbolic tangent of num:
\[
\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}.
\]
In complex expressions, num is complex, and tanh(num) returns a complex value.

sinh, cosh, coth

Text2Bezier

Text2Bezier[ flags ] fontNameStr, fstyle, textStr, xWaveName, yWaveName
The Text2Bezier operation creates the data for a Bezier curve corresponding to the outline of some text using the supplied font information. The output waves are formatted to be drawn using Igor's DrawBezier operation.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fontNameStr</td>
<td>A string expression containing the name of a font to be used for generating outlines.</td>
</tr>
<tr>
<td>fstyle</td>
<td>fstyle is a bitwise parameter with each bit controlling one aspect of the font style as follows:</td>
</tr>
<tr>
<td></td>
<td>Bit 0: Bold</td>
</tr>
<tr>
<td></td>
<td>Bit 1: Italic</td>
</tr>
<tr>
<td></td>
<td>Bit 2: Underline</td>
</tr>
<tr>
<td></td>
<td>Bit 4: Strikethrough</td>
</tr>
</tbody>
</table>

See Setting Bit Parameters on page IV-12 for details about bit settings.

textStr A string expression containing the text to be transformed into Bezier outlines.
xWaveName Specifies X output wave to receive the Bezier curve data.
yWaveName Specifies Y output wave to receive the Bezier curve data.

Flags

/O Allow overwriting the output waves.

Details
To draw the text outline, pass the output waves from Text2Bezier to the DrawBezier operation. The coordinates are such that the DrawBezier origin will be the left baseline of the text. In most cases you will want to use the SetDrawEnv operation to set the coordinate system to absolute. If you wish to fill the text with color or gradient, you will need to use the SetDrawEnv subpaths keyword.

Output Variables

<table>
<thead>
<tr>
<th>V_Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>for success</td>
</tr>
<tr>
<td>1</td>
<td>for general failure</td>
</tr>
<tr>
<td>2</td>
<td>for extraction failure</td>
</tr>
</tbody>
</table>

Examples

// Extract text to Bezier data
Text2Bezier/O/FS=20 "Helvetica", 0, "Text2Bezier", textx, texty

// Draw outline in a graph window with no fill
Display /W=(100,100,700,450)
SetDrawLayer UserFront
SetDrawEnv fillpat=0,xcoord= abs,ycoord= abs// fillpat=0 specifies no fill
DrawBezier 100,100,1,1,textx,texty

// Draw outline three times larger and filled with a gradient shading
// subpaths=1 draws the entire Bezier as a series of subpaths for correct filling
SetDrawEnv xcoord= abs,ycoord= abs,subpaths= 1,
    gradient= {0, 0, 0, 1, 0, (65535,65535,0), (65535,0,0)}
DrawBezier 100,150,3,3,textx,texty

See Also

DrawBezier, SetDrawEnv

TextBox

**TextBox** [flags] [textStr]

The TextBox operation puts a textbox on the target or named graph window. A textbox is an annotation that is not associated with any particular trace.

Parameters

textStr is the text that is to appear in the textbox. It is optional.
Flags

/A=anchorCode

Specifies position of textbox anchor point.

<table>
<thead>
<tr>
<th>anchorCode</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>LT</td>
<td>left top</td>
</tr>
<tr>
<td>LC</td>
<td>left center</td>
</tr>
<tr>
<td>LB</td>
<td>left bottom</td>
</tr>
<tr>
<td>MT</td>
<td>middle top</td>
</tr>
<tr>
<td>MC</td>
<td>middle center</td>
</tr>
<tr>
<td>MB</td>
<td>middle bottom</td>
</tr>
</tbody>
</table>

**anchorCode** is a literal, not a string.

For interior textboxes, the anchor point is on the rectangular edge of the plot area of
the graph window (where the left, bottom, right, and top axes are drawn).

For exterior textboxes, the anchor point is on the rectangular edge of the entire graph
window.

/B=(r,g,b,[a])

Sets the color of the textbox background. r, g, b, and a specify the color and optional
opacity as RGBA Values.

/B=b

Controls the textbox background.

- b=0: Opaque background.
- b=1: Transparent background.
- b=2: Same background as the graph plot area background.
- b=3: Same background as the window background.

/C

Changes existing textbox.

/D={thickMult [, shadowThick [, haloThick]]}

**thickMult** multiplies the normal frame thickness of a text-box. The thickness may be
set using just /D=thickMult.

**shadowThick**, if present, overrides Igor’s normal shadow thickness. It is in units of
fractional points.

**haloThick** governs the annotation’s halo thickness (a surrounding band of the
annotation’s background color), which can be -1 to 10 points wide.

The default **haloThick** value is -1, which preserves the behavior of previous versions of
Igor where the halo of all annotations was set by the global variable
\texttt{root:V\_TBBufZone}. Any negative value of **haloThick** (-0.5, for example) will be
overridden by \texttt{V\_TBBufZone} if it exists, otherwise the absolute value of **haloThick**
will be used. A zero or positive value overrides \texttt{V\_TBBufZone}.

Any of the parameters may be missing. To set **haloThick** to 0 without changing other
parameters, use /D={ , 0 }.

/E=exterior

/E or /E=1 forces textbox (or legend) to be exterior to graph (provided anchorCode is
not MC) and pushes the graph margins away from the anchor edge(s). /E=2 also forces
exterior mode but does not push the margins.

/E=0 returns it to the default (an “interior textbox” which can be anywhere in the
graph window).
### TextBox

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
</table>
| /F=frame | Controls the textbox frame.  
frame=0: No frame.  
frame=1: Underline frame.  
frame=2: Box frame. |
| /G=(r,g,b[a]) | Sets color of the text in the textbox. r, g, b, and a specify the color and optional opacity as RGBA Values. |
| /H=legendSymbolWidth | legendSymbolWidth sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width. |
| /K | Kills existing textbox. |
| /LS=linespace | Specifies a tweak to the normal line spacing where linespace is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line. |
| /M[=sameSize] | /M or /M=1 specifies that legend markers should be the same size as the marker in the graph.  
/M=0 turns same-size mode off so that the size of the marker in the legend is based on text size. |
| /N=name | Specifies the name of the textbox to change or create. |
| /O=rot | Sets the text’s rotation. rot is in (integer) degrees, counterclockwise and must be a number from -360 to 360.  
0 is normal horizontal left-to-right text, 90 is vertical bottom-to-top text. |
| /R=newName | Renames the textbox. |
| /S=style | Controls the textbox frame style.  
style=0: Single frame.  
style=1: Double frame.  
style=2: Triple frame.  
style=3: Shadow frame. |
| /T=tabSpec | tabSpec is a single number in points, such as /T=72, for evenly spaced tabs or a list of tab stops in points such as /T={50, 150, 225}. |
| /V=vis | Controls annotation visibility.  
vis=0: Invisible annotation; not selectable. The annotation is still listed in AnnotationList.  
vis=1: Visible annotation (default). |
| /W=winName | Operates in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  
When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy. |
| /X=xOffset | For interior textboxes xOffset is the distance from anchor to textbox as a percentage of the plot area width.  
For exterior textboxes xOffset is the distance from anchor to textbox as a percentage of the graph window width. See /E and /A. |
| /Y=yOffset | yOffset is the distance from anchor to textbox as a percentage of the plot area height (interior textboxes) or graph window height (exterior textboxes). See /E and /A. |
Details

Use the optional /W=winName flag to specify a specific graph or layout window. When used on the command line or in a Macro, Proc, or Window procedure, /W must precede all other flags.

If the /C flag is used, it must be the first flag in the command (except that if may follow an initial /W) and must be followed immediately by the /N=name flag.

If the /K flag is used, it must be the first flag in the command (or follow an initial /W) and must be followed immediately by the /N=name flag with no further flags or parameters.

textStr is optional. If missing, the textbox text is unchanged. This allows changes to the textbox to be made through the flags without changing the text.

A textbox can have at most 100 lines.

textStr can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-53 for details.

The characters “<??>” in a textbox indicate that you specified an invalid escape code or used a font that is not available.

Examples

TextBox/C/N=t1/X=25/Y=50

moves the textbox named t1 to the location defined by X=25 and Y=50.

TextBox/C/N=t1 "New Text"

changes the text for t1.

Programming with Annotations on page III-52.

Trace Names on page II-282, Programming With Trace Names on page IV-87.

TextEncoding

#pragma TextEncoding = "<text encoding name>"

#pragma TextEncoding is a compiler directive that tells Igor the text encoding used by a procedure file. Igor needs to know this in order to correctly interpret non-ASCII characters in the file. We recommend that you add a TextEncoding pragma to your procedure files.

All new procedure files should use the UTF-8 text encoding:

#pragma TextEncoding = "UTF-8"

See Text Encoding Names and Codes on page III-490 for a list of accepted text encoding names.

This statement must be flush against the left edge of the procedure file with no indentation. It is usually placed at or near the top of the file.

The TextEncoding pragma was added in Igor Pro 7.00 and is ignored by earlier versions.

See The TextEncodingPragma on page IV-55 for further explanation.
TextEncodingCode

TextEncodingCode(textEncodingNameStr)
The TextEncodingCode function returns the Igor text encoding code for the named text encoding or 0 if the
text encoding is unknown.
The TextEncodingCode function was added in Igor Pro 7.00.

Parameters
textEncodingNameStr is an Igor text encoding name as listed under Text Encoding Names and Codes on
page III-490.

Details
Igor ignores all non-alphanumeric characters in text encoding names so “Shift JIS”, "ShiftJIS", "Shift_JIS" and
"Shift-JIS" are equivalent.
It also ignores leading zeros in numbers embedded in text encoding names so "ISO-8859-1" and "ISO-8859-
01" are equivalent.
TextEncodingCode does a case-insensitive comparison.

See Also
Text Encodings on page III-459, Text Encoding Names and Codes on page III-490, TextEncodingName

TextEncodingName

TextEncodingName(textEncoding, index)
The TextEncodingName function returns one or more text encoding names corresponding to the specified
text encoding code. The result is returned as a string value.

If textEncoding is not a valid Igor text encoding code or if index is out of range, TextEncodingName returns
"Unknown".

This function is mainly useful for providing a human-readable string corresponding to a given text
encoding code for display purposes. You might use it to generate some Internet-compatible text, such as an
HTML page, if you need a string to specify the charset.
The TextEncodingName function was added in Igor Pro 7.00.

Parameters
textEncoding is an Igor text encoding code as listed under Text Encoding Names and Codes on page III-490.
index specifies which text encoding name you want. A given text encoding can be identified by more than
one name. Normally you will pass 0 to get the first text encoding name for the specified text encoding code.
This is the preferred text encoding name. You can pass 1 for the second name, if any, 2 for the third, if any,
and so on. You can pass -1 to get a semicolon-separated list of all text encoding names for the specified text
encoding.

Details
Internally Igor has a table of text encoding codes and the corresponding text encoding names. For a given
code there may be more than one acceptable name. For example, for the code 2 (MacRoman), the names
"macintosh", "MacRoman" and "x-macroman" are accepted, with "macintosh" being preferred. The
TextEncodingName function returns a text encoding name from the internal table.
The preferred name is usually the name recognized by the Internet Assigned Numbers Authority (IANA)
as listed at http://www.iana.org/assignments/character-sets.

Examples
// Get the preferred name for the MacRoman text encoding (2)
String firstName = TextEncodingName(2, 0); Print firstName

// Get the second name for the MacRoman text encoding (2)
String secondName = TextEncodingName(2, 1); Print secondName

// Get a semicolon-separated list of all text encoding names for MacRoman
String names = TextEncodingName(2, -1); Print names
TextFile

**TextFile** *(pathname, index [, creatorStr]*)

**Note:** TextFile is antiquated. Use IndexedFile instead.

The TextFile function returns a string containing the name of the *index*th TEXT file from the folder specified by *pathname*.

On Macintosh, TextFile returns only files whose file type property is TEXT, regardless of the file's extension.

On Windows, Igor considers files with “.txt” extensions to be of type TEXT.

**Details**

TextFile returns an empty string ("") if there is no such file.

*pathname* is the name of an Igor symbolic path; it is not a string.

*index* starts from zero.

*creatorStr* is an optional string argument containing four ASCII characters such as “IGR0”. Only files of the specified Macintosh creator code are indexed. Set *creatorStr* to “????” to index all text files (or omit the argument altogether). This argument is ignored on Windows systems.

The order of files in a folder is determined by the operating system.

**Examples**

You can use TextFile in a procedure to sequence through each TEXT file in a folder, put the name of the text file into a string variable, and use this string variable as a parameter to the LoadWave or Open operations:

Function/S PrintFirstLineOfTextFiles(pathName)
String pathName // Name of an Igor symbolic path.
Variable refNum, index
String str, fileName
index = 0
do
    fileName = TextFile($pathname, index)
    if (strlen(fileName) == 0)
        break // No more files
    endif
    Open/R/P=$pathname refNum as fileName
    FReadLine refNum, str // Read first line including CR/LF
    Print fileName + ":" + str // Print file name and first line
    Close refNum
    index += 1 // Next file
while (1)
End

See Also

See the IndexedFile function, which is similar to TextFile but works on files of any type, and also IndexedDir. Also see the LoadWave and Open the operations.

TextHistogram

**TextHistogram** [flags] srcTextWave

The TextHistogram operation computes the histogram of a text wave where the output bins represent the count of occurrences of each unique string found in *srcTextWave*.

The TextHistogram operation was added in Igor Pro 9.00.
TextHistogram

Flags

/CI              Performs case-insensitive string comparison.

If you omit /CI TextHistogram performs case-sensitive comparison unless you include /LOC.

/DT=binsTextWave Specifies the text output wave that contains the strings corresponding to each bin. If you omit /DT, the text output wave is created in the current data folder and named T_TextHistogram.

/LOC Performs case-insensitive string comparison following locale-aware rules. This option results in significantly slower performance.

/SORT=mode       Sets the order of the output bins.

mode=0: The output waves are ordered from the bin with the largest count to the bin with the smallest count. This is the default if you omit /SORT.

mode=1: The output waves are ordered from the bin with the longest string to the bin with the shortest string.

/Z                Suppress errors. You can use V_Flag to detect and handle errors yourself.

Details

TextHistogram does case-sensitive string comparisons unless you specify /CI or /LOC in which case it does case-insensitive string comparisons.

TextHistogram scans srcTextWave and counts matching string entries. It treats text waves of all dimensions as if they were 1D waves.

The output of the operation consists of two waves: a text wave containing the text corresponding to each bin and a numeric wave containing the bin counts. You can specify the destination waves using the /DT and /DN flags. If you omit /DT the text output wave is created in the current data folder and named T_TextHistogram. If you omit /DN the numeric output wave is created in the current data folder and named W_TextHistogram. The output waves overwrite any previously-existing waves with the same names.

The operation creates automatic wave references for the output waves specified by /DT and /DN. See Automatic Creation of WAVE References on page IV-72 for details. It does not create wave references for the default output waves created if you omit /DT or /DN so you need explicit wave references.

When using case-insensitive mode the output text wave may use any one of the equivalent forms of the text represented by the bin.

Output Variables

TextHistogram sets the following output variable:

V_flag 0 if the operation succeeded or a non-zero error code.

Histogram, FindDuplicates, Sort
ThreadGroupCreate

ThreadGroupCreate

ThreadGroupCreate(nt)
The ThreadGroupCreate function creates a thread group containing nt threads and returns a thread ID number. Use the number of computer processors for nt when trying to improve computation speed using parallel threads. A background worker might use just one thread regardless of the number of processors.

See Also
ThreadSafe Functions on page IV-106 and ThreadSafe Functions and Multitasking on page IV-329.

ThreadGroupGetDF

ThreadGroupGetDF(tgID, waitms)
ThreadGroupGetDFR should be used instead of ThreadGroupGetDF which causes memory leaks.
The ThreadGroupGetDF function retrieves a data folder path string from a thread group queue and removes the data folder from the queue. When called from a preemptive thread it returns a data folder from the thread group’s input queue. When called from the main thread it returns a data folder from the thread group’s output queue.
tgID is a thread group ID returned by ThreadGroupCreate. You can pass 0 for tgID when calling ThreadGroupGetDF from a preemptive thread. You must pass a valid thread group ID when calling ThreadGroupGetDF from the main thread.
waitms is the maximum number of milliseconds to wait for a data folder to become available in the queue. Pass 0 to test if a data folder is available immediately. Pass INF to wait indefinitely or until a user abort. ThreadGroupGetDF returns "" if the timeout period specified by waitms expires and no data folder is available in the queue.

See Also
ThreadSafe Functions on page IV-106 and ThreadSafe Functions and Multitasking on page IV-329.
The ThreadGroupGetDFR function.

ThreadGroupGetDFR

ThreadGroupGetDFR(tgID, waitms)
The ThreadGroupGetDFR function retrieves a data folder reference from a thread group queue and removes the data folder from the queue. The data folder becomes a free data folder. When called from a preemptive thread it returns a data folder from the thread group’s input queue. When called from the main thread it returns a data folder from the thread group’s output queue.
tgID is a thread group ID returned by ThreadGroupCreate. You can pass 0 for tgID when calling ThreadGroupGetDFR from a preemptive thread. You must pass a valid thread group ID when calling ThreadGroupGetDFR from the main thread.
waitms is the maximum number of milliseconds to wait for a data folder to become available in the queue. Pass 0 to test if a data folder is available immediately. Pass INF to wait indefinitely or until a user abort. ThreadGroupGetDFR returns a NULL data folder reference if the timeout period specified by waitms expires and no data folder is available in the queue. You can test for NULL using DataFolderRefStatus.

See Also
ThreadSafe Functions on page IV-106, ThreadSafe Functions and Multitasking on page IV-329 and Free Data Folders on page IV-96.

ThreadGroupPutDF

ThreadGroupPutDF tgID, datafolder
The ThreadGroupPutDF operation posts data to a preemptive thread group.

Parameters
tgID is thread group ID returned by ThreadGroupCreate, datafolder is the data folder you wish to send to the thread group.
ThreadGroupRelease

```
datafolder can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.
```

**Details**

When you call it from the main thread, `ThreadGroupPutDF` removes `datafolder` from the main thread’s data hierarchy and posts to the input queue of the thread group specified by `tgID`.

When you call it from a preemptive thread, use 0 for `tgID` and the data folder will be posted to the output queue of thread group to which thread belongs.

Input and output data folders may be retrieved from the queues by calling the string function `ThreadGroupGetDF` or `ThreadGroupGetDFR`.

**Warning:** Take care not to use any stale WAVE, NVAR, or SVAR variables that might contain references to objects in the data folder. Use `WAVEClear` on all WAVE reference variables that might contain references to waves that are in the data folder being posted before calling `ThreadGroupPutDF`. An error will occur if any waves in the data folder are in use or referenced in a WAVE variable.

From the standpoint of the source thread, `ThreadGroupPutDF` is conceptually similar to `KillDataFolder` and, like `KillDataFolder`, if the current data folder is within `datafolder`, the current data folder is set to the parent of `datafolder`. You can not pass `root:` as `datafolder`.

**See Also**

The `ThreadGroupCreate` function, `ThreadSafe Functions` on page IV-106, and `ThreadSafe Functions and Multitasking` on page IV-329.

ThreadGroupRelease

```
ThreadGroupRelease(tgID [, beGraceful])
```

The `ThreadGroupRelease` function releases the thread group referenced by `tgID`. `tgID` is the thread group ID returned by `ThreadGroupCreate`. Any data folders remaining in the group’s input or output queues are discarded.

Specifying `tgID=-2` kills all running threads in all thread groups.

Normally you call `ThreadGroupRelease` after all threads in the group have completed. In the event that threads are still running, they are aborted. An attempt is made to safely stop running threads but, if they continue to run, they are killed.

The `beGraceful` parameter, added in Igor Pro 9.00, affects thread worker functions that include catch blocks to handle aborts gracefully. If `beGraceful` is omitted or is 0, `ThreadGroupRelease` performs aborts in a way that interferes with such catch blocks. If `beGraceful` is 1, the catch blocks run normally. See `Aborting Threads` on page IV-337 for details.

`ThreadGroupRelease` returns zero if successful, -1 if an error occurred (probably invalid `tgID`), or -2 if a force quit was needed. In the latter case, you should restart Igor Pro.

**See Also**

The `ThreadGroupCreate` function, `ThreadSafe Functions` on page IV-106, and `ThreadSafe Functions and Multitasking` on page IV-329.

ThreadGroupWait

```
ThreadGroupWait(tgID, waitms)
```

The `ThreadGroupWait` function returns index+1 of the first thread found still running after `waitms` milliseconds or returns zero if all are done.

`tgID` is the thread group ID returned by `ThreadGroupCreate` and `waitms` is milliseconds to wait.

If any of the threads of the group encountered a runtime error, the first such error will be reported now.
Use zero for *waitms* to just test or provide a large value to cause the main thread to sleep until the threads are finished. You can use INF to wait forever or until a user abort. If you know the maximum time the threads should take, you can use that value so you can print an error message or take other action if the threads don’t return in time.

When ThreadGroupWait is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling **ThreadReturnValue**.

ThreadGroupWait updates the internal state of all threads in the group.

**Finding a Free Thread**

If you pass -2 for *waitms*, ThreadGroupWait returns index+1 of the first free (not running) thread or 0 if all threads in the group are running.

This allows you to dispatch a thread anytime a free thread is available. See **Parallel Processing - Thread-at-a-Time Method** on page IV-332 for an example.

**See Also**
The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-106, and **ThreadSafe Functions and Multitasking** on page IV-329.

---

**ThreadProcessorCount**

The **ThreadProcessorCount** function returns the number of processors in your computer. For example, on a Macintosh Core Duo, it would return 2.

---

**ThreadReturnValue**

**ThreadReturnValue(tgID, index)**

The **ThreadReturnValue** function returns the value that the specified thread function returned when it exited. Returns NAN if thread is still running. *tgID* is the thread group ID returned by **ThreadGroupCreate** and *index* is the thread number.

When **ThreadGroupWait** is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling **ThreadReturnValue**.

**See Also**
The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-106, and **ThreadSafe Functions and Multitasking** on page IV-329.

---

**ThreadSafe**

**ThreadSafe Function funcName()**

The **ThreadSafe** keyword declaration specifies that a user function can be used for preemptive multitasking background tasks on multiprocessor computer systems.

A **ThreadSafe** function is one that can operate correctly during simultaneous execution by multiple threads. Such functions are generally limited to numeric or utility functions. Functions that access windows are not **ThreadSafe**. To determine if an operation is **ThreadSafe**, use the Command Help tab of the Help Browser and choose **ThreadSafe** from the pop-up menu.

**ThreadSafe** functions can call other **ThreadSafe** functions but may not call non-**ThreadSafe** functions. Non-**ThreadSafe** functions can call **ThreadSafe** functions.

**See Also**
**ThreadSafe Functions** on page IV-106 and **ThreadSafe Functions and Multitasking** on page IV-329.

---

**ThreadStart**

**ThreadStart tgID, index, WorkerFunc(param1, param2,...)**

The **ThreadStart** operation starts the specified function running in a preemptive thread.
### ticks

**Parameters**

tgid is thread group ID returned by `ThreadGroupCreate`, index is the desired thread of the group to set up to execute the specified ThreadSafe WorkerFunc.

**Details**
The worker function starts running immediately.

The worker function must be defined as ThreadSafe and must return a real or complex numeric result.

The worker function’s return value can be obtained after the function finishes by calling `ThreadReturnValue`. Igor records the fact that a thread has terminated when you call `ThreadGroupWait` so you must call `ThreadGroupWait` before calling `ThreadReturnValue`.

The worker function can take variable and wave parameters. It can not take pass-by-reference parameters or data folder reference parameters.

Any waves you pass to the worker are accessible to both the main thread and to your preemptive thread. Such waves are marked as being in use by a thread and Igor will refuse to perform any manipulations that could change the size of the wave.

**See Also**
The `ThreadGroupCreate` and `ThreadReturnValue` functions; **ThreadSafe Functions** on page IV-106, and **ThreadSafe Functions and Multitasking** on page IV-329.

### ticks

ticks

The ticks function returns the number of ticks (approximately 1/60 second) elapsed since the operating system was initialized.

**See Also**
The StopMSTimer function.

### TickWavesFromAxis

TickWavesFromAxis [ /W=graphName /DEST={textWaveName, numericWaveName} /O /AUTO=mode ] axisName

The TickWavesFromAxis operation generates a pair of waves suitable for use as user tick waves (see User Ticks from Waves on page II-313). This allows you to programmatically determine the tick marks and tick labels that Igor would create for a given graph axis in auto mode.

TickWavesFromAxis was added in Igor Pro 8.00.

TickWavesFromAxis generates two waves: a two-column text wave containing tick labels and the names of tick types, and a numeric wave giving the positions of the ticks along the axis. By default, the information stored in the output waves reflects the automatically generated ticks based on the current axis settings but you can change this using the /AUTO flag.

By default the waves are given names derived from the graph window and axis name: <graphname>_<axisname>_labels and <graphname>_<axisname>_values. Use /DEST to give the waves custom names.

**Parameters**

axisName is the name of the axis for which the tick waves are generated. This will usually be left, bottom, right or top, but may be the name of a free axis.
Tile

Flags

/A=rows,cols Specifies number of rows/columns in which to tile objects.

/BBOX=ubb Specifies that you want to use the bounding box of the objects to be tiled as the tiling area. /BBOX overrides /W. See Specifying the Tiling Area on page II-489 for details. Added in Igor Pro 9.00.

/G=grout Specifies grout, the spacing between window tiles, in prevailing coordinates (points unless preceded by /I, /M or /R).

/I Specifies coordinates in inches.
TileWindows

/\texttt{M} Specifies coordinates in centimeters.
/\texttt{O}=&\texttt{objTypes} Adds objects of type(s) specified by bitwise mask to list of objects to be tiled:
Bit 0: Tile graphs.
Bit 1: Tile tables.
Bit 3: Tile pictures.
Bit 5: Tile textboxes.

See Setting Bit Parameters on page IV-12 for details about bit settings.

/\texttt{PA}[=\texttt{preserve}] /\texttt{PA} and /\texttt{PA}=1 specify that you want to preserve the rough arrangement of the objects to be tiled. See Preserving Your Rough Arrangement on page II-490 for details. Added in Igor Pro 9.00.

/\texttt{R} Specifies coordinates measured in percent of the printable page.

/\texttt{S} Adds selected objects to objects to be tiled.

/\texttt{W}=(\texttt{left},\texttt{top},\texttt{right},\texttt{bottom}) Specifies page layout area in which to tile objects. Coordinates are in points unless /I, /\texttt{M} or /\texttt{R} are specified before /\texttt{W}. /\texttt{BBOX} overrides /\texttt{W}.

Details

If /\texttt{A}=(\texttt{rows,cols}) is not used, Tile uses an appropriate number of rows and columns. If /\texttt{A}=(\texttt{rows,cols}) is used, objects are tiled in a grid of that many rows and columns. If \texttt{rows} or \texttt{cols} is zero, it substitutes an appropriate number for the zero parameter.

Objects to be tiled are determined by the /S and /\texttt{O}=\texttt{objTypes} flags and by any objectNames.

If no /S or /\texttt{O} flags are present and there are no objectNames, then all objects in the layout are tiled.

Otherwise the objects to be tiled are determined as follows:

• All objects specified by objectNames are tiled.
• If the /S flag is present, the selected objects, if any, are also tiled.
• If the /\texttt{O}=\texttt{objTypes} flag is present then any objects specified by \texttt{objTypes} are also tiled. \texttt{objTypes} is a bitwise mask, so /\texttt{O}=3 tiles both graphs and tables.

See Also

The \texttt{Stack} operation.

TileWindows

\texttt{TileWindows [flags] [\texttt{windowName [, windowName] ...}]}
The TileWindows operation tiles the specified windows on the desktop (Macintosh) or in the Igor frame window (Windows).

Flags

/\texttt{A}=(\texttt{rows,cols}) Specifies number of rows/columns in which to tile windows.
/\texttt{C} Adds the command window to the windows to be tiled.
/\texttt{G}=\texttt{grout} Specifies grout, the spacing between tiles, in prevailing units (points unless /I or /\texttt{M} are used).
/\texttt{I} Specifies coordinates in inches.
/\texttt{M} Specifies coordinates in centimeters.
/\texttt{O}=\texttt{objTypes} Adds windows of types specified by \texttt{objTypes} to windows to be tiled.
**objTypes** is a bitwise mask where:
- Bit 0: Graphs
- Bit 1: Tables
- Bit 2: Page layouts
- Bit 4: Notebooks
- Bit 6: Control panels
- Bit 7: Procedure windows
- Bit 9: Help windows
- Bit 12: XOP target windows
- Bit 14: Camera windows
- Bit 16: Gizmo windows

Other bits should always be zero. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

**/P**
Adds the main procedure window to the windows to be tiled.

**/R**
Specifies coordinates measured as % of tiling rectangle.

**/W=(left,top,right,bottom)**
Specifies tiling rectangle on the screen. Coordinates are in points unless /I, /M, or /R are specified before /W.

**/WINS=windowListStr**
Specifies the windows to be tiled using a semicolon-separated list of window names. Added in Igor Pro 9.00.

**Details**
If you omit the /W flag, the default tiling area is used. This is the area above your preferred command window position. You can set this using Misc→Command Buffer→Capture Prefs or Misc→History Area→Capture Prefs.

The windows to be tiled are determined by the /WINS, /C, /P, and /O=objTypes flags and by the windowNames. If none of these flags are present and there is no windowNames then all windows are tiled.

Otherwise the windows to be tiled are determined as follows:
- All visible named windows are tiled.
- All visible windows specified by /WINS are tiled.
- If the /C flag is present and the command window is visible, the command window is also tiled.
- If the /P flag is present and the procedure window is visible, the procedure window is also tiled.
- If the /O=objTypes flag is present, any visible windows specified by objTypes are also tiled.

**Examples**
To tile all the visible procedure windows, including the main one, use:

`TileWindows/P/O=128  // 2^7=128`

**See Also**
The **StackWindows** operation.

**time**

**time()**
The time function returns a string containing the current local time. The empty parentheses are required.

**See Also**
The [date](#), [date2secs](#) and [DateTime](#) functions.
The TitleBox operation creates the named title box in the target window. For information about the state or status of the control, use the ControlInfo operation.

**Parameters**

ctrlName is the name of the TitleBox control to be created or changed.

The following keyword=value parameters are supported:

- **anchor=** hv
  Specifies the anchor mode using a two letter code, hv. h may be L, M, or R for left, middle, and right. v may be T, C, or B for top, center and bottom. Default is LT.
  
  If fixedSize=1, the anchor code sets the positioning of text within the frame.

- **align=** alignment
  Sets the alignment mode of the control. The alignment mode controls the interpretation of the leftOrRight parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.
  
  If alignment=0 (default), leftOrRight specifies the position of the left end of the control and the position of the control depends on the anchor keyword.
  
  If alignment=1, leftOrRight specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.
  
  There is a conflict between the align keyword and the anchor keyword. See TitleBox Positioning on page V-1040.

- **appearance={kind [, platform]}**
  Sets the appearance of the control. platform is optional. Both parameters are names, not strings.
  
  kind can be one of default, native, or os9.
  
  platform can be one of Mac, Win, or All.
  
  See Button and DefaultGUIControls for more appearance details.

- **disable=d**
  Sets user editability of the control.
  
  d=0: Normal.
  
  d=1: Hide.
  
  d=2: Draw in gray state.

- **fColor=(r,g,b[,a])**
  Sets color of the titlebox. r, g, b, and a specify the color and optional opacity as RGBA Values.

- **fixedSize=f**
  Controls title box sizing:
  
  f=0: The titlebox automatically sizes itself to fit the title text (default).
  
  f=1: The size settings are honored, and the titlebox does not automatically size itself to fit the title text.

- **font=fontName**
  Sets the font used for the control, e.g., font="Helvetica".

- **frame=f**
  Sets frame style:
  
  f=0: No frame.
  
  f=1: Default (same as f=3).
  
  f=2: Simple box.
  
  f=3: 3D sunken frame.
  
  f=4: 3D raised frame.
  
  f=5: Text well.

- **fsize=s**
  Sets font size.
**Flags**

* /Z * No error reporting. 

**Details**

The text can come from either the `title=titleStr` or `variable=svar` method. Whichever is used last is the current method. The maximum length of text with the `title=titleStr` method is 255 bytes while the `variable=svar` method has no limit.

Using escape codes you can change the font, size, style, and color of text, and apply other effects. See **Annotation Escape Codes** on page III-53 for details.

By default, the titlebox automatically resizes itself relative to the anchor point on the rectangle that encloses the text. Therefore you can specify a size of 0,0 along with a pos value in order to place the anchor point at the desired position. When `fixedSize=1` is used, the titlebox does not resize itself and instead honors the values specified via the size keyword.

TitleBoxes can be used not only for titles but also as status or results readout areas, especially in conjunction with the `variable=svar` mode. When using a titlebox like this, you may find it useful to use `fixedSize=1` so that the titlebox doesn’t change size as the text changes.
TitleBox Positioning
For compatibility with other controls, you can use the align=1 to maintain the position of the right end of a TitleBox control. This presents a conflict with the anchor keyword. To resolve the conflict, these rules are applied:

Applying align=1, which sets the alignment mode to right alignment, overrides any horizontal positioning specified using the anchor keyword.

Applying the anchor keyword resets the alignment mode to 0 and the anchor mode controls the horizontal position of the control.

If you specify fixedSize=1, only the align and pos keywords affect horizontal positioning; the anchor keyword has no effect.

For clarity, don’t mix the anchor and align keywords unless you are using fixedSize=1. Use anchor in preference to align unless you are trying to keep the right ends of various types of controls aligned, especially on high-resolution displays on Windows.

Examples
NewPanel /W=(94,72,459,294)
DrawLine 150,32,150,140
DrawLine 70,100,213,100 // draw crossing lines at 150,100

// illustrate a default box
TitleBox tb1,title="A title box\r\nwith 2 lines",pos={150,100}

// Move center to 150,100
TitleBox tb1,pos={150,100},size={0,0},anchor=MC

// Set background color and therefore opaque mode
TitleBox tb1,labelBack=(55000,55000,65000)

// Now a few frame styles. Run these one at a time
TitleBox tb1,frame= 0 // no frame
TitleBox tb1,frame= 2 // plain frame
TitleBox tb1,frame= 3 // 3D sunken
TitleBox tb1,frame= 4 // 3D raised
TitleBox tb1,frame= 5 // text well

// Now some fancy text...
TitleBox tb1,frame= 1 // back to default (3D raised)
TitleBox tb1,title= "\Z18\[020 log\B10\M|\[1 + 2K(jwt) + (jwt)\S2\M|\S-1"

// Create a string variable and hook up to the TitleBox
String s1= "text from a string variable"
TitleBox tb1,variable=s1

// Change string variable contents & note automatic update of TitleBox
s1= "something new"

// A TitleBox with right end at X=200 because the align keyword takes precedence
TitleBox tb, pos={200,40},size={0,0},align=1,anchor=MT,title="Short Title"

// A TitleBox with right end at X=200 because align by itself overrides
// any preexisting anchor
TitleBox tb, pos={200,40},size={0,0},align=1,title="Short Title"

// A TitleBox with text centered in the frame and right end at X=200,
// with frame always 75 points wide
TitleBox tb, pos={200,40},size={75,20},align=1,fixedSize=1,anchor=MT,title="Short Title"

ToCommandLine
ToCommandLine commandsStr
The ToCommandLine operation sends command text to the command line without executing the command(s).
The intended usage is for user-created panel windows with “To Cmd Line” buttons that are mimicking built-in Igor dialogs. You’ll usually want to use Execute, instead.

**Parameters**

- **commandsStr**
  The text of one or more commands.

**Details**

To send more than one line of commands, separate the commands with “\r” characters.

**Note:** ToCommandLine does not work when typed on the command line; use it only in a Macro, Proc, or Function.

**Examples**

Macro CmdPanel()
    PauseUpdate; Silent 1
    NewPanel /W=(150,50,430,229)
    Button toCmdLine,pos={39,148},size={103,20},title="To Cmd Line"
    Button toCmdLine,proc=ToCmdLineButtonProc
End

Function ToCmdLineButtonProc(ctrlName) : ButtonControl
    String ctrlName
    String cmd="MyFunction(xin,yin,\"yResult\")"// line 1: generate results
    cmd +=="\rDisplay yOutput vs wx as \"results\"" // line 2: display results
    ToCommandLine cmd
    return 0
End

**See Also**
The Execute and DoIgorMenu operations.

---

**ToolsGrid**

**ToolsGrid [ /W=winName ] keyword = value [, keyword = value ...]**

The ToolsGrid operation controls the grid you can use for laying out draw or control objects.

**Parameters**

ToolsGrid can accept multiple keyword = value parameters on one line.

- **snap=n**
  Turns snap to grid on (n=1) or off (n=0).

- **visible=n**
  Turns on grid visibility (n=1) or hides it (n=0).

- **grid=(xy0,dxy,ndiv)**
  Defines both X and Y grids where ndiv is the number of subdivisions between major grid lines and xy0 and dxy define the origin and spacing. Units are in points.

- **gridx=(x0,dx,ndiv)**
  Defines the X grid where ndiv is the number of subdivisions between major grid lines and x0 and dx define the origin and spacing. Units are in points.

- **gridy=(y0,dy,ndiv)**
  Defines the Y grid where ndiv is the number of subdivisions between major grid lines and y0 and dy define the origin and spacing. Units are in points.

**Flags**

- **/W=winName**
  Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

  When identifying a subwindow with winName, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

The default grid is 1 inch with 8 subdivisions. The grid is visible only in draw or selector mode and appears in front of the currently active draw layer.
TraceFromPixel

**TraceFromPixel**

**TraceFromPixel(xpixel, ypixel, optionsString)**

The TraceFromPixel function returns a string based on an attempt to hit test the provided X and Y coordinates. Used to determine if the mouse was clicked on a trace in a graph.

When a trace is found, TraceFromPixel returns a string containing the following KEY:value; pairs:

```
TRACE:tracename
HITPOINT:pnt
```

`tracename` will be quoted if necessary and may contain instance notation. `pnt` is the point number index into the trace’s wave when the hit was detected. If a trace is not found near the coordinate point, a zero length string is returned.

**Parameters**

`xpixel` and `ypixel` are the X and Y pixel coordinates.

`optionsString` can contain the following:

- `WINDOW:winName;`
- `PREF:traceName;`
- `ONLY:traceName;`
- `DELTAX:dx;DELTAY:dy;`

Use the `WINDOW` option to hit test in a graph other than the top graph. Use the `ONLY` option to search only for a special target trace. If the `PREF` option is used then the search will start with the specified trace but if no hit is detected, it will go on to the others.

When identifying a subwindow with `WINDOW:winName`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

The `DELTAX` and `DELTAY` values must both be specified to alter the region that Igor searches for traces. The `dx` and `dy` values are in pixels and the region searched is the rectangle from `xpixel-dx` to `xpixel+dx` and `ypixel-dy` to `ypixel+dy`.

If `DELTAX` or `DELTAY` are omitted, the search region depends on whether `PREF` or `ONLY` are specified. If either are specified then Igor first searches for the trace using `dx = 3` and `dy = 3`. If the trace is not identified, Igor searches again using `dx = 6` and `dy = 6`. If the trace is still not identified, Igor gives up and returns a zero-length result string.

If neither `PREF` nor `ONLY` are specified then Igor uses tries 3, 6, 12, and 24 for `dx` and `dy` until it finds a trace or gives up and returns a zero-length result string.

**ModifyGraph** (traces) and **Instance Notation** on page IV-20 for discussions of trace names and instance notation.

**Trace Names** on page II-282, **Programming With Trace Names** on page IV-87.

TraceInfo

**TraceInfo**

**TraceInfo(graphNameStr, ywaveNameStr, instance)**

The TraceInfo function returns a string containing a semicolon-separated list of information about the trace in the named graph window or subwindow.

**Parameters**

`graphNameStr` can be "" to refer to the top graph.

When identifying a subwindow with `graphNameStr`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

`yWaveNameStr` is either the name of a wave containing data displayed as a trace in the named graph, or a trace name (wave name with “#n” appended to distinguish the nth image of the wave in the graph). You might get a trace name from the **TraceNameList** function.

If `yWaveNameStr` contains a wave name, `instance` identifies which trace of `yWaveNameStr` you want information about. `instance` is usually 0 because there is normally only one instance of a given wave
displayed in a graph. Set instance to 1 for information about the second trace of the wave named by yWaveNameStr, etc. If yWaveNameStr is "", then information is returned on the instance th trace in the graph.

If yWaveNameStr is a trace name, and instance is zero, the instance is extracted from yWaveNameStr. If instance is greater than zero, the wave name is extracted from yWaveNameStr, and information is returned concerning the instance th instance of the wave.

Details
The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>AXISFLAGS</td>
<td>Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.</td>
</tr>
<tr>
<td>AXISSZ</td>
<td>Z value of a contour level trace or NaN if the trace is not a contour trace.</td>
</tr>
<tr>
<td>ERRORBARS</td>
<td>The ErrorBars command for the trace, as it would appear in the recreation macro (without the beginning tab character).</td>
</tr>
</tbody>
</table>
| RECREATION    | List of keyword commands as used by ModifyGraph command. The format of these keyword commands is:

```
keyword(x)=modifyParameters;
```

<table>
<thead>
<tr>
<th>TYPE</th>
<th>The type of trace:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:</td>
<td>XY or waveform trace</td>
</tr>
<tr>
<td>1:</td>
<td>Contour trace</td>
</tr>
<tr>
<td>2:</td>
<td>Box plot trace</td>
</tr>
<tr>
<td>3:</td>
<td>Violin plot trace</td>
</tr>
</tbody>
</table>

TYPE was added in Igor Pro 8.00.

<table>
<thead>
<tr>
<th>XAXIS</th>
<th>X axis name.</th>
</tr>
</thead>
<tbody>
<tr>
<td>XWAVE</td>
<td>X wave name if any, else blank.</td>
</tr>
<tr>
<td>XWAVEDF</td>
<td>Full path to the data folder containing the X wave or blank if no X wave.</td>
</tr>
<tr>
<td>YAXIS</td>
<td>Y axis name.</td>
</tr>
<tr>
<td>YRANGE</td>
<td>Point subrange of the trace’s Y data wave or “[*]”.</td>
</tr>
</tbody>
</table>

Note: Unlike the actual syntax of a trace subrange specification where increment is preceded by a semicolon character, here it is preceded by a colon character to preserve the notion that semicolon is what separates the keyword-value groups.

If the entire X wave is displayed (the usual case), the XRANGE value is “[*]”.

If an X wave is not used to display the trace, then the XRANGE value is “"".”.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “;”, prepend “ModifyGraph “, replace the “x” with the name of a trace (“data#1” for instance) and then Execute the resultant string as a command.

Note: The syntax of any subrange specifications in the RECREATION information are modified in the same way as for XRANGE and YRANGE. Currently only the zColor, zmrkSize, and zmrkNum keywords might have a subrange specification.

Examples
This example shows how to extract a string value from the keyword-value list returned by TraceInfo:

```java
String yAxisName= StringByKey("YAXIS", TraceInfo("","",0))
```

This example shows how to extract a subrange and put the semicolon back:
String yRange= StringByKey("YRANGE", TraceInfo("","",0))
Print yRange // prints "[30,40:2]"
yRange= ReplaceString(";", yRange, ";")
Print yRange // prints "[30,40;2]"

The next example shows the trace information for the second instance of the wave “data” (which has an instance number of 1) displayed in the top graph:

Make/O data=x;Display/L/T data,data // two instances of data: 0 and 1
Print TraceInfo("","data",1)[0,64]
Print TraceInfo("","data",1)[65,128]

Prints the following in the history area:
XWAVE:;YAXIS:left;XAXIS:top;AXISFLAGS:/T;AXISZ:NaN;XWAVEDF:;YRANGE:
E:*;XRANGE:;TYPE:0;ERRORBARS:;RECREATION:zColor(x)=0;zColorMax

Following is a function that returns the marker code from the given instance of a named wave in the top graph. This example uses the convenient GetNumFromModifyStr() function provided by the #include <Readback ModifyStr> procedures, which are useful for parsing strings returned by TraceInfo.

#include <Readback ModifyStr>
Function MarkerOfWave(wv,instance)
  Wave wv
  Variable instance
  Variable marker
  String info = TraceInfo("",NameOfWave(wv),instance)
  marker = GetNumFromModifyStr(info,"marker","",0)
  return marker
End

See Also
Trace Names on page II-282, Programming With Trace Names on page IV-87.
The Execute operation.

TraceNameList

TraceNameList(graphNameStr, separatorStr, optionsFlag)
The TraceNameList function returns a string containing a list of trace names in the graph window or subwindow identified by graphNameStr.

Parameters
graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

The parameter separatorStr should contain a single ASCII character such as “,” or “;” to separate the names.

Details
The bits of optionsFlag have the following meanings:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Bit Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Include normal graph traces</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Include contour traces</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Omit hidden traces (the default is to list even hidden traces)</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
<td>Include box plot traces</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>Include violin plot traces</td>
</tr>
</tbody>
</table>

See Setting Bit Parameters on page IV-12 for details about bit settings.

A trace name is defined as the name of the Y wave that defines the trace with an optional #ddd suffix that distinguishes between two or more traces that have the same wave name. It may also be a user-defined trace name. Since the trace name has to be parsed, it is quoted if necessary.
Commands that take a trace name as a parameter or in a keyword can use a string containing a trace name with the $ operator to specify traceName. For instance, to change the display mode of a wave, you might use

```
ModifyGraph mode(myWave#1)=3
```

but

```
String myTraceName="myWave#1"
ModifyGraph mode($myTraceName)=3
```

will also work.

**Examples**

Make/O jack,'jack # 2';Display jack,jack,'jack # 2','jack # 2'
Print TraceNameList("";'";",1)
Prints: jack;jack#1;'jack # 2';'jack # 2'#1;

// Generate a list of hidden traces
Make/O jack,jill,joy;Display jack,jill,joy
ModifyGraph hideTrace(joy)=1// hide joy

String visibleTraces=TraceNameList("";'";",1+4)// only visible normal traces
String allNormalTraces=TraceNameList("";'";",1)// hidden + visible normal traces
String hiddenTraces= RemoveFromList(visibleTraces,allNormalTraces)
Print hiddenTraces
// Prints: joy;

**See Also**

For a description of traces: ModifyGraph. For a discussion of contour traces: Contour Traces on page II-370.

For commands referencing other waves in a graph: ImageNameList, ImageNameToWaveRef, ContourNameList, and ContourNameToWaveRef.

ModifyGraph (traces) and Instance Notation on page IV-20 for discussions of trace names and instance notation.

**TraceNameToWaveRef**

```
TraceNameToWaveRef(graphNameStr, traceNameStr)
```

The TraceNameToWaveRef function returns a wave reference to the Y wave corresponding to the given trace in the graph window or subwindow named by `graphNameStr`.

**Parameters**

`graphNameStr` can be "" to refer to the top graph window.

When identifying a subwindow with `graphNameStr`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

The trace is identified by the string in `traceNameStr`, which could be a string determined using TraceNameList. Note that the same trace name can refer to different waves in different graphs.

Use Instance Notation (see page IV-20) to choose from traces in a graph that represent waves of the same name. For example, if `traceNameStr` is “myWave#2”, it refers to the third instance of wave “myWave” in the graph (“myWave#0” or just “myWave” is the first instance).

**See Also**

For a discussion of wave references, see Wave Reference Functions on page IV-197.
Triangulate3D

For commands referencing other waves in a graph: ImageNameList, ImageNameToWaveRef, ContourNameList, and ContourNameToWaveRef.

Triangulate3D

**Triangulate3D [/OUT=format] srcWave**

The Triangulate3D operation creates a Delaunay “triangulation” of a 3D scatter wave. The output is a list of tetrahedra that completely span the convex volume defined by `srcWave`. Triangulate3D can also generate the triangulation needed for performing 3D interpolation for the same domain. Normally `srcWave` is a triplet wave (a 2D wave of 3 columns), but can use any 2D wave that has more than 3 columns (the operation ignores all but the first 3 columns).

**Flags**

**/OUT=format** Specifies how to save the output triangulation data.

- **format=1**: Default; saves the triangulation result in the wave `M_3DVertexList`, which contains in each row, indices to rows in `srcWave` that describe the X, Y, Z coordinates of a single tetrahedral vertex. Each tetrahedron is described by one row in `M_3DVertexList`.

- **format=2**: Saves the triangulation result in the wave `M_TetraPath`, which is a triplet path wave describing the tetrahedra edges. For each tetrahedron, there are four rows (triangles) separated by row of NaNs. The total number of rows in `M_TetraPath` is 20 times the number of tetrahedra in the triangulation.

- **format=4**: Saves a wave containing internal diagnostic information generated during the triangulation process.

**/VOL** Computes the volume of the full convex hull by summing the volumes of the tetrahedra generated in the triangulation. The result is stored in the variable `V_value`. This flag requires Igor Pro 7.00 or later.

**Details**

Triangulate3D implements Watson’s algorithm for tetrahedralization of a set of points in three dimensions. It starts by creating a very large tetrahedron which inscribes all the data points followed by a sequential insertion of one datum at a time. With each new datum the algorithm finds the tetrahedron in which the datum falls. It then proceeds to subdivide the tetrahedron so that the datum becomes a vertex of new tetrahedra.

The algorithm suffers from two known problems. First, it may, due to numerical instabilities, result in tetrahedra that are too thin. You can get around this problem by introducing a slight random perturbation in the input wave. For example:

```plaintext
srcWave+=enoise(amp)
```

Here `amp` is chosen so that it is much smaller than the smallest cartesian distance between two input points.

The second problem has to do with memory allocations which may exhaust available memory for some pathological spatial distributions of data points. The operation reports both problems in the history area.

**Examples**

Make/O/N=(10,3) ddd=gnoise(5) // create random 10 points in space

Triangulate3d/out=2 ddd

// now display the triangulation in Gizmo:

Window Gizmo0() : GizmoPlot
PauseUpdate; Silent 1
if(exists("NewGizmo")!=4)
    DoAlert 0, "Gizmo XOP must be installed"
return
endif
NewGizmo/N=Gizmo0 /W=(309,44,642,373)
ModifyGizmo startRecMacro
ModifyGizmo scalingMode=2
AppendToGizmo Scatter=root:ddd,name=scatter0
ModifyGizmo ModifyObject=scatter0 property={ scatterColorType,0}
ModifyGizmo ModifyObject=scatter0 property={ Shape,2}
ModifyGizmo ModifyObject=scatter0 property={ size,0.2}
TrimString

TrimString(str [, simplifyInternalSpaces])
The TrimString function returns a string identical to str except that leading and trailing whitespace characters are removed. The whitespace characters are space, tab, carriage-return and linefeed.

If the optional second parameter is non-zero, then each run of whitespace characters between words in str is "simplified" to a single space character.

TrimString was added in Igor Pro 7.00.

Examples
Print TrimString("   spaces   at  ends ")  // Prints "spaces at ends"
Print TrimString("   spaces   at  ends ", 1)  // Prints "spaces at ends"

See Also
SplitWave, RemoveEnding, ReplaceString

trunc

trunc(num)
The trunc function returns the integer closest to num in the direction of zero.
The result for INF and NAN is undefined.

See Also
The round, floor, and ceil functions.

try

try
The try flow control keyword marks the beginning of the initial code block in a try-catch-endtry flow control construct.

See Also
The try-catch-endtry flow control statement for details.

try-catch-endtry

try
  <code>
  catch
  <code to handle abort>
endtry
A try-catch-endtry flow control statement provides a means for catching and responding to abort conditions in user functions. A programmatic abort is generated when the code executes Abort, AbortOnRTE or

References

Further information about this algorithm can be found in:

See Also
The Interpolate3D operation and the Interp3D function.
AbortOnValue. A user abort is generated when the user clicks the Abort button or presses the user abort key combination.

When code executes in the try-catch area, a programmatic abort immediately jumps to the code in the catch-endtry area rather than jumping to the end of the user function. A user abort jumps to the catch-endtry area when a flow control keyword such as for or while executes or at the end of the try code. Normal flow (no aborts) skips all code within the catch-endtry area.

Details
During execution of code in the catch-endtry area, user aborts are suppressed. This means that, if the user attempts to abort procedure execution by pressing the User Abort Key Combinations or by clicking the Abort button, this will not abort the catch code itself.

When an abort occurs, information about the cause of the abort is returned via the V_AbortCode variable as follows:

-4: Abort triggered by AbortOnRTE.
-3: Abort caused by Abort operation.
-2: Stack overflow abort.
-1: User abort.
>=1: Abort triggered by AbortOnValue.

See Also
Flow Control for Aborts on page IV-48 and try-catch-endtry Flow Control on page IV-49 for further details.

The AbortOnRTE and AbortOnValue keywords, and the Abort operation.

**UInt64**

`uint64 localName`

Declares a local unsigned 64-bit integer in a user-defined function or structure.

UInt64 is available in Igor Pro 7 and later. See Integer Expressions on page IV-38 for details.

See Also
Int, Int64

**UniqueName**

`UniqueName(baseName, objectType, startSuffix [, windowNameStr])`

The UniqueName function returns the concatenation of `baseName` and a number such that the result is not in conflict with any other object name.

`windowNameStr` is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of `objectType`.

In Igor Pro 9.00 or later, you can use the CreateDataObjectName function as a replacement for some combination of CheckName, CleanupName, and UniqueName to create names of waves, global variables, and data folders.

Details
`baseName` should be an unquoted name, such as you might receive from the user via a dialog or control panel.
GetUniqueName

**objectType** is one of the following:

1. Wave
2. Reserved
3. Numeric variable
4. String variable
5. XOP target window
6. Graph window
7. Table window
8. Layout window
9. Control panel window
10. Notebook window
11. Data folder
12. Symbolic path
13. Picture
14. Annotation in the named or topmost graph or layout
15. Control in the named or topmost graph or panel
16. Notebook action character in the named or topmost notebook
17. Gizmo window (added in Igor Pro 9.00)

**startSuffix** is the number used as a starting point when generating the numeric suffix that makes the name unique. Normally you should pass zero for **startSuffix**. If you know that names of the form base0 through baseN are in use, you can make GetUniqueName run a bit faster by passing N+1 as the **startSuffix**.

The **windowNameStr** argument is used only with object types 14, 15, and 16. The returned name is unique only to the window (other windows might have objects with the same name). If a named window is given but does not exist, GetUniqueName returns **baseName** **startSuffix**. **windowNameStr** is ignored for other object types.

**The Main Namespace**

Waves, numeric variables, string variables, built-in and external functions, built-in and external operations, user-defined functions, macros and reserved keywords exist in the main namespace. The names of each of those objects must be unique in that namespace.

**Window Namespace**

Values of **objectType** from 5 through 10 refer to the window namespace.

The expression

```plaintext
CheckName("<name>", x) // where x is 5, 6, 7, 8, 9 or 10
```

returns 0 if the specified name is syntactically legal and unique in the window namespace.

That does not guarantee that the name is allowed as a window name because the DoWindow/C operation, which changes a window’s name, requires that the name also not conflict with objects in the main namespace. Consequently, to determine if a name is allowed as a window name, use this:

```plaintext
// Window names must be unique in both the window and main namespaces
Variable nameOK = CheckName("<name>",6)==0 & CheckName("<name>",1)==0
```

**Window Macro Names**

Window macro names are treated different from other main namespace names. DoWindow/C allows you to change the name of a window to the name of an existing window macro but not to any other name in the main namespace. Also this expression:

```plaintext
CheckName("<name>", x) // where x is 1, 3, 4 (main namespace)
```

returns 0 even if the specified name is used as a window macro name.

**GetUniqueName Thread Safety**

As of Igor Pro 8.00, you can call GetUniqueName from an Igor preemptive thread but only if **objectType** is 1 (wave), 3 (global numeric variable), 4, (global string variable), 11 (data folder), or 12 (symbolic path). For any other value of **objectType**, GetUniqueName returns a runtime error.
**UnPadString**

Examples

```csharp
String uniqueWaveName = UniqueName(baseWaveName, 1, 0)
String uniqueControlName = UniqueName("ctrl", 15, 0, "Panel0")
```

See Also

Object Names on page III-501, Programming with Liberal Names on page IV-168,
CreateDataObjectName, CheckName, CleanupName

**UnPadString**

**UnPadString**(str, padValue)
The UnPadString function undoes the action of PadString. It returns a string identical to str except that trailing bytes of padValue are removed.

See Also

PadString

**UnsetEnvironmentVariable**

**UnsetEnvironmentVariable**(varName)
The UnsetEnvironmentVariable function deletes the variable named varName from the environment of Igor's process, if it exists

The function returns 0 if it succeeds or a nonzero value if it fails.

The UnsetEnvironmentVariable function was added in Igor Pro 7.00.

Parameters

- **varName**: The name of an environment variable which does not need to actually exist. It must not be an empty string and may not contain an equals sign (=).

Details

The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables.

The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables. Any child process created by calling ExecuteScriptText inherits the environment variables of Igor's process.

UnsetEnvironmentVariable changes the environment variables present in Igor's process and any future process created by ExecuteScriptText but does not affect any other processes already created.

On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

Examples

```csharp
Variable result
result = SetEnvironmentVariable("SOME_VARIABLE", "15")  // Sets the variable
result = UnsetEnvironmentVariable("SOME_VARIABLE")  // Unsets the variable
```

See Also

GetEnvironmentVariable, SetEnvironmentVariable

**Unwrap**

**Unwrap**(modulus, waveName [ , waveName]...)
The Unwrap operation scans through each named wave trying to undo the effect of a modulus operation.

Parameters

- **modulus**: is the value applied to the named waves through the mod function as if the command:
  ```csharp
  waveName = mod(waveName, modulus)
  ```
  had been executed. It is this calculation which Unwrap attempts to undo.
Details
The unwrap operation works with 1D waves only. See ImageUnwrapPhase for phase unwrapping in two dimensions.

Examples
If you perform an FFT on a wave, the result is a complex wave in rectangular coordinates. You can create a real wave that contains the phase of the result of the FFT with the command:

\[ \text{wave2} = \text{imag(r2polar(wave1))} \]

However, the rectangular to polar conversion leaves the phase information modulo \(2\pi\). You can restore the phase information with the command:

\[ \text{Unwrap 2*pi, wave2} \]

Because the first point of a wave that has been FFTed has no phase information, in this example you would precede the Unwrap command with the command:

\[ \text{wave2}[0] = \text{wave2}[1] \]

See Also
The ImageUnwrapPhase operation and `mod` function.

UnzipFile

UnzipFile [ /O[=mode] /PASS=passwordStr /PIN=inputPathName /POUT=outputPathName /Z[=z] ] inputFileStr, outputFolderStr

The UnzipFile operation unzips a file and saves the contents of the file in the specified output directory.

Warning: If you specify /O=2 for an output directory that already exists, all previous contents of the directory are deleted.

The UnzipFile operation was added in Igor Pro 9.00.

Input File Parameter

inputFileStr specifies the zip file to unzip. The file name extension is not important but the file must be a zip file.

inputFileStr can be a full path to the file, in which case /PIN=inputPathName is not needed, a partial path relative to the directory associated with inputPathName, or the name of a file in the folder associated with inputPathName.

If you use a full or partial path for inputFileStr, see Path Separators on page III-451 for details on forming the path.

Output Folder Parameter

outputFolderStr specifies the directory into which the contents of the zip file will be extracted.

outputFolderStr can be a full path to the directory, in which case /POUT=outputPathName is not needed, a partial path relative to the directory associated with outputPathName, or an empty string in which case the directory specified by /POUT=outputPathName is used for the output directory.

If outputFolderStr is an empty string, the /POUT flag specifies the output directory.

If outputFolderStr is not an empty string, it must end with a directory name and not a path separator such as colon or backslash.

If you use a full or partial path for outputFolderStr, see Path Separators on page III-451 for details on forming the path.

If the output directory does not exist, it is created automatically.
UnzipFile

Flags

/\O\[=mode\] Controls whether the contents of the output directory are overwritten.

mode=0: Does not overwrite. If the output directory exists and is not empty, the operation generates an error. This is the default behavior if you omit /O.

mode=1: Merges the contents of the zip file with the existing contents of the output directory. Any existing file with the same name as a file within the zip file is overwritten.

Unlike /O=2, the contents of the output directory and any subdirectories are not deleted. If the output directory already contains files whose names do not conflict with files in the zip file, those files remain untouched.

mode=2: Deletes all contents of the output directory before extracting the contents of the zip file. Use this option if you want the contents of the output directory to exactly reflect the contents of the zip file.

Warning: If you specify /O=2 for an output directory that already exists, all previous contents of the directory are deleted.

/PASS=passwordStr

Specifies the password for a password-protected zip file. Only the older ZipCrypto "encryption" algorithm is supported, not the newer and much more secure AES-256 algorithm.

/PIN=inputPathName

Contributes to the specification of the input zip file to be extracted. inputPathName is the name of an existing symbolic path. See Input File Parameter above for details.

/\POUT=\outputPathName\]

Contributes to the specification of the output directory into which the zip file's contents will be extracted. outputPathName is the name of an existing symbolic path. See Output Folder Parameter above for details.

/Z=[z]

Suppress error generation.

/Z=0: Do not suppress errors. If an error occurs, Igor aborts procedure execution. This is the default behavior if you omit /Z.

/Z=1: Suppress errors. Errors do not abort procedure execution. Check the V_Flag output variable to see if an error occurred.

/Z alone has the same effect as /Z=1.

Output Variables

UnzipFile sets the following output variables:

V_flag V_flag is set to zero if the operation succeeds or to a non-zero Igor error code if it fails. You can use V_flag along with the /Z flag to handle errors and prevent them from halting procedure execution.

S_outputFullPath A string containing the full path to the output directory. If the operation fails, S_outputFullPath is set to "".

Limitations

File and directory names within a zip file that contain non-ASCII characters may not have the correct names after unzipping.

The created and modified timestamps of a file are reconstructed with limited range and precision. Some zip files store these timestamps in an alternative format that allows for greater precision and range, but the current unzip algorithm does not support this newer format.
Examples

// Unzip a file using full paths
String zipFileString = "C:Users:Fred:Documents:Test.zip"
String outputPathString = "C:Users:Fred:Documents:Extracted"
UnzipFile zipFileString, outputPathString

// Unzip a file using symbolic paths
String zipFileName = "Test.zip"
String outputFolderName = "" // Unzip to folder specified by /POUT
UnzipFile/PIN=home/POUT=home zipFileName, outputFolderName

UpperStr

UpperStr(str)
The UpperStr function returns a string expression in which all lower-case ASCII characters in str are converted to upper-case.

See Also
The LowerStr function.

URLDecode

URLDecode(inputStr)
The URLDecode function returns a percent-decoded copy of the percent-encoded string inputStr. It is unlikely that you will need to use this function; it is provided for completeness.

For an explanation of percent-encoding, see Percent Encoding on page IV-268.

Example

String theURL = "http://google.com?key1=35%25%20larger"
theURL = URLDecode(theURL)
Print theURL
    http://google.com?key1=35% larger

See Also
URLEncode, URLRequest, URLs on page IV-267.

URLEncode

URLEncode(inputStr)
The URLEncode function returns a percent-encoded copy of inputStr.

Percent-encoding is useful when encoding the query part of a URL or when the URL contains special characters that might otherwise be misinterpreted by a web server. For an explanation of percent-encoding, see Percent Encoding on page IV-268.

Example

String baseURL = "http://google.com"
String key1 = "key1"
String value1 = URLEncode("35% larger")
String theURL = ""
sprintf theURL, "%s%s%s", baseURL, key1, value1
Print theURL
    http://google.com?key1=35%25%20larger

See Also
URLDecode, URLRequest, URLs on page IV-267.

URLRequest

URLRequest [ flags ] url=urlStr [method=methodName, headers=headersStr]
The URLRequest operation connects to a URL using the specified method and optionally stores the response from the server. urlStr can point to a remote server or to a local file. The server's response is stored in the S_serverResponse output variable or in a file if you use the /FILE flag.

The URLRequest operation was added in Igor Pro 7.00.
Keywords
The url=urlStr keyword is require. All others are optional.

url=urlStr
A string containing the URL to retrieve. See URLs on page IV-267 for details.

methodName
Specifies which method to use for the request. The get method is used by default.
This table shows the valid methods for each supported scheme. Not all servers support all of the listed methods.

<table>
<thead>
<tr>
<th>Scheme</th>
<th>Supported Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>http, https</td>
<td>get, post, put, head, delete</td>
</tr>
<tr>
<td>ftp</td>
<td>get, put</td>
</tr>
<tr>
<td>file</td>
<td>get, put</td>
</tr>
</tbody>
</table>

Because methodName is a name, not a string, you must not enclose it in quotes.

Before using the post method, you should read The HTTP POST Method on page V-1058 so that you know how to use the optional headers parameter.

If you use the head method, URLRequest sets the S_serverResponse output variable to "" because only the headers are retrieved. As with other methods, the headers are stored in the S_headers output variable.

headers=headersStr
Specifies a string containing additional or replacement headers to use with the request. This parameter is ignored unless the scheme is http or https.

The headers parameter is provided primarily for use with the post method when making HTTP requests and is ignored for schemes other than http/https. The header consists of a colon-separated key:value pair (though see the next paragraph for an exception). Pairs must be separated by a carriage return (\r) character.

Certain standard headers (such as Content-Type and User-Agent) may automatically be set when making the request. You can override those default values by using this keyword and setting a different value. If you add a header with no content, as in "Accept:" (there is no data on the right side of the colon), the internally used header is disabled. To actually add a header with no content, use the form "MyHeader;" (note the trailing semicolon).

Any headers specified with this keyword are sent only to the http server, not to the proxy server, if one is in use.

See The HTTP POST Method on page V-1058 for a detailed explanation and examples.

Flags

/Auth={username, password}

Uses the specified username and password string parameters for authentication. Values provided here override any username and/or password provided as part of the URL. To specify a username but not a password, pass "" for the password parameter.

Note: See Safe Handling of Passwords on page IV-270 for more information on how to use URLRequest to prevent authentication information, such as passwords, from being accidentally revealed.
URLRequest

/DFIL=dataFileNameStr
Specifies a file name to use as a source of data. Typically this flag is used only with the put or post methods, but it is accepted with all methods. Unless dataFileNameStr is a full path, the /P flag must also be used. When using the post or put methods, one and only one of the /DFIL or /DSTR flags must be used.

When you use /DFIL and the method is anything other than put, the "Content-Type: application/x-www-form-urlencoded" header is automatically added. If necessary, you can override this behavior using the headers keyword. See The HTTP POST Method on page V-1058 for more information.

/DSTR=dataStr
Specifies the string to use as a source of data. Typically you use this flag only with the put or post methods, but it is accepted with all methods. When using the post or put methods, one and only one of the /DFIL or /DSTR flags must be used.

When /DSTR is used and the method is anything other than put, the "Content-Type: application/x-www-form-urlencoded" header is automatically added. If necessary, you can override this behavior using the headers keyword. See The HTTP POST Method on page V-1058 for more information.

/FILE=destFileNameStr
If present, URLRequest saves the server’s response in a file instead of in the S_serverResponse output variable.

URLRequest ignores /FILE if you include the /IGN flag and the ignoreResponse parameter is not 0.

destFileNameStr can be a full path to the file, in which case /P=pathName is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If the file already exists, URLRequest returns an error unless you include the /O flag.

If you include /O and the file already exists, the existing file is overwritten. This happens even in the event of an empty response or transfer error.

You should consider using the /FILE flag when you are expecting the server to return a large amount of data, such as when downloading a file.

/IGN=ignoreResponse
Ignore and do not store the server’s response to the request. /IGN alone has the same effect as /IGN=1.

If ignore is turned on, URLRequest sets the S_serverResponse output variable to "", regardless of whether the server responded to the request or not. If you include the /FILE flag, URLRequest does not create the output file and sets S_fileName is set to "".

This flag is useful only when your goal is to establish a connection with a server and the server’s response is not important. All error message codes and strings are still set when ignore is on.

/IGN=0: Same as no /IGN.
/IGN=1: Ignore server response completely. S_headers is set to "".
/IGN=2: Ignore server response but capture the headers of the response. S_serverResponse is set to "" but S_headers will contain the headers.

/NRED=maxNumRedirects
Specifies the maximum number of redirects that are allowed. A redirect means that when a certain URL is requested, the server responds telling the client to try a different URL. Most web browsers automatically follow server redirects, up to a certain limit. For security purposes, it is sometimes useful to prevent redirects from being followed at all.

maxNumRedirects is a number between -1 and 1000. To allow infinite redirection, set maxNumRedirects to -1. If you omit the /NRED flag, a moderate value (currently 20, but subject to change in the future) is used.
/O Specifies that the file is to be overwritten when you use the /FILE flag and the output file already exists. If you omit /O and the file exists, URLRequest returns an error.

/P=pathName Specifies the folder to use for the output file, specified by the /FILE flag, and/or the source data file, specified by the /DFIL flag. pathName is the name of an existing Igor symbolic path.

The /P flag affects both the /FILE and /DFIL flags. If you use both flags and want to use different directories, you must provide a full path for one or both of the /FILE and /DFIL flag parameters.

If the /P flag is used without one or both of the /FILE and /DFIL flags, it is ignored.

/PROX=[{proxyURLStr, proxyUserNameStr, proxyPassStr, proxyOptions}]

NOTE: This flag is experimental and has not been extensively tested. The behavior of this flag may change in the future, or it may be eliminated entirely.

Designates a proxy server to be used when making the connection.

proxyURLStr is either the host name or IP address of the proxy server, or a full URL. If a full URL is used, the scheme specifies which kind of proxy is used. Typically the scheme for a proxy server should be either http or socks5. If no scheme is provided, http is assumed. See URLs on page IV-267 for more information.

If the proxy server does not require authentication, or if the username and password for the proxy server are specified in proxyURLStr, the optional proxyUserNameStr and proxyPassStr parameters do not need to be provided.

The following two examples do the same thing:

/PROX={"http://proxy.example.com:800"}
/PROX={"http://proxy.example.com:800", "", ""}

As with other URLs, you can also provide the username and password as part of the URL itself. The following two examples do the same thing:

/PROX={"http://proxy.example.com:800", "user", "pass"}
/PROX={"http://user:pass@proxy.example.com:800"}

proxyOptions is optional and for future use. It is currently ignored. If provided, you must set it to 0.

If you use the /PROX flag without any parameters, Igor attempts to get proxy information from the operating system’s proxy configuration information. If Igor cannot get any proxy server information from the system, no proxy server is used.

See Safe Handling of Passwords on page IV-270 for more information on how to use URLRequest to prevent authentication information, such as passwords, from being accidentally revealed.

/TIME=timeoutSeconds Forces the operation to time out after timeoutSeconds seconds if it has not completed by that time. If this flag is not provided, URLRequest runs until the server has finished sending and receiving data. For simple requests a value of a few seconds is appropriate. However, because uploading and/or downloading large amounts of data may take a long time, if timeoutSeconds is too small the request might be prematurely terminated. If you omit the /TIME flag, or if timeoutSeconds = 0, there is no timeout.

Regardless of whether or not you include /TIME, you can abort the operation by pressing the User Abort Key Combinations.
URLRequest

/\=diagnosticMode
This flag is useful only when your goal is to establish a connection with a server and the server's response is not important. All error message codes Controls diagnostic messages printed in the history area of the command window.

/\=0: Do not print any diagnostic messages. This is the default if you omit /\.

/\=1: Prints an error message if a run time error occurs.

/\=2: Prints full debugging information.

/Z[\=z]
Suppress error generation. Use this if you want to handle errors yourself.

/Z=0: Do not suppress errors. This is the default if /Z is omitted.

/Z=1: Any errors generated by Igor do not stop execution. If there is an error the error code is stored in V_Flag.

/Z alone has the same effect as /Z=1.

Output Variables
URLRequest sets the following output variables:

V_flag
V_flag is zero if the operation succeeds without an error or a non-zero Igor error code if it fails.

Note that "succeeds without an error" does not necessarily mean that the operation performed as you intended. For example, if you attempt to connect to a server that requires a username and password for authentication but you do not provide this information, V_flag is likely to be 0, indicating no error. You need to inspect the value of V_responseCode to ensure that it is what you expect.

V_responseCode
Contains the status code provided by the server.

V_responseCode is valid only if V_flag is 0, meaning that no error occurred. If V_flag is nonzero, an error occurred and V_responseCode will be 0.

Different schemes use different sets of status codes.

A list of http/https status codes and their definitions can be found at:
http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html

A list of FTP status codes can be found at:

S_serverResponse
Contains the server's response to the request.

S_serverResponse is set to "" if you use the /FILE flag or the /IGN=1 or /IGN=2 flags.

We recommend that you use the /FILE flag when you expect the size of the server response to be large, such as when downloading a large file.

S_headers
Contains a list of all of the headers received as part of the response. Header names are separated from their value by a colon and pairs are separated by a carriage return followed by a line feed (\r\n). For schemes other than http and https, S_headers is set to "".

S_fileName
Contains the full Igor-style path to the output file if the /FILE flag was used. If there was an error saving to the specified file, or another kind of error, or if the /FILE flag was not used, S_fileName is set to "".

Basic Examples

// Retrieve the contents of the WaveMetrics home page.
// Output is stored in S_serverResponse
URLRequest url="http://www.wavemetrics.com"

// Download the Windows Igor6 installer and save it as a file on the desktop.
Using the File Scheme

URLRequest supports the file scheme in URLs. You must provide the full path to the file as a native Windows-style or UNIX-style path, depending on which platform the code is running.

You must specify the schema as "file://". Note that you must use three front slash characters (/) between the colon and the full file path (for most URLs you would only use two slashes).

```java
// Download a file to the desktop from an FTP server.
NewPath/O Desktop, SpecialDirPath("Desktop", 0, 0, 0)
String theURL = "ftp://ftp.wavemetrics.com/test/test.htm"
URLRequest/O/FILE="test.htm"/P=Desktop method=post, url=theURL
// Upload the same file to the FTP server.
theURL = "ftp://user:pass@ftp.wavemetrics.com/test.htm"
URLRequest/DFIL="test.htm"/P=Desktop method=put, url=theURL
```

The following example shows how to convert a full Igor file path to a native path suitable for use as a file URL:

```java
String nativeFilePath
#ifdef WINDOWS
    String igorFilePath = "C:Documents:myFile.txt"
    nativeFilePath = ParseFilePath(5, igorFilePath, ":", 0, 0)
#endif
#ifdef MACINTOSH
    String igorFilePath = "MacintoshHD:Documents:myFile.txt"
    nativeFilePath = ParseFilePath(5, igorFilePath, ":", 0, 0)
    // Remove the leading ":/" from nativeFilePath. Otherwise,
    // when we prepend "file:///" below, we'd end up with four
    // slashes, which isn't allowed.
    nativeFilePath = nativeFilePath[1,INF]
#endif
URLRequest url="file:///" + nativeFilePath
```

The HTTP POST Method

Like the HTTP GET method, the HTTP POST method can be used to transmit information to a web server. When using the GET method, all information must be contained within the URL itself. As an example, making a GET request to the URL <http://www.google.com/search?q=Igor+Pro+WaveMetrics> searches Google using the keywords "Igor", "Pro", and "WaveMetrics".

Unlike the GET method, the POST method allows the client to send information to the server that is not contained within the URL itself. This is necessary in many situations, such as when uploading a file or transferring a large amount of data. In addition, because the data contained in POST requests is typically not stored in the log files of web servers, it is more appropriate for sending data that is secure, such as login credentials and form submissions which might contain sensitive information.

When using the POST method, the client must encode its data using one of several methods and must tell the server what type of data is being sent and how it is encoded. The client does this by setting the Content-Type header that is part of the request. The most commonly used content type is "application/x-www-form-urlencoded". Unless you provide your own Content-Type header using the optional headers parameter, URLRequest will set this header for you. This is true regardless of which data source (/DSTR for string or /DFIL for file) you use for the POST.

Here is a simple example that uses the POST method with URL encoded data (the default Content-Type).

```java
String theURL = "http://www.example.com/process.php"
String nameData = URLEncode("name") + "=" + URLEncode("Dan P. Ikes, Jr.")
String address = "650 E. Chicago Ave."
String addressData = URLEncode("address") + "=" + URLEncode(address)
String postData = nameData + ";" + addressData
URLRequest/DSTR=postData method=post, url=theURL
```

There are two things to note in this example.
First, both the key name and value string are passed through URLEncode so that any special characters can be percent-encoded.

Second, keys and values are separated by an equal sign ("=") and key/value pairs are separated by an ampersand ("&"). These characters are not passed through URLEncode because doing so would cause them to lose their meaning as special characters.

For more information on using the application/x-www-form-urlencoded content type, see http://www.w3.org/TR/html401/interact/forms.html#h-17.13.4.1

It is also possible to transmit more complicated data using the POST method, such as simulating a form that contains regular text fields as well as a file upload field. To do so you must set the Content-Type header using the headers parameter. You must also build your post data using a multi-part header. Here is an example:

```java
String theURL = "http://www.example.com/process.php"
String postData = ""
// Note: The boundary is arbitrary. It needs to be
// unique enough that it is not contained within any
// of the actual data being transmitted in the post.
String boundary = "AaBbCcDd0987"

// name
postData += "--" + boundary + "\r\n" // beginning of this part
postData += "Content-Disposition: form-data; name="name"
postData += "\r\n"
postData += "Dan P. Ikes, Jr.\r\n"

// address
postData += "--" + boundary + "\r\n"
postData += "Content-Disposition: form-data; name="address"
postData += "\r\n"
postData += "650 E. Chicago Ave.\r\n"

// file
// Open the file we plan to send and store the binary
// contents of the file in a string.
Variable refNum
Open/R/Z/P=Igor refNum as "ReadMe.ihf"
FStatus refNum
Variable fileSize = V_logEOF
String fileContents = ""
fileContents = PadString(fileContents, fileSize, 0)
FBinRead refNum, fileContents
Close refNum
postData += "--" + boundary + "\r\n"
postData += "Content-Disposition: form-data; name="file"; filename="ReadMe.ihf"
postData += "\r\n"
postData += "Content-Type: application/octet-stream\r\n"
postData += "Content-Transfer-Encoding: binary\r\n"
postData += "\r\n"
postData += fileContents + "\r\n"

postData += "--" + boundary + "--\r\n" // end of this part

String headers
headers = "Content-Type: multipart/form-data; boundary=" + boundary
URLRequest/DSTR=postData method=post, url=theURL, headers=headers
```

For more information on using the multipart/form-data content type, see http://www.w3.org/TR/html401/interact/forms.html#h-17.13.4.2

Handling JSON Data

JSON (JavaScript Object Notation) is a lightweight data-interchange format that is commonly used when interacting with websites - see https://www.json.org/json-en.html. For full read and write JSON support in Igor Pro, we recommend using the JSON XOP, developed by byte physics. You can download it from https://docs.byte-physics.de/json-xop.

URLEncode, URLDecode, Base64Encode, Base64Decode, FetchURL, BrowseURL

Network Communication on page IV-267, URLs on page IV-267
ValDisplay

ValDisplay [/Z] ctrlName [keyword = value [, keyword = value ...]]

The ValDisplay operation creates or modifies the named control that displays a numeric value in the target window. The appearance of the control varies; see the Examples section.

For information about the state or status of the control, use the ControlInfo operation.

Parameters

ctrlName is the name of the ValDisplay control to be created or changed.

The following keyword=value parameters are supported:

align=alignment

Sets the alignment mode of the control. The alignment mode controls the interpretation of the leftOrRight parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

If alignment=0 (default), leftOrRight specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If alignment=1, leftOrRight specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

appearance={kind [, platform]}

Sets the appearance of the control. platform is optional. Both parameters are names, not strings.

kind can be one of default, native, or os9.

platform can be one of Mac, Win, or All.

See Button and DefaultGUIControls for more appearance details.

barBackColor=(r,g,b,[a])

Sets the background color under the bar (if any). r, g, and a specify the color and optional opacity as RGBA Values.

barBackColor=0 Sets the background color under the bar to the default color, the standard document background color used on the current operating system, which is usually white.

barmisc={lts, valwidth}

Sets the “limits text size” and the size of the type showing the bar limits. If lts is zero, the bar limits are not displayed. Otherwise, lts must be between 5 and 100. valwidth is the “value readout width”. It claims the amount of horizontal space for the numeric part of the display.

If valwidth equals or exceeds the control width available to it, the numeric readout uses all the room, and prevents display of any bar.

If valwidth is zero, there is no numeric readout, and only the bar is displayed.

valwidth can range from zero to 4000, and it defaults to 1000 (which usually leaves no room for the display bar).

bodyWidth=width

Specifies an explicit size for the body (nontitle) portion of a ValDisplay control. By default (bodyWidth=0), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size, or text of the title changes, then the body portion may grow or shrink. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.
disable=d  Sets user editability of the control.
   d=0: Normal.
   d=1: Hide.
   d=2: Disable user input.  
        Does not change control appearance because it is read-only.
   d=3: Hide and disable the control.  
        This is useful to disable a control that is also hidden because it is 
        in a hidden tab.

fColor=(r,g,b,[a])  Sets the initial color of the title.  r, g, b, and a specify the color and optional opacity 
                     as RGBA Values.  The default is opaque black.

To further change the color of the title text, use escape sequences as described for 

    title=titleStr

font="fontName"  Sets the font used to display the value of the variable, e.g.,
font="Helvetica"

format=formatStr  Sets the numeric format of the displayed value.  The default format is "%g".  For a 
                     description of formatStr, see the printf operation.

frame=f  Sets frame style:
   f=0: Value is unframed.
   f=1: Default; value is framed (same as f=3).
   f=2: Simple box.
   f=3: 3D sunken frame.
   f=4: 3D raised frame.
   f=5: Text well.

fs=m  Sets the size of the type used to display the value in the numeric readout.  The 
     default is 12 points.

fst=fs  fs is a bitwise parameter with each bit controlling one aspect of the font style 
         as follows:
   Bit 0: Bold
   Bit 1: Italic
   Bit 2: Underline
   Bit 4: Strikethrough

See Setting Bit Parameters on page IV-12 for details about bit settings.

help=helpStr  Sets the help for the control.

    helpStr is limited to 1970 bytes (255 in Igor Pro 8 and before).
    You can insert a line break by putting "\r" in a quoted string.

highColor=(r,g,b,[a])  Specifies the bar color when the value is greater than base in the limits keyword. 
                        r, g, b, and a specify the color and optional opacity as RGBA Values.

labelBack=(r,g,b,[a]) or 0  Specifies the background fill color for labels.  r, g, b, and a specify the color and 
                              optional opacity as RGBA Values.  The default is 0, which uses the window’s 
                              background color.

limits=[low,high,base]  Controls how the value is translated into a graphical representation when the display 
                        includes a bar (described fully in Details).  Defaults are [0,0,0], which aren’t too 
                        useful.

limitsColor=(r,g,b,[a])  Sets the color of the limits text, if any.  r, g, b, and a specify the color and optional 
                         opacity as RGBA Values.

limitsBackColor=(r,g,b,[a])
**Sets the background color under the limits text.** \( r, g, b, \) and \( a \) specify the color and optional opacity as **RGBA Values**.

- **limitsBackColor=0**
  - Sets the background color under the limits text to the default color, the standard document background color used on the current operating system, which is usually white.

- **lowColor=(r,g,b[a])**
  - Specifies the bar color when the value is less than \( base \) in the limits keyword. \( r, g, b, \) and \( a \) specify the color and optional opacity as **RGBA Values**.

- **mode=m**
  - Specifies the type of LED display to use, if any.
    - \( m=0 \): Bar mode (default).
    - \( m=1 \): Oval LED.
    - \( m=2 \): Rectangular LED.
    - \( m=3 \): Bar mode with no fractional part.
    - \( m=4 \): Candy-stripe effect for the bar area to support indefinite-style progress windows. The value is taken to be the phase of the candy stripe. When using \( value=\_NUM:n \), \( n \) is taken as an increment value so you would normally just use 1. Uses the native platform appearance if the high and low colors are left as default. Note native formats may not fill vertical space. See **Progress Windows** on page IV-156 for an example.

- **pos=[leftOrRight,top]**
  - Sets the position in **Control Panel Units** of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

- **pos+=[dx,dy]**
  - Offsets the position of the display in **Control Panel Units**.

- **rename=newName**
  - Gives the ValDisplay control a new name.

- **size=[width,height]**
  - Sets width and height of display in **Control Panel Units**. \( width \) can range from 10 to 200 units, \( height \) from 5 to 200 units. Default width is 50, default height is determined by the numeric readout font size.

- **title=titleStr**
  - Sets title of display to the specified string expression. The title appears to the left of the display. If this title is too long, it won’t leave enough room to display the bar or even the numeric readout! Defaults to “” (no title).

  Using escape codes you can change the font, size, style, and color of the title. See **Annotation Escape Codes** on page III-53 or details.

- **value=valExpr**
  - Displays the numeric expression \( valExpr \). It is **not a string**.

  As of version 6.1, you can use the syntax \( _NUM: \) num to specify a numeric value without using a dependency.

- **valueColor=(r,g,b[a])**
  - Sets the color of the value readout text, if any. \( r, g, b, \) and \( a \) specify the color and optional opacity as **RGBA Values**.

- **valueBackColor=(r,g,b[a])**
  - Sets the background color under the value readout text. \( r, g, b, \) and \( a \) specify the color and optional opacity as **RGBA Values**.

- **valueBackColor=0**
  - Sets the background color under the value readout text to the default color, the standard document background color used on the current operating system, which is usually white.

- **win=winName**
  - Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

  When identifying a subwindow with \( winName \), see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
ValDisplay

flags
/Z No error reporting.

Details
The target window must be a graph or panel.
The appearance of the ValDisplay control depends primarily on the width and valwidth parameters and the width of the title. Space for the individual elements is allocated from left to right, with the title receiving first priority. If the control width hasn’t all been used by the title, then the value display gets either valwidth Control Panel Units of room, or what is left. If the control width hasn’t been used up, the bar is displayed in the remaining control width:

If you use the bodyWidth keyword, the value readout width and bar width occupy the body width. The total control width is then bodyWidth+title width, and the width from the size keyword is ignored.

The limits values low, high, and base and the value of valExpr control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the base value to an ending position determined by the value of valExpr, low and high. low corresponds to the left side of the bar, and high corresponds to the right. The position that corresponds to the base value is linearly interpolated between low and high.

For example, with low=-10, high=10, and base=0, a valExpr value of 5 will draw from the center of the bar area (0 is centered between -10 and 0) to the right, halfway from the center to the right of the bar area (5 is halfway from 0 to 10):

The valExpr must be executable at any time. The expression is stored and executed when the ValDisplay needs to be updated. However, execution will occur outside the routine that creates the ValDisplay, so you must not use local variables in the expression.

valExpr may be enclosed in quotes and preceded with a # character (see When Dependencies are Updated on page IV-233) to defer evaluation of the validity of the numeric expression, which may be needed if the expression references as-yet-nonexistent global variables or user-defined functions:

ValDisplay valdisp0 value=notAVar*2 // "unknown name or symbol" error
ValDisplay valdisp0 value=#"notAVar*2" // still not valid, no error
Variable notAVar=3 // now valid; ValDisplay works

valColor=(r,g,b[,...]) Governs the LED color (in LED mode only). r, g, b, and a specify the color and optional opacity as RGBA Values. Used in conjunction with the limits keyword such that zeroColor determines one endpoint color when base is between low and high, or LED color when the value is less than low.

/ValDisplacement
ValDisplay

In a ValDisplay, the "#" syntax permits use of a string expression. Normally, the # prefix signifies that the following text must be a literal quoted string. String expressions are evaluated at runtime to obtain the final expression for the ValDisplay. In other words, there is a level of indirection.

Examples

Here is a sampling of the various types of ValDisplay controls available:

![ValDisplay Controls Example](image)

You can use a ValDisplay to replace the bar mode with a solid color fill designed to look like an LED. Use the mode keyword with mode=1 to create an oval LED or mode=2 to create a rectangular LED. You can specify different frames with the rectangular LED but only a simple frame is available for the oval mode. Use mode=0 to revert to bar mode.

The color and brightness of the LED depends on the value that the ValDisplay is monitoring combined with the limits={low, high, base} setting, the two color settings used in bar mode along with a third color (zeroColor) that is used only in LED mode. When the value is between low and high, the color is a linear combination of endpoint colors. If base is between low and high, the endpoint colors are the low color and the zero color, or the zero color and the high color. For values outside the limits, the appropriate limiting color is chosen.

If base is less than the low, the endpoint colors are the low color and the high color. In this case, if the value is less than low the LED takes on the zero color.

You should use the bodyWidth setting in conjunction with LED mode to keep the LED from dramatically changing size or disappearing when the title is changed or if your experiment is moved to a different platform (Macintosh vs PC).

Try the ValDisplay Demo example experiment to see these different modes in action. Choose File→Example Experiments→Feature Demos→ValDisplay Demo.

Progress Windows on page IV-156 for an example of candy-stripe mode=4.
The Variable operation creates real or complex variables and gives them the specified name.

Flags

/C    Declares a complex variable.

/D    Obsolete, included only for backward compatibility (see Details).

/G    Creates a variable with global scope and overwrites any existing variable.

/N=name  Specifies a local name for the global string variable. /N was added in Igor Pro 8.00 and is available in user-defined functions only. See NVAR Creation below for details.

Details

The variable is initialized when it is created if you supply the initial value. However, when Variable is used to declare a function parameter, it is an error to attempt to initialize it.

You can create more than one variable at a time by separating the names and optional initializers for multiple variables with a comma.

Numeric variables are double precision. In ancient times, variables could be single or double precision and the /D flag meant double precision. The /D flag is allowed for backward compatibility but is no longer needed and should not be used in new code.

If used in a macro or function the new variable is local to that macro or function unless the /G flag is used. If used on the command line, the new variable is global.

varName can include a data folder path.

NVAR Creation

In a user-defined function, you need a local NVAR reference to access a global string variable. If you use a simple name rather than a path, Igor automatically creates an NVAR:

Variable/G nVar1  // Creates an NVAR named nVar1

If you use a path or a $ expression, Igor does not create an automatic NVAR reference. You can explicitly create NVARs like this:

Variable/G root:nVar2
NVAR nVar2 = root:nVar2  // Creates an NVAR named nVar2

String path = "root:nVar3"
Variable/G $path
NVAR nVar3 = $path  // Creates an NVAR named nVar3

In Igor Pro 8.00 and later, you can explicitly create an NVAR reference in a user-defined function using the /N flag, like this:

Variable/G nVar4/N=nVar4  // Creates an NVAR named nVar4
Variable/G root:nVar5/N=nVar5  // Creates an NVAR named nVar5
String path = "root:nVar6"
Variable/G $path/N=nVar6  // Creates an NVAR named nVar6

The name used for the NVAR does not need to be the same as the name of the global variable:

Variable/G nVar7/N=nv7  // Creates an NVAR named nv7
Variable/G root:nVar8/N=nv8  // Creates an NVAR named nv8
String path = "root:nVar9"
Variable/G $path/N=nv9  // Creates an NVAR named nv9

Examples

To initialize a complex variable, use the cmplx function. For example:

Variable/C cv1 = cmplx(1,2)

This sets the real part of cv1 to 1 and the imaginary part to 2.

Numeric Variables on page II-104, Accessing Global Variables and Waves on page IV-65
Variance

Variance\(\text{(inWave [, \ x_1, \ x_2 \ ] )}\)

Returns the variance of the real-valued \(\text{inWave}\). The function ignores NaN and INF values in \(\text{inWave}\).

Parameters

\(\text{inWave}\) is expected to be a real-valued numeric wave. If \(\text{inWave}\) is a complex or text wave, Variance returns NaN.

\(\ x_1\) and \(\ x_2\) specify a range in \(\text{inWave}\) over which the variance is to be calculated. They are used only to locate the points nearest to \(x=x_1\) and \(x=x_2\). The variance is then calculated over that range of points. The order of \(\ x_1\) and \(\ x_2\) is immaterial.

If omitted, \(\ x_1\) and \(\ x_2\) default to \(-\infty\) and \(+\infty\) respectively and the variance is calculated for the entire wave.

Details

The variance is defined by

\[
\text{var} = \frac{\sum_{i=1}^{n} (x_i - \bar{x})^2}{n - 1}
\]

where

\[
\bar{x} = \frac{\sum_{i=1}^{n} X_i}{n}.
\]

Examples

Make/O/N=5 test = p
SetScale/P x, 0, .1, test
// Print variance of entire wave
Print Variance(test)
// Print variance from x=0 to x=.2
Print Variance(test, 0, .2)
// Print variance for points 1 through 3
Variable x1=pnt2x(test, 1)
Variable x2=pnt2x(test, 3)
Print Variance(test, x1, x2)

See Also
mean, median, WaveStats, APMath

VariableList

VariableList\(\text{(matchStr, separatorStr, variableTypeCode [, dfr ])}\)

The VariableList function returns a string containing a list of the names of global variables selected based on the \(\text{matchStr}\) and \(\text{variableTypeCode}\) parameters. The variables listed are all in the current data folder or the data folder specified by \(\text{dfr}\).

Details

For a variable name to appear in the output string, it must match \(\text{matchStr}\) and also must fit the requirements of \(\text{variableTypeCode}\). \(\text{separatorStr}\) is appended to each variable name as the output string is generated.

The name of each variable is compared to \(\text{matchStr}\), which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

\n
\n
*\n
Matches all variable names.
"xyz"    Matches variable name xyz only.
"xyz"    Matches variable names which end with xyz.
"xyz"    Matches variable names which begin with xyz.
"xyz"    Matches variable names which contain xyz.
"abcxyz" Matches variable names which begin with abc and end with xyz.

matchStr may begin with the ! character to return items that do not match the rest of matchStr. For example:

"!xyz"    Matches variable names which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.

variableTypeCode is used to further qualify the variable. The variable name goes into the output string only if it passes the match test and its type is compatible with variableTypeCode. variableTypeCode is any one of:

2: System variables (K0, K1 . . .)
4: Scalar variables
5: Complex variables
dfr is an optional data folder reference: a data folder name, an absolute or relative data folder path, or a reference returned by, for example, GetDataFolderDFR.

Examples

VariableList("*",";",4)    Returns a list of all scalar variables.
VariableList("!V_*",";",5) Returns a list of all complex variables except those whose names begin with “V_”.
VariableList("*",";",4,root:MyData) Returns a list of all scalar variables in the root:MyData data folder.

See Also
See the StringList and WaveList functions.
See Setting Bit Parameters on page IV-12 for details about bit settings.

VCsr

vcsr(cursorName [, graphNameStr])
The vcsr function returns the Y (vertical) value of the point which the specified cursor (A through J) is attached to in the top (or named) graph.

Parameters
cursorName identifies the cursor, which can be cursor A through J.
graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
The result is computed from the coordinate system of the graph’s Y axis. The Y axis used is the one used to display the wave on which the cursor is placed.

See Also
The hcsr, pcsr, qcsr, xcsr, and zcsr functions.
Programming With Cursors on page II-321.
VoigtFunc

VoigtFunc(X,Y)

The VoigtFunc function computes the Voigt function using an approximation that has, as described by the
author, "accuracy is typically at least 13 significant digits".

VoigtFunc returns values from a normalized Voigt peak centered at X=0 for the given value of X. The X
input is a normalized distance from the peak center:

\[ X = \sqrt{\ln(2)} \frac{V - V_0}{\gamma_g} \]

where \( \gamma_g \) is the Gaussian component half-width, and \( V - V_0 \) is the distance from the peak center.

The parameter Y is the shape parameter: when Y is zero, the peak is pure Gaussian. When Y approaches
infinity, the shape becomes pure Lorentzian. When Y is \( \sqrt{\ln(2)} \), the mix is half-and-half.

VoigtFunc was added in Igor Pro 7.00. The approximation used to compute it was changed Igor 8.00 for
greater accuracy.

Details

The VoigtFunc function returns values from a normalized peak that can be used as the basis for user-
defined fitting functions. The function is used as the basis for the built-in Voigt fitting function and the
VoigtPeak function.

VoigtFunc Curve Fitting Example

Here is an example of a user-defined fitting function built on VoigtFunc:

```plaintext
Constant sqrtln2=0.832554611157698 // sqrt(ln(2))
Constant sqrtln2pi=0.469718639349826 // sqrt(ln(2)/pi)
Function MyVoigtFit(w,xx) : FitFunc
    Wave w
    Variable xx

    //CurveFitDialog/ These comments were created by the Curve Fitting dialog.
    //CurveFitDialog/ Equation:
    //CurveFitDialog/ Variable ratio = sqrtln2/gw
    //CurveFitDialog/ Variable xprime = ratio*(xx-x0)
    //CurveFitDialog/ Variable voigtY = ratio*shape
    //CurveFitDialog/ f(xx) = y0 + area*sqrtln2pi*VoigtFunc(xprime, voigtY)
    //CurveFitDialog/ End of Equation
    //CurveFitDialog/ Independent Variables 1
    //CurveFitDialog/ xx
    //CurveFitDialog/ Coefficients 5
    //CurveFitDialog/ w[0] = y0
    //CurveFitDialog/ w[1] = area
    //CurveFitDialog/ w[2] = x0
    //CurveFitDialog/ w[3] = gw (FWHM)
    //CurveFitDialog/ w[4] = shape (Lw/Gw)

    Variable voigtX = 2*sqrtln2*(xx-w[2])/w[3]
    Variable voigtY = sqrtln2*w[4]
    return w[0] + (w[1]/w[3])*2*sqrtln2pi*VoigtFunc(voigtX, voigtY)
End
```
Parameter \( w[0] \) sets the vertical offset, \( w[1] \) sets the peak area, \( w[2] \) sets the location of the peak, \( w[3] \) gives the Gaussian component’s full width at half max and \( w[4] \) is the ratio of the Lorentzian width to the Gaussian width.

After the fit, assuming you used a coefficient wave named `voigtCoefs`, you can calculate the width of the full Voigt peak as follows:

```plaintext
Variable/G/wl = voigtCoefs[4]*voigtCoefs[3]
Variable/G/wg = voigtCoefs[3]
Variable/wv = wl/2 + sqrt( wl^2/4 + wg^2)
```

**References**
The code used to compute the Voigt Func was written by Steven G. Johnson of MIT. You can learn more about it at http://ab-initio.mit.edu/Faddeeva.

**See Also**
*VoigtPeak, Faddeeva, Built-in Curve Fitting Functions* on page III-206

**VoigtPeak**

**VoigtPeak(\(w, x\))**
The VoigtPeak function returns a value from a Voigt peak shape defined by coefficients in wave \( w \) at location \( x \). It was added in Igor Pro 8.00.

The Voigt peak shape is defined as a convolution of a Gaussian and a Lorentzian peak. We use an approximation that is described by the author as having “accuracy typically at least 13 significant digits”. This function is equivalent to the built-in Voigt fitting function. See *Built-in Curve Fitting Functions* on page III-206.

The coefficients are:

- \( w[0] \): Vertical offset.
- \( w[1] \): Peak area.
- \( w[2] \): Peak center location.
- \( w[3] \): Gaussian component width expressed as Full Width at Half Max (FWHM).
- \( w[4] \): Ratio of Lorentzian component width to the Gaussian component width. For \( w[4]=0 \), the peak shape is purely Gaussian, as \( w[4] \to \infty \), the peak shape become purely Lorentzian. A value of 1 results in Gaussian and Lorentzian components of equal width.

**References**
The code used to compute VoigtPeak was written by Steven G. Johnson of MIT. You can learn more about it at http://ab-initio.mit.edu/Faddeeva.

**See Also**
*VoigtFunc, Faddeeva, Built-in Curve Fitting Functions* on page III-206.

**WAVE**

localName1 [=pathToWave1]]...

WAVE is a declaration that identifies the nature of a user-defined function parameter or creates a local reference to a wave accessed in the body of a user-defined function.

The optional parameter /SDFR flag and `pathToWave` parameter are used only in the body of a function, not in a parameter declaration.

The WAVE declaration is required when you use a wave in an assignment statement in a function. At compile time, the WAVE statement specifies that the local name references a wave. At runtime, it makes the connection between the local name and the actual wave. For this connection to be made, the wave must exist when the WAVE statement is executed.

The WAVE declaration is also required if you use a wave name as a parameter to an operation or function if \( rtGlobals=3 \) is in effect which is the usual case.
When `localName` is the same as the global wave name and you want to reference a wave in the current data folder, you can omit the `pathToWave`.

`pathToWave` can be a full literal path (e.g., `root:FolderA:wave0`), a partial literal path (e.g., `:FolderA:wave0`) or `$` followed by string variable containing a computed path (see *Converting a String into a Reference Using $* on page IV-62).

You can also use a data folder reference or the `/SDFR` flag to specify the location of the wave if it is not in the current data folder. See *Data Folder References* on page IV-78 and *The /SDFR Flag* on page IV-80 for details.

If the wave may not exist at runtime, use the `/Z` flag and call `WaveExists` before accessing the wave. The `/Z` flag prevents Igor from flagging a missing wave as an error and dropping into the debugger. For example:

```igor
WAVE/Z wv=<pathTo Possibly Missing Wave>
if( WaveExists(wv) )
    <do something with wv>
endif
```

In Igor Pro 9.00 and later, you can avoid the runtime lookup of `localName` in the current data folder by including the `/ZZ` flag. For example:

```igor
Function CallingRoutine()
    WAVE/ZZ w
    PassByRefRoutine(w)
    Print w
End

Function PassByRefRoutine(WAVE& wr)
    WAVE wr = NewFreeWave(2,2)
End
```

Without the `/ZZ` flag, at runtime Igor would attempt to find a wave named `w` in the current data folder. This is unnecessary in this case since `PassByRefRoutine` sets the `w` variable.

**Flags**

- `/C` Complex wave
- `/T` Text wave
- `/WAVE` Wave reference wave
- `/DF` Data folder reference wave
- `/SDFR=dfr` Specifies the source data folder. See *The /SDFR Flag* on page IV-80 for details.
- `/Z` Ignores wave reference checking failures
- `/ZZ` Ignores wave reference checking failures and prevents wave lookup

**See Also**

- `WaveExists` function.
- *WAVE Reference Type Flags* on page IV-74 for additional wave type flags and information.
- *Accessing Global Variables and Waves* on page IV-65.
- *Accessing Waves in Functions* on page IV-82.
- *Converting a String into a Reference Using $* on page IV-62.

**WAVEClear**

```igor
WAVEClear localName [, localName1 ...]
```

The WAVEClear operation clears out a wave reference variable. WAVEClear is equivalent to `WAVE/Z localName= ""`.

**Details**

Use WAVEClear to avoid unexpected results from certain operations such as `Duplicate` or `Concatenate`, which will reuse the contents of a WAVE reference variable and may not generate the wave in the desired data folder or with the desired name.
WaveCRC ensures that memory is deallocated after waves are killed as in this example:

```igor
Function foo()
    Make wave1
    FunctionThatKillsWave1()
    WAVEClear wave1
    AnotherFunction()
End
```

Although memory used for `wave1` will be deallocated when `foo` returns, that memory will not be automatically released while the function executes because the WAVE variable still contains a reference to the wave. In this example, `WAVEClear` deallocates that memory before `AnotherFunction` executes.

You can also use `WAVEClear` before passing a data folder to preemptive threads using `ThreadGroupPutDF`.

See Also

**WaveCRC**

WaveCRC(`inCRC`, `waveName` [, `checkHeader`])

The WaveCRC function returns a 32-bit cyclic redundancy check value of the bytes in the named wave starting with `inCRC`.

Pass 0 for `inCRC` the first time you call WaveCRC for a particular stream of bytes as represented by the wave data.

Pass the last-returned value from WaveCRC for `inCRC` if you are creating a CRC value for a given stream of bytes through multiple calls to WaveCRC.

`waveName` may be a numeric or text wave.

The optional `checkHeader` parameter determines how much of the wave is checked:

<table>
<thead>
<tr>
<th><code>checkHeader</code></th>
<th>What It Does</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Check only the wave data (default).</td>
</tr>
<tr>
<td>1</td>
<td>Check only the internal binary header.</td>
</tr>
<tr>
<td>2</td>
<td>Check both.</td>
</tr>
</tbody>
</table>

**Details**

Polynomial used is:

\[x^{32} + x^{26} + x^{23} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1\]

See `crc32.c` in the public domain source code for zlib for more information.

See Also
- StringCRC, Hash, WaveHash, WaveModCount

**WaveDataToString**

WaveDataToString(`wave`)

The WaveDataToString function returns a string containing an exact copy of the data from the numeric wave `wave`. The returned string may contain null bytes.

The WaveDataToString function was added in Igor Pro 9.00.

If `wave` has 0 points, WaveDataToStrings return an empty string. If `wave` is an invalid wave reference or a non-numeric wave, the WaveDataToStrings returns a null string.

If the size of the data in the wave is larger than about 2^31 bytes, the function returns a null string because Igor strings are limited to about 2GB in size. You can determine the size of the wave's data by multiplying the number of points by the size per point (double=8 bytes/point, float=4 bytes/point, etc.). The per-point size is doubled for complex waves.
WaveDims

Parameters

wave is a wave reference to a numeric wave.

Details

Only the wave’s data is present in the returned string. Other information, such as scaling, dimension labels, etc., is not included. You may need to use the Redimension operation to change the type of the wave or to perform an endian swap before you use WaveDataToString.

While Igor strings can contain embedded nulls, some parts of Igor are not prepared to handle them. For example, printing a string with a null will only print the part of the string before the null. For more information, see Embedded Nulls in Literal Strings on page IV-16.

Example

Function WaveDataToStringDemo1()
    Make/FREE/B/U w1 = {49, 50, 51}
    // This requires Igor 9.00
    String s1 = WaveDataToString(w1)
    Print s1 // Prints 123
    // This approach works in older versions of Igor
    Variable np = numpnts(w1)
    String s2 = ""
    s2 = PadString(s2, np, 0)
    Variable n
    For (n=0; n < np; n++)
        s2[n,n] = num2char(w1[n])
    EndFor
    Print s2 // Prints 123
End

// Round trip using WaveDataToString and StringToUnsignedByteWave
Function WaveDataToStringDemo2()
    Make/FREE/D w2 = {1}
    String w2Str = WaveDataToString(w2)
    Print w2Str // Prints nothing because w2Str contains leading null bytes
    Print strlen(w2Str)
    WAVE/B/U w2ByteWave = StringToUnsignedByteWave(w2Str)
    Print w2ByteWave // Prints {0,0,0,0,0,240,63}
    // Redimension the byte wave to a double precision floating point wave
    Redimension/E=1/D/N=1 w2ByteWave
    Print w2ByteWave // Prints {1}
End

// Generate mixed-case random letters
Function WaveDataToStringDemo3()
    Make/O/FREE/N=(1e3) letters
    MultiThread letters = trunc(abs(enoise(52)))
    // 0-25 uppercase, 26-51 become lowercase
    Redimension/B/U letters
    // Create a string with all the letters.
    String lettersStr = WaveDataToString(letters)
    Print lettersStr[0,100]
End

StringToUnsignedByteWave, wfprintf, Working With Binary String Data on page IV-175

WaveDims

WaveDims (wave)

The WaveDims function returns the number of dimensions used by wave.

Returns zero if wave reference is null. See WaveExists for a discussion of null wave references.

Also returns zero if wave has zero rows. A matrix will return 2.
WaveExists

WaveExists(wave)
The WaveExists function returns one if wave reference is valid, or zero if the wave reference is null. For example if, in a user function, you have:

Wave w = "$no such wave"
then WaveExists(w) will return zero.

Details
If wave is not a valid wave reference, WaveExists also checks whether wave itself is the name of an existing wave when executing the function. WaveExists should be used in functions only. In macros, use the exists function instead.

See Also
WAVE, exists, NVAR_Exists, SVAR_Exists, and Accessing Global Variables and Waves on page IV-65.

WaveHash

WaveHash(wave, method)
The WaveHash function returns a cryptographic hash of the bytes of the wave's data using the specified method. All contents of the wave's header are ignored.

Parameters
wave may reference a numeric or text wave.
method is a number indicating the hash algorithm to use:

1 SHA-256 (SHA-2)
2 MD4
3 MD5
4 SHA-1
5 SHA-224 (SHA-2)
6 SHA-384 (SHA-2)
7 SHA-512 (SHA-2)

See Also
WaveModCount, WaveCRC, StringCRC, Hash

WaveInfo

WaveInfo(waveName, 0)
The WaveInfo function returns a string containing a semicolon-separated list of information about the named wave.

The second parameter is reserved for future use and must be zero.

Details
The result string contains a list of keyword-value pairs. Each pair consists of a keyword, a colon, the value text, and a semicolon.

Here are the keywords:
Always pass 0 as the second input parameter. In future versions of Igor, this parameter may request other kinds of information to be returned.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using WaveRefIndexedDFR in a loop to act on all waves in a data folder, and the loop has incremented beyond the highest valid index.
Keyword | Information Following Keyword
--- | ---
DUNITS | The wave’s data units.
FULLSCALE | Three numbers indicating whether the wave has any data full scale information, and the min and max data full scale values. The format of the FULLSCALE description is:
FULLSCALE: validFS, minFS, maxFS;
validFS is 1 if minFS and maxFS have been set via a SetScale d command; otherwise it is 0.
LOCK | Reads back the value set by SetWaveLock.
MODIFIED | 1 if the wave has been modified since the experiment was last saved, else 0.
MODTIME | The date and time that the wave was last modified in seconds since January 1, 1904.
NUMTYPE | A number denoting the data type of the wave.
For text waves this is 0.
For wave reference waves it is 16384.
For data folder reference waves it is 256.
For numeric waves it is one of the following:
1: Complex, added to one of the following
2: 32-bit (single precision) floating point
4: 64-bit (double precision) floating point
8: 8-bit signed integer
16: 16-bit signed integer
32: 32-bit signed integer
128: 64-bit signed integer
64: Unsigned, added to 8, 16, 32 or 128 if wave is unsigned
For example, the number denoting a complex double precision wave is 5 (i.e., 1+4).
PATH | The name of the symbolic path in which the wave file is stored (e.g., PATH:home;) or nothing if there is no path for the wave (PATH:).
SIZEINBYTES | The total size of the wave in bytes. This includes the wave’s header, data, note, dimension labels, and unit strings. This keyword was added in Igor Pro 7.00.
XUNITS | The wave’s X units.

Examples
Make/O wave1;SetScale x,0,1,"dyn",wave1;SetScale y,3,20,"v",wave1
String info = WaveInfo(wave1,0)
Print NumberByKey("NUMTYPE", info) // Prints 2
Print StringByKey("DUNITS", info) // Prints "v"

See Also
The functions and operations listed under “About Waves” categories in the Command Help tab of the Igor Help Browser; among them are CreationDate, ModDate, WaveModCount, WaveType, note, and numpnts.

NumberByKey and StringByKey functions for parsing the returned keyword list.

WaveInfo lacks information about multidimensional waves. Individual functions are provided to return dimension-related information: DimDelta, DimOffset, DimSize, WaveUnits, and GetDimLabel.
**WaveList**

`WaveList(matchStr, separatorStr, optionsStr [, dfr ])`

The WaveList function returns a string containing a list of wave names selected from the current data folder or the data folder specified by `dfr` based on `matchStr` and `optionsStr` parameters. The `dfr` parameter requires Igor Pro 9.00 or later.

See **Details** for information on listing waves in graphs, and for references to newer, data folder-aware functions.

**Details**

For a wave name to appear in the output string, it must match `matchStr` and also must fit the requirements of `optionsStr` and it must be in the current data folder. `separatorStr` is appended to each wave name as the output string is generated.

The name of each wave is compared to `matchStr`, which is some combination of normal characters and the asterisk wildcard character that matches anything.

For example:

- "*" Matches all wave names in current data folder.
- "xyz" Matches wave name xyz only, if xyz is in the current data folder.
- "*xyz" Matches wave names which end with xyz and are in the current data folder.
- "xyz*" Matches wave names which begin with xyz and are in the current data folder.
- "*xyz*" Matches wave names which contain xyz and are in the current data folder.
- "abc*xyz" Matches wave names which begin with abc and end with xyz and are in the current data folder.

`matchStr` may begin with the ! character to return items that do not match the rest of `matchStr`. For example:

- "!*xyz" Matches wave names which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of `matchStr`.

`optionsStr` is used to further qualify the wave.

Use "" to accept all waves in the current data folder that are permitted by `matchStr`.

Set `optionsStr` to one or more of the following comma-separated keyword-value pairs:

<table>
<thead>
<tr>
<th><code>optionsStr</code></th>
<th>Selection Criteria</th>

<td>Waves that are not unsigned integer (if 0) or only waves that are unsigned integer (if 1).</td>
</tr>
<tr>
<td>&quot;WAVE:0&quot; or &quot;WAVE:1&quot;</td>
<td>Consider waves that do not contain wave references (if 0) or only waves that contain wave references (if 1). You can create waves that contain wave references using the Make/WAVE flag.</td>
</tr>
<tr>
<td>&quot;WIN:&quot;</td>
<td>All waves in the current or specified data folder that are displayed in the top graph or table. The WIN option is not threadsafe.</td>
</tr>
<tr>
<td>&quot;WIN:windowName&quot;</td>
<td>All waves in the current or specified data folder that are displayed in the named table or graph window or subwindow. The WIN option is not threadsafe.</td>
</tr>
<tr>
<td>&quot;WORD:0&quot; or &quot;WORD:1&quot;</td>
<td>Waves that are not 16-bit integer (if 0) or only waves that are 16-bit integer (if 1).</td>
</tr>
</tbody>
</table>

You can specify more than one option by separating the options with a comma. See the Examples.

Note: Even when optionsStr is used to list waves used in a graph or table, the waves must be in the current data folder.

Note: In addition to waves displayed as normal graph traces, WaveList will list matrix waves used with AppendImage or NewImage and the X, Y, and Z waves used with AppendXYZContour.

Note: Individual contour traces are not listed because they have no corresponding waves. See Contour Traces on page II-370.

There are several functions that are more useful for listing waves in graphs and tables.

WaveList with WIN:windowName gives only the names of the waves in the graph or table and does not include the data folder for each wave. If you need to know what data folder the waves are in, use WaveRefIndexed to get the wave itself and then if needed use GetWavesDataFolder to get the path.

When identifying a subwindow with WIN:windowName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
To list the actual waves used in a graph, or to distinguish two or more instances of the same named wave in a graph, use TraceNameList. This function can be used in conjunction with TraceNameToWaveRef, and XWaveRefFromTrace.

Use ContourNameList to list contour plots in a given window and ContourNameToWaveRef to access the waves used to generate the contour plot.

To list the contour traces (that is, the contour lines themselves) use TraceNameList with the appropriate option.

Use ImageNameList to list images in a given window and ImageNameToWaveRef to access the waves used to generate the images.

**Processing Lists of Waves**

Contrary to what you might expect, you can not use the output of WaveList directly with operations that have a list of waves as their parameters. See Processing Lists of Waves on page IV-198 for ways of dealing with this.

**Examples**

```
// Returns a list of all waves in the current data folder.
WaveList("*",";","")

// Returns a list of all waves in the current data folder and displayed in the top table or graph.
WaveList("*", ";","WIN:")

// Returns a list of waves in the current data folder whose names end in ".bkg" and which are displayed in Graph0 as 1D traces.
WaveList("*.bkg", ";", ",WIN:Graph0")

// Returns a list of waves in the current data folder whose names do not
// end in "X" and which are displayed in Graph0 as 1D traces or as one
// of the X, Y, and Z waves of an AppendXYZContour plot.
WaveList("!*X", ";", ",WIN:Graph0,DIMS:1")

// Returns a list of waves in the root:Packages:MyPackage data folder
WaveList("*", ";", ",root:Packages:MyPackage")
```

Chapter II-6, Multidimensional Waves.

Execute, ContourNameList, ImageNameList, TraceNameList, and WaveRefIndexed.

---

### WaveMax

**WaveMax(waveName [, x1, x2])**

The WaveMax function returns the maximum value in the wave for points between x=x1 to x=x2, inclusive.

**Details**

If x1 and x2 are not specified, they default to -inf and +inf, respectively.

The X scaling of the wave is used only to locate the points nearest to x=x1 and x=x2. To use point indexing, replace x1 with pnt2x(waveName, pointNumber1), and a similar expression for x2.

If the points nearest to x1 or x2 are not within the point range of 0 to numpnts(waveName)-1, WaveMax limits them to the nearest of point 0 or point numpnts(waveName)-1.

NaN values in the wave are ignored.

**See Also**

WaveMin, WaveMinAndMax, WaveStats

---

### WaveMeanStdv

**WaveMeanStdv srcWave binSizeWave**

The WaveMeanStdv operation calculates the standard deviation of the means for the specified bin distribution saving the result in the wave W_MeanStdv.

For each entry in binSizeWave, srcWave is divided into the specified number of bins. Values in each bin are averaged and then the mean and standard deviation of the averages (among all bins) are calculated. The value of the standard deviation of the bin averages divided by the mean is then stored in W_MeanStdv corresponding to the bin size entry in binSizeWave.

All entries in binSizeWave must be positive integers.
**WaveMin**

WaveMin(waveName [, x1, x2])

The WaveMin function returns the minimum value in the wave for points between x=x1 to x=x2, inclusive.

**Details**

If x1 and x2 are not specified, they default to -inf and +inf, respectively.

The X scaling of the wave is used only to locate the points nearest to x=x1 and x=x2. To use point indexing, replace x1 with pnt2x(waveName, pointNumber1), and a similar expression for x2.

If the points nearest to x1 or x2 are not within the point range of 0 to numpnts(waveName)-1, WaveMin limits them to the nearest of point 0 or point numpnts(waveName)-1.

NaN values in the wave are ignored.

**See Also**

WaveMax, WaveMinAndMax, WaveStats

**WaveMinAndMax**

WaveMinAndMax(wave [, x1, x2])

The WaveMinAndMax function returns the minimum and maximum values in the wave for points between x=x1 to x=x2, inclusive.

WaveMinAndMax must be called from a function, not from the command line, because it uses multiple return syntax as shown in the example below.

WaveMinAndMax was added in Igor Pro 9.00.

**Details**

If x1 and x2 are omitted, they default to -inf and +inf.

The X scaling of the wave is used only to locate the points nearest to x=x1 and x=x2. To use point indexing, replace x1 with "pnt2x(wave,pointNumber1)", and a similar expression for x2. The resulting point numbers are clipped to the range 0..n where n is the numpnts(wave)-1.

NaN values in the wave are ignored.

**Example**

Function DemoWaveMinAndMax()

Make/FREE wave0 = p
wave0[0] = NaN // NaN values are ignored
SetScale/P x, 0, 0.1, "s", wave0
double minValue, maxValue

double minValue, maxValue = WaveMinAndMax(wave0)
Printf "Entire wave: min=%g, max=%g\r", minValue, maxValue

double minValue, maxValue = WaveMinAndMax(wave0, 5, 10)
Printf "From x=5 to x=10: min=%g, max=%g\r", minValue, maxValue
End

**See Also**

WaveMin, WaveMax, WaveStats
WaveModCount

WaveModCount (wave)
The WaveModCount function returns a value that can be used to tell if a global wave has been changed between one call to WaveModCount and another.

WaveModCount was added in Igor Pro 8.00.

The exact value returned by WaveModCount has no significance. The only use for it is to compare the values returned by two calls to WaveModCount. If they are different, the wave was changed in the interim.

The wave mod count for free and thread-local waves is undefined, so WaveModCount should only be used with global waves in the data hierarchy of the main thread.

A wave's mod count changes when the wave's data or properties, such as scaling, note, and dimensionality, are set. The mod count changes even if the new data or property values are the same as the old. For example, executing:

```plaintext
wave1 += 0
```
causes the mod count to change even though the data itself was not actually changed.

Examples

```plaintext
Make/O wave1 = 5
Variable waveModCount1, waveModCount2
waveModCount1 = WaveModCount (wave1);  // Modify wave1
waveModCount2 = WaveModCount (wave1);
if (waveModCount2 != waveModCount1)
    Print "Wave has changed"
endif
```

See Also

WaveInfo, ModDate

WaveName

WaveName (winNameStr, index, type)
The WaveName function returns a string containing the name of the indexth wave of the specified type in the named window or subwindow.

Parameters

* winNameStr* can be "" to refer to the top graph or table.

When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

WaveName works on waves displayed in a graph, in a table or on the list of waves in the current data folder. If the window is a table, WaveName returns the column name (e.g., "wave0.d"), rather than the name of the wave itself (e.g., "wave0").

For most uses, we recommend that you use WaveRefIndexed or WaveRefIndexedDFR instead of WaveName. WaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a data folder that is not the current data folder, you will not be able to refer to the named wave. Use WaveRefIndexedDFR instead.

*winNameStr* is a string expression containing the name of a graph or table or an empty string (""). If the string is empty and *type* is 4 then WaveName works on the list of all waves in the current data folder. If the string is empty and the type parameter is not 4 then WaveName works on the top graph or table.

*index* starts from zero.

*type* is a number from 1 to 4. When type is 4 and *winNameStr* is "", WaveName works on the list of all waves in the current data folder.

For graph windows, *type* is 1 for y waves, 2 for x waves, 3 for either y or x waves.
WaveRefIndexed

For table windows, type is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveName returns an empty string (""") if there is no wave matching the parameters.

Examples

WaveName("",0,4)    // Returns name first wave current data folder.
WaveName("",0,1)    // Returns name of first Y wave in the top graph.
WaveName("Graph0",1,2) // Returns name of second X wave in Graph0.
WaveName("Table0",1,3) // Returns name of second column in Table0.

WaveRefIndexed

WaveRefIndexed(winNameStr, index, type)

The WaveRefIndexed function returns a wave reference to the indexth wave of the specified type in the named window or subwindow.

To iterate through the waves in a data folder, use WaveRefIndexedDFR instead of WaveRefIndexed.

Parameters

winNameStr can be "" to refer to the top graph or table window or the current data folder.

When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

WaveRefIndexed is analogous to WaveName but works better with data folders. We recommend that you use it instead of WaveName.

winNameStr is a string expression containing the name of a graph or table or an empty string (""). If the string is empty and type is 4 then WaveRefIndexed works on Igor’s list of all waves in the current data folder. If the string is empty and the type parameter is not 4 then WaveRefIndexed works on the top graph or table.

index starts from zero.

type is a number from 1 to 4. When type is 4 and winNameStr is "", WaveRefIndexed works on the list of all waves in the current data folder.

For graph windows, type is 1 for y waves, 2 for x waves, 3 for either y or x waves.

For table windows, type is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveRefIndexed returns a null reference (see WaveExists) if there is no wave matching the parameters.

Examples

WaveRefIndexed("",0,1)    // Returns first Y wave in the top graph.
WaveRefIndexed("Graph0",1,2) // Returns second X wave in Graph0.
WaveRefIndexed("Table0",1,3) // wave in second column in Table0.

See Also

WaveRefIndexedDFR, NameOfWave, GetWavesDataFolder

For a discussion of wave references, see Wave Reference Functions on page IV-197.

WaveRefIndexedDFR

WaveRefIndexedDFR(dfr, index)

The WaveRefIndexedDFR function returns a wave reference to the indexth wave in the specified data folder.

Parameters

dfr is a data folder reference.

index is the zero-based index of the wave you want to access.

Details

WaveRefIndexedDFR returns a null reference (see WaveExists) if there is no wave corresponding to index in the specified data folder.
Example

// DemoWaveRefIndexedDFR can be called like this:
// DemoWaveRefIndexedDFR(root:, 0)    // Work on root
// DemoWaveRefIndexedDFR(root:SubDataFolder, 0)  // Work on root:SubDataFolder
// DemoWaveRefIndexedDFR(:, 0)    // Work on current data folder
Function DemoWaveRefIndexedDFR(dfr, recurse)
    DREF dfr
    Variable recurse
    Variable index = 0
    do
        Wave/Z w = WaveRefIndexedDFR(dfr, index)
        if (!WaveExists(w))
            break
        endif
        String path = GetWavesDataFolder(w, 2)
        Print path
        index += 1
    while(1)
    if (recurse)
        Variable numChildDataFolders = CountObjectsDFR(dfr, 4)
        Variable i
        for(i=0; i<numChildDataFolders; i+=1)
            String childDFName = GetIndexedObjNameDFR(dfr, 4, i)
            DREF childDFR = dfr:$childDFName
            DemoWaveRefIndexedDFR(childDFR, 1)
        endfor
    endif
End

See Also
WaveRefIndexed, NameOfWave, GetWavesDataFolder
For a discussion of wave references, see Wave Reference Functions on page IV-197.

WaveRefsEqual

WaveRefsEqual(w1, w2)
The WaveRefsEqual function returns the truth the two wave references are the same.

See Also
Wave Reference Functions on page IV-197

WaveRefWaveToList

WaveRefWaveToList(waveRefWave, option)
The WaveRefWaveToList function returns a semicolon-separated string list containing data folder paths.
Each element of the returned string list is the full or partial path to the wave referenced by the corresponding element of waveRefWave. Entries in waveRefWave that are NULL or entries that correspond to free waves result in an empty list element.
The WaveRefWaveToList function was added in Igor Pro 7.00.

Parameters
waveRefWave is a wave reference wave each element of which contains a reference to an existing wave or NULL (0).

option determines if the returned path is a full path or a partial path relative to the current data folder:

option=0:  Full path.
option=1:  Partial path relative to the current data folder.

Other values of option are reserved for the future.
Example

Function Test()
    SetDataFolder root:
    Make/O/FREE aaa
    Make/O bbb
    Make/O/WAVE/N=3 wr
    Wr[0]=aaa
        // Wr[1] is null by initialization.
    Wr[2]=bbb
    Print WaveRefWaveToList(wr,0)
End

// Executing Test() gives:
;;;root:bbb;

The first empty string corresponds to the free wave 'aaa' and the second empty string corresponds to the null entry in the wave reference wave.

See Also
ListToWaveRefWave, ListToTextWave, Wave References on page IV-71

WaveStats

WaveStats [flags] waveName

The WaveStats operation computes several statistics on the named wave.

Flags

/ALPH=val
Sets the significance level for the confidence interval of the mean (default val=0.05).

/C=method
Calculates statistics for complex waves only. Does not affect real waves.

You can use method in various combinations to process the real, imaginary, magnitude, and phase of the wave. The result is stored in the wave M_WaveStats (see Details for format).

method is defined as follows:

method=0: Default; ignores the imaginary part of waveName. Use /W to also store statistics in M_WaveStats.

method=1: Calculates statistics for real part of waveName and stores it in M_WaveStats.

method=2: Calculates statistics for imaginary part of waveName and stores the result in M_WaveStats.

method=4: Calculates statistics for magnitude of waveName, i.e., sqrt(real^2 +imag^2), and stores the result in M_WaveStats.

method=8: Calculate statistics for phase of waveName using atan2(imag,real).

/CCL

When computing per-column statistics using /PCST, /CCL tells Igor to copy the column dimension labels of the input to the corresponding columns of M_WaveStats. /CCL was added in Igor Pro 9.00.

If you use a single method the results are stored both in M_WaveStats and in the standard variables (e.g., V_avg, etc.). If you specify method as a combination of more than one binary field then the variables reflect the results for the lowest chosen field and all results are stored in the wave M_WaveStats.

For example, if you use /C=12, the variables will be set for the statistics of the magnitude and M_WaveStats will contain columns corresponding to the magnitude and to the phase.

In this mode V_numInfs will always be zero.

Note: If you invoke this operation and M_WaveStats already exists in the current data folder, it will be either overwritten or initialized to NaN.
WaveStats

/M=moment
Calculates statistical moments.

*moment* is defined as follows:

*moment*=1: Calculates only lower moments: V_avg, V_npnts, V_numInfs, and V_numNaNs. Use it if you do not need the higher moments.

*moment*=2: Default; calculates both lower moments and higher order quantities: V_sdev, V_rms, V_adev, V_skew, and v_kurt.

/Q
Prevents results from being printed in history.

/P
Causes WaveStats to set the location output variables in terms of unscaled index values instead of the default scaled index values. The location output variables are:

V_minRowLoc, V_maxRowLoc, V_minColLoc, V_maxColLoc
V_minLayerLoc, V_maxLayerLoc, V_minChunkLoc, V_maxChunkLoc

For 1D waves, V_minRowLoc and V_maxRowLoc are always unscaled.

/P requires Igor Pro 8.03 or later.

/PCST
Computes the statistics on a per-column basis for a real valued wave of two or more dimensions. The results are saved in the wave M_WaveStats which has the same number of columns, layers and chunks as the input wave and where the rows, designated by dimension labels, contain the standard WaveStats statistics. All the V_ variables are set to NaN. Note that this flag is not compatible with the flags /C, /R, /RMD.

The /PCST flag was added in Igor Pro 7.00.

/R=(startX,endX)
Specifies an X range of the wave to evaluate.

/R=[startP,endP]
Specifies a point range of the wave to evaluate.

If you specify the range as /R=[startP] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is evaluated.

/RMD=[[firstRow,lastRow][firstColumn,lastColumn][firstLayer,lastLayer][firstChunk,lastChunk]]
Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 7.00.

You can include all higher dimensions by leaving off the corresponding brackets. For example:

/RMD=[[firstRow,lastRow]]
includes all available columns, layers and chunks.

You can use empty brackets to include all of a given dimension. For example:

/RMD=[][firstColumn,lastColumn]
means "all rows from column A to column B".

You can use a * to specify the end of any dimension. For example:

/RMD=[[firstRow,*]]
means "from firstRow through the last row".

/W
Stores results in the wave M_WaveStats in addition to the various V_ variables when /C=0.

/Z
No error reporting.

/ZSCR
Computes z scores

\[ z_i = \frac{Y_i - \bar{Y}}{\sigma}, \]

which are saved in W_ZScores.
WaveStats

Details
WaveStats uses a two-pass algorithm to produce more accurate results than obtained by computing the binomial expansions of the third and fourth order moments.

WaveStats returns the statistics in the automatically created variables:

\( V_{\text{npnts}} \) Number of points in range excluding points whose value is NaN or INF.

\( V_{\text{numNans}} \) Number of NaNs.

\( V_{\text{numINFs}} \) Number of INFs.

\( V_{\text{avg}} \) Average of data values.

\( V_{\text{sum}} \) Sum of data values.

\( V_{\text{sdev}} \) Standard deviation of data values,

\[
\sigma = \sqrt{\frac{\sum (Y_i - V_{\text{avg}})^2}{V_{\text{npnts}} - 1}}
\]

"Variance" is \( V_{\text{sdev}}^2 \).

\( V_{\text{sem}} \) Standard error of the mean

\[
sem = \frac{\sigma}{\sqrt{V_{\text{npnts}}}}
\]

\( V_{\text{rms}} \) RMS of Y values

\[
V_{\text{rms}} = \sqrt{\frac{1}{V_{\text{npnts}}} \sum Y_i^2}
\]

\( V_{\text{adev}} \) Average deviation

\[
V_{\text{adev}} = \frac{1}{V_{\text{npnts}}} \sum_{i=0}^{V_{\text{npnts}} - 1} |Y_i - \overline{Y}|
\]

\( V_{\text{skew}} \) Skewness

\[
V_{\text{skew}} = \frac{1}{V_{\text{npnts}}} \sum_{i=0}^{V_{\text{npnts}} - 1} \left( \frac{Y_i - \overline{Y}}{\sigma} \right)^3
\]

\( V_{\text{kurt}} \) Kurtosis

\[
V_{\text{kurt}} = \left( \frac{1}{V_{\text{npnts}}} \sum_{i=0}^{V_{\text{npnts}} - 1} \left( \frac{Y_i - \overline{Y}}{\sigma} \right)^4 \right) - 3
\]

\( V_{\text{minloc}} \) X location of minimum data value.

\( V_{\text{min}} \) Minimum data value.

\( V_{\text{maxloc}} \) X location of maximum data value.

\( V_{\text{max}} \) Maximum data value.

\( V_{\text{minRowLoc}} \) Row containing minimum data value. See /P above for further information.

\( V_{\text{maxRowLoc}} \) Row containing maximum data value. See /P above for further information.

\( V_{\text{minColLoc}} \) Column containing minimum data value (2D or higher waves). See /P above for further information.

\( V_{\text{maxColLoc}} \) Column containing maximum data value (2D or higher waves). See /P above for further information.
V_minLayerLoc  Layer containing minimum data value (3D or higher waves). See /P above for further information.

V_maxLayerLoc  Layer containing maximum data value (3D or higher waves). See /P above for further information.

V_minChunkLoc  Chunk containing minimum data value (4D waves only). See /P above for further information.

V_maxChunkLoc  Chunk containing maximum data value (4D waves only). See /P above for further information.

V_startRow  The unscaled index of the first row included in calculating statistics.

V_endRow  The unscaled index of the last row included in calculating statistics.

V_startCol  The unscaled index of the first column included in calculating statistics. Set only when /RMD is used.

V_endCol  The unscaled index of the last column included in calculating statistics. Set only when /RMD is used.

V_startLayer  The unscaled index of the first layer included in calculating statistics. Set only when /RMD is used.

V_endLayer  The unscaled index of the last layer included in calculating statistics. Set only when /RMD is used.

V_startChunk  The unscaled index of the first chunk included in calculating statistics. Set only when /RMD is used.

V_endChunk  The unscaled index of the last chunk included in calculating statistics. Set only when /RMD is used.

WaveStats prints the statistics in the history area unless /Q is specified. The various multidimensional min and max location variables will only print to the history area for waves having the appropriate dimensionality.

The format of the M_WaveStats wave is:

<table>
<thead>
<tr>
<th>Row</th>
<th>Statistic</th>
<th>Row</th>
<th>Statistic</th>
<th>Row</th>
<th>Statistic</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>numPoints</td>
<td>9</td>
<td>minLoc</td>
<td>18</td>
<td>maxColLoc</td>
</tr>
<tr>
<td>1</td>
<td>numNaNs</td>
<td>10</td>
<td>min</td>
<td>19</td>
<td>maxLayerLoc</td>
</tr>
<tr>
<td>2</td>
<td>numInfs</td>
<td>11</td>
<td>maxLoc</td>
<td>20</td>
<td>maxChunkLoc</td>
</tr>
<tr>
<td>3</td>
<td>avg</td>
<td>12</td>
<td>max</td>
<td>21</td>
<td>startRow</td>
</tr>
<tr>
<td>4</td>
<td>sdev</td>
<td>13</td>
<td>minRowLoc</td>
<td>22</td>
<td>endRow</td>
</tr>
<tr>
<td>5</td>
<td>rms</td>
<td>14</td>
<td>minColLoc</td>
<td>23</td>
<td>sum</td>
</tr>
<tr>
<td>6</td>
<td>adev</td>
<td>15</td>
<td>minLayerLoc</td>
<td>24</td>
<td>meanL1</td>
</tr>
<tr>
<td>7</td>
<td>skew</td>
<td>16</td>
<td>minChunkLoc</td>
<td>25</td>
<td>meanL2</td>
</tr>
<tr>
<td>8</td>
<td>kurt</td>
<td>17</td>
<td>maxRowLoc</td>
<td>26</td>
<td>sem</td>
</tr>
</tbody>
</table>

meanL1 and meanL2 are the confidence intervals for the mean

\[
\text{MeanL1} = V_{\text{avg}} - t_{\alpha,v} \frac{V_{\text{sdev}}}{\sqrt{V_{\text{npnts}}}}, \quad \text{MeanL2} = V_{\text{avg}} + t_{\alpha,v} \frac{V_{\text{sdev}}}{\sqrt{V_{\text{npnts}}}}
\]

where \( t_{\alpha,v} \) is the critical value of the Student T distribution for alpha significance and degree of freedom \( v=V_{\text{npnts}}-1 \).
Use Edit M_WaveStats.ld to display the results in a table with dimension labels identifying each of the row statistics.

WaveStats is not entirely multidimensional aware. Even so, much of the information computed by WaveStats is useful. See Analysis on Multidimensional Waves on page II-95 for details.

See the APMath operation if you require higher precision than provided by double-precision floating point.
WaveMax, WaveMin, WaveMinAndMax, mean, median, Variance

WaveTextEncoding
WaveTextEncoding(wave, element, getEffectiveTextEncoding)
The WaveTextEncoding function returns the text encoding code for the specified element of a wave. See Wave Text Encodings on page III-472 for background information.
This function is used to deal with text encoding issues that sometimes arise in when you load pre-Igor Pro 7 experiments. Most users will have no need to use it.
The WaveTextEncoding function was added in Igor Pro 6.30. The getEffectiveTextEncoding parameter was added in Igor Pro 7.00.

Parameters
wave specifies the wave of interest.
element specifies a part of the wave, as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Wave name</td>
</tr>
<tr>
<td>2</td>
<td>Wave units</td>
</tr>
<tr>
<td>4</td>
<td>Wave note</td>
</tr>
<tr>
<td>8</td>
<td>Wave dimension labels</td>
</tr>
<tr>
<td>16</td>
<td>Text wave content</td>
</tr>
</tbody>
</table>

getEffectiveTextEncoding determines if WaveTextEncoding returns a raw text encoding code or an effective text encoding code as explained below.

Details
WaveTextEncoding returns a integer text encoding code. See Text Encoding Names and Codes on page III-490 for details.
As explained under Wave Text Encodings on page III-472, each of the wave elements has a corresponding text encoding setting. Because the notion of text encoding settings was added in Igor Pro 6.30, waves created by earlier versions have their text encoding settings set to unknown (0).
The text encoding setting stored for a given element is the "raw" text encoding. If it is unknown, then Igor applies some rules when the wave is accessed to determine an "effective" text encoding for the element being accessed. The rules are explained under Determining the Text Encoding for a Plain Text File on page III-467.
If getEffectiveTextEncoding is non-zero then WaveTextEncoding returns the effective text encoding. If getEffectiveTextEncoding is zero it returns the raw text encoding.

See Also
Wave Text Encodings on page III-472, Text Encoding Names and Codes on page III-490, Determining the Text Encoding for a Plain Text File on page III-467
WaveTracking

WaveTracking [/FREE /GLBL /LOCL] keyword

The WaveTracking operation is a debugging aid that can help you determine if your code creates waves and fails to kill them. This is especially helpful for finding free wave leaks. For background information, see Wave Reference Counting on page IV-205, Free Wave Leaks on page IV-94 and Wave Tracking on page IV-207.

WaveTracking was added in Igor Pro 9.00.

A fast and lightweight complement to wave tracking is IgorInfo(16). For details, see Detecting Wave Leaks on page IV-206.

Flags

There are three flags that tell the WaveTracking operation what category of waves an invocation of the WaveTracking operation is aimed at. You can simultaneously track or count all three categories of waves, but you must use separate invocations of the operation to control or query the tracking of each category. See Wave Tracking on page IV-207 for a discussion of the wave categories.

You must include one of these flags.

/FREE Specifies that the current command applies to counting or tracking free waves.

/GLBL Specifies that the current command applies to counting or tracking global waves (waves in the main data hierarchy starting with the root data folder).

/LOCL Specifies that the current command applies to counting or tracking local waves (waves contained by a free data folder).

/Q Used with the dump keyword to suppress the information printed to the history.
**Keywords**

**counter**
- Turns on wave tracking in *counter* mode for the category specified by /FREE, /GLBL, or /LOCL. Clears any existing count or tracking information for that specified category.

**tracker**
- Turns on wave tracking in *tracker* mode for the category specified by /FREE, /GLBL, or /LOCL. In this mode, a list of waves of the specified category is kept. Clears any existing count or tracking information for that category.

**count**
- Stores the count of waves in the variable V_numWaves for the category specified by /FREE, /GLBL, or /LOCL. The count is the number of waves created and not killed since *counter* or *tracker* mode was turned on for that category.

**dump[n]**
- Prints information into the history for the category specified by /FREE, /GLBL, or /LOCL. In *counter* mode, it prints just the number of waves. In *tracker* mode, it prints a line showing the count, and a number of lines showing the name of each wave that was created but not killed since tracking began, and the wave's reference count. If waves are global or local waves, the name of the containing data folder is also printed.
  - If you omit *n*, the list is limited to 10 lines. Otherwise *n* sets the maximum number of lines to print. Due to the method used for tracking, the list is in random order.
  - In addition, in *tracker* mode it creates a string variable S_waveTracker containing the same information. See below.
  - Use the /Q flag to suppress the history printout.

**status**
- Stores a number for the category specified by /FREE, /GLBL, or /LOCL indicating the type of tracking or zero into the variable V_Flag. 0 means no counting or tracking, 1 means counting, 2 means tracking.

**stop**
- Stops wave tracking for the category specified by /FREE, /GLBL, or /LOCL and clears the count and list of waves of that category.

**Details**

In *counter* mode, each time a wave in the specified category is created the counter is incremented. Each time a wave is killed, the counter is decremented. If you start counting after some waves have been created, and get the count after killing those waves, it is possible for the count to become negative.

In *tracker* mode, the count is the number of waves created and not killed since you started tracking; it cannot be negative.

Creation of short waves takes approximately twice as long when *tracker* mode is turned on. Using *counter* mode has negligible effect on performance.

By default, all free waves have the name _free_, which limits the usefulness of the tracker dump. Starting with Igor Pro 9.00, to aid wave leak investigation, both NewFreeWave and Make/FREE have options for giving names to free waves. See Free Wave Names on page IV-95.

**Output Variables**

These variables are created and set by all keywords.

**V_Flag**
- Indicates the type of tracking currently being used. The values are:
  - 0: Not tracking or counting
  - 1: Counter mode
  - 2: Tracker mode

**V_numWaves**
- The number of waves of the specified category created and not killed since the last time the counter or tracker keywords were used. If no tracking is enabled, this value will be zero. Set to zero if no tracking is currently enabled.

**S_waveTracker**
- When you use the dump keyword in tracker mode, this string variable is created with a list of waves created since tracking started. The contents are a list of keyword-value strings separated by a carriage return. Each line of the contents is a keyword-value string containing the name, reference count and data folder for one of the list waves.
Examples

WaveTracking/GLBL counter // start global tracker in counter mode
Make/O/N=1 jack, jill // make two waves
WaveTracking/GLBL count // ask for the count of waves in V_numWaves
print V_numWaves // print "2" in the history
WaveTracking/GLBL stop // stops counting waves
KillWaves jack, jill // so that we can count them all over again
WaveTracking/GLBL tracker // start global tracker in tracker mode
Make/O/N=1 jack, jill // make two waves
WaveTracking/GLBL count // ask for the count of waves in V_numWaves
print V_numWaves // print "2" in the history
WaveTracking/GLBL dump // ask for the history report on waves created
print S_waveTracker // print the info string to the history
WaveTracking/GLBL stop // stops counting waves

The dump keyword above prints this in the history:
Since tracking began, 2 global waves have been created and not killed.
Wave 'jill'; data folder: 'root'; refcount: 1
Wave 'jack'; data folder: 'root'; refcount: 1
The print command prints this:
WAVE:jill;REFCOUNT:1;DF:root;
WAVE:jack;REFCOUNT:1;DF:root;
To extract information from S_waveTracker:
print StringFromList(1, S_waveTracker, ";")// extract and print second line
String str = StringFromList(0, S_waveTracker, ";")// extract first line of information into string variable
print StringByKey("WAVE", str)// print the name of the wave from the first line
print StringByKey("DF", str)// print the wave's data folder from the first line
The first line prints the entire second line from S_waveTracking:
WAVE:jack;REFCOUNT:1;DF:root;
The second print statement prints this, though the ordering of the lines will be different each time the code
above is run again. These are free waves, which do not have a data folder:
jill
root
One more example showing both global and free trackers in use together:
WaveTracking/GLBL tracker
WaveTracking/FREEtracker
Make/N=3/WAVE wavewave // make a global wave reference wave
// make three named free waves with references in the wave wave
wavewave = NewFreeWave(2, 1, "free_"+num2str(p))
WaveTracking/GLBL/Q dump // /Q: we only want the S_waveTracker info
print S_waveTracker
WaveTracking/FREE/Q dump // /Q: we only want the S_waveTracker info
print S_waveTracker
WaveTracking/GLBL stop // stops counting waves
WaveTracking/FREE stop // stops counting waves
The first print statement prints this:
WAVE:wavewave;REFCOUNT:1;DF:root;
The second print statement prints this, though the ordering of the lines will be different each time the code
above is run again. These are free waves, which do not have a data folder:
WAVE:free_2;REFCOUNT:1;DF:;
WAVE:free_0;REFCOUNT:1;DF:;
WAVE:free_1;REFCOUNT:1;DF:;
WaveTransform

WaveTransform \([\text{flags}]\) \(\text{keyword} \ src\Wave\)

The WaveTransform operation transforms \(src\Wave\) in various ways. If the /O flag is not specified unless otherwise indicated the output is stored in the wave W_WaveTransform, which will be of the same data type as \(src\Wave\) and saved in the current data folder.

Parameters

\(\text{keyword}\) is one of the following:

- **abs**: Calculates the absolute value of the entries in \(src\Wave\). It stores results in W_Abs if \(src\Wave\) is 1D or M_Abs otherwise. It will overwrite \(src\Wave\) when used with the /O flag. \(src\Wave\) must be single or double precision real wave.

- **acos**: Calculates the inverse cosine of the entries in \(src\Wave\). It stores results in W_Acos if \(src\Wave\) is 1D or M_Acos otherwise. It will overwrite \(src\Wave\) when used with the /O flag. \(src\Wave\) must be single or double precision real wave.

- **asin**: Calculates the inverse sine of the entries in \(src\Wave\). It stores results in W_Asin if \(src\Wave\) is 1D or M_Asin otherwise. It will overwrite \(src\Wave\) when used with the /O flag. \(src\Wave\) must be single or double precision real wave.

- **atan**: Calculates the inverse tangent of the entries in \(src\Wave\). It stores results in W_Atan if \(src\Wave\) is 1D or M_Atan otherwise. It will overwrite \(src\Wave\) when used with the /O flag. \(src\Wave\) must be single or double precision real wave.

- **cconjugate**: Calculates the complex conjugate of \(src\Wave\). Stores results in W_CConjugate or M_CConjugate, depending on wave dimensionality, or overwrites \(src\Wave\) if /O is used.

- **cos**: Calculates the cosine of the entries in \(src\Wave\). It stores results in W_Cos if \(src\Wave\) is 1D or M_Cos otherwise. It will overwrite \(src\Wave\) when used with the /O flag. \(src\Wave\) must be single or double precision real wave.

- **crystalToRect**: Converts triplet (three column \([x,y,z]\)) waves from nonorthogonal crystallographic coordinates to rectangular cartesian system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by \([a, b, c, \alpha, \beta, \gamma]\). The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation sets the first component parallel to the vector \(a\) and the third component parallel to \(c^*\). The output is stored in the current data folder in the wave M_CrystalToRect which has the same data type. If the /O flag is specified, the output overwrites the original data.

- **flip**: Flips the data in \(src\Wave\) about its center. If /O flag is used, \(src\Wave\) is overwritten. Otherwise a new wave is created in the current data folder. The wave is named W_flipped or M_flipped according to the dimensionality of \(src\Wave\).

- **index**: Fills \(src\Wave\) as in \(jack=p\). If /P is specified then \(jack=p+\text{param}1\).

The /O flag does not apply here.

- **inverse**: Computes \(1/\text{srcWave}[i]\) for each point in \(src\Wave\) and stores it in W_Inverse or M_Inverse depending on the dimensionality of \(src\Wave\).

- **inverseIndex**: Fills \(src\Wave\) as in \(jack=\text{numPnts}-1-p\). If /P is specified the \(jack=\text{numPnts}-1-p+\text{param}1\).

- **magnitude**: Creates a real-valued wave that is the magnitude of \(src\Wave\). If you do not specify the /O flag, the output is stored in W_Magnitude or M_Magnitude depending on the dimensionality of \(src\Wave\); the output precision will be the same as \(src\Wave\).

- **magsqr**: Creates a real-valued wave that is the magnitude squared of \(src\Wave\). If \(src\Wave\) is a double precision complex wave, the output is also double precision, otherwise the output is a single precision wave. Stores the result in wave W_MagSqr or M_MagSqr, depending on the dimensionality of \(src\Wave\), or overwrites \(src\Wave\) if /O is used.
max
Calculates the maximum of a point in srcWave and a fixed number specified as a single parameter with the /P flag. It stores results in W_max if srcWave is 1D or M_max otherwise. It will overwrite srcWave when used with the /O flag. See also the min keyword and the example below.

min
Calculates the minimum of a point in srcWave and a fixed number specified as a single parameter with the /P flag. It stores results in W_min if srcWave is 1D or M_min otherwise. It will overwrite srcWave when used with the /O flag. See also the max keyword and the example below.

normalizeArea
Calculates the area under the curve and rescales the wave so that the area is 1. Note that waves with negative areas will be rescaled to positive values. Applies to 1D real-valued waves. It does not affect wave scaling. Stores the result in the wave W_normalizedArea or overwrites srcWave if /O is used.

phase
Creates a real-valued wave containing the phase of the complex input wave. If the /O flag is not used, the output is stored in W_Phase or M_Phase depending on the dimensionality of imageMatrix. You can also use /P={norm} to divide the output wave by the value of norm.

rectToCrystal
Converts triplet (three column \(x,y,z\)) waves from cartesian coordinates to nonorthogonal crystallographic coordinate system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by \(a, b, c, \alpha, \beta, \gamma\). The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation assumes the first component parallel to the vector a and the third component parallel to \(c^*\). The output is stored in the current data folder in the wave M_RectToCrystal which has the same data type. If the /O flag is specified, the output overwrites the original data.

setConstant
Sets srcWave points to a constant value specified by the /V flag. This keyword applies to real, numeric waves only.

You can use /R with setConstant to set a subset of a wave.

setConstant was added in Igor Pro 7.00.

setZero
Sets all srcWave points to zero. setZero was added in Igor Pro 7.00.

sgn
Sets the value to -1 if the entry is negative, 1 otherwise. Stores the results in W_Sgn or overwrites srcWave if /O is used. This operation will not work on UNSIGNED waves.

shift
Shifts the position of data in srcWave by the specified number of points.

Unlike Rotate, WaveTransform discards data points that shift outside existing wave boundaries. After the shift, vacated wave points are set to the specified fillValue. The shift and the fillValue are specified with the /P flag using the syntax: /P={numPoints, fillValue}. If you do not provide a fill value, it will be 0 for integer waves and NaN for SP and DP.

sin
Calculates the sine of the entries in srcWave. Stores results in W_Sin if srcWave is 1D or M_Sin otherwise. Overwrites srcWave when used with the /O flag. srcWave must be a real single or double precision floating point wave.

sqrt
Calculates the square root of the entries in srcWave. It stores results in W_sqrt if srcWave is 1D or M_sqrt otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single- or double-precision real wave.

tan
Calculates the tangent of the entries in srcWave. The results are stored in W_tan if srcWave is 1D or M_tan otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single- or double-precision real wave.

zapINFs
Deletes elements whose value is infinity or -infinity. This is relevant for 1D single-precision and double-precision floating point waves only and does nothing for other types of 1D waves. It is not suitable for multidimensional waves and returns an error if srcWave is multidimensional. Use MatrixOp replace for multidimensional waves.
WaveType

**zapNaNs** Deletes elements whose value is NaN. This is relevant for 1D single-precision and double-precision floating point waves only and does nothing for other types of 1D waves. It is not suitable for multidimensional waves and returns an error if `srcWave` is multidimensional. Use `MatrixOp replaceNaNs` for multidimensional waves.

**zapZeros** Deletes wave elements whose value is zero. `zapZeros` works only with 1D 8-bit, 16-bit, and 32-bit integer waves and returns an error if `srcWave` is multidimensional or another data type. `zapZeros` was added in Igor Pro 9.00.

**Flags**

- `/D` If present, angles in wave data are interpreted as in degrees. Otherwise they are interpreted as in radians.
- `/O` Overwrites input wave.
- `/P={param1…}` Specifies parameters as appropriate for the keyword that you are using. The number of parameters and their order depends on the keyword.
- `/R=[startRow,endRow][startCol,endCol][startLayer,endLayer][startChunk,endChunk]` Specifies the range of elements to set for the `setConstant` keyword.
  You can omit parameters for dimensions that don’t exist in `srcWave`. For example, if `srcWave` is 1D, specify just `/R=[startRow,endRow].`
  `/R` was added in Igor Pro 7.00.
- `/V=value` Specifies the value to use for the `setConstant` keyword. `/V` was added in Igor Pro 7.00.

**Examples**

```
// Produce output values in the range [-1,1]:
WaveTransform /P={(pi)} phase complexWave

// Faster than myWave=myWave>1 ? 1 : myWave
WaveTransform /P={1} /O min myWave
```

**See Also**
The `Rotate` operation.

**References**

**WaveType**

`WaveType(waveName [,selector ] )`

The `WaveType` function returns the type of data stored in the wave.

- If `selector = 1`, `WaveType` returns 0 for a null wave, 1 if numeric, 2 if text, 3 if the wave holds data folder references or 4 if the wave holds wave references.
- If `selector = 2`, `WaveType` returns 0 for a null wave, 1 for a normal global wave or 2 for a free wave or a wave that is stored in a free data folder.
- If `selector = 3`, `WaveType` returns 0 for a null wave reference or a global wave, 1 for a free wave (a wave that is not stored in any data folder) or 2 for a local wave (a wave that is stored in a free data folder hierarchy).
- If `selector` is omitted or zero, the returned value for numeric waves is a combination of bit values shown in the following table:

<table>
<thead>
<tr>
<th>Type</th>
<th>Bit Number</th>
<th>Decimal Value</th>
<th>Hexadecimal Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>complex</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>32-bit float</td>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>64-bit float</td>
<td>2</td>
<td>4</td>
<td>4</td>
</tr>
</tbody>
</table>
The unsigned bit is used only with the integer types while the complex bit can be used with any numeric type. Set only one of bits 1-5 or bit 7 as they are mutually exclusive. See Setting Bit Parameters on page IV-12 for details about bit settings.

The returned value for non-numeric waves (text waves, wave-reference waves and data folder-reference waves) is 0.

Examples

Variable waveIsComplex = WaveType(wave) & 0x01
Variable waveIs32BitFloat = WaveType(wave) & 0x02
Variable waveIs64BitFloat = WaveType(wave) & 0x04
Variable waveIs8BitInteger = WaveType(wave) & 0x08
Variable waveIs16BitInteger = WaveType(wave) & 0x10
Variable waveIs32BitInteger = WaveType(wave) & 0x20
Variable waveIs64BitInteger = WaveType(wave) & 0x80
Variable waveIsUnsigned = WaveType(wave) & 0x40

See Also

For concepts related to selector = 1 or 2, see Free Waves on page IV-91, Wave Reference Waves on page IV-77 and Data Folder Reference Waves on page IV-82.

WaveUnits

WaveUnits(waveName, dimNumber)

The WaveUnits function returns a string containing the units for the given dimension.

Use dimNumber=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. Use -1 to get the data units. If the wave is just 1D, dimNumber=0 returns X units and 1 returns data units. This behavior is just like the WaveMetrics procedure WaveUnits found in the WaveMetrics Procedures folder in previous versions of Igor Pro.

wfprintf

wfprintf refNumOrStr, formatStr [flags] waveName [, waveName]...

The wfprintf operation is like the printf operation except that it prints the contents of the named waves to a file whose file reference number is in refNum.

The Save operation also outputs wave data to a text file. Use Save unless you need the added flexibility provided by wfprintf.

Parameters

refNumOrStr is a numeric expression, a string variable or an SVAR pointing to a global string variable.

If a numeric expression, then it is a file reference number returned by the Open operation or an expression that evaluates to 1.

If refNumOrStr is 1, Igor prints to the history area instead of to a file.

If refNumOrStr is the name of a string variable, the wave contents are “printed” to the named string variable. refNumOrStr can also be the name of an SVAR to print to a global string:

SVAR sv = root:globalString
wfprintf sv, "", wave0

<table>

</tbody>
</table>

Requires Igor Pro 7 or later
`wfprintf` can not be an element of a text wave.

The value of each named wave is printed to the file according to the conversion specified in `formatStr`. `formatStr` contains one numeric conversion specification per column. See `printf`. If `formatStr` is "", `wfprintf` uses a default format which gives tab-delimited columns.

### Flags

**Note:** `/R` must follow the `formatStr` parameter directly without an intervening comma.

- `/R=(startX,endX)` Specifies an X range in the wave(s) to print.
- `/R=[startP,endP]` Specifies a point range in the wave(s) to print.

### Details

As of Igor7, `wfprintf` supports 1D and 2D waves. Previously it supported 1D waves only.

The number of conversion characters in `formatStr` must exactly match the number of wave columns in all input waves. With real waves, the total number of columns is limited to 100. With complex waves, the real column and imaginary column each count as a column and the total number of columns is limited to 200. The only conversion characters allowed are FeEgdouxXcs (the floating point, integer and string conversion characters). You cannot use an asterisk to specify field width or precision. If any of these restrictions is intolerable, you can use `fprintf` in a loop.

With integer conversion characters d, o, u, x, and X, applied to floating point waves, `wfprintf` rounds the fractional part.

In Igor Pro 9.00 and later, there is no limit to the length of an element of a text wave parameter passed to the `wfprintf` operation. Previously text wave element contents were clipped to about 500 bytes. There is also no limit to the length of `formatStr`. Previously it was limited to 800 bytes.

### Examples

#### Function Example1()

```i
Function Example1()
    Make/O/N=10 wave0=sin(p*pi/10) // test numeric wave
    Make/O/N=10/T textWave= "row "+num2istr(p) // test text wave
    Variable refNum
    Open/P=home refNum as "output.txt"/// open file for write
    wfprintf refNum, "%s = %g\r"/R=[0,5], textWave, wave0 // print 6 values each
    Close refNum
End
```

The resulting output.txt file contains:

```
row 0 = 0
row 1 = 0.309017
row 2 = 0.587785
row 3 = 0.809017
row 4 = 0.951057
row 5 = 1
```

#### Function/S NumericWaveToStringList(w)

```i
Function/S NumericWaveToStringList(w)
    Wave w // numeric wave (if text, use /T here and %s below)
    String list
    wfprintf list, "%g;" w // semicolon-separated list
    return list
End
```

Print NumericWaveToStringList(wave0)

```
0;0.309017;0.587785;0.809017;0.951057;1;0.951057;0.809017;0.587785;0.309017;
```

The `Save` operation.
WhichListItem

WhichListItem(itemStr, listStr [, listSepStr [, startIndex [, matchCase]]])

The WhichListItem function returns the index of the first item of listStr that matches itemStr. listStr should contain items separated by listSepStr which typically is ",". If the item is not found in the list, -1 is returned.

Use WhichListItem to locate an item in a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.

listSepStr, startIndex, and matchCase are optional; their defaults are ",", 0, and 1 respectively.

Details

WhichListItem differs from FindListItem in that WhichListItem returns a list index, while FindListItem returns a character offset into a string.

listStr is searched for itemStr bound by listSepStr on the left and right.

listStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for listSepStr are always case-sensitive. The comparison of itemStr to the contents of listStr is usually case-sensitive. Setting the optional matchCase parameter to 0 makes the comparison case insensitive.

If itemStr is not found, if listStr is "", or if startIndex is not within the range of 0 to ItemsInList(listStr)-1, then -1 is returned.

In Igor6, only the first byte of listSepStr was used. In Igor7 and later, all bytes are used.

Items can be empty. In "abc;def;;ghi", the third item, whose zero-based index is 2, is empty. In ":def;;ghi;" the first and third items, whose zero-based indices are 0 and 2, are empty.

If startIndex is specified, then listSepStr must also be specified. If matchCase is specified, startIndex and listSepStr must be specified.

Examples

Print WhichListItem("wave0", "wave0;wave1;") // prints 0
Print WhichListItem("c", "a;b;") // prints -1
Print WhichListItem("", "a;;b;") // prints 1
Print WhichListItem("c", "a,b,c,x,c", ",", ") // prints 2
Print WhichListItem("c", "a,b,c,x,c", ",", 3) // prints 4
Print WhichListItem("c", "x;c:C;") // prints 2
Print WhichListItem("c", "x;c:C;", ",", 0, 0) // prints 1

WignerTransform

The WignerTransform operation computes the Wigner transformation of a 1D signal in srcWave, which is the name of a real or complex wave. The result of the WignerTransform is stored in destWave or in the wave M_Wigner in the current data folder.

Flags

/DEST=destWave Creates by default a real wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-72 for details.

/GAUS=gWidth Computes the Gaussian Wigner Transform, which is a convolution of the Wigner Transform with a two-dimensional Gaussian (in the two parameters of the transform). The computation of the transform simplifies significantly when the product of the widths of the two Gaussians is unity (minimum uncertainty ellipse).

gWidth uses the same units as the srcWave scaling.
The Wigner transform maps a time signal $U(t)$ into a 2D time-frequency representation:

$$W(t,\nu) = \int_{-\infty}^{\infty} U(t + \frac{x}{2}) U^* \left( t - \frac{x}{2} \right) e^{-2\pi i \nu x} \, dx.$$  

The computation of the Wigner transform evaluates the offset product

$$U \left( t + \frac{x}{2} \right) U^* \left( t - \frac{x}{2} \right)$$

over a finite window and then Fourier transforms the result. The offset product can be evaluated over a finite window width, which can vary from a few elements of the input wave to the full length of the wave. You can control the width of this window using the /WIDE flag. If you do not specify the output destination, WignerTransform saves the results in the wave M_Wigner in the current data folder.

Although the Wigner transform is real, the output will be complex when srcWave is complex. By inspecting the complex wave you can gain some insight into the numerical stability of the algorithm. The X-scaling of the output wave is identical to the scaling of srcWave. The Y-scaling of the input wave is determined by the X-scaling of srcWave.

Specifically, if $dx = \text{DimDelta}(\text{srcWave}, 0)$ and srcWave has N points then

$$dy = \text{DimDelta}(M_{\text{Wigner}}, 1) = 1 / (dx \times N).$$

WignerTransform does not set the units of the output wave.

The Ambiguity Function is related to the Wigner Transform by a Fourier Transform, and is defined by

$$A(\tau, \nu) = \int_{-\infty}^{\infty} U \left( t + \frac{\tau}{2} \right) U^* \left( t - \frac{\tau}{2} \right) e^{-2\pi i \nu \tau} \, dt.$$  

Convolving the Wigner Transform with a 2D Gaussian leads to what is sometimes called the Gaussian Wigner Transform or GWT. Formally the GWT is given by the equation:

$$\text{GWT}(t,\nu; \delta_t, \delta_\nu) = \frac{1}{\delta_t \delta_\nu} \int dt' \int d\nu' W(t', \nu') \exp \left\{ -2\pi \left[ \left( \frac{t-t'}{\delta_t} \right)^2 + \left( \frac{\nu-\nu'}{\delta_\nu} \right)^2 \right] \right\}.$$  

Computationally this equation simplifies if the respective widths of the two Gaussians satisfy the minimum uncertainty condition $\delta_t \delta_\nu = 1$. The /GAUS flag calculates the Gaussian Wigner Transform using your specified width, $\delta_t$, and it selects a $\delta_\nu$ such that it satisfies the minimum uncertainty condition.
Window

See Also
CWT, FFT, and WaveTransform operations.

For further discussion and examples see Wigner Transform on page III-281.

References

Window

Window macroName([parameters]) [:macro type]
The Window keyword introduces a macro that recreates a graph, table, layout, or control panel window. The macro appears in the appropriate submenu of the Windows menu. Window macros are automatically created when you close a graph, table, layout, control panel, or XOP target window. You should use Macro, Proc, or Function instead of Window for your own window macros. Otherwise, it works the same as Macro.

See Also
Macro Syntax on page IV-118 for further information.

WindowFunction

WindowFunction [/FFT=[f] /DEST=destWave] windowKind, srcWave
The WindowFunction operation multiplies a one-dimensional (real or complex) srcWave by the named window function.
By default the result overwrites srcWave.

Parameters

srcWave A one-dimensional wave of any numerical type. See ImageWindow for windowing two-dimensional data.

windowKind Specifies the windowing function. Choices for windowKind are:
Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, Riemann, and an assortment of flat-top windows listed under FFT.
See FFT for window equations and details. The equations assume that /FFT=1.

Flags

/DEST=destWave Creates or overwrites destWave with the result of the multiplication of srcWave and the window function.
When used in a function, the WindowFunction operation by default creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-72 for details.

/FFT [=1] The window interval is 0…N=numpnts(srcWave). This sets the first value of srcWave to zero, but not the last value. This is appropriate for windowing data in preparation for Fourier Transforms, and is the same algorithm used by FFT.
The window interval is 0…N=numpnts(srcWave)-1 if /FFT is missing or /FFT=0. This sets the first and last value of srcWave to 0. This is the (only) algorithm that the Hanning operation uses.
WinList

Details
A “window function” alters the input data by decreasing values near the start and end of the data smoothly towards zero, so that when the FFT of the data is computed the effects of nonintegral-periodic signals are diminished. This improves the ability of the FFT to distinguish among closely-spaced frequencies. Each window function has advantages and disadvantages, usually trading off rejection of “leakage” against the ability to discriminate adjacent frequencies. For more details, see the References.

WindowFunction stores the window function’s normalization value (the average squared window value) in \( V_{value} \). This is the value you would get from WaveStats’s \( V_{rms} \) for a wave of \( srcWave \)’s length whose values were all equal to 1:

\[
\text{Make/O data} = 1 \\
\text{WindowFunction Bartlet, data} \quad \text{// Bartlet allowed as synonym for Bartlett} \\
\text{Print} \ V_{value} \quad \text{// Prints 0.330709, mean of squared window values}
\]

\[
\begin{array}{c}
\text{WaveStats/Q data} \\
\text{Print} \ V_{rms} \times V_{rms} \quad \text{// Prints 0.330709}
\end{array}
\]

See Also
FFT, ImageWindow, DPSS

References
For more information about the use of window functions see:

WinList

\[ \text{WinList}(matchStr, separatorStr, optionsStr) \]

The WinList function returns a string containing a list of windows selected based on the \( matchStr \) and \( optionsStr \) parameters.

Details
For a window name to appear in the output string, it must match \( matchStr \) and also must fit the requirements of \( optionsStr \). \( separatorStr \) is appended to each window name as the output string is generated.

The name of each window is compared to \( matchStr \), which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

- "*" Matches all window names
- "xyz" Matches window name xyz only
- "*xyz" Matches window names which end with xyz
- "xyz*" Matches window names which begin with xyz
- "*xyz*" Matches window names which contain xyz
- "abc*xyz" Matches window names which begin with abc and end with xyz

\( matchStr \) may begin with the ! character to return items that do not match the rest of \( matchStr \). For example:

- "!*xyz" Matches window names which do not end with xyz

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of \( matchStr \).
optionsStr is used to further qualify the window. The acceptable values for optionsStr are:

"" Consider all windows.

"WIN:" The target window.

"WIN:windowTypes" Consider windows that match windowTypes.

"INCLUDE:includeTypes" Consider procedure windows that match includeTypes.

"INDEPENDENTMODULE:1" Consider procedure windows that are part of any independent module as well as those that are not. Matching windows names are actually the window titles followed by " [<independent module name>]".

"INDEPENDENTMODULE:0" Consider procedure windows only if they are not part of any independent module. Matching windows names are actually the window titles, which for an external file includes the file extension, such as "WMMenus.ipf".

"FLT:1" Return only panels that were created with NewPanel/FLT=1. Specifying "FLT" also implies "WIN:64".

Omit FLT or use "FLT:0" to return windows that do not float (and most do not).

"FLT:2" Return only panels that were created with NewPanel/FLT=2. Specifying "FLT" also implies "WIN:64".

"VISIBLE:1" Return only visible windows (ignore hidden windows).

windowTypes is a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with windowTypes. windowTypes is a bitwise parameter:

1: Graphs
2: Tables
4: Layouts
16: Notebooks
64: Panels
128: Procedure windows
512: Help windows
4096: XOP target windows
16384: Camera windows in Igor Pro 7.00 or later
65536: Gizmo windows in Igor Pro 7.00 or later

See Setting Bit Parameters on page IV-12 for details about bit settings.

Procedure windows and help windows don't have names. WinList returns the window title instead.

includeTypes is also a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with includeTypes. includeTypes is one of:

1: Procedure windows that are not #included.
2: Procedure windows included by #include "someFileName".
WinName

The WinName function returns a string containing the name of the \texttt{index}th window of the specified \texttt{windowTypes}, or an empty string (""") if no window fits the parameters.

If the optional \texttt{visibleWindowsOnly} parameter is nonzero, only visible windows are considered. Otherwise both visible and hidden windows are considered.

If the optional \texttt{floatKind} parameter is 1, only floating windows created with \texttt{NewPanel/FLT=1} are considered. If \texttt{floatKind} is 2, only \texttt{NewPanel/FLT=2} windows are considered. \texttt{windowTypes} must contain at least 64 (panels).

If \texttt{floatKind} is omitted or is 0 only non-floating ("normal") windows are considered.

Procedure windows don't have names. WinName returns the procedure window title instead.

\textbf{Examples}

<table>
<thead>
<tr>
<th>Command</th>
<th>Returned List</th>
</tr>
</thead>
<tbody>
<tr>
<td>WinList(&quot;*&quot;,&quot;;&quot;,&quot;&quot;)</td>
<td>All existing non-floating windows.</td>
</tr>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;, &quot;WIN:3&quot;)</td>
<td>All graph and table windows.</td>
</tr>
<tr>
<td>WinList(&quot;Result_*&quot;, &quot;;&quot;, &quot;WIN:1&quot;)</td>
<td>Graphs whose names start with &quot;Result_&quot;.</td>
</tr>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;, &quot;WIN:64,FLT:1,FLT:2&quot;)</td>
<td>All floating panel windows.</td>
</tr>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;, &quot;INCLUDE:6&quot;)</td>
<td>All #included procedure windows.</td>
</tr>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;, &quot;WIN:1,INCLUDE:6&quot;)</td>
<td>All graphs and #included procedure windows.</td>
</tr>
</tbody>
</table>

\textbf{See Also}

Independent Modules on page IV-238. The ChildWindowList and WinType functions.
WinRecreation

Details

*index* starts from zero, and returns the top-most window matching the parameters.

The window names are ordered in window-stacking order, as returned by WinList.

*DoWindow/B* moves the window to the back and changes the index needed to retrieve its name to the greatest index that returns any name.

Hiding or showing a window (with *SetWindow hide=1* or *Notebook visible=0* or by manual means) does not affect the index associated with the window.

*windowTypes* is a bitwise parameter:

1: Graphs.
2: Tables.
4: Layouts.
16: Notebooks.
64: Panels.
128: Procedure windows.
4096: XOP target windows.
16384: Camera windows in Igor Pro 7.00 or later
65536: Gizmo windows in Igor Pro 7.00 or later

See Setting Bit Parameters on page IV-12 for details about bit settings.

Examples

Print WinName(0,1) // Prints the name of the top graph.
Print WinName(0,3) // Prints the name of the top graph or table.
String win=WinName(0,1) // The name of the top visible graph.
SetWindow $win hide=1 // Hide the graph (it may already be hidden).
Print WinName(0,1) // Prints the name of the now-hidden graph.
Print WinName(0,1,1) // Prints the name of the top visible graph.
Print WinName(0,64,1,1) // Name of the top visible NewPanel/FLT=1 window.

See Also

WinList, DoWindow (/F and /B flags), SetWindow (hide keyword), Notebook (Miscellaneous) (visible keyword), NewPanel (/FLT flag).

WinRecreation

**WinRecreation**(*winStr*, *options*)

The WinRecreation function returns a string containing the window recreation macro (or style macro) for the named window.

Parameters

*winStr* is the name of a graph, table, page layout, panel, notebook, Gizmo, camera, or XOP target window or the title of a procedure window or help file. If *winStr* is "" and *options* is 0 or 1, information for the top graph, table, page layout, panel, notebook, or XOP target window is returned.

As of Igor Pro 7.00, *winStr* may be a subwindow path. The returned recreation macro is generated as if the subwindow were extracted from its host as a standalone window. See Subwindow Syntax on page III-92 for details on forming the subwindow path.

The meaning of *options* depends on the type of window as described in the following sections.

Target Window Details

Target windows include graphs, tables, page layouts, panels, notebooks, and XOP target windows.

If *options* is 0, WinRecreation returns the window recreation macro.

If *options* is 1, WinRecreation returns the style macro or an empty string if the window does not support style macros.
**WinRecreation**

**Graphs Details**
If `options` is 2, WinRecreation returns a recreation macro in which all occurrences of wave names are replaced with an ID number having the form `##<number>##` (for instance, `##25##`). These ID numbers can be found easily using the `strsearch` function. This is intended for applications that need to alter the recreation macro by replacing wave names with something else, usually other wave names. The ID numbers are the same as those returned by the `GetWindow` operation with the wavelist keyword.

**Graphs and Panels Details**
If `options` is 4, WinRecreation returns the window recreation macro without the default behavior of causing the graph to revert to “normal” mode (as if the GraphNormal operation had been called). This allows the use of WinRecreation when a graph or panel is in drawing tools mode without exiting that mode. For windows other than graphs or panels, this is equivalent to an `options` value of 0.

**Notebooks Details**
If `options` is -1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Selected paragraphs radio button selected and all the checkboxes selected (includes text commands).

If `options` is 0, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes except “Generate text commands” selected.

If `options` is 1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes selected (includes text commands).

Regardless of the value of `options` the text returned by WinRecreation for notebook always ends with 5 lines of file-related information formatted as comments:

```plaintext
// File Name: MyNotebook.txt
// Path: "Macintosh HD:Desktop Folder:"
// Symbolic Path: home
// Selection Start: paragraph 100, position 31
// Selection End: paragraph 100, position 31
```

**Help Windows Details**
WinRecreation returns the same 5 lines of file-related information as described above for notebooks.

Set `options` to -3 to ensure that `winStr` is interpreted as a help window title (help windows have only titles, not window names).

**Procedures Details**
WinRecreation returns the same 5 lines of file-related information as described above for notebooks.

Set `options` to -2 to ensure that `winStr` is interpreted as a procedure window title (procedure windows have only titles, not window names).

If `SetIgorOption IndependentModuleDev=1` is in effect, `winStr` can also be a procedure window title followed by a space and, in brackets, an independent module name. In such cases WinRecreation returns text from or information about the specified procedure file which is part of that independent module. (See Independent Modules on page IV-238 for independent module details.)

For example, in an experiment containing:

```plaintext
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

code like this:

```plaintext
String text=WinRecreation("Axis Utilities.ipf [myIM]",-2)
```

will return the file-related information for the Axis Utilities.ipf procedure window, which is normally a hidden part of the myIM independent module.

To get the text content of a procedure window, use the `ProcedureText` function.

**Examples**

```plaintext
WinRecreation("Graph0",0)  // Returns recreation macro for Graph0.
WinRecreation("",1)         // Style macro for top window.
String win= WinName(0,16,1)  // top visible notebook
String str= WinRecreation(str,-1) // Selected Text commands
Variable line= itemsInList(str,"\r")-5 // First file info line
Print StringFromList(line, str,"\r") // Print File Name:
```
WinType

WinType (winNameStr)
The WinType function returns a value indicating the type of the named window.

Details
winNameStr is a string or string expression containing the name of a window or subwindow, or "" to signify the target window. When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

WinType returns the following values:
0: No window by that name.
1: Graph
2: Table
3: Layout
5: Notebook
7: Panel
13: XOP target window
15: Camera window in Igor Pro 7.00 or later
17: Gizmo window in Igor Pro 7.00 or later

Because command and procedure windows do not have names (they only have titles), WinType cannot even be asked about those windows.

See Also
The WinName, ChildWindowList, and WinList functions.

WMAxisHookStruct
See NewFreeAxis for further explanation of WMAxisHookStruct.

Structure WMAxisHookStruct
char win[200] // Host window or subwindow name
char axName[32] // Name of axis
char mastName[32] // Name of controlling axis or ""
char units[50] // Axis units.
Variable min // Current axis range minimum value
Variable max // Current axis range maximum value
EndStructure

WMBackgroundStruct
See CtrlNamedBackground, Background Tasks on page IV-319, and Preemptive Background Task on page IV-335 for further explanation of WMBackgroundStruct.

Structure WMBackgroundStruct
char name[32] // Background task name
UInt32 curRunTicks // Tick count when task was called
Int32 started // TRUE when CtrlNamedBackground start is issued
UInt32 nextRunTicks // Precomputed value for next run
// but user functions may change this
EndStructure
WMButtonAction

This structure is passed to action procedures for button controls created using the Button operation.

Structure WMButtonAction

- char ctrlName[32] // Control name
- char win[200] // Host window or subwindow name
- STRUCT Rect winRect // Local coordinates of host window
- STRUCT Rect ctrlRect // Enclosing rectangle of the control
- STRUCT Point mouseLoc // Mouse location
- Int32 eventCode // See details below
- Int32 eventMod // See Control Structure eventMod Field on page III-438
- String userData // Primary unnamed user data
- Int32 blockReentry // Obsolete, see Control Structure blockReentry Field on page III-439

EndStructure

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

WMButtonAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to the button action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>1</td>
<td>Mouse down</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up</td>
</tr>
<tr>
<td>3</td>
<td>Mouse up outside control</td>
</tr>
<tr>
<td>4</td>
<td>Mouse moved</td>
</tr>
<tr>
<td>5</td>
<td>Mouse enter</td>
</tr>
<tr>
<td>6</td>
<td>Mouse leave</td>
</tr>
<tr>
<td>7</td>
<td>Mouse dragged while outside the control</td>
</tr>
</tbody>
</table>

Events 2 and 3 happen only after event 1.

Events 4, 5, and 6 happen only when the mouse is over the control but happen regardless of the mouse button state.

Event 7 happens only when the mouse is pressed inside the control and then dragged outside.

WMCheckboxAction

This structure is passed to action procedures for checkbox controls created using the CheckBox operation.

Structure WMCheckboxAction

- char ctrlName[MAX_OBJ_NAME+1] // Control name
- char win[MAX_WIN_PATH+1] // Host window or subwindow name
- STRUCT Rect winRect // Local coordinates of host window
- STRUCT Rect ctrlRect // Enclosing rectangle of the control
- STRUCT Point mouseLoc // Mouse location
- Int32 eventCode // See details below
- Int32 eventMod // See Control Structure eventMod Field on page III-438
- String userData // Primary unnamed user data
- Int32 blockReentry // Obsolete, see Control Structure blockReentry Field on page III-439
- Int32 checked // Checkbox state
- char vName[MAX_OBJ_NAME+2 + (MAXDIMS * (MAX_OBJ_NAME+5)) + 1] // Name of variable
- WAVE ckWave; // Valid if using wave
- Int32 rowIndex // Row index for a wave, if rowLabel is empty
- char rowLabel[MAX_OBJ_NAME+1] // Wave row dimension label
- Int32 colIndex // Column index for a wave if colLabel is empty
- char colLabel[MAX_OBJ_NAME+1] // Wave column dimension label
- Int32 layerIndex // Layer index for a wave if layerLabel is empty
- char layerLabel[MAX_OBJ_NAME+1] // Wave layer dimension label
The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

**WMCheckboxAction eventCode Field**

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to the checkbox action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up, checkbox toggled</td>
</tr>
</tbody>
</table>

**WMCustomControlAction**

This structure is passed to action procedures for custom controls created using the *CustomControl* operation.

Structure `WMCustomControlAction`

```c
struct WMCustomControlAction {
    char ctrlName[32] // Control name
    char win[200] // Host window or subwindow name
    struct Rect winRect // Local coordinates of host window
    struct Rect ctrlRect // Enclosing rectangle of the control
    struct Point mouseLoc // Mouse location
    int32 eventCode // See details below
    int32 eventMod // See Control Structure eventMod Field on page III-438
    string userData // Primary unnamed user data
    int32 blockReentry // Obsolete, see Control Structure blockReentry Field on page III-439
    int32 missedEvents // TRUE when events occurred but the user function was not available for action
    int32 mode // General purpose
    // Used only when eventCode==kCCE_frame
    int32 curFrame // Input and output
    // Used when eventCode is kCCE_mousemoved, kCCE_mousesenter or kCCE_mousesleave
    int32 needAction // See below for details
    // These fields are valid only with value=varName
    int32 isVariable // TRUE if varName is a variable
    int32 isWave // TRUE if varName referenced a wave
    int32 isString // TRUE if varName is a String type
    nvvar nVal // Valid if isVariable and not isString
    svar sVal // Valid if isVariable and isString
    wave nWave // Valid if isWave and not isString
    wave/T sWave // Valid if isWave and isString
    int32 rowIndex // If isWave, this is the row index
    // unless rowLabel is not empty
    char rowLabel[32] // Wave row label
    // These fields are valid only when eventCode==kCCE_char
    int32 kbcChar // Keyboard key character code
    int32 specialKeyCode // See Keyboard Events on page IV-300 - Added in Igor Pro 7
    char keyText[16] // UTF-8 string representing key struck - Added in Igor Pro 7
    int32 kbMods // Keyboard key modifiers bit field. See details below.
} EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

**WMCustomControlAction eventCode Field**

When determining the state of the eventCode member in the WMCustomControlAction structure, the various values you use are listed in the following table. You can define the kCCE symbolic constants by adding this to your procedure file:
#include <CustomControl Definitions>

## Event Code Description

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kCCE_mousedown = 1</td>
<td>Mouse down in control.</td>
</tr>
<tr>
<td>kCCE_mouseup = 2</td>
<td>Mouse up in control.</td>
</tr>
<tr>
<td>kCCE_mouseup_out = 3</td>
<td>Mouse up outside control.</td>
</tr>
<tr>
<td>kCCE_mousemoved = 4</td>
<td>Mouse moved (happens only when mouse is over the control).</td>
</tr>
<tr>
<td>kCCE_enter = 5</td>
<td>Mouse entered control.</td>
</tr>
<tr>
<td>kCCE_leave = 6</td>
<td>Mouse left control.</td>
</tr>
<tr>
<td>kCCE_mouseDraggedOutside = 7</td>
<td>The mouse moved while it was outside the control. This event is delivered only after the mouse is pressed inside the control and dragged outside. While the mouse is inside the control, kCCE_mousemoved is delivered whether the mouse button is up or down.</td>
</tr>
<tr>
<td>kCCE_draw = 10</td>
<td>Time to draw custom content.</td>
</tr>
<tr>
<td>kCCE_mode = 11</td>
<td>Sent when executing CustomControl name, mode=m.</td>
</tr>
<tr>
<td>kCCE_frame = 12</td>
<td>Sent before drawing a subframe of a custom picture.</td>
</tr>
<tr>
<td>kCCEDispose = 13</td>
<td>Sent as the control is killed.</td>
</tr>
<tr>
<td>kCCE_modernize = 14</td>
<td>Sent when dependency (variable or wave set by value=varName parameter) fires. It will also get draw events, which probably don't need a redraw.</td>
</tr>
<tr>
<td>kCCE_tab = 15</td>
<td>Sent when user tabs into the control. If you want keystrokes (kCCE_char), then set needAction.</td>
</tr>
<tr>
<td>kCCE_char = 16</td>
<td>Sent on keyboard events. Stores the keyboard character in kbChar and modifiers bit field is stored in kbMods. Sets needAction if key event was used and requires a redraw.</td>
</tr>
<tr>
<td>kCCE_drawOSBM = 17</td>
<td>Called after drawing pict from picture parameter into an offscreen bitmap. You can draw custom content here.</td>
</tr>
<tr>
<td>kCCE_idle = 18</td>
<td>Idle event typically used to blink insertion points etc. Set needAction to force the control to redraw. Sent only when the host window is topmost.</td>
</tr>
</tbody>
</table>

### WMCustomControl needAction Field

The meaning of needAction depends on the event.

Events kCCE_mousemoved, kCCE_enter, kCCE_leave, and kCCE_mouseDraggedOutside set needAction to TRUE to force redraw, which is normally not done for these events.

Events kCCE_tab and kCCE_mousedown set needAction to TRUE to request keyboard focus (and get kCCE_char events).

Event kCCE_idle sets needAction to TRUE to request redraw.

### WMCustomControl kbMods Field

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Command (Macintosh)</td>
</tr>
<tr>
<td>1</td>
<td>Shift</td>
</tr>
<tr>
<td>2</td>
<td>Alpha Lock. Not supported in Igor7 or later.</td>
</tr>
<tr>
<td>3</td>
<td>Option (Macintosh) or Alt (Windows)</td>
</tr>
<tr>
<td>4</td>
<td>Control (Macintosh) or Windows key (Windows)</td>
</tr>
</tbody>
</table>

### WMDrawUserShapeStruct

See DrawUserShape for further explanation of WMDrawUserShapeStruct.

V-1106
Structure WMDrawUserShapeStruct

Int32 options // Input: Value from /MO flag.
// Output: When action is getInfo, set bits as follows:
// Set bit 0 if the shape should behave like a simple line.
// When resizing end-points, you will get live updates.
// Set bit 1 if the shape is to act like a button;
// You will get mouse down in normal operate mode.
// Set bit 2 to get roll-over action.
// You will get hitTest action and
// if 1 is returned, the mouse will be captured.

Int32 operateMode // Input: If 0, the shape is being edited;
// if 1, normal operate mode
// (only if options bit 1 or 2 was set during getInfo).

PointF mouseLoc // Input: The location of the mouse in normalized coordinates.

Int32 doSetCursor // Output: If action is hitTest, set true
// to use the following cursor number.
// Also used for mouseMoved in rollover mode.

Int32 cursorCode // Output: If action is hitTest and doSetCursor is set,
// then set this to the desired Igor cursor number.

double x0,y0,x1,y1 // Input: Coordinates of the enclosing rectangle of the shape.

RectF objectR // Input: Coordinates of the enclosing rectangle of the shape
// in device units.

char winName[MAX_HostChildSpec+1] // Input: Full path to host subwindow

// Information about the coordinate system
Rect drawRect // Draw rect in device coordinates
Rect plotRect // In a graph, this is the plot area
Rect axRect // In a graph, this is the plot area including axis standoff
char xcName[MAX_OBJ_NAME+1] // Name of X coordinate system, may be axis name
char ycName[MAX_OBJ_NAME+1] // Name of Y coordinate system, may be axis name

double angle // Input: Rotation angle, use when displaying text
String textString // Input: Use or ignore; special output for "getInfo"
String privateString // Input and output: Maintained by Igor
// but defined by user function;
// may be binary; special output for "getInfo"

EndStructure

WMFitInfoStruct

See The WMFitInfoStruct Structure on page III-263 for further explanation of WMFitInfoStruct.

Structure WMFitInfoStruct

char IterStarted // Nonzero on the first call of an iteration
char DoingDestWave // Nonzero when called to evaluate autodest wave
char StopNow // Fit function sets this to nonzero to
// indicate that a problem has occurred
// and fitting should stop

Int32 IterNumber // Number of iterations completed
Int32 ParamPerturbed // See The WMFitInfoStruct Structure on page III-263

EndStructure

WMGizmoHookStruct

See Gizmo Named Hook Functions on page II-472 for further explanation of WMGizmoHookStruct.

Structure WMGizmoHookStruct

Int32 version
char winName[MAX_HostChildSpec+1] // Full path to host window or subwindow
char eventName[32]
Int32 width
Int32 height
Int32 mouseX
Int32 mouseY
Variable xmin
Variable xmax
WMListboxAction

This structure is passed to action procedures for listbox controls created using the ListBox operation.

Structure WMListboxAction
  char ctrlName[32] // Control name
  char win[200] // Host window or subwindow name
  STRUCT Rect winRect // Local coordinates of host window
  STRUCT Rect ctrlRect // Enclosing rectangle of the control
  STRUCT Point mouseLoc // Mouse location
  Int32 eventCode // See details below
  Int32 eventMod // See Control Structure eventMod Field on page III-438
  String userData // Primary unnamed user data
  Int32 blockReentry // Obsolete, see Control Structure blockReentry Field on page III-439
  Int32 eventCode2 // Obsolete
  Int32 row // Selection row. See ListBox for details.
  Int32 col // Selection column. See ListBox for details.
  WAVE/T listWave // List wave specified by ListBox command
  WAVE selWave // Selection wave specified by ListBox command
  WAVE colorWave // Color wave specified by ListBox command
  WAVE/T titleWave // Title wave specified by ListBox command
EndStructure

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

WMListboxAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to the listbox action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed.</td>
</tr>
<tr>
<td>1</td>
<td>Mouse down.</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up.</td>
</tr>
<tr>
<td>3</td>
<td>Double click.</td>
</tr>
<tr>
<td>4</td>
<td>Cell selection (mouse or arrow keys).</td>
</tr>
<tr>
<td>5</td>
<td>Cell selection plus Shift key.</td>
</tr>
<tr>
<td>6</td>
<td>Begin edit.</td>
</tr>
<tr>
<td>7</td>
<td>Finish edit.</td>
</tr>
<tr>
<td>8</td>
<td>Vertical scroll. See Scroll Event Warnings on page V-495.</td>
</tr>
<tr>
<td>9</td>
<td>Horizontal scroll by user or by the hScroll=h keyword.</td>
</tr>
<tr>
<td>10</td>
<td>Top row set by row=r or first column set by col=c keywords.</td>
</tr>
</tbody>
</table>
### WMListboxAction row and col Fields

The row field is the zero-based row number of the first selected row in the list or -1 if the selection is in title area. If an event occurs in the empty space below the last row, the row field is set to the number of rows in the list which is one greater than the row number of the last row. A mouse down event in an empty list reports row=0.

The col field is the column number of the selection.

The meanings of row and col are different for eventCodes 8 through 11:

<table>
<thead>
<tr>
<th>Code</th>
<th>Row Description</th>
<th>Col Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Top visible row</td>
<td>Horiz shift in pixels.</td>
</tr>
<tr>
<td>9</td>
<td>Top visible row</td>
<td>Horiz shift (user scroll).</td>
</tr>
<tr>
<td>9 -1</td>
<td>-1</td>
<td>Horiz shift (hScroll keyword).</td>
</tr>
<tr>
<td>10</td>
<td>Top visible row</td>
<td>-1 (row keyword).</td>
</tr>
<tr>
<td>10 -1</td>
<td>-1</td>
<td>First visible col (col keyword).</td>
</tr>
<tr>
<td>11</td>
<td>Column shift</td>
<td>Column resized by user.</td>
</tr>
</tbody>
</table>

If eventCode is 11, row is the horizontal shift in pixels of the column col that was resized, not the total horizontal shift of the list as reported in V_horizScroll by ControlInfo. If row is negative, the divider was moved to the left. col=0 corresponds to adjusting the divider on the right side of the first column. Use ControlInfo to get a list of all column widths.

### Selection Events 4 and 5

These events are sent when a click on the Listbox could result in a change in selection. If it is important to you to respond only when the selection actually changes, you will need to keep track of the selection yourself.

These events are not sent if the list is empty.

### WMMarkerHookStruct

See Custom Marker Hook Functions on page IV-308 for further explanation of WMMarkerHookStruct.

#### Structure WMMarkerHookStruct

```c
struct WMMarkerHookStruct {
    int32 usage; // 0 = normal draw, 1 = legend draw
    int32 marker; // Marker number minus start
    float x, y; // Location of desired center of marker
    float size; // Half width/height of marker
    int32 opaque; // 1 if marker should be opaque
    float penThick; // Stroke width
    struct RGBColor mrkRGB; // Fill color
    struct RGBColor eraseRGB; // Background color
    struct RGBColor penRGB; // Stroke color
    WAVE ywave; // Trace's y wave
    char winName[MAX_HostChildSpec+1]; // Full path to window or subwindow
    char traceName[MAX_OBJ_INST+1]; // Full name of trace or "" if no trace
} EndStructure
```

### WMPopupAction

This structure is passed to action procedures for popup menu controls created using the PopupMenu operation.
Structure WMSetVariableAction
  char ctrlName[32] // Control name
  char win[200] // Host window or subwindow name
  STRUCT Rect winRect // Local coordinates of host window
  STRUCT Rect ctrlRect // Enclosing rectangle of the control
  STRUCT Point mouseLoc // Mouse location
  Int32 eventCode // See details below
  Int32 eventMod // See Control Structure eventMod Field on page III-438
  String userData // Primary unnamed user data
  Int32 blockReentry // Obsolete, see Control Structure blockReentry Field on page III-439
  Int32 popNum // Item number currently selected or hovered over (1-based)
  char popStr[MAXCMDLEN] // Contents of current popup item or item hovered over
EndStructure

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

WMSetVariableAction

This structure is passed to action procedures for SetVariable controls created using the SetVariable operation.

Structure WMSetVariableAction
  char ctrlName[32] // Control name
  char win[200] // Host window or subwindow name
  STRUCT Rect winRect // Local coordinates of host window
  STRUCT Rect ctrlRect // Enclosing rectangle of the control
  STRUCT Point mouseLoc // Mouse location
  Int32 eventCode // See details below
  Int32 eventMod // See Control Structure eventMod Field on page III-438
  String userData // Primary unnamed user data
  Int32 blockReentry // Obsolete, see Control Structure blockReentry Field on page III-439
  Int32 isStr // TRUE for a string variable
  Variable dval // Numeric value of variable
  char vName[MAXCMDLEN] // Value of variable as a string
  char sval[MAX_OBJ_NAME+2 + (MAXDIMS * (MAX_OBJ_NAME+5)) + 1]
  WAVE svWave // Valid if using wave
  Int32 rowIndex // Row index for a wave if rowLabel is empty
  char rowLabel[ MAXOBJ_NAME+1] // Wave row dimension label
  Int32 colIndex // Column index for a wave if colLabel is empty
  char colLabel[ MAXOBJ_NAME+1] // Wave column dimension label
  Int32 layerIndex // Layer index for a wave if layerLabel is empty
  char layerLabel[ MAXOBJ_NAME+1] // Wave layer label
  Int32 chunkIndex // Chunk index for a wave if chunkLabel is empty
  char chunkLabel[ MAXOBJ_NAME+1] // Wave chunk label
  Int32 mousePart // Part of the control where mouse down occurred
EndStructure

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.
### WMSliderAction

This structure is passed to action procedures for slider controls created using the `Slider` operation.

**Structure WMSliderAction**

```plaintext
char ctrlName[32] // Control name
char win[200] // Host window or subwindow name
STRUCT Rect winRect // Local coordinates of host window
STRUCT Rect ctrlRect // Enclosing rectangle of the control
STRUCT Point mouseLoc // Mouse location
```
**WMTabControlAction**

```plaintext
Int32 eventCode    // See details below
Int32 eventMod     // See Control Structure eventMod Field on page III-438
String userData   // Primary unnamed user data
Int32 blockReentry // Obsolete, see Control Structure blockReentry Field on page III-439
Variable curval   // Value of slider
```

EndStructure

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

**WMSliderAction eventCode Field**

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to slider action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>1</td>
<td>Value set</td>
</tr>
<tr>
<td>2</td>
<td>Mouse down</td>
</tr>
<tr>
<td>4</td>
<td>Mouse up</td>
</tr>
<tr>
<td>8</td>
<td>Mouse moved or arrow key moved the slider</td>
</tr>
<tr>
<td>16</td>
<td>Repeat timer fired (see Repeating Sliders on page III-418)</td>
</tr>
</tbody>
</table>

The event codes greater than zero are bits that may be combined in certain cases. For instance, if your slider does not have the live mode set, you may receive event code 5 = 1+4. This indicates that a mouse up event was detected, and that mouse up set the slider’s value.

For a demo of many of these events, see Handling Slider Events on page III-430.

**WMTabControlAction**

This structure is passed to action procedures for tab controls created using the TabControl operation.

```plaintext
Structure WMTabControlAction
  char ctrlName[32]    // Control name
  STRUCT Rect winRect // Host window or subwindow name
  STRUCT Rect ctrlRect // Enclosing rectangle of the control
  STRUCT Point mouseLoc // Mouse location
  Int32 eventCode      // See details below
  Int32 eventMod       // See Control Structure eventMod Field on page III-438
  String userData      // Primary unnamed user data
  Int32 blockReentry   // Obsolete, see Control Structure blockReentry Field on page III-439
  Int32 tab            // Tab number
```

EndStructure

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

**WMTabControlAction eventCode Field**

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to tab control action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up</td>
</tr>
</tbody>
</table>
WMTooltipHookStruct

See Tooltip Hook Functions on page IV-310 for further explanation of WMTooltipHookStruct.

Structure WMTooltipHookStruct

char winName[50] // Host window name or subwindow path
double ticks // Tick count when event happened
STRUCT Rect winRect // Local coordinates of the window or subwindow
STRUCT Point mouseLoc // Mouse location
STRUCT Rect trackRect // Tooltip tracking rect
double duration_ms // Time to display the tooltip, in milliseconds
char traceName[50] // If in a graph window, name of the trace
char imageName[50] // If in a graph window, name of the image
waveHndl yWave // Y wave for trace, image, or table column
double row // Row in trace, image or wave
double column // Column in trace, image or wave
double layer // Layer in trace, image or wave
double chunk // Chunk in trace, image or wave
char ctrlName[50] // Name of control during hover event
Int32 isHtml // Set to indicate tooltip contains HTML tags
String tooltip // Set this to your tooltip text
EndStructure

WMWinHookStruct

See Named Window Hook Functions on page IV-295 for further explanation of WMWinHookStruct.

Structure WMWinHookStruct

char winName[200] // Host window or subwindow name
STRUCT Rect winRect // Local coordinates of the affected (sub)window
STRUCT Point mouseLoc // Mouse location
Variable ticks // Tick count when event happened
Int32 eventCode // See Named Window Hook Events on page IV-295
char eventName[32] // See Named Window Hook Events on page IV-295
Int32 eventMod // See Control Structure eventMod Field on page III-438
char menuName[256] // Name of the menu item as for SetIgorMenuMode
char menuItem[256] // Text of the menu item as for SetIgorMenuMode
char traceName[32] // See Named Window Hook Functions on page IV-295
Variable pointNumber // See Named Window Hook Functions on page IV-295
Variable yPointNumber // See Named Window Hook Functions
Int32 isFree // 1 if the cursor is not attached to anything
Int32 keyCode // ASCII value of key struck
Int32 specialKeyCode // See Keyboard Events on page IV-300 - Igor Pro 7 or later
char oldWinName[32] // Simple name of the window or subwindow
Int32 doSetCursor // Set to 1 to change cursor to cursorCode
Int32 cursorCode // See Setting the Mouse Cursor on page IV-302
Variable wheelDx // Vertical lines to scroll
Variable wheelDy // Horizontal lines to scroll
char focusCtrl[50] // Added in Igor Pro 9.00. See EarlyKeyboard Events.
EndStructure

wnoise

wnoise(shape, scale)

The wnoise function returns a pseudo-random value from the two-parameter Weibull distribution characterized by the shape and scale, the respective gamma and alpha parameters. The two-parameter Weibull probability distribution function is

\[ f(x; \alpha, \gamma) = \frac{\gamma}{\alpha} x^{\gamma-1} \exp\left[-\frac{1}{\alpha} x^\gamma\right] \quad \alpha > 0 \quad \gamma > 0 \]

The mean of the Weibull distribution is

\[ \frac{\gamma}{\alpha} \]

x \geq 0
and the variance is

\[
\frac{2}{\alpha^2} \left( 1 + \frac{2}{\gamma} \right) - \frac{2}{\alpha^2} \left( \Gamma \left( 1 + \frac{1}{\gamma} \right) \right)^2.
\]

Note that this definition of the PDF uses different scaling than the one used in StatsWeibullPDF. To match the scaling of StatsWeibullPDF multiply the result from Wnoise by the factor scale^{(1-1/shape)}.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

See Also
The SetRandomSeed operation.
Noise Functions on page III-390.
Chapter III-12, Statistics for a function and operation overview.

**x**

The x function returns the scaled row index for the current point of the destination wave in a wave assignment statement. This is the same as the X value if the destination wave is a vector (1D wave).

Details
Outside of a wave assignment statement, x acts like a normal variable. That is, you can assign a value to it and use it in an expression.

See Also
The p function and Waveform Arithmetic and Assignments on page II-74.

**x2pnt**

\[\text{x2pnt}(\text{waveName}, x1)\]

The x2pnt function returns the integer point number on the wave whose X value is closest to \(x1\). For higher dimensions, use ScaleToIndex.

See Also
DimDelta, DimOffset, pnt2x, ScaleToIndex
For an explanation of waves and X scaling, see Changing Dimension and Data Scaling on page II-68.

**xcsr**

\[\text{xcsr}(\text{cursorName}[, \text{graphNameStr}])\]

The xcsr function returns the X value of the point which the named cursor (A through J) is on in the top or named graph.

**Parameters**

\text{cursorName} identifies the cursor, which can be cursor A through J.
\text{graphNameStr} specifies the graph window or subwindow.

When identifying a subwindow with \text{graphNameStr}, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
**Details**
The result is derived from the wave that the cursor is on, not from the X axis of the graph. If the wave is displayed as an XY pair, the X axis and the wave’s X scaling will usually be different.

**See Also**
The hcsr, pcsr, qcsr, vcsr, and zcsr functions.

**Programming With Cursors** on page II-321.

**XLLoadWave**

XLLoadWave [flags] [fileNameStr]
The XLLoadWave operation loads data from the named Excel .xls, .xlsx or .xlsm file into waves.

XLLoadWave does not support .xlsx files and can not load password-protected Excel files.

**Parameters**
The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If XLLoadWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-451 for details on forming the path.

If fileNameStr is omitted or is "", or if the /I flag is used, XLLoadWave presents an Open File dialog from which you can choose the file to load.

**Flags**

/A  Automatically assigns arbitrary wave names using “wave” as the base name. Skips names already in use.

/A=baseName  Same as /A but it automatically assigns wave names of the form baseName0, baseName1.

/C=columnType  XLLoadWave will use the Deduce from Row method of determining the type of the Excel file columns, using the row specified by columnType to deduce column types. See Deduce from row on page II-160.

/COLT=columnTypeStr  columnTypeStr specifies how XLLoadWave should treat each column. For example, "1T3N" means 1 text column followed by 3 numeric columns. See Determining Wave Types on page V-1117.

/D  Creates double-precision floating point waves. If omitted, XLLoadWave creates single-precision floating point waves.

/F=f  New programming should use the /T flag instead of the /D, /L and /F flags.

f specifies the data format of the file:

f=1:  Signed integer (8, 16, 32 bits allowed)

f=2:  Creates double-precision waves

f=3:  Floating point (default, 32, 64 bits allowed)

/I  Forces XLLoadWave to display an Open File dialog even if the file is fully specified via /P and fileNameStr.

/I=infoMode  If infoMode is 1, 2 or 3, XLLoadWave does not load the file but instead returns information about the worksheets within the workbook via the string variable S_value. See Getting Information About the Excel File on page V-1117.

/K=k  Discards waves with fewer than k points. For historical reasons, k defaults to 2.
**XLLoadWave**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/N</td>
<td>Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.</td>
</tr>
<tr>
<td>/N=baseName</td>
<td>Same as /N except that it automatically assigns wave names of the form baseName0, baseName1.</td>
</tr>
<tr>
<td>/NAME=nameList</td>
<td>nameList is a semicolon-separated list of wave names to be used for the loaded waves. See Wave Names on page V-1116 for details.</td>
</tr>
<tr>
<td>/O</td>
<td>Overwrites existing waves in case of a name conflict.</td>
</tr>
<tr>
<td>/P=pathName</td>
<td>Specifies the folder to look in for fileNameStr. pathName is the name of an existing symbolic path.</td>
</tr>
<tr>
<td>/Q</td>
<td>Suppresses the normal messages in the history area.</td>
</tr>
<tr>
<td>/R=(cell1,cell2)</td>
<td>Restricts loading to the specified cells, e.g. /R=(A3,D21). Row and column numbers start from 1. The /R flag supports an optional extra parameter that should be used only in very rare cases. XLLoadWave reads the range of defined cells from the file itself and clips cell1 and cell2 to that range. In very rare cases the file does not accurately identify the range of defined cells so the clipping prevents loading cells that exist in the file. In this rare case, use /R=(cell1, cell2,1). The last parameter tells XLLoadWave to skip the clipping. If you specify incorrect values for cell1 or cell2 you may get errors or garbage results.</td>
</tr>
<tr>
<td>/S=sheetNameStr</td>
<td>Specifies which worksheet to load from a workbook file. If you omit /S=sheetNameStr, or if sheetNameStr is &quot;&quot;, XLLoadWave loads the first worksheet in the workbook.</td>
</tr>
<tr>
<td>/T</td>
<td>Automatically creates a table of loaded waves.</td>
</tr>
<tr>
<td>/V=v</td>
<td>Controls the handling of blanks at the end of a column.</td>
</tr>
<tr>
<td>/W=w</td>
<td>w specifies the row in which XLLoadWave will look for wave names. The first row is row number 1.</td>
</tr>
</tbody>
</table>

**Wave Names**
The names of the loaded waves are determined by the /A, /N, /W and /NAME flags. If all of the flags are omitted, default names, like ColumnA and ColumnB, are used.

If /W=w is present, names are loaded from row w of the worksheet and then converted to standard Igor names by replacing spaces and punctuation characters with underscores.

If /NAME=nameList is present, the wave names come from nameList, a semicolon-separated list of names. For example:

```
/NAME="StartTime;UnitA;UnitB;"
```

The names in nameList can be standard or liberal names. For example, this specifies names two standard names and one liberal name which contains a space:

```
/NAME="Signal;Ambient Temp;Response;"
```

If a name in the list is _skip_, the corresponding Excel column is skipped. For example, this would load the first and third columns and skip the second:

```
/NAME="Signal;_skip_;Response;"
```

If a name in the list is empty, the name used for the corresponding wave is as it would be if /NAME were omitted. This can be used to skip columns while taking wave names from the spreadsheet for loaded columns. In this example, the names of the first and third waves would be determined by row 1 of the spreadsheet while the second column would be skipped.
The \texttt{\textbackslash W=1 /NAME=";\_skip_;";} flag instructs Igor to automatically name new waves "wave", or baseName if \texttt{\textbackslash N=baseName} is used, plus a number. The number starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The \texttt{/A} flag is like \texttt{/N} except that it skips names already in use.

\texttt{/NAME} overrides \texttt{/W}. \texttt{/A or /N} overrides both \texttt{/NAME} and \texttt{/W}.

No matter how the wave names are generated, if there is a name conflict and overwrite is off (\texttt{/O} is omitted), a unique name is generated. See \texttt{XLLoadWave} and \texttt{Wave Names} on page II-161 for further details.

\textbf{Determining Wave Types}

The \texttt{/C} or \texttt{/COLT} flag tells \texttt{XLLoadWave} how to decide what kind of wave, numeric, text, or date/time, to make for each Excel column.

Using \texttt{/C=columnType} causes \texttt{XLLoadWave} to use the Deduce from Row method of determining the type of the Excel file columns. columnType is the Excel row number that XLLoadWave should use to make the deduction.

Using \texttt{/COLT=columnTypeStr} causes XLLoadWave to treat the columns based on the columnTypeStr parameter. If columnTypeStr is "N", XLLoadWave uses the Treat all Columns as Numeric method. If columnTypeStr is "T", XLLoadWave uses the Treat all Columns as Text method. If columnTypeStr is "D", XLLoadWave uses the Treat all Columns as Date method.

For any other value of columnTypeStr, XLLoadWave uses the Use Column Type String method. For example, "1T5N" tells XLLoadWave to create a text wave for the first column and numeric waves for the next 5 or more columns.

If you omit \texttt{/C} and \texttt{/COLT}, XLLoadWave uses the Treat all Columns as Numeric method.

See \texttt{What XLLoadWave Loads} on page II-159 for further details.

\textbf{Output Variables}

\texttt{XLLoadWave} sets the following output variables:

- \texttt{V\_flag} Number of waves loaded.
- \texttt{S\_fileName} Name of the file being loaded.
- \texttt{S\_path} File system path to the folder containing the file.
- \texttt{S\_waveNames} Semicolon-separated list of the names of loaded waves.
- \texttt{S\_worksheetName} Name of the loaded worksheet within the workbook file.
- \texttt{S\_value} Set only if you use the \texttt{/J} flag. See \texttt{Getting Information About the Excel File} below.

\texttt{S\_path} uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

When \texttt{XLLoadWave} presents an Open File dialog and the user cancels, \texttt{V\_flag} is set to 0 and \texttt{S\_fileName} is set to "".

\textbf{Getting Information About the Excel File}

The \texttt{/J} flag allows you to get information about an Excel file without actually loading it.

If \texttt{infoMode} is 1, XLLoadWave does not load the file but instead returns a semicolon-separated list of the names of the worksheets within the workbook via the string variable \texttt{S\_value}.

If \texttt{infoMode} is 2, XLLoadWave does not load the file but instead returns information about the first worksheet or the worksheet specified by \texttt{/S} via the string variable \texttt{S\_value}. The format of the returned information is:

NAME:worksheet name;FIRSTROW:first row;FIRSTCOL:first col;LASTROW:last row;LASTCOL:last col;
XWaveName

XWaveName(graphNameStr, traceNameStr)
The XWaveName function returns a string containing the name of the wave supplying the X coordinates for the named trace in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

traceNameStr is the name of the trace in question.

Details

XWaveName returns an empty string ("") if the trace is not plotted versus an X wave.

For most uses, we recommend that you use XWaveRefFromTrace instead of WaveName. XWaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the X wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a folder that is not the current data folder, you will not be able to refer to the named wave.

graphNameStr and traceNameStr are strings, not names.

Examples

Display ywave vs xwave // XY graph
Print XWaveName("","ywave") // prints xwave

See also

Trace Names on page II-282, Programming With Trace Names on page IV-87.
XWaveRefFromTrace

XWaveRefFromTrace(graphNameStr, traceNameStr)

The XWaveRefFromTrace function returns a wave reference to the wave supplying the X coordinates against which the named trace is displayed in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

XWaveRefFromTrace returns a null reference (see WaveExists) if the wave is not plotted versus an X wave. graphNameStr and traceNameStr are strings, not names.

Examples

Display ywave vs xwave // XY graph
Print XWaveRefFromTrace("","ywave")[50] // prints value of xwave at point 50

For a description of traces: ModifyGraph.

For a discussion of contour traces see Contour Traces on page II-370.

For commands referencing other waves in a graph: ImageNameList, ImageNameToWaveRef, ContourNameList, and ContourNameToWaveRef.

For a discussion of wave references, see Wave Reference Functions on page IV-197.

See Also

Trace Names on page II-282, Programming With Trace Names on page IV-87.

y

The y function returns the Y value for the current column of the destination wave when used in a multidimensional wave assignment statement. Y is the scaled column index whereas q is the column index itself.

Details

Unlike x, outside of a wave assignment statement, y does not act like a normal variable.

See Also

x, z, and t functions for other dimensions.

p, q, r, and s functions for the scaled indices.

z

The z function returns the Z value for the current layer of the destination wave when used in a multidimensional wave assignment statement. z is the scaled layer index whereas r is the layer index itself.

Details

Unlike x, outside of a wave assignment statement, z does not act like a normal variable.

See Also

x, y, and t functions for other dimensions.

p, q, r, and s functions for the scaled indices.
The `zcsr` function returns a Z value when the specified cursor is on a contour, image, or waterfall plot. Otherwise, it returns NaN.

**Parameters**
- `cursorName` identifies the cursor, which can be cursor A through J.
- `graphNameStr` specifies the graph window or subwindow.

When identifying a subwindow with `graphNameStr`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

**Examples**
```
Print zcsr(A) // not zcsr("A")
Print zcsr(A,"Graph0") // specifies the graph
```

**See Also**
The `hcsr`, `pcsr`, `qcsr`, `vcsr`, and `xcsr` functions.

**Programming With Cursors** on page II-321.

The `zeta` function returns the Hurwitz Zeta function for real or complex arguments $a$ and $b$

\[
\zeta(a,b) = \sum_{k=0}^{\infty} \frac{1}{(k+b)^a},
\]

$\Re(a) > 1,$

$b \neq 0, -1, -2, ...$

The Riemann zeta function is the special case:

\[
\zeta(a) = \zeta(a,1).
\]

The zeta function was added in Igor Pro 7.00.

**Parameters**
The `terms` parameter defaults to 40. In practice evaluation may terminate before the specified number of terms when convergence is achieved.

**References**

**See Also**
Dilogarithm

The `ZernikeR` function returns the Zernike radial polynomials of degree $n$ that contains no power of $r$ that is less than $m$. Here $m$ is even or odd according to whether $n$ is even or odd, and $r$ is in the range 0 to 1.

Note that the full circle polynomials are complex. For any angle $t$ (theta), they are given by:

\[
ZernikeR(n,m,r) = \exp(i m t).
\]
