Here we have used the `/B` flag to create an overlay image but it can also be used to create an ROI wave for use in further processing. This example represents the simplest use of the operation. In some situations the criteria for a pixel's inclusion in the filled region are not so sharp and the operation may work better if you use the adaptive or fuzzy algorithms. For example (**Note:** the command is wrapped over two lines):

```
ImageSeedFill/B=64/c seedX=144,seedY=83,min=60,max=150,target=255,
srcWave=mri,adaptive=3
```

Note that the min and max values have been relaxed but the adaptive parameter provides alternative continuity criterion.

## Other Tools

Igor provides a number of utility operations that help you manage and manipulate image data.

### Working with ROI

Many of the image processing operations support a region of interest (ROI). The region of interest is the portion of the image that we want to affect by an operation. Igor supports a completely general ROI, specified as a binary wave (unsigned byte) that has the same dimensions as the image. Set the ROI wave to zero for all pixels within the region of interest and to any other value outside the region of interest. Note that in some situations it is useful to set the ROI pixels to a nonzero value (e.g., if you use the wave as a multiplicative factor in a mathematical operation). You can use ImageTransform with the invert keyword to quickly convert between the two options.

The easiest way to create an ROI wave is directly from the command line. For example, an ROI wave that covers a quarter of the blobs image may be generated as follows:

```
Duplicate root:images:blobs myROI
Redimension/B/U myROI
myROI=64 // arbitrary nonzero value
myROI[0,128][0,127]=0 // the actual region of interest

// Example of usage:
ImageThreshold/Q/M=1/R=myROI root:images:blobs
NewImage M_ImageThresh
```

If you want to define the ROI using graphical drawing tools you need to open the tools and set the drawing layer to progFront. This can be done with the following instructions:

```
SetDrawLayer progFront
ShowTools/A rect // selects the rectangle drawing tool first
```

### Generating ROI Masks

You can now define the ROI as the area inside all the closed shapes that you draw. When you complete drawing the ROI you need to execute the commands:

```
HideTools/A // Drawing tools are not needed any more.
// M_ImageThresh is the top image in this example.
ImageGenerateROIMask M_ImageThresh
// The ROI wave has been created; To see it,
NewImage M_ROIMask
```

The Image Processing procedures provide a utility for creating an ROI wave by drawing on a displayed image.

### Converting Boundary to a Mask

A third way of generating an ROI mask is using the **ImageBoundaryToMask** operation (see page V-314). This operation takes a pair of waves (y versus x) that contain pixel values and scan-converts them into a mask. When you invoke the operation you also have to specify the rectangular width and height of the output mask.

```
// Create a circle.
Make/N=100 ddx,ddy
ddx=50*(1-sin(2*pi*x/100))
ddy=50*(1-cos(2*pi*x/100))
ImageBoundaryToMask width=100,height=100,xwave=ddx,ywave=ddy
// The result is an image not a curve!
NewImage M_ROIMask
```

Note that the resulting binary wave has the values 0 and 255, which you may need to invert before using them in certain operations.

In many situations the operation ImageBoundaryToMask is followed by ImageSeedFill in order to convert the mask to a filled region. You can obtain the desired mask in one step using the keywords seedX and seedY in ImageBoundaryToMask but you must make sure that the mask created by the boundary waves is a closed domain.

```
ImageBoundaryToMask width=100,height=100,xwave=ddx,ywave=ddy,
seedX=50,seedY=50
ModifyImage M_ROIMask explicit=0
```

### Marquee Procedures

A fourth way to create an ROI mask is using the Marquee2Mask procedures. To use this in your own experiment you will have to add the following line to your procedure window:

```
#include <Marquee2Mask>
```

You can now create the ROI mask by selecting one or more rectangular marquees (drag the mouse) in the image. After you select each marquee click inside the marquee and choose MarqueeToMask or Append-MarqueeToMask.

### Subimage Selection

You can use an ROI to apply various image processing operations to selected portions of an image. The ROI is a very useful tool especially when the region of interest is either not contiguous or not rectangular. When the region of interest is rectangular, you can usually improve performance by creating a new subimage which consists entirely of the ROI. If you know the coordinates and dimensions of the ROI it is simplest to use the Duplicate/R operation. If you want to make an interactive selection you can use the marquee together with CopyImageSubset marquee procedure (after making a marquee selection in the image, click inside the marquee and choose CopyImageSubset).

### Handling Color

Most of the image operations are designed to work on grayscale images. If you need to perform an operation on a color image certain aspects become a bit more complicated. In the next example we illustrate how you might sharpen a color image.

```
NewImage root:images:rose
ImageTransform rgb2hsl root:images:rose // first convert to hsl
ImageTransform/P=2 getPlane M_RGB2HSL
ImageFilter Sharpen M_ImagePlane // you can also use sharpenmore
ImageTransform /D=M_ImagePlane /P=2 setPlane M_RGB2HSL
ImageTransform hsl2rgb M_RGB2HSL
NewImage M_HSL2RGB
```

### Background Removal

There are many approaches to removing the effect of a nonuniform background from an image. If the non uniformity is additive, it is sometimes useful to fit a polynomial to various points which you associate with the background and then subtract the resulting polynomial surface from the whole image. If the nonuniformity is multiplicative, you need to generate an image corresponding to the polynomial surface and use it to scale the original image.

### Additive Background

```
Duplicate/O root:images:blobs addBlobs
Redimension/S addBlobs           // convert to single precision
addBlobs+=0.01*x*y               // add a tilted plane
NewImage addBlobs
```

To use the **ImageRemoveBackground** operation (see page V-347), we need an ROI mask designating regions in the image that represent the background. You can create one using one of the ROI construction methods that we discussed above. For the purposes of this example, we choose the ROI that consists of the 7 rectangles shown in the Degraded Source image below.

```
// Show the ROI background selection.
AppendImage root:images:addMask
ModifyImage addMask explicit=1, eval={1,65000,0,0}

// Create a corrected image and display it.
ImageRemoveBackground /R=root:images:addMask /w/P=2 addBlobs
NewImage M_RemovedBackground
```

If the source image contains relatively small particles on a nonuniform background, you may remove the background (for the purpose of particle analysis) by iterating grayscale erosion until the particles are all gone. You are then left with a fairly good representation of the background that can be subtracted from the original image.

### Multiplicative Background

This case is much more complicated because the removal of the background requires division of the image by the calculated background (it is assumed here that the system producing the image has an overall gamma of 1). The first complication has to do with the possible presence of zeros in the calculated background. The second complication is that the calculations give us the additional freedom to choose one constant factor to scale the resulting image. There are many approaches for correcting a multiplicative background. The following example shows how an image can be corrected if we assume that the peak values (identified by the ROI mask) would all have the same value in the absence of a background.

```
Duplicate/O root:images:blobs mulBlobs
Redimension/S mulBlobs           // convert to single precision
mulBlobs*=(1+0.005*x*y)
NewImage mulBlobs

// Show us the ROI foreground selection; you can use histogram
// equalization to find fit regions in the dark area.
AppendImage root:images:multMask
ModifyImage multMask explicit=1, eval={1,65000,0,0}

ImageRemoveBackground /R=root:images:multMask/F/w/P=2 mulBlobs
// Normalize the fit.
WaveStats/Q/M=1 M_RemovedBackground

// Renormalize the fit--we can use that one free factor.
```

```
M_RemovedBackground=(M_RemovedBackground-V_min)/(V_max-V_min)
// Remove zeros by replacing with average value.
WaveStats/Q/M=1 M_RemovedBackground
MatrixOp/O M_RemovedBackground=M_RemovedBackground+V_avg*equal(M_RemovedBackground,0)
MatrixOp/O mulBlobs=mulBlobs/M_RemovedBackground // scaled image.
```

In the example above we have manually created the ROI masks that were needed for the fit. You can automate this process (and actually improve performance) by subdividing the image into a number of smaller rectangles and selecting in each one the highest (or lowest) pixel values. An example of such procedure is provided in connection with the ImageStats operation above.

### General Utilities: ImageTransform Operation

As we have seen above, the **ImageTransform** operation (see page V-361) provides a number of image utilities. As a rule, if you are unable to find an appropriate image operation check the options available under ImageTransform. Here are some examples:

When working with RGB or HSL images it is frequently necessary to access one plane at a time. For example, the green plane of the peppers image can be obtained as follows:

```
NewImage root:images:peppers // display original
Duplicate/O root:images:peppers peppers
ImageTransform /P=1 getPlane peppers
NewImage M_ImagePlane // display green plane in grayscale
```

The complementary operation can insert a plane into a 3D wave. For example, suppose you wanted to modify the green plane of the peppers image:

```
DoWindow/K WM_temp
ImageHistModification/o M_ImagePlane
ImageTransform /p=1 /D=M_ImagePlane setPlane peppers
NewImage peppers // display the processed image
```

Some operations are restricted to waves of particular dimensions. For example, if you want to use the Adaptive histogram equalization, the number of horizontal and vertical partitions is restricted by the requirement that the image be an exact multiple of the dimensions of the subregion. The ImageTransform operation provides three image padding options: If you specify a negative number to the changed rows or columns, the corresponding rows and columns are removed from the image. If the numbers are positive, rows and columns are added. By default the added rows and columns contain exactly the same pixel values as the last row and column in the image. If you specify the /W flag the operation duplicates the relevant portion of the image into the new rows and columns. Here are some examples:

```
Duplicate/o root:images:baboon baboon
NewImage baboon
ImageTransform/N={-20,-10} padImage baboon
Rename M_PaddedImage, cropped
NewImage cropped
ImageTransform/N={40,40} padImage baboon
Rename M_PaddedImage, padLastVals
NewImage padLastVals
ImageTransform/W/N={100,100} padImage baboon
NewImage M_PaddedImage
```

Another utility operation is the conversion of any 2D wave into a normalized (0-255) 8-bit image wave. This is accomplished with the ImageTransform operation using the keyword convert2gray. Here is an example:

```
// Create some numerical data
Make/O/N=(50,80) numericalWave=x*sin(x/10)*y*exp(y/100)
ImageTransform convert2gray numericalWave
NewImage M_Image2Gray
```

The conversion to an 8-bit image is required for certain operation. It is also useful sometimes when you want to reduce the size of your image waves.

## Overview

This chapter describes operations and functions for statistical analysis together with some general guidelines for their use. This is not a statistics tutorial; for that you can consult one of the references at the end of this chapter or the references listed in the documentation of a particular operation or function. The material below assumes that you are familiar with techniques and methods of statistical analysis.

Most statistics operations and functions are named with the prefix “Stats”. Naming exceptions include the random noise functions that have traditionally been named based on the distribution they represent.

There are six natural groups of statistics operations and functions. They include:

- Test operations
- Noise functions
- Probability distribution functions (PDFs)
- Cumulative distribution functions (CDFs)
- Inverse cumulative distribution functions
- General purpose statistics operations and functions

## Statistics Test Operations

Test operations analyze the input data to examine the validity of a specific hypothesis. The common test involves a computation of some numeric value (also known as “test statistic”) which is usually compared with a critical value in order to determine if you should accept or reject the test hypothesis ( $H_0$ ). Most tests compute a critical value for the given significance *alpha* which has the default value 0.05 or a user-provided value via the /ALPH flag. Some tests directly compute the P value which you can compare to the desired significance value.

Critical values have been traditionally published in tables for various significance levels and tails of distributions. They are by far the most difficult technical aspect in implementing statistical tests. The critical values are usually obtained from the inverse of the CDF for the particular distribution, i.e., from solving the equation

$$cdf(criticalValue) = 1 - alpha,$$

where *alpha* is the significance. In some distributions (e.g., Friedman’s) the calculation of the CDF is so computationally intensive that it is impractical (using desktop computers in 2006) to compute for very large parameters. Fortunately, large parameters usually imply that the distributions can be approximated using simpler expressions. Igor’s tests provide whenever possible exact critical values as well as the common relevant approximations.

Comparison of critical values with published table values can sometimes be interesting as there does not appear to be a standard for determining the published critical value when the CDF takes a finite number of discrete values (step-like). In this case the CDF attains the value  $(1 - alpha)$  in a vertical transition so one could use the X value for the vertical transition as a critical value or the X value of the subsequent vertical transition. Some tables reflect a “conservative” approach and print the X value of subsequent transitions.

Statistical test operations can print their results to the history area of the command window and save them in a wave in the current data folder. Result waves have a fixed name associated with the operation. Elements in the wave are designated by dimension labels. You can use the /T flag to display the results of the operation in a table with dimension labels. The argument for this flag determines what happens when you kill the table. You can use /Q in all test operations to prevent printing information in the history area and you can use the /Z flag to make sure that the operations do not report errors except by setting the V\_Flag variable to -1.

Statistical test operations tend to include several variations of the named test. You can usually choose to execute one or more variations by specifying the appropriate flags. The following table can be used as a guide for identifying the operation associated with a given test name.

**Statistical Test Operations by Name**

<b>Test Name</b>	<b>Where to find it</b>
Angular Distance	<b>StatsAngularDistanceTest</b>
Bartlett's test for variances	<b>StatsVariancesTest</b>
BootStrap	<b>StatsResample</b>
Brown and Forsythe	<b>StatsANOVA1Test</b>
Chi-squared test for means	<b>StatsChiTest</b>
Cochran's test	<b>StatsCochranTest</b>
Dunn-Holland-Wolfe	<b>StatsNPMCTest</b>
Dunnette multicomparison test	<b>StatsDunnettTest, StatsLinearRegression</b>
Fisher's Exact Test	<b>StatsContingencyTable</b>
Fixed Effect Model	<b>StatsANOVA1Test</b>
Friedman test on randomized block	<b>StatsFriedmanTest</b>
F-test on two distributions	<b>StatsFTest</b>
Hodges-Ajne (Batschelet)	<b>StatsHodgesAjneTest</b>
Hartigan test for unimodality	<b>StatsDIPTest</b>
Hotelling	<b>StatsCircularTwoSampleTest, StatsCircularMeans</b>
Jackknife	<b>StatsResample</b>
Jarque-Bera Test	<b>StatsJBTest</b>
Kolmogorov-Smirnov	<b>StatsKSTest</b>
Kruskal-Wallis	<b>StatsKWTest</b>
Kuiper Test	<b>StatsCircularMoments</b>
Levene's test for variances	<b>StatsVariancesTest</b>
Linear Correlation Test	<b>StatsLinearCorrelationTest</b>
Linear Order Statistic	<b>StatsCircularMoments</b>
Mann-Kendall	<b>StatsKendallTauTest</b>
Moore test	<b>StatsCircularTwoSampleTest, StatsCircularMeans</b>
Nonparametric multiple contrasts	<b>StatsNPMCTest</b>
Nonparametric angular-angular correlation	<b>StatsCircularCorrelationTest</b>
Nonparametric second order circular analysis	<b>StatsCircularMeans</b>
Nonparametric serial randomness (nominal)	<b>StatsNPNominalSRTest</b>
Parametric angular-angular correlation	<b>StatsCircularCorrelationTest</b>
Parametric angular-Linear correlation	<b>StatsCircularCorrelationTest</b>
Parametric second order circular analysis	<b>StatsCircularMeans</b>
Parametric serial randomness test	<b>StatsSRTest</b>
Rayleigh	<b>StatsCircularMoments</b>
Repeated Measures	<b>StatsANOVA2RMTest</b>

Test Name	Where to find it
Scheffe equality of means	<code>StatsScheffeTest</code>
Shapiro-Wilk test for normality	<code>StatsShapiroWilkTest</code>
Spearman	<code>StatsRankCorrelationTest</code>
Student-Newman-Keuls	<code>StatsNPMCTest</code>
Tukey Test	<code>StatsTukeyTest</code> <code>StatsLinearRegression</code> , <code>StatsMultiCorrelationTest</code> , <code>StatsNPMCTest</code>
Two-Factor ANOVA	<code>StatsANOVA2NRTest</code>
T-test	<code>StatsTTest</code>
Watson's nonparametric two-sample U2	<code>StatsWatsonUSquaredTest</code> , <code>StatsCircularTwoSampleTest</code>
Watson-Williams	<code>StatsWatsonWilliamsTest</code>
Weighted-rank correlation test	<code>StatsWRCorrelationTest</code>
Wheeler-Watson nonparametric test	<code>StatsWheelerWatsonTest</code>
Wilcoxon-Mann-Whitney two-sample	<code>StatsWilcoxonRankTest</code>
Wilcoxon signed rank	<code>StatsWilcoxonRankTest</code>

### Statistical Test Operations by Data Format

The following tables group statistical operations and functions according to the format of the input data.

**Tests for Single Waves**

<b>Analysis Method</b>	<b>Comments</b>
<b>StatsChiTest</b>	Compares with known binned values
<b>StatsCircularMoments</b>	WaveStats for circular data
<b>StatsKendallTauTest</b>	Similar to Spearman's correlation
<b>StatsMedian</b>	Returns the median
<b>StatsNPNominalSRTest</b>	Nonparametric serial randomness test
<b>StatsQuantiles</b>	Computes quantiles and more
<b>StatsResample</b>	Bootstrap analysis
<b>StatsSRTest</b>	Serial randomness test
<b>StatsTrimmedMean</b>	Returns the trimmed mean
<b>StatsTTest</b>	Compares with known mean
<b>Sort</b>	Reorders the data
<b>WaveStats</b>	Basic statistical description
<b>StatsJBTest</b>	Jarque-Bera test for normality
<b>StatsKSTest</b>	Limited scope test for normality
<b>StatsDIPTest</b>	Hartigan test for unimodality
<b>StatsShapiroWilkTest</b>	Shapiro-Wilk test for normality

**Tests for Two Waves**

<b>Analysis Method</b>	<b>Comments</b>
<b>StatsChiTest</b>	Chi-squared statistic for comparing two distributions
<b>StatsCochranTest</b>	Randomized block or repeated measures test
<b>StatsCircularTwoSampleTest</b>	Second order analysis of angles
<b>StatsDunnettTest</b>	Compares multiple groups to a control
<b>StatsFTest</b>	Computes ratio of variances
<b>StatsFriedmanTest</b>	Nonparametric ANOVA
<b>StatsKendallTauTest</b>	Similar to Spearman's correlation
<b>StatsTTest</b>	Compares the means of two distributions
<b>StatsANOVA1Test</b>	One-way analysis of variances
<b>StatsLinearRegression</b>	Linear regression analysis
<b>StatsLinearCorrelationTest</b>	Linear correlation coefficient and its error
<b>StatsRankCorrelationTest</b>	Computes Spearman's rank correlation
<b>StatsVariancesTest</b>	Compares variances of waves
<b>StatsWilcoxonRankTest</b>	Two-sample or signed rank test
<b>StatsWatsonUSquaredTest</b>	Compares two populations of circular data
<b>StatsWatsonWilliamsTest</b>	Compares mean values of angular distributions
<b>StatsWheelerWatsonTest</b>	Compares two angular distributions

**Tests for Multiple or Multidimensional Waves**

Analysis Method	Comments
StatsANOVA1Test	One-way analysis of variances
StatsANOVA2Test	Two-factor analysis of variances
StatsANOVA2RMTest	Two-factor repeated measure ANOVA
StatsCochranTest	Randomized block or repeated measures test
StatsContingencyTable	Contingency table analysis
StatsDunnettTest	Comparing multiple groups to a control
StatsFriedmanTest	Nonparametric ANOVA
StatsNPMCTest	Nonparametric multiple comparison tests
StatsScheffeTest	Tests equality of means
StatsTukeyTest	Multiple comparisons based on means
StatsWatsonWilliamsTest	Compares mean values of angular distributions
StatsWheelerWatsonTest	Compares two angular distributions

**Statistical Test Operations for Angular/Circular Data**

StatsAngularDistanceTest	StatsHodgesAjneTest
StatsCircularMoments	StatsWatsonUSquaredTest
StatsCircularMeans	StatsWatsonWilliamsTest
StatsCircularTwoSampleTest	StatsWheelerWatsonTest
StatsCircularCorrelationTest	

**Statistical Test Operations: Nonparametric Tests**

Operation	Comments
StatsAngularDistanceTest	
StatsFriedmanTest	
StatsCircularTwoSampleTest	Parametric or nonparametric
StatsCircularCorrelationTest	Parametric or nonparameteric
StatsCircularMeans	Parametric or nonparameteric
StatsHodgesAjneTest	
StatsKendallTauTest	
StatsKWTest	
StatsNPMCTest	
StatsNPNominalSRTest	
StatsRankCorrelationTest	
StatsWatsonUSquaredTest	
StatsWheelerWatsonTest	
StatsWilcoxonRankTest	

## Noise Functions

The following functions return numbers from a pseudo-random distribution of the specified shapes and parameters. Except for `enoise` and `gnoise` where you have an option to select a random number generator, the remaining noise functions use a Mersenne Twister algorithm for the initial uniform pseudo-random distribution. Note that whenever you need repeatable results you should use `SetRandomSeed` prior to executing any of the noise functions.

The following noise generation functions are available:

<b>binomialNoise</b>	<b>logNormalNoise</b>
<b>enoise</b>	<b>lorentzianNoise</b>
<b>expnoise</b>	<b>poissonNoise</b>
<b>gammaNoise</b>	<b>StatsPowerNoise</b>
<b>gnoise</b>	<b>StatsVonMisesNoise</b>
<b>hyperGNoise</b>	<b>wnoise</b>

## Cumulative Distribution Functions

A cumulative distribution function (CDF) is the integral of its respective probability distribution function (PDF). CDFs are usually well behaved functions with values in the range  $[0,1]$ . CDFs are important in computing critical values, P values and power of statistical tests.

Many CDFs are computed directly from closed form expressions. Others can be difficult to compute because they involve evaluating a very large number of states, e.g., Friedman or USquared distributions. In these cases you have the following options:

1. Use a built-in table that consists of exact, precomputed values.
2. Compute an approximate CDF based on the prevailing approximation method or using a Monte-Carlo approach.
3. Compute the exact CDF.

Built-in tables are ideal if they cover the range of the parameters that you need. Monte-Carlo methods can be tricky in the sense that repeated application may return small variations in values. Computing the exact CDF may be desirable, but it is often impractical. In most situations the range of parameters that is practical to compute on a desktop machine is already covered in the built-in tables. Larger parameters not have been considered because they take days to compute or because they require 64 bit processors. In addition, most of the approximations tend to improve with increasing size of the parameters.

The functions to calculate values from CDFs are as follows:

<b>StatsBetaCDF</b>	<b>StatsHyperGCDF</b>	<b>StatsQCDF</b>
<b>StatsBinomialCDF</b>	<b>StatsKuiperCDF</b>	<b>StatsRayleighCDF</b>
<b>StatsCauchyCDF</b>	<b>StatsLogisticCDF</b>	<b>StatsRectangularCDF</b>
<b>StatsChiCDF</b>	<b>StatsLogNormalCDF</b>	<b>StatsRunsCDF</b>
<b>StatsCMSSDCDF</b>	<b>StatsMaxwellCDF</b>	<b>StatsSpearmanRhoCDF</b>
<b>StatsDExpCDF</b>	<b>StatsInvMooreCDF</b>	<b>StatsStudentCDF</b>
<b>StatsErlangCDF</b>	<b>StatsNBinomialCDF</b>	<b>StatsTopDownCDF</b>
<b>StatsEValueCDF</b>	<b>StatsNCFCDF</b>	<b>StatsTriangularCDF</b>
<b>StatsExpCDF</b>	<b>StatsNCTCDF</b>	<b>StatsUSquaredCDF</b>

<code>StatsFCDF</code>	<code>StatsNormalCDF</code>	<code>StatsVonMisesCDF</code>
<code>StatsFriedmanCDF</code>	<code>StatsParetoCDF</code>	<code>StatsQCDF</code>
<code>StatsGammaCDF</code>	<code>StatsPoissonCDF</code>	<code>StatsWaldCDF</code>
<code>StatsGeometricCDF</code>	<code>StatsPowerCDF</code>	<code>StatsWeibullCDF</code>

## Probability Distribution Functions

Probability distribution functions (PDF) are sometimes known as probability densities. In the case of continuous distributions, the area under the curve of the PDF for each interval equals the probability for the random variable to fall within that interval. The PDFs are useful in calculating event probabilities, characteristic functions and moments of a distribution.

The functions to calculate values from PDFs are as follows:

<code>StatsBetaPDF</code>	<code>StatsGammaPDF</code>	<code>StatsParetoPDF</code>
<code>StatsBinomialPDF</code>	<code>StatsGeometricPDF</code>	<code>StatsPoissonPDF</code>
<code>StatsCauchyPDF</code>	<code>StatsHyperGPDF</code>	<code>StatsPowerPDF</code>
<code>StatsChiPDF</code>	<code>StatsLogNormalPDF</code>	<code>StatsRayleighPDF</code>
<code>StatsDExpPDF</code>	<code>StatsMaxwellPDF</code>	<code>StatsRectangularPDF</code>
<code>StatsErlangPDF</code>	<code>StatsBinomialPDF</code>	<code>StatsStudentPDF</code>
<code>StatsErrorPDF</code>	<code>StatsNCChiPDF</code>	<code>StatsTriangularPDF</code>
<code>StatsEValuePDF</code>	<code>StatsNCFPDF</code>	<code>StatsVonMisesPDF</code>
<code>StatsExpPDF</code>	<code>StatsNCTPDF</code>	<code>StatsWaldPDF</code>
<code>StatsFPDF</code>	<code>StatsNormalPDF</code>	<code>StatsWeibullPDF</code>

## Inverse Cumulative Distribution Functions

The inverse cumulative distribution functions return the values at which their respective CDFs attain a given level. This value is typically used as a critical test value. There are very few functions for which the inverse CDF can be written in closed form. In most situations the inverse is computed iteratively from the CDF.

The functions to calculate values from inverse CDFs are as follows:

<code>StatsInvBetaCDF</code>	<code>StatsInvKuiperCDF</code>	<code>StatsInvQpCDF</code>
<code>StatsInvBinomialCDF</code>	<code>StatsInvLogisticCDF</code>	<code>StatsInvRayleighCDF</code>
<code>StatsInvCauchyCDF</code>	<code>StatsInvLogNormalCDF</code>	<code>StatsInvRectangularCDF</code>
<code>StatsInvChiCDF</code>	<code>StatsInvMaxwellCDF</code>	<code>StatsInvSpearmanCDF</code>
<code>StatsInvCMSSDCDF</code>	<code>StatsInvMooreCDF</code>	<code>StatsInvStudentCDF</code>
<code>StatsInvDExpCDF</code>	<code>StatsInvNBinomialCDF</code>	<code>StatsInvTopDownCDF</code>
<code>StatsInvEValueCDF</code>	<code>StatsInvNCFCDF</code>	<code>StatsInvTriangularCDF</code>
<code>StatsInvExpCDF</code>	<code>StatsInvNormalCDF</code>	<code>StatsInvUSquaredCDF</code>
<code>StatsInvFCDF</code>	<code>StatsInvParetoCDF</code>	<code>StatsInvVonMisesCDF</code>

StatsInvFriedmanCDF	StatsInvPoissonCDF	StatsInvWeibullCDF
StatsInvGammaCDF	StatsInvPowerCDF	
StatsInvGeometricCDF	StatsInvQCDF	

## General Purpose Statistics Operations and Functions

This group includes operations and functions that existed before IGOR Pro 6.0 and some general purpose operations and functions that do not belong to the main groups listed.

binomial	Sort	StatsTrimmedMean
binomialln	StatsCircularMoments	StudentA
erf	StatsCorrelation	StudentT
erfc	StatsMedian	WaveStats
inverseErf	StatsQuantiles	StatsPermute
inverseErfc	StatsResample	

## Hazard and Survival Functions

Igor does not provide built-in functions to calculate the Survival or Hazard functions. They can be calculated easily from the **Probability Distribution Functions** on page III-345 and **Cumulative Distribution Functions** on page III-344.

In the following, the cumulative distribution functions are denoted by  $F(x)$  and the probability distribution functions are denoted by  $p(x)$ .

The Survival Function  $S(x)$  is given by

$$S(x) = 1 - F(x).$$

The Hazard function  $h(x)$  is given by

$$h(x) = \frac{p(x)}{S(x)} = \frac{p(x)}{1 - F(x)}.$$

The cumulative hazard function  $H(x)$  is

$$H(x) = \int_{-\infty}^x h(u) du,$$

$$H(x) = -\ln[1 - F(x)].$$

Inverse Survival Function  $Z(a)$  is

$$Z(\alpha) = G(1 - \alpha),$$

where  $G()$  is the inverse CDF (see **Inverse Cumulative Distribution Functions** on page III-345).

## Statistics Procedures

Several procedure files are provided to extend the built-in statistics capability described in this chapter. Some of these procedure files provide user interfaces to the built-in statistics functionality. Others extend the functionality.

In the Analysis menu you will find a Statistics item that brings up a submenu. Selecting any item in the submenu will cause all the statistics-related procedure files to be loaded, making them ready to use. Alternatively, you can load all the statistics procedures by adding the following include statement to the top of your procedure window:

```
#include <AllStatsProcedures>
```

Functionality provided by the statistics procedure files includes the 1D Statistics Report package for automatic analysis of single 1D waves, and the ANOVA Power Calculations Panel, as well as functions to create specialized graphs:

StatsAutoCorrPlot()	StatsPlotLag()	StatsPlotHistogram()
StatsBoxPlot()	StatsProbPlot()	

Also included are these convenience functions:

WM_2MeanConfidenceIntervals()	WM_MCPPointOnRegressionLines()
WM_2MeanConfidenceIntervals2()	WM_MeanConfidenceInterval()
WM_BernoulliCdf()	WM_OneTailStudentA()
WM_BinomialPdf()	WM_OneTailStudentT()
WM_CIforPooledMean()	WM_PlotBiHistogram()
WM_CompareCorrelations()	WM_RankForTies()
WM_EstimateMinDetectableDiff()	WM_RankLetterGradesWithTies()
WM_EstimateReqSampleSize()	WM_RegressionInversePrediction()
WM_EstimateReqSampleSize2()	WM_SSEstimatorFunc()
WM_EstimateSampleSizeForDif()	WM_SSEstimatorFunc2()
WM_GetANOVA1Power()	WM_SSEstimatorFunc3()
WM_GetGeometricAverage()	WM_VarianceConfidenceInterval()
WM_GetHarmonicMean()	WM_WilcoxonPairedRanks()
WM_GetPooledMean()	WM_StatsKaplanMeier()

### Overview

This chapter explains what procedure windows are, how they are created and organized, and how you work with them. It does not cover programming. See Chapter IV-2, **Programming Overview** for an introduction.

A procedure window is where Igor procedures are stored. Igor procedures are the macros, functions and menu definitions that you create or that Igor creates automatically for you.

The content of a procedure window is stored in a procedure file. In the case of a packed Igor experiment, the procedure file is packed into the experiment file.

### Types of Procedure Files

There are four types of procedure files:

- The experiment procedure file, displayed in the built-in procedure window
- Global procedure files, displayed in auxiliary procedure windows
- Shared procedure files, displayed in auxiliary procedure windows
- Auxiliary experiment procedure files, displayed in auxiliary procedure windows

The built-in procedure window holds experiment-specific procedures of the currently open experiment. This is the only procedure window that beginning or casual Igor users may need.

All other procedure windows are called **auxiliary** to distinguish them from the built-in procedure window. You create an auxiliary procedure window using Windows→New→Procedure. You can then save it to a standalone file, using File→Save Procedure As, or allow Igor to save it as part of the current experiment.

A global procedure file contains procedures that you might want to use in any experiment. It must be saved as a standalone file in the "Igor Procedures" folder of your **Igor Pro User Files** folder. Procedure files in "Igor Procedures" are automatically opened by Igor at startup and left open until Igor quits. This is the easiest way to make procedures available to multiple experiments.

A shared procedure file contains procedures that you want to use in more than one experiment but that you don't want to be open all of the time. It must be saved as a standalone file. The recommended location is the "User Procedures" folder of your **Igor Pro User Files** folder.

An auxiliary experiment procedure file contains procedures that you want to use in a single experiment but want to keep separate from the built-in procedure window for organizational purposes. In a packed experiment it is saved as a packed file within the experiment file. In an unpacked experiment it is saved as a standalone file in the experiment folder.

### Working with the Built-in Procedure Window

Procedures that are specific to the current experiment are usually stored in the built-in procedure window. Also, when Igor automatically generates procedures, it stores them in the built-in procedure window.

To show the built-in procedure window, choose Windows→Procedure Windows→Procedure Window or press Command-M (*Macintosh*) or Ctrl+M (*Windows*). To hide it, click the close button or press Command-W (*Macintosh*) or Ctrl+W (*Windows*).

To create a procedure, just type it into the procedure window.

The contents of the built-in procedure window are automatically stored when you save the current Igor experiment. For unpacked experiments, the contents are stored in a file called "procedure" in the experiment folder. For packed experiments, the contents are stored in the packed experiment file. When you open an experiment Igor loads its procedures back into the built-in procedure window.

## Compiling the Procedures

When you modify the text in the procedure window, you will notice that a Compile button appears at the bottom of the window.

Clicking the Compile button scans the procedure window looking for macros, functions and menu definitions. Igor compiles user-defined functions, generating low-level instructions that can be executed quickly.

Igor also compiles the code in the procedure window if you choose Compile from the Macros menu or if you activate any window other than a procedure or help window.

## Templates Pop-Up Menu

The Templates pop-up menu lists all of the built-in and external operations and functions in alphabetical order and also lists the common flow control structures.

If you choose an item from the menu, Igor inserts the corresponding template in the procedure window.

If you select, click in, or click after a recognized operation, function or flow-control keyword in the procedure window, two additional items are listed at the top of the menu. The first item inserts a template and the second takes you to help.

## Procedure Navigation Bar

The procedure navigation bar appears at the top of each procedure window. It consists of a menu and a settings button. The menu provides a quick way to find procedures in the active procedure window.

Certain syntax errors prevent Igor from parsing procedures. In that case, the menu shows no procedures.

You can hide the navigation bar by choosing Misc-Miscellaneous Settings, selecting the Text Editing section, and unchecking the Show Navigation Bar checkbox.

## Write-Protect Icon

Procedure windows have a write-enable/write-protect icon which appears in the lower-left corner of the window and resembles a pencil. If you click this icon, Igor Pro displays an icon indicating that the procedure window is write-protected. The main purpose of this is to prevent accidental alteration of shared procedure files.

Igor opens included user procedure files for writing but turns on the write-protect icon so that you will get a warning if you attempt to change them. If you do want to change them, simply click the write-protect icon to turn protection off. You can turn this default write-protection off via the Text Encoding section of the Miscellaneous Settings dialog.

If a procedure file is opened for reading only, you will see a lock icon instead of the pencil icon. A file opened for read-only can not be modified.

WaveMetrics procedures, in the WaveMetrics Procedures folder, are assumed to be the same for all Igor users and should not be modified by users. Therefore, Igor opens included WaveMetrics procedures for reading only.

## Magnifier Icon

You can magnify procedure text to make it more readable. See **Text Magnification** on page II-47 for details.

## Creating Procedure Windows

There are three ways to create procedures:

- Automatically by Igor
- Manually, when you type in a procedure window
- Semiautomatically, when you use various dialogs

Igor offers to automatically create a **window recreation macro** when you close a target window. A window recreation macro is a procedure that can recreate a graph, table, page layout or control panel window. See **Saving a Window as a Recreation Macro** on page II-42 for details.

You can add procedures by merely typing them in a procedure window.

You can create user-defined controls in a graph or control panel. Each control has an optional **action procedure** that runs when the control is used. You can create a control and its corresponding action procedure using dialogs that you access through the Add Controls submenu in the Graph or Panel menus. These action procedures are initially stored in the built-in procedure window.

You can create user-defined curve fitting functions via the Curve Fitting dialog. These functions are initially stored in the built-in procedure window.

### Creating New Procedure Files

You create a new procedure file if you want to write procedures to be used in more than one experiment.

**Note:** There is a risk in sharing procedure files among experiments. If you copy the experiment to another computer and forget to also copy the shared files, the experiment will not work on the other computer. See **References to Files and Folders** on page II-22 for further details.

If you do create a shared procedure file then you are responsible for copying the shared file when you copy an experiment that relies on it.

To create a new procedure file, choose Windows→New→Procedure. This creates a new procedure *window*. The procedure *file* is not created until you save the procedure window or save the experiment.

You can explicitly save the procedure window by choosing File→Save Procedure As or by closing it and choosing to save it in the resulting dialog. This saves the file as an auxiliary procedure file, separate from the experiment.

If you don't save the procedure window explicitly, Igor saves it as part of the current experiment the next time you save the experiment.

### Opening an Auxiliary Procedure File

You can open a procedure file using the File→Open File→Procedure menu item.

When you open a procedure file, Igor displays it in a new procedure window. The procedures in the window can be used in the current experiment. When you save the current experiment, Igor will save a *reference* to the shared procedure file in the experiment file. When you later open the experiment, Igor will reopen the procedure file.

For procedure files that you use from a large number of experiments, it is better to configure the files as global procedure files. See **Global Procedure Files** on page III-353.

For commonly used auxiliary files, it is better to use the include statement. See **Including a Procedure File** on page III-354.

## Showing Procedure Windows

We usually show procedure windows when we are doing programming and hide them for normal use.

To show the built-in procedure window, choose Windows→Procedure Windows→Procedure Window or press Command-M (*Macintosh*) or Ctrl+M (*Windows*). To show auxiliary procedure windows, use the Windows→Procedure Windows submenu.

If you have more than one procedure window, you can cycle to the next procedure window by pressing Command-Option-M (*Macintosh*) or Ctrl+Alt+M (*Windows*). Pressing Command-Shift-Option-M (*Macintosh*) or Ctrl+Shift+Alt+M (*Windows*) hides the active procedure window and shows the next one.

You can also show a procedure window by choosing a menu item added by that window while pressing Option (*Macintosh*) or Alt (*Windows*). This feature works only if the top window is a procedure window.

You can show all procedure windows and hide all procedure windows using the Windows→Show and Windows→Hide submenus.

## Hiding and Killing Procedure Windows

The built-in procedure window always exists as part of the current experiment. You can hide it by clicking the close button, pressing Command-W (*Macintosh*) or Ctrl+W (*Windows*) or by choosing Hide from the Windows menu. You can not kill it.

Auxiliary procedure files can be opened (added to the experiment), hidden and killed (removed from the experiment). This leads to a difference in behavior between auxiliary procedure windows and the built-in procedure window.

When you click the close button of an auxiliary procedure file, Igor presents the Close Procedure Window dialog to find out what you want to do.

If you just want to hide the window, you can press Shift while clicking the close button. This skips the dialog and just hides the window.

Killing a procedure window closes the window and removes it from the current experiment but does not delete or otherwise affect the procedure file with which the window was associated. If you have made changes or the procedure was not previously saved, you will be presented with the choice of saving the file before killing the procedure.

The Close item of the Windows menu and the equivalent, Command-W (*Macintosh*) or Ctrl+W (*Windows*), behave the same as the close button.

## Global Procedure Files

Global procedure files contain procedures that you want to be available in all experiments. They differ from other procedure files in that Igor opens them automatically and never closes them. Configuring a procedure file as a global procedure file is the easiest way to make it widely available.

When Igor starts running, it searches "Igor Pro 7 Folder/Igor Procedures" and "Igor Pro User Files/Igor Procedures" (see **Igor Pro User Files** on page II-31 for details), as well as files and folders referenced by aliases or shortcuts. Igor opens any procedure file that it finds during this search as a global procedure file.

You should save your global procedure files in "Igor Pro User Files/Igor Procedures". You can locate this folder by choosing Help→Show Igor Pro User Files.

Igor opens global procedure files with write-protection on since they presumably contain procedures that you have already debugged and which you don't want to inadvertently modify. If you *do* want to modify a global procedure file, click the write-protect icon (pencil in lower-left corner of the window). You can turn this default write-protection off via the Text Encoding section of the Miscellaneous Settings dialog.

When you create a new experiment or open an existing one, Igor normally closes any open procedure files, but it leaves global procedure files open. You can explicitly close a global procedure window at any time and then you can manually reopen it. Igor will not automatically reopen it until the next time Igor is launched.

Although its procedures can be used by the current experiment, a global procedure file is not part of the current experiment. Therefore, Igor does not save a global procedure file or a reference to a global procedure file inside an experiment file.

**Note:** There is a risk in using global procedure files. If you copy an experiment that relies on a global procedure file to another computer and forget to also copy the global procedure file, the experiment will not work on the other computer.

### Saving Global Procedure Files

If you modify a global procedure file, Igor will save it when you save the current experiment even though the global procedure file is not part of the current experiment. However, you might want to save the procedure file without saving the experiment. For this, use the File→Save Procedure menu item.

### Shared Procedure Files

You may develop procedures that you want to use in several but not all of your experiments. You can facilitate this by creating a shared procedure file. This is a procedure file that you save in its own file, separate from any experiment. Such a file can be opened from any experiment.

There are two ways to open a shared procedure file from an experiment:

- By explicitly opening it, using the File→Open File submenu or by double-clicking it or by drag-and-drop
- By adding an include statement to your experiment procedure window

The include method is preferred and is described in detail under **Including a Procedure File** on page III-354.

When Igor encounters an include statement, it searches for the included file in "Igor Pro 7 Folder/User Procedures" and in "Igor Pro User Files/User Procedures" (see **Igor Pro User Files** on page II-31 for details). The Igor Pro User Files folder is the recommended place for storing user files. You can locate it by choosing Help→Show Igor Pro User Files.

You can store your shared procedure file directly in "Igor Pro User Files/User Procedures" or you can store it elsewhere and put an alias (*Macintosh*) or shortcut (*Windows*) for it in "Igor Pro User Files/User Procedures". If you have many shared procedure files you can put them all in your own folder and put an alias/shortcut for the folder in "Igor Pro User Files/User Procedures".

When you explicitly open a procedure file using the Open File submenu, by double-clicking it, or by drag-and-drop, you are adding it to the current experiment. When you save the experiment, Igor saves a *reference* to the procedure file in the experiment file. When you close the experiment, Igor closes the procedure file. When you later reopen the experiment, Igor reopens the procedure file.

When you use an include statement, the included file is not considered part of the experiment but is still referenced by the experiment. Igor automatically opens the included file when it hits the include statement during procedure compilation.

**Note:** There is a risk in sharing procedure files among experiments. If you copy the experiment to another computer and forget to also copy the shared files, the experiment will not work on the other computer. See **References to Files and Folders** on page II-22 for more explanation.

### Saving Shared Procedure Files

If you modify a shared procedure file, Igor saves it when you save the experiment that is sharing it. However, you might want to save the procedure file without saving the experiment. For this, choose File→Save Procedure.

### Including a Procedure File

You can put an include statement in any procedure file. An include statement automatically opens another procedure file. This is the recommended way of accessing files that contain utility routines which you may want to use in several experiments. Using an include statement is preferable to opening a procedure file explicitly because it doesn't rely on the exact location of the file in the file system hierarchy.

Here is a typical include statement:

```
#include <MatrixToXYZ>
```

This automatically opens the MatrixToXYZ.ipf file supplied by WaveMetrics in "Igor Pro 7 Folder/WaveMetrics Procedures/Data Manipulation". The angle brackets tell Igor to search the "Igor Pro 7 Folder/WaveMetrics Procedures" hierarchy.

To see what WaveMetrics procedure files are available, choose Help→Help Windows→WM Procedures Index.

You can include your own utility procedure files by using double-quotes instead of the angle-brackets shown above:

```
#include "Your Procedure File"
```

The double-quotes tell Igor to search the "Igor Pro 7 Folder/User Procedures" and "Igor Pro User Files/User Procedures" hierarchies (see **Igor Pro User Files** on page II-31 for details) for the named file. Igor searches those folders and subfolders and files or folders referenced by aliases/shortcuts in those folders.

These are the two main variations on the include statement. For details on less frequently used variations, see **The Include Statement** on page IV-155.

Included procedure files are not considered part of the experiment but are automatically opened by Igor when it compiles the experiment's procedures.

To prevent accidental alteration of an included procedure file, Igor opens it either write-protected (User Procedures) or read-only (WaveMetrics Procedures). See **Write-Protect Icon** on page III-351.

A #include statement must omit the file's ".ipf" extension:

```
#include <Strings as Lists>          // RIGHT
#include <Strings as Lists.ipf>      // WRONG
```

## Creating Packages

A package is a set of procedure files, help files and other support files that add significant functionality to Igor.

Igor comes pre-configured with numerous WaveMetrics packages accessed through the Data→Packages, Analysis→Packages, Misc→Packages, Windows→New→Packages and Graph→Packages submenus as well as others.

Intermediate to advanced programmers can create their own packages. See **Packages** on page IV-232 for details.

## Invisible Procedure Files

If you create a package of Igor procedures to be used by regular Igor users (as opposed to programmers), you may want to hide the procedures to reduce clutter or to eliminate the possibility that they might inadvertently change them. You can do this by making the procedure files invisible.

Invisible procedure files are omitted from Igor's Procedure Windows submenu which appears in the Windows menu. This keeps them out of the way of regular users.

There are three ways to make a procedure file invisible. In order of difficulty they are:

- Using the #pragma hide compiler directive
- Using an independent module
- Using the operating-system-supplied file visibility property

### Invisible Procedure Windows Using #pragma hide

You can make a procedure file invisible by inserting this compiler directive in the file:

```
#pragma hide=1
```

This prevents the procedure window from being listed in the Windows→Procedures submenu. Procedures windows that include this compiler directive become invisible on the next compile.

You can make these windows visible during development by executing:

```
SetIgorOption IndependentModuleDev=1
```

and return them to invisible by executing:

```
SetIgorOption IndependentModuleDev=0
```

You must force a compile for this to take effect.

Prior to Igor Pro 6.30 this feature worked for #included procedure files only, not for packed and standalone procedure files.

### Invisible Procedure Windows Using Independent Modules

You can also make a set of procedure files invisible by making them an independent module. The independent module technique is more difficult to implement but has additional advantages. For details, see **The IndependentModule Pragma** on page IV-51.

### Invisible Procedure Files Using The Files Visibility Property

This section discusses making procedure files invisible by setting the operating-system-supplied file "visible" property.

**Note:** This is an old technique that is no longer recommended. It may not be supported in future versions of Igor.

When Igor opens a procedure file, it asks the operating system if the file is invisible (*Macintosh*) or hidden (*Windows*). We will use the term "invisible" to mean invisible on Macintosh and hidden on Windows.

If the file is invisible, Igor makes the file inaccessible to the user. Igor checks the invisible property only when it opens the file. It does not pay attention to whether the property is changed while the file is open.

You create Igor procedures using normal visible procedure files, typically all in a folder or hierarchy of folders. When it comes time to ship to the end user, you set the files to be invisible. If you set a file to be invisible, you should also make it read-only.

You can use the **SetFileFolderInfo** operation (see page V-722) to set the visibility and read-only properties of a file:

```
SetFileFolderInfo /INV=1 /RO=1 "<path to file>"
```

The file will be invisible in Igor the next time you open it, typically by opening an experiment or using a #include statement.

On Macintosh, the file disappears from the Finder when you execute the command.

On Windows, merely setting the hidden property is not sufficient to actually hide the file. It is actually hidden only if the Hide Files of These Types radio button in the View Options dialog is turned on. You can access this dialog by opening a folder in the Windows desktop and choosing View→Options from the folder's menu bar. Although the hidden property in Windows does not guarantee that the file will be hidden in the Windows desktop, it does guarantee that it will be hidden from within Igor.

After the files are set to be invisible and read-only, if you want to edit them in Igor, you must close them (typically by closing the open experiment), set the files to be visible and read/write again, and then open them again.

Igor's behavior is changed in the following ways for a procedure file set to invisible:

1. The window will not appear in the Windows→Procedure Windows menu.
2. Procedures in the window will not appear in the contextual pop-up menu in other procedure windows (Control-click on *Macintosh*, right-click on *Windows*).

3. If the user presses Option (*Macintosh*) or Alt (*Windows*) while choosing the name of a procedure from a menu, Igor will do nothing rather than its normal behavior of displaying the procedure window.
4. When cycling through procedure windows using Command-Shift-Option-M (*Macintosh*) or Ctrl+Shift+Alt+M (*Windows*), Igor will omit the procedure window.
5. The Button Control dialog, Pop-Up Menu Control dialog, and other control dialogs will not allow you to edit procedures in the invisible file.
6. The Edit Procedure and Debug buttons will not appear in the Macro Execute Error dialog.
7. If an error occurs in a function in the invisible file and the Debug On Error flag (Procedure menu) is on, the debugger will act as if Debug On Error were off.
8. The debugger won't allow you to step into procedures in the invisible file.
9. The **ProcedureText** function (see page V-663) and **DisplayProcedure** operation (see page V-144) will act as if procedures in the invisible file don't exist. The **MacroList** and **FunctionList** functions will, however work as usual.
10. The GetIgorProcedure and SetIgorProcedure XOPSupport routines in the XOP Toolkit will act as if procedures in the invisible file don't exist. The GetIgorProcedureList function will, however work as usual.

## Inserting Text Into a Procedure Window

On occasion, you may want to copy text from one procedure file to another. With the procedure window active, choose Edit→Insert File. This displays an Open File dialog in which you can choose a file and then inserts its contents into the procedure window.

## Adopting a Procedure File

Adoption is a way for you to copy a procedure file into the current experiment and break the connection to its original file. The reason for doing this is to make the experiment self-contained so that, if you transfer it to another computer or send it to a colleague, all of the files needed to recreate the experiment are stored in the experiment itself.

To adopt a file, open its associated window and choose File→Adopt Window. This item is available only if the active window is a notebook or procedure file that is stored separate from the current experiment and the current experiment has been saved to disk.

If the current experiment is stored in packed form then, when you adopt a file, Igor does a save-as to a temporary file. When you subsequently save the experiment, the contents of the temporary file are stored in the packed experiment file.

If the current experiment is stored in unpacked form then, when you adopt a file, Igor does a save-as to the experiment's home folder. When you subsequently save the experiment, Igor updates the experiment's recreation procedures to open the new file in the home folder instead of the original file. If you adopt a file in an unpacked experiment and then you do not save the experiment, the new file will still exist in the home folder but the experiment's recreation procedures will still refer to the original file. Thus, you should normally save the experiment soon after adopting a file.

Adoption does not cause the original file to be deleted. You can delete it from the desktop if you want.

To "unadopt" a procedure file, choose Save Procedure File As from the File menu.

It is possible to do adopt multiple files at one time. For details see **Adopt All** on page II-24.

### Auto-Compiling

If you modify a procedure window and then activate a non-procedure window other than a help window, Igor automatically compiles the procedures.

If you have a lot of procedures and compiling takes a long time, you may want to turn auto-compiling off. You can do this by deselecting the Auto-compile item in the Macros menu. This item appears only when the procedures need to be compiled (you have modified a procedure file or opened a new one). If you uncheck it item, Igor will not auto-compile and compilation will be done only when you click the Compile button or choose Compile from the Macros menu.

### Debugging Procedures

Igor includes a symbolic debugger. This is described in **The Debugger** on page IV-198.

### Finding Text

To find text in the active window, choose Edit→Find or press Command-F (*Macintosh*) or Ctrl+F (*Windows*). This displays the Find bar. See **Finding Text in the Active Window** on page II-46 for details.

To search multiple windows for text, choose Edit→Find in Multiple Windows. See **Finding Text in Multiple Windows** on page II-47 for details.

On Macintosh, you can search for the next occurrence of a string by selecting the string, pressing Command-E (Use Selection for Find in the Edit menu), and pressing Command-G (Find Same in the Edit menu).

On Windows, you can search for the next occurrence of a string by selecting the string and pressing Ctrl+H (Find Selection in the Edit menu).

After doing a find, you can search for the same text again by pressing Command-G (*Macintosh*) or Ctrl+G (*Windows*) (Find Same in the Edit menu). You can search for the same text but in the reverse direction by pressing Command-Shift-G (*Macintosh*) or Shift+Ctrl+G (*Windows*).

You can search back and forth through a procedure window by repeatedly pressing Command-G and Command-Shift-G (*Macintosh*) or Ctrl+G and Shift-Ctrl+G (*Windows*).

### Replacing Text

To replace text in the active window, press Command-R (*Macintosh*) or Ctrl+R (*Windows*). This displays the Find bar in replace mode. See **Find and Replace** on page II-46 for details.

The Search Selected Text Only option is handy for limiting the replacement to a particular procedure.

While replacing text is undoable, the potential for unintended and wide-ranging consequences is such that we recommend saving the file before doing a mass replace so you can revert-to-saved if necessary.

Another method for searching and replacing consists of repeating Command-F or Ctrl-F (Find) followed by Command-V or Ctrl-V (Paste). This has the virtue of allowing you to inspect each occurrence of the target text before replacing it.

### Printing Procedure Text

To print the active procedure window, first deselect all text and then choose File→Print Procedure Window.

To print part of the active procedure window, select the text you want to print and choose File→Print Procedure Selection.

## Indentation

We use indentation to indicate the structure of a procedure. This is described in **Indentation Conventions** on page IV-24.

To make it easy to use the indentation conventions, Igor maintains indentation when you press Return or Enter in a procedure window. It automatically inserts enough tabs in the new line to have the same indentation as the previous line.

To indent more, as when going into the body of a loop, press Return or Enter and then Tab. To indent less, as when leaving the body of a loop, press Return or Enter and then Delete. When you don't want to change the level of indentation, just press Return.

Included in the Edit menu for Procedure windows, is the Adjust Indentation item, which adjusts indentation of all selected lines of text to match Igor standards. The Edit menu also contains Indent Left and Indent Right commands that add or remove indentation for all selected lines.

## Document Settings

The Document Settings dialog controls settings that affect the procedure window as a whole. You can summon it via the Procedure menu.

Igor does not store document settings for plain text files. When you open a procedure file, these settings are determined by preferences. You can capture preferences by choosing Procedure→Capture Procedure Prefs.

## Text Format Settings

You can specify the font, text size, style and color using items in the Procedure menu. Since procedure windows are always plain text windows (as opposed to notebooks, which can be formatted text) these text settings are the same for all characters in the window.

Igor does not store text format settings for plain text files. When you open a procedure file, these settings are determined by preferences. You can capture preferences by choosing Procedure→Capture Procedure Prefs.

## Syntax Coloring

Procedure windows and the command window colorize comments, literal strings, flow control, and other syntax elements. Colors of various elements can be adjusted in two ways.

The first is from the Miscellaneous Settings dialog. Select the Text Editing category and then select the Editor Behavior tab.

The second is by executing the following **SetIgorOption** colorize commands::

Command	Effect
<code>SetIgorOption colorize,doColorize=&lt;1 or 0&gt;</code>	Turn all colorize on or off
<code>SetIgorOption colorize,OpsColorized=&lt;1 or 0&gt;</code>	Turn operation keyword colorization on or off
<code>SetIgorOption colorize,BIFuncsColorized=&lt;1 or 0&gt;</code>	Turn function keyword colorization on or off
<code>SetIgorOption colorize,keywordColor=(r,g,b[,a])</code>	Color for language keywords
<code>SetIgorOption colorize,commentColor=(r,g,b[,a])</code>	Color for comments
<code>SetIgorOption colorize,stringColor=(r,g,b[,a])</code>	Color for strings

Command	Effect
<code>SetIgorOption colorize,operationColor=(r,g,b[,a])</code>	Color for operation keywords
<code>SetIgorOption colorize,functionColor=(r,g,b[,a])</code>	Color for built-in function keywords
<code>SetIgorOption colorize,poundColor=(r,g,b[,a])</code>	Color for #keywords such as #pragma
<code>SetIgorOption colorize,UserFuncsColorized=1</code>	Turn colorizing on for user functions
<code>SetIgorOption colorize,userFunctionColor=(r,g,b[,a])</code>	Color for user-defined functions

Values for *r*, *g*, *b*, and the optional alpha range from 0 to 65535. Alpha defaults to 65535 (opaque).

Changes to syntax coloring settings, made via the dialog or via `SetIgorOption`, are saved to preferences and used for future sessions.

## Procedure Window Preferences

The procedure window preferences affect the creation of *new* procedure windows. This includes the creation of auxiliary procedure windows and the initialization of the built-in procedure window that occurs when you create a new experiment.

To set procedure preferences, set the attributes of any procedure window and then choose Procedure→Capture Procedure Prefs.

To determine the current preference settings, you must create a new procedure window and examine its settings.

Preferences are stored in the Igor Preferences file. See Chapter III-18, **Preferences**, for further information on preferences.

## Double and Triple-Clicking

Double-clicking a word conventionally selects the entire word. Igor extends this idea a bit. In addition to supporting double-clicking, if you triple-click in a line of text, it selects the entire line. If you drag after triple-clicking, it extends the selection an entire line at a time.

## Matching Characters

Igor includes a handy feature to help you check parenthesized expressions. If you double-click a parenthesis, Igor tries to find a matching parenthesis on the same line of text. If it succeeds, it selects all of the text between the parentheses. If it fails, it beeps. Consider the command

```
wave1 = exp(log(x))
```

If you double-clicked on the first parenthesis, it would select “log(x)”. If you double-clicked on the last parenthesis, it would beep because there is no matching parenthesis.

If you double-click in-between adjacent parentheses Igor considers this a click on the outside parenthesis.

Igor does matching if you double-click the following characters:

Left and right parentheses	(xxx)
Left and right brackets	[xxx]
Left and right braces	{xxx}
Plain single quotes	'xxx'
Plain double quotes	"xxx"

---

## Code Comments

The Edit menu for procedures contains two items, Commentize and Decommentize, to help you edit and debug your procedure code when you want to comment out large blocks of code, and later, to remove these comments. Commentize inserts comment symbol at the start of each selected line of text. Decommentize deletes any comment symbols found at beginning of each selected line of text.

## Procedure File Text Encodings

Igor Pro 7 uses Unicode internally. Older versions of Igor used non-Unicode text encodings such as Mac-Roman, Windows-1252 and Shift JIS.

Igor Pro 7 must convert from the old text encodings to Unicode when opening old files. It is not always possible to get this conversion right. You may get incorrect characters or receive errors when opening files containing non-ASCII text.

For a discussion of these issues, see **Text Encodings** on page III-409 and **Plain Text File Text Encodings** on page III-417.

## Procedure Window Shortcuts

To view text window keyboard navigation shortcuts, see **Text Window Navigation** on page II-45.

Action	Shortcut (Macintosh)	Shortcut (Windows)
To show the built-in procedure window	Press Command-M.	Press Ctrl+M.
To hide the active procedure file and cycle to the next	Press Command-Shift-Option-M.	Press Ctrl+Shift+Alt+M.
To cycle through the open procedure windows	Press Command-Option-M.	Press Ctrl+Alt+M.
To get a contextual menu of commonly-used actions	Press Control and click in the body of the procedure window.	Right-click the body of the procedure window.
To execute commands in a procedure window	Select the commands or click in the line containing the commands and press Control-Return or Control-Enter.	Select the commands or click in the line containing the commands and press Ctrl+Enter.
To insert a template	Type or select the name of an operation, Control-click, and choose Insert Template.	Type or select the name of an operation, right-click, and choose Insert Template.
To get help for a built-in or external operation or function	Type or select the name of an operation, Control-click, and choose Help for <name>.	Type or select the name of an operation, right-click, and choose Help for <name>.
To view the definition of a user-defined function	Type or select the name of an operation, Control-click, and choose Go to <name>.	Type or select the name of an operation, right-click, and choose Go to <name>.
To find a procedure in the active procedure window	Click the navigation bar at the top of the procedure window.	Click the navigation bar at the top of the procedure window.
To find the definition of a procedure when you have selected an invocation of it	Control-click the selected invocation and choose "Go to <procedure name>" from the resulting contextual menu.	Right-click the selected invocation and choose "Go to <procedure name>" from the resulting contextual menu.
To find in the procedure window	Press Command-F.	Press Ctrl+F.
To find the same text again	Press Command-G.	Press Ctrl+G.
To find again but in the reverse direction	Press Command-Shift-G.	Press Ctrl+Shift+G.
To find the selected text	Press Command-E and Command-G.	Press Ctrl+H.
To find the selected text but in the reverse direction	Press Command-E and Command-Shift-G.  This shortcut can be changed through the Miscellaneous Settings dialog.	Press Ctrl+Shift+H.

<b>Action</b>	<b>Shortcut (<i>Macintosh</i>)</b>	<b>Shortcut (<i>Windows</i>)</b>
To find a user-defined menu's procedure	Open any procedure window and press Option while selecting a user-defined menu item.	Open any procedure window and press Alt while selecting the user-defined menu item.
To select a word	Double-click.	Double-click.
To select an entire line	Triple-click.	Triple-click.

## Overview

We use the term *controls* for a number of user-programmable objects that can be employed by Igor programmers to create a graphical user interface for Igor users. We call them *controls* even though some of the objects only display values. The term *widgets* is sometimes used by other application programs.

Here is a summary of the types of controls available.

Control Type	Control Description
Button	Calls a procedure that the programmer has written.
Chart	Emulates a mechanical chart recorder. Charts can be used to monitor data acquisition processes or to examine a long data record. Programming a chart is quite involved.
CheckBox	Sets an off/on value for use by the programmer's procedures.
CustomControl	Custom control type. Completely specified and modified by the programmer.
GroupBox	An organizational element. Groups controls with a box or line.
ListBox	Lists items for viewing or selecting.
PopupMenu	Used by the user to choose a value for use by the programmer's procedures.
SetVariable	Sets and displays a numeric or string global variable. The user can set the variable by clicking or typing. For numeric variables, the control can include up/down buttons for incrementing/decrementing the value stored in the variable.
Slider	Duplicates the behavior of a mechanical slider. Selects either discrete or continuous values.
TabControl	Selects between groups of controls in complex panels.
TitleBox	An organizational element. Provides explanatory text or message.
ValDisplay	Presents a readout of a numeric expression which usually references a global variable. The readout can be in the form of numeric text or a thermometer bar or both.

The programmer can specify a procedure to be called when the user clicks on or types into a control. This is called the control's *action procedure*. For example, the action procedure for a button may interrogate values in PopUpMenu, Checkbox, and SetVariable controls and then perform some action.

Control panels are simple windows that contain these controls. These windows have no other purpose. You can also place controls in graph windows and in panel panes embedded into graphs. Controls are not available in any other window type such as tables, notebooks, or layouts. When used in graphs, controls are not considered part of the *presentation* and thus are **not** included when a graph is printed or exported.

Nonprogrammers will want to skim only the Modes of Operation and Using Controls sections, and skip the remainder of the chapter. Igor programmers should study the entire chapter.

## Modes of Operation

With respect to controls, there are two modes of operation: one mode to use the control and another to modify it. To see this, choose Show Tools from the Graph or Panel menu. Two icons will appear in the top-left corner window. When the top icon is selected, you are able to use the controls. When the next icon is selected, the draw tool palette appears below the second icon. To modify the control, select the arrow tool from the draw tool palette.

When the top icon is selected or when the icons are hidden, you are in the *use* or *operate* mode. You can momentarily switch to the *modify* or *draw* mode by pressing Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*). Use this to drag or resize a control as well as to double-click it. Double-clicking with the Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*) pressed brings up a dialog that you use to modify the control.

## Chapter III-14 — Controls and Control Panels

You can also switch to modify mode by choosing an item from the Select Control submenu of the Graph or Panel menu.

**Important:** To enable the Add Controls submenu in the Graph and Panel menus, you must be in modify mode; either by clicking the second icon or by pressing Command-Option (*Macintosh*) or the Ctrl+Alt (*Windows*) while choosing the Add Controls submenu.

## Using Controls

The following panel window illustrates most of the control types.

## Buttons

When you click a button, it runs whatever procedure the programmer may have specified.

If nothing happens when you click a button, then there is no procedure assigned to the button. If the procedure window(s) haven't been compiled, clicking a button that has an assigned procedure will produce an error dialog.

You should choose Compile from the Macros menu to correct this situation. If no error occurs then the button will now be functional.

Buttons usually have a rounded appearance, but a programmer can assign a custom picture so that the button can have nearly any appearance.

## Charts

Chart controls can be used to emulate a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. Charts can be used to monitor data acquisition processes or to examine a long data record.

For further discussion of using chart controls, see **Using Chart Recorder Controls** on page IV-296.

Although programming a chart is quite involved, using a chart is actually very easy. See **FIFOs and Charts** on page IV-291 for details.

## Checkboxes

Clicking a checkbox changes its selected state and may run a procedure if the programmer specified one. A checkbox may be connected to a global variable. Checkboxes can be configured to look and behave like radio buttons.

## CustomControl

CustomControls are used to create completely new types of controls that are custom-made by the programmer. You can define and control the appearance and all aspects of a custom control's behavior. See **Creating Custom Controls** on page III-377 for examples.

## GroupBox

GroupBox controls are organizational or decorative elements. They are used to graphically group sets of controls. They may either draw a box or a separator line and can have optional titles.

## ListBox

ListBox controls can present a single or multiple column list of items for viewing or selection. ListBoxes can be configured for a variety of selection modes. Items in the list can be made editable and can be configured as checkboxes.

Col0	Col1
row 0, col 0	row 0, col 1
row 1, col 0	row 1, col 1
row 2, col 0	new value
<input type="checkbox"/> row 3, col 0	row 3, col 1
<input checked="" type="checkbox"/> row 4, col 0	row 4, col 1
row 5, col 0	row 5, col 1

## Pop-Up Menus

These controls come in two forms: one where the current item is shown in the pop-up menu box:

and another where there is no current item and a title is shown in the box:

The first form is usually used to choose one of many items while the second is used to run one of many commands.

Pop-up menus can also be configured to act like Igor's color, line style, pattern, or marker pop-up menus. These always show the current item.

### SetVariable

SetVariable controls also can take on a number of forms and can display numeric values. Unlike Value Display controls that display the value of an expression, SetVariable controls are connected to individual global variables and can be used to set or change those variables in addition to reading out their current value. SetVariable controls can also be used with global string variables to display or set short one line strings. SetVariable controls are automatically updated whenever their associated variables are changed.

When connected to a numeric variable, these controls can optionally have up or down arrows that increment or decrement the current value of the variable by an amount specified by the programmer. Also, the programmer can set upper and lower limits for the numeric readouts.

New values for both numeric and string variables can be entered by directly typing into the control. If you click the control once you will see a thick border form around the current value.

You can then edit the readout text using the standard techniques including Cut, Copy, and Paste. If you want to discard changes you have made, press Escape. To accept changes, press Return, Enter, or Tab or click anywhere outside of the control. Tab enters the current value and also takes you to the next control if any. Shift-Tab is similar but takes you to the previous control if any.

If the control is connected to a numeric variable and the text you have entered can not be converted to a number then a beep will be emitted when you try to enter the value and no change will be made to the value of the variable. If the value you are trying to enter exceeds the limits set by the programmer then your value will be replaced by the nearest limit.

When a numeric control is selected for editing, the Up and Down Arrow keys on the keyboard act like the up and down buttons on the control.

Changing a value in a SetVariable control may run a procedure if the programmer has specified one.

### SetVariable Controls and Data Folders

SetVariable controls remember the data folder in which the variable exists, and continue to function properly when the current data folder is different than the controlled variable. See **SetVariable** on page III-370.

The system variables (K0 through K19) belong to no particular data folder (they are available from any data folder), and there is only *one* copy of these variables. If you create a SetVariable controlling K0 while the current data folder is "aFolder", and another SetVariable controlling K0 while the current data folder is "bFolder", *they are actually controlling the same K0*.

## Sliders

Slider controls can be used to graphically select either discrete or continuous values. When used to select discrete values, a slider is similar to a pop-up menu or a set of radio buttons. Sliders can be live, updating a variable or running a procedure as the user drags the slider, or they can be configured to wait until the user finishes before performing any action.

## TabControl

TabControl controls are used to create complex panels containing many more controls than would otherwise fit. When the user clicks on a tab, the programmer's procedure runs and hides the previous set of controls while showing the new set.

## TitleBox

TitleBox controls are mainly decorative elements. They are used to provide explanatory text in a control panel. They may also be used to display textual results. The text can be unchanging, or can be the contents of a global string variable. In either case, the user can't inadvertently change the text.

## ValDisplays

ValDisplay controls display numeric or string values in a variety of forms ranging from a simple numeric readout to a thermometer bar. Regardless of the form, ValDisplays are just readouts. There is no interaction with the user. They display the current value of whatever expression the programmer specified. Often this will be just the value of a numeric variable, but it can be any numeric expression including calls to user-defined functions and external functions.

Here is a sampling of the forms that ValDisplay controls can assume.

When a thermometer bar is shown, the left edge of the thermometer region represents a low limit set by the programmer while the right edge represents a high limit. The low and high limits appear in some of the above examples. The bar is drawn from a nominal value set by the programmer and will be red if the current value exceeds the nominal value and will be blue if it is less than the nominal value. In the above

examples the nominal value is 60. There is no numeric indication of the nominal value. If the nominal value is less than the low limit then the bar will grow from the left to the right. If the nominal value is greater than the high limit then the bar will grow from the right to the left.

If you carefully observe a thermometer bar that is connected to an expression whose value is slowly changing with time you will see that the bar is drawn in a zig-zag fashion. This provides a much finer resolution than if the bar were to be extended or contracted by an entire column of screen pixels at once.

## Creating Controls

The ease of creating the various controls varies widely. Anyone capable of writing a simple procedure can create buttons and checkboxes, but creating charts and custom controls requires more expertise. Most controls can be created and modified using dialogs that you invoke via the Add Controls submenu in the Graph or Panel menu.

The Add Controls and Select Control menus are enabled only when the arrow tool in the tool palette is selected. To do this, choose Show Tools from the Graph or Panel menu and then click the second icon from the top in the graph or panel tool palette.

You can temporarily use the arrow tool without the tool palette showing by pressing Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*). While you press these keys, the normally-disabled Add Controls and Select Control submenus are enabled.

When you click a control with the arrow tool, small handles are drawn that allow you to resize the control. Note that some controls can not be resized in this way and some can only be resized in one dimension. You will know this when you try to resize a control and it doesn't budge. You can also use the arrow tool to reposition a control. You can select a control by name with the Select Control submenu in the Graph or Panel menu.

With the arrow tool, you can double-click most controls to get a dialog that modifies or duplicates the control. Charts and CustomControls do not have dialog support.

When you right-click (*Windows*) or Control-click (*Macintosh*) a control, you get a contextual menu that varies depending on the type of control.

You can select multiple controls, mix selections with drawing objects, and perform operations such as move, cut, copy, paste, delete, and align. These operations are undoable. You can't group buttons or use Send to Back as you can with drawing objects.

In panels, when you do a Select All, the selection includes all controls and drawing objects, but in the case of graphs, only drawing objects are selected. This is because drawing objects in graphs are used for presentation graphics whereas in panels they are used to construct the user interface.

If you want to copy controls from one window to another, simply use the Edit menu to copy and paste. You can also duplicate controls using copy and paste.

When you copy controls to the clipboard, the command and control names are also copied as text. This is handy for programming.

Press Option (*Macintosh*) or Alt (*Windows*) while choosing Edit-Copy to copy the complete commands for creating the copied controls.

If you copy a control from the extreme right side or bottom of a window, it may not be visible when you paste it into a smaller window. Use the smaller window's Retrieve submenu in the Mover tool palette icon to make it visible.

## General Command Syntax

All of the control commands use the following general syntax:

```
ControlOperation Name [,keyword[=value] [,keyword[=value]]...]
```

*Name* is the control's name. It must be unique among controls in the window containing the control. If *Name* is not already in use then a new control is created. If a control with the same name already exists then that control is modified, so that multiple commands using the same name result in only one control. This is useful for creating controls that require many keywords.

All keywords are optional. Not all controls accept all keywords, and some controls accept a keyword but do not actually use the value. The value for a keyword with one control can have a different form from the value for the same keyword used with a different type of control. See the specific control operation documentation in Chapter V-1, **Igor Reference** for details.

Some controls utilize a format keyword to set a format string. The format string can be any printf-style format that expects a single numeric value. Think of the output as being the result of the following command:

```
Printf formatString, value_being_displayed
```

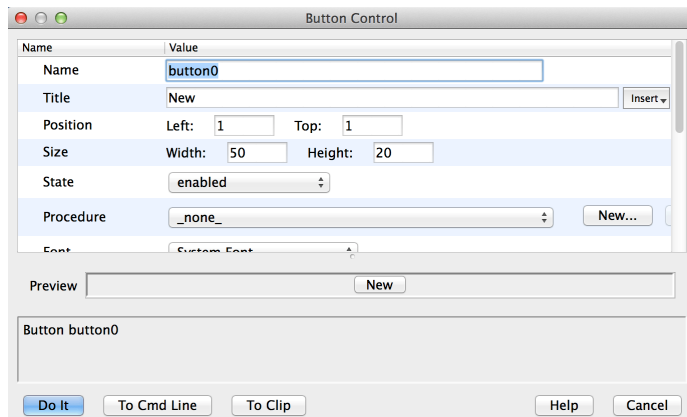

See the **printf** operation on page V-654 for a discussion of printf format strings. The maximum length of the format string is 63 bytes. The format is used only for controls that display numeric values.

All of the clickable controls can optionally call a user-defined function when the user releases the mouse button. We use the term *action procedure* for such a function. Each control passes one or more parameters to the action procedure. The dialogs for each control can create a blank user function with the correct parameters.

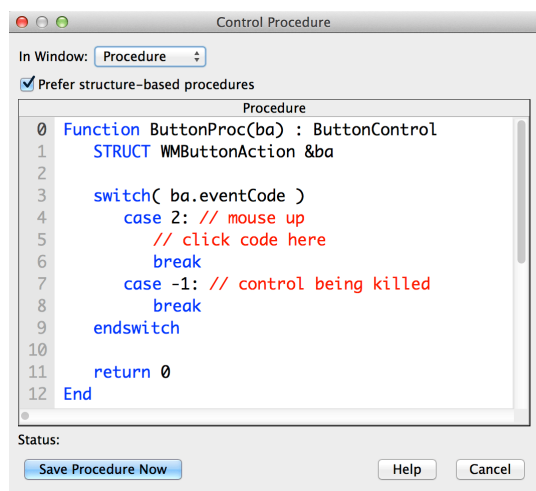

## Creating Button Controls

The **Button** operation (page V-45) creates or modifies a rounded-edge or custom button with the title text centered in the button. The default font depends on the operating system, but you can change the font, font size, text color and use annotation-like escape codes (see **Annotation Escape Codes** on page III-53). The amount of text does not change the button size, which you can set to what you want.

Here we create a simple button that will just emit a beep when pressed. Start by choosing the Add Button menu item in the Graph or Panel menu to invoke the Button Control dialog:

Clicking the procedure's New button brings up a dialog containing a procedure template that you can edit, rename, and save. Here we started with the standard ButtonControl template, replaced the default name with MyBeepProc, and added the Beep command:

The controls can work with procedures using two formats: the old procedure format used in Igor 3 and 4, and the “structure-based” format introduced in Igor 5.

Selecting the “Prefer structure-based procedures” checkbox creates new procedure templates using the structure-based format.

The “Prefer structure-based procedures” checkbox is checked by default because structure-based procedures are recommended for all new code. If you uncheck this checkbox before editing the template, Igor switches the template to the old procedure format. Use of the old format is discouraged.

Click Help to get help about the Button operation. In the Details section of the help, you can find information about the WMBUTTONACTION structure.

The fact that you can create the action procedure for a control in a dialog may lead you to believe that the procedure is stored with the button. This is not true. The procedure is actually stored in a procedure window. This way you can use the same action procedure for several controls. The parameters which are passed to a given procedure can be used to differentiate the individual controls.

For more information on using action procedures, see **Control Structures** on page III-388, the **Button** operation (page V-45), and **Using Structures with Windows and Controls** on page IV-95.

### Button Example

Here is how to make a button whose title alternates between Start and Stop.

Enter the following in the procedure window:

```
Function MyStartProc()
  Print "Start"
End
```

```
Function MyStopProc()
  Print "Stop"
End
```

```
Function StartStopButton(ba) : ButtonControl
  STRUCT WMBUTTONACTION &ba

  switch(ba.eventCode)
    case 2: // Mouse up
      if (CmpStr(ba.ctrlName,"bStart") == 0)
        Button $ba.ctrlName,title="Stop",rename=bStop
        MyStartProc()
      else
```

```

        Button $ba.ctrlName,title="Start",rename=bStart
        MyStopProc()
    endif
    break
endswitch

    return 0
End

```

Now execute:

```

NewPanel
Button bStart,size={50,20},proc=StartStopButton,title="Start"

```

### Custom Button Control Example

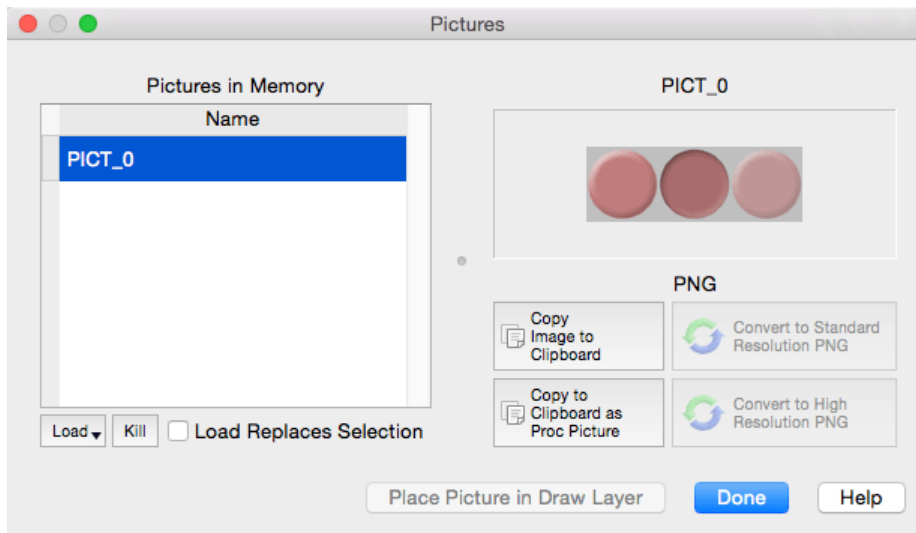

You can create custom buttons by following these steps:

1. Using a graphics-editing program, create a picture that shows the button in its normal ("relaxed") state, then in the pressed-in state, and then in the disabled state. Each portion of the picture should be the same size:

If the button blends into the background it will look better if the buttons are created on the background you will use in the panel. Igor looks at the pixels in the upper left corner, and if they are a light neutral color, Igor omits those pixels when the button is drawn.

2. Copy the picture to the clipboard.
3. Switch to Igor, choose Misc→Pictures, click Load and then From Clipboard.

4. Click Copy to Clipboard as Proc Picture to create Proc Picture text on the Clipboard.
5. Click Done.
6. Open a procedure window, paste the text, and give a suitable name to the picture:

```
// PNG: width= 144, height= 50
Picture friendlyRedButton|
  ASCII85Begin
  M,6r;%14!\!!!!.80u6I!!!!\!!!!S#Qau+!'Kbi$31&+&TgHDFAm*!
  =U&[k8!5u`*!m9JIC)qV?eR<-Y+5=JG6AQa%_a#2kpD,?lWP!0RSdD!
  DQ.J`Nh%0'Zo/okKM_:fj.L]j@H`#huXcI"H)!r%d,c,B?klUrq3IEI
  'c:.1&+0@?Tk9'g++@8ZJCq"m.Q52l!aC',!,qq(fna$p&gK2*N0--
```

7. Activate an existing control panel or create a new one.
8. If the tool palette is not showing, choose Panel→Show Tools.
9. Choose Panel-Add Control→Add Button to display the Button Control dialog.
10. Locate the Picture setting in the dialog, check the checkbox, and select the proc picture from the pop-up menu:

11. Locate the Size setting in the dialog and set the appropriate size for the button:

### Creating Chart Controls

The **Chart** operation creates or modifies a chart control. There is no dialog support for chart controls. You need at least intermediate-level Igor programming skills to create a functional chart control.

For further information, see **FIFOs and Charts** on page IV-291.

### Creating Checkbox Controls

The **CheckBox** creates or modifies a checkbox or a radio button.

CheckBox controls automatically size themselves in both height and width. They can optionally be connected to a global variable.

For an example of using checkbox controls as radio buttons, see the reference documentation for the **CheckBox** operation.

The user-defined action procedure that you will need to write for CheckBoxes must have the following form:

```
Function CheckProc(cba) : CheckBoxControl
    STRUCT WMCheckboxAction &cba

    switch(cba.eventCode)
        case 2:                // Mouse up
            Variable checked = cba.checked
            break
        case -1:               // Control being killed
            break
    endswitch

    return 0
End
```

The checked structure member is set to the new checkbox value; 0 or 1.

You often do not need an action procedure for a checkbox because you can read the state of the checkbox with the **ControlInfo** operation.

You can create custom checkboxes by following steps similar to those for custom buttons (see **Custom Button Control Example** on page III-375), except that the picture has six states side-by-side instead of three. The checkbox states are:

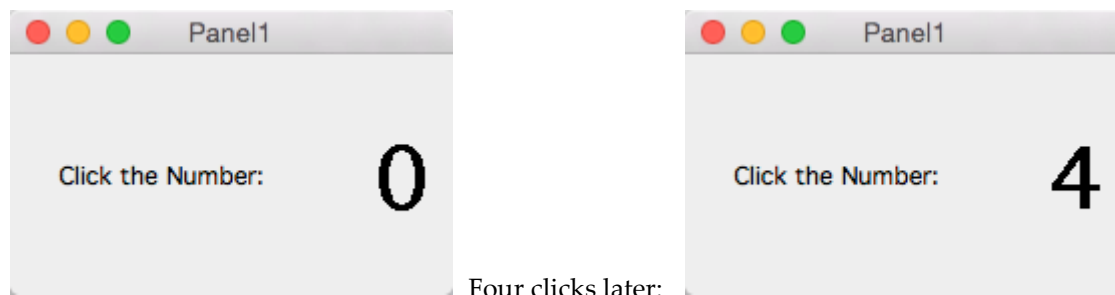

Image Order	Control State
Left	Deselected enabled.
	Deselected enabled and clicked down (about to be selected).
	Deselected disabled.
	Selected enabled.
	Selected enabled and clicked down (about to be deselected).
	Selected disabled.
Right	

## Creating Custom Controls

The CustomControl operation creates or modifies a custom control, all aspects of which are completely defined by the programmer. See the **CustomControl** operation on page V-115 for a complete description.

The examples in this section are also available in the Custom Controls demo experiment. Choose File→Example Experiments→Feature Demos 2→Custom Control Demo.

What you can create with a CustomControl can be fairly simple such as this counter that increments when you click on it.

The following code implements the counter custom control using the kCCE\_frame event. In the panel, click on the number to increment the counter; also try clicking and then dragging outside the control.

```
static constant kCCE_mouseup= 2
static constant kCCE_frame= 12
```

## Chapter III-14 — Controls and Control Panels

```
// PNG: width= 280, height= 49

EndMacro
```

You can create even more sophisticated controls, such as this voltage meter control.

Choose File→Example Experiments→Feature Demos 2→Custom Control Demo to try this control and see the code that implements it.

## Creating GroupBox Controls

The **GroupBox** operation creates or modifies a listbox control. See the **GroupBox** operation on page V-290 for a complete description and examples.

## Creating ListBox Controls

The **ListBox** operation creates or modifies a listbox control.

We will illustrate listbox creation by example.

1. Create a panel with a listbox control:

```
NewPanel
ListBox list0 size={200,60}, mode=1
```

The simplest functional listbox needs at least one text wave to contain the list items. Without the text wave, a listbox control has no list items. In this state, the listbox is drawn with a red X over the control.

2. We need a text wave to contain the list items:

```
Make/O/T textWave0 = {"first list item", "second list item", "etc..."}
```

3. Choose Panel→Show Tools.

This puts the panel in edit mode so you can modify controls.

4. Double-click the listbox control to invoke the ListBox Control dialog.
5. For the List Text Wave property, select the wave you created to assign it as the list's text wave.
6. Click Do It.

You now have a functional listbox control.

7. Click the operate (top) icon, or choose Panel→Hide Tools, so you can use, rather than edit, the list.

In this example, we created a single-selection list. You can query the selection by calling **ControlInfo** and checking the **V\_Value** output variable.

See the **ListBox** for a complete description and further examples.

Right-clicking (*Windows*) or Control-clicking (*Macintosh*) a listbox shows a contextual menu with commands for editing the list waves and action procedure, and for creating a numeric selection wave, if the control is a multi-selection listbox.

## Creating PopupMenu Controls

The **PopupMenu** creates or modifies a pop-up menu control. Pop-up menus are usually used to provide a choice of text items but can also present colors, line styles, patterns, and markers.

The control automatically sizes itself as a function of the title or the currently selected menu item. You can specify the **bodyWidth** keyword to force the body (non-title portion) of the pop-up menu to be a fixed size. You might do this to get a set of pop-up menus of nicely aligned with equal width. The **bodywidth** keyword also affects the non-text pop-up menus.

The **font** and **fsize** keywords affect only the title of a pop-up menu. The pop-up menu itself uses standard system fonts.

Unlike color, line style, pattern, or marker pop-up menus, text pop-up menu controls can operate in two distinct modes as set by the **mode** keyword's value.

If the argument to the **mode** keyword is nonzero then it is considered to be the number of the menu item to be the initial current item *and* displays the current item in the pop-up menu box. This is the *selector mode*. There is often no need for an action procedure since the value of the current item can be read at any time using the **ControlInfo** operation (page V-75).

## Chapter III-14 — Controls and Control Panels

---

If mode is zero then the title appears inside the pop-up menu box, hence the name *title-in-box mode*. This mode is generally used to select a command for the action procedure to execute. The current item has no meaning except when the pop-up menu is activated and the selected item is passed to the action procedure.

The menu that pops up when the control is clicked is determined by a string expression that you pass as the argument to the value keyword. For example:

```
PopupMenu name value="Item 1;Item 2;Item 3;"
```

To create the color, line style, pattern or marker pop-up menus, set the string expression to one of these fixed values:

```
"*COLORPOP*"
"*LINESTYLEPOP*"
"*MARKERPOP*"
"*PATTERNPOP*"
```

For text pop-up menus, the string expression must evaluate to a list of items separated by semicolons. This can be a fixed literal string or a dynamically-calculated string. For example:

```
PopupMenu name value="Item 1;Item 2;Item 3;"
PopupMenu name value="_none_" + WaveList(";", ";", "")
```

It is possible to apply certain special effects to the menu items, such as disabling an item or marking an item with a check. See **Special Characters in Menu Item Strings** on page IV-125 for details.

The literal text of the string expression is stored with the control rather than the results of the evaluation of the expression. Igor evaluates the expression when the PopupMenu value=<value> command runs and reevaluates it every time the user clicks on the pop-up menu box. This reevaluation ensures that dynamic menus, such as created by the WaveList example above, reflect the conditions at click time rather than the conditions that were in effect when the PopupMenu control was created.

When the user clicks and Igor reevaluates the string expression, the procedure that created the pop-up menu is no longer running. Consequently, its local variables no longer exist, so the string expression can not reference them. To incorporate the value of local variables in the value expression use the **Execute** operation:

```
String str = <code that generates item list>    // str is a local variable
Execute "PopupMenu name value=" + str
```

Igor evaluates the string expression as if it were typed on the command line. You can not know what the current data folder will be when the user clicks the pop-up menu. Consequently, if you want to refer to objects in specific data folders, you must use full paths. For example:

```
PopupMenu name value="#func(root:DF234:wave0, root:gVar)"
```

Because of click-time reevaluation, the pop-up menu does not automatically update if the value of the string expression changes. Normally this is not a problem, but you can use the **ControlUpdate** operation (page V-80) to force the pop-up menu to update. Here is an example:

```
NewPanel/N=PanelX
String/G gPopupMenu="First;Second;Third"
PopupMenu oneOfThree value=gPopupMenu    // pop-up shows "First"
gPopupMenu="1;2;3"                      // pop-up is unchanged
ControlUpdate/W=PanelX oneOfThree        // pop-up shows "1"
```

If the string expression can not be evaluated at the time the command is compiled, you can defer the evaluation of the expression by enclosing the value this way:

In some cases, the string expression can not be compiled at the time the PopupMenu command is compiled because it references a global object that does not yet exist. In this case, you can prevent a compile-time error by using this special syntax:

```
PopupMenu name value= #"pathToNonExistentGlobalString"
```

If a deferred expression has quotes in it, they need to be escaped with backslashes:

```
PopupMenu name value= #"\"_none_\";\"+UserFunc(\"foo\")"
```

The optional user defined action procedure is called after the user makes a selection from the popup menu. Popup menu procedures have the following form:

```
Function PopMenuProc(pa) : PopupMenuControl
    STRUCT WMPopupAction pa

    switch(pa.eventCode)
        case 2:          // Mouse up
            Variable popNum = pa.popNum          // 1-based item number
            String popStr = pa.popStr             // Text of selected item
            break
        case -1:         // Control being killed
            break
    endswitch
End
```

`pa.popNum` is the item number, *starting from one*, and `pa.popStr` is the text of the selected item.

For the color pop-up menus the easiest way to determine the selected color is to use the **ControlInfo**.

## Creating SetVariable Controls

The **SetVariable** operation (page V-730) creates or modifies a SetVariable control. SetVariable controls are useful for both viewing and setting values.

SetVariable controls are tied to numeric or string global variables, to a single element of a wave, or to an internal value stored in the control itself. To minimize clutter, you should use internal values in most cases.

When used with numeric variables, Igor draws up and down arrows that the user can use to increment or decrement the value.

You can set the width of the control but the height is determined from the font and font size. The width of the readout area is the width of the control less the width of the title and up/down arrows. However, you can use the `bodyWidth` keyword to specify a fixed width for the body (nontitle) portion of the control.

For example, executing the commands:

```
Variable/G globalVar=99
SetVariable setvar0 size={120,20},frame=1,font="Helvetica", value=globalVar
```

creates the following SetVariable control: 

To associate a SetVariable control with a variable that is not in the current data folder at the time SetVariable runs, you must use a data folder path:

```
Variable/G root:Packages:ImagePack:globalVar=99
SetVariable setvar0 value=root:Packages:ImagePack:globalVar
```

Unlike PopupMenu controls, SetVariable controls remember the current data folder when the SetVariable command executes. Thus an equivalent set of commands is:

```
SetDataFolder root:Packages:ImagePack
Variable/G globalVar=99
SetVariable setvar0 value=globalVar
```

Also see **SetVariable Controls and Data Folders** on page III-370.

You can control the style of the numeric readout via the format keyword. For example, the string `"%.2d"` will display the value with 2 digits past the decimal point. You should not use the format string to include text in the readout because Igor has to read back the numeric value. You may be able to add suffixes to the readout but prefixes will not work. When used with string variables the format string is not used.

## Chapter III-14 — Controls and Control Panels

---

Often it is sufficient to query the value using **ControlInfo** and you there is no need for an action procedure. If you want to do something every time the value is changed, then you need to create an action procedure of the following form:

```
Function SetVarProc(sva) : SetVariableControl
    STRUCT WMSetVariableAction sva

    switch(sva.eventCode)
        case 1:                // Mouse up
        case 2:                // Enter key
        case 3:                // Live update
            Variable dval = sva.dval
            String sval = sva.sval
            break
        break
        case -1:               // Control being killed
            break
    endswitch

End
```

varName will be the name of the variable being used. If the variable is a string variable then varStr will contain its contents and varNum will be set to the results of an attempt to convert the string to a number. If the variable is numeric then varNum will contain its contents and varStr will be set to the results of a number to string conversion.

If the value is a string, then sva.sval contains the value. If it is numeric, then sva.dval contains the value. sva.isStr is 0 for numeric values and non-zero for string values.

When the user presses and holds in the up or down arrows then the value of the variable will be steadily changed by the increment value but your action procedure will not be called until the user releases the mouse button.

### Creating Slider Controls

The **Slider** creates or modifies a slider control.

A slider control is tied to a numeric global variables or to a numeric internal value stored in the control itself. To minimize clutter, you should use internal values in most cases. The value is changed by dragging the “thumb” part of the control.

There are many options for labelling the numeric range such as setting the number of ticks.

You can also provide custom labels in two waves, one numeric and another providing the corresponding text label. For example:

```
NewPanel
Make/O tickNumbers= {0,25,60,100}
Make/O/T tickLabels= {"Off","Slow","Medium","Fast"}
Slider speed,pos={86,28},size={74,73}
Slider speed,limits={0,100,0},value= 40
Slider speed,userTicks={tickNumbers,tickLabels}
```

Often it is sufficient to query the value using **ControlInfo** and you there is no need for an action procedure. If you want to do something every time the value is changed, then you need to create an action procedure.

Igor calls the action procedure when the user drags the thumb, when the user clicks the thumb, and when a procedure modifies the slider’s global variable, if any.

See the **Slider** operation on page V-746 for a complete description and more examples.

## Creating TabControl Controls

The **TabControl** creates or modifies a TabControl control. Tabs are used to group controls into visible and hidden groups.

The tabs are numbered. The first tab is tab 0, the second is tab 1, etc.

A default tab control has one tab:

```
NewPanel/W=(150,50,650,400)
TabControl tb, tabLabel(0)="Settings", size={400,250}
```

You add tabs to the control by providing additional tab labels:

```
TabControl tb, tabLabel(1)="More Settings"
```

When you click on a tab, the control's action procedure receives the number of the clicked-on tab.

The showing and hiding of the controls are accomplished by your action procedure. In this example, the This, That, and Color controls are shown when the Settings tab is clicked, and the Multiplier checkbox is hidden. When the More Settings tab is clicked, the action procedure makes the opposite occur.

The simplest way to create a tabbed user interface is to create an over-sized panel with all the controls visible and outside of the tab control. Place controls in their approximate positions relative to one another. By positioning the controls this way you can more easily modify each control until you are satisfied with them.

Before you put the controls into the tab control, get a list of the non-tab control names:

```
Print ControlNameList("", "\r", "!tb")           // all but "tb"
thisCheck
thatCheck
colorPop
multCheck
multVar
```

Determine which controls are to be visible in which tabs:

Tab 0: Settings	Tab 1: More Settings
thisCheck	multCheck
thatCheck	multVar
colorPop	

Write the action procedure for the tab control to show and hide the controls:

```
Function TabProc(tca) : TabControl

    STRUCT WMTabControlAction &tca

    switch (tca.eventCode)
        case 2:                                // Mouse up
            Variable tabNum = tca.tab           // Active tab number
```

```
Variable isTab0 = tabNum==0
Variable isTab1 = tabNum==1

ModifyControl thisCheck disable=!isTab0          // Hide if not Tab 0

ModifyControl thatCheck disable=!isTab0          // Hide if not Tab 0
ModifyControl colorPop disable=!isTab0          // Hide if not Tab 0

ModifyControl multCheck disable=!isTab1          // Hide if not Tab 1
ModifyControl multVar disable=!isTab1           // Hide if not Tab 1
break
endswitch

return 0
End
```

A more elegant method, useful when you have many controls, is to systematically name the controls inside each tab using a prefix or suffix that is unique to that tab, such as `tab0_thisCheck`, `tab0_thatCheck`, `tab1_multVar`. Then use the `ModifyControlList` operation to show and hide the controls. See the **Modify-ControlList** operation for an example.

Assign the action procedure to the tab control:

```
TabControl tb, proc=TabProc
```

Click on the tabs to see whether the showing and hiding is working correctly.

Verify that the action procedure correctly shows and hides controls as you click the tabs. When this works correctly, move the controls into their final positions, inside the tab control.

During this process, the "temporary selection" shortcut comes in handy. While you are in operate mode, pressing **Command-Option** (*Macintosh*) or **Ctrl+Alt** (*Windows*) temporarily switches to select mode, allowing you to select and drag controls.

Save the panel as a recreation macro (**Windows→Control→Window Control**) to record the final control positions. Rewrite the macro as a function that initially creates the panel:

```
Function CreatePanel()
  DoWindow/K TabPanel
  NewPanel/N=TabPanel/W=(596,59,874,175) as "Tab Demo Panel"
  TabControl tb,pos={15,19},size={250,80},proc=TabProc
  TabControl tb,tblLabel(0)="Settings"
  TabControl tb,tblLabel(1)="More Settings",value= 0
  CheckBox thisCheck,pos={53,52},size={39,14},title="This"
  CheckBox thisCheck,value= 1,mode=1
  CheckBox thatCheck,pos={53,72},size={39,14},title="That"
  CheckBox thatCheck,value= 0,mode=1
  PopupMenu colorPop,pos={126,60},size={82,20},title="Color"
  PopupMenu colorPop,mode=1,popColor= (65535,0,0)
  PopupMenu colorPop,value= #"\"*COLORPOP*\""
  CheckBox multCheck,pos={50,60},size={16,14},disable=1
  CheckBox multCheck,title="",value= 1
  SetVariable multVar,pos={69,60},size={120,15},disable=1
  SetVariable multVar,title="Multiplier",value=multiplier
End
```

See the **TabControl** operation on page V-877 for a complete description and examples.

### Creating TitleBox Controls

The **TitleBox** operation creates or modifies a **TitleBox** control. The control's text can be static or can be tied to a global string variable. See the **TitleBox** operation on page V-898 for a complete description and examples.

## Creating ValDisplay Controls

The **ValDisplay** operation (page V-917) creates or modifies a value display control.

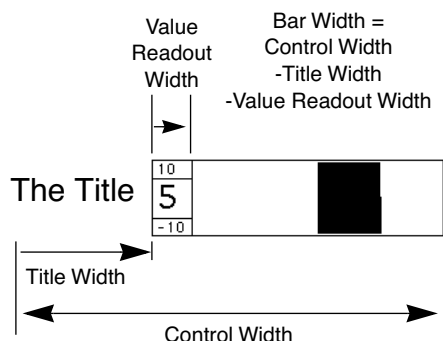

ValDisplay controls are very flexible and multifaceted. They can range from simple numeric readouts to thermometer bars or a hybrid of both. A ValDisplay control is tied to a numeric expression that you provide as an argument to the value keyword. Igor automatically updates the control whenever anything that the numeric expression depends on changes.

ValDisplay controls evaluate their value expression in the context of the root data folder. To reference a data object that is not in the root, you must use a data folder path, such as "root:Folder1:var1".

Here are a few selected keywords extracted from the **ValDisplay** operation on page V-917:

```
size={width,height}
barmisc={lts, valwidth}
limits={low,high,base}
```

The size and appearance of the ValDisplay control depends primarily on the *valwidth* and size parameters and the width of the title. However, you can use the *bodyWidth* keyword to specify a fixed width for the body (non-title) portion of the control. Essentially, space for each element is allocated from left to right, with the title receiving first priority. If the control width hasn't all been used by the title, then the value readout width is the smaller of *valwidth* points or what is left. If the control width hasn't been used up, the bar is displayed in the remaining control width:

Here are the various major possible forms of ValDisplay controls. Some of these examples modify previous examples. For instance, the second bar-only example is a modification of the `valdisp1` control created by the first bar-only example.

### Numeric Readout Only

```
// Default readout width (1000) is >= default control width (50)
ValDisplay valdisp0 value=K0
```

0

### LED Display

```
// Create the three LED types
ValDisplay led1,pos={67,17},size={75,20},title="Round LED"
ValDisplay led1,limits={-50,100,0},barmisc={0,0},mode=1
ValDisplay led1,bodyWidth= 20,value= #"K1",zeroColor=(0,65535,0)

ValDisplay led2,pos={38,48},size={104,20},title="Rectangular LED"
ValDisplay led2,frame=5,limits={0,100,0},barmisc={0,0},mode=2
ValDisplay led2,bodyWidth= 20,value= #"K2"
ValDisplay led2,zeroColor= (65535,49157,16385)

ValDisplay led3,pos={60,76},size={82,20},title="Bicolor LED"
ValDisplay led3,limits={-40,100,-100},barmisc={0,0},mode= 2
ValDisplay led3,bodyWidth= 20,value= #"K3"
```

### Bar Only

```
// Readout width = 0
ValDisplay valdisp1, frame=1, barmisc={12,0}, limits={-10,10,0}, value=K0
K0= 5 // halfway from base of 0 to high limit of 10.
```

The nice thing about a bar-only ValDisplay is that you can make it 5 to 200 points tall whereas with a numeric readout, the height is set by the font sizes of the readout and printed limits.

```
// Set control height= 80
ValDisplay valdisp1, size={50,80}
```

### Numeric Readout and Bar

```
// 0 < readout width (50) < control width (150)
ValDisplay valdisp2 size={150,20}, frame=1, limits={-10,10,0}
ValDisplay valdisp2 barmisc={0,50}, value=K0 // no limits shown
```

### Optional Limits

Whenever the numeric readout is visible, the optional limit values may be displayed too.

```
// Set limits font size to 10 points. Readout widths unchanged.
ValDisplay valdisp2 barmisc={10,50}
ValDisplay valdisp0 barmisc={10,1000}
```

### Optional Title

The control title steals horizontal space from the numeric readout and the bar, pushing them to the right. You may need to increase the control width to prevent them from disappearing.

```
// Add titles. Readout widths, control widths unchanged.
ValDisplay valdisp2 title="Readout+Bar"
ValDisplay valdisp0 title="K0="
```

The limits values *low*, *high*, and *base* and the value of *valExpr* control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the *base* value to an ending position determined by the value of *valExpr*, *low* and *high*. *low* corresponds to the left side of the bar, and *high* corresponds to the right. The position that corresponds to the *base* value is linearly interpolated between *low* and *high*.

For example, with *low* = -10, *high*=10, and *base*= 0, a *valExpr* value of 5 will draw from the center of the bar area (0 is centered between -10 and 10) to the right, halfway from the center to the right of the bar area (5 is halfway from 0 to 10):

You can force the control to not draw bars with fractional parts by specifying `mode=3`.

## Killing Controls

You can kill (delete) a control from within a procedure using the **KillControl** operation (page V-409). This might be useful in creating control panels that change their appearance depending on other settings.

You can interactively kill a control by selecting it with the arrow tool or the Select Control submenu and press Delete.

## Getting Information About Controls

You can use the **ControlInfo** operation (page V-75) to obtain information about a given control. This is useful to obtain the current state of a checkbox or the current setting of a pop-up menu.

**ControlInfo** is usually used for control panels that have a Do It button or equivalent. When the user clicks the button, its action procedure calls **ControlInfo** to query the state of each relevant control and acts accordingly.

**ControlInfo** is generally not used for the other style of control panel in which the action procedure for each control acts as soon as that control is clicked.

## Updating Controls

You can use the **ControlUpdate** operation (page V-80) to cause a given control to redraw with its current value. You would use this in a procedure after changing the value or appearance of a control to display the changes before the normal update occurs.

## Help Text for User-Defined Controls

Each control type has a help text property, set using the help keyword, through which you add a help tip. Tips are limited to 255 bytes.

Here is an example:

```
Button button0 title="Beep", help={"This button beeps."}
```

The tip appears when the user moves the mouse over the control, if tool tips are enabled in the Help section of the Miscellaneous Settings dialog.

## Modifying Controls

The control operations create a new control if the name parameter doesn't match a control already in the window. The operations modify an existing control if the name does match a control in the window, but generate an error if the control kind doesn't match the operation.

For example, if a panel already has a button control named `button0`, you can modify it with another `Button button0` command:

```
Button button0 disable=1           // hide
```

However, if you use a `Checkbox` instead of `Button`, you get a “`button0` is not a `Checkbox`” error.

You can use the **ModifyControl** operation (page V-516) and **ModifyControlList** operation (page V-518) to modify a control without needing to know what kind of control it is:

```
ModifyControl button0 disable=1    // hide
```

This is especially handy when used in conjunction with tab controls.

## Disabling and Hiding Controls

All controls support the keyword “`disable=d`” where *d* can be:

- 0: Normal operation
- 1: Hidden
- 2: User input disabled
- 3: Hidden and user input disabled

Charts and `ValDisplays` do not change appearance when `disable=2` because they are read-only.

`SetVariables` also have the `noedit` keyword. This is different from `disable=2` mode in that `noedit` allows user input via the up or down arrows but `disable=2` does not.

## Control Background Color

The background color of control panel windows and the area at the top of a graph as reserved by the **ControlBar** operation (page V-74) is a shade of gray chosen to match the operating system look. This gray is used when the control bar background color, as set by `ModifyGraph cbRGB` or `ModifyPanel cbRGB`, is the default pure white, where the red, green and blue components are all 65535. Any other `cbRGB` setting, including not quite pure white, is honored. However, some controls or portions of controls are drawn by the operating system and may look out of place if you choose a different background color.

For special purposes, you can specify a background color for an individual control using the `labelBack` keyword. See the reference help of the individual control types for details.

## Control Structures

Control action procedures can take one of two forms: structure-based or an old form that is not recommended. This section assumes that you are using the structure-based form.

The action procedure for a control uses a predefined, built-in structure as a parameter to the function. The procedure has this format:

```
Function ActionProcName(s)
    STRUCT <WMControlTypeActio>& s    // <WMControlTypeActio> is one of the
    ...                               // structures listed below
End
```

The names of the various control structures are:

Control Type	Structure Name
Button	WMButtonAction
CheckBox	WMCheckboxAction
CustomControl	WMCustomControlAction
ListBox	WMListboxAction
PopupMenu	WMPopupAction
SetVariable	WMSetVariableAction
Slider	WMSliderAction
TabControl	WMTabControlAction

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields in the future. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

You can use the same action procedure for different controls of the same type, for all the buttons in one window, for example. Use the `ctrlName` field of the structure to identify the control and the `win` field to identify the window containing the control.

## Control Structure Example

This example illustrates the extended event codes available for a button control. The function prints various text messages to the history area of the command window, depending what actions you take while in the button area.

```
Function ControlStructureTest()
    NewPanel
    Button b0,proc= NewButtonProc
End

Structure MyButtonInfo
    Int32 mousedown
    Int32 isLeft
EndStructure

Function NewButtonProc(s)
    STRUCT WMButtonAction &s

    STRUCT MyButtonInfo bi
    Variable biChanged= 0

    StructGet/S bi,s.userdata
    if( s.eventCode==1 )
        bi.mousedown= 1
        bi.isLeft= s.mouseLoc.h < (s.ctrlRect.left+s.ctrlRect.right)/2
        biChanged= 1
    elseif( s.eventCode==2 || s.eventCode==3 )
        bi.mousedown= 0
        biChanged= 1
    elseif( s.eventCode==5 )
        print "Enter button"
    elseif( s.eventCode==6 )
        print "Leave button"
    endif
end
```

```
if( s.eventCode==4 )                // mousemoved
    if( bi.mousedown )
        if( bi.isLeft )
            printf "L"
        else
            printf "R"
        endif
    else
        printf "*"
    endif
endif
if( biChanged )
    StructPut/S bi,s.userdata        // written out to control
endif

return 0
End
```

### Control Structure eventMod Field

The eventMod field appears in the built-in structure for each type of control. It is a bitfield defined as follows:

EventMod Bit	Meaning
Bit 0	A mouse button is down.
Bit 1	Shift key is down.
Bit 2	Option (Macintosh ) or Alt (Windows ) is down.
Bit 3	Command (Macintosh ) or Ctrl (Windows ) is down.
Bit 4	Contextual menu click occurred.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

### Control Structure blockReentry Field

Because of architectural differences, reentry of the action procedure occurs on Macintosh only in Igor6 and does not occur at all in Igor7. Because reentry may be affected by internal changes in Igor or by operating system changes, it may reappear as an issue in the future.

The blockReentry field appears in the built-in structure for each type of control. It allows you to prevent Igor from sending your control action procedure another event while you are servicing the first event. This is useful for action procedures that take a long time to service a click event. In such cases you typically do not want to service a second click until you finish servicing the first. This technique prevents an accidental double-click on a button from invoking a time-consuming procedure twice.

You tell Igor that you want to block further events until your action procedure returns by setting the blockReentry field to 1 when your action procedure is called:

```
Function ButtonProc(ba) : ButtonControl
    STRUCT WMButtonAction &ba

    // Tell Igor not to invoke ButtonProc again until this invocation is finished
    ba.blockReentry = 1
    . . .
```

Igor tests this field before invoking your action procedure while it is already running from a previous invocation. You do not need to test this field or reset it to 0 - just set it to 1 to block reentry.

## Control Structure blockReentry Advanced Example

This example further illustrates the use of the blockReentry field. It is of interest only to those who want to experiment with this issue.

The ReentryDemoPanel procedure below creates a panel with two buttons. Each button prints a message in the history area when the action procedure receives the "mouse up" message, then pauses for two seconds, and then prints another message in the history before returning. The pause is a stand-in for a procedure that takes a long time.

The top button does not block reentry so, if you click it twice in quick succession, the action procedure is reentered and you get nested messages in the history area.

The bottom button does block reentry so, if you click it twice in quick succession, the action procedure is not reentered.

Because of architectural differences, reentry of the action procedure occurs on Macintosh only in Igor6 and does not occur at all in Igor7. Because reentry may be affected by internal changes in Igor or by operating system changes, it may reappear as an issue in the future.

```
Function ButtonProc(ba) : ButtonControl
    STRUCT WMBUTTONACTION &ba

    switch( ba.eventCode )
        case 2: // mouse up
            // Block bottom button only
            ba.blockReentry= CmpStr(ba.ctrlName,"Block") == 0
            print "Start button ",ba.ctrlName
            Variable t0= ticks
            do
                DoUpdate
                while(ticks < (t0+120) )
                    Print "Finish button",ba.ctrlName
                    break
            endswitch

    return 0
End

Window ReentryDemoPanel() : Panel
    PauseUpdate; Silent 1// building window...
    NewPanel /K=1 /W=(322,55,622,255)
    Button NoBlock,pos={25,10},size={150,20},proc=ButtonProc,title="No Block Reentry"
    Button Block,pos={25,50},size={150,20},proc=ButtonProc,title="Block
Reentry"
End
```

## User Data for Controls

You can store arbitrary data with a control using the userdata keyword. You can set user data for the following controls: Button, CheckBox, CustomControl, ListBox, PopupMenu, SetVariable, Slider, and TabControl.

Each control has a primary, unnamed user data string that is used by default. You can also store an unlimited number of additional user data strings by specifying a name for each one. The name can be any legal standard Igor name.

You can retrieve information from the default user data using the **ControlInfo** operation (page V-75), which returns such information in the S\_UserData string variable. To retrieve any named user data, you must use the **GetUserData** operation (page V-274).

## Chapter III-14 — Controls and Control Panels

---

Although there is no size limit to how much user data you can store, it does have to be generated as part of the recreation macro for the window when experiments are saved. Consequently, huge user data strings can slow down experiment saving and loading

User data is intended to replace or reduce the usage of global variables for maintaining state information related to controls.

### Control User Data Examples

:Here is a simple example of a button with user data:

```
NewPanel
Button b0, userdata="user data for button b0"
Print GetUserData("", "b0", "")
```

Here is a more complex example.

Copy the following code into the procedure window of a new experiment and run the Panel0 macro. Then click the buttons.

```
Structure mystruct
    Int32 nclicks
    double lastTime
EndStructure

Function ButtonProc(ctrlName) : ButtonControl
    String ctrlName

    STRUCT mystruct s1
    String s= GetUserData("", ctrlName, "")
    if( strlen(s) == 0 )
        print "first click"
    else
        StructGet/S s1,s
        // Warning: Next command is wrapped to fit on the page.
        printf "button %s clicked %d time(s), last click = %s\r",ctrlName, s1.nclicks,
Secs2Date(s1.lastTime, 1 )+" "+Secs2Time(s1.lastTime,1)
    endif
    s1.nclicks += 1
    s1.lastTime= datetime
    StructPut/S s1,s
    Button $ctrlName,userdata= s
End

Window Panel0() : Panel
    PauseUpdate; Silent 1 // building window...
    NewPanel /W=(150,50,493,133)
    SetDrawLayer UserBack
    Button b0,pos={12,8},size={50,20},proc=ButtonProc,title="Click"
    Button b1,pos={65,8},size={50,20},proc=ButtonProc,title="Click"
    Button b2,pos={119,8},size={50,20},proc=ButtonProc,title="Click"
    Button b3,pos={172,8},size={50,20},proc=ButtonProc,title="Click"
    Button b4,pos={226,8},size={50,20},proc=ButtonProc,title="Click"
EndMacro
```

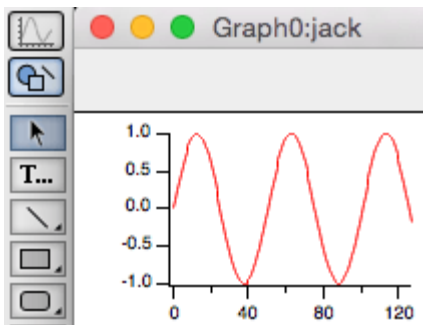

## Action Procedures for Multiple Controls

You can use the same action procedure for different controls of the same type, for all the buttons in one window, for example. The name of the control is passed to the action procedure so that it can know which control was clicked. This is usually the name of the control *in the target/active window*, which is what most control operations assume.

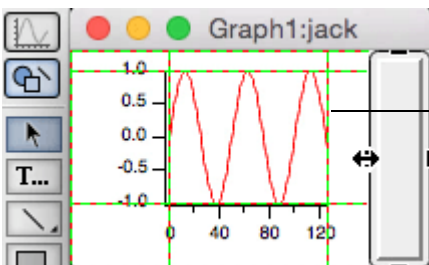

## Controls in Graphs

The combination of controls and graphs provides a nice user interface for tinkering with data. You can create such a user interface by embedding controls in a graph or by embedding a graph in a control panel. This section explains the former technique, but the latter technique is usually recommended. See Chapter III-4, **Embedding and Subwindows** for details.

Although controls can be placed anywhere in a graph, you can and should reserve an area just for controls at the edge of a graph window. Controls in graphs operate much more smoothly if they reside in these reserved areas. The **ControlBar** operation (page V-74) or the Control Bar dialog can be used to set the height of a nonembedded control area at the top of the graph.

The simplest way to add a panel is to click near the edge of the graph and drag out a control area:

The background color of a control area or embedded panel can be set by clicking the background to exit any subwindow layout mode, then Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the background,

## Chapter III-14 — Controls and Control Panels

and then selecting a color from the contextual menu's pop-up color palette. See **Control Background Color** on page III-388 for details.

The contextual menu adjusts the style of the frame around the panel.

You can use the same contextual menu to remove an embedded panel, leaving only the bare control area underneath. Remove the control area by dragging the inside edge back to the outside edge of the graph.

### Drawing Limitations

The drawing tools can not be used in bare control areas of a graph. If you want to create a fancy set of controls with drawing tools, you have to embed a panel subwindow into the graph.

### Updating Problems

You may occasionally run into certain updating problems when you use controls in graphs. One class of update problems occurs when the action procedure for one control changes a variable used by a ValDisplay control in the same graph and also forces the graph to update while the action procedure is being executed. This short-circuits the normal chain of events and results in the ValDisplay not being updated.

You can force the ValDisplay to update using the **ControlUpdate** operation (page V-80). Another solution is to use a control panel instead of a graph.

The ControlUpdate operation can also solve problems in updating pop-up menus. This is described above under **Creating PopupMenu Controls** on page III-379.

## Control Panels

Control panels are windows designed to contain controls. The **NewPanel** creates a control panel.

Drawing tools can be used in panel windows to decorate control panels. Control panels have two drawing layers, UserBack and ProgBack, behind the controls and one layer, Overlay, in front of the controls. See **Drawing Layers** on page III-68 for details.

A panel window's background color can be set by Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the background and then selecting a color from the pop-up color palette. See **Control Background Color** on page III-388 for details.

### Embedding into Control Panels

You can embed a graph, table, notebook, or another panel into a control panel window. See Chapter III-4, **Embedding and Subwindows** for details. This technique is cleaner than adding control areas to a graph. It also allows you to embed multiple graphs in one window with controls.

Use the contextual menu while in drawing mode to add an embedded window. Click on the frame of the embedded window to adjust the size and position.

You can use a notebook subwindow in a control panel to display status information or to accept lengthy user input. See **Notebooks as Subwindows in Control Panels** on page III-86 for details.

### Exterior Control Panels

Exterior subwindows are panels that act like subwindows but live in their own windows attached to a host graph window. The host graph and its exterior subwindows move together and, in general, act as single window. Exterior subwindows have the advantage of not disturbing the host graph and, unlike normal subwindows, are not limited in size by the host graph.

Exterior subwindows must be panels and the only host supported is a graph window.

To create an exterior subwindow panel, use **NewPanel** with the /EXT flag in combination with /HOST.

### Floating Control Panels

Floating control panels float above all other windows, except dialogs. To create a floating panel, use **NewPanel** with the /FLT flag.

## Control Panel Preferences

Control panel preferences allow you to control what happens when you create a new control panel. To set preferences, create a panel and set it up to your taste. We call this your *prototype* panel. Then choose Capture Panel Prefs from the Panel menu.

Preferences are normally in effect only for *manual* operations, not for automatic operations from Igor procedures. This is discussed in more detail in Chapter III-18, **Preferences**.

When you initially install Igor, all preferences are set to the factory defaults. The dialog indicates which preferences you have changed.

The preferences affect the creation of new panels only.

Selecting the Show Tools category checkbox captures whether or not the drawing tools palette is initially shown or hidden when a new panel is created.

## Controls Shortcuts

Action	Shortcut ( <i>Macintosh</i> )	Shortcut ( <i>Windows</i> )
To show or hide a panel's or graph's tool palette	Press Command-T.	Press Ctrl+T.
To move or resize a user-defined control without using the tool palette	Press Command-Option and click the control. With Command-Option still pressed, drag or resize it.	Press Ctrl+Alt and click the control. With Ctrl+Alt still pressed, drag or resize it.
To add a user-defined control without using the tool palette	Press Command-Option and choose from the Panel or Graph menu's Add Control submenu.	Press Ctrl+Alt and choose from the Panel or Graph menu's Add Control submenu.
To modify a user-defined control	Press Command-Option and double-click the control.  This displays a dialog for modifying all aspects of the control. If the control is already selected, you don't need to press Command-Option.	Press Ctrl+Alt and double-click the control.  This displays a dialog for modifying all aspects of the control. If the control is already selected, you don't need to press Ctrl+Alt.
To edit a user-defined control's action procedure	With the panel in modify mode (tools showing, second icon from the top selected) press the Control key and click the control. This displays a contextual menu with a "Go to <action procedure>" item.	With the panel in modify mode (tools showing, second icon from the top selected) right-click the control. This displays a contextual menu with a "Go to <action procedure>" item.
To create an embedded graph or table in the panel	With the panel in modify mode, press the Control key and click the panel background. Choose the subwindow type from the resulting contextual menu's "New" submenu.	With the panel in modify mode, right-click the panel background. Choose the subwindow type from the resulting contextual menu's "New" submenu.
To change an embedded window's border style	With the panel in modify mode, press the Control key and click the embedded window. Choose the border style from the resulting contextual menu's "Frame" and "Style" submenus.	With the panel in modify mode, right-click the embedded window. Choose the border style from the resulting contextual menu's "Frame" and "Style" submenus.
To remove an embedded window	With the panel in modify mode, press the Control key and click the embedded window. Choose the Delete from the resulting contextual menu.	With the panel in modify mode, right-click the embedded window. Choose the Delete from the resulting contextual menu.
To eliminate a control area at the edge of a graph	In modify mode or while pressing Command-Option, click the inside edge of the control area and drag it to the outside edge of the graph.	In modify mode or while pressing Ctrl+Alt, click the inside edge of the control area and drag it to the outside edge of the graph.
To nudge a user-defined control's position	Select the control and press arrow keys. Press Shift to nudge faster.	Select the control and press arrow keys. Press Shift to nudge faster.

### Platform-Related Issues

Igor Pro runs on Macintosh and Windows. This chapter contains information that is platform-specific and also information for people who use Igor on both platforms.

### Windows-Specific Issues

On Windows, the name of the Igor program file must be “Igor64.exe” for the 64-bit version of Igor or “Igor.exe” for the 32-bit version, exactly. If you change the name, Igor extensions will not work because they will be unable to find Igor.

### Cross-Platform File Compatibility

Version 3.1 was the first version of Igor Pro that ran on Windows as well as Macintosh.

#### Crossing Platforms

When crossing from one platform to another, page setups are only partially translated. Igor tries to preserve the page orientation and margins.

When crossing platforms, Igor attempts to do font substitution where necessary. If Igor can not determine an appropriate font it displays the font substitution dialog where you can choose the font.

Platform-specific picture formats are displayed as gray boxes when you attempt to display them on the non-native platform. PDF pictures are supported on Macintosh only and appear as gray boxes on Windows. Windows Metafile, Enhanced Metafile, and Windows bitmap (BMP) pictures are supported on Windows only and appear as gray boxes on Macintosh. The EPS, PNG, JPEG, TIFF, and SVG formats are platform-independent and are displayed on both platforms.

#### Transferring Files Using File Transfer Programs

Some transfer programs offer the option of translating file formats as they transfer the program from one computer to another. This translation usually consists of replacing each carriage return character with a carriage return/linefeed pair (Macintosh to Windows) or vice-versa (Windows to Macintosh). This is called a “text mode” transfer, as opposed to a “binary mode” transfer. This translation is appropriate for plain text files only. In Igor, plain text notebooks, procedure files, and Igor Text data files are plain text. All other files are not plain text and will be corrupted if you transfer in text mode. If you get flaky results after transferring a file, transfer it again making sure text mode is off.

If you have a problem opening a binary file after doing a transfer, compare the number of bytes in the file on both computers. If they are not the same, the transfer has corrupted the file.

#### File Name Extensions, File Types, and Creator Codes

This table shows the file name extension and corresponding Macintosh file type for Igor Pro files:

Extension	File Type	What’s in the File
.pxp	IGsU	Packed experiment file
.pxt	IGsS	Packed experiment template (stationery)
.uxp	IGSU	Unpacked experiment file
.uxt	IGSS	Unpacked experiment template (stationery)
.ifn	WMT0	Igor formatted notebook (last character is zero)
.txt	TEXT	Igor plain notebook
.ihf	WMT0	Igor help file

Extension	File Type	What's in the File
.ibw	IGBW	Igor binary data file

The Macintosh creator code for Igor is 'IGR0' (last character is zero).

## Experiments and Paths

An Igor experiment sometimes refers to wave, notebook, or procedure files that are stored separate from the experiment file itself. This is discussed under **References to Files and Folders** on page II-22. In this case, Igor creates a symbolic path that points to the folder containing the referenced file. It writes a **NewPath** command in the experiment file to recreate the symbolic path when the experiment is opened. When you move the experiment to another computer or to another platform, this path may not be valid. However, Igor goes to great lengths to find the folder, if possible.

Igor stores the path to the folder containing the file as a relative path, relative to the experiment file, if possible. This means that Igor will be able to find the folder, even on another computer, if the folder's relative location in the disk hierarchy is the same on both computers. You can minimize problems by using the same disk hierarchy on both computers.

If the folder is not on the same volume as the experiment file, then Igor can not use a relative path and must use an absolute path. Absolute paths cause problems because, although your disk hierarchy may be the same on both computers, often the name of the root volume will be different. For example, on the Macintosh your hard disk may be named "hd" while on Windows it may be named "C:".

If Igor can not locate a folder or file needed to recreate an experiment, it displays a dialog asking you to locate it.

## Picture Compatibility

Igor displays pictures in graphs, page layouts, control panels and notebooks. The pictures are stored in the Pictures collection (Misc→Pictures) and in notebooks. Graphs, page layouts and control panels reference pictures stored in the Pictures collection while notebooks store private copies of pictures.

This table shows the graphic formats that Igor can use to store pictures:

Format	How To Create	Notes
PDF	Paste or use Misc→Pictures	Macintosh only
EMF (Enhanced Metafile)	Paste or use Misc→Pictures	Windows only See <b>Graphics Technology on Windows</b> on page III-445 for information about different types of EMF pictures.
BMP (bitmap)	Use Misc→Pictures	Windows Only. BMP also called DIB (device-independent bitmap).
PNG (Portable Network Graphics)	Use Misc→Pictures	Cross-platform bitmap format
JPEG	Use Misc→Pictures	Cross-platform bitmap format
TIFF (Tagged Image File Format)	Use Misc→Pictures	Cross-platform bitmap format
EPS (Encapsulated PostScript)	Use Misc→Pictures	High resolution vector format. EPS is largely obsolete. Use PDF instead.
SVG (Scalable Vector Graphics)	Use Misc→Pictures	Cross-platform high resolution vector format.

Formats that are not supported on the current platform are drawn as gray boxes.

Although Igor does not display non-native graphic formats, it does preserve them. For example, you can create an experiment on Macintosh and paste a Macintosh PDF into a page layout, graph, or notebook window. If you save the experiment and open it on Windows, the PDF will be displayed as a gray box. You can now paste a Windows metafile into the page layout, graph, or notebook window. If you save the experiment and open it on Macintosh, the Windows metafile will be displayed as a gray box but the PDF will be displayed correctly. If you now save and open the experiment on Windows again, the Windows metafile will be displayed correctly.

If you want platform-specific pictures to be displayed correctly on both platforms, you must convert the pictures to PNG. To convert to PNG, use the Pictures dialog (Misc menu) for pictures in graphs and page layouts, or for pictures in notebooks, use the Special submenu in the Notebook menu.

Converting a picture to PNG makes it a bitmap format and may degrade resolution. This is fine for graphics intended to be viewed on the screen but not for graphics intended to be printed at high resolution. You can convert to a high resolution PNG without losing much picture quality.

### Page Setup Compatibility

Page setup records store information regarding the size and orientation of the page. Prior to Igor Pro 7, page setups contained platform-dependent and printer-dependent data. This is no longer the case, but as a consequence, only minimal information is stored.

In each experiment file, Igor stores a separate page setup for each page layout, notebook, and procedure window, and stores a single page setup for all graphs and a single page setup for all tables.

## File System Issues

This section discusses file system issues that you need to take into account if you use Igor on both Macintosh and Windows.

### File and Folder Names

On Windows, the following characters are illegal in file and folder names: backslash (\), forward slash (/), colon (:), asterisk (\*), question mark (?), double-quote ("), left angle bracket (<), right angle bracket (>), vertical bar (|). On Macintosh, the only illegal character is colon.

This means, for example, that you can not create a file with a name like "Data 1/23/98" on Windows. You can create a file with this name on Macintosh. If you write an Igor procedure that generates a file name like this, it will run on Macintosh but fail on Windows.

Therefore, if you are concerned about cross-platform compatibility, you must not use any of the Windows illegal characters in a file or folder name, even if you are running on Macintosh. Also, don't use period except before a file name extension.

File and folder names in Windows can theoretically be up to 255 characters in length. Because of some limitations in Windows and also in Igor, you will encounter errors if you use file names that long. However, both Igor and Windows are capable of dealing with file names up to about 250 characters in length. It is unlikely that you will approach this limit.

An exception to this is that Igor limits names of XOP files to 31 characters, plus the ".xop" extension. Igor will not recognize an XOP file with a longer name.

Paths in Windows are limited to 259 characters in length. Neither Windows nor Igor can deal with a path that exceeds this limit. For example, if you create a directory with a 250 character name and try to create a file with a 15 character name, neither Windows nor Igor will permit this.

This boils down to the following: Feel free to use long file and directory names, but expect to see errors if you use outrageously long names or if you have directories so deeply nested that paths approach the theoretical limit.

## Path Separators

The Macintosh HFS file system uses a colon to separate elements in a file path. For example:

```
hd:Igor Pro 7 Folder:Examples:Sample Graphs:Contour Demo.pxp
```

The Windows file system uses a backslash to separate elements in a file path. For example:

```
C:\Igor Pro 7 Folder\Examples\Sample Graphs:Contour Demo.pxp
```

Some Igor operations (e.g., LoadWave) allow you to enter file paths. Igor accepts Macintosh-style or Windows-style paths regardless of the platform on which you are running.

**Note:** Igor uses the backslash character as an escape character in literal strings. This can cause problems when using Windows-style paths.

For example, the following command creates a textbox with two lines of text. “\r” is an escape code inserts a carriage return character:

```
Textbox "This is line 1.\rThis is line 2."
```

Because Igor interprets a backslash as an escape character, the following command will not execute properly:

```
LoadWave "C:\Data Files\really good data.ibw"
```

Instead of loading a file named “really good data.ibw”, Igor would try to load a file named “Data Files<CR>really good data.ibw”, where <CR> represents the carriage return character. This happens because Igor interprets “\r” in literal strings to mean carriage return.

To solve this problem, you must use “\\” instead of “\” in a file path. Igor will correctly execute the following:

```
LoadWave "C:\\Data Files\\really good data.ibw"
```

This works because Igor interprets “\\” as an escape sequence that means “insert a backslash character here”.

Another solution to this problem is to use a Macintosh HFS-style path, even on Windows:

```
LoadWave "C>Data Files:really good data.ibw"
```

Igor converts the Macintosh HFS-style path to a Windows-style path before using it. This avoids the backslash issue.

For a complete list of escape sequences, see **Escape Sequences in Strings** on page IV-13.

If you are writing procedures that need to extract sections of file paths or otherwise manipulate file paths, the **ParseFilePath** function on page V-622 may come in handy.

## UNC Paths

“UNC” stands for “Universal Naming Convention”. This is a Windows convention for identifying resources on a network. One type of network resource is a shared directory. Consequently, when running under Windows, in order to reference a network directory from an Igor command, you need to use a UNC path.

The format of a UNC path that points to a file in a folder on a shared server volume or directory is:

```
"\\server\share\directory\filename"
```

“server” is the name of the file server and “share” is the name of the top-level shared volume or directory on that server.

Because Igor treats a backslash as an escape character, in order to reference this from an Igor command, you would have to write:

```
"\\\\server\\share\\directory\\filename"
```

As described in the preceding section, you could also use Macintosh HFS path syntax by using a colon in place of two backslashes. However, you can not do this for the “\\server\share” part of the path. Thus, using Macintosh HFS syntax, you would write:

```
"\\\\server\\share:directory:filename"
```

### Unix Paths

Unix paths use the forward slash character as a path separator. Igor does not recognize Unix paths. Use Macintosh HFS paths instead.

## Keyboard and Mouse Usage

This section describes how keyboard and mouse usage differs on Macintosh versus Windows. It is intended to help Igor users more easily adapt when switching platforms.

There are three main differences between Macintosh and Windows input mechanisms:

1. The Macintosh mouse may have one button and the Windows mouse has two.
2. The Macintosh keyboard has four modifier keys (Shift, Command, Option, Control) while the Windows keyboard has three (Shift, Ctrl, Alt).
3. The Macintosh keyboard has Return and an Enter keys while the Windows keyboard (usually) has two Enter keys.

For the most part, Igor maps between Macintosh and Windows input as follows:

Macintosh	Windows	Macintosh	Windows
Shift	Shift	Return	Enter
Command	Ctrl	Enter	Enter
Option	Alt	Control-click	Right-click
Control	<not mapped>		

In notebooks, procedure windows and help windows, pressing Control-Return or Control-Enter executes the selected text or, if there is no selection, to execute the line of text containing the caret.

### Command Window Input

This table compares command window mouse actions:

Action	Macintosh	Windows
Copy history selection to command line	Option-click	Alt+click
Copy history to command and start execution	Command-Option-click	Ctrl+Alt+click
Invoke contextual menu	Control-click	Right-click

## Cross-Platform Text and Fonts

### Text Encoding Compatibility

Prior to Igor7, Igor used system text encoding. On Macintosh, this was usually MacRoman. On Windows, it was usually Windows-1252. On Japanese systems, it was Shift JIS on both platforms.

As of Igor7, Igor uses UTF-8 text encoding internally on both Macintosh and Windows.

When opening old files, Igor must convert from the file's text encoding to UTF-8 for storage in memory.

Dealing with various text encodings is a complex issue. See **Text Encodings** on page III-409 for details.

### Carriage Returns and Linefeeds

The character or character pattern that marks the end of a line of text in a plain text file is called the "line terminator". There are three common line terminators, carriage return (CR, ASCII 13, used on old Macin-

tosh systems), linefeed (LF, ASCII 10, used on Unix) and carriage return plus linefeed (CRLF, used on Windows).

When Igor Pro opens a text file (procedure file, plain text notebook or plain text data file), it accepts CR, LF or CRLF as the line terminator.

If you create a new procedure file or plain text notebook, Igor writes LF on Mac OS and CRLF on Windows. If you open an existing plain text file, edit it and then save it, Igor preserves the original terminator as determined by examining the first line in the file.

By default, the **FReadLine** operation treats CR, LF, or CRLF as terminators. Use this to write a procedure that can read lines from a text file without caring whether it is a Macintosh, Windows, or Unix file.

## Font Substitution

When a font specified in a command or document is not installed, Igor applies font substitution to choose an installed font to use in place of the missing font. Dealing with these missing fonts often occurs when transferring a Windows-originated document to Macintosh or vice versa.

Igor employs two levels of font substitution: user-level editable substitution and built-in uneditable substitution.

The first level is an optional user-level font substitution facility that you will usually encounter for the first time when Igor displays the Substitute Font Dialog while opening an experiment or file. Use the dialog to choose a temporary or permanent replacement for the missing font:

The second level is Igor's built-in substitution table which substitutes between fonts normally installed on various Macintosh and Windows operating systems. For example, it substitutes Arial (a standard Windows font) for Geneva (a standard Macintosh font) if Geneva is not installed (which it usually isn't on a Windows computer).

The user-level substitutions have priority over the built-in substitutions.

The Substitute Font dialog appears when neither level of font substitution specifies a replacement for the missing font. You can prevent this dialog from appearing by selecting the Don't Prompt for Missing Fonts checkbox in the Substitute Font dialog.

You can manage font substitutions without waiting for a missing font situation to occur by choosing Misc-Edit Font Substitutions.

The user-level font substitution table is maintained in the "Igor Font Substitutions.txt" text file in Igor's preferences folder. The file format is:

```
<name of missing font to replace> = <name of font to use instead>
```

one entry per line. For example:

Palatino=New Times Roman

spaces or tabs are allowed around the equals sign.

When a missing font is replaced, Igor uses the name of the replacement font instead of the name of the font in the command.

The name of the missing font is replaced only in the sense that the altered or created object (window, control, etc.) uses and remembers only the name of the replacement font. Recreation macros, including experiment recreation procedures, use the name of the replacement font when the experiment is saved. The command, however, is unaltered and still contains the name of the missing font.

## Cross-Platform Procedure Compatibility

Igor procedures are about 99.5% platform-independent. For the other 0.5%, you need to test which platform you are running on and act accordingly. You can use `ifdefs` to achieve this. For example:

```
Function Demo()  
  #ifdef MACINTOSH  
    Print "We are running on Macintosh"  
  #else  
    #ifdef WINDOWS  
      Print "We are running on Windows"  
    #else  
      Print "Unknown OS"  
    #endif  
  #endif  
End
```

## File Paths

As described under **Path Separators** on page III-401, Igor accepts paths with either colons or backslashes on either platform.

The use of backslashes is complicated by the fact that Igor uses the backslash character as an escape character in literal strings. This is also described in detail under **Path Separators** on page III-401. The simplest solution to this problem is to use a colon to separate path elements, even when you are running on Windows.

If you are writing procedures that need to extract sections of file paths or otherwise manipulate file paths, the **ParseFilePath** function on page V-622 may come in handy.

## File Types and Extensions

On Mac OS 9, all files had a file type property. This property is a four letter code that is stored with the file by the Macintosh file system. For example, plain text files have the file type TEXT. Igor binary wave files have the file type IGBW. The file type property controlled the icon displayed for the file and which programs could open the file.

The file type property is no longer used on Macintosh. On Mac OS X, as well as on Windows, the file type is indicated by the file name extension.

For backward compatibility, some Igor operations and functions, such as **IndexedFile**, still accept Macintosh file types. New code should use extensions instead.

## Points Versus Pixels

A pixel is the area taken up by the smallest displayable dot on an output device such as a display screen or a printer. The physical width and height of a pixel depend on the device.

In Igor, most measurements of length are in terms of points. A point is roughly 1/72 of an inch. 72 points make up 1 “logical inch”. Because of hardware differences and system software adjustments, the actual size of a logical inch varies from screen to screen and system to system.

### Window Position Coordinates

With one exception, Igor stores and interprets window position coordinates in units of points. For example the command

```
Display/W=(5, 42, 405, 242)
```

specifies the left, top, right, and bottom coordinates of the window in points relative to a reference point which is, roughly speaking, the top/left corner of the menu bar. Other Igor operations that use window position coordinates in points include Edit, Layout, NewNotebook, NewGizmo and MoveWindow.

The exception is the control panel window when running on a standard resolution screen. This is explained under **Control Panel Resolution on Windows** on page III-405.

Most users do not need to worry about the exact meaning of these coordinates. However, for the benefit of programmers, here is a discussion of how Igor interprets them.

On Macintosh, the reference point, (0, 0), is the top/left corner of the menu bar on the main screen. On Windows, the reference point is 20 points above the bottom/left corner of the main Igor menu bar. This difference is designed so that a particular set of coordinates will produce approximately the same effect on both platforms, so that experiments and procedures can be transported from one platform to another.

The coordinates specify the location of the content region, in Macintosh terminology, or the client area, in Windows terminology, of the window. They do not specify the location of the window frame or border.

On Macintosh, a point is always interpreted to be one pixel except on Retina displays where it is two.

On Windows, the correspondence between a point and a pixel can be controlled by the user using system settings. Since Igor stores window positions in units of points, if the user changes the number of pixels per point, the size of Igor windows in pixels will change.

### Control Panel Resolution on Windows

In the past, by default, Windows screens ran at 96 DPI (dots-per-inch) resolution. In recent years, high-resolution displays, also called UltraHD displays and 4K displays, have become common.

In Igor6 and before, commands that create control panels and controls use screen pixel units to specify sizes and coordinates. This results in tiny controls on high-resolution displays.

In Igor7 and later, control panels and control sizes and coordinates can be specified in units of points instead of pixels. Since a point is a resolution-independent unit, this results in controls that are the same logical size regardless of the physical resolution of the screen.

By default, panels are drawn using pixels if the screen resolution is 96 DPI but using points for higher-DPI settings. This gives backward compatibility on standard screens and reasonably-sized controls on high-resolution screens.

You can change the way control panel coordinates and sizes are interpreted using this using:

```
SetIgorOption PanelResolution = <resolution>
```

## Chapter III-15 — Platform-Related Issues

---

<resolution> controls how Igor interprets coordinates and sizes in control panels. It must be one of these values:

- 0: Coordinates and sizes are treated as points regardless of the screen resolution.
- 1: Coordinates and sizes are treated as pixels if the screen resolution is 96 DPI, points otherwise. This is the default setting in effect when Igor starts.
- 72: Coordinates and sizes are treated as pixels regardless of the screen resolution (Igor6 mode).

This setting is not remembered across Igor sessions.

The resolution for a panel is set when the panel is created so changing the panel resolution does not affect already-existing control panels.

Programmers are encouraged to test their control panels at various resolution settings.

For the most part, Igor6 control panels will work fine in Igor7 and later. However, if you have panels that rearrange their components depending on the window size, you probably have some code that uses the ratio of 72 and ScreenResolution. For example, here is a snippet from the WaveMetrics procedure Axis Slider.ipf:

```
case "Resize":
    GetWindow kwTopWin, gsize           // Returns points
                                         // Controls are positioned in pixels
    grfName= WinName(0, 1)
    V_left *= ScreenResolution / 72    // Convert points to pixels
    V_right *= ScreenResolution / 72
    Slider WMAxSlSl, size={V_right-V_left-kSliderLMargin, 16}
    break
```

To make this work properly at variable resolution, we use the **PanelResolution** function, added in Igor Pro 7.00:

```
case "Resize":
    GetWindow kwTopWin, gsize           // Returns points
    grfName= WinName(0, 1)
    V_left *= ScreenResolution / PanelResolution(grfName) // Variable
    V_right *= ScreenResolution / PanelResolution(grfName) // resolution
    Slider WMAxSlSl, size={V_right-V_left-kSliderLMargin, 16}
    break
```

The PanelResolution function, when called with "" as the parameter returns the current screen resolution or, if in Igor6 mode, 72. When called with the name of a control panel or graph, it returns the resolution that was in effect when the panel or graph was created.

If you want your procedures to work with Igor6, you should insert this into each procedure file that needs the PanelResolution function:

```
#if Exists("PanelResolution") != 3
Static Function PanelResolution(wName) // For compatibility with Igor7
    String wName
    return 72
End
#endif
```

To find other examples, use the Help Browser to search procedure files for PanelResolution.

## Pictures in Notebooks

If you want to display notebook pictures on both platforms, they must be in one of these cross-platform formats: PNG, JPEG, TIFF, SVG.

If you have pictures in other formats and you want them to be viewable on both platforms, you should convert them to PNG. Igor uses PNGs for Igor help files which need to be platform-independent.

There are two ways to create a PNG picture in an Igor notebook. You can load it from a file using Misc→Pictures and then place it in a notebook or you can convert a picture that you have pasted into a notebook using Notebook→Special→Convert to PNG.

The Convert to PNG command in the Notebook→Special menu converts the selected picture or pictures into PNG. It skips selected pictures that are already PNG or that are foreign (not native to the platform on which you are running). You can determine the type of a picture in a notebook by clicking in it and looking at the notebook status line.

The Convert to PNG dialog allows you to choose the desired resolution. Usually 4x or 8x is best.

When you create a PNG file from within Igor, from a graph window for example, you can create it at screen resolution or at higher resolution. For good quality when viewed at higher magnifications and when printed, use 4x or 8x.

## Overview

Starting with Igor Pro 7, Igor stores text internally as UTF-8, a Unicode text encoding format. Using Unicode improves Igor's interoperability with other software and gives you easy access to a wide array of characters including Greek, mathematical and special characters.

Previous versions of Igor used non-Unicode text encodings such as MacRoman, Windows-1252, and Shift JIS (Japanese), depending on the operating system you were running. Consequently Igor7 needs to do text encoding conversions when opening files from earlier versions.

If a file contains accented characters, special symbols, and other non-ASCII text, it is not always possible to get this conversion right. You may see incorrect characters or receive "Unicode conversion errors" or other types of errors.

Text encoding is not an issue with files that contain only ASCII characters as these characters are represented using the same codes in UTF-8 as in other text encodings.

This chapter provides information that a technically-oriented Igor user can use to understand the conversions and to deal with issues that can arise. To understand these issues, it helps to understand what text encodings are and how they are used in Igor, so we start with an overview.

## Text Encoding Overview

A text encoding is a mapping from a set of numbers to a set of characters. The terms "text encoding", "character encoding" and "code page" represent the same thing.

In most commonly-used text encodings, text is stored as an array of bytes. For example, the text "ABC" is stored in memory as three bytes with the numeric values 0x41, 0x42 and 0x43. (The 0x notation means the number is expressed in hexadecimal, also called base 16.)

In the 1960's the ASCII text encoding was defined. It specifies the mapping of 128 numbers, from 0x00 to 0x7F, to characters. ASCII defines mappings for:

- Unaccented letters (A-Z and a-z)
- Numerals (0-9)
- Common punctuation marks (comma, period, dash, question mark ...)
- Other printable characters (space, brackets, slash, backslash, ...)
- Control characters (carriage-return, linefeed, tab, ...)

The "ABC" example above uses the ASCII codes for A, B and C.

Over time, other text encodings were created to permit the representation of characters not supported by ASCII such as:

- Accented western letters
- Asian characters

- Mathematical symbols

Hundreds of text encodings were created for encoding characters used in different languages. Even for a given language, different operating systems often adopted different text encodings.

In ASCII, each character is represented by a 7-bit code which is typically stored in a single 8-bit byte with one bit unused. 7 bits can represent 128 different characters. To represent more characters, other text encodings use 8 bits per character, multiple bytes per character, 16-bit codes or 32-bit codes.

We use the term "byte-oriented text encoding" to distinguish text encodings that represent characters using one byte or multiple bytes per character from those that use 16-bit or 32-bit codes.

The characters represented by the ASCII codes 0x00 to 0x7F are called "ASCII characters" with all other characters called "non-ASCII characters". All byte-oriented text encodings that you are likely to encounter are supersets of ASCII.

Multiple-byte text encodings, such as Shift-JIS and UTF-8, typically use one byte for ASCII characters, and for some frequently-used non-ASCII characters, and two or more bytes for other non-ASCII characters.

In order to properly display and process text, a program must convert any text it reads from outside sources (e.g., files) into whatever text encoding the program uses for internal storage if the source text encoding and the internal text encoding are different.

Since all byte-oriented text encodings that you are likely to encounter are supersets of ASCII, ASCII characters do not require conversion when treated as any byte-oriented text encoding. Non-ASCII characters require conversion and problems arise if the conversion is not done or not done correctly.

### Text Encodings Commonly Used in Igor

In Igor the most commonly-used text encodings are:

- MacRoman (Macintosh Western European)
- Windows-1252 (Windows Western European)
- Shift JIS (Japanese)
- UTF-8 (Unicode using a byte-oriented encoding form)

Igor6 and earlier versions of Igor stored text in "system text encoding". For western users this means MacRoman on Macintosh and Windows-1252 on Windows. For Japanese users it means Shift JIS on both platforms.

Igor7 uses UTF-8 exclusively.

The system text encoding is determined by the system locale. The system locale determines the text encoding used by non-Unicode programs such as Igor6. It has no effect on Igor7.

On Macintosh you set the system locale through the preferred languages list in the Language & Region preference panel. On Windows you set it through the Region control panel. Most users never have to set the system locale because their systems are initially configured appropriately for them.

Because Igor7 uses UTF-8 internally, when it loads a pre-Igor7 file, it must convert the text from system text encoding to UTF-8. If the file contains ASCII text only this conversion is trivial. But if the file contains non-ASCII characters, such as accented letters, Greek letters, math symbols or Japanese characters, issues may arise, as explained in the following sections.

In order to convert text to UTF-8, Igor must know the text encoding of the file from which it is reading the text. This is tricky because plain text files, including computer program source files, data files, and plain text documentation files, usually provide no information that identifies the text encoding they use. As explained below, Igor7 employs several strategies for determining a file's text encoding so that it can correctly convert the file's text to UTF-8 for internal storage and processing.

### Western Text Encodings

MacRoman and Windows-1252 (also called "Windows Latin 1") are used for Western European text and are collectively called "western".

In MacRoman and Windows-1252, the numeric code for each character is stored in a single byte. A byte can represent 256 values, from 0x00 to 0xFF. The 128 values 0x00 through 0x7F represent the same characters as ASCII in both text encodings. The remaining 128 values, from 0x80 to 0xFF, represent different characters in each text encoding. For example the value 0xA5 in MacRoman represents a bullet character while in Windows-1252 it represents a yen symbol.

When Igor6, running on Macintosh, loads an experiment written on Windows, it converts text from Windows-1252 to MacRoman. The opposite occurs if, running on Windows, it loads an experiment written on Macintosh.

When Igor7 loads an Igor6 experiment written on Macintosh, it converts from MacRoman to UTF-8. If the experiment was written on Windows it converts from Windows-1252 to UTF-8.

### Asian Text Encodings

Asian languages have thousands of characters so it is not possible to map one character to one byte as in western text encodings. Consequently various multi-byte text encodings were devised for different Asian languages. Such systems are sometimes called MBCS for "multi-byte character system".

Shift JIS is the predominant MBCS text encoding for Japanese. It uses a single byte for all ASCII characters and some Japanese characters and two bytes for all other Japanese characters.

In Shift JIS, the codes from 0x00 to 0x7F have the same meaning as in ASCII except for 0x5C which represents a backslash in ASCII but a yen symbol in Shift JIS. The codes from 0xA1 to 0xDF represent single-byte katakana characters. The codes from 0x81 to 0x9F and 0xE0 to 0xEF are the first bytes of double-byte characters.

Chinese and Korean text encodings also use MBCS.

Unlike the situation for western text, Macintosh and Windows both use the same, or practically the same, text encodings for Japanese. The same is true for Traditional Chinese and Simplified Chinese.

The MacJapanese and Windows-932 text encodings are variants of Shift JIS. In this documentation, "Shift JIS" and "Japanese" mean "Shift JIS or its variants MacJapanese and Windows-932".

When Igor7 loads an Igor6 experiment written in Shift JIS it converts text from Shift JIS to UTF-8.

### Unicode

The proliferation of text encodings for different languages and even for the same language on different operating systems complicated the exchange and handling of text. This led to the creation of Unicode - a system for representing virtually all characters in all languages with a single text encoding. The first iteration of Unicode was released in the early 1990's. It was based on 16-bit numbers rather than the 8-bit bytes of previous text encodings.

In 1993 Microsoft released Windows NT, one of the first operating systems to use Unicode internally. Mac OS X, developed in the late 1990's and released in 2001, also uses Unicode internally. Most applications at the time still used system text encoding and the operating systems transparently translated between it and Unicode as necessary.

In the mid-1990's the developers of Unicode realized that 16-bits, which can represent 65,536 distinct numbers, were not enough to represent all characters. They extended Unicode so that it can represent over one million characters by using two 16-bit numbers for some characters. However nearly all of the commonly-used characters can still be represented by a single 16-bit number.

Over time most applications migrated to Unicode for internal storage of text. Igor7 is the first version of Igor that uses Unicode internally.

## Unicode Character Encoding Schemes

Unicode maps each character to a unique number between 0 and 0x10FFFF (1,114,111 decimal). Each of these numbers is called a "code point".

There are several ways of storing a code point in memory or in a file. Each of them is called a "character encoding scheme". Each character encoding scheme is based on a "code unit" which may be a byte, a 16-bit value or a 32-bit value.

The most straight-forward character encoding scheme is UTF-32. The code unit is a 32-bit value and each code point is directly represented by a single code unit. UTF-32 is not widely used for historical reasons and because it is not memory-efficient.

UTF-16 is a widely-used character encoding scheme in which the code unit is a 16-bit value and each code point is represented by either one or two code units. Nearly all of the commonly-used characters require just one. Both Mac OS X and Windows use UTF-16 internally.

UTF-8 is a widely-used character encoding scheme in which the code unit is a byte and each code point is represented by one, two, three or four code units. The ASCII characters are represented by a single byte using the same code as in ASCII itself. All other characters are represented by two, three or four bytes. UTF-8 is the predominant character encoding scheme on the Worldwide Web and in email. It is the scheme used internally by Igor7 and later.

## Problems Caused By Text Encodings

The use of different text encodings on different operating systems, for different languages, and in different versions of Igor requires that Igor convert between text encodings when reading files. In Igor7 this means converting from the file's text encoding to UTF-8 which Igor7 uses for internal storage. Since ASCII text is the same in UTF-8 as in other byte-oriented text encodings, conversion and the problems it can cause are issues only for files that contain non-ASCII text.

Broadly speaking, when Igor7 opens an Igor6 file, three types of text encoding-related problems can occur:

- Igor's idea of the file's text encoding might be wrong (text encoding misidentification)
- The file may contain invalid byte sequences for its text encoding (invalid text)
- The file may contain a mixture of text encodings (mixed text encodings)

## Text Encoding Misidentification Problems

This problem stems from the fact that it is often unclear what text encoding a given file uses. The clearest example of this is the plain text file - the format used for text data files, Igor procedure files and plain text notebooks. A plain text file usually stores just the text and nothing else. This means that there is often nothing in a plain text file that tells Igor what text encoding the file uses.

The problem is similar for plain text items stored within Igor experiment files. These include:

- wave names, wave units, wave notes, wave dimension labels
- text wave contents
- the experiment recreation procedures stored in an experiment file
- the history area contents
- the built-in procedure window's contents
- packed procedure files
- packed plain text notebook files

Igor Pro 6.30 and later, which we will call Igor6.3x for short, store text encoding information in the experiment file for these items but earlier versions of Igor did not.

The text encoding information stored by Igor6.3x and later is not foolproof. Igor6.3x determines the text encoding for a procedure file or a plain text notebook based on the font used to display it. Usually this is correct but it is not guaranteed as the Igor6 user can change a font at any time.

Waves created pre-Igor6.3x have unknown text encodings for their various items.

Igor6.3x determines the text encoding for wave items when the wave is created based on the text encoding used to enter text into the user interface (e.g., into dialogs). This will be the system text encoding except that in IgorJ (the Japanese version of Igor), it is Japanese regardless of the system text encoding. Usually this produces the correct text encoding but it is not guaranteed as it is possible in Igor6 to make waves using any text encoding. For example, when running IgorJ you can switch the command line to an English font and create a wave whose name contains non-ASCII English characters. This name will therefore use MacRoman on Macintosh and Windows-1252 on Windows but IgorJ63x will record the wave name's text encoding as Shift JIS because that is the user interface text encoding. It is similarly possible to create a Japanese wave name when running an English Igor, causing Igor to record the wave name's text encoding as MacRoman or Windows-1252 even though the wave name is really Japanese.

Igor6.3x sets a wave's text encoding information when the wave is created. If a wave was created prior to Igor6.3x and is opened in Igor6.3x, its text encoding is unknown. Saving the experiment in Igor6.3x does not change this - the wave's text encoding is still unknown. So an Igor6.3x experiment can contain a mix of Igor6.3x waves with known text encodings and pre-Igor6.3x waves with unknown text encodings.

The three main causes of text encoding misidentification are:

- The file is a plain text file which contains no text encoding information
- The file is a pre-Igor6.3x experiment file which contains no text encoding information
- The Igor6.3x assumption that the text encoding can be deduced from the text encoding used to enter text into the user interface was incorrect

In order to convert text to UTF-8, Igor7 has to know the text encoding used when the text was created. If it gets this wrong then errors or garbled text will result. Some strategies for fixing such problems are described below.

### Invalid Text Problems

A file that contains text in a particular text encoding can be damaged, creating sequences of bytes that are illegal in that text encoding.

In Shift JIS, for example, there are rules about how double-byte characters are formed. The first byte must be in a certain range of values and a second byte must be in a different range of values. If, by error, a line break is inserted between the first and second bytes, the resulting text is not valid as Shift JIS.

Damage like this can happen in Igor6 with long Japanese textboxes. When Igor generates a recreation macro for a graph, it generates TextBox commands for textboxes. If the text is long, Igor breaks it up into an initial TextBox command and subsequent AppendText commands. Igor6 is not smart enough to know that it must keep the two bytes of a double-byte Japanese characters together. This problem is asymptomatic in Igor6 because the two bytes of the double-byte character are reassembled when the macro runs. But it causes an error if you load the Igor6 file into Igor7 because Igor7 must convert the entire file to UTF-8 for internal storage before any reassembly occurs.

There are many other ways to damage a Shift JIS file. Similar damage can occur with other multi-byte text encodings such as UTF-8.

When a file contains invalid text but you suspect that it is mostly OK, you can use the Choose Text Encoding dialog to change the text encoding conversion error handling mode. This allows you to open the file despite the invalid text.

### Mixed Text Encoding Problems

In Igor6, you can enter text in different text encodings by merely using different fonts. For example:

1. Run Igor6.3x with an English font controlling the built-in procedure window.
2. Create a graph.
3. Create an annotation using a Japanese font and Japanese characters in the graph.
4. Save the graph as a recreation macro.
5. Save the experiment.

Because an English font controls the built-in procedure window, Igor6.3x thinks that the text encoding for the procedure window is western (MacRoman or Windows-1252) and records this information in the experiment.

When Igor7 opens this experiment, it must convert the procedure window text to UTF-8. Since the Igor6.3x recorded the file's text encoding as western (MacRoman or Windows-1252), Igor7 attempts to convert the text from western to UTF-8. You will wind up with gibberish western characters where the Japanese text should be.

In this example Igor mistook Japanese text for western and the result was gibberish. If Igor mistakes western text for Japanese, you can either wind up with gibberish, or you may get an error, or you may see the Unicode replacement character (a white question mark on a black background) where the misidentified text was.

Fortunately this kind of problem is relatively rare. To fix it you need to manually repair the gibberish text in Igor7.

### **The Experiment File Text Encoding**

Experiments saved by Igor6.3x or later record the "experiment file text encoding". This is the text encoding used by the built-in procedure window at the time the experiment was saved. As explained below, Igor uses the experiment file text encoding as the source text encoding when converting a wave element to UTF-8 if the element's text encoding is unknown.

Prior to version 6.30 Igor did not record the experiment file text encoding so it defaults to unknown when a pre-Igor6.3x experiment is loaded into Igor7. It also defaults to unknown when you first launch Igor7 and when you create a new experiment.

You can display the experiment file text encoding for the currently open experiment in Igor7 by right-clicking the status bar and choosing Show Experiment Info. Igor will display something like "Unknown / 6.22" or "Mac Roman / 6.36". The first item is the experiment file text encoding while the second is the version of Igor that saved the experiment file. This information is usually of interest only to experts investigating text encoding issues.

### **The Default Text Encoding**

Because it is not always possible for Igor7 to correctly determine a file's text encoding, it sometimes needs additional information. You supply this information through the Default Text Encoding submenu in the Text Encoding submenu in the Misc menu. Igor uses your selected default text encoding when it can not otherwise determine the text encoding of a file or wave.

You can display the default text encoding for the currently open experiment in Igor7 by right-clicking the status bar and choosing Show Default Text Encoding. Displaying this information in the status bar is usually of interest only to experts investigating text encoding issues.

Igor experiment files record the platform (Macintosh or Windows) on which they were last saved. In Igor6.3x and later, Igor records text encoding information for most of the items stored in an experiment file. Neither platform information nor text encoding information is stored in standalone plain text files. Consequently determining the text encoding of an experiment file is different from determining the text encoding of a standalone file. This makes Igor's handling of text encodings and the meaning of the default text encoding setting more complicated than we would like.

The Default Text Encoding submenu contains the following items:

UTF-8  
Western  
MacRoman  
Windows-1252  
Japanese  
Simplified Chinese  
Traditional Chinese  
<Other text encodings>  
Override Experiment

When you open an experiment in Igor7, Western means MacRoman if the experiment was last saved on Macintosh and Windows-1252 if it was last saved on Windows. When you open a standalone file, Western means MacRoman if you are running on Macintosh and Windows-1252 if you are running on Windows.

The remaining text encoding items, such as MacRoman, Windows-1252 and Japanese, specify the text encoding to use for conversions to UTF-8 without regard to the platform on which the file was last saved or on which you are currently running.

When opening an experiment saved in Igor6.3x or later, Igor normally uses the text encoding information in the experiment file. As explained above under **Text Encoding Misidentification Problems** on page III-413, occasionally this information will be wrong. The Override Experiment item gives you a way to force Igor to use your selected text encoding even when opening experiments that contain text encoding information.

When Igor7 first runs it sets the default text encoding to Western or Japanese based on your system locale. This will give the right behavior when opening Igor6 experiments in most cases. Igor stores the default text encoding in preferences so when you launch Igor again it is restored.

For normal operation, leave the default text encoding setting on Western if you use a Western language or on the appropriate Asian language if you use an Asian language and leave Override Experiment unchecked.

Change these only if a problem arises. For example, if you are running an English system but you are opening a file containing Japanese, or if you are running a Japanese system but you are opening a file containing non-ASCII western text, you may get incorrect text or errors. To fix this, change the settings in this menu and reload the file. After loading the problematic file, reset the menu items for normal operation.

Igor sets the Override Experiment setting to unchecked each time Igor is launched since this is less likely to result in undetected erroneous text conversion than if you turned it on and unintentionally left it turned on.

In addition to affecting text encoding conversion during the loading of files, the default text encoding setting is used as follows:

- When you choose New Experiment, it determines the text encoding of the history area and built-in procedure window. This determines the text encoding used for these items when the experiment is saved to disk.
- When you create a new procedure or notebook window, if a text encoding was not explicitly specified, it determines the text encoding used when the file is saved to disk.
- When you insert text into an existing document using Edit→Insert File, it determines the source text encoding for conversion to UTF-8.
- When Igor loads a wave, it determines the source text encoding for conversion to UTF-8 if the source text encoding is not otherwise specified. This will be the case for waves created before Igor6.3x.
- When the help browser searches procedure files, notebook files and help files, it determines the source text encoding for conversion to UTF-8 if it is not otherwise known.

## Plain Text File Text Encodings

Plain text files include procedure files, plain text notebook files, the built-in procedure window text and history text.

Igor converts text that it reads from plain text files to UTF-8 for storage in memory. In order to do this, it needs to know what text encoding to convert from. Most plain text files contain no indication of their text encoding so it can be tricky to determine the source text encoding. If Igor gets the source text encoding wrong, you will get errors or see incorrect characters in the text.

Starting with Igor6.3x, Igor stores text encoding information for plain text files stored in or accessed by experiment files. Experiment files saved before Igor6.3x do not contain text encoding information. Stand-alone plain text files not part of an experiment file, such as Igor6 global procedure files, plain text notebook files and data files, also do not contain text encoding information.

Igor7 looks for the optional byte order mark (see **Byte Order Marks** on page III-420) that some programs write at the start of a Unicode plain text file. If present, the byte order mark unambiguously identifies the file as Unicode and identifies which encoding scheme (UTF-8, UTF-16 or UTF-32) the file uses.

Starting with Igor7, Igor supports a TextEncoding pragma in procedure files that looks like this:

```
#pragma TextEncoding = "<text encoding name>"
```

This is described under **The TextEncoding Pragma** on page IV-51. The TextEncoding pragma allows you to unambiguously specify the text encoding for an Igor procedure file. It is ignored by Igor6.

Igor7 must deal with a variety of circumstances including:

- Standalone files versus experiment files
- Pre-Igor6.3x experiment files versus experiment files from Igor6.3x and later
- Macintosh versus Windows versus Japanese experiment files
- Procedure files with and without a TextEncoding pragma

Because of these complications there is no simple way for Igor7 to determine the source text encoding for any given plain text file. To cope with this situation, Igor7 employs rules described in the next section.

The status bar of a plain text file's window includes a text encoding button which shows you the "file text encoding" - the text encoding that Igor used to convert the file's text to UTF-8. When the file is saved, Igor converts from UTF-8 back to the file text encoding. You can change the file text encoding by clicking the text encoding button to display the Text Encoding dialog.

### Determining the Text Encoding for a Plain Text File

This section describes the rules that Igor7 uses to determine the source text encoding for a plain text file.

The rules depend on whether Override Experiment (Misc→Default Text Encoding→Override Experiment) is checked.

#### Override Experiment Unchecked

If Override Experiment is unchecked, Igor tries the following text encodings, one-after-another, until it succeeds (i.e., it is able to convert to UTF-8 without error), in this order:

```
Byte order mark
TextEncoding pragma if present (for procedure files only)
The specified text encoding (described below)
UTF-8 if the text contains non-ASCII characters
The default text encoding
Choose Text Encoding dialog (described below)
```

## Chapter III-16 — Text Encodings

---

Note that a conversion can "succeed" without being correct. For example, Japanese can be successfully interpreted as MacRoman or Windows but you will get the wrong characters.

The "specified text encoding" is the explicit text encoding if present (e.g., specified by the /ENCG flag for the OpenNotebook operation) or the item text encoding (e.g., a text encoding stored in an experiment file for its built-in procedure window text).

If Igor can not otherwise find a valid text source encoding it displays the Choose Text Encoding dialog. This dialog asks you to choose the text encoding to use for the plain text file being opened.

### Override Experiment Checked

If the Misc→Default Text Encoding→Override Experiment menu item is checked then the order changes to this:

```
Byte order mark
TextEncoding pragma if present (for procedure files only)
The default text encoding
The specified text encoding (described below)
UTF-8 if the text contains non-ASCII characters
Choose Text Encoding dialog (described below)
```

In this mode the default text encoding, as set in the Misc→Default Text Encoding submenu, is given a higher priority. This should be used only if the normal mode fails to give the correct results. If you turn Override Experiment on, make sure to select the appropriate default text encoding from the submenu. You should turn Override Experiment on only in emergencies and turn it off for normal use.

## Potential Problems Determining Plain Text File Text Encodings

The rules listed above have the following potential problems:

### TextEncoding pragma (for procedure files only)

The pragma could be wrong. For example, if you set TextEncoding="MacRoman" and then change the file to UTF-8 in an external editor, it will still succeed in Igor but give the wrong characters. This is a programmer error and it is up to you to fix it.

### The specified text encoding

There is no specified text encoding for plain text files in a pre-Igor6.3x experiment.

In Igor6.3x and later, Igor includes text encoding information in the experiment restart procedures for each plain text file to be opened. This information is the "specified text encoding".

In Igor6.3x the specified text encoding can be wrong. For example, if the user adds some Japanese characters to a graph annotation, the recreation macro will include Shift-JIS. If the font controlling the procedure window is MacRoman or Windows, the specified text encoding will be MacRoman or Windows and the Japanese characters will show up wrong in Igor7.

### UTF-8 if the text contains non-ASCII characters

MacRoman, Windows and ShiftJIS can all masquerade as UTF-8 though this will be rare. By "masquerade" we mean that the non-ASCII bytes in the text are legal as UTF-8 but the text really is encoded using another text encoding.

For a procedure file you can fix this by adding a TextEncoding pragma.

There is currently no fix for plain text notebooks other than setting "Override Experiment" and setting the default text encoding to the correct encoding and reloading or converting the file to UTF-8 with a byte order mark.

### The default text encoding

If set to MacRoman or Windows, the default text encoding will always succeed but it might be wrong. For example, Japanese can be successfully interpreted as MacRoman or Windows but you will get the wrong characters.

For a procedure file you can fix this by adding a TextEncoding pragma.

There is currently no fix for plain text notebooks other than setting "Override Experiment" and setting the default text encoding to the correct encoding and reloading or converting the file to UTF-8.

### Plain Text Text Encoding Conversion Errors

When Igor7 opens a plain-text file or an Igor6-compatible experiment file, it must convert plain text to UTF-8. In order to do this, it needs to determine the text encoding of the plain text file or the plain text item within an experiment file.

As the previous section briefly outlined, it is possible that Igor might get this wrong. To illustrate the types of problems that can occur in this situation, we will consider the following scenario:

In Igor6.x you have created a standalone (not part of an experiment) plain text file on Windows with English as the system locale so the text in the file is encoded as Windows-1252. The file contains some non-ASCII characters. You transfer the file to Macintosh. Your default text encoding, as selected in the Default Text Encoding submenu of the Misc menu, is Western. You open the plain text file as a notebook in Igor.

Since the file is a plain text file, it contains nothing but plain text; it does not contain information indicating the platform of origin or the text encoding. Consequently Igor uses your selected default text encoding - Western. In the case of a plain text file, Western means "MacRoman when running on Macintosh, Windows-1252 when running on Windows", so Igor uses MacRoman to convert the text to UTF-8. This does not cause an error but gives an incorrect translation of the non-ASCII characters in the file.

Unfortunately, Igor has no way to detect this kind of misidentification error. The conversion completes without error but produces some incorrect characters and there is no way for Igor to know that this has happened. This is an example of a conversion that succeeds but is incorrect.

To get the correct characters you must close the file, choose Windows-1252 from the Default Text Encoding menu, and reopen the file. Now Igor will correctly translate the text to UTF-8. You should restore the default text encoding to its normal value for future use.

An alternative solution is to execute OpenNotebook/ENCG=3. This explicitly tells Igor that the file's text encoding is Windows-1252. Igor's text encoding codes are listed under **Text Encoding Names and Codes** on page III-434.

Now let's change the scenario slightly:

Instead of your default text encoding being set to Windows-1252, it is set to Japanese. You open the standalone plain text file containing Windows western non-ASCII characters as a notebook on either Macintosh or Windows.

Since the file does not contain any text encoding information, Igor tries to convert the text to UTF-8 using default text encoding, Japanese, as the original text encoding. Two things may happen:

- The conversion may succeed. In this case you will see some seemingly random Japanese characters in your notebook because, although the conversion succeeded, it incorrectly interpreted the text.
- The conversion may fail because the file contains byte patterns that are illegal in the Shift JIS text encoding. In this case Igor will display the Choose Text Encoding dialog and you can choose the correct text encoding.

### Some Plain Text Files Must Be Saved as UTF-8

When Igor saves a plain text file, it tries to save using the file's original text encoding. Sometimes this is not possible. For example:

You open a file that contains MacRoman text including non-ASCII characters as an Igor procedure file and Igor converts it to UTF-8 for internal storage. Now you add a Japanese character to the procedure file and save it.

The file can not be saved as MacRoman because MacRoman can not represent Japanese characters. In this event, Igor saves the file in UTF-8 and displays an alert informing you of that fact. If you open this file in Igor6, any non-ASCII characters will be incorrect.

If you tell Igor to save a plain text file in a specific text encoding, for example via `SaveNote-book/ENCG=<textEncoding>`, and if it is not possible to save in that text encoding, Igor returns a text encoding conversion error. You can then explicitly tell Igor to save as UTF-8 using `SaveNote-book/ENCG=1`.

### History Text Encoding

When an experiment is saved, Igor saves the history text as plain text.

When you create a new experiment, Igor sets the history area text encoding to your chosen default text encoding. When you save the experiment, Igor tries to save the history text using that text encoding. If the history text contains characters that can not be represented in your default text encoding, Igor then saves the history text as UTF-8 and sets the history area text encoding to UTF-8. If you open this experiment in Igor6, any non-ASCII characters in the history, including the bullet characters used to mark commands, will appear as garbage.

The Shift JIS (Japanese) text encoding does not have a character that maps to the bullet character (U+2022). Consequently, if your default text encoding is Shift JIS, when you save an experiment, Igor will be unable to save the history text as Shift JIS and will save it as UTF-8 instead.

### Byte Order Marks

A byte order mark, called a BOM for short, is a special character sometimes used in Unicode plain text files to identify the file as Unicode and to identify the Unicode encoding form used by the file. The BOM, if present, must appear at the beginning of the file.

A FAQ about BOMs can be found at [http://www.unicode.org/faq/utf\\_bom.html#BOM](http://www.unicode.org/faq/utf_bom.html#BOM).

Most Unicode plain text files omit the BOM. However, including it has the advantage of unambiguously identifying the file's text encoding.

The BOM is the Unicode "zero width no-break space" character. It's code point is U+FEFF which is represented by the following bytes:

UTF-8	0xEF 0xBB 0xBF
UTF-16 Little Endian	0xFF 0xFE
UTF-16 Big Endian	0xFE 0xFF
UTF-32 Little Endian	0x00 0x00 0xFF 0xFE
UTF-32 Big Endian	0xFE 0xFF 0x00 0x00

If a Unicode file contains a BOM, Igor preserves it when saving the file.

By default Igor7 writes a BOM when writing a Unicode plain text file and removes the BOM, if present, when reading a plain text file into memory.

When Igor creates a new plain text file, it sets an internal writeBOM flag for that file to true. If the file is later saved to disk as Unicode and if the writeBOM flag is still set, Igor writes the BOM to the file.

When Igor opens a plain text file, it checks to see if the file contains a BOM. If not it clears the file's writeBOM flag. If the file does contain a BOM, Igor sets the writeBOM flag for the file and removes the BOM from the text as loaded into memory. When Igor writes the text back disk, if the writeBOM flag is set, Igor writes the BOM and then the text.

You can see the state of the writeBOM flag using the File Information dialog which you access via the Notebook or Procedure menu. If the file's text encoding is a form of Unicode and the writeBOM flag is set, the Text Encoding section of the File Information dialog will say "with byte order mark".

You can specify the value of the writeBOM flag for a plain text notebook file using **NewNotebook** with the /ENCG flag.

You can set or clear the writeBOM flag for a plain text notebook or procedure file using the Text Encoding dialog accessed via the Notebook or Procedure menu. The Write Byte Order Mark checkbox is visible only if a Unicode text encoding is selected. You can also set the writeBOM flag for a plain text notebook using the **Notebook** operation, writeBOM keyword.

The built-in procedure window is a special case. Its writeBOM flag defaults to false and it is set to false each time you do New Experiment. We make this exception to allow Igor6 to open an Igor7 experiment whose procedure window text encoding is UTF-8 without generating an error. Igor6 does not know about UTF-8 so non-ASCII characters will be wrong, but at least you will be able to open the experiment.

If you modify a plain text file that is open as a notebook or procedure file using an external editor, Igor reloads the text from the modified file. This sets the internal writeBOM flag for the notebook or procedure file to true if the modified text includes a BOM or false otherwise. This then determines whether Igor writes the BOM if you later save the file. This process of reloading an externally-modified plain text file overwrites the writeBOM flag that you may have set using the Text Encoding dialog or Notebook operation.

BOMs are irrelevant for formatted text notebooks.

## **Formatted Text Notebook File Text Encodings**

Formatted notebook files use an Igor-specific file format. You can open such a file as a formatted notebook or as an Igor help file.

Unlike plain text files, in which all text must be encoded using a single text encoding, Igor6 formatted notebook files can use multiple text encodings in a single file. In Igor6, the text encoding for a given format run is determined by the font controlling that run. For example, a single Igor6 formatted text file can contain western text and Shift JIS (Japanese) text encodings. In fact a single paragraph can contain multiple text encodings.

We use the term MBCS (multi-byte character system) to distinguish these Igor6 formatted text files from Igor7 formatted text files saved using UTF-8.

Igor7 stores text internally (in memory) as UTF-8. Consequently it must convert MBCS text into UTF-8 when opening Igor6 formatted files. When doing this conversion, Igor uses text encoding information written to the file by IP6.3x and later. Pre-IP6.3x formatted text notebook files lack this text encoding information and so may be misinterpreted by Igor7. If you open a formatted text notebook in Igor7 and you get incorrect characters or text encoding conversion errors, try opening and resaving the file in Igor Pro 6.3x, and then reopen in Igor7.

When Igor7 saves a formatted text notebook, it first tries to save it in Igor6-compatible MBCS format. If any format run in the file uses characters that can not be encoded in a single non-Unicode text encoding then it is not possible to save in MBCS format. This would happen, for example, if you mix non-ASCII western characters and Shift JIS characters in a single format run (i.e., controlled by a single font) or if you use a Unicode character that can not be represented in MBCS. In this case, Igor7 saves the file in UTF-8 and dis-

plays an alert explaining the change. If you try to open this file in Igor6.3x, it displays a message in the history area explaining that the file uses UTF-8 so any non-ASCII characters will appear garbled.

In Igor7, to determine how a particular file is saved, click the page icon in the lower-lefthand corner of a formatted notebook or help window. The resulting File Information dialog will say either "MBCS" or "UTF-8" in the Text Encoding area.

If you open an Igor7 UTF-8 formatted text notebook in Igor Pro 6.36 or before and then save the notebook, it is marked as an Igor6 notebook using MBCS even though it really contains UTF-8 text. If you subsequently open the notebook in Igor7, all non-ASCII characters will be incorrectly interpreted as MBCS and will be wrong.

If you open a UTF-8 Igor7 formatted text notebook in Igor Pro 6.37 or a later 6.x version and then save the notebook, it is marked as an Igor7 notebook using UTF-8 text encoding. Igor6 will still display the wrong characters for non-ASCII text, but if you subsequently open the notebook in Igor7, the non-ASCII characters will be correctly interpreted as UTF-8.

## Wave Text Encodings

Each wave internally stores several plain text elements. They are:

- wave name
- wave units
- wave note
- wave dimension labels
- text wave content (applies to text waves only)

Each wave stores five settings corresponding to these five plain text elements. The settings record the text encoding used for the corresponding element.

You can inspect the text encodings of the wave elements of a particular wave using the Data Browser. To do so, you must first enable the Text Encoding checkbox in the Info pane of the Data Browser section of the Miscellaneous Settings dialog.

For waves created prior to Igor6.3x, all of the settings are set to 0 which means "unknown". This is because the notion of wave text encodings was added only in Igor Pro 6.30, in anticipation of Igor7 and its use of Unicode as the primary text storage format.

When you make a wave in Igor6.3x the text encoding for each element is set to the system text encoding (typically MacRoman, Windows-1252 or Japanese) except for the text wave content element which is set to "unknown". The reason for treating the text wave content element differently is because the data may be binary data as explained below under **Text Waves Containing Binary Data** on page III-424.

When you make a wave in Igor7, including when you overwrite an existing wave, the text encoding for each element, including the text wave content element, is set to UTF-8.

These defaults are set when you make or overwrite a wave using Make, Duplicate, LoadWave and any other operation that creates a wave. After creating the wave, you can change them explicitly using **SetWaveTextEncoding**, but only advanced users should do this.

If you overwrite an existing text wave, the text encoding for each element, including the text wave content element, is set to UTF-8, the same as when you first create the wave. However, the wave's text content is not cleared or converted to UTF-8 because it is presumed that you will be completely rewriting the content and, if Igor cleared or converted it on overwriting, it would be a waste of time. If the wave contains non-ASCII text and its previous text content text encoding was not UTF-8, this leaves the wave with invalid text content. This is normally not a problem since you will completely rewrite the text anyway. But if you want to make sure that there is no invalid text, you can clear the wave's text content in the Make/T/O statement. For example:

```
Make/T/O textWave = ""
```

In addition, the text encoding setting for the wave name is set if you rename the wave and the text encoding for the wave note is set if you change the wave note text. However the text encoding for the wave units is not set if you set the units using `SetScale`, the text encoding for the dimension labels is not set if you set a dimension label using `SetDimLabel`, and the text encoding for the text content of a text wave is not set if you store text in an element of the wave.

Opening an experiment does not change the text encoding settings for the waves in the experiment. Neither does saving an experiment.

When Igor7 uses one of these wave elements, it must convert the text from its original text encoding into UTF-8. It uses the rules listed in the next section to determine the original text encoding.

## Determining the Text Encoding for Wave Elements

This section describes the rules that Igor7 uses to determine the source text encoding for a wave element when loading a wave from an Igor binary wave file or from a packed experiment file. You don't need to know these rules. We present them for technically-oriented users who are interested or who need to understand the details to facilitate troubleshooting.

1. If the element's text encoding is set to UTF-8, Igor uses UTF-8 as the source text encoding.

Igor7 saves text as UTF-8 if it can not be represented in another text encoding. This rule ensures that Igor7 correctly loads such text.

2. Otherwise if Override Experiment is turned on, Igor uses the selected default text encoding as the source text encoding.

This provides a way for you to override incorrect text encoding settings when loading an experiment. For example, if you know that an experiment uses Japanese but you get gibberish or Unicode conversion errors when loading it, you can choose Japanese as your default text encoding, select Override Experiment, and reload the experiment. You should restore the default text encoding to its normal value and turn Override Experiment off for future use.

3. Otherwise if the text encoding for the specific element being converted is known, because it was previously set to a value other than "unknown", Igor uses it as the source text encoding.

This is the effective rule for waves created by Igor6.3x and later.

This is also the effective rule if you explicitly set a wave's text encoding settings using the **SetWaveTextEncoding** operation.

4. Otherwise if the experiment file text encoding is known, Igor uses it as the source text encoding.

This rule takes effect for waves created in earlier versions if the experiment was later saved from Igor6.3x or later. Wave text encoding settings would still be unknown but the experiment file text encoding would reflect the text encoding of the experiment's procedure window when it was saved. This will give correct results for most experiments.

5. Otherwise Igor uses the selected default text encoding as the source text encoding.

This rule takes effect for experiments saved before Igor6.3x in which both the experiment file text encoding and the element-specific text encodings are unknown. This is the effective rule for experiments of this vintage.

## Wave Text Encoding Problems

This section describes the problems that may occur when loading a wave from an Igor binary wave file or from a packed experiment file.

If Igor7 is not able to correctly determine a wave element's text encoding and if the element contains non-ASCII text you may see gibberish text or Igor may generate a text encoding conversion error.

If Igor7 is not able to correctly determine the text encoding of a wave name you will see gibberish for the name and Igor will be unable to find the wave when it is referenced from procedures such as experiment recreation procedures. This may cause errors when the experiment is loaded.

Igor's handling of invalid text in tables is described under **Editing Invalid Text** on page II-194.

The **SetWaveTextEncoding** operation allows you to set the text encodings for one or more waves or for all waves in the experiment. This is especially useful for pre-IP6.3x experiments. You can run it in Igor6.3x as well as Igor7. It is discussed below under **Manually Setting Wave Text Encodings** on page III-427.

If you get text encoding conversion errors when opening an experiment you can try the following:

- Choose a different text encoding from the Default Text Encoding menu and reopen the experiment
- Select Override Experiment in the Default Text Encoding menu so that it is checked and reopen the experiment
- Manually fix the errors after opening the experiment in Igor7
- Use the **SetWaveTextEncoding** operation to specify the text encodings used by waves
- For pre-IP63x experiments, open the experiment in Igor6.3x, resave it, and reopen it in Igor7

After attempting to fix a text encoding problem you should restore your default text encoding to the most reasonable setting for your situation and turn Override Experiment off.

If you are unable to solve the problem you can send the experiment to WaveMetrics support with the following information:

- What operating system you are running
- What Igor version you are running
- What incorrect output you are seeing and what you expect to see

### LoadWave Text Encodings for Igor Binary Wave Files

The rules that LoadWave uses to determine the source text encoding of an Igor binary wave file are the same as the rules described under **Determining the Text Encoding for Wave Elements** on page III-423. The LoadWave /ENCG flag is ignored when loading an Igor binary wave file.

### LoadWave Text Encodings for Plain Text Files

This section describes the rules that the LoadWave operation uses to determine the source text encoding when loading a plain text file. This includes general text, delimited text and Igor text files but not Igor binary wave files.

The rules that LoadWave uses to determine the source text encoding of a plain text file are the same as the rules described under **Determining the Text Encoding for a Plain Text File** on page III-417. The "specified text encoding", which is one of the factors used by the rules, is unknown unless you use the /ENCG flag to tell LoadWave the file's text encoding.

For further details see *LoadWave Text Encoding Issues* in the reference documentation for **LoadWave**.

### Text Waves Containing Binary Data

You can set a text wave's content text encoding to the special value 255 using **SetWaveTextEncoding**. This marks a text wave as really containing binary data, not text.

Text is data that is represented by numeric codes which map to characters using some recognized text encoding such as MacRoman, Windows-1252, Shift JIS or UTF-8. By contrast, binary data does not follow any recognized text encoding and generally does not map to characters. Whereas text data is typically

intended to be readable by humans using a text editor, binary data is intended to be processed only by programs.

You can mark any text wave element as binary but it is normally done only for text wave content because it is rare to store binary data in wave units, wave notes or wave dimension labels.

Igor text waves were designed to store text but are able to store any collection of bytes.

While a numeric wave stores a fixed number of bytes in each element, a text wave has the ability to store a different number of bytes in each point. For example:

```
Make /O /T /N=2 twave0
twave0[0] = "Hello"           // 5 bytes
twave0[1] = "Goodbye"        // 7 bytes
```

This capability makes a text wave a convenient way to store a collection of binary arrays of different length. For example, you could store the contents of a different downloaded file in each element of a text wave:

```
Make /O /T /N=2 twave0
twave0[0] = FetchURL("http://www.wavemetrics.net/images/tbg.gif")
twave0[1] = FetchURL("http://www.wavemetrics.net/images/mbg.gif")
```

While most text waves contain text data, clever programmers sometimes use text waves to store binary data. Since binary data does not follow any recognized text encoding, it must not be treated as text. For example, you can convert a text wave from Shift JIS to UTF-8 and preserve the meaning of the text; you are merely changing how the characters are encoded. By contrast, if you attempt to convert binary data which you have mistaken for text, you turn your data into garbage.

The **SetWaveTextEncoding** operation can convert text waves from one text encoding to another but you never want to convert binary text waves. SetWaveTextEncoding conveniently skips text waves marked as binary when doing a conversion but it is up to you to mark such waves appropriately. Here is an example that illustrates the utility of marking a text wave as containing binary data:

```
// Mark contents as binary
SetWaveTextEncoding 255, 16, root:MyBinaryTextWave
// Convert contents to UTF-8 skipping binary waves
SetWaveTextEncoding /DF={root:,1} /CONV=1 1, 16
```

The first command marks a particular wave's content (16) as containing binary (255) as opposed to text. The second command converts all text wave text to UTF-8 (1) except that it automatically skips waves marked as binary.

This is fine but it would be tedious to identify and mark each text wave containing binary data. So SetWaveTextEncoding provides a way to do it automatically:

```
// Mark all binary waves as binary
SetWaveTextEncoding /BINA=1 /DF={root:,1} 255, 16
// Convert to UTF-8 skipping binary waves
SetWaveTextEncoding /DF={root:,1} /CONV=1 1, 16
```

The first command goes through each wave in the experiment. If it is a text wave, it examines its contents. If the wave contains control characters (codes less than 0x20) other than carriage-return (0x0D), linefeed (0x0A) and tab (0x09), it marks the wave as containing binary. Then the second command converts all non-binary text waves to UTF-8. These commands can be combined into one:

```
// Mark as binary then convert non-binary to UTF-8
SetWaveTextEncoding /BINA=1 /DF={root:,1} /CONV=1 1, 16
```

**NOTE:** The heuristic used by the /BINA flag is not foolproof. While most binary data will contain 0x00 bytes or other bytes that flag it as binary, it is possible to have binary data that contains no such bytes. In that case, the first command would fail to mark the text waves as containing binary and the second command would

## Chapter III-16 — Text Encodings

---

either return an error or clobber the binary data. For this reason, it is imperative that you back up any data before doing text encoding conversions.

**PROGRAMMER'S NOTE:** If you are a programmer and you create text waves to store binary data, be sure to mark them as binary. For example:

```
Wave/T bw = <path to some text wave used to contain binary data>
SetWaveTextEncoding 255, 16, bw           // Mark text wave as binary
```

Doing this will ensure that your binary data is not "converted" to some text encoding, thereby clobbering it.

### Handling Text Waves Containing Binary Data

Usually you use a text wave containing binary data only as a container to be accessed by procedures that understand how to interpret the contents. You normally should not treat it as text. For example, you should not print its contents to the history because this treat the wave's binary contents as text. If you do treat it as text you are likely to get gibberish or a Unicode conversion error.

You can view a text wave marked as binary in a table and you can cut and paste its cells but you can not edit the binary data in the table's entry line. You can dump the contents of a cell as hex to the history area by pressing Cmd (Macintosh) or Ctrl (Windows) and double-clicking the cell.

Igor7 normally does automatic text encoding conversion when fetching data from a text wave or storing data into a text wave. For example:

```
// Make a wave to contain text in UTF-8 text encoding
Make /O /T UTF8 = {"<some Japanese text>"}           // UTF-8 by default
```

```
// Make a wave to contain text in Shift JIS text encoding
Make /O /T /N=1 ShiftJIS                             // UTF-8 by default
SetWaveTextEncoding 4, 16, ShiftJIS                   // Now Shift JIS
```

```
ShiftJIS = UTF8
```

The last statement triggers a fetch from the wave UTF8 and a store into the wave ShiftJIS. A fetch converts a text wave's data to UTF-8. In this case it is already UTF-8 so no conversion is done. A store converts the data to the text encoding of the destination wave - Shift JIS in this case. You wind up with the same characters in ShiftJIS and in UTF8 but not the same raw bytes because they are governed by different text encodings.

Igor7 does not do text encoding conversion when fetching from a wave or storing into a wave if the wave is marked as binary. For example:

```
// Make a wave to contain binary data
Make /O /T /N=1 Binary                               // UTF-8 by default
SetWaveTextEncoding 255, 16, Binary                   // Now binary
Binary = UTF8
```

The last statement's storing action does not do text encoding conversion because the destination wave is marked as binary. Thus Binary will wind up with the same bytes as in UTF8.

Now consider this:

```
Binary = ShiftJIS
```

Once again the last statement's storing action does not do text encoding conversion because the destination wave is marked as binary. You might think that Binary would wind up with the same bytes as in ShiftJIS but you would be wrong. The reason is that the fetching action triggered by evaluating the righthand side of the assignment statement converts the Shift JIS text in ShiftJIS to Igor's internal standard, UTF-8. Consequently the same bytes wind up being stored in Binary after each of the two previous statements.

The moral of the story is that, if you want to transfer binary data between text waves, make sure that both waves are marked as binary. It will also work if the source wave is marked as UTF-8 since the fetch conversion does nothing if the source is UTF-8.

## Manually Setting Wave Text Encodings

**NOTE:** Back up your experiment before fiddling with text encoding settings.

With the concepts of wave plain text elements, their text encoding settings, and text waves containing binary data in mind, we can now consider a general approach for setting wave text encodings. This is a task for advanced users only.

As a test case, we will assume that you created an experiment using Igor Pro 6.22 on Windows with English as the system locale. Consequently the experiment contains waves with all text encoding settings set to unknown. You then opened the experiment in Igor Pro 6.30, again on Windows with English as the system locale, and created additional waves. These added waves have text encoding settings set to Windows-1252 except for the text wave content element which is set to unknown. Finally, somewhere along the line, some text waves were created to store binary data, possibly by a package that you use and without your knowledge.

We now open the experiment in Igor7 and try to set all of the text encoding settings to correct known values using the `SetWaveTextEncoding` operation. The magic numbers used in the following commands are detailed below under **Text Encoding Names and Codes** on page III-434 and **SetWaveTextEncoding**.

```
// Mark any text waves containing binary data as such.
// 255 means "binary". 16 means "text wave content".
// /DF={root:,1} means "all waves in all data folders".
// /BINA=1 means "automatically mark text waves containing binary data".
SetWaveTextEncoding /DF={root:,1} /BINA=1 255, 16

// Mark any wave text elements currently set to unknown as Windows-1252.
// 0 means "unknown". 3 means Windows-1252. 31 means "all wave elements".
// /ONLY=0 means apply the command only to wave elements currently marked as
// unknown.
SetWaveTextEncoding /DF={root:,1} /ONLY=0 3, 31
```

Now all elements of all waves are set to Windows-1252 except for the content element of text waves containing binary data which are so marked. In other words, there are no unknown text encodings and all elements are correctly marked. Marking all waves correctly ensures that Igor7 can correctly convert the wave plain text elements to UTF-8 for internal use.

If you were starting from a MacRoman experiment (Macintosh western text), you would use 2 instead of 3. If you were starting from a Japanese experiment (Shift JIS), you would use 4 instead of 3.

**NOTE:** The heuristic used by the `/BINA` flag is not foolproof. See **Text Waves Containing Binary Data** on page III-424 for details.

At this point you may want to convert your waves from Windows-1252 to UTF-8. This provides two advantages. First, Igor7 will not need to convert to UTF-8 when fetching the text waves' contents since the waves will already be UTF-8. Second, you will be able to use a wider repertoire of characters. The disadvantage is that you will get gibberish for non-ASCII characters if you open the experiment in any pre-Igor7 version. Assuming that you do want to convert to UTF-8, you would execute this:

```
// 1 means UTF-8. 31 means "all wave elements".
// /CONV means "convert text encoding". It automatically skips text wave
// content marked as binary.
SetWaveTextEncoding /DF={root:,1} /CONV=1 1, 31
```

### Data Folder Name Text Encodings

Igor Pro 7.00 through 7.01 were unable to correctly load non-ASCII data folder names from Igor6 packed experiment files. Starting with version 7.02, in most cases, Igor correctly loads such data folder names.

If Igor mangles a non-ASCII data folder name when loading an Igor6 experiment, try choosing the correct text encoding from the Misc->Text Encoding->Default Text Encoding menu and turn Misc->Text Encoding->Default Text Encoding->Override Experiment on. Remember to restore these settings to their original settings after loading the experiment.

Starting with Igor Pro 7.02, Igor writes non-ASCII data folder names to packed experiment files using the text encoding of the built-in procedure window if possible. This will be Igor6-compatible if that text encoding is MacRoman on Macintosh or Windows-1252 on Windows. Igor Pro 7.00 through 7.01 expect UTF-8 and will therefore misinterpret such data folder names unless the text encoding of the built-in procedure window is UTF-8.

### String Variable Text Encodings

Unlike the plain text elements of waves, there is no text encoding setting for string variables. Consequently Igor7 treats a string variable as if it contains UTF-8 text when printing it to the history area or when displaying it in an annotation or control panel or otherwise treating it as text.

If you have string variables in Igor6 experiments that contain non-ASCII characters, they will be misinterpreted by Igor7. This may cause gibberish text or it may cause a Unicode conversion error. In either case you must manually fix the problem by storing valid UTF-8 text in the string variable.

For a local string variable, you can achieve this by assigning a new value to the string variable or by converting its contents from its original text encoding to UTF-8 using the **ConvertTextEncoding** function.

For a global string variable, you can achieve this by converting its contents from its original text encoding to UTF-8 using the **ConvertGlobalStringTextEncoding** operation. You need to know the original text encoding. It will typically be MacRoman if the Igor6 experiment was created on Macintosh, Windows-1252 if it was created on Windows, or Shift JIS if it was created using a Japanese version of Igor.

ConvertGlobalStringTextEncoding can convert all global string variables in the current experiment at once. Choose Misc->Text Encoding->Convert Global String Text Encoding to generate a ConvertGlobalStringTextEncoding command.

If you don't print or display a string variable or compare it to other text then its text encoding does not matter. For example, if you have a string variable that contains binary data and it is treated by your procedures as binary data, then everything will work out.

### String Variable Text Encoding Error Example

This section gives a concrete example of a text encoding error which may help you to understand text encoding issues. As you read the example, keep these thoughts in mind:

- A text wave stores the raw bytes representing its text and an explicit setting that tells Igor the text encoding of the raw bytes. When you access an element of a text wave, Igor converts it to UTF-8 if it is not already stored as UTF-8 and is not marked as binary. During this conversion Igor uses the wave's explicit text encoding setting.
- String variables and other string expressions do not have text encoding settings and are always assumed to contain text encoded as UTF-8.

This example shows how you can create a text encoding problem and how you can avoid it.

```
Function TextEncodingErrorExample()  
    // Make a text wave. Its text encoding defaults to UTF-8.  
    Make /O/T/N=1 textWave0
```

```

// Create a string variable containing non-ASCII text (the character ¹).
// Igor converts literal text ("¹ != 3" in this case) to UTF-8
// and stores it in the string variable.
String text = "¹ != 3"                                // Stored as UTF-8

// Convert the string variable contents to MacRoman.
// Since the string has no text encoding setting, Igor still assumes it
// contains UTF-8 but we know it really contains MacRoman.
Variable textEncodingUTF8 = TextEncodingCode("UTF-8")
Variable textEncodingMacRoman = TextEncodingCode("MacRoman")
text = ConvertTextEncoding(text, textEncodingUTF8, textEncodingMacRoman, 1, 0)

// Store the MacRoman text in the text wave. This creates bad data
// because Igor assumes you are storing UTF-8 text in a UTF-8 text wave
// when in fact you are storing MacRoman into a UTF-8 text wave.
textWave0 = text                                        // Store incorrect data

// Print - an incorrect character will be printed because the wave's
// text encoding setting is incorrect for the raw data bytes stored in it.
Print textWave0[0]

// Here is one way to fix the problem - convert the string variable to UTF-8.
String textUTF8 = ConvertTextEncoding(text, textEncodingMacRoman,
                                     textEncodingUTF8, 1, 0)
textWave0 = textUTF8                                    // Store correct data

// Print again - this time it prints correctly because the wave's
// raw text bytes are consistent with the wave text encoding setting.
Print textWave0[0]

// Create the problem again so we can see another way to fix it.
textWave0 = text                                        // Store incorrect data

// Here is another way to fix the problem - by correcting Igor's idea
// of what text encoding the wave is using.
// Tell Igor that the text wave stores text encoded as MacRoman.
SetWaveTextEncoding textEncodingMacRoman, 16, textWave0

// Print again - this time it prints correctly because Igor knows
// that the wave contains MacRoman and so converts from MacRoman
// to UTF-8 before sending the text to the history.
Print textWave0[0]
End

```

## Text Encoding Programming Issues

Igor6 and earlier versions of Igor stored text in "system text encoding". For western users this means MacRoman on Macintosh and Windows-1252 on Windows. For Japanese users it means Shift JIS on both platforms.

Igor7 uses UTF-8, a form of Unicode, exclusively.

If you are an Igor programmer attempting to support both Igor6 and Igor7, and if you or your users use non-ASCII text, the introduction of Unicode in Igor7 entails compatibility challenges.

If you fall in this category, we highly recommend that you abandon the idea of supporting Igor6 and Igor7 with the same procedure files. Instead, freeze your Igor6 code, and do all new development in the Igor7 fork. Here are the reasons for not attempting to support Igor6 and Igor7 with the same code base:

1. You will be unable to use new Igor7 features without using `ifdefs` and other workarounds.

2. The use of `ifdefs` and workarounds will clutter your code and introduce bugs in formerly working Igor6 code.
3. You will have to deal with tricky text encoding issues, as explained in the next section.
4. Eventually Igor6 will be ancient history.

The alternative to supporting both Igor6 and Igor7 with the same procedure files is to create two versions of your procedures, one version for Igor6 and another for Igor7 and beyond. The benefits of this approach are:

1. You avoid cluttering your Igor6 code or introducing new bugs in it.
2. It will be much easier to write Igor7 code and it will be cleaner.
3. Your Igor7 code can use the full range of Unicode characters.

The costs of this approach are:

1. If you fix a bug in the Igor6 version of your code, you will have to fix it in the Igor7 version also.
2. New features of your code will be unavailable to Igor6 users.

The next section gives a taste of the text encoding issues raised by the use of Unicode in Igor7.

### Literal Strings in Igor Procedures

Consider this function, which prints a temperature with a degree sign in Igor's history area:

```
Function PrintTemperature(temperature)
    Variable temperature

    // The character after %g is the degree sign
    Printf "The temperature is %g°\r", temperature
End
```

The degree sign is a non-ASCII character. It is encoded as follows:

MacRoman	0xA1
Windows-1252	0xB0
Shift JIS (Japanese)	0x81 0x8B
UTF-8	0xC2 0xB0

To simplify the discussion, we will ignore the issue of Japanese.

If you created the procedure file in Igor6 on Macintosh, it would work correctly in Igor6 on Macintosh but would print the wrong character in Igor6 on Windows. If you opened the procedure file in Igor7 with "Western" selected in Misc→Text Encoding→Default Text Encoding, it would work correctly on Macintosh but would print the wrong character on Windows. If you added this to the procedure file:

```
#pragma TextEncoding = "MacRoman"
```

it would work correctly in Igor7 on both Macintosh and Windows.

### Literal Strings in Igor6/Igor7 Procedures

If you want it to work in Igor6 and Igor7, on Macintosh and Windows, and irrespective of the text encoding of the procedure file and the Misc→Text Encoding→Default Text Encoding setting, you will need to do this:

```
#if IgorVersion() >= 7.00
    static StrConstant kDegreeSignCharacter = "\xC2\xB0"
```

```

#else
    #ifdef MACINTOSH
        static StrConstant kDegreeSignCharacter = "\241"
    #else
        static StrConstant kDegreeSignCharacter = "\260"
    #endif
#endif

Function PrintTemperature(temperature)
    Variable temperature

    // The character after %g is the degree sign
    Printf "The temperature is %g%s\r", temperature, kDegreeSignCharacter
End

```

This code uses escape sequences instead of literal characters to keep non-ASCII characters out of the procedure file. This allows it to work regardless of the text encoding of the procedure file in which it appears. For Igor7, it uses the \xxx hexadecimal escape sequence. Igor6 does not support \xxx so it uses octal (\ooo) instead.

The section **Determining the Encodings of a Particular Character** on page III-432 shows how we determined the hex and octal codes.

The reason for making the StrConstants static is that other programmers may include the same code, causing a compile error if a user uses both sets of procedures.

The string constant kDegreeSignCharacter produces the correct string in Igor6 on Macintosh and Windows, and in Igor7 on Macintosh and Windows.

This will not print the right character for an Igor6 user using a Japanese font for the history area. Since you can not know the user's history area font, there is no way to cope with that.

If you have code that assumes that degree sign is one byte, you will need to modify it, since it is two bytes in UTF-8.

If the degree sign is the only non-ASCII character that you need to represent in Igor6 and Igor7, this problem is manageable. If not, you will need similar code for other characters. The additional complexity and kludginess will get out of hand. That's why we recommend against supporting Igor6 and Igor7 with the same set of procedures.

### **Literal Strings in Igor7-only Code**

If your procedure file requires Igor7 or later, you can write the PrintTemperature function in the obvious way:

```

#pragma TextEncoding = "UTF-8"
#pragma IgorVersion = 7.00

Function PrintTemperature(temperature)
    Variable temperature

    // The character after %g is the degree sign
    Printf "The temperature is %g°\r", temperature
End

```

This will work in Igor7 or later on Macintosh and Windows, and without regard to the user's history font or the Misc→Text Encoding→Default Text Encoding setting.

Unlike the previous approaches, this technique allows you to use any Unicode character, not just the small subset available in MacRoman or Windows-1252.

### Determining the Encodings of a Particular Character

This section shows a method for determining how a given character is encoded in MacRoman, Windows-1252, and UTF-8. The commands must be executed in Igor7 because they use the ConvertTextEncoding function which does not exist in Igor6.

```
// Print MacRoman code for degree sign as octal - Prints 241
Printf "%03o\r", char2num(ConvertTextEncoding("°", 1, 2, 1, 0)) & 0xFF

// Print Windows-1252 code for degree sign as octal - Prints 260
Printf "%03o\r", char2num(ConvertTextEncoding("°", 1, 3, 1, 0)) & 0xFF

// Print number of bytes of UTF-8 degree sign character - Prints 2
Printf "%d\r", strlen("°")

// Print first byte of UTF-8 for degree sign as hex - Prints C2
Printf "%02X\r", char2num("°"[0]) & 0xFF

// Print second byte of UTF-8 for degree sign as hex - Prints B0
Printf "%02X\r", char2num("°"[1]) & 0xFF
```

Using the printed information, we created the following Igor6/Igor7 code. It uses a hex escape sequence in Igor7 and an octal escape sequence in Igor6 because Igor6 does not support hex escape sequences.

```
#if IgorVersion() >= 7.00
    static StrConstant kDegreeSignCharacter = "\xC2\xB0"
#else
    #ifdef MACINTOSH
        static StrConstant kDegreeSignCharacter = "\241"
    #else
        static StrConstant kDegreeSignCharacter = "\260"
    #endif
#endif

Function PrintTemperature(temperature)
    Variable temperature

    // The character after %g is the degree sign
    Printf "The temperature is %g%s\r", temperature, kDegreeSignCharacter
End
```

This web page is a useful resource for comparing MacRoman and Windows-1252 text encodings:  
<https://kb.iu.edu/d/aesh>

The MacRoman column is labeled "Mac OS" and the Windows-1252 column is labeled "Windows". The Latin1 column is a subset of Windows-1252.

You can see from the table that there are many characters that are available in MacRoman but not in Windows-1252 (e.g., Greek small letter pi) and vice-versa (e.g., multiplication sign). This is one of the reasons for switching to Unicode.

The left column of the table shows UTF-16 character codes. The table does not show UTF-8. You can convert a UTF-16 character code to UTF-8 text in Igor7 like this:

```
String piCharacter = "\u03C0"
```

For details on "\u", see **Escape Sequences in Strings** on page IV-13.

### Other Text Encodings Issues

This section discusses miscellaneous issues relating to text encodings.

## Characters Versus Bytes

In olden times, each character was represented in memory by a single byte. For example, in ASCII, A was represented by 0x41 (0x means hexadecimal) and B was represented by 0x42. Life was simple.

A single byte can represent 256 unique values so it was possible to represent 256 unique characters using a single byte. This was enough for western languages.

There came a time when people wanted to represent Asian text in computers. There are far more than 256 Asian characters, so multi-byte character sets (MBCS), such as Shift JIS, were invented. In MBCS, the ASCII characters are represented by one byte but most Asian characters are represented by two or more bytes. At this point, the equivalence of character and byte was no more and it became important to distinguish the two.

For example, in Igor6, the documentation for `strlen` said that it returns the number of characters in a string. This was true for western text but not for Asian text. The documentation was changed in Igor7 to say that `strlen` returns the number of bytes in a string.

In Igor7, Igor was changed to store text internally as UTF-8, a byte-oriented Unicode encoding form. In UTF-8, ASCII characters are represented by the same single-byte codes as in ASCII, thus providing complete backward compatibility for ASCII text. However, all non-ASCII characters, including accented characters, Greek letters, math symbols and special symbols, are represented by multiple bytes. A given character can consist of 1, 2, 3 or 4 bytes. The payback for this complexity is that UTF-8 can represent nearly every character of nearly every language.

In Igor6, this command prints 1 but in Igor7, it prints 2:

```
Print strlen("μ")
```

This distinction is immaterial when you treat a string as a single entity, which is most of the time. For example, this code works correctly regardless of how characters are represented:

```
String units = "μs"
Printf "The units are %s\r", units
```

It is when you tinker with the contents of a string that it makes a difference. This works correctly in Igor6 and incorrectly in Igor7:

```
String units = "μs"
Printf "The unit prefix is %s\r", units[0]
```

This fails in Igor7, and prints a missing character symbol, because the expression `units[0]` returns a single byte, but in UTF-8, "μ" is represented by two bytes. Therefore `units[0]` returns the first byte of a two-byte character and that is an invalid character in UTF-8.

If you are tinkering with the contents of a string, and if the string may contain non-ASCII text, you need to be clear when you want to go byte-by-byte and when you want to go character-by-character. To go byte-by-byte, you merely use sequential indices. At present, there is no built-in support in Igor for going character-by-character. See **Character-by-Character Operations** on page IV-162 for an example of stepping through characters using user-defined functions.

## Automatic Text Encoding Detection

Techniques exist for attempting to determine a file's text encoding from the codes it contains. Such techniques are unreliable, especially with the kind of text commonly used in Igor. Consequently Igor does not use them.

Much of Igor plain text is procedure text. Procedure text is mostly ASCII, sometimes with a smattering of non-ASCII characters. The non-ASCII characters may be, for example, MacRoman, Windows-1252, or Japanese.

## Chapter III-16 — Text Encodings

---

There is no reliable way to distinguish MacRoman from Windows-1252 or to reliably distinguish a procedure file that contains a smattering of non-ASCII western text from one that contains a smattering of Japanese.

For example, consider an Igor procedure file that contains just one Japanese two-byte character encoded in Shift JIS by the bytes 0x95 and 0x61. This can be interpreted as:

Shift JIS:	CJK UNIFIED IDEOGRAPH-75C5
MacRoman:	LATIN SMALL LETTER I WITH DIERESIS, LOWERCASE LETTER A
Windows-1252:	BULLET, LOWERCASE LETTER A

All three of these interpretations are possible and choosing among them is guesswork so Igor does not attempt to do it.

### Shift JIS Backslash Issue

Because Igor7 internally process all text as UTF-8, it must convert text that it reads from files that use other encodings. A special issue arises with Japanese text stored in Shift JIS format.

In Shift JIS, the single-byte code 0x5C is hijacked to represent the half-width yen symbol. In ASCII, 0x5C represents the backslash character. When Shift JIS text is converted to UTF-8, Igor's conversion software leaves 0x5C unchanged. Thus its interpretation changes from a half-width yen symbol to a backslash symbol.

In most cases this is the desired behavior because the half-width yen symbol is used in Japanese like the backslash in ASCII - to separate elements of Windows file system paths and to introduce escape sequences in literal strings.

If you are using a half-width yen symbol as a currency symbol then this conversion will be wrong and you will have to manually convert it to a half-width yen symbol by editing the text.

In UTF-8, the half-width yen currency symbol is represented by the code units 0xC2 and 0xA5. It can be entered in a literal text string as "\xC2\xA5".

## Text Encoding Names and Codes

Igor operations and functions such as **ConvertTextEncoding**, **SaveNotebook**, **WaveTextEncoding** and **SetWaveTextEncoding** accept text encoding codes as parameters or return them as results.

The functions **TextEncodingName** and **TextEncodingCode** provide conversion between names and codes. For most Igor programming purpose, you need the code, not the name.

For each text encoding supported by Igor there is one text encoding code. This code may correspond to one or more text encoding names. For example, code 2 is the Macintosh Roman text encoding and corresponds to the text encoding names "macintosh", "MacRoman" and "x-macroman".

Because spelling of text encoding names is inconsistent in practice, Igor recognizes variant spellings such as "Shift JIS", "ShiftJIS", "Shift\_JIS" and "Shift-JIS". When comparing text encoding names, Igor ignores all non-alphanumeric characters. It also ignores leading zeros in numbers embedded in text encoding names so that "ISO-8859-1" and "ISO-8859-01" refer to the same text encoding. It uses a case-insensitive comparison.

Some of the entries in the table below are marked NOT SUPPORTED. These are not supported because the ICU (International Components for Unicode) library, which Igor uses for text encoding conversions, does

not support it. "Not supported" means that the TextEncodingName and TextEncodingCode functions do not recognize these text encodings and Igor can not convert to them or from them.

Text Encoding Name	Code	Notes
None	0	Means the text encoding is unknown
UTF-8	1	Unicode UTF-8
macintosh, MacRoman, x-macroman	2	Macintosh Western European
Windows-1252	3	Windows Western European
Shift_JIS	4	Predominant Japanese text encoding
MacJapanese, x-mac-japanese	4	Virtually the same as Shift_JIS
Windows-932	4	Virtually the same as Shift_JIS
EUC-JP	5	Japanese, typically used on Unix
Big5	20	Traditional Chinese
x-mac-chinesetrad	20	Virtually the same as Big5
Windows-950	20	Virtually the same as Big5
EUC-CN	21	Simplified Chinese
x-mac-chinesesimp	21	Simplified Chinese
Windows-936	21	Simplified Chinese
ISO-2022-CN	22	Simplified Chinese
GB18030	23	Official text encoding of the PRC. Encompasses Traditional Chinese and Simplified Chinese. Compatible with Windows-936.
EUC-KR, x-mac-korean	40	Macintosh Korean
Windows-949, ks_c_5601-1987	41	Windows Korean
ISO-2022-KR	42	Korean text encoding not used on Macintosh or Windows
x-mac-arabic	50	Macintosh Arabic. NOT SUPPORTED.
Windows-1256	51	Windows Arabic
x-mac-hebrew	55	Macintosh Hebrew
Windows-1255	56	Windows Hebrew
x-mac-greek	60	Macintosh Greek
Windows-1253	61	Windows Greek
x-mac-cyrillic	65	Macintosh Cyrillic
Windows-1251	66	Windows Cyrillic
x-mac-thai	70	Macintosh Thai. NOT SUPPORTED.
Windows-874	71	Windows Thai
x-mac-ce	80	Macintosh Central European
Windows-1250	81	Windows Central European
x-mac-turkish	90	Macintosh Turkish
Windows-1254	91	Windows Turkish

Text Encoding Name	Code	Notes
UTF-16BE	100	UTF-16, big-endian
UTF-16LE	101	UTF-16, little-endian
UTF-32BE	102	UTF-32, big-endian
UTF-32LE	103	UTF-32, little-endian
ISO-8859-1, Latin1	120	ISO standard western European
Symbol	150	Used by Symbol font
Binary	255	Indicates data is really binary, not text

Binary is not a real text encoding. Rather it marks data stored in a text wave as containing binary rather than text. See **Text Waves Containing Binary Data** on page III-424 for details.

## Symbol Font

Igor Pro 6 and before used "system text encoding", typically MacRoman on Macintosh and Windows-1252 on Windows. These text encodings can represent a maximum of 256 characters because each character is represented by a single byte and a single byte can represent only 256 unique values from 0 to 255.

Most Greek letters can not be represented in MacRoman or Windows-1252. Because of that, people resorted to Symbol font when they wanted to display special characters, such as Greek letters. In system text encoding, Symbol font is treated specially. For example, the byte value 0x61 (61 hex, 97 decimal), which is normally interpreted as "small letter a", is interpreted in Symbol font as "Greek small letter alpha".

Thus, in Igor6, to create a textbox that displayed a Greek small letter alpha, you needed to execute this:

```
TextBox "\\F'Symbol'a"
```

Because Igor Pro 7 uses Unicode, you have at your disposal a wide range of characters of all types without changing fonts. To create a textbox that displays a Greek small letter alpha, in Igor7 you simply execute this:

```
TextBox "α"
```

Also, in Igor7, Symbol font is not treated specially. Consequently, in Igor7, this:

```
TextBox "\\F'Symbol'a"
```

displays a "small letter a", not a "small Greek letter alpha". This is a departure from Igor6 and creates compatibility issues.

You can copy Symbol font characters to the clipboard as Unicode using the **Symbol Font Characters** table. You can insert Unicode characters using Edit→Special Characters. In the Add Annotation dialog and in the Axis Label tab of the Modify Axis dialog, you can click Special and choose a character from the Character submenu.

## Igor7 Symbol Font Backward Compatibility

The use of Unicode in Igor7 greatly simplifies the display of Greek letters and other special characters. But it creates an incompatibility with Igor6. Without special handling, when Igor7 loads an Igor6 file, Symbol font text meant to display Greek letters would display Roman letters instead. This section explains how Igor7 deals with this issue to provide backward compatibility.

When loading procedure files, including the experiment recreation procedures that execute when you open an Igor experiment file, Igor7 attempts to convert incoming Symbol font characters to Unicode. For compatibility with Igor6, the reverse is done on writing procedure files, including experiment recreation procedures. This conversion is done using a heuristic that involves scanning for certain patterns and consequently is not, and can not be, perfect.

There may be cases where this attempt at backward compatibility creates problems, for example, if you don't care about Igor6 compatibility. If you want to turn Symbol font compatibility off, you can execute

```
SetIgorOption EnableSymbolToUnicode=0
```

and reload the experiment.

If you encounter Symbol font problems and the information below does not provide the solution, please let us know, and provide the original Igor6 text that caused the problem.

### Igor7 Symbol Font Backward Compatibility Limitations

An important limitation is that, in the original Igor6 experiment, Symbol font specification must not include anything other than the Symbol characters. No escape sequences, such as font size specifications, are allowed. For example, Igor7 will not handle this Igor6 text:

```
TextBox/C/N=text0/F=0/A=MC "\\Z18A\\F'Symbol '\\Bq\\F] 0"
```

because the subscript escape code, "\\B", is inside the Symbol font escape sequence and prevents Igor7 from recognizing this as a Symbol font sequence. As a result, you will see a "q" character instead of the intended small Greek letter theta character.

To enable Igor7 to recognize this as Symbol text, move the subscript escape code outside the Symbol font escape sequence, like this:

```
TextBox/C/N=text0/F=0/A=MC "\\Z18A\\B\\F'Symbol 'q\\F] 0"
```

When creating graphics in Igor7, for compatibility with Igor6 or for EPS export, use Unicode characters, like this:

```
TextBox/C/N=text0/F=0/A=MC "\\Z18A\\B\\F'Symbol 'θ\\F] 0"
```

When Igor7 writes this out to a procedure file, it will convert the Symbol font sequence into an Igor6-compatible sequence, by replacing the Unicode theta character with "q".

When creating graphics in Igor7, if you don't care about compatibility with Igor6 or EPS export, you don't need to use Symbol font. You can instead write:

```
TextBox/C/N=text0/F=0/A=MC "\\Z18A\\Bθ"
```

On Macintosh, you might still want to specify Symbol font because it provides almost all of the Symbol characters and you may prefer its style compared to other fonts.

### Zapf Dingbat Font

Igor deals with Zapf Dingbats font in the same way. Zapf Dingbats was widely available on Macintosh in previous millennium.

### Symbol Tips

On Windows, because Igor7 uses Unicode, Symbol font does not appear to be useful. Consequently, Igor7 substitutes another font when Symbol is encountered.

To insert frequently used symbol characters, choose Edit→Special Characters. This displays Character Viewer on Macintosh and Character Map on Windows, allowing you to insert any Unicode character.

You can copy Symbol font characters to the clipboard as Unicode using the **Symbol Font Characters** table. In the Add Annotation dialog and in the Axis Label tab of the Modify Axis dialog, you can click Special and choose a character from the Character submenu.

### Symbol Font Characters

The "Text Encoding.ihf" help file includes a list of Symbol font characters. To display it, execute:

DisplayHelpTopic "Symbol Font Characters"

You can copy the characters as Unicode from that section of the help file and paste them into another Igor7 window.

### **Symbols with EPS and Igor PDF**

Both EPS and PDF include Symbol font as one of their standard supported fonts. When inserting a character from the above list, you can either specify Symbol font or you can use a Unicode font that supports those characters.

In the case of Symbol font, Igor translates the Unicode code point to the corresponding Symbol single byte code (unless you have specified that even standard fonts be embedded) and such characters in the resulting file will be editable in a program such as Adobe Illustrator. The alternative is to specify a font such as Lucida Sans Unicode in which case the characters are embedded using an outline font and will not be editable.

Be sure to specify either Symbol or a font that will be embedded because it is likely that the current default font is one of the EPS or PDF standard supported fonts. These are not Unicode and the result will not be what you expect.

## Dashed Lines

You can display traces in graphs, as well as drawn lines, rectangles, ovals, and polygons, using various line styles. This table, generated from the ColorsMarkersLinesPatterns.pxp example experiment, shows Igor's default line styles:

It is usually not necessary, but you can edit the built-in dashed line styles using the Dashed Lines dialog by choosing Misc→Dashed Lines.

Dashed line 0 (the solid line) cannot be edited. If you need to create a custom dashed line pattern, we recommend that you modify the high numbered dashed lines, leaving the low number ones in their default state. This ensures that the low numbered patterns will be the same for everyone.

You can also change dashed lines with the **SetDashPattern** operation.

Dashed lines are stored with the experiment, so each experiment can have different dashed lines. You can capture the current dashed lines as the preferred dashed lines for new experiments.

## The Color Environment

Igor has a main color palette that contains colors that you can use for traces in graphs, text, axes, backgrounds and so on. The main color palette appears as a pop-up menu in a number of dialogs, such as the Modify Trace Appearance dialog. This section discusses this palette.

Igor also has color tables and color index waves you can select among when displaying contour plots and images. These are discussed in Chapter II-14, **Contour Plots**, and Chapter II-15, **Image Plots**.

You can select a color from the colors presented in a color palette:

You can use the Other button to select colors that are not in the palette. As you use Igor, colors are added to the palette in the Recent Colors area.

The recent colors are remembered by Igor when it quits and restored when it restarts if you have selected the "Save and restore color palette's recent colors" checkbox in the Miscellaneous Settings dialog's Color Settings category.

## Color Blending

In places where you can supply a color in RGB format, you can optionally provide a fourth parameter called "alpha". Alpha, like the R, G and B values, can range from 65535 (100% opaque) down to 0 (100% transparent). Intermediate values provide translucency. For example:

```
Make jack=sin(x/8),sam=cos(x/6); Display jack, sam
ModifyGraph mode=7,hbFill=2
```

```
ModifyGraph rgb(jack)=(65535,32768,32768)
ModifyGraph rgb(sam)=(0,0,65535,40000)           // Translucent
```

Color blending was added in Igor Pro 7.

Color blending does not work on Windows in the old GDI graphics mode explained under **Graphics Technology on Windows** on page III-445.

Color blending does not work in graphics exported as EPS. Use PDF instead.

## Fill Patterns

Fill patterns can be used in graphs and drawing layers. This table, generated from the ColorsMarkersLine-SPatterns.pxp example experiment, shows the available fill patterns:

## Gradient Fills

As of Igor Pro 7, you can specify gradient fills for drawing elements, graph trace fills, and graph window and plot area background fills. A gradient fill is a gradual change of color.

Programmatically you specify gradients using two keywords, `gradient` and `gradientExtra`, when calling the `ModifyGraph`, `ModifyLayout` or `SetDrawEnv` operations.

The syntax for the `gradient` keyword has two forms. The first form provides overall control of the gradient while the second form controls the color details.

The first form for the `gradient` keyword is:

```
gradient = 0, 1, 2, or 3
```

0 deletes the gradient entirely.

1 turns on an existing gradient or creates a new one with default values.

2 turns off a gradient but keeps the settings.

3 is used in combination with the `ModifyLayout` operation and signals that a particular page should not display a gradient even when a layout global gradient is set.

The second form for the `gradient` keyword is:

```
gradient = {type, x0, y0, x1, y1 [,color0 [, color1 ] ]}
```

*type* is a bitfield.

Bits 0 through 3 specify the gradient mode. 0 is linear, 1 is radial and other values are reserved.

Bits 4 through 7 specify the coordinate mode. 0 is object rect, 1 is window rect.

To construct a type parameter signifying a radial gradient in window rect mode you could write:

```
Variable gradientType = 1 | (1*16)
```

The following commands illustrate the difference between object rect and window rect mode. Execute these commands and then drag the rectangles around:

```
Display /W=(150,50,474,365)
SetDrawLayer UserFront
SetDrawEnv xcoord=abs,ycoord=abs
SetDrawEnv save
SetDrawEnv fillfgc=(16385,16388,65535),fillbgc=(65535,16385,16385)
SetDrawEnv gradient={16, 0, 0, 1, 1} // Window rect mode
DrawRect 25,38,95,138
SetDrawEnv gradient={1, 0.5, 0.5, 0, 1, (0,65535,0), (65535,0,65535)}
DrawRect 130,150,273,289
ShowTools/A
```

The *x0*, *y0*, *x1*, and *y1* parameters specify normalized locations that define the gradient. (0,0) is the upper left corner of the bounding rectangle while (1,1) is the lower right corner. For a linear gradient, (*x0*, *y0*) defines the start while (*x1*, *y1*) defines the end. Only the slope of the line is used, not the actual extent. For a radial gradient, (*x0*, *y0*) defines the center of a bounding circle while (*x1*, *y1*) is not used at present.

The optional *color0* and *color1* keywords are specified as (r,g,b) or (r,g,b,a) but use of alpha is not fully supported on all platforms (Quartz PDF on Macintosh for example). When omitted or with a value of (0,0,0) the actual color used is a default for the given circumstance. The default values are specified in the individual operation documentation.

The *gradientExtra* keyword adds an additional color change point. You can add as many change points as desired. The syntax for the *gradientExtra* keyword is:

```
gradientExtra = {loc, color}
```

*loc* is in the range 0.0 to 1.0. Values of exactly 0 or 1 replace the original *color0* or *color1* values as specified by the *gradient* keyword.

*color* is specified as (r,g,b) or (r,g,b,a) but use of alpha is not fully supported on all platforms (Quartz PDF on Macintosh for example).

The following operations support the *gradient* and *gradientExtra* keywords.

### SetDrawEnv

If you specify a gradient it overrides the fill for drawing elements.

If you omit the *color0* parameter or specify (0,0,0,0) then the current pattern background color is used.

If you omit the *color1* parameter or specify (0,0,0,0) then the current foreground color is used.

All *gradientExtra* keywords must be on the same line as the *gradient* keyword itself.

### ModifyLayout

You can specify gradients for individual pages by combining the *gradient* and *gradientExtra* keywords with the */PAGE=pageNum* flag.

Page numbers start from 1. Use */PAGE=0* to use the currently active page.

*/PAGE=1* causes the operation to modify the layout global gradient which applies to any pages in the targeted page layout for which no explicit gradient has been set.

**ModifyGraph (traces)**

If you specify a gradient it overrides the fill for traces.

The gradient and gradientExtra keywords apply to all traces unless you specify a trace name like this:

```
gradient(<trace name>) = {...}
gradientExtra(<trace name>) = {...}
```

If you omit the *color0* parameter or specify (0,0,0,0) then the current pattern background color is used.

If you omit the *color1* parameter or specify (0,0,0,0) then the plusRGB color is used.

When the *type* parameter specifies a window rect, the plus and neg areas are used automatically and the *color1* is away from the zero level.

**ModifyGraph (colors)**

The wbGradient and wbGradientExtra keywords control the window background gradient, if any.

The gbGradient and gbGradientExtra keywords control the graph plot area background gradient, if any.

The "Demo Experiment #1" and "Demo Experiment #2" example experiments demonstrate these gradients. You can turn the on and off using the Macros menu.

**Miscellaneous Settings**

You can customize many aspects of how Igor works using the Miscellaneous Settings dialog. Choose Misc→Miscellaneous Settings to display the dialog.

Most of the settings are self-explanatory. Many have tool tips that describe what they do.

**Object Names**

Every Igor object has a name which you give to the object when you create it or which Igor automatically assigns. You use an object's name to refer to it in dialogs, from commands and from Igor procedures. The named objects are:

Waves	Data folders	Variables (numeric and string)
Windows	Symbolic paths	Pictures
Annotations	Controls	Rulers

In Igor Pro, the rules for naming waves and data folders are not as strict as the rules for naming all other objects, including string and numeric variables, which are required to have standard names. These sections describe the standard and liberal naming rules.

**Standard Object Names**

Here are the rules for standard object names:

- May be 1 to 31 bytes in length.
- Must start with an alphabetic character (A-Z or a-z).
- May include alphabetic or numeric characters or the underscore character.
- Must not conflict with other names (of operations, functions, etc.).

All names in Igor are case insensitive. wave0 and WAVE0 refer to the same wave.

Characters other than letters and numbers, including spaces and periods, are not allowed. We put this restriction on names so that Igor can identify them unambiguously in commands, including waveform arithmetic expressions.

### Liberal Object Names

The rules for liberal names are the same as for standard names except that almost any character can be used in a liberal name. Liberal name rules are allowed for waves and data folders only.

If you are willing to expend extra effort when you use liberal names in commands and waveform arithmetic expressions, you can use wave and data folder names containing almost any character. If you create liberal names then you will need to enclose the names in single (not curly) quotation marks whenever they are used in commands or waveform arithmetic expressions. This is necessary to identify where the name ends. Liberal names have the same rules as standard names except you may use any character except control characters and the following:

" ' : ;

Here is an example of the creation and use of liberal names:

```
Make 'wave 0';      // 'wave 0' is a liberal name
'wave 0' = p
Display 'wave 0'
```

**Note:** Providing for liberal names requires extra effort and testing on the part of Igor programmers (see **Programming with Liberal Names** on page IV-157) so you may occasionally experience problems using liberal names with user-defined procedures.

### Name Spaces

When you refer to an object by name, in a user function for example, each object must be referenced unambiguously. In general, an object must have a unique name so. Sometimes the object type can be inferred from the context, in which case the name can be the same as objects of other types. Objects whose names can be the same are said to be in different name spaces.

Data folders are in their own name space. Therefore the name of a data folder can be the same as the name of any other object, except for another data folder at the same level of the hierarchy.

Waves and variables (numeric and string) are in the same name space and so Igor will not let you create a wave and a variable in a single data folder with the same name.

An annotation is local to the window containing it. Its name must be unique only among annotations in the same window. The same applies for controls and rulers. Data folders, waves, variables, windows, symbolic paths and pictures are global objects, not associated with a particular window.

The names of global objects, except for data folders, are required to be distinct from the names of macros, functions (built-in, external or user-defined) and operations (built-in or external).

Here is a summary of the four global name spaces:

Name Space	Requirements
Data folders	Names must be distinct from other data folders at the same level of the hierarchy.
Waves, variables, windows	Names must be distinct from other waves, variables (numeric and string), windows.
Pictures	Names must be distinct from other pictures.
Symbolic paths	Names must be distinct from other symbolic paths.

### Renaming Objects

You can use Misc→Rename Objects or Data→Rename to rename waves, variables, strings, symbolic paths, and pictures. Both of these invoke the Rename Objects dialog.

Graphs, tables, page layouts, notebooks, control panels, Gizmo windows, and XOP target windows are renamed using the **DoWindow** operation (see page V-148) which you can build using the Window Control dialog (see **The Window Control Dialog** on page II-44).

You can use the Data Browser to rename data folders, waves, and variables. See **The Data Browser** on page II-106.

## Graphics Technology

As of version 7, Igor Pro is based on the cross-platform Qt framework and, by default, Igor uses Qt for graphics. However, for special purposes, Igor provides access to platform-native graphics.

You should avoid native graphics and stick with Qt graphics if possible because it is the focus for future development. Native graphics is provided mainly for emergency use.

You can select native graphics on a global basis (all windows are affected) in two ways:

1. From the Miscellaneous category of the Miscellaneous Settings dialog (Misc→Miscellaneous Settings menu item).
2. By executing

```
SetIgorOption GraphicsTechnology=n
```

where *n* is 0, 1, 2 or 3 for default, new, old and Qt. Unlike most other SetIgorOption cases, this change is saved to preferences on disk and applies to future Igor sessions.

In addition to changing the global graphics technology setting, you can change individual windows using

```
SetWindow winName, graphicsTech=n
```

where *n* is the same as above. *winName* can be kwTopWin or the actual name of a window. This not saved with the window.

Over time, it is our intention that Qt graphics will replace the other technologies and the SetIgorOption GraphicsTechnology option may no longer be supported.

### Graphics Technology on Windows

In general, you should use the Qt graphics (GraphicsTechnology=3). If you experience problems with graphics, you might try GraphicsTechnology=1 or 2. High-resolution displays are supported using Qt graphics only.

On Windows, GraphicsTechnology=1 utilizes the GDI+ interface. This provides support for transparency and other advanced features. Unfortunately, GDI+ is very slow, especially when rendering text.

If speed is an issue, you can try GraphicsTechnology=2 to use the older GDI interface. However, transparency is not honored - colors will be opaque regardless of the alpha value (see **Color Blending** on page III-440 for a discussion of alpha).

In GraphicsTechnology=1 mode, EMF export uses a hybrid format, called “dual EMF”, that contains both GDI+ and, for compatibility, the older GDI. In GraphicsTechnology=2 mode, only the older GDI-only style is exported. In Qt graphics mode (GraphicsTechnology=3), GDI+ is used for rendering the EMF for export, resulting in the dual EMF format. Some applications don’t work well with EMF+ or dual EMF. In that case, try setting GraphicsTechnology=2 (old GDI mode) to export an EMF without the EMF+ component.

## Chapter III-17 — Miscellany

When you import or paste an EMF picture, the method by which Igor renders the EMF depends on the chosen graphics technology:

Technology	EMF	EMF+	Dual EMF
Qt (GraphicsTechnology=3)	GDI	GDI+	GDI+
GDI+ (GraphicsTechnology=2)	GDI+	GDI+	GDI+
GDI (GraphicsTechnology=1)	GDI	Not supported	GDI+

Our experience indicates that plain EMF is rendered better by GDI mode. In Qt graphics, the best rendering technology is chosen based on the contents of the picture you are pasting.

Regardless of the selected technology, exporting as EMF on Windows uses native interfaces.

### Graphics Technology on Macintosh

On Macintosh, there is only one native format, Core Graphics, also known as Quartz, and it works the same as in Igor Pro 6.3. The native picture format is PDF.

High-resolution screen graphics on Retina displays is supported in Qt graphics technology mode only.

Regardless of the chosen graphics technology, PDF export is drawn using Core Graphics.

PDF pictures pasted into Igor are also rendered using Core Graphics. This produces the same picture regardless of the chosen Igor graphics technology, except on a Retina display, in which case the PDF is rendered on-screen at high-resolution only when using Qt graphics.

### SVG Graphics

In Qt mode (GraphicsTechnology=3), SVG (Scalable Vector Graphics) is available as an alternative object-based picture format. This can replace EMF and PDF whenever the destination program supports it. In Qt mode, other imported object-based pictures (PDF on Macintosh, EMF on Windows) are rendered as high-resolution bitmap images.

In native graphics modes, imported SVG pictures are rendered as high-resolution bitmap images using Qt graphics.

Regardless of the selected technology, exporting as SVG format is rendered using Qt.

### High-Resolution Displays

High-resolution screen graphics is supported in Qt graphics technology mode only.

Macintosh Retina and Windows high-resolution displays, also called Retina, 4K, 5K, Ultra HD, and Quad HD, bring a more pleasing visual experience but also present performance challenges. Depending on the operating system, graphics technology, and your actual data, graph updates can be thousands of times slower. This situation is expected to be temporary as operating systems optimize high-resolution graphics. See the “Graphs and High-Resolution Displays” topic in the release notes for the latest information.

On Windows, prior to Igor Pro 7, control panels were drawn using pixels for coordinates. Now, when the resolution exceeds 96 DPI, those coordinates are taken to be points. This prevents panels from appearing tiny on high-resolution displays. See **Control Panel Resolution on Windows** on page III-405 for more information.

### Windows High-DPI Recommendations

High-DPI (dots-per-inch) displays have resolutions substantially higher than the Windows standard 96 DPI. These displays sometimes go by the names Retina, 4K, 5K, Ultra HD and Quad HD.

Since the pixels of a high-DPI monitor are typically about one-half the size of pixels on standard monitors, software running on a high-DPI monitor must make adjustments. These adjustments are made by some combination of the operating system and the program itself.

On Macintosh, with its “Retina” high-DPI screens, the operating system handles most resolution issues and there are few problems with Igor on Retina monitors.

On Windows, both the operating system and the Qt framework that Igor uses introduce complexities that sometimes result in less than perfect behavior. This section provides guidance for Windows user to minimize these issues.

To get the best experience when using a high-DPI display, we recommend that you use Windows 10 or later. We do not test or explicitly support high-DPI features on older Windows versions.

There are two factors that may affect your experience on high-DPI displays.

The first factor is the "style" that is used. By default, Igor uses a style that is specific to the operating system. This allows user interface elements such as title bars and dialog controls to look native. However, as of this writing (early 2016), the style used by Qt on Windows has not been completely updated to support high-DPI displays. Therefore, you may notice that elements, such as the arrows on scroll bar buttons and the check marks of checkboxes, are pixelated, that the window icons at the left end of the window title bar are misaligned, etc.

As an alternative to the default style, you can configure Igor to use the "Fusion" style. This style looks better on high-DPI displays though most user interface elements do not look native. To turn use the Fusion style, open the Miscellaneous Settings dialog, select the Miscellaneous category, and check the Use Fusion Style checkbox. We expect that the native style will improve over time and it may eventually be unnecessary to use the Fusion style.

The second factor is the way that Windows and the Qt framework scale user interface elements such as dialogs and windows. You may encounter undesirable behavior when using multiple display configurations in which there is one high-DPI display, such as a laptop monitor, and one or more additional standard-resolution displays such as an external monitor.

If you only have one monitor, such as a laptop with a high-DPI monitor, and no external displays are connected, you should not need to make any changes to Igor's default configuration to achieve the correct behavior. You may wish to use the Fusion theme, as described above, but it's not necessary to do so.

If you have multiple displays connected, Windows requires that you designate one of the displays as your main display. As of this writing, our experience indicates that acceptable behavior on a mixed display system can be obtained only by making the external (standard-DPI) display the main display.

When using Igor on a machine with multiple displays, we suggest you follow these steps to get the best results:

1. Connect the external standard-resolution display.
2. Open the Display settings page. You can do this by clicking the Start menu, clicking Settings, clicking System, and selecting Display in the lefthand pane.
3. Click the Identify link below the diagram of your displays to confirm which display is which. For these instructions, assume that display #1 is the high-DPI display of a laptop and display #2 is a standard-DPI external monitor.
4. Click the box representing the external monitor (display #2 for this example).
5. Check the Make This My Main Display check box.
6. In the Multiple Displays setting, select Extend These Displays.
7. Click the Apply button.

8. Reboot your machine **twice**.
9. To get the best results, you must reboot your machine **2 times** after any changes to the display settings.
10. After your machine restarts **twice**, start Igor.
11. Move Igor's outer frame window to monitor #2 (the external monitor).
12. Open the Miscellaneous Settings dialog and select the Miscellaneous category. Check the Disable High-DPI Scaling checkbox. Also check the Use Fusion Style checkbox.
13. Restart Igor.

If you later remove the standard-DPI display and wish to use Igor with only a high-DPI display connected, do the following:

1. Reboot the machine **twice**.
2. Start Igor. Open the Miscellaneous Settings dialog and select the Miscellaneous category. Uncheck the Disable High-DPI Scaling checkbox. You can check or uncheck the Use Fusion Style checkbox depending on your preference.
3. Restart Igor.

## Pictures

Igor can import pictures from other programs for display in graphs, page layouts and notebooks. It can also export pictures from graphs, page layouts and tables for use in other programs. Exporting is discussed in Chapter III-5, **Exporting Graphics (Macintosh)**, and Chapter III-6, **Exporting Graphics (Windows)**. This section discusses how you can import pictures into Igor, what you can do with them and how Igor stores them.

For information on importing images as data rather than as graphics, see **Loading Image Files** on page II-138.

### Importing Pictures

There are three ways to import a picture.

- Pasting from the Clipboard into a graph, layout, or notebook
- Using the Pictures dialog (Misc menu) to import a picture from a file or from the Clipboard
- Using the **LoadPICT** operation (see page V-442) to import a picture from a file or from the Clipboard

Each of these methods, except for pasting into a notebook, creates a *named*, global picture object that you can use in one or more graphs or layouts. Pasting into a notebook creates a picture that is local to the notebook.

This table shows the types of graphics formats from which Igor can import pictures:

Format	Notes
PDF (Portable Document Format)	Supported in Macintosh native graphics only.
EMF (Enhanced Metafile)	Supported in Windows native graphics only. See <b>Graphics Technology on Windows</b> on page III-445 for information about different types of EMF pictures.
BMP (Windows bitmap)	Supported in on Windows only. BMP is sometimes called DIB (Device Independent Bitmap).
PNG (Portable Network Graphics)	Lossless cross-platform bitmap format
JPEG	Lossy cross-platform bitmap format
TIFF (Tagged Image File Format)	Lossless cross-platform bitmap format

Format	Notes
EPS (Encapsulated PostScript)	High resolution vector format. Requires PostScript printer. On Windows and on Macintosh in Qt graphics mode, a screen preview is displayed on screen.
SVG (Scalable Vector Graphics)	Cross-platform vector and bitmap format. Always rendered using Qt graphics. In other graphics technology modes, it is drawn into a high-resolution bitmap which is then drawn on the screen, exported, or printed.

Formats that are not supported on the current platform are drawn as gray boxes.

See also **Picture Compatibility** on page III-399 for a discussion of Macintosh graphics on Windows and vice-versa.

## The Picture Gallery

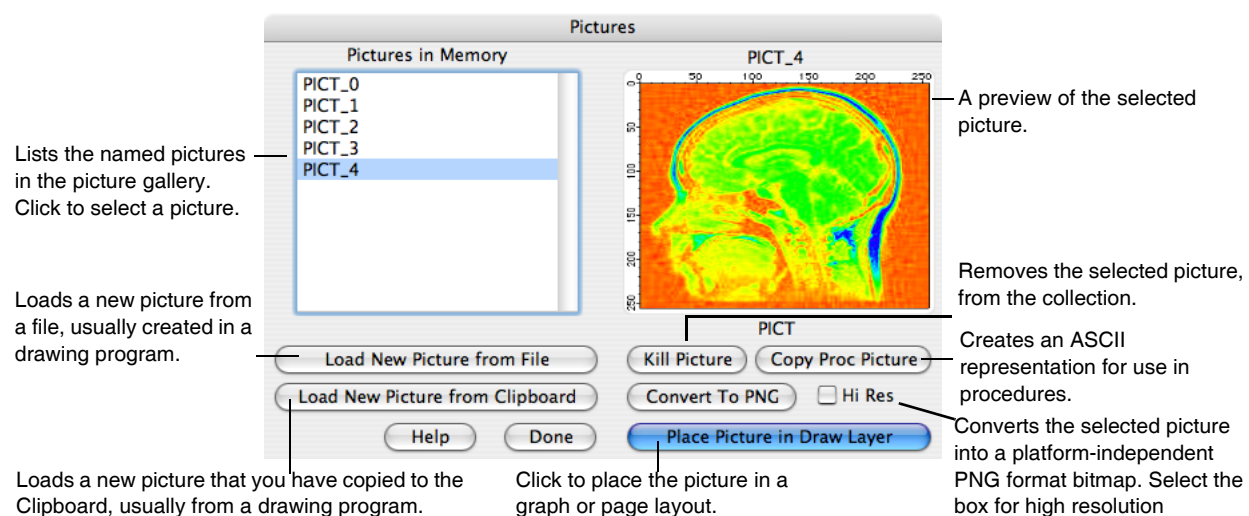

When you create a named picture using one of the techniques listed above, Igor stores it in the current experiment's **picture gallery**. When you save the experiment, the picture gallery is stored in the experiment file. You can inspect the collection using the Pictures dialog via the Misc menu.

Igor gives names to pictures so they can be referenced from an Igor procedure. For example, if you paste a picture into a layout, Igor assigns it a name of the form "PICT\_0" and stores it in the picture gallery. If you then close the layout and ask Igor to create a recreation macro, the macro will reference the picture by name.

You can rename a named picture using the Pictures dialog in the Misc menu, the Rename Objects dialog in the Misc menu, the Rename dialog in the Data menu, or the **RenamePICT** operation (see page V-678). You can kill a named picture using the Pictures dialog or the **KillPICTs** operation (see page V-411).

## Pictures Dialog

The Pictures dialog permits you to view the picture gallery, to add pictures, to remove pictures and to place a picture into a graph or page layout. It also can place a copy of a picture into a formatted notebook. To invoke it, choose Pictures from the Misc menu.

The Kill This Picture button will be dimmed if the selected picture is used in a currently open graph or layout.

**Note:** Igor determines if a picture is in use by checking to see if it is used in an *open* graph or layout window.

If you kill a graph or layout that contains a picture and create a recreation macro, the recreation macro will *refer* to the picture by name. However, Igor does not check for this. It will consider the picture to be unused and will allow you to kill it. If you later run the recreation macro, an error will occur when the macro attempts to append the picture to the graph or layout. Therefore, don't kill a picture unless you are sure that it is not needed.

### Notebook Pictures

When you paste a picture into a formatted notebook, you create a notebook picture. These work just like pictures in a word processor document. You can copy and paste them. These pictures will not appear in the Pictures or Rename Objects dialogs.

## Igor Extensions

Igor includes a feature that allows a C or C++ programmer to extend its capabilities. An Igor extension is called an "XOP" (short for "external operation"). The term XOP comes from that fact that, originally, adding a command line operation was all that an extension could do. Now extensions can add operations, functions, menus, dialogs and windows.

### WaveMetrics XOPs

The "Igor Pro 7 Folder/Igor Extensions" and "Igor Pro 7 Folder/More Extensions" folders contain XOPs that we developed at WaveMetrics. These add capabilities such as file-loading and instrument control to Igor and also serve as examples of what XOPs can do. These XOPs range from very simple to rather elaborate. Most XOPs come with help files that describe their operation.

The WaveMetrics XOPs are described in the XOP Index help file, accessible through the Help→Help Windows submenu.

### Third Party Extensions

A number of Igor users have written XOPs to customize Igor for their particular fields. Some of these are freeware, some are shareware and some are commercial programs. WaveMetrics publicizes third party XOPs through our Web page. User-developed XOPs are available from <http://www.igorexchange.com>.

### Activating Extensions

The Igor installer creates a folder called Igor Extensions inside the Igor Pro 7 Folder. The Igor installer puts some XOP files in this folder. XOPs in this folder are loaded when Igor starts up.

The installer puts less-frequently used XOPs in "Igor Pro 7 Folder/More Extensions". These are not available unless you activate them.

If you place in "Igor Pro 7 Folder/Igor Extensions" an alias (Macintosh ) or shortcut (Windows ) for an XOP file or a folder containing XOP files, Igor loads those files also. However, this is not the recommended way to activate an XOP.

Your operating system may not allow you to make changes to the contents of your Igor Pro 7 Folder, for example, if you do not have permission to write to that folder. For that reason, Igor also loads extensions from another folder - "Igor Pro User Files/Igor Extensions" (see **Igor Pro User Files** on page II-31 for details). You can locate this folder by selecting Help→Show Igor Pro User Files.

If you press the shift key while clicking the Help menu, you can choose Help→Show Igor Pro 7 Folder and User Files. Igor then opens the Igor Pro 7 Folder and the Igor Pro User Files folder on the desktop, making it easy to drag aliases/shortcuts into "Igor Pro User Files/Igor Extensions". This is the recommended way to activate additional WaveMetrics XOPs for a given user.

If you want to activate an extension for all users on a given machine, you can put the alias or shortcut in "Igor Pro 7 Folder/Igor Extensions" folder. You may need to run as administrator to do this.

Changes that you make to either Igor Extensions folder take effect the next time Igor is launched.

See **Creating Igor Extensions** on page IV-195 if you are a programmer interested in writing your own XOPs.

## Memory Management

For many years, virtually all new machines have shipped with 64-bit operating systems. Consequently, in this section, we assume that you are running a 64-bit OS.

Igor7 comes in 32-bit and 64-bit versions called IGOR32 and IGOR64 respectively. The only reason to run IGOR32 is if you depend on 32-bit XOPs that have not been ported to 64 bits.

IGOR32 can theoretically address 4GB of virtual address space. For the vast majority of Igor applications, this is more than sufficient. If you must load gigabytes of data into memory at one time, you may run out of memory. This may happen long before you load 4GB of data into memory, because, to allocate a wave for example, you not only need free memory, but the free memory must also be contiguous, and memory becomes fragmented over time.

IGOR64 can theoretically address about a billion gigabytes. However, actual operating systems impose far lower limits. On Windows 10, 64-bit programs can address between 128 GB (home edition) and 512 GB (professional edition). On Mac OS X, 64-bit programs can theoretically address the full 64-bit address space.

If you load more data than fits in physical memory, the system starts using "virtual memory", meaning that it swaps data between physical memory and disk, as needed. This is very slow. Consequently, you should avoid loading more data into memory than can fit in physical memory.

Even if your data fits in physical memory, graphing and manipulating very large waves, such as 10 million, 100 million, or 1 billion points, will be slow.

All of this boils down to the following rules:

1. If you don't need to load gigabytes of data into memory at one time then you don't need to worry about memory management.
2. Run IGOR64 unless you rely on 32-bit XOPs that can not be ported to 64 bits.
3. Install enough physical memory to avoid the need for virtual memory swapping.

For further information about very large waves, see **IGOR64 Experiment Files** on page II-35.

## Macintosh System Requirements

Igor Pro requires Mac OS X 10.9.0 or later.

## Windows System Requirements

Igor Pro requires Windows 7 or later.

**Preferences**

Overview ..... 454

Igor Preferences Directory ..... 454

How to Use Preferences ..... 454

Captured Preferences ..... 454

### Overview

Preferences affect the creation of *new* graphs, panels, tables, layouts, notebooks, and procedure windows, and the *appending* of traces to graphs and columns to tables. In addition, preferences affect the command window, and default font for graphs.

You can turn preferences off or on using the Misc menu. Normally you will run with preferences on.

Preferences are automatically off while a procedure is running so that the effects of the procedure will be the same for all users. See the **Preferences** operation (see page V-652) for further information.

When preferences are off, factory default values are used for settings such as graph size, position, line style, size and color. When preferences are on, Igor applies your preferred values for these settings.

Preferences differ from *settings*, as set in the Miscellaneous Settings dialog, in that settings generally take effect immediately, while preferences are used when something is created.

### Igor Preferences Directory

Igor preferences are stored in a per-user directory. The location of this directory depends on your operating system. You generally don't need to access your Igor preferences directory, but you can open it in the desktop by pressing the Shift key while choosing Help→Show Igor Preferences Folder.

You can also determine the location of your Igor preferences directory by executing this command:

```
Print SpecialDirPath("Preferences", 0, 0, 0)
```

For technical reasons, most of the built-in preferences are stored not in the Igor preferences directory but rather one level up in a file named "Igor Pro 7.ini".

Deleting the preferences directory and the "Igor Pro 7.ini" file effectively reverts all preferences to factory defaults. You should use the Capture Prefs dialogs, described in **Captured Preferences** operation on page III-454, to revert preferences more selectively.

Other information is stored in preferences, such as the screen position of dialogs, a few dialog settings, colors recently selected in the color palette, window stacking and tiling information, page setups, font substitution settings, and dashed line settings.

### How to Use Preferences

Preferences are always on when Igor starts up. You can turn preferences off by choosing Preferences Off in the Misc menu.

You can also turn preferences on and off with the **Preferences** operation (see page V-652).

Preferences are set by Capture Preferences dialogs, the Tile or Stack Windows dialog, and some dialogs such as the Dashed Lines dialog.

In general, *preferences are applied only when something new is created* such as a new graph, a new trace in a graph, a new notebook, a new column in a table, and then only if preferences are on.

Preferences are normally in effect only for *manual* ("point-and-click") operation, not for user-programmed operations in Igor procedures. See **Procedures and Preferences** on page IV-192.

### Captured Preferences

You set most preference values by capturing the current settings of the active window with the Capture Prefs item in the menu for that window. (The dialog to capture the Command Window preferences is found

in the Command/History Settings submenu of the Misc menu.) The dialogs are described in more detail in the chapter that discusses each type of window. For instance, see **Graph Preferences** on page II-260.

### Overview

You can execute commands by typing them into the command line and pressing Return or Enter.

You can also use a notebook for entering commands. See **Notebooks as Worksheets** on page III-4.

You can type commands from scratch but often you will let Igor dialogs formulate and execute commands. You can view a record of what you have done in the history area of the command window and you can easily reenter, edit and reexecute commands stored there. See **Command Window Shortcuts** on page II-13 for details.

### Multiple Commands

You can place multiple commands on one line if you separate them with semicolons. For example:

```
wave1= x; wave1= wave2/(wave1+1); Display wave1
```

You don't need a semicolon after the last command but it doesn't hurt.

### Comments

Comments start with //, which end the executable part of a command line. The comment continues to the end of the line.

### Maximum Length of a Command

The total length of the command line can not exceed 1000 bytes.

There is no line continuation character in the command line. However, it is nearly always possible to break a single command up into multiple lines using intermediate variables. For example:

```
Variable a = sin(x-x0)/b + cos(y-y0)/c
```

can be rewritten as:

```
Variable t1 = sin(x-x0)/b  
Variable t2 = cos(y-y0)/c  
Variable a = t1 + t2
```

### Parameters

Every place in a command where Igor expects a numeric parameter you can use a numeric expression. Similarly for a string parameter you can use a string expression. In an operation flag (e.g., /N=<number>), you must parenthesize expressions. See **Expressions as Parameters** on page IV-11 for details.

### Liberal Object Names

In general, object names in Igor are limited to a restricted set of characters. Only letters, digits and the underscore character are allowed. Such names are called "standard names". This restriction is necessary to identify where the name ends when you use it in a command.

For waves and data folders only, you can also use "liberal" names. Liberal names can include almost any character, including spaces and dots (see **Liberal Object Names** on page III-444 for details). However, to define where a liberal name ends, you must quote them using single quotes.

In the following example, the wave names are liberal because they include spaces and therefore they must be quoted:

```
'wave 1' = 'wave 2'           // Right  
wave 1 = wave 2               // Wrong - liberal names must be quoted
```

**Note:** Providing for liberal names requires extra effort and testing by Igor programmers (see **Programming with Liberal Names** on page IV-157) so you may occasionally experience problems using liberal names with user-defined procedures.

## Commands and Data Folders

Data folders provide a way to keep separate sets of data from interfering with each other. You can examine and create data folders using the Data Browser (Data menu). There is always a root data folder and this is the only data folder that many users will ever need. Advanced users may want to create additional data folders to organize their data.

You can refer to waves and variables either in the current data folder, in a specific data folder or in a data folder whose location is relative to the current data folder:

```
// wave1 is in the current data folder
wave1 = <expression>

// wave1 is in a specific data folder
root:'Background Curves':wave1 = <expression>

// wave1 is in a data folder inside the current data folder
:'Background Curves':wave1 = <expression>
```

In the first example, we use an object name by itself (wave1) and Igor looks for the object in the current data folder.

In the second example, we use a full data folder path (root:'Background Curves:') plus an object name. Igor looks for the object in the specified data folder.

In the third example, we use a relative data folder path (: 'Background Curves:') plus an object name. Igor looks in the current data folder for a subdata folder named Background Curves and looks for the object within that data folder.

**Important:** The right-hand side of an assignment statement (described under **Assignment Statements** on page IV-4) is evaluated in the context of the data folder containing the destination object. For example:

```
root:'Background Curves':wave1 = wave2 + var1
```

For this to work, wave2 and var1 must be in the Background Curves data folder.

Examples in the rest of this chapter use object names alone and thus reference data in the current data folder. For more on data folders, see Chapter II-8, **Data Folders**.

## Types of Commands

There are three fundamentally different types of commands that you can execute from the command line:

- assignment statements
- operation commands
- user-defined procedure commands

Here are examples of each:

```
wave1 = sin(2*pi*freq*x)           // assignment statement
Display wave1,wave2 vs xwave       // operation command
MyFunction(1.2,"hello")            // user-defined procedure command
```

As Igor executes commands you have entered, it must determine which of the three basic types of commands you have typed. If a command starts with a wave or variable name then Igor assumes it is an assignment statement. If a command starts with the name of a built-in or external operation then the command is treated as an operation. If a command begins with the name of a user-defined macro, user-defined function or external function then the command is treated accordingly.

## Chapter IV-1 — Working with Commands

---

Note that built-in functions can only appear in the right-hand side of an assignment statement, or as a parameter to an operation or function. Thus, the command:

```
sin(x)
```

is not allowed and you will see the error, “Expected wave name, variable name, or operation.” On the other hand, these commands are allowed:

```
Print sin(1.567)           // sin is parameter of print operation
wave1 = 5*sin(x)           // sin in right side of assignment
```

If, perhaps due to a misspelling, Igor can not determine what you want to do, it will display an error dialog and the error will be highlighted in the command line.

## Assignment Statements

Assignment statement commands start with a wave or variable name. The command assigns a value to all or part of the named object. An assignment statement consists of three parts: a destination, an assignment operator, and an expression. For example:

<u>wave1</u>	=	<u>1 + 2 * 3^2</u>
Destination		Expression
Assignment operator		

This assigns 19 to every point in wave1.

The spaces in the above example are not required. You could write:

```
wave1=1+2*3^2
```

See **Waveform Arithmetic and Assignments** on page II-69 for details on wave assignment statements.

In the following examples, str1 is a string variable, created by the String operation, var1 is a numeric variable, created by the Variable operation, and wave1 is a wave, created by the Make operation.

```
str1 = "Today is " + date()           // string assignment
str1 += ", and the time is " + time()  // string concatenation
var1 = strlen(str1)                   // variable assignment
var1 = pnt2x(wave1,numpts(wave1)/2)    // variable assignment
wave1 = 1.2*exp(-0.2*(x-var1)^2)       // wave assignment
wave1[3] = 5                          // wave assignment
wave1[0,;3] = wave2[p/3] *exp(-0.2*x) // wave assignment
```

These all operate on objects in the current data folder. To operate on an object in another data folder, you need to use a data folder path:

```
root:'run 1':wave1[3] = 5             // wave assignment
```

See Chapter II-8, **Data Folders**, for further details.

If you use liberal wave names (see **Object Names** on page III-443), you must use quotes:

```
'wave 1' = 'wave 2'                  // Right
wave 1 = wave 2                       // Wrong
```

## Assignment Operators

The assignment operator determines the way in which the expression is combined with the destination. Igor supports the following assignment operators:

Operator	Assignment Action
=	Destination contents are set to the value of the expression.
+=	Expression is added to the destination.
-=	Expression is subtracted from the destination.
*=	Destination is multiplied by the expression.
/=	Destination is divided by the expression.
:=	Destination is dynamically updated to the value of the expression whenever the value of any part of the expression changes. The := operator is said to establish a “dependency” of the destination on the expression.

For example:

```
wave1 = 10
```

sets each Y value of the wave1 equal to 10, whereas:

```
wave1 += 10
```

adds 10 to each Y value of wave1. This is equivalent to:

```
wave1 = wave1 + 10
```

The assignment operators =, := and += work with string assignment statements but -=, \*= and /= do not. For example:

```
String str1; str1 = "Today is "; str1 += date(); Print str1
```

prints something like “Today is Fri, Mar 31, 2000”.

For more information on the := operator, see Chapter IV-9, **Dependencies**.

## Operators

Here is a complete list of the operators that Igor supports in the expression part of an assignment statement in order of precedence:

Operator	Effect
++    --	Prefix and postfix increment and decrement. Require Igor Pro 7 or later. Available only for local variables in user-defined functions.
^    <<    >>	Exponentiation, bitwise left shift, bitwise right shift. Shifts require Igor Pro 7 or later.
-    !    ~	Negation, logical complement, bitwise complement.
*    /	Multiplication, division.
+    -	Addition or string concatenation, subtraction.
==    !=    >    <    >=    <=	Comparison operators.
&         %^	Bitwise AND, bitwise OR, bitwise XOR.
&&          ?    :	Logical AND, logical OR, conditional operator.
\$	Substitute following string expression as name.

Comparison operators do not work with NaN parameters because, by definition, NaN compared to anything, even another NaN, is false. Use numtype to test if a value is NaN.

## Chapter IV-1 — Working with Commands

---

Comparison operators, bitwise AND, bitwise OR, bitwise XOR associate right to left. Therefore  $a==b>=c$  means  $(a==(b>=c))$ . For example,  $2==1>=0$  evaluates to 0, not 1.

All other binary operators associate left to right.

Aside from the precedence of common operators that everyone intuitively knows, it is useful to include parentheses to avoid confusion. You may know the precedence and associativity but someone reading your code may not.

Unary negation changes the sign of its operand. Logical complementation changes nonzero operands to zero and zero operands to 1. Bitwise complementation converts its operand to an unsigned integer by truncation and then changes it to its binary complement.

Exponentiation raises its left-hand operand to a power specified by its right-hand operand. That is,  $3^2$  is written as  $3^2$ . In an expression  $a^b$ , if the result is assigned to a real variable or wave, then  $a$  must not be negative if  $b$  is not an integer. If the result is used in a complex expression, any combination of negative  $a$ , fractional  $b$  or complex  $a$  or  $b$  is allowed.

If the exponent is an integer, Igor evaluates the expression using only multiplication. There is no need to write  $a^2$  as  $a*a$  to get efficient evaluation — Igor does the equivalent automatically. If, on the other hand, the exponent is not an integer then the evaluation is performed using logarithms, hence the restriction on negative  $a$  in a real expression.

Logical OR (`||`) and logical AND (`&&`) determine the truth or falseness of pairs of expressions. The AND operation returns true only when both expressions are true; OR will return true if *either* is true. As in C, true is *any* nonzero value, and false is zero. The operations are undefined for NaNs. These operators are not available in complex expressions.

The logical operators are evaluated from left to right, and an operand will not be evaluated if it is not necessary. For the example:

```
if (MyFunc1() && MyFunc2())
```

when `MyFunc1()` returns false (zero), then `MyFunc2()` will not be evaluated because the entire expression is already false. This can produce unexpected consequences when the right-hand expression has side effects, such as creating waves or setting global values.

Bitwise AND (`&`), OR (`|`), and XOR (`%^`) convert their operands to an unsigned integer by truncation and then return their binary AND, OR or exclusive OR.

Bitwise shifts, `<<` and `>>`, return the lefthand operand shifted by the specified number of bits. They require Igor Pro 7 or later. The lefthand operation is truncated to an integer before shifting.

The conditional operator (`? :`) is a shorthand form of an if-else-endif expression. In the statement:

```
<expression> ? <TRUE> : <FALSE>
```

the first operand, `<expression>`, is the test condition; if it is nonzero then Igor evaluates the `<TRUE>` operand; otherwise `<FALSE>` is evaluated. Only one operand is evaluated according to the test condition. This is the same as if you had written:

```
if( <expression> )
    <TRUE>
else
    <FALSE>
endif
```

The `“.”` character in the conditional operator must always be separated from the two adjacent operands with a space. If you omit either space, you will get an error (“No such data folder”) because the expression can also be interpreted as part of a data folder path. To be safe, always separate the operands from the operator symbols with a space.

The operands must be numeric; for strings, use the **SelectString** function. When using complex expressions with the conditional operator, only the real portion is used when the operator evaluates the expression.

The conditional operator can easily cause confusion, so you should exercise caution when using it. For example, it is unclear from simple inspection what Igor may return for

```
1 ? 2 : 3 ? 4 : 5
```

(4 in this case), whereas

```
1 ? 2 : (3 ? 4 : 5)
```

will return 2. Always use parentheses to remove any ambiguity.

The comparison operators return 1 if the result of the comparison is true or 0 if it is false. For example, the `==` operator returns 1 if its operands are equal or 0 if they are not equal. The `!=` operator returns the opposite. Because comparison operators return the values 1 or 0 they can be used in interesting ways. The assignment:

```
wave1 = sin(x) * (x<=50) + cos(x) * (x>50)
```

sets wave1 so that it is a sine wave below  $x=50$  and a cosine wave above  $x=50$ . See also **Example: Comparison Operators and Wave Synthesis** on page II-74.

Note that the double equal sign, `==`, is used to mean equality while the single equal sign, `=`, is used to indicate assignment.

Because of roundoff error, using `==` to test two numbers for equality may give incorrect results. It is safer to use `<=` and `>=` to see if a number falls in a narrow range. For example, imagine that you want to compare a variable to see if it is equal to one-third. The expression:

```
(v1 == 1/3)
```

is subject to failure because of roundoff. It is safer to use something like

```
((v1 > .33332) && (v1 < .33334))
```

If the numbers are integers then the use of `==` is safe because integers smaller than  $2^{53}$  (approximately  $10^{16}$ ) are represented precisely in double-precision floating point numbers.

The previous discussion on operators has assumed numeric operands. The `+` operator is the only one that works with both numeric *and* string operands. For example, if `str1` is a string variable then the assignment statement

```
str1 = "Today is " + "a nice day"
```

assigns the value "Today is a nice day" to `str1`. The other string operator, `$` is discussed in **String Substitution Using \$** on page IV-17.

Unless specified otherwise by parentheses, unary negation or complementation are carried out first followed by exponentiation then by multiplication or division followed by addition or subtraction then by comparison operators. The wave assignment:

```
wave1 = ((1 + 2) * 3) ^ 2
```

assigns the value 81 to every point in wave1, but

```
wave1 = 1 + 2 * 3 ^ 2
```

assigns the value 19.

`-a^b` is an exception to this rule and is evaluated as `-(a^b)`.

The precedence of string substitution, substrings, and wave indexing is somewhat complex. When in doubt, use parenthesis to enforce the precedence you want.

### Obsolete Operators

As of Igor Pro 4.0, the old bitwise complement (%~), bitwise AND (%&), and bitwise OR (%|) operators have been replaced by new versions that omit the % character from the operator. These old bitwise operators can still be used interchangeably with the new versions but are not recommended for new code.

### Operands

In addition to literal numbers like 3.141 or 27, operators can operate on variables and function values. In the assignment statement:

```
var1 = log(3.7) + var2
```

the operator + operates on the function value returned by log and on the variable var2. Functions and function values are discussed later in this chapter.

### Numeric Type

In Igor, each numeric destination object (wave or variable) has its own numeric type. The numeric type consists of the numeric precision (e.g., double precision floating point) and the number type (real or complex). Waves can be single or double precision floating point or various sizes of integer but variables are always double precision floating point.

The numeric precision of the destination does not affect the calculations. With the exception of a few operations that are done in place such as the FFT, all calculations are done in double precision.

Although waves can have integer numeric types, wave expressions are always evaluated in double precision floating point. The floating point values are converted to integers by rounding as the final step before storing the value in the wave. If the value to be stored exceeds the range of values that the given integer type can represent, the results are undefined.

Starting with Igor Pro 7, Igor supports integer local variables and 64-bit integer waves. When one of these is the destination of an assignment statement, Igor performs calculations using integer arithmetic. See **Expression Evaluation** on page IV-36 for details.

The number type of the destination determines the initial number type (real or complex) of the assignment expression. This is important because Igor can not deal with “surprise” or “runtime” changes in number type. An example would be taking the square root of a negative number requiring that all following arithmetic be done using complex numbers.

Here are some examples:

```
Variable a, b, c, var1  
Variable/C cvar1  
Make wave1
```

```
var1= a*b  
cvar1= c*cmplx(a+1,b-1)  
wave1= var1 + real(cvar1)
```

The first expression is evaluated using the real number type. The second expression contains a mixture of two types. The multiplication of c with the result of the cmplx function is evaluated as complex while the arguments to the cmplx function are evaluated as real. The third example is evaluated as real except for the argument to the real function which is evaluated as complex.

### Constant Type

You can define named numeric and string constants in Igor procedure files and use them in the body of user-defined functions.

Constants are defined in procedure files using following syntax:

```
Constant <name1> = <literal number> [, <name2> = <literal number>]
```

```
StrConstant <name1> = <literal string> [, <name2> = <literal string>]
```

You can use the static prefix to limit the scope to the given source file. For debugging, you can use the Override keyword as with functions.

These declarations can be used in the following ways:

```
Constant kFoo=1,kBar=2
StrConstant ksFoo="hello",ksBar="there"

static Constant kFoo=1,kBar=2
static StrConstant ksFoo="hello",ksBar="there"

Override Constant kFoo=1,kBar=2
Override StrConstant ksFoo="hello",ksBar="there"
```

Programmers may find that using the “k” and “ks” prefixes will make their code easier to read.

Names for numeric and string constants can conflict with all other names. Duplicate constants of a given type are not allowed except for static constants in different files and when used with Override. The only true conflict is with variable names and with certain built-in functions that do not take parameters such as pi. Variable names override constants, but constants override functions such as pi.

## Dependency Assignment Statements

You can set up global variables and waves so that they automatically recalculate their contents when other global objects change. See Chapter IV-9, **Dependencies**, for details.

## Operation Commands

An operation is a built-in or external routine that performs an action but, unlike a function, does not directly return a value. Here are some examples:

```
Make/N=512 wave1
Display wave1
Smooth 5, wave1
```

Operation commands perform the majority of the work in Igor and are automatically generated and executed as you work with Igor using dialogs.

You can use these dialogs to experiment with operations of interest to you. As you click in a dialog, Igor composes a command. This provides a handy way for you to check the syntax of the operation or to generate a command for use in a user-defined procedure. See Chapter V-1, **Igor Reference**, for a complete list of all built-in operations. Another way to learn their syntax is to use the Igor Help Browser’s Command Help tab.

The syntax of operation commands is highly variable but in general consists of the operation name, followed by a list of flags (e.g., /N=512), followed by a parameter list. The operation name specifies the main action of the operation and determines the syntax of the rest of the command. The list of flags specifies variations on the default behavior of the operation. If the default behavior of the operation is satisfactory then no flags are required. The parameter list identifies the objects on which the operation is to operate. Some commands take no parameters. For example, in the command:

```
Make/D/N=512 wave1, wave2, wave3
```

the operation name is “Make”. The list of flags is “/D/N=512”. The parameter list is “wave1, wave2, wave3”.

## Chapter IV-1 — Working with Commands

---

You can use numeric expressions in the parameter list of an operation where Igor expects a numeric parameter, but in an operation flag you need to parenthesize the expression. For example:

```
Variable val = 1.0
Make/N=(val) wave0, wave1
Make/N=(numpnts(wave0)) wave2
```

The most common types of parameters are literal numbers or numeric expressions, literal strings or string expressions, names, and waves. In the example above, `wave1` is a name parameter when passed to the `Make` operation. It is a wave parameter when passed to the `Display` and `Smooth` operations. A name parameter can refer to a wave that may or may not already exist whereas a wave parameter must refer to an existing wave.

See **Parameter Lists** on page IV-11 for general information that applies to all commands.

## User-Defined Procedure Commands

User-defined procedure commands start with a procedure name and take a list of parameters in parentheses. Here are a few examples:

```
MyFunction1(5.6, wave0, "igneous")
```

### Macro and Function Parameters

You can invoke macros, but not functions, with one or more of the input parameters missing. When you do this, Igor displays a dialog to allow you to enter the missing parameters.

You can add similar capabilities to user-defined functions using the **Prompt** (see page V-665) and **DoPrompt** (see page V-147) keywords.

Macros provide very limited programming features so, with rare exceptions, you should program using functions.

### Function Commands

A function is a routine that directly returns a numeric or string value. There are three classes of functions available to Igor users:

- Built-in
- External (XFUNCs)
- User-defined

Built-in numeric functions enjoy one advantage over external or user-defined functions: a few come in real and complex number types and Igor automatically picks the appropriate version depending on the current number type in an expression. External and user-defined functions must have different names when different types are needed. Generally, only real user and external functions need be provided.

For example, in the wave assignment:

```
wave1 = enoise(1)
```

if `wave1` is real then the function `enoise` returns a real value. If `wave1` is complex then `enoise` returns a complex value.

You can use a function as a parameter to another function, to an operation, to a macro or in an arithmetic or string expression so long as the data type returned by the function makes sense in the context in which you use it.

User-defined and external functions can also be used as commands by themselves. Use this to write a user function that has some purpose other than calculating a numeric value, such as displaying a graph or making new waves. Built-in functions cannot be used this way. For instance:

```
MyDisplayFunction(wave0)
```

External and user-defined functions can be used just like built-in functions. In addition, numeric functions can be used in curve fitting. See Chapter IV-3, **User-Defined Functions** and **Fitting to a User-Defined Function** on page III-163.

Most functions consist of a function name followed by a left parenthesis followed by a parameter list and followed by a right parenthesis. In the wave assignment shown at the beginning of this section, the function name is `enoise`. The parameter is 1. The parameter is enclosed by parentheses. In this example, the result from the function is assigned to a wave. It can also be assigned to a variable or printed:

```
K0 = enoise(1)
Print enoise(1)
```

User and external functions, but not built-in functions, can be executed on the command line or in other functions or macros without having to assign or print the result. This is useful when the point of the function is not its explicit result but rather its side effects.

Nearly all functions require parentheses even if the parameter list is empty. For example the function `date()` has no parameters but requires parentheses anyway. There are a few exceptions. For example the function `Pi` returns  $\pi$  and is used with no parentheses or parameters.

Igor's built-in functions are described in detail in Chapter V-1, **Igor Reference**.

## Parameter Lists

Parameter lists are used for operations, functions, and macros and consist of one or more numbers, strings, keywords or names of Igor objects. The parameters in a parameter list must be separated with commas.

### Expressions as Parameters

In an operation, function, or macro parameter list which has a numeric parameter you can always use a numeric expression instead of a literal number. A numeric expression is a legal combination of literal numbers, numeric variables, numeric functions, and numeric operators. For example, consider the command

```
SetScale x, 0, 6.283185, "v", wave1
```

which sets the X scaling for `wave1`. You could also write this as

```
SetScale x, 0, 2*PI, "v", wave1
```

Literal numbers include hexadecimal literals introduced by `"0x"`. For example:

```
Printf "The largest unsigned 16-bit number is: %d\r", 0xFFFF
```

### Parentheses Required for /N=<expression>

Many operations accept flags of the form `"/A=n"` where A is some letter and n is some number. You can use a numeric expression for n but you must parenthesize the expression.

For example, both:

```
Make/N=512 wave1
Make/N=(2^9) wave1
```

are legal but this isn't:

```
Make/N=2^9 wave1
```

A variable name is a form of numeric expression. Thus, assuming `v1` is the name of a variable:

```
Make/N=(v1)
```

is legal, but

```
Make/N=v1
```

is not. This parenthesization is required only when you use a numeric expression in an operation flag.

### String Expressions

A string expression can be used where Igor expects a string parameter. A string expression is a legal combination of literal strings, string variables, string functions, UTF-16 literals, and the string operator + which concatenates strings.

A UTF-16 literal represents a Unicode code value and consists of "U+" followed by four hexadecimal digits. For example:

```
Print "This is a bullet character: " + U+2022
```

### Setting Bit Parameters

A number of commands require that you specify a bit value to set certain parameters. In these instances you set a certain bit *number* by using a specific bit *value* in the command. The bit value is  $2^n$ , where  $n$  is the bit number. So, to set bit 0 use a bit value of 1, to set bit 1 use a bit value of 2, etc.

For the example of the `TraceNameList` function the last parameter is a bit setting. To select normal traces you must set bit 0:

```
TraceNameList("", ";", 1)
```

and to select contour traces set bit 1:

```
TraceNameList("", ";", 2)
```

Most importantly, you can set multiple bits at one time by adding the bit values together. Thus, for `TraceNameList` you can select both normal (bit 0) and contour (bit 1) traces by using:

```
TraceNameList("", ";", 3)
```

See also **Using Bitwise Operators** on page IV-39.

## Working With Strings

Igor has a rich repertoire of string handling capabilities. See **Strings** on page V-11 for a complete list of Igor string functions. Many of the techniques described in this section will be of interest only to programmers.

Many Igor operations require *string* parameters. For example, to label a graph axis, you can use the `Label` operation:

```
Label left, "Volts"
```

Other Igor operations, such as `Make`, require *names* as parameters:

```
Make wave1
```

Using the string substitution technique, described in **String Substitution Using \$** on page IV-17, you can generate a name parameter by making a string containing the name and using the `$` operator:

```
String stringContainingName = "wave1"  
Make $stringContainingName
```

### String Expressions

Wherever Igor requires a string parameter, you can use a string expression. A string expression can be:

- A literal string ("Today is")
- The output of a string function (`date()`)
- An element of a text wave (`textWave0[3]`)
- A UTF-16 literal (`U+2022`)
- Some combination of string expressions ("Today is" + `date()`)

In addition, you can derive a string expression by indexing into another string expression. For example,

```
Print ("Today is" + date())[0,4]
```

prints "Today".

A string variable can store the result of a string expression. For example:

```
String str1 = "Today is" + date()
```

A string variable can also be part of a string expression, as in:

```
Print "Hello. " + str1
```

## Strings in Text Waves

A text wave contains an array of text strings. Each element of the wave can be treated using all of the available string manipulation techniques. In addition, text waves are commonly used to create category axes in bar charts. See **Text Waves** on page II-79 for further information.

## String Properties

Strings in Igor can contain up to roughly two billion bytes.

Igor strings are usually used to store text data but you can also use them to store binary data.

When you treat a string as text data, for example if you print it to the history area of the command window or display its contents in an annotation or control, internal Igor routines treat a null byte as meaning "end-of-string". Consequently, if you treat a binary string as if it were text, you may get unexpected results.

When you treat a string as text, Igor assumes that the text is encoded using the UTF-8 text encoding. For further discussion, see **String Variable Text Encodings** on page III-428.

## Unicode Literal Characters

A Unicode literal represents a character using its UTF-16 code value. It consists of "U+" followed by four hexadecimal digits. For example:

```
Print "This is a bullet character: " + U+2022
```

The list of Unicode character codes is maintained at <http://www.unicode.org/charts>.

## Escape Sequences in Strings

Igor treats the backslash character in a special way when reading literal (quoted) strings in a command line. The backslash is used to introduce an "escape sequence". This just means that the backslash plus the next character or next few characters are treated like a different character — one you could not otherwise include in a quoted string. The escape sequences are:

<code>\t</code>	Represents a tab character
<code>\r</code>	Represents a return character (CR)
<code>\n</code>	Represents a linefeed character (LF)
<code>\'</code>	Represents a ' character (single-quote)
<code>\"</code>	Represents a " character (double-quote)
<code>\\</code>	Represents a \ character (backslash)
<code>\ddd</code>	Represents an arbitrary byte code ddd is a 3 digit octal number
<code>\xdd</code>	Represents an arbitrary byte code dd is a 2 digit hex number Requires Igor Pro 7.00 or later

<code>\udddd</code>	Represents a UTF-16 code point dddd is a 4 digit hex number Requires Igor Pro 7.00 or later
<code>\Udddddddd</code>	Represents a UTF-32 code point dddddddd is an 8 digit hex number Requires Igor Pro 7.00 or later

For example, if you have a string variable called "fileName", you could print it in the history area using:

```
fileName = "Test"
Printf "The file name is \"%s\"\\r", fileName
```

which prints

```
The file name is "Test"
```

In the Printf command line, `\` embeds a double-quote character in the format string. If you omitted the backslash, the `"` would end the format string. The `\r` specifies that you want a carriage return in the format string.

### Unicode Escape Sequences in Strings

Igor Pro 7 represents text internally in UTF-8 format. UTF-8 is a byte-oriented encoding format for Unicode. In this section we see how to use the `\u`, `\U` and `\x` escape sequences to represent Unicode characters in literal strings.

The use of UTF-8 and these escape sequences requires Igor Pro 7.00 or later. If you use them, you will get incorrect data or errors in Igor Pro 6.x.

In the first set of examples, we use the hexadecimal code 0041. This is hexadecimal for the Unicode code point representing CAPITAL LETTER A.

```
String str
str = "\x41"           // Specify code point using UTF-8 escape sequence
Print str
str = "\u0041"         // Specify code point using UTF-16 escape sequence
Print str
str = "\U00000041"     // Specify code point using UTF-32 escape sequence
Print str
```

When you use `\xdd`, Igor replaces the escape sequence with the byte specified by `dd`. Therefore you must specify byte values representing a valid UTF-8 character. 41 is hexadecimal for the UTF-8 encoding for CAPITAL LETTER A. If the code point that you specify is not a valid UTF-16 or UTF-32 code point, Igor replaces the escape sequence with the Unicode replacement character.

When you use `\u` or `\U`, Igor replaces the escape sequence with the UTF-8 bytes for the corresponding Unicode code point as represented in UTF-16 or UTF-32 format.

Now we specify the characters for "Toyota" in Japanese Kanji:

```
str = "\xE8\xB1\x8A\xE7\x94\xB0"      // UTF-8
Print str
str = "\u8C4A\u7530"                  // UTF-16
Print str
str = "\U00008C4A\U00007530"          // UTF-32
Print str
```

In order to see the correct characters you must be using a font that includes Japanese characters.

`\U` is mainly of use to enter rare Unicode characters that are not in the Basic Multilingual Plane. Such characters can not be specified with single 16-bit UTF-16. Here is an example:

```
str = "\U00010300" // UTF-32 for OLD ITALIC LETTER A
Print str
str = "\xF0\x90\x8C\x80" // UTF-8 for OLD ITALIC LETTER A
Print str
```

OLD ITALIC LETTER A is located in the Unicode Supplementary Multilingual Plane (plane 1).

## Embedded Nulls in Literal Strings

A null in a byte-oriented string is a byte with the value 0.

Unlike Igor Pro 6, in Igor Pro 7 it is possible to embed a null byte in a string:

```
String test = "A\x00B" // OK in Igor Pro 7
Print strlen(test) // Prints 3
Print char2num(test[0]),char2num(test[1]),char2num(test[2]) // Prints 65 0 66
```

Here Igor converts the escape sequence `\x00` to a null byte.

You typically have no need to embed a null in an Igor string because strings are usually used to store readable text and null does not represent a readable character. The need might arise, however, if you are using the string to store binary rather than text data. For example, if you need to send a small amount of binary data to an instrument, you can do so using `\x` escape sequences to represent the data in a literal string.

Although Igor Pro 7 allows you to embed nulls in literal strings, other parts of Igor are not prepared to handle them. For example:

```
Print test // Prints "A", not "A<null>B"
```

In C null is taken to mean "end-of-string". Because of the use of C strings and C library routines in Igor, many parts of Igor will treat an embedded null as end-of-string. That is why the Print statement above prints just "A".

The bottom line is: You can store binary data, including nulls, in an Igor string but most parts of Igor that expect readable text will treat a null as end-of-string.

## String Indexing

Indexing can extract a part of a string. This is done using a string expression followed by one or two numbers in brackets. The numbers are byte positions. Zero is the byte position of the first byte; `n-1` is the byte position of the last byte of an `n` byte string value. For example, assume we create a string variable called `s1` and assign a value to it as follows:

```
String s1="hello there"
```

h	e	l	l	o		t	h	e	r	e
0	1	2	3	4	5	6	7	8	9	10

Then,

```
Print s1[0,4] // prints hello
Print s1[0,0] // prints h
Print s1[0] // prints h
Print s1[1]+s1[2]+s1[3] // prints ell
Print (s1+" jack")[6,15] // prints there jack
```

## Chapter IV-1 — Working with Commands

---

A string indexed with one index, such as `s1[p]`, is a string with one byte in it if `p` is in range (i.e.  $0 \leq p \leq n-1$ ). `s1[p]` is a string with no bytes in it if `p` is not in range. For example:

```
Print s1[0]           prints  h
Print s1[-1]          prints  (nothing)
Print s1[10]          prints  e
Print s1[11]          prints  (nothing)
```

A string indexed with two indices, such as `s1[p1,p2]`, contains all of the bytes from `s1[p1]` to `s1[p2]`. For example:

```
Print s1[0,10]         prints  hello there
Print s1[-1,11]        prints  hello there
Print s1[-2,-1]        prints  (nothing)
Print s1[11,12]        prints  (nothing)
Print s1[10,0]         prints  (nothing)
```

The indices in these examples are byte positions, not character positions. See **Characters Versus Bytes** on page III-433 for a discussion of this distinction. See **Character-by-Character Operations** on page IV-162 for an example of stepping through characters using user-defined functions.

Because the syntax for string indexing is identical to the syntax for wave indexing, you have to be careful when using text waves. For example:

```
Make/T textWave0 = {"Red", "Green", "Blue"}

Print textWave0[1]           prints  Green
Print textWave0[1][1]        prints  Green
Print textWave0[1][1][1]     prints  Green
Print textWave0[1][1][1][1]  prints  Green
Print textWave0[1][1][1][1][1] prints  r
```

The first four examples print row 1 of column 0. Since waves may have up to four dimensions, the first four `[1]`'s act as dimension indices. The column, layer, and chunk indices were out of range and were clipped to a value of 0. Finally in the last example, we ran out of dimensions and got string indexing. Do not count on this behavior because future versions of Igor may support more than four dimensions.

The way to avoid the ambiguity between wave and string indexing is to use parentheses like so:

```
Print (textWave0[1])[1]      prints  r
```

The way to avoid the ambiguity between wave and string indexing is to use parentheses like so:

```
String tmp = textWave0[1]
Print tmp[1]                 prints  r
```

### String Assignment

You can assign values to string variables using string assignment. We have already seen the simplest case of this, assigning a literal string value to a string variable. You can also assign values to a subrange of a string variable, using string indexing. Once again, assume we create a string variable called `s1` and assign a value to it as follows:

```
String s1="hello there"
```

Then,

```
s1[0,4]="hi"; Print s1           prints  hi there
s1[0,4]="greetings"; Print s1   prints  greetings there
s1[0,0]="j"; Print s1           prints  jello there
s1[0]="well "; Print s1         prints  well hello there
s1[100000]=" jack"; Print s1    prints  hello there jack
s1[-100]="well ";print s1       prints  well hello there
```

When the `s1[p1,p2]=` syntax is used, the right-hand side of the string assignment *replaces* the subrange of the string variable identified by the left-hand side, after `p1` and `p2` are clipped to 0 to `n`, where `n` is the number of bytes in the destination.

When the `s1[p]=` syntax is used, the right-hand side of the string assignment *is inserted before* the byte identified by `p` after `p` is clipped to 0 to `n`.

The subrange assignment just described for string variables is not supported when a text wave is the destination. To assign a value to a range of a text wave element, you will need to create a temporary string variable. For example:

```
Make/O/T tw = {"Red", "Green", "Blue"}
String stmp= tw[1]
stmp[1,2]="XX"
tw[1]= stmp;

Print tw[0],tw[1],tw[2]           prints           Red GXXen Blue
```

The indices in these examples are byte positions, not character positions. See **Characters Versus Bytes** on page III-433 for a discussion of this distinction.

### String Substitution Using \$

Wherever Igor expects the literal *name* of an operand, such as the name of a wave, you can instead provide a string expression preceded by the `$` character. The `$` operator evaluates the string expression and returns the *value* as a *name*.

For example, the Make operation expects the name of the wave to be created. Assume we want to create a wave named `wave0`:

```
Make wave0                      // OK: wave0 is a literal name.
Make $"wave0"                   // OK: $"wave0" evaluates to wave0.

String str = "wave0"
Make str                        // WRONG: This makes a wave named str.
Make $str                       // OK: $str evaluates to wave0.
```

`$` is often used when you write a function which receives the name of a wave to be created as a parameter. Here is a trivial example:

```
Function MakeWave(w)
    String wName      // name of the wave

    Make $wName
End
```

We would invoke this function as follows:

```
MakeWave ("wave0")
```

We use `$` because we need a wave name but we have a string containing a wave name. If we omitted the `$` and wrote:

```
Make wName
```

Igor would make a wave whose name is `wName`, not on a wave whose name is `wave0`.

String substitution is capable of converting a string expression to a *single* name. It can not handle multiple names. For example, the following will *not* work:

```
String list = "wave0;wave1;wave2"
Display $list
```

See **Processing Lists of Waves** on page IV-187 for ways to accomplish this.

### \$ Precedence Issues In Commands

There is one case in which string substitution does not work as you might expect. Consider this example:

```
String str1 = "wave1"
wave2 = $str1 + 3
```

You might expect that this would cause Igor to set wave2 equal to the sum of wave1 and 3. Instead, it generates an “expected string expression” error. The reason is that Igor tries to concatenate str1 and 3 *before* doing the substitution implied by \$. The + operator is also used to concatenate two string expressions, and it has higher precedence than the \$ operator. Since str1 is a string but 3 is not, Igor cannot do the concatenation.

You can fix this by changing this wave assignment to one of the following:

```
wave2 = 3 + $str1
wave2 = ($str1) + 3
```

Both of these accomplish the desired effect of setting wave2 equal to the sum of wave1 and 3. Similarly,

```
wave2 = $str1 + $str2    // Igor sees "$ (str1 + $str2) "
```

generates the same “expected string expression” error. The reason is that Igor is trying to concatenate str1 and \$str2. \$str2 is a name, not a string. The solution is:

```
wave2 = ($str1) + ($str2) // sets wave2 to sum of two named waves
```

Another situation arises when using the \$ operator and [. The [ symbol can be used for either point indexing into a wave, or byte indexing into a string. The commands

```
String wvName = "wave0"
$wvName[1,2] = wave1[p]    // sets two values in wave named "wave0"
```

are interpreted to mean that points 1 and 2 of wave0 are set values from wave1.

If you intended “\$wvName[1,2] = wave1” to mean that a wave whose name comes from bytes 1 and 2 of the wvName string (“av”) has all of its values set from wave1, you must use parenthesis:

```
$(wvName[1,2]) = wave1    // sets all values of wave named "av"
```

### String Utility Functions

WaveMetrics provides a number of utility functions for dealing with strings. To see a list of the built-in string functions:

1. Open the Igor Help Browser Command Help tab.
2. Open the Advanced Filtering control.
3. Uncheck all checkboxes except for Functions.
4. Choose String from the Functions pop-up menu.

See **Character-by-Character Operations** on page IV-162 for an example of stepping through characters using user-defined functions.

### Special Cases

This section documents some techniques that were devised to handle certain specialized situations that arise with respect to Igor’s command language.

## Instance Notation

There is a problem that occurs when you have multiple instances of the same wave in a graph or multiple instances of the same object in a layout. For example, assume you want to graph yWave versus xWave0, xWave1, and xWave2. To do this, you need to execute:

```
Display yWave vs xWave0
AppendToGraph yWave vs xWave1
AppendToGraph yWave vs xWave2
```

The result is a graph in which yWave occurs three times. Now, if you try to remove or modify yWave using:

```
RemoveFromGraph yWave
```

or

```
ModifyGraph lsize(yWave)=2
```

Igor will always remove or modify the first instance of yWave.

Instance notation provides a way for you to specify a particular instance of a particular wave. In our example, the command

```
RemoveFromGraph yWave#2
```

will remove instance number 2 of yWave and

```
ModifyGraph lsize(yWave#2)=2
```

will modify instance number 2 of yWave. Instance numbers start from zero so “yWave” is equivalent to “yWave#0”. Instance number 2 is the instance of yWave plotted versus xWave2 in our example.

Where necessary to avoid ambiguity, Igor operation dialogs (e.g., Modify Trace Appearance) automatically use instance notation. Operations that accept trace names (e.g., ModifyGraph) or layout object names (e.g., ModifyObject) accept instance notation.

A graph can also display multiple waves with the same name if the waves reside in different datafolders. Instance notation applies to the this case also.

## Instance Notation and \$

The \$ operator can be used with instance notation. The # symbol may be either inside the string operand or may be outside. For example \$"wave0#1" or \$"wave0"#1. However, because the # symbol may be inside the string, the string must be parsed by Igor. Consequently, unlike other uses of \$, the wave name portion must be surrounded by single quotes if liberal names are used. For example, suppose you have a wave with the liberal name of 'ww#1' plotted twice. The first instance would be \$" 'ww#1' " and the second \$" 'ww#1' #1" whereas \$"ww#1" would reference the second instance of the wave ww.

## Object Indexing

The ModifyGraph, ModifyTable and ModifyLayout operations, used to modify graphs, tables and page layouts, each support another method of identifying the object to modify. This method, object indexing, is used to generate style macros (see **Graph Style Macros** on page II-262). You may also find it handy in other situations.

Normally, you need to know the name of the object that you want to modify. For example, assume that we have a graph with three traces in it and we want to set the traces' markers from a procedure. We can write:

```
ModifyGraph marker(wave0)=1, marker(wave1)=2, marker(wave2)=3
```

Because it uses the names of particular traces, this command is specific to a particular graph. What do we do if we want to write a command that will set the markers of three traces in *any* graph, regardless of the names of the traces? This is where object indexing comes in.

Using object indexing, we can write:

```
ModifyGraph marker[0]=1, marker[1]=2, marker[2]=3
```

This command sets the markers for the first three traces in a graph, no matter what their names are.

## Chapter IV-1 — Working with Commands

---

Indexes start from zero. For graphs, the object index refers to traces starting from the first trace placed in the graph. For tables the index refers to columns from left to right. For page layouts, the index refers to objects starting from the first object placed in the layout.

### /Z Flag

The ModifyGraph marker command above works fine if you know that there *are* three waves in the graph. It will, however, generate an error if you use it on a graph with fewer than 3 waves. The ModifyGraph operation supports a flag that can be used to handle this:

```
ModifyGraph/Z marker[0]=1, marker[1]=2, marker[2]=3
```

The /Z flag ignores errors if the command tries to modify an object that doesn't exist. The /Z flag works with the SetAxis and Label operations as well as with the ModifyGraph, ModifyTable and ModifyLayout operations. Like object indexing, the /Z flag is primarily of use in creating style macros, which is done automatically, but it may come in handy for other uses.

## **Programming Overview**

Overview .....	22
Organizing Procedures .....	22
WaveMetrics Procedure Files.....	23
Macros and Functions .....	23
Scanning and Compiling Procedures.....	24
Indentation Conventions .....	24
What's Next .....	25

### Overview

You can perform powerful data manipulation and analysis interactively using Igor's dialogs and the command line. However, if you want to automate common tasks or create custom data analysis features, then you need to use procedures.

You can write procedures yourself, use procedures supplied by WaveMetrics, or find someone else who has written procedures you can use. Even if you don't write procedures from scratch, it is useful to know enough about Igor programming to be able to understand code written by others.

Programming in Igor entails creating procedures by entering text in a procedure window. After entering a procedure, you can execute it via the command line, by choosing an item from a menu, or using a button in a control panel.

The bulk of the text in a procedure window falls into one of the following categories:

- Pragmas, which send instructions from the programmer to the Igor compiler
- Include statements, which open other procedure files
- Constants, which define symbols used in functions
- Structure definitions, which can be used in functions
- Proc Pictures, which define images used in control panels, graphs, and layouts
- Menu definitions, which add menu items or entire menus to Igor
- Functions — compiled code which is used for nearly all Igor programming
- Macros — interpreted code which, for the most part, is obsolete

Functions are written in Igor's programming language. Like conventional procedural languages such as C or Pascal, Igor's language includes:

- Data storage elements (variables, strings, waves)
- Assignment statements
- Flow control (conditionals and loops)
- Calls to built-in and external operations and functions
- Ability to define and call subroutines

Igor programming is easier than conventional programming because it is much more interactive — you can write a routine and test it right away. It is designed for interactive use within Igor rather than for creating stand-alone programs.

### Organizing Procedures

Procedures can be stored in the built-in Procedure window or in separate auxiliary procedure files. Chapter III-13, **Procedure Windows**, explains how to edit the Procedure window and how to create auxiliary procedure files.

At first you will find it convenient to do all of your Igor programming in the built-in Procedure window. In the long run, however, it will be useful to organize your procedures into categories so that you can easily find and access general-purpose procedures and keep them separate from special-case procedures.

This table shows how we categorize procedures and how we store and access the different categories.

Category	What	Where	How
Experiment Procedures	<p>These are specific to a single Igor experiment.</p> <p>They include procedures you write as well as window recreation macros created automatically when you close a graph, table, layout, control panel, or Gizmo plot.</p>	<p>Usually experiment procedures are stored in the built-in Procedure window.</p> <p>You can optionally create additional procedure windows in a particular experiment but this is usually not needed.</p>	<p>You create an experiment procedure by typing in the built-in Procedure window.</p>
Utility Procedures	<p>These are general-purpose and potentially useful for any Igor experiment.</p> <p>WaveMetrics supplies utility procedures in the WaveMetrics Procedures folder. You can also write your own procedures or get them from colleagues.</p>	<p>WaveMetrics-supplied utility procedure files are stored in the WaveMetrics Procedures folder.</p> <p>Utility procedure files that you or other Igor users create should be stored in your own folder, in the Igor Pro User Files folder (see <b>Igor Pro User Files</b> on page II-31 for details) or at another location of your choosing. Place an alias or shortcut for your folder in "Igor Pro User Files/User Procedures".</p>	<p>Use an include statement to use a WaveMetrics or user utility procedure file.</p> <p>Include statements are described in <b>The Include Statement</b> on page IV-155.</p>
Global Procedures	<p>These are procedures that you want to be available from all experiments.</p>	<p>Store your global procedure files in "Igor Pro User Files/Igor Procedures" (see <b>Igor Pro User Files</b> on page II-31 for details).</p> <p>You can also store them in another folder of your choice and place an alias or shortcut for your folder in "Igor Pro User Files/Igor Procedures".</p>	<p>Igor automatically opens any procedure file in "Igor Pro 7 Folder/Igor Procedures" and "Igor Pro User Files/Igor Procedures" and subfolders or referenced by an alias or shortcut in those folders, and leaves it open in all experiments.</p>

Following this scheme, you will know where to put procedure files that you get from colleagues and where to look for them when you need them.

Utility and global procedures should be general-purpose so that they can be used from any experiment. Thus, they should not rely on specific waves, global variables, global strings, specific windows or any other objects specific to a particular experiment. See **Writing General-Purpose Procedures** on page IV-156 for further guidelines.

After they are debugged and thoroughly tested, you may want to share your procedures with other Igor users via **IgorExchange**.

## WaveMetrics Procedure Files

WaveMetrics has created a large number of utility procedure files that you can use as building blocks. These files are stored in the WaveMetrics Procedures folder. They are described in the WM Procedures Index help file, which you can access through the Help→Help Windows menu.

You access WaveMetrics procedure files using include statements. Include statements are explained under **The Include Statement** on page IV-155.

Using the Igor Help Browser, you can search the WaveMetrics Procedures folder to find examples of particular programming techniques.

## Macros and Functions

There are two kinds of Igor procedures: **macros** and **functions**. They use similar syntax. The main difference between them is that Igor compiles user functions but interprets macros.

## Chapter IV-2 — Programming Overview

---

Because functions are compiled, they are dramatically faster than macros. Compilation also allows Igor to detect errors in functions when you write the function, whereas errors in macros are detected only when they are executed.

Functions provide many programming features that are not available in macros.

Macros are a legacy of Igor's early days. With rare exceptions, **all new programming should use functions**, not macros. To simplify the presentation of Igor programming, most discussion of macros is segregated into Chapter IV-4, **Macros**.

## Scanning and Compiling Procedures

When you modify text in a procedure window, Igor must process it before you can execute any procedures. There are two parts to the processing: scanning and function compilation. In the scanning step, Igor finds out what procedures exist in the window. In the compilation step, Igor's function compiler converts the function text into low-level instructions for later execution.

For the sake of brevity, we use the term "compile" to mean "scan and compile" except when we are specifically pointing out the distinction between these two steps.

You can *explicitly* compile the procedures using the Compile button in the Procedure window or the Compile item in the Macros menu.

By default, Igor *automatically* compiles the procedure text at appropriate times. For example, if you type in the Procedure window and then hide it by clicking in the close button, Igor will automatically compile.

If you have many procedures that take long to compile, you may want to turn auto-compiling off using the Macros menu.

When Auto-compile is deselected, Igor compiles only when you explicitly request it. Igor will still scan the procedures when it needs to know what macros and functions exist.

## Indentation Conventions

We use indentation to indicate the structure of a procedure.

	<b>Function</b>	Example()	
		<Input parameter declarations>	
		<Local variable declarations>	
		<b>if</b> (condition)	
		<true part>	Indentation clearly shows what is
		<b>else</b>	executed if the condition is true and
		<false part>	what is executed if it is false.
		<b>endif</b>	
		<b>do</b>	
		<loop body>	The body of the loop is
		<b>while</b> (condition)	indented by one tab.
		<b>End</b>	

The body of the function is indented by one tab.

The structural keywords, shown in bold here, control the flow of the procedure. The purpose of the indentation is to make the structure of the procedure apparent by showing which lines are within which structural keywords. Matching keywords are at the same level of indentation and all lines within those keywords are indented by one tab.

The Edit menu contains aids for maintaining or adjusting indentation. You can select multiple lines and choose Indent Left or Indent Right. You can have Igor automatically adjust the indentation of a procedure by selecting the whole procedure or a subset and then choosing Adjust Indentation.

Igor does not require that you use indentation but we recommend it for readability.

## What's Next

The next chapter covers the core of Igor programming — writing user-defined functions.

Chapter IV-4, **Macros**, explains macros. Because new programming does not use macros, that chapter is mostly of use for understanding old Igor code.

Chapter IV-5, **User-Defined Menus**, explains user-defined menus. It explains how you can add menu items to existing Igor menus and create entire new menus of your own.

Chapter IV-6, **Interacting with the User**, explains other methods of interacting with the user, including the use of dialogs, control panels, and cursors.

Chapter IV-7, **Programming Techniques**, covers an assortment of programming topics. An especially important one is the use of the include statement, which you use to build procedures on top of existing procedures.

Chapter IV-8, **Debugging**, covers debugging using Igor's symbolic debugger.

Chapter IV-9, **Dependencies**, covers dependencies — a way to tie a variable or wave to a formula.

Chapter IV-10, **Advanced Topics**, covers advanced topics, such as communicating with other programs, doing FTP transfers, doing data acquisition, and creating a background task.

### Overview

Most of Igor programming consists of writing user-defined functions.

A function has zero or more parameters. You can use local variables to store intermediate results. The function body consists of Igor operations, assignment statements, flow control statements, and calls to other functions.

A function can return a numeric, string, wave reference or data folder reference result. It can also have a side-effect, such as creating a wave or creating a graph.

Before we dive into the technical details, here is an informal look at some simple examples.

```
Function Hypotenuse(side1, side2)
    Variable side1, side2

    Variable hyp
    hyp = sqrt(side1^2 + side2^2)

    return hyp
End
```

The Hypotenuse function takes two numeric parameters and returns a numeric result. “hyp” is a local variable and sqrt is a built-in function. You could test Hypotenuse by pasting it into the built-in Procedure window and executing the following statement in the command line:

```
Print Hypotenuse(3, 4)
```

Now let’s look at a function that deals with text strings.

```
Function/S FirstStr(str1, str2)
    String str1, str2

    String result

    if (CmpStr(str1, str2) < 0)
        result = str1
    else
        result = str2
    endif

    return result
End
```

The FirstStr function takes two string parameters and returns the string that is first in alphabetical order. CmpStr is a built-in function. You could test FirstStr by executing pasting it into the built-in Procedure window the following statement in the command line:

```
Print FirstStr("ABC", "BCD")
```

Now a function that deals with waves.

```
Function CreateRatioOfWaves(w1, w2, nameOfOutputWave)
    WAVE w1, w2
    String nameOfOutputWave

    Duplicate/O w1, $nameOfOutputWave
    WAVE wOut = $nameOfOutputWave
    wOut = w1 / w2
End
```

The CreateRatioOfWaves function takes two wave parameters and a string parameter. The string is the name to use for a new wave, created by duplicating one of the input waves. The “WAVE wOut” statement creates a wave reference for use in the following assignment statement. This function has no direct result (no return statement) but has the side-effect of creating a new wave.

Here are some commands to test CreateRatioOfWaves:

```
Make test1 = {1, 2, 3}, test2 = {2, 3, 4}
CreateRatioOfWaves(test1, test2, "ratio")
Edit test1, test2, ratio
```

## Function Syntax

The basic syntax of a function is:

```
Function <Name> (<Parameter list> [<Optional Parameters>]) [:<Subtype>]
    <Parameter declarations>

    <Local variable declarations>

    <Body code>

    <Return statement>
End
```

Here is an example:

```
Function Hypotenuse(side1, side2)
    Variable side1, side2          // Parameter declaration

    Variable hyp                   // Local variable declaration

    hyp = sqrt( side1^2 + side2^2 ) // Body code

    return hyp                     // Return statement
End
```

You could test this function from the command line using one of these commands:

```
Print Hypotenuse(3,4)
Variable/G result = Hypotenuse(3,4); Print result
```

As shown above, the function returns a real, numeric result. The Function keyword can be followed by a flag that specifies a different result type.

Flag	Return Value Type
/D	Double precision number (obsolete)
/C	Complex number
/S	String
/WAVE	Wave reference
/DF	Data folder reference

The /D flag is obsolete because all calculations are now performed in double precision. However, it is still permitted.

## The Function Name

The names of functions must follow the standard Igor naming conventions. Names can consist of up to 31 characters. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names must not conflict with the names of other Igor objects, functions or operations. Names in Igor are case insensitive.

### The Procedure Subtype

You can identify procedures designed for specific purposes by using a subtype. Here is an example:

```
Function ButtonProc(ctrlName) : ButtonControl
    String ctrlName

    Beep
End
```

Here, “ : ButtonControl” identifies a function intended to be called when a user-defined button control is clicked. Because of the subtype, this function is added to the menu of procedures that appears in the Button Control dialog. When Igor automatically generates a procedure it generates the appropriate subtype. See **Procedure Subtypes** on page IV-193 for details.

### The Parameter List and Parameter Declarations

The parameter list specifies the name for each input parameter. There is no limit on the number of parameters.

All parameters must be declared immediately after the function declaration. In Igor Pro 7 or later you can use inline parameters, described below.

The parameter declaration declares the type of each parameter using one of these keywords:

Variable	Numeric parameter
Variable/C	Complex numeric parameter
String	String parameter
Wave	Wave reference parameter
Wave/C	Complex wave reference parameter
Wave/T	Text wave reference parameter
DFREF	Data folder reference parameter
FUNCREF	Function reference parameter
STRUCT	Structure reference parameter
int	Signed integer parameter- requires Igor7 or later
int64	Signed 64-bit integer parameter - requires Igor7 or later
uint64	Unsigned 32-bit integer parameter - requires Igor7 or later
double	Numeric parameter - requires Igor7 or later
complex	Complex numeric parameter - requires Igor7 or later

int is 32 bits in IGOR32 and 64 bits in IGOR64.

double is a synonym for Variable and complex is a synonym for Variable/C.

WAVE/C tells the Igor compiler that the referenced wave is complex.

WAVE/T tells the Igor compiler that the referenced wave is text.

Variable and string parameters are usually passed to a subroutine *by value* but can also be passed by reference. For an explanation of these terms, see **How Parameters Work** on page IV-53.

## Integer Parameters

In Igor Pro 7 and later you can use these integer types for parameters and local variables in user-defined functions:

<code>int</code>	32-bit integer in IGOR32; 64-bit integer in IGOR64
<code>int64</code>	64-bit signed integer
<code>uint64</code>	64-bit unsigned integer

`int` is a generic signed integer that you can use for wave indexing or general use. It provides a speed improvement over `Variable` or `double` in most cases.

Signed `int64` and unsigned `uint64` are for special purposes where you need explicit access to bits. You can also use them in structures.

## Optional Parameters

Following the list of required function input parameters, you can also specify a list of optional input parameters by enclosing the parameter names in brackets. You can supply any number of optional parameter values when calling the function by using the *ParamName=Value* syntax. Optional parameters may be of any valid data type. There is no limit on the number of parameters.

All optional parameters must be declared immediately after the function declaration. As with all other variables, optional parameters are initialized to zero. You must use the **ParamIsDefault** function to determine if a particular optional parameter was supplied in the function call.

See **Using Optional Parameters** on page IV-55 for an example.

## Inline Parameters

In Igor Pro 7 and later you can declare user-defined functions parameters inline. This means that the parameter types and parameter names are declared in the same statement as the function name:

```
Function Example(Variable a, [ Variable b, double c ])  
    Print a,b,c  
End
```

or, equivalently:

```
Function Example2(  
    Variable a, // The comma is optional  
    [  
        Variable b,  
        double c  
    ]  
)  
    Print a,b,c  
End
```

### Local Variable Declarations

The parameter declarations are followed by the local variable declarations if the procedure uses local variables. Local variables exist only during the execution of the procedure. They are declared using one of these keywords:

Variable	Numeric variable
Variable/C	Complex numeric variable
String	String variable
NVAR	Global numeric variable reference
NVAR/C	Global complex numeric variable reference
SVAR	Global variable reference
Wave	Wave reference
Wave/C	Complex wave reference
Wave/T	Text wave reference
DFREF	Data folder reference
FUNCREF	Function reference
STRUCT	Structure
int	Signed integer - requires Igor7 or later
int64	Signed 64-bit integer - requires Igor7 or later
uint64	Unsigned 32-bit integer - requires Igor7 or later
double	Numeric variable - requires Igor7 or later
complex	Complex numeric variable - requires Igor7 or later

double is a synonym for Variable and complex is a synonym for Variable/C.

Numeric and string local variables can optionally be initialized. For example:

```
Function Example(p1)
    Variable p1

    // Here are the local variables
    Variable v1, v2
    Variable v3=0
    Variable/C cv1=cplx(0,0)
    String s1="test", s2="test2"

    <Body code>
End
```

If you do not supply explicit initialization, Igor automatically initializes local numeric variables with the value zero. Local string variables are initialized with a null value such that, if you try to use the string before you store a value in it, Igor reports an error.

Initialization of other local variable types is discussed below. See **Wave References** on page IV-65, **Data Folder References** on page IV-72, **Function References** on page IV-98, and **Structures in Functions** on page IV-91.

The name of a local variable is allowed to conflict with other names in Igor, but they must be unique within the function. If you create a local variable named “sin”, for example, then you will be unable to use Igor’s built-in sin function within the function.

You can declare local variables anywhere in the function after the parameter declarations.

## Body Code

This table shows what can appear in body code of a function.

What	Allowed in Functions?	Comment
Assignment statements	Yes	Includes wave, variable and string assignments.
Built-in operations	Yes, with a few exceptions.	See <b>Operations in Functions</b> on page IV-102 for exceptions.
Calls to user functions	Yes	
Calls to macros	No	
External functions	Yes	
External operations	Yes, with exceptions.	

Statements are limited to 1000 characters per line except for assignment statements which, in Igor Pro 7 or later, can be continued on subsequent lines.

## Line Continuation

In user-defined functions in Igor Pro 7 or later, you can use arbitrarily long expressions by including a line continuation character at the very end of a line. The line continuation character is backslash. For example:

```
Function Example1(double v1)
    return v1 + \
    2
End
```

Line continuation is supported for any numeric or string expression in a user-defined function. Here is an example using a string expression:

```
Function/S Example2(string s1)
    return s1 + \
    " " + \
    "there"
End
```

Line continuation is supported for numeric and string expressions only. It is not supported on other types of commands. For example, this generates a compile error:

```
Function Example3(double v1)
    Make wave0 \
    wave1
End
```

## The Return Statement

A return statement often appears at the end of a function, but it can appear anywhere in the function body. You can also have more than one return statement.

The return statement immediately stops executing the function and returns a value to the calling function. The type of the returned value must agree with the type declared in the function declaration.

If there is no return statement, or if a function ends without hitting a return statement, then the function returns the value NaN (Not a Number) for numeric functions and null for other types of functions. If the calling function attempts to use the null value, Igor reports an error.

### Expression Evaluation

An expression is a combination of literal values, variable references, wave references, function calls, parentheses and operators. Expressions appear on the right-hand side of assignment statements and as parameters in commands. For example:

```
Variable v = ((123 + someVariable) * someWave[3]) / SomeFunction()
```

In most cases Igor evaluates expressions using double-precision floating point. However, if the destination is an integer type, then Igor uses integer calculations.

### Integer Expressions

Prior to Igor Pro 7, all calculations were performed in double-precision floating point. Double-precision can represent integers of up to 53 bits precisely. Integers larger than 53 bits are represented approximately in double-precision.

Igor Pro 7 and later can perform integer calculations instead of floating point. You trigger this by assigning a value to a local variable declared using the integer types `int`, `int64` and `uint64`. Calculations are done using 32 bits or 64 bits depending on the type of the integer.

When an integer type variable is the destination in an expression in a function, the right-hand side is compiled using integer math. This avoids the limitation of 53 bits for double precision and may also provide a speed advantage. If you use a function such as `sin` that is inherently floating point, it is calculated as a double and then converted to an integer. You should avoid using anything that causes a double-to-integer conversion when the destination is a 64-bit integer.

This example shows various ways to use integer expressions:

```
Function Example()  
    int a = 0x101           // 0x introduces a hexadecimal literal number  
    int b = a<<2  
    int c = b & 0x400  
    printf "a=%x, b=%x, c=%x\r", a, b, c  
End
```

This prints

```
a=101, b=404, c=400
```

To set bits in an integer, use the left-shift operator, `<<`. For example to set bit 60 in a 64-bit integer, use `1<<60`. This is the integer equivalent of  $2^{60}$ , but you can not use `^` because exponentiation is not supported in integer expressions.

To print all the bits in a 64-bit integer, use `Printf` with the `%x` or `%d` conversion specification. You can also use a `Print` command as long as the compiler can clearly see the number is an integer from the first symbol. For example:

```
Function Example()  
    int64 i = 1<<60 // 1152921504606846976 (decimal), 1000000000000000 (hex)  
    Printf "i = %0.16X\r", i  
    Printf "i = %d\r", i  
    Print "i =", i  
    Print "i =", 0+i // First symbol is not an integer variable or wave  
End
```

This prints:

```
i = 1000000000000000  
i = 1152921504606846976  
i = 1152921504606846976  
i = 1.15292e+18
```

## Integer Expressions in Wave Assignment Statements

When compiling a wave assignment statement, the right-hand expression is compiled as 64-bit integer if the compiler knows that the destination wave is 64-bit integer. Otherwise, the expression is compiled as double. For example:

```
Function ExpressionCompiledAsInt64()
    Make/O/N=1/L w64
    w64 = 0x7FFFFFFFFFFFFFFF
    Print w64[0]
End
```

0x7FFFFFFFFFFFFFFF is the largest signed 64-bit integer value expressed in hexadecimal. It can not be precisely represented in double precision.

Here the /L flag tells Igor that the wave is signed 64-bit integer. This causes the compiler to compile the right-hand expression using signed 64-bit signed operations. The correct value is assigned to the wave and the correct value is printed.

In the next example, the compiler does not know that the wave is signed 64-bit integer because the /L flag was not used. Consequently the right-hand expression is compiled using double-precision operations. Because 0x7FFFFFFFFFFFFFFF can not be precisely represented in double precision, the value assigned to the wave is incorrect, as is the printed value:

```
Function ExpressionCompiledAsDouble()
    Make/O/N=1/Y=(0x80) w64      // Wave is int64 but Igor does not know it
    w64 = 0x7FFFFFFFFFFFFFFF    // Expression compiled as double
    Print w64[0]
End
```

You can use the /L flag in a wave declaration. For example:

```
Function ExpressionCompiledAsInt64()
    Make/O/N=1Y=(0x80) w64      // Wave is int64 but Igor does not know it
    Wave/L w = w64              // Igor knows that w refers to int64 wave
    w = 0x7FFFFFFFFFFFFFFF      // Expression compiled as int64
    Print w[0]
End
```

This tells Igor that the wave reference by w is signed 64-bit integer, causing the compiler to use signed 64-bit integer to compile the right-hand expression.

If the wave was unsigned 64-bit, we would need to use Wave/L/U.

In summary, to assign values to a 64-bit integer wave, make sure to use the correct flags so that Igor will compile the right-hand expression using 64-bit integer operations.

To view the contents of an integer wave, especially a 64-bit integer wave, display it in a table using an integer column format or print individual elements on the command line. Print on an entire wave is not yet integer-aware and uses doubles.

## Conditional Statements in Functions

Igor Pro supports two basic forms of conditional statements: if-else-endif and if-elseif-endif statements. Igor also supports multiway branching with switch and strswitch statements.

### If-Else-Endif

The form of the if-else-endif structure is

```
if ( <expression> )
    <true part>
else
```

```
<false part>
endif
```

<expression> is a numeric expression that is considered true if it evaluates to any nonzero number and false if it evaluates to zero. The true part and the false part may consist of any number of lines. If the expression evaluates to true, only the true part is executed and the false part is skipped. If the expression evaluates to false, only the false part is executed and the true part is skipped. After the true part or false part code is executed, execution continues with any code immediately following the if-else-endif statement.

The keyword “else” and the false part may be omitted to give a simple conditional:

```
if ( <expression> )
    <true part>
endif
```

Because Igor is line-oriented, you may not put the if, else and endif keywords all on the same line. They must each be in separate lines with no other code.

### If-Elseif-Endif

The if-elseif-endif statement provides a means for creating nested if structures. It has the form:

```
if ( <expression1> )
    <true part 1>
elseif ( <expression2> )
    <true part 2>
[else
    <false part>]
endif
```

These statements follow similar rules as for if-else-endif statements. When any expression evaluates as true (nonzero), the code immediately following the expression is executed. If all expressions evaluate as false (zero) and there is an else clause, then the statements following the else keyword are executed. Once any code in a true part or the false part is executed, execution continues with any code immediately following the if-elseif-endif statement.

### Comparisons

The relational comparison operators are used in numeric conditional expressions.

Symbol	Meaning	Symbol	Meaning
==	equal	<=	less than or equal
!=	not-equal	>	greater than
<	less than	>=	greater than or equal

These operators return 1 for true and 0 for false.

The comparison operators work with numeric operands only. To do comparisons with string operands, use the **CmpStr** function.

Comparison operators are usually used in conditional structures but can also be used in arithmetic expressions. For example:

```
wave0 = wave0 * (wave0 < 0)
```

This clips all positive values in wave0 to zero.

See also **Example: Comparison Operators and Wave Synthesis** on page II-74.

## Operators in Functions

This section discusses operators in the context of user-defined functions. See **Operators** on page IV-5 for a discussion of operators used in the command line and macros as well as functions.

### Bitwise and Logical Operators

The bitwise and logical operators are also used in conditional expressions.

Symbol	Meaning
~	Bitwise complement
&	Bitwise AND
	Bitwise OR
!	Logical NOT
&&	Logical AND
	Logical OR
<<	Shift left (requires Igor7 or later)
>>	Shift right (requires Igor7 or later)

The precedence of operators is shown in the table under **Operators** on page IV-5. In the absence of parentheses, an operator with higher precedence (higher in the table) is executed before an operator with lower precedence.

Because the precedence of the arithmetic operators is higher than the precedence of the comparison operators, you can write the following without parentheses:

```
if (a+b != c+d)
    Print "a+b is not equal to c+d"
endif
```

Because the precedence of the comparison operators is higher than the precedence of the logical OR operator, you can write the following without parentheses:

```
if (a==b || c==d)
    Print "Either a equals b or c equals d"
endif
```

The same is true of the logical AND operator, &&.

For operators with the same precedence, there is no guaranteed order of execution and you must use parentheses to be sure of what will be executed. For example:

```
if ((a&b) != (c&d))
    Print "a ANDED with b is not equal to c ANDED with d"
endif
```

See **Operators** on page IV-5 for more discussion of operators.

### Using Bitwise Operators

The bitwise operators are used to test, set, and clear bits. This makes sense only when you are dealing with integer operands.

Bit Action	Operation
Test	AND operator (&)
Set	OR operator ( )
Clear	Bitwise complement operator (~) followed by the bitwise AND operator (&)

## Chapter IV-3 — User-Defined Functions

---

Bit Action	Operation
Shift left	<< operator (requires Igor7 or later)
Shift right	>> operator (requires Igor7 or later)

This function illustrates various bit manipulation techniques.

```
Function DemoBitManipulation(vIn)
    Variable vIn

    vIn = trunc(vIn)                // Makes sense with integers only
    Printf "Original value: %d\r", vIn

    Variable vOut

    if ((vIn & 2^3) != 0)           // Test if bit 3 is set
        Print "Bit 3 is set"
    else
        Print "Bit 3 is cleared"
    endif

    vOut = vIn | (2^3)              // Set bit 3
    Printf "Set bit 3: %d\r", vOut

    vOut = vIn & ~(2^3)            // Clear bit 3
    Printf "Clear bit 3: %d\r", vOut

    vOut = vIn << 3                // Shift three bits left
    Printf "Shift three bits left: %d\r", vOut

    vOut = vIn >> 3                // Shift three bits right
    Printf "Shift three bits right: %d\r", vOut
End
```

For a simple demonstration, try this function passing 1 as the parameter.

### Bit Shift Operators

Igor Pro 7 and later support the bit shift operators << and >>.  $a << n$  shifts the bits of the integer  $a$  left by  $n$  bits.  $a >> n$  shifts the bits of the integer  $a$  right by  $n$  bits.

Normally you should apply bit shift operators to integer values. If you apply a bit shift operator to a floating point value, any fractional part is truncated.

### Increment and Decrement Operators

In Igor7 and later, in a user-defined function, you can use these operators on local variables:

++var	Pre-increment
var++	Post-increment
--var	Pre-decrement
var--	Post-decrement

var must be a real local variable.

The pre-increment functions increment the variable and then return its new value. In this example,  $a$  is initialized to 0.  $++a$  then increments  $a$  to 1 and returns the new value. Consequently 1 is stored in  $b$ .

```
Function PreIncrementDemo()  
    int a = 0  
    int b = ++a  
End
```

The post-increment functions return the variable's original value and then increment it. In this example, *a* is initialized to 0. *a++* returns the original value, 0, and then increments *a* to 1. Consequently 0 is stored in *b*.

```
Function PostIncrementDemo()  
    int a = 0  
    int b = a++  
End
```

The pre-decrement and post-decrement work the same but decrement the variable rather than incrementing it.

## Switch Statements

The switch construct can sometimes be used to simplify complicated flow control. It chooses one of several execution paths depending on a particular value.

Instead of a single form of switch statement, as is the case in C, Igor has two types: *switch* for numeric expressions and *strswitch* for string expressions. The basic syntax of these switch statements is as follows:

```
switch(<numeric expression>)           // numeric switch  
    case <literal number or numeric constant>:  
        <code>  
        [break]  
    case <literal number or numeric constant>:  
        <code>  
        [break]  
    . . .  
    [default:  
        <code>]  
endswitch  
  
strswitch(<string expression>)         // string switch  
    case <literal string or string constant>:  
        <code>  
        [break]  
    case <literal string or string constant>:  
        <code>  
        [break]  
    . . .  
    [default:  
        <code>]  
endswitch
```

The switch numeric or string expression is evaluated and execution proceeds with the code following the matching case label. When none of the case labels match, execution continues at the default label, if it is present, or otherwise the switch exits with no action taken.

All of the case labels must be numeric or string constant expressions and they must all have unique values within the switch statement. The constant expressions can either be literal values or they must be declared using the *Constant* and *StrConstant* keywords for numeric and string switches respectively.

Execution proceeds within each case until a *break* statement is encountered or the *endswitch* is reached. The *break* statement explicitly exits the switch construct. Usually, you should put a *break* statement at the end of each case. If you omit the *break* statement, execution continues with the next case label. Do this when you want to execute a single action for more than one switch value.

## Chapter IV-3 — User-Defined Functions

---

The following examples illustrate how switch constructs can be used in Igor:

```
Constant kThree=3
StrConstant ksHow="how"

Function NumericSwitch(a)
    Variable a

    switch(a)                                // numeric switch
    case 1:
        print "a is 1"
        break
    case 2:
        print "a is 2"
        break
    case kThree:
    case 4:
        print "a is 3 or 4"
        break
    default:
        print "a is none of those"
        break
    endswitch
End

Function StringSwitch(a)
    String a

    strswitch(a)                            // string switch
    case "hello":
        print "a is hello"
        break
    case ksHow:
        print "a is how"
        break
    case "are":
    case "you":
        print "a is are or you"
        break
    default:
        print "a is none of those"
        break
    endswitch
End
```

## Loops

Igor implements two basic types of looping structures: do-while and for loops.

The do-while loop iterates through the loop code and tests an exit condition at the end of each iteration.

The for loop is more complex. The beginning of a for loop includes expressions for initializing and updating variables as well as testing the loop's exit condition at the start of each iteration.

### Do-While Loop

The form of the do-while loop structure is:

```
do
    <loop body>
while(<expression>)
```

This loop runs until the expression evaluates to zero or until a break statement is executed.

This example will always execute the body of the loop at least once, like the do-while loop in C.

```
Function Test(lim)
    Variable lim          // We use this parameter as the loop limit.

    Variable sum=0
    Variable i=0          // We use i as the loop variable.
    do
        sum += i          // This is the body; equivalent to sum=sum+i.
        i += 1            // Increment the loop variable.
    while(i < lim)
    return sum
End
```

### **Nested Do-While Loops**

A nested loop is a loop within a loop. Here is an example:

```
Function NestedLoopTest(numOuterLoops, numInnerLoops)
    Variable numOuterLoops, numInnerLoops

    Variable i, j
    i = 0
    do
        j = 0
        do
            <inner loop body>
            j += 1
            while (j < numInnerLoops)
            i += 1
        while (i < numOuterLoops)
    End
```

### **While Loop**

This fragment will execute the body of the loop zero or more times, like the while loop in C.

```
do
    if (i > lim)
        break          // This breaks out of the loop.
    endif
    <loop body>
    i += 1
while(1)              // This would loop forever without the break.
...                  // Execution continues here after the break.
```

In this example, the loop increment is 1 but it can be any value.

### **For Loop**

The basic syntax of a for loop is:

```
for(<initialize loop variable>; <continuation test>; <update loop variable>)
    <loop body>
endfor
```

Here is a simple example:

```
Function Example1()
    Variable i

    for(i=0; i<5; i+=1)
        print i
    endfor
End
```

## Chapter IV-3 — User-Defined Functions

---

The beginning of a for loop consists of three semicolon-separated expressions. The first is usually an assignment statement that initializes one or more variables. The second is a conditional expression used to determine if the loop should be terminated — if true, nonzero, the loop is executed; if false, zero, the loop terminates. The third expression usually updates one or more loop variables.

When a for loop executes, the initialization expression is evaluated only once at the beginning. Then, for each iteration of the loop, the continuation test is evaluated at the start of every iteration, terminating the loop if needed. The third expression is evaluated at the end of the iteration and usually increments the loop variable.

All three expressions in a for statement are optional and can be omitted independent of the others; only the two semicolons are required. The expressions can consist of multiple assignments, which must be separated by commas.

In addition to the continuation test expression, for loops may also be terminated by break or return statements within the body of the loop.

A continue statement executed within the loop skips the remaining body code and execution continues with the loop's update expression.

Here is a more complex example:

```
Function Example2()  
    Variable i,j  
  
    for(i=0,j=10; ;i+=1,j*=2)  
        if (i == 2)  
            continue  
        endif  
        Print i,j  
        if (i == 5)  
            break  
        endif  
    endfor  
End
```

### Break Statement

A break statement terminates execution of do-while loops, for loops, and switch statements. The break statement continues execution with the statement after the *enclosing* loop's while, endfor, or endswitch statement. A nested do-while loop example demonstrates this:

```
...  
Variable i=0, j  
  
do                                // Starts outer loop.  
    if (i > numOuterLoops)  
        break                    // Break #1, exits from outer loop.  
    endif  
    j = 0  
    do                            // Start inner loop.  
        if (j > numInnerLoops)  
            break                // Break #2, exits from inner loop only.  
        endif  
        j += 1  
    while (1)                    // Ends inner loop.  
    ...                          // Execution continues here from break #2.  
    i += 1  
while (1)                        // Ends outer loop.  
...                              // Execution continues here from break #1.
```

## Continue Statement

The continue statement can be used in do-while and for loops to short-circuit the loop and return execution back to the top of the loop. When Igor encounters a continue statement during execution, none of the code following the continue statement is executed during that iteration.

## Flow Control for Aborts

Igor Pro includes a specialized flow control construct and keywords that you can use to test for and respond to abort conditions. The AbortOnRTE and AbortOnValue keywords can be used to trigger aborts, and the try-catch-endtry construct can be used to control program execution when an abort occurs. You can also trigger an abort by pressing the **User Abort Key Combinations** or by clicking the Abort button in the status bar.

These are advanced techniques. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

### AbortOnRTE Keyword

The AbortOnRTE (abort on runtime error) keyword can be used to raise an abort whenever a runtime error occurs. Use AbortOnRTE immediately after a command or sequence of commands for which you wish to catch a runtime error.

See **AbortOnRTE** on page V-18 for further details. For a usage example see **Simple try-catch-endtry Example** on page IV-46.

### AbortOnValue Keyword

The AbortOnValue keyword can be used to abort function execution when a specified abort condition is satisfied. When AbortOnValue triggers an abort, it can also return a numeric abort code that you can use to characterize the cause.

See **AbortOnValue** on page V-19 for further details. For a usage example see **Simple try-catch-endtry Example** on page IV-46.

## try-catch-endtry Flow Control

The try-catch-endtry flow control construct has the following syntax:

```
try
    <code>
catch
    <code to handle abort>
endtry
```

The try-catch-endtry flow control construct can be used to catch and respond to abnormal conditions in user functions. Code within the try and catch keywords tests for abnormal conditions and calls Abort, AbortOnRTE or AbortOnValue if appropriate. An abort also occurs if the user clicks the Abort button in the command window or presses the **User Abort Key Combinations**.

When an abort occurs, execution immediately jumps to the first statement after the catch keyword. This catch code handles the abnormal condition, and execution then falls through to the first statement after endtry.

If no abort occurs, then the code between catch and endtry is skipped, and execution then falls through to the first statement after endtry.

When an abort occurs within the try-catch area, Igor stores a numeric code in the V\_AbortCode variable. The catch code can use V\_AbortCode to determine what caused the abort.

See **try-catch-endtry** on page V-908 for further details.

## Chapter IV-3 — User-Defined Functions

---

### Simple try-catch-endtry Example

We start with a simple example that illustrates the most common try-catch use. It catches and handles a runtime error.

```
Function DemoTryCatch0(name)
    String name                // Name to use for a new wave

    try
        Make $name             // Generates error if name is illegal or in use
        AbortOnRTE             // Abort if an error occurred

        // This code executes if no error occurred
        Printf "The wave '%s' was successfully created\r", name
    catch
        // This code executes if an error occurred in the try block
        Variable err = GetRTErr(1) // Get error code and clear error
        String errMsg = GetErrMsg(err)
        Printf "While executing Make, the following error occurred: %s\r", errMsg
    endtry
End
```

Copy the code to the Procedure window of a new experiment and then execute:

```
DemoTryCatch0("wave0")
```

Since wave0 does not exist in a new experiment, DemoTryCatch0 creates it.

Now execute the same command again. This time the call to Make generates a runtime error because wave0 already exists. The call to AbortOnRTE generates an abort, because of the error generated by Make. The abort causes the catch code to run. It reports the error to the user and clears it to allow execution to continue.

Without the clearing of the runtime error, via the GetRTErr call, the error would cause procedure execution to halt and Igor would report the error to the user via an error dialog.

### Complex try-catch-endtry Example

The following example demonstrates how aborting flow control works. Copy the code to the Procedure window and execute the DemoTryCatch1 function with 0 to 6 as input parameters. When you execute DemoTryCatch1(6), the function loops until you click the Abort button in the bottom/right corner of the command window.

```
Function DemoTryCatch1(a)
    Variable a

    Print "A"
    try
        Print "B1"
        AbortOnValue a==1 || a==2,33
        Print "B2"
        DemoTryCatch2(a)
        Print "B3"
        try
            Print "C1"
            if( a==4 || a==5 )
                Make $""; AbortOnRTE
            endif
            Print "C2"
        catch
            Print "D1"
            // will be runtime error so pass along to outer catch
            AbortOnValue a==5, V_AbortCode
            Print "D2"
        endtry
    endtry
```

```

    Print "B4"
    if( a==6 )
        do
            while(1)
            endif
        Print "B5"
    catch
        Print "Abort code= ", V_AbortCode
        if( V_AbortCode == -4 )
            Print "Runtime error= ", GetRTErr(1)
        endif
        if( a==1 )
            Abort "Aborting again"
        endif
        Print "E"
    endtry
    Print "F"
End

Function DemoTryCatch2(b)
    Variable b

    Print "DemoTryCatch2 A"
    AbortOnValue b==3,99
    Print "DemoTryCatch2 B"
End

```

## User Abort Key Combinations

You can abort procedure execution by clicking the Abort button in the status bar or by pressing the following user abort key combinations:

Command-dot	Macintosh only
Ctrl+Break	Windows only
Shift+Escape	All platforms

## Constants

You can define named numeric and string constants in Igor procedure files and use them in the body of user-defined functions.

Constants are defined in procedure files using following syntax:

```

Constant <name1> = <literal number> [, <name2> = <literal number>]
StrConstant <name1> = <literal string> [, <name2> = <literal string>]

```

For example:

```

Constant kIgorStartYear=1989, kIgorEndYear=2099
StrConstant ksPlatformMac="Macintosh", ksPlatformWin="Windows"

Function Test1()
    Variable v1 = kIgorStartYear
    String s1 = ksPlatformMac
    Print v1, s1
End

```

We suggest that you use the “k” prefix for numeric constants and the “ks” prefix for string constants. This makes it immediately clear that a particular keyword is a constant.

Constants declared like this are public and can be used in any function in any procedure file. A typical use would be to define constants in a utility procedure file that could be used from other procedure files as parameters to the utility routines. Be sure to use precise names to avoid conflicts with public constants declared in other procedure files.

If you are defining constants for use in a single procedure file, for example to improve readability or make the procedures more maintainable, you should use the `static` keyword (see **Static** on page V-776 for details) to limit the scope to the given procedure file.

```
static Constant kStart=1989, kEnd=2099
static StrConstant ksMac="Macintosh", ksWin="Windows"
```

Names for numeric and string constants are allowed to conflict with all other names. Duplicate constants of a given type are not allowed, except for static constants in different files and when used with the `override` keyword. The only true conflict is with variable names and with certain built-in functions that do not take parameters such as `pi`. Variable names, including local variable names, waves, NVARs, and SVARs, override constants, but constants override functions such as `pi`.

## Pragmas

A pragma is a statement in a procedure file that sets a compiler mode or passes other information from the programmer to Igor. The form of a pragma statement is:

```
#pragma keyword [= parameter]
```

The pragma statement must be flush against the left margin of the procedure window, with no indentation.

Igor ignores unknown pragmas such as pragmas introduced in later versions of the program.

Currently, Igor supports the following pragmas:

```
#pragma rtGlobals = value
#pragma version = versionNumber
#pragma IgorVersion = versionNumber
#pragma hide = value
#pragma ModuleName = name
#pragma IndependentModule = name
#pragma TextEncoding = textEncodingNameStr
```

The effect of a pragma statement lasts until the end of the procedure file that contains it.

### The rtGlobals Pragma

The `rtGlobals` pragma controls aspects of the Igor compiler and runtime error checking in user-defined functions.

Prior to Igor Pro 3, to access a global (wave or variable) from a user-defined function, the global had to already exist. Igor Pro 3 introduced "runtime lookup of globals" under which the Igor compiler did not require globals to exist at compile time but rather connected references, declared with `WAVE`, `NVAR` and `SVAR` statements, to globals at runtime. Igor Pro 6.20 introduced stricter compilation of wave references and runtime checking of wave index bounds.

You enable and disable these behaviors using an `rtGlobals` pragma. For example:

```
#pragma rtGlobals = 3    // Strict wave reference mode, runtime bounds checking
```

A given `rtGlobals` pragma governs just the procedure file in which it appears. The pragma must be flush left in the procedure file and is typically put at the top of the file.

The rtGlobals pragma is defined as follows:

#pragma rtGlobals=0	Specifies the old, pre-Igor Pro 3 behavior. This is no longer supported and acts like rtGlobals=1.
#pragma rtGlobals=1	Turns on runtime lookup of globals. This is the default setting if there is no rtGlobals pragma in a given procedure file.
#pragma rtGlobals=2	Forces old experiments out of compatibility mode. This is superceded by rtGlobals=3. It is described under <b>Legacy Code Issues</b> on page IV-104.
#pragma rtGlobals=3	Turns on runtime lookup of globals, strict wave references and runtime checking of wave index bounds. Requires Igor Pro 6.2 or later.

rtGlobals=3 is recommended.

Under strict wave references (rtGlobals=3), you must create a wave reference for any use of a wave. Without strict wave references (rtGlobals=1), you do not need to create a wave reference unless the wave is used in an assignment statement. For example:

```
Function Test()
    jack = 0      // Error under rtGlobals=1 and under rtGlobals=3
    Display jack  // OK under rtGlobals=1, error under rtGlobals=3

    Wave jack     // jack is now a wave reference rather than a bare name
    Display jack  // OK under rtGlobals=1 and under rtGlobals=3
End
```

Even with rtGlobals=3, this compiles without error:

```
Function Test()
    // Make creates an automatic wave reference when used with a simple name
    Make jack
    Display jack  // OK under rtGlobals=1 and rtGlobals=3
End
```

See **Automatic Creation of WAVE References** on page IV-66 for details.

Under runtime wave index checking (rtGlobals=3), Igor reports an error if a wave index is out-of-bounds:

```
Function Test()
    Make/O/N=5 jack = 0  // Creates automatic wave reference

    jack[4] = 123        // OK
    jack[5] = 234        // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.

    Variable index = 5
    jack[index] = 234     // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.

    // Create and use a dimension label for point 4 of jack
    SetDimLabel 0,4,four,jack
    jack[%four] = 234     // OK

    // Use a non-existent dimension label.
    jack[%three] = 345    // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.
    // Under rtGlobals=1, this statement writes to point 0 of jack.
End
```

**Automatic Creation of WAVE, NVAR and SVAR References** on page IV-65

**Legacy Code Issues** on page IV-104

### The version Pragma

The version pragma sets the version of the procedure file. It is optional and is of interest mostly if you are the developer of a package used by a widespread group of users.

For details on the version pragma, see **Procedure File Version Information** on page IV-155.

### The IgorVersion Pragma

The IgorVersion pragma is also optional and of interest to developers of packages. It gives you a way to prevent procedures from compiling under versions of Igor Pro older than the specified version number.

For example, the statement:

```
#pragma IgorVersion = 7.00
```

tells Igor that the procedure file requires Igor Pro 7.00 or later.

### The hide Pragma

The hide pragma allows you to make a procedure file invisible.

For details on the hide pragma, see **Invisible Procedure Files** on page III-355.

### The ModuleName Pragma

The ModuleName pragma gives you the ability to use static functions and proc pictures in a global context, such as in the action procedure of a control or on the command line. Using this pragma entails a two step process: define a name for the procedure file, and then use a special syntax to access objects in the named procedure file.

To define a module name for a procedure file use the format:

```
#pragma ModuleName = name
```

This statement associates the specified module name with the procedure file in which the statement appears.

You can then use objects from the named procedure file by preceding the object name with the name of the module and the # character. For example:

```
#pragma ModuleName = MyModule
```

```
Static Function Test(a)  
    Variable a
```

```
        return a+100  
End
```

Then, on the command line or from another procedure file, you can execute:

```
Print MyModule#Test(3)
```

Choose a distinctive module name so that it does not clash with module names used by other programmers. WaveMetrics uses module names with a `WM_` prefix, so you must not use such names.

For further discussion see **Regular Modules** on page IV-222.

## The IndependentModule Pragma

The IndependentModule pragma is a way for you to designate groups of one or more procedure files to be compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows your control panels, menus, and procedures to continue to work regardless of user programming errors.

A file is designated as an independent module using

```
#pragma IndependentModule=imName
```

This is similar to `#pragma ModuleName=modName` (see **The ModuleName Pragma** on page IV-50) and, just as in the case of calling static functions in a procedure with `#pragma ModuleName`, calling nonstatic function in an IndependentModule from outside the module requires the use of `imName#functionName()` syntax.

To call any function, static or not, defined in an independent module from outside that module, you must qualify the call with the independent module name:

```
MyIndependentModule#Test()
```

For further discussion see **Independent Modules** on page IV-224.

## The rtFunctionErrors Pragma

Normally, when an error occurs in a built-in function, the built-in function does not post an error but rather returns 0, NaN, or an empty string as the function result. For example, by default, the Sum built-in function in this user-defined function returns 0 but does not post an error:

```
Function Test()
    Make/T/FREE textWave = ""
    Variable val = Sum(textWave)      // Error: Expected numeric wave
    Print val
End
```

As a debugging aid, you can force Igor to post an error that occurs in a built-in function called from a user-defined function by adding this statement to the procedure file:

```
#pragma rtFunctionErrors = 1
```

Now, if you run the Test function, Igor displays an error dialog telling you that the Sum function expects a numeric wave.

The rtFunctionErrors pragma works for most errors in built-in functions called from user-defined functions, but not in all.

The rtFunctionErrors pragma was added in Igor Pro 7.00. Earlier versions of Igor ignore it.

## The TextEncoding Pragma

The TextEncoding pragma provides a way for a programmer to mark an Igor procedure file as using a particular text encoding. This pragma was added in Igor Pro 7.00 and is ignored by earlier versions.

Here is an example:

```
#pragma TextEncoding = "Windows-1252"
```

This pragma tells Igor7 that the procedure file is encoded using Windows-1252, also known as "Windows Latin 1" or "Western". This is the text encoding used by Igor Pro 6 and before on Windows English and Western European systems.

Like all pragmas, the TextEncoding pragma must be flush against the left margin of the procedure file. It is an error to have more than one TextEncoding pragma in a given procedure file. The TextEncoding pragma can appear anywhere in the file and affects the whole file. By convention it is placed near the top of the file.

## Chapter IV-3 — User-Defined Functions

---

If your procedure file uses only ASCII characters then all versions of Igor on all platforms will interpret it correctly and there is no need for a TextEncoding pragma.

If your procedure file uses non-ASCII characters then we recommend that you add a TextEncoding pragma as this will allow Igor7 to reliably interpret it regardless of the user's operating system, system locale and default text encoding setting.

If the procedure file is to be used in Igor7 and later only then you should use the UTF-8 text encoding. This allows you to use any Unicode character in the file.

If the procedure file is to be used in both Igor6 and Igor7 and later, you should not use UTF-8 because Igor6 does not support it. If you primarily work on Macintosh in a Western language, use "MacRoman". If you primarily work on Windows in a Western language, use "Windows-1252". If you work in Japanese, use "Japanese".

The following text encodings are not supported for procedure files:

UTF-16LE, UTF-16BE, UTF32-LE, UTF32-BE

If you attempt to use these in a procedure file Igor will report an error.

To understand the utility of the TextEncoding pragma, consider this scenario. You are an Igor programmer who has created a package of procedures that is used by many users around the world. Your procedures contain some non-ASCII characters such as Greek letters. Some of your users are using Igor6 and some are using Igor7. You do not want to maintain separate code for each version of Igor. This means that your procedure files must use an Igor6-compatible text encoding which excludes UTF-8.

When Igor7 opens a procedure file it must convert it from the text encoding used to store the file to UTF-8. To do this it must determine the text encoding used by the file. As noted under **Plain Text Text Encoding Conversion Errors** on page III-419, for plain text files this is tricky. Without a TextEncoding pragma and lacking any other means to determine it, Igor7 would determine the file's text encoding using the user's default text encoding setting. This would inevitably be wrong for some users.

The TextEncoding pragma solves this problem by allowing you to explicitly mark a procedure file as using a particular text encoding.

In the example above you would choose Windows-1252 if you edit your procedure files on a Windows western system. If you edit them on a Macintosh western system, you would use "Macintosh" (also called "MacRoman"). If you edit them on a Japanese system, you would use "Shift JIS". These are the text encodings used by Igor6 on the respective systems. With the right TextEncoding pragma, you can reliably edit and run your procedures in Igor6 or Igor7.

In Igor7, Igor automatically adds a TextEncoding pragma under some circumstances.

It adds a TextEncoding pragma if you set the text encoding of a procedure file by clicking the Text Encoding button at the bottom of the window or by choosing Procedure->Text Encoding.

It adds a TextEncoding pragma if it displays the Choose Text Encoding dialog when you open a procedure file because it is unable to convert the text to UTF-8 without your help.

It is possible for the TextEncoding pragma to be in conflict with the text encoding used to open the file. For example, imagine that you open a file containing

```
#pragma TextEncoding = "Windows-1252"
```

and then you change "Windows-1252" to "UTF-8" by editing the file. You have now created a conflict where the text encoding used to open the file was one thing but the TextEncoding pragma is another. To resolve this conflict, Igor displays the Resolve Text Encoding Conflict dialog. In the dialog you can choose to make the file's text encoding match the TextEncoding pragma or to make the TextEncoding pragma match the file's text encoding. You can also cancel the dialog and manually edit the TextEncoding pragma.

For background information, see **Text Encodings** on page III-409.

## Unknown Pragmas

Igor ignores pragmas that it does not know about. This allows newer versions of Igor to use new pragmas while older versions ignore them. The downside of this change is that, if you misspell a pragma keyword, Igor will not warn you about it.

## Proc Pictures

Proc pictures are binary PNG or JPEG images encoded as printable ASCII text in procedure files. They are intended for programmers who need images as part of the user interface for a procedure package. They can be used with the **DrawPICT** operation and with the picture keyword of the **Button**, **CheckBox**, and **CustomControl** operations.

The syntax for defining and using a proc picture is illustrated in the following example:

```
// PNG: width= 56, height= 44
static Picture myPictName
  ASCII85Begin
    M,6r;%14!\!!!!.8Ou6I!!!!Y!!!!M#Qau+!5G;q_uKc;&TgHDFAm*iFE_/6AH5;7DfQssEc39jTBQ
    =U!7FG,5u`*!m?g0PK.mR"U!k63rtBW)]$T)Q*!=Sa1TCDV*V+l:Lh^NW!fu1>;(.<VU1bs4L8&@Q_
    <4e(%^F50:Jg6);j!CQdUA[dh6]%(OkHSC,ht+Q7ZO#.6U,IgfSZ!Rlg':oO_iLF.GQ@RF[/*G98D
    bjE.g?NCte(pX-($m^_FhhfL`D9uO6Qi5c[r4849Fc7+*)*O[tY(6<rk m^)/KLIc]VdDEbF-n5&Am
    2^hbTu:U#8ies_W<LGkp_LEU1bs4L8&?fqRJ[h#sVSSz8OZBBY!QNJ
  ASCII85End
End

Function Demo()
  NewPanel
  DrawPict 0,0,1,1,ProcGlobal#myPictName
End
```

The ASCII text in the myPictName procedure between the ASCII85Begin and ASCII85End is similar to output from the Unix `btoa` command, but with the header and trailer removed.

You can create proc pictures in Igor Pro from normal, global pictures using the Pictures dialog (Misc menu) which shows the experiment's picture gallery. Select a picture in the dialog and click the Copy Proc Picture button to place the text on the clipboard. Then paste it in your procedure file. If the existing picture is not a JPEG or PNG, it is converted to PNG.

Proc pictures can be either global or local in scope. Global pictures can be used in all procedure files. Local pictures can be used only within the procedure file in which they are defined. Proc pictures are global by default and the picture name must be unique for all open procedure files. Proc pictures are local if they are declared static.

When you reference a proc picture in a **DrawPICT** command, the picture name must be qualified using the **ProcGlobal** keyword or the procedure file module name. This prevents conflicts with global pictures in the experiment's picture gallery.

For a global proc picture, you must use the **ProcGlobal** keyword as the prefix:

```
ProcGlobal#gProcPictName
```

For a static proc picture, you must use the module name defined in the procedure file by the `#pragma ModuleName = modName` statement (see **ModuleName** on page V-554) as the prefix:

```
modName#ProcPictName
```

## How Parameters Work

There are two ways of passing parameters from a routine to a subroutine:

- Pass-by-value
- Pass-by-reference

## Chapter IV-3 — User-Defined Functions

---

“Pass-by-value” means that the routine passes the *value* of an expression to the subroutine. “Pass-by-reference” means that the routine passes *access to a variable* to the subroutine. The important difference is that, in pass-by-reference, the subroutine can change the original variable in the calling routine.

Like C++, Igor allows either method for numeric and string variables. You should use pass-by-value in most cases and reserve pass-by-reference for those situations in which you need multiple return values.

### Example of Pass-By-Value

```
Function Routine()  
    Variable v = 4321  
    String s = "Hello"  
  
    Subroutine(v, s)  
End  
  
Function Subroutine(v, s)  
    Variable v  
    String s  
  
    Print v, s  
  
    // These lines have NO EFFECT on the calling routine.  
    v = 1234  
    s = "Goodbye"  
End
```

Note that *v* and *s* are *local variables* in Routine. In Subroutine, they are *parameters* which act very much like local variables. The names “*v*” and “*s*” are local to the respective functions. The *v* in Subroutine is not the same variable as the *v* in Routine although it initially has the same value.

The last two lines of Subroutine set the value of the local variables *v* and *s*. They have no effect on the value of the variables *v* and *s* in the calling Routine. What is passed to Subroutine is the numeric value 4321 and the string value “Hello”.

### Pass-By-Reference

You can specify that a parameter to a function is to be passed by reference rather than by value. In this way, the function called can change the value of the parameter and update it in the calling function. This is much like using pointers to arguments in C++. This technique is needed and appropriate only when you need to return more than one value from a function.

Functions with pass-by-reference parameters can only be called from other functions — not from the command line.

Only numeric variables (declared by variable, double, int, int64, uint64 or complex), string variables, and structures can be passed by reference. Structures are always passed by reference.

The variable or string being passed must be a local variable and can not be a global variable. To designate a variable or string parameter for pass-by-reference, simply prepend an ampersand symbol before the name in the parameter declaration:

```
Function Subroutine(num1,num2,str1)  
    Variable &num1, num2  
    String &str1  
  
    num1= 12+num2  
    str1= "The number is"  
End
```

and then call the function with the name of a local variable in the reference slot:

```
Function Routine()
    Variable num= 1000
    String str= "hello"
    Subroutine(num,2,str)
    Print str, num
End
```

When executed, Routine prints “The number is 14” rather than “hello 1000”, which would be the case if pass-by-reference were not used.

A pass-by-reference parameter can be passed to another function that expects a reference:

```
Function SubSubroutine(b)
    Variable &b
    b= 123
End
```

```
Function Subroutine(a)
    Variable &a
    SubSubroutine(a)
End
```

```
Function Routine()
    Variable num
    Subroutine(num)
    print num
End
```

You can not pass wave references, NVARs, SVARS, DFREFs or FUNCREFs by reference to a function. You can use a structure containing fields of these types to achieve the same end.

### How Waves Are Passed

Here is an example of a function “passing a wave” to a subroutine.

```
Function Routine()
    Make/O wave0 = x
    Subroutine(wave0)
End
```

```
Function Subroutine(w)
    WAVE w

    w = 1234    // This line DOES AFFECT the wave referred to by w.
End
```

We are really not passing a wave to Subroutine, but rather we are passing a reference to a wave. The parameter w is the wave reference.

Waves are global objects that exist independent of functions. The subroutine can use the wave reference to modify the contents of the wave. Using the terminology of “pass-by-value” and “pass-by-reference”, the wave reference is passed by value, but this has the effect of “passing the wave” by reference.

### Using Optional Parameters

Following is an example of a function with two optional input parameters:

```
Function OptionalParameterDemo(a,b, [c,d])
    Variable a,b,c,d           // c and d are optional parameters

    // Determine if the optional parameters were supplied
    if( ParamIsDefault(c) && ParamIsDefault(d) )
        Print "Missing optional parameters c and d."
    endif
```

```
Print a,b,c,d
End
```

Executing on the command line with none of the optional inputs:

```
OptionalParameterDemo(8,6)
Missing optional parameters c and d.
8 6 0 0
```

Executing with an optional parameter as an input:

```
OptionalParameterDemo(8,6, c=66)
8 6 66 0
```

Note that the optional parameter is explicitly defined in the function call using the *ParamName=Value* syntax. All optional parameters must come after any required function parameters.

## Local Versus Global Variables

Numeric and string variables can be **local** or **global**. “Local” means that the variable can be accessed only from within the procedure in which it was created. “Global” means that the variable can be accessed from the command line or from within any procedure. The following table shows the characteristics of local and global variables:

Local Variables	Global Variables
Are part of a procedure.	Are part of the data folder hierarchy of an Igor experiment.
Created using Variable or String within a procedure.	Created using Variable or String or Variable/G or String/G from the command line or within a procedure.
Used to store temporary results while the procedure is executing.	Used to store values that are saved from one procedure invocation to the next.
Cease to exist when the procedure ends.	Exist until you use KillVariables, KillStrings, or KillDataFolder.
Can be accessed only from within the procedure in which they were created.	Can be accessed from the command line or from within any procedure.

Local variables are private to the function in which they are declared and cease to exist when the function exits. Global variables are public and persistent — they exist until you explicitly delete them.

If you write a function whose main purpose is to display a dialog to solicit input from the user, you may want to store the user’s choices in global variables and use them to initialize the dialog the next time the user invokes it. This is an example of saving values from one invocation of a function to the next.

If you write a set of functions that loads, displays and analyzes experimentally acquired data, you may want to use global variables to store values that describe the conditions under which the data was acquired and to store the results from the analyses. These are examples of data accessed by many procedures.

With rare exceptions, you should not use global variables to pass information to procedures or from one procedure to another. Instead, use parameters. Using global variables for these purposes creates a web of hidden dependencies which makes understanding, reusing, and debugging procedures difficult.

## Local Variables Used by Igor Operations

When invoked from a function, many Igor’s operations return results via local variables. For example, the WaveStats operation creates a number of local variables with names such as V\_avg, V\_sigma, etc. The following function illustrates this point.

```
Function PrintWaveAverage(w)
WAVE w
```

```
WaveStats/Q w
Print V_avg
End
```

When the Igor compiler compiles the WaveStats operation, it creates various local variables, V\_avg among them. When the WaveStats operation runs, it stores results in these local variables.

In addition to creating local variables, a few operations, such as CurveFit and FuncFit, check for the existence of specific local variables to provide optional behavior. For example:

```
Function ExpFitWithMaxIterations(w, maxIterations)
    WAVE w
    Variable maxIterations

    Variable V_FitMaxIters = maxIterations

    CurveFit exp w
End
```

The CurveFit operation looks for a local variable named V\_FitMaxIters, which sets the maximum number of iterations before the operation gives up.

The documentation for each operation lists the special variables that it creates or looks for.

## Converting a String into a Reference Using \$

The \$ operator converts a string expression into an object reference. The referenced object is usually a wave but can also be a global numeric or global string variable, a window, a symbolic path or a function. This is a common and important technique.

We often use a *string* to pass the *name* of a wave to a procedure or to algorithmically generate the name of a wave. Then we use the \$ operator to convert the string into a wave reference so that we can operate on the wave.

The following trivial example shows why we need to use the \$ operator:

```
Function MakeAWave(str)
    String str

    Make $str
End
```

Executing

```
MakeAWave("wave0")
```

creates a wave named wave0.

Here we use \$ to convert the contents of the string parameter str into a name. The function creates a wave whose name is stored in the str string parameter.

If we omitted the \$ operator, we would have

```
Make str
```

This would create a wave named str, not a wave whos name is specified by the contents of str.

As shown in the following example, \$ can create references to global numeric and string variables as well as to waves.

```
Function Test(vStr, sStr, wStr)
    String vStr, sStr, wStr

    NVAR v = $vStr          // v is local name for global numeric var
    v += 1
```

```
SVAR s = $sStr          // s is local name for global string var
s += "Hello"
WAVE w = $wStr          // w is local name for global wave
w += 1
End
```

```
Variable/G gVar = 0; String/G gStr = ""; Make/O/N=5 gWave = p
Test("gVar", "gStr", "gWave")
```

The NVAR, SVAR and WAVE references are necessary in functions so that the compiler can identify the kind of object. This is explained under **Accessing Global Variables and Waves** on page IV-59.

### Using \$ to Refer to a Window

A number of Igor operations modify or create windows, and optionally take the name of a window. You need to use a string variable if the window name is not determined until run time but must convert the string into a name using \$.

For instance, this function creates a graph using a name specified by the calling function:

```
Function DisplayXY(xWave, yWave, graphNameStr)
    Wave xWave, yWave
    String graphNameStr      // Contains name to use for the new graph

    Display /N=$graphNameStr yWave vs xWave
End
```

The \$ operator in /N=\$graphNameStr converts the contents of the string graphNameStr into a graph name as required by the Display operation /N flag. If you forget \$, the command would be:

```
Display /N=graphNameStr yWave vs xWave
```

This would create a graph literally named graphNameStr.

### Using \$ In a Data Folder Path

\$ can also be used to convert a string to a name in a data folder path. This is used when one of many data folders must be selected algorithmically.

Assume you have a string variable named dfName that tells you in which data folder a wave should be created. You can write:

```
Make/O root:$(dfName):wave0
```

The parentheses are necessary because the \$ operator has low precedence.

## Compile Time Versus Runtime

Because Igor user-defined functions are compiled, errors can occur during compilation (“compile time”) or when a function executes (“runtime”). It helps in programming if you have a clear understanding of what these terms mean.

Compile time is when Igor analyzes the text of all functions and produces low-level instructions that can be executed quickly later. This happens when you modify a procedure window and then:

- Choose Compile from the Macros menu.
- Click the Compile button at the bottom of a procedure window.
- Activate a window other than a procedure or help window.

Runtime is when Igor actually executes a function’s low-level instructions. This happens when:

- You invoke the function from the command line.

- The function is invoked from another procedure.
- Igor updates a dependency which calls the function.
- You use a button or other control that calls the function.

Conditions that exist at compile time are different from those at runtime. For example, a function can reference a global variable. The global does not need to exist at compile time, but it does need to exist at runtime. This issue is discussed in detail in the following sections.

Here is an example illustrating the distinction between compile time and runtime:

```
Function Example(w)
    WAVE w

    w = sin(x)
    FFT w
    w = r2polar(w)
End
```

The declaration “WAVE w” specifies that w is expected to be a real wave. This is correct until the FFT executes and thus the first wave assignment produces the correct result. After the FFT is executed at runtime, however, the wave becomes complex. The Igor compiler does not know this and so it compiled the second wave assignment on the assumption that w is real. A compile-time error will be generated complaining that r2polar is not available for this number type — i.e., real. To provide Igor with the information that the wave is complex after the FFT you need to rewrite the function like this:

```
Function Example(w)
    WAVE w

    w= sin(x)
    FFT w
    WAVE/C wc = w
    wc = r2polar(wc)
End
```

A statement like “WAVE/C wc = w” has the compile-time behavior of creating a symbol, wc, and specifying that it refers to a complex wave. It has the runtime behavior of making wc refer to a specific wave. The runtime behavior can not occur at compile time because the wave may not exist at compile time.

## Accessing Global Variables and Waves

Global numeric variables, global string variables and waves can be referenced from any function. A function can refer to a global that does not exist at compile-time. For the Igor compiler to know what type of global you are trying to reference, you need to declare references to globals.

Consider the following function:

```
Function BadExample()
    gStr1 = "The answer is:"
    gNum1 = 1.234
    wave0 = 0
End
```

The compiler can not compile this because it doesn’t know what gStr1, gNum1 and wave0 are. We need to specify that they are references to a global string variable, a global numeric variable and a wave, respectively:

```
Function GoodExample1()
    SVAR gStr1 = root:gStr1
    NVAR gNum1 = root:gNum1
    WAVE wave0 = root:wave0

    gStr1 = "The answer is:"
```

```
gNum1 = 1.234
wave0 = 0
End
```

The SVAR statement specifies two important things for the compiler: first, that gStr1 is a global string variable; second, that gStr1 refers to a global string variable named gStr1 in the root data folder. Similarly, the NVAR statement identifies gNum1 and the WAVE statement identifies wave0. With this knowledge, the compiler can compile the function.

The technique illustrated here is called “runtime lookup of globals” because the compiler compiles code that associates the symbols gStr1, gNum1 and wave0 with specific global variables at runtime.

### Runtime Lookup of Globals

The syntax for runtime lookup of globals is:

```
NVAR <local name1>[= <path to var1>][, <loc name2>[= <path to var2>]]...
SVAR <local name1>[= <path to str1>][, <loc name2>[= <path to str2>]]...
WAVE <local name1>[= <path to wave1>][, <loc name2>[= <path to wave2>]]...
```

NVAR creates a reference to a global numeric variable.

SVAR creates a reference to a global string variable.

WAVE creates a reference to a wave.

At compile time, these statements identify the referenced objects. At runtime, the connection is made between the local name and the actual object. Consequently, the object must exist when these statements are executed.

<local name> is the name by which the global variable, string or wave is to be known within the user function. It does not need to be the same as the name of the global variable. The example function could be rewritten as follows:

```
Function GoodExample2()
    SVAR str1 = root:gStr1      // str1 is the local name.
    NVAR num1 = root:gNum1      // num1 is the local name.
    WAVE w = root:wave0         // w is the local name.

    str1 = "The answer is:"
    num1 = 1.234
    w = 0
End
```

If you use a local name that is the same as the global name, and if you want to refer to a global in the current data folder, you can omit the <path to ...> part of the declaration:

```
Function GoodExample3()
    SVAR gStr1                // Refers to gStr1 in current data folder.
    NVAR gNum1                // Refers to gNum1 in current data folder.
    WAVE wave0                // Refers to wave0 in current data folder.

    gStr1 = "The answer is:"
    gNum1 = 1.234
    wave0 = 0
End
```

GoodExample3 accesses globals in the current data folder while GoodExample2 accesses globals in a specific data folder.

If you use <path to ...>, it may be a simple name (gStr1) or it may include a full or partial path to the name.

The following are valid examples, referencing a global numeric variable named gAvg:

```
NVAR gAvg= gAvg
NVAR avg= gAvg
NVAR gAvg
NVAR avg= root:Packages:MyPackage:gAvg
NVAR avg= :SubDataFolder:gAvg
NVAR avg= $"gAvg"
NVAR avg= $("g"+ "Avg")
NVAR avg= ::$"gAvg"
```

As illustrated above, the local name can be the same as the name of the global object and the lookup expression can be either a literal name or can be computed at runtime using \$<string expression>.

If your function creates a global variable and you want to create a reference to it, put the NVAR statement after the code that creates the global. The same applies to SVARs and, as explained next, to WAVES.

### Put WAVE Declaration After Wave Is Created

A wave declaration serves two purposes. At compile time, it tells Igor the local name and type of the wave. At runtime, it connects the local name to a specific wave. In order for the runtime purpose to work, you must put wave declaration after the wave is created.

```
Function BadExample()
    String path = "root:Packages:MyPackage:wave0"
    Wave w = $path          // WRONG: Wave does not yet exist.
    Make $path
    w = p                   // w is not connected to any wave.
End

Function GoodExample()
    String path = "root:Packages:MyPackage:wave0"
    Make $path
    Wave w = $path          // RIGHT
    w = p
End
```

Both of these functions will successfully compile. BadExample will fail at runtime because w is not associated with a wave, because the wave does not exist when the "Wave w = \$path" statement executes.

This rule also applies to NVAR and SVAR declarations.

### Runtime Lookup Failure

At runtime, it is possible that a NVAR, SVAR or WAVE statement may fail. For example,

```
NVAR v1 = var1
```

will fail if var1 does not exist in the current data folder when the statement is executed. You can use the NVAR\_Exists, SVAR\_Exists, and WaveExists functions to test if a given global reference is valid:

```
Function Test()
    NVAR/Z v1 = var1
    if (NVAR_Exists(v1))
        <use v1>
    endif
End
```

## Chapter IV-3 — User-Defined Functions

---

The /Z flag is necessary to prevent an error if the NVAR statement fails. You can also use it with SVAR and WAVE.

A common cause for failure is putting a WAVE statement in the wrong place. For example:

```
Function BadExample()  
    WAVE w = resultWave  
    <Call a function that creates a wave named resultWave>  
    Display w  
End
```

This function will compile successfully but will fail at runtime. The reason is that the `WAVE w = resultWave` statement has the runtime behavior of associating the local name `w` with a particular wave. But that wave does not exist until the following statement is executed. The function should be rewritten as:

```
Function GoodExample()  
    <Call a function that creates a wave named resultWave>  
    WAVE w = resultWave  
    Display w  
End
```

### Runtime Lookup Failure and the Debugger

You can break whenever a runtime lookup fails using the symbolic debugger (described in Chapter IV-8, **Debugging**). It is a good idea to do this, because it lets you know about runtime lookup failures at the moment they occur.

Sometimes you may create a WAVE, NVAR or SVAR reference knowing that the referenced global may not exist at runtime. Here is a trivial example:

```
Function Test()  
    WAVE w = testWave  
    if (WaveExists(testWave))  
        Printf "testWave had %d points.\r", numpnts(testWave)  
    endif  
End
```

If you enable the debugger's WAVE checking and if you execute the function when `testWave` does not exist, the debugger will break and flag that the WAVE reference failed. But you wrote the function to handle this situation, so the debugger break is not helpful in this case.

The solution is to rewrite the function using `WAVE/Z` instead of just `WAVE`. The /Z flag specifies that you know that the runtime lookup may fail and that you don't want to break if it does. You can use `NVAR/Z` and `SVAR/Z` in a similar fashion.

### Accessing Complex Global Variables and Waves

You must specify if a global numeric variable or a wave is complex using the /C flag:

```
NVAR/C gc1 = gc1  
WAVE/C gcw1 = gcw1
```

### Accessing Text Waves

Text waves must be accessed using the /T flag:

```
WAVE/T tw= MyTextWave
```

### Accessing Global Variables and Waves Using Liberal Names

There are two ways to initialize a reference an Igor object: using a literal name or path or using a string variable. For example:

```
Wave w = root:MyDataFolder:MyWave           // Using literal path
String path = "root:MyDataFolder:MyWave"
Wave w = $path                               // Using string variable
```

Things get more complicated when you use a liberal name rather than a standard name. A standard name starts with a letter and includes letters, digits and the underscore character. A liberal name includes other characters such as spaces or punctuation.

In general, you must quote liberal names using single quotes so that Igor can determine where the name starts and where it ends. For example:

```
Wave w = root:'My Data Folder':'My Wave'     // Using literal path
String path = "root:'My Data Folder':'My Wave'"
Wave w = $path                               // Using string variable
```

However, there is an exception to the quoting requirement. The rule is:

You must quote a literal liberal name and you must quote a liberal path stored in a string variable but you must not quote a simple liberal liberal name stored in a string variable.

The following functions illustrate this rule:

```
// Literal liberal name must be quoted
Function DemoLiteralLiberalNames()
    NewDataFolder/O root:'My Data Folder'

    Make/O root:'My Data Folder':'My Wave' // Literal name must be quoted

    SetDataFolder root:'My Data Folder'    // Literal name must be quoted

    Wave w = 'My Wave'                     // Literal name must be quoted
    w = 123

    SetDataFolder root:
End

// String liberal PATH must be quoted
Function DemoStringLiberalPaths()
    String path = "root:'My Data Folder'"
    NewDataFolder/O $path

    path = "root:'My Data Folder':'My Wave'" // String path must be quoted
    Make/O $path

    Wave w = $path
    w = 123

    SetDataFolder root:
End

// String liberal NAME must NOT be quoted
Function DemoStringLiberalNames()
    SetDataFolder root:

    String dfName = "My Data Folder"       // String name must NOT be quoted
    NewDataFolder/O $dfName

    String wName = "My Wave"               // String name must NOT be quoted
    Make/O root:$(dfName):$wName

    Wave w = root:$(dfName):$wName         // String name must NOT be quoted
```

```
w = 123

SetDataFolder root:
End
```

The last example illustrates another subtlety. This command would generate an error at compile time:

```
Make/O root:$dfName:$wName          // ERROR
```

because Igor would interpret it as:

```
Make/O root:$(dfName:$wName)         // ERROR
```

To avoid this, you must use parentheses like this:

```
Make/O root:$(dfName):$wName         // OK
```

### Runtime Lookup Example

In this example, a function named Routine calls another function named Subroutine and needs to access a number of result values created by Subroutine. To make it easy to clean up the temporary result globals, Subroutine creates them in a new data folder. Routine uses the results created by Subroutine and then deletes the temporary data folder.

```
Function Subroutine(w)
    WAVE w

    NewDataFolder/O/S SubroutineResults    // Results go here

    WaveStats/Q w                        // WaveStats creates local variables
    Variable/G gAvg = V_avg              // Return the V_avg result in global gAvg
    Variable/G gMin = V_min
    String/G gWName = NameOfWave(w)

    SetDataFolder ::                     // Back to original data folder
End

Function Routine()
    Make aWave= {1,2,3,4}
    Subroutine(aWave)

    DFREF dfr = :SubroutineResults

    NVAR theAvg = dfr:gAvg                // theAvg is local name
    NVAR theMin = dfr:gMin
    SVAR theName = dfr:gWName
    Print theAvg, theMin, theName

    KillDataFolder SubroutineResults      // We are done with results
End
```

Note that the NVAR statement must appear *after* the call to the procedure (Subroutine in this case) that creates the global variable. This is because NVAR has both a compile-time and a runtime behavior. At compile time, it creates a local variable that Igor can compile (theAvg in this case). At runtime, it actually looks up and creates a link to the global (variable gAvg stored in data folder SubroutineResults in this case).

Often a function needs to access a large number of global variables stored in a data folder. In such cases, you can write more compact code using the ability of NVAR, SVAR and WAVE to access multiple objects in one statement:

```
Function Routine2()
    Make aWave= {1,2,3,4}
    Subroutine(aWave)
```

```

DFREF dfr = :SubroutineResults

NVAR theAvg=dfr:gAvg, theMin=dfr:gMin      // Access two variables
SVAR theName = dfr:gWName
Print theAvg, theMin, theName

KillDataFolder SubroutineResults          // We are done with results
End

```

## Automatic Creation of WAVE, NVAR and SVAR References

The Igor compiler sometimes automatically creates WAVE, NVAR and SVAR references. For example:

```

Function Example1()
    Make/O wave0
    wave0 = p

    Variable/G gVar1
    gVar1= 1

    String/G gStr1
    gStr1= "hello"
End

```

In this example, we did not use WAVE, NVAR or SVAR references and yet we were still able to compile assignment statements referencing waves and global variables. This is a feature of *Make*, *Variable/G* and *String/G* that automatically create local references for simple object names.

Simple object names are names which are known at compile time for objects which will be created in the current data folder at runtime. *Make*, *Variable/G* and *String/G* do not create references if you use *\$<name>*, a partial data folder path or a full data folder path to specify the object.

## Wave References

A wave reference is a value that identifies a particular wave. Wave references are used in commands that operate on waves, including assignment statements and calls to operations and functions that take wave reference parameters.

Wave reference variables hold wave references. They can be created as local variables, passed as parameters and returned as function results.

Here is a simple example:

```

Function Test(wIn)
    Wave wIn          // Reference to the input wave received as parameter

    String newName = NameOfWave(wIn) + "_out" // Compute output wave name

    Duplicate/O wIn, $newName                // Create output wave

    Wave wOut = $newName                     // Create wave reference for output wave
    wOut += 1                                // Use wave reference in assignment statement
End

```

This function might be called from the command line or from another function like this:

```

Make/O/N=5 wave0 = p
Test(wave0)                // Pass wave reference to Test function

```

A Wave statement declares a wave reference variable. It has both a compile-time and a runtime effect.

At compile time, it tells Igor what type of object the declared name references. In the example above, it tells Igor that `wOut` references a wave as opposed to a numeric variable, a string variable, a window or some other type of object. The Igor compiler allows `wOut` to be used in a waveform assignment statement (`wOut += 1`) because it knows that `wOut` references a wave.

The compiler also needs to know if the wave is real, complex or text. Use `Wave/C` to create a complex wave reference and `Wave/T` to create a text wave reference. `Wave` by itself creates a real wave reference.

At runtime the `Wave` statement stores a reference to a specific wave in the wave reference variable (`wOut` in this example). The referenced wave must already exist when the wave statement executes. Otherwise Igor stores a NULL reference in the wave reference variable and you get an error when you attempt to use it. We put the `Wave wOut = $newName` statement *after* the `Duplicate` operation to insure that the wave exists when the `Wave` statement is executed. Putting the `Wave` statement before the command that creates the wave is a common error.

### Automatic Creation of WAVE References

The Igor compiler sometimes automatically creates WAVE references. For example:

```
Function Example1()  
    Make wave1  
    wave1 = x^2  
End
```

In this example, we did not declare a wave reference, and yet Igor was still able to compile an assignment statement referring to a wave. This is a feature of the **Make** operation (see page V-465) which automatically creates local references for simple object names. The **Duplicate** operation (see page V-165) and many other operations that create output waves also automatically create local wave references for simple object names.

Simple object names are names which are known at compile time for objects which will be created in the current data folder at runtime. `Make` and `Duplicate` do not create references if you use `$<name>`, a partial data folder path, or a full data folder path to specify the object.

In the case of `Make` and `Duplicate` with simple object names, the type of the automatically created wave reference (real, complex or text) is determined by flags. `Make/C` and `Duplicate/C` create complex wave references. `Make/T` and `Duplicate/T` create text wave references. `Make` and `Duplicate` without type flags create real wave references. See **WAVE Reference Types** on page IV-67 and **WAVE Reference Type Flags** on page IV-68 for a complete list of type flags and further details.

Most built-in operations that create output waves (often called "destination" waves) also automatically create wave references. For example, if you write:

```
DWT srcWave, destWave
```

it is as if you wrote:

```
DWT srcWave, destWave  
WAVE destWave
```

After the discrete wavelet transform executes, you can reference `destWave` without an explicit wave reference.

### Standalone WAVE Reference Statements

In cases where Igor does not automatically create a wave reference, because the output wave is not specified using a simple object name, you need to explicitly create a wave reference if you want to access the wave in an assignment statement.

You can create an explicit standalone wave reference using a statement following the command that created the output wave. In this example, the name of the output wave is specified as a parameter and therefore we can not use a simple object name when calling `Make`:

```
Function Example2(nameForOutputWave)  
    String nameForOutputWave // String contains the name of the wave to make
```

```
Make $nameForOutputWave      // Make a wave
Wave w = $nameForOutputWave  // Make a wave reference
w = x^2
End
```

If you make a text wave or a complex wave, you need to tell the Igor compiler about that by using Wave/T or Wave/C. The compiler needs to know the type of the wave in order to properly compile the assignment statement.

### Inline WAVE Reference Statements

You can create a wave reference variable using /WAVE=<name> in the command that creates the output wave. For example:

```
Function Example3(nameForOutputWave)
    String nameForOutputWave

    Make $nameForOutputWave/WAVE=w    // Make a wave and a wave reference
    w = x^2
End
```

Here /WAVE=w is an inline wave reference statement. It does the same thing as the standalone wave reference in the preceding section.

Here are some more examples of inline wave declarations:

```
Function Example4()
    String name = "wave1"
    Duplicate/O wave0, $name/WAVE=wave1
    Differentiate wave0 /D=$name/WAVE=wave1
End
```

When using an inline wave reference statement, you do not need to, and in fact can not, specify the type of the wave using WAVE/T or WAVE/C. Just use WAVE by itself regardless of the type of the output wave. The Igor compiler automatically creates the right kind of wave reference. For example:

```
Function Example5()
    Make real1, $"real2"/WAVE=r2    // real1, real2 and r2 are real
    Make/C cplx1, $"cplx2"/WAVE=c2  // cplx1, cplx2 and c2 are complex
    Make/T text1, $"text2"/WAVE=t2  // text1, text2 and t2 are text
End
```

Inline wave reference statements are accepted by those operations which automatically create a wave reference for a simple object name.

Inline wave references are not allowed after a simple object name.

Inline wave references are allowed on the command line but do nothing.

### WAVE Reference Types

When wave references are created at compile time, they are created with a specific numeric type or are defined as text. The compiler then uses this type when compiling expressions based on the WAVE reference or when trying to match two instances of the same name. For example:

```
Make rWave          // Creates single-precision real wave reference
Make/C cWave        // Creates single-precision complex wave reference
Make/L int64Wave    // Creates signed 64-bit integer wave reference
Make/L/U int64Wave  // Creates unsigned 64-bit integer wave reference
```

## Chapter IV-3 — User-Defined Functions

---

```
Make/T tWave          // Creates text wave reference
```

These types then define what kind of right-hand side expression Igor compiles:

```
rWave = expression    // Compiles real expression as double precision
cWave = expression    // Compiles complex expression as double precision
int64Wave = expression // Compiles signed 64-bit integer expression
uint64Wave = expression // Compiles unsigned 64-bit integer expression
tWave = expression    // Compiles text expression
```

See also **Integer Expressions in Wave Assignment Statements** on page IV-37.

The compiler is sometimes picky about the congruence between two declarations of wave reference variables of the same name. For example:

```
WAVE aWave
if (!WaveExists(aWave))
    Make/D aWave
endif
```

This generates a compile error complaining about inconsistent types for a wave reference. Because Make automatically creates a wave reference, this is equivalent to:

```
WAVE aWave
if (!WaveExists(aWave))
    Make/D aWave
    WAVE/D aWave
endif
```

This creates two wave references with the same name but different types. To fix this, change the explicit wave reference declaration to:

```
WAVE/D aWave
```

### WAVE Reference Type Flags

The **WAVE** reference (see page V-925) along with certain operations such as Duplicate can accept the following flags identifying the type of WAVE reference:

/B	8-bit signed integer destination waves, unsigned with /U.
/C	Complex destination waves.
/D	Double precision destination waves.
/I	32-bit signed integer destination waves, unsigned with /U.
/L	64-bit signed integer destination waves, unsigned with /U. Requires Igor Pro 7.00 or later.
/S	Single precision destination waves.
/T	Text destination waves.
/U	Unsigned destination waves.
/W	16-bit signed integer destination waves, unsigned with /U.
/DF	Wave holds data folder references.
/WAVE	Wave holds wave references.

These are the same flags used by the **Make**. In the case of WAVE declarations and Duplicate, they do not affect the actual wave but rather tell Igor what kind of wave is expected at runtime. The compiler uses this informa-

tion to determine what kind of code to compile if the wave is used as the destination of a wave assignment statement later in the function. For example:

```
Function DupIt(wv)
    WAVE/C wv                                // complex wave

    Duplicate/O/C wv,dupWv                    // dupWv is complex
    dupWv[0]=cplx(5.0,1.0)                    // no error, because dupWv known complex
    . . .
End
```

If Duplicate did not have the /C flag, you would get a “function not available for this number type” message when compiling the assignment of dupWv to the result of the cplx function.

## Problems with Automatic Creation of WAVE References

Operations that change a wave's type or which can create output waves of more than one type, such as **FFT**, **IFFT** and **WignerTransform** present special issues.

In some cases, the wave reference automatically created by an operation might be of the wrong type. For example, the FFT operation automatically creates a complex wave reference for the destination wave, so if you write:

```
FFT/DEST=destWave srcWave
```

it is as if you wrote:

```
FFT/DEST=destWave srcWave
WAVE/C destWave
```

However, if a real wave reference for the same name already exists, FFT/DEST does not create a new wave reference. For example:

```
Wave destWave                                // Real wave reference
. . .
FFT /DEST=destWave srcWave                    // FFT does not create wave reference
                                           // because it already exists.
```

In this case, you would need to create a complex wave reference using a different name, like this:

```
Wave/C cDestWave = destWave
```

The output of the FFT operation can sometimes be real, not complex. For example:

```
FFT/DEST=destWave/OUT=2 srcWave
```

The /OUT=2 flag creates a real destination wave. Thus the complex wave reference automatically created by the FFT operation is wrong and can not be used to subsequently access the destination wave. In this case, you must explicitly create a real wave reference, like this:

```
FFT/DEST=destWave/OUT=2 srcWave
WAVE realDestWave = destWave
```

Note that you can not write:

```
FFT/DEST=destWave/OUT=2 srcWave
WAVE destWave
```

because the FFT operation has already created a complex wave reference named destWave, so the compiler will generate an error. You must use a different name for the real wave reference.

The **IFFT** has a similar problem but in reverse. IFFT automatically creates a real wave reference for the destination wave. In some cases, the actual destination wave will be complex and you will need to create an explicit wave reference in order to access it.

### WAVE Reference Is Needed to Pass a Wave By Name

As of Igor Pro 6.3, new procedure windows are created with this pragma statement:

```
#pragma rtGlobals=3 // Use modern global access method and strict wave access.
```

The strict wave access mode causes a compile error if you pass a literal wave name as a parameter to an operation or function. Instead you must pass a wave reference.

With `rtGlobals=3`, this function has errors on both lines:

```
Function Test()  
    Display jack                                // Error: Expected wave reference  
    Variable tmp = mean(jack,0,100)             // Error: Expected wave reference  
End
```

The proper way to do this is to create a wave reference, like this:

```
Function Test()  
    WAVE jack  
    Display jack                                // OK  
    Variable tmp = mean(jack,0,100)             // OK  
End
```

The purpose of the strict wave access mode is to detect inadvertent name mistakes. This applies to simple names only, not to full or partial paths. Even with `rtGlobals=3`, it is OK to use a full or partial path where a wave reference is expected:

```
Function Test()  
    Display :jack                                // OK  
    Variable tmp = mean(root:jack,0,100)         // OK  
End
```

If you have old code that is impractical to fix, you can revert to using `rtGlobals=1` or `rtGlobals=2`.

### Wave Reference Function Results

Advanced programmers can create functions that return wave references using `Function/WAVE`:

```
Function/WAVE Test(wIn) // /WAVE flag says function returns wave reference  
    Wave wIn           // Reference to the input wave received as parameter  
  
    String newName = NameOfWave(wIn) + "_out" // Compute output wave name  
  
    Duplicate/O wIn, $newName                  // Create output wave  
  
    Wave wOut = $newName                       // Create wave reference for output wave  
    wOut += 1                                  // Use wave reference in assignment statement  
  
    return wOut                                // Return wave reference  
End
```

This function might be called from another function like this:

```
Make/O/N=5 wave0 = p  
Wave wOut = Test(wave0)  
Display wave0, wOut
```

This technique is useful when a subroutine creates a free wave for temporary use:

```
Function Subroutine()  
    Make/FREE tempWave = <expression>  
    return tempWave  
End
```

```
Function Routine()
    Wave tempWave = Subroutine()
    <Use tempWave>
End
```

When Routine returns, tempWave is automatically killed because all references to it have gone out of scope.

### Wave Reference Waves

You can create waves that contain wave references using the Make /WAVE flag. You can use a wave reference wave as a list of waves for further processing and in multithreaded wave assignment using the **MultiThread** keyword.

Wave reference waves are recommended for advanced programmers only.

**Note:** Wave reference waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only.

Here is an example:

```
Make/O wave0, wave1, wave2           // Make some waves
Make/O/WAVE wr                       // Make a wave reference wave
wr[0]=wave0; wr[1]=wave1; wr[2]=wave2 // Assign values
```

The wave reference wave wr could now be used, for example, to pass a list of waves to a function that performs display or analysis operations.

Make/WAVE without any assignment creates a wave containing null wave references. Similarly, inserting points or redimensioning to a larger size initializes the new points to null. Deleting points or redimensioning to a smaller size deletes any free waves if the deleted points contained the only reference to them.

To determine if a given wave is a type that stores wave references, use the **WaveType** function with the optional selector = 1.

In the next example, a subroutine supplies a list of references to waves to be graphed by the main routine. A wave reference wave is used to store the list of wave references.

```
Function MainRoutine()
    Make/O/WAVE/N=5 wr           // Will contain references to other waves
    wr= Subroutine(p)           // Fill w with references

    WAVE w= wr[0]               // Get reference to first wave
    Display w                   // and display in a graph

    Variable i
    for(i=1;i<5;i+=1)
        WAVE w= wr[i]           // Get reference to next wave
        AppendToGraph w         // and append to graph
    endfor
End

Function/WAVE Subroutine(i)
    Variable i

    String name = "wave"+num2str(i)

    // Create a wave with a computed name and also a wave reference to it
    Make/O $name/WAVE=w = sin(x/(8+i))

    return w                    // Return the wave reference to the calling routine
End
```

## Chapter IV-3 — User-Defined Functions

---

As another example, here is a function that returns a wave reference wave containing references to all of the Y waves in a graph:

```
Function/WAVE GetListOfYWavesInGraph(graphName)
    String graphName          // Must contain the name of a graph

    // If graphName is not valid, return NULL wave
    if (strlen(graphName)==0 || WinType(graphName)!=1)
        return $" "
    endif

    // Make a wave to contain wave references
    Make /FREE /WAVE /N=0 listWave

    Variable index = 0
    do
        // Get wave reference for next Y wave in graph
        WAVE/Z w = WaveRefIndexed(graphName,index,1)
        if (WaveExists(w) == 0)
            break                // No more waves
        endif

        // Add wave reference to list
        InsertPoints index, 1, listWave
        listWave[index] = w

        index += 1
    while(1)                    // Loop till break above

    return listWave
End
```

The returned wave reference wave is a free wave. See **Free Waves** on page IV-84 for details.

For an example using a wave reference wave for multiprocessing, see **Wave Reference MultiThread Example** on page IV-306.

## Data Folder References

The data folder reference is a lightweight object that refers to a data folder, analogous to the wave reference which refers to a wave. You can think of a data folder reference as an identification number that Igor uses to identify a particular data folder.

Data folder reference variables (DFREFs) hold data folder references. They can be created as local variables, passed as parameters and returned as function results.

The most common use for a data folder reference is to save and restore the current data folder during the execution of a function:

```
Function Test()
    DFREF savedFR = GetDataFolderDFR() // Get reference to current data folder

    NewDataFolder/O/S MyNewDataFolder // Create a new data folder
    . . .                             // Do some work in it

    SetDataFolder savedFR              // Restore current data folder
End
```

Data folder references can be used in commands where Igor accepts a data folder path. For example, this function shows three equivalent methods of accessing waves in a specific data folder:

```

Function Test()
    // Method 1: Using paths
    Display root:Packages:'My Package':yWave vs root:Packages:'My Package':xWave

    // Method 2: Using the current data folder
    DFREF dfSave = GetDataFolderDFR() // Save the current data folder
    SetDataFolder root:Packages:'My Package'
    Display yWave vs xWave
    SetDataFolder dfSave                // Restore current data folder

    // Method 3: Using data folder references
    DFREF dfr = root:Packages:'My Package'
    Display dfr:yWave vs dfr:xWave
End

```

Using data folder references instead of data folder paths can streamline programs that make heavy use of data folders.

### Using Data Folder References

In an advanced application, the programmer often defines a set of named data objects (waves, numeric variables and string variables) that the application acts on. These objects exist in a data folder. If there is just one instance of the set, it is possible to hard-code data folder paths to the objects. Often, however, there will be a multiplicity of such sets, for example, one set per graph or one set per channel in a data acquisition application. In such applications, procedures must be written to act on the set of data objects in a data folder specified at runtime.

One way to specify a data folder at runtime is to create a path to the data folder in a string variable. While this works, you wind up with code that does a lot of concatenation of data folder paths and data object names. Using data folder references, such code can be streamlined.

You create a data folder reference variable with a DFREF statement. For example, assume your application defines a set of data with a wave named wave0, a numeric variable named num0 and a string named str0 and that we have one data folder containing such a set for each graph. You can access your objects like this:

```

Function DoSomething(graphName)
    String graphName
    DFREF dfr = root:Packages:MyApplication:$graphName
    WAVE w0 = dfr:wave0
    NVAR n0 = dfr:num0
    SVAR s0 = dfr:str0
    . . .
End

```

Igor accepts a data folder reference in any command in which a data folder path would be accepted. For example:

```

Function Test()
    Display root:MyDataFolder:wave0 // OK

    DFREF dfr = root:MyDataFolder
    Display dfr:wave0                // OK

    String path = "root:MyDataFolder:wave0"
    Display $path                    // OK. $ converts string to path.

    path = "root:MyDataFolder"
    DFREF dfr = $path                // OK. $ converts string to path.
    Display dfr:wave0                // OK

    String currentDFPath

```

## Chapter IV-3 — User-Defined Functions

---

```
currentDFPath = GetDataFolder(1) // OK
DFREF dfr = GetDataFolder(1)     // ERROR: GetDataFolder returns a string
                                // not a path.

DFREF dfr = GetDataFolderDFR()   // OK
End
```

### The /SDFR Flag

You can also use the /SDFR (source data folder reference) flag in a WAVE, NVAR or SVAR statement. The utility of /SDFR is illustrated by this example which shows three different ways to reference multiple waves in the same data folder:

```
Function Test()
    // Assume a data folder exists at root:Run1

    // Use explicit paths
    Wave wave0=root:Run1:wave0, wave1=root:Run1:wave1, wave2=root:Run1:wave2

    // Use a data folder reference
    DFREF dfr = root:Run1
    Wave wave0=dfr:wave0, wave1=dfr:wave1, wave2=dfr:wave2

    // Use the /SDFR flag
    DFREF dfr = root:Run1
    Wave/SDFR=dfr wave0, wave1, wave2
End
```

### The DFREF Type

In functions, you can define data folder reference variables using the DFREF declaration:

```
DFREF localname [= <DataFolderRef or path>] [<more defs>]
```

You can then use the data folder reference in those places where you can use a data folder path. For example:

```
DFREF dfr = root:df1
Display dfr:wave1           // Equivalent to Display root:df1:wave1
```

The syntax is limited to a single name after the data folder reference, so this is not legal:

```
Display dfr:subfolder:wave1 // Illegal
```

You can use DFREF to define input parameters for user-defined functions. For example:

```
Function Test(df)
    DFREF df
    Display df:wave1
End
```

You can also use DFREF to define fields in structures. However, you can not directly use a DFREF structure field in those places where Igor is expecting a path and object name. So, instead of:

```
Display s.dfr:wave1         // Illegal
```

you would need to write:

```
DFREF dftmp = s.dfr
Display dftmp:wave1         // OK
```

You can use a DFREF structure field where just a path is expected. For example:

```
SetDataFolder s.dfr         // OK
```

## Built-in DFREF Functions

Some built-in functions take string data folder paths as parameters or return them as results. Those functions can not take or return data folder references. Here are equivalent DFREF versions that take or return data folder references:

```
GetDataFolderDFR()

GetIndexedObjNameDFR(dfr, type, index)

GetWavesDataFolderDFR(wave)

CountObjectsDFR(dfr, type)
```

These additional data folder reference functions are available:

```
DataFolderRefStatus(dfr)

NewFreeDataFolder()

DataFolderRefsEqual(dfr1, dfr2)
```

Just as operations that take a data folder path accept a data folder reference, these DFREF functions can also accept a data folder path:

```
Function Test()
    DFREF dfr = root:MyDataFolder
    Print CountObjectsDFR(dfr,1)           // OK
    Print CountObjectsDFR(root:MyDataFolder,1) // OK
End
```

## Checking Data Folder Reference Validity

The **DataFolderRefStatus** function returns zero if the data folder reference is invalid. You should use it to test any DFREF variables that might not be valid, for example, when you assign a value to a data folder reference and you are not sure that the referenced data folder exists:

```
Function Test()
    DFREF dfr = root:MyDataFolder // MyDataFolder may or may not exist
    if (DataFolderRefStatus(dfr) != 0)
        . . .
    endif
End
```

For historical reasons, an invalid DFREF variable will often act like root.

## Data Folder Reference Function Results

A user-defined function can return a data folder reference. This might be used for a subroutine that returns a set of new objects to the calling routine. The set can be returned in a new data folder and the subroutine can return a reference it.

For example:

```
Function/DF Subroutine(newDFName)
    String newDFName
    NewDataFolder/O $newDFName
    DFREF dfr = $newDFName
    Make/O dfr:wave0, dfr:wave1
    return dfr
End

Function/DF MainRoutine()
    DFREF dfr = Subroutine("MyDataFolder")
```

```
    Display dfr:wave0, dfr:wave1
End
```

### Data Folder Reference Waves

You can create waves that contain data folder references using the **Make** /DF flag. You can use a data folder reference wave as a list of data folders for further processing and in multithreaded wave assignment using the **MultiThread** keyword.

Data folder reference waves are recommended for advanced programmers only.

**Note:** Data folder reference waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the **SaveData** operation or the Data Browser's **Save Copy** button. In general, they are intended for temporary computation purposes only.

**Make**/DF without any assignment creates a wave containing null data folder references. Similarly, inserting points or redimensioning to a larger size initializes the new points to null. Deleting points or redimensioning to a smaller size deletes any free data folders if the wave contained the only reference to them.

To determine if a given wave is a type that stores data folder references, use the **WaveType** function with the optional selector = 1.

For an example using a data folder reference wave for multiprocessing, see **Data Folder Reference Multi-Thread Example** on page IV-304.

## Accessing Waves in Functions

To access a wave in a user-defined function, we need to create, one way or another, a wave reference. The section **Accessing Global Variables and Waves** on page IV-59 explained how to access a wave using a **WAVE** reference. This section introduces several additional techniques.

We can create the wave reference by:

- Declaring a wave parameter
- Using \$<string expression>
- Using a literal wave name
- Using a wave reference function

Each of these techniques is illustrated in the following sections.

Each example shows a function and commands that call the function. The function itself illustrates how to deal with the wave within the function. The commands show how to pass enough information to the function so that it can access the wave. Other examples can be found in **Writing Functions that Process Waves** on page III-143.

### Wave Reference Passed as Parameter

This is the simplest method. The function might be called from the command line or from another function.

```
Function Test(w)
    WAVE w                                // Wave reference passed as a parameter

    w += 1                                // Use in assignment statement
    Print mean(w)                          // Pass as function parameter
    WaveStats w                            // Pass as operation parameter
    AnotherFunction(w)                     // Pass as user function parameter
End

Make/O/N=5 wave0 = p
Test(wave0)
Test($"wave0")
String wName = "wave0"; Test($wName)
```

In the first call to Test, the wave reference is a literal wave name. In the second call, we create the wave reference using \$<literal string>. In the third call, we create the wave reference using \$<string variable>. \$<literal string> and \$<string variable> are specific cases of the general case \$<string expression>.

If the function expected to receive a reference to a text wave, we would declare the parameter using:

```
WAVE/T w
```

If the function expected to be receive a reference to a complex wave, we would declare the parameter using:

```
WAVE/C w
```

If you need to return a large number of values to the calling routine, it is sometimes convenient to use a parameter wave as an output mechanism. The following example illustrates this technique:

```
Function MyWaveStats(inputWave, outputWave)
    WAVE inputWave
    WAVE outputWave

    WaveStats/Q inputWave

    outputWave[0] = V_npts
    outputWave[1] = V_avg
    outputWave[2] = V_sdev
End

Function Test()
    Make/O testwave= gnoise(1)

    Make/O/N=20 tempResultWave
    MyWaveStats(testwave, tempResultWave)
    Variable npts = tempResultWave[0]
    Variable avg = tempResultWave[1]
    Variable sdev = tempResultWave[2]
    KillWaves tempResultWave

    Printf "Points: %g; Avg: %g; SDev: %g\r", npts, avg, sdev
End
```

If the calling function needs the returned values only temporarily, it is better to return a free wave as the function result. See **Wave Reference Function Results** on page IV-70.

### Wave Accessed Via String Passed as Parameter

This technique is of most use when the wave might not exist when the function is called. It is appropriate for functions that create waves.

```
Function Test(wName)
    String wName                // String containing a name for wave

    Make/O/N=5 $wName
    WAVE w = $wName             // Create a wave reference
    Print NameOfWave(w)
End

Test("wave0")
```

This example creates wave0 if it does not yet exist or overwrites it if it does exist. If we knew that the wave had to already exist, we could and should use the wave parameter technique shown in the preceding section. In this case, since the wave may not yet exist, we can not use a wave parameter.

Notice that we create a wave reference immediately after making the wave. Once we do this, we can use the wave reference in all of the ways shown in the preceding section. We can not create the wave reference before making the wave because a wave reference must refer to an existing wave.

## Chapter IV-3 — User-Defined Functions

---

The following example demonstrates that \$wName and the wave reference w can refer to a wave that is not in the current data folder.

```
NewDataFolder root:Folder1
Test("root:Folder1:wave0")
```

### Wave Accessed Via String Calculated in Function

This technique is used when creating multiple waves in a function or when algorithmically selecting a wave or a set of waves to be processed.

```
Function Test(baseName, startIndex, endIndex)
    String baseName
    Variable startIndex, endIndex

    Variable index = startIndex
    do
        String name = baseName + num2istr(index)
        WAVE w = $name
        Variable avg = mean(w)
        Printf "Wave: %s; average: %g\r", NameOfWave(w), avg
        index += 1
    while (index <= endIndex)
End

Make/O/N=5 wave0=gnoise(1), wave1=gnoise(1), wave2=gnoise(1)
Test("wave", 0, 2)
```

We need to use this method because we want the function to operate on any number of waves. If the function were to operate on a small, fixed number of waves, we could use the wave parameter method.

As in the preceding section, we create the wave reference using \$<string expression>.

### Wave Accessed Via Literal Wave Name

In data acquisition or analysis projects, you often need to write procedures that deal with runs of identically-structured data. Each run is stored in its own data folder and contains waves with the same names. In this kind of situation, you can write a set of functions that use literal wave names specific for your data structure.

```
Function CreateRatio()
    WAVE dataA, dataB
    Duplicate dataA, ratioAB
    WAVE ratioAB
    ratioAB = dataA / dataB
End

Make/O/N=5 dataA = 1 + p, dataB = 2 + p
CreateRatio()
```

The CreateRatio function assumes the structure and naming of the data. The function is hard-wired to this naming scheme and assumes that the current data folder contains the appropriate data.

We don't need explicit wave reference variables because Make and Duplicate create automatic wave reference for simple wave names, as explained under **Automatic Creation of WAVE References** on page IV-66.

### Wave Accessed Via Wave Reference Function

A wave reference function is a built-in Igor function or user-defined function that returns a reference to a wave. Wave reference functions are typically used on the right-hand side of a WAVE statement. For example:

```
WAVE w = WaveRefIndexedDFR(:,i) // ith wave in current data folder
```

A common use for a wave reference function is to get access to waves displayed in a graph, using the TraceNameToWaveRef function. Here is an example.

```

Function PrintAverageOfDisplayedWaves()
    String list, traceName

    list = TraceNameList("", ";", 1)    // List of traces in top graph
    Variable index = 0
    do
        traceName = StringFromList(index, list)    // Next trace name
        if (strlen(traceName) == 0)
            break                                // No more traces
        endif
        WAVE w = TraceNameToWaveRef("", traceName) // Get wave ref
        Variable avg = mean(w)
        Printf "Wave: %s; average: %g\r", NameOfWave(w), avg
        index += 1
    while (1)                                // loop till break above
End

Make/O/N=5 wave0=gnoise(1), wave1=gnoise(1), wave2=gnoise(1)
Display wave0, wave1, wave2
PrintAverageOfDisplayedWaves()

```

See **Wave Reference Waves** on page IV-71 for an example using `WaveRefIndexed` to return a list of all of the Y waves in a graph.

There are other built-in wave reference functions (see **Wave Reference Functions** on page IV-186), but **WaveRefIndexed**, **WaveRefIndexedDFR** and **TraceNameToWaveRef** are the most used.

See **Wave Reference Function Results** on page IV-70 for details on user-defined functions that return wave references.

## Destination Wave Parameters

Many operations create waves. Examples are `Make`, `Duplicate` and `Differentiate`. Such operations take "destination wave" parameters. A destination wave parameter can be:

A simple name	<code>Differentiate fred /D=jack</code>
A path	<code>Differentiate fred /D=root:FolderA:jack</code>
\$ followed by a string expression	<code>String str = "root:FolderA:jack"</code> <code>Differentiate fred /D=\$str</code>
A wave reference to an existing wave	<code>Wave w = jack</code> <code>Differentiate fred /D=w</code>

The wave reference works only in a user-defined function. The other techniques work in functions, in macros and from the command line.

Using the first three techniques, the destination wave may or may not already exist. It is created if it does not exist and overwritten if it does exist.

In the last technique, the destination wave parameter is a wave reference. This technique works properly only if the referenced wave already exists. Otherwise the destination wave is a wave with the name of the wave reference itself (`w` in this case) in the current data folder. This situation is further explained below under **Destination Wave Reference Issues** on page IV-80.

## Wave Reference as Destination Wave

Here are the rules for wave references when used as destination waves:

## Chapter IV-3 — User-Defined Functions

---

1. If a simple name (not a wave reference) is passed as the destination wave parameter, the destination wave is a wave of that name in the current data folder whether it exists or not.
2. If a path or \$ followed by a string containing a path is passed as the destination wave parameter, the destination wave is specified by the path whether the specified wave exists or not.
3. If a wave reference is passed as the destination wave parameter, the destination wave is the referenced wave if it exists. See **Destination Wave Reference Issues** on page IV-80 for what happens if it does not exist.

### Exceptions To Destination Wave Rules

The Make operation is an exception in regard to wave references. The following statements make a wave named w in the current data folder whether root:FolderA:jack exists or not:

```
Wave/Z w = root:FolderA:jack
Make/O w
```

Prior to Igor Pro 6.20, many operations behaved like Make in this regard. In Igor Pro 6.20 and later, most operations behave like Differentiate.

### Updating of Destination Wave References

When a simple name is provided as the destination wave parameter in a user-defined function, Igor automatically creates a wave reference variable of that name at compile time if one does not already exist. This is an implicit automatic wave reference variable.

When a wave reference variable exists, whether implicit or explicit, during the execution of the command, the operation stores a reference to the destination wave in that wave reference variable. You can use the wave reference to access the destination wave in subsequent commands.

Similarly, when the destination is specified using a wave reference field in a structure, the operation updates the field to refer to the destination wave.

### Inline Wave References With Destination Waves

When the destination wave is specified using a path or a string containing a path, you can use an inline wave reference to create a reference to the destination wave. For example:

```
String dest = "root:FolderA:jack"
Differentiate input /D=$dest/WAVE=wDest
Display wDest
```

Here the Igor compiler creates a wave reference named wDest. The Differentiate operation stores a reference to the destination wave (root:FolderA:jack in this case) in wDest which can then be used to access the destination wave in subsequent commands.

Inline wave references do not determine which wave is the destination wave but merely provide a wave reference pointing to the destination wave when the command finishes.

### Destination Wave Reference Issues

You will get unexpected behavior when a wave reference variable refers to a wave with a different name or in a different data folder and the referenced wave does not exist. For example, if the referenced wave does not exist:

```
Wave/Z w = jack
Differentiate fred /D=w      // Creates a wave named w in current data folder

Wave/Z w = root:FolderA:jack
Differentiate fred /D=w      // Creates a wave named w in current data folder

Wave/Z jack = root:FolderA:jack
Differentiate fred /D=jack    // Creates a wave named jack in current data folder
```

```
STRUCT MyStruct s          // Contains wave ref field w
Differentiate fred /D=s.w   // Creates a wave named w in current data folder
```

In a situation like this, you should add a test using `WaveExists` to verify that the destination wave is valid and throw an error if not or otherwise handle the situation. For example:

```
Wave/Z w = root:FolderA:jack
if (!WaveExists(w))
    Abort "Destination wave does not exist"
endif
Differentiate fred /D=w
```

As noted above, when you use a simple name as a destination wave, the Igor compiler automatically creates a wave reference. If the automatically-created wave reference conflicts with a pre-existing wave reference, the compiler generates an error. For example, this function generates an "inconsistent type for wave reference error":

```
Function InconsistentTypeError()
    Wave/C w          // Explicit complex wave reference
    Differentiate fred /D=w   // Implicit real wave reference
End
```

Another consideration involves loops. Suppose in a loop you have code like this:

```
SetDataFolder <something depending on loop index>
Duplicate/O srcWave, jack
```

You may think you are creating a wave named `jack` in each data folder but, because the contents of the automatically-created wave reference variable `jack` is non-null after the first iteration, you will simply be overwriting the same wave over and over. To fix this, use

```
Duplicate/O srcWave, jack
WaveClear jack
```

or

```
Duplicate/O srcWave, $"jack"/WAVE=jack
```

This creates a wave named `jack` in the current data folder and stores a reference to it in a wave reference variable also named `jack`.

## Changes in Destination Wave Behavior

Igor's handling of destination wave references was improved for Igor Pro 6.20. Previously some operations treated wave references as simple names, did not set the wave reference to refer to the destination wave on output, and exhibited other non-standard behavior.

## Programming With Trace Names

A trace is the graphical representation of a 1D wave or a subset of a multi-dimensional wave. Each trace in a given graph has a unique name within that graph.

The name of a trace is, by default, the same as the name of the wave that it represents, but this is not always the case. For example, if you display the same wave twice in a given graph, the two trace names will be unique. Also, for programming convenience, an Igor programmer can create a trace whose name has no relation to the represented wave.

Trace names are used when changing traces in graphs, when accessing waves associated with traces in graphs, and when getting information about traces in graphs. See **Trace Names** on page II-216 for a general discussion.

## Chapter IV-3 — User-Defined Functions

---

These operations take trace name parameters:

**ModifyGraph (traces), ErrorBars, RemoveFromGraph, ReplaceWave, ReorderTraces, GraphWaveEdit Tag, TextBox, Label, Legend**

These operations return trace names:

**GetLastUserMenuInfo**

These functions take trace name parameters:

**TraceInfo, TraceNameToWaveRef, XWaveRefFromTrace**

These functions return trace names:

**TraceNameList, CsrInfo, CsrWave, TraceFromPixel**

### Trace Name Parameters

A trace name is not the same as a wave. An example may clarify this subtle point:

```
Function Test()  
    Wave w = root:FolderA:wave0  
    Display w  
    ModifyGraph rgb(w) = (65535,0,0)           // WRONG  
End
```

This is wrong because **ModifyGraph** is looking for the name of a trace in a graph and **w** is not the name of a trace in a graph. The name of the trace in this case is **wave0**. The function should be written like this:

```
Function Test()  
    Wave w = root:FolderA:wave0  
    Display w  
    ModifyGraph rgb(wave0) = (65535,0,0)       // CORRECT  
End
```

In the next example, the wave is passed to the function as a parameter so the name of the trace is not so obvious:

```
Function Test(w)  
    Wave w  
    Display w  
    ModifyGraph rgb(w) = (65535,0,0)           // WRONG  
End
```

This is wrong for the same reason as the first example: **w** is not the name of the trace. The function should be written like this:

```
Function Test(w)  
    Wave w  
    Display w  
  
    String name = NameOfWave(w)  
    ModifyGraph rgb($name) = (65535,0,0)       // CORRECT  
End
```

### User-defined Trace Names

As of Igor Pro 6.20, you can provide user-defined names for traces using **/TN=<name>** with **Display** and **AppendToGraph**. For example:

```
Make/O jack=sin(x/8)  
NewDataFolder/O foo; Make/O :foo:jack=sin(x/9)  
NewDataFolder/O bar; Make/O :bar:jack=sin(x/10)  
Display jack/TN='jack in root', :foo:jack/TN='jack in foo'  
AppendToGraph :bar:jack/TN='jack in bar'
```

```
ModifyGraph mode('jack in bar')=7,hbFill('jack in bar')=6
ModifyGraph rgb('jack in bar')=(0,0,65535)
```

## Trace Name Programming Example

This example illustrates applying some kind of process to each trace in a graph. It appends a smoothed version of each trace to the graph. To try it, copy the code below into the procedure window of a new experiment and execute these commands one-at-a-time:

```
SetupForSmoothWavesDemo()
AppendSmoothedWavesToGraph("", 5)          // Less smoothing
AppendSmoothedWavesToGraph("", 15)         // More smoothing

Function SetupForSmoothWavesDemo()
    Variable numTraces = 3

    Display /W=(35,44,775,522)              // Create graph

    Variable i
    for(i=0; i<numTraces; i+=1)
        String xName, yName
        sprintf xName, "xWave%d", i
        sprintf yName, "yWave%d", i
        Make /O /N=100 $xName = p + 20*i
        Wave xW = $xName
        Make /O /N=100 $yName = p + gnoise(5)
        Wave yW = $yName
        AppendToGraph yW vs xW
    endfor
End

Function CopyTraceOffsets(graphName, sourceTraceName, destTraceName)
    String graphName          // Name of graph or "" for top graph
    String sourceTraceName    // Name of source trace
    String destTraceName      // Name of dest trace

    // info will be "" if no offsets or something like "offset(x)={10,20}"
    String info = TraceInfo(graphName, sourceTraceName, 0)

    String offsetStr = StringByKey("offset(x)", info, "=")    // e.g., "{10,20}"
    Variable xOffset=0, yOffset=0
    if (strlen(offsetStr) > 0)
        sscanf offsetStr, "{%g,%g}", xOffset, yOffset
    endif
    ModifyGraph offset($destTraceName) = {xOffset, yOffset}
End

Function AppendSmoothedWavesToGraph(graphName, numSmoothingPasses)
    String graphName          // Name of graph or "" for top graph
    Variable numSmoothingPasses // Parameter to Smooth operation, e.g., 15

    // Get list of all traces in graph
    String traceList = TraceNameList(graphName, ";", 3)
    Variable numTraces = ItemsInList(traceList)
    Variable traceIndex

    // Remove traces representing smoothed waves previously added
    for(traceIndex=0; traceIndex<numTraces; traceIndex+=1)
        String traceName = StringFromList(traceIndex, traceList)
        if (StringMatch(traceName, "*_sm"))
            traceList = RemoveFromList(traceName, traceList)
            numTraces -= 1
        endif
    endfor
End
```

```
        traceIndex -= 1
    endif
endfor

// Create smoothed versions of the traces
for(traceIndex=0; traceIndex<numTraces; traceIndex+=1)
    traceName = StringFromList(traceIndex, traceList)

    Variable isXYTrace = 0

    Wave yW = TraceNameToWaveRef(graphName, traceName)
    DFREF dfr = $GetWavesDataFolder(yW, 1)
    String ySmoothedName = NameOfWave(yW) + "_sm"
    // Create smoothed wave in data folder containing Y wave
    Duplicate /O yW, dfr:$ySmoothedName
    Wave yWSmoothed = dfr:$ySmoothedName
    Smooth numSmoothingPasses, yWSmoothed

    Wave/Z xW = XWaveRefFromTrace(graphName, traceName)
    if (WaveExists(xW))           // It is an XY pair?
        isXYTrace = 1
    endif

    // Append smoothed wave to graph if it is not already in it
    CheckDisplayed /W=$graphName yWSmoothed
    if (V_flag == 0)              // Not yet already in graph?
        if (isXYTrace)
            AppendToGraph yWSmoothed vs xW
        else
            AppendToGraph yWSmoothed
        endif
        ModifyGraph /W=$graphName rgb($ySmoothedName) = (0, 0, 65535)
    endif

    // Copy trace offsets from input trace to smoothed trace
    CopyTraceOffsets(graphName, traceName, ySmoothedName)
endfor
End
```

## Free Waves

Free waves are waves that are not part of any data folder hierarchy. Their principal use is in multithreaded wave assignment using the `MultiThread` keyword in a function. They can also be used for temporary storage within functions.

Free waves are recommended for advanced programmers only.

**Note:** Free waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the `SaveData` operation or the Data Browser's `Save Copy` button. In general, they are intended for temporary computation purposes only.

You create free waves using the **NewFreeWave** function and the **Make/FREE** and **Duplicate/FREE** operations.

Here is an example:

```
Function ReverseWave(w)
    Wave w

    Variable lastPoint = numpnts(w) - 1
    if (lastPoint > 0)
```

```
// This creates a free wave named wTemp.
// It also creates an automatic wave reference named wTemp
// which refers to the free wave.
Duplicate /FREE w, wTemp

    w = wTemp[lastPoint-p]
endif
End
```

In this example, wTemp is a free wave. As such, it is not contained in any data folder and therefore can not conflict with any other wave.

As explained below under **Free Wave Lifetime** on page IV-86, a free wave is automatically deleted when there are no more references to it. In this example that happens when the function ends.

You can access a free wave only using the wave reference returned by NewFreeWave, Make/FREE or Duplicate/FREE.

Free waves can not be used in situations where global persistence is required such as in graphs, tables and controls. In other words, you should use free waves for computation purposes only.

For a discussion of multithreaded assignment statements, see **Automatic Parallel Processing with Multi-Thread** on page IV-303. For an example using free waves, see **Wave Reference MultiThread Example** on page IV-306.

### Free Wave Created When Free Data Folder Is Deleted

In addition to the explicit creation of free waves, a wave that is created in a free data folder becomes free if the host data folder is deleted but a reference to the wave still exists. For example:

```
Function/WAVE Test()
    DFREF dfSav= GetDataFolderDFR()

    SetDataFolder NewFreeDataFolder()
    Make jack={1,2,3} // jack is not a free wave at this point.
    // This also creates an automatic wave reference named jack.

    SetDataFolder dfSav
    // The free data folder is now gone but jack persists
    // because of the wave reference to it and is now a free wave.

    return jack
End
```

### Free Wave Created For User Function Input Parameter

If a user function takes a wave reference as in input parameter, you can create and pass a short free wave using a list of values as illustrated here:

```
Function Test(w)
    WAVE/D w
    Print w
End
```

You can invoke this function like this:

```
Test({1,2,3})
```

Igor automatically creates a free wave and passes it to Test. The free wave is automatically deleted when Test returns.

The data type of the free wave is determined by the type of the function's wave parameter. In this case the free wave is created as double-precision floating point because the wave parameter is defined using the /D

## Chapter IV-3 — User-Defined Functions

---

flag. If /D were omitted, the free wave would be single-precision floating point. Wave/C/D would give a double-precision complex free wave. Wave/T would give a text free wave.

This list of values syntax is allowed only for user-defined functions because only they have code to test for and delete free waves upon exit.

### Free Wave Lifetime

A free wave is automatically deleted when the last reference to it disappears.

Wave references can be stored in:

1. Wave reference variables in user-defined functions
2. Wave reference fields in structures
3. Elements of a wave reference wave (created by Make/WAVE)

The first case is the most common.

A wave reference disappears when:

1. The wave reference variable containing it is explicitly cleared using WaveClear.
2. The wave reference variable containing it is reassigned to refer to another wave.
3. The wave reference variable containing it goes out-of-scope and ceases to exist when the function in which it was created returns.
4. The wave reference wave element containing it is deleted or the wave reference wave is killed.

When there are no more references to a free wave, Igor automatically deletes it. This example illustrates the first three of these scenarios:

```
Function TestFreeWaveDeletion1()  
    Wave w = NewFreeWave(2,3) // Create a free wave with 3 points  
    WaveClear w               // w no longer refers to the free wave  
    // There are no more references to the free wave so it is deleted  
  
    Wave w = NewFreeWave(2,3) // Create a free wave with 3 points  
    Wave w = root:wave0       // w no longer refers to the free wave  
    // There are no more references to the free wave so it is deleted  
  
    Wave w = NewFreeWave(2,3) // Create a free wave with 3 points  
End // Wave reference w ceases to exist so the free wave is deleted
```

In the preceding example we used NewFreeWave which creates a free wave named 'f' that is not part of any data folder. Next we will use Make/FREE instead of NewFreeWave. Using Make allows us to give the free wave a name of our choice but it is still free and not part of any data folder. When reading this example, keep in mind that "Make jack" creates an automatic wave reference variable named jack:

```
Function TestFreeWaveDeletion2()  
    Make /D /N=3 /FREE jack // Create a free DP wave with 3 points  
    // Make created an automatic wave reference named jack  
  
    Make /D /N=5 /FREE jack // Create a free DP wave with 5 points  
    // Make created an automatic wave reference named jack  
    // which refers to the 5-point jack.  
    // There are now no references to 3-point jack so it is automatically deleted.  
  
End // Wave reference jack ceases to exist so free wave jack is deleted
```

In the next example, a subroutine returns a reference to a free wave to the calling routine:

```
Function/WAVE Subroutine1()  
    Make /D /N=3 /FREE jack=p // Create a free DP wave with 3 points  
    return jack               // Return reference to calling routine
```

End

```
Function MainRoutine1()
    WAVE w= Subroutine1()    // Wave reference w references the free wave jack
    Print w
End    // Wave reference w ceases to exist so free wave jack is deleted
```

In the next example, the wave jack starts as an object in a free data folder (see **Free Data Folders** on page IV-88). It is not free because it is part of a data folder hierarchy even though the data folder is free. When the free data folder is deleted, jack becomes a free wave.

When reading this example, keep in mind that the free data folder is automatically deleted when there are no more references to it. Originally, it survives because it is the current data folder and therefore is referenced by Igor internally. When it is no longer the current data folder, there are no more references to it and it is automatically deleted:

```
Function/WAVE Subroutine2()
    DFREF dfSav= GetDataFolderDFR()

    // Create free data folder and set as current data folder
    SetDataFolder NewFreeDataFolder()

    // Create wave jack and an automatic wave reference to it
    Make jack={1,2,3}    // jack is not free - it is an object in a data folder

    SetDataFolder dfSav // Change the current data folder
    // There are now no references to the free data folder so it is deleted
    // but wave jack remains because there is a reference to it.
    // jack is now a free wave.

    return jack          // Return reference to free wave to calling routine
End
```

```
Function MainRoutine2()
    WAVE w= Subroutine2()    // Wave reference w references free wave jack
    Print w
End    // Wave reference w ceases to exist so free wave jack is deleted
```

Not shown in this section is the case of a free wave that persists because a reference to it is stored in a wave reference wave. That situation is illustrated by the **Automatic Parallel Processing with MultiThread** on page IV-303 example.

### Free Wave Leaks

A leak occurs when an object is created and is never released. Leaks waste memory. Igor uses wave reference counting to prevent leaks but in the case of free waves there are special considerations.

A free wave must be stored in a wave reference variable in order to be automatically released because Igor does the releasing when a wave reference variable goes out of scope.

The following example results in two memory leaks:

```
Function/WAVE GenerateFree()
    return NewFreeWave(2,3)
End

Function Leaks()
    Duplicate GenerateFree(), dummy          // This leaks
    Variable maxVal = WaveMax(generateFree()) // So does this
End
```

## Chapter IV-3 — User-Defined Functions

---

Both lines leak because the free wave returned by `GenerateFree` is not stored in any wave reference variable. By contrast, this function does not leak:

```
Function NoLeaks()  
    Wave w = GenerateFree()           // w references the free wave  
    Duplicate w,dummy  
    Variable maxVal = WaveMax(w)       // WaveMax is a built-in function  
    // The free wave is released when w goes out of scope  
End
```

In the `Leaks` function, there would be no leak if you replaced the call to `WaveMax` with a call to a user-defined function. This is because Igor automatically creates a wave reference variable when you pass a wave to a user-defined function. Because this distinction is subtle, it is best to always store a free wave in your own explicit wave reference variable.

### Converting a Free Wave to a Global Wave

You can use **MoveWave** to move a free wave into a global data folder, in which case it ceases to be free. If the wave was created by `NewFreeWave` its name will be 'f'. You can use `MoveWave` to provide it with a more descriptive name.

Here is an example illustrating `Make/FREE`:

```
Function Test()  
    Make/FREE/N=(50,50) w  
    SetScale x,-5,8,w  
    SetScale y,-7,12,w  
    w= exp(-(x^2+y^2))  
    NewImage w  
    if( GetRTErrors(1) != 0 )  
        Print "Can't use a free wave here"  
    endif  
    MoveWave w,root:wasFree  
    NewImage w  
End
```

Note that `MoveWave` requires that the new wave name, `wasFree` in this case, be unique within the destination data folder.

To determine if a given wave is free or global, use the **WaveType** function with the optional selector = 2.

## Free Data Folders

Free data folders are data folders that are not part of any data folder hierarchy. Their principal use is in multithreaded wave assignment using the `MultiThread` keyword in a function. They can also be used for temporary storage within functions.

Free data folders are recommended for advanced programmers only.

**Note:** Free data folders are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the `SaveData` operation or the Data Browser's `Save Copy` button. In general, they are intended for temporary computation purposes only.

You create a free data folder using the `NewFreeDataFolder` function. You access it using the data folder reference returned by that function.

After using `SetDataFolder` with a free data folder, be sure to restore it to the previous value, like this:

```
Function Test()  
    DFREF dfrSave = GetDataFolderDFR()  
  
    SetDataFolder NewFreeDataFolder() // Create new free data folder.
```

```
. . .  
    SetDataFolder dfrSave  
End
```

This is good programming practice in general but is especially important when using free data folders.

Free data folders can not be used in situations where global persistence is required such as in graphs, tables and controls. In other words, you should use objects in free data folders for short-term computation purposes only.

For a discussion of multithreaded assignment statements, see **Automatic Parallel Processing with MultiThread** on page IV-303. For an example using free data folders, see **Data Folder Reference MultiThread Example** on page IV-304.

### Free Data Folder Lifetime

A free data folder is automatically deleted when the last reference to it disappears.

Data folder references can be stored in:

1. Data folder reference variables in user-defined functions
2. Data folder reference fields in structures
3. Elements of a data folder reference wave (created with Make/DF)
4. Igor's internal current data folder reference variable

A data folder reference disappears when:

1. The data folder reference variable containing it is explicitly cleared using KillDataFolder.
2. The data folder reference variable containing it is reassigned to refer to another data folder.
3. The data folder reference variable containing it goes out-of-scope and ceases to exist when the function in which it was created returns.
4. The data folder reference wave element containing it is deleted or the data folder reference wave is killed.
5. The current data folder is changed which causes Igor's internal current data folder reference variable to refer to another data folder.

When there are no more references to a free data folder, Igor automatically deletes it.

In this example, a free data folder reference variable is cleared by KillDataFolder:

```
Function Test1()  
    DFREF dfr= NewFreeDataFolder()      // Create new free data folder.  
    // The free data folder exists because dfr references it.  
    . . .  
    KillDataFolder dfr    // dfr no longer refers to the free data folder  
End
```

KillDataFolder kills the free data folder only if the given DFREF variable contains the last reference to it.

In the next example, the free data folder is automatically deleted when the DFREF that references it is changed to reference another data folder:

```
Function Test2()  
    DFREF dfr= NewFreeDataFolder()      // Create new free data folder.  
    // The free data folder exists because dfr references it.  
    . . .  
    DFREF dfr= root:  
    // The free data folder is deleted since there are no references to it.  
End
```

## Chapter IV-3 — User-Defined Functions

---

In the next example, a free data folder is created and a reference is stored in a local data folder reference variable. When the function ends, the DFREF ceases to exist and the free data folder is automatically deleted:

```
Function Test3()  
    DFREF dfr= NewFreeDataFolder()      // Create new free data folder.  
    // The free data folder exists because dfr references it.  
    . . .  
End    // The free data folder is deleted because dfr no longer exists.
```

The fourth case, where a data folder reference is stored in a data folder reference wave, is discussed under **Data Folder Reference Waves** on page IV-76.

In the next example, the free data folder is referenced by Igor's internal current data folder reference variable because it is the current data folder. When the current data folder is changed, there are no more references to the free data folder and it is automatically deleted:

```
Function Test4()  
    SetDataFolder NewFreeDataFolder()    // Create new free data folder.  
    // The free data folder persists because it is the current data folder  
    // and therefore is referenced by Igor's internal  
    // current data folder reference variable.  
    . . .  
  
    // Change Igor's internal current data folder reference  
    SetDataFolder root:  
    // The free data folder is since there are no references to it.  
End
```

### Free Data Folder Objects Lifetime

Next we consider what happens to objects in a free data folder when the free data folder is deleted. In this event, numeric and string variables in the free data folder are unconditionally automatically deleted. A wave is automatically deleted if there are no wave references to it. If there is a wave reference to it, the wave survives and becomes a free wave. Free waves are waves that exists outside of any data folder as explained under **Free Waves** on page IV-84.

For example:

```
Function Test()  
    SetDataFolder NewFreeDataFolder()    // Create new free data folder.  
    // The free data folder exists because it is the current data folder.  
  
    Make jack        // Make a wave and an automatic wave reference  
  
    . . .  
  
    SetDataFolder root:  
    // The free data folder is deleted since there are no references to it.  
    // Because there is a reference to the wave jack, it persists  
    // and becomes a free wave.  
  
    . . .  
  
End    // The wave reference to jack ceases to exist so jack is deleted
```

When this function ends, the reference to the wave jack ceases to exist, there are no references to jack, and it is automatically deleted.

Next we look at a slight variation. In the following example, Make does not create an automatic wave reference because of the use of \$, and we do not create an explicit wave reference:

```

Function Test()
    SetDataFolder NewFreeDataFolder()    // Create new free data folder.
    // The free data folder exists because it is the current data folder.

    Make $"jack"                        // Make a wave but no wave reference
    // jack persists because the current data folder references it.

    . . .

    SetDataFolder root:
    // The free data folder is deleted since there are no references to it.
    // jack is also deleted because there are no more references to it.

    . . .

End

```

### Converting a Free Data Folder to a Global Data Folder

You can use **MoveDataFolder** to move a free data folder into the global hierarchy. The data folder and all of its contents then become global. The name of a free data folder created by **NewFreeDataFolder** is 'free-root'. You should rename it after moving to a global context. For example:

```

Function Test()
    DFREF savedF = GetDataFolderDFR()
    DFREF dfr = NewFreeDataFolder()    // Create free data folder
    SetDataFolder dfr                  // Set as current data folder
    Make jack=sin(x/8)                 // Create some data in it
    SetDataFolder savedF               // Restore original current data folder
    MoveDataFolder dfr, root:          // Free DF becomes root:freeroot
    RenameDataFolder root:freeroot,TestDF // Rename with a proper name
    Display root:TestDF:jack
End

```

Note that **MoveDataFolder** requires that the data folder name, **freeroot** in this case, be unique within the destination data folder.

## Structures in Functions

You can define structures in procedure files and use them in functions. Structures can be used only in user-defined functions as local variables and their behavior is defined almost entirely at compile time. Runtime or interactive definition and use of structures is not currently supported; for this purpose, use Data Folders (see Chapter II-8, **Data Folders**), the **StringByKey** function (see page V-865), or the **NumberByKey** function (see page V-603).

Use of structures is an advanced technique. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

### Simple Structure Example

Before we get into the details, here is a quick example showing how to define and use a structure.

```

Structure DemoStruct
    double dval
    int32 ival
    char str[100]
EndStructure

Function Subroutine(s)
    STRUCT DemoStruct &s           // Structure parameter

```

## Chapter IV-3 — User-Defined Functions

---

```
Printf "dval=%g; ival=%d; str=\"%s\"\\r", s.dval, s.ival, s.str
End

Function Routine()
    STRUCT DemoStruct s           // Local structure instance
    s.dval = 1.234
    s.ival = 4321
    s.str = "Hello"
    Subroutine(s)
End
```

As this example shows, you define a structure type using the `Structure` keyword in a procedure file. You define a local structure variable using the `STRUCT` keyword in a user-defined function. And you pass a structure from one user-defined function to another as a pass-by-reference parameter, as indicated by the use of `&` in the subroutine parameter declaration.

### Defining Structures

Structures are defined in a procedure file with the following syntax:

```
Structure structureName
    memType memName [arraySize] [, memName [arraySize]]
...
EndStructure
```

Structure member types (*memType*) can be any of the following Igor objects: `Variable`, `String`, `WAVE`, `NVAR`, `SVAR`, `DFREF`, `FUNCREF`, or `STRUCT`.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

Igor Member Type	C Equivalent	Byte Size	Note
char	signed char	1	
uchar	unsigned char	1	
int16	16-bit int	2	
uint16	unsigned 16-bit int	2	
int32	32-bit int	4	
uint32	unsigned 32-bit int	4	
int64	64-bit int	8	Igor7 or later
uint64	unsigned 64-bit int	8	Igor7 or later
float	float	4	
double	double	8	

The `Variable` and `double` types are identical although `Variable` can be also specified as complex using the `/C` flag.

The optional *arraySize* must be specified using an expression involving literal numbers or locally-defined constants enclosed in brackets. The value must be between 1 and 400 for all but `STRUCT` where the upper limit is 100. The upper limit is a consequence of how memory is allocated on the stack frame.

Structures are two-byte aligned. This means that if an odd number of bytes has been allocated and then a nonchar field is defined, an extra byte of padding is inserted in front of the new field. This is mainly of concern only when reading and writing structures from and to disk files.

The Structure keyword can be preceded with the **Static** keyword (see page V-776) to make the definition apply only to the current procedure window. Without the Static designation, structures defined in one procedure window may be used in any other.

## Using Structures

To use (“instantiate”) a structure in a function, you must allocate a STRUCT variable using:

```
STRUCT sName name
```

where *sName* is the name of an existing structure and *name* is the local structure variable name.

To access a member of a structure, specify the STRUCT variable name followed by a “.” and the member name:

```
STRUCT Point pt
pt.v= 100
```

When a member is defined as an array:

```
Structure mystruct
    Variable var1
    Variable var2[10]
...
EndStructure
```

you must specify [*index*] to use a given element in the array:

```
STRUCT mystruct ms
ms.var2[n] = 22
```

Structure and field names must be literal and can not use *\$str* notation.

The *index* value can be a variable calculated at runtime or a literal number.

If the field is itself a STRUCT, continue to append “.” and field names as needed.

You can define an array of structures as a field in a structure:

```
Structure mystruct
    STRUCT Point pt[100]    // Allowed as a sub-structure
EndStructure
```

However, you can not define an array of structures as a local variable in a function:

```
STRUCT Point pt[100]    // Not allowed as a function local variable
```

WAVE, NVAR, SVAR, and FUNCREF members can be initialized using the same syntax as used for the corresponding non-structure variables. See **Runtime Lookup of Globals** on page IV-60 and **Function References** on page IV-98.

Structures can be passed to functions **only** by reference, which allows them to be both input and output parameters (see **Pass-By-Reference** on page IV-54). The syntax is:

```
STRUCT sName &varName
```

In a user function you define the input parameter:

```
Function myFunc(s)
    STRUCT mystruct &s
...
End
```

Char and uchar arrays can be treated as zero-terminated strings by leaving off the brackets. Because the Igor compiler knows the size, the entire array can be used with no zero termination. Like normal string variables, concatenation using += is allowed but substring assignment using [p1, p2] = subStr is not supported.

## Chapter IV-3 — User-Defined Functions

---

Structures, including substructures, can be copied using simple assignment from one structure to the other. The source and destination structures must be defined using the same structure name.

The **Print** can print individual elements of a structure or can print a summary of the entire STRUCT variable.

### Structure Example

Here is a contrived example using structures. Try executing `foo(2)`:

```
Constant kCaSize = 5

Structure substruct
  Variable v1
  Variable v2
EndStructure

Structure mystruct
  Variable var1
  Variable var2[10]
  String s1
  WAVE fred
  NVAR globVar1
  SVAR globStr1
  FUNCREF myDefaultFunc afunc
  STRUCT substruct ss1[3]
  char ca[kCaSize+1]
EndStructure

Function foo(n)
  Variable n

  Make/O/N=20 fred
  Variable/G globVar1 = 111
  String/G aGlobStr="a global string var"

  STRUCT mystruct ms
  ms.var1 = 11
  ms.var2[n] = 22
  ms.s1 = "string s1"
  WAVE ms.fred // could have =name if want other than waves named fred
  NVAR ms.globVar1
  SVAR ms.globStr1 = aGlobStr
  FUNCREF myDefaultFunc ms.afunc = anotherfunc
  ms.ss1[n].v1 = ms.var1/2
  ms.ss1[0] = ms.ss1[n]
  ms.ca = "0123456789"
  bar(ms,n)
  Print ms.var1,ms.var2[n],ms.s1,ms.globVar1,ms.globStr1,ms.ss1[n].v1
  Print ms.ss1[n].v2,ms.ca,ms.afunc()
  Print "a whole wave",ms.fred
  Print "the whole ms struct:",ms

  STRUCT substruct ss
  ss = ms.ss1[n]
  Print "copy of substruct",ss
End

Function bar(s,n)
  STRUCT mystruct &s
  Variable n

  s.ss1[n].v2 = 99
  s.fred = sin(x)
  Display s.fred
End

Function myDefaultFunc()
  return 1
End

Function anotherfunc()
  return 2
End
```

Note the use of WAVE, NVAR, SVAR and FUNCREF in the function foo. These keywords are required both in the structure definition and again in the function, when the structure members are initialized.

## Built-In Structures

Igor includes a few special purpose, predefined structures for use with certain operations. Some of those structures use these predefined general purpose structures:

```
Structure Rect
    Int16 top, left, bottom, right
EndStructure
```

```
Structure Point
    Int16 v, h
EndStructure
```

```
Structure RGBColor
    UInt16 red, green, blue
EndStructure
```

A number of operations use built-in structures that the Igor programmer can use. See the command reference information for details about these structures and their members.

Operation	Structure Name
Button	WMButtonAction
CheckBox	WMCheckboxAction
CustomControl	WMCustomControlAction
ListBox	WMListboxAction
ModifyFreeAxis	WMAxisHookStruct
PopupMenu	WMPopupAction
SetVariable	WMSetVariableAction
SetWindow	WMWinHookStruct
Slider	WMSliderAction
TabControl	WMTabControlAction

## Applications of Structures

Structures are useful for reading and writing disk files. The **FBinRead** and the **FBinWrite** understand structure variables and read or write the entire structure from or to a disk file. The individual fields of the structure are byte-swapped if you use the /B flag.

Structures can be used in complex programming projects to reduce the dependency on global objects and to simplify passing data to and getting data from functions. For example, a base function might allocate a local structure variable and then pass that variable on to a large set of lower level routines. Because structure variables are passed by reference, data written into the structure by lower level routines is available to the higher level. Without structures, you would have to pass a large number of individual parameters or use global variables and data folders.

## Using Structures with Windows and Controls

Action procedures for controls and window hook functions take parameters that use predefined structure types. These are listed under **Built-In Structures** on page IV-95.

Advanced programmers should also be aware of userdata that can be associated with windows using the **SetWindow** operation (see page V-740). Userdata is binary data that persists with individual windows; it

## Chapter IV-3 — User-Defined Functions

---

is suitable for storing structures. Storing structures in a window's userdata is very handy in eliminating the need for global variables and reduces the bookkeeping needed to synchronize those globals with the window's life cycle. Userdata is also available for use with controls. See the **ControlInfo**, **GetWindow**, **GetUserData**, and **SetWindow** operations.

Here is an example illustrating built-in and user-defined structures along with userdata in a control. Put the following in the procedure window of a new experiment and run the Panel0 macro. Then click on the buttons. Note that the buttons remember their state even if the experiment is saved and reloaded. To fully understand this example, examine the definition of WMButtonAction in the **Button** operation (see page V-45).

```
#pragma rtGlobals=1          // Use modern global access method.

Structure mystruct
    Int32 nclicks
    double lastTime
EndStructure

Function ButtonProc(bStruct) : ButtonControl
    STRUCT WMButtonAction &bStruct

    if( bStruct.eventCode != 1 )
        return 0          // we only handle mouse down
    endif

    STRUCT mystruct s1
    if( strlen(bStruct.userdata) == 0 )
        Print "first click"
    else
        StructGet/S s1,bStruct.userdata
        String ctime= Secs2Date(s1.lastTime, 1 )+" "+Secs2Time(s1.lastTime,1)
        // Warning: Next command is wrapped to fit on the page.
        Printf "button %s clicked %d time(s), last click =
%s\r",bStruct.ctrlName,s1.nclicks,ctime
    endif
    s1.nclicks += 1
    s1.lastTime= datetime
    StructPut/S s1,bStruct.userdata
    return 0
End

Window Panel0() : Panel
    PauseUpdate; Silent 1          // building window...
    NewPanel /W=(150,50,493,133)
    SetDrawLayer UserBack
    Button b0,pos={12,8},size={50,20},proc=ButtonProc,title="Click"
    Button b1,pos={65,8},size={50,20},proc=ButtonProc,title="Click"
    Button b2,pos={119,8},size={50,20},proc=ButtonProc,title="Click"
    Button b3,pos={172,8},size={50,20},proc=ButtonProc,title="Click"
    Button b4,pos={226,8},size={50,20},proc=ButtonProc,title="Click"
EndMacro
```

### Limitations of Structures

Although structures can reduce the need for global variables, they do not eliminate them altogether. A structure variable, like all local variables in functions, disappears when its host function returns. In order to maintain state information, you need to store and retrieve structure information using global variables. You can do this using a global variable for each field or, with certain restrictions, you can store entire structure variables in a single global using the **StructPut** operation (see page V-870) and the **StructGet** operation (see page V-869).

As of Igor Pro 5.03, a structure can be passed to an external operation or function. See the Igor XOP Toolkit manual for details.

### Static Functions

You can create functions that are local to the procedure file in which they appear by inserting the keyword *Static* in front of *Function* (see **Static** on page V-776 for usage details). The main reason for using this technique is to minimize the possibility of your function names conflicting with other names, thereby making the use of common intuitive names practical.

Functions normally have global scope and are available in any part of an Igor experiment, but the `static` keyword limits the scope of the function to its procedure file and hides it from all other procedure files. Static functions can only be used in the file in which they are defined. They can not be called from the command line and they cannot be accessed from macros.

Because static functions cannot be executed from the command line, you will have to write a public test function to test them.

You can break this rule and access a static function using a module name; see **Regular Modules** on page IV-222.

Non-static functions (functions without the `static` keyword) are sometimes called “public” functions.

## ThreadSafe Functions

A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads.

ThreadSafe user functions provide support for multiprocessing and can be used for preemptive multitasking background tasks.

**Note:** Writing a multitasking program is for expert programmers only. Intermediate programmers can write thread-safe curve-fitting functions and multithreaded assignment statements; see **Automatic Parallel Processing with MultiThread** on page IV-303. Beginning programmers should gain experience with regular programming before using multitasking.

You create thread safe functions by inserting the keyword `ThreadSafe` in front of `Function`. For example:

```
ThreadSafe Function myadd(a,b)
    Variable a,b

    return a+b
End
```

Only a subset of Igor’s built-in functions and operations can be used in a threadsafe function. Generally, numeric or utility functions can be used but those that access windows can not. To determine if a routine is ThreadSafe, use the Command Help tab of the Help Browser.

Although file operations are listed as threadsafe, they have certain limitations when running in a threadsafe function. If a file load hits a condition that normally would need user assistance, the load is aborted. No printing to history is done and there is no support for symbolic paths; use **PathInfo** and pass the path as a string input parameter.

Threadsafe functions can call other threadsafe functions but may not call non-threadsafe functions. Non-threadsafe functions can call threadsafe functions.

When threadsafe functions execute in the main thread, they have normal access to data folders, waves, and variables. But when running in a preemptive thread, threadsafe functions use their own private data folders, waves, and variables.

When a thread is started, waves can be passed to the function as input parameters. Such waves are flagged as being in use by the thread, which prevents any changes to the size of the wave. When all threads under a given main thread are finished, the waves return to normal. You can pass data folders between the main thread and preemptive threads but such data folders are never shared.

See **ThreadSafe Functions and Multitasking** on page IV-308 for a discussion of programming with preemptive multitasking threads.

### Function Overrides

In some very rare cases, you may need to temporarily change an existing function. When that function is part of a package provided by someone else, or by WaveMetrics, it may be undesirable or difficult to edit the original function. By using the keyword “Override” in front of “Function” you can define a new function that will be used in place of another function of the same name that is defined in a *different and later* procedure file.

Although it is difficult to determine the order in which procedure files are compiled, the main procedure window is always first. Therefore, always define override functions in the main procedure file.

Although you can override static functions, you may run into a few difficulties. If there are multiple files with the same static function name, your override will affect all of them, and if the different functions have different parameters then you will get a link error.

Here is an example of the Override keyword. In this example, start with a new experiment and create a new procedure window. Insert the following in the new window (not the main procedure window).

```
Function foo()  
    print "this is foo"  
End
```

```
Function Test()  
    foo()  
End
```

Now, on the command line, execute Test(). You will see “this is foo” in the history.

Open the main procedure window and insert the following:

```
Override Function foo()  
    print "this is an override version of foo"  
End
```

Now execute Test() again. You will see the “this is an override version of foo” in the history.

### Function References

Function references provide a way to pass a function to a function. This is a technique for advanced programmers. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

To specify that an input parameter to a function is a function reference, use the following syntax:

```
Function Example(f)  
    FUNCREF myprotofunc f  
    . . .  
End
```

This specifies that the input parameter *f* is a function reference and that a function named *myprotofunc* specifies the kind of function that is legal to pass. The calling function passes a reference to a function as the *f* parameter. The called function can use *f* just as it would use the prototype function.

If a valid function is not passed then the prototype function is called instead. The prototype function can either be a default function or it can contain error handling code that makes it obvious that a proper function was not passed.

Here is the syntax for creating function reference variables in the body of a function:

```
FUNCREF protoFunc f = funcName  
FUNCREF protoFunc f = $"str"  
FUNCREF protoFunc f = <FuncRef>
```

As shown, the right hand side can take either a literal function name, a \$ expression that evaluates to a function name at runtime, or it can take another FUNCREF variable.

FUNCREF variables can refer to external functions as well as user-defined functions. However, the prototype function must be a user-defined function and it must not be static.

Although you can store a reference to a static function in a FUNCREF variable, you can not then use that variable with Igor operations that take a function as an input. FuncFit is an example of such an operation.

Following are some example functions and FUNCREFs that illustrate several concepts:

```
Function myprotofunc(a)
    Variable a

    print "in myprotofunc with a= ",a
End

Function foo1(var1)
    Variable var1

    print "in foo1 with a= ",var1
End

Function foo2(a)
    Variable a

    print "in foo2 with a= ",a
End

Function foo3(a)
    Variable a

    print "in foo3 with a= ",a
End

Function badfoo(a,b)
    Variable a,b

    print "in badfoo with a= ",a
End

Function bar(a,b,fin)
    Variable a,b
    FUNCREF myprotofunc fin

    if( a==1 )
        FUNCREF myprotofunc f= foo1
    elseif( a==2 )
        FUNCREF myprotofunc f= $"foo2"
    elseif( a==3 )
        FUNCREF myprotofunc f= fin
    endif
    f(b)
End
```

For the above functions, the following table shows the results for various invocations of the bar function executed on the command line:

Executing `bar(3, 55, badfoo)` generates a syntax error dialog that highlights “badfoo” in the command. This error results because the format of the badfoo function does not match the format of the prototype function, myprotofunc.

Command	Result
<code>bar(1,33,foo3)</code>	in foo1 with a= 33
<code>bar(2,44,foo3)</code>	in foo2 with a= 44
<code>bar(3,55,foo3)</code>	in foo3 with a= 55
<code>bar(4,55,foo3)</code>	in myprotofunc with a= 55

## Conditional Compilation

Compiler directives can be used to conditionally include or exclude blocks of code. This is especially useful when an XOP may or may not be available. It is also convenient for supporting different versions of Igor with the same code and for testing and debugging code.

For example, to enable a block of procedure code depending on the presence or absence of an XOP, use

```
#if Exists("nameOfAnXopRoutine")
    <code using XOP routines>
#endif
```

To conditionally compile based on the version of Igor, use:

```
#if IgorVersion() < 7.00
    <code for Igor6 or before>
#else
    <code for Igor7 or later>
#endif
```

## Conditional Compilation Directives

The conditional compiler directives are modeled after the C/C++ language. Unlike other `#keyword` directives, these may be indented. For defining symbols, the directives are:

```
#define symbol
#undef symbol
```

For conditional compilation, the directives are:

```
#ifdef symbol
#ifndef symbol
#if expression
#elif expression
#else
#endif
```

Expressions are ordinary Igor expressions, but cannot involve any user-defined objects. They evaluate to TRUE if the absolute value is  $> 0.5$ .

Conditionals must be either completely outside or completely inside function definitions; they cannot straddle a function definition. Conditionals cannot be used within macros but the **defined** function can.

Nesting depth is limited to 16 levels. Trailing text other than a comment is illegal.

## Conditional Compilation Symbols

`#define` is used purely for defining symbols (there is nothing like C's preprocessor) and the only use of a symbol is with `#if`, `#ifdef`, `#ifndef` and the `defined` function.

The `defined` function allows you to test if a symbol was defined using `#define`:

```
#if defined(symbol)
```

Unlike C, you cannot use `#if defined(symbol)`.

Symbols exist only in the file where they are defined; the only exception is for symbols defined in the main procedure window, which are available to all other procedure files except independent modules. In addition, you can define global symbols that are available in all procedure windows (including independent modules) using:

```
SetIgorOption poundDefine=symb
```

This adds one symbol to a global list. You can query the global list using:

```
SetIgorOption poundDefine=symb?
```

This sets `V_flag` to 1 if `symb` exists or 0 otherwise. To remove a symbol from the global list use:

```
SetIgorOption poundUndefine=symb
```

For non-independent module procedure windows, a symbol is defined if it exists in the global list *or* in the main procedure window's list *or* in the given procedure window.

For independent module procedure windows, a symbol is defined if it exists in the global list *or* in the given procedure window; it does not use the main procedure window list.

A symbol defined in a global list is not undefined by a `#undef` in a procedure window.

## Predefined Global Symbols

These global symbols are predefined if appropriate and available in all procedure windows:

Symbol	Automatically Predefined If
MACINTOSH	The Igor application is a Macintosh application.
WINDOWS	The Igor application is a Windows application.
IGOR64	The Igor application is a 64-bit application.

## Conditional Compilation Examples

```
#define MYSYMBOL

#ifdef MYSYMBOL

Function foo()
    Print "This is foo when MYSYMBOL is defined"
End

#else

Function foo()
    Print "This is foo when MYSYMBOL is NOT defined"
End

#endif    // MYSYMBOL

// This works in Igor Pro 6.10 or later
#if IgorVersion() >= 7.00
    <Conditionally for Igor7 or later here>
#else
    <Conditionally for Igor6 or before here>
#endif

// This works in Igor Pro 6.20 or later
#if defined(MACINTOSH)
    <conditionally compiled code here>
```

```
#endif
```

### Function Errors

During function compilation, Igor checks and reports syntactic errors and errors in parameter declarations. The normal course of action is to edit the offending function and try to compile again.

Runtime errors in functions are not reported on the spot. Instead, Igor saves information about the error and function execution continues. Igor presents an error dialog only after the last function ceases execution and Igor returns to the idle state. If multiple runtime errors occur, only the first is reported.

When a runtime error occurs, after function execution ends, Igor presents an error dialog:

In this example, we tried to pass to the `AppendToGraph` function a reference to a wave that did not exist. To find the source of the error, you should use Igor's debugger and set it to break on error (see **Debugging on Error** on page IV-199 for details).

Sophisticated programmers may want to detect and deal with runtime errors on their own. The `GetRTError` function (see page V-271) can be used to check if an error occurred, and optionally to clear the error so that Igor doesn't report it.

Normally, when an error occurs in a built-in function, the built-in function does not post an error but instead returns 0, NaN or an empty string as the function result. As a debugging aid, you can use the `rtFunctionErrors` pragma to force Igor to post an error. See **The `rtFunctionErrors` Pragma** on page IV-51 for details.

### Coercion in Functions

The term “coercion” means the conversion of a value from one numeric precision or numeric type to another. Consider this example:

```
Function foo(awave)
    WAVE/C awave

    Variable/C var1

    var1 = awave[2]*cplx(2,3)
    return real(var1)
End
```

The parameter declaration specifies that `awave` is complex. You can pass any kind of wave you like but it will be coerced into complex before use. For example, if you pass a real valued integer wave the value at point index 2 will be converted to double precision and zero will be used for the imaginary part.

### Operations in Functions

You can call most operations from user-defined functions. To provide this capability, WaveMetrics had to create special code for each operation. Some operations weren't worth the trouble or could cause problems. If an operation can't be invoked from a function, an error message is displayed when the function is compiled. The operations that can't be called from a function are:

---

AppendToLayout	Layout	Modify	OpenProc
PrintGraphs	Quit	See Also	Stack
StackWindows	Tile	TileWindows	

If you need to invoke one of these operations from a user-defined function, use the Execute operation. See **The Execute Operation** on page IV-190.

While Modify can not be called from a function, ModifyGraph, ModifyTable and ModifyLayout can.

You can use the **NewLayout** instead of Layout, the **AppendLayoutObject** instead of AppendToLayout, and the **RemoveLayoutObjects** instead of RemoveFromLayout.

External operations implemented by very old XOPs also can not be called directly from user-defined functions. Again, the solution is to use the Execute operation.

## Updates During Function Execution

An update is an action that Igor performs which consists of:

- Reexecuting formulas for dependent objects whose antecedents have changed (see Chapter IV-9, **Dependencies**)
- Redrawing graphs, tables and Gizmo plots which display waves that have changed
- Redrawing page layouts containing graphs, tables, Gizmo plots, or annotations that have changed
- Redrawing windows that have been uncovered

When no procedure is executing, Igor continually checks whether an update is needed and does an update if necessary.

When a user-defined function is executing, Igor does no automatic updates at all. You can force an update by calling the **DoUpdate** operation (see page V-148). Call DoUpdate if you don't want to wait for the next automatic update which will occur when function execution finishes.

## Aborting Functions

There are two ways to prematurely stop procedure execution: a user abort or a programmed abort. Both stop execution of all procedures, no matter how deeply nested.

You can abort function execution by pressing the **User Abort Key Combinations** or by clicking the Abort button in the status bar. You may need to press the keys down for a while because Igor looks at the keyboard periodically and if you don't press the keys long enough, Igor will not see them.

A user abort does not directly return. Instead it sets a flag that stops loops from looping and then returns using the normal calling chain. For this reason some code will still be executed after an abort but execution should stop quickly. This behavior releases any temporary memory allocations made during execution.

A **programmed abort** occurs during procedure execution according to conditions set by the programmer.

The simplest programmed abort occurs when the **Abort** operation (see page V-18) is executed. Here is an example:

```
if (numCells > 10)
    Abort "Too many cells! Quitting."
endif
// code here doesn't execute if numCells > 10
```

Other programmed aborts can be triggered using the AbortOnRTE and AbortOnValue flow control keywords. The try-catch-endtry flow control construct can be used for catching and testing for aborts. See **Flow Control for Aborts** on page IV-45 for more details.

### Igor Pro 7 Programming Extensions

The following programming features were added in Igor Pro 7. They bring Igor programming closer to the C language. If you use these features, your procedures will not compile in Igor Pro 6.

#### Double and Complex Variable Types

You can use `double` and `complex` in functions as aliases for `Variable` and `Variable/C`:

```
Function foo()  
    double d = 4  
    complex c = cmplx(2,3)  
    Print d,c  
End
```

#### Integer Variable Types

In Igor Pro 7 and later you can use the integer types `int`, `int64` and `uint64` for parameters and local variables in user-defined functions. You can also use `int64` and `uint64` in structures. See **Integer Parameters** on page IV-33 for details.

#### Integer Expressions in User-Defined Functions

Prior to Igor Pro 7, all calculations were performed in double-precision floating point. In Igor Pro 7 or later, Igor uses integer calculations when the destination is an integer type. See **Expression Evaluation** on page IV-36 for details.

#### Inline Parameters in User-Defined Functions

In Igor Pro 7 and later you can declare user-defined functions parameters inline. See **Inline Parameters** on page IV-33 for details.

#### Line Continuation in User-Defined Functions

In user-defined functions in Igor Pro 7 or later, you can use arbitrarily long expressions by including a line continuation character at the very end of a line. See **Line Continuation** on page IV-35 for details.

#### Bit Shift Operators in User-Defined Functions

Igor Pro 7 and later support the bit shift operators `<<` and `>>` on local variables. See **Bit Shift Operators** on page IV-40 for details.

#### Increment and Decrement Operators in User-Defined Functions

In a user-defined function in Igor Pro 7 or later, you can use increment and decrement operators on local variables. See **Increment and Decrement Operators** on page IV-40 for details.

### Legacy Code Issues

This section discusses changes that have occurred in Igor programming over the years. If you are writing new code, you don't need to be concerned with these issues. If you are working with existing code, you may run into some of them.

If you are just starting to learn Igor programming, you have enough to think about already, so it is a good idea to skip this section. Once you are comfortable with the modern techniques described above, come back and learn about these antiquated techniques.

## Old-Style Comments and Compatibility Mode

As of Igor Pro 4.0, the old comment character, a vertical bar (`|`), has been replaced and should no longer be used when writing new procedures. In Igor Pro 4.0 and later, the `|` character is used as the bitwise OR operator (see **Operators** on page IV-5).

In order to run old procedures which use `|` as the comment symbol, Igor supports a compatibility mode. This mode is a property of an experiment. When the current experiment is in compatibility mode, Igor interprets `|` as a comment symbol. Normally, when the current experiment is not in compatibility mode, Igor interprets `|` as bitwise OR.

You put the current experiment in compatibility mode by executing the following on the command line:

```
Silent 100
```

You take the current experiment out of compatibility mode by executing:

```
Silent 101
```

When you execute these commands, Igor automatically recompiles all procedure files in the current experiment using the new mode.

All experiments created pre-Igor 4 are automatically in compatibility mode until you update them and their procedures.

We strongly recommend that you update old experiments and procedures so that you don't need to use compatibility mode. Until you do so, your old experiments will not work with new procedure files that use `|` as bitwise OR. Here are the steps to update an experiment and its procedures:

1. In each old procedure file, replace each `|` symbol that is used to introduce a comment with `//`. Use Edit→Find and Edit→Find Same to find each occurrence of `|`. Do not do a mass replace because you may inadvertently change a `|` symbol used in the old bitwise OR operator (`%|`, which is still supported) or in a string.
2. On the command line, take the experiment out of compatibility mode by executing:  

```
Silent 101
```

 Igor will recompile procedures.
3. If there are any remaining obsolete uses of `|`, Igor will display a compile error dialog. Fix the error and recompile the procedures until you get no more errors.

If you create procedure files that are used by other people (either in your group or for public use) and you want to use the new logic operations, such as `|` (bitwise OR) or `||` (logical OR), which require compatibility mode to be off (`Silent 101`), then you can specify

```
#pragma rtGlobals=2
```

in place of the normal `rtGlobals=1`.

If your procedure file is included in an experiment running in compatibility mode (`Silent 100`) then an alert dialog will be presented that will allow the user to turn compatibility mode off. However, keep in mind that when the procedures are recompiled in the new mode, the user's other procedures will generate errors if they use the obsolete comment symbol.

## Text After Flow Control

Prior to Igor Pro 4, Igor ignored any extraneous text after a flow control statement. Such text was an error, but Igor did not detect it.

Igor now checks for extra text after flow control statements. When found, a dialog is presented asking the user if such text should be considered an error or not. The answer lasts for the life of the Igor session.

Because previous versions of Igor ignored this extra text, it may be common for existing procedure files to have this problem. The text may in many cases simply be a typographic error such as an extra closing parenthesis:

```
if ( a==1 ) )
```

## Chapter IV-3 — User-Defined Functions

---

In other cases, the programmer may have thought they were creating an elseif construct:

```
else if( a==2 )
```

even though the “if(a==2)” part was simply ignored. In some cases this may represent a bug in the programmer’s code but most of the time it is asymptomatic.

### Global Variables Used by Igor Operations

The section **Local Variables Used by Igor Operations** on page IV-56 explains that certain Igor operations create and set certain special local variables. Very old procedure code expects such variables to be created as global variables and must be rewritten.

Also explained in **Local Variables Used by Igor Operations** on page IV-56 is the fact that some operations, such as CurveFit, look for certain special local variables which modify the behavior of the operations. For historic reasons, operations that look for special variables will look for global variables in the current data folder if the local variable is not found. This behavior is unfortunate and may be removed from Igor some day. New programming should use local variables for this purpose.

### Direct Reference to Globals

The section **Accessing Global Variables and Waves** on page IV-59 explains how to access globals from a procedure file. Very old procedure files may attempt to reference globals directly, without using WAVE, NVAR, or SVAR statements. This section explains how to update such procedures.

Here are the steps for converting a procedure file to use the runtime lookup method for accessing globals:

1. Insert the #pragma rtGlobals=3 statement, with no indentation, at or near the top of the procedure in the file.
2. Click the Compile button to compile the procedures.
3. If the procedures use a direct references to access a global, Igor will display an error dialog indicating the line on which the error occurred. Add an NVAR, SVAR or WAVE reference.
4. If you encountered an error in step 3, fix it and return to step 2.

### Overview

When we first created Igor, some time in the last millennium, it supported automation through macros. The idea of the macro was to allow users to collect commands into conveniently callable routines. Igor interpreted and executed each command in a macro as if it were entered in the command line.

WaveMetrics soon realized the need for a faster, more robust technology that would support full-blown programming. This led to the addition of user-defined functions. Because functions are compiled, they execute much more quickly. Also, compilation allows Igor to catch syntactic errors sooner. Functions have a richer set of flow control capabilities and support many other programming refinements.

Over time, the role of macros has diminished in favor of functions. With rare exceptions, new programming should be done using user-defined functions.

Macros are still supported and there are still a few uses in which they are preferred. When you close a graph, table, page layout, Gizmo plot, or control panel, Igor offers to automatically create a window recreation macro which you can later run to recreate the window. You can also ask Igor to automatically create a window style macro using the Window Control dialog. The vast majority of programming, however, should be done using functions.

The syntax and behavior of macros are similar to the syntax and behavior of functions, but the differences can be a source of confusion for someone first learning Igor programming. If you are just starting, you can safely defer reading the rest of this chapter until you need to know more about macros, if that time ever comes.

### Comparing Macros and Functions

Like functions, macros are created by entering text in procedure windows. Each macro has a name, a parameter list, parameter declarations, and a body. Unlike functions, a macro has no return value.

Macros and functions use similar syntax. Here is an example of each. To follow along, open the Procedure window (Windows menu) and type in the macro and function definitions.

```
Macro MacSayHello(name)
    String name

    Print "Hello "+name
End

Function FuncSayHello(name)
    String name

    Print "Hello "+name
End
```

Now click in the command window to bring it to the front.

If you execute the following on the command line

```
MacSayHello("John"); FuncSayHello("Sue")
```

you will see the following output printed in the history area:

```
Hello John
Hello Sue
```

This example may lead you to believe that macros and functions are nearly identical. In fact, there are a lot of differences. The most important differences are:

- Macros automatically appear in the Macros menu. Functions must be explicitly added to a menu, if desired, using a menu definition.
- Most errors in functions are detected when procedures are compiled. Most errors in macros are detected when the macro is executed.

- Functions run a lot faster than macros.
- Functions support wave parameters, for loops, switches, structures, multithreading, and many other features not available in macros.
- Functions have a richer syntax.

If you look in the Macros menu, you will see MacSayHello but not FuncSayHello.

If you execute `FuncSayHello()` on the command line you will see an error dialog. This is because you must supply a parameter. You can execute, for example:

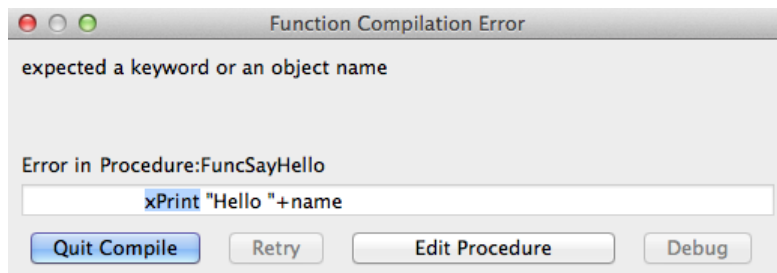

```
FuncSayHello("Sam")
```

On the other hand, if you run MacSayHello from the Macros menu or if you execute `MacSayHello()` on the command line, you will see a dialog that you use to enter the name before continuing:

This is called the “missing parameter dialog”. It is described under **The Missing Parameter Dialog** on page IV-113. Functions can display a similar dialog, called a simple input dialog, with a bit of additional programming.

Now try this: In both procedures, change “Print” to “xPrint”. Then click in the command window. You will see an error dialog complaining about the xPrint in the function:

Click the Edit Procedure button and change “xPrint” back to “Print” in the function but not in the macro. Then click in the command window.

Notice that no error was reported once you fixed the error in the function. This is because only functions are compiled and thus only functions have their syntax completely checked at compile time. Macros are interpreted and most errors are found only when the line in the procedure window in which they occur is executed.

To see this, run the macro by executing “`MacSayHello("Sam")`” on the command line. Igor displays an error dialog:

Notice the outline around the line containing the error. This outline means you can edit the erroneous command. If you change “xPrint” to “Print” in this dialog, the Retry button becomes enabled. If you click Retry, Igor continues execution of the macro. When the macro finishes, take a look at the Procedure window. You will notice that the correction you made in the dialog was put in the procedure window and your “broken” macro is now fixed.

## Macro Syntax

Here is the basic syntax for macros.

```
<Defining keyword> <Name> ( <Input parameter list> ) [:<Subtype>]
    <Input parameter declarations>

    <Local variable declarations>

    <Body code>
End
```

### The Defining Keyword

<Defining keyword> is one of the following:

Defining Keyword	Creates Macro In
Window	Windows menu
Macro	Macros menu
Proc	—

The Window keyword is used by Igor when it automatically creates a window recreation macro. Except in rare cases, you will not write window recreation macros but instead will let Igor create them automatically.

### The Procedure Name

The names of macros must follow the standard Igor naming conventions. Names can consist of up to 31 characters. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names must not conflict with the names of other Igor objects, functions or operations. Names in Igor are case insensitive.

### The Procedure Subtype

You can identify procedures designed for specific purposes by using a subtype. Here is an example:

```
Proc ButtonProc(ctrlName) : ButtonControl
    String ctrlName

    Beep
End
```

Here, “ : ButtonControl” identifies a macro intended to be called when a user-defined button control is clicked. Because of the subtype, this macro is added to the menu of procedures that appears in the Button

Control dialog. When Igor automatically generates a procedure it generates the appropriate subtype. See **Procedure Subtypes** on page IV-193 for details.

## The Parameter List and Parameter Declarations

The parameter list specifies the name for each input parameter. Macros have a limit of 10 parameters.

The parameter declaration must declare the type of each parameter using the keywords `Variable` or `String`. If a parameter is a complex number, it must be declared `Variable/C`.

**Note:** There should be no blank lines or other commands until after all the input parameters are defined. There should be one blank line after the parameter declarations, before the rest of the procedure. Igor will report errors if these conditions are not met.

Variable and string parameters in macros are always passed to a subroutine by value.

When macros are invoked with some or all of their input parameters missing, Igor displays a missing parameter dialog to allow the user to enter those parameters. In the past this has been a reason to use macros. However, as of Igor Pro 4, functions can present a similar dialog to fetch input from the user, as explained under **The Simple Input Dialog** on page IV-132.

## Local Variable Declarations

The input parameter declarations are followed by the local variable declarations if the macro uses local variables. Local variables exist only during the execution of the macro. They can be numeric or string and are declared using the `Variable` or `String` keywords. They can optionally be initialized. Here is an example:

```
Macro Example(p1)
    Variable p1

    // Here are the local variables
    Variable v1, v2
    Variable v3=0
    Variable/C cv1=cplx(0,0)
    String s1="test", s2="test2"

    <Body code>
End
```

If you do not supply explicit initialization, Igor automatically initializes local numeric variables with the value zero and local string variables with the value "".

The name of a local variable is allowed to conflict with other names in Igor although they must be unique within the macro. Clearly if you create a local variable named "sin" then you will be unable to use Igor's built-in sin function within the macro.

You can declare a local variable in any part of a macro with one exception. If you place a variable declaration inside a loop in a macro then the declaration will be executed multiple times and Igor will generate an error since local variable names must be unique.

## Body Code

The local variable declarations are followed by the body code. This table shows what can appear in body code of a macro.

What	Allowed in Macros?	Comments
Assignment statements	Yes	Includes wave, variable and string assignments.
Built-in operations	Yes	
External operations	Yes	
External functions	Yes	

What	Allowed in Macros?	Comments
Calls to user functions	Yes	
Calls to macros	Yes	
if-else-endif	Yes	
if-elseif-endif	No	
switch-case-endswitch	No	
strswitch-case-endswitch	No	
try-catch-endtry	No	
structures	No	
do-while	Yes	
for-endfor	No	
Comments	Yes	Comments start with //.
break	Yes	Used in loop statements.
continue	No	
default	No	
return	Yes, but with no return value.	
Structures	No	

## Conditional Statements in Macros

The conditional if-else-endif statement is allowed in macros. It works the same as in functions. See **If-Else-Endif** on page IV-37.

## Loops in Macros

The do-while loop is supported in macros. It works the same as in functions. See **Do-While Loop** on page IV-42.

## Return Statement in Macros

The return keyword immediately stops executing the current macro. If it was called by another macro, control returns to the calling macro.

A macro has no return value so return is used just to prematurely quit the macro. Most macros will have no return statement.

## Invoking Macros

There are several ways to invoke a macro:

- From the command line
- From the Macros, Windows or user-defined menus
- From another macro
- From a button or other user control

The menu in which a macro appears, if any, is determined by the macro's type and subtype.

This table shows how a macro's type determines the menu that Igor puts it in.

Macro Type	Defining Keyword	Menu
Macro	Macro	Macros menu
Window Macro	Window	Windows menu
Proc	Proc	—

If a macro has a subtype, it may appear in a different menu. This is described under **Procedure Subtypes** on page IV-193. You can put macros in other menus as described in Chapter IV-5, **User-Defined Menus**.

You can not directly invoke a macro from a user function. You can invoke it indirectly, using the **Execute** operation (see page V-177).

## Using \$ in Macros

As shown in the following example, the \$ operator can create references to global numeric and string variables as well as to waves.

```
Macro MacroTest(vStr, sStr, wStr)
    String vStr, sStr, wStr

    $vStr += 1
    $sStr += "Hello"
    $wStr += 1
End
```

```
Variable/G gVar = 0; String/G gStr = ""; Make/O/N=5 gWave = p
MacroTest("gVar", "gStr", "gWave")
```

See **String Substitution Using \$** on page IV-17 for additional examples using \$.

## Waves as Parameters in Macros

The only way to pass a wave to a macro is to pass the name of the wave in a string parameter. You then use the \$ operator to convert the string into a wave reference. For example:

```
Macro PrintWaveStdDev(w)
    String w

    WaveStats/Q $w
    Print V_sdev
End

Make/O/N=100 test=gnoise(1)
Print NamedWaveStdDev("test")
```

## The Missing Parameter Dialog

When a macro that is declared to take a set of input parameters is executed with some or all of the parameters missing, it displays a dialog in which the user can enter the missing values. For example:

```
Macro MacCalcDiag(x,y)
    Variable x=10
    Prompt x, "Enter X component: "      // Set prompt for y param
    Variable y=20
    Prompt y, "Enter Y component: "      // Set prompt for x param

    Print "diagonal=",sqrt(x^2+y^2)
End
```

If invoked from the command line or from another macro with parameters missing, like this:

```
MacCalcDiag()
```

Igor displays the Missing Parameter dialog in which the parameter values can be specified.

The Prompt statements are optional. If they are omitted, the variable name is used as the prompt text.

There must be a blank line after the set of input parameter and prompt declarations and there must not be any blank lines within the set.

The missing parameter dialog supports the creation of pop-up menus as described under **Pop-Up Menus in Simple Dialogs** on page IV-133. One difference is that in a missing parameter dialog, the menu item list can be continued using as many lines as you need. For example:

```
Prompt color, "Select Color", popup "red;green;blue;"  
"yellow;purple"
```

## Macro Errors

Igor can find errors in macros at two times:

- When it scans the macros
- When it executes the macros

After you modify procedure text, scanning occurs when you activate a non-procedure window, click the Compile button or choose Compile from the Macros menu. At this point, Igor is just looking for the names of procedures. The only errors that it detects are name conflicts and ill-formed names. If it finds such an error, it displays a dialog that you use to fix it.

Igor detects other errors when the macro executes. Execution errors may be recoverable or non-recoverable. If a recoverable error occurs, Igor puts up a dialog in which you can edit the erroneous line.

You can fix the error and retry or quit macro execution.

If the error is non-recoverable, you get a similar dialog except that you can't fix the error and retry. This happens with errors in the parameter declarations and errors related to if-else-endif and do-while structures.

## The Silent Option

Normally Igor displays each line of a macro in the command line as it executes the line. This gives you some idea of what is going on. However it also slows macro execution down considerably. You can prevent Igor from showing macro lines as they are executed by using the `Silent 1` command.

You can use `Silent 1` from the command line. It is more common to use it from within a macro. The effect of the `Silent` command ends at the end of the macro in which it occurs. Many macros contain the following line:

```
Silent 1; PauseUpdate
```

## The Slow Option

You can observe the lines in a macro as they execute in the command line. However, for debugging purposes, they often whiz by too quickly. The `Slow` operation slows the lines down. It takes a parameter which controls how much the lines are slowed down. Typically, you would execute something like "`Slow 10`" from the command line and then "`Slow 0`" when you are finished debugging.

You can also use the `Slow` operation from within a macro. You must explicitly invoke "`Slow 0`" to revert to normal behavior. It does not automatically revert at the end of the macro from which it was invoked.

We never use this feature. Instead, we generally use print statements for debugging or we use the Igor symbolic debugger, described in Chapter IV-8, **Debugging**.

## Accessing Variables Used by Igor Operations

A number of Igor's operations return results via variables. For example, the WaveStats operation creates a number of variables with names such as V\_avg, V\_sigma, etc.

When you invoke these operations from the command line, they create global variables in the current data folder.

When you invoke them from a user-defined function, they create local variables.

When you invoke them from a macro, they create local variables unless a global variable already exists. If both a global variable and a local variable exist, Igor uses the local variable.

In addition to creating variables, a few operations, such as CurveFit and FuncFit, check for the existence of specific variables to provide optional behavior. The operations look first for a local variable with a specific name. If the local variable is not found, they then look for a global variable.

## Updates During Macro Execution

An update is an action that Igor performs. It consists of:

- Reexecuting assignments for dependent objects whose antecedents have changed (see Chapter IV-9, **Dependencies**);
- Redrawing graphs and tables which display waves that have changed;
- Redrawing page layouts containing graphs, tables, or annotations that have changed;
- Redrawing windows that have been uncovered.

When no procedure is executing, Igor continually checks whether an update is needed and does an update if necessary.

During macro execution, Igor checks if an update is needed after executing each line. You can suspend checking using the PauseUpdate operation. This is useful when you want an update to occur when a macro finishes but not during the course of the macro's execution.

PauseUpdate has effect only inside a macro. Here is how it is used.

```
Window Graph0() : Graph
    PauseUpdate; Silent 1
    Display /W=(5,42,400,250) w0,w1,w2
    ModifyGraph gFont="Helvetica"
    ModifyGraph rgb(w0)=(0,0,0),rgb(w1)=(0,65535,0),rgb(w2)=(0,0,0)
    <more modifies here...>
End
```

Without the PauseUpdate, Igor would do an update after each modify operation. This would take a long time.

At the end of the macro, Igor automatically reverts the state of update-checking to what it was when this macro was invoked. You can use the ResumeUpdate operation if you want to resume updates before the macro ends or you can call DoUpdate to force an update to occur at a particular point in the program flow. Such explicit updating is rarely needed.

## Aborting Macros

There are two ways to prematurely stop macro execution: a user abort or a programmed abort. Both stop execution of all macros, no matter how deeply nested.

You can abort macro execution by pressing the **User Abort Key Combinations** or by clicking the Abort button in the status bar. You may need to press the keys down for a while because Igor looks at the keyboard periodically and if you don't press the keys long enough, Igor will not see them.

A user abort does not directly return. Instead it sets a flag that stops loops from looping and then returns using the normal calling chain. For this reason some code will still be executed after an abort but execution should stop quickly. This behavior releases any temporary memory allocations made during execution.

A **programmed abort** occurs when the Abort operation is executed. Here is an example:

```
if (numCells > 10)
    Abort "Too many cells! Quitting."
endif
// code here doesn't execute if numCells > 10
```

## Converting Macros to Functions

If you have old Igor procedures written as macros, as you have occasion to revisit them, you can consider converting them to functions. In most cases, this is a good idea. An exception is if the macros are so complex that there would be a substantial risk of introducing bugs. In this case, it is better to leave things as they are.

If you decide to do the conversion, here is a checklist that you can use in the process.

1. Back up the old version of the procedures.
2. Change the defining keyword from Macro or Proc to Function.
3. If the macro contained Prompt statements, then it was used to generate a missing parameter dialog. Change it to generate a simple input dialog as follows:
  - a. Remove the parameters from the parameter list. The old parameter declarations now become local variable declarations.
  - b. Make sure that the local variable for each prompt statement is initialized to some value.
  - c. Add a DoPrompt statement after all of the Prompt statements.
  - d. Add a test on V\_Flag after the DoPrompt statement to see if the user canceled.
4. Look for statements that access global variables or strings and create NVAR and SVAR references for them.
5. Look for any waves used in assignment statements and create WAVE references for them.
6. Compile procedures. If you get an error, fix it and repeat step 6.

### Overview

You can add your own menu items to many Igor menus by writing a menu definition in a procedure window. A simple menu definition looks like this:

```
Menu "Macros"  
    "Load Data File/1"  
    "Do Analysis/2"  
    "Print Report"  
End
```

This adds three items to the Macros menu. If you choose Load Data File or press Command-1 (*Macintosh*) or Ctrl+1 (*Windows*), Igor executes the procedure LoadDataFile which, presumably, you have written in a procedure window. The command executed when you select a particular item is derived from the text of the item. This is an *implicit* specification of the item's execution text.

You can also *explicitly* specify the execution text:

```
Menu "Macros"  
    "Load Data File/1", Beep; LoadWave/G  
    "Do Analysis/2"  
    "Print Report"  
End
```

Now if you choose Load Data File, Igor will execute "Beep; LoadWave/G".

When you choose a user menu item, Igor checks to see if there is execution text for that item. If there is, Igor executes it. If not, Igor makes a procedure name from the menu item string. It does this by removing any characters that are not legal characters in a procedure name. Then it executes the procedure. For example, choosing an item that says

```
"Set Sampling Rate..."
```

executes the SetSamplingRate procedure.

If a procedure window is the top window and if Option (*Macintosh*) or Alt (*Windows*) is pressed when you choose a menu item, Igor tries to find the procedure in the window, rather than executing it.

A menu definition can add submenus as well as regular menu items.

```
Menu "Macros"  
    Submenu "Load Data File"  
        "Text File"  
        "Binary File"  
    End  
  
    Submenu "Do Analysis"  
        "Method A"  
        "Method B"  
    End  
  
    "Print Report"  
End
```

This adds three items to the Macros menu, two submenus and one regular item. You can nest submenus to any depth.

### Menu Definition Syntax

The syntax for a menu definition is:

```
Menu <Menu title string> [, <menu options>]  
    [<Menu help strings>]  
    <Menu item string> [, <menu item flags>] [, <execution text>]  
    [<Item help strings>]
```

```
...
Submenu <Submenu title string>
  [<Submenu help strings>]
  <Submenu item string> [, <execution text>]
  [<Item help strings>]
...
End
End
```

<Menu title string> is the title of the menu to which you want to add items. Often this will be Macros but you can also add items to Analysis, Misc and many other built-in Igor menus, including some sub-menus and the graph marquee and layout marquee menus. If <Menu title string> is not the title of a built-in menu then Igor creates a new main menu on the menu bar.

<Menu options> are optional comma-separated keywords that change the behavior of the menu. The allowed keywords are `dynamic`, `hideable`, and `contextualmenu`. For usage, see **Dynamic Menu Items** (see page IV-120), **HideIgorMenus** (see page V-295), and **PopupContextualMenu** (see page V-640) respectively.

<Menu help strings> specifies the help for the menu title. This is optional. As of Igor7, menu help is not supported and the menu help specification, if present, is ignored.

<Menu item string> is the text to appear for a single menu item, a semicolon-separated string list to define **Multiple Menu Items** (see page IV-122), or **Specialized Menu Item Definitions** (see page IV-123) such as a color, line style, or font menu.

<Menu item flags> are optional flags that modify the behavior of the menu item. The only flag currently supported is `/Q`, which prevents Igor from storing the executed command in the history area. This is useful for menu commands that are executed over and over through a keyboard shortcut. This feature was introduced in Igor Pro 5. Using it will cause errors in earlier versions of Igor. Menus defined with the `contextualmenu` keyword implicitly set all the menu item flags in the entire menu to `/Q`; it doesn't matter whether `/Q` is explicitly set or not, the executed command is not stored in the history area.

<Execution text> is an Igor command to execute for the menu item. If omitted, Igor makes a procedure name from the menu item string and executes that procedure. Use `""` to prevent command execution (useful only with `PopupContextualMenu/N`).

<Item help strings> specifies the help for the menu item. This is optional. As of Igor7, menu help is not supported and the menu item help specification, if present, is ignored.

The Submenu keyword introduces a submenu with <Submenu title string> as its title. The submenu continues until the next End keyword.

<Submenu item string> acts just like <Menu item string>.

### Built-in Menu That Can Be Extended

Here are the titles of built-in Igor menus to which you can add items:

Add Controls	AllTracesPopup	Analysis	Append to Graph
Control	Data	Edit	File
Gizmo	Graph	GraphMarquee	GraphPopup
Help	Layout	LayoutMarquee	Load Waves
Macros	Misc	Statistics	New
Notebook	Open File	Panel	Procedure
Save Waves	Table	TracePopup	

These menu titles must appear in double quotes when used in a menu definition.

Use these menu titles to identify the menu to which you want to append items even if you are working with a version of Igor translated into a language other than English.

The GraphMarquee, LayoutMarquee, TracePopup, AllTracesPopup, and GraphPopup menus are contextual menus. See **Marquee Menus** on page IV-129 and **Trace Menus** on page IV-129. The contextual Graph-Popup appears when you control-click (*Macintosh*) or right-click (*Windows*) in a graph, away from any trace, while in operate mode.

All other Igor menus, including menus added by XOPs, can not accept user-defined items.

The **HideIgorMenus** operation (see page V-295) and the **ShowIgorMenus** operation (see page V-742) hide or show most of the built-in main menus (not the Marquee and Popup menus). User-defined menus that add items to built-in menus are normally not hidden or shown by these operations. When a built-in menu is hidden, the user-defined menu items create a user-defined menu with only user-defined items. For example, this user-defined menu:

```
Menu "Table"  
    "Append Columns to Table...", DoIgorMenu "Table", "Append Columns to Table"  
End
```

will create a Table menu with only one item in it after the HideIgorMenus "Table" command is executed.

To have your user-defined menu items hidden along with the built-in menu items, add the **hideable** keyword after the Menu definition:

```
Menu "Table", hideable  
    "Append Columns to Table...", DoIgorMenu "Table", "Append Columns to Table"  
End
```

### Adding a New Main Menu

You can add an entirely new menu to the main menu bar by using a menu title that is not used by Igor. For example:

```
Menu "Test"  
    "Load Data File"  
    "Do Analysis"  
    "Print Report"  
End
```

### Dynamic Menu Items

In the examples shown so far all of the user-defined menu items are static. Once defined, they never change. This is sufficient for the vast majority of cases and is by far the easiest way to define menu items.

Igor also provides support for dynamic user-defined menu items. A dynamic menu item changes depending on circumstances. The item might be enabled under some circumstances and disabled under others. It might be checked or deselected. Its text may toggle between two states (e.g. "Show Tools" and "Hide Tools").

Because dynamic menus are much more difficult to program than static menus and also slow down Igor's response to a menu-click, we recommend that you keep your use of dynamic menus to a minimum. The effort you expend to make your menu items dynamic may not be worth the time you spend to do it.

For a menu item to be dynamic, you must define it using a string expression instead of the literal strings used so far. Here is an example.

```
Function DoAnalysis()
    Print "Analysis Done"
End

Function ToggleTurboMode()
    Variable prevMode = NumVarOrDefault("root:gTurboMode", 0)
    Variable/G root:gTurboMode = !prevMode
End

Function/S MacrosMenuItem(itemNumber)
    Variable itemNumber

    Variable turbo = NumVarOrDefault("root:gTurboMode", 0)

    if (itemNumber == 1)
        if (strlen(WaveList("*", ";", ""))=0) // any waves exist?
            return "(Do Analysis)" // disabled state
        else
            return "Do Analysis" // enabled state
        endif
    endif

    if (itemNumber == 2)
        if (turbo)
            return "!" + num2char(18) + "Turbo" // Turbo with a check
        else
            return "Turbo"
        endif
    endif
End

Menu "Macros", dynamic
    MacrosMenuItem(1)
    MacrosMenuItem(2), /Q, ToggleTurboMode()
End
```

In this example, the text for the menu item is computed by the `MacrosMenuItem` function. It computes text for item 1 and for item 2 of the menu. Item 1 can be enabled or disabled. Item 2 can be checked or unchecked.

The `dynamic` keyword specifies that the menu definition contains a string expression that needs to be reevaluated each time the menu item is drawn. This rebuilds the user-defined menu each time the user clicks in the menu bar. Under the current implementation, it rebuilds *all* user menus each time the user clicks in the menu bar if *any* user-defined menu is declared dynamic. If you use a large number of user-defined items, the time to rebuild the menu items may be noticeable.

There is another technique for making menu items change. You define a menu item using a string expression rather than a literal string but you do not declare the menu dynamic. Instead, you call the `BuildMenu` operation whenever you need the menu item to be rebuilt. Here is an example:

```
Function ToggleItem1()
    String item1Str = StrVarOrDefault("root:MacrosItem1Str", "On")
    if (CmpStr(item1Str, "On") == 0) // Item is now "On"?

```

```
String/G root:MacroItem1Str = "Off"
else
String/G root:MacroItem1Str = "On"
endif
BuildMenu "Macros"
End

Menu "Macros"
StrVarOrDefault("root:MacroItem1Str","On"), /Q, ToggleItem1()
End
```

Here, the menu item is controlled by the global string variable MacroItem1Str. When the user chooses the menu item, the ToggleItem1 function runs. This function changes the MacroItem1Str string and then calls BuildMenu, which rebuilds the user-defined menu the next time the user clicks in the menu bar. Under the current implementation, it rebuilds *all* user-defined menus if BuildMenu is called for *any* user-defined menu.

### Optional Menu Items

A dynamic user-defined menu item *disappears* from the menu if the menu item string expression evaluates to ""; the remainder of the menu definition line is then ignored. This makes possible a variable number of items in a user-defined menu list. This example adds a menu listing the names of up to 8 waves in the current data folder. If the current data folder contains less than 8 waves, then only those that exist are shown in the menu:

```
Menu "Waves", dynamic
WaveName("",0,4), DoSomething($WaveName("",0,4))
WaveName("",1,4), DoSomething($WaveName("",1,4))
WaveName("",2,4), DoSomething($WaveName("",2,4))
WaveName("",3,4), DoSomething($WaveName("",3,4))
WaveName("",4,4), DoSomething($WaveName("",4,4))
WaveName("",5,4), DoSomething($WaveName("",5,4))
WaveName("",6,4), DoSomething($WaveName("",6,4))
WaveName("",7,4), DoSomething($WaveName("",7,4))
End

Function DoSomething(w)
Wave/Z w

if( WaveExists(w) )
Print "DoSomething: wave's name is "+NameOfWave(w)
endif
End
```

This works because WaveName returns "" if the indexed wave doesn't exist.

Note that each potential item must have a menu definition line that either appears or disappears.

### Multiple Menu Items

A menu item string that contains a semicolon-separated "string list" (see **StringFromList** on page V-866) generates a menu item for each item in the list. For example:

```
Menu "Multi-Menu"
"first item;second item;", DoItem()
End
```

Multi-Menu is a two-item menu. When either item is selected the DoItem procedure is called.

This begs the question: How does the DoItem procedure know which item was selected? The answer is that DoItem must call the **GetLastUserMenuInfo** operation (see page V-265) and examine the appropriate returned variables, usually V\_value (the selected item's one-based item number) or S\_Value (the selected item's text).

The string list can be dynamic, too. The above "Waves" example can be rewritten to handle an arbitrary number of waves using this definition:

```
Menu "Waves", dynamic
  WaveList("*", ";", ""), DoItem()
End

Function DoItem()
  GetLastUserMenuInfo          // Sets S_value, V_value, etc.
  WAVE/Z w= $S_value
  if( WaveExists(w) )
    Print "The wave's name is "+NameOfWave(w)
  endif
End
```

## Consolidating Menu Items Into a Submenu

It is common to have many utility procedure files open at the same time. Each procedure file could add menu items which would clutter Igor's menus. When you create a utility procedure file that adds multiple menu items, it is usually a good idea to consolidate all of the menu items into one submenu. Here is an example.

Let's say we have a procedure file full of utilities for doing frequency-domain data analysis and that it contains the following:

```
Function ParzenDialog()
  ...
End

Function WelchDialog()
  ...
End

Function KaiserDialog()
  ...
End
```

We can consolidate all of the menu items into a single submenu in the Analysis menu:

```
Menu "Analysis"
  Submenu "Windows"
    "Parzen...", ParzenDialog()
    "Welch...", WelchDialog()
    "Kaiser...", KaiserDialog()
  End
End
```

## Specialized Menu Item Definitions

A menu item string that contains certain special values adds a specialized menu such as a color menu.

Only one specialized menu item string is allowed in each menu or submenu, it must be the first item, and it must be the only item.

Menu Item String	Result
"*CHARACTER"	"Character menu, no character is initially selected, font is Geneva, font size is 12.
"*CHARACTER*(Symbol)	"Character menu of Symbol font.
"*CHARACTER*(Symbol,36)	"Character menu of Symbol font in 36 point size.
"*CHARACTER*(,36)	"Character menu of Geneva font in 36 point size.

Menu Item String	Result
"*CHARACTER*(Symbol,36,p)	"Character menu of Symbol font in 36 point size, initial character is p ( $\pi$ ).
"*COLORTABLEPOP*	"Color table menu, initial table is Grays.
"*COLORTABLEPOP*(YellowHot)	"Color table menu, initial table is YellowHot. See <b>CTabList</b> on page V-101 for a list of color tables.
"*COLORTABLEPOP*(YellowHot,1)	"Color table menu with the colors drawn reversed.
"*COLORPOP*	"Color menu, initial color is black.
"*COLORPOP*(0,65535,0)	"Color menu, initial color is green.
"*FONT*	"Font menu, no font is initially selected, does not include "default" as a font choice.
"*FONT*(Arial)	"Font menu, Arial is initially selected.
"*FONT*(Arial,default)	"Font menu with Arial initially selected and including "default" as a font choice.
"*LINESTYLEPOP*	"Line style menu, no line style is initially selected.
"*LINESTYLEPOP*(3)	"Line style menu, initial line style is style=3 (coarse dashed line).
"*MARKERPOP*	"Marker menu, no marker is initially selected.
"*MARKERPOP*(8)	"Marker menu, initial marker is 8 (empty circle).
"*PATTERNPOP*	"Pattern menu, no pattern is initially selected.
"*PATTERNPOP*(1)	"Pattern menu, initial pattern is 1 (SW-NE light diagonal).

To retrieve the selected color, line style, etc., the execution text must be a procedure that calls the **GetLastUserMenuInfo** operation (see page V-265). Here's an example of a color submenu implementation:

```
Menu "Main", dynamic
    "First Item", /Q, Print "First Item"
    Submenu "Color"
        CurrentColor(), /Q, SetSelectedColor() // Must be first submenu item
        // No items allowed here
    End
End

Function InitializeColors()
    NVAR/Z red= root:red
    if(!NVAR_Exists(red))
        Variable/G root:red=65535, root:green=0, root:blue=1, root:alpha=65535
    endif
End

Function/S CurrentColor()
    InitializeColors()
    NVAR red = root:red
    NVAR green = root:green
    NVAR blue = root:blue
    NVAR alpha = root:alpha
    String menuText
    sprintf menuText, "*COLORPOP*(%d,%d,%d,%d)", red, green, blue, alpha
    return menuText
End

Function SetSelectedColor()
    GetLastUserMenuInfo// Sets V_Red, V_Green, V_Blue, V_Alpha, S_value, V_value
```

```

NVAR red = root:red
NVAR green = root:green
NVAR blue = root:blue
NVAR alpha = root:alpha
red = V_Red
green = V_Green
blue = V_Blue
alpha = V_Alpha

Make/O/N=(2,2,4) root:colorSpot
Wave colorSpot = root:colorSpot
colorSpot[] [] [0] = V_Red
colorSpot[] [] [1] = V_Green
colorSpot[] [] [2] = V_Blue
colorSpot[] [] [3] = V_Alpha

CheckDisplayed/A colorSpot
if (V_Flag == 0)
    NewImage colorSpot
endif
End

```

## Special Characters in Menu Item Strings

You can control some aspects of a menu item using special characters. These special characters are based on the behavior of the Macintosh menu manager and are only partially supported on Windows (see **Special Menu Characters on Windows** on page IV-126). They affect user-defined menus in the main menu bar. On Macintosh, but not on Windows, they also affect user-defined pop-up menus in control panels, graphs and simple input dialogs.

By default, special character interpretation is enabled in user-defined menu bar menus and is disabled in user-defined control panel, graph and simple input dialog pop-up menus. This is almost always what you would want. In some cases, you might want to override the default behavior. This is discussed under **Enabling and Disabling Special Character Interpretation** on page IV-127.

This table shows the special characters and their effect if special character interpretation is enabled. See **Special Menu Characters on Windows** on page IV-126 for Windows-specific considerations.

Character	Behavior
/	Creates a keyboard shortcut for the menu item.  The character after the slash defines the item's keyboard shortcut. For example, "Low Pass/1" makes the item "Low Pass" with a keyboard shortcut for Command-1 (Macintosh) or Ctrl-1 (Windows). You can also use function keys. To avoid conflicts with Igor, use the numeric keys and the function keys only. See <b>Keyboard Shortcuts</b> on page IV-127 and <b>Function Keys</b> on page IV-128 for further details.  Keyboard shortcuts are not supported in the graph marquee and layout marquee menus.
-	Creates a divider between menu items.  If a hyphen (minus sign) is the first character in the item then the item will be a disabled divider. This can be a problem when trying to put negative numbers in a menu. Use a leading space character to prevent this. The string "(-" also disables the corresponding divider.
(	Disables the menu item.  If the first character of the item text is a left parenthesis then the item will be disabled.

## Chapter IV-5 — User-Defined Menus

Character	Behavior
!	Adds a mark to the menu item.  If an exclamation point appears in the item, any character after the exclamation point adds a checkmark to the left of the menu item. For example:  <code>"Low Pass!*"</code>  makes an item "Low Pass" with an checkmark to the left.  For compatibility with Igor6, use:  <code>"Low Pass!" + num2char(18)</code>
;	Separates one menu item from the next.  Example: <code>"Item 1;Item 2"</code>

Whereas it is standard practice to use a semicolon to separate items in a pop-up menu in a control panel, graph or simple input dialog, you should avoid using the semicolon in user-defined main-menu-bar menus. It is clearer if you use one item per line. It is also necessary in some cases (see **Menu Definition Syntax** on page IV-118).

If special character interpretation is disabled, these characters will appear in the menu item instead of having their special effect. The semicolon character is treated as a separator of menu items even if special character interpretation is disabled.

### Special Menu Characters on Windows

On Windows, these characters are treated as special in menu bar menus but not in pop-up menus in graphs, control panels, and simple input dialogs. The following table shows which special characters are supported.

Character	Meaning
/	Defines accelerator
-	Divider
(	Disables item
!	Adds mark to item
;	Separates items

In general, Windows does not allow using `Ctrl+<punctuation>` as an accelerator. Therefore, in the following example, the accelerator will not do anything:

```
Menu "Macros"  
  "Test/[" // "/" will not work on Windows.  
End
```

On Windows, you can designate a character in a menu item as a mnemonic keystroke by preceding the character with an ampersand:

```
Menu "Macros"  
  "&Test", Print "This is a test"  
End
```

This designates "T" as the mnemonic keystroke for Test. To invoke this menu item, press Alt and release it, press the "M" key to highlight the Macros menu, and press the "T" key to invoke the Test item. If you hold the Alt key pressed while pressing the "M" and "T" keys and if the active window is a procedure window, Igor will not execute the item's command but rather will bring up the procedure window and display the menu definition. This is a programmer's shortcut.

**Note:** The mnemonic keystroke is not supported on Macintosh. For this reason, if you care about cross-platform compatibility, you should not use ampersands in your menu items.

On Macintosh, if you include a single ampersand in a menu item, it does not appear in the menu item. If you use a double ampersand, it appears as a single ampersand.

### Enabling and Disabling Special Character Interpretation

The interpretation of special characters in menu items can sometimes get in the way. For example, you may want a menu item to say "m/s" or "A<B". With special character interpretation enabled, the first of these would become "m" with "s" as the keyboard shortcut and the second would become "A" in a bold typeface.

Igor provides WaveMetrics-defined escape sequences that allow you to override the default state of special character interpretation. These escape sequences are case sensitive and must appear at the very start of the menu item:

Escape Code	Effect	Example
"\\M0"	Turns special character interpretation off.	"\\M0m/s"
"\\M1"	Turns special character interpretation on.	"\\M1m/s"

The most common use for this will be in a user-defined menu bar menu in which the default state is on and you want to display a special character in the menu item text itself. That is what you can do with the "\\M0" escape sequence.

Another possible use on Macintosh is to create a disabled menu item in a control panel, graph or simple input dialog pop-up menu. The default state of special character interpretation in pop-up menus is off. To disable the item, you either need to turn it on, using "\\M1" or to use the technique described in the next paragraph.

What if we want to include a special character in the menu item itself *and* have a keyboard shortcut for that item? The first desire requires that we turn special character interpretation off and the second requires that we turn it on. The WaveMetrics-defined escape sequence can be extended to handle this. For example:

```
"\\M0:/1:m/s"
```

The initial "\\M0" turns normal special character interpretation off. The first colon specifies that one or more special characters are coming. The /1 makes Command-1 (*Macintosh*) or Ctrl+1 (*Windows*) the keyboard shortcut for this item. The second colon marks the end of the menu commands and starts the regular menu text which is displayed in the menu without special character interpretation. The final result is as shown above.

Any of the special characters can appear between the first colon and the second. For example:

```
Menu "Macros"
  "\\M0:/1:(Cmd-1 on Macintosh, Ctrl+1 on Windows)"
  "\\M0::(Disabled item)"
  "\\M0:!*: (Checked)"
  "\\M0:/2!*:(Cmd-2 on Macintosh, Ctrl+2 on Windows and checked)"
End
```

The \\M escape code affects just the menu item currently being defined. In the following example, special character interpretation is enabled for the first item but not for the second:

```
"\\M1(First item;(Second item"
```

To enable special character interpretation for both items, we need to write:

```
"\\M1(First item;\\M1(Second item"
```

### Keyboard Shortcuts

A keyboard shortcut is a set of one or more keys which invoke a menu item. In a menu item string, a keyboard shortcut is introduced by the / special character. For example:

```
Menu "Macros"
  "Test/1"          // The keyboard shortcut is Cmd-1 (Macintosh)
End                 // or Ctrl+1 (Windows).
```

## Chapter IV-5 — User-Defined Menus

---

All of the plain alphabetic keyboard shortcuts (/A through /Z) are used by Igor.

Numeric keyboard shortcuts (/0 through /9) are available for use in user menu definitions as are Function Keys, described below.

You can define a numeric keyboard shortcut that includes one or more modifier keys. The modifier keys are:

Macintosh:	Shift (S), Option (O), Control (L)
Windows:	Shift (S), Alt (O), Meta (L) (Meta is often called the “Windows key”).

---

For example:

```
Menu "Macros"
  "Test/1"      // Cmd-1, Ctrl+1
  "Test/S1"     // Shift-Cmd-1, Ctrl+Shift+1.
  "Test/O1"     // Option-Cmd-1, Ctrl+Alt+1
  "Test/OS1"    // Option-Shift-Cmd-1, Ctrl+Shift+Alt+1
End
```

### Function Keys

Most keyboards have function keys labeled F1 through F12. In Igor, you can treat a function key as a keyboard shortcut that invokes a menu item.

**Note:** Mac OS X reserves nearly all function keys for itself. In order to use function keys for an application, you must check a checkbox in the Keyboard control panel. Even then the OS will intercept some function keys.

**Note:** On Windows, Igor uses F1 for help-related operations. F1 will not work as a keyboard shortcut on Windows. Also, the Windows OS reserves Ctrl-F4 and Ctrl-F6 for closing and reordering windows. On some systems, F12 is reserved for debugging.

Here is a simple function key example:

```
Menu "Macros"
  "Test/F5"     // The keyboard shortcut is F5.
End
```

As with other keyboard shortcuts, you can specify that one or more modifier keys must be pressed along with the function key. By including the “C” modifier character, you can specify that Command (*Macintosh*) or Ctrl (*Windows*) must also be pressed:

```
Menu "Macros"
  // Function keys without modifiers
  "Test/F5"     // F5

  // Function keys with Shift and/or Option/Alt modifiers
  "Test/SF5"    // Shift-F5 (Macintosh), Shift+F5 (Windows)
  "Test/OF5"    // Option-F5, Alt+F5
  "Test/SOF5"   // Shift-Option-F5, Shift+Alt+F5

  // Function keys with Command (Macintosh) or Ctrl (Windows) modifiers
  "Test/CF5"    // Cmd-F5, Ctrl+F5
  "Test/SCF5"   // Shift-Cmd-F5, Shift-Ctrl-F5
  "Test/OCF5"   // Option-Cmd-F5, Alt-Ctrl-F5
  "Test/OSCF5"  // Option-Shift-Cmd-F5, Alt-Shift-Ctrl-F5

  // Function keys with Ctrl (Macintosh) or Meta (Windows) modifiers
  "Test/LOSCF5" // Control-Option-Shift-Cmd-F5, Meta+Alt+Shift+Ctrl+F5
End
```

Although some keyboards have function keys labeled F13 and higher, they do not behave consistently and are not supported.

## Marquee Menus

Igor has two menus called “marquee menus”. In graphs and page layouts you create a marquee when you drag diagonally. Igor displays a dashed-line box indicating the area of the graph or layout that you have selected. If you click inside the marquee, you get a marquee menu.

You can add your own menu items to a marquee menu by creating a GraphMarquee or LayoutMarquee menu definition. For example:

```
Menu "GraphMarquee"
    "Print Marquee Coordinates", GetMarquee bottom; Print V_left, V_right
End
```

The use of keyboard shortcuts is not supported in marquee menus.

See **Marquee Menu as Input Device** on page IV-151 for details.

## Trace Menus

Igor has two “trace” menus named “TracePopup” and “AllTracesPopup”. When you control-click or right-click in a graph on a trace you get the TracesPopup menu. If you press Shift while clicking, you get the AllTracesPopup (standard menu items in that menu operated on all the traces in the graph). You can append menu items to these menus with Menu “TracePopup” and Menu “AllTracesPopup” definitions.

For example, this code adds an Identify Trace item to the TracePopup contextual menu but not to the AllTracesPopup menu:

```
Menu "TracePopup"
    "Identify Trace", /Q, IdentifyTrace()
End

Function IdentifyTrace()
    GetLastUserMenuInfo
    Print S_graphName, S_traceName
End
```

## GraphPopup Menu

Igor has a contextual menu named "GraphPopup". When you control-click or right-click in a graph away from any trace, you get the GraphPopup menu. You can append menu items to this menu with a GraphPopup menu definition.

For example, the following code adds an "Identify Graph" item to the GraphPopup contextual menu:

```
Menu "GraphPopup"
    "Identify Graph", /Q, IdentifyGraph()
End

Function IdentifyGraph()
    Print WinName(0,1)
End
```

### Popup Contextual Menus

You can create a custom pop-up contextual menu to respond to a control-click or right-click. For an example, see **Creating a Contextual Menu** on page IV-149.

Cursors as Input Device .....	150
Marquee Menu as Input Device .....	151
Polygon as Input Device .....	151

### Overview

The following sections describe the various programming techniques available for getting input from and for interacting with a user during the execution of your procedures. These techniques include:

- The simple input dialog
- Control panels
- Cursors
- Marquee menus

The simple input dialog provides a bare bones but functional user interfaces with just a little programming. In situations where more elegance is required, control panels provide a better solution.

### Modal and Modeless User Interface Techniques

Before the rise of the graphical user interface, computer programs worked something like this:

1. The program prompts the user for input.
2. The user enters the input.
3. The program does some processing.
4. Return to step 1.

In this model, the program is in charge and the user must respond with specific input at specific points of program execution. This is called a “modal” user interface because the program has one mode in which it will only accept specific input and another mode in which it will only do processing.

The Macintosh changed all this with the idea of event-driven programming. In this model, the computer waits for an event such as a mouse click or a key press and then acts on that event. The user is in charge and the program responds. This is called a “modeless” user interface because the program will accept any user action at any time.

You can use both techniques in Igor. Your program can put up a modal dialog asking for input and then do its processing or you can use control panels to build a sophisticated modeless event-driven system.

Event-driven programming is quite a bit more work than dialog-driven programming. You have to be able to handle user actions in any order rather than progressing through a predefined sequence of steps. In real life, a combination of these two methods is often used.

### The Simple Input Dialog

The simple input dialog is a way by which a function can get input from the user in a modal fashion. It is very simple to program and is also simple in appearance.

A simple input dialog is presented to the user when a DoPrompt statement is executed in a function. Parameters to DoPrompt specify the title for the dialog and a list of local variables. For each variable, you must include a Prompt statement that provides the text label for the variable.

Generally, the simple input dialog is used in conjunction with routines that run when the user chooses an item from a menu. This is illustrated in the following example which you can type into the procedure window of a new experiment:

```
Menu "Macros"  
    "Calculate Diagonal...", CalcDiagDialog()  
End  
  
Function CalcDiagDialog()  
    Variable x=10,y=20  
    Prompt x, "Enter X component: " // Set prompt for x param  
    Prompt y, "Enter Y component: " // Set prompt for y param  
    DoPrompt "Enter X and Y", x, y
```

```

    if (V_Flag)
        return -1                // User canceled
    endif

    Print "Diagonal=",sqrt(x^2+y^2)
End

```

If you run the CalcDiagDialog function, you see the following dialog:

If the user presses Continue without changing the default values, “Diagonal= 22.3607” is printed in the history area of the command window. If the user presses Cancel, nothing is printed because DoPrompt sets the V\_Flag variable to 1 in this case.

The simple input dialog allows for up to 10 numeric or string variables. When more than 5 items are used, the dialog uses two columns and you may have to limit the length of your Prompt text.

The simple input dialog is unique in that you can enter not only literal numbers or strings but also numeric expressions or string expressions. Any literal strings that you enter must be quoted.

If the user presses the Help button, Igor searches for a help topic with a name derived from the dialog title. If such a help topic is not found, then generic help about the simple input dialog is presented. In both cases, the input dialog remains until the user presses either Continue or Cancel.

## Pop-Up Menus in Simple Dialogs

The simple input dialog supports pop-up menus as well as text items. The pop-up menus can contain an arbitrary list of items such as a list of wave names. To use a pop-up menu in place of the normal text entry item in the dialog, you use the following syntax in the prompt declaration:

```
Prompt <variable name>, <title string>, popup <menu item list>
```

The popup keyword indicates that you want a pop-up menu instead of the normal text entry item. The menu list specifies the items in the pop-up menu separated by semicolons. For example:

```
Prompt color, "Select Color", popup "red;green;blue;"
```

If the menu item list is too long to fit on one line, you can compose the list in a string variable like so:

```
String stmp= "red;green;blue;"
stmp += "yellow;purple"
Prompt color, "Select Color", popup stmp
```

The pop-up menu items support the same special characters as the user-defined menu definition (see **Special Characters in Menu Item Strings** on page IV-125) except that items in pop-up menus are limited to 50 characters, keyboard shortcuts are not supported, and special characters are disabled by default.

You can use pop-up menus with both numeric and string parameters. When used with numeric parameters the number of the item chosen is placed in the variable. Numbering starts from one. When used with string parameters the text of the chosen item is placed in the string variable.

There are a number of functions, such as the **WaveList** function (see page V-928) and the **TraceNameList** function (see page V-904), that are useful in creating pop-up menus.

## Chapter IV-6 — Interacting with the User

---

To obtain a menu item list of all waves in the current data folder, use:

```
WaveList("*", ";", "")
```

To obtain a menu item list of all waves in the current data folder whose names end in “\_X”, use:

```
WaveList("*_X", ";", "")
```

To obtain a menu item list of all traces in the top graph, use:

```
TraceNameList("", ";", 1)
```

For a list of all contours in the top graph, use ContourNameList. For a list of all images, use ImageNameList. For a list of waves in a table, use WaveList.

This next example creates two pop-up menus in the simple input dialog.

```
Menu "Macros"  
    "Color Trace...", ColorTraceDialog()  
End  
  
Function ColorTraceDialog()  
    String traceName  
    Variable color=3  
    Prompt traceName, "Trace", popup, TraceNameList("", ";", 1)  
    Prompt color, "Color", popup, "red;green;blue"  
    DoPrompt "Color Trace", traceName, color  
    if( V_Flag )  
        return 0          // user canceled  
    endif  
  
    if (color == 1)  
        ModifyGraph rgb($traceName)=(65000, 0, 0)  
    elseif(color == 2)  
        ModifyGraph rgb($traceName)=(0, 65000, 0)  
    elseif(color == 3)  
        ModifyGraph rgb($traceName)=(0, 0, 65000)  
    endif  
End
```

If you choose Color Trace from the Macros menu, Igor displays the simple input dialog with two pop-up menus. The first menu contains a list of all traces in the target window which is assumed to be a graph. The second menu contains the items red, green and blue with blue (item number 3) initially chosen.

After you choose the desired trace and color from the pop-up menus and click the Continue button, the function continues execution. The string parameter traceName will contain the name of the trace chosen from the first pop-up menu. The numeric parameter color will have a value of 1, 2 or 3, corresponding to red, green and blue.

In the preceding example, we needed a trace name to pass to the ModifyGraph operation. In another common situation, we need a wave reference to operate on. For example:

```

Menu "Macros"
    "Smooth Wave In Graph...",SmoothWaveInGraphDialog()
End

Function SmoothWaveInGraphDialog()
    String traceName
    Prompt traceName,"Wave",popup,TraceNameList("",",",1)
    DoPrompt "Smooth Wave In Graph",traceName

    WAVE w = TraceNameToWaveRef("", traceName)
    Smooth 5, w
End

```

The traceName parameter alone is not sufficient to specify which wave we want to smooth because it does not identify in which data folder the wave resides. The TraceNameToWaveRef function returns a wave reference which solves this problem.

## Saving Parameters for Reuse

It is possible to write a procedure that presents a simple input dialog with default values for the parameters saved from the last time it was invoked. To accomplish this, we use global variables to store the values between calls to the procedure. Here is an example that saves one numeric and one string variable.

```

Function TestDialog()
    String saveDF = GetDataFolder(1)
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S :TestDialog

    Variable num = NumVarOrDefault("gNum", 42)
    Prompt num, "Enter a number"
    String str = StrVarOrDefault("gStr", "Hello")
    Prompt str, "Enter a string"
    DoPrompt "test",num,str

    Variable/G gNum = num          // Save for next time
    String/G gStr = str

    // Put function body here
    Print num,str

    SetDataFolder saveDF
End

```

This example illustrates the NumVarOrDefault and StrVarOrDefault functions. These functions return the value of a global variable or a default value if the global variable does not exist. 42 is the default value for gNum. NumVarOrDefault returns 42 if gNum does not exist. If gNum does exist, it returns the value of gNum. Similarly, “Hello” is the default value for gStr. StrVarOrDefault returns “Hello” if gStr does not exist. If gStr does exist, it returns the value of gStr.

## Multiple Simple Input Dialogs

Prompt statements can be located anywhere within the body of a function and they do not need to be grouped together, although it will aid code readability if associated Prompt and DoPrompt code is kept together. Functions may contain multiple DoPrompt statements, and Prompt statements can be reused or redefined.

The following example illustrates multiple simple input dialogs and prompt reuse:

```

Function Example()
    Variable a= 123
    Variable/C ca= cmplx(3,4)
    String s

    Prompt a,"Enter a value"
    Prompt ca,"Enter complex value"

```

```
Prompt s,"Enter a string", popup "red;green;blue"
DoPrompt "Enter Values",a,s,ca
if(V_Flag)
    Abort "The user pressed Cancel"
endif

Print "a= ",a,"s= ",s,"ca=",ca

Prompt a,"Enter a again please"
Prompt s,"Type a string"
DoPrompt "Enter Values Again", a,s

if(V_Flag)
    Abort "The user pressed Cancel"
endif

Print "Now a=",a," and s=",s
End
```

When this function is executed, it produces two simple input dialogs, one after the other after the user clicks Continue.

### Help For Simple Input Dialogs

You can create, for each simple input dialog, custom help that appears when the user clicks the Help button. You do so by providing a custom help file with topics that correspond to the titles of your dialogs as specified in the DoPrompt commands.

If there is no exactly matching help topic or subtopic for a given dialog title, Igor munges the presumptive topic by replacing underscore characters with spaces and inserting spaces before capital letters in the interior of the topic. For example, if the dialog title is “ReallyCoolFunction”, and there is no matching help topic or subtopic, Igor looks for a help topic or subtopic named “Really Cool Function”.

See **Creating Your Own Help File** on page IV-241 for information on creating custom help files.

## Displaying an Open File Dialog

You can display an Open File dialog to allow the user to choose a file to be used with a subsequent command. For example, the user can choose a file which you will then use in a **LoadWave** command. The Open File dialog is displayed using an **Open/D/R** command. Here is an example:

```
Function/S DoOpenFileDialog()
    Variable refNum
    String message = "Select a file"
    String outputPath
    String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
    fileFilters += "All Files:.*;"

    Open /D /R /F=fileFilters /M=message refNum
    outputPath = S_fileName

    return outputPath    // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays an Open File dialog. If the user chooses a file and clicks the Open button, the Open operation returns the full path to the file in the S\_fileName output string variable. If the user cancels, Open sets S\_fileName to "".

The /M flag is used to set the prompt message. As of OS X 10.11, Apple no longer shows the prompt message in the Open File dialog. It continues to work on Windows.

The /F flag is used to control the file filter which determines what kinds of files the user can select. This is explained further under **Open File Dialog File Filters**.

### Prompt Does Not Work on Macintosh

As of OS X 10.11, Apple no longer shows the title bar in the Open File, Choose Folder, and Create Folder dialogs. Consequently, the prompt specified by the /M flag, which was displayed in the title bar, is no longer visible. Apple still shows the title bar in the Save File dialog.

### Displaying a Multi-Selection Open File Dialog

You can display an Open File dialog to allow the user to choose multiple files to be used with subsequent commands. The multi-selection Open File dialog is displayed using an **Open/D/R/MULT=1** command. The list of files selected is returned via S\_fileName in the form of a carriage-return-delimited list of full paths.

Here is an example:

```
Function/S DoOpenMultiFileDialog()
  Variable refNum
  String message = "Select one or more files"
  String outputPaths
  String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
  fileFilters += "All Files:.*;"

  Open /D /R /MULT=1 /F=fileFilters /M=message refNum
  outputPaths = S_fileName

  if (strlen(outputPaths) == 0)
    Print "Cancelled"
  else
    Variable numFilesSelected = ItemsInList(outputPaths, "\r")
    Variable i
    for(i=0; i<numFilesSelected; i+=1)
      String path = StringFromList(i, outputPaths, "\r")
      Printf "%d: %s\r", i, path
    endfor
  endif

  return outputPaths // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays an Open File dialog. Because /MULT=1 was used, if the user chooses one or more files and clicks the Open button, the Open operation returns the list of full paths to files in the S\_fileName output string variable. If the user cancels, Open sets S\_fileName to "".

The list of full paths is delimited with a carriage return character, represented by "\r" in the example above. We use carriage return as the delimiter because the customary delimiter, semicolon, is a legal character in a Macintosh file name.

The /M flag is used to set the prompt message. As of OS X 10.11, Apple no longer shows the prompt message in the Open File dialog. It continues to work on Windows.

The /F flag is used to control the file filter which determines what kinds of files the user can select. This is explained further under **Open File Dialog File Filters**.

### Open File Dialog File Filters

The **Open** operation displays the open file dialog if you use the /D/R flags or if the file to be opened is not fully specified using the pathName and fileNameStr parameters. The Open File dialog includes a file filter menu that allows the user to choose the type of file to be opened. By default this menu contains "Plain Text Files" and "All Files". You can use the /T and /F flags to override the default filter behavior.

The /T flag uses obsolescent Macintosh file types or file name extensions consisting of a dot plus three characters. The /F flag, added in Igor Pro 6.10, supports file name extensions only (not Macintosh file types) and extensions can be from one to 31 characters. Procedures written for Igor Pro 6.10 or later should use the /F flag in most cases but can use /T or both /T and /F. Procedures that must run with Igor Pro 6.0x and earlier must use the /T flag.

Using the /T=typeStr flag, you specify acceptable Macintosh-style file types represented by four-character codes (e.g., "TEXT") or acceptable three-character file name extensions (e.g., ".txt"). The pattern "???" means "any type of file" and is represented by "All Files" in the filter menu.

typeStr may contain multiple file types or extensions (e.g., "TEXTEPSF???" or ".txt.eps???"). Each file type or extension must be exactly four characters in length. Consequently the /T flag can accommodate only three-character file name extensions. Each file type or extension creates one entry in the Open File dialog filter menu.

If you use the /T flag, the Open operation automatically adds a filter for All Files ("???" ) if you do not add one explicitly.

Igor maps Macintosh file types to extensions. For example, if you specify /T="TEXT", you can open files with the extension ".txt" as well as any file whose Macintosh file type property is "TEXT". Igor does similar mappings for other extensions. See **File Types and Extensions** on page III-404 for details.

Using the /F=fileFilterStr flag, you specify a filter menu string plus acceptable file name extensions for each filter. fileFilterStr specifies one or more filters in a semicolon-separated list. For example, this specifies three filters:

```
String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
fileFilters += "HTML Files (*.htm,*.html):.htm,.html;"
fileFilters += "All Files:.*;"
Open /F=fileFilters . . .
```

Each file filter consists of a filter menu string (e.g., "Data Files") followed by a colon, followed by one or more file name extensions (e.g., ".txt,.dat,.csv") followed by a semicolon. The syntax is rigid - no extra characters are allowed and the semicolons shown above are required. In this example the filter menu would contain "Data Files" and would accept any file with a ".txt", ".dat", or ".csv" extension. ".\*" creates a filter that accepts any file.

If you use the /F flag, it is up to you to add a filter for All Files as shown above. It is recommended that you do this.

## Displaying a Save File Dialog

You can display a Save File dialog to allow the user to choose a file to be created or overwritten by a subsequent command. For example, the user can choose a file which you will then create or overwrite via a Save command. The Save File dialog is displayed using an **Open/D** command. Here is an example:

```
Function/S DoSaveFileDialog()
    Variable refNum
    String message = "Save a file"
    String outputPath
    String fileFilters = "Data Files (*.txt):.txt;"
    fileFilters += "All Files:.*;"

    Open /D /F=fileFilters /M=message refNum
    outputPath = S_fileName

    return outputPath    // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays a Save File dialog. If the user chooses a file and clicks the Save button, the Open operation returns the full path to the file in the S\_fileName output string variable. If the user cancels, Open sets S\_fileName to "".

The /M flag is used to set the prompt message. As of OS X 10.11, Apple no longer shows the prompt message in the Save File dialog. It continues to work on Windows.

The /F flag is used to control the file filter which determines what kinds of files the user can create. This is explained further under **Save File Dialog File Filters**.

### Save File Dialog File Filters

The Save File dialog includes a file filter menu that allows the user to choose the type of file to be saved. By default this menus contain "Plain Text File" and, on Windows only, "All Files". You can use the /T and /F flags to override the default filter behavior.

The /T and /F flags work as explained under Open File Dialog File Filters. Using the /F flag for a Save File dialog, you would typically specify just one filter plus All Files, like this:

```
String fileFilters = "Data File (*.dat):.dat;"
```

```
fileFilters += "All Files:.*;"
```

```
Open /F=fileFilters . . .
```

The file filter chosen in the Save File dialog determines the extension for the file being saved. For example, if the "Plain Text Files" filter is selected, the ".txt" extension is added if you don't explicitly enter it in the File Name edit box. However if you select the "All Files" filter then no extension is automatically added and the final file name is whatever you enter in the File Name edit box. You should include the "All Files" filter if you want the user to be able to specify a file name with any extension. If you want to force the file name extension to an extension of your choice rather than the user's, omit the "All Files" filter.

## Using Open in a Utility Routine

To be as general and useful as possible, a utility routine that acts on a file should have a pathName parameter and a fileName parameter, like this:

```
Function ShowFileInfo(pathName, fileName)
    String pathName    // Name of symbolic path or "" for dialog.
    String fileName    // File name or "" for dialog.

    <Show file info here>
End
```

This provides flexibility to the calling function. The caller can supply a valid symbolic path name and a simple leaf name in fileName, a valid symbolic path name and a partial path in fileName, or a full path in fileName in which case pathName is irrelevant.

If pathName and fileName fully specify the file of interest, you want to just open the file and perform the requested action. However, if pathName and fileName do not fully specify the file of interest, you want to display an Open File dialog so the user can choose the file. This is accomplished by using the **Open** operation's /D=2 flag.

With /D=2, if pathName and fileName fully specify the file, the Open operation merely sets the S\_fileName output string variable to the full path to the file. If pathName and fileName do not fully specify the file, Open displays an Open File dialog and then sets the S\_fileName output string variable to the full path to the file. If the user cancels the Open File dialog, Open sets S\_fileName to "". In all cases, Open/D=2 just sets S\_fileName and does not actually open the file.

If pathName and fileName specify an alias (*Macintosh*) or shortcut (*Windows*), Open/D=2 returns the file referenced by the alias or shortcut.

## Chapter IV-6 — Interacting with the User

---

Here is how you would use Open /D=2.

```
Function ShowFileInfo(pathName, fileName)
    String pathName      // Name of symbolic path or "" for dialog.
    String fileName      // File name or "" for dialog.

    Variable refNum

    Open /D=2 /R /P=$pathName refNum as fileName    // Sets S_fileName

    if (strlen(S_fileName) == 0)
        Print "ShowFileInfo was canceled"
    else
        String fullPath = S_fileName
        Print fullPath
        Open /R refNum as fullPath
        FStatus refNum    // Sets S_info
        Print S_info
        Close refNum
    endif
End
```

In this case, we wanted to open the file for reading. To create a file and open it for writing, omit /R from both calls to Open.

### Pause For User

The **PauseForUser** operation (see page V-627) allows an advanced programmer to create a more sophisticated semimodal user interface. When you invoke it from a procedure, Igor suspends procedure execution and the user can interact with graph, table or control panel windows using the mouse or keyboard. Execution continues when the user kills the main window specified in the **PauseForUser** command.

**PauseForUser** is fragile because it attempts to create a semi-modal mode which is not supported by the operating system. For code that needs to be bulletproof, use an alternative modeless approach, if possible.

Pausing execution can serve two purposes. First, the programmer can pause function execution so that the user can, for example, adjust cursors in a graph window before continuing with a curve fit. In this application, the programmer creates a control panel with a continue button that the user presses after adjusting the cursors in the target graph. Pressing the continue button kills the host control panel (see example below).

In the second application, the programmer may wish to obtain input from the user in a more sophisticated manner than can be done using DoPrompt commands. This method uses a control panel as the main window with no optional target window. It is similar to the control panel technique shown above, except that it is modal.

Following are some examples of how you can use the **PauseForUser** operation (see page V-627) in your own user functions.

#### PauseForUser Simple Cursor Example

This example shows how to allow the user to adjust cursors on a graph while a procedure is executing. Most of the work is done by the UserCursorAdjust function. UserCursorAdjust is called by the Demo function which first creates a graph and shows the cursor info panel.

This example illustrates two modes of **PauseForUser**. When called with autoAbortSecs=0, UserCursorAdjust calls **PauseForUser** without the /C flag in which case **PauseForUser** retains control until the user clicks the Continue button.

When called with autoAbortSecs>0, UserCursorAdjust calls **PauseForUser/C**. This causes **PauseForUser** to handle any pending events and then return to the calling procedure. The procedure checks the V\_flag variable, set by **PauseForUser**, to determine when the user has finished interacting with the graph. **PauseFo-**

rUser/C, which requires Igor Pro 6.1 or later, is for situations where you want to do something while the user interacts with the graph.

To try this yourself, copy and paste all three routines below into the procedure window of a new experiment and then run the Demo function with a value of 0 and again with a value such as 30.

```
Function UserCursorAdjust (graphName, autoAbortSecs)
    String graphName
    Variable autoAbortSecs

    DoWindow/F $graphName                // Bring graph to front
    if (V_Flag == 0)                      // Verify that graph exists
        Abort "UserCursorAdjust: No such graph."
        return -1
    endif

    NewPanel /K=2 /W=(187,368,437,531) as "Pause for Cursor"
    DoWindow/C tmp_PauseforCursor        // Set to an unlikely name
    AutoPositionWindow/E/M=1/R=$graphName // Put panel near the graph

    DrawText 21,20,"Adjust the cursors and then"
    DrawText 21,40,"Click Continue."
    Button button0,pos={80,58},size={92,20},title="Continue"
    Button button0,proc=UserCursorAdjust_ContButtonProc
    Variable didAbort= 0
    if( autoAbortSecs == 0 )
        PauseForUser tmp_PauseforCursor,$graphName
    else
        SetDrawEnv textyjust= 1
        DrawText 162,103,"sec"
        SetVariable sv0,pos={48,97},size={107,15},title="Aborting in "
        SetVariable sv0,limits={-inf,inf,0},value= _NUM:10
        Variable td= 10,newTd
        Variable t0= ticks
        Do
            newTd= autoAbortSecs - round((ticks-t0)/60)
            if( td != newTd )
                td= newTd
                SetVariable sv0,value= _NUM:newTd,win=tmp_PauseforCursor
                if( td <= 10 )
                    SetVariable sv0,valueColor= (65535,0,0),win=tmp_PauseforCursor
                endif
            endif
            if( td <= 0 )
                DoWindow/K tmp_PauseforCursor
                didAbort= 1
                break
            endif

            PauseForUser/C tmp_PauseforCursor,$graphName
        while(V_flag)
    endif
    return didAbort
End

Function UserCursorAdjust_ContButtonProc(ctrlName) : ButtonControl
    String ctrlName

    DoWindow/K tmp_PauseforCursor        // Kill panel
End

Function Demo(autoAbortSecs)
```

```
Variable autoAbortSecs

Make/O jack;SetScale x,-5,5,jack
jack= exp(-x^2)+gnoise(0.1)
DoWindow Graph0
if( V_Flag==0 )
    Display jack
    ShowInfo
endif

if (UserCursorAdjust("Graph0",autoAbortSecs) != 0)
    return -1
endif

if (strlen(CsrWave(A))>0 && strlen(CsrWave(B))>0) // Cursors are on trace?
    CurveFit gauss,jack[pcsr(A),pcsr(B)] /D
endif
End
```

### PauseForUser Advanced Cursor Example

Now for something a bit more complex. Here we modify the preceding example to include a Cancel button. For this, we need to return information about which button was pressed. Although we could do this by creating a single global variable in the root data folder, we use a slightly more complex technique using a temporary data folder. This technique is especially useful for more complex panels with multiple output variables because it eliminates name conflict issues. It also allows much easier clean up because we can kill the entire data folder and everything in it with just one operation.

```
Function UserCursorAdjust(graphName)
    String graphName

    DoWindow/F $graphName // Bring graph to front
    if (V_Flag == 0) // Verify that graph exists
        Abort "UserCursorAdjust: No such graph."
        return -1
    endif

    endif
    CurveFit gauss,jack[pcsr(A),pcsr(B)] /D
End

```

### PauseForUser Control Panel Example

This example illustrates using a control panel as a modal dialog via `PauseForUser`. This technique is useful when you need a more sophisticated modal user interface than provided by the simple input dialog.

We started by manually creating a control panel. When the panel design was finished, we closed it to create a recreation macro. We then used code copied from the recreation macro in the `DoMyInputPanel` function and deleted the recreation macro.

```

Function UserGetInputPanel_ContButton(ctrlName) : ButtonControl
    String ctrlName

    DoWindow/K tmp_GetInputPanel    // kill self
End

// Call with these variables already created and initialized:
//     root:tmp_PauseForUserDemo:numvar
//     root:tmp_PauseForUserDemo:strvar
Function DoMyInputPanel()
    NewPanel /W=(150,50,358,239)
    DoWindow/C tmp_GetInputPanel    // set to an unlikely name
    DrawText 33,23,"Enter some data"
    SetVariable setvar0,pos={27,49},size={126,17},limits={-Inf,Inf,1}
    SetVariable setvar0,value= root:tmp_PauseForUserDemo:numvar
    SetVariable setvar1,pos={24,77},size={131,17},limits={-Inf,Inf,1}
    SetVariable setvar1,value= root:tmp_PauseForUserDemo:strvar
    Button button0,pos={52,120},size={92,20}
    Button button0,proc=UserGetInputPanel_ContButton,title="Continue"

    PauseForUser tmp_GetInputPanel
End

Function Demo1()
    NewDataFolder/O root:tmp_PauseForUserDemo
    Variable/G root:tmp_PauseForUserDemo:numvar= 12
    String/G root:tmp_PauseForUserDemo:strvar= "hello"

```

```
DoMyInputPanel ()

NVAR numvar= root:tmp_PauseForUserDemo:numvar
SVAR strvar= root:tmp_PauseForUserDemo:strvar

printf "You entered %g and %s\r",numvar,strvar

KillDataFolder root:tmp_PauseForUserDemo
End
```

## Progress Windows

Sometimes when performing a long calculation, you may want to display an indication that the calculation is in progress, perhaps showing how far along it is, and perhaps providing an abort button. As of Igor Pro 6.1, you can use a control panel window for this task using the **DoUpdate** /E and /W flags and the mode=4 setting for **ValDisplay**.

DoUpdate /W=win /E=1 marks the specified window as a progress window that can accept mouse events while user code is executing. The /E flag need be used only once to mark the panel but it does not hurt to use it in every call. This special state of the control panel is automatically cleared when procedure execution finishes and Igor's outer loop again runs.

For a window marked as a progress window, DoUpdate sets V\_Flag to 2 if a mouse up happened in a button since the last call. When this occurs, the full path to the subwindow containing the button is stored in S\_path and the name of the control is stored in S\_name.

Here is a simple example that puts up a progress window with a progress bar and a Stop button. Try each of the four input flag combinations.

```
//      ProgressDemo1 (0,0)
//      ProgressDemo1 (1,0)
//      ProgressDemo1 (0,1)
//      ProgressDemo1 (1,1)
Function ProgressDemo1(indefinite, useIgorDraw)
    Variable indefinite
    Variable useIgorDraw// True to use Igor's own draw method rather than native

    NewPanel /N=ProgressPanel /W=(285,111,739,193)
    ValDisplay valdisp0,pos={18,32},size={342,18}
    ValDisplay valdisp0,limits={0,100,0},barmisc={0,0}
    ValDisplay valdisp0,value= _NUM:0
    if( indefinite )
        ValDisplay valdisp0,mode= 4// candy stripe
    else
        ValDisplay valdisp0,mode= 3// bar with no fractional part
    endif
    if( useIgorDraw )
        ValDisplay valdisp0,highColor=(0,65535,0)
    endif
    Button bStop,pos={375,32},size={50,20},title="Stop"
    DoUpdate /W=ProgressPanel /E=1// mark this as our progress window

    Variable i,imax= indefinite ? 10000 : 100
    for(i=0;i<imax;i+=1)
        Variable t0= ticks
        do
            while( ticks < (t0+3) )
                if( indefinite )
                    ValDisplay valdisp0,value= _NUM:1,win=ProgressPanel
                else
                    ValDisplay valdisp0,value= _NUM:i+1,win=ProgressPanel
```

```

        endif
        DoUpdate /W=ProgressPanel
        if( V_Flag == 2 )// we only have one button and that means stop
            break
        endif
    endfor
    KillWindow ProgressPanel
End

```

When performing complex calculations, it is often difficult to insert DoUpdate calls in the code. In this case, you can use a window hook that responds to event #23, spinUpdate. This is called at the same time that the beachball icon in the status bar spins. The hook can then update the window's control state and then call DoUpdate/W on the window. If the window hook returns non-zero, then an abort is performed. If you desire a more controlled quit, you might set a global variable that your calculation code can test

The following example provides an indefinite indicator and an abort button. Note that if the abort button is pressed, the window hook kills the progress window since otherwise the abort would cause the window to remain.

```

// Example: ProgressDemo2(100)
Function ProgressDemo2(nloops)
    Variable nloops

    Variable useIgorDraw=0 // set true for Igor draw method rather than native

    NewPanel/FLT /N=myProgress/W=(285,111,739,193) as "Calculating..."
    ValDisplay valdisp0,pos={18,32},size={342,18}
    ValDisplay valdisp0,limits={0,100,0},barmisc={0,0}
    ValDisplay valdisp0,value= _NUM:0
    ValDisplay valdisp0,mode=4 // candy stripe
    if( useIgorDraw )
        ValDisplay valdisp0,highColor=(0,65535,0)
    endif
    Button bStop,pos={375,32},size={50,20},title="Abort"
    SetActiveSubwindow _endfloat_
    DoUpdate/W=myProgress/E=1 // mark this as our progress window

    SetWindow myProgress,hook(spinner)=MySpinnHook

    Variable t0= ticks,i
    for(i=0;i<nloops;i+=1)
        PerformLongCalc(1e6)
    endfor
    Variable timeperloop= (ticks-t0)/(60*nloops)

    KillWindow myProgress

    print "time per loop=",timeperloop
End

Function MySpinnHook(s)
    STRUCT WMWinHookStruct &s

    if( s.eventCode == 23 )
        ValDisplay valdisp0,value= _NUM:1,win=$s.winName
        DoUpdate/W=$s.winName
        if( V_Flag == 2 ) // we only have one button and that means abort
            KillWindow $s.winName
            return 1
        endif
    endif
endif

```

```
    return 0
End

Function PerformLongCalc(nmax)
    Variable nmax

    Variable i,s
    for(i=0;i<nmax;i+=1)
        s+= sin(i/nmax)
    endfor
End
```

## Control Panels and Event-Driven Programming

The CalcDiagDialog function shown under **The Simple Input Dialog** on page IV-132 creates a modal dialog. “Modal” means that the function retains complete control until the user clicks Cancel or Continue. The user can not activate another window or choose a menu item until the dialog is dismissed.

This section shows how to implement the same functionality using a control panel as a modeless dialog. “Modeless” means that the user can activate another window or choose a menu item at any time. The modeless window accepts input whenever the user wants to enter it but does not block the user from accessing other windows.

The control panel looks like this:

The code implementing this control panel is given below. Before we look at the code, here is some explanation of the thinking behind it.

The X Component and Y Component controls are SetVariable controls. We attach each SetVariable control to a global variable so that, if we kill and later recreate the panel, the SetVariable control is restored to its previous state. In other words, we use global variables to remember settings across invocations of the panel. To keep the global variables from cluttering the user’s space, we bury them in a data folder located at root:Packages:DiagonalControlPanel.

The DisplayDiagonalControlPanel routine creates the data folder and the global variables if they do not already exist. DisplayDiagonalControlPanel creates the control panel or, if it already exists, just brings it to the front.

We added a menu item to the Macros menu so the user can easily invoke DisplayDiagonalControlPanel.

We built the control panel manually using techniques explained in Chapter III-14, **Controls and Control Panels**. Then we closed it so Igor would create a display recreation macro which we named DiagonalControlPanel. We then manually tweaked the macro to attach the SetVariable controls to the desired globals and to set the panel’s behavior when the user clicks the close button by adding the /K=1 flag.

Here are the procedures.

```
// Add a menu item to display the control panel.
Menu "Macros"
    "Display Diagonal Control Panel", DisplayDiagonalControlPanel()
End
```

```

// This is the display recreation macro, created by Igor
// and then manually tweaked. The parts that were tweaked
// are shown in bold. NOTE: Some lines are wrapped to fit on the page.
Window DiagonalControlPanel() : Panel
    PauseUpdate; Silent 1    // building window...

    NewPanel/W=(162,95,375,198)/K=1 as "Compute Diagonal"

    SetVariable XSetVar,pos={22,11},size={150,15},title="X Component:"
    SetVariable XSetVar,limits={-Inf,Inf,1},value=
        root:Packages:DiagonalControlPanel:gXComponent

    SetVariable YSetVar,pos={22,36},size={150,15},title="Y Component:"
    SetVariable YSetVar,limits={-Inf,Inf,1},value=
        root:Packages:DiagonalControlPanel:gYComponent

    Button ComputeButton,pos={59,69},size={90,20},
        proc=ComputeDiagonalProc,title="Compute"
EndMacro

// This is the action procedure for the Compute button.
// We created it using the Button dialog.
Function ComputeDiagonalProc(ctrlName) : ButtonControl
    String ctrlName

    DFREF dfr = root:Packages:DiagonalControlPanel

    NVAR gXComponent = dfr:gXComponent
    NVAR gYComponent = dfr:gYComponent
    Variable diagonal
    diagonal = sqrt(gXComponent^2 + gYComponent^2)
    Printf "Diagonal=%g\r", diagonal
End

// This is the top level routine which makes sure that the globals
// and their enclosing data folders exist and then makes sure that
// the control panel is displayed.
Function DisplayDiagonalControlPanel()
    // If the panel is already created, just bring it to the front.
    DoWindow/F DiagonalControlPanel
    if (V_Flag != 0)
        return 0
    endif

    String dfSave = GetDataFolder(1)

    // Create a data folder in Packages to store globals.
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S root:Packages:DiagonalControlPanel

    // Create global variables used by the control panel.
    Variable xComponent = NumVarOrDefault(":gXComponent", 10)
    Variable/G gXComponent = xComponent
    Variable yComponent = NumVarOrDefault(":gYComponent", 20)
    Variable/G gYComponent = yComponent

    // Create the control panel.
    Execute "DiagonalControlPanel()"

    SetDataFolder dfSave
End

```

To try this example, copy all of the procedures and paste them into the procedure window of a new experiment. Close the procedure window to compile it and then choose Display Diagonal Control Panel from the Macros menu. Next enter values in the text entry items and click the Compute button. Close the control

panel and then reopen it using the Display Diagonal Control Panel menu item. Notice that the values that you entered were remembered. Use the Data Browser to inspect the root:Packages:DiagonalControlPanel data folder.

Although this example is very simple, it illustrates the process of creating a control panel that functions as a modeless dialog. There are many more examples of this in the Examples folder. You can access them via the File→Example Experiments submenu.

See Chapter III-14, **Controls and Control Panels**, for more information on building control panels.

## Detecting a User Abort

If you have written a user-defined function that takes a long time to execute, you may want to provide a way for the user to abort it. One solution is to display a progress window as discussed under **Progress Windows** on page IV-144.

Here is a simple alternative using the escape key:

```
Function PressEscapeToAbort(phase, title, message)
    Variable phase    // 0: Display control panel with message.
                    // 1: Test if Escape key is pressed.
                    // 2: Close control panel.
    String title      // Title for control panel.
    String message    // Tells user what you are doing.

    if (phase == 0)   // Create panel
        DoWindow/F PressEscapePanel
        if (V_flag == 0)
            NewPanel/K=1 /W=(100,100,350,200)
            DoWindow/C PressEscapePanel
            DoWindow/T PressEscapePanel, title
        endif
        TitleBox Message,pos={7,8},size={69,20},title=message
        String abortStr = "Press escape to abort"
        TitleBox Press,pos={6,59},size={106,20},title=abortStr
        DoUpdate
    endif

    if (phase == 1)   // Test for Escape key
        Variable doAbort = 0
        if (GetKeyState(0) & 32)      // Is Escape key pressed now?
            doAbort = 1
        else
            if (strlen(message) != 0) // Want to change message?
                TitleBox Message,title=message
                DoUpdate
            endif
        endif
        return doAbort
    endif

    if (phase == 2)   // Kill panel
        DoWindow/K PressEscapePanel
    endif

    return 0
End

Function Demo()
    // Create panel
    PressEscapeToAbort(0, "Demonstration", "This is a demo")
End
```

```

Variable startTicks = ticks
Variable endTicks = startTicks + 10*60
Variable lastMessageUpdate = startTicks

do
  String message
  message = ""
  if (ticks>=lastMessageUpdate+60) // Time to update message?
    Variable remaining = (endTicks - ticks) / 60
    sprintf message, "Time remaining: %.1f seconds", remaining
    lastMessageUpdate = ticks
  endif

  if (PressEscapeToAbort(1, "", message))
    Print "Test aborted by Escape key."
    break
  endif
while(ticks < endTicks)

PressEscapeToAbort(2, "", "") // Kill panel.
End

```

## Creating a Contextual Menu

You can use the **PopupContextualMenu** operation to create a pop-up menu in response to a contextual click (control-click (*Macintosh*) or right-click). You would do this from a window hook function or from the action procedure for a control in a control panel.

In this example, we create a control panel with a list. When the user right-clicks on the list, Igor sends a mouse-down event to the listbox procedure, `TickerListProc` in this case. The listbox procedure uses the `eventMod` field of the `WMListboxAction` structure to determine if the click is a right-click. If so, it calls `HandleTickerListRightClick` which calls `PopupContextualMenu` to display the contextual menu.

```

Menu "Macros"

  "Show Demo Panel", ShowDemoPanel()
End

static Function HandleTickerListRightClick()
  String popupItems = ""
  popupItems += "Refresh;"

  PopupContextualMenu popupItems
  strswitch (S_selection)
    case "Refresh":
      DoAlert 0, "Here is where you would refresh the ticker list."
      break
    endswitch
End

Function TickerListProc(lba) : ListBoxControl
  STRUCT WMListboxAction &lba

  switch (lba.eventCode)
    case 1: // Mouse down
      if (lba.eventMod & 0x10) // Right-click?
        HandleTickerListRightClick()
      endif
      break
    endswitch

```

```
    return 0
End

Function ShowDemoPanel()
    DoWindow/F DemoPanel
    if (V_flag != 0)
        return 0 // Panel already exists.
    endif

    // Create panel data.
    Make/O/T ticketListWave = {{ "AAPL", "IBM", "MSFT" }, { "90.25", "86.40", "17.17" }}

    // Create panel.
    NewPanel /N=DemoPanel /W=(321,121,621,321) /K=1
    ListBox TickerList,pos={48,16},size={200,100},fSize=12
    ListBox TickerList,listWave=root:ticketListWave
    ListBox TickerList,mode= 1,selRow= 0, proc=TickerListProc
End
```

## Cursors as Input Device

You can use the cursors on a trace in a graph to identify the data to be processed.

The examples shown above using `PauseForUser` are modal - the user adjusts the cursors in the middle of procedure execution and can do nothing else. This technique is non-modal — the user is expected to adjust the cursors before invoking the procedure.

This function does a straight-line curve fit through the data between cursor A (the round cursor) and cursor B (the square cursor). This example is written to handle both waveform and XY data.

```
Function FitLineBetweenCursors()
    Variable isXY

    // Make sure both cursors are on the same wave.
    WAVE wA = CsrWaveRef(A)
    WAVE wB = CsrWaveRef(B)
    String dfA = GetWavesDataFolder(wA, 2)
    String dfB = GetWavesDataFolder(wB, 2)
    if (CmpStr(dfA, dfB) != 0)
        Abort "Both cursors must be on the same wave."
        return -1
    endif

    // Find the wave that the cursors are on.
    WAVE yWave = CsrWaveRef(A)

    // Decide if this is an XY pair.
    WAVE xWave = CsrXWaveRef(A)
    isXY = WaveExists(xWave)

    if (isXY)
        CurveFit line yWave(xcsr(A),xcsr(B)) /X=xWave /D
    else
        CurveFit line yWave(xcsr(A),xcsr(B)) /D
    endif
End
```

This technique is demonstrated in the **Fit Line Between Cursors** example experiment in the “Examples:Curve Fitting” folder.

Advanced programmers can set things up so that a hook function is called whenever the user adjusts the position of a cursor. For details, see **Cursors — Moving Cursor Calls Function** on page IV-316.

## Marquee Menu as Input Device

A marquee is the dashed-line rectangle that you get when you click and drag diagonally in a graph or page layout. It is used for expanding and shrinking the range of axes, for selecting a rectangular section of an image, and for specifying an area of a layout. You can use the marquee as an input device for your procedures. This is a relatively advanced technique.

This menu definition adds a user-defined item to the graph marquee menu:

```
Menu "GraphMarquee"
  "Print Marquee Coordinates", PrintMarqueeCoords()
End
```

To add an item to the layout marquee menu, use `LayoutMarquee` instead of `GraphMarquee`.

When the user chooses `Print Marquee Coordinates`, the following function runs. It prints the coordinates of the marquee in the history area. It assumes that the graph has left and bottom axes.

```
Function PrintMarqueeCoords()
  String format
  GetMarquee/K left, bottom
  format = "flag: %g; left: %g; top: %g; right: %g; bottom: %g\r"
  printf format, V_flag, V_left, V_top, V_right, V_bottom
End
```

The use of the marquee menu as an input device is demonstrated in the **Marquee Demo** and **Delete Points from Wave** example experiments.

## Polygon as Input Device

This technique is similar to the marquee technique except that you can identify a nonrectangular area. It is implemented using **FindPointsInPoly** operation (see page V-214).

## Overview

This chapter discusses programming techniques and issues that go beyond the basics of the Igor programming language and which all Igor programmers should understand. Techniques for advanced programmers are discussed in Chapter IV-10, **Advanced Topics**.

## The Include Statement

The include statement is a compiler directive that you can put in your procedure file to open another procedure file. A typical include statement looks like this:

```
#include <Split Axis>
```

This statement opens the file "Split Axis.ipf" in the WaveMetrics Procedures folder. Once this statement has been compiled, you can call routines from that file. This is the recommended way to access procedure files that contain utility routines.

The # character at the beginning specifies that a compiler directive follows. Compiler directives, except for conditional compilation directives, must start at the far left edge of the procedure window with no leading tabs or spaces. Include statements can appear anywhere in the file but it is conventional to put them near the top.

It is possible to include a file which in turn includes other files. Igor opens all of the included files.

Igor opens included files when it compiles procedures. If you remove an include statement from a procedure file, Igor automatically closes the file on the next compile.

There are four forms of the include statement:

1. Igor searches for the named file in "Igor Pro 7 Folder/WaveMetrics Procedures" and in any subfolders:

```
#include <fileName>
```

Example:           #include <Split Axis>

2. Igor searches for the named file in "Igor Pro 7 Folder/User Procedures" and "Igor Pro User Files/User Procedures" and in any subfolders:

```
#include "fileName"
```

Example:           #include "Utility Procs"

3. Igor looks for the file only in the exact location specified:

```
#include "full file path"
```

Example:           #include "Hard Disk:Procedures:Utility Procs"

4. Igor looks for the file relative to the Igor Pro 7 folder and the Igor Pro User Files folder and the folder containing the procedure file that contains the #include statement:

```
#include ":partial file path"
```

Example:           #include ":Spectroscopy Procedures:Voigt Procs"

Igor looks first relative to the Igor Pro 7 Folder. If that fails, it looks relative to the **Igor Pro User Files** folder. If that fails it looks relative to the procedure file containing the #include statement or, if the #include statement is in the built-in procedure window, relative to the experiment file.

The name of the file being included must end with the standard ".ipf" extension but the extension is not used in the include statement.

## Procedure File Version Information

If you create a procedure file to be used by other Igor users, it's a good idea to add version information to the file. You do this by putting a #pragma version statement in the procedure file. For example:

```
#pragma version = 1.10
```

This statement must appear with no indentation and must appear in the first 50 lines of the file. If Igor finds no version pragma, it treats the file as version 1.00.

Igor looks for the version information when the user invokes the File Information dialog from the Procedure menu. If the file has version information, Igor displays the version next to the file name in the dialog.

Igor also looks for version information when it opens an included file. An include statement can require a certain version of the included file using the following syntax:

```
#include <Bivariate Histogram> version>=1.02
```

If the required version of the procedure file is not available, Igor displays a warning to inform the user that the procedure file needs to be updated.

### Turning the Included File's Menus Off

Normally an included procedure file's menus and menu items are displayed. However, if you are including a file merely to call one of its procedures, you may not want that file's menu items to appear. To suppress the file's menus and menu items, use:

```
#include <Decimation> menus=0
```

To use both the menus and version options, you must separate them with a comma:

```
#include <Decimation> menus=0, version>=1.1
```

### Optionally Including Files

Compilation usually ceases and returns an error if the included file isn't found. On occasion it is advantageous to allow compilation to proceed if an included file isn't present or is the wrong version. Optionally including a procedure file is appropriate only if the file truly isn't needed to make procedures compile or operate.

Use the "optional" keyword to optionally include a procedure file:

```
#include <Decimation> version>=1.1, optional
```

## Writing General-Purpose Procedures

Procedures can be placed on a scale ranging from general to specific. Usually, the high-level procedures of a program are specific to the task at hand and call on more general, lower-level procedures. The most general procedures are often called "utility" procedures.

You can achieve a high degree of productivity by building a library of utility procedures that you reuse in different programs. In Igor, you can think of the routines in an experiment's built-in Procedure window as a program. It can call utility routines which should be stored in a separate procedure file so that they are available to multiple experiments.

The files stored in the WaveMetrics Procedures folder contain general-purpose procedures on which your high-level procedures can build. Use the include statement (see **The Include Statement** on page IV-155) to access these and other utility files.

When you write utility routines, you should keep them as general as possible so that they can be reused as much as possible. Here are some guidelines.

- Avoid the use of global variables as inputs or outputs. Using globals hard-wires the routine to specific names which makes it difficult to use and limits its generality.
- If you use globals to store state information between invocations of a routine, package the globals in data folders.

WaveMetrics packages usually create data folders inside "root:Packages". We use the prefix "WM" for data folder names to avoid conflict with other packages. Follow this lead and should pick your own data folder names so as to minimize the chance of conflict with WaveMetrics packages or with others. See **Managing Package Data** on page IV-234 for details.

- Choose a clear and specific name for your utility routine.

By choosing a name that says precisely what your utility routine does, you minimize the likelihood of collision with the name of another procedure. You also increase the readability of your program.

- Make functions which are used only internally by your procedures static.

By making internal functions static (i.e., private), you minimize the likelihood of collision with the name of another procedure.

## Programming with Liberal Names

Standard names in Igor can contain letters, numbers and the underscore character only.

It is possible to use wave names and data folder names that contain almost any character. Such names are called “liberal names” (see **Liberal Object Names** on page III-444).

As this section explains, programmers need to use special techniques for their procedures to work with liberal names. Consequently, if you do use liberal names, some existing Igor procedures may break.

Whenever a liberal name is used in a command or expression, the name must be enclosed in single quotes. For example:

```
Make 'Wave 1', wave2, 'miles/hour'
'Wave 1' = wave2 + 'miles/hour'
```

Without the single quotes, Igor has no way to know where a particular name ends. This is a problem whenever Igor parses a command or statement. Igor parses commands at the following times:

- When it compiles a user-defined function.
- When it compiles the right-hand side of an assignment statement, including a formula (:= dependency expression).
- When it interprets a macro.
- When it interprets a command that you enter in the command line or via an Igor Text file.
- When it interprets a command you submit for execution via the Execute operation.
- When it interprets a command that an XOP submits for execution via the XOPCommand or XOPSilentCommand callback routines.

When you use an Igor dialog to generate a command, Igor automatically uses quotes where necessary.

Programmers need to be concerned about liberal names whenever they create a command and then execute it, via an Igor Text file, the Execute operation or the XOPCommand and XOPSilentCommand callback routines, and when creating a formula. In short, when you create something that Igor has to parse, names must be quoted if they are liberal. Names that are not liberal can be quoted or unquoted.

If you have a procedure that builds up a command in a string variable and then executes it via the Execute operation, you must use the PossiblyQuoteName function to provide the quotes if needed.

Here is a trivial example showing the liberal-name unaware and liberal-name aware techniques:

```
Function AddOneToWave(w)
    WAVE w

    String cmd
    String name = NameOfWave(w)

    // Liberal-name unaware - generates error with liberal name
    sprintf cmd, "%s += 1", name
    Execute cmd

    // Liberal-name aware way
    sprintf cmd, "%s += 1", PossiblyQuoteName(name)
    Execute cmd
End
```

## Chapter IV-7 — Programming Techniques

---

Imagine that you pass a wave named *wave 1* to this function. Using the old technique, the Execute operation would see the following text:

```
wave 1 += 1
```

Igor would generate an error because it would try to find an operation, macro, function, wave or variable named *wave*.

Using the new technique, the Execute operation would see the following text:

```
'wave 1' += 1
```

This works correctly because Igor sees 'wave 1' as a single name.

When you pass a string expression containing a simple name to the \$ operator, the name must not be quoted because Igor does no parsing:

```
String name = "wave 1"; Display $name           // Right
String name = "'wave 1'"; Display $name         // Wrong
```

However, when you pass a *path* in a string to \$, any liberal names in the path must be quoted:

```
String path = "root:'My Data':'wave 1'"; Display $path // Right
String path = "root:My Data:wave 1"; Display $path    // Wrong
```

For further explanation of liberal name quoting rules, see **Accessing Global Variables and Waves Using Liberal Names** on page IV-62.

Some built-in string functions return a list of waves. WaveList is the most common example. If liberal wave names are used, you will have to be extra careful when using the list of names. For example, you can't just append the list to the name of an operation that takes a list of names and then execute the resulting string. Rather, you will have to extract each name in turn, possibly quote it and then append it to the operation.

For example, the following will work if all wave names are standard but not if any wave names are liberal:

```
Execute "Display " + WaveList("*", ",", "")
```

Now you will need a string function that extracts out each name, possibly quotes it, and creates a new string using the new names separated by commas. The PossiblyQuoteList function in the WaveMetrics procedure file Strings as Lists does this. The preceding command becomes:

```
Execute "Display " + PossiblyQuoteList(WaveList("*", ",", ""), ",")
```

To include the Strings as Lists file in your procedures, see **The Include Statement** on page IV-155.

For details on using liberal names in user-defined functions, see **Accessing Global Variables and Waves Using Liberal Names** on page IV-62.

## Programming with Data Folders

For general information on data folders, including syntax for using data folders in command line operations, see Chapter II-8, **Data Folders**.

Data folders provide a powerful way to organize data and reduce clutter. However, using data folders introduces some complexity in Igor programming. The name of a variable or wave is no longer sufficient to uniquely identify it because the name alone does not indicate in which data folder it resides.

If a procedure is designed to work on the current data folder, then it is the user's responsibility to set the current data folder correctly before running the procedure. When writing such a procedure, you can use **WaveExists**, **NVAR\_Exists**, and **SVAR\_Exists** to check the existence of expected objects and fail gracefully if they do not exist.

## Data Folder Applications

There are two main uses for data folders:

- To store globals used by procedures to keep track of their state
- To store runs of data with identical structures

The following sections explore these applications.

### Storing Procedure Globals

If you create packages of procedures, for example data acquisition, data analysis, or a specialized plot type, you typically need to store global variables, strings and waves to maintain the state of your package. You should keep all such items in a data folder that you create with a unique name to reduce clutter and avoid conflicts with other packages.

If your package is inherently global in nature, data acquisition for example, create your data folder within a data folder named Packages that you create in the root data folder. If your package is named MyDataAcq, you would store your globals in root:Packages:MyDataAcq. See **Managing Package Data** on page IV-234 for details and examples.

On the other hand, if your package needs to create a group of variables and waves as a result of an operation on a single input wave, it makes sense to create your data folder in the one that holds the input wave (see the **GetWavesDataFolder** function on page V-274). Similarly, if you create a package that takes an entire data folder as input (via a DFREF parameter pointing to the data folder) and needs to create a data folder containing output, it should create the output data folder in the one, or possibly at the same level as the one containing the input.

If your package creates and maintains windows, it should create a master data folder in root:Packages and then create individual data folders within the master that correspond to each instance of a window. For example, a Smith Chart package would create a master data folder as root:Packages:SmithCharts: and then create individual data folders inside the master with names that correspond to the individual graphs.

A package designed to operate on traces within graphs would go one step further and create a data folder for each trace that it has worked on, inside the data folder for the graph. This technique is illustrated by the Smooth Control Panel procedure file. For a demonstration, choose File→Examples→Feature Demos→Smoothing Control Panel.

### Storing Runs of Data

If you acquire data using a well-established experimental protocol, your data will have a well-defined structure. Each time you run your protocol, you produce a new data set with the same structure. Storing each data set in its own data folder avoids name conflicts between corresponding items of different data sets. It also simplifies the writing of procedures to analyze and compare data set.

To use a trivial example, your data might have a structure like this:

```
<Run of data>
  String: conditions
  Variable: temperature
  Wave: appliedVoltage
  Wave: luminosity
```

Having defined this structure, you could then write procedures to:

1. Load your data into a data folder
2. Create a graph showing the data from one run
3. Create a graph comparing the data from many runs

Writing these procedures is greatly simplified by the fact that the names of the items in a run are fixed. For example, step 2 could be written as:

```
Function GraphOneRun() // Graphs data run in the current data folder.
    SVAR conditions
    NVAR temperature
    WAVE appliedVoltage, luminosity

    Display luminosity vs appliedVoltage

    String text
    sprintf text, "Temperature: %g.\rExperimental conditions: %s.",
        temperature, conditions
    Textbox text
End
```

To create a graph, you would first set the current data folder to point to a run of data and then you would invoke the GraphOneRun function.

The Data Folder Tutorial experiment shows in detail how to accomplish the three steps listed above. Choose File→Example Experiments→Tutorials→Data Folder Tutorial.

### Setting and Restoring the Current Data Folder

There are many reasons why you might want to save and restore the current data folder. In this example, we have a function that does a curve fit to a wave passed in as a parameter. The CurveFit operation creates two waves, W\_coef and W\_sigma, in the current data folder. If you use the /D option, it also creates a destination wave in the current data folder. In this function, we make sure that the W\_coef, W\_sigma and destination waves are all created in the same data folder as the source wave.

```
Function DoLineFit(w)
    WAVE w

    String saveDF = GetDataFolder(1)
    SetDataFolder GetWavesDataFolder(w,1)
    CurveFit line w /D
    SetDataFolder saveDF
End
```

Many other operations create output waves in the current data folder. Depending on what your goal is, you may want to use the technique shown here to control where the output waves are created.

A function should always save and restore the current data folder unless it is designed explicitly to change the current data folder.

### Determining a Function's Target Data Folder

There are three common methods for determining the data folder that a function works on or in:

1. Passing a wave in the target data folder as a parameter
2. Having the function work on the current data folder
3. Passing a DFREF parameter that points to the target data folder

For functions that operate on a specific wave, method 1 is appropriate.

For functions that operation on a large number of variables within a single data folder, methods 2 or 3 are appropriate. In method 2, the calling routine sets the data folder of interest as the current data folder. In method 3, the called function does this, and restores the original current data folder before it returns.

### Clearing a Data Folder

There are times when you might want to clear a data folder before running a procedure, to remove things left over from a preceding run. If the data folder contains no child data folders, you can achieve this with:

```
KillWaves/A/Z; KillVariables/A/Z
```

If the data folder does contain child data folders, you could use the KillDataFolder operation. This operation kills a data folder and its contents, including any child data folders. You could kill the main data folder and then recreate it. A problem with this is that, if the data folder or its children contain a wave that is in use, you will generate an error which will cause your function to abort.

Here is a handy function that kills the contents of a data folder and the contents of its children without killing any data folders and without attempting to kill any waves that may be in use.

```
Function ZapDataInFolderTree(path)
    String path

    String saveDF = GetDataFolder(1)
    SetDataFolder path

    KillWaves/A/Z
    KillVariables/A/Z
    KillStrings/A/Z

    Variable i
    Variable numDataFolders = CountObjects(":", 4)
    for(i=0; i<numDataFolders; i+=1)
        String nextPath = GetIndexedObjName(":", 4, i)
        ZapDataInFolderTree(nextPath)
    endfor

    SetDataFolder saveDF
End
```

## Using Strings

This section explains some common ways in which Igor procedures use strings. The most common techniques use built-in functions such as StringFromList and FindListItem. In addition to the built-in functions, there are a number of handy Igor procedure files in the WaveMetrics Procedures:Utilities:String Utilities folder.

### Using Strings as Lists

Procedures often need to deal with lists of items. Such lists are usually represented as semicolon-separated text strings. The StringFromList function is used to extract each item, often in a loop. For example:

```
Function Test()
    Make jack,sam,fred,sue
    String list = WaveList("*",";","")
    Print list

    Variable numItems = ItemsInList(list), i
    for(i=0; i<numItems; i+=1)
        Print StringFromList(i,list)    // Print ith item
    endfor
End
```

For lists with a large number of items, using StringFromList as shown above is slow. This is because it must search from the start of the list to the desired item each time it is called. In Igor7 or later, you can iterate quickly using the optional StringFromList offset parameter:

```
Function Test()
    Make jack,sam,fred,sue
    String list = WaveList("*",";","")
    Print list

    Variable numItems = ItemsInList(list), i
    Variable offset = 0
    for(i=0; i<numItems; i+=1)
```

```
String item = StringFromList(0, list, ";", offset) // Get ith item
Print item
offset += strlen(item) + 1
endfor
End
```

See **ListToTextWave** for another fast way to iterate through the items in a large string list.

### Using Keyword-Value Packed Strings

A collection of disparate values is often stored in a list of keyword-value pairs. For example, the **TraceInfo** and **AxisInfo** functions return such a list. The information in these strings follows this form

```
KEYWORD:value;KEYWORD:value; ...
```

The **keyword** is always upper case and followed by a colon. Then comes the **value** and a semicolon. When parsing such a string, you should avoid reliance on the specific ordering of keywords — the order is likely to change in future releases of Igor.

Two functions will extract information from keyword-value strings. **NumberByKey** is used when the data is numeric, and **StringByKey** is used when the information is in the form of text.

### Using Strings with Extractable Commands

The **AxisInfo** and **TraceInfo** readback functions provide much of their information in a form that resembles the commands that you use to make the settings in the first place. For example, to set an axis to log mode, you would execute something like this:

```
ModifyGraph log(left)=1
```

If we now look at the characters of the string returned by **AxisInfo** we see:

```
AXTYPE:left;CWAVE:jack; ... RECREATION:grid(x)=0;log(x)=1 ...
```

To use this information, we need to extract the value following “log(x)=” and then use it in a **ModifyGraph** command with the extracted value with the desired graph as the target. Here is a user function that sets the log mode of the bottom axis to the same value as the left axis:

```
Function CopyLogMode()
String info,text
Variable pos
info=AxisInfo("", "left")
pos= StrSearch(info, "RECREATION:", 0) // skip to start of "RECREATION:"
pos += strlen("RECREATION:")          // skip "RECREATION:", too
                                     // get text after "log(x)="
text= StringByKey("log(x)", info[pos,inf], "=", ";")

String cmd = "ModifyGraph log(bottom)=" + text
Execute cmd
End
```

### Character-by-Character Operations

Igor functions like **strlen** and **strsearch**, as well as Igor string indexing (see **String Indexing** on page IV-15), are byte-oriented. That is, **strlen** returns the number of bytes in a string. **Strsearch** takes a byte position as a parameter. Expressions like **str[<index>]** return a single byte.

In Igor6, for western languages, each character is represented by a single byte, so the distinction between bytes and characters is insignificant, and byte-by-byte operations are sufficient.

In Igor7 and later, which use the UTF-8 text encoding to represent text in strings, all ASCII characters are represented by one byte but all non-ASCII characters are represented by multiple bytes (see **Text Encodings** on page III-409 for details). Consequently, byte-by-byte operations are insufficient for stepping through characters. Character-by-character operations are needed.

There is no straightforward way in Igor7 to step through text containing non-ASCII characters. In the rare cases where this is necessary, you can use the user-defined functions shown in this section.

The following functions show how to step through UTF-8 text character-by-character rather than byte-by-byte.

```
// NumBytesInUTF8Character(str, byteOffset)
// Returns the number of bytes in the UTF-8 character that starts byteOffset
// bytes from the start of str.
// NOTE: If byteOffset is invalid this routine returns 0.
// Also, if str is not valid UTF-8 text, this routine return 1.
Function NumBytesInUTF8Character(str, byteOffset)
    String str
    Variable byteOffset

    Variable numBytesInString = strlen(str)
    if (byteOffset<0 || byteOffset>=numBytesInString)
        return 0 // Programmer error
    endif

    Variable firstByte = char2num(str[byteOffset]) & 0x00FF

    if (firstByte < 0x80)
        return 1
    endif

    if (firstByte>=0xC2 && firstByte<=0xDF)
        return 2
    endif

    if (firstByte>=0xE0 && firstByte<=0xEF)
        return 3
    endif

    if (firstByte>=0xF0 && firstByte<=0xF4)
        return 4
    endif

    // If we are here, str is not valid UTF-8.
    // Treat the first byte as a 1-byte character.
    // This prevents infinite loops.
    return 1
End

Function UTF8CharactersInString(str)
    String str

    Variable numCharacters = 0

    Variable length = strlen(str)
    Variable byteOffset = 0
    do
        if (byteOffset >= length)
            break
        endif
        Variable numBytesInCharacter = NumBytesInUTF8Character(str, byteOffset)
        if (numBytesInCharacter <= 0)
            Abort "Bug in CharactersInUTF8String" // Should not happen
        endif
        numCharacters += 1
        byteOffset += numBytesInCharacter
    while(1)

    return numCharacters
End
```

End

```
Function/S UTF8CharacterAtPosition(str, charPos)
    String str
    Variable charPos

    if (charPos < 0)
        // Print "charPos is invalid"           // For debugging only
        return ""
    endif

    Variable length = strlen(str)
    Variable byteOffset = 0
    do
        if (byteOffset >= length)
            // Print "charPos is out-of-range"   // For debugging only
            return ""
        endif
        if (charPos == 0)
            break
        endif
        Variable numBytesInCharacter = NumBytesInUTF8Character(str, byteOffset)
        byteOffset += numBytesInCharacter
        charPos -= 1
    while(1)

    numBytesInCharacter = NumBytesInUTF8Character(str, byteOffset)
    String result = str[byteOffset, byteOffset+numBytesInCharacter-1]
    return result
```

End

```
Function DemoCharacterByCharacter()
    String str = "<string containing non-ASCII text>"

    Variable numCharacters = UTF8CharactersInString(str)
    Variable charPos

    for(charPos=0; charPos<numCharacters; charPos+=1)
        String character = UTF8CharacterAtPosition(str, charPos);
        Printf "CharPos=%d, char=\"%s\"\\r", charPos, character
    endfor
```

End

See Also: **Text Encodings** on page III-409, **String Indexing** on page IV-15

## Regular Expressions

A regular expression is a pattern that is matched against a subject string from left to right. Regular expressions are used to identify lines of text containing a particular pattern and to extract substrings matching a particular pattern.

A regular expression can contain regular characters that match the same character in the subject and special characters, called "metacharacters", that match any character, a list of specific characters, or otherwise identify patterns.

The regular expression syntax is based on PCRE — the Perl-Compatible Regular Expression Library.

Igor syntax is similar to regular expressions supported by various UNIX and POSIX `egrep (1)` commands.

See **Regular Expressions References** on page IV-183 for details on PCRE.

## Regular Expression Operations and Functions

Here are the Igor operations and functions that work with regular expressions:

### Grep

The **Grep** operation identifies lines of text that match a pattern.

The subject is each line of a file or each row of a text wave or each line of the text in the clipboard.

Output is stored in a file or in a text wave or in the clipboard.

#### *Grep Example*

```
Function DemoGrep()
    Make/T source={"Monday", "Tuesday", "Wednesday", "Thursday", "Friday"}
    Make/T/N=0 dest
    Grep/E="sday" source as dest          // Find rows containing "sday"
    Print dest
End
```

The output from Print is:

```
dest [0] = {"Tuesday", "Wednesday", "Thursday"}
```

### GrepList

The **GrepList** function identifies items that match a pattern in a string containing a delimited list.

The subject is each item in the input list.

The output is a delimited list returned as the function result.

#### *GrepList Example*

```
Function DemoGrepList()
    String source = "Monday;Tuesday;Wednesday;Thursday;Friday"
    String dest = GrepList(source, "sday") // Find items containing "sday"
    Print dest
End
```

The output from Print is:

```
Tuesday;Wednesday;Thursday;
```

### GrepString

The **GrepString** function determines if a particular pattern exists in the input string.

The subject is the input string.

The output is 1 if the input string contains the pattern or 0 if not.

#### *GrepString Example*

```
Function DemoGrepString()
    String subject = "123.45"
    String regExp = "[0-9]+"          // Match one or more digits
    Print GrepString(subject, regExp) // True if subject contains digit(s)
End
```

The output from Print is: 1

### SplitString

The **Demo** operation identifies subpatterns in the input string.

The subject is the input string.

Output is stored in one or more string output variables.

### *SplitString Example*

```
Function DemoSplitString()  
    String subject = "Thursday, May 7, 2009"  
    String regExp = "([[:alpha:]]+), ([[:alpha:]]+) ([[:digit:]]+), ([[:digit:]]+)"  
    String dayOfWeek, month, dayOfMonth, year  
    SplitString /E=(regExp) subject, dayOfWeek, month, dayOfMonth, year  
    Print dayOfWeek, month, dayOfMonth, year  
End
```

The output from Print is:

```
Thursday May 7 2009
```

## Basic Regular Expressions

Here is a **Grep** command that uses "Fred" as the regular expression. "Fred" contains no metacharacters so this command identifies lines of text containing the literal string "Fred". It examines each line from the input file, afile.txt. All lines containing the pattern "Fred" are written to the output file, "FredFile.txt":

```
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
```

Character matching is case-sensitive by default. Prepending the Perl 5 modifier (?i) gives a case-insensitive pattern that matches upper and lower-case versions of "Fred":

```
// Copy lines that contain "Fred", "fred", "FRED", "fREd", etc  
Grep/P=myPath/E="( ?i)fred" "afile.txt" as "AnyFredFile.txt"
```

To copy lines that do not match the regular expression, use the Grep /E flag with the optional *reverse* parameter set to 1 to reverse the sense of the match:

```
// Copy lines that do NOT contain "Fred", "fred", "fREd", etc  
Grep/P=myPath/E="{ ( ?i)fred",1} "afile.txt" as "NotFredFile.txt"
```

**Note:** Igor doesn't use the Perl opening and closing regular expression delimiter character which is the forward slash. In Perl you would use `/Fred/` and `/( ?i)fred/`.

## Regular Expression Metacharacters

The power of regular expressions comes from the ability to include alternatives and repetitions in the pattern. These are encoded in the pattern by the use of "metacharacters", which do not stand for themselves but instead are interpreted in some special way.

There are two different sets of metacharacters: those that are recognized anywhere in the pattern except within brackets, and those that are recognized in brackets. Outside brackets, the metacharacters are as follows:

<code>\</code>	General escape character with several uses
<code>^</code>	Match start of string
<code>\$</code>	Match end of string
<code>.</code>	Match any character except newline (by default) (To match newline, see <b>Matching Newlines</b> on page IV-173)
<code>[</code>	Start character class definition (for matching one of a set of characters)
<code> </code>	Start of alternative branch (for matching one or the other of two patterns)
<code>(</code>	Start subpattern
<code>)</code>	End subpattern
<code>?</code>	0 or 1 quantifier (for matching 0 or 1 occurrence of a pattern) Also extends the meaning of ( Also quantifier minimizer
<code>*</code>	0 or more quantifier (for matching 0 or more occurrence of a pattern)
<code>+</code>	1 or more quantifier (for matching 1 or more occurrence of a pattern) Also possessive quantifier
<code>{</code>	Start min/max quantifier (for matching a number or range of occurrences)

### Character Classes in Regular Expressions

A character class is a set of characters and is used to specify that one character of the set should be matched. Character classes are introduced by a left-bracket and terminated by a right-bracket. For example:

<code>[abc]</code>	Matches a or b or c
<code>[A-Z]</code>	Matches any character from A to Z
<code>[A-Za-z]</code>	Matches any character from A to Z or a to z.

POSIX character classes specify the characters to be matched symbolically. For example:

<code>[:alpha:]</code>	Matches any alphabetic character (A to Z or a to z).
<code>[:digit:]</code>	Matches 0 to 9.

In a character class the only metacharacters are:

<code>\</code>	General escape character
<code>^</code>	Negate the class, but only if ^ is the first character
<code>-</code>	Indicates character range
<code>[</code>	POSIX character class (only if followed by POSIX syntax)
<code>]</code>	Terminates the character class

### Backslash in Regular Expressions

The backslash character has several uses. First, if it is followed by a nonalphanumeric character, it takes away any special meaning that character may have. This use of backslash as an escape character applies both inside and outside character classes.

## Chapter IV-7 — Programming Techniques

For example, the `*` character normally means "match zero or more of the preceding subpattern". If you want to match a `*` character, you write `\*` in the pattern. This escaping action applies whether or not the following character would otherwise be interpreted as a metacharacter, so it is always safe to precede a nonalphanumeric with backslash to specify that it stands for itself. In particular, if you want to match a backslash, you write `\\`.

**Note:** Because Igor also has special uses for backslash (see **Escape Sequences in Strings** on page IV-13), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes sends one backslash to, say, the **Grep** command.

For example, to copy lines that contain a backslash followed by a `z` character, the Perl pattern would be `"\\z"`, but the equivalent Igor Grep expression would be `/E="\\\\z"`.

Igor's input string parser converts `"\\"` to `"\"` so, when you write `/E="\\\\z"`, the regular expression engine sees `/E="\\z"`.

This difference is important enough that the PCRE and Igor Patterns (using Grep `/E` syntax) are both shown below when they differ.

Only ASCII numbers and letters have any special meaning after a backslash. All other characters are treated as literals.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between `\Q` and `\E`. This is different from Perl in that `$` and `@` are handled as literals in `\Q...\E` sequences in PCRE, whereas in Perl, `$` and `@` cause variable interpolation. Note the following examples:

Igor Pattern	PCRE Pattern	PCRE Matches	Perl Matches
<code>\\Qabc\$xyz\E</code>	<code>\Qabc\$xyz\E</code>	<code>abc\$xyz</code>	<code>abc</code> followed by the contents of <code>\$xyz</code>
<code>\\Qabc\\\$xyz\E</code>	<code>\Qabc\\$xyz\E</code>	<code>abc\$xyz</code>	<code>abc\</code> <code>\$xyz</code>
<code>\\Qabc\\E\\\$\\Qxyz\E</code>	<code>\Qabc\E\\\$\\Qxyz\E</code>	<code>abc\$xyz</code>	<code>abc\$xyz</code>

The `\Q...\E` sequence is recognized both inside and outside character classes.

### Backslash and Nonprinting Characters

A second use of backslash provides a way of encoding nonprinting characters in patterns in a visible manner. There is no restriction on where nonprinting characters can occur, apart from the binary zero that terminates a pattern, but when a pattern is being prepared by text editing, it is usually easier to use one of the following escape sequences than the binary character it represents:

Igor Pattern	PCRE Pattern	Character Matched
<code>\\a</code>	<code>\a</code>	Alarm, that is, the BEL character (hex 07)
<code>\\cx</code>	<code>\cx</code>	"Control-x", where x is any character
<code>\\e</code>	<code>\e</code>	Escape (hex 1B)
<code>\\f</code>	<code>\f</code>	Formfeed (hex 0C)
<code>\\n</code>	<code>\n</code>	Newline (hex 0A)
<code>\\r</code>	<code>\r</code>	Carriage return (hex 0D)
<code>\\t</code>	<code>\t</code>	Tab (hex 09)
<code>\\ddd</code>	<code>\ddd</code>	Character with octal code ddd, or backreference
<code>\\xhh</code>	<code>\xhh</code>	Character with hex code hh

### Backslash and Nonprinting Characters Arcania

The material in this section is arcane and rarely needed. We recommend that you skip it.

The precise effect of `\cx` is if `x` is a lower case letter, it is converted to upper case. Then bit 6 of the character (hex 40) is inverted. Thus `\cz` becomes hex 1A, but `\c{` becomes hex 3B, while `\c;` becomes hex 7B.

After `\x`, from zero to two hexadecimal digits are read (letters can be in upper or lower case). If characters other than hexadecimal digits appear between `\x{` and `}`, or if there is no terminating `}`, this form of escape is not recognized. Instead, the initial `\x` will be interpreted as a basic hexadecimal escape, with no following digits, giving a character whose value is zero.

After `\0` up to two further octal digits are read. In both cases, if there are fewer than two digits, just those that are present are used. Thus the sequence `\0\x\07` specifies two binary zeros followed by a BEL character (code value 7). Make sure you supply two digits after the initial zero if the pattern character that follows is itself an octal digit.

The handling of a backslash followed by a digit other than 0 is complicated. Outside a character class, PCRE reads it and any following digits as a decimal number. If the number is less than 10, or if there have been at least that many previous capturing left parentheses in the expression, the entire sequence is taken as a back reference. A description of how this works is given later, following the discussion of parenthesized subpatterns.

Inside a character class, or if the decimal number is greater than 9 and there have not been that many capturing subpatterns, PCRE rereads up to three octal digits following the backslash, and generates a single byte from the least significant 8 bits of the value. Any subsequent digits stand for themselves. For example:

Igor Pattern	PCRE Pattern	Character(s) Matched
<code>\\040</code>	<code>\040</code>	Another way of writing a space
<code>\\40</code>	<code>\40</code>	A space, provided there are fewer than 40 previous capturing subpatterns
<code>\\7</code>	<code>\7</code>	Always a back reference
<code>\\11</code>	<code>\11</code>	Might be a back reference, or another way of writing a tab
<code>\\011</code>	<code>\011</code>	Always a tab
<code>\\0113</code>	<code>\0113</code>	A tab followed by the character "3"
<code>\\113</code>	<code>\113</code>	Might be a back reference, otherwise the character with octal code 113
<code>\\377</code>	<code>\377</code>	Might be a back reference, otherwise the byte consisting entirely of 1 bits
<code>\\81</code>	<code>\81</code>	Either a back reference or a binary zero followed by the two characters "8" and "1"

Note that octal values of 100 or greater must not be introduced by a leading zero, because no more than three octal digits are ever read.

All the sequences that define a single byte value can be used both inside and outside character classes. In addition, inside a character class, the sequence `\b` is interpreted as the backspace character (hex 08), and the sequence `\X` is interpreted as the character X. Outside a character class, these sequences have different meanings (see **Backslash and Nonprinting Characters** on page IV-168).

### Backslash and Generic Character Types

The third use of backslash is for specifying generic character types. The following are always recognized:

Igor Pattern	PCRE Pattern	Character(s) Matched
<code>\\d</code>	<code>\d</code>	Any decimal digit
<code>\\D</code>	<code>\D</code>	Any character that is not a decimal digit
<code>\\s</code>	<code>\s</code>	Any whitespace character
<code>\\S</code>	<code>\S</code>	Any character that is not a whitespace character

## Chapter IV-7 — Programming Techniques

Igor Pattern	PCRE Pattern	Character(s) Matched
<code>\\w</code>	<code>\w</code>	Any “word” character
<code>\\W</code>	<code>\W</code>	Any “nonword” character

Each pair of escape sequences, such as `\d` and `\D`, partitions the complete set of characters into two disjoint sets. Any given character matches one, and only one, of each pair.

These character type sequences can appear both inside and outside character classes. They each match one character of the appropriate type. If the current matching point is at the end of the subject string, all of them fail, since there is no character to match.

The `\s` whitespace characters are HT (9), LF (10), VT (11), FF (12), CR (13), and space (32). In Igor Pro 6 `\s` did not match the VT character (code 11).

A “word” character is an underscore or any character that is a letter or digit.

### Backslash and Simple Assertions

The fourth use of backslash is for certain simple assertions. An assertion specifies a condition that has to be met at a particular point in a match without consuming any characters from the subject string. The use of subpatterns for more complicated assertions is described in **Assertions** on page IV-179. The backslashed assertions are:

Igor Pattern	PCRE Pattern	Character(s) Matched
<code>\\b</code>	<code>\b</code>	At a word boundary
<code>\\B</code>	<code>\B</code>	Not at a word boundary
<code>\\A</code>	<code>\A</code>	At start of subject
<code>\\Z</code>	<code>\Z</code>	At end of subject or before newline at end
<code>\\z</code>	<code>\z</code>	At end of subject
<code>\\G</code>	<code>\G</code>	At first matching position in subject

These assertions may not appear in character classes (but note that `\b` has a different meaning, namely the backspace character, inside a character class).

A word boundary is a position in the subject string where the current character and the previous character do not both match `\w` or `\W` (i.e. one matches `\w` and the other matches `\W`), or the start or end of the string if the first or last character matches `\w`, respectively.

While PCRE defines additional simple assertions (`\A`, `\Z`, `\z` and `\G`), they are not any more useful to Igor’s regular expression commands than the `^` and `$` characters.

### Circumflex and Dollar

Outside a character class, in the default matching mode, the circumflex character `^` is an assertion that is true only if the current matching point is at the start of the subject string. Inside a character class, circumflex has an entirely different meaning (see **Character Classes and Brackets** on page IV-171).

Circumflex need not be the first character of the pattern if a number of alternatives are involved, but it should be the first thing in each alternative in which it appears if the pattern is ever to match that branch. If all possible alternatives start with a circumflex, that is, if the pattern is constrained to match only at the start of the subject, it is said to be an “anchored” pattern. (There are also other constructs that can cause a pattern to be anchored.)

A dollar character `$` is an assertion that is true only if the current matching point is at the end of the subject string, or immediately before a newline character that is the last character in the string (by default). Dollar need not be the last character of the pattern if a number of alternatives are involved, but it should be the last item in any branch in which it appears. Dollar has no special meaning in a character class.

## Dot, Period, or Full Stop

Outside a character class, a dot in the pattern matches any one character in the subject, including a nonprinting character, but not (by default) newline. Dot has no special meaning in a character class.

The match option setting (?s) changes the default behavior of dot so that it matches any character including newline. The setting can appear anywhere before the dot in the pattern. See **Matching Newlines** on page IV-173 for details.

## Character Classes and Brackets

An opening bracket introduces a character class which is terminated by a closing bracket. A closing bracket on its own is not special. If a closing bracket is required as a member of the class, it must be the first data character in the class (after an initial circumflex, if present) or escaped with a backslash.

A character class matches a single character in the subject. A matched character must be in the set of characters defined by the class, unless the first character in the class definition is a circumflex, in which case the subject character must not be in the set defined by the class. If a circumflex is actually required as a member of the class, ensure it is not the first character, or escape it with a backslash.

For example, the character class [aeiou] matches any English lower case vowel, whereas [^aeiou] matches any character that is not an English lower case vowel. Note that a circumflex is just a convenient notation for specifying the characters that are in the class by enumerating those that are not.

When caseless matching is set, using the (?i) match option setting, any letters in a class represent both their upper case and lower case versions, so for example, the caseless pattern (?i) [aeiou] matches *A* as well as *a*, and the caseless pattern (?i) [^aeiou] does not match *A*.

The minus (hyphen) character can be used to specify a range of characters in a character class. For example, [d-m] matches any letter between *d* and *m*, inclusive. If a minus character is required in a class, it must be escaped with a backslash or appear in a position where it cannot be interpreted as indicating a range, typically as the first or last character in the class.

To include a right-bracket in a range you must use \]. As usual, this would be represented in a literal Igor string as \].

Though it is rarely needed, you can specify a range using octal numbers, for example [\000-\037].

The character types \d, \D, \p, \P, \s, \S, \w, and \W may also appear in a character class, and add the characters that they match to the class. For example, [\dABCDEF] matches any hexadecimal digit. A circumflex can conveniently be used with the upper case character types to specify a more restricted set of characters than the matching lower case type. For example, the class [^\W\_] matches any letter or digit, but not underscore. The corresponding **Grep** command would begin with

```
Grep/E=" [^\W_] "...
```

The only metacharacters that are recognized in character classes are backslash, hyphen (only where it can be interpreted as specifying a range), circumflex (only at the start), opening bracket (only when it can be interpreted as introducing a POSIX class name — see **POSIX Character Classes** on page IV-171), and the terminating closing bracket. However, escaping other nonalphanumeric characters does no harm.

## POSIX Character Classes

Perl supports the POSIX notation for character classes. This uses names enclosed by [: and :] within the enclosing brackets. PCRE also supports this notation. For example,

```
[01[:alpha:]]%
```

matches "0", "1", any alphabetic character, or "%".

## Chapter IV-7 — Programming Techniques

---

The supported class names, all of which must appear between [ : and : ] inside a character class specification, are

<code>alnum</code>	Letters and digits.
<code>alpha</code>	Letters.
<code>ascii</code>	Character codes 0 - 127.
<code>blank</code>	Space or tab only.
<code>cntrl</code>	Control characters.
<code>digit</code>	Decimal digits (same as <code>\d</code> ).
<code>graph</code>	Printing characters, excluding space.  [:graph:] matches all characters with the Unicode L, M, N, P, S, or Cf properties with a few arcane exceptions.
<code>lower</code>	Lower case letters.
<code>print</code>	Printing characters, including space.  [:print:] matches the same characters as [:graph:] plus space characters that are not controls, that is, characters with the Unicode Zs property.
<code>punct</code>	Printing characters, excluding letters and digits.  [:punct:] matches all characters that have the Unicode P (punctuation) property, plus those characters whose code points are less than 128 that have the S (Symbol) property.
<code>space</code>	White space (not quite the same as <code>\s</code> ).
<code>upper</code>	Upper case letters.
<code>word</code>	“Word” characters (same as <code>\w</code> ).
<code>xdigit</code>	Hexadecimal digits.

The “space” characters are horizontal tab (HT-9), linefeed (LF-10), vertical tab (VT-11), formfeed (FF-12), carriage-return (CR-13), and space (32).

The class name `word` is a Perl extension, and `blank` is a GNU extension from Perl 5.8. Another Perl extension is negation that is indicated by a `^` character after the colon. For example,

```
[12[:^digit:]]
```

matches “1”, “2”, or any nondigit. PCRE (and Perl) also recognize the POSIX syntax `[.ch.]` and `[=ch=]` where “ch” is a “collating element”, but these are not supported, and an error is given if they are encountered.

### Alternation

Vertical bar characters are used to separate alternative patterns. For example, the pattern

```
gilbert|sullivan
```

matches either “gilbert” or “sullivan”. Any number of alternative patterns may be specified, and an empty alternative is permitted (matching the empty string). The matching process tries each alternative in turn, from left to right, and the first one that succeeds is used. If the alternatives are within a subpattern (defined in **Subpatterns** on page IV-175), “succeeds” means matching the rest of the main pattern as well as the alternative in the subpattern.

## Match Option Settings

Character matching options can be changed from within the pattern by a sequence of Perl option letters enclosed between ( ? and ). The option letters are:

Option	PCRE Name	Characters Matched
i	PCRE_CASELESS	Upper and lower case.
m	PCRE_MULTILINE	^ matches start of string and just after a new line (\n). \$ matches end of string and just before a new line. Without (?m), ^ and \$ match only the start and end of the entire string.
s	PCRE_DOTALL	. matches all characters including newline. Without (?s), . does not match newlines. See <b>Matching Newlines</b> on page IV-173.
U	PCRE_UNGREEDY	Reverses the "greediness" of the quantifiers so that they are not greedy by default, but become greedy if followed by ?.

For example, (?i) sets caseless matching.

You can unset these options by preceding the letter with a hyphen: (?-i) turns off caseless matching.

You can combine a setting and unsetting such as (?i-U), which sets PCRE\_CASELESS while unsetting PCRE\_UNGREEDY.

When an option change occurs at top level (that is, not inside subpattern parentheses), the change applies to the remainder of the pattern that follows. If the change is placed right at the start of a pattern, PCRE extracts it into the global options.

An option change within a subpattern affects only that part of the current pattern that follows it, so

```
(a(?i)b)c
```

matches abc and aBc and no other strings.

Any changes made in one alternative do carry on into subsequent branches within the same subpattern. For example,

```
(a(?i)b|c)
```

matches "ab", "aB", "c", and "C", even though when matching "C" the first branch is abandoned before the option setting. This is because the effects of option settings happen at compile time.

The other PCRE 5-specific options, such as (?e), (?A), (?D), (?S), (?x) and (?X), are implemented but are not very useful with Igor's regular expression commands.

## Matching Newlines

Igor generally uses carriage-return (ASCII code 13) return to indicate a new line in text. This is represented in a literal string by "\r". For example:

```
Print "Hello\rGoodbye"
```

prints two lines of text to the history area.

However, in regular expressions, the newline character is linefeed (ASCII code 10). This is represented in a literal string by "\n". Carriage-return has no special status in regular expressions.

The match option setting (?s) changes the default behavior of dot so that it matches any character including newline. The setting can appear anywhere before the dot in the pattern. For example:

```
Function DemoNewline(includeNewline)
    Variable includeNewline

    String subject = "Hello\nGoodbye"    // \n represents newline
```

```
String regExp
if (includeNewline)
    regExp = "(?s)(.*)"      // One or more of any character
else
    regExp = "(.*)"          // One or more of any character except newline
endif

String result
SplitString /E=(regExp) subject, result
Print result
End
```

The output from DemoNewline(0) is:

Hello

The output from DemoNewline(1) is:

Hello\nGoodbye

Here is a more realistic example:

```
Function DemoDotAll()
    String theString = ExampleHTMLString()

    // This regular expression attempts to extract items from
    // HTML code for an ordered list. It fails because the HTML
    // code contains newlines and, by default, . does not match newlines.
    String regExpFails="<li>(.*?)</li>.*<li>(.*?)</li>"
    String str1, str2
    SplitString/E=regExpFails theString, str1, str2
    Print V_flag, " subpatterns were matched using regExpFails"
    Printf "\"%s\", \"%s\"\\r", str1, str2

    // This regular expression works because the "(?s)" match
    // option setting causes . to match newlines.
    String regExpWorks="( ?s)<li>(.*?)</li>.*<li>(.*?)</li>"
    SplitString/E=regExpWorks theString, str1, str2
    Print V_flag, " subpatterns were matched using regExpWorks"
    Printf "\"%s\", \"%s\"\\r", str1, str2
End

Function/S ExampleHTMLString()    // Returns HTML code containing newlines
    String theString = ""
    theString += "<ol>\\n"
    theString += "\\t<li>item 1</li>\\n"
    theString += "\\t<li>item 2</li>\\n"
    theString += "<\\ol>\\n"
    return theString
End

•DemoDotAll()
0    subpatterns were matched using regExpFails
"", ""
2    subpatterns were matched using regExpWorks
"item 1", "item 2"
```

## Subpatterns

Subpatterns are used to group alternatives, to match a previously-matched pattern again, and to extract match text using **Demo**.

Subpatterns are delimited by parentheses, which can be nested. Turning part of a pattern into a subpattern localizes a set of alternatives. For example, this pattern (which includes two vertical bars signifying alternation):

```
cat(aract|erpillar|)
```

matches one of the words "cat", "cataract", or "caterpillar". Without the parentheses, it would match "cataract", "erpillar" or the empty string.

## Named Subpatterns

Specifying subpatterns by number is simple, but it can be very hard to keep track of the numbers in complicated regular expressions. Furthermore, if an expression is modified, the numbers may change. To help with this difficulty, PCRE supports the naming of subpatterns, something that Perl does not provide. The Python syntax (*?P<name>...*) is used. For example:

```
My (?P<catdog>cat|dog) is cooler than your (?P=catdog)
```

Here catdog is the name of the first and only subpattern. *?P<catdog>* names the subpattern and *(?P=catdog)* matches the previous match for that subpattern.

Names consist of alphanumeric characters and underscores, and must be unique within a pattern.

Named capturing parentheses are still allocated numbers as well as names. This has the same effect as the previous example:

```
My (?P<catdog>cat|dog) is cooler than your \1
```

## Repetition

Repetition is specified by quantifiers:

?	0 or 1 quantifier
	Example: <code>[abc] ?</code> - Matches 0 or 1 occurrences of a or b or c
*	0 or more quantifier
	Example: <code>[abc] *</code> - Matches 0 or more occurrences of a or b or c
+	1 or more quantifier
	Example: <code>[abc] +</code> - Matches 1 or more occurrences of a or b or c
{n}	n times quantifier
	Example: <code>[abc] { 3 }</code> - Matches 3 occurrences of a or b or c
{n,m}	n to m times quantifier
	Example: <code>[abc] { 3 , 5 }</code> - Matches 3 to 5 occurrences of a or b or c

Quantifiers can follow any of the following items:

- A literal data character
- The `.` metacharacter
- The `\C` escape sequence
- An escape such as `\d` that matches a single character
- A character class

## Chapter IV-7 — Programming Techniques

---

- A back reference (see **Back References** on page IV-178)
- A parenthesized subpattern (unless it is an assertion)

The general repetition quantifier specifies a minimum and maximum number of permitted matches, by giving the two numbers in braces, separated by a comma. The numbers must be less than 65536, and the first must be less than or equal to the second. For example:

`z{2,4}`

matches “zz”, “zzz”, or “zzzz”.

If the second number is omitted, but the comma is present, there is no upper limit; if the second number and the comma are both omitted, the quantifier specifies an exact number of required matches. Thus

`[aeiou]{3,}`

matches at least 3 successive vowels, but may match many more, while

`\d{8}`

matches exactly 8 digits. A left brace that appears in a position where a quantifier is not allowed, or one that does not match the syntax of a quantifier, is taken as a literal character. For example, `{,6}` is not a quantifier, but a literal string of four characters.

Quantifiers apply to characters rather than to individual data units. Thus, for example, `\x{100}{2}` matches two characters, each of which is represented by a two-byte sequence in a UTF-8 string. Similarly, `\X{3}` matches three Unicode extended grapheme clusters, each of which may be several data units long (and they may be of different lengths).

The quantifier `{0}` is permitted, causing the expression to behave as if the previous item and the quantifier were not present.

For convenience (and historical compatibility) the three most common quantifiers have single-character abbreviations:

*	Equivalent to <code>{0,}</code>
+	Equivalent to <code>{1,}</code>
?	Equivalent to <code>{0,1}</code>

It is possible to construct infinite loops by following a subpattern that can match no characters with a quantifier that has no upper limit, for example:

`(a?)*`

Earlier versions of Perl and PCRE used to give an error at compile time for such patterns. However, because there are cases where this can be useful, such patterns are now accepted, but if any repetition of the subpattern does in fact match no characters, the loop is forcibly broken.

### Quantifier Greediness

By default, the quantifiers are “greedy”, that is, they match as much as possible (up to the maximum number of permitted times), without causing the rest of the pattern to fail. The classic example of where this gives problems is in trying to match comments in C programs. These appear between `/*` and `*/` and within the comment, individual `*` and `/` characters may appear. An attempt to match C comments by applying the pattern

`/\*.*/` or `Grep/E="/\*.*/"`

to the string

`/* first comment */ not comment /* second comment */`

fails because it matches the entire string owing to the greediness of the `.*` item.

However, if a quantifier is followed by a question mark, it ceases to be greedy, and instead matches the minimum number of times possible, so the pattern

```
/\*.*?\*/      or      Grep/E="/\*.*?\*/"
```

does the right thing with the C comments. The meaning of the various quantifiers is not otherwise changed, just the preferred number of matches.

Do not confuse this use of question mark with its use as a quantifier in its own right. Because it has two uses, it can sometimes appear doubled, as in

```
\d??\d      or      Grep/E="\d??\d"
```

which matches one digit by preference, but can match two if that is the only way the rest of the pattern matches.

If the PCRE\_UNGREEDY option (?U) is set, the quantifiers are not greedy by default, but individual ones can be made greedy by following them with a question mark. In other words, it inverts the default behavior.

## Quantifiers With Subpatterns

When a parenthesized subpattern is quantified with a minimum repeat count that is greater than 1 or with a limited maximum, more memory is required for the compiled pattern, in proportion to the size of the minimum or maximum.

When a capturing subpattern is repeated, the value captured is the substring that matched the final iteration. For example, after

```
(tweedle[dume]{3}\s*)+  or      Grep/E="(tweedle[dume]{3}\s*)+"

```

has matched "tweedledum tweedledee" the value of the captured substring is "tweedledee". However, if there are nested capturing subpatterns, the corresponding captured values may have been set in previous iterations. For example, after

```
/(a|(b))+/

```

matches "aba" the value of the second captured substring is "b".

## Atomic Grouping and Possessive Quantifiers

With both maximizing and minimizing repetition, failure of what follows normally reevaluates the repeated item to see if a different number of repeats allows the rest of the pattern to match. Sometimes it is useful to prevent this, either to change the nature of the match, or to cause it fail earlier than it otherwise might, when the author of the pattern knows there is no point in carrying on.

Consider, for example, the pattern `\d+foo` when applied to the subject line

```
123456bar

```

After matching all 6 digits and then failing to match "foo", the normal action of the matcher is to try again with only 5 digits matching the `\d+` item, and then with 4, and so on, before ultimately failing. "Atomic grouping" provides the means for specifying that once a subpattern has matched, it is not to be reevaluated in this way.

If we use atomic grouping for the previous example, the matcher would give up immediately on failing to match "foo" the first time. The notation is a kind of special parenthesis, starting with `(?>` as in this example:

```
(?>\d+)foo      or      Grep/E="(?>\d+)foo"

```

This kind of parenthesis "locks up" the part of the pattern it contains once it has matched, and a failure further into the pattern is prevented from backtracking into it. Backtracking past it to previous items, however, works as normal.

An alternative description is that a subpattern of this type matches the string of characters that an identical standalone pattern would match, if anchored at the current point in the subject string.

Atomic grouping subpatterns are not capturing subpatterns. Simple cases such as the above example can be thought of as a maximizing repeat that must swallow everything it can. So, while both `\d+` and `\d+?`

## Chapter IV-7 — Programming Techniques

---

are prepared to adjust the number of digits they match in order to make the rest of the pattern match, `(?>\d+)` can only match an entire sequence of digits.

Atomic groups in general can of course contain arbitrarily complicated subpatterns, and can be nested. However, when the subpattern for an atomic group is just a single repeated item, as in the example above, a simpler notation, called a “possessive quantifier” can be used. This consists of an additional `+` character following a quantifier. Using this notation, the previous example can be rewritten as

```
\d++foo           or      Grep/E="\d++foo"
```

Possessive quantifiers are always greedy; the setting of the `PCRE_UNGREEDY` option is ignored. They are a convenient notation for the simpler forms of atomic group. However, there is no difference in the meaning or processing of a possessive quantifier and the equivalent atomic group.

The possessive quantifier syntax is an extension to the Perl syntax. It originates in Sun’s Java package.

When a pattern contains an unlimited repeat inside a subpattern that can itself be repeated an unlimited number of times, the use of an atomic group is the only way to avoid some failing matches taking a very long time indeed. The pattern

```
(\D+|<\d+>)*[!?]   or      Grep/E="(\D+|<\d+>)*[!?] "
```

matches an unlimited number of substrings that either consist of nondigits, or digits enclosed in `<>`, followed by either `!` or `?`. When it matches, it runs quickly. However, if it is applied to

```
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
```

it takes a long time before reporting failure. This is because the string can be divided between the internal `\D+` repeat and the external `*` repeat in a large number of ways, and all have to be tried. (The example uses `[!?]` rather than a single character at the end, because both PCRE and Perl have an optimization that allows for fast failure when a single character is used. They remember the last single character that is required for a match, and fail early if it is not present in the string.) If the pattern is changed so that it uses an atomic group, like this:

```
((?>\D+)|<\d+>)*[!?]   or      Grep/E="((?>\D+)|<\d+>)*[!?] "
```

sequences of nondigits cannot be broken, and failure happens quickly.

### Back References

Outside a character class, a backslash followed by a digit greater than 0 (and possibly further digits) is a back reference to a capturing subpattern earlier (that is, to its left) in the pattern, provided there have been that many previous capturing left parentheses.

However, if the decimal number following the backslash is less than 10, it is always taken as a back reference, and causes an error only if there are not that many capturing left parentheses in the entire pattern. In other words, the parentheses that are referenced need not be to the left of the reference for numbers less than 10. See **Backslash and Nonprinting Characters** on page IV-168 for further details of the handling of digits following a backslash.

A back reference matches whatever actually matched the capturing subpattern in the current subject string, rather than anything matching the subpattern itself (see **Subpatterns as Subroutines** on page IV-183 for a way of doing that). So the pattern

```
(sens|respons)e and \1bility or /E="(sens|respons)e and \1bility"
```

matches “sense and sensibility” and “response and responsibility”, but not “sense and responsibility”. If careful matching is in force at the time of the back reference, the case of letters is relevant. For example,

```
((?i)rah)\s+\1      or      Grep/E="((?i)rah)\s+\1"
```

matches “rah rah” and “RAH RAH”, but not “RAH rah”, even though the original capturing subpattern is matched caselessly.

Back references to named subpatterns use the Python syntax `(?P<name>)`. We could rewrite the above example as follows:

```
(?P<p1>(?!rah)\s+(?P=p1)    or    Grep/E="( ?P<p1>(?!rah)\s+(?P=p1) "
```

There may be more than one back reference to the same subpattern. If a subpattern has not actually been used in a particular match, any back references to it always fail. For example, the pattern

```
(a|bc)\2
```

always fails if it starts to match “a” rather than “bc”. Because there may be many capturing parentheses in a pattern, all digits following the backslash are taken as part of a potential back reference number. If the pattern continues with a digit character, some delimiter must be used to terminate the back reference. An empty comment (see **Regular Expression Comments** on page IV-182) can be used.

A back reference that occurs inside the parentheses to which it refers fails when the subpattern is first used, so, for example, `(a\1)` never matches. However, such references can be useful inside repeated subpatterns. For example, the pattern

```
(a|b\1)+    or    Grep/E="(a|b\1)+"
```

matches any number of *a*’s and also “aba”, “ababbaa” etc. At each iteration of the subpattern, the back reference matches the character string corresponding to the previous iteration. In order for this to work, the pattern must be such that the first iteration does not need to match the back reference. This can be done using alternation, as in the example above, or by a quantifier with a minimum of zero.

## Assertions

An assertion is a test on the characters following or preceding the current matching point that does not actually consume any characters. The simple assertions coded as `\b`, `\B`, `^` and `$` are described in **Backslash and Simple Assertions** on page IV-170.

More complicated assertions are coded as subpatterns. There are two kinds: those that look ahead of the current position in the subject string, and those that look behind it. An assertion subpattern is matched in the normal way, except that it does not cause the current matching position to be changed.

Assertion subpatterns are not capturing subpatterns, and may not be repeated, because it makes no sense to assert the same thing several times. If any kind of assertion contains capturing subpatterns within it, these are counted for the purposes of numbering the capturing subpatterns in the whole pattern. However, substring capturing is carried out only for positive assertions, because it does not make sense for negative assertions.

### Lookahead Assertions

Lookahead assertions start with `(?=` for positive assertions and `(?!` for negative assertions. For example,

```
\w+(?=;)    or    Grep/E="\w+(?=;)"
```

matches a word followed by a semicolon, but does not include the semicolon in the match, and

```
foo(?!bar)
```

matches any occurrence of “foo” that is not followed by “bar”. Note that the apparently similar pattern

```
(?!foo)bar
```

does not find an occurrence of “bar” that is preceded by something other than “foo”; it finds any occurrence of “bar” whatsoever, because the assertion `(?!foo)` is always true when the next three characters are “bar”. A lookbehind assertion is needed to achieve the other effect.

If you want to force a matching failure at some point in a pattern, the most convenient way to do it is with `(?!)` because an empty string always matches, so an assertion that requires there not to be an empty string must always fail.

### Lookbehind Assertions

Lookbehind assertions start with `(?<=` for positive assertions and `(?<!` for negative assertions. For example,

```
(?<!foo)bar
```

does find an occurrence of “bar” that is not preceded by “foo”. The contents of a lookbehind assertion are restricted such that all the strings it matches must have a fixed length. However, if there are several alternatives, they do not all have to have the same fixed length. Thus

```
(?<=bullock|donkey)
```

is permitted, but

```
(?<!dogs?|cats?)
```

causes an error at compile time. Branches that match different length strings are permitted only at the top level of a lookbehind assertion. This is an extension compared with Perl (at least for 5.8), which requires all branches to match the same length of string. An assertion such as

```
(?<=ab(c|de))
```

is not permitted, because its single top-level branch can match two different lengths, but it is acceptable if rewritten to use two top-level branches:

```
(?<=abc|abde)
```

In some cases, the escape sequence `\K` (see above) can be used instead of a lookbehind assertion to get round the fixed-length restriction.

The implementation of lookbehind assertions is, for each alternative, to temporarily move the current position back by the fixed width and then try to match. If there are insufficient characters before the current position, the match is deemed to fail.

PCRE does not allow the `\C` escape (which matches a single data unit) to appear in lookbehind assertions, because it makes it impossible to calculate the length of the lookbehind. The `\X` and `\R` escapes, which can match different numbers of data units, are also not permitted.

Atomic groups can be used in conjunction with lookbehind assertions to specify efficient matching at the end of the subject string. Consider a simple pattern such as

```
abcd$
```

when applied to a long string that does not match. Because matching proceeds from left to right, PCRE will look for each *a* in the subject and then see if what follows matches the rest of the pattern. If the pattern is specified as

```
^.*abcd$
```

the initial `.*` matches the entire string at first, but when this fails (because there is no following *a*), it backtracks to match all but the last character, then all but the last two characters, and so on. Once again the search for *a* covers the entire string, from right to left, so we are no better off. However, if the pattern is written as

```
^(?>.*)(?<=abcd)
```

or, equivalently, using the possessive quantifier syntax,

```
^.*+(?<=abcd)
```

there can be no backtracking for the `.*` item; it can match only the entire string. The subsequent lookbehind assertion does a single test on the last four characters. If it fails, the match fails immediately. For long strings, this approach makes a significant difference to the processing time.

### Using Multiple Assertions

Several assertions (of any sort) may occur in succession. For example,

```
(?<=\d{3})(?<!999)foo or Grep/E="( ?<=\d{3})(?<!999)foo"
```

matches “foo” preceded by three digits that are not “999”. Notice that each of the assertions is applied independently at the same point in the subject string. First there is a check that the previous three characters are all digits, and then there is a check that the same three characters are not “999”. This pattern does not match “foo” preceded by six characters, the first of which are digits and the last three of which are not “999”. For example, it doesn’t match “123abcfoo”. A pattern to do that is

```
(?<=\d{3}\. . .) (?<!999) foo or Grep/E=" (?<=\d{3}\. . .) (?<!999) foo"
```

This time the first assertion looks at the preceding six characters, checking that the first three are digits, and then the second assertion checks that the preceding three characters are not “999”.

Assertions can be nested in any combination. For example,

```
(?<=(?<!foo)bar) baz
```

matches an occurrence of “baz” that is preceded by “bar” which in turn is not preceded by “foo”, while

```
(?<=\d{3}(?!999)\. . .) foo or Grep/E=" (?<=\d{3}(?!999)\. . .) foo"
```

is another pattern that matches “foo” preceded by three digits and any three characters that are not “999”.

## Conditional Subpatterns

It is possible to cause the matching process to obey a subpattern conditionally or to choose between two alternative subpatterns, depending on the result of an assertion, or whether a previous capturing subpattern matched or not. The two possible forms of conditional subpattern are

```
(?(condition)yes-pattern)
(?(condition)yes-pattern|no-pattern)
```

If the condition is satisfied, the yes-pattern is used; otherwise the no-pattern (if present) is used. If there are more than two alternatives in the subpattern, a compile-time error occurs.

There are three kinds of condition. If the text between the parentheses consists of a sequence of digits, the condition is satisfied if the capturing subpattern of that number has previously matched. The number must be greater than zero. Consider the following pattern, which contains nonsignificant white space to make it more readable and to divide it into three parts for ease of discussion:

```
( \ ( ) ?      [ ^ ( ) ] +      ( ? ( 1 ) \ ) )
```

The first part matches an optional opening parenthesis, and if that character is present, sets it as the first captured substring. The second part matches one or more characters that are not parentheses. The third part is a conditional subpattern that tests whether the first set of parentheses matched or not. If they did, that is, if subject started with an opening parenthesis, the condition is true, and so the yes-pattern is executed and a closing parenthesis is required. Otherwise, since no-pattern is not present, the subpattern matches nothing. In other words, this pattern matches a sequence of nonparentheses, optionally enclosed in parentheses.

If the condition is the string (R), it is satisfied if a recursive call to the pattern or subpattern has been made. At “top level”, the condition is false. This is a PCRE extension. Recursive patterns are described in the next section.

If the condition is not a sequence of digits or (R), it must be an assertion. This may be a positive or negative lookahead or lookbehind assertion. Consider this pattern, again containing nonsignificant white space, and with the two alternatives on the second line:

```
(? ( ? = [ ^ a - z ] * [ a - z ] )
 \ d { 2 } - [ a - z ] { 3 } - \ d { 2 }      |      \ d { 2 } - \ d { 2 } - \ d { 2 } )
```

The condition is a positive lookahead assertion that matches an optional sequence of nonletters followed by a letter. In other words, it tests for the presence of at least one letter in the subject. If a letter is found, the subject is matched against the first alternative; otherwise it is matched against the second. This pattern matches strings in one of the two forms dd-aaa-dd or dd-dd-dd, where aaa are letters and dd are digits.

### Regular Expression Comments

The sequence `(?#` marks the start of a comment that continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part in the pattern matching at all.

### Recursive Patterns

Consider the problem of matching a string in parentheses, allowing for unlimited nested parentheses. Without the use of recursion, the best that can be done is to use a pattern that matches up to some fixed depth of nesting. It is not possible to handle an arbitrary nesting depth. Perl provides a facility that allows regular expressions to recurse (amongst other things). It does this by interpolating Perl code in the expression at runtime, and the code can refer to the expression itself. A Perl pattern to solve the parentheses problem can be created like this:

```
$re = qr{\( (? : (?>[^\(\)]+) | (?p{$re}) ) * \) }x;
```

The `(?p{...})` item interpolates Perl code at runtime, and in this case refers recursively to the pattern in which it appears. Obviously, PCRE cannot support the interpolation of Perl code. Instead, it supports some special syntax for recursion of the entire pattern, and also for individual subpattern recursion.

The special item that consists of `(?` followed by a number greater than zero and a closing parenthesis is a recursive call of the subpattern of the given number, provided that it occurs inside that subpattern. (If not, it is a “subroutine” call, which is described in **Subpatterns as Subroutines** on page IV-183.) The special item `(?R)` is a recursive call of the entire regular expression.

For example, this PCRE pattern solves the nested parentheses problem (additional nonfunction whitespace has been added to separate the expression into parts):

```
\( ( (?>[^\(\)]+) | (?R) ) * \)
```

First it matches an opening parenthesis. Then it matches any number of substrings which can either be a sequence of nonparentheses, or a recursive match of the pattern itself (that is a correctly parenthesized substring). Finally there is a closing parenthesis.

If this were part of a larger pattern, you would not want to recurse the entire pattern, so instead you could use this:

```
( \ ( ( (?>[^\(\)]+) | (?1) ) * \ ) )
```

We have put the pattern into parentheses, and caused the recursion to refer to them instead of the whole pattern. In a larger pattern, keeping track of parenthesis numbers can be tricky. It may be more convenient to use named parentheses instead. For this, PCRE uses `(?P>name)`, which is an extension to the Python syntax that PCRE uses for named parentheses (Perl does not provide named parentheses). We could rewrite the above example as follows:

```
(?P<pn> \ ( ( (?>[^\(\)]+) | (?P>pn) ) * \ ) )
```

This particular example pattern contains nested unlimited repeats, and so the use of atomic grouping for matching strings of nonparentheses is important when applying the pattern to strings that do not match. For example, when this pattern is applied to

```
(aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa())
```

it yields “no match” quickly. However, if atomic grouping is not used, the match runs for a very long time indeed because there are so many different ways the `+` and `*` repeats can carve up the subject, and all have to be tested before failure can be reported.

At the end of a match, the values set for any capturing subpatterns are those from the outermost level of the recursion at which the subpattern value is set. If you want to obtain intermediate values, a callout function can be used (see **Subpatterns as Subroutines** on page IV-183). If the pattern above is matched against

```
(ab(cd)ef)
```

the value for the capturing parentheses is “ef”, which is the last value taken on at the top level. If additional parentheses are added, giving

```
\( ( ( (?>[^\()]+) | (?R) ) * ) \)
      ↑               ↑
```

the string they capture is “ab(cd)ef”, the contents of the top level parentheses. If there are more than 15 capturing parentheses in a pattern, PCRE has to obtain extra memory to store data during a recursion, which it does by using `pcre_malloc`, freeing it via `pcre_free` afterward. If no memory can be obtained, the match fails with the `PCRE_ERROR_NOMEMORY` error.

Do not confuse the `(?R)` item with the condition `(R)`, which tests for recursion. Consider this pattern, which matches text in angle brackets, allowing for arbitrary nesting. Only digits are allowed in nested brackets (that is, when recursing), whereas any characters are permitted at the outer level.

```
< (? : (? (R) \d++ | [^<>] * ) | (?R) ) * >
```

In this pattern, `(? (R))` is the start of a conditional subpattern, with two different alternatives for the recursive and nonrecursive cases. The `(?R)` item is the actual recursive call.

## Subpatterns as Subroutines

If the syntax for a recursive subpattern reference (either by number or by name) is used outside the parentheses to which it refers, it operates like a subroutine in a programming language. An earlier example pointed out that the pattern

```
(sens|respons)e and \libility
```

matches “sense and sensibility” and “response and responsibility”, but not “sense and responsibility”. If instead the pattern

```
(sens|respons)e and (?1)ibility
```

is used, it does match “sense and responsibility” as well as the other two strings. Such references must, however, follow the subpattern to which they refer.

## Regular Expressions References

The regular expression syntax supported by **Grep**, **GrepString**, **GrepList**, and **Demo** is based on the *PCRE — Perl-Compatible Regular Expression Library* by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.

Visit <http://pcre.org/> for more information about the PCRE library, and <http://www.perldoc.com/> for more about Perl regular expressions. This description, *Regular Expressions In Igor*, is taken from the PCRE documentation.

A good introductory book on regular expressions is: Forta, Ben, *Regular Expressions in 10 Minutes*, Sams Publishing, 2004.

A good comprehensive book on regular expressions is: Friedl, Jeffrey E. F., *Mastering Regular Expressions*, 2nd ed., 492 pp., O'Reilly Media, 2002.

A good web site is: <http://www.regular-expressions.info>

## Working with Files

Here are the built-in operations that you can use to read from or write to files:

Operation	What It Does
Open	Opens an existing file for reading or writing. Can also create a new file. Can also append to an existing file. Returns a file reference number that you must pass to the other file operations.  Use <code>Open/D</code> to present a dialog that allows the user to choose a file without actually opening the file.

## Chapter IV-7 — Programming Techniques

Operation	What It Does
fprintf	Writes formatted text to an open file.
wfprintf	Writes wave data as formatted text to an open file.
FGetPos	Gets the position at which the next file read or write will be done.
FSetPos	Sets the position at which the next file read or write will be done.
FStatus	Given a file reference number, returns miscellaneous information about the file.
FBinRead	Reads binary data from a file into an Igor string, variable or wave. This is used mostly to read nonstandard file formats.
FBinWrite	Writes binary data from an Igor string, variable or wave. This is used mostly to write nonstandard file formats.
FReadLine	Reads a line of text from a text file into an Igor string variable. This can be used to parse an arbitrary format text file.
Close	Closes a file opened by the Open operation.

Before working with a file, you must use the Open operation to obtain a file reference number that you use with all the remaining commands. The Open operation creates new files, appends data to an existing file, or reads data from an existing file. There is no facility to deal with the resource fork of a Macintosh file.

Sometimes you may write a procedure that uses the Open operation and the Close operation but, because of an error, the Close operation never gets to execute. You then correct the procedure and want to rerun it. The file will still be open because the Close operation never got a chance to run. In this case, execute:

```
Close/A
```

from the command line to close all open files.

### Finding Files

Two functions are provided to help you to determine what files exist in a particular folder:

- **TextFile**
- **IndexedFile**

IndexedFile is a more general version of TextFile.

You can also use the Open operation with the /D flag to present an open dialog.

### Other File- and Folder-Related Operations and Functions

Igor Pro also supports a number of operations and functions for file or folder manipulation:

CopyFile	CopyFolder
DeleteFile	DeleteFolder
GetFileFolderInfo	SetFileFolderInfo
MoveFile	MoveFolder
CreateAliasShortcut	
NewPath	PathInfo
ParseFilePath	

**Warning:** Use caution when writing code that deletes or moves files or folders. These actions are not undoable.

Because the DeleteFolder, CopyFolder and MoveFolder operations have the potential to do a lot of damage if used incorrectly, they require user permission before overwriting or deleting a folder. The user controls the permission process using the Miscellaneous Settings dialog (Misc menu).

## Writing to a Text File

You can generate output text files from Igor procedures or from the command line in formats acceptable to other programs. To do this, you need to use the **Open** and **Close** operations and the **fprintf** operation (page V-224) and the **wfprintf** operation (page V-943).

The following commands illustrate how you could use these operations to create an output text file. Each operation is described in detail in following sections:

```
Function WriteFileDemo(pathName, fileName)
    String pathName    // Name of Igor symbolic path (see Symbolic Paths)
    String fileName    // File name, partial path or full path

    Variable refNum
    Open refNum as "A New File"           // Create and open file
    fprintf refNum, "wave1\twave2\twave3\r" // Write column headers
    Wave wave1, wave2, wave3
    wfprintf refNum, "" wave1, wave2, wave3 // Write wave data
    Close refNum                          // Close file
End
```

## Open and Close Operations

You use the **Open** operation (page V-605) to open a file. For our purposes, the syntax of the Open operation is:

```
Open [/R/A/P=pathName/M=messageStr] variableName [as "filename"]
```

*variableName* is the name of a numeric variable. The Open operation puts a file reference number in that variable. You use the reference number to access the file after you've opened it.

A file specifications consists of a path (directions for finding a folder) and a file name. In the Open operation, you can specify the path in three ways:

Using a full path as the filename parameter:

```
Open refNum as "hd:Data:Run123.dat"
```

Or using a symbolic path name and a file name:

```
Open/P=DataPath refNum as "Run123.dat"
```

Or using a symbolic path name and a partial path including the file name:

```
Open/P=HDPATH refNum as ":Data:Run123.dat"
```

A symbolic path is a short name that refers to a folder on disk. See **Symbolic Paths** on page II-21.

If you do not provide enough information to find the folder and file of interest, Igor displays a dialog which lets you select the file to open. If you supply sufficient information, Igor open the file without displaying the dialog.

To open an existing file for reading, use the /R flag. To append new data to an existing file, use the /A flag. If you omit both of these flags and if the file already exists, you overwrite any data that is in the file.

If you open a file for writing (you don't use /R) then, if there exists a file with the specified name, Igor opens the file and overwrites the existing data in the file. If there is no file with the specified name, Igor creates a new file.

**Warning:** If you're not careful you can inadvertently lose data using the Open operation by opening for writing without using the /A flag. To avoid this, use the /R (open for read) or /A (append) flags.

## Wave Reference Functions

It is common to write a user-defined function that operates on all of the waves in a data folder, on the waves displayed in a graph or table, or on a wave identified by a cursor in a graph. For these purposes, you need to use wave reference functions.

Wave reference functions are built-in Igor functions that return a reference that can be used in a user-defined function. Here is an example that works on the top graph. Cursors are assumed to be placed on a region of a trace in the graph.

```
Function WaveAverageBetweenCursors()
    WAVE/Z w = CsrWaveRef(A)
    if (!WaveExists(w))           // Cursor is not on any wave.
        return NaN
    endif

    Variable xA = xcsrc(A)
    Variable xB = xcsrc(B)
    Variable avg = mean(w, xA, xB)

    return avg
End
```

CsrWaveRef returns a wave reference that identifies the wave a cursor is on.

An older function, CsrWave, returns the *name* of the wave the cursor is on. It would be tempting to use this to determine the wave the cursor is on, but it would be incorrect. The name of a wave by itself does not uniquely identify a wave because it does not specify the data folder in which the wave resides. For this reason, we usually need to use the wave reference function CsrWaveRef instead of CsrWave.

This example uses a wave reference function to operate on the waves displayed in a graph:

```
Function SmoothWavesInGraph()
    String list = TraceNameList("", ";", 1)
    String traceName
    Variable index = 0
    do
        traceName = StringFromList(index, list)
        if (strlen(traceName) == 0)
            break           // No more traces.
        endif
        WAVE w = TraceNameToWaveRef("", traceName)
        Smooth 5, w
        index += 1
    while(1)
End
```

Use **WaveRefIndexedDFR** to iterate over the waves in a given data folder.

Here are the wave reference functions. See Chapter V-1, **Igor Reference**, for details on each of them.

Function	Comment
<b>CsrWaveRef</b>	Returns a reference to the Y wave to which a cursor is attached.
<b>CsrXWaveRef</b>	Returns a reference to the X wave when a cursor is attached to an XY pair.
<b>WaveRefIndexedDFR</b>	Returns a reference to a wave in the specified data folder.
<b>WaveRefIndexed</b>	Returns a reference to a wave in a graph or table or to a wave in the current data folder.
<b>XWaveRefFromTrace</b>	Returns a reference to an X wave in a graph. Used with the output of TraceNameList.

Function	Comment
<b>ContourNameToWaveRef</b>	Returns a reference to a wave displayed as a contour plot. Used with the output of ContourNameList.
<b>ImageNameToWaveRef</b>	Returns a reference to a wave displayed as an image. Used with the output of ImageNameList.
<b>TraceNameToWaveRef</b>	Returns a reference to a wave displayed as a waveform or as the Y wave of an XY pair in a graph. Used with the output of TraceNameList.
<b>TagWaveRef</b>	Returns a reference to a wave to which a tag is attached in a graph. Used in creating a smart tag.
<b>WaveRefsEqual</b>	Returns the truth two wave references are the same.
<b>WaveRefWaveToList</b>	Returns a semicolon-separated string list containing the full or partial path to the wave referenced by each element of the input wave reference wave.
<b>ListToWaveRefWave</b>	Returns a free wave containing a wave reference for each of the waves in the semicolon-separated input string list.

This simple example illustrates the use of the CsrWaveRef wave reference function:

```
Function/WAVE CursorAWave()
    WAVE/Z w = CsrWaveRef(A)
    return w
End

Function DemoCursorAWave()
    WAVE/Z w = $CursorAWave()
    if (WaveExists(w)==0)
        Print "oops: no wave"
    else
        Printf "Cursor A is on the wave '%s'\r", NameOfWave(w)
    endif
End
```

## Processing Lists of Waves

Igor users often want to use a string list of waves in places where Igor is looking for just the name of a single wave. For example, they would like to do this:

```
Display "wave0;wave1;wave2"
```

or, more generally:

```
Function DisplayListOfWaves(list)
    String list // e.g., "wave0;wave1;wave2"

    Display $list
End
```

Unfortunately, Igor can't handle this. However, there are techniques for achieving the same result.

## Graphing a List of Waves

This example illustrates the basic technique for processing a list of waves.

```
Function DisplayWaveList(list)
    String list // A semicolon-separated list.

    Variable index = 0
    do
        // Get the next wave name
        String name = StringFromList(index, list)
        if (strlen(name) == 0)
```

```
        break                                // Ran out of waves
    endif

    Wave w = $name
    if (index == 0)                          // Is this the first wave?
        Display w
    else
        AppendToGraph w
    endif
    index += 1
while (1)                                // Loop until break above
End
```

To make a graph of all of the waves in the current data folder, you could execute

```
DisplayWaveList(WaveList("*", ";", ""))
```

### Operating on the Traces in a Graph

In a previous section, we showed an example that operates on the waves displayed in a graph. It used a wave reference function, `TraceNameToWaveRef`. If you want to write a function that operates on *traces* in a graph, you would *not* use wave reference functions. That's because Igor operations that operate on *traces* expect *trace names*, not wave references. For example:

```
Function GrayOutTracesInGraph()
    String list = TraceNameList("", ";", 1)
    Variable index = 0
    do
        String traceName = StringFromList(index, list)
        if (strlen(traceName) == 0)
            break                                // No more traces.
        endif

        // WRONG: ModifyGraph expects a trace name and w is not a trace name
        WAVE w = TraceNameToWaveRef("", traceName)
        ModifyGraph rgb(w)=(50000,50000,50000)

        // RIGHT
        ModifyGraph rgb($traceName)=(50000,50000,50000)

        index += 1
    while(1)
End
```

### Using a Fixed-Length List

In the previous examples, the number of waves in the list was unimportant and all of the waves in the list served the same purpose. In this example, the list has a fixed number of waves and each wave has a different purpose.

```
Function DoLineFit(list)
    String list                                // List of waves names: source, weight

    // Pick out the expected wave names

    String sourceStr = StringFromList(0, list)
    Wave source = $sourceStr

    String weightStr = StringFromList(2, list)
    Wave weight = $weightStr

    CurveFit line source /D /W=weight
End
```

You could invoke this function as follows:

```
DoLineFit("wave0;wave1;")
```

For most purposes, it is better to design the function to take wave reference parameters rather than a string list.

## Operating on Qualified Waves

This example illustrates how to operate on waves that match a certain criterion. It is broken into two functions - one that creates the list of qualified waves and a second that operates on them. This organization gives us a general purpose routine (ListOfMatrices) that we would not have if we wrote the whole thing as one function.

```
Function/S ListOfMatrices()
  String list = ""
  Variable index=0
  do
    WAVE/Z w=WaveRefIndexedDFR(:,index)    // Get next wave.
    if (WaveExists(w) == 0)
      break                                // No more waves.
    endif
    if (WaveDims(w) == 2)
      // Found matrix. Add to list with separator.
      list += NameOfWave(w) + ";"
    endif
    index += 1
  while(1)                                // Loop till break above.
  return list
End

Function ChooseAndDisplayMatrix()
  String theList = ListOfMatrices()

  String theMatrix
  Prompt theMatrix, "Matrix to display:", popup theList
  DoPrompt "Display Matrix", theMatrix
  if (V_Flag != 0)
    return -1
  endif

  WAVE m = $theMatrix
  NewImage m
End
```

In the preceding example, we needed a list of wave names in a string to use in a Prompt statement. More often we want a list of wave references on which to operate. The next example illustrates how to do this using a general purpose routine that returns a list of wave references in a free wave:

```
// Returns a free wave containing wave references
// for each 2D wave in the current data folder
Function/WAVE GetMatrixWavesInCDF()
  Variable numWavesInCDF = CountObjects(":", 1)
  Make/FREE/WAVE/N=(numWavesInCDF) list

  Variable numMatrixWaves = 0
  Variable i
  for(i=0; i<numWavesInCDF; i+=1)
    WAVE w = WaveRefIndexedDFR(:,i)
    Variable numDimensions = WaveDims(w)
    if (numDimensions == 2)
      list[numMatrixWaves] = w
      numMatrixWaves += 1
    endif
  endfor
```

```
endfor

Redimension/N=(numMatrixWaves) list
return list      // Ownership of the wave is passed to the calling routine
End

Function DemoMatrixWaveList()
Wave/WAVE freeList = GetMatrixWavesInCDF()    // We now own the freeList wave
Variable numMatrixWaves = numpnts(freeList)
Printf "Number of matrix waves in current data folder: %d\r", numMatrixWaves

Variable i
for(i=0; i<numMatrixWaves; i+=1)
    Wave w = freeList[i]
    String name = NameOfWave(w)
    name = PossiblyQuoteName(name)
    Printf "Wave %d: %s\r", i, name
endfor

// freeList is automatically killed when the function returns
End
```

### The ExecuteCmdOnList Function

The ExecuteCmdOnList function is implemented by a WaveMetrics procedure file and executes any command for each wave in the list. For example, the following commands do a WaveStats operation on each wave.

```
Make wave0=gnoise(1), wave1=gnoise(10), wave2=gnoise(100)
ExecuteCmdOnList("WaveStats %s", "wave0;wave1;wave2;")
```

The ExecuteCmdOnList function is supplied in the “Execute Cmd On List” procedure file. See **The Include Statement** on page IV-155 for instructions on including a procedure file.

This technique is on the kludgy side. If you can achieve your goal in a more straightforward fashion without heroic efforts, you should use regular programming techniques.

### The Execute Operation

Execute is a built-in operation that executes a string expression as if you had typed it into the command line. The main purpose of Execute is to get around the restrictions on calling macros and external operations from user functions.

We try to avoid using Execute because it makes code obscure and difficult to debug. If you can write a procedure without Execute, do it. However, there are some cases where using Execute can save pages of code or achieve something that would otherwise be impossible. For example, the TileWindow operation can not be directly called from a user-defined function and therefore must be called using Execute.

It is a good idea to compose the command to be executed in a local string variable and then pass that string to the Execute operation. Use this to print the string to the history for debugging. For example:

```
Function DemoExecute(list)
String list      // Semicolon-separated list of names of windows to tile
list = ReplaceString(";", list, ",")    // We need commas for TileWindows
list = RemoveEnding(list, ",")        // Remove trailing comma, if any
String cmd
sprintf cmd, "TileWindows %s", list
Print cmd      // For debugging only
Execute cmd
End
```

When you use Execute, you must be especially careful in the handling of wave names. See **Programming with Liberal Names** on page IV-157 for details.

When Execute runs, it is as if you typed a command in the command line. Local variables in macros and functions are not accessible. The example in **Calling an External Operation From a User-Defined Function** on page IV-191 shows how to use the sprintf operation to solve this problem.

### Using a Macro From a User-Defined Function

A macro can not be called directly from a user function. To do so, we must use Execute. This is a trivial example for which we would normally not resort to Execute but which clearly illustrates the technique.

```
Function Example()
    Make wave0=enoise(1)
    Variable/G V_avg           // Create a global
    Execute "MyMacro(\"wave0\")" // Invokes MyMacro("wave0")
    return V_avg
End

Macro MyMacro(wv)
    String wv
    WaveStats $wv           // Sets global V_avg and 9 other local vars
End
```

Execute does not supply good error messages. If the macro generates an error, you may get a cryptic message. Therefore, debug the macro *before* you call it with the Execute operation.

### Calling an External Operation From a User-Defined Function

Prior to Igor Pro 5, external operations could not be called directly from user-defined functions and had to be called via Execute. Now it is possible to write an external operation so that it can be called directly. However, very old XOPs that have not been updated still need to be called through Execute. This example shows how to do it.

If you attempt to directly use an external operation which does not support it, Igor displays an error dialog telling you to use Execute for that operation.

The external operation in this case is VDTWrite which sends text to the serial port. It is implemented by the VDT XOP (no longer shipped as of Igor7).

```
Function SetupVoltmeter(range)
    Variable range           // .1, .2, .5, 1, 2, 5 or 10 volts

    String voltmeterCmd
    sprintf voltmeterCmd, "DVM volts=%g", range
    String vdtCmd
    sprintf vdtCmd "VDTWrite \"%s\"\\r\\n", voltmeterCmd
    Execute vdtCmd
End
```

In this case, we are sending the command to a voltmeter that expects something like:

```
DVM volts=.2<CR><LF>
```

to set the voltmeter to the 0.2 volt range.

The parameter that we send to the Execute operation is:

```
VDTWrite "DVM volts=.2\\r\\n"
```

The backslashes used in the second sprintf call insert two quotation marks, a carriage return, and a linefeed in the command about to be executed.

A newer VDT2 XOP exists which includes external operations that *can* be directly called from user-functions. Thus, new programming should use the VDT2 XOP and will not need to use Execute.

### Other Uses of Execute

Execute can also accept as an argument a string variable containing commands that are algorithmically constructed. Here is a simple example:

```
Function Fit(w, fitType)
    WAVE w                // Source wave
    String fitType        // One of the built-in Igor fit types

    String name = NameOfWave(w)
    name = PossiblyQuoteName(name)    // Liberal names need quotes

    String cmd
    sprintf cmd, "CurveFit %s %s", fitType, name
    Execute cmd
End
```

Use this function to do any of the built-in fits on the specified wave. Without using the Execute operation, we would have to write it as follows:

```
Function Fit(w, fitType)
    WAVE w                // Source wave
    String fitType        // One of the built-in Igor fit types

    strswitch(fitType)
        case "line":
            CurveFit line w
            break

        case "exp":
            CurveFit exp w
            break

        <and so on for each fit type>
    endswitch
End
```

Note the use of sprintf to prepare the string containing the command to be executed. The following would not work because when Execute runs, local variables and parameters are not accessible:

```
Execute "CurveFit fitType name"
```

### Deferred Execution Using the Operation Queue

It is sometimes necessary to execute a command after the current function has finished. This is done using the Execute/P operation. For details, see [Operation Queue](#) on page IV-263.

## Procedures and Preferences

As explained under **Preferences** on page III-453, Igor allows you to set many preferences. Most of the preferences control the style of new objects, including new graphs, traces and axes added to graphs, new tables, columns added to tables, and so on.

Preferences are usually used only for manual “point-and-click” operation. We usually don’t want preferences to affect the behavior of procedures. The reason for this is that we want a procedure to do the same thing no matter who runs it. Also, we want it to do the same thing tomorrow as it does today. If we allowed preferences to take effect during procedure execution, a change in preferences could change the effect of a procedure, making it unpredictable.

By default, preferences do not take effect during procedure execution. If you want to override the default behavior, you can use the Preferences operation. From within a procedure, you can execute Preferences 1 to turn preferences on. This affects the procedure and any subroutines that it calls. It stays in effect until you execute Preferences 0.

When a *macro* ends, the state of preferences reverts to what it was when that macro started. If you change the preference setting within a *function*, the preferences state does *not* revert when that function ends. You must turn preferences on, save the old preferences state, execute Igor operations, and then restore the preferences state. For example:

```
Function DisplayWithPreferences(w)
    Wave w

    Variable oldPrefState
    Preferences 1                // Turn preferences on
    oldPrefState = V_Flag        // Save the old state

    Display w                    // Create graph using preferences

    Preferences oldPrefState     // Restore old prefs state
End
```

## Experiment Initialization Procedures

When Igor loads an experiment, it checks to see if there are any commands in the procedure window before the first macro, function or menu declaration. If there are such commands Igor executes them. This provides a way for you to initialize things. These initialization commands can invoke procedures that are declared later in the procedure window.

Also see **BeforeFileOpenHook** on page IV-271 and **IgorStartOrNewHook** on page IV-275 for other initialization methods.

## Procedure Subtypes

A procedure subtype identifies the purpose for which a particular procedure is intended and the appropriate menu from which it can be chosen. For example, the Graph subtype puts a procedure in the Graph Macros submenu of the Windows menu.

```
Window Graph0() : Graph
    PauseUpdate; Silent 1        // building window...
    Display/W=(5,42,400,250) wave0, wave1, wave2
    <more commands>
End
```

When Igor automatically creates a procedure, for example when you close and save a graph, it uses the appropriate subtype. When you create a curve fitting function using the Curve Fitting dialog, the dialog automatically uses the FitFunc subtype. You usually don't need to use subtypes for procedures that you write.

This table shows the available subtypes and how they are used.

Subtype	Effect	Available for
Graph	Displayed in Graph Macros submenu.	Macros
GraphStyle	Displayed in Graph Macros submenu and in Style pop-up menu in New Graph dialog.	Macros
GraphMarquee	Displayed in graph marquee. This keyword is no longer recommended. See <b>Marquee Menu as Input Device</b> on page IV-151 for details.	Macros and functions
CursorStyle	Displayed in Style Function submenu of cursor pop-up menu in graph info pane.	Functions
DrawUserShape	Marks a function as suitable for drawing a user-defined drawing object. See <b>DrawUserShape</b> .	Functions
GridStyle	Displayed in Grid-Style submenu of mover pop-up menu in drawing tool palette.	Functions

## Chapter IV-7 — Programming Techniques

Subtype	Effect	Available for
Table	Displayed in Table Macros submenu.	Macros
TableStyle	Displayed in Table Macros submenu and in Style pop-up menu in New Table dialog.	Macros
Layout	Displayed in Layout Macros submenu.	Macros
LayoutStyle	Displayed in Layout Macros submenu and in Style pop-up menu in New Layout dialog.	Macros
LayoutMarquee	Displayed in layout marquee. This keyword is no longer recommended. See <b>Marquee Menu as Input Device</b> on page IV-151 for details.	Macros and functions
ListBoxControl	Displayed in Procedure pop-up menu in ListBox Control dialog.	Macros and functions
Panel	Displayed in Panel Macros submenu.	Macros
GizmoPlot	Displayed in Other Macros submenu.	Macros
CameraWindow	Displayed in Other Macros submenu.	Macros
FitFunc	Displayed in Function pop-up menu in Curve Fitting dialog.	Functions
ButtonControl	Displayed in Procedure pop-up menu in Button Control dialog.	Macros and functions
CheckBoxControl	Displayed in Procedure pop-up menu in Checkbox Control dialog.	Macros and functions
PopupMenuControl	Displayed in Procedure pop-up menu in PopupMenu Control dialog.	Macros and functions
SetVariableControl	Displayed in Procedure pop-up menu in SetVariable Control dialog.	Macros and functions
SliderControl	Displayed in Procedure pop-up menu in Slider Control dialog.	Macros and functions
TabControl	Displayed in Procedure pop-up menu in Tab Control dialog.	Macros and functions
CDFFunc	Displayed in the Kolmogorov-Smirnov Test dialog. See <b>StatsKSTest</b> for details.	Functions

## Memory Considerations

Running out of memory is usually not an issue unless you load gigabytes of data into memory at one time. If this is true in your case, make sure to run IGOR64 (the 64-bit version of Igor) rather than IGOR32 (the 32-bit version). IGOR32 is provided only for users who rely on 32-bit XOPs that have not yet been ported to 64 bits.

On most systems, IGOR32 can access 4 GB of virtual memory. The limits for IGOR64 are much higher and depend on your operating system.

If memory becomes fragmented, you may get unexpected out-of-memory errors. This is more likely in IGOR32 than IGOR64.

See **Memory Management** on page III-451 for further information.

## Wave Reference Counting

Igor uses reference counting to determine when a wave is no longer referenced anywhere and memory can be safely deallocated.

Because memory is not deallocated until all references to a given wave are gone, memory may not be freed when you think. Consider the function:

```
Function myfunc()
    Make/N=10E6 bigwave
    // do stuff
    FunctionThatKillsBigwave()
    // do more stuff
End
```

The memory allocated for bigwave is not deallocated until the function returns because Make creates an automatic wave reference variable which, by default, exists until the function returns. To free memory before the function returns, use the **WAVEClear**:

```
Function myfunc()
    Make/N=10E6 bigwave
    // do stuff
    FunctionThatKillsBigwave()
    WAVEClear bigwave
    // do more stuff
End
```

The WAVEClear command takes a list of WAVE reference variables and stores NULL into them. It is the same as:

```
WAVE/Z wavref= $"
```

## Creating Igor Extensions

Igor includes a feature that allows a C or C++ programmer to extend its capabilities. Using Apple's Xcode or Microsoft Visual C++, a programmer can add command line operations and functions to Igor. These are called external operations and external functions. Experienced programmers can also add menu items, dialogs and windows.

A file containing external operations or external functions is called an "XOP file" or "XOP" (pronounced "ex-op") for short.

Here are some things for which you might want to write an XOP:

- To do number-crunching on waves.
- To import data from a file format that Igor does not support.
- To acquire data directly into Igor waves.
- To communicate with a remote computer, instrument or database.

The main reasons for writing something as an XOP instead of writing it as an Igor procedure are:

- It needs to be blazing fast.
- You already have a lot of C code that you want to reuse.
- You need to call drivers for data acquisition.
- It requires programming techniques that Igor doesn't support.
- You want to add your own dialogs or windows.

Writing an XOP that does number-crunching is considerably easier than writing a stand-alone program. You don't need to know anything about Macintosh or Windows APIs.

If you are a C or C++ programmer and would like to extend Igor with your own XOP, you need to purchase the Igor External Operations Toolkit from WaveMetrics. This toolkit contains documentation on writing XOPs as well as the source code for several WaveMetrics sample XOPs. It supplies a large library of routines that enable communication between Igor and the external code. You will also need the a recent version of Xcode, or Microsoft Visual C++.

## Debugging Procedures

There are two techniques for debugging procedures in Igor:

- Using print statements
- Using the symbolic debugger

For most situations, the symbolic debugger is the most effective tool. In some cases, a strategically placed print statement is sufficient.

## Debugging With Print Statements

This technique involves putting print statements at a certain point in a procedure to display debugging messages in Igor's history area. In this example, we use `Printf` to display the value of parameters to a function and then `Print` to display the function result.

```
Function Test(w, num, str)
    Wave w
    Variable num
    String str

    Printf "Wave=%s, num=%g, str=%s\r", NameOfWave(w), num, str

    <body of function>

    Print result
    return result
End
```

See [Creating Formatted Text](#) on page IV-244 for details on the `Printf` operation.

## The Debugger

When a procedure doesn't produce the results you want, you can use Igor's built-in debugger to observe the execution of macros and user-defined functions while single-stepping through the lines of code.

The debugger is normally disabled. Select **Enable Debugger** in either the **Procedure** menu or the contextual menu shown by control-clicking (Macintosh) or by right-clicking (Windows) in any procedure window.

Igor displays the debugger window when one of the following events occurs:

1. A breakpoint that you previously set is hit
2. An error occurs, and you have enabled debugging on that kind of error
3. An error dialog is presented, and you click the Debug button
4. The **Debugger** command is executed

## Setting Breakpoints

When you want to observe a particular routine in action, set a breakpoint on the line where you want the debugger to appear. To do this, open the procedure window which contains the routine, and click in the left “breakpoint margin”. The breakpoint margin appears only if the debugger has been enabled. These graphics show the procedure window with the debugger disabled (left) and enabled (right):

The red dot denotes a breakpoint that you have set.

When a line of code marked with a breakpoint is about to execute, Igor displays the debugger window.

Click the red dot again to clear the breakpoint. Control-click (*Macintosh*) or right-click (*Windows*) and use the pop-up menu to clear all breakpoints or disable a breakpoint on the currently selected line of the procedure window.

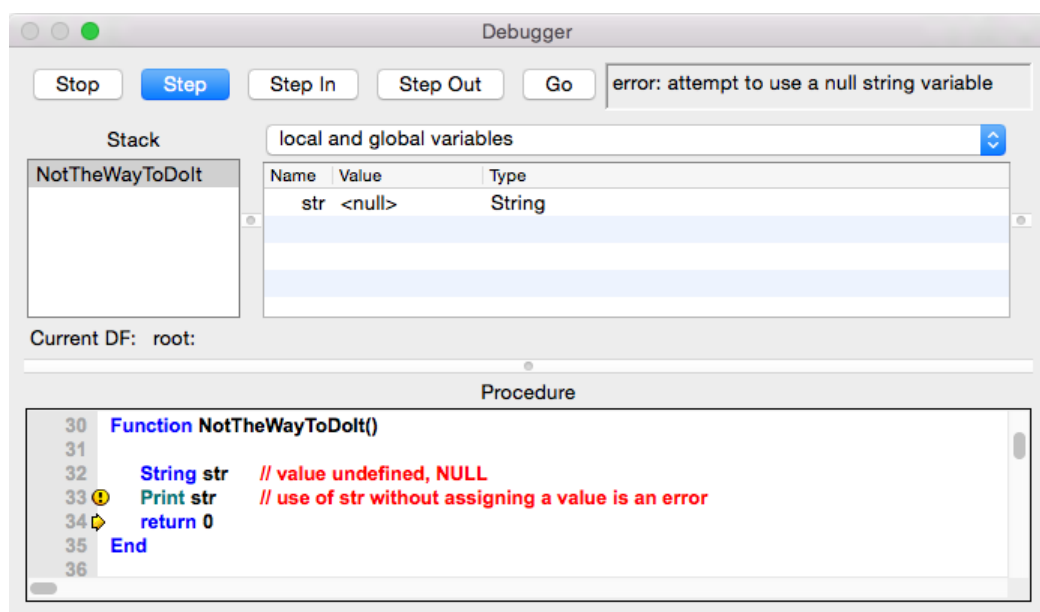

## Debugging on Error

You can automatically open the debugger window when an error occurs. There are two categories of errors to choose from:

Debug On Error	Any runtime error except failed NVAR, SVAR, or WAVE references.
NVAR SVAR WAVE Checking	Failed NVAR, SVAR, or WAVE references.

We recommend that Igor programmers turn both of these options on to get timely information about errors.

Use the Procedure or contextual menus to enable or disable both error categories. If the selected error occurs, Igor displays the debugger with an error message in its status area. The error message was generated by the command indicated by a round yellow icon, in this example the Print str command:

Sometimes you do something that you know may cause an error and you want to handle the error yourself, without breaking into the debugger. One such case is attempting to access a wave or variable that may or may not exist. You want to test its existence without breaking into the debugger.

You can use the /Z flag to prevent the Debug on Error feature from kicking in when an NVAR, SVAR, or WAVE reference fails. For example:

```
WAVE/Z w = <path to possibly missing wave>
if (WaveExists(w))
    <do something with w>
endif
```

In other cases where an error may occur and you want to handle it yourself, you need to temporarily disable the debugger and use **GetRTErr** to get and clear the error. For example:

```
Function DemoDisablingDebugger()
    DebuggerOptions          // Sets V_enable to 1 if debugger is enabled
    Variable debuggerEnabled=V_enable
    DebuggerOptions enable=0 // Disable debugger

    String name = ";"        // This is an illegal wave name
    Make/O $name              // So this will generate an error

    DebuggerOptions enable=debuggerEnabled // Restore

    Variable err = GetRTErr(1) // Clear error
    if (err != 0)
        Printf "Error %d\r", err
    else
        Print "No error"
    endif
End
```

### Macro Execute Error: The Debug Button

When the debugger is enabled and an error occurs in a macro, Igor presents an error dialog with, in most cases, a Debug button. Click the Debug button to open the debugger window.

Errors in macros (or procs) are reported immediately after they occur.

When an error occurs in a user-defined function, Igor displays an error dialog long after the error actually occurred. The Debug On Error option is for programmers and displays errors in functions when they occur.

## Stepping Through Your Code

Single-stepping through code is useful when you are not sure what path it is taking or how variables wound up containing their values.

Begin by enabling the debugger and setting a breakpoint on the line of code you are interested in, or begin when the debugger automatically opens because of an error. Use the buttons at the top of the debugger window to step through your code:

### *The Stop Button*

The Stop button ceases execution of the running function or macro before it completes. This is equivalent to clicking Igor's Abort button while the procedure is running.

Keyboard shortcuts: (none)

Pressing Command-period on a Macintosh while the debugger window is showing is equivalent to clicking the Go button, not the Stop button.

### *The Step Button*

The Step button executes the next line. If the line contains a call to one or more subroutines, execution continues until the subroutines return or until an error or breakpoint is encountered. Upon return, execution halts until you click a different button.

Keyboard shortcuts: Enter, keypad Enter, or Return

### *The Step Into Button*

The Step Into button executes the next line. If that line contains a call to one or more subroutines, execution halts when the first subroutine is entered. The Stack list of currently executing routines shows the most recently entered routine as the last item in the list.

Keyboard shortcuts: +, =, or keypad +

### *The Step Out Button*

The Step Out button executes until the current subroutine is exited, or an error or breakpoint is encountered.

Keyboard shortcuts: -, \_ (underscore) or keypad -

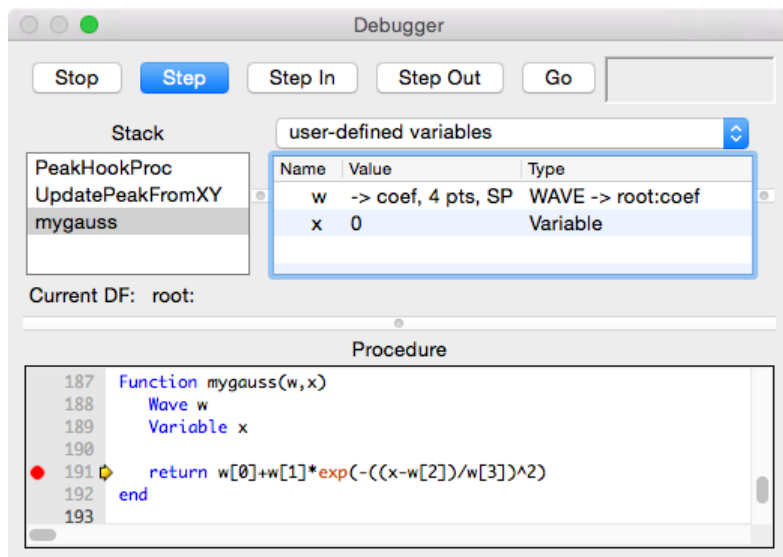

### *The Go Button*

The Go button resumes program execution. The debugger window remains open until execution completes or an error or breakpoint is encountered.

Keyboard shortcuts:      Esc

### The Stack and Variables Lists

The Stack List shows the routine that is currently executing and the chain of routines that called it. The top item in the list is the routine that began execution and the bottom item is the routine which is currently executing.

In this example, the routine that started execution is PeakHookProc, which most recently called UpdatePeakFromXY, which then called the currently executing mygauss user function.

The Variables List, to the right of the Stack List, shows that the function parameters w and x have the values coef (a wave) and 0 (a number). The pop-up menu controls which variables are displayed in the list; the example shows only user-defined local variables.

You can examine the variables associated with any routine in the Stack List by simply selecting the routine:

Here we've selected UpdatePeakFromXY, the routine that called mygauss (see the light blue arrow). Notice that the Variables List is showing the variables that are local to UpdatePeakFromXY.

For illustration purposes, the Variables List has been resized by dragging the dividing line, and the pop-up menu has been set to show local and global variables and type information.

## The Variables List Columns

The Variables List shows either two or three columns, depending on whether the "show variable types" item in the Variable pop-up menu is checked.

Double-clicking a column's header resizes the column to fit the contents. Double-clicking again resizes the column to a default width.

The first column is the name of the local variable. The name of an NVAR, SVAR, or WAVE reference is a name local to the macro or function that refers to a global object in a data folder.

The second column is the value of the local variable. Double-click the second column to edit numbers in-place, double-click anywhere on the row to "inspect" waves, strings, SVARS, or char arrays in structures in the appropriate Inspector.

In the case of a wave, the size and precision of the wave are shown here. The "->" characters mean "refers to". In our example wcoef is a local name that refers to a (global) wave named coef, which is one-dimensional, has 4 points, and is single precision.

To determine the value of a particular wave element, use an inspector as described under **Inspecting Waves**.

## Chapter IV-8 — Debugging

The optional third column shows what the type of the variable is, whether Variable, String, NVAR, SVAR, WAVE, etc. For global references, the full data folder path to the global is shown.

### Variables Pop-Up Menu

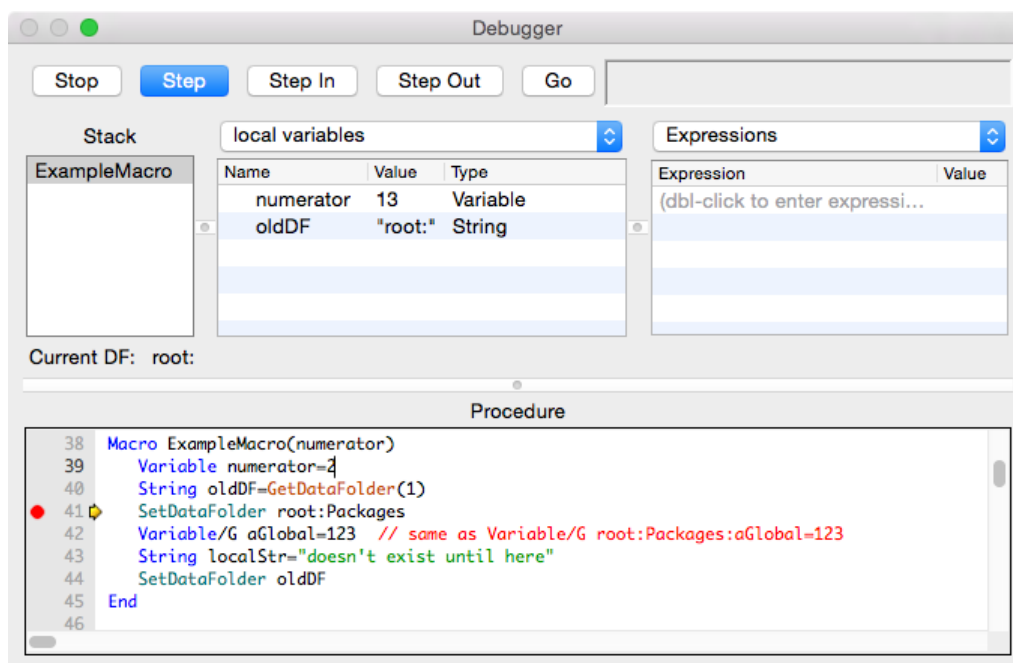

The Variables pop-up menu controls which information is displayed in the Variables List. When debugging a function, it looks like this:

When debugging a macro, proc or window macro, the first two items in the popup menu are unavailable.

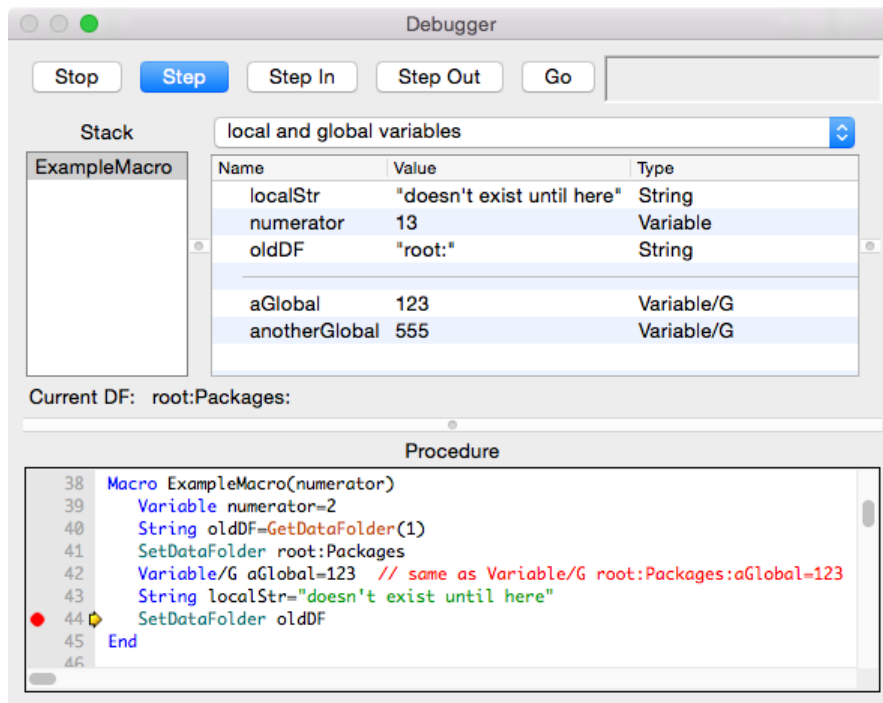

### Macro Variables

The ExampleMacro below illustrates how variables in Macros, Procs or Window procedures are classified as locals or globals:

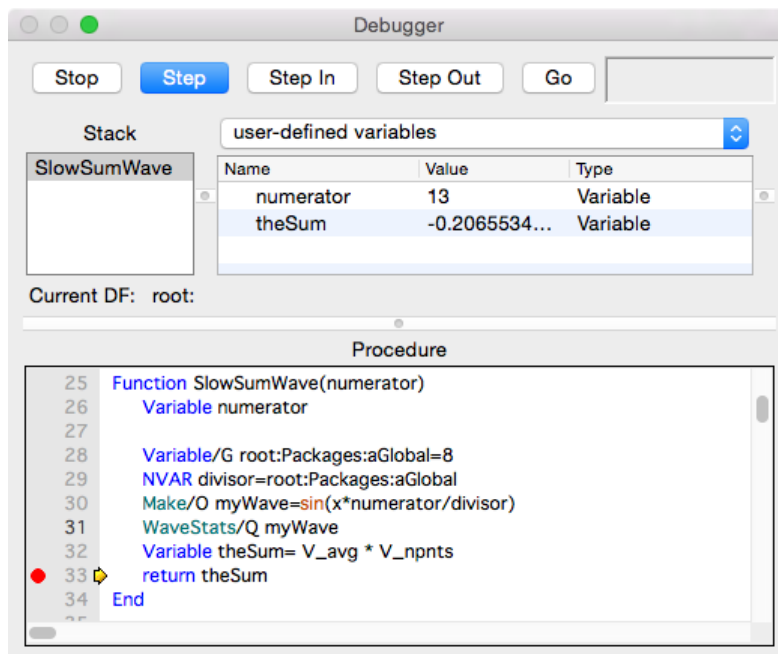

Local variables in macros include all items passed as parameters (numerator in this example) and local variables and local strings (oldDF) whose definitions have been executed, and Igor-created local variables created by operations such as WaveStats after the operation has been executed. Note that localStr isn't listed, because the command has not yet executed.

Global variables in macros include all items in the current data folder, whether they are used in the macro or not. If the data folder changes because of a SetDataFolder operation, the list of global variables also changes. Note that there are no NVAR, SVAR, WAVE or STRUCT references in a macro.

## Function Variables

The SlowSumWaveFunction example below illustrates how different kinds of variables in functions are classified:

User-defined variables in functions include all items passed as parameters (numerator in this example) and any local strings and variables.

Local variables exist while a procedure is running, and cease to exist when the procedure returns; they never exist in a data folder like globals do.

## Chapter IV-8 — Debugging

NVAR, SVAR, WAVE, Variable/G and String/G references point to global variables, and therefore, aren't listed as user-defined (local) variables.

Use “Igor-created variables” to show local variables that Igor creates for functions when they call an operation or function that returns results in specially-named variables. The **WaveStats** operation (see page V-935), for example, defines V\_adev, V\_avg, and other variables to contain the statistics results:

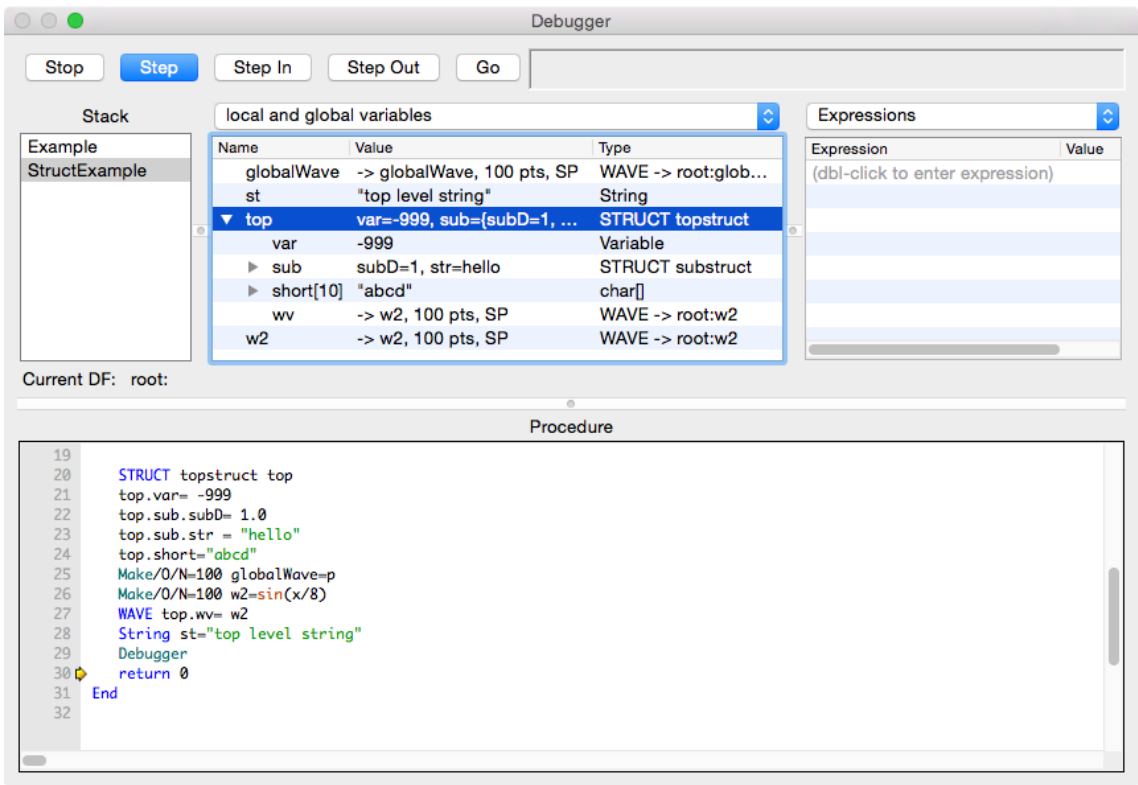

The “user- and Igor-created” menu item shows both kinds of local variables.

The “local and global variables” item shows user-created local variables, most Igor-created local variables, and references to global variables and waves through NVAR, SVAR, and WAVE references:

Function Structures

The elements of a structure (see **Structures in Functions** on page IV-91) are displayed in tree form in the Variables "list". Click the triangles to expand or collapse a node in the structure, or double-click the row:

Double-clicking a WAVE element (such as top.wv) will send it to the Wave Inspector (either a table or graph depending on what is checked in the Inspector popup):

Double-clicking a String element or char array (such as top.short) will send it to the String Inspector:

### The Current Data Folder

The "Current DF" displays the path to the current data folder. You can select and copy the data folder path. See **Data Folders** on page II-99 for more information about data folders.

### Graph, Table, String, and Expressions Inspectors

One of the Wave, String, or Expressions Inspectors is visible to right side of the variables list. This pane is hidden when the divider between the pane and the variables list is dragged all the way to the right. Drag the divider to the left to show the pane. You may need to widen the window to make room.

Use the popup to select the Inspector you want.

The pop-up menu controls what is shown in the pane:

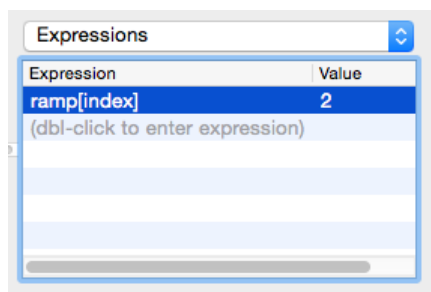

Pop-up Menu Selection	Pane Contents
Local WAVES, SVARs, and Strings	A list of these things in the selected function. References to free waves are also listed here, as are elements in a STRUCT that are "inspectable", including char arrays which can be viewed as if they were Strings.
Local Strings	A list of Strings local to the selected function, macro or proc.
Expressions	Numeric or string expressions which are evaluated in the context of the selected function or macro.
Global Waves	A popup wave selector to display any wave in a global data folder. Free waves are not listed here.
Show Waves in Table Show Waves in Graph	Waves will be displayed in a table or graph, depending on which one of these two is checked.

## Expressions Inspector

Selecting "Expressions" from the inspector popup shows a list of Expressions and their values:

Replace the "(dbl-click to enter expression)" invitation by clicking it, typing a numeric or string expression, and pressing Return.

Adding an expression adds a blank row at the end of the list that can be double-clicked to enter another expression. You can edit any of the expressions by double-clicking and typing.

The expression can be removed by selecting it and pressing Delete or Backspace.

The result of the expression is recomputed when stepping through procedures. The expressions are evaluated in the context of the currently selected procedure.

Global expressions are evaluated in the context of the current data folder, though you can specify the data folder explicitly as in the example below.

If an expression is invalid the result is shown as "?" and the expression is changed to red:

The expressions are discarded when a new Igor experiment is opened or when Igor quits.

## Inspecting Waves

You can "inspect" (view) the contents of a wave in either a table or a graph. They aren't full-featured tables or graphs, as there are no supporting dialogs for them. You can change their properties using contextual menus.

Select the Wave to be inspected by one of three methods:

1. Choose "Global Waves", and then choose a wave from the popup wave browser.
2. Choose "Local WAVES, SVARs, and Strings", and then choose a wave from among the objects listed.
3. Double-click any WAVE reference in the Variables list.

### Inspecting Waves in a Table

You can edit the values in a wave using the table, just like a regular table. With the contextual menu you can alter the column format, among other things.

### Inspecting Waves in a Graph

You can view waves in a Graph. With the contextual menu, you can choose to show or hide the axes and change display modes.

Two-dimensional waves are displayed as an image plot.

### Inspecting Strings

Select a String or char array to be inspected by two methods:

1. Choose "Local WAVES, SVARs, and Strings", and then choose a String, SVAR or char array from among the objects listed.
2. Double-click any String, SVAR or char array in the Variables list.

### The Procedure Pane

The procedure pane contains a copy of the procedure window of the routine selected in the Stack List. You can set and clear breakpoints in this pane just as you do in a procedure window, using the breakpoint margin and the Control-click (*Macintosh*) or right-click (*Windows*) menu.

A very useful feature of the debugger is the automatic text expression evaluator that shows the value of a variable or expression under the cursor. The value is displayed as a tooltip. This is often faster than scrolling through the Variables List or entering an expression in the Expressions List to determine the value of a variable, wave, or structure member reference.

The value of a variable can be displayed whether or not the variable name is selected. To evaluate an expression such as "wave[ii]+3", the expression must be selected and the cursor must be over the selection.

The debugger won't evaluate expressions that include calls to user-defined functions; this prevents unintended side effects (a function could overwrite a wave's contents, for example). You can remove this limitation by creating the global variable root:V\_debugDangerously and setting it to 1.

### After You Find a Bug

Editing in the debugger window is disabled because the code is currently executing. Tracking down the routine after you've exited the debugger is easy if you follow these steps:

1. Scroll the debugger text pane back to the name of the routine you want to modify, and select it.
2. Control-click (Macintosh) or Right-click (Windows) the name, and choose "Go to <routineName>" from the pop-up menu.
3. Exit the debugger by clicking the "Go" button or by pressing Escape.

Now the selected routine will be visible in the top procedure window, where you can edit it.

## Debugger Shortcuts

Action	Shortcut
To enable debugger	Choose Enable Debugger from the Procedure menu or choose Enable Debugger from the procedure window's pop-up menu after Control-clicking ( <i>Macintosh</i> ) or right-clicking ( <i>Windows</i> ).
To automatically enter the debugger when an error occurs	Choose Debug on Error from the Procedure menu or choose Enable Debugger from a procedure window's pop-up menu after Control-clicking ( <i>Macintosh</i> ) or right-clicking ( <i>Windows</i> ).
To set or clear a breakpoint	Click in the left margin of the procedure window or click anywhere on the procedure window line where you want to set or clear the breakpoint and choose Set Breakpoint or Clear Breakpoint from a procedure window's pop-up menu after Control-clicking ( <i>Macintosh</i> ) or right-clicking ( <i>Windows</i> ).
To enable or disable a breakpoint	Shift-click a breakpoint in the left margin of the procedure window.  Click anywhere on the procedure window line where you want to enable or disable the breakpoint and choose Enable Breakpoint or Disable Breakpoint procedure window's pop-up menu after Control-clicking ( <i>Macintosh</i> ) or right-clicking ( <i>Windows</i> ).
To execute the next command	On <i>Macintosh</i> press Enter, keypad Enter, or Return. For <i>Windows</i> , if no button has the focus, press Enter or Return. Otherwise, click the yellow arrow button.
To step into a subroutine	Press the +, =, or keypad + keys, or click the blue descending arrow button.
To step out of a subroutine to the calling routine	Press the -, _ (underscore) or keypad - keys, or click the blue ascending arrow button.
To resume executing normally	Press Escape (Esc), or click the green arrow button.
To cancel execution	Click the red stop sign button.
To edit the value of a macro or function variable	Double-click the second column of the variables list, edit the value, and press Return or Enter.
To set the value of a function's string to null	Double-click the second column of the variables list, type "<null>" (without the quotes), and press Return or Enter.
To view the current value of a macro or function variable	Move the cursor to the procedure text of the variable name and wait. On <i>Macintosh</i> , the value appears to the right of the debugger buttons. On <i>Windows</i> , the value appears in a tooltip window.
To view the current value of an expression	Select the expression text with the cursor, position the cursor over the selection, and wait.  (Expressions involving user-defined functions will not be evaluated unless V_debugDangerously is set to 1.)
To view global values in the current data folder	Choose "local and global variables" from the debugger pop-up menu.
To view type information about variables	Choose "show variable types" from the debugger pop-up menu.
To resize the columns in the variables list	Drag a divider in the list to the left or right.
To show or hide the Waves, Structs, and Expressions pane	Drag the divider on the right side of the Variables list left or right.

When Dependencies are Updated .....	217
Programming with Dependencies .....	217
Using Operations in Dependency Formulas .....	218
Dependency Caveats .....	218

### Dependency Formulas

Igor Pro supports “dependent objects”. A dependent object can be a wave, a global numeric variable or a global string variable that has been linked to an expression. The expression to which an object is linked is called the object’s “dependency formula” or “formula” for short.

The value of a dependent object is updated whenever any other global object involved in the formula is modified, even if its value stays the same. We say that the dependent object *depends* on these other global objects *through* the formula.

You might expect that an assignment such as:

```
Variable var0 = 1
Make wave0
wave0 = sin(var0*x/16)
```

meant that wave0 would be updated whenever var0 changed. It doesn’t. Values are computed for wave0 only once, and the relationship between wave0 and var0 is forgotten.

However, if the equal sign in the above assignment is replaced by a colon followed by an equal sign:

```
wave0 := sin(var0*x/16)
```

then Igor *does* create just such a dependency. Now whenever var0 changes, Igor reevaluates the assignment statement and updates wave0. In this example, wave0 is a dependent object. It depends on var0, and “sin(var0\*x/16)” is wave0’s dependency formula.

You can also establish a dependency using the SetFormula operation, like this:

```
SetFormula wave0, "sin(var0*x/16) "
```

Wave1 depends on var0 because var0 is a changeable variable. Wave1 *also* depends on the function x which returns the X scaling of the destination wave (wave0). When the X scaling of wave0 changes, the values that the x function returns change, so this dependency assignment is reevaluated. The remaining terms (sin and 16) are not changeable, so wave0 does not depend on them.

From the command line, you can use either a dependency assignment statement or SetFormula to establish a dependency. In a user-defined function, you must use SetFormula.

Like other assignment statements, the data folder context for the right-hand side is that of the destination object. Therefore, in the following example, wave2 and var1 must be in the data folder named foo, var2 must be in root, and var3 must be in root:bar.

```
root:foo:wave0 := wave2*var1 + ::var2 + root:bar:var3
```

Data Folders are described in Chapter II-8, **Data Folders**.

A dependency assignment is often used in conjunction with SetVariable controls and ValDisplay controls.

Here’s a simple example. Execute these commands on the command line:

```
Variable/G var0 = 1
Make/O wave0:=sin(var0*x/16)
Display /W=(4,53,399,261) wave0
ControlBar 23
SetVariable setvar0,size={60,15},value=var0
```

Click the SetVariable control’s up and down arrows to adjust var0 and observe that wave0 is automatically updated.

### Dependencies and the Object Status Dialog

You can use the Object Status dialog, which you can access via the the Misc menu, to check dependencies. After executing the commands in the preceding section, the dialog looks like this:

The Status area indicates any dependency status:

- “No dependency” means that the current object does not depend on anything.
- “Dependency is OK” means that the dependency formula successfully updated the current object.
- “Update failed” means that the dependency formula used to compute the current object’s value failed.

An update may fail because there is a syntax error in the formula or one of the objects referenced in the formula does not exist or has been renamed. If the formula includes a call to a user-defined function then the update will fail if the function does not exist or if procedures are not compiled.

If an update fails, then the objects that depend on that update are broken. See **Broken Dependent Objects** on page IV-217 for details.

You can create a new dependency formula with the New Formula button, which appears only if the current object is not the target of a dependency formula.

You can delete a dependency formula using the Delete Formula button.

You can change an existing dependency formula by typing in the Dependency Formula window, and clicking the Change Formula button.

For further details on the Object Status dialog, click the Help button in the dialog.

## Numeric and String Variable Dependencies

Dependencies can also be created for global user-defined numeric and string variables. You can not create a dependency that uses a local variable on either side of the dependency assignment statement.

Here is a user-defined function that creates a dependency. The global variable `recalculateThis` is made to depend on the global variable `dependsOnThis`:

```
Function TestRecalculation()
    Variable/G recalculateThis
    Variable/G dependsOnThis = 1

    // Create dependency on global variable
    SetFormula recalculateThis, "dependsOnThis"

    Print recalculateThis           // Prints original value

    dependsOnThis = 2               // Changes something recalculateThis
```

```
DoUpdate                                // Make Igor recalculate formulae
Print recalculateThis                    // Prints updated value
End
```

Running this function prints the following to the history area:

```
•TestRecalculation()
  1
  2
```

The call to DoUpdate is needed because Igor recalculates dependency formulas only when no user-defined functions are running or when DoUpdate is called.

This function uses SetFormula to create the dependency because the := operator is not allowed in user-defined functions.

## Wave Dependencies

The assignment statement:

```
dependentWaveName := formula
```

creates a dependency and links the dependency formula to the dependent wave. Whenever any change is made to any object in the formula, the contents of the dependent wave are updated.

The command

```
SetFormula dependentWaveName, "formula"
```

establishes the same dependency.

From the command line, you can use either a dependency assignment statement or SetFormula to establish a dependency. In a user-defined function, you must use SetFormula.

## Cascading Dependencies

“Cascading dependencies” refers to the situation that arises when an object depends on a second object, which in turn depends on a third object, etc. When an object changes, all objects that directly depend on that object are updated, *and* objects that depend directly on those updated objects are updated until no more updates are needed.

You can use the Object Status dialog to investigate cascading dependencies.

## Deleting a Dependency

A dependency is deleted when the dependent object is assigned a value using the = operator:

```
recalculateThis := dependsOnThis    // Creates a dependency
recalculateThis = 0                  // Deletes the dependency
```

This method of deleting a dependency does not work in user-defined functions. You must use the SetFormula operation.

For example:

```
Execute "recalculateThis = 0"
```

will delete the dependency even in a user-defined function.

You can also delete this dependency using the SetFormula operation.

```
SetFormula recalculateThis, ""
```

Wave dependencies are also deleted by operations that overwrite the values of their wave parameters. Some of these operations are:

```
FFT          Convolve          Correlate    Smooth    GraphWaveEdit
Hanning      Differentiate      Integrate    UnWrap
```

Dependencies can also be deleted using the Object Status dialog.

## Broken Dependent Objects

Igor compiles the text of a dependency formula to low-level code and stores both the original text and the low-level code with the dependent object. At various times, Igor may need to recompile the dependency formula text. At that time, a compilation error will occur if:

- The dependency formula contains an error
- An object used in the dependency formula has been deleted, renamed, or moved
- The dependency formula references a user-defined function that is missing
- The dependency formula references a user-defined function and procedures are not compiled

When this happens, the dependent object will no longer update but will retain its last value. We call such an object “broken”.

To inspect broken objects, invoke the Object Status dialog. Choose Broken Objects from the pop-up menu above the status area. If there are any broken objects, they will appear in the Current Object pop-up. Select an object from the Current Object pop-up to inspect it.

## When Dependencies are Updated

Dependency updates take place at the same time that graphs are updated. This happens after each line in a macro is executed, or when DoUpdate is called from a macro or user function, or continuously if a macro or function is not running.

Dependency formulas used as input to the SetBackground and ValDisplay operations, and in some other contexts, can alternately be specified as a literal string of characters using the following syntax:

```
#"text_of_the_dependency_expression"
```

Note that what follows the # char must be a literal string — not a string expression.

This sets the dependency formula *without* compiling it or checking it for validity. If you need to set the dependency formula of an object to something that is not currently valid but will be in the future, then use this alternate method.

## Programming with Dependencies

You cannot use := to create dependencies in user-defined functions. Instead you must use the **SetFormula** operation (see page V-724).

```
Function TestFunc()
    Variable/G varNum=-666
    Make wave0
    SetFormula wave0, "varNum"    // Equivalent to wave0 := varNum
End
```

### Using Operations in Dependency Formulas

The dependency formula must be a single expression — and you can not use operations, such as FFT's, or other command type operations. However, you can invoke user-defined functions which invoke operations. For example:

```
Function MakeDependencyUsingOperation()  
    Make/O/N=128 data = p          // A ramp from 0 to 127  
    Variable/G power  
  
    SetFormula power, "RMS(data)" // Dependency on function and wave  
    Print power  
  
    data = p * 2                  // Changes something power depends  
    DoUpdate                      // Make Igor recalc formulae  
    Print power  
EndMacro  
  
Function RMS(w)  
    Wave w  
  
    WaveStats/Q w                // An operation! One output is V_rms  
    return V_rms  
End
```

When MakeDependencyUsingOperation is executed, it prints the following in the history area:

```
•MakeDependencyUsingOperation()  
  73.4677  
 146.935
```

### Dependency Caveats

The extensive use of dependencies can create a confusing tangle that can be difficult to manage. Although you can use the Object Status dialog to explore the dependency hierarchy, you can still become very confused very quickly, especially when the dependencies are highly cascaded. You should use dependencies only where they are needed. Use conventional assignments for the majority of your calculations.

Dependency formulas are generally not recalculated when a user-defined function is running unless you explicitly call the DoUpdate operation. However, they can run at other unpredictable times so you should not make any assumptions as to the timing or the current data folder when they run.

The text of the dependency formula that is saved for a dependent object is the original literal text. The dependency formula needs to be recompiled from time to time, for example when procedures are compiled. Therefore, any objects used in the formula must persist until the formula is deleted.

We recommend that you never use \$ expressions in a dependency formula.

### Regular Modules

Regular modules, or "modules" for short, provide a way to avoid name conflicts between procedure files. Regular modules are distinct from "independent modules" which are discussed in the next section.

Igor's module concept provides a way to group related procedure files and to prevent name conflicts between procedure packages.

By default, a procedure file is in the built-in ProcGlobal module. A procedure file that does not contain a `#pragma ModuleName` statement (or a `#pragma IndependentModule` statement - discussed below) is in ProcGlobal. Neither `#pragma ModuleName` nor `#pragma IndependentModule` are allowed in the built-in procedure window which is always in ProcGlobal.

When you execute a function from the command line or use the **Execute** operation, you are operating in the ProcGlobal context.

Functions in ProcGlobal are either public, or, if they are declared using the static keyword, private. For example:

```
// In a procedure file with no #pragma ModuleName or #pragma IndependentModule

static Function Test()           // Private to its procedure file
    Print "Test in ProcGlobal"
End

Function TestInProcGlobal()      // Public
    Print "TestInProcGlobal in ProcGlobal"
End
```

Because it is declared static, the Test function is private to its procedure file. Each procedure file can have its own static Test function without causing a name conflict. The TestInProcGlobal function is public so there can be only one public function with this name.

In this example the static Test function is accessible only from the procedure file in which it is defined. Sometimes you have a need to avoid name conflicts but still want to be able to call functions from other procedure files, from control action procedures or from the command line. This is where a regular module is useful.

You specify that a procedure file is in a different module (other than ProcGlobal) using the ModuleName pragma. For example:

```
#pragma ModuleName = ModuleA      // The following procedures are in ModuleA

static Function Test()           // Semi-private
    Print "Test in ModuleA"
End

Function TestModuleA()           // Public
    Print "Test in ModuleA"
End
```

Because it is declared static, this Test function does not conflict with Test functions in other procedure files. But because it is in a named regular module (ModuleA), it can be called from other procedure files using a qualified name:

```
ModuleA#Test()                   // Call Test from ModuleA
```

This qualified name syntax overrides the static nature of Test and tells Igor that you want to execute the Test function defined in ModuleA. The only way to access a static function from another procedure file is to put it in a regular module and use a qualified name.

If you are writing a non-trivial set of procedures, it is a good idea to use a module and to declare your functions static, especially if other people will be using your code. This prevents name conflicts with other procedures that you or other programmers write. Make sure to choose a distinctive module name.

## Regular Modules in Action Procedures and Hook Functions

Control action procedures and hook functions are called by Igor at certain times. They are executed in the ProcGlobal context. This means that a static function can not be used as an action procedure or a hook function without using a qualified name. For example:

```
// In a procedure file with no #pragma ModuleName or #pragma IndependentModule

static Function ButtonProc(ba) : ButtonControl
    STRUCT WMBUTTONACTION &ba

    switch (ba.eventCode)
        case 2: // mouse up
            Print "Running ProcGlobal#ButtonProc"
            break
    endswitch

    return 0
End

Function CreatePanel()
    NewPanel /W=(375,148,677,228)
    // This will not work because ButtonProc is private to the procedure file
    Button button0,pos={106,23},size={98,20},title="Click Me"
    Button button0,proc=ButtonProc
End
```

When you click the Click Me button, Igor tries to run the ButtonProc action procedure. However, because it is static, it is not accessible from outside the procedure file so Igor displays an error.

There are two possible solutions for this problem:

1. Make ButtonProc global by removing the static keyword
2. Use a regular module

If you make ButtonProc global, you run the risk of a name conflict with some other programmer's ButtonProc function. You can prevent this by changing ButtonProc to a very distinctive name, like AcmeDataAcqButtonProc, but this becomes tedious.

Here is the solution using a module:

```
#pragma ModuleName = RegularModuleA

static Function ButtonProc(ba) : ButtonControl
    STRUCT WMBUTTONACTION &ba

    switch (ba.eventCode)
        case 2: // mouse up
            Print "Running RegularModuleA#ButtonProc"
            break
    endswitch

    return 0
End
```

```
static Function CreatePanel()  
    NewPanel /W=(375,148,677,228)  
    Button button0,pos={106,23},size={98,20},title="Click Me"  
    Button button0,proc=RegularModuleA#ButtonProc  
End
```

RegularModuleA is the name we have chosen for the regular module for demonstration purposes. You should choose a more descriptive module name.

The use of a qualified name, RegularModuleA#ButtonProc, allows Igor to find and execute the static ButtonProc function in the RegularModuleA module even though ButtonProc is running in the ProcGlobal context.

To protect the CreatePanel function from name conflicts we also made it static. To create the panel, execute:

```
RegularModuleA#CreatePanel()
```

### Regular Modules and User-Defined Menus

Menu item execution text also runs in the ProcGlobal context. If you want to call a routine in a regular module you must use a qualified name.

Continuing the example from the preceding section, here is how you would write a menu definition:

```
#pragma ModuleName = RegularModuleA  
  
Menu "Macros"  
    "Create Panel", RegularModuleA#CreatePanel()  
End
```

See also **Independent Modules** below, **Controls and Control Panels** on page III-365, **User-Defined Hook Functions** on page IV-265 and **User-Defined Menus** on page IV-117.

## Independent Modules

An independent module is a set of procedure files that are compiled separately from all other procedures. Because it is compiled separately, an independent module can run when other procedures are in an uncompiled state because the user is editing them or because an error occurred in the last compile. This allows the independent module's control panels and menus to continue to work regardless of user programming errors.

Creating an independent module adds complexity and requires a solid understanding of Igor programming. You should use an independent module if it is important that your procedures be runnable at all times. For example, if you have created a data acquisition package that must run regardless of what the user is doing, that would be a good candidate for an independent module.

A file is designated as being part of an independent module using the IndependentModule pragma:

```
#pragma IndependentModule = imName
```

Make sure to use a distinctive name for your independent module.

The IndependentModule pragma is not allowed in the built-in procedure window which is always in the ProcGlobal module.

An independent module creates an independent namespace. Function names in an independent module do not conflict with the same names used in other modules. To call an independent module function from another module, including the default ProcGlobal module, the function must be public (non-static) and you must use a qualified name as illustrated in the next section.

## Independent Modules - A Simple Example

Here is a simple example using an independent module. This code must be in its own procedure file and not in the built-in procedure file:

```
#pragma IndependentModule = IndependentModuleA

static Function Test()           // static means private to file
  Print "Test in IndependentModuleA"
End

// This must be non-static to call from command line (ProcGlobal context)
Function CallTestInIndependentModuleA()
  Test()
End
```

From the command line (the ProcGlobal context):

```
CallTestInIndependentModuleA()           // Error
IndependentModuleA#CallTestInIndependentModuleA() // OK
IndependentModuleA#Test()                // Error
```

The first command does not work because the functions in the independent module are accessible only using a qualified name. The second command does work because it uses a qualified name and because the function is public (non-static). The third command does not work because the function is private (static) and therefore is accessible only from the file in which it is defined. A static function in an independent module is not accessible from outside the procedure file in which it is defined unless it is in an enclosed regular module as described under **Regular Modules Within Independent Modules** on page IV-228.

## SetIgorOption IndependentModuleDev=1

By default, the debugger is disabled for independent modules. It can be enabled using:

```
SetIgorOption IndependentModuleDev=1
```

Also by default, independent module procedure windows are not listed in the Windows→Procedure Windows submenu unless you use `SetIgorOption IndependentModuleDev=1`.

When `SetIgorOption IndependentModuleDev=1` is in effect, the Windows→Procedure Windows submenu shows all procedure windows, and those that belong to an independent module are listed with the independent module name in brackets. For example:

```
DemoLoader.ipf [WMDemoLoader]
```

This bracket syntax is used in the **WinList**, **FunctionList**, **DisplayProcedure**, and **ProcedureText** functions and operations.

To get the user experience, as opposed to the programmer experience, return to normal operation by executing:

```
SetIgorOption IndependentModuleDev=0
```

## Independent Module Development Tips

Development of an independent module may be easier if it is first done as for normal code. Add the module declaration

```
#pragma IndependentModule = moduleName
```

only after the code has been fully debugged and is working properly.

A procedure file that is designed to be #included should ideally work inside or outside of an independent module. Read the sections on independent modules below to learn what the issues are.

When developing an independent module, you will usually want to execute:

```
SetIgorOption IndependentModuleDev=1
```

### Independent Modules and #include

If you #include a procedure file from an independent module, Igor copies the #included file into memory and makes it part of the independent module by inserting a #pragma IndependentModule statement at the start of the copy. If the same file is included several times, there will be several copies, each with a different independent module name.

**Warning:** Do not edit the procedure windows created by #including into an independent module because they are temporary and your changes will not be saved. You would not want to save them anyway because Igor has modified them.

**Warning:** Do not #include files that already contain a #pragma IndependentModule statement unless the independent module name is the same.

### Limitations of Independent Modules

Independent modules are not for every-day programming and are more difficult to create than normal modules because of the following limitations:

1. Macros and Procs are not supported.
2. Button and control dialogs do not list functions in an independent module.
3. Functions in an independent module can not call functions in other modules except through the Execute operation.

### Independent Modules in Action Procedures and Hook Functions

Normally you must use a qualified name to invoke a function defined in an independent module from the ProcGlobal context. Control action procedures and hook functions execute in the ProcGlobal context. But, as a convenience and to make #include files more useful, Igor eliminates this requirement when you create controls and specify hook functions from a user-defined function in an independent module.

When you execute an operation that creates a control or specifies a hook function while running in an independent module, Igor examines the specified control action function name or hook function name. If the named function is defined in the same independent module, Igor automatically inserts the independent module name. This means you can write something like:

```
#pragma IndependentModule = IndependentModuleA
Button b0, proc=ButtonProc
SetWindow hook(Hook1)=HookFunc
```

You don't have to write:

```
#pragma IndependentModule = IndependentModuleA
Button b0, proc=IndependentModuleA#ButtonProc
SetWindow hook(Hook1)=IndependentModuleA#HookFunc
```

Such independent module name insertion is only done when an operation called from a function defined in an independent module. It is not done if the operation is executed from the command line or via **Execute**.

The control action function or hook function must be public (non-static) except as describe under **Regular Modules Within Independent Modules** on page IV-228.

Here is a working example:

```
#pragma IndependentModule = IndependentModuleA
```

```

Function ButtonProc(ba) : ButtonControl    // Must not be static
    STRUCT WMBUTTONACTION &ba

    switch (ba.eventCode)
        case 2: // mouse up
            Print "Running IndependentModuleA#ButtonProc"
            break
        endswitch

    return 0
End

Function CreatePanel()
    NewPanel /W=(375,148,677,228)
    Button button0,pos={106,23},size={98,20},title="Click Me"
    Button button0,proc=ButtonProc
End

```

## Independent Modules and User-Defined Menus

Independent modules can contain user-defined menus. When you choose a user-defined menu item, Igor determines if the menu item was defined in an independent module. If so, and if the menu item's execution text starts with a call to a function defined in the independent module, then Igor prepends the independent module name before executing the text. This means that the second and third menu items in the following example both call `IndependentModuleA#DoAnalysis`:

```

#pragma IndependentModule = IndependentModuleA

Menu "Macros"
    "Load Data File/1", Beep; LoadWave/G
    "Do Analysis/2", DoAnalysis() // Igor automatically prepends IndependentModuleA#
    "Do Analysis/3", IndependentModuleA#DoAnalysis()
End

Function DoAnalysis()
    Print "DoAnalysis in IndependentModuleA"
End

```

This behavior on Igor's part makes it possible to `#include` a procedure file that creates menu items into an independent module and have the menu items work. However, in many cases you will not want a `#included` file's menu items to appear. You can suppress them using `menus=0` option in the `#include` statement. See **Turning the Included File's Menus Off** on page IV-156.

**Note:** If a procedure file with menu definitions is included into multiple independent modules, the menus are repeatedly defined (see **Independent Modules and #include** on page IV-226). Judicious use of the `menus=0` option in the `#include` statements helps prevent this. See **Turning the Included File's Menus Off** on page IV-156.

When the execution text doesn't start with a user-defined function name, as for the first menu item in this example, Igor executes the text without altering it.

## Independent Modules and Popup Menus

In an independent module, implementing a popup menu whose items are determined by a function call at click time requires special care. For example, outside of an independent module, this works:

```

Function/S MyPopupMenuList()
    return "Item 1;Item2;"
End
...
PopupMenu pop0 value=#"MyPopupMenuList()" // Note the quotation marks

```

But inside an independent module you need this:

```
#pragma IndependentModule=MyIM
Function/S MyPopupMenuList()
    return "Item 1;Item2;"
End
...
String cmd= GetIndependentModuleName()+"#MyPopupMenuList()"
PopupMenu pop0 value=#cmd // No enclosing quotation marks
```

**GetIndependentModuleName** returns the name of the independent module to which the currently-running function belongs or "ProcGlobal" if the currently-running function is not part of an independent module.

You could change the command string to:

```
PopupMenu pop0 value=#"MyIM##MyPopupMenuList()"
```

but using `GetIndependentModuleName` allows you to disable the `IndependentModule` pragma by commenting it out and have the code still work which can be useful during development. With the pragma commented out you are running in `ProcGlobal` context and `GetIndependentModuleName` returns "ProcGlobal".

When the user clicks the popup menu, Igor generates the menu items by evaluating the text specified by the `PopupMenu` value keyword as an Igor expression. The expression `("MyIM#MyPopupMenuList()"` in this case) is evaluated in the `ProcGlobal` context. In order for Igor to find the function in the independent module, it must be public (non-static), except as describe under **Regular Modules Within Independent Modules** on page IV-228, and you must use a qualified name.

Note that `#cmd` is not the same as `#"cmd"`. The `#cmd` form was introduced with Igor Pro 6. The string variable `cmd` is evaluated when `PopupMenu` runs which occurs in the context of the independent module. The contents of `cmd` (`"MyIM#MyPopupMenuList()"` in this case) are stored in the popup menu's internal data structure. When the popup menu is clicked, Igor evaluates the stored text as an Igor expression. This causes the function `MyIM#MyPopupMenuList` to run.

With the older `#"cmd"` syntax, the stored text is evaluated only when the popup menu is clicked, not when the `PopupMenu` operation runs, and this evaluation occurs in the `ProcGlobal` context. It is too late to capture the independent module in which the text should be evaluated.

### Regular Modules Within Independent Modules

It is usually not necessary but you can create a regular module within an independent module. For example:

```
#pragma IndependentModule = IndependentModuleA
#pragma ModuleName = RegularModuleA
Function Test()
    Print "Test in RegularModuleA within IndependentModuleA"
End
```

Here `RegularModuleA` is a regular module within `IndependentModuleA`.

To call the function `Test` from outside of the independent module you must qualify the call like this:

```
IndependentModuleA#RegularModuleA#Test()
```

This illustrates that the independent module establishes its own namespace (`IndependentModuleA`) which can host one level of sub-namespace (`RegularModuleA`). By contrast, a regular module creates a namespace within the global namespace (called `ProcGlobal`) and can not host additional sub-namespaces.

This nesting of modules is useful to prevent name conflicts in a large independent module project comprising multiple procedure files. Otherwise it is not necessary.

Because all procedure files in a given independent module are compiled separately from all other files, function names never conflict with those outside the group and there is little or no need to use the static

designation on functions in an independent module. However, if need be, you can call static functions in a regular module inside an independent module from outside the independent module using a triple-qualified name:

```
IndependentModuleName#RegularModuleName#FunctionName()
```

## Calling Routines From Other Modules

Code in an independent module can not directly call routines in other modules and usually should not need to. If you must call a routine from another module, you can do it using the **Execute** operation. You must use a qualified name. For example:

```
Execute "ProcGlobal#foo()" "
```

To call a function in a regular module, you must prepend ProcGlobal and the regular module name to the function name:

```
Execute "ProcGlobal#MyRegularModule#foo()" "
```

Calling a nonstatic function in a different independent modules requires prepending just the other independent module name:

```
Execute "OtherIndependentModule#bar()" "
```

Calling static functions in other independent modules requires prepending the independent module name and a regular module name:

```
Execute "OtherIndependentModule#RegularModuleName#staticbar()" "
```

## Using Execute Within an Independent Module

If you need to call a function in the current independent module using Execute, you can compose the name using the **GetIndependentModuleName** function. For example, outside of an independent module the commands would be:

```
String cmd = "WS_UpdateWaveSelectorWidget(\"Panel0\", \"selectorWidgetName\")"
Execute cmd
```

But inside an independent module the commands are:

```
#pragma IndependentModule=MyIM
String cmd="WS_UpdateWaveSelectorWidget(\"Panel0\", \"selectorWidgetName\")"
cmd = GetIndependentModuleName() + "#" + cmd // Make qualified name
Execute cmd
```

You could change the command string to:

```
cmd = "MyIM#" + cmd
```

but using GetIndependentModuleName allows you to disable the IndependentModule pragma by commenting it out and have the code still work which can be useful during development. With the pragma commented out you are running in ProcGlobal context and GetIndependentModuleName returns "ProcGlobal".

## Independent Modules and Dependencies

**GetIndependentModuleName** is also useful for defining dependencies using functions in the current independent module. Dependencies are evaluated in the global procedure context (ProcGlobal). In order for dependencies to evaluate correctly, the dependency must use GetIndependentModuleName to create a formula to pass to the **SetFormula** operation. For example, outside of an independent module, this works:

```
String formula = "foo(root:wave0)"
SetFormula root:aVariable $formula
```

But inside an independent module you need this:

```
#pragma IndependentModule=MyIM
String formula = GetIndependentModuleName() + "#foo(root:wave0)"
SetFormula root:aVariable $formula
```

### Independent Modules and Pictures

To allow DrawPICT to use a picture in the picture gallery, you must prepend GalleryGlobal# to the picture name:

```
DrawPICT 0,0,1,1,GalleryGlobal#PICT_0
```

Without GalleryGlobal, only proc pictures can be used in an independent module.

### Making Regular Procedures Independent-Module-Compatible

You may want to make an existing set of procedures into an independent module. Alternatively, you may want to make an existing procedure independent-module-compatible so that it can be #included into an independent module. This section outlines the necessary steps.

1. If you are creating an independent module, add the IndependentModule pragma:  
`#pragma IndependentModule=<NameOfIndependentModule>`
2. Change any Macro or Proc procedures to functions.
3. Make Execute commands suitable for running in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Using Execute Within an Independent Module** on page IV-229.
4. Make PopupMenu controls that call a string function to populate the menu work in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Independent Modules and Popup Menus** on page IV-227.
5. Make any dependencies work in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Independent Modules and Dependencies** on page IV-229.

See also **Regular Modules** on page IV-222, **Controls and Control Panels** on page III-365, **User-Defined Hook Functions** on page IV-265, **User-Defined Menus** on page IV-117, and **GetIndependentModuleName** on page V-262.

## Sound

Two operations are provided for playing of sound through the computer speakers:

- PlaySound
- PlaySnd (*Macintosh*)

The **PlaySound** operation takes the sound data from a wave.

The obsolete **PlaySnd** operation gets its data from a Macintosh 'snd' resource stored in a file.

A number of sound input operations are provided: **SoundInStatus** (page V-759), **SoundInSet** (page V-758), **SoundInRecord** (page V-757), **SoundInStartChart** (page V-758) and **SoundInStopChart** (page V-759). Several example experiments that use these routines can be found in your Igor Pro 7 Folder in the Examples folder.

The **SoundLoadWave** operation loads various sound file formats into waves and **SoundSaveWave** saves wave data to sound files. These operations replace SndLoadWave, SoundSaveAIFF and SoundSaveWAV from the obsolete SndLoadSaveWave XOP.

## Movies

You can play movies in Igor. You can also create movies, optionally with a soundtrack. And you can extract frames from movies for analysis.

On Macintosh Igor can play QuickTime and AVI movies. It can create QuickTime movies only.

On Windows Igor can create and play AVI movies only.

## **Playing Movies**

Use the PlayMovie operation to play a movie whether the movie was created in Igor or not.

Playing a movie requires that you have the codecs required by the movie installed on your machine.

On Macintosh, both QuickTime and AVI movies open in the Igor application.

On Windows, AVI movies open in your default movie viewing program - typically Windows Media Player.

## **Creating Movies**

You can create a movie from a graph, page layout, or Gizmo window. To do this, you write a procedure that modifies the window and adds a frame to the movie in a loop. On Windows, you can include audio.

Here are the operations used to create and play a movie:

- **NewMovie**
- **AddMovieFrame**
- **AddMovieAudio**
- **CloseMovie**
- **PlayMovie**
- **PlayMovieAction**

The NewMovie operation creates a movie file and also defines the movie frame rate and optional audio track specifications.

On Macintosh NewMovie always creates a QuickTime movie and the /A (AVI) flag is ignored.

On Windows NewMovie creates an AVI movie.

Before calling NewMovie, you need to prepare the first frame of your movie as the target graph, page layout, or Gizmo window.

If you will be using audio you also need to prepare a sound wave. The sound wave can be of any time duration but usually will either be the entire length of the movie or will be the length of one video frame. As of Igor Pro 7, sound is not supported on Macintosh.

After creating the file and the first video frame and optional audio, you use AddMovieFrame to add as many video frames as you wish. You may also add more audio using the AddMovieAudio operation. Finally you use the CloseMovie and PlayMovie operations.

When you write a procedure to generate a movie, you need to call the DoUpdate operation after all modifications to the graph, page layout, or Gizmo window and before calling AddMovieFrame. This allows Igor to process any changes you have made to the window.

In addition to creating a movie from a window, you can also create movies from pictures in the picture gallery (see **Pictures** on page III-448) using the /PICT flag with NewMovie and AddMovieFrame. You can put pictures of Igor graphs, tables, page layouts, and Gizmo plots in the gallery using **SavePICT**.

## **Extracting Movie Frames**

You can extract individual frames from a movie and can control movie playback using **PlayMovieAction**.

## **Movie Programming Examples**

For examples of programming with movies, choose File→Example Experiments→Movies & Audio.

### Timing

There are two methods you can use when you want to measure elapsed time:

- The ticks counter using the ticks function
- The microsecond timer using **StartMSTimer** and **StopMSTimer**

#### Ticks Counter

You can easily measure elapsed time with a precision of 1/60th of a second using the ticks function. It returns the tick count which starts at zero when you first start your computer and is incremented at a rate of approximately 60 Hz rate from then on.

Here is an example of typical use:

```
...
Variable t0
...
t0= ticks
<operations you wish to time>
printf "Elapsed time was %g seconds\r", (ticks-t0)/60
...
```

#### Microsecond Timer

You can measure elapsed time to microsecond accuracy for durations up to 35 minutes using the microsecond timer. See the **StartMSTimer** function (page V-776) for details and an example.

### Packages

A package is a set of files that adds significant functionality to Igor. Packages consist of procedure files and may also include XOPs, help files and other supporting files.

A package usually adds one or more items to Igor's menus that allow the user to interactively load the package, access its functionality, and unload the package.

A package typically provides some level of user-interface, such as a menu item and a control panel, for accessing the added functionality. It may store settings in experiments or in global preferences.

A package is typically loaded into memory and unloaded at the user's request.

Igor comes pre-configured with numerous WaveMetrics packages accessed through the Data→Packages, Analysis→Packages, Misc→Packages, Windows→New→Packages and Graph→Packages submenus as well as others. Take a peek at these submenus to see what packages are supplied with Igor.

Menu items for WaveMetrics packages are added to Igor's menus by the WMMenus.ipf procedure file which is shipped in the Igor Procedures folder. WMMenus.ipf is hidden unless you enable independent module development. See **Independent Modules** on page IV-224.

#### Creating a Package

This section shows how to create a package through a simple example. The package is called "Sample Package". It adds a Load Sample Package item to the Macros menu. When the user chooses Load Sample Package, the package's procedure file is loaded. This adds two additional items to the Macros menu: Hello From Sample Package and Unload Sample Package.

The package consists of two procedure files stored in a folder in the Igor Pro User Files folder. If you are not familiar with Igor Pro User Files, take a short detour and read **Special Folders** on page II-29 and **Igor Pro User Files** on page II-31.

The sample package is installed as follows:

```
Igor Pro 7 User Files
  Sample Package
    Sample Package Loader.ipf
    Sample Package.ipf
  Igor Procedures
    Alias or shortcut pointing to the "Sample Package Loader.ipf" file
  User Procedures
    Alias or shortcut pointing to the "Sample Package" folder
```

Putting the alias/shortcut for the "Sample Package Loader.ipf" in Igor Procedures causes Igor to load that file at launch time. The file adds the "Load Sample Package" item to the Macros menu. See **Global Procedure Files** on page III-353 for details.

Putting the alias/shortcut for the "Sample Package" folder in User Procedures causes Igor to search that folder when a #include is invoked. See **Shared Procedure Files** on page III-354 for details.

A real package might include other procedure files and a help file in the "Sample Package" folder.

To try this out yourself, follow these steps:

1. Create the "Sample Package" folder in your Igor Pro User Files folder.  
You can locate your Igor Pro User Files folder using the Help menu.
2. Create a new procedure file named "Sample Package Loader.ipf" in the "Sample Package" folder and enter the following contents in the file:

```
Menu "Macros"
  "Load Sample Package", /Q, LoadSamplePackage()
End

Function LoadSamplePackage()
  Execute/P/Q/Z "INSERTINCLUDE \"Sample Package\""
  Execute/P/Q/Z "COMPILEPROCEDURES //" Note the space before final quote
End
```

Save the procedure file.

3. Create a new procedure file named "Sample Package.ipf" in the "Sample Package" folder and enter the following contents in the file:

```
Menu "Macros"
  "Hello From Sample Package", HelloFromSamplePackage()
  "Unload Sample Package", UnloadSamplePackage()
End

Function HelloFromSamplePackage()
  DoAlert /T="Sample Package Wants to Say" 0, "Hello!"
End

Function UnloadSamplePackage()
  Execute /P /Q /Z "DELETEINCLUDE \"Sample Package\""
  Execute /P /Q /Z "COMPILEPROCEDURES //" Note the space before final quote
End
```

Save the procedure file.

4. In the desktop, make an alias or shortcut for "Sample Package Loader.ipf" file and put it in the Igor Procedures folder in the Igor Pro User Files folder.  
This causes Igor to load the "Sample Package Loader.ipf" file at launch time. This is how the Load Sample Package menu item gets into the Macros menu.
5. In the desktop, make an alias or shortcut for the "Sample Package" folder and put it in the User Procedures folder in the Igor Pro User Files folder.

This causes Igor to search the "Sample Package" folder when a #include is invoked. This allows Igor to find the "Sample Package.ipf" file when it is #included.

6. Quit and restart Igor so that Igor will load the "Sample Package Loader.ipf" file.

If you prefer you can just manually make sure that "Sample Package Loader.ipf" is open and "Sample Package.ipf" is closed. This simulates the state of affairs after restarting Igor.

7. Choose Windows→Procedure Windows and verify that Igor has loaded the "Sample Package Loader.ipf" file.
8. Click the Macros menu and verify that the "Load Sample Package" item is present.
9. Choose Macros→Load Sample Package.

The LoadSamplePackage function runs, adds a #include statement to the built-in procedure window, and forces procedures to be recompiled. This cause Igor to load the "Sample Package.ipf" procedure file which contains the bulk of the package's procedures and adds items to the Macros menu.

10. Click the Macros menu and notice that the "Hello From Sample Package" and "Unload Sample Package" items have been added.
11. Choose Macros→Hello From Sample Package.

The package displays an alert. A real package would do something more exciting.

12. Choose Macros→Unload Sample Package.

The UnloadSamplePackage function runs, removes the #include statement from the built-in procedure window, and forces procedures to be recompiled. This cause Igor to unload the "Sample Package.ipf" procedure.

13. Click the Macros menu and notice that the "Hello From Sample Package" and "Unload Sample Package" items have been removed.

Most real packages do not create Unload menu items. Instead they provide an Unload Package button in a control panel or automatically unload when a control panel is closed. Or they might not support unloading.

A real package typically does not include "Package" in its name or in its menu items.

### Lightweight Packages

A lightweight package is one that consists of at most a few procedure files and does not create clutter in the current experiment unless it is actually used.

If your package is lightweight you might prefer to dispense with loading and unload it and just keep it loaded all the time. To do this you would organize your files like this:

```
Igor Pro 7 User Files
  Your Package
    Your Package Part 1.ipf
    Your Package Part 2.ipf
  Igor Procedures
    Alias or shortcut pointing to the "Your Package" folder
```

Here both of your package procedure files are global, meaning that Igor loads them at launch time and never unloads them. You do not need procedures for loading and unloading your package.

If you have an ultra-light package, consisting of just a single procedure file, you can dispense with the "Your Package" folder and put the procedure file directly in the Igor Procedures folder.

### Managing Package Data

When you create a package of procedures, you need some place to store private data used by the package to keep track of its state. It's important to keep this data separate from the user's data to avoid clutter and to protect your data from inadvertent changes.

Private data should be stored in a data folder named after the package inside a generic data folder named Packages. For example, if your package is named My Package you would store your private data in `root:Packages:My Package`.

There are two general types of private data that you might need to store: overall package data and per-instance data. For example, for a data acquisition package, you may need to store data describing the state of the acquisition as a whole and other data on a per-channel basis.

## Creating and Accessing the Package Data Folder

This section demonstrates the recommended way to create and access a package data folder. We use a bottleneck function that returns a **DFREF** for the package data folder. If the package data folder does not yet exist, the bottleneck function creates and initializes it. This way calling functions don't need to worry about whether the package data folder has been created.

First we write a function to create and initialize the package data folder:

```
Function/DF CreatePackageData()      // Called only from GetPackageDFREF
    // Create the package data folder
    NewDataFolder/O root:Packages
    NewDataFolder/O root:Packages:'My Package'

    // Create a data folder reference variable
    DFREF dfr = root:Packages:'My Package'

    // Create and initialize package data
    Variable/G dfr:gVar1 = 1.0
    String/G dfr:gStr1 = "hello"
    Make/O dfr:wavel
    WAVE wavel = dfr:wavel
    wavel= x^2

    return dfr
End
```

Now we can write the bottleneck function:

```
Function/DF GetPackageDFREF()
    DFREF dfr = root:Packages:'My Package'
    if (DataFolderRefStatus(dfr) != 1) // Data folder does not exist?
        DFREF dfr = CreatePackageData() // Create package data folder
    endif
    return dfr
End
```

GetPackageDFREF would be used like this:

```
Function/DF DemoPackageDFREF()
    DFREF dfr = GetPackageDFREF()

    // Read a package variable
    NVAR gVar1 = dfr:gVar1
    Printf "On entry gVar1=%g\r", gVar1

    // Write to a package variable
    gVar1 += 1
    Printf "Now gVar1=%g\r", gVar1
End
```

All functions that access the package data folder should do so through GetPackageDFREF. The calling functions do not need to worry about whether the data folder has been created and initialized because GetPackageDFREF does this for them.

### Creating and Accessing the Package Per-Instance Data Folders

Here we extend the technique of the preceding section to handle per-instance data. This example shows how you might handle per-channel data in a data acquisition package. If your package does not use per-instance data then you can skip this section.

First we write a function to create and initialize the per-instance package data folder:

```
Function/DF CreatePackageChannelData(channel)    // Called only from
Variable channel                               // 0 to 3                // GetPackageChannelDFREF

DFREF dfr = GetPackageDFREF()                  // Access main package data folder

String dfName = "Channel" + num2istr(channel)  // Channel0, Channel1, ...

// Create the package channel data folder
NewDataFolder/O dfr:$dfName

// Create a data folder reference variable
DFREF channelDFR = dfr:$dfName

// Initialize per-instance data
Variable/G channelDFR:gGain = 5.0
Variable/G channelDFR:gOffset = 0.0

return channelDFR
End
```

Now we can write the bottleneck function:

```
Function/DF GetPackageChannelDFREF(channel)
Variable channel                               // 0 to 3

DFREF dfr = GetPackageDFREF()                  // Access main package data folder

String dfName = "Channel" + num2istr(channel)  // Channel0, Channel1, ...
DFREF channelDFR = dfr:$dfName
if (DataFolderRefStatus(channelDFR) != 1)      // Data folder does not exist?
    DFREF channelDFR = CreatePackageChannelData(channel) // Create it
endif
return channelDFR
End
```

GetPackageChannelDFREF would be used like this:

```
Function/DF DemoPackageChannelDFREF(channel)
Variable channel                               // 0 to 3

DFREF channelDFR = GetPackageChannelDFREF(channel)

// Read a package variables
NVAR gGain = channelDFR:gGain
NVAR gOffset = channelDFR:gOffset
Printf "Channel %d: Gain=%g, offset=%g\r", channel, gGain, gOffset
End
```

All functions that access a package channel data folder should do so through GetPackageChannelDFREF. The calling functions do not need to worry about whether the data folder has been created and initialized because GetPackageChannelDFREF does this for them.

## Saving Package Preferences

If you are writing a sophisticated package of Igor procedures you may want to save preferences for your package. For example, if your package creates a control panel that can be opened in any experiment, you may want it to remember its position on screen between invocations. Or you may want to remember various settings in the panel from one invocation to the next.

Such “state” information can be stored either separately in each experiment or it can be stored just once for all experiments in preferences. These two approaches both have their place, depending on circumstances. But, if your package creates a control panel that is intended to be present at all times and used in any experiment, then the preferences approach is usually the best fit.

If you choose the preferences approach, you will store your package preference file in a directory created for your package. Your package directory will be in the Packages directory, inside Igor’s own preferences directory.

The location of Igor’s Packages directory depends on the operating system and the particular user’s configuration. You can find where it is on a particular system by executing:

```
Print SpecialDirPath("Packages", 0, 0, 0)
```

**Important:** You must choose a very distinctive name for your package because that is the only thing that prevents some other package from overwriting yours. All package names starting with “WM” are reserved for WaveMetrics.

A package name is limited to 31 bytes and must be a legal name for a directory on disk.

There are two ways to store package preference data:

- In a special-format binary file stored in your package directory
- As Igor waves and variables in an Igor experiment file stored in your package directory

The special-format binary file approach is relatively simple to implement but is not suitable for storing very large amounts of data. In most cases it is not necessary to store very large amounts of data so this is the way to go.

The use of the Igor experiment file supports storing a large amount of preference data but creates a problem of synchronizing your preference data stored in memory and your preference data stored on disk. It also leads to a proliferation of preference data stored in various experiments. You should avoid using this technique if possible.

### Saving Package Preferences in a Special-Format Binary File

This approach supports preference data consisting of a collection of numeric and string data. You define a structure encapsulating your package preference data. You use the **LoadPackagePreferences** operation (page V-441) to load your data from disk and the **SavePackagePreferences** operation (page V-704) to save it to disk.

SavePackagePreferences stores data from your package’s preferences data structure in memory. LoadPackagePreferences returns that data to you via the same structure.

SavePackagePreferences also creates a directory for your package preferences and stores your data in a file in that directory. Your package directory is located in the Packages directory in Igor’s preferences directory. The job of storing the preferences data in the file is handled transparently which, by default, automatically flushes your data to the file when the current experiment is saved or closed and when Igor quits.

You would call LoadPackagePreferences every time you need to access your package preference data and SavePackagePreferences every time you want to change your package preference data. You pass to these operations an instance of a structure that you define.

Here are example functions from the Package Preferences Demo experiment that use the LoadPackagePreferences and SavePackagePreferences operations to implement preferences for a particular package:

```
// NOTE: The package name you choose must be distinctive!
static StrConstant kPackageName = "Acme Data Acquisition"
static StrConstant kPrefsFileName = "PanelPreferences.bin"
```

## Chapter IV-10 — Advanced Topics

---

```
static Constant kPrefsVersion = 100
static Constant kPrefsRecordID = 0

Structure AcmeDataAcqPrefs
    uint32 version    // Preferences structure version number. 100 means 1.00.
    double panelCoords[4]    // left, top, right, bottom
    uchar phaseLock
    uchar triggerMode
    double ampGain
    uint32 reserved[100]    // Reserved for future use
EndStructure

// DefaultPackagePrefsStruct(prefs)
// Sets prefs structure to default values.
static Function DefaultPackagePrefsStruct(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    prefs.version = kPrefsVersion

    prefs.panelCoords[0] = 5        // Left
    prefs.panelCoords[1] = 40       // Top
    prefs.panelCoords[2] = 5+190    // Right
    prefs.panelCoords[3] = 40+125   // Bottom
    prefs.phaseLock = 1
    prefs.triggerMode = 1
    prefs.ampGain = 1.0

    Variable i
    for(i=0; i<100; i+=1)
        prefs.reserved[i] = 0
    endfor
End

// SyncPackagePrefsStruct(prefs)
// Syncs package prefs structures to match state of panel.
// Call this only if the panel exists.
static Function SyncPackagePrefsStruct(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    // Panel does exists. Set prefs to match panel settings.
    prefs.version = kPrefsVersion

    GetWindow AcmeDataAcqPanel wsize
    // NewPanel uses device coordinates. We therefore need to scale from
    // points (returned by GetWindow) to device units for windows created
    // by NewPanel.
    Variable scale = ScreenResolution / 72
    prefs.panelCoords[0] = V_left * scale
    prefs.panelCoords[1] = V_top * scale
    prefs.panelCoords[2] = V_right * scale
    prefs.panelCoords[3] = V_bottom * scale

    ControlInfo /W=AcmeDataAcqPanel PhaseLock
    prefs.phaseLock = V_Value    // 0=unchecked; 1=checked

    ControlInfo /W=AcmeDataAcqPanel TriggerMode
    prefs.triggerMode = V_Value    // Menu item number starting from on

    ControlInfo /W=AcmeDataAcqPanel AmpGain
    prefs.ampGain = str2num(S_value) // 1, 2, 5 or 10
End

// InitPackagePrefsStruct(prefs)
// Sets prefs structures to match state of panel or
// to default values if panel does not exist.
static Function InitPackagePrefsStruct(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    DoWindow AcmeDataAcqPanel
    if (V_flag == 0)
        // Panel does not exist. Set prefs struct to default.
        DefaultPackagePrefsStruct(prefs)
    else
        // Panel does exists. Sync prefs struct to match panel state.
        SyncPackagePrefsStruct(prefs)
    end
end
```

```

endif
End

static Function LoadPackagePrefs(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    // This loads preferences from disk if they exist on disk.
    LoadPackagePreferences kPackageName, kPrefsFileName, kPrefsRecordID, prefs

    // If error or prefs not found or not valid, initialize them.
    if (V_flag!=0 || V_bytesRead==0 || prefs.version!=kPrefsVersion)
        InitPackagePrefsStruct(prefs) // Set from panel if it exists or to default values.
        SavePackagePrefs(prefs)      // Create initial prefs record.
    endif
End

static Function SavePackagePrefs(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    SavePackagePreferences kPackageName, kPrefsFileName, kPrefsRecordID, prefs
End

```

**NOTE:** The package preferences structure, `AcmeDataAcqPrefs` in this case, must not use fields of type `Variable`, `String`, `WAVE`, `NVAR`, `SVAR` or `FUNCREF` because these fields refer to data that may not exist when `LoadPackagePreferences` is called.

The structure can use fields of type `char`, `uchar`, `int16`, `uint16`, `int32`, `uint32`, `int64`, `uint64`, `float` and `double` as well as fixed-size arrays of these types and substructures with fields of these types.

Use the reserved field to add fields to the structure in a backward-compatible fashion. For example, a subsequent version of the structure might look like this:

```

Structure AcmeDataAcqPrefs
    uint32    // Preferences structure version number. 100 means 1.00.
    double panelCoords[4]    // left, top, right, bottom
    uchar phaseLock
    uchar triggerMode
    double ampGain
    uint32 triggerDelay
    uint32 reserved[99]      // Reserved for future use
EndStructure

```

Here the `triggerDelay` field was added and size of the reserved field was reduced to keep the overall size of the structure the same. The `AcmeDataAcqLoadPackagePrefs` function would also need to be changed to set the default value of the `triggerDelay` field.

If you need to change the structure such that its size changes or its fields are changed in an incompatible manner then you must change your structure version, which will overwrite old preferences with new preferences.

A functioning example using this technique can be found in:

“Igor Pro 7 Folder:Examples:Programming:Package Preferences Demo.pxp”

In the example above we store just one structure in the preference file. However `LoadPackagePreferences` and `SavePackagePreferences` allow storing any number of structures of the same or different types in the preference file. You can store either multiple instances of the same structure or multiple different structures. You must assign a unique nonnegative integer as a record ID for each structure stored and pass this record ID to `LoadPackagePreferences` and `SavePackagePreferences`. You could use this feature, for example, to store a different structure for each type of control panel that your package presents. Since all data is cached in memory you should not attempt to store hundreds or thousands of structures.

In almost all cases a particular package will need just one preference file. For the rare cases where this is inconvenient, `LoadPackagePreferences` and `SavePackagePreferences` allow each package to create any number of preference files, each with a distinct file name. All of the preference files for a particular package are stored in the same directory, the package’s preferences directory. Each file can store a different set of

structure. However, the code that implements this feature is not tuned to handle large numbers of files so you should not use this feature indiscriminately.

### Saving Package Preferences in an Experiment File

This approach supports package preference data consisting of waves, numeric variables and string variables. It is more difficult to implement than the special-format binary file approach and is not recommended except for expert programmers and then only if the previously described approach is not suitable.

You use the SaveData operation to store your waves and variables in a packed experiment file in your package directory on disk. You can later use the LoadData operation to load the waves and variables into a new experiment.

You must create your package directory as illustrated by the SavePackagePrefs function below.

The following example functions save and load package preferences. These functions assume that the package preferences consist of all waves and variables at the top level of the package's data folder. You may need to customize these functions for your situation.

```
// SavePackagePrefs(packageName)
// Saves the top-level waves, numeric variables and string variables
// from the data folder for the named package into a file in the Igor
// preferences hierarchy on disk.
Function SavePackagePrefs(packageName)
    String packageName // NOTE: Use a distinctive package name.

    // Get path to Packages preferences directory on disk.
    String fullPath = SpecialDirPath("Packages", 0, 0, 0)
    fullPath += packageName

    // Create a directory in the Packages directory for this package
    NewPath/O/C/Q tempPackagePrefsPath, fullPath

    fullPath += ":Preferences.pxp"

    DFREF saveDF = GetDataFolderDFR()
    SetDataFolder root:Packages:$packageName
    SaveData/O/Q fullPath // Save the preference file
    SetDataFolder saveDF

    // Kill symbolic path but leave directory on disk.
    KillPath/Z tempPackagePrefsPath
End

// LoadPackagePrefs(packageName)
// Loads the data from the previously-saved package preference file,
// if it exist, into the package's data folder.
// Returns 0 if the preference file existed, -1 if it did not exist.
// In either case, this function creates the package's data folder if it
// does not already exist.
// LoadPackagePrefs does not affect any other data already in the
// package's data folder.
Function LoadPackagePrefs(packageName)
    String packageName // NOTE: Use a distinctive package name.

    Variable result = -1
    DFREF saveDF = GetDataFolderDFR()

    NewDataFolder/O/S root:Packages // Ensure root:Packages exists
    NewDataFolder/O/S $packageName // Ensure package data folder exists

    // Find the disk directory in the Packages directory for this package
    String fullPath = SpecialDirPath("Packages", 0, 0, 0)
    fullPath += packageName
    GetFileFolderInfo/Q/Z fullPath
    if (V_Flag == 0) // Disk directory exists?
        fullPath += ":Preferences.pxp"
        GetFileFolderInfo/Q/Z fullPath
        if (V_Flag == 0) // Preference file exist?
            LoadData/O/R/Q fullPath // Load the preference file.
            result = 0
        endif
    endif
endif
```

```

    SetDataFolder saveDF
    return result
End

```

The hard part of using the experiment file for saving package preferences is not in saving or loading the package preference data but in choosing when to save and load it so that the latest preferences are always used. There is no ideal solution to this problem but here is one strategy:

1. When package preference data is needed (e.g., you are about to create your control panel and need to know the preferred coordinates), check if it exists in memory. If not load it from disk.
2. When the user does a New Experiment or quits Igor, if package preference data exists in memory, save it to disk. This requires that you create an IgorNewExperimentHook function and an IgorQuitHook function.
3. When the user opens an experiment file, if it contains package preference data, delete it and reload from disk. This requires that you create an AfterFileOpenHook function. This is necessary because the package preference data in the just opened experiment is likely to be older than the data in the package preference file.

## Creating Your Own Help File

If you are an advanced user, you can create an Igor help file that extends the Igor help system. This is something you might want to do if you write a set of Igor procedures or extensions for use by your colleagues. If your procedures or extensions are generally useful, you might want to make them available to all Igor users. In either case, you can provide documentation in the form of an Igor help file.

Here are the steps for creating an Igor help file.

1. Create a formatted-text notebook.  
A good way to do this is to open the Igor Help File Template provided by WaveMetrics in the More Help Files folder. Alternatively, you can start by duplicating another WaveMetrics-supplied help file and then open it as a notebook using File→Open File→Notebook. Either way, you are starting with a notebook that contains the rulers used to format an Igor help file.
2. Choose Save Notebook As from the File menu to create a new file. Use a “.ihf” extension so that Igor will recognize it as a help file.
3. Enter your help text in the new file.
4. Save and kill the notebook.
5. Open the file as a help file using File→Open File→Help File.

When you open the file as a help file, it needs to be compiled. When Igor compiles a help file, it scans through it to find out where the topics start and end and makes a note of subtopics. When the compilation is finished, it saves the help file which now includes the help compiler information.

Once Igor has successfully compiled the help file, it acts like any other Igor help file. That is, when opened it appears in the Help Windows submenu, its topics will appear in the Help Browser, and you can click links to jump around.

Here are the steps for modifying a help file.

1. If the help file is open, kill it by pressing Option (*Macintosh*) or Alt (*Windows*) and clicking the close button.
2. Open it as a notebook, using File→Open File→Notebook.  
Alternatively, you can press Shift while choosing the file from File→Recent Files. Then, in the resulting dialog, specify that you want to open the file as a formatted notebook.
3. Modify it using normal editing techniques.
4. Choose Save Notebook from the File menu.
5. Click the close button and kill the notebook.
6. Reopen it as a help file using File→Open File→Help File.  
Alternatively, you can press Shift while choosing the file from File→Recent Files. Then, in the resulting

dialog, specify that you want to open the file as a help file.

### Syntax of a Help File

Igor needs to be able to identify topics, subtopics, related topics declarations, and links in Igor help files. To do this it looks for certain rulers, text patterns and text formats described in **Creating Links** on page IV-242. You can get most of the required text formats by using the appropriate ruler from the Igor Help File Template file.

Igor considers a paragraph to be a help topic declaration if it starts with a bullet character followed by a tab and if the paragraph's ruler is named Topic. By convention, the Topic ruler's font is Geneva on Macintosh or Arial on Windows, its text size is 12 and its text style is bold-underlined. The bullet and tab characters should be plain, not bold or underlined.

The easiest way to create a new topic with the right formatting is to copy an existing topic and then modify it.

Once Igor finds a topic declaration, it scans the body of the topic. The body is all of the text until the next topic declaration, a related-topics declaration, or the end of the file. While scanning, it notes any subtopics.

Igor considers a paragraph to be a subtopic declaration if the name of the ruler governing the paragraph starts with "Subtopic". Thus if the ruler is named Subtopic or Subtopic+ or Subtopic2, the paragraph is a subtopic declaration. By convention, the Subtopic ruler's font is Geneva on Macintosh or Arial on Windows, its text size is 10 and its text style is bold and underlined. Text following the subtopic name that is not bold and underlined is not part of the subtopic name.

The easiest way to create a new subtopic with the right formatting is to copy an existing subtopic and then modify it.

Igor considers a paragraph to be a related-topics declaration if the ruler governing the paragraph is named RelatedTopics and if the paragraph starts with the text pattern "Related Topics:". When Igor sees this pattern it knows that this is the end of the current topic. The related-topics declaration is optional. Prior to Igor Pro 4, Igor displayed a list of related topics in the Igor Help Browser. Igor Pro no longer displays this list. The user can still click the links in the related topics paragraph to jump to the referenced topics.

Igor knows that it has hit the end of the current topic when it finds the related-topics declaration or when it finds a new topic declaration. In either case, it proceeds to compile the next topic. It continues compiling until it hits the end of the file.

When compiling the help file, Igor may encounter syntax that it can't understand. For example, if you have a related-topics declaration paragraph, Igor will expect the next paragraph to be a topic declaration. If it is not, Igor will stop the compilation and display an error dialog. You need to open the file as a notebook, fix the error, save and kill it and then reopen it as a help file.

Another error that is easy to make is to fail to use the plain text format for syntactic elements like bullet-tab, "Related Topics:" or the comma and space between related topics. If you run into a non-obvious compile error in a topic, subtopic or related topics declaration, recreate the declaration by copying from a working help file.

The help files supplied by WaveMetrics contain a large number of rulers to define various types of paragraphs such as topic paragraphs, subtopic paragraphs, related topic paragraphs, topic body paragraphs and so on. The Igor Help File Template contains many but not all of these rulers. If you find that you need to use a ruler that exists in a WaveMetrics help file but not in your help file then copy a paragraph governed by that ruler from the WaveMetrics help file and paste it into your file. This transfers the ruler to your file.

### Creating Links

A link is text in an Igor help file that, when clicked, takes the user to some other place in the help. Igor considers any pure blue, underlined text to be a link. Pure blue means that the RGB value is (0, 0, 65535). By convention links use the Geneva font on Macintosh and the Arial font on Windows.

To create a link, select the text in the notebook that you are preparing to be a help file. Then choose Make Help Link from the Notebook menu. This sets the text format for the selected text to pure blue and underlined.

The link text refers to another place in the help using one of these forms:

- The name of a help topic (e.g., Command Window)
- The name of a help subtopic (e.g., History Area)
- A combined topic and subtopic (e.g., Command Window[History Area])

Use the combined form if there is a chance that the help topic or subtopic name by itself may be ambiguous. For example, to refer to the Preferences operation, use Operations[Preferences] rather than Preferences by itself.

When the user double-clicks a link, Igor performs the following search:

1. If the link is a topic name, Igor goes to that topic.
2. If the link is in topic[subtopic] form, Igor goes to that subtopic.
3. If steps 1 and 2 fail, Igor searches for a subtopic with the same name as the link. First, it searches for a subtopic in the current topic. If that fails, it searches for a subtopic in the current help file. If that fails, it searches for a subtopic in all help files.
4. If step 3 fails, Igor searches all help files in the Igor Pro 7 folder. If it finds the topic in a closed help file, it opens and displays it.
5. If step 4 fails, Igor searches all help files in the Igor Pro User Files folder. If it finds the topic in a closed help file, it opens and displays it.
6. If all of the above fail, Igor displays a dialog saying that the required help file is not available.

You can create a link in a help file that will open a Web page or FTP site in the user's Web or FTP browser. You do this by entering the Web or FTP URL in the help file while you are editing it as a notebook. The URL must appear in this format:

```
<http://www.wavemetrics.com>  
<ftp://ftp.wavemetrics.com>
```

The URL must include the angle brackets and the "http://", "https://" or "ftp://" protocol specifier. Support for https was added in Igor Pro 7.02.

After entering the URL, select the entire URL, including the angle brackets, and choose Make Help Link from the notebook menu. Once the file is compiled and opened as a help file, clicking the link will open the user's Web or FTP browser and display the specified URL.

For any other kind of URL, such as sftp or mailto, use a notebook action that calls BrowseURL instead of a help link.

It is currently not possible make ordinary text into a Web or FTP link. The text must be an actual URL in the format shown above or you can insert a notebook action which brings up a web page using the **BrowseURL** operation on page V-45. See **Notebook Action Special Characters** on page III-14 for details.

### Checking Links

You can tell Igor to check your help links as follows:

1. Open your Igor help file and compile it as a help file if necessary.
2. Activate your help window.
3. Right-click in the body of the help file and choose Check Help Links. Igor will check your links from where you clicked to the end of the file and note any problems by writing diagnostics to the history area of the command window.
4. When Igor finishes checking, if it found bad links, kill the help file and open it as a notebook.
5. Use the diagnostics that Igor wrote in the history to find and fix any link errors.
6. Save the notebook and kill it.
7. Open the notebook as a help file. Igor will compile it.
8. Repeat the check by going back to Step 1 until you have no bad links.

During this process, Igor searches for linked topics and subtopics in open and closed help files and opens any closed help file to which a link refers. If a link is not satisfied by an already open help file, Igor searches closed help files in:

- The Igor Pro 7 Folder and subfolders
- The Igor Pro User Files folder and subfolders
- Files and folders referenced by aliases or shortcuts in one of those folders

You can abort the check by pressing the **User Abort Key Combinations**.

The diagnostic that Igor writes to the history in case of a bad link is in the form:

```
Notebook $nb selection={ (33,292) , (33,334) } ...
```

This is set up so that you can execute it to find the bad link. At this point, you have opened the help file as a notebook. Assuming that it is named Notebook0, execute

```
String/G nb = "Notebook0"
```

Now, you can execute the diagnostic commands to find the bad link and activate the notebook. Fix the bad link and then proceed to the next diagnostic. It is best to do this in reverse order, starting with the last diagnostic and cutting it from the history after fixing the problem.

If you press the Shift key while right-clicking a help window, you can choose Check Help Links in All Open Help Files. Then Igor checks all help links all help files open at that time. While checking a help file, Igor may open a previously unopened help file. Such newly opened help files are not checked. Only those help files open when you chose Check Help Links in All Open Help Files are checked. However, if you repeat the process, help files opened during the previous iteration are checked.

When fixing a bad link, check the following:

- A link is the name of a topic or subtopic in a currently open help file. Check spelling.
- There are no extraneous blue/underlined characters, such as tabs or spaces, before or after the link. (You can not identify the text format of spaces and tabs by looking at them. Check them by selecting them and then using the Set Text Format dialog.)
- There are no duplicate topics. If you specify a link in topic[subtopic] form and there are two topics with the same topic name, Igor may not find the subtopic.

## Creating Formatted Text

The `printf`, `sprintf`, and `fprintf` operations print formatted text to Igor's history area, to a string variable or to a file respectively. The `wfprintf` operation prints formatted text based on data in waves to a file.

All of these operations are based on the C `printf` function which prints the contents of a variable number of string and numeric variables based on the contents of a format string. The format string can contain literal text and conversion specifications. Conversion specifications define how a variable is to be printed.

Here is a simple example:

```
printf "The minimum is %g and the maximum is %g\r", V_min, V_max
```

In this example, the format string is "The minimum is %g and the maximum is %g\r" which contains some literal text along with two conversion specifications — both of which are "%g" — and an escape code ("\\r") indicating "carriage-return". If we assume that the Igor variable `V_min` = .123 and `V_max` = .567, this would print the following to Igor's history area:

```
The minimum is .123 and the maximum is .567
```

We could print this output to an Igor string variable or to a file instead of to the history using the **`sprintf`** (see page V-772) or **`fprintf`** (see page V-224) operations.

where *stringVariable* is the name of the string variable to print to and the remaining parameters are as for printf. sprintf is useful for generating text to use as prompts in macros, in axis labels and in annotations.

### fprintf Operation

The fprintf operation is very similar to printf except that it prints to a file instead of to Igor's history. The syntax of the fprintf operation is:

```
fprintf variable, format [, parameter [, parameter ] . . .]
```

where *variable* is the name of a numeric variable containing the file reference number for the file to print to and the remaining parameters are as for printf. You get the file reference number using the Open operation, described under **Open and Close Operations** on page IV-185.

For debugging purposes, if you specify 1 for the file reference number, Igor prints to the history area instead of to a file, as if you used printf instead of fprintf.

### fprintf Operation

The fprintf operation is similar to printf except that it prints the contents of one to 100 waves to a file. The syntax of the fprintf operation is:

```
fprintf variable, format [/R=(start,end)] wavelist
```

*variable* is the name of a numeric variable containing the file reference number for the file to print to.

Unlike printf, which rounds, fprintf converts floating point values to integers by truncating, if you use an integer conversion specification such as "%d".

### Example Using fprintf and fprintf

Here is an example of a command sequence that creates some waves and put values into them and then writes them to an output file with column headers.

```
Make/N=25 wave1, wave2, wave3
wave1 = 100+x; wave2 = 200+x; wave3 = 300+x
Variable f1
Open f1
fprintf f1, "wave1, wave2, wave3\r"
fprintf f1, "%g, %g, %g\r" wave1, wave2, wave3
Close f1
```

This generates a comma delimited file. To generate a tab delimited file, use:

```
fprintf f1, "wave1\twave2\twave3\r"
fprintf f1, "%g\t%g\t%g\r" wave1, wave2, wave3
```

Since tab-delimited is the default format for fprintf, this last command is equivalent to:

```
fprintf f1, "" wave1, wave2, wave3
```

## Client/Server Overview

An application can interact with other software as a server or as a client.

A server accepts commands and data from a client and returns results to the client.

A client sends commands and data to a server program and receives results from the server.

For the Macintosh, see **Apple Events** on page IV-247 for server information and **AppleScript** on page IV-249 for client capabilities.

For Windows, see **ActiveX Automation** on page IV-251. Igor can play the role of an Automation server but not an Automation client. However it is possible to generate script files that allow Igor to indirectly play the role of client.

On Windows, Igor also supports Dynamic Data Exchange (DDE) and can be a DDE server or DDE client. Because DDE is obsolescent and being phased out by Microsoft, new programming should use ActiveX automation. Igor's support for DDE is described in the Obsolete Topics help file.

## Apple Events

This topic is of interest to *Macintosh* programmers. Windows users should see the section for **ActiveX Automation** on page IV-251.

This topic contains information for Igor users who wish to control Igor from other programs (e.g., AppleScript). It also contains information useful to people who are writing their own programs and wish to use Igor Pro as a computing or graphing engine.

There is also a mechanism that allows Igor to act like a controller and initiate Apple event communication with other programs. See **AppleScript** on page IV-249.

### Apple Event Capabilities

Igor Pro supports the following Apple events:

Event	Suite	Action
Open Application	Required	Basically a nop; don't use.
Open Document	Required	Loads an experiment.
Print Document	Required	NA; don't use.
Quit Application	Required	Quits.
Close	Core	Acts on experiment, window or PPC port.
Save	Core	Acts on experiment only.
Open	Core	NA; don't use.
Do Script	Misc	Executes commands; can return ASCII results.
Eval Expression	Misc	Same as Do Script; obsolete but included for compatibility.

### Apple Events — Basic Scenario

You use the Open Document event to cause Igor to load an experiment with whatever goodies you find useful. You then use the Do Script or Eval Expression events to send commands to Igor for execution and to retrieve results. To get data into Igor you write files and then send commands to Igor to load the data. To get data waves from Igor you do the reverse. To get graphics, you send commands to Igor that cause it to write a graphics file that you can read. You may then close the experiment and start over with a new one. You will not likely use the Save event.

### Apple Events — Obtaining Results from Igor

To return information from Igor, you will need to embed special commands in the script you send to Igor for execution. When Igor encounters these commands, it appends results to a packet that is returned to your application after script execution ends. The special commands are variations on the standard Igor commands `FBinWrite` and `fprintf`. Both of these commands take a file reference number as a parameter. If the magic value zero is used rather than a real file reference number, then the data that would normally be written to a file is appended to the result packet.

As far as Igor is concerned, there is no difference between the Do Script and Eval Expression events. However, old applications may expect results from Eval Expression and not from Do Script.

To use waves and graphics with Apple events, you will need to write or read the data via standard Igor files. For example, you might include

```
SavePICT /E=-8 /P=MyPath as "Graphics.pdf"
```

## Chapter IV-10 — Advanced Topics

---

in a script that you send to Igor for execution. You could then read the file in your application.

### Apple Event Details

This information is intended for programmers familiar with Apple events terminology.

Some of the following events can act on experiments or windows.

To specify an experiment, use object class `cDocument` ('docu') and specify either `formAbsolutePosition` with `index=1` or `formName` with `name=name of experiment`.

To specify a window, use object class `cWindow` ('cwin') and either `formAbsolutePosition` or `formName` with `name=title of window`.

Event	Class	Code	Action
Open Application	'aevt'	'oapp'	Basically a nop; don't use.
Open Document	'aevt'	'odoc'	Loads an experiment. Direct object is assumed to be coercible to a File System Spec record.
Print Document	'aevt'	'pdoc'	NA; don't use.
Quit Application	'aevt'	'quit'	<p>Quits the program. If the experiment was modified, then Igor attempts to interact with the user to get save/no save directions. If interaction is not allowed, then an error is returned and nothing is done.</p> <p>To prevent errors, send the close event with appropriate save options prior to sending quit.</p>
Close	'core'	'clos'	<p>Acts on an experiment or window.</p> <p>For a window, the save/no save/ask optional parameter (<code>keyAESaveOptions</code>) is allowed and refers to making/replacing a recreation macro.</p> <p>For a document (experiment), <code>keyAESaveOptions</code> is allowed and an additional optional parameter <code>keyAEDestination</code> may be used to specify where to save (must be coercible to a FSS). If this is not given and the experiment is untitled and if an attempt to interact with the user fails then the experiment is not saved and an error (such as <code>errAENoUserInteraction</code>) is returned.</p> <p>Note that if the optional destination is given then the save options are ignored (why give a destination and then say no save?).</p>
Save	'core'	'save'	<p>Acts on experiment only.</p> <p>Takes same optional destination parameters as Close. A save with a destination is the same as a Save as.</p>

Event	Class	Code	Action
Do Script	'misc'	'doscl'	Same as Eval Expression.
Eval Expression	'aevt'	'eval'	<p>Executes commands. Acts just as if commands had been typed into the command line except the individual command lines are preceded by a percent symbol rather than the usual bullet symbol. Also, errors are returned in the error reply parameter of the event rather than putting up a dialog.</p> <p><b>Note:</b> You can suppress history logging by executing the command, “Silent 2”, and you can turn it back on by executing “Silent 3”.</p> <p>Direct parameter must be text and not a file. Text can be of any length.</p> <p>You can return a string containing results by using the <code>fprintf</code> command with a file reference number of zero.</p>

## AppleScript

This topic is of interest to *Macintosh* programmers. Windows users should see the section for **ActiveX Automation** on page IV-251.

Igor supports the creation and execution of simple AppleScripts in order to send commands to other programs.

To execute an AppleScript program, you first compose it in a string and then pass it to the `ExecuteScriptText` operation, which in turn passes the text to Apple’s scripting module for compilation and execution. The result, which might be an error message, is placed in a string variable named `S_value`. Igor does not save the compiled script so every time you call `ExecuteScriptText` your script will have to be recompiled. See the **ExecuteScriptText** operation on page V-178 for additional details.

The documentation for the **ExecuteScriptText** operation (page V-178) includes an example that shows how to execute a Unix command.

Because there is no easy way to edit a script or to see where errors occur, you should first test your script using Apple’s Script Editor application.

You can use “Silent 2” to prevent commands your script sends to Igor from being placed in the history area.

You can send commands to Igor without using the `tell` keyword.

You should check your quoting carefully. Your text must be quoted both for Igor and for Apple’s scripting system. For example,

```
ExecuteScriptText "Do Script \"Print \\\"hello\\\"\""
```

You should compose scripts in string variables one line at a time to improve readability.

If an error occurs that you can’t figure out, print the string, copy from the history and paste into a Script Editor for debugging.

If the script returns a text return value, it will be quoted within the `S_value` string.

Don’t forget to include the carriage return escape code, `\r`, at the end of each line of a multiline script.

The first time you call this routine, it may take an extra long time while the Mac OS loads the scripting modules.

### Executing Unix Commands on Mac OS X

On Mac OS X, you can use AppleScript to send a command to the Unix shell. Here is a function that illustrates this:

```
Function/S ExecuteUnixShellCommand(uCommand, printCommandInHistory,
                                   printResultInHistory [, asAdmin])
    String uCommand                // Unix command to execute
    Variable printCommandInHistory
    Variable printResultInHistory
    Variable asAdmin               // Optional - defaults to 0

    if (ParamIsDefault(asAdmin))
        asAdmin = 0
    endif

    if (printCommandInHistory)
        Printf "Unix command: %s\r", uCommand
    endif

    String cmd
    sprintf cmd, "do shell script \"%s\"", uCommand
    if (asAdmin)
        cmd += " with administrator privileges"
    endif
    ExecutescriptText/UNQ/Z cmd // /UNQ removes quotes surrounding reply

    if (printResultInHistory)
        Print S_value
    endif

    return S_value
End
```

You can test the function with this command:

```
ExecuteUnixShellCommand("ls", 1, 1)
```

Life is a bit more complicated if the command that you want to execute contains spaces or other nonstandard Unix command characters. For example, imagine that you want to execute this:

```
ls /System/Library/Image Capture
```

These commands will not work because of the space in the command's file path:

```
String unixCmd = "ls /System/Library/Image Capture"
ExecuteUnixShellCommand(unixCmd, 1, 1)
```

You need to quote the path part of the command so that the UNIX parses:

```
/System/Library/Image Capture
```

as one argument, not two (/System/Library/Image and ./Capture).

There are two ways to do this:

1. Use single-quote characters around the parts of the command where needed:

```
String unixCmd = "ls '/System/Library/Image Capture'"
ExecuteUnixShellCommand(unixCmd, 1, 1)
```

2. Use double-quote characters with the backslashes needed to make it through Igor's parser and AppleScript's parser:

```
String unixCmd = "ls \"/System/Library/Image Capture\"/"
ExecuteUnixShellCommand(unixCmd, 1, 1)
```

Igor's parser converts `\" to \ and \" to , so AppleScript sees this:`

```
"ls \"/System/Library/Image Capture\"/"
```

AppleScript's parser converts `\" to " so Unix sees this:`

```
ls "/System/Library/Image Capture"
```

## ActiveX Automation

ActiveX Automation, often called just Automation, is Microsoft's technology for allowing one program to control another. The program that does the controlling is called the Automation client. The program that is controlled is called the Automation Server. The client initiates things by making calls to the server which carries out the requested actions and returns results.

Automation client programs are most often written in Visual Basic or C#. They can also be written in C++ and other programming languages, and in various scripting languages such as VBScript, JavaScript, Perl, Python and so on.

Igor can play the role of Automation Server. If you want to write an client program to drive Igor, see "Automation Server Overview" in the "Automation Server" help file in "\Igor Pro 7 Folder\Miscellaneous\Windows Automation".

Igor Pro does not directly support playing the role of Automation client. However, it is possible to write an Igor program which generates a script file which can act like an Automation client. For an example, choose File→Example Experiments→Programming→CallMicrosoftWord.

## Calling Igor from Scripts

You can call Igor from shell scripts, batch files, Apple Script, and the Macintosh terminal window using an operation-like syntax. You can also use this feature to register an Igor license.

The syntax for calling Igor is:

```
<IGOR> [/I /Q /X /N /Automation] [pathToFileOrCommands] [pathToFile] ...
<IGOR> [/I /N /Automation] [pathToFileOrCommands] [pathToFile] ...
<IGOR> [/I /Q /X /Automation] "commands"
<IGOR> /SN=num /KEY="key" /NAME="name" [/ORG="org" /QUIT]
```

where <IGOR> is the full path to the Igor executable file.

On Windows, the Igor executable file resides in a folder within the Igor Pro folder. The full path will be something like:

```
"C:\Program Files\WaveMetrics\IgorBinaries_x64\Igor Pro 7 Folder\Igor64.exe"
```

On Macintosh, the Igor application is an "application bundle" and the actual executable file is inside the bundle. The full path will be something like:

```
'/Applications/Igor Pro 7 Folder/Igor64.app/Contents/MacOS/Igor64'
```

In the following discussions, <IGOR> means "the full path to the Igor executable file".

### Parameters

All parameters are optional. If you omit all parameters, including just the full path to the Igor executable, a new instance of Igor is launched.

The usual parameter is a file for Igor to open. It is recommended that both the path and the path to the file parameter be enclosed in quotes.

You can open multiple files by using a space between one quoted file path and the next.

With the /X flag, only one parameter is allowed and it is interpreted as an Igor command.

### Flags

When you specify a flag, you can use a - instead of /. For example, you can write /Q or -Q.

/Automation	This flag is supported on Windows only. The Windows OS uses it when launching Igor Pro as an ActiveX Automation server. It is not intended for use in batch files.
/I	Launches a new instance of Igor if one would otherwise not be launched. See <i>Details</i> for a discussion of instances.
/KEY="key"	Specifies the license activation key when registering a license. For example: <code>/KEY="ABCD-EFGH-IJKL-MNOP-QRST-UVWX-Y"</code> Do not omit the quotes, or it will fail.
/N	Forces the current experiment to be closed without saving if any of the file parameters are an experiment file. To save a currently open experiment, use: <code>&lt;IGOR&gt; /X "SaveExperiment"</code>
/NAME="name"	Specifies the name of the licensed user when registering a license. A name is required when registering.
/ORG="org"	Specifies the optional name of the licensed organization when registering a license. /ORG is optional and defaults to "".
/Q	Prevents the command from being displayed in Igor's command line as it is executing.
/QUIT	Quits Igor Pro after entering license information when used with /SN, /KEY, and /NAME. Otherwise /QUIT is ignored. To quit Igor Pro, use: <code>&lt;IGOR&gt; /X "Quit/N"</code>
/SN=num	Specifies the license serial number when registering a license.
/X	Executes the commands in the parameter. Only one parameter is allowed with /X. Use semicolons to separate Igor commands within the parameter.

### Details

If an existing instance of Igor is running, the command is sent to the existing instance if you omit the /I flag and you include /X, /SN, or a path to a file. Otherwise, a new instance of Igor is launched.

### Registering a License

You can register an Igor license using the /SN, /KEY, and /NAME flags. All of these flags must be present to successfully register a license. The optional /ORG parameter defaults to "".

These batch file commands register Igor Pro with the given serial number and license activation key:

```
<IGOR> /SN=1234567 /KEY="ABCD-EFGH-IJKL-MNOP-QRST-UVWX-Y" /NAME="Jack" /ORG="Acme Scientific" /QUIT
```

## Network Communication

The following sections contain material related to the network communication and Internet-related capabilities of Igor Pro:

**URLs** on page IV-252

**Safe Handling of Passwords** on page IV-255

**Network Timeouts and Aborts** on page IV-255

**Network Connections From Multiple Threads** on page IV-256

**File Transfer Protocol (FTP)** on page IV-257

**Hypertext Transfer Protocol (HTTP)** on page IV-261

## URLs

URLs, or Uniform Resource Locators, are compact strings that represent a resource available via the Internet. The description of the URL standard is described in RFC1738 (<http://www.rfc-editor.org/rfc/rfc1738.txt>) and updated in RFC3986 (<http://www.rfc-editor.org/rfc/rfc3986.txt>).

Each URL is composed of several different parts, most of which are optional:

```
<scheme>://<username>:<password>@<host>:<port>/<path>?<query>
```

Some examples of valid URLs are:

```
http://www.example.com
http://www.example.com/afolder?key1=45&key2=66
http://myusername:Passw0rD@www.example.com:8010/index.html
ftp://ftp.wavemetrics.com
file:///C:\\Data\\Trial1\\control.ibw (on Windows only)
file:///Users/bob/Data/Trial1/control.ibw (on Macintosh only)
```

For most operations and functions that take a *urlStr* parameter, only the scheme and host parts of the URL are required. See the **Supported Network Schemes** section for information on which schemes are supported by which operations and functions, and which port is used by default if it is not provided as part of the URL.

## Username and Passwords

You can provide a username and password as part of the URL. However authentication credentials may not be supported by all schemes (such as file://). Some operations allow you to provide a username and password by using a flag, such as the /U and /W flags with **FTPDownload** or the /AUTH flag with **URLRequest**.

If a URL contains a username and password in the URL and the authentication flags are also used, the values specified in the flags override values provided in the URL.

If you do not provide a username and password as part of the URL, and you do not use the authentication flags, then no authentication is attempted. An exception to this rule is that the FTP operations will login to the FTP server using "anonymous" as the username and a generic email address as the password.

If either the username or password contains special or reserved characters, those characters must be percent-encoded.

## Supported Network Schemes

Different operations and functions support different schemes:

Operation	Supported Schemes	Default Port
<b>FetchURL</b> and <b>URLRequest</b>	http	80
	https	443
	ftp	21
	file	Not applicable
FTP operations*	ftp	21

\* Includes **FTPUpload**, **FTPDownload**, **FTPDelete**, and **FTPCreateDirectory**.

## Percent Encoding

Percent encoding is a way to encode characters in URLs that would otherwise have a special meaning or could be misinterpreted by servers. For example, a space character in a URL is encoded as "%20" using a percent character followed by the hex code for a space in the ASCII character set.

Most URLs contain only the letters A-Z and a-z, the digits 0-9, and a few other characters such as the underscore (\_), hyphen (-), period (.), and tilde (~).

## Chapter IV-10 — Advanced Topics

---

A URL may also contain "reserved characters" that may have special meaning depending on the way that they are used. Every URL contains the reserved characters ":" and "/" and may also contain one or more of the following reserved characters: !\*():@&=+\$,?#[].

All operations and functions provided by Igor Pro that accept a URL string parameter expect that the URL has already been percent-encoded as necessary.

In most cases you don't need to worry about percent encoding because most URLs don't use reserved characters except for their special meaning. If you need to use a reserved character in a way that differs from the character's special meaning, you must percent-encode the character. You can use the **URLEncode** function for this purpose.

It is important that you not pass your entire URL to URLEncode to be encoded because that URL will not be understood by a server. URLEncode percent-encodes all reserved characters in the string you pass to it, because it cannot distinguish between reserved characters used for their special meaning and reserved characters used outside of their special meaning. Instead, you must pass each piece of the URL through URLEncode so that the final URL uses the correct syntax.

As an example, we'll use URLEncode to properly encode a URL that contains the following parts:

Part Name	Example
Scheme	http
Username	A. MacGyver
Password	yj@!2M
Host	www.example.com
Path	/tape/duct
Query	discount=10%&color=red

Without any percent-encoding, the URL is:

```
http://A. MacGyver:yj@!2M@www.example.com/tape/duct?discount=10%&color=red
```

If this URL were passed to **FetchURL**, the result would be an error because the URL contains several reserved characters that are not intended to be used in their standard way. For example, the "@" character indicates the separation between the username:password information and the start of the host name, but in this case the password itself also contains the "@" character. In addition, the "%" character is typically used to indicate that the next two characters represent a percent-encoded character, but in this example it is also part of the query. Finally, the username contains a space character. The space character is not technically a reserved character, but should be percent-encoded to ensure that it is handled correctly.

The following table shows the values of the parts of the URL that need to be percent-encoded by passing them through the URLEncode function:

Part Name	Encoded Value
Username	A%2E%20MacGyver
Password	yj%40%212M
Host	www.example.com
Path	/tape/duct
Query	discount=10%25&color=red

The properly percent-encoded URL is:

```
http://A%2E%20MacGyver:yj%40%212M@www.example.com/tape/duct?discount=10%25&color=red
```

For keyword-value pairs that make up the query part, each keyword and value must be percent-encoded separately because the "=" character that separates the key from the value and the "&" character that separates the pairs in the list must not be percent-encoded.

For more information on percent-encoding and reserved characters, see <http://en.wikipedia.org/wiki/Percent-encoding>.

## Safe Handling of Passwords

Some operations and functions support the use of a username and password when making a network connection. If you use sensitive passwords you must take certain precautions to prevent them from being accidentally revealed.

1. Always use the /V=0 flag when using a username or password with the /U (username) and /W (password) flags or the /AUTH flag. Otherwise, the debugging information that is printed to the history area will contain those values and anyone who sees the experiment could see them.
2. Do not hard code username or password values into procedures, since anyone with access to the procedure file could read them.
3. Do not store username or password values in global variables. Since global variables are saved with an experiment, if someone else had access to your experiment they could see this information.

Here is an example of how a username and sensitive password can be used in a secure manner:

```
Function SafeLogin()
    String username = ""
    String password = ""
    Prompt username, "Username"
    Prompt password, "Password"
    DoPrompt "Enter username and password", username, password
    if (V_flag == 1)
        // User hit cancel button, so do nothing.
        return 0
    endif

    // Percent-encode in case username and password contain reserved characters.
    String encodedUser = URLEncode(username)
    String encodedPass = URLEncode(password)

    String theURL
    sprintf theURL, "http://%s:%s@www.example.com", encodedUser, encodedPass
    String response = FetchURL(theURL)
    // NOTE: For FTP operations and URLRequest, make sure to use /V=0 so that
    // the username and password are not printed to the history.

    return 0
End
```

Note that the user is prompted to provide the username and password when the function is called and that only local string variables are used to store the username and password. The values in those string variables are not stored once the function is done executing.

Note also that the password is not hidden during entry in the dialog. Igor currently does not provide a way to do this.

## Network Timeouts and Aborts

Some network calls may return an error code to Igor if they timeout. Depending on the specific operation or function, there can be a number of causes for a timeout.

If a network connection cannot be made after a period of time it will timeout. The amount of time allowed for a connection to be established is dependent on several factors.

You can always abort a network operation or function by pressing the **User Abort Key Combinations**.

## Network Connections From Multiple Threads

All network-related operations and functions are thread-safe, which means that they can be called from multiple preemptive threads at the same time. This capability can be useful when:

- You want to retrieve information from several different URLs as quickly as possible.
- You want to do a long download or other operation in the background to avoid tying Igor up.

The following example illustrates the first of these cases. It uses **FetchURL** to retrieve a list of the most frequently downloaded books from the Project Gutenberg web site. It then uses **FetchURL** to download the entire text of the top four books and prints the number of bytes in each.

```
ThreadSafe Function GetThePage(url)
    String url

    String response = FetchURL(url)
    return strlen(response)
End

Function ListGutenbergTopBooks()
    String topBooksURL = "http://www.gutenberg.org/browse/scores/top"
    String baseURL = "http://www.gutenberg.org/files/"

    // Get the contents of the page.
    String response = FetchURL(topBooksURL)
    Variable error = GetRTErrors(1)
    if (error || numtype(strlen(response)) != 0)
        Print "Error getting the list of most popular books."
        return 0
    endif

    String topBooksHTML = response

    // Remove all line endings.
    topBooksHTML = ReplaceString("\n", topBooksHTML, "")
    topBooksHTML = ReplaceString("\r", topBooksHTML, "")

    // Parse the page to get the section of the page
    // with the list of the most popular books from yesterday.
    // This could break if the format of the web page changes.
    String regExp = "(?i)<h2 id=\"books-last1\">.*?<ol>(.*?)</ol>"
    String topYesterdayHTML = ""
    SplitString/E=regExp topBooksHTML, topYesterdayHTML
    if (V_flag != 1)
        Print "Error parsing the top 100 books section."
        return 0
    endif

    // Replace the line endings.
    topYesterdayHTML = ReplaceString("</li><li>", topYesterdayHTML, "\r")

    // Create a wave to store text info about the top four books.
    Variable numBooksToUse = 4
    Make/O/T/N=(numBooksToUse, 2) topBooksInfo

    Make/O/N=(numBooksToUse) byteCounts
```

```

Variable n
String bookNumStr
Variable bookNum
String titleAuthor
String thisLine
Variable pos
String bookURL = ""
RegExp = "(?i)a href=\".*?(\\d+)\">(.*?)</a>"
for (n=0; n<numBooksToUse; n+=1)
    // For each book we're going to look at, get the
    // partial URL and the title/author text.
    thisLine = StringFromList(n, topYesterdayHTML, "\\r")
    SplitString/E=RegExp thisLine, bookNumStr, titleAuthor
    if (V_flag != 2)
        Print "Error parsing the URL and title/author information."
        return 0
    endif

    // Remove the (###) stuff at the end of titleAuthor if it's there.
    pos = strsearch(titleAuthor, "(", 0)
    if (pos > 0)
        titleAuthor = titleAuthor[0, pos - 1]
    endif

    bookNum = str2num(bookNumStr)

    // Store the information about the book in the text wave.
    sprintf bookURL, "%s%d/%d.txt", baseURL, bookNum, bookNum
    topBooksInfo[n][0] = bookURL
    topBooksInfo[n][1] = titleAuthor
endfor

// Download each book (using multiple threads if possible)
// and count the number of bytes in each.
MultiThread byteCounts = GetThePage(topBooksInfo[p][0])

// Print the results.
Print "The top four books by download from yesterday are:"
for (n=0; n<numBooksToUse; n+=1)
    Printf "%s (%d bytes)\\r", topBooksInfo[n][1], byteCounts[n]
endfor
End

```

Here is an example of what the output was when this help file was written:

The top four books by download from yesterday are:

```

Ulysses by James Joyce (1573044 bytes)
Alice's Adventures in Wonderland by Lewis Carroll (167529 bytes)
Piper in the Woods by Philip K. Dick (62214 bytes)
Pride and Prejudice by Jane Austen (704160 bytes)

```

## File Transfer Protocol (FTP)

The **FTPDownload**, **FTPUpload**, **FTPDelete**, and **FTPCreateDirectory** operations support simple transfers of files and directories over the Internet.

Since Igor's **SaveNotebook** operation can generate HTML files from notebooks, it is possible to write an Igor procedure that downloads data, analyzes it, graphs it, and uploads an HTML file to a directory used by a

Web server. You can then use the BrowseURL operation to verify that everything worked as expected. For a demo of some of these features, choose File→Example Experiments→Feature Demos→Web Page Demo.

### FTP Limitations

All FTP operations run “synchronously”. This means that, if the operation executes in the main thread, Igor can not do anything else. However, it is possible to perform these operations using an Igor preemptive thread so that they execute in the background and you can continue to use Igor for other purposes. For more information, see **Network Connections From Multiple Threads** on page IV-256.

Igor does not currently provide any way for the user to browse the remote server from within Igor itself.

Igor does not provide any secure way to store passwords. Consequently, you should not use Igor for FTP in situations where tight security is required. See **Safe Handling of Passwords** on page IV-255 for an example of how to securely prompt the user for a password.

Igor does not provide any support for using proxy servers. Proxy servers are security devices that stand between the user and the Internet and permit some traffic while prohibiting other traffic. If your site uses a proxy server, FTP operations may fail. Your network administrator may be able to provide a solution.

Igor does not include operations for listing a server directory or changing its current directory.

### Downloading a File

The following function transfers a file from an FTP server to the local hard disk:

```
Function DemoFTPDownload()  
    String url = "ftp://ftp.wavemetrics.net/welcome.msg"  
    String localFolder = SpecialDirPath("Desktop",0,0,0)  
    String localPath = localFolder + "DemoFTPDownloadFile.txt"  
    FTPDownload/U="anonymous"/W="password" url, localPath  
End
```

The output directory must already exist on the local hard disk. The target file may or may not exist on the local hard disk. If it does not exist, the FTPDownload command creates it. If it does exist, FTPDownload asks if you want to overwrite it. To overwrite it without being asked, use the /O flag.

**Warning:** If you elect to overwrite it, all previous contents of the local target file are obliterated.

FTPDownload presents a dialog asking you to specify the local file name and location in the following cases:

1. You use the /I (interactive) flag.
2. The parent directory specified by the local path does not exist.
3. The specified local file exists and you do not use the /O (overwrite) flag.

### Downloading a Directory

The following function transfers a directory from an FTP server to the local hard disk:

```
Function DemoFTPDownloadDirectory()  
    String url = "ftp://ftp.wavemetrics.net/Utilities"  
    String localFolder = SpecialDirPath("Desktop",0,0,0)  
    String localPath = localFolder + "DemoFTPDownloadDirectory"  
    FTPDownload/D/U="anonymous"/W="password" url, localPath  
End
```

The /D flag specifies that you are transferring a directory.

The output directory may or may not already exist on the local hard disk. If it does not exist, the FTPDownload command creates it. If it does exist, FTPDownload asks if you want to overwrite it. To overwrite it without being asked, use the /O flag.

**Warning:** If you elect to overwrite it, all previous contents of the local directory are obliterated.

If the local path that you specify ends with a colon or backslash, FTPDownload presents a dialog asking you to specify the local directory because it is looking for the name of the directory to be created on the local hard disk.

FTPDownload presents a dialog asking you to specify the local directory in the following cases:

1. You use the /I (interactive) flag.
2. The parent directory specified by the local path does not exist.
3. The specified directory (DemoFTPDownloadFolder in the example above) exists and you have not used the /O (overwrite) flag.
4. FTPDownload gets an error when it tries to create the specified directory. This could happen, for example, if you don't have write privileges for the parent directory.

## Uploading a File

The following function uploads a file to an FTP server:

```
Function DemoFTPUUploadFile()
    String url = "ftp://ftp.wavemetrics.com/pub"
    String localFolder = SpecialDirPath("Desktop", 0, 0, 0)
    String localPath = localFolder + "DemoFTPUUploadFile.txt"
    FTPUpload/U="username"/W="password" url, localPath
End
```

To successfully execute this, you need a real user name and a real password.

**Note:** The /O flag has no effect on the FTPUpload operation when uploading a file. FTPUpload *always* overwrites an existing server file, whether /O is used or not.

**Warning:** If you overwrite a server file, all previous contents of the file are obliterated.

To overwrite an existing file on the server, you must have permission to delete files on that server. The server administrator determines what permission a particular user has.

FTPUpload presents a dialog asking you to specify the local file in the following cases:

1. You use the /I (interactive) flag.
2. The local parent directory or the local file does not exist.

## Uploading a Directory

The following function uploads a directory to an FTP server:

```
Function DemoFTPUUploadDirectory()
    String url = "ftp://ftp.wavemetrics.com/pub"
    String localFolder = SpecialDirPath("Desktop", 0, 0, 0)
    String localPath = localFolder + "DemoFTPUUploadDirectory"
    FTPUpload/D/U="username"/W="password" url, localPath
End
```

To successfully execute this, you need a real user name and a real password. Also, the server would have to allow uploading directories.

**Note:** FTPUpload *always* overwrites an existing server directory, whether /O is used or not.

**Warning:** If you omit /O or specify /O or /O=1, all previous contents of the directory are obliterated.

If you specify /O=2, FTPUpload performs a merge of the directory contents. This means that files and directories in the source overwrite files and directories on the server that have the same name, but files and directories on the server whose names do not conflict with those in the source directory are not modified.

To overwrite an existing directory on the server, you must have permission to delete directories on that server. The server administrator determines what permission a particular user has.

If the local path that you specify ends with a colon or backslash, FTPUpload presents a dialog asking you to specify the local directory because it is looking for the name of the directory to be uploaded.

FTPUpload presents a dialog asking you to specify the local directory in the following cases:

1. You use the /I (interactive) flag.
2. The specified directory or any of its parents do not exist.

If you don't have permission to remove and to create directories on the server, FTPUpload will fail and return an error.

### Creating a Directory

The **FTPCreateDirectory** operation creates a new directory on an FTP server.

If the directory already exists on the server, the operation does nothing. This is not treated as an error, though the `V_Flag` output variable is set to -1 to indicate that the directory already existed.

If you don't have permission to create directories on the server, **FTPCreateDirectory** fails and returns an error.

### Deleting a Directory

The **FTPDelete** operation with the /D flag deletes a directory on an FTP server.

If you don't have permission to delete directories on the server, or if the specified directory does not exist on the server, **FTPDelete** fails and returns an error.

### FTP Transfer Types

The FTP protocol supports two types of transfers: image and ASCII. Image transfer is appropriate for binary files. ASCII transfer is appropriate for text files.

In an image transfer, also called a binary transfer, the data on the receiving end will be a replica of the data on the sending end. In an ASCII transfer, the receiving FTP agent changes line terminators to match the local convention. On Macintosh and Unix, the conventional line terminator is linefeed (LF, ASCII code 0x0A). On Windows, it is carriage-return plus linefeed (CR+LF, ASCII code 0x0D + ASCII code 0x0A).

If you transfer a text file using an image transfer, the file may not use the local conventional line terminator, but the data remains intact. Igor Pro can display text files that use any of the three conventional line terminators, but some other programs, especially older programs, may display the text incorrectly.

On the other hand, if you transfer a binary file, such as an Igor experiment file, using an ASCII transfer, the file will almost certainly be corrupted. The receiving FTP agent will convert any byte that happens to have the value 0x0D to 0x0A or vice versa. If the local convention calls for CRLF, then a single byte 0x0D will be changed to two bytes, 0x0D0A. In either case, the file will become unusable.

### FTP Troubleshooting

FTP involves a lot of hardware and software on both ends and a network in between. This provides ample opportunity for errors.

Here are some tips if you experience errors using the FTP operations.

1. Use an FTP client or web browser to connect to the FTP site. This confirms that your network is operating, the FTP server is operating, and that you are using the correct URL.
2. Use an FTP client or web browser to verify that the user name and password that you are using is correct or that the server allows anonymous FTP access.

Many web browser accept URLs of the form:

```
ftp://username:password@ftp.example.com
```

However the password is not transferred securely.

3. Use an FTP client or web browser to verify that the directory structure of the FTP server is what you think it is.
4. Using an FTP client or web browser, do the operation that you are attempting to do with Igor. This verifies that you have sufficient permissions on the server.
5. Use /V=7 to tell the Igor operation to display status information in the history area.
6. Try the simplest transfer you can. For example, try to download a single file that you know exists on the server.
7. If you have access to the FTP server, examine the FTP server log for clues.

## Hypertext Transfer Protocol (HTTP)

The **FetchURL** function supports simple URL requests over the Internet from web or FTP servers and to local files. For example, you can use FetchURL to get the source code of a web page in text form, and then process the text to extract specific information from the response.

The **URLRequest** operation supports both simple URL requests and more complicated requests such as using the http POST, PUT, and DELETE methods. It also provides experimental support for using a proxy server.

### HTTP Limitations

At this time, **FetchURL** and **BrowseURL** routines work with the HTTP protocol.

Currently not supported are features such as using network proxy servers, using the HTTP POST method to submit forms and upload files to a web server, and making secure network connections using the Secure Socket Layer (SSL) protocol.

### Downloading a Web Page Via HTTP

This example uses FetchURL to download the contents of the WaveMetrics home page into a string, and then counts the number of times that the string "Igor" occurs in the text of the page.

```
Function DownloadWebPageExample()
    String webPageText = FetchURL("http://www.wavemetrics.com")
    if (numtype(strlen(webPageText)) == 2)
        Print "There was an error while downloading the web page."
    endif
    Variable count, pos
    do
        pos = strsearch(webPageText, "Igor", pos, 2)
        if (pos == -1)
            break // No more occurrences of "Igor"
        else
            pos += 1
            count += 1
        endif
    while (1)
    Printf "The text \"Igor\" was found %d times on the web page.\r", count
End
```

### Downloading a File Via HTTP

This example uses FetchURL to download a file from a web server. Because FetchURL does not support storing the downloaded data into a file directly, we store the data in memory and then use Igor to write that data to a file on disk.

Though the example uses a URL that begins with http://, FetchURL also supports https://, ftp:// and file://. You could use the code below with a different URL to download a file from an FTP server or even to access a local on-disk file.

```
Function DownloadWebFileExample()
    String url = "http://www.wavemetrics.net/IgorManual.zip"

    // Based on the URL, determine what the destination
    // file name should be. This will be the default in the
    // Save As... dialog.
    String urlStrParam = RemoveEnding(url, "/")
    Variable parts = ItemsInList(urlStrParam, "/")
    String destFileNameStr = StringFromList(parts - 1, urlStrParam, "/")
    if (strlen(destFileNameStr) < 1)
        Print "Error: Could not determine the name of the destination file."
        return 0
    endif

    Variable refNum
    Open/D/M="Save File As..."/T="???" refNum as destFileNameStr
    String fullFilePath = S_fileName

    if (strlen(fullFilePath) > 0) // No error and user didn't cancel in dialog.
        // Open the selected file so that it can later be written to.
        Open/Z/T="???" refNum as fullFilePath
        if (V_flag != 0)
            Print "There was an error opening the local destination file."
        else
            String response = FetchURL(url)
            Variable error = GetRTErrors(1)
            if (error == 0 && numtype(strlen(response)) == 0)
                FBinWrite refNum, response
                Close refNum
                Print "The file was successfully downloaded as " + fullFilePath
            else
                Close refNum
                DeleteFile/Z fullFilePath // Clean up the empty file.
                Print "There was an error downloading the file."
            endif
        endif
    endif
End
```

### Making a Query Via HTTP

Another use for HTTP requests is to get the server's response to a query. Many simple web forms use the HTTP GET method, which both FetchURL and URLRequest support. For example, you can simulate the submission of the basic Google search form using the following code.

```
Function WebQueryExample()
    String keywords
    String baseURL = "http://www.gutenberg.org/ebooks/search/"

    // Prompt the user to enter search keywords.
    Prompt keywords, "Enter search term"
    DoPrompt "Search Gutenberg.org", keywords
    if (V_flag == 1)
        return -1 // User clicked cancel button
    endif

    // Pass the search terms through URLEncode to
    // properly percent-encode them.
    keywords = URLEncode(keywords)

    // Build the full URL.
```

```

String url = ""
sprintf url, "%s?query=%s", baseURL, keywords

// Fetch the results.
String response
response = FetchURL(url)
Variable error = GetRTErrors(1)
if (error != 0 || numtype(strlen(response)) != 0)
    Print "Error fetching search results."
    return -1
endif

// Try to extract the thumbnail image of the first result.
String regExp = "(?s)<img class=\"cover-thumb\" src=\"(.+?)\".*"
String firstURL
SplitString/E=regExp response, firstURL
firstURL = TrimString(firstURL)
firstURL = "http:" + firstURL
if (V_flag == 1)
    BrowseURL firstURL
else
    Print "Could not extract the first result from the"
    Print "results page. Your search terms might not"
    Print "have given any results, or the format of"
    Print "the results may have changed so that the"
    Print "first result cannot be extracted."
    return -1
endif

return 0
End

```

Examples using the POST method can be found in the section *The HTTP POST Method* of the documentation for the **URLRequest** operation.

## HTTP Troubleshooting

Here are some tips if you experience errors using **FetchURL** or **URLRequest**:

1. Use a web browser to connect to the site. This confirms that your network is operating, the server is operating, and that you are using the correct URL.
2. **FetchURL** and **URLRequest** generate an error if it cannot connect to the destination server, which could happen if your computer is not connected to the network or if the target URL contains an invalid host name or port number.

However if the URL contains an invalid path or if the destination URL requires you to provide a username and password, these operations will likely not generate an error. The reason is these errors typically result in a web page being returned, though not the one you expected. If you need to check that a call to **FetchURL** returned a valid web page and not an error web page, you must do that in your own code. One possibility would be to try searching the page for key phrases, such as "File Not Found" or "Page Not Found".

With **URLRequest**, you can inspect the value of the **V\_responseCode** output variable. For successful HTTP requests, this value will usually be 200. A different value may indicate that there was an error making the request.

## Operation Queue

Igor implements an operation queue that supports deferred execution of commands and some special commands for dealing with files, procedures, and experiments.

Igor services the operation queue when no procedures are running and the command line is empty. If the operation queue is not empty, Igor then executes the oldest command in the queue.

You can append a command to the operation queue using

```
Execute/P <command string>
```

The /P flag tells Igor to post the command to operation queue instead of executing it immediately.

You can also specify the /Q (quiet) or /Z (ignore error) flags. See **Execute/P** operation (page V-178) for details about /Q and /Z.

The command string can contain either a special command that is unique to the operation queue or ordinary Igor commands. The special commands are:

INSERTINCLUDE *procedureSpec*

DELETEINCLUDE *procedureSpec*

COMPILEPROCEDURES

NEWEXPERIMENT

LOADFILE *filePath*

MERGEEXPERIMENT *filePath*

**Note:** The special operation queue keywords must be all caps and must have exactly one space after the keyword.

INSERTINCLUDE and DELETEINCLUDE insert or delete #include lines in the main procedure window. *procedureSpec* is whatever you would use in a #include statement except for “#include” itself.

COMPILEPROCEDURES does just what it says, compiles procedures. You must call it after operations such as INSERTINCLUDE that modify, add, or remove procedure files.

NEWEXPERIMENT closes the current experiment without saving.

LOADFILE opens the file specified by *filePath*. *filePath* is either a full path or a path relative to the Igor Pro Folder. The file can be any file that Igor can open. If the file is an experiment file, execute NEWEXPERIMENT first to avoid displaying a “Do you want to save” dialog. If you want to save the changes in an experiment before loading another, you can use the standard SaveExperiment operation.

MERGEEXPERIMENT merges the experiment file specified by *filePath* into the current experiment. Before using this, make sure you understand the caveats regarding merging experiments. See **Merging Experiments** on page II-19 for details.

Here is an example:

```
Function DemoQueue()  
    Execute/P "INSERTINCLUDE <Multi-peak fitting 1.3>"  
    Execute/P "INSERTINCLUDE <Peak Functions>"  
    Execute/P "COMPILEPROCEDURES "  
    Execute/P "CreateFitSetupPanel() "  
    Execute/P "Sleep 00:00:04 "  
    Execute/P "NEWEXPERIMENT "  
    Execute/P "LOADFILE :Examples:Feature Demos:Live mode.pxp"  
    Execute/P "DoWindow/F Graph0"  
    Execute/P "StartButton(\"StartButton\") "  
End
```

One important use of the operation queue is providing easy access to useful procedure packages. The "Igor Pro 7 Folder/Igor Procedures" folder contains a procedure file named “DemoLoader.ipf” that creates the Packages submenus found in various menus. To try it out, choose one of the items from the Analysis→Packages menu.

DemoLoader.ipf is an independent module. To examine it, execute:

```
SetIgorOption IndependentModuleDev=1
```

and then use the Windows→Procedure Windows submenu.

## User-Defined Hook Functions

Igor calls specific user-defined functions, called “hook” functions, if they exist, when it performs certain actions. This allows savvy programmers to customize Igor’s behavior.

In some cases the hook function may inform Igor that the action has been completely handled, and that Igor shouldn’t perform the action. For example, you could write a hook function to load data from a certain kind of text file that Igor can not handle directly.

This section discusses general hook functions that do not apply to a particular window. For information on window-specific events, see Window Hook Functions.

There are two ways to get Igor to call your general hook function. The first is by using a predefined function name. For example, if you create a function named `AfterFileOpenHook`, Igor will automatically call it after opening a file. The second way is to explicitly tell Igor that you want it to call your hook using the **SetIgorHook** operation.

If you use a predefined hook function name, you should make the function static (private to the file containing it) so that other procedure files can use the same predefined name.

Here are the predefined hook functions.

Action	Hook Function Called
Procedures were successfully compiled	<b>AfterCompiledHook</b>
A file or experiment was opened	<b>AfterFileOpenHook</b>
The Windows-only "MDI frame" (main application window) was resized	<b>AfterMDIFrameSizedHook</b>
A target window was created	<b>AfterWindowCreatedHook</b>
The debugger window is about to open	<b>BeforeDebuggerOpensHook</b>
An experiment is about to be saved	<b>BeforeExperimentSaveHook</b>
A file or XOP is about to be opened	<b>BeforeFileOpenHook</b>
Igor is about to open a new experiment	<b>IgorBeforeNewHook</b>
Igor is about to quit	<b>IgorBeforeQuitHook</b>
Igor is building and enabling menus or about to handle a menu selection	<b>IgorMenuHook</b>
Igor is about to quit	<b>IgorQuitHook</b>
Igor launching or creating a new experiment	<b>IgorStartOrNewHook</b>

To create hook functions, you must write functions with the specified names and store them in any procedure file. If you store the procedure file in "Igor Pro User Files/Igor Procedures" (see **Igor Pro User Files** on page II-31 for details), Igor will automatically open the file and compile the functions when it starts up and will execute the `IgorStartOrNewHook` function if it exists.

To allow for multiple procedure files to define the same predefined hook function, you should declare your hook function static. For example:

```
static Function IgorStartOrNewHook(igorApplicationNameStr)
    String igorApplicationNameStr
```

The use of the static keyword makes the function private to the procedure file containing it and allows other procedure files to have their own static function with the same name.

Igor calls static hook functions after the **SetIgorHook** functions are called. The static hook functions themselves are called in the order in which their procedure file was opened. You should not rely on any execution order among the static hook functions. However, any hook function which returns a nonzero result prevents remaining hook functions from being called and prevents Igor from performing its usual processing of the hook event. In most cases hook functions should exercise caution in returning any value other than 0. For hook functions only, returning a NaN or failing to return a value (which returns a NaN) is considered the same as returning 0.

The following sections describe the individual hook functions in detail.

### AfterCompiledHook

#### **AfterCompiledHook()**

**AfterCompiledHook** is a user-defined function that Igor calls after the procedure windows have all been compiled successfully.

You can use **AfterCompiledHook** to initialize global variables or data folders, among other things.

The function result from **AfterCompiledHook** must be 0. All other values are reserved for future use.

#### See Also

**SetIgorHook**, **User-Defined Hook Functions** on page IV-265.

### AfterFileOpenHook

#### **AfterFileOpenHook(refNum, fileNameStr, pathNameStr, fileTypeStr, fileCreatorStr, fileKind)**

**AfterFileOpenHook** is a user-defined function that Igor calls after it has opened a file because the user dragged it onto the Igor icon or into Igor or double-clicked it.

**AfterFileOpenHook** is not called when a file is opened via a menu.

Windows system files with .bin, .com, .dll, .exe, and .sys extensions aren't passed to the hook functions.

The parameters contain information about the file, which has already been opened for read-only access.

**AfterFileOpenHook**'s return value is ignored unless *fileKind* is 9. If the returned value is zero, the default action is performed.

#### Parameters

*refNum* is the file reference number. You use this number with file I/O operations to read from the file. Igor closes the file when the user-defined function returns, and *refNum* becomes invalid. The file is opened for read-only; if you want to write to it, you must close and reopen it with write access. *refNum* will be -1 for experiment files and XOPs. In this case, Igor has not opened the file for you.

*fileNameStr* contains the name of the file.

*pathNameStr* contains the name of the symbolic path. *pathNameStr* is not the value of the path. Use the **PathInfo** operation to determine the path's value.

*fileTypeStr* contains the Macintosh file type, if applicable. File type codes are obsolete. Use the file name extension to determine if you want to handle the file. You can use **ParseFilePath** to obtain the extension from *fileNameStr*.

*fileCreatorStr* contains the Macintosh creator code, if applicable. Creator codes are obsolete so ignore this parameter.

*fileKind* is a number that identifies what kind of file Igor thinks it is. Values for *fileKind* are listed in the next section.

### AfterFileOpenHook *fileKind* Parameter

This table describes the AfterFileOpenHook function *fileKind* parameter.

If the user's AfterFileOpenHook function returns 0, Igor performs the default action listed in the table:

Kind of File	<i>fileKind</i>	Default Action, if Any
Unknown	0	
Igor Experiment, packed (stationery, too)	1	
Igor Experiment, unpacked (stationery, too)	2	
Igor XOP	3	
Igor Binary File	4	
Igor Text (data and commands)	5	
Text, no numbers detected in first two lines	6	
General Numeric text (no tabs)	7	
Numeric text Tab-Separated-Values	8	
Numeric text Tab-Separated-Values, MIME	9	Display loaded data in a new table and a new graph.
Text, with tabs	10	
Igor Notebook (unformatted or formatted)	11	
Igor Procedure	12	
Igor Help	13	

### Details

AfterFileOpenHook's return value is ignored, except when *fileKind* is 9 (Numeric text, Tab-Separated-Values, MIME). If you return a value of 0, Igor executes the default action, which displays the loaded data in a table and a graph. If you return a value of 1, Igor does nothing.

Another way to disable the MIME-TSV default action is define a global variable named `V_no_MIME_TSV_Load` (in the root data folder) and set its value to 1. In this case any file of *fileKind* = 9 is reassigned a *fileKind* of 8.

The default action for *fileKind* = 9 makes Igor a MIME-TSV document Helper Application for Web browsers such as Netscape or Internet Explorer.

The exact criteria for Igor to consider a file to be of kind 9 are:

- *fileTypeStr* must be "TEXT" or "WMT0" (that's a zero, not an oh).
- Either the first line of the file must begin with a # character, or the name of the file must end with ".tsv" in either lower or upper case.
- The first line must contain one or more column titles. If the line starts with a # character, the first column title must not start with "include", "pragma" or the ! character. Spaces are allowed in the titles, but if two or more title columns are present, they must be separated by one tab character.
- The second line must contain one or more numbers. If two or more numbers, they must be separated by one tab character, and the first line's words must also be separated by tabs.

When the MIME-TSV file contains one column of data, it is graphed as a series of Y values.

Short columns (less than 50 values) are graphed with lines and markers, longer columns with lines only. Preferences are turned on when the graph is made.

Two columns are assumed to be X followed by Y, and are graphed as Y versus X. More columns do not affect the graph, though they are shown in the table.

### Example

```
// This hook function prints the first line of opened TEXT files
// into the history area
Function AfterFileOpenHook(refNum,file,pathName,type,creator,kind)
    Variable refNum,kind
    String file,pathName,type,creator
    // Check that the file is open (read only), and of correct type
    if( (refNum >= 0) && (CmpStr(type,"TEXT")==0) ) // also "text", etc.
        String line1
        FReadLine refNum, line1 // Read the line (and carriage return)
        Print line1 // Print line in the history area.
    endif
    return 0 // don't prevent MIME-TSV from displaying
End
```

### See Also

**BeforeFileOpenHook** and **SetIgorHook**.

## BeforeDebuggerOpensHook

**BeforeDebuggerOpensHook(*errorInRoutineStr*, *stoppedByBreakpoint*)**

**BeforeDebuggerOpensHook** is a user-defined function that Igor calls when the debugger window is about to be opened, whether by hitting a breakpoint or when Debug on Error is enabled.

**BeforeDebuggerOpensHook** can be used to prevent the debugger window opening for certain error codes or in selected user-defined functions when Debug on Error is enabled. This is a feature for advanced programmers only. Most programmers will not need it.

This hook does not work well for macros or procs, because their runtime errors don't automatically open the debugger, but instead present an error dialog from which the user manually enters the debugger by clicking the Debug button.

### Parameters

*errorInRoutineStr* contains the name of the routine (function or macro) the debugger will be stopping in as a fully-qualified name, comprised of at least "ModuleName#RoutineName", suitable for use with **FunctionInfo**.

If the routine is in a regular module procedure window (see **Regular Modules** on page IV-222), *errorInRoutineStr* will be a triple name such as "MyIM#MyModule#MyFunction".

*stoppedByBreakpoint* is 0 if the debugger is about to be shown because of Debug on Error, or non-zero if the debugger encountered a user-set breakpoint (see **Setting Breakpoints** on page IV-199).

If a breakpoint exists at the line where an error caused the debugger to appear, *stoppedByBreakpoint* will be non-zero, even though the cause was Debug on Error.

### Details

If **BeforeDebuggerOpensHook** returns 0 or NaN (or doesn't return a value), the debugger window is opened normally.

If it returns 1, the debugger window is not shown and program execution continues.

All other return values are reserved for future use.

### Example

The following hypothetical example:

1. Prevents breakpoints from bringing up the debugger, unless **DEBUGGING** is defined.
2. Prints the name of the routine with the error, and the error message.
3. Beeps before the debugger appears.

```
Function ProvokeDebuggerInFunction()
    DebuggerOptions enable=1, debugOnError=1 // Enable debug on error

    ProvokeDebugger()
```

```

End

Function ProvokeDebugger()
    Variable var=0 // Put a breakpoint here.
                        // Without a #define DEBUGGING, the breakpoint is skipped.
    Make/O $" " // Cause an error
    Print "Back from bad Make command in function"
End

static Function BeforeDebuggerOpensHook(pathToErrorFunction,isUserBreakpoint)
    String pathToErrorFunction
    Variable isUserBreakpoint

    #ifndef DEBUGGING
        if( isUserBreakpoint )
            return 1 // Ignore user breakpoints we forgot to clear.
                        // Don't use this during development!
        endif
    #endif

    Print "stackCrawl = ", GetRTStackInfo(0)
    Print "FunctionInfo = ", FunctionInfo(pathToErrorFunction)

    // Don't clear errors unless you're preventing the debugger from appearing
    Variable clearErrors= 0
    Variable rtErr= GetRTErrors(clearErrors) // Get the error #

    Variable substitutionOption= exists(pathToErrorFunction)== 3 ? 3 : 2
    String errorMessage= GetErrMsg(rtErr,substitutionOption)

    Beep // Audible cue that the debugger is showing up!

    Print "Error \""+errorMessage+"\" in "+pathToErrorFunction+"

    return 0 // Return 0 to show the debugger; an unexpected error occurred.
End

•ProvokeDebuggerInFunction() // Execute this in the command line
    stackCrawl =
        ProvokeDebuggerInFunction;ProvokeDebugger;BeforeDebuggerOpensHook;
    FunctionInfo =
        NAME:ProvokeDebugger;PROCWIN:Procedure;MODULE:;INDEPENDENTMODULE:;...
    Error "Expected name" in ProcGlobal#ProvokeDebugger
    Back from bad Make command in function

```

**AfterMDIFrameSizedHook****AfterMDIFrameSizedHook (param)**

AfterMDIFrameSizedHook is a user-defined function that Igor calls when the Windows-only "MDI frame" (main application window) has been resized.

AfterMDIFrameSizedHook can be used to resize windows to fit the new frame size. See **GetWindow** **kwFrame** and **MoveWindow**.

### Parameters

*param* is one of the following values:

Size Event	<i>param</i>
Normal resize	0
Minimized	1
Maximized	2
Moved	3

### Details

This function is not called on Macintosh.

Resizing the MDI frame by the top left corner calls `AfterMDIFrameSizedHook` twice: first for the move (*param* = 3) and then for the normal resize (*param* = 0).

Igor currently ignores the value returned by `AfterMDIFrameSizedHook`. Return 0 in case Igor uses this value in the future.

### See Also

`SetWindow`, `GetWindow`, `SetIgorHook`, and **User-Defined Hook Functions** on page IV-265.

## AfterWindowCreatedHook

**AfterWindowCreatedHook**(*windowNameStr*, *winType*)

`AfterWindowCreatedHook` is a user-defined function that Igor calls when a target window is first created.

`AfterWindowCreatedHook` can be used to set a window hook on target windows created by the user or by other procedures.

### Parameters

*windowNameStr* contains the name of the created window.

*winType* is the type of the window, the same value as returned by **WinType**.

### Details

“Target windows” are graphs, tables, layout, panels, and notebook windows.

`AfterWindowCreatedHook` is not called when an Igor experiment is being opened.

Igor ignores the value returned by `AfterWindowCreatedHook`.

### See Also

`SetWindow`, `SetIgorHook`, and **User-Defined Hook Functions** on page IV-265.

## BeforeExperimentSaveHook

**BeforeExperimentSaveHook**(*refNum*, *fileNameStr*, *pathNameStr*, *fileTypeStr*, *fileCreatorStr*, *fileKind*)

`BeforeExperimentSaveHook` is a user-defined function that Igor calls when an experiment is about to be saved by Igor.

Igor ignores the value returned by `BeforeExperimentSaveHook`.

### Parameters

*refNum* is -1. Ignore this parameter.

*fileNameStr* contains the name of the file.

*pathNameStr* contains the name of the symbolic path. *pathNameStr* is not the value of the path. Use the **PathInfo** operation to determine the path’s value.

*fileTypeStr* contains the Macintosh file type, if applicable. File type codes are obsolete. Use the file name extension to determine if you want to handle the file. You can use **ParseFilePath** to obtain the extension from *fileNameStr*.

*fileCreatorStr* contains the Macintosh creator code, if applicable. Creator codes are obsolete so ignore this parameter.

Variable *fileKind* is a number that identifies what kind of file Igor will be saving:

Kind of File	<i>fileKind</i>
Igor Experiment, packed*	1
Igor Experiment, unpacked*	2

\* Including stationery experiment files.

### Details

You can determine the full directory and file path of the experiment by calling the **PathInfo** operation with *\$pathNameStr*.

### Example

This example prints the full file path of the about-to-be-saved experiment to the history area, and deletes all unused symbolic paths.

```
#pragma rtGlobals=1          // treat S_path as local string variable
Function BeforeExperimentSaveHook(rN, fileName, path, type, creator, kind)
    Variable rN, kind
    String fileName, path, type, creator

    PathInfo $path           // puts path value into (local) S_path
    Printf "Saved \"%s\" experiment\r", S_path+fileName

    KillPath/A/Z             // Delete all unneeded symbolic paths
End
```

### See Also

The **SetIgorHook** operation.

## BeforeFileOpenHook

**BeforeFileOpenHook(refNum, fileNameStr, pathNameStr, fileTypeStr, fileCreatorStr, fileKind)**

**BeforeFileOpenHook** is a user-defined function that Igor calls when a file is about to be opened because the user dragged it onto the Igor icon or into Igor or double-clicked it.

**BeforeFileOpenHook** is not called when a file is opened via a menu.

Windows system files with .bin, .com, .dll, .exe, and .sys extensions aren't passed to the hook functions.

The value returned by **BeforeFileOpenHook** informs Igor whether the hook function handled the open event and therefore Igor should not perform its default action. In some cases, this return value is ignored, and Igor performs the default action anyway.

### Parameters

*refNum* is the file reference number. You use this number with file I/O operations to read from the file. Igor closes the file when the user-defined function returns, and *refNum* becomes invalid. The file is opened for read-only; if you want to write to it, you must close and reopen it with write access. *refNum* will be -1 for experiment files and XOPs. In this case, Igor has not opened the file for you.

*fileNameStr* contains the name of the file.

*pathNameStr* contains the name of the symbolic path. *pathNameStr* is not the value of the path. Use the **PathInfo** operation to determine the path's value.

*fileTypeStr* contains the Macintosh file type, if applicable. File type codes are obsolete. Use the file name extension to determine if you want to handle the file. You can use **ParseFilePath** to obtain the extension from *fileNameStr*.

*fileCreatorStr* contains the Macintosh creator code, if applicable. Creator codes are obsolete so ignore this parameter.

*fileKind* is a number that identifies what kind of file Igor thinks it is. Values for *fileKind* are listed in the next section.

### BeforeFileOpenHook *fileKind* Parameter

This table describes the BeforeFileOpenHook function *fileKind* parameter.

Kind of File	<i>fileKind</i>	Default Action, if Any
Unknown	0	
Igor Experiment, packed *	1	(Hook not called)
Igor Experiment, unpacked *	2	(Hook not called)
Igor XOP	3	
Igor Binary file	4	Data loaded
Igor Text (data and commands)	5	Data loaded, commands executed
Text, no numbers detected in first two lines	6	Opened as unformatted notebook
General Numeric text (no tabs)	7	Data loaded as general text
Numeric text Tab-Separated-Values	8	Data loaded as delimited text
Numeric text Tab-Separated-Values, MIME	9	Display loaded data in a new table and a new graph.
Text, with tabs	10	Opened as unformatted notebook
Igor Notebook (unformatted or formatted)	11	Opened as notebook
Igor Procedure	12	<i>Always</i> opened as procedure file
Igor Help	13	<i>Always</i> opened as help file

\* Including stationery experiment files.

### Details

BeforeFileOpenHook must return 1 if Igor is not to take action on the file (it won't be opened), or 0 if Igor is permitted to take action on the file. Igor ignores the return value for *fileKind* values of 3, 12, and 13. The hook function is not called for Igor experiments (*fileKind* values of 1 and 2).

Igor always closes the file when the user-defined function returns, and *refNum* becomes invalid (don't store the value of *refNum* in a global for use by other routines, since the file it refers to has been closed).

### Example

This example checks the first line of the file about to be opened to determine whether it has a special, presumably user-specific, format. If it does, then LoadMyFile (another user-defined function) is called to load it. LoadMyFile presumably loads this custom data file, and returns 1 if it succeeded. If it returns 0 then Igor will open it using the Default Action from the above table.

```
Function BeforeFileOpenHook (refNum, fileName, path, type, creator, kind)
    Variable refNum, kind
    String fileName, path, type, creator

    Variable handledOpen=0
    if( CmpStr(type, "TEXT")==0 )           // text files only
        String line1
        FReadLine refNum, line1 // First line (and carriage return)
        if( CmpStr(line1[0,4], "XYZZY") == 0 ) // My special file
            FSetPos refNum, 0           // rewind to start of file
            handledOpen= LoadMyFile(refNum) // returns 1 if loaded OK
        endif
    endif
    return handledOpen // 1 tells Igor not to open the file
End
```

**See Also**

**AfterFileOpenHook** and **SetIgorHook**.

**IgorBeforeNewHook**

**IgorBeforeNewHook** (*igorApplicationNameStr*)

IgorBeforeNewHook is a user-defined function that Igor calls before a new experiment is opened in response to the New Experiment, Revert Experiment, or Open Experiment menu items in the File menu.

You can use IgorBeforeNewHook to clean up the current experiment, or to avoid losing unsaved data even if the user chooses to not save the current experiment.

Igor ignores the value returned by IgorBeforeNewHook.

**Parameters**

*igorApplicationNameStr* contains the name of the currently running Igor Pro application.

**See Also**

**IgorStartOrNewHook** and **SetIgorHook**.

**IgorBeforeQuitHook**

**IgorBeforeQuitHook** (*unsavedExp*, *unsavedNotebooks*, *unsavedProcedures*)

IgorBeforeQuitHook is a user-defined function that Igor calls just before Igor is about to quit, before any save-related dialogs have been presented.

**Parameters**

*unsavedExp* is 0 if the experiment is saved, non-zero if unsaved.

*unsavedNotebooks* is the count of unsaved notebooks.

*unsavedProcedures* is the count of unsaved procedures.

The save state of packed procedure and notebook files is part of *unsavedExp*, not *unsavedNotebooks* or *unsavedProcedures*. This applies to adopted procedure and notebook files and new procedure and notebook windows that have never been saved.

**Details**

IgorBeforeQuitHook should normally return 0. In this case, Igor presents the “Do you want to save” dialog, and if the user approves, proceeds with the quit, which includes calling IgorQuitHook.

If IgorBeforeQuitHook returns 1, then the quit is aborted. The current experiment, notebooks, and procedures are not saved, no dialogs are presented to the user, and IgorQuitHook is not called.

**See Also**

**IgorQuitHook** and **SetIgorHook**.

**IgorMenuHook**

**IgorMenuHook** (*isSelection*, *menuStr*, *itemStr*, *itemNo*, *activeWindowStr*, *wType*)

IgorMenuHook is a user-defined function that Igor calls just before and just after menu selection, whether by mouse or keyboard.

**Parameters**

*isSelection* is 0 before a menu item has been selected and 1 after a menu item has been selected.

When *isSelection* is 1, *menuStr* is the name of the selected menu. It is always in English, regardless of the localization of Igor. When *isSelection* is 0, *menuStr* is "".

When *isSelection* is 1, *itemStr* is the name of the selected menu item. When *isSelection* is 0, *itemStr* is "".

When *isSelection* is 1, *itemNo* is the one-based item number of the selected menu item. When *isSelection* is 0, *itemNo* is 0.

*activeWindowStr* identifies the active window. See details below.

*wType* identifies the kind of window that *activeWindowStr* identifies. It returns the same values as the **WinType** function.

### activeWindowStr Parameter

*activeWindowStr* identifies the window to which the menu selection will apply. It can be a window name, window title, or special keyword, as follows:

Window	<i>activeWindowStr</i>
Target window	Window name.  The target window is that top graph, table, page layout, notebook, control panel, Gizmo plot, or XOP target window.
Command window	kwCmdHist (as used with <b>GetWindow</b> ).
Procedure window	Window title as shown in the window's title bar. The built-in procedure window is "Procedure".
XOP non-target window	The window title as shown in the window's title bar.

See **Window Names and Titles** on page II-40 for a discussion of the distinction.

### Details

IgorMenuHook is called with *isSelection* set to 0 after all the menus have been enabled and before a mouse click or keyboard equivalent is handled.

The return value should normally be 0. If the return value is nonzero (1 is usual) then the active window's hook function (see **SetWindow** operation on page V-740) is not called for the enablemenu event.

IgorMenuHook is called with *isSelection* set to 1 after the menu has been selected and before Igor has acted on the selection.

If the IgorMenuHook function returns 0, Igor proceeds to call the active window's hook function for the menu event. (If the window hook function exists and returns nonzero, Igor ignores the menu selection. Otherwise Igor handles the menu selection normally.)

If the IgorMenuHook function returns nonzero (1 is recommended), Igor does not call the remaining hook functions and Igor ignores the menu selection.

### Example

This example invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for all graphs, preventing Igor from performing the usual Copy.

```
Function IgorMenuHook(isSel, menuStr, itemStr, itemNo, activeWindowStr, wt)
  Variable isSel
  String menuStr, itemStr
  Variable itemNo
  String activeWindowStr
  Variable wt

  Variable handled= 0
  if( CmpStr(menuStr,"Edit") == 0 && CmpStr(itemStr,"Copy") == 0 )
    if( wt == 1 ) // graph
      // DoIgorMenu would cause recursion, so we defer execution
      Execute/P/Q/Z "DoIgorMenu \"Edit\", \"Export Graphics\""
      handled= 1
    endif
  endif

  return handled
End
```

### See Also

**SetWindow**, **Execute**, and **SetIgorHook**.

### IgorQuitHook

**IgorQuitHook**(*igorApplicationNameStr*)

IgorQuitHook is a user-defined function that Igor calls when Igor is about to quit.

The value returned by IgorQuitHook is ignored.

**Parameters**

*igorApplicationNameStr* contains the name of the currently running Igor Pro application (including the .exe extension under Windows).

**Details**

You can determine the full directory and file path of the Igor application by calling the **PathInfo** operation with the Igor path name. See the example in **IgorStartOrNewHook** on page IV-275.

**See Also**

**IgorBeforeQuitHook** and **SetIgorHook**.

**IgorStartOrNewHook**

**IgorStartOrNewHook** (*igorApplicationNameStr*)

IgorStartOrNewHook is a user-defined function that Igor calls when starting up and when creating a new experiment. It is also called if Igor is launched as a result of double-clicking a saved Igor experiment.

Igor ignores the value returned by IgorStartOrNewHook.

**Parameters**

*igorApplicationNameStr* contains the name of the currently running Igor Pro application (including the .exe extension under Windows).

**Details**

You can determine the full directory and file path of the Igor application by calling the **PathInfo** operation with the Igor path name.

**Example**

This example prints the full path of Igor application whenever Igor starts up or creates a new experiment:

```
Function IgorStartOrNewHook(igorApplicationNameStr)
    String igorApplicationNameStr

    PathInfo Igor // puts path value into (local) S_path
    printf "\"%s\" (re)starting\r", S_path + igorApplicationNameStr
End
```

**See Also**

**IgorBeforeNewHook** and **SetIgorHook**.

**Window User Data**

The window user data feature provides a way for packages that create or manage windows to store per-window settings. You can store arbitrary data with a window using the **userdata** keyword with the **SetWindow**.

Each window has a primary, unnamed user data that is used by default.

You can also store an unlimited number of different user data strings by specifying a name for each different user data string. The name can be any legal Igor name. It should be distinct to prevent clashes between packages.

Packages should use named user data.

You can retrieve information from the default user data using the **GetWindow**. To retrieve named user data, you must use the **GetUserData**.

Here is a simple example of user data using the top window:

```
SetWindow kwTopWin,userdata= "window data"
Print GetUserData("", "", "")
```

Although there is no size limit to how much user data you can store, it does have to be stored as part of the recreation macro for the window when experiments are saved. Consequently, huge user data can slow down experiment saving and loading

## Window Hook Functions

A window hook function is a user-defined function that receives notifications of events that occur in a specific window. Your window hook function can detect and respond to events of interest. You can then allow Igor to also process the event or inform Igor that you have handled it.

This section discusses window hook functions that apply to a specific window. For information on general events hooks, see **User-Defined Hook Functions** on page IV-265.

To handle window events, you first write a window hook function and then use the **SetWindow** operation to install the hook on a particular window. This example shows how you would detect arrow key events in a particular window. To try it, paste the code below into the procedure window and then execute `DemoWindowHook()`:

```
Function MyWindowHook(s)
    STRUCT WMWinHookStruct &s

    Variable hookResult = 0 // 0 if we do not handle event, 1 if we handle it.

    switch(s.eventCode)
        case 11: // Keyboard event
            switch (s.keycode)
                case 28:
                    Print "Left arrow key pressed."
                    hookResult = 1
                    break
                case 29:
                    Print "Right arrow key pressed."
                    hookResult = 1
                    break
                case 30:
                    Print "Up arrow key pressed."
                    hookResult = 1
                    break
                case 31:
                    Print "Down arrow key pressed."
                    hookResult = 1
                    break
                default:
                    // The keyText field requires Igor Pro 7 or later
                    // See Keyboard Events on page IV-281
                    Printf "Key pressed: %s\r", s.keyText
                    break
            endswitch
        break
    endswitch

    return hookResult // If non-zero, we handled event and Igor will ignore it.
End

Function DemoWindowHook()
    DoWindow/F DemoGraph // Does graph exist?
    if (V_flag == 0)
        Display /N=DemoGraph // Create graph
        SetWindow DemoGraph, hook(MyHook)=MyWindowHook // Install window hook
    endif
End
```

The window hook function receives a `WMWinHookStruct` structure as a parameter. `WMWinHookStruct` is a built-in structure that contains all of the information you might need to respond to an event. One of its fields, the `eventCode` field, specifies what kind of event occurred.

If your hook function returns 1, this tells Igor that you handled the event and Igor does not handle it. If your hook function returns 0, this tells Igor that you did not handle the event, so Igor does handle it.

This example uses a named window hook. In this case the name is MyHook. More than one procedure file can install a hook on a given window. The purpose of the name is to allow a package to install and remove its own hook function without disturbing the hook functions of other packages. Choose a distinct hook function name that is unlikely to conflict with other hook names.

Earlier versions of Igor supported only one unnamed hook function. This meant that only one package could hook any particular window. Unnamed hook functions are still supported for backward compatibility but new code should always use named hook functions.

## Window Hooks and Subwindows

Igor calls window hook functions for top-level windows only, not for subwindows. If you want to hook a subwindow, you must set the hook on the top-level window. In the hook function, test to see if the subwindow is active. For example, this code, at the start of a window hook function, insures that the hook runs only if a subwindow named G0 is active.

```
GetWindow $s.winName activeSW
String activeSubwindow = S_value
if (CmpStr(activeSubwindow,"G0") != 0)
    return 0
endif
```

Exterior panels (see **Exterior Control Panels** on page III-394) are top-level windows even though they are subwindows. To hook an exterior subwindow, you must install the hook on the exterior panel using subwindow syntax.

## Named Window Hook Functions

A named window hook function takes one parameter - a `WMWinHookStruct` structure. This built-in structure provides your function with information about the status of various window events.

The named window hook function has this format:

```
Function MyWindowHook(s)
    STRUCT WMWinHookStruct &s

    Variable hookResult = 0

    switch(s.eventCode)
        case 0:                // Activate
            // Handle activate
            break

        case 1:                // Deactivate
            // Handle deactivate
            break

        // And so on . . .
    endswitch

    return hookResult          // 0 if nothing done, else 1
End
```

If you handle a particular event and you want Igor to ignore it, return 1 from the hook function. However, you cannot make Igor ignore a window kill event - once the kill event is received the window will be killed.

## Named Window Hook Events

Here are the events passed to a named window hook function:

## Chapter IV-10 — Advanced Topics

---

eventCode	eventName	Notes
0	"Activate"	
1	"Deactivate"	
2	"Kill"	Returning 1 when you receive this event does not cause Igor to ignore the event. At this point, you cannot prevent the window from being killed. See the killVote event to prevent the window being killed.
3	"MouseDown"	
4	"MouseMove"	
5	"MouseUp"	
6	"Resize"	
7	"CursorMoved"	See <b>Cursors — Moving Cursor Calls Function</b> on page IV-316.
8	"Modified"	A modification to the window has been made. This is sent to graph and notebook windows only. It is an error to try to kill a notebook window from the window hook during the modified event.
9	"EnableMenu"	
10	"Menu"	
11	"Keyboard"	
12	"moved"	
13	"renamed"	
14	"subwindowKill"	One of the window's subwindows is about to be killed.
15	"hide"	The window or one of its subwindows is about to be hidden. See <b>Window Hook Show and Hide Events</b> on page IV-284.
16	"show"	The window or one of its subwindows is about to be unhidden. See <b>Window Hook Show and Hide Events</b> on page IV-284.
17	"killVote"	Window is about to be killed. Return 2 to prevent the window from being killed, otherwise return 0.  <b>Note:</b> Don't delete data structures during this event, use killVote only to decide whether the window kill should actually happen. Delete data structures in the kill event. See <b>Window Hook Deactivate and Kill Events</b> on page IV-283.
18	"showTools"	
19	"hideTools"	
20	"showInfo"	
21	"hideInfo"	
22	"mouseWheel"	
23	"spinUpdate"	This event is sent only to windows marked via DoUpdate/E=1 as progress windows. It is sent when Igor spins the beachball cursor. See <b>Progress Windows</b> on page IV-144 for details.

**WMWinHookStruct**

The WMWinHookStruct structure has members as described in the following tables:

**Base WMWinHookStruct Structure Members**

Member	Description
char winName[MAX_PATH_LENGTH+1]	hcSpec of the affected (sub)window.
STRUCT Rect winRect	Local coordinates of the affected (sub)window.
STRUCT Point mouseLoc	Mouse location.
double ticks	Tick count when event happened.
Int32 eventCode	See <b>eventCode</b> table on page IV-278.
char eventName[31+1]	Name-equivalent of eventCode, see <b>eventCode</b> table on page IV-278. Added in Igor 5.03.
Int32 eventMod	Bitfield of modifiers. See description for MODIFIERS: <i>flags</i> .

**Members of WMWinHookStruct Structure Used with menu Code**

Member	Description
char menuName[255+1]	Name of menu (in English) as used by <b>SetIgorMenuMode</b> .
char menuItem[255+1]	Text of the menu item as used by SetIgorMenuMode

**Members of WMWinHookStruct Structure Used with keyboard Code**

Member	Description
Int32 keycode	ASCII value of key struck. Function keys are not available but navigation keys are translated to specific values and will be the same on Macintosh and Windows.  This field can not represent non-ASCII text such as accented characters. Use keyText instead.
Int32 specialKeyCode	See <b>Keyboard Events</b> on page IV-281. This field was added in Igor Pro 7.
char keyText[16]	UTF-8 representation of key struck. This field was added in Igor Pro 7.

**Members of WMWinHookStruct Structure Used with cursormoved Code**

Member	Description
char traceName[MAX_OBJ_NAME+1]	The name of the trace or image to which the moved cursor is attached or which supplies the X (and Y) values. Can be "" if the cursor is free.
char cursorName[2]	Cursor name A through J.
double pointNumber	Point number of the trace or the X (row) point number of the image where the cursor is attached.

### Members of `WMWinHookStruct` Structure Used with `cursorMoved` Code

Member	Description
	If the cursor is “free”, <code>pointNumber</code> is actually the fractional relative <i>xValue</i> as used in the <b>Cursor</b> /F/P command.
<code>double yPointNumber</code>	Valid only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot, or when the cursor is free.  If attached to an image, contour, or waterfall plot, <code>yPointNumber</code> is the Y (column) point number of the image where the cursor is attached.  If the cursor is “free”, <code>yPointNumber</code> is actually the fractional relative <i>yValue</i> as used in the <b>Cursor</b> /F/P command.
<code>Int32 isFree</code>	Has value of 1 if the cursor is not attached to anything, or value of 0 if it is attached to a trace, image, contour, or waterfall.

### Members of `WMWinHookStruct` Structure Used with `mouseWheel` Code

Member	Description
<code>double wheelDy</code>	Vertical lines to scroll. Typically +1 or -1.
<code>double wheelDx</code>	Horizontal lines to scroll. Typically +1 or -1.  On Windows, horizontal mouse wheel requires Vista.

### Members of `WMWinHookStruct` Used with `renamed` Code

Member	Description
<code>char oldWinName [MAX_OBJ_NAME+1]</code>	Old name of the window or subwindow. Not the absolute path <i>hcSpec</i> , just the name.

### User-Modifiable Members of `WMWinHookStruct` Structure

Member	Description
<code>Int32 doSetCursor</code>	Set to 1 to change cursor to that specified by <code>cursorCode</code> .
<code>Int32 cursorCode</code>	See <b>Setting the Mouse Cursor</b> .

## Mouse Events

Igor sends mouse down and mouse up events with the `eventCode` field of the `WMWinHookStruct` structure set to 3 or 5. With rare exceptions, your hook function should act on the mouse up event.

In Igor7, a mouse click on a table cell causes Igor to send a mouse down event to your hook function before Igor acts on the click, allowing you to block the action by returning a non-zero result. Igor then sends a mouse down event after Igor has acted on the click.

In Igor6, the mouse down event was sent only when the selection was finished, that is, after the mouse up event occurred. If you have existing code that uses the mouse down event to get a table selection, you need to change your code to use the mouse up event.

## Keyboard Events

The `WMWinHookStruct` structure has three members used with keyboard events.

The `keyCode` field works with ASCII characters and some special keys such as keyboard navigation keys.

The `specialKeyCode` fields works with navigation keys, function keys and other special keys. `specialKeyCode` is zero for normal text such as letters, numbers and punctuation.

The `keyText` field works with ASCII characters and non-ASCII characters such as accented characters.

The `specialKeyCode` and `keyText` fields were added in Igor Pro 7. New code that does not need to run with earlier Igor versions should use these new fields instead of the `keyCode` field. See **Keyboard Events Example** on page IV-281 for an example.

Here are the codes for the `specialKeyCode` and `keyCode` fields:

Key	specialKeyCode	keyCode	Note
F1 through F39	1 through 39	Not supported	Function keys
LeftArrow	100	28	
RightArrow	101	29	
UpArrow	102	30	
DownArrow	103	31	
PageUp	104	11	
PageDown	105	12	
Home	106	1	
End	107	4	
Return	200	13	
Enter	201	3	
Tab	202	27	
BackTab	203	Not supported	Tab with Shift pressed
Escape	204	27	
Delete	300	8	Backspace key
ForwardDelete	301	127	
Clear	302	Not supported	
Insert	303	Not supported	
Help	400	Not supported	
Break	401	Not supported	Pause/Break key
Print	402	Not supported	
SysReq	403	Not supported	

## Keyboard Events Example

This example illustrates the use of the various keyboard event fields in the `WMWinHookStruct` structure. It requires Igor Pro 7 or later.

```
Function KeyboardWindowHook(s)
    STRUCT WMWinHookStruct &s
```

```
Variable hookResult = 0    // 0 if we do not handle event, 1 if we handle it.

String message = ""

switch(s.eventCode)
    case 11:                // Keyboard event
        String keyCodeInfo
        sprintf keyCodeInfo, "s.keycode = 0x%04X", s.keycode
        if (strlen(message) > 0)
            message += "\r"
        endif
        message +=keyCodeInfo

        message += "\r"
        String specialKeyCodeInfo
        sprintf specialKeyCodeInfo, "s.specialKeyCode = %d", s.specialKeyCode
        message +=specialKeyCodeInfo
        message += "\r"

        String keyTextInfo
        sprintf keyTextInfo, "s.keyText = \"%s\"", s.keyText
        message +=keyTextInfo

        String text = "\\Z24" + message
        Textbox /C/N=Message/W=KeyboardEventsGraph/A=MT/X=0/Y=15 text

        hookResult = 1    // We handled keystroke
        break
endswitch

return hookResult // If non-zero, we handled event and Igor will ignore it.
End

Function DemoKeyboardWindowHook()
    DoWindow/F KeyboardEventsGraph    // Does graph exist?
    if (V_flag == 0)
        // Create graph
        Display /N=KeyboardEventsGraph as "Keyboard Events"

        // Install hook
        SetWindow KeyboardEventsGraph, hook(MyHook)=KeyboardWindowHook

        String text = "\\Z24" + "Press a key"
        Textbox /C/N=Message/W=KeyboardEventsGraph/A=MT/X=0/Y=15 text
    endif
End
```

### Setting the Mouse Cursor

An advanced programmer can use a named window hook function to change the mouse cursor.

You might want to do this, for example, if your window hook function intercepts mouse events on certain items (e.g., waves) and performs custom actions. By setting a custom mouse cursor you indicate to the user that clicking the items results in different-from-normal actions.

See the Mouse Cursor Control example experiment - in Igor choose File→Example Experiments→Programming→Mouse Cursor Control.

## Panel Done Button Example

This example uses a window hook and button action procedure to implement a panel dialog with a Done button such that the panel can't be closed by clicking the panel's close widget, but can be closed by the Done button's action procedure:

```
Proc ShowDialog()
    PauseUpdate; Silent 1          // building window...
    NewPanel/N=Dialog/W=(225,105,525,305) as "Dialog"
    Button done,pos={119,150},size={50,20},title="Done"
    Button done,proc=DialogDoneButtonProc
    TitleBox warning,pos={131,83},size={20,20},title=""
    TitleBox warning,anchor=MC,fColor=(65535,16385,16385)
    SetWindow Dialog hook(dlog)=DialogHook, hookevents=2
EndMacro

Function DialogHook(s)
    STRUCT WMWinHookStruct &s
    Variable statusCode= 0
    strswitch( s.eventName )
    case "killVote":
        TitleBox warning win=$s.winName, title="Press the Done button!"
        Beep
        statusCode=2                // prevent panel from being killed.
        break
    case "mousemoved":              // to reset the warning
        TitleBox warning win=$s.winName, title=""
        break
    endswitch
    return statusCode
End

Function DialogDoneButtonProc(ba) : ButtonControl
    STRUCT WMBUTTONACTION &ba
    switch( ba.eventCode )
    case 2:                         // mouse up
        // turn off the named window hook
        SetWindow $ba.win hook(dlog)=""
        // kill the window AFTER this routine returns
        Execute/P/Q/Z "DoWindow/K "+ba.win
        break
    endswitch
    return 0
End
```

## Window Hook Deactivate and Kill Events

The actions caused by these events (eventCode 2, 14, 15, 16 and 17) potentially affect multiple subwindows.

If you kill a subwindow, the root window's hook functions receives a subwindowKill event for that subwindow and any child subwindows.

If you kill a root window, the root window's hook function(s) receives a subwindowKill event for each child subwindow, and then the root window's hook function(s) receive a kill event.

Likewise, hiding and showing windows can result in subwindows being hidden or shown. In each case, the window hook function receives a hide or show event for each affected window or subwindow.

The winName member of WMWinHookStruct will be set to the full subwindow path of the subwindow that is affected.

Events for an exterior subwindow are a special case. See **Hook Functions for Exterior Subwindows** on page IV-285.

The hook functions attached to an exterior subwindow will receive a subwindowKill event if the exterior subwindow is killed as a result of killing the parent window. But it will receive a regular kill event if it is killed directly. Normal subwindows always receive only subwindowKill events.

The kill-related events are sent in this order when a window or subwindow is killed:

1. A killVote event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed.
2. If the window is not a subwindow and wasn't created with /K=1, /K=2 or /K=3, the standard window close dialog appears. If the close is cancelled, the window is not killed, the window will receive an activate event when the dialog is dismissed, and no further events are generated. Otherwise, proceed to step 3.
3. If the window being killed has subwindows, starting from the bottom-most subwindow and working back toward the window being killed:
  - 3a. If the subwindow is a panel, action procedures for controls contained in the subwindow are called with event -1, "control being killed".
  - 3b. The root window's hook function(s) receive a subwindowKill event for the subwindow. If any hook function returns 1, no further subwindow hook events or control being killed events are sent, but the window killing process continues.

Steps 3a and 3b are repeated for each subwindow until the window or subwindow being killed is reached.

4. If the killed window is a root window, a kill event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed. This method of preventing a window from closing is to be avoided: use the killVote event or the window-equivalent of NewPanel /K=2.

Prior to Igor 7, you could return 2 when the window hook received a kill event to prevent the killing of the window. This is no longer supported. Use the killVote event instead.

There are several ways to prevent a window being killed. You might want to do this in order to enforce use of a Done or Do It button, or to prevent killing a control panel while some hardware action is taking place.

The best method is to use /K=2 when creating the window (see **Display** or **NewPanel**). Then the only way to kill the window is via the DoWindow/K command, or KillWindow command. In general, you would provide a button that kills the window after checking for any conditions that would prevent it.

The KillVote event is more flexible but harder to use. It gives your code a chance to decide whether or not killing is allowed. This means the user can close and kill the window with the window close box when it is allowed.

Returning 2 for the window kill event is not recommended. If you have old code that uses this method, we strongly recommend changing it to return 2 for the killVote event. New code should never return 2 for the kill event.

As of Igor Pro 7, returning 2 for the window kill event does not prevent the window from being killed. If you have old code that uses this technique, change it to return 2 for the killVote event instead.

### Window Hook Show and Hide Events

Igor sends the show event to your hook function when the affected window is about to be shown but is still hidden. Likewise, Igor sends the hide event when the window is about to be hidden but is still visible. Other events, notably resize or move events, may be triggered by showing or hiding a window and may be sent before the change in visibility actually occurs. Here is an example that illustrates this issue:

```
Function MyHookFunction(s)
    STRUCT WMWinHookStruct &s

    strswitch(s.eventName)
        case "resize":
            GetWindow $(s.winName) hide
```

```

        if (V_value)
            Print "Resized while hidden"
        else
            Print "Resized while visible"
        endif
        break

    case "moved":
        GetWindow $(s.winName) hide
        if (V_value)
            Print "Moved while hidden"
        else
            Print "Moved while visible"
        endif
        break

    case "hide":
        print "Hide event"
        break

    case "show":
        print "Show event"
        break
endswitch

return 0    // Don't interfere with Igor's handling of events
End

Function MakePanelWithHook()
    NewPanel/N=MyPanel/HIDE=1
    SetWindow MyPanel, hook(myHook)=MyHookFunction
End

```

If you run the MakePanelWithHook function on the command line, you see nothing because the panel is hidden. Now select Windows→Other Windows→MyPanel. The following is printed in the history:

```

Show event
Moved while hidden
Resized while hidden

```

The hook function received the Move and Resize events *after* the Show event, but before the window actually became visible.

## Hook Functions for Exterior Subwindows

A regular subwindow lives inside a host window and receives events through a hook function attached to its host window.

An exterior subwindow is different because, although it is a subwindow (it is controlled by a host window), unlike a regular subwindow, it has its own actual window and therefore you can attach a hook function directly to it. A hook function attached to the root window does not receive events for an exterior subwindow. To handle events for an exterior subwindow, you must attach a hook function to the exterior subwindow itself. For example:

```

// Make a panel
NewPanel/N=RootPanel

// Make an exterior subwindow attached to RootPanel
NewPanel/HOST=RootPanel/EXT=0

// Attach a hook function to the exterior subwindow

```

```
SetWindow RootPanel#P0 hook(myhook)=MyHookFunction
```

### Unnamed Window Hook Functions

Unnamed window hook functions are supported for backward compatibility only. New code should use named window hook functions. See **Named Window Hook Functions** on page IV-277.

Each window can have one unnamed hook function. You designate a function as the unnamed window hook function using the **SetWindow** operation with the hook keyword.

The unnamed hook function is called when various window events take place. The reason for the hook function call is stored as an event code in the hook function's `infoStr` parameter.

The hook function is not called during experiment creation or load time so as to prevent the hook function from failing because the experiment is not fully recreated.

The hook function has the following syntax:

```
Function procName(infoStr)
    String infoStr
    String event= StringByKey("EVENT",infoStr)
    ...
    return statusCode    // 0 if nothing done, else 1
End
```

`infoStr` is a string containing a semicolon-separated list of *key:value* pairs:

Key	Value
EVENT	<i>eventKey</i> See list of <i>eventKey</i> values below.
HCSPEC	Absolute path of the window or subwindow. See <b>Subwindow Command Concepts</b> on page III-87.
MODIFIERS	Bit flags as follows: Bit 0: Set if mouse button is down. Bit 1: Set if Shift is down. Bit 2: Set if Option ( <i>Macintosh</i> ) or Alt ( <i>Windows</i> ) is down. Bit 3: Set if Command ( <i>Macintosh</i> ) or Ctrl ( <i>Windows</i> ) is down. Bit 4: Contextual menu click: right-click or Control-click ( <i>Macintosh</i> ), or right-click ( <i>Windows</i> ). See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.
OLDWINDOW	Previous name of the window or subwindow (for renamed event). Not the old absolute path <i>hcSpec</i> , just the name. WINDOW and HCSPEC contain the new name and new <i>hcSpec</i> .
WINDOW	Name of the window.

The value accompanying the EVENT keyword is one of the following:

<i>eventKey</i>	Meaning
activate	Window has just been activated.
copy	Copy menu item has been selected.

<b>eventKey</b>	<b>Meaning</b>
<code>cursormoved</code>	A graph cursor was moved. This event is sent only if bit 2 of the <b>SetWindow</b> operation <code>hookevents</code> flag is set.
<code>deactivate</code>	Window has just been deactivated.
<code>enablemenu</code>	Menus are being built and enabled.
<code>hide</code>	Window or subwindows about to be hidden.
<code>hideInfo</code>	The window info panel or window has just been hidden by <b>HideInfo</b> .
<code>hideTools</code>	The window tool palette or window has just been hidden by <b>HideTools</b> .
<code>kill</code>	Window is being killed. As of Igor Pro version 7, returning 2 as the hook function result no longer prevents Igor from killing the window. Use the <code>killVote</code> event instead.
<code>killVote</code>	Window is about to be killed. Return 2 to prevent that, otherwise return 0. See <b>Window Hook Deactivate and Kill Events</b> on page IV-283.
<code>menu</code>	A built-in menu item has been selected.
<code>modified</code>	A modification to the window has been made. This is sent to graph and notebook windows only. It is an error to try to kill a notebook window from the window hook during the modified event.
<code>mousedown</code>	Mouse button was clicked. This event is sent only if bit 0 of the <b>SetWindow</b> operation <code>hookevents</code> flag is set.
<code>mousemoved</code>	The mouse moved. This event is sent only if bit 1 of the <b>SetWindow</b> operation <code>hookevents</code> flag is set.
<code>mouseup</code>	Mouse button was released. This event is sent only if bit 0 of the <b>SetWindow</b> operation <code>hookevents</code> flag is set.
<code>moved</code>	Window has just been moved.
<code>renamed</code>	Window has just been renamed. The previous name is available under the <code>OLDWINDOW</code> key.
<code>resize</code>	Window has just been resized.
<code>show</code>	Window or subwindow is about to be unhidden.
<code>showInfo</code>	The window info panel or window has just been shown by <b>ShowInfo</b> .
<code>showTools</code>	The window tool palette or window has just been shown by <b>ShowTools</b> .
<code>subwindowKill</code>	One of the window's subwindows is about to be killed.

The modified event is issued only when a graph updates (See **DoUpdate**, **PauseUpdate**, and **ResumeUpdate**). Most changes to the graph are reported by the `modified` event, but not all: changing an annotation will not trigger the event, nor will adding, removing, or modifying a control or showing or hiding the drawing tools while using the `/A` flag. The modified event is not sent while a trace is being dragged or when the values of a trace's wave change (unless one the trace's axes is autoscaled). However, changing an axis range or indeed changing almost anything about axes or showing or hiding the info pane will send the modified event (only one event per graph update). When in doubt, use a print statement to determine when the event is sent.

## Chapter IV-10 — Advanced Topics

---

If mouse events are enabled then the following key:value pairs will also be present in `infoStr`:

Key	Value
MOUSEX	X coordinate in pixels of the mouse.
MOUSEY	Y coordinate in pixels of the mouse.
TICKS	Time event happened.

Note that a mouseup event may or may not correspond to a previous mousedown. If the user clicks in the window, drags out and releases the button then the mouseup event will be missing. If the user clicks in another window, drags into this one and then releases then a mouseup will be sent that had no previous mousedown.

In the case of mousedown or mousemoved messages, a nonzero return value will skip normal processing of the message. This is most useful with mousedown.

The `cursormoved` event is not reported if Option (*Macintosh*) or Alt (*Windows*) is held down.

If the `cursormoved` event is enabled then the following key:value pairs will also be present in `infoStr`:

Key	Value
CURSOR	Name of the cursor that moved (A through J).
TNAME	Name of the trace the cursor is attached to (invalid if <code>ISFREE=1</code> ).
ISFREE	1 if the cursor is “free” (not attached to a trace), 0 if it is attached to a trace or image.
POINT	Point number of the trace if not a free cursor. If the cursor is attached to an image, value is the row number of the image. If a free cursor, value is the fraction of the plot width, 0 being the left edge of the plot area, and 1 being the right edge.
YPOINT	Column number if the cursor is attached to an image, NaN if attached to a trace. If a free cursor, value is the fraction of the plot height, 0 being the top edge, and 1 being the bottom edge.

When the a menu event is reported then the following key:value pairs will also be present in `infoStr`:

Key	Value
MENUNAME	Name of menu (in English) as used by <b>SetIgorMenuMode</b> .
MENUITEM	Text of menu item as used by <b>SetIgorMenuMode</b> .

The `enablemenu` event does not pass `MENUNAME` or `MENUITEM`.

The menu and `enablemenu` messages are not sent when drawing tools are in use in a graph or layout or when waves are being edited in a graph.

Returning a value of 0 for the `enablemenu` message is recommended, though the return value is (currently) ignored.

You can use the **SetIgorMenuMode** operation to alter the enable state of Igor’s built-in menus in a way you find appropriate for the window. If you do this, usually you will also handle the menu message and perform your idea of an appropriate action.

**Note:** Dynamic user-defined menus (see **Dynamic Menu Items** on page IV-120) are built and enabled by using string functions in the menu definitions.

Returning a value of 0 for any menu message allows Igor to perform the normal action. Returning any other value (1 is commonly used) tells Igor to skip performing the normal action.

See the user function description with **IgorMenuHook** on page IV-273 for details on the sequence of menu building, enabling, and handling.

## Custom Marker Hook Functions

You can define custom marker shapes for use with graph traces. To do this, you must define a custom marker hook function, activate it by calling `SetWindow` with the `markerHook` keyword, and set a trace to use it via the `ModifyGraph` operation `marker` keyword.

A custom marker hook function takes one parameter - a `WMMarkerHookStruct` structure. This structure provides your function with information you need to draw a marker.

The function prototype used with a custom marker hook has the format:

```
Function MyMarkerHook(s)
    STRUCT WMMarkerHookStruct &s
    <code to draw marker>
    ...
    return statusCode          // 0 if nothing done, else 1
End
```

Your function can use the `DrawXXX` operations to draw the marker. The function is called each time the marker is drawn and should not do anything other than drawing the marker. The function should return 1 if it handled the marker or 0 if not.

The marker number range, which you specify via the `SetWindow` `markerHook` call, can be any positive integers less than 1000 and can overlap built-in marker numbers.

### WMMarkerHookStruct

The `WMMarkerHookStruct` structure has the following members:

**WMMarkerHookStruct Structure Members**

Member	Description
Int32 usage	0= normal draw, 1= legend draw (others reserved).
Int32 marker	Marker number minus start (i.e., starts from zero).
float x,y	Location of desired center of marker
float size	Half width/height of marker
Int32 opaque	1 if marker should be opaque
float penThick	Stroke width
STRUCT RGBColor mrkRGB	Fill color
STRUCT RGBColor eraseRGB	Background color
STRUCT RGBColor penRG	Stroke color
WAVE ywave	Trace's y wave
double ywIndex	Point number; ywave[ywIndex] is the y value where the marker is being drawn.

When your marker function is called, the pen thickness and colors of the drawing environment of the target window are already set consistent with the penThick, mrkRGB, eraseRGB and penRGB members.

### Marker Hook Example

Here is an example that draws audiology symbols:

```
Function AudiologyMarkerProc(s)
    STRUCT WMMarkerHookStruct &s

    if( s.marker > 3 )
        return 0
    endif

    Variable size= s.size - s.penThick/2

    if( s.opaque )
        SetDrawEnv linethick=0,fillpat=-1
        DrawRect s.x-size,s.y-size,s.x+size,s.y+size
        SetDrawEnv linethick=s.penThick
    endif
    SetDrawEnv fillpat= 0          // polys are not filled

    if( s.marker == 0 )           // 90 deg U open to the right
        DrawPoly s.x+size,s.y-size,1,1,{size,-size,-size,-size,-size,size,size,size}
    elseif( s.marker == 1 )       // 90 deg U open to the left

    SetWindow kwTopWin,markerHook={AudiologyMarkerProc,100,103}
EndMacro
```

See also the Custom Markers Demo experiment - in Igor choose File→Example Experiments→Feature Demos 2→Custom Markers Demo.

## Data Acquisition

Igor Pro provides a number of facilities to allow working with live data:

- Live mode traces in graphs
- FIFOs and Charts
- Background task
- External operations and external functions
- Controls and control panels
- User-defined functions

Live mode traces in graphs are useful when you acquiring complete waveforms in a single short operation and you want to update a graph many times per second to create an oscilloscope type display. See **Live Graphs and Oscilloscope Displays** on page II-259 for details.

FIFOs and Charts are used when you have a continuous stream of data that you want to capture and, perhaps, monitor. See **FIFOs and Charts** on page IV-291 details.

You can set up a background task that periodically performs data acquisition while allowing you to continue to work with Igor in the foreground. The background operations are *not* done using interrupts and therefore are easily disrupted by foreground operations. Background tasks are useful only for relatively infrequent tasks that can be quickly accomplished and do not cause a cascade of graph updates or other things that take a long time. See **Background Tasks** on page IV-298 for details.

You can create an instrument-like front panel for your data acquisition setup using user-defined controls in a panel window. Refer to Chapter III-14, **Controls and Control Panels**, for details. There are many example experiments that can be found in the Examples folder.

Igor Pro comes with an XOP named VDT2 for communicating with instruments via serial port (RS232), another XOP named NIGPIB2 for communicating via General Purpose Interface Bus (GPIB), and another XOP named VISA for communicating with VISA-compatible instruments. See the Igor Pro 7 Folder:More Extensions>Data Acquisition folder.

Sound I/O can be done using the built-in **SoundInRecord** and **PlaySound** operations.

The **NewCamera**, **GetCamera** and **ModifyCamera** operations support frame grabbing.

WaveMetrics produces the NIDAQ Tools software package for doing data acquisition using National Instruments cards. NIDAQ Tools is built on top of Igor using all of the techniques mentioned in this section. Information about NIDAQ Tools is available via the WaveMetrics Web site <<http://www.wavemetrics.com/Products/NIDAQTools/nidaqtools.htm>>.

Third parties have created data acquisition packages that use other hardware. Information about these is also available at <<http://www.wavemetrics.com/Products/thirdparty.htm>>.

If an XOP package is not available for your hardware you can write your own. For this, you will need to purchase the XOP Toolkit product from WaveMetrics. See **Creating Igor Extensions** on page IV-195 for details.

## FIFOs and Charts

This section will be of interest principally to programmers writing data acquisition packages.

Most people who use FIFOs and chart recorder controls will do so via packages provided by expert Igor programmers. For information on using, as opposed to programming, chart controls, see **Using Chart Recorder Controls** on page IV-296.

### FIFO Overview

A FIFO is an invisible data objects that can act as a First-In-First-Out buffer between a data source and a disk file. Data is placed in a FIFO either via the AddFIFOData operation or via an XOP package designed to interface to a particular piece of hardware. Chart recorder controls provide a graphical view of a portion of the data in a FIFO. When data acquisition is complete a FIFO can operate as a bidirectional buffer to a disk file. This allows the user to review the contents of a file by scrolling the chart “paper” back and forth. FIFOs can be used without a chart but charts have no use without a FIFO to monitor.

A FIFO can have an arbitrary number of channels each with its own number type, scaling, and units. All channels of a given FIFO share a common “timebase”.

### Chart Recorder Overview

Chart recorder controls can be used to emulate a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. Charts can be used to monitor data acquisition processes or to examine a long data record. Although programming a chart is quite involved, using a chart is very easy.

Here is a typical chart recorder control:

The First-In-First-Out (FIFO) buffer is an invisible Igor component that buffers the data coming from data acquisition hardware and software and also writes the data to a file. The data that is streaming through the FIFO can be observed using a chart recorder control. When data acquisition is finished the process can be reversed with data coming back out of the file and into the FIFO where it can be reviewed using the chart. The FIFO file is optional but if missing then all data pushed out the end of the FIFO is lost.

Chart recorder controls can take on quite a number of forms from the simple to the sophisticated:

A given chart recorder control can monitor an arbitrary selection of channels from a single FIFO. Each trace can have its own display gain, color and line style and can either have its own area on the “paper” or can share an area with one or more other traces. There can be multiple chart recorder controls active at one time in one or more panel or graph windows.

Chart recorders can display an image strip when hooked up to a FIFO channel defined using the optional vectPnts parameter to NewFIFOChan. An example experiment, Image Strip FIFO Demo, is provided to illustrate how to use this feature.

Chart recorders can operate in two modes — live and review. When a chart is in live mode and data acquisition is in progress, the chart “paper” scrolls by from right to left under the influence of the acquisition process. When in review mode, you are in control of the chart. When you position the mouse over the chart area you will see that the cursor turns into a hand. You can move the chart paper right or left by dragging with the hand. If you give the paper a push it will continue scrolling until it hits the end.

You can place the chart in review mode even as data acquisition is in progress by clicking in the paper with the hand cursor. To go back to live mode, give the paper a hard push to the left. When the paper hits the

end then the chart will go into live mode. You can also go back to live mode by clicking anywhere in the margins of the chart.

Depending on the exact details of the data acquisition hardware and software you may run the risk of corrupting the data if you use review mode while acquisition is in progress. The person that created the hardware and software system you are using should have provided guidelines for the use of review mode during acquisition. In general, if the acquisition process is paced by hardware then it should be OK to use review mode.

In the chart recorder graphics above, you may have noticed the line directly under the scrolling paper area. This line represents the current extent of data while the gray bar represents the data that is being shown in the chart. The right edge of the gray bar represents the right edge of the section of data being shown in the chart window. The above example is shown in live mode. Here are two examples shown in review mode:

While data acquisition is in progress, the horizontal line represents the extent of the data in the FIFO's memory. After acquisition is over then the line includes all of the data in the FIFO's output file, if any.

If you are in review mode while data acquisition is taking place, you will notice that the gray bar indicates the view area is moving even though the paper appears to be motionless. This is because the FIFO is moving out from under the chart. Eventually it will reach a position where the chart display can not be valid since the data it wants to display has been flushed off the end of the FIFO. When this happens the view area will go blank. Because it is very time-consuming for Igor to try to keep the chart updated in this situation your data acquisition rate may suffer.

Chart recorder controls sometimes try to auto-configure themselves to match their FIFO. Generally this action is exactly what you want and is unobtrusive. Here are the rules that charts use:

When the FIFO becomes invalid or if it ceases to exist then the chart marks itself as being in auto-configure mode. If the FIFO then becomes valid the chart will read the FIFO information and configure itself to monitor all channels. It tries to set the ppStrip parameter to a value appropriate for the deltaT value of the FIFO. It does so by assuming a desirable update rate of around 10 strips per second. Thus, for example, if deltaT was 1 millisecond then ppStrip would be set to 100. The moral is: deltaT had better be valid or weird values of ppStrip may be created.

Any chart recorder channel configuration commands executed after the FIFO becomes invalid but before the FIFO becomes valid again will prevent auto-configuration from taking place.

## Programming with FIFOs

You can create a FIFO by using the NewFIFO operation. When you are done using a FIFO you use the KillFIFO operation. A freshly created FIFO is not useful until either channels are created with the NewFIFO-Chan operation or until the FIFO is attached to a disk file for review using a variant of the CtrlFIFO operation.

You can obtain information about a FIFO using the FIFOStatus operation and you can extract data from a FIFO using the FIFO2Wave operation. Once a FIFO is set up and ready to accept data, you can insert data using the AddFIFOData operation. Alternately, you can insert data using an XOP package.

Once data is stored in a file you can review the data using a FIFO or extract data using user-defined functions. See the example experiment, "FIFO File Parse", for sample utility routines.

## Chapter IV-10 — Advanced Topics

---

Here are the operations and functions used in FIFO programming:

<b>NewFIFO</b>	<b>KillFIFO</b>
<b>NewFIFOChan</b>	<b>CtrlFIFO</b>
<b>FIFO2Wave</b>	<b>AddFIFOData</b>
<b>AddFIFOVectData</b>	<b>FIFOStatus</b>

As with background tasks, FIFOs are considered transient objects — they are not saved and restored as part of an experiment.

A FIFO does not need to be attached to a file to be useful. Note, however, that the oldest data is lost when a FIFO overflows.

A FIFO set up to acquire data does not become valid until the start command is issued. Chart controls will report invalid FIFOs on their status line. FIFO2Wave will give an error if it is invoked on an invalid FIFO. A stopped FIFO remains valid until the first command is issued that could potentially change the FIFO's setup.

Data in a running FIFO is written to disk when Igor notices that the FIFO is half full or when the AddFIFOData command is issued and the FIFO is full. The amount of time it takes to write data to disk can be quite considerable and at the same time unpredictable. If the computer disk cache size is large then writes to disk will be less frequent but when they do occur they will take a long time. This will matter to you most if you are attempting to take data rapidly using software, perhaps using an Igor background task.

If you are taking data via interrupt transfer to an intermediate buffer of adequate size or if your hardware has an adequate internal buffer then the disk write latency may not be a concern. If dead time due to disk writes is a concern then you may want to decrease the size of the disk cache and you may want to run with a relatively small FIFO. Note that if you change the size of the disk cache you may have to reboot for the change to take effect.

When the stop command is given to a running FIFO then it goes into review mode and remains valid. If the FIFO is attached to a file then the entire contents of the file can be reviewed or be transferred to a wave using the FIFO2Wave command.

The act of attaching a FIFO to an existing file for review using the rfile keyword of the CtrlFIFO command reads in the file contents and sets itself up for review. You should not use the NewFIFOChan command or any of the other CtrlFIFO keywords except size. Here is all that is required to review a preexisting file:

```
Variable refnum
Open/R/P=mypath refnum as "my file"
NewFIFO dave
CtrlFIFO dave,rfile=refnum
```

If any chart controls have been set up to monitor FIFO dave then they will automatically configure themselves to display all the channels of dave using default parameters.

The connection between FIFOs and chart controls relies on Igor's dependency manager. The dependency manager does not automatically run during function execution — you have to explicitly call it by executing the DoUpdate command.

The dependency manager sends messages to a chart control when:

- A FIFO is created
- A FIFO is killed
- A FIFO becomes valid (start command)
- Data is added to a FIFO

In particular, if inside a user function, you kill a FIFO and then create it again you should call DoUpdate after the kill so that the chart control notices the kill and can get ready for the creation.

## FIFO File Format

This information is for users who may wish to create FIFO files with their own programs or for those who need to analyze data stored in a FIFO file. You will need to have a reading familiarity with the C programming language to understand the following. Note, the following information may be out of date. For the most up to date information, refer to the most recent version of the auxiliary file named NamedFIFO.h located in the “Miscellaneous:More Documentation:” folder.

Consider the following data structures....

```
#define CUR_FIFOFILE_VERSION 0

typedef struct FIFOFileHeader{
    long typeP1,typeP2;          // 'IGOR','fifo'
    long version;                // CUR_FIFOFILE_VERSION
    long datasize; // bytes of data following ChartChunkInfo field if known
    long hsize;    // size of following ChartChunkInfo field; data follows
}FIFOFileHeader;

#define MAX_NOTESIZE 255
#define FIFO_CHAN_VERSION_NUM 0x01

typedef struct ChartChanInfo{
    long ntype;                  // number type -- NT_FP32 or NT_I16 or ...
    double offset,gain;          // result= (measval-offset)*gain
    double fsPlus,fsMinus;      // value of + & - full scale
    char name[MAX_OBJ_NAME+1];  // name of this channel
    char units[4];              // SU abbrev of units
    long chanRefcon;            // for use by data acquisition sw
}ChartChanInfo;

typedef struct ChartChunkInfo{
    long type;                  // 'chrt'
    short version;              // version number of this data structure
    short pad1;                 // maintain 32 bit alignment
    unsigned long startDate;    // datetime of start command
    char note[MAX_NOTESIZE+1];  // room for a short note from user
    double deltaT;              // data acquisition speed (if known, in seconds)
    long xopRefcon;             // for use by data acquisition sw
    long nchan;                 // number of channels
    ChartChanInfo info[];       // info for each channel
}ChartChunkInfo;
```

The FIFO file consists of the FIFOFileHeader followed by the ChartChunkInfo and finally by chunks of data until the end of the file. It is expected that the format of this file will undergo evolutionary changes. You should be prepared to keep up with such changes. In particular you should always check for the proper version numbers when trying to interpret such a file.

An example of a user-defined function that can parse a FIFO file can be found in:

Igor Pro Folder:Examples:Programming:FIFO File Parse.pxp

The vectpnts field allows FIFO channels to contain a vector of data rather than just a single data point.

Igor also supports a split file FIFO header:

```
#define CUR_FIFOSplitFILE_VERSION (CUR_FIFOFILE_VERSION+1)
typedef struct FIFOSplitFileHeader{
    long typeP1,typeP2;          // 'IGOR','fifo'
    long version;                // CUR_FIFOSplitFILE_VERSION

    /*
    ** The split file header differs from the unified by the
    ** insertion of the following 3 fields.
```

```
*/
char datafile[256];           // c-string containing name of file
                               // containing actual data
long dataoffset;              // offset into data file
long dsize;                   // number of bytes of data or zero
                               // to use entire rest of file

long datasize;                // bytes of data following ChartChunkInfo
                               // field if known
long hsize;                   // size of following ChartChunkInfo field;
                               // data follows that
}FIFOSplitFileHeader;
```

This format allows the raw data to reside in its own file rather than having to be in the same file as the header. This was provided to allow the review of large binary files generated by third-party programs.

Another way to use a FIFO and chart control to review a raw binary file is to use the `rdfile` keyword with the `CtrlFIFO` command.

See the example experiment, *Wave Review Chart Demo*, for sample code for both the split header and raw binary formats.

### FIFO and Chart Demos

Igor Pro Folder:Examples:Imaging:Image Strip FIFO Demo.pxp
```

## Using Chart Recorder Controls

The information provided here pertains to using rather than programming a chart recorder control. For information on programming chart controls, see **FIFOs and Charts** on page IV-291.

An Igor chart recorder control works in conjunction with a FIFO to display data as it is acquired or to review data that has previously been acquired.

### Chart Reorder Control Basics

An Igor chart recorder control is neither an analytical tool nor a presentation quality graphic. It is meant only for real time monitoring of incoming data or to review data from a FIFO file. When you want an analytical or presentation quality graph you must transfer the data to a wave and then use a conventional Igor graph.

An Igor chart recorder control emulates a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. It differs from a real chart recorder in that the paper of the latter moves at a constant velocity whereas the “paper” of an Igor chart moves only when data becomes available in the FIFO it is monitoring. If data is placed in the FIFO at a constant rate then the “paper” will scroll by at a constant rate. However, since there can be no guarantee that the data is coming in at a constant rate, we refer to the horizontal axis not in terms of time but rather in terms of data sample number.

A given chart recorder control can monitor an arbitrary selection of channels from a single FIFO. Each chart trace can have its own display gain, color and line style and can either have its own area on the “paper” or can share an area with one or more other traces. There can be multiple charts active at one time in one or more control panel or graph windows.

### Operating a Chart Recorder

Here is a typical chart recorder while taking data:

And here is the same chart recorder while reviewing data even though data acquisition is still taking place:

And here we are while reviewing data from the file after data acquisition is complete:

Notice the positioning strip just under the chart and above the status line. It consists of a horizontal line and a horizontal, gray bar. The line, called the positioning line, represents the extent of available data. The bar, called the positioning bar, represents the currently displayed region of this data.

While data acquisition is in progress, the available data is the data in the FIFO's memory. After the acquisition is over then the available data includes all of the data in the FIFO's output file, if any. The vertical bars at the ends of the positioning line indicate we are reviewing from a file.

You can instantly jump to any portion of the data by clicking on the positioning line. The spot that you click on indicates the part of the available data that you want to view. After clicking you can drag the "paper" region around.

The chart recorder will be in one of two modes: live mode or review mode. While data acquisition is under way, the chart recorder will display incoming data if it is in live mode. If it is in review mode, you can review previously acquired data.

Clicking on the positioning line or in the positioning bar puts the chart recorder into review mode even if data acquisition is taking place. To exit review mode and go into live mode, simply click anywhere in the chart recorder outside of the "paper" and the positioning strip. Of course, if you are not acquiring data you can not go into live mode.

Another way to go into review mode and navigate is to grab the "paper" with the mouse and fling it to the left or right. It will keep going until it hits the end of available data. The speed at which the "paper" moves depends on how hard you fling it.

If you are in review mode while data acquisition is taking place, you will notice that the positioning bar indicates the view area is moving even though the "paper" appears to be motionless. This is because the FIFO is moving out from under the chart. Eventually it will reach a position where the chart display can not be valid since the data it wants to display has been flushed off the end of the FIFO. When this happens the paper will go blank. Because it is very time consuming for Igor to try to keep the chart updated in this situation, your data acquisition rate may suffer. To get an idea of what kind of data rates can be sustained using an Igor background task, spend some time experimenting with the "FIFO/Chart Overhead" example experiment.

## Background Tasks

Background tasks allow procedures to run periodically "in the background" while you continue to interact normally with Igor. This is useful for data acquisition, simulations and other processes that run indefinitely, over long periods of time, or need to run at regular intervals. Using a background task allows you to continue to interact with Igor while your data acquisition or simulation runs.

Originally Igor supported just one unnamed background task controlled using the **CtrlBackground** operation (page V-101). New code should use the **CtrlNamedBackground** operation (page V-102) to create named background tasks instead, as shown in the following sections. You can run any number of named backgrounds tasks.

In addition to the documentation provided here, the Background Task Demo experiment provides sample code that is designed to be redeployed for other projects. We recommend reading this documentation first and then opening the demo by choosing File→Example Experiments→Programming→Background Task Demo.

### Background Task Example #1

You create and control background tasks using the **CtrlNamedBackground** operation. The main parameters of CtrlNamedBackground are the background task name, the name of a procedure to be called periodically, and the period. Here is a simple example:

```
Function TestTask(s)      // This is the function that will be called periodically
    STRUCT WMBBackgroundStruct &s

    Printf "Task %s called, ticks=%d\r", s.name, s.curRunTicks
    return 0              // Continue background task
End

Function StartTestTask()
    Variable numTicks = 2 * 60    // Run every two seconds (120 ticks)
    CtrlNamedBackground Test, period=numTicks, proc=TestTask
    CtrlNamedBackground Test, start
End

Function StopTestTask()
    CtrlNamedBackground Test, stop
End
```

You start this background task by calling `StartTestTask()` from the command line or from another procedure. `StartTestTask` creates a background task named `Test`, sets the period which is specified in units of

ticks (1 tick = 1/60th of a second), and specifies the user-defined function to be called periodically (TestTask in this example).

You stop the Test background task by calling `StopTestTask()`.

As shown above, the background procedure takes a **WMBackgroundStruct** parameter. In most cases you won't need to access it.

## Background Task Exit Code

The background procedure (TestTask in the example above) returns an exit code to Igor. The code is one of the following values:

- 0: The background procedure executed normally.
- 1: The background procedure wants to stop the background task.
- 2: The background procedure encountered an error and wants to stop the background task.

Normally the background procedure should return 0 and the background task will continue to run. If you return a non-zero value, Igor stops the background task. You can tell Igor to terminate the background task by returning the value 1 from the background function.

If you forget to add a return statement to your background procedure, this acts like a non-zero return value and stops the background task.

## Background Task Period

The `CtrlNamedBackground` operation's period keyword takes an integer parameter expressed in ticks. A tick is approximately 1/60th of a second. Thus the timing of Igor background tasks has a nominal resolution of 1/60th of a second.

You can override the specified period in the background task procedure by writing to the `nextRunTicks` field of the **WMBackgroundStruct** structure. This is needed only if you want your procedure to run at irregular intervals.

The actual time between calls to the background procedure is not guaranteed. Igor runs the background task from its outer loop, when Igor is doing nothing else. If you do something in Igor that takes a long time, for example performing a lengthy curve fit, running a user-defined function that takes a long time, or saving a large experiment, Igor's outer loop does not run so the background task will not run. If you do something that causes a compilation of Igor procedures to fail, the background task is not called. On Macintosh, the background task is not called while a menu is displayed or while the mouse button is pressed.

If you need your background task to continue running even if you edit other procedures in Igor, you need to make your project an independent module. See **Independent Modules** on page IV-224 for details.

If you need precise timing that can not be interrupted, things get much more complicated. You need to do your data acquisition in an Igor thread running in an independent module or in a thread created by an XOP that you write. See **ThreadSafe Functions and Multitasking** on page IV-308 for details.

The shortest supported period is one tick. The minimum actual period for the background task depends on your hardware and what your background task is doing. If you set the period too low for your background task, interacting with Igor becomes sluggish.

It is very easy to bog your computer down using background tasks. If the background task takes a long time to execute or if it triggers something that takes a long time (like a wave dependency formula or updating a complex graph) then it may appear that the system is hung. It is not, but it may take longer to respond to user actions than you are willing to wait.

### Background Task Limitations

The principal limitation of Igor background tasks is that they are stopped while other operations are taking place. Thus, although you can type commands into the command line without disrupting the background task, when you press Return the task is stopped until execution of the command line is finished.

Background tasks do not run if procedures are in an uncompiled state. If you need your background task to continue running even if you edit other procedures in Igor, you need to make your project an independent module. See **Independent Modules** on page IV-224 for details.

On Macintosh, the background task does not run when the mouse button is pressed or when a menu is displayed.

### Background Tasks and Errors

If a background task procedure contains a bug, it will typically generate an error each time the procedure runs. Normally an error generates an error dialog. If this happened over and over again, it would prevent you from fixing the bug.

Igor handles such repeated errors as follows: The first time an error occurs during the execution of the background task procedure, Igor displays an error dialog. On subsequent errors, Igor prints an error message in the history. After printing 10 such error messages, Igor stops printing messages. When you click a control, execute a command from the command line or execute a command through a menu item, the process starts over.

If the Igor debugger is enabled and Debug on Error is turned on, Igor will break into the debugger each time an error occurs in the background task procedure. You may have to turn Debug on Error off to give you time to stop the background task. You can do this from within the debugger by right-clicking.

### Background Tasks and Dialogs

By default, a background task created by `CtrlNamedBackground` continues to run while a dialog is displayed. You can change this behavior using the `CtrlNamedBackground dialogsOK` keyword.

If you allow background tasks to run while an Igor dialog is present, you should ensure that your background task does not kill anything that a dialog might depend on. It should not kill waves or variables. It should never directly modify a window (except for a status panel) and especially should never remove something from a window (such as a trace from a graph). Otherwise your background task may kill something that the dialog depends on which will cause a crash.

### Background Task Tips

Background tasks should be designed to execute quickly. They do not run in separate threads and they hang Igor's event processing as long as they run. For maximum responsiveness, your task procedure should take no more than a fraction of a second to run even when the period is long. If you have to perform a lengthy computation, let the user know what is going on, perhaps via a message in a status control panel.

Background tasks should never attempt to put up dialogs or directly wait for user input. If you need to get the attention of the user, you should design your system to include a status control panel with an area for messages or some other change in appearance. If you need to wait for the user, you should do so by monitoring global variables set by nonbackground code such as a button procedure in a panel.

Your task procedure should always leave the current data folder unchanged on exit.

## Background Task Example #2

Here is an example that uses many of the concepts discussed above. The task prints a message in the history area at one second intervals five times, performs a “lengthy calculation”, and then waits for the user to give the go-ahead for another run.

The task does its own timing and consequently is set to run at the maximum rate (60 times per second). The task procedure, MyBGTask, tests to see if one second has elapsed since the last time it printed a message. In a real application, you might test to see if some external event has occurred.

To try the example, copy the code below to the Procedure window and execute:

```

BGDemo()

Function BGDemo()
  DoWindow/F BGDemoPanel          // bring panel to front if it exists
  if( V_Flag != 0 )
    return 0                      // panel already exists
  endif

  String dfSav= GetDataFolderDFR() // so we can leave current DF as we found it
  NewDataFolder/O/S root:Packages

### Background Task Example #3

For another example including code that you can easily redeploy for your own project, open the Background Task Demo experiment by choosing File→Example Experiments→Programming→Background Task Demo.

### Old Background Task Techniques

Originally Igor supported just one unnamed background task. This is still supported for backward compatibility but new code should use `CtrlNamedBackground` to create and control named background tasks instead.

The unnamed background task is designated using **SetBackground**, controlled using **CtrlBackground** and killed using **KillBackground**. The **BackgroundInfo** operation returns information about the unnamed background task.

The `SetBackground`, `CtrlBackground`, `KillBackground` and `BackgroundInfo` operations work only with the unnamed background task. For named background tasks, the `CtrlNamedBackground` operation provides all necessary functionality.

By default, a background task created by `CtrlBackground` does not run while a dialog is displayed. You can change this behavior using the `CtrlBackground dialogsOK` keyword.

## Automatic Parallel Processing with TBB

TBB stands for “Threading Building Blocks”. It is an Intel technology that facilitates the use of multiple processors on a given task. The home page for TBB is:

<https://www.threadingbuildingblocks.org>

Starting with Igor Pro 7, some Igor operations, such as `CurveFit`, `DSPPeriodogram`, and `ImageProfile`, automatically use TBB. To see which operations use TBB, choose Help→Command Help, click Show All, and then check the Automatically Multithreaded Only checkbox.

You don't need to do anything to take advantage of automatic multithreading with TBB. It happens automatically.

Running on multiple threads reduces the time required for number crunching tasks when the benefit of using multiple processors exceeds the overhead. Operations that use TBB automatically use multiple threads only when the size of the data or the complexity of the problem crosses a certain threshold. Igor is programmed to use a reasonable threshold for each supported operation. You can control the threshold using the **MultiThreadingControl** operation.

## Automatic Parallel Processing with MultiThread

Intermediate-level Igor programmers can make use of multiple processors to speed up wave assignment statements in user-defined functions. To do this, simply insert the keyword **MultiThread** in front of a normal wave assignment. For example, in a function:

```
Make wave1
Variable a=4
MultiThread wave1= sin(x/a)
```

The expression, on the right side of the assignment statement, is compiled as threadsafe even if the host function is not.

Because of the overhead of spawning threads, you should use **MultiThread** only when the destination has a large number of points or the expression takes a significant amount of time to evaluate. Otherwise, you may see a performance penalty rather than an improvement.

The assignment is automatically parceled into as many threads as there are processors, each evaluating the right-hand expression for a different output point.

The **MultiThread** keyword causes Igor to evaluate the expression for multiple output points simultaneously. Do not make any assumptions as to the order of processing and certainly do not try to use a point from the destination wave other than the current point in the expression. For example, do not do something like this:

```
wave1 = wave1[p+1] - wave1[p-1] // Result is indeterminate
```

Expressions like give unexpected results even in the absence of threading.

Here is a simple example to try on your own machine:

```
Function TestMultiThread(n)
    Variable n // Number of wave points

    Make/O/N=(n) testWave

    // To prime processor data cache so comparison will be valid
    testWave= 0

    Variable t1,t2
    Variable timerRefNum

    // First, non-threaded
    timerRefNum = StartMSTimer
    testWave= sin(x/8)
    t1= StopMSTimer(timerRefNum)

    // Now, automatically threaded
    timerRefNum = StartMSTimer
    MultiThread testWave= sin(x/8)
    t2= StopMSTimer(timerRefNum)
```

```
Variable processors = ThreadProcessorCount
Print "On a machine with",processors,"cores,MultiThread is", t1/t2,"faster"
End
```

Here is the output on a Mac Pro:

```
•TestMultiThread(100)
  On a machine with 8 cores, MultiThread is 0.059746 faster

•TestMultiThread(10000)
  On a machine with 8 cores, MultiThread is 3.4779 faster

•TestMultiThread(1000000)
  On a machine with 8 cores, MultiThread is 6.72999 faster

•TestMultiThread(10000000)
  On a machine with 8 cores, MultiThread is 8.11069 faster
```

The first result shows that the MultiThread keyword slowed the assignment down. This is because the assignment involved a small number of points and MultiThread has some overhead.

The remaining results illustrate that MultiThread can provide increased speed for assignments involving large waves.

In the last result, the speed improvement factor was greater than the number of processors. This is explained by the fact that, once running, a threadsafe expression has slightly less overhead than a normal expression.

If the right-hand expression involves calling user-defined functions, those functions must be threadsafe (see **ThreadSafe Functions** on page IV-97) and must also follow these rules:

1. Do not do anything to waves that are passed as parameters that might disturb memory. For example, do not change the number of points in the wave or change its data type or kill it or write to a text wave.
2. Do not write to a variable that is passed by reference.
3. Note that any waves or global variables created by the function will disappear when the wave assignment is finished.
4. Each thread has its own private data folder tree. You can not use WAVE, NVAR or SVAR to access objects in the main thread.

Failure to heed rule #1 will likely result in a crash.

Although it is legal to use the MultiThread mechanism in a threadsafe function that is already running in a preemptive thread via **ThreadStart**, it is not recommended and will likely result in a substantial loss of speed.

For an example using MultiThread, open the Mandelbrot demo experiment file by choosing “File→Example Experiments→Programming→MultiThreadMandelbrot”.

### Data Folder Reference MultiThread Example

Advanced programmers can use waves containing data folder references and wave references along with MultiThread to perform multithreaded calculations more involved than evaluating an arithmetic expression. Here we use **Free Data Folders** (see page IV-88) to facilitate multithreading.

In this example, we extract each of the planes of a 3D wave, perform a filtering operation on the planes, and then finally assemble the planes into an output 3D wave. The main function, Test, executes a multithreaded assignment statement where the expression includes a call to a subroutine named Worker.

Because MultiThread is used, multiple instances of Worker execute simultaneously on different cores. Each instance runs in its own thread, working on a different plane. Each instance returns one filtered plane in a wave named M\_ImagePlane in a thread-specific free data folder. The use of free data folders allows each instance of Worker to work on its own M\_ImagePlane wave without creating a name conflict.

When the multithreaded assignment is finished, the main function assembles an output 3D wave by concatenating the filtered planes.

```
// Extracts a plane from the 3D input wave, filters it, and returns the
// filtered output as M_ImagePlane in a new free data folder
ThreadSafe Function/DF Worker(w3DIn, plane)
    WAVE w3DIn
    Variable plane

    DFREF dfSav= GetDataFolderDFR()

    // Create a free data folder to hold the extracted and filtered plane
    DFREF dfFree= NewFreeDataFolder()
    SetDataFolder dfFree

    // Extract the plane from the input wave into M_ImagePlane.
    // M_ImagePlane is created in the current data folder
    // which is a free data folder.
    ImageTransform/P=(plane) getPlane, w3DIn
    Wave M_ImagePlane // Created by ImageTransform getPlane

    // Filter the plane
    WAVE wOut= M_ImagePlane
    MatrixFilter/N=21 gauss,wOut

    SetDataFolder dfSav

    // Return a reference to the free data folder containing M_ImagePlane
    return dfFree
End

Function Demo(numPlanes)
    Variable numPlanes

    // Create a 3D wave and fill it with data
    Make/O/N=(200,200,numPlanes) src3D= (p==(2*r))*(q==(2*r))

    // Create a wave to hold data folder references returned by Worker.
    // /DF specifies the data type of the wave as "data folder reference".
    Make/DF/N=(numPlanes) dfw

    Variable timerRefNum = StartMSTimer

    MultiThread dfw= Worker(src3D,p)

    Variable elapsedTime = StopMSTimer(timerRefNum) / 1E6

    Printf "Statement took %g seconds for %d planes\r", elapsedTime, numPlanes

    // At this point, dfw holds data folder references to 50 free
    // data folders created by Worker. Each free data folder holds the
    // extracted and filtered data for one plane of the source 3D wave.

    // Create an output wave named out3D by cloning the first filtered plane
    DFREF df= dfw[0]
    Duplicate/O df:M_ImagePlane, out3D

    // Concatenate the remaining filtered planes onto out3D
    Variable i
    for(i=1; i<numPlanes; i+=1)
        df= dfw[i] // Get a reference to the next free data folder
```

```
        Concatenate {df:M_ImagePlane}, out3D
    endfor

    // dfw holds references to the free data folders. By killing dfw,
    // we kill the last reference to the free data folders which causes
    // them to be automatically deleted. Because there are no remaining
    // references to the various M_ImagePlane waves, they too are
    // automatically deleted.
    KillWaves dfw
End
```

To run the demo, execute:

Demo (50)

On an eight-core Mac Pro, this took 4.1 seconds with the MultiThread keyword and 0.6 seconds without the MultiThread keyword for a speedup of about 6.8 times.

### Wave Reference MultiThread Example

In the preceding example, free data folders were used to hold data processed by threads. Since each free data folder held just a single wave, the example can be simplified by using free waves instead of free data folders. So here we perform the same threaded filtering of planes using free waves.

Because MultiThread is used, multiple instances of Worker execute simultaneously on different cores. Each instance runs in its own thread, working on a different plane. Each instance returns one filtered plane in a free wave named M\_ImagePlane. The use of free waves allows each instance of Worker to work on its own M\_ImagePlane wave without creating a name conflict.

This version of the example relies on the fact that a wave in a free data folder becomes a free wave when the free data folder is automatically deleted. See **Free Wave Lifetime** on page IV-86 for details.

```
ThreadSafe Function/WAVE Worker(w3DIn, plane)
    WAVE w3DIn
    Variable plane

    DFREF dfSav= GetDataFolderDFR()

    // Create a free data folder and set it as the current data folder
    SetDataFolder NewFreeDataFolder()

    // Extract the plane from the input wave into M_ImagePlane.
    // M_ImagePlane is created in the current data folder
    // which is a free data folder.
    ImageTransform/P=(plane) getPlane, w3DIn
    Wave M_ImagePlane // Created by ImageTransform getPlane

    // Filter the plane
    WAVE wOut= M_ImagePlane
    MatrixFilter/N=21 gauss,wOut

    // Restore the current data folder
    SetDataFolder dfSav

    // Since the only reference to the free data folder created above
    // was the current data folder, there are now no references it.
    // Therefore, Igor has automatically deleted it.
    // Since there IS a reference to the M_ImagePlane wave in the free
    // data folder, M_ImagePlane is not deleted but becomes a free wave.

    return wOut // Return a reference to the free M_ImagePlane wave
End
```

```

Function Demo(numPlanes)
    Variable numPlanes

    // Create a 3D wave and fill it with data
    Make/O/N=(200,200,numPlanes) srcData= (p==(2*r))*(q==(2*r))

    // Create a wave to hold data folder references returned by Worker.
    // /WAVE specifies the data type of the wave as "wave reference".
    Make/WAVE/N=(numPlanes) ww

    Variable timerRefNum = StartMSTimer

    MultiThread ww= Worker(srcData,p)

    Variable elapsedTime = StopMSTimer(timerRefNum) / 1E6

    Printf "Statement took %g seconds for %d planes\r", elapsedTime, numPlanes

    // At this point, ww holds wave references to 50 M_ImagePlane free waves
    // created by Worker. Each M_ImagePlane holds the extracted and filtered
    // data for one plane of the source 3D wave.

    // Create an output wave named out3D by cloning the first filtered plane
    WAVE w= ww[0]
    Duplicate/O w, out3D

    // Concatenate the remaining filtered planes onto out3D
    Variable i
    for(i=1;i<numPlanes;i+=1)
        WAVE w= ww[i]
        Concatenate {w}, out3D
    endfor

    // ww holds references to the free waves. By killing ww, we kill
    // the last reference to the free waves which causes them to be
    // automatically deleted.
    KillWaves ww
End

```

To run the demo, execute:

```
Demo(50)
```

## Structure Array MultiThread Example

In a preceding example, free data folders were used to hold data processed by threads. A somewhat simpler approach is to use one or more structures to pass input data and to receive output data. The following example uses a single structure for both input and output. An array of these structures stored in a wave ensures that each thread works on its own data. After the calculation, the results are extracted. The net result for this simple example is nothing more than: `dataOutput = sin(p)`.

```

Structure ThreadIOData
    // Input to thread
    double x

    // Output from thread
    double out
EndStructure

Function Demo()
    if (IgorVersion() < 6.36)

```

```
// This example crashes in Igor Pro 6.35 or before
// because of a bug in StructGet/StructPut
Abort "Function requires Igor Pro 6.36 or later."
endif

STRUCT ThreadIOData ioData

// Prepare input
Make/O ioDataArray          // This wave will be redimensioned by StructPut
Variable i, imax=100
for(i=0; i<imax; i+=1)
    ioData.x = i              // Set input data
    StructPut ioData, ioDataArray[i] // Pack structure into wave column
endfor

// Generate output
Make/O/N=(imax) threadOutput
MultiThread threadOutput = Worker(ioDataArray, p)

// Extract output
Make/O/N=(imax) outputData
for(i=0; i<imax; i+=1)
    StructGet ioData, ioDataArray[i]
    outputData[i] = ioData.out
endfor

KillWaves ioDataArray, threadOutput
End

ThreadSafe Function Worker(w, point)
    WAVE w
    Variable point

    STRUCT ThreadIOData ioData
    StructGet ioData, w[point]          // Extract structure from wave column

    ioData.out = sin(ioData.x)          // Calculate of output data

    StructPut ioData, w[point]          // Pack structure into wave column

    // The return value from the thread worker function is accessible
    // via ThreadReturnValue. It is not used in this example.
    return point
End

To run the demo, execute:

Demo()
```

## ThreadSafe Functions and Multitasking

Igor supports two multitasking techniques that are easy to use:

- **Automatic Parallel Processing with TBB**
- **Automatic Parallel Processing with MultiThread**

This section discusses the third technique, **ThreadSafe Functions**, which expert programmers can use to create complex, preemptive multitasking background tasks.

Preemptive multitasking uses the following functions and operations:

<b>ThreadProcessorCount</b>	<b>ThreadGroupCreate</b>
<b>ThreadStart</b>	<b>ThreadGroupPutDF</b>
<b>ThreadGroupGetDF</b> (deprecated)	<b>ThreadGroupGetDFR</b>
<b>ThreadGroupWait</b>	<b>ThreadReturnValue</b>
<b>ThreadGroupRelease</b>	

To run a threadsafe function preemptively, you first create a thread group using **ThreadGroupCreate** and then call **ThreadStart** to start your worker function. Usually you will use the same function for each thread of a group although they can be different.

The worker function must be defined as threadsafe and must return a real or complex numeric result. The return value can be obtained after the function finishes by calling **ThreadReturnValue**.

The worker function can take variable and wave parameters. It can not take pass-by-reference parameters or data folder reference parameters.

Any waves you pass to the worker are accessible to both the main thread and to your preemptive thread. Such waves are marked as being in use by a thread and Igor will refuse to perform any operations that could change the size of the wave.

You can determine if any threads of a group are still running by calling **ThreadGroupWait**. Use zero for the “milliseconds to wait” parameter to just test if all threads are finished. Use a larger value to cause the main thread to sleep until all threads are finished. If you know the maximum time the threads should take, you can use that value and print an error message or take other action if the threads don’t finish in time.

When **ThreadGroupWait** is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call **ThreadGroupWait** before calling **ThreadReturnValue**.

Once you are finished with a given thread group, call **ThreadGroupRelease**.

The Igor debugger can not be used with preemptive threads. You will need to use print statements for debugging.

The hard part of using multithreading is devising a scheme for partitioning your data processing algorithms into threads.

## Thread Data Environment

When a thread is started, Igor creates a root data folder for that thread. This root data folder and any data objects that the thread creates in it are private to the thread. This constitutes a separate data hierarchy for each thread.

Data is transferred, when you request it, from the main thread to a preemptive thread and vice-versa using input and output queues. The “currency” of these queues is the data folder, which provides considerable flexibility for passing data to threads and for retrieving results. Each thread group has an input queue to which the main thread may post data and an output queue from which the main thread may retrieve results.

The terms “input” and “output” are relative to the preemptive thread. The main thread posts a data folder to the input queue to send input to the preemptive thread. The preemptive thread retrieves the data folder from the input queue. After processing, the preemptive thread may post a data folder to the output queue. The main thread reads output from the preemptive thread by retrieving the data folder from the output queue.

Use **ThreadGroupPutDF** to post data folders and **ThreadGroupGetDFR** to retrieve them. These are called from both the main thread and from preemptive threads.

**ThreadGroupPutDF** clips the specified data folder, and everything it contains, out of the source thread's data hierarchy and puts it in the queue. From the standpoint of the source thread, it is as if **KillDataFolder** had been called. While a data folder resides in a queue, it is not accessible by any thread. See the documentation for **ThreadGroupPutDF** for some warnings about its use.

**ThreadGroupGetDFR** removes the data folder from the queue and returns it, as a free data folder, to the calling thread. Because it is a free data folder, Igor will automatically delete it when there are no more references to it, for example, when the thread returns.

Except for waves passed to the thread worker function as parameters and the thread worker's return value, the input and output queues are the only way for a thread to share data with the main thread. Examples below illustrate the use of these queues.

### Parallel Processing - Group-at-a-Time Method

In this example, we attempt to improve the speed of filling columns of a 2D wave with a sin function. The traditional method is compared with parallel processing. Notice how much more complicated the multi-threaded version, **MTFillWave**, is compared to the single threaded **STFillWave**.

```
ThreadSafe Function MyWorkerFunc(w,col)
    WAVE w
    Variable col

    w[][col]= sin(x/(col+1))

    return stopMSTimer(-2)           // Time when we finished
End

Function MTFillWave(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable i,col,nthreads= ThreadProcessorCount
    Variable threadGroupID= ThreadGroupCreate(nthreads)

    for(col=0; col<ncol;)
        for(i=0; i<nthreads; i+=1)
            ThreadStart threadGroupID,i,MyWorkerFunc(dest,col)
            col+=1
            if( col>=ncol )
                break
            endif
        endfor

        do
            Variable threadGroupStatus= ThreadGroupWait(threadGroupID,100)
            while( threadGroupStatus != 0 )
            endfor
        Variable dummy= ThreadGroupRelease(threadGroupID)
    End

Function STFillWave(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable col

    for(col= 0;col<ncol;col+=1)
        MyWorkerFunc(dest,col)
    endfor
End

Function ThreadTest(rows)
    Variable rows

    Variable cols=10

    make/o/n=(rows,cols) jack

    Variable i
```

```

for(i=0;i<10;i+=1)      // get any pending pause events out of the way
endfor

Variable ttime= stopMSTimer(-2)

Variable t0= stopMSTimer(-2)
MTFillWave(jack)
Variable t1= stopMSTimer(-2)
STFillWave(jack)
Variable t2= stopMSTimer(-2)

ttime= (stopMSTimer(-2) - ttime)*1e-6

// Times are in microseconds
printf "ST: %d, MT: %d; ",t2-t1,t1-t0
printf "speed up factor: %.3g; total time= %.3gs\r", (t2-t1)/(t1-t0),ttime
End

```

The empty loop above is necessary because of periodic pauses in execution when Igor checks for user aborts. If a pause was pending, we want to get it out of the way beforehand to avoid it affecting the first timing test.

After starting Igor Pro, there is initially some extra overhead associated with creating new threads. Consequently, in the test results to follow, the first test is run twice.

Results for Mac Mini 1.66 GHz Core Duo, OS X 10.4.6:

```

•ThreadTest(100)
  ST: 223, MT: 1192; speed up factor: 0.187; total time= 0.00146s
•ThreadTest(100)
  ST: 211, MT: 884; speed up factor: 0.239; total time= 0.0011s
•ThreadTest(1000)
  ST: 1991, MT: 1821; speed up factor: 1.09; total time= 0.00381s
•ThreadTest(10000)
  ST: 19857, MT: 11921; speed up factor: 1.67; total time= 0.0318s
•ThreadTest(100000)
  ST: 199174, MT: 113701; speed up factor: 1.75; total time= 0.313s
•ThreadTest(1000000)
  ST: 2009948, MT: 1146113; speed up factor: 1.75; total time= 3.16s

```

As you can see, when there is sufficient work to be done, the speed up factor approaches the theoretical maximum of 2 for dual processors.

Now on the same computer but booting into Windows XP Pro:

```

•ThreadTest(100)
  ST: 245, MT: 523; speed up factor: 0.468; total time= 0.000776s
•ThreadTest(100)
  ST: 399, MT: 247; speed up factor: 1.61; total time= 0.000655s
•ThreadTest(1000)
  ST: 3526, MT: 1148; speed up factor: 3.07; total time= 0.00468s
•ThreadTest(10000)
  ST: 34830, MT: 10467; speed up factor: 3.33; total time= 0.0453s
•ThreadTest(100000)
  ST: 350253, MT: 99298; speed up factor: 3.53; total time= 0.45s
•ThreadTest(1000000)
  ST: 2837645, MT: 1057275; speed up factor: 2.68; total time= 3.89s

```

So, what is happening here? The speed-up factors for Windows XP are greater than for Mac OS X, but mostly because the ST version is much slower. We do not know why the ST version runs more slowly — the Benchmark 2.01 example experiment shows similar values for OS X vs. XP on this same computer.

## Parallel Processing - Thread-at-a-Time Method

In the previous section, we dispatched a group of threads, waited for them to all finish, and then dispatched another group of threads. Using that technique, a slow thread in the group would cause all of the group's threads to wait.

In this section, we dispatch a thread anytime there is a free thread in the group. This technique requires Igor Pro 6.23 or later.

## Chapter IV-10 — Advanced Topics

---

The only thing that changes from the preceding example is that the MTFillWave function is replaced with this MTFillWaveThreadAtATime function:

```
Function MTFillWaveThreadAtATime(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable col,nthreads= ThreadProcessorCount
    Variable threadGroupID= ThreadGroupCreate(nthreads)
    Variable dummy

    for(col=0; col<ncol; col+=1)
        // Get index of a free thread - Requires Igor Pro 6.23 or later
        Variable threadIndex = ThreadGroupWait(threadGroupID,-2) - 1
        if (threadIndex < 0)
            dummy = ThreadGroupWait(threadGroupID, 50)// Let threads run a while
            col -= 1                                // Try again for the same column
            continue                                // No free threads yet
        endif
        ThreadStart threadGroupID, threadIndex, MyWorkerFunc(dest,col)
    endfor

    // Wait for all threads to finish
    do
        Variable threadGroupStatus = ThreadGroupWait(threadGroupID,100)
        while(threadGroupStatus != 0)

        dummy = ThreadGroupRelease(threadGroupID)
    End
```

The ThreadGroupWait statement suspends the main thread for a while so that the preemptive threads get more processor time. The parameter 50 is the number of milliseconds to wait. You should tune this for your application.

### Input/Output Queues

In this example, data folders containing a data wave and a string variable that specifies the task to be performed are created and posted to the thread group's input queue. The thread worker function waits for an input data folder to become available. It then processes the input and posts an output data folder to the thread group's output queue from which it is retrieved by the main thread.

```
ThreadSafe Function MyWorkerFunc()
    do
        do
            DFREF dfr = ThreadGroupGetDFR(0,1000)// Get free data folder from input queue
            if (DataFolderRefStatus(dfr) == 0)
                if( GetRTError(2) ) // New in 6.20 to allow this distinction:
                    Print "worker closing down due to group release"
                else
                    Print "worker thread still waiting for input queue"
                endif
            else
                break
            endif
        while(1)

        SVAR todo = dfr:todo
        WAVE jack = dfr:jack

        NewDataFolder/S outDF

        Duplicate jack,outw // WARNING: outw must be cleared. See WAVEClear below
        String/G did= todo
        if( CmpStr(todo,"sin") )
            outw= sin(outw)
        else
```

```

        outw= cos(outw)
    endif

    // Clear outw so Duplicate above does not try to use it and to allow
    // ThreadGroupPutDF to succeed.
    WAVEClear outw

    ThreadGroupPutDF 0,: // Put current data folder in output queue

    KillDataFolder dfr // We are done with the input data folder
while(1)

return 0
End

Function DemoThreadQueue()
    Variable i,ntries= 5,nthreads= 2

    Variable/G threadGroupID = ThreadGroupCreate(nthreads)

    for(i=0;i<nthreads;i+=1)
        ThreadStart threadGroupID,i,MyWorkerFunc()
    endfor

    for(i=0;i<ntries;i+=1)
        NewDataFolder/S forThread
        String/G todo
        if( mod(i,3) == 0 )
            todo= "sin"
        else
            todo= "cos"
        endif
        Make/N= 5 jack= x + gnoise(0.1)

        WAVEClear jack

        ThreadGroupPutDF threadGroupID,: // Send current data folder to input queue
    endfor

    for(i=0;i<ntries;i+=1)
        do
            // Get results in free data folder
            DFREF dfr= ThreadGroupGetDFR(threadGroupID,1000)
            if ( DatafolderRefStatus(dfr) == 0 )
                Print "Main still waiting for worker thread results."
            else
                break
            endif
        while(1)

        SVAR did = dfr:did
        WAVE outw = dfr:outw

        Print "task= ",did,"results= ",outw

        // The next two statements are not really needed as the same action
        // will happen the next time through the loop or, for the last iteration,
        // when this function returns.
        WAVEClear outw // Redundant because of the WAVE statement above
        KillDataFolder dfr // Redundant because dfr refers to a free data folder
    endfor

    // This terminates the MyWorkerFunc by setting an abort flag
    Variable tstatus= ThreadGroupRelease(threadGroupID)
    if( tstatus == -2 )
        Print "Thread would not quit normally, had to force kill it. Restart Igor."
    endif
End

```

Typical output:

```

•DemoThreadQueue()
  task=   sin   results=
outw[0]= {0.994567,0.660904,-0.516692,-0.996884,-0.63106}
  task=   cos   results=

```

```
outw[0]= {0.0786631,0.709576,0.873524,0.0586175,-0.718122}  
task=    cos results=  
outw[0]= {-0.23686,0.848603,0.871922,0.0992451,-0.856209}  
task=    sin results=  
outw[0]= {0.999734,0.531563,-0.172071,-0.931296,-0.750942}  
task=    cos results=  
outw[0]= {-0.166893,0.767707,0.925874,0.114511,-0.662994}  
worker closing down due to group release  
worker closing down due to group release
```

### Parallel Processing With Large Datasets

In the preceding section we synthesized the input data. In the real-world, your input data would most-likely be in an existing wave and you would have to copy it to a data folder to put into the input queue.

If your input data is very large, for example, a 3D stack of images, copying would require too much memory. In that case, a good choice is to pass the input directly to the thread using parameters to the thread worker function and use the output queue to return output to the main thread.

To do this you can use the **Parallel Processing - Thread-at-a-Time Method** and the output queue to return results.

### Preemptive Background Task

In this example, we create a single worker thread that runs while the user does other things. A normal cooperative background task retrieves results from the preemptive thread. Although the background task will sometimes be blocked (as described in **Background Tasks** on page IV-298) the preemptive worker thread will always be running or waiting for data.

Another example of this kind of multitasking can be found in the “Slow Data Acq” demo experiment referenced under **More Multitasking Examples** on page IV-316.

In some cases, it may be possible to run two instances of Igor instead of using a preemptive background task. Running two instances is far simpler, so use that approach if it is feasible.

We put the code for the background tasks in an independent module (see **The IndependentModule Pragma** on page IV-51) so that the user can recompile procedures, which is done automatically when a recreation macro is created, without stopping the background task.

You might use a preemptive background task is when you have lengthy computations but want to continue to do other things, such as creating graphics for publication. Although you can do anything you want while the task runs in the experiment, if you load a different experiment, the thread is killed.

For this example, our “lengthy computation” is simply creating a wave of sine values which is not lengthy at all and consequently there is no reason for using a preemptive thread in this case. To simulate a lengthy computation, the code delays for a few seconds before posting its results.

The named background task checks the output queue every 10 ticks, when it is not blocked, and updates a graph with data retrieved from the queue.

Independent modules can not be defined in the built-in procedure window so paste the following code in a new procedure window:

```
#pragma IndependentModule= PreemptiveExample  
  
ThreadSafe Function MyWorkerFunc()  
do  
    DFREF dfr = ThreadGroupGetDFR(0,inf)  
    if( DataFolderRefStatus(dfr) == 0 )  
        return -1 // Thread is being killed  
    endif  
  
    WAVE frequencies = dfr:frequencies // Array of frequencies to calculate  
    Variable i, n= numpts(frequencies)  
  
    for(i=0;i<n;i+=1)
```

```

        NewDataFolder/S resultsDF
        Make jack= sin(frequencies[i]*x)

        Variable t0= ticks
        do
            // waste cpu for a few seconds
            while(ticks < (t0+120))

            // ThreadGroupPutDF requires that no waves in the data folder be referenced
            WAVEClear jack

            ThreadGroupPutDF 0,:          // Send current data folder to input queue
        endfor

        KillDataFolder dfr          // We are done with the input data folder
    while(1)

    return 0
End

```

```

Function DisplayResults(s)    // Called from cooperative background task
    STRUCT WMBBackgroundStruct &s

    DFREF dfSav= GetDataFolderDFR()

    SetDataFolder root:testdf
    NVAR threadGroupID
    DFREF dfr = ThreadGroupGetDFR(threadGroupID,0) // Get free data folder from queue
    if( DataFolderRefStatus(dfr) != 0 )
        // Make free data folder a regular data folder in root:testdf
        MoveDataFolder dfr, :

        // Give data folder a unique name
        String dfName = UniqueName("Results", 11, 0)
        RenameDataFolder dfr, $dfName

        WAVE jack = dfr:jack          // This is the output from the thread
        AppendToGraph/W=ThreadResultsGraph jack
    endif

    SetDataFolder dfSav
    return 0
End

```

And put this in the main procedure window:

```

Function DemoPreemptiveBackgroundTask()
    DFREF dfSav= GetDataFolderDFR()

    NewDataFolder/O/S root:testdf // thread group ID and result datafolders go here
    variable/G threadGroupID= ThreadGroupCreate(1)
    ThreadStart threadGroupID,0,PreemptiveExample#MyWorkerFunc()

    // MyWorkerFunc is now running and waiting for input data
    // now, let's give it something to do
    NewDataFolder/S tasks
    Make/N=10 frequencies= 1/(10+p/2+enoise(0.2))// array of frequencies to calculate
    WAVEClear frequencies

    ThreadGroupPutDF threadGroupID,:          // thread is now crunching away

    // Results will be appended to this graph
    Display /N=ThreadResultsGraph as "Thread Results"

    // ...by this named task
    CtrlNamedBackground ThreadResultsTask,period=10,proc=PreemptiveExample#DisplayResults,start

    SetDataFolder dfSav          // restore current df
End

Function PostMoreFreqs()
    NVAR threadGroupID = root:testdf:threadGroupID

    NewDataFolder/S moretasks
    Make/N=50 frequencies= 1/(15+p/2+enoise(0.2)) // array of frequencies to calculate
    WAVEClear frequencies

```

## Chapter IV-10 — Advanced Topics

---

```
ThreadGroupPutDF threadGroupID, :           // thread continues crunching
End
```

Open the Data Browser and then, on the command line, execute:

```
DemoPreemptiveBackgroundTask()
```

After the action stops, send more tasks to the background thread by executing

```
PostMoreFreqs()
```

While this is running, experiment with creating graphs, using dialogs, creating functions, etc. Note that both tasks run indefinitely.

To start over you need to stop the preemptive background task, stop the named background task, kill the graph, and delete the data. This function, which you can paste into the main procedure window, will do it.

```
Function StopDemo()
    NVAR threadGroupID = root:testdf:threadGroupID

    // Stop preemptive thread
    Variable status = ThreadGroupRelease(threadGroupID)

    // Stop named background task
    CtrlNamedBackground ThreadResultsTask, stop

    // Kill graph
    DoWindow /K ThreadResultsGraph

    // Kill data
    KillDataFolder root:testdf
End
```

### More Multitasking Examples

More multitasking examples can be found in the following example experiments:

The Multithreaded LoadWave demo experiment in “Igor Pro 7 Folder/Examples/Programming”.

The Multithreaded Mandelbrot demo experiment in “Igor Pro 7 Folder/Examples/Programming”.

The Multiple Fits in Threads demo experiment in Igor “Pro Folder/Examples/Curve Fitting”.

The Slow Data Acq demo experiment in “Igor Pro 7 Folder/Examples/Programming”.

The Thread-at-a-Time demo experiment in “Igor Pro 7 Folder/Examples/Programming”.

## Cursors — Moving Cursor Calls Function

You can write a hook function which Igor calls whenever a cursor is moved.

### Graph-Specific Cursor Moved Hook

The preferred way to do this is to use SetWindow to designate a window hook function for a specific graph window (see **Window Hook Functions** on page IV-276). In your window hook function, look for the cursor-moved event. Your hook function receives a **WMWinHookStruct** structure containing fields that describe the cursor and its properties.

For a demo of this technique, choose File→Example Experiments→Techniques→Cursor Moved Hook Demo.

### Global Cursor Moved Hook

This section describes an old technique in which you create a hook function that is called any time a cursor is moved in any graph. This technique is more difficult to implement and kludgy, so it is no longer recommended.

You can write a hook function named `CursorMovedHook`. Igor automatically calls it whenever any cursor is moved in any graph, unless Option (*Macintosh*) or Alt (*Windows*) is pressed.

The `CursorMovedHook` function takes one string argument containing information about the graph, trace or image, and cursor in the following format:

```
GRAPH:graphName;CURSOR:<A - J>;TNAME:traceName; MODIFIERS:modifierNum;
ISFREE:freeNum;POINT:xPointNumber; [YPOINT:yPointNumber;]
```

The `traceName` value is the name of the graph trace or image to which the cursor is attached.

The `modifierNum` value represents the state of some of the keyboard keys summed together:

- 1 If Command (*Macintosh*) or Ctrl (*Windows*) is pressed.
- 2 If Control (*Macintosh only*) is pressed.
- 4 If Shift is pressed.
- 8 If Caps Lock is pressed.

The Option key (*Macintosh*) or Alt key (*Windows*) is not represented because it prevents the hook from being called.

The YPOINT keyword and value are present only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot or when the cursor is free.

If cursor is free, POINT and YPOINT values are fractional relative positions (see description in **Cursor** operation on page V-104). If TNAME is empty, fields POINT, ISFREE and YPOINT are not present.

This example hook function simply prints the information in the history area:

```
Function CursorMovedHook(info)
    String info
    Print info
End
```

Whenever any cursor on any graph is moved, this `CursorMovedHook` function will print something like the following in the history area:

```
GRAPH:Graph0;CURSOR:A;TNAME:jack;MODIFIERS:0;ISFREE:0;POINT:6;
```

## Cursor Globals

On older technique involving globals named `S_CursorAInfo` and `S_CursorBInfo` is no longer recommended. For details, see the “Cursor Globals” subtopic in the Igor6 help files.

## Profiling Igor Procedures

You can find bottlenecks in your procedures using profiling.

Profiling is supported by the `FunctionProfiling.ipf` file. To use it, add this to your procedures:

```
#include <FunctionProfiling
```

Then choose Windows→Procedures→`FunctionProfiling.ipf` and read the instructions in the file.

## Crashes

A crash results from a software bug and prevents a program from continuing to run. Crashes are highly annoying at best and, at worst, can cause you to lose valuable work.

WaveMetrics uses careful programming practices and extensive testing to make Igor as reliable and bug-free as we can. However in Igor as in any complex piece of software it is impossible to exterminate all bugs. Also, crashes can sometimes occur in Igor because of bugs in other software, such as printer drivers, video drivers or system extensions.

We are committed to keeping Igor a solid and reliable program. If you experience a crash, we would like to know about it.

When reporting a crash to WaveMetrics, please start by choosing Help-Contact Support. This provides us with important information such as your Igor version and your OS version.

Please include the following in your report:

- A description of what actions preceded the crash and whether it is reproducible.
- A recipe for reproducing the crash, if possible.
- A crash log (described below), if possible.

In most cases, to fix a crash, we need to be able to reproduce it.

### Crash Logs on Mac OS X

When a crash occurs on Mac OS X, most of the time the system is able to generate a crash log. You can usually find it at:

`/Users/<user>/Library/Logs/DiagnosticReports/Igor Pro_<date>_<machinename>.crash`

where <user> is your user name.

The `/Users/<user>/Library` folder is hidden. To reveal the DiagnosticReports folder:

1. Choose Finder->Go to Folder
2. Enter `~/Library/Logs/DiagnosticReports`
3. Click Go

Send this log as an attachment when reporting a crash.

### Crashes On Windows

When a crash occurs on Windows, Igor attempts to write a crash report that may help WaveMetrics determine and fix the cause of the crash. If Igor is able to write a crash report, it displays a dialog showing the location of the crash report on disk. The location is in your Igor preferences folder and will be something like:

`C:\Users\<user>\AppData\Roaming\WaveMetrics\Igor Pro 7\Diagnostics\Igor Crash Reports.txt`

If the "Igor Crash Reports.txt" file already exists when a crash occurs, Igor appends a new report to the existing file.

Igor may also write a minidump file to the same folder. A minidump file, which has a ".dmp" extension, contains additional information about the crash. There will typically be one minidump file for each crash.

When a crash occurs, Igor attempts to open the Diagnostics folder on your desktop to make it easy for you to find the report and minidump files.

Please send the "Igor Crash Reports.txt" file, along with the minidump files related to the current crash, as email attachments to WaveMetrics support. If possible, include instructions for reproducing the crash and any other details that may help us understand what you were doing leading to the crash.

Once the problem has been resolved, if you want to reduce clutter and reclaim disk space, you can delete the Diagnostics folder and its contents. Igor will recreate the folder if necessary.

There may be cases where Igor is not able to write a crash report. This would happen if a library, security software or the operating system has overridden Igor's crash handler for some reason.

# Igor Reference

This volume contains detailed information about Igor Pro's built-in operations, functions, and keywords. They are listed alphabetically after the category sections that follow.

External operations (XOPs) and external functions (XFUNCS) are not covered here. For information about them, use the Command Help tab of the Igor Help Browser.

## Built-In Operations by Category

**Note:** Some operations may appear in more than one category.

### Graphs

AppendText	AppendToGraph	AppendToLayout	CheckDisplayed
ColorScale	ColorTab2Wave	ControlBar	Cursor
DefaultFont	DefineGuide	DelayUpdate	DeleteAnnotations
Display	DoUpdate	DoWindow	ErrorBars
GetAxis	GetMarquee	GetSelection	GetWindow
GraphNormal	GraphWaveDraw	GraphWaveEdit	HideInfo
HideTools	KillFreeAxis	KillWindow	Label
Legend	ModifyFreeAxis	ModifyGraph	ModifyWaterfall

## Alphabetic Listing of Functions, Operations and Keywords

This section alphabetically lists all built-in functions, operations and keywords. Much of this information is also accessible online in the Command Help tab of the Igor Help Browser.

External operations (XOPs) and external functions (XFUNCs) are not covered here. For information about them, use the Command Help tab of the Igor Help Browser and the XOP help file in the same folder as the XOP file.

### Reference Syntax Guide

In the descriptions of functions and operations that follow, italics indicate parameters for which you can supply numeric or string expressions. Non-italic keywords must be entered literally as they appear. Commas, slashes, braces and parentheses in these descriptions are always literals. Brackets surround optional flags or parameters. Ellipses (...) indicate that the preceding element may be repeated a number of times.

Italicized parameters represent values you supply. Italic words ending with “*Name*” are names (wave names, for example), and those ending with “*Str*” are strings. Italic words ending with “*Spec*” (meaning “specification”) are usually further defined in the description. If none of these endings are employed, the italic word is a numeric expression, such as a literal number, the name of a variable or function, or some valid combination.

Strings and names are different, but you can use a string where a name is expected using “string substitution”: precede a string expression with the \$ operator. See **String Substitution Using \$** on page IV-17.

A syntax description may span several lines, but the actual command you create must occupy a single line.

Many operations have optional “flags”. Flags that accept a value (such as the Make operation’s /N=*n* flag) sometimes require additional parentheses. For example:

```
Make/N=1 aNewWave
```

is acceptable because here *n* is the literal “1”. To use a numeric expression (anything other than a literal number) for *n*, parentheses are needed:

```
Make/N=(numberOfPoints) aNewWave           // error if no parentheses!
```

For more about using functions, operations and keywords, see Chapter IV-1, **Working with Commands**, Chapter IV-2, **Programming Overview**, and Chapter IV-10, **Advanced Topics**.

### #define

**#define** *symbol*

The **#define** statement is a conditional compilation directive that defines a *symbol* for use only with **#ifdef** or **#ifndef** expressions. **#undef** removes the definition.

#### Details

The defined *symbol* exists only in the file where it is defined; the only exception is in the main procedure window where the scope covers all other procedures except independent modules. See **Conditional Compilation** on page IV-100 for information on defining a global *symbol*.

**#define** cannot be combined inline with other conditional compilation directives.

#### See Also

The **#undef**, **#ifdef-#endif**, and **#ifndef-#endif** statements.

**Conditional Compilation** on page IV-100.

### #if-#elif-#endif

```
#if expression1
    <TRUE part 1>
#elif expression2
    <TRUE part 2>
[...]
[#else
    <FALSE part>]
#endif
```

In a **#if-#elif-#endif** conditional compilation statement, when an expression evaluates as TRUE (absolute value > 0.5), then only code corresponding to the TRUE part of that expression is compiled, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then *FALSE part* is compiled when present.

#### Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

#### See Also

**Conditional Compilation** on page IV-100 for more usage details.

### #if-#endif

```
#if expression
    <TRUE part>
[#else
    <FALSE part>]
#endif
```

A **#if-#endif** conditional compilation statement evaluates *expression*. If *expression* is TRUE (absolute value > 0.5) then the code in *TRUE part* is compiled, or if FALSE (zero) then the optional *FALSE part* is compiled.

#### Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

#### See Also

**Conditional Compilation** on page IV-100 for more usage details.

## #ifdef-#endif

```
#ifdef symbol
  <TRUE part>
[#else
  <FALSE part>]
#endif
```

A #ifdef-#endif conditional compilation statement evaluates *symbol*. When *symbol* is defined the code in *TRUE part* is compiled, or if undefined then the optional *FALSE part* is compiled.

### Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

*symbol* must be defined before the conditional with #define.

### See Also

The #define statement and **Conditional Compilation** on page IV-100 for more usage details.

## #ifndef-#endif

```
#ifndef symbol
  <TRUE part>
[#else
  <FALSE part>]
#endif
```

An #ifndef-#endif conditional compilation statement evaluates *symbol*. When *symbol* is undefined the code in *TRUE part* is compiled, or if defined then the optional *FALSE part* is compiled.

### Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

*symbol* must be defined before the conditional with #define.

### See Also

The #define statement and **Conditional Compilation** on page IV-100 for more usage details.

## #include

```
#include "file spec" or <file spec>
```

A #include statement in a procedure file automatically opens another procedure file. You should use #include in any procedure file that you write if it requires that another procedure file be open. A #include statement must always appear flush against the left margin in a procedure window.

### Parameters

*file spec* is the procedure file name, which can incorporate a full or partial path. The form used depends of the procedure file location: <*file spec*> is in "Igor Pro 7 Folder/WaveMetrics Procedures" and "*file spec*" is in "Igor Pro 7 Folder/User Procedures" or "Igor Pro User Files/User Procedures".

### See Also

**The Include Statement** on page IV-155 for usage details.

**Igor Pro User Files** on page II-31.

## #pragma

```
#pragma pragmaName = value
```

#pragma introduces a compiler directive, which is a message to the Igor procedure compiler. A #pragma statement must always appear flush against the left margin in a procedure window.

Igor ignores unknown pragmas such as pragmas introduced in later versions of the program.

Currently Igor supports the following pragmas:

## #undef

---

```
#pragma rtGlobals = value
#pragma version = versionNumber
#pragma IgorVersion = versionNumber
#pragma hide = value
#pragma ModuleName = name
#pragma IndependentModule = name
#pragma rtFunctionErrors = value
#pragma TextEncoding = "textEncodingName"
```

### See Also

**Pragmas** on page IV-48

**The rtGlobals Pragma** on page IV-48

**The version Pragma** on page IV-50

**The IgorVersion Pragma** on page IV-50

**The hide Pragma** on page IV-50

**The ModuleName Pragma** on page IV-50

**The IndependentModule Pragma** on page IV-51

**The rtFunctionErrors Pragma** on page IV-51

**The TextEncoding Pragma** on page IV-51

## #undef

### #undef *symbol*

A `#undef` statement removes a nonglobal *symbol* created previously by `#define`. See **Conditional Compilation** on page IV-100 for information on undefining a global *symbol*.

### See Also

The `#define` statement and **Conditional Compilation** on page IV-100 for more usage details.

## Abort

### Abort [*errorMessageStr*]

The Abort operation aborts procedure execution.

### Parameters

The optional *errorMessageStr* is a string expression, which, if present, specifies the message to be displayed in the error alert.

### Details

Abort provides a way for a procedure to abort execution when it runs into an error condition.

### See Also

**Aborting Functions** on page IV-103, **Aborting Macros** on page IV-115, and **Flow Control for Aborts** on page IV-45. The **DoAlert** operation.

## AbortOnRTE

### AbortOnRTE

The AbortOnRTE flow control keyword raises an abort with a runtime error.

AbortOnRTE should be used after a command that might give rise to a runtime error.

You can place AbortOnRTE immediately after a command that might give rise to a runtime error that you want to handle instead of allowing Igor to handle it by halting procedure execution. Use a **try-catch-endtry** block to catch the abort, if it occurs.

AbortOnRTE has very low overhead and should not significantly slow program execution.

### Details

In terms of programming style, you should consider using AbortOnRTE (preceded by a semicolon) on the same line as the command that may give rise to an abort condition.

When using AbortOnRTE after a related sequence of commands, then it should be placed on its own line. When used with try-catch-endtry, you should place a call to **GetRTEError**(1) in your catch section to clear the runtime error.

#### Example

Abort if the wave does not exist:

```
WAVE someWave; AbortOnRTE
```

#### See Also

**Flow Control for Aborts** on page IV-45 and **AbortOnRTE Keyword** on page IV-45 for further details. The **try-catch-endtry** flow control statement.

## AbortOnValue

**AbortOnValue** *abortCondition*, *abortCode*

The AbortOnValue flow control keyword will abort function execution when the *abortCondition* is nonzero and it will then return the numeric *abortCode*. No dialog will be displayed when such an abort occurs.

#### Parameters

*abortCondition* can be any valid numeric expression using comparison or logical operators.

*abortCode* is a nonzero numeric value returned to any abort or error handling code by AbortOnValue whenever it causes an abort.

#### Details

When used with try-catch-endtry, you should place a call to **GetRTEError**(1) in your catch section to clear the runtime error.

#### See Also

**Flow Control for Aborts** on page IV-45 and **AbortOnValue Keyword** on page IV-45 for further details. The **AbortOnRTE** keyword and the **try-catch-endtry** flow control statement.

## abs

**abs** (*num*)

The abs function returns the absolute value of the real number *num*. To calculate the absolute value of a complex number, use the cabs function.

#### See Also

The **cabs** function.

## acos

**acos** (*num*)

The acos function returns the inverse cosine of *num* in radians in the range  $[0, \pi]$ .

In complex expressions, *num* is complex and acos returns a complex value.

#### See Also

**cos**

## acosh

**acosh** (*num*)

The acosh function returns the inverse hyperbolic cosine of *num*. In complex expressions, *num* is complex and acosh returns a complex value.

### AddFIFOData

**AddFIFOData** *FIFOName*, *FIFO\_channelExpr* [, *FIFO\_channelExpr*]...

The AddFIFOData operation evaluates *FIFO\_channelExpr* expressions as double precision floating point and places the resulting values into the named FIFO.

#### Details

There must be one *FIFO\_channelExpr* for each channel in the FIFO.

#### See Also

FIFOs are used for data acquisition. See **FIFOs and Charts** on page IV-291.

Other operations used with FIFOs: **NewFIFO**, **NewFIFOChan**, **CtrlFIFO**, and **FIFOStatus**.

### AddFIFOVectData

**AddFIFOVectData** *FIFOName*, *FIFO\_channelKeyExpr* [, *FIFO\_channelKeyExpr*]...

The AddFIFOVectData operation is similar to AddFIFOData except the expressions use a keyword to allow either a single numeric value for a normal channel or a wave containing the data for a special image vector channel.

#### Details

There must be one *FIFO\_channelKeyExpr* for each channel in the FIFO.

A *FIFO\_channelKeyExpr* may be one of:

```
num = numericExpression
vect = wave
```

For best results, the wave should have the same number of points as used to define the FIFO channel and the same number type. See the **NewFIFOChan** operation.

#### See Also

**FIFOs and Charts** on page IV-291.

### AddListItem

**AddListItem**(*itemStr*, *listStr* [, *listSepStr* [, *itemNum*]])

The AddListItem function returns *listStr* after adding *itemStr* to it. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use AddListItem to add an item to a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or to a line from a delimited text file.

*listSepStr* and *itemNum* are optional; their defaults are ";" and 0, respectively.

#### Details

By default *itemStr* is added to the start of the list. Use the optional list index *itemNum* to add *itemStr* at a different location. The returned list will have *itemStr* at the index *itemNum* or at **ItemsInList**(*returnedListStr*)-1 when *itemNum* equals or exceeds **ItemsInList**(*listStr*).

*itemNum* can be any value from -infinity (-Inf) to infinity (Inf). Values from -infinity to 0 prepend *itemStr* to the list, and values from **ItemsInList**(*listStr*) to infinity append *itemStr* to the list.

*itemStr* may be "", in which case an empty item (consisting of only a separator) is added.

If *listSepStr* is "", then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case an empty string ("") is returned).

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't.

In Igor6, only the first byte of *listSepStr* was used. In Igor7 and later, all bytes are used.

#### Examples

```
Print AddListItem("hello","kitty;cat;")           // prints "hello;kitty;cat;"
Print AddListItem("z", "b,c", "", "", 1)          // prints "b,z,c,"
Print AddListItem("z", "b,c", "", "", 999)         // prints "b,c,z,"
Print AddListItem("z", "b,c", "", "", Inf)         // prints "b,c,z,"
Print AddListItem("", "b-c-", "-")                 // prints "-b-c-"
```

**See Also**

The **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveFromList**, **RemoveListItem**, **StringFromList**, **StringList**, **TraceNameList**, **VariableList**, and **WaveList** functions.

## AddMovieAudio

**AddMovieAudio** *soundWave*

The AddMovieAudio operation adds audio samples to the audio track of the currently open movie.

In Igor Pro 7.00 and later, this operation is not supported on Macintosh.

**Parameters**

*soundWave* contains audio samples with an amplitude from -128 to +127 and with the same time scale as the prototype *soundWave* used to open the movie.

**Details**

You can create movies with 16-bit and stereo sound by providing a sound wave in the appropriate format. To specify 16-bit sound, the wave type must be signed 16-bit integer (/W flag in **Make** or **Redimension**). To specify stereo, use a wave with two columns (or any other number of channels as desired).

**See Also**

**Movies** on page IV-230.

The **NewMovie** operation.

## AddMovieFrame

**AddMovieFrame** [/PICT=*pictName*]

The AddMovieFrame operation adds the top graph, page layout, Gizmo window, or the specified picture to the currently open movie.

Support for page layout and Gizmo windows was added in Igor Pro 7.00.

When you write a procedure to generate a movie, you need to call the **DoUpdate** operation after all modifications to the target window and before calling AddMovieFrame. This allows Igor to process any changes you have made to the window.

In Igor7 or later, the target window at the time you call NewMovie is remembered and is used by AddMovieFrame even if it is not the target window when you call AddMovieFrame.

If the /PICT flag is provided, then the specified picture from the picture gallery (see **Pictures** on page III-448) is used in place of the target window.

**See Also**

**Movies** on page IV-230.

The **NewMovie** operation.

## AdoptFiles

**AdoptFiles** [*flags*]

The AdoptFiles operation adopts external files and waves into the current experiment.

When the experiment is next saved, the files and waves are saved in the experiment file for a packed experiment or in the experiment folder for an unpacked experiment. References to the external files are eliminated.

AdoptFiles cannot be called from a function except via Execute/P.

**Flags**

/A	Adopts all external notebooks and user procedure files and all waves in the experiment. WaveMetrics Procedure files are not adopted. /A is equivalent to /NB/UP/DF.
/DF	Adopts all waves saved external to the experiment.

<code>/DF=<i>dataFolderPathStr</i></code>	Adopts all waves saved external to the experiment that are in the specified data folder.
<code>/I</code>	Shows the Adopt All dialog and adopts what the user selects there.
<code>/NB</code>	Adopts all external notebook files.
<code>/UP</code>	Adopts all external user procedure files.
<code>/W=<i>winTitleOrName</i></code>	Adopts the specified notebook or procedure file. <code>/W</code> was added in Igor Pro 7.02. <i>winTitleOrName</i> is a name, not a string, so you construct <code>/W</code> like this: <code>/W=\$"New Polar Graph.ipf"</code> or: <code>/W=Notebook0</code> When working with independent modules, <i>winTitleOrName</i> is a procedure window title followed by a space and, in brackets, an independent module name. See <b>Independent Modules</b> on page IV-224 for details.
<code>/WP</code>	Adopts all WaveMetrics Procedure procedure files.
<code>/WV=<i>wave</i></code>	Adopts only the specified wave.

### Details

Only files and waves saved external to the current experiment are adopted. See **References to Files and Folders** on page II-22 for a discussion of such standalone files.

The number of objects actually adopted is returned in `V_Flag`.

To adopt just one wave, use:

```
AdoptFiles/WV=wave
```

To adopt just one notebook or procedure window use `AdoptFiles/W=winTitleOrName`.

### Command Line and Macro Examples

```
// Using AdoptFiles from the command line or from a macro
AdoptFiles/I           // Show the Adopt All dialog.
AdoptFiles/A/WP        // Adopt everything that can be adopted.
AdoptFiles/DF/NB/UP/WP // Adopt everything that can be adopted.
AdoptFiles/DF=root:subfolder // Adopt any externally saved waves in root:subfolder.
AdoptFiles/W=$"Proc0.ipf" // Adopt Proc0.ipf if it is saved externally.
AdoptFiles/WV=GetWavesDataFolder(wave0,2) // Adopt wave0 if it is saved externally.
```

### Function Examples

```
// Using AdoptFiles from a user-defined function - you must use Execute/P
Execute/P "AdoptFiles/A" // Schedule adoption of all user files and waves
Execute/P "AdoptFiles/WV="+GetWavesDataFolder(w,2) // Schedule adoption of wave w
```

## airyA

**airyA**(*x* [, *accuracy*])

The airyA function returns the value of the Airy  $Ai(x)$  function:

$$Ai(x) = \frac{1}{\pi} \sqrt{\frac{x}{3}} K_{1/3} \left( \frac{2}{3} x^{3/2} \right),$$

where  $K$  is the modified Bessel function.

### Details

See the **bessI** function for details on accuracy and speed of execution.

#### See Also

The **airyAD** and **airyB** functions.

#### References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

## airyAD

**airyAD**(*x* [, *accuracy*])

The airyAD function returns the value of the derivative of the Airy function.

#### Details

See the **bessI** function for details on accuracy and speed of execution.

#### See Also

The **airyA** function.

## airyB

**airyB**(*x* [, *accuracy*])

The airyB function returns the value of the Airy  $Bi(x)$  function:

$$Bi(x) = \sqrt{\frac{x}{3}} \left[ I_{-1/3} \left( \frac{2}{3} x^{3/2} \right) + I_{1/3} \left( \frac{2}{3} x^{3/2} \right) \right],$$

where  $I$  is the modified Bessel function.

#### Details

See the **bessI** function for details on accuracy and speed of execution.

#### See Also

The **airyBD** and **airyA** functions.

#### References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

## airyBD

**airyBD**(*x* [, *accuracy*])

The airyBD function returns the value of the derivative  $Bi'(x)$  of the Airy function.

#### Details

See the **bessI** function for details on accuracy and speed of execution.

#### See Also

The **airyB** function.

## a log

**a log**(*num*)

The alog function returns  $10^{num}$ .

## AnnotationInfo

**AnnotationInfo**(*winNameStr*, *annotationNameStr* [, *options*])

The AnnotationInfo function returns a string containing a semicolon-separated list of information about the named annotation in the named graph or page layout window or subwindow.

The main purpose of AnnotationInfo is to use a tag or textbox as an input mechanism to a procedure. This is illustrated in the "Tags as Markers Demo" sample experiment, which includes handy utility functions (supplied by AnnotationInfo Procs.ipf).

### Parameters

*winNameStr* can be "" to refer to the top graph or layout window or subwindow.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

*options* is an optional parameter that controls the text formatting in the annotation output. The default value is 0.

Omit *options* or use 0 for *options* to escape the returned annotation text, which is appropriate for printing the output to the history or for using the text in an Execute operation.

Use 1 for *options* to not escape the returned annotation text because you intend to extract the text for use in a subsequent command such as Textbox or Tag.

### Details

The string contains thirteen pieces of information. The first twelve pieces are prefaced by a keyword and colon and terminated with a semicolon. The last piece is the annotation text, which is prefaced with a keyword and a colon but is not terminated with a semicolon.

Keyword	Information Following Keyword
ABSX	X location, in points, of the anchor point of the annotation. For graphs, this is relative to the top-left corner of the graph window. For layouts, it is relative to the top-left corner of the page.
ABSY	Y location, in points, of the anchor point of the annotation. For graphs, this is relative to the top-left corner of the graph window. For layouts, it is relative to the top-left corner of the page.
ATTACHX	For tags, it is the X value of the wave at the point where the tag is attached, as specified with the Tag operation. For textboxes, color scales, and legends, this will be zero and has no meaning.
AXISX	X location of the anchor point of the annotation. For tags or color scales in graphs, it is in terms of the X axis against which the tagged wave is plotted. For textboxes and legends in graphs, it is in terms of the first X axis. For layouts, this has no meaning and is always zero.
AXISY	Y location of the anchor point of the annotation. For layouts, this has no meaning and is always zero. For tags or color scales in graphs, it is in terms of the Y axis against which the tagged wave is plotted. For textboxes and legends in graphs, it is in terms of the first Y axis.
AXISZ	Z value of the image or contour level trace to which the tag is attached or NaN if the trace is not a contour level trace or the annotation is not a tag.
COLORSCALE	Parameters used in a ColorScale operation to create the annotation.
FLAGS	Flags used in a Tag, Textbox, ColorScale, or Legend operation to create the annotation.
RECT	The outermost corners of the annotation (values are in points): RECT:left, top, right, bottom
TEXT	Text that defines the contents of the annotation or the main axis label of a color scale.
TYPE	Annotation type: "Tag", "TextBox", "ColorScale", or "Legend".
XWAVE	For tags, it is the name of the X wave in the XY pair to which the tag is attached. If the tag is attached to a single wave rather than an XY pair, this will be empty. For textboxes, color scales, and legends, this will be empty and has no meaning.
XWAVEDF	For tags, the full path to the data folder containing the X wave associated with the trace to which the tag is attached. For textboxes, color scales, and legends, this will be empty and has no meaning.

Keyword	Information Following Keyword
YWAVE	For tags, it is the name of the trace or image to which the tag is attached. See <b>ModifyGraph (traces)</b> and <b>Instance Notation</b> on page IV-19 for discussions of trace names and instance notation. For color scales, it is the name of the wave displayed in associated the contour plot, image plot, f(z) trace, or the name of the color scale's cindex wave. For textboxes and legends, this will be empty and has no meaning.
YWAVEDF	Full path to the data folder containing the Y wave or blank if the annotation is not a tag or color scale.

## AnnotationList

**AnnotationList** (*winNameStr*)

The AnnotationList function returns a semicolon-separated list of annotation names from the named graph or page layout window or subwindow.

### Parameters

*winNameStr* can be "" to refer to the top graph or layout window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

## APMath

**APMath** [*flags*] *destStr* = *Expression*

The APMath operation provides arbitrary precision calculation of basic mathematical expressions. It converts the final result into the assigned string *destStr*, which can then be printed or used to represent a value (at the given precision) in another APMath operation.

### Parameters

<i>destStr</i>	Specifies a destination string for the assignment expression. If <i>destStr</i> is not an existing variable, it is created by the operation. When executing in a function, <i>destStr</i> will be a local variable if it does not already exist.
<i>Expression</i>	Algebraic expression containing constants, local, global, and reference variables or strings, as well as wave elements together with the operators shown below.

### APMath Operators

+	Scalar addition	Lowest precedence
-	Scalar subtraction	Lowest precedence
*	Scalar multiplication	Medium precedence
/	Scalar division	Medium precedence
^	Exponentiation	Highest precedence

### APMath Functions

sqrt ( <i>x</i> )	Square root of <i>x</i> .
cbrt ( <i>x</i> )	Cube root of <i>x</i> .
pi	Value of $\pi$ (without parentheses).
sin ( <i>x</i> )	Sine of <i>x</i> .
cos ( <i>x</i> )	Cosine of <i>x</i> .
tan ( <i>x</i> )	Tangent of <i>x</i> .
asin ( <i>x</i> )	Inverse sine of <i>x</i> .

<code>acos(x)</code>	Inverse cosine of $x$ .
<code>atan(x)</code>	Inverse tangent of $x$ .
<code>atan2(y, x)</code>	Inverse tangent of $y/x$ .
<code>log(x)</code>	Logarithm of $x$ .
<code>log10(x)</code>	Logarithm based 10 of $x$ .
<code>exp(x)</code>	Exponential function $e^x$ .
<code>pow(x, n)</code>	$x$ to the power $n$ ( $n$ not necessarily integer).
<code>sinh(x)</code>	Hyperbolic sine of $x$ .
<code>cosh(x)</code>	Hyperbolic cosine of $x$ .
<code>tanh(x)</code>	Hyperbolic tangent of $x$ .
<code>asinh(x)</code>	Inverse hyperbolic sine of $x$ .
<code>acosh(x)</code>	Inverse hyperbolic cosine of $x$ .
<code>atanh(x)</code>	Inverse hyperbolic tangent of $x$ .
<code>ceil(x)</code>	Smallest integer larger than $x$ .
<code>comp(x, y)</code>	Returns 0 for $x == y$ , 1 if $x > y$ and -1 if $y > x$ .
<code>factorial(n)</code>	Factorial of integer $n$ .
<code>floor(x)</code>	Greatest integer smaller than $x$ .
<code>gcd(x, y)</code>	Greatest common divisor of $x$ and $y$ .
<code>lcd(x, y)</code>	Lowest common denominator of $x$ and $y$ (given by $x*y/\text{gcd}(x,y)$ ).
<code>sgn(x)</code>	Sign of $x$ or zero if $x == 0$ .

### Flags

<code>/EX=exDigits</code>	Specifies the number of extra digits added to the precision digits ( <code>/N</code> ) for intermediate steps in the calculation.
<code>/N=numDigits</code>	Specifies the precision of the final result. To add digits to the intermediate computation steps, use <code>/EX</code> .
<code>/V</code>	Verbose mode; prints the result in the history in addition to performing the assignment.
<code>/Z</code>	No error reporting.

### Details

By default, all arbitrary precision math calculations are performed with `numDigits=50` and `exDigits=6`, which yields a final result using at least 56 decimal places. Because none of the built-in variable types can express numbers with such high accuracy, the arbitrary precision numbers must be stored as strings. The operation automatically converts between strings and constants. It evaluates all of the numerical functions listed above using the specified accuracy. If you need functions that are not supported by this operation, you may have to precompute them and store the results in a local variable.

The operation stores the result in `destStr`, which may or may not exist prior to execution. When you execute the operation from the command line, `destStr` becomes a global string in the current data folder if it does not already exist. If it exists, then the result of the operation overwrites its value (as with any normal string assignment). In a user function, `destStr` can be a local string, an SVAR, or a string passed by reference. If `destStr` is not one of these then the operation creates a local string by that name.

Arbitrary precision math calculations are much slower (by a factor of about 300) than equivalent floating point calculations. Execution time is a function of the number of digits, so you should use the /N flag to limit the evaluation to the minimum number of required digits.

### Examples

Evaluate pi to 50 digits:

```
APMath/v aa=pi
```

Evaluate ratios of large factorials:

```
APMath/v aa=factorial(500)/factorial(499)
```

Evaluate ratios of large exponentials:

```
APMath/v aa=exp(-1000)/exp(-1001)
```

Division of mixed size values:

```
APMath/v aa=1-sgn(1-(1-0.00000000000000000001234)/(1-0.000000000000000000012345))
```

you'll get a different result trying to evaluate this using double precision.

Difference between built-in pi and the arbitrary precision pi:

```
Variable/G biPi=pi
APMath/v aa=biPi-pi
```

Precision control:

```
Function test()
    APMath aa=pi                // Assign 50 digit pi to the string aa.
    APMath/v bb=aa              // Create local string bb equal to aa.
    APMath/v bb=aa-pi           // Subtract arb. prec. pi from aa.
                                // note the default exDigits=6.
    APMath/v/n=50/ex=0 bb=aa-pi // setting exDigits=0.
End
```

Numerical recreation:

```
APMath/v/n=16 aa=111111111^2
```

## Append

### Append

The Append operation is interpreted as **AppendToGraph**, **AppendToTable**, or **AppendToLayout**, depending on the target window. This does not work when executing a user-defined function. Therefore we now recommend that you use **AppendToGraph**, **AppendToTable**, or **AppendLayoutObject** rather than Append.

## AppendImage

**AppendImage** [/G=g/W=winName] [axisFlags] matrix [vs {xWaveName, yWaveName}]

The AppendImage operation appends the matrix as an image to the target or named graph. By default the image is plotted versus the left and bottom axes.

### Parameters

*matrix* is either an NxM 2D wave for false color or indexed color images, or it can be a 3D NxMx3 wave containing a layer of data for red, a layer for green and a layer for blue. It can also be a 3D NxMx4 wave with the fourth plane containing alpha values.

If *matrix* contains multiple planes other than three or four or if it contains three or four and multiple chunks, the **ModifyImage** plane keyword can be used to specify the desired subset to display.

If you provide *xWaveName* and *yWaveName*, *xWaveName* provides X coordinate values, and *yWaveName* provides Y coordinate values. This makes an image with uneven pixel sizes. In both cases, you can use \* to specify calculated values based on the dimension scaling of *matrix*. See **Details** if you use *xWaveName* or *yWaveName*.

### Flags

<i>axisFlags</i>	Flags /L, /R, /B, and /T are the same as used by <b>AppendToGraph</b> .
<i>/G=g</i>	Controls the interpretation of three-plane images as direct RGB.  g=1    Suppresses the auto-detection of three or four plane images as direct (RGB) color.  g=0    Same as no /G flag (default).
<i>/W=winName</i>	Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

When appending an image to a graph each image data point is displayed as a rectangle. You can supply optional X and Y waves to define the coordinates of the rectangle edges. *These waves need to contain one more data point than the X (row) or Y (column) dimension of the matrix.* The waves must also be either strictly increasing or strictly decreasing. See **Image X and Y Coordinates** on page II-301 for details.

For false color, the values in the matrix are linearly mapped into a color table. See the **ModifyImage** ctab keyword. For indexed color, the values in the matrix are interpreted as Z values to be looked up in a user-supplied 3 column matrix of colors. See the **ModifyImage** cindex keyword. Direct color NxMx3 waves contain the actual red, green, and blue values for each pixel. NxMx4 waves add an alpha channel. If the number type is unsigned bytes, then the range of intensity ranges from 0 to 255. For all other number types, the intensity ranges from 0 to 65535.

By default, nondirect color matrices are initially displayed as false color using the Grays color table and autoscale mode.

If the matrix is complex, the image is displayed in terms of the magnitude of the Z value, that is,  $\sqrt{\text{real}^2 + \text{imag}^2}$ .

### See Also

**Image X and Y Coordinates** on page II-301, **Color Blending** on page III-440.

The **NewImage**, **ModifyImage**, and **RemoveImage** operations. For general information on image plots see Chapter II-15, **Image Plots**.

## AppendLayoutObject

**AppendLayoutObject** [*flags*] *objectType* *objectName*

The **AppendLayoutObject** operation appends a single object to the top layout or to the layout specified via the /W flag. It targets the active page or the page specified by the /PAGE flag.

Unlike the **AppendToLayout** operation, **AppendLayoutObject** can be used in user-defined functions. Therefore, **AppendLayoutObject** should be used in new programming instead of **AppendToLayout**.

### Parameters

*objectType* identifies the type of object to be appended. It is one of the following keywords: graph, table, picture, gizmo.

*objectName* is the name of the graph, table, picture or Gizmo window to be appended.

Use a space between *objectType* and *objectName*. A comma is not allowed.

### Flags

<i>/D=fidelity</i>	Draws layout objects in low fidelity ( <i>fidelity</i> =0) or high fidelity ( <i>fidelity</i> =1; default). This affects drawing on the screen only, not exporting or printing. Low fidelity is somewhat faster but less accurate and should be used only for graphs that take a very long time to draw.
--------------------	--

<i>/F=frame</i>	Specifies the type of frame enclosing the object. <i>frame =1</i> Single frame (default). <i>frame =2</i> Double frame. <i>frame =3</i> Triple frame. <i>frame =4</i> Shadow frame.
<i>/T=trans</i>	Sets the transparency of the object background to opaque ( <i>trans =0</i> ; default) or transparent ( <i>trans =1</i> ).  For transparency to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. PICTs may have been created transparent or opaque. Opaque PICTs cannot be made transparent.
<i>/R=(l, t, r, b)</i>	Sets the size and position of the object. If omitted, the object is placed with a default size and position. <i>l</i> , <i>t</i> , <i>r</i> , and <i>b</i> are the left, top, right, and bottom coordinates of the object, respectively. Coordinates are expressed in units of points, relative to the top/left corner of the paper.
<i>/PAGE=page</i>	Appends the object to the specified page. Page numbers start from 1. To target the active page, omit <i>/PAGE</i> or use <i>page=0</i> . The <i>/PAGE</i> flag was added in Igor Pro 7.00.
<i>/W=winName</i>	Appends the object to the named page layout window. If <i>/W</i> is omitted or if <i>winName</i> is \$" ", the top page layout is used.

**See Also**

**NewLayout, ModifyLayout, LayoutPageAction, RemoveLayoutObjects, TextBox, Legend**

## AppendMatrixContour

**AppendMatrixContour** [*axisFlags*] [*/F=formatStr* */W=winName*] *zWave*  
[*vs {xWave, yWave}*]

The AppendMatrixContour operation appends to the target or named graph a contour plot of a matrix of *z* values with autoscaled contour levels, using the Rainbow color table.

**Note:** There is no DisplayContour operation. Use `Display; AppendMatrixContour`.

**Parameters**

*zWave* must be a matrix (2D wave).

To contour a set of XYZ triplets, use **AppendXYZContour**.

If you provide the *xWave* and *yWave* specification, *xWave* provides X values for the rows, and *yWave* provides Y values for the columns. This results in an “uneven grid” of Z values.

If you omit the *xWave* and *yWave* specification, Igor uses the *zWave*’s X and Y scaled indices as the X and Y values. Igor also uses the *zWave*’s scaled indices if you use \* (asterisk symbol) in place of *xWave* or *yWave*.

In a macro, to modify the appearance of contour levels before the contour is calculated and displayed with the default values, append `”;DelayUpdate”` and immediately follow the AppendMatrixContour command with the appropriate **ModifyContour** commands. All but the last ModifyContour command should also have `”;DelayUpdate”` appended. DelayUpdate is not needed in a function, but DoUpdate is useful in a function to force the contour traces to be built immediately rather than the default behavior of waiting until all functions have completed.

On the command line, the Display command and subsequent AppendMatrixContour commands and any ModifyContour commands can be typed all on one line with semicolons between:

```
Display; AppendMatrixContour MyMatrix; ModifyContour ...
```

### Flags

<i>axisFlags</i>	Flags /L, /R, /B, /T are the same as used by <b>AppendToGraph</b> .
<i>/F=formatStr</i>	Determines the names assigned to the contour level traces. See <b>Details</b> .
<i>/W=winName</i>	Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

AppendMatrixContour creates and displays contour level traces. You can modify these all together using the Modify Contour Appearance dialog or individually using the Modify Trace Appearance dialog. In most cases, you will not need to modify the individual traces.

By default, Contour level traces are automatically named with names that show the *zWave* and the contour level, for example, "zWave=1.5". You will see these trace names in the Modify Trace Appearance dialog and in Legends. In most cases, the default trace names will be just fine.

If you want to control the names of the contour level traces (which you might want to do for names in a Legend), use the */F=formatStr* flag. This flag uses a format string as described for the **printf** operation. The default format string is "% .17s=%g", resulting in trace names such as "zWave=1.5". *formatStr* must contain at least %f or %g (used to insert the contour level) or %d (used to insert the zero-based index of the contour level). Include %s, to insert the *zWave* name.

Here are some examples of format strings.

<i>formatStr</i>	Examples of Resulting Name	Format
"%g"	"100", "1e6", "-2.05e-2"	(<level>)
"z=%g"	"z=100", "z=1e6", "z=-2.05e-2"	(z=<level>)
"%s %f"	"zWave 100.000000"	(<wave>, space, <level>)
" [%d] =%g"	"[0]=100", "[1]=1e6"	([<index>]=<level>)

### Examples

```
Make/O/N=(25,25) w2D           // Make a matrix
SetScale x -1, 1, w2D         // Set row scaling
SetScale y -1, 1, w2D         // Set column scaling
w2D = sin(x) * cos(y)         // Store values in the matrix
Display; AppendMatrixContour w2D
ModifyContour w2D autoLevels={*,*,9} // Roughly 9 automatic levels
```

### See also

**Display, AppendToGraph, AppendXYZContour, ModifyContour, RemoveContour, FindContour.**

For general information on contour plots, see Chapter II-14, **Contour Plots**.

## AppendText

**AppendText** [/W=*winName*/N/NOCR [=*n*]] *textStr*

The AppendText operation appends a carriage return and *textStr* to the most recently created or changed annotation, or to the named annotation in the target or graph or layout window. Annotations include tags, textboxes, color scales, and legends.

### Parameters

*textStr* can contain escape codes to control font, font size and other stylistic variations. See **Annotation Escape Codes** on page III-53 for details.

### Flags

/N= <i>name</i>	Appends <i>textStr</i> to the named tag or textbox.
/NOCR[= <i>n</i> ]	Omits the initial appending of a carriage return (allows a long line to be created with multiple AppendText commands). /NOCR=0 is the same as no /NOCR, and /NOCR=1 is the same as just /NOCR.
/W= <i>winName</i>	Appends to an annotation in the named graph, layout window, or subwindow. Without /W, AppendText appends to an annotation in the topmost graph or layout window or subwindow. This must be the first flag specified when AppendText is used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

A textbox, tag, or legend can contain at most 100 lines. A color scale can have at most one line, and this line is the color scale's main axis label.

### See Also

The **Tag**, **TextBox**, **ColorScale**, **ReplaceText**, and **Legend** operations.

**Annotation Escape Codes** on page III-53.

## AppendToGizmo

**AppendToGizmo** [*flags*] *keyword* [=*value*]

The AppendToGizmo operation appends a Gizmo object or attribute operation to the top Gizmo window or to the Gizmo window specified by the /N flag.

Documentation for the AppendToGizmo operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "AppendToGizmo"
```

## AppendToGraph

**AppendToGraph** [*flags*] *waveName* [, *waveName*]...[*vs xwaveName*]

The AppendToGraph operation appends the named waves to the target or named graph. By default the waves are plotted versus the left and bottom axes.

### Parameters

The *waveNames* parameters are the names of existing waves.

*vs xwaveName* plots the data values of *waveNames* against the data values of *xwaveName*.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-250.

You can provide a custom name for a trace by appending /TN=*traceName* to the *waveName* specification. This is useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-82 for more information.

## AppendToLayout

---

### Flags

/B [=axisName]	Plots X coordinates versus the standard or named bottom axis.
/C=( <i>r,g,b</i> )	<i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue in the color of the appended waves as an integer from 0 to 65535.
/L [=axisName]	Plots Y coordinates versus the standard or named left axis.
/NCAT	Causes trace to be plotted normally on what otherwise is a category plot. X values are just category numbers but can be fractional. Category numbers start from zero. This can be used to overlay the original data points for a box plot.  See <b>Combining Numeric and Category Traces</b> on page II-273 for details.
/Q	Uses a special, quick update mode when appending to a pair of existing axes. A side effect of this mode is that waves that are appended are marked as not modified. This will prevent other graphs containing these waves, if any, from being updated properly.
/R [=axisName]	Plots Y coordinates versus the standard or named right axis.
/T [=axisName]	Plots X coordinates versus the standard or named top axis.
/TN= <i>traceName</i>	Allows you to provide a custom trace name for a trace. This is useful when displaying waves with the same name but from different data folders. See <b>User-defined Trace Names</b> on page IV-82 for details.
/VERT	Plots data vertically. Similar to SwapXY ( <b>ModifyGraph (axes)</b> ) but on a trace-by-trace basis.
/W= <i>winName</i>	Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### See Also

The **Display** operation.

## AppendToLayout

**AppendToLayout** [*flags*] *objectSpec* [, *objectSpec*]...

The AppendToLayout operation appends the specified objects to the top layout.

The AppendToLayout operation can not be used in user-defined functions. Use the AppendLayoutObject operation instead.

### Parameters

The optional *objectSpec* parameters identify a graph, table, textbox or PICT to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See the **Layout** operation for details.

### Flags

/G= <i>g</i>	Specifies grout, the spacing between tiled objects. Units are points unless /I, /M, or /R are specified.
/I	<i>objectSpec</i> coordinates are in inches.
/M	<i>objectSpec</i> coordinates are in centimeters.
/R	<i>objectSpec</i> coordinates are in percent of printing part of the page.
/S	Stacks objects.

/T Tiles objects.

#### See Also

The **Layout** and **AppendLayoutObject** operations for use with user-defined functions.

## AppendToTable

**AppendToTable** [/W=*winName*] *columnSpec* [, *columnSpec*]...

The AppendToTable operation appends the specified columns to the top table. *columnSpecs* are the same as for the **Edit** operation; usually they are just the names of waves.

#### Flags

/W=*winName* Appends columns to the named table window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

#### See Also

**Edit** for details about *columnSpecs*, and **RemoveFromTable**.

## AppendXYZContour

**AppendXYZContour** [/W=*winName* /F=*formatStr*] [*axisFlags*] *zWave* [vs {*xWave*, *yWave*}]

The AppendXYZContour operation appends to the target or named graph a contour of a 2D wave consisting of XYZ triples with autoscaled contour levels and using the Rainbow color table.

To contour a matrix of Z values, use **AppendMatrixContour**.

**Note:** There is no DisplayContour operation. Use Display; AppendXYZContour.

#### Parameters

If you provide the *xWave* and *yWave* specification, *xWave* provides X values for the rows, and *yWave* provides Y values for the columns, *zWave* provides Z values and all three waves must be 1D. All must have at least four rows and must have the same number of rows.

If you omit the *xWave* and *yWave* specification, *zWave* must be a 2D wave with 4 or more rows and 3 or more columns. The first column is X, the second is Y, and the third is Z. Any additional columns are ignored.

If any of X, Y, or Z in a row is blank, (NaN), that row is ignored.

In a macro, to modify the appearance of contour levels before the contour is calculated and displayed with the default values, append ";DelayUpdate" and immediately follow the AppendXYZContour command with the appropriate **ModifyContour** commands. All but the last ModifyContour command should also have ;DelayUpdate appended. DelayUpdate is not needed in a function, but DoUpdate is useful in a function to force the contour traces to be built immediately rather than the default behavior of waiting until all functions have completed.

On the command line, the **Display** command and subsequent AppendXYZContour commands and any **ModifyContour** commands can be typed all on one line with semicolons between:

```
Display; AppendXYZContour zWave; ModifyContour ...
```

#### Flags

*axisFlags* Flags /L, /R, /B, and /T are the same as used by **AppendToGraph**.

/F=*formatStr* Determines names assigned to the contour level traces. This is the same as for **AppendMatrixContour**.

/W=*winName* Appends to the named graph window or subwindow. When omitted, action affects the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

**Details**

AppendXYZContour creates and displays contour level traces. You can modify these as a group using the Modify Contour Appearance dialog or individually using the Modify Trace Appearance dialog. In most cases, you will have no need to modify the traces individually.

See **AppendMatrixContour** for a discussion of how the contour level traces are named.

**Examples**

```
Make/O/N=(100) xW, yW, zW           // Make X, Y, and Z waves
xW = sawtooth(2*PI*p/10)           // Generate X values
yW = trunc(p/10)/10                // Generate Y values
zW = sin(2*PI*xW)*cos(2*PI*yW)     // Generate Z values
Display; AppendXYZContour zW vs {xW, yW}; DelayUpdate
ModifyContour zW autoLevels={*,*,9} // roughly 9 automatic levels
```

**See Also**

The **Display** operation. **AppendToGraph** for details about other axis flags. The **AppendMatrixContour**, **ModifyContour**, and **RemoveContour** operations. For general information on contour plots, see Chapter II-14, **Contour Plots**.

**area**

**area**(*waveName* [, *x1*, *x2*])

The area function returns the signed area between the named wave and the line  $y=0$  from  $x=x1$  to  $x=x2$  using trapezoidal integration, accounting for the wave's X scaling. If your data are in the form of an XY pair of waves, see **areaXY**.

**Details**

If *x1* and *x2* are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

If *x1* or *x2* are not within the X range of *waveName*, area limits them to the nearest X range limit of *waveName*.

If any values in the X range are NaN, area returns NaN.

The function returns NaN if the input wave has zero points.

Reversing the order of *x1* and *x2* changes the sign of the returned area.

The area function is intended to work on 1D real or complex waves only.

The area function returns a complex result for a complex input wave. The real part of the result is the area of the real components in the input wave, and the imaginary part of the result is the area of the imaginary components.

**Examples**

```
Make/O/N=100 data; SetScale/I x 0,Pi,data
data=sin(x)
Print area(data,0,Pi)           // the entire X range, and no more
Print area(data)                // same as -infinity to +infinity
Print area(data,Inf,-Inf)       // +infinity to -infinity
```

The following is printed to the history area:

```
Print area(data,0,Pi)           // the entire X range, and no more
1.99983
Print Print area(data)          // same as -infinity to +infinity
1.99983
Print area(data,Inf,-Inf)       // +infinity to -infinity
-1.99983
```

The -Inf value was limited to 0 and Inf was limited to Pi to keep them within the X range of data.

**See Also**

The figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the **Details** section of the **faverage** function.

**Integrate**, **areaXY**, **faverage**, **faverageXY**, **PolygonArea**

## areaXY

**areaXY**(*XWaveName*, *YWaveName* [, *x1*, *x2*])

The areaXY function returns the signed area between the named *YWaveName* and the line  $y=0$  from  $x=x1$  to  $x=x2$  using trapezoidal integration with X values supplied by *XWaveName*.

This function is identical to the **area** function except that it works on an XY wave pair and does not work with complex waves.

### Details

If *x1* and *x2* are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

If *x1* or *x2* are outside the X range of *XWaveName*, areaXY limits them to the nearest X range limit of *XWaveName*.

If any values in the Y range are NaN, areaXY returns NaN.

If any values in the entire X wave are NaN, areaXY returns NaN.

The function returns NaN if the input wave has zero points.

Reversing the order of *x1* and *x2* changes the sign of the returned area.

If *x1* or *x2* are not found in *XWaveName*, a Y value is found by linear interpolation based on the two bracketing X values and the corresponding values from *YWaveName*.

The values in *XWaveName* may be increasing or decreasing. AreaXY assumes that the values in *XWaveName* are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any X values are NaN, the result is NaN.

See the figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the **Details** section of the **faverage** function.

The areaXY operation is intended to work on 1D waves only.

### Examples

```
Make/O/N=101 Xdata, Ydata
Xdata = x*pi/100
Ydata = sin(Xdata[p])
Print areaXY(Xdata, Ydata,0,Pi)           // the entire X range, and no more
Print areaXY(Xdata, Ydata)                // same as -infinity to +infinity
Print areaXY(Xdata, Ydata,Inf,-Inf)       // +infinity to -infinity
```

The following is printed to the history area:

```
Print areaXY(Xdata, Ydata,0,Pi)           // the entire X range, and no more
1.99984
Print areaXY(Xdata, Ydata)                // same as -infinity to +infinity
1.99984
Print areaXY(Xdata, Ydata,Inf,-Inf)       // +infinity to -infinity
-1.99984
```

The -Inf value was limited to 0, and Inf was limited to Pi to stay within the X range of data.

**Integrate**, **area**, **faverage**, **faverageXY**, **PolygonArea**

## asin

**asin**(*num*)

The asin function returns the inverse sine of *num* in radians in the range  $[-\pi/2, \pi/2]$ .

In complex expressions, *num* is complex, and asin returns a complex value.

### See Also

**sin**

## asinh

**asinh**(*num*)

The asinh function returns the inverse hyperbolic sine of *num*. In complex expressions, *num* is complex, and asinh returns a complex value.

## atan

**atan** (*num*)

The atan function returns the inverse tangent of *num* in radians. In complex expressions, *num* is complex, and atan returns a complex value. Results are in the range  $-\pi/2$  to  $\pi/2$ .

See Also

tan, atan2

## atan2

**atan2** (*y1*, *x1*)

The atan2 function returns the angle in radians whose tangent is  $y1/x1$ . Results are in the range  $-\pi$  to  $\pi$ .

See Also

tan, atan

## atanh

**atanh** (*num*)

The atanh function returns the inverse hyperbolic tangent of *num*. In complex expressions, *num* is complex, and atanh returns a complex value.

## AutoPositionWindow

**AutoPositionWindow** [/E/M=*m*/R=*relWindow*] [*windowName*]

The AutoPositionWindow operation positions the window specified by *windowName* relative to the next lower window of the same kind or relative to the window given by the /R flag. If *windowName* is not specified, AutoPositionWindow acts on the target window.

### Flags

/E	Uses entire area of the monitor. Otherwise, it takes into account the command window.
/M= <i>m</i>	Specifies the window positioning method. <i>m</i> =0: Positions <i>windowName</i> to the right of the other window, if possible. If there is no room, then it positions <i>windowName</i> just below the other window but at the left edge of the display area. If that is not possible, then the position is not affected. <i>m</i> =1: Positions <i>windowName</i> just under the other window lined up on the left edge, if possible. If there is no room, then it positions <i>windowName</i> just to the right of the other window lined up on the bottom edges. If neither are possible then it positions <i>windowName</i> as far to the bottom and right as it will go.
/R= <i>relWindow</i>	Positions <i>windowName</i> relative to <i>relWindow</i> .

## AxisInfo

**AxisInfo** (*graphNameStr*, *axisNameStr*)

The AxisInfo function returns a string containing a semicolon-separated list of information about the named axis in the named graph window or subwindow.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

*axisNameStr* is the name of the graph axis.

**Details**

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are:

Keyword	Information Following Keyword
AXFLAG	Flag used to select the axis in any of the operations that display waves (Display, AppendMatrixContour, AppendImage, etc.).
AXTYPE	Axis type, such as “left”, “right”, “top”, or “bottom”.
CATWAVE	Wave supplying the categories for the axis if this is a category plot.
CATWAVEDF	Full path to data folder containing category wave.
CWAVE	Name of wave controlling named axis.
CWAVEDF	Full path to data folder containing controlling wave.
HOOK	Name set by ModifyFreeAxis with hook keyword.
ISCAT	Truth that this is a category axis (used in a category plot).
ISTFREE	Truth that this is truly free axis (created via NewFreeAxis).
MASTERAXIS	Name set by ModifyFreeAxis with master keyword.
RECREATION	List of keyword commands as used by ModifyGraph command. The format of these keyword commands is: <i>keyword(x)=modifyParameters;</i>
SETAXISCMD	Full SetAxis command.
SETAXISFLAGS	Flags that would be used with the SetAxis function to set the particular auto-scaling behavior that the axis uses. If the axis uses a manual axis range, SETAXISFLAGS is blank.
UNITS	Axis units, if any.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword up to the “;”, prepend “ModifyGraph”, replace the “x” with the name of an actual axis and then **Execute** the resultant string as a command.

**Examples**

```
Make/O data=x;Display data
Print StringByKey("CWAVE", AxisInfo("", "left"))           // prints data
```

**See Also**

The **StringByKey** and **NumberByKey** functions.

The **GetAxis** and **SetAxis** operations.

The #include <Readback ModifyStr> procedures are useful for parsing strings returned by AxisInfo.

**AxisList****AxisList (graphNameStr)**

The AxisList function returns a semicolon-separated list of axis names from the named graph window or subwindow.

**Parameters**

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

**Examples**

```
Make/O data=x;Display/L/T data
Print AxisList("")           // prints left;top;
```

### AxisValFromPixel

**AxisValFromPixel**(*graphNameStr*, *axNameStr*, *pixel*)

The **AxisValFromPixel** function returns an axis value corresponding to the local graph pixel coordinate in the graph window or subwindow.

#### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

If the specified axis is not found and if the name is "left" or "bottom" then the first vertical or horizontal axis will be used. Sources for *pixel* value may be the **GetWindow** operation or a user window hook with the **mousemoved** and **mousedown** event messages (see the **SetWindow** operation).

If *graphNameStr* references a subwindow, *pixel* is relative to top left corner of base window, not the subwindow.

#### See Also

The **PixelFromAxisVal** and **TraceFromPixel** functions; the **GetWindow** and **SetWindow** operations.

### BackgroundInfo

#### BackgroundInfo

The **BackgroundInfo** operation returns information about the current unnamed background task.

**BackgroundInfo** works only with the unnamed background task. New code should use named background tasks instead. See **Background Tasks** on page IV-298 for details.

#### Details

Information is returned via the following variables:

<i>V_flag</i>	0: No background task is defined. 1: Background task is defined, but not running (is idle). 2: Background task is defined and is running.
<i>V_period</i>	DeltaTicks value set by <b>CtrlBackground</b> . This is how often the background task runs.
<i>V_nextRun</i>	Ticks value when the task will run again. 0 if the task is not scheduled to run again.
<i>S_value</i>	Text of the numeric expression that the background task executes, as set by <b>SetBackground</b> .

#### See Also

The **SetBackground**, **CtrlBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and the **ticks** function. See **Background Tasks** on page IV-298 for usage details.

### Beep

#### Beep

The **Beep** operation plays the current alert sound (*Macintosh*) or the system beep sound (*Windows*).

### Besseli

**Besseli**(*n*, *z*)

The **Besseli** function returns the modified Bessel function of the first kind,  $I_n(z)$ , of order *n* and argument *z*. Replaces the **bessI** function, which is supported for backwards compatibility only.

If *z* is real, **Besseli** returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

**Details**

The calculation is performed using the SLATEC library. The function supports fractional and negative orders  $n$ , as well as real or complex arguments  $z$ .

**See Also**

The **Besselj**, **Besselk**, and **Bessely** functions.

## Besselj

**Besselj** ( $n, z$ )

The Besselj function returns the Bessel function of the first kind,  $J_n(z)$ , of order  $n$  and argument  $z$ . Replaces the **bessJ** function, which is supported for backwards compatibility only.

If  $z$  is real, Besselj returns a real value, which means that if  $z$  is also negative, it returns NaN unless  $n$  is an integer.

For complex  $z$  a complex value is returned, and there are no restrictions on  $z$  except for possible overflow.

**Details**

The calculation is performed using the SLATEC library. The function supports fractional and negative orders  $n$ , as well as real or complex arguments  $z$ .

**See Also**

The **Besseli**, **Besselk**, and **Bessely** functions.

## Besselk

**Besselk** ( $n, z$ )

The Besselk function returns the modified Bessel function of the second kind,  $K_n(z)$ , of order  $n$  and argument  $z$ . Replaces the **bessK** function, which is supported for backwards compatibility only.

If  $z$  is real, Besselk returns a real value, which means that if  $z$  is also negative, it returns NaN unless  $n$  is an integer.

For complex  $z$  a complex value is returned, and there are no restrictions on  $z$  except for possible overflow.

**Details**

The calculation is performed using the SLATEC library. The function supports fractional orders  $n$ , as well as real or complex arguments  $z$ .

**See Also**

The **Besseli**, **Besselj**, and **Bessely** functions.

## Bessely

**Bessely** ( $n, z$ )

The Bessely function returns the Bessel function of the second kind,  $Y_n(z)$ , of order  $n$  and argument  $z$ . Replaces the **bessY** function, which is supported for backwards compatibility only.

If  $z$  is real, Bessely returns a real value, which means that if  $z$  is also negative, it returns NaN unless  $n$  is an integer.

For complex  $z$  a complex value is returned, and there are no restrictions on  $z$  except for possible overflow.

**Details**

The calculation is performed using the SLATEC library. The function supports fractional and negative orders  $n$ , as well as real or complex arguments  $z$ .

**See Also**

The **Besseli**, **Besselj**, and **Besselk** functions.

## bessI

**bessI** ( $n, x$  [, *algorithm* [, *accuracy*] ])

Obsolete — use **Besseli**.

The **bessI** function returns the modified Bessel function of the first kind,  $I_n(x)$  of order  $n$  and argument  $x$ .

For real  $x$ , the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order  $n$  is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If  $x$  is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order  $n$  can be fractional, and must be real.

### Details

The *algorithm* parameter has three options, each selecting a different calculation method:

Algorithm	What You Get
0 (default)	Uses a calculation method that has fractional accuracy better than $10^{-6}$ everywhere and is generally better than $10^{-8}$ . This method does not handle fractional order $n$ ; the order is truncated to an integer before the calculation is performed.  Algorithm 0 is fastest by a large margin.
1	Allows fractional order. The calculation is performed using methods described in <i>Numerical Recipes in C</i> , 2nd edition, pp. 240-245.  Using algorithm 1, <i>accuracy</i> specifies the fractional accuracy that you desire. That is, if you set <i>accuracy</i> to 1e-7 (that is, $10^{-7}$ ), that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$ be better than $10^{-7}$ . Asking for less accuracy gives some increase in speed.  You pay a heavy price for higher accuracy or fractional order. When <i>algorithm</i> is nonzero, calculation time is increased by an order of magnitude for small $x$ ; at larger $x$ the penalty is even greater.  If <i>accuracy</i> is greater than $10^{-8}$ and $n$ is an integer, algorithm 0 is used.  The algorithm calculates bessI and bessK simultaneously. Both values are stored, and if a call to bessI is followed by a call to bessK (or bessK is followed by bessI) with the same $n$ , $x$ , and <i>accuracy</i> the previously-stored value is returned, making the second call very fast.
2	Fractional order is allowed. The calculation is performed using code from the SLATEC library. The accuracy achievable is often better than algorithm 1, but not always. Algorithm 2 is 1.5 to 3 times faster than algorithm 1, but still slower than algorithm 0. The accuracy parameter is ignored.

The achievable accuracy of algorithms 1 and 2 is a complicated function  $n$  and  $x$ . To see a summary of achievable accuracies choose File→Example Experiments→Testing and Misc→Bessel Accuracy menu item.

## bessJ

**bessJ**( $n$ ,  $x$  [, *algorithm* [, *accuracy* ] ] )

Obsolete — use **Besselj**.

The bessJ function returns the Bessel function of the first kind,  $J_n(x)$  of order  $n$  and argument  $x$ .

For real  $x$ , the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order  $n$  is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If  $x$  is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order  $n$  can be fractional, and must be real.

### Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for bessJ and bessY are calculated simultaneously. The values are stored, and a subsequent call to bessY after a call to bessJ (or vice versa) with the same  $n$ ,  $x$ , and *accuracy* will be very fast.

## bessK

**bessK**(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Besselk**.

The **bessK** function returns the modified Bessel function of the second kind,  $K_n(x)$  of order  $n$  and argument  $x$ .

For real  $x$ , the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order  $n$  is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If  $x$  is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order  $n$  can be fractional, and must be real.

### Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for **bessJ** and **bessY** are calculated simultaneously. The values are stored, and a subsequent call to **bessY** after a call to **bessJ** (or vice versa) with the same  $n$ ,  $x$ , and *accuracy* will be very fast.

## bessY

**bessY**(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Bessely**.

The **bessY** function returns the Bessel function of the second kind,  $Y_n(x)$  of order  $n$  and argument  $x$ .

For real  $x$ , the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order  $n$  is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If  $x$  is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order  $n$  can be fractional, and must be real.

### Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for **bessJ** and **bessY** are calculated simultaneously. The values are stored, and a subsequent call to **bessY** after a call to **bessJ** (or vice versa) with the same  $n$ ,  $x$ , and *accuracy* will be very fast.

## beta

**beta**(*a*, *b*)

The beta function returns for real or complex arguments as

$$B(a,b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)},$$

with  $\text{Re}(a), \text{Re}(b) > 0$ .  $\Gamma$  is the gamma function.

### See Also

The **gamma** function.

## betai

**betai**(*a*, *b*, *x* [, *accuracy*])

The **betai** function returns the regularized incomplete beta function  $I_x(a,b)$ ,

$$I_x(a,b) = \frac{B(x;a,b)}{B(a,b)}.$$

Here

$$B(x; a, b) = \int_0^x t^{a-1} (1-t)^{b-1} dt.$$

where  $a, b > 0$ , and  $0 \leq x \leq 1$ .

Optionally, *accuracy* can be used to specify the desired fractional accuracy.

### Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

Larger values of *accuracy* (poorer accuracy) result in evaluation of fewer terms of a series, which means the function executes somewhat faster.

A single-precision level of accuracy is about  $3 \times 10^{-7}$ , double-precision is about  $2 \times 10^{-16}$ . The *betai* function will return full double-precision accuracy for small values of  $a$  and  $b$ . Achievable accuracy declines as  $a$  and  $b$  increase:

$a$	$b$	$x$	<b>betai</b>	<b>Accuracy Achievable</b>
1	1.5	0.5	0.646447	$2 \times 10^{-16}$ (full double precision)
8	10	0.5	0.685470	$6 \times 10^{-16}$
20	21	0.5	0.562685	$2 \times 10^{-15}$
20	21	0.1	$1.87186 \times 10^{-10}$	$5 \times 10^{-15}$

## BinarySearch

**BinarySearch(waveName, val)**

The BinarySearch function performs a binary search of the one-dimensional *waveName* for the value *val*. BinarySearch returns an integer point number  $p$  such that *waveName*[ $p$ ] and *waveName*[ $p+1$ ] bracket *val*. If *val* is in *waveName*, then *waveName*[ $p$ ]==*val*.

### Details

BinarySearch is useful for finding the point in an XY pair that corresponds to a particular X coordinate.

*WaveName* must contain monotonically increasing or decreasing values.

BinarySearch returns -1 if *val* is not within the range of values in the wave, but would numerically be placed before the first value in the wave.

BinarySearch returns -2 if *val* is not within the range of values in the wave, but would fall after the last value in the wave.

BinarySearch returns -3 if the wave has zero points.

### Examples

```
Make/O data = {1, 2, 3.3, 4.9}           // Monotonic increasing
Print BinarySearch(data,3)               // Prints 1
// BinarySearch returns 1 because data[1] <= 3 < data[2].

Make/O data = {9, 4, 3, -6}             // Monotonic decreasing
Print BinarySearch(data,2.5)             // Prints 2
// BinarySearch returns 2 because data[2] >= 2.5 > data[3].
Print BinarySearch(data,10)              // Prints -1, precedes first value
Print BinarySearch(data,-99)             // Prints -2, beyond last value
```

### See Also

The **BinarySearchInterp** and **FindLevel** operations. See **Indexing and Subranges** on page II-71.

## BinarySearchInterp

**BinarySearchInterp(waveName, val)**

The BinarySearchInterp function performs a binary interpolated search of the named wave for the value *val*. The returned value, *pt*, is a floating-point point index into the named wave such that *waveName*[*pt*] == *val*.

### Details

BinarySearchInterp is useful for finding the point in an XY pair that corresponds to a particular X coordinate.

*WaveName* must contain monotonically increasing or decreasing values.

When the named wave does not actually contain the value *val*, BinarySearchInterp locates a value below *val* and a value above *val* and uses reverse linear interpolation to figure out where *val* would fall if a straight line were drawn between them. It includes that fractional amount in the resulting point index.

BinarySearchInterp returns NaN if *val* is not within the range of values in the wave.

### Examples

```
Make/O data = {1, 2, 3.3, 4.9}           // Monotonic increasing
Print BinarySearchInterp(data,3)         // Prints 1.76923
Print data[1.76923]                     // Prints 3

Make/O data = {9, 4, 3, 1}              // Monotonic decreasing
Print BinarySearchInterp(data,2.5)       // Prints 2.25
Print data[2.25]                         // Prints 2.5
```

### See Also

The **BinarySearch** and **FindLevel** operations. See **Indexing and Subranges** on page II-71.

## binomial

**binomial**(*n*, *k*)

The binomial function returns the ratio:

$$\frac{n!}{k!(n-k)!}$$

It is assumed that *n* and *k* are integers and  $0 \leq k \leq n$  and ! denotes the factorial function.

Note that although the binomial function is an integer-valued function, a double-precision number has 53 bits for the mantissa. This means that numbers over  $2^{52}$  (about  $4.5 \times 10^{15}$ ) will be accurate to about one part in  $2 \times 10^{16}$ .

## binomialln

**binomialln**(*a*, *b*)

The binomialln function returns the natural log of the binomial coefficient for *a* and *b*.

$$\text{binomialln}(a,b) = \ln(a!) - \ln(b!) - \ln((a-b)!)$$

### See Also

Chapter III-12, **Statistics** for an overview of the various functions and operations; **binomial**, **StatsBinomialPDF**, **StatsBinomialCDF**, and **StatsInvBinomialCDF**.

## binomialNoise

**binomialNoise**(*n*, *p*)

The binomialNoise function returns a pseudo-random value from the binomial distribution

$$f(x) = \binom{n}{x} p^x (1-p)^{n-x}, \quad \begin{array}{l} 0 \leq p \leq 1 \\ x = 1, 2, \dots, n \end{array}$$

whose mean is *np* and variance is *np*(1-*p*).

When *n* is large such that  $p^n$  is zero to machine accuracy the function returns NaN. When *n* is large such that  $np(1-p) > 5$  and  $0.1 < p < 0.9$  you can replace the binomial variate with a normal variate with mean *np* and standard deviation  $\sqrt{n \cdot p \cdot (1-p)}$ .

## BoundingBox

---

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat the same sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

### See Also

The **SetRandomSeed** operation.

**Noise Functions** on page III-344.

Chapter III-12, **Statistics** for an overview of the various functions and operations.

## BoundingBox

**BoundingBox** [/F/Z] *scatterWave*

The BoundingBox operation calculates a bounding circle or the bounding sphere for a set of scatter points. The operation accepts 2D waves that have two, three or more columns; data in the additional columns are ignored.

When *scatterWave* consists of two columns the operation computes the bounding circle. Otherwise it computes the bounding 3D sphere.

### Parameters

*scatterWave* is a two-dimensional wave with X coordinates in column 0, Y in column 1, and optional Z coordinates in column 2.

### Flags

/F	This flag applies to 3D scatter only. It uses an algorithm from “An Efficient Bounding Sphere” by Jack Ritter originally from <i>Graphics Gems</i> . Unfortunately it does not give an accurate bounding ball but something that is sufficiently large. This algorithm is less accurate but it produces a ball which is sufficiently large to contain all the points.
/Z	No error reporting.

### Details

The center and radius of the bounding sphere are stored in the variables: V\_CenterX, V\_CenterY, V\_CenterZ, and V\_Radius.

If you are not using the /F flag, the operation also accepts a 2 column wave consisting of X, Y pairs for calculating the center and radius of a bounding circle in the plane.

### Example

```
Make/N=(33,2) ddd=enoise(4)           // Create random data
BoundingBox ddd
Display ddd[] [1] vs ddd[] [0]
ModifyGraph mode=3
Make/n=360 xxx,yyy
yyy=v_centerY+V_radius*cos(p*2*pi/360)
xxx=v_centerX+V_radius*sin(p*2*pi/360)
AppendToGraph yyy vs xxx
```

### References

Glassner, Andrew S., (Ed.), *Graphics Gems*, 833 pp., Academic Press, San Diego, 1990.

## break

### break

The break flow control keyword immediately terminates execution of a loop, switch, or strswitch. Execution then continues with code following the loop, switch, or strswitch.

### See Also

**Break Statement** on page IV-44, **Switch Statements** on page IV-41, and **Loops** on page IV-42 for usage details.

## BrowseURL

**BrowseURL** [/Z] *urlStr*

The BrowseURL operation opens the Web browser or FTP browser on your computer and asks it to display a particular Web page or to connect to an FTP server.

BrowseURL sets a variable named *V\_flag* to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if an error occurs.

### Parameters

*urlStr* specifies a Web page or FTP server directory to be browsed. It is constructed of a naming scheme (e.g., "http://" or "ftp://"), a computer name (e.g., "www.wavemetrics.com" or "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/Test/TestFile1.txt"). See **Examples** for sample usage.

### Flags

/Z                      Errors are not fatal. Will not abort procedure execution if the URL is bad or if the server is down. Your procedure can inspect the *V\_flag* variable to see if the transfer succeeded. *V\_flag* will be zero if it succeeded or nonzero if it failed.

Syntactic errors, such as omitting the URL altogether or omitting quotes, are still fatal.

### Examples

```
// Browse a Web page.
String url = "http://www.wavemetrics.com/News/index.html"
BrowseURL url

// Browse an FTP server.
String url = "ftp://ftp.wavemetrics.com/pub/test"
BrowseURL url
```

### See Also

URLRequest

## BuildMenu

**BuildMenu** *menuNameStr*

The BuildMenu operation rebuilds the user-defined menu items in the specified menu the next time the user clicks in the menu bar.

### Parameters

*menuNameStr* is a string expression containing a menu name or "All".

### Details

Call BuildMenu when you've defined a custom menu using string variables for the menu items. After you change the string variables, call BuildMenu to update the menu.

BuildMenu "All" rebuilds all the menu items and titles and updates the menu bar.

Under the current implementation, if *menuNameStr* is not "All", Igor will rebuild *all* user-defined menu items if BuildMenu is called for *any* user-defined menu.

### See Also

Dynamic Menu Items on page IV-120.

## Button

**Button** [/Z] *ctrlName* [*keyword* = *value* [, *keyword* = *value* ...]]

The Button operation creates or modifies the named button control.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*name* is the name of the Button control to be created or changed.

## Button

---

appearance= { <i>kind</i> [, <i>platform</i> ]}	<p>Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings.</p> <p><i>kind</i>=default:      Appearance determined by <b>DefaultGUIControls</b>.</p> <p><i>kind</i>=native:        Creates standard-looking controls for the current computer platform.</p> <p><i>kind</i>=os9:            Igor Pro 5 appearance (quasi-Macintosh OS 9 controls that look the same on Macintosh and Windows).</p> <p><i>platform</i>=Mac:       Changes the appearance of controls only on Macintosh; affects the experiment whenever it is used on Macintosh.</p> <p><i>platform</i>=Win:       Changes the appearance of controls only on Windows; affects the experiment whenever it is used on Windows.</p> <p><i>platform</i>=All:        Changes the appearance on both Macintosh and Windows computers.</p>
disable= <i>d</i>	<p>Sets the state of the control. <i>d</i> is a bit field: bit 0 (the least significant bit) is set when the control is hidden. Bit 1 is set when the control is disabled:</p> <p><i>d</i>=0:                  Normal (visible), enabled.</p> <p><i>d</i>=1:                  Hidden.</p> <p><i>d</i>=2:                  Visible and disabled. Drawn in grayed state, also disables action procedure.</p> <p><i>d</i>=3:                  Hidden and disabled.</p> <p>See the <b>ModifyControl</b> example for setting the bits individually.</p>
fColor=( <i>r,g,b</i> )	<p>Sets color of the button. <i>r</i>, <i>g</i>, and <i>b</i> are integers from 0 to 65535. To set the color of the title text, use escape sequences as described below for title. fColor defaults to black (0,0,0). To set the color of the title text, see valueColor.</p>
focusRing= <i>fr</i>	<p>Enables or disables the drawing of a rectangle indicating keyboard focus:</p> <p><i>fr</i>=0:                  Focus rectangle will not be drawn.</p> <p><i>fr</i>=1:                  Focus rectangle will be drawn (default).</p> <p>On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.</p>
font=" <i>fontName</i> "	<p>Sets button font, e.g., font="Helvetica".</p>
fsize= <i>s</i>	<p>Sets font size.</p>
fstyle= <i>fs</i>	<p>Specifies the font style. <i>fs</i> is a bitwise parameter with each bit controlling one aspect of the font style:</p> <p>Bit 0:                Bold</p> <p>Bit 1:                Italic</p> <p>Bit 2:                Underline</p> <p>Bit 4:                Strikethrough</p> <p>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.</p>
help={ <i>helpStr</i> }	<p>Specifies the help for the control. Help text is limited to a total of 255 bytes. On Macintosh, help appears if you turn Igor Tips on. On Windows, help for the first 127 bytes or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.</p>
noproc	<p>No procedure is executed when clicking the button.</p>

<code>picture= pict</code>	<p>Draws the button using the named picture. The picture is taken to be three side-by-side frames that show the control appearance in the normal state, when the mouse is down, and in the disabled state. The picture may be either a global (imported) picture or a Proc Picture (see <b>Proc Pictures</b> on page IV-53).</p> <p>In Igor6, the size keyword is ignored when a picture is used with a button control. To make it easier to size graphics for high-resolution screens, as of Igor7, the size keyword is respected in this case.</p>
<code>pos={left,top}</code>	Sets the position of the button in pixels.
<code>pos+={dx,dy}</code>	Offsets the position of the button in pixels.
<code>proc=procName</code>	Names the procedure to execute when clicking the button.
<code>rename=newName</code>	Gives the button a new name.
<code>size={width,height}</code>	Sets <i>width</i> and <i>height</i> of button in pixels.
<code>title=titleStr</code>	<p>Sets title of button (text that appears in the button) to the specified string expression. If not given then title will be "New". If you use " " the button will contain no text.</p> <p>Using escape codes you can change the font, size, style, and color of the title. See <b>Annotation Escape Codes</b> on page III-53 or details.</p>
<code>userdata(UDName)=UDStr</code>	Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.
<code>userdata(UDName)+=UDStr</code>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .
<code>valueColor=(r,g,b)</code>	Sets initial color of the button's text (title). <i>r</i> , <i>g</i> , and <i>b</i> range from 0 to 65535. <i>valueColor</i> defaults to black (0,0,0). To further change the color of the title text, use escape sequences as described for <code>title=titleStr</code> .
<code>win=winName</code>	<p>Specifies which window or subwindow contains the named button control. If not given, then the top-most graph or panel window or subwindow is assumed.</p> <p>When identifying a subwindow with <i>winName</i>, see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.</p>

## Details

The target window must be a graph or panel.

## Button Action Procedure

The action procedure for a Button control takes a predefined structure `WMButtonAction` as a parameter to the function:

```
Function ActionProcName(B_Struct) : ButtonControl
    STRUCT WMButtonAction &B_Struct
    ...
    return 0
End
```

The “: ButtonControl” designation tells Igor to include this procedure in the Procedure pop-up menu in the Button Control dialog.

See **WMButtonAction** for details on the `WMButtonAction` structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format button action procedure in old code:

```
Function procName(ctrlName) : ButtonControl
    String ctrlName
    ...
    return 0
End
```

This old format should not be used in new code.

### See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

## ButtonControl

### ButtonControl

ButtonControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined button control. See **Procedure Subtypes** on page IV-193 for details. See **Button** for details on creating a button control.

## cabs

### cabs (z)

The cabs function returns the real-valued absolute value of complex number z.

### See Also

The **magsqr** function.

## CameraWindow

### CameraWindow

CameraWindow is a procedure subtype keyword that identifies a macro as being a camera window recreation macro. It is automatically used when Igor creates a window recreation macro for a camera window. See **Procedure Subtypes** on page IV-193 and **Saving and Recreating Graphs** on page II-261 for details.

## CaptureHistory

### CaptureHistory(refnum, stopCapturing)

The CaptureHistory function returns a string containing text from the history area of the command window since a matching call to the **CaptureHistoryStart** function.

### Parameters

*refnum* is a number returned from a call to CaptureHistoryStart. It identifies the starting point in the history for the returned string.

Set *stopCapturing* to nonzero to indicate that no more history should be captured for the given refnum. Subsequent calls to CaptureHistory with the same *refnum* will result in an error.

Set *stopCapturing* to zero to retrieve history text captured so far. Further calls to CaptureHistory with the same reference number will return this text, plus any additional history text added subsequently.

### Details

You can have multiple captures active at one time. Each call to CaptureHistoryStart will return a unique reference number identifying a start point in the history. The capture corresponding to each reference number can be terminated at any time, regardless of the order of the CaptureHistoryStart calls.

## CaptureHistoryStart

### CaptureHistoryStart()

The CaptureHistoryStart function returns a reference number to identify a starting point in the history area text. Subsequently, the CaptureHistory function can be used to retrieve captured history text. See **CaptureHistory** for details.

## catch

### catch

The catch flow control keyword marks the beginning of code in a try-catch-entry flow control construct for handling any abort conditions.

### See Also

The **try-catch-endtry** flow control statement for details.

## cd

**cd** *dataFolderSpec*

The **cd** operation sets the current data folder to the specified data folder. It is identical to the longer-named **SetDataFolder** operation.

**cd** is named after the UNIX "change directory" command.

**See Also**

**SetDataFolder**, **pwd**, **Dir**, **Data Folders** on page II-99

## CDFFunc

**CDFFunc**

**CDFFunc** is a procedure subtype keyword that identifies a function as being suitable for calling from the **StatsKSTest** operation.

## ceil

**ceil**(*num*)

The **ceil** function returns the closest integer greater than or equal to *num*.

**See Also**

The **round**, **floor**, and **trunc** functions.

## cequal

**cequal**(*z1*, *z2*)

The **cequal** function determines the equality of two complex numbers *z1* and *z2*. It returns 1 if they are equal, or 0 if not.

This is in contrast to the **=** operator, which compares only the real components of *z1* and *z2*, ignoring the imaginary components.

### Examples

```
Function TestComplexEqualities()
  Variable/C z1= cmplx(1,2), z2= cmplx(1,-2)
  // This test compares only the real parts of z1 and z2:
  if( z1 == z2 )
    Print "== match"
  else
    Print "no == match"
  endif
  // This test compares both real and imaginary parts of z1 and z2:
  if( cequal(z1,z2) )
    Print "cequal match"
  else
    Print "no cequal match"
  endif
End

•TestComplexEqualities()
  == match
  no cequal match
```

**See Also**

The **imag**, **real**, and **cmplx** functions.

## char2num

### **char2num**(*str*)

The **char2num** function returns a numeric code representing the first byte of *str* or the first character of *str*.

If *str* contains zero bytes, **char2num** returns NaN.

If *str* contains exactly one byte, **char2num** returns the value of that byte, treated as a signed byte. For backward compatibility with Igor6, if the input is a single byte in the range 0x80..0xFF, **char2num** returns a negative number.

If *str* contains more than one byte, **char2num** returns a number which is the Unicode code point for the first character in *str* treated as UTF-8 text. If *str* does not start with a valid UTF-8 character, **char2num** returns NaN.

Prior to Igor Pro 7.00, **char2num** always returned the value of the first byte, treated as a signed byte.

### Examples

```
Function DemoChar2Num()  
    String str  
  
    str = "A"  
    Printf "Single ASCII character: %02X\r", char2num(str)           // Prints 0x41  
  
    str = "ABC"  
    Printf "Multiple ASCII characters: %02X\r", char2num(str)       // Prints 0x41  
  
    str = U+2022           // Bullet character  
    Printf "Valid UTF-8 text: U+%04X\r", char2num(str)             // Prints U+2022  
    Printf "First byte value: %02X\r", char2num(str[0]) & 0xFF     // Prints E2  
    Printf "Second byte value: %02X\r", char2num(str[1]) & 0xFF     // Prints 80  
  
    str = num2char(0xE2, 0) + num2char(0x41, 0)                   // Invalid UTF-8 text  
    Printf "Invalid UTF-8 text: U+%04X\r", char2num(str)           // Prints NaN  
  
    str = ""  
    Printf "Empty string: %g\r", char2num(str)                     // Prints NaN  
End
```

### See Also

The **num2char**, **str2num** and **num2str** functions.

**Text Encodings** on page III-409.

## Chart

**Chart** [/Z] *ctrlName* [**keyword** = **value** [, **keyword** = **value** ...]]

The **Chart** operation creates or modifies a chart control. Charts are generally used in conjunction with data acquisition. Charts do not have to be connected to a FIFO, but they are not useful until they are.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the Chart control to be created or changed.

The following keyword=value parameters are supported:

<b>chans</b> ={ <i>ch#</i> , <i>ch#</i> ,...}	List of FIFO channel numbers that Chart is to monitor.
<b>color</b> ( <i>ch#</i> )=( <i>r</i> , <i>g</i> , <i>b</i> )	Sets the color of the specified trace. <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue in the color as an integer from 0 to 65535.
<b>ctab</b> = <i>colortableName</i>	When a channel is connected to an image strip FIFO channel, the data is displayed as an image using this built-in color table. Valid names are the same as used in images. Invalid name will result in the default Grays color table being used.

<code>disable=<i>d</i></code>	<p>Sets user editability of the control.</p> <p><i>d</i>=0: Normal.</p> <p><i>d</i>=1: Hide.</p> <p><i>d</i>=2: Disable user input.</p> <p>Charts do not change appearance because they are read-only. When disabled, the hand cursor is not shown.</p>
<code>fbkRGB=(<i>r,g,b</i>)</code>	Sets frame background color. <i>r</i> , <i>g</i> and <i>b</i> are integers from 0 to 65535.
<code>fgRGB=(<i>r,g,b</i>)</code>	Sets foreground color (text, etc.). <i>r</i> , <i>g</i> and <i>b</i> are integers from 0 to 65535
<code>fifo=FIFOName</code>	Sets which named FIFO the chart will monitor. See the <b>NewFIFO</b> operation.
<code>font="fontName"</code>	Sets the font used in the chart, e.g., <code>font="Helvetica"</code> .
<code>fsize=<i>s</i></code>	Sets font size for chart.
<code>fstyle=<i>fs</i></code>	<p>Specifies the font style. <i>fs</i> is a bitwise parameter with each bit controlling one aspect of the font style:</p> <p>Bit 0: Bold</p> <p>Bit 1: Italic</p> <p>Bit 2: Underline</p> <p>Bit 4: Strikethrough</p> <p>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.</p>
<code>gain(<i>ch#</i>)=<i>g</i></code>	Sets the display gain <i>g</i> of the specified channel relative to nominal. Values greater than unity expand the display.
<code>gridRGB=(<i>r,g,b</i>)</code>	Sets grid color. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>help={helpStr}</code>	Specifies help for the control. Help text is limited to a total of 255 bytes. On Macintosh, help appears if you turn Igor Tips on. On Windows, help for the first 127 bytes or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting “\r” in a quoted string.
<code>jumpTo=<i>p</i></code>	Jumps to point number <i>p</i> . This works in review mode only.
<code>lineMode(<i>ch#</i>)=<i>lm</i></code>	<p>Sets the display line mode for the given channel.</p> <p><i>lm</i>=0: Dots mode. Draws values as dots. However, if the number of dots in a strip exceeds maxDots then Igor draws a vertical line from the min to the max of the values packed into the strip.</p> <p><i>lm</i>=1: Lines mode. Draws a vertical line encompassing the min and the max of the points in a given strip along with the last point of the preceding strip. Since which strip is the preceding strip depends on the direction of motion then the appearance may slightly shift depending on which direction the chart is moving.</p> <p><i>lm</i>=2: Dots mode. Draws values as dots. However, if the number of dots in a strip exceeds maxDots then Igor draws a vertical line from the min to the max of the values packed into the strip.</p>
<code>mass=<i>m</i></code>	Sets the “feel” of the chart paper when you move it with the mouse. The larger the mass <i>m</i> , the slower the chart responds. Odd values cause the movement of the paper to stop the instant the mouse is clicked while even values continue with the illusion of mass.
<code>maxDots=<i>md</i></code>	Controls whether points in a given vertical strip of the chart are displayed as dots or as a solid line. See lineMode above. Default is 20.

<code>offset(ch#)=o</code>	Sets the display offset of the specified channel. The offset value <i>o</i> is subtracted from the data before the gain is applied.
<code>oMode=om</code>	Chart operation mode. <i>om</i> =0: Live mode. <i>om</i> =1: Review mode.
<code>pbkRGB=(r,g,b)</code>	Sets plot area background color. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>ppStrip=pps</code>	Number of data points packed into each vertical strip of the chart.
<code>rSize(ch#)=rs</code>	Sets the relative vertical size allocated to the given channel. Nominal is unity. If the value of <i>rs</i> is zero then this channel shares space with the previous channel.
<code>sMode=sm</code>	Status line mode. <i>sm</i> =0: Turns off fancy status line and positioning bar. <i>sm</i> =1: Normal mode. <i>sm</i> =2: Uses alternate style for bar.
<code>sRate=sr</code>	Sets the scroll rate (vertical strips/second). If the chart control is in review mode negative numbers scroll in reverse.
<code>title=titleStr</code>	Specifies the chart title. Use " " for no title.
<code>uMode=um</code>	Status line mode. <i>um</i> =1: Fast update with no bells and whistles. <i>um</i> =2: Status line and positioning bar. <i>um</i> =3: Status line, positioning bar, and animated pens.
<code>win=winName</code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Flags

<code>/Z</code>	No error reporting.
-----------------	---------------------

### Details

The target window must be a graph or panel.

The action of some of the Chart keywords depends on whether or not data acquisition is taking place. If the chart is in review mode then all keywords cause the chart to be redrawn. If data acquisition is taking place and the chart is in live mode then some keywords affect new data but do not attempt to update the part of the "paper" that has already been drawn. The following keywords affect only new data during live mode:

`ppStrip`, `maxDots`, `gain`, `offset`, `color`, `lineMode`

## chebyshev

**chebyshev** (*n*, *x*)

The `chebyshev` function returns the Chebyshev polynomial of the first kind and of degree *n*.

The Chebyshev polynomials satisfy the recurrence relation:

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$$

$$T_0(x) = 1$$

with:  $T_1(x) = x$

$$T_2(x) = 2x^2 - 1.$$

The orthogonality of the polynomial is expressed by the integral:

$$\int_{-1}^1 \frac{T_n(x)T_m(x)}{\sqrt{1-x^2}} dx = \begin{cases} 0 & m \neq n \\ \pi/2 & m = n \neq 0 \\ \pi & m = n = 0 \end{cases}.$$

### See Also

**chebyshevU**.

## chebyshevU

### **chebyshevU**(*n*, *x*)

The **chebyshevU** function returns the Chebyshev polynomial of the second kind, degree *n* and argument *x*.

The Chebyshev polynomial of the second kind satisfies the recurrence relation

$$U(n+1, x) = 2xU(n, x) - U(n-1, x)$$

which is also the recurrence relation of the Chebyshev polynomials of the first kind.

The first 10 polynomials of the second kind are:

$$U(0, x) = 1$$

$$U(1, x) = 2x$$

$$U(2, x) = 4x^2 - 1$$

$$U(3, x) = 8x^3 - 4x$$

$$U(4, x) = 16x^4 - 12x^2 + 1$$

$$U(5, x) = 32x^5 - 32x^3 + 6x$$

$$U(6, x) = 64x^6 - 80x^4 + 24x^2 - 1$$

$$U(7, x) = 128x^7 - 192x^5 + 80x^3 - 8x$$

$$U(8, x) = 256x^8 - 448x^6 + 240x^4 - 40x^2 + 1$$

$$U(9, x) = 512x^9 - 1024x^7 + 672x^5 - 160x^3 + 10x$$

### See Also

The **chebyshev** function.

## CheckBox

**CheckBox** [/Z] *ctrlName* [*keyword* = *value* [, *keyword* = *value* ...]]

The **CheckBox** operation creates or modifies a checkbox, radio button or disclosure triangle in the target or named window, which must be a graph or control panel.

*ctrlName* is the name of the checkbox.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the **CheckBox** control to be created or changed.

The following keyword=value parameters are supported:

appearance= { <i>kind</i> [, <i>platform</i> ]}	<p>Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings.</p> <p><i>kind</i> can be one of <code>default</code>, <code>native</code>, or <code>os9</code>.</p> <p><i>platform</i> can be one of <code>Mac</code>, <code>Win</code>, or <code>All</code>.</p> <p>See <b>Button</b> and <b>DefaultGUIControls</b> for more appearance details.</p>
disable= <i>d</i>	<p>Sets user editability of the control.</p> <p><i>d</i>=0:        Normal.</p> <p><i>d</i>=1:        Hide.</p> <p><i>d</i>=2:        Disable user input.</p>
fsize= <i>s</i>	<p>Sets font size for checkbox.</p>
fColor=( <i>r,g,b</i> )	<p>Sets the initial color of the title. <i>r</i>, <i>g</i>, and <i>b</i> range from 0 to 65535. fColor defaults to black (0,0,0). To further change the color of the title text, use escape sequences as described for <code>title=titleStr</code>.</p>
focusRing= <i>fr</i>	<p>Enables or disables the drawing of a rectangle indicating keyboard focus:</p> <p><i>fr</i>=0:                Focus rectangle will not be drawn.</p> <p><i>fr</i>=1:                Focus rectangle will be drawn (default).</p> <p>On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.</p>
help={ <i>helpStr</i> }	<p>Sets the help for the control. The help text is limited to a total of 255 bytes. You can insert a line break by putting “\r” in a quoted string.</p>
mode= <i>m</i>	<p>Specifies checkbox appearance.</p> <p><i>m</i>=0:                Default checkbox appearance.</p> <p><i>m</i>=1:                Display as a radio button control.</p> <p><i>m</i>=2:                Display as a disclosure triangle (<i>Macintosh</i>) or treeview expansion node (<i>Windows</i>).</p>
noproc	<p>Specifies that no procedure is to execute when clicking the checkbox.</p>
picture= <i>pict</i>	<p>Draws the checkbox using the named picture. The picture is taken to be six side-by-side frames which show the control appearance in the normal state, when the mouse is down, and in the disabled state. The first three frames are used when the checked state is false and the next three show the true state. The picture may be either a global (imported) picture or a Proc Picture (see <b>Proc Pictures</b> on page IV-53).</p>
pos={ <i>left,top</i> }	<p>Sets the position of the checkbox in pixels.</p>
pos+= <i>{dx,dy}</i>	<p>Offsets the position of the checkbox in pixels.</p>
proc= <i>procName</i>	<p>Specifies the procedure to execute when the checkbox is clicked.</p>
rename= <i>newName</i>	<p>Renames the checkbox to <i>newName</i>.</p>
side= <i>s</i>	<p>Sets the location of the title relative to the box:</p> <p><i>s</i> =0:                Checkbox is on the left, title is on the right (default).</p> <p><i>s</i> =1:                Checkbox is on the right, title is on the left.</p>
size={ <i>width,height</i> }	<p>Sets checkbox size in pixels.</p>

<code>title=titleStr</code>	Sets title of checkbox to the specified string expression. The title is the text that appears in the checkbox. If not given or if "" then the title will be "New". Using escape codes you can change the font, size, style, and color of the title. See <b>Annotation Escape Codes</b> on page III-53 or details.
<code>userdata(UDName)=UDStr</code>	Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.
<code>userdata(UDName)+=UDStr</code>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .
<code>value=v</code>	Specifies whether the checkbox is selected ( <i>v</i> =1) or not ( <i>v</i> =0).
<code>variable= varName</code>	Specifies a global numeric variable to be set to the current state of a checkbox whenever it is clicked or when it is set by the value parameter. The variable is two-way: setting the variable also changes the state of the checkbox.
<code>win=winName</code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

## Flags

`/Z` No error reporting.

## Details

The target window must be a graph or panel.

### Checkbox Action Procedure

The action procedure for a CheckBox control can takes a predefined structure `WMCheckboxAction` as a parameter to the function:

```
Function ActionProcName(CB_Struct) : CheckBoxControl
    STRUCT WMCheckboxAction &CB_Struct
    ...
    return 0
End
```

The " : CheckBoxControl" designation tells Igor to include this procedure in the Procedure pop-up menu in the Checkbox Control dialog.

See **WMCheckboxAction** for details on the `WMCheckboxAction` structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format checkbox action procedure in old code:

```
Function procName(ctrlName,checked) : CheckBoxControl
    String ctrlName
    Variable checked // 1 if selected, 0 if not
    ...
    return 0
End
```

This old format should not be used in new code.

When using radio button controls, it is the responsibility of the Igor programmer to turn off other radio buttons when one of a group of radio buttons is pressed.

## Examples

The following code is an example of how to program such a group.

```
Window Panel0() : Panel
    PauseUpdate; Silent 1 // building window ...
    NewPanel /W=(150,50,353,212)
    Variable/G gRadioVal= 1
    CheckBox check0,pos={52,25},size={78,15},title="Radio 1"
    CheckBox check0,value=1,mode=1,proc=MyCheckProc
    CheckBox check1,pos={52,45},size={78,15},title="Radio 2"
```

## CheckBoxControl

---

```
CheckBox check1,value=0,mode=1,proc=MyCheckProc
CheckBox check2,pos={52,65},size={78,15},title="Radio 3"
CheckBox check2,value= 0,mode=1,proc=MyCheckProc
EndMacro

Function MyCheckProc(cb) : CheckBoxControl
    STRUCT WMCheckboxAction& cb

    NVAR gRadioVal= root:gRadioVal

    strswitch (cb.ctrlName)
        case "check0":
            gRadioVal= 1
            break
        case "check1":
            gRadioVal= 2
            break
        case "check2":
            gRadioVal= 3
            break
    endswitch
    CheckBox check0,value= gRadioVal==1
    CheckBox check1,value= gRadioVal==2
    CheckBox check2,value= gRadioVal==3

    return 0
End
```

See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

## CheckBoxControl

### CheckBoxControl

CheckBoxControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined checkbox control. See **Procedure Subtypes** on page IV-193 for details. See **CheckBox** for details on creating a checkbox control.

## CheckDisplayed

**CheckDisplayed** [/A/W] *waveName* [, *waveName*]...

The CheckDisplayed operation determines if named waves are displayed in a host window or subwindow.

### Flags

/A	Checks all graph and table windows
/W= <i>winName</i>	Checks only the named graph or table window
	When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

If neither /A nor /W are used, CheckDisplayed checks only the top graph or table.

CheckDisplayed sets a bit in the variable V\_flag for each wave that is displayed.

### Examples

CheckDisplayed/W=Graph0 aWave,bWave,cWave

Checks Graph0 to see if aWave, bWave, and cWave are displayed in it. If aWave is displayed, CheckDisplayed sets bit 0 of V\_flag (V\_flag=1). If bWave is displayed, sets bit 1 (V\_flag=2). If cWave is displayed, sets bit 2 (V\_flag=4). If all three waves are displayed, V\_flag=7.

### See Also

**Setting Bit Parameters** on page IV-12 for information about bit settings.

## CheckName

**CheckName**(*nameStr*, *objectType* [, *windowNameStr*])

The CheckName function returns a number which indicates if the specified name is legal and unique among objects in the namespace of the specified object type.

Waves, global numeric variables, and global string variables are all in the same namespace and need to be unique only within the data folder containing them. However, they also need to be distinct from names of Igor operations and functions and from names of user-defined procedures.

Data folders are in their own namespace and need to be unique only among other data folders at the same level of the data folder hierarchy.

*windowNameStr* is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of *objectType*.

### Details

A result of zero indicates that the name is legal and unique within its namespace. Any nonzero result indicates that the name is illegal or not unique. You can use the **CleanupName** and **UniqueName** functions to guarantee legality and uniqueness.

*nameStr* should contain an unquoted name (i.e., no single quotes for liberal names), such as you might receive from the user through a dialog or control panel.

*objectType* is one of the following:

- |                             |   |
|-----------------------------|---|
| 1: Wave.                    | 9: Control panel window.  |
| 2: Reserved.                | 10: Notebook window.  |
| 3: Global numeric variable. | 11: Data folder.  |
| 4: Global string variable.  | 12: Symbolic path.  |
| 5: XOP target window.       | 13: Picture.  |
| 6: Graph window.            | 14: Annotation in the named or topmost graph or layout.         |
| 7: Table window.            | 15: Control in the named topmost graph or panel.                |
| 8: Layout window.           | 16: Notebook action character in the named or topmost notebook. |

The *windowNameStr* argument is used only with *objectTypes* 14, 15, and 16. The *nameStr* is checked for uniqueness only within the named window (other windows might have objects with the given name). If a named window is given but does not exist, any valid *nameStr* is permitted

### Examples

```
Variable waveNameIsOK = CheckName(proposedWaveName, 1) == 0
Variable annotationNameIsOK = CheckName("text0", 14, "Graph0") == 0
```

```
// Create a valid and unique wave name
Function/S CreateValidAndUniqueWaveName(proposedName)
    String proposedName

    String result = proposedName

    if (CheckName(result,1) != 0)           // 1 for waves
        result = CleanupName(result, 1)    // Make sure it's valid
        result = UniqueName(result, 1, 0)   // Make sure it's unique
    endif

    return result
End
```

### See Also

**CleanupName** and **UniqueName** functions.

### ChildWindowList

**ChildWindowList** (*hostNameStr*)

The ChildWindowList function returns a string containing a semicolon-separated list of immediate subwindow window names of the specified host window or subwindow.

#### Parameters

*hostNameStr* is a string or string expression containing the name of an existing host window or subwindow.

When identifying a subwindow with *hostNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

#### Details

Error if the host does not exist or if it is not an allowed host type.

#### See Also

**WinList** and **WinType** functions.

### ChooseColor

**ChooseColor** [/A [=a] /C= (*r, g, b*) ]

The ChooseColor operation displays a dialog for choosing a color.

The color initially shown is black unless you specify a different color with /C.

#### Flags

/A[=*a*]                      *a*=1 shows the alpha (opacity) channel. /A is the same as /A=1.  
                                 *a*=0 hides the alpha channel. This is the default setting.  
                                 The /A flag was added in Igor Pro 7.00.

/C=(*r,g,b*)                    *r*, *g*, and *b* specify the amount of red, green, and blue in the color initially displayed in the dialog as an integer from 0 to 65535.

#### Details

ChooseColor sets the variable V\_flag to 1 if the user clicks OK in the dialog or to 0 otherwise.

If V\_flag is 1 then V\_Red, V\_Green, V\_Blue, and V\_Alpha are set to the selected color as integers from 0 to 65535.

A completely opaque color sets V\_Alpha=65535. A fully transparent color sets V\_Alpha=0.

#### See Also

ImageTransform **rgb2hsl** and **hsl2rgb**.

### CleanupName

**CleanupName** (*nameStr*, *beLiberal*)

The CleanupName function returns the input name string, possibly altered to make it a legal object name.

#### Details

*nameStr* should contain an unquoted (i.e., no single quotes for liberal names) name, such as you might receive from the user through a dialog or control panel.

*beLiberal* is 0 to use strict name rules or 1 to use liberal name rules. Strict rules allow only letters, digits and the underscore character. Liberal rules allow other characters such as spaces and dots. Liberal rules were introduced with Igor Pro 3.0 and are allowed for names of waves and data folders only.

Note that a cleaned up name is not necessarily unique. Call **CheckName** to check for uniqueness or **UniqueName** to ensure uniqueness.

#### Examples

```
String cleanStrVarName = CleanupName(proposedStrVarName, 0)
```

**See Also**

**CheckName** and **UniqueName** functions.

**Close**

**Close** [/A] *fileRefNum*

The Close operation closes a file previously opened by the **Open** operation or closes all such files if /A is used.

**Parameters**

*fileRefNum* is the file reference number of the file to close. This number comes from the Open operation. If /A is used, *fileRefNum* should be omitted.

**Flags**

/A Closes all files. Mainly useful for cleaning up after an error during procedure execution occurs so that the normal Close operation is never executed.

**CloseHelp**

**CloseHelp** [ /FILE=*fileNameStr* /NAME=*helpNameStr* /P=*pathName* ]

The CloseHelp operation closes a help window.

The CloseHelp operation was added in Igor Pro 7.00.

**Flags**

/FILE=*fileNameStr* Identifies the help window to close using the help file's location on disk. The file is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-401 for details on forming the path.

/NAME=*helpNameStr* Identifies the help window to close using the window's title as specified by *helpNameStr*. This is the text that appears in the help window title bar.

/P=*pathName* Specifies the folder to look in for the file specified by /FILE. *pathName* is the name of an existing Igor symbolic path.

**Details**

You must provide either the /NAME or /FILE flag.

**See Also**

**OpenHelp**

**CloseMovie**

**CloseMovie**

The CloseMovie operation closes the currently open movie. You must close a movie before you can play it.

**See Also**

**Movies** on page IV-230.

The **NewMovie** operation.

**CloseProc**

**CloseProc** /NAME=*procNameStr* [*flags*]

**CloseProc** /FILE=*fileNameStr* [*flags*]

The CloseProc operation closes a procedure window. You cannot call CloseProc on the main Procedure window.

## CloseProc

---

CloseProc provides a way to programmatically create and alter procedure files. You might do this in order to make a user-defined menu-bar menu with contents that change.

**Note:** CloseProc alters procedure windows so it cannot be called while functions or macros are running. If you want to call it from a function or macro, use **Execute/P**.

**Warning:** If you close a procedure window that has no source file or without specifying a destination file, the window contents will be permanently lost.

### Flags

<code>/COMP[=<i>compile</i>]</code>	Specifies whether procedures should be compiled after closing the procedure window.  <i>compile</i> =1: Compiles procedures (same as <code>/COMP</code> only). <i>compile</i> =0: Leaves procedures in an uncompiled state.
<code>/D[=<i>delete</i>]</code>	Specifies whether the procedure file should be deleted after closing the procedure window.  <i>delete</i> =1: Deletes procedure file (same as <code>/D</code> only). <b>Warning:</b> You cannot recover any file deleted this way. <i>delete</i> =0: Leaves any associated file unaffected.
<code>/FILE=<i>fileNameStr</i></code>	Identifies the procedure window to close using the file name and path to the file given by <i>fileNameStr</i> . The string can be just the file name if <code>/P</code> is used to specify a symbolic path name of the enclosing folder. It can be a partial path if <code>/P</code> points to a folder enclosing the start of the partial path. It can also be a full path the file.
<code>/NAME=<i>procNameStr</i></code>	Identifies the procedure window to close with the string expression <i>procNameStr</i> . This is the same text that appears in the window title. If the procedure window is associated with a file, it will be the file name and extension.  To close a procedure file that is part of an independent module, you must include the independent module name in <i>procNameStr</i> . For example: <pre>CloseProc /NAME="GraphBrowser.ipf [WM_GrfBrowser]"</pre> Note that there is a space after the file name followed by the independent module name in brackets.
<code>/P=<i>pathName</i></code>	Specifies the folder to look in for the file specified by <code>/FILE</code> . <i>pathName</i> is the name of an existing symbolic path.
<code>/SAVE[=<i>savePathStr</i>]</code>	Saves the procedure before closing the window. If the flag is used with no argument, it saves any changes to the procedure window to its source file before closing it. If <i>savePathStr</i> is present, it must be a full path naming a file in which to save the procedure window contents. The <code>/P</code> flag is not used with <i>savePathStr</i> so it must be a full path.

### Details

Specify which window to close using either the `/NAME` or `/FILE` flag. You must use one or the other. Usually you would use `/NAME`, as it is usually more convenient. If by some chance two procedures have the same name, `/FILE` can be used to distinguish between them.

You cannot call CloseProc on a nonmain procedure window that someone has had the bad taste to call "Procedure".

### See Also

Chapter III-13, **Procedure Windows**.

The **Execute/P** operation.

## cmplx

**cmplx(realPart, imagPart)**

The cmplx function returns a complex number whose real component is *realPart* and whose imaginary component is *imagPart*.

Use this to assign a value to a complex variable or complex wave.

### Examples

Assume wave1 is complex. Then:

```
wave1(0) = cmplx(1,2)
```

sets the Y value of wave1 at x=0 such that its real component is 1 and its imaginary component is 2.

Assuming wave2 and wave3 are real, then:

```
wave1 = cmplx(wave2, wave3)
```

sets the real component of wave1 equal to the contents of wave2 and the imaginary component of wave1 equal to the contents of wave3.

You may get unexpected results if the number of points in wave2 or wave3 differs from the number of points in wave1. If wave2 or wave3 are shorter than wave1, the last element of the short wave is copied repeatedly to fill wave1.

### See Also

**conj**, **imag**, **magsqr**, **p2rect**, **r2polar**, and **real** functions.

## CmpStr

**CmpStr(str1, str2 [, flags])**

The CmpStr function returns zero if *str1* is equal to *str2* or non-zero otherwise.

### Parameters

*flags* controls the type of comparison that is done. It defaults to 0 and supports the following values:

- |    |                                  |
|----|----------------------------------|
| 0: | Case-insensitive text comparison |
| 1: | Case-sensitive text comparison   |
| 2: | Binary comparison                |
- 

Binary comparison (*flags*=2) was added Igor Pro 7.05 and is appropriate if *str1* and *str2* contain binary data, which may contain null bytes (bytes with the value 0), rather than human-readable strings.

### Details

If *flags* is omitted, 0, or 1, CmpStr does a text comparison and returns the following values:

- |     |  |
|-----|--|
| -1: | <i>str1</i> is alphabetically before <i>str2</i> |
| 0:  | <i>str1</i> and <i>str2</i> are equal            |
| 1:  | <i>str1</i> is alphabetically after <i>str2</i>  |
- 

The alphabetic order represented by -1 and 1 is valid only for ASCII text. It is not valid for non-ASCII text, such as text containing accented characters.

If *flags* is 2, CmpStr does a binary comparison and returns the following values:

- |    |   |
|----|---|
| 0: | <i>str1</i> and <i>str2</i> are equal     |
| 1: | <i>str1</i> and <i>str2</i> are not equal |
- 

Usually strings do not contain null bytes. Text comparison treats a null byte as meaning "end of string". Binary comparison does not treat a null byte specially. The example below illustrates the treatment of null bytes.

### Example

```
Function TestCmpStr()  
  String str1 = "A" + num2char(0) + "B"      // num2char(0) is a null byte  
  Print strlen(str1)                          // Prints 3  
  
  String str2 = "A" + num2char(0) + "C"  
  Print strlen(str2) // Prints 3  
  
  Print CmpStr(str1,str2,0)                   // Prints 0 meaning "equal"  
  Print CmpStr(str1,str2,1)                   // Prints 0 meaning "equal"  
  Print CmpStr(str1,str2,2)                   // Prints 1 meaning "unequal"  
End
```

The "Print strlen" statements illustrate that strlen does not treat null as meaning end of string.

The results from CmpStr with *flags*=0 and *flags*=1 illustrate that CmpStr treated null as meaning "end of string" and consequently compared only the first byte of *str1* to the first byte of *str2*. Both are "A" so CmpStr returned 0 meaning "equal".

The result from CmpStr with *flags*=2 illustrates that CmpStr did not treat null as meaning "end of string" and consequently compared all three bytes of *str1* to all three bytes of *str2*. The third bytes do not match so CmpStr returned 1 meaning "unequal".

### See Also

**ReplaceString, Using Strings** on page IV-161

## ColorScale

**ColorScale** [*flags*] [, *keyword* = *value*, ...] [*axisLabelStr*]

The ColorScale operation puts a color scale (or "color legend") annotation on the top graph or page layout.

The ColorScale operation can be executed with no flags and no parameters.

When a graph is the top window the color scale represents the colors and values associated with the first image plot that was added to the graph.

If there is no image plot in the graph, the color scale represents the first contour plot or first *f(z)* trace added to the graph, one of which must exist for the command to execute without error when executed without parameters.

Executing ColorScale (with no parameters) when a layout is the top window displays a color bar as if the *ctab*={0,100,Rainbow} parameters had been specified.

### Flags

Use the */W=winName* flag to specify a specific graph or layout window. When used on the command line or in a Macro or Proc, */W* must precede all other flags.

To change a color scale, use the */C/N=name* flags. Annotations are automatically named "text0", "text1", etc. if no name is specified when it is created, and you must use that name to modify an existing annotation or else a new one will be created.

For explanations of all flags see the **TextBox** operation.

### Parameters

The following keyword-value pairs are the important parameters to the ColorScale operation, because they specify what object the color scale is representing.

For use with page layouts, the keyword =*{graphName,...}* form is required.

For graphs it is simpler to use the *image=imageInstanceName* form (omitting *graphName*), though you can use \$ " " to mean the top graph, or specify the name of another graph with the long form. See the **Examples**.

<i>axisLabelStr</i>	Contains the text printed beside the color scale's main axis.  Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See <b>Annotation Escape Codes</b> on page III-53 for details.  You can use <b>AppendText</b> or <b>ReplaceText</b> to modify this axis label string. The default value for <i>axisLabelStr</i> is " ".
---------------------	--

`cindex=cindexMatrixWave`

The colors shown are those in the named color index wave with axis values derived from the wave's X (row) scaling and units.

The image colors are determined by doing a lookup in the specified matrix wave. See the `ModifyImage cindex` keyword.

`contour=contourInstanceName`

`contour={graphName,contourInstanceName}`

The colors show the named contour plot's colors and associated contour (Z) values and contour data units. All of the image plot's characteristics are represented, including color table, `cindex`, and fixed colors.

`ctab={zMin,zMax,ctName, reverse}`

The color table specified by `ctName` is drawn in the color legend.

`zMin` and `zMax` set the range of z values to map.

The color table name can be omitted if you want to leave it unchanged.

`ctName` can be any color table name returned by the `CTabList` function, such as `Grays` or `Rainbow` (see **Image Color Tables** on page II-305) or the name of a 3 column or 4 column color table wave (**Color Table Waves** on page II-311).

A color table wave name supplied to `ctab` must not be the name of a built-in color table (see **CTabList**). A 3 column or 4 column color table wave must have values that range between 0 and 65535. Column 0 is red, 1 is green, and 2 is blue. In column 3 a value of 65535 is opaque, and 0 is fully transparent.

Set `reverse` to 1 to reverse the color table. Setting it to 0 or omitting it leaves the color table unreversed.

`image=imageInstanceName`

`image={graphName,imageInstanceName}`

The colors show the named image plot's colors and associated image (Z) values and image data units. All of the image plot's characteristics are represented, including color table, `cindex`, lookup wave, eval colors, and NaN transparency. **Note:** only false-color image plots can be used with `ColorScale` (see **Indexed Color Details** on page II-312).

`logLabel=t`

`t` is the maximum number of decades before minor tick labels are suppressed. The default value is 3.

The `logLabel` keyword was added in Igor Pro 7.00.

`logTicks=t`

`t=0` means "auto". This is the default value.

If `t` is not 0 then it represents the maximum number of decades before minor ticks are suppressed.

The `logLabel` keyword was added in Igor Pro 7.00.

`lookup=waveName`

Specifies an optional 1D wave used to modify the mapping of scaled Z values into the color table specified with the `ctab` keyword. Values should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the image. Used to apply gamma correction to grayscale images or for special effects. Use `lookup=$ " "` to remove option.

This keyword is not needed with the `image` keyword, even if the image plot uses a lookup wave. The image plot's lookup wave is used instead of the `ColorScale` lookup wave.

`trace=traceInstanceName`

`trace={graphName,traceInstanceName}`

The colors show the color(s) of the named trace. This is useful when the trace has its color set by a “Z wave” using the `ModifyGraph zColor(traceName)=...` feature. In the Modify Trace Appearance dialog this is selected in the “Set as f(z)” subdialog. The color scale’s main axis shows the range of values in the Z wave, and displays any data units the wave may have.

### Size Parameters

The following keyword-value parameters modify the size of the color scale annotation. These keywords are similar to those used by the **Slider** control. The size of the annotation is indirectly controlled by setting the size of the “color bar” and the various axis parameters. The annotation sizes itself to accommodate the color bar, tick labels, and axis labels.

<code>height=h</code>	Sets the height of the color bar in points, overriding any <code>heightPct</code> setting. The default height is 75% of the plot area height if the color scale is vertical, or a constant of 15 points if the color scale is horizontal. The default is restored by specifying <code>height=0</code> . Specifying a <code>heightPct</code> value resets <code>height</code> to this default.
<code>heightPct=hpct</code>	Sets height as a percentage of the graph’s plot area, overriding any <code>height</code> setting. The default height is 75% of the plot area height if the color scale is vertical, or a constant of 15 points if the color scale is horizontal. The default height is restored by setting <code>heightPct=0</code> . Specifying a <code>height</code> value resets <code>heightPct</code> to this default.
<code>side=s</code>	Selects on which axis to draw main axis ticks. <code>s=1:</code> Right of the color bar if <code>vert=1</code> , or below if <code>vert=0</code> . <code>s=2:</code> Left of the color bar if <code>vert=1</code> , or above if <code>vert=0</code> .
<code>vert=v</code>	Specifies color scale orientation. <code>v=0:</code> Horizontal. <code>v=1:</code> Vertical (default).
<code>width=w</code>	Sets the width of the color bar in points, overriding any <code>widthPct</code> setting. The default width is a constant 15 points if the color scale is vertical, or 75% of the plot area width if the color scale is horizontal. The default is restored by specifying <code>width=0</code> . Specifying a <code>widthPct</code> value resets <code>width</code> to this default.
<code>widthPct=wpct</code>	Sets width as a percentage of the graph’s plot area, overriding any <code>width</code> setting. The default width is a constant 15 points if the color scale is vertical, or 75% of the plot area width if the color scale is horizontal. The default is restored by setting <code>widthPct=0</code> . Specifying a <code>width</code> value resets <code>widthPct</code> to this default.

### Color Bar Parameters

The following keyword-value parameters modify the appearance of the color scale color bar.

<code>colorBoxesFrame=on</code>	Draws frames surrounding up to 99 swatches of colors in the color bar ( <code>on=1</code> ).  When specifying more than 99 colors in the color bar (such as the Rainbow color table, which has 100 colors), the boxes aren’t framed. Framing color boxes is effective only for small numbers of colors. Set the width of the frame with the <code>frame</code> keyword.  Use <code>on=0</code> to turn off color box frames.
<code>frame=f</code>	Specifies the thickness of the frame drawn around the color bar in points ( <code>f</code> can range from 0 to 5 points). The default is 1 point. Fractional values are permitted.  Turn frames off with <code>f=0</code> . Values less than 0.5 do not display on screen, but the thin frame will print.

`frameRGB=(r, g, b)` or 0 Sets the color of the frame around the color bar. *r*, *g*, and *b* specify the amount of red, green, and blue as an integer from 0 to 65535. The frame includes the individual color bar colors when `colorBoxesFrame=1`.

The frame will use the colorscale foreground color, as set by the `/G` flag, when `frameRGB=0`.

### Axis Parameters

The following keyword-value parameters modify the appearance of the color scale axes. These keywords are based on the **ModifyGraph** Axis keywords because they modify the main or secondary color scale axes.

`axisRange={zMin, zMax}`

Sets the color bar axis range to values specified by *zMin* and *zMax*. Use `*` to use the default axis range for either or both values.

Omit *zMin* or *zMax* to leave that end of the range unchanged. For example, use `{zMin, }` to change *zMin* and leave *zMax* alone, or use `{ , * }` to set only the axis maximum value to the default value.

`dateInfo={sd,tm,dt}`

Controls formatting of date/time axes.

*sd*=0: Show date in the date&time format.

*sd*=1: Suppress date.

*tm*=0: 12 hour (AM/PM) time.

*tm*=1: 24 hour (military) time.

*tm*=2: Elapsed time.

*dt*=0: Short dates (2/22/90).

*dt*=1: Long dates (Thursday, February 22, 1990).

*dt*=2: Abbreviated dates (Thurs, Feb 22, 1990).

These have no effect unless the axis is controlled by a wave with 'dat' data units.

For an *f(z)* color scale:

`SetScale d, 0,0, "dat", fOfZWave`

For a contour plot or image plot color scale:

`SetScale d, 0,0, "dat", ZorXYZorImageWave`

See **Date/Time Axes** on page II-244 and **Date, Time, and Date&Time Units** on page II-64 for details on how date/time axes work.

`font=fontNameStr`

Name of font as string expression. If the font does not exist, the default font is used. Specifying "default" has the same effect. Unlike **ModifyGraph**, the *fontNameStr* is evaluated at runtime, and its absence from the system is not an error.

`fsize=s`

Sets the font size in points.

*s*=0: Use the graph font size for tick labels and axis labels (default).

`fstyle=fs`

Sets the font style. *fs* is a bitwise parameter with each bit controlling one aspect of the font style for the tick mark labels:

Bit 0: Bold

Bit 1: Italic

Bit 2: Underline

Bit 4: Strikethrough

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

<code>highTrip=<i>h</i></code>	If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation. The default highTrip is 100,000.
<code>lblLatPos=<i>p</i></code>	Sets a lateral offset for the main axis label. This is an offset parallel to the axis. <i>p</i> is in points. Positive is down for vertical axes and to the right for horizontal axes. The default is 0.
<code>lblMargin=<i>m</i></code>	Moves the main axis label by <i>m</i> points (default is 0) from the normal position. The default value is -5, which brings the axis label closer to the axis. Use more positive values to move the axis label away from the axis.
<code>lblRot=<i>r</i></code>	Rotates the axis label by <i>r</i> degrees. <i>r</i> is a value from -360 to 360. Rotation is counterclockwise and starts from the label's normal orientation.
<code>log=<i>l</i></code>	Specifies the axis type: <code>l=0:</code> Linear (default). <code>l=1:</code> Log base 10. <code>l=2:</code> Log base 2.
<code>logHTrip=<i>h</i></code>	Same as highTrip but for log axes. The default is 10,000.
<code>logLTrip=<i>l</i></code>	Same as lowTrip but for log axes. The default is 0.0001.
<code>logTicks=<i>t</i></code>	Specifies the maximum number of decades in log axis before minor ticks are suppressed.
<code>lowTrip=<i>l</i></code>	If the axis extrema are between its lowTrip and its highTrip, then tick mark labels use fixed point notation. Otherwise, they use exponential (scientific or engineering) notation. The default lowTrip is 0.1.
<code>minor=<i>m</i></code>	Controls minor tick marks: <code>m=0:</code> Disables minor ticks (default). <code>m=1:</code> Enables minor ticks.
<code>notation=<i>n</i></code>	Controls tick label notation: <code>n=0:</code> Engineering notation (default). <code>n=1:</code> Scientific notation.
<code>nticks=<i>n</i></code>	Specifies the approximate number of ticks to be distributed along the main axis. Ticks are labelled using the same automatic algorithm used for graph axes. The default is 5.  Set <code>n=0</code> for no ticks.
<code>prescaleExp=<i>exp</i></code>	Multiplies axis range by $10^{exp}$ for tick labeling and <i>exp</i> is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. The default is 0 (no modification). See the discussion in the <b>ModifyGraph (axes) Details</b> section.
<code>tickExp=<i>te</i></code>	Controls tick label exponential notation: <code>te=1:</code> Forces tick labels to exponential notation when labels have units with a prefix. <code>te=0:</code> Turns off exponential notation.

tickLen= <i>t</i>	<p>Sets the length of the ticks. <i>t</i> is the major tick mark length in points. This value must be between -100 and 50.</p> <p><i>t</i>= 0 to 50: Draws tick marks between the tick labels and the colors box.</p> <p><i>t</i>= -1: Default; auto tick length, equal to 70% of the tick label font size. Draws tick marks between the tick labels and the colors box.</p> <p><i>t</i>= -2 to -50: Draws tick marks crossing the edge of the colors box nearest the tick labels. The actual total tick mark length is -<i>t</i>.</p> <p><i>t</i>= -100 to -51: Draws tick marks inside the edge of the colors box nearest the tick labels. Actual tick mark length is -(<i>t</i>+50). For example, -58 makes in an inside tick mark that is 8 points long.</p>
tickThick= <i>t</i>	<p>Sets the tick mark thickness in points (from 0 to 5 points). The default is 1 point. Fractional values are permitted.</p> <p><i>t</i>=0: Turns tick marks off, but not the tick labels.</p>
tickUnit= <i>tu</i>	Turns on ( <i>tu</i> =0) or off ( <i>tu</i> =1) units labels attached to tick marks.
userTicks={ <i>tvWave</i> , <i>tlblWave</i> }	<p>Supplies user defined tick positions and labels for the main axis. <i>tvWave</i> contains the numeric tick positions while text wave <i>tlblWave</i> contains the corresponding labels.</p> <p>Overrides normal ticking specified by <i>nticks</i>.</p> <p>See <b>User Ticks from Waves</b> on page II-241 for details.</p> <p>The tick mark labels can be multiline and use styled text. For more details, see <b>Fancy Tick Mark Labels</b> on page II-270.</p>
ZisZ= <i>z</i>	<i>z</i> =1 labels the zero tick mark (if any) with the single digit "0" regardless of the number of digits used for other labels. Default is <i>z</i> =0.

### Secondary Axis Parameters

axisLabel2= <i>axisLabelString2</i>	Axis label for the secondary axis. This axis label is drawn only if <i>userTicks2</i> is in effect. Text after any \r character is ignored, as is the \r character. The default is " ".
lblLatPos2= <i>p</i>	Sets lateral offset for secondary axis labels. This is an offset parallel to the axis. <i>p</i> is in points. Positive is down for vertical axes and to the right for horizontal axes. The default is 0.
lblMargin2= <i>m</i>	Specifies the distance in points (default 0) to move the secondary axis label from the position that would be normal for a graph. The default is value is -5, which brings the axis label closer to the axis. Use more positive values to move the axis label away from the axis.
lblRot2= <i>r</i>	Rotates the secondary axis label by <i>r</i> degrees counterclockwise starting from the normal label orientation. <i>r</i> is a value from -360 to 360.
userTicks2={ <i>tvWave</i> , <i>tlblWave</i> }	Supplies user defined tick positions and labels for a second axis which is always on the opposite side of the color bar from the main axis. The tick mark labels can be multiline and use styled text. For more details, see <b>Fancy Tick Mark Labels</b> on page II-270. This is the only way to draw a second axis.

### Examples

```
Make/O/N=(20,20) img=p*q; NewImage img      // Make and display an image
ColorScale                                  // Create default color scale
// First annotation is text0
ColorScale/C/N=text0 nticks=3,minor=1,"Altitude"
```

```
ModifyImage img ctab= {*,*,Relief19,0}      // 19-color color table
ColorScale/C/N=text0 axisRange={100,300}    // Detail for 100-300 range
ColorScale/C/N=text0 colorBoxesFrame=1      // Frame the color boxes
ColorScale/C/N=text0 frameRGB=(65535,0,0)   // Red frame
```

### See Also

For all other flags see the **TextBox** and **AppendText** operations.

**AnnotationInfo**, **AnnotationList**

## ColorTab2Wave

**ColorTab2Wave** *colorTableName*

The ColorTab2Wave operation extracts colors from the built-in color table and places them in an Nx3 matrix of red, green, and blue columns named M\_colors. Values are unsigned 16-bit integers and range from 0 to 65535.

N will typically be 100 but may be as little as 9 and as large as 476. Use

```
Variable N= DimSize(M_colors,0)
```

to determine the actual number of colors.

The wave M\_colors is created in the current data folder. Red is in column 0, green is in column 1, and blue in column 2.

### Parameters

*colorTableName* can be any of those returned by **CTabList**, such as Grays or Rainbow.

*colorTableName* can also be Igor or IgorRecent, to return either the 128 standard or 0-32 user-selected colors from Igor's color menu.

### Details

See **Image Color Tables** on page II-305.

## Complex

**Complex** *localName*

Declares a local complex 64-bit double-precision variable in a user-defined function or structure.

Complex is another name for Variable/C. It is available in Igor Pro 7 and later.

## Concatenate

**Concatenate** [*type flags*] [*flags*] *waveListStr*, *destWave*

**Concatenate** [*type flags*] [*flags*] {*wave1*, *wave2*, *wave3*,...}, *destWave*

The Concatenate operation combines data from the source waves into *destWave*, which is created if it does not already exist. If *destWave* does exist and overwrite is not specified, the source waves' data is concatenated with the existing data in the destination wave.

By default the concatenation increases the dimensionality of the destination wave if possible. For example, if you concatenate two 1D waves of the same length you get a 2D wave with two columns. The destination wave is said to be "promoted" to a higher dimensionality.

If you use the /NP (no promotion) flag, the dimensionality of the destination wave is not changed. For example, if you concatenate two 1D waves of the same length using /NP you get a 1D wave whose length is the sum of the lengths of the source waves.

If the source waves are of different lengths, no promotion is done whether /NP is used or not.

### Parameters

*waveListStr* is a string expression containing a list of wave names separated by semicolons. The list must be terminated with a semicolon. The alternate syntax using {*wave1*, *wave2*, ...} is limited to 100 waves or less, but there is no limit when using *waveListStr*.

*destWave* is the name of a new or existing wave that will contain the concatenation result.

### Flags

/DL	Sets dimension labels. For promotion, it uses source wave names as new dimension labels otherwise it uses existing labels.
/KILL	Kills source waves.
/NP	Prevents promotion to higher dimension.
/NP= <i>dim</i>	Prevents promotion and appends data along the specified dimension (0= rows, 1= columns, 2=layers, 3=chunks). All dimensions other than the one specified by <i>dim</i> must be the same in all waves.
/O	Overwrites <i>destWave</i> .

### Type Flags (used only in functions)

Concatenate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-67 and **WAVE Reference Type Flags** on page IV-68 for a complete list of type flags and further details.

### Details

If *destWave* does not already exist or, if the /O flag is used, *destWave* is created by duplication of the first source wave. Waves are concatenated in order through the list of source waves. If *destWave* exists and the /O flag is not used, then the concatenation starts with *destWave*.

*destWave* cannot be used in the source wave list.

Source waves must be either all numeric or all text.

If promotion is allowed, the number of low-order dimensions that all waves share in common determines the dimensionality of *destWave* so that the dimensionality of *destWave* will then be one greater. The default behaviors will vary according to the source wave sizes. Concatenating 1D waves that are all the same length will produce a 2D wave, whereas concatenating 1D waves of differing lengths will produce a 1D wave. Similarly, concatenating 2D waves of the same size will produce a 3D wave; but if the 2D source waves have differing numbers of columns then *destWave* will be a 2D wave, or if the 2D waves have differing numbers of rows then *destWave* will be a 1D wave. Concatenating 1D and 2D waves that have the same number of rows will produce a 2D wave, but when the number of rows differs, *destWave* will be a 1D wave. See the examples.

## conj

Use the /NP flag to suppress dimension promotion and keep the dimensionality of *destWave* the same as the input waves.

### Examples

```
// Given the following waves:
Make/N=10 w1,w2,w3
Make/N=11 w4
Make/N=(10,7) m1,m2,m3
Make/N=(10,8) m4
Make/N=(9,8) m5

// Concatenate 1D waves
Concatenate/O {w1,w2,w3},wdest           // wdest is a 10x3 matrix
Concatenate {w1,w2,w3},wdest             // wdest is a 10x6 matrix
Concatenate/NP/O {w1,w2,w3},wdest        // wdest is a 30-point 1D wave
Concatenate/O {w1,w2,w3,w4},wdest        // wdest is a 41-point 1D wave

// Concatenate 2D waves
Concatenate/O {m1,m2,m3},wdest           // wdest is a 10x7x3 volume
Concatenate/NP/O {m1,m2,m3},wdest        // wdest is a 10x21 matrix
Concatenate/O {m1,m2,m3,m4},wdest        // wdest is a 10x29 matrix
Concatenate/O {m4,m5},wdest              // wdest is a 152-point 1D wave
Concatenate/O/NP=0 {m4,m5},wdest         // wdest is a 19x8 matrix

// Concatenate 1D and 2D waves
Concatenate/O {w1,m1},wdest              // wdest is a 10x8 matrix
Concatenate/O {w4,m1},wdest              // wdest is a 81-point 1D wave

// Append rows to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=0 {m6}, m7                // m7 is a 6x2 matrix

// Append columns to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=1 {m6}, m7                // m7 is a 3x4 matrix

// Append layer to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=2 {m6}, m7               // m7 is a 3x2x2 volume
// The last command has the same effect as:
// Concatenate {m6}, m7
// Both versions extend add a third dimension to m7
```

**Duplicate, Redimension, SplitWave**

## conj

### conj (z)

The conj function returns the complex conjugate of the complex value z.

### See Also

**cmplx, imag, magsqr, p2rect, r2polar, and real** functions.

## Constant

**Constant** *kName* = *literalNumber*

**Constant/C** *kName* = (*literalNumberReal*, *literalNumberImag*)

The Constant declaration defines the number *literalNumber* under the name *kName* for use by other code, such as in a switch construct.

The complex form, using the /C flag to create a complex constant, requires Igor Pro 7.00 or later.

### See Also

The **Strconstant** keyword for string types, **Constants** on page IV-47 and **Switch Statements** on page IV-41.

## continue

### continue

The continue flow control keyword returns execution to the beginning of a loop, bypassing the remainder of the loop's code.

### See Also

**Continue Statement** on page IV-45 and **Loops** on page IV-42 for usage details.

## ContourInfo

**ContourInfo**(*graphNameStr*, *contourWaveNameStr*, *instanceNumber*)

The ContourInfo function returns a string containing a semicolon-separated list of information about the specified contour plot in the named graph.

### Parameters

*graphNameStr* can be "" to refer to the top graph.

*contourWaveNameStr* is a string containing either the name of a wave displayed as a contour plot in the named graph, or a contour instance name (wave name with “#n” appended to distinguish the nth contour plot of the wave in the graph). You might get a contour instance name from the **ContourNameList** function.

If *contourWaveNameStr* contains a wave name, *instanceNumber* identifies which instance you want information about. *instanceNumber* is usually 0 because there is normally only one instance of a wave displayed as a contour plot in a graph. Set *instanceNumber* to 1 for information about the second contour plot of the wave, etc. If *contourWaveNameStr* is "", then information is returned on the *instanceNumber*th contour plot in the graph.

If *contourWaveNameStr* contains an instance name, and *instanceNumber* is zero, the instance is taken from *contourWaveNameStr*. If *instanceNumber* is greater than zero, the wave name is extracted from *contourWaveNameStr*, and information is returned concerning the *instanceNumber*th instance of the wave.

### Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
DATAFORMAT	Either XYZ or Matrix.
LEVELS	A comma-separated list of the contour levels, including the final automatic levels, (or manual or from-wave levels), and the “more levels”, all sorted into ascending Z order.
RECREATION	List of keyword commands as used by <b>ModifyContour</b> command. The format of these keyword commands is: <i>keyword (x)=modifyParameters;</i>
TRACESFORMAT	The format string used to name the contour traces (see <b>AppendMatrixContour</b> or <b>AppendXYZContour</b> ).
XAXIS	X axis name.
XWAVE	X wave name if any, else blank.
XWAVEDF	Full path to the data folder containing the X wave or blank if there is no X wave.
YAXIS	Y axis name.
YWAVE	Y wave name if any, else blank.
YWAVEDF	Full path to the data folder containing the Y wave or blank if there is no Y wave.
ZWAVE	Name of wave containing Z data from which the contour plot was calculated.
ZWAVEDF	Full path to the data folder containing the Z data wave.

---

## ContourNameList

---

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “;”, prepend “ModifyContour”, replace the “x” with the name of a contour plot (“data#1” for instance) and then **Execute** the resultant string as a command.

### Examples

The following command lines create a very unlikely contour display. If you did this, you would most likely want to put each contour plot on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack
Display;AppendMatrixContour jack
AppendMatrixContour/T/R jack           // Second instance of jack
```

This example accesses the contour information for the second contour plot of the wave “jack” (which has an instance number of 1) displayed in the top graph:

```
Print StringByKey("ZWAVE", ContourInfo("", "jack", 1))    // prints jack
```

### See Also

The **Execute** and **ModifyContour** operations.

## ContourNameList

**ContourNameList**(*graphNameStr*, *separatorStr*)

The ContourNameList function returns a string containing a list of contours in the graph window or subwindow identified by *graphNameStr*.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

The parameter *separatorStr* should contain a single character such as “,” or “;” to separate the names.

A contour name is defined as the name of the wave containing the data from which a contour plot is calculated, with an optional #n suffix that distinguishes between two or more contour plots in the same graph window that have the same wave name. Since the contour name has to be parsed, it is quoted if necessary.

### Examples

The following command lines create a very unlikely contour display. If you did this, you would most likely want to put each contour plot on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack, 'jack # 2';
Display;AppendMatrixContour jack
AppendMatrixContour/T/R jack
AppendMatrixContour 'jack # 2'
AppendMatrixContour/T/R 'jack # 2'
Print ContourNameList("", ";")

prints jack;jack#1;'jack # 2';'jack # 2'#1;
```

### See Also

Another command related to contour plots and waves: **ContourNameToWaveRef**.

For commands referencing other waves in a graph: **TraceNameList**, **WaveRefIndexed**, **XWaveRefFromTrace**, **TraceNameToWaveRef**, **CsrWaveRef**, **CsrXWaveRef**, **ImageNameList**, and **ImageNameToWaveRef**.

## ContourNameToWaveRef

**ContourNameToWaveRef**(*graphNameStr*, *contourNameStr*)

Returns a wave reference to the wave corresponding to the given contour name in the graph window or subwindow named by *graphNameStr*.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

The contour name is identified by the string in *contourNameStr*, which could be a string determined using ContourNameList. Note that the same contour name can refer to different waves in different graphs, if the waves are in different data folders.

#### See Also

The **ContourNameList** function.

For a discussion of wave reference functions, see **Wave Reference Functions** on page IV-186.

## ContourZ

**ContourZ**(*graphNameStr*, *contourInstanceNameStr*, *x*, *y* [,*pointFindingTolerance*])

The ContourZ function returns the interpolated Z value of the named contour plot data displayed in the named graph.

For gridded contour data, ContourZ returns the bilinear interpolation of the four surrounding XYZ values.

For XYZ triplet contour data, ContourZ returns the value interpolated from the three surrounding XYZ values identified by the Delaunay triangulation.

#### Parameters

*graphNameStr* can be "" to specify the topmost graph.

*contourNameStr* is a string containing either the name of the wave displayed as a contour plot in the named graph, or a contour instance name (wave name with “#n” appended to distinguish the nth contour plot of the wave in the graph). You might get a contour instance name from the **ContourNameList** function.

If *contourNameStr* contains a wave name, *instance* identifies which contour plot of *contourNameStr* you want information about. *instance* is usually 0 because there is normally only one instance of a wave displayed as a contour plot in a graph. Set *instance* to 1 for information about the second contour plot of *contourNameStr*, etc. If *contourNameStr* is "", then information is returned on the *instanceth* contour plot in the graph.

If *contourNameStr* contains an instance name, and *instance* is zero, the instance is taken from *contourNameStr*. If *instance* is greater than zero, the wave name is extracted from *contourNameStr*, and information is returned concerning the *instanceth* instance of the wave.

*x* and *y* specify the X and Y coordinates of the value to be returned. This may or may not be the location of a data point in the wave selected by *contourNameStr* and *instance*.

Set *pointFindingTolerance* = 1e-5 to overcome the effects of perturbation (see the perturbation keyword of the **ModifyContour** operation).

The default value is 1e-15 to account for rounding errors created by the triangulation scaling (see **ModifyContour**'s *equalVoronoiDistances* keyword), which works well **ModifyContour** *perturbation*=0.

A value of 0 would require an exact match between the scaled x/y coordinate and the scaled and possibly perturbed coordinates to return the original z value; that is an unlikely outcome.

#### Details

For gridded contour data, ContourZ returns NaN if *x* or *y* falls outside the XY domain of the contour data. If *x* and *y* fall on the contour data grid, the corresponding Z value is returned.

For XYZ triplet contour data, ContourZ returns the null value if *x* or *y* falls outside the XY domain of the contour data. You can set the null value to *v* with this command:

```
ModifyContour contourName nullValue=v
```

If *x* and *y* match one of the XYZ triplet values, the corresponding Z value from the triplet usually won't be returned because Igor uses the Watson contouring algorithm which perturbs the x and y values by a small random amount. This also means that normally x and y coordinates on the boundary will return a null value about half the time if perturbation is on and *pointFindingTolerance* is greater than 1e-5.

#### Examples

Because ContourZ can interpolate the Z value of the contour data at any X and Y coordinates, you can use ContourZ to convert XYZ triplet data into gridded data:

```
// Make example XYZ triplet contour data
Make/O/N=50 wx,wy,wz
```

## ControlBar

---

```
wx= enoise(2)           // x = -2 to 2
wy= enoise(2)           // y = -2 to 2
wz= exp(-(wx[p]*wx[p] + wy[p]*wy[p])) // XY gaussian, z= 0 to 1

// ContourZ requires a displayed contour data set
Display; AppendXYZContour wz vs {wx,wy};DelayUpdate
ModifyContour wz autolevels={*,*,0} // no contour levels are needed
ModifyContour wz xymarkers=1 // show the X and Y locations

// Set the null (out-of-XY domain) value
ModifyContour wz nullValue=NaN // default is min(wz) - 1

// Convert to grid: Make matrix that spans X and Y
Make/O/N=(30,30) matrix
SetScale/I x, -2, 2, "", matrix
SetScale/I y, -2, 2, "", matrix
matrix= ContourZ("", "wz", 0, x, y) // or = ContourZ("", "", 0, x, y)
AppendImage matrix
```

## ControlBar

**ControlBar** [*flags*] *barHeight*

The ControlBar operation sets the height and location of the control bar in a graph.

### Parameters

*barHeight* is in points on Macintosh and pixels or points on Windows, depending on the screen resolution. See **Control Panel Resolution on Windows** on page III-405 for details.

Setting *barHeight* to zero removes the control bar.

### Flags

- |                      |  |
|----------------------|--|
| /L/R/B/T             | Designates whether to use the Left, Right, Bottom, or Top (default) window edge, respectively, for the control bar location. |
| /W= <i>graphName</i> | Specifies the name of a particular graph containing a control bar.   |

### Details

The control bar is an area at the top of graphs reserved for controls such as buttons, checkboxes and pop-up menus. A line is drawn between this area and the graph area. The control bar may be assigned a separate background color by pressing Control (*Macintosh*) or Ctrl (*Windows*) and clicking in the area, by right-clicking it (*Windows*), or with the **ModifyGraph** operation. You can not use draw tools in this area.

For graphs with no controls you do not need to use this operation.

### Examples

```
Display myData
ControlBar 35 // 35 pixels high
Button button0, pos={56,8}, size={90,20}, title="My Button"
```

### See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

## ControlInfo

**ControlInfo** [/W=*winName*] *controlName*

The ControlInfo operation returns information about the state or status of the named control in a graph or control panel window or subwindow.

### Flags

- /G [=*doGlobal*]      If *doGlobal* is non-zero or absent, the position returned via V\_top and V\_left is in global screen coordinates rather relative to the window containing the control.
- /W=*winName*      Looks for the control in the named graph or panel window or subwindow. If /W is omitted, ControlInfo looks in the top graph or panel window or subwindow.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

### Parameters

*controlName* is the name of a control in the window specified by /W or in the top graph or panel window. *controlName* may also be the keyword kwBackgroundColor to set V\_Red, V\_Green, V\_Blue, and V\_Alpha, the keyword kwControlBar or kwControlBarBottom to set V\_Height, the keyword kwControlBarLeft or kwControlBarRight to set V\_Width, or the keyword kwSelectedControl to set S\_value and V\_flag.

### Details

Information for all controls is returned via the following string and numeric variables:

- S\_recreation      Commands to recreate the named control.
- V\_disable      Disable state of control:
- 0:      Normal (enabled, visible).
  - 1:      Hidden.
  - 2:      Disabled, visible.
- V\_Height, V\_Width, V\_top, V\_left      Dimensions and position of the named control in pixels.

The kind of control is returned in V\_flag as a positive or negative integer. A negative value indicates the control is incomplete or not active. If V\_flag is zero, then the named control does not exist. Information returned for specific control types is as follows:

### Buttons

- V\_flag      1
- V\_value      Tick count of last mouse up.
- S\_UserData      Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
- See also the descriptions of S\_recreation, V\_disable, V\_Height, V\_Width, V\_top, V\_left at the beginning of the Details section.

### Chart

- V\_flag      6 or -6
- V\_value      Current point number.
- S\_UserData      Keyword-packed information string. See **S\_value for Chart Details** for more keyword information.
- See also the descriptions of S\_recreation, V\_disable, V\_Height, V\_Width, V\_top, V\_left at the beginning of the Details section.

### Checkbox

V_flag	2
V_value	0 if it is deselected or 1 if it is selected.
S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the <b>GetUserData</b> operation.  See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left at the beginning of the Details section.

### CustomControl

V_flag	12
V_value	Tick count of last mouse up.
S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the <b>GetUserData</b> operation.
S_value	Name of the picture used to define the control appearance.  See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left at the beginning of the Details section.

### GroupBox

V_flag	9
S_value	Title text.  See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left at the beginning of the Details section.

### ListBox

V_flag	11
V_value	Currently selected row (valid for mode 1 or 2 or modes 5 and 6 when no selWave is used). If no list row is selected, then it is set to -1.
V_selCol	Currently selected column (valid for modes 5 and 6 when no selWave is used).
V_horizScroll	Number of pixels the list has been scrolled horizontally to the right.
V_vertScroll	Number of pixels the list has been scrolled vertically downwards.
V_rowHeight	Height of a row in pixels.
V_startRow	The current top visible row.
S_columnWidths	A comma-separated list of column widths in pixels.
S_dataFolder	Full path to listWave (if any).
S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the <b>GetUserData</b> operation.
S_value	Name of listWave (if any).  See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left at the beginning of the Details section.

### PopupMenu

V_flag	3 or -3
--------	---------

V_Red, V_Green, V_Blue, V_Alpha	For color array pop-up menus, these are the encoded color values.
V_value	Current item number (counting from one).
S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the <b>GetUserData</b> operation.
S_value	Text of the current item. If PopupMenu is a color array then it contains color values encoded as $(r,g,b)$ where $r$ , $g$ , and $b$ are integers from 0 to 65535.  See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left at the beginning of the Details section.

**SetVariable**

V_flag	5 or -5
V_value	Value of the variable. If the SetVariable is used with a string variable, then it is the interpretation of the string as a number, which will be NaN if conversion fails.
S_dataFolder	Full path to the variable.
S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the <b>GetUserData</b> operation.
S_value	Name of the variable or, if the value was set using _STR: syntax, the string value itself.  See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left at the beginning of the Details section.

**Slider**

V_flag	7
V_value	Numeric value of the variable.
S_dataFolder	Full path to the variable.
S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the <b>GetUserData</b> operation.
S_value	Name of the variable.  See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left at the beginning of the Details section.

**TabControl**

V_flag	8
V_value	Number of the current tab.
S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the <b>GetUserData</b> operation.
S_value	Tab text.  See also the descriptions of S_recreation, V_disable, V_Height, V_Width, V_top, V_left at the beginning of the Details section.

**TitleBox**

V_flag	10
S_dataFolder	Full path if text is from a string variable.
S_value	Name if text is from a string variable.

See also the descriptions of S\_recreation, V\_disable, V\_Height, V\_Width, V\_top, V\_left at the beginning of the Details section.

### ValDisplay

V\_flag 4 or -4

V\_value Displayed value.

S\_value Text of expression that ValDisplay evaluates.

See also the descriptions of S\_recreation, V\_disable, V\_Height, V\_Width, V\_top, V\_left at the beginning of the Details section.

### kwBackgroundColor

V\_Red, V\_Green, V\_Blue, V\_Alpha If *controlName* is kwBackgroundColor then this is the color of the control panel background. This color is usually the default user interface background color, as set by the Appearance control panel on the Macintosh or by the Appearance tab of the Display Properties on Windows, until changed by ModifyPanel cbRGB.

### kwControlBar or kwControlBarTop

V\_Height The height in pixels of the top control bar area in a graph as set by **ControlBar**.

### kwControlBarBottom

V\_Height The height in pixels of the bottom control bar area in a graph as set by **ControlBar/B**.

### kwControlBarLeft

V\_Width The width in pixels of the left control bar area in a graph as set by **ControlBar/L**.

### kwControlBarRight

V\_Width The width in pixels of the right control bar area in a graph as set by **ControlBar/R**.

### kwSelectedControl

V\_flag Set to 1 if a control is selected or 0 if not.

**SetVariable** and **ListBox** controls can be selected, most other controls can not.

S\_value Name of selected control (if any) or "".

### S\_value for Chart Details

The following applies *only* to the keyword-packed information string returned in S\_value for a chart. S\_value will consist of a sequence of sections with the format: "*keyword:value*;" You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions. Here are the S\_value keywords:

Keyword	Type	Meaning
FNAME	string	Name of the FIFO chart is monitoring.
LHSAMP	number	Left hand sample number.
NCHANS	number	Number of channels displayed in chart.
PPSTRIP	number	The chart's points per strip value.
RHSAMP	number	Right hand sample number (same as V_value).

In addition, `ControlInfo` writes fields to `S_value` for each channel in the chart. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named "Pressure" then the following would appear in the `S_value` string: "CHNAME4:Pressure". In the following table, the channel's number is represented by #:

Keyword	Type	Meaning
CHCTAB#	number	Channel's color table value as set by Chart ctab keyword.
CHGAIN#	number	Channel's gain value as set by Chart gain keyword.
CHNAME#	string	Name of channel defined by FIFO.
CHOFFSET#	number	Channel's offset value as set by Chart offset keyword.

### Examples

```
ControlInfo myChart; Print S_value
```

Prints the following to the history area:

```
FNAME:myFIFO;NCHANS:1;PPSTRIP:1100;RHSAMP:271;LHSAMP:-126229;
```

### See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

## ControlNameList

```
ControlNameList(winNameStr [, listSepStr [, matchStr]])
```

The `ControlNameList` function returns a string containing a list of control names in the graph or panel window or subwindow identified by `winNameStr`.

### Parameters

`winNameStr` can be "" to refer to the top graph or panel window.

When identifying a subwindow with `winNameStr`, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

The optional parameter `listSepStr` should contain a single character such as "," or ";" to separate the names; the default value is ";".

The optional parameter `matchStr` is some combination of normal characters and the asterisk wildcard character that matches anything. To use `matchStr`, `listSepStr` must also be used. See **StringMatch** for wildcard details.

Only control names that satisfy the match expression are returned. For example, "\*\_tab0" matches all control names that end with "\_tab0". The default is "\*", which matches all control names.

### Examples

```
NewPanel
Button myButton
Checkbox myCheck
Print ControlNameList("")           // prints "myButton;myCheck;"
Print ControlNameList("", ";", "*Check") // prints "myCheck;"
```

### See Also

The **ListMatch**, **StringFromList** and **StringMatch** functions, and the **ControlInfo** and **ModifyControlList** operations. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

### ControlUpdate

**ControlUpdate** [/A/W=*winName*] [*controlName*]

The ControlUpdate operation updates the named control or all controls in a window, which can be the top graph or control panel or the named graph or control panel if you use /W.

#### Flags

/A	Updates all controls in the window. You must omit <i>controlName</i> .
/W= <i>winName</i>	Specifies the window or subwindow containing the control. If you omit <i>winName</i> it will use the top graph or control panel window or subwindow.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

#### Details

ControlUpdate is useful for forcing a pop-up menu to rebuild, to update a ValDisplay control, or to forcibly accept a SetVariable's currently-being-edited value.

Normally, a pop-up menu rebuilds only when the user clicks on it. If you set up a pop-up menu so that its contents depend on a global string variable, on a user-defined string function or on an Igor function (e.g., **WaveList**), you may want to force the pop-up menu to be updated at your command.

Usually, a ValDisplay control displays the value of a global variable or of an expression involving a global variable. If the global variable changes, the ValDisplay will automatically update. However, you can create a ValDisplay that displays a value that does not depend on a global variable. For example, it might display the result of an external function. In a case like this, the ValDisplay will not automatically update. You can update it by calling ControlUpdate.

When a SetVariable control is being edited, the text the user types isn't "accepted" (or processed) until the user presses Return or Enter. ControlUpdate effectively causes the named control to act as though the user has pressed one of those keys. If /A is specified, the currently active SetVariable control (if any) is affected this way. The motivation here is that the user may have typed a new value without having yet pressed return, and then may click a button in a different panel which runs a routine that uses the SetVariable value as input. The user expected the typed value to have been accepted but the variable has not yet been set. Calling ControlUpdate/A on the first panel will read the typed value in the variable, avoiding a discrepancy between the visible value of the SetVariable control and the actual value of the variable.

#### Examples

```
NewPanel;DoWindow/C PanelX
String/G popupList="First;Second;Third"
PopupMenu oneOfThree value=popupList           // popup shows "First"
popupList="1;2;3"                               // popup is unchanged
ControlUpdate/W=PanelX oneOfThree              // popup shows "1"
```

#### See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **ValDisplay** and **WaveList** operations.

### ConvertGlobalStringTextEncoding

**ConvertGlobalStringTextEncoding** [flags] originalTextEncoding, newTextEncoding,  
[string, string, ...]

The ConvertGlobalStringTextEncoding operation converts the contents of the specified global string variables or the contents of all global string variables in the data folder specified with the /DF flag from one text encoding to another.

The ConvertGlobalStringTextEncoding operation was added in Igor Pro 7.00.

By default, the contents of global string variables containing control characters (codes less than 32) other than carriage return (13), linefeed (10), and tab (9) are not converted. To convert the contents of global string variables containing control characters, you must include the /SKIP=0 flag.

In Igor Pro 7, the contents of all global string variables are assumed to be encoded as UTF-8. You should convert the text encoding of a global string variable if, for example, you have global string variables in

experiments created prior to Igor7 and they contain non-ASCII characters. For those strings to be displayed and interpreted correctly in Igor Pro 7, their contents need to be converted to UTF-8.

Most users will have no need to worry about the text encoding of Igor global string variables since most global string variables do not contain non-ASCII text. You should not use this operation unless you have a thorough understanding of text encoding issues or are instructed to use it by someone who has a thorough understanding.

See **String Variable Text Encodings** on page III-428 for essential background information.

ConvertGlobalStringTextEncoding can work on a list of specific global string variables or on all of the global string variables in a data folder (/DF flag). When working on a data folder, it can work on just the data folder itself or recursively on sub-data folders as well.

Conversion does not change the characters that make up text - it merely changes the numeric codes used to represent those characters.

### Parameters

*originalTextEncoding* specifies the original (current) text encoding used by the specified global string variables. See **Text Encoding Names and Codes** on page III-434 for a list of codes. It will typically be 2 (MacRoman), 3 (Windows-1252) or 4 (Shift JIS), depending on the system on which the string variables were created.

*newTextEncoding* specifies the output text encoding. See **Text Encoding Names and Codes** on page III-434 for a list of codes. It will typically be 1 which stands for UTF-8.

*string , string , ...* is a list of targeted global string variables. Only the name of string variables, not a path specification plus the name, is allowed. Therefore, the string variables must be in the current data folder. The list is optional and must be omitted if you use the /DF flag. Using both the /DF flag and a list of string variables is treated as an error. Use of local string variables in this list is also an error. Use **ConvertTextEncoding** to convert local string variables.

### Flags

/CONV={*errorMode* [, *diagnosticsFlags*]}

*errorMode* determines how ConvertGlobalStringTextEncoding behaves if the conversion can not be done because the text can not be mapped to the specified text encoding. This occurs if the string variable's original text is not valid in the specified *originalTextEncoding* or if it contains characters that can not be represented in the specified *newTextEncoding*.

*errorMode* takes one of these values:

- 1: Generate error. SetWaveTextEncoding returns an error to Igor.
- 2: Use a substitute character for any unmappable characters. The substitute character for most text encodings is either control-Z or a question mark.
- 3: Skip unmappable input characters. Any unmappable characters will be missing in the output.
- 4: Use escape sequences representing any unmappable characters or invalid source text.

If the source text is valid in the source text encoding but can not be represented in the destination text encoding, unmappable characters are replaced with \uXXXX where XXXX specifies the UTF-16 code point of the unmappable character in hexadecimal.

If the conversion can not be done because the source text is not valid in the source text encoding, invalid bytes are replaced with \xXX where XX specifies the value of the invalid byte in

*diagnosticsFlags* is an optional bitwise parameter defined as follows:

- Bit 0: Emit diagnostic message if text conversion succeeds.
- Bit 1: Emit diagnostic message if text conversion fails.
- Bit 2: Emit diagnostic message if text conversion is skipped.
- Bit 3: Emit summary diagnostic message.

All other bits are reserved for future use.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*diagnosticsFlags* defaults to 6 (bits 1 and 2 set) if the /DF flag is not present and to 14 (bits 1, 2 and 3 set) if the /DF flag is present.

ConvertGlobalStringTextEncoding skips text conversion if the global string variable's contents are detected as binary and you omit /SKIP=0.

/DF={*dfr*, *recurse*, *excludedDFR*}

*dfr* is a reference to a data folder. ConvertGlobalStringTextEncoding operates on all global string variables in the specified data folder. If *dfr* is null (\$) ConvertGlobalStringTextEncoding acts as if /DF was omitted.

If you use the /DF flag, you must omit the optional string variable list.

If *recurse* is 1, ConvertGlobalStringTextEncoding works recursively on all sub-data folders. Otherwise it affects only the data folder referenced by *dfr*.

*excludedDFR* is an optional reference to a data folder to be skipped by ConvertGlobalStringTextEncoding. For example, this command converts the string data for all global string variables in all data folders except for root:Packages and its sub-data folders:

```
ConvertGlobalStringTextEncoding /DF={root:,1,root:Packages} 4, 1
```

If *excludedDFR* is null (\$) ConvertGlobalStringTextEncoding acts as if *excludedDFR* was omitted and no data folders are excluded.

/SKIP=*skip*

Skips conversion of a string variable if the string contains control characters (codes less than 32) other than carriage return (13), linefeed (10), and tab (9).

- skip=0: Do not skip conversion of any string variables.
- skip=1: Skip conversion of string variables containing binary data.

This is the default behavior if /SKIP is omitted.

/Z[=*z*]

Prevents procedure execution from aborting if ConvertGlobalStringTextEncoding generates an error. Use /Z or the equivalent, /Z=1, if you want to handle errors in your procedures rather than having execution abort.

/Z does not suppress invalid parameter errors. It suppresses only errors in doing text encoding reinterpretation or conversion.

### Details

For general background information on text encodings, see **Text Encodings** on page III-409.

For background information on string variable text encodings, see **String Variable Text Encodings** on page III-428.

ConvertGlobalStringTextEncoding is used to change the numeric codes representing the text - i.e., to convert the content to a different text encoding. Its main use is to convert Igor Pro 6 global string variables from whatever text encoding they use, which typically will be MacRoman, Windows-1252, or Shift JIS, to UTF-8. UTF-8 is a form of Unicode which is more modern but is not backward compatible with Igor Pro 6. Igor Pro 7 assumes that string variables are encoded as UTF-8.

For example, if you have global string variables from Igor Pro 6 that are encoded in Japanese (Shift JIS) and contain non-ASCII characters, you should convert them to UTF-8. Otherwise you will get errors or garbled text if you print the string variable or use it, for example, to label a graph. This also applies to western text

encoded as MacRoman or Windows-1252 which contain non-ASCII characters. Conversion changes the underlying numeric codes but does not change the characters represented by the text.

### Output Variables

The ConvertGlobalStringTextEncoding operation returns information in the following variables:

V_numConversionsSucceeded	V_numConversionsSucceeded is set to the number of successful text conversions.
V_numConversionsFailed	V_numConversionsFailed is set to the number of unsuccessful text conversions.
V_numConversionsSkipped	V_numConversionsSkipped is set to the number of skipped text conversions. Text conversion is skipped if the string variable contains binary data and the /SKIP=0 flag is omitted.

### Examples

```
// In the following examples 1 means UTF-8, 4 means Shift JIS.

// Convert specific strings' content from Shift JIS to UTF-8
ConvertGlobalStringTextEncoding 4, 1, string0, string1

// Convert all strings' content from Shift JIS to UTF-8
ConvertGlobalStringTextEncoding /DF={root:,1} 4, 1

// Same as before but exclude the root:Packages data folder
ConvertGlobalStringTextEncoding /DF={root:,1,root:Packages} 4, 1

// Convert all strings' content from Shift JIS to UTF-8 except strings containing binary
ConvertGlobalStringTextEncoding /DF={root:,1}/SKIP=0 4, 1
```

**ConvertTextEncoding**, **SetWaveTextEncoding**

## ConvertTextEncoding

**ConvertTextEncoding**(*sourceTextStr*, *sourceTextEncoding*, *destTextEncoding*, *mapErrorMode*, *options*)

ConvertTextEncoding converts text from one text encoding to another.

The ConvertTextEncoding function was added in Igor Pro 7.00.

In Igor Pro 7, all text in memory is assumed to be in UTF-8 format except for text stored in waves which can be stored in any text encoding. You might want to convert text from UTF-8 to Windows-1252 (Windows Western European), for example, to export it to a program that expects Windows-1252.

You might have text already loaded into Igor that you know to be in Windows-1252. To display it correctly in Igor Pro 7 you need to convert it to UTF-8.

You can also use ConvertTextEncoding to test if text is valid in a given text encoding, by specifying the same text encoding for *sourceTextEncoding* and *destTextEncoding*.

### Parameters

*sourceTextStr* is the text that you want to convert.

*sourceTextEncoding* specifies the source text encoding.

*destTextEncoding* specifies the output text encoding.

See **Text Encoding Names and Codes** on page III-434 for a list of acceptable text encoding codes.

*mapErrorMode* determines what happens if an input character can not be mapped to the output text encoding because the character does not exist in the output text encoding. It takes one of these values:

*options* is a bitwise parameter which defaults to 0 and with the bits defined as follows:

All other bits are reserved and must be cleared.

- 1: Generate error. The function returns "" and generates an error.
  - 2: Return a substitute character for the unmappable character. The substitute character for most text encodings is either control-Z or a question mark.
  - 3: Skip unmappable input character.
  - 4: Return escape sequences representing unmappable characters and invalid source text.  
If the source text is valid in the source text encoding but can not be represented in the destination text encoding, unmappable characters are replaced with \uXXXX where XXXX specifies the UTF-16 code point of the unmappable character in hexadecimal. The DemoUnmappable example function below illustrates this.  
If the conversion can not be done because the source text is not valid in the source text encoding, invalid bytes are replaced with \xxx where xx specifies the value of the invalid byte in hexadecimal. The DemoInvalid example function below illustrates this.  
If mapErrorMode is 2, 3 or 4, the function does not return an error in the event of an unmappable character.
- Bit 0: If cleared, in the event of a text conversion error, a null string is returned and an error is generated. Use this if you want to abort procedure execution if an error occurs.  
If set, in the event of a text conversion error, a null string is returned but no error is generated. Use this if you want to detect and handle a text conversion error. You can test for null using strlen as shown in the example below.
- Bit 1: If cleared (default), null bytes in *sourceTextStr* are considered invalid and ConvertTextEncoding returns an error. If set, null bytes are considered valid.
- Bit 2: If cleared (default) and *sourceTextEncoding* and *destTextEncoding* are the same, ConvertTextEncoding attempts to do the conversion anyway. If *sourceTextStr* is invalid in the specified text encoding, the issue is handled according to *mapErrorMode*. This allows you to check the validity of text whose text encoding you think you know, by passing 1 for *mapErrorMode* and 5 for *options*. Use **strlen** to test if the returned string is null, indicating that *sourceTextStr* is not valid in the specified text encoding.  
If set and *sourceTextEncoding* and *destTextEncoding* are the same, ConvertTextEncoding merely returns *sourceTextStr* without doing any conversion.

### Details

ConvertTextEncoding returns a null result string if *sourceTextEncoding* or *destTextEncoding* are not valid text encoding codes or if a text conversion error occurs. You can test for a null string using strlen which returns NaN if the string is null.

If bit 0 of the *options* parameter is cleared, Igor generates an error which halts procedure execution. If it is set, Igor generates no error and you should test for null and attempt to handle the error, as illustrated by the example below.

A text conversion error occurs if *mapErrorMode* is 1 and the source text contains one or more characters that are not mappable to the destination text encoding. A text conversion error also occurs if the source text contains a sequence of bytes that is not valid in the source text encoding.

The "binary" text encoding (255) is not a real text encoding. If either *sourceTextEncoding* or *destTextEncoding* are binary (255), ConvertTextEncoding does no conversion and just returns *sourceTextStr* unchanged.

See **Text Encodings** on page III-409 for further details.

### Example

In reading these examples, keep in mind that Igor converts escape codes such as "\u8C4A", when they appear in literal text, to the corresponding UTF-8 characters. See **Unicode Escape Sequences in Strings** on page IV-14 for details.

```
Function DemoConvertTextEncoding()  
  // Get text encoding codes for text the text encodings used below  
  Variable teUTF8 = TextEncodingCode("UTF-8")  
  Variable teWindows1252 = TextEncodingCode("Windows-1252")
```

```

Variable teShiftJIS = TextEncodingCode("ShiftJIS")

// Convert from Windows-1252 to UTF-8
String source = "Division sign: " + num2char(0xF7)
String result = ConvertTextEncoding(source, teWindows1252, teUTF8, 1, 0)
Print result

// Convert unmappable character from UTF-8 to Windows-1252
// \u8C4A is an escape sequence representing a Japanese character in Unicode
// for which there is no corresponding character in Windows-1252

// Demonstrate mapErrorMode = 1 (fail unmappable character)
source = "Unmappable character causes failure: {\u8C4A}"
// Pass 1 for options parameter to tell Igor to ignore error and let us handle it
result = ConvertTextEncoding(source, teUTF8, teWindows1252, 1, 1)
Variable len = strlen(result) // Will be NaN if conversion failed
if (NumType(len) == 2)
    Print "Conversion failed (as expected). Result is NULL."
    // You could cope with this error by trying again with the mapErrorMode
    // parameter set to 2, 3 or 4.
else
    // We should not get here
    Print "Conversion succeeded (should not happen).\"
    Print result
endif

// Demonstrate mapErrorMode = 2 (substitute for unmappable character)
source = "Unmappable character replaced by question mark: {\u8C4A}"
result = ConvertTextEncoding(source, teUTF8, teWindows1252, 2, 0)
Print result // Prints "?" in place of unmappable character

// Demonstrate mapErrorMode = 3 (skip unmappable character)
source = "Unmappable character skipped: {\u8C4A}"
result = ConvertTextEncoding(source, teUTF8, teWindows1252, 3, 0)
Print result // Skips unmappable character

// Demonstrate mapErrorMode = 4 (insert escape sequence for unmappable character)
source = "Unmappable character replaced by escape sequence: {\u8C4A}"
result = ConvertTextEncoding(source, teUTF8, teWindows1252, 4, 0)
Print result // Unmappable character represented as escape sequence

// Demonstrate mapErrorMode = 4 (insert escape sequence for unmappable character)
source = "Unmappable character replaced by escape sequence: {\u8C4A}"
// First convert UTF-8 to Shift_JIS (Japanese). This will succeed.
result = ConvertTextEncoding(source, teUTF8, teShiftJIS, 1, 0)
// Next convert Shift_JIS (Japanese) to Windows-1252. The character can not
// be mapped and is replaced by an escape sequence.
result = ConvertTextEncoding(result, teShiftJIS, teWindows1252, 4, 0)
Print result // Unmappable character represented as escape sequence
End

// Demo unmappable character
// In this example, the source text is valid but not representable in destination
// text encoding. Because we pass 4 for the mapErrorMode parameter, ConvertTextEncoding
// uses an escape sequence to represent the unmappable text.
Function DemoUnmappable()
    String input = "\u2135" // Alef symbol - available in UTF-8 but not in MacRoman
    String output = ConvertTextEncoding(input, 1, 2, 4, 0)
    Print output // Prints "\u2135"
End

// Demo invalid input text
// In this example, the source text is invalid in the source text encoding.
// Because we pass 4 for the mapErrorMode parameter, ConvertTextEncoding uses an escape
// sequences
// to represent the invalid text.
Function DemoInvalidInput()
    String input = "\x8E" // Represents "é" in MacRoman but is not valid in UTF-8
    String output = ConvertTextEncoding(input, 1, 2, 4, 0)
    Print output // Prints "\x8E"
End

```

## ConvexHull

**convexHull** [*flags*] *xwave*, *ywave*

**convexHull** [*flags*] *tripletWave*

The ConvexHull operation calculates the convex hull in either 2 or 3 dimensions. The dimensionality is deduced from the input wave(s). If the input consists of two 1D waves of the same length, the number of dimensions is assumed to be 2. If the input consists of a single triplet wave (a wave of 3 columns), then the number of dimensions is 3.

In 2D cases the operation calculates the convex hull and produces the result in a pair of x and y waves, W\_XHull and W\_YHull.

In 3D cases the operation calculates the convex hull and stores it in a triplet wave M\_Hull that describes ordered facets of the convex hull.

ConvexHull returns an error if the input waves have fewer than 3 data points.

### Flags

/C	(2D convex hull only) adds the first point to the end of the W_XHull and W_YHull waves so that the first and the last points are the same.
/E	(3D case only) if you use this flag the operation also creates a wave that lists the indices of the vertices which are not part of the convex hull, i.e., vertices which are interior to the hull. The output is in the wave W_HullExcluded.
/I	(3D convex hull only) use this flag to get the corresponding index of the vertex as the fourth column in the M_Hull wave.
/S	(3D convex hull only) use this flag if you want the resulting M_Hull to have NaN lines separating each triangle.
/T= <i>tolerance</i>	(3D case only) default tolerance for measuring if a point is inside or outside the convex hull is $1.0 \times 10^{-20}$ . You can use any other positive value.
/V	(3D case only) if you use this flag the operation also creates a wave containing the output in a list of vertex indices. The wave M_HullVertices contains a row per triangle where each entry on a row corresponds to the index of the input vertex.
/Z	No error reporting.

### Examples

```
Make/O/N=33 xxx=gnoise(5),yyy=gnoise(7)
Convexhull/c xxx,yyy
Display W_Yhull vs W_Xhull
Appendtograph yyy vs xxx
ModifyGraph mode(yyy)=3,marker(yyy)=8,rgb(W_YHull)=(0,15872,65280)
```

## Convolve

**Convolve** [/A/C] *srcWaveName*, *destWaveName* [, *destWaveName*]...

The Convolve operation convolves *srcWaveName* with each destination wave, putting the result of each convolution in the corresponding destination wave.

Convolve is not multidimensional aware. Some multidimensional convolutions are covered by the **MatrixConvolve**, **MatrixFilter**, and **MatrixOp** operations

**Flags**

/A	Acausal linear convolution.
/C	Circular convolution.

**Details**

Convolve performs linear convolution unless the /C or /A flag is used. See the diagrams in the examples below.

Depending on the type of convolution, the destination waves' lengths may increase. *srcWaveName* is not altered unless it also appears as a destination wave.

If *srcWaveName* is real-valued, each destination wave must be real-valued, and if *srcWaveName* is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; calculations are performed in the higher precision.

The linear convolution equation is:

$$destWaveOut[p] = \sum_{m=0}^{N-1} destWaveIn[m] \cdot srcWave[p - m]$$

where  $N$  is the number of points in the longer of *destWaveIn* and *srcWave*. For circular convolution, the index  $[p - m]$  is wrapped around when it exceeds the range of  $[0, \text{numpts}(srcWave)-1]$ . For acausal convolution, when  $[p - m]$  exceeds the range a zero value is substituted for *srcWave*  $[p - m]$ . Similar operations are applied to *destWaveIn*  $[m]$ .

Another way of looking at this equation is that, for all  $p$ , *destWaveOut* $[p]$  equals the sum of the point-by-point products from 0 to  $p$  of the destination wave and an end-to-end reversed copy of the source wave that has been shifted to the right by  $p$ .

The following diagram shows the reversed/shifted *srcWave* that would be combined with *destWaveIn*. The points numbered 0 through 4 of the reversed *srcWave* would be multiplied with *destWaveIn* $[0...4]$  and summed to produce *destWaveOut* $[4]$ :

For linear and acausal convolution, the destination wave is first zero-padded by one less than the length of the source wave. This prevents the “wrap-around” effect that occurs in circular convolution. The zero-padded points are removed after acausal convolution, and retained after linear convolution. The X scaling of the waves is ignored.

The convolutions are performed by transforming the source and destination waves with the Fast Fourier Transform, multiplying them in the frequency domain, and then inverse-transforming them into the destination wave(s).

The convolution is performed in segments if the resulting wave has more than 256 points and the destination wave has twice as many points as the source wave. For acausal convolution, the length of the resulting wave is considered to be  $(\text{numpts}(srcWaveName) + \text{numpts}(destWaveName) - 1)$  for this calculation.

**Applications**

The usual application of convolution is to compute the response of a linear system defined by its impulse response to an input signal. *srcWaveName* would contain the impulse response, and the destination wave would initially contain the input signal. After the Convolve operation has completed, the destination wave contains the output signal.

Use linear convolution when the source wave contains an impulse response (or filter coefficients) where the first point of *srcWave* corresponds to no delay ( $t = 0$ ).

## CopyFile

---

Use circular convolution for the case where the data in *srcWaveName* and *destWaveName* are considered to endlessly repeat (or “wrap around” from the end back to the start), which means no zero padding is needed.

Use acausal convolution when the source wave contains an impulse response where the middle point of *srcWave* corresponds to no delay ( $t = 0$ ).

### See Also

**Convolution** on page III-253 for illustrated examples. **MatrixOp**.

### References

A very complete explanation of circular and linear convolution can be found in sections 2.23 and 2.24 of Rabiner and Gold, *Theory and Application of Digital Signal Processing*, Prentice Hall, 1975.

## CopyFile

**CopyFile** [*flags*] [*srcFileStr*] [*as destFileOrFolderStr*]

The CopyFile operation copies a file on disk.

### Parameters

*srcFileStr* can be a full path to the file to be copied (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the source file from *srcFileStr* and *pathName*, it displays a dialog allowing you to specify the source file.

*destFileOrFolderStr* is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with *pathName*.

If /D is specified, the source file is copied inside the folder using the source file's name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-401 for details on forming the path.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

### Flags

/D	Interprets <i>destFileOrFolderStr</i> as the name of (or path to) an existing folder (or “directory”). Without /D, <i>destFileOrFolderStr</i> is interpreted as the name of (or path to) a file.  If <i>destFileOrFolderStr</i> is not a full path to a folder, it is relative to the folder associated with <i>pathName</i> .
/I [=i]	Specifies the level of user interactivity.  /I=0:      Interactive only if one of <i>srcFileStr</i> or <i>destFileOrFolderStr</i> is not specified or if the source file is missing. (Same as if /I was not specified.)  /I=1:      Interactive even if <i>srcFileStr</i> is specified and the source file exists. /I=2:      Interactive even if <i>destFileOrFolderStr</i> is specified. /I=3:      Interactive even if <i>srcFileStr</i> is specified, the source file exists, and <i>destFileOrFolderStr</i> is specified. Same as /I only.
/M=messageStr	Specifies the prompt message in the Open File dialog. If /S is not used, then <i>messageStr</i> will be used for both Open File and for Save File dialogs. But see <b>Prompt Does Not Work on Macintosh</b> on page IV-137.
/O	Overwrites any existing destination file.

<code>/P=<i>pathName</i></code>	Specifies the folder to look in for the source file, and the folder into which the file is copied. <i>pathName</i> is the name of an existing symbolic path. Using <code>/P</code> means that both <i>srcFileStr</i> and <i>destFileOrFolderStr</i> must be either simple file or folder names, or paths relative to the folder specified by <i>pathName</i> .
<code>/S=<i>saveMessageStr</i></code>	Specifies the prompt message in the Save File dialog.
<code>/Z [=z]</code>	Prevents procedure execution from aborting if it attempts to copy a file that does not exist. Use <code>/Z</code> if you want to handle this case in your procedures rather than aborting execution. <code>/Z=0:</code> Same as no <code>/Z</code> . <code>/Z=1:</code> Copies a file only if it exists. <code>/Z</code> alone has the same effect as <code>/Z=1</code> . <code>/Z=2:</code> Copies a file if it exists or displays a dialog if it does not exist.

### Variables

The CopyFile operation returns information in the following variables:

<code>V_flag</code>	Set to zero if the file was copied, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
<code>S_fileName</code>	Stores the full path to the file that was copied. If an error occurred or if the user cancelled, it is set to an empty string.
<code>S_path</code>	Stores the full path to the file copy. If an error occurred or if the user cancelled, it is set to an empty string.

### Examples

Copy a file within the same folder using a new name:

```
CopyFile/P=myPath "afile.txt" as "destFile.txt"
```

Copy a file into subfolder using the original name (using `/P`):

```
CopyFile/D/P=myPath "afile.txt" as ":subfolder"
Print S_Path // prints "Macintosh HD:folder:subfolder:afile.txt"
```

Copy file into subfolder using the original name (using full paths):

```
CopyFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"
```

Copy a file from one folder to another, assigning the copy a new name:

```
CopyFile "Macintosh HD:folder:afile.txt" as "Server:archive:destFile.txt"
```

Copy user-selected file in any folder as `destFile.txt` in `myPath` folder (prompt to save even if `destFile.txt` doesn't exist):

```
CopyFile/I=2/P=myPath as "destFile.txt"
```

Copy user-selected file in any folder as `destFile.txt` in any folder:

```
CopyFile as "destFile.txt"
```

### See Also

The **Open**, **MoveFile**, **DeleteFile**, and **CopyFolder** operations. The **IndexedFile** function. **Symbolic Paths** on page II-21.

## CopyFolder

**CopyFolder** [*flags*] [*srcFolderStr*] [*as destFolderStr*]

The CopyFolder operation copies a folder (and its contents) on disk.

### Parameters

*srcFolderStr* can be a full path to the folder to be copied (in which case `/P` is not needed), a partial path relative to the folder associated with *pathName*, or the name of a folder inside the folder associated with *pathName*.

If Igor can not determine the location of the folder from *srcFolderStr* and *pathName*, it displays a dialog allowing you to specify the source folder.

**Warning:** The *CopyFolder* command can destroy data by overwriting another folder and contents!

When overwriting an existing folder on disk, CopyFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category.

If permission is denied, the folder will not be copied and *V\_Flag* will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the */Z* flag is specified.

If */P=pathName* is given, but *srcFolderStr* is not, then the folder associated with *pathName* is copied.

*destFolderStr* can be a full path to the output (destination) folder (in which case */P* is not needed), or a partial path relative to the folder associated with *pathName*.

An error is returned if the destination folder would be inside the source folder.

If Igor can not determine the location of the destination folder from *destFolderStr* and *pathName*, it displays a dialog allowing you to specify or create the destination folder.

If you use a full or partial path for either folder, see **Path Separators** on page III-401 for details on forming the path.

### Flags

<i>/D</i>	Interprets <i>destFolderStr</i> as the name of (or path to) an existing folder (or directory) to copy the source folder into. Without <i>/D</i> , <i>destFolderStr</i> is interpreted as the name of (or path to) the copied folder.  If <i>destFolderStr</i> is not a full path to a folder, it is relative to the folder associated with <i>pathName</i> .
<i>/I [=i]</i>	Specifies the level of user interactivity.  <i>/I=0:</i> Interactive only if the source or destination folder is not specified or if the source folder is missing. (Same as if <i>/I</i> was not specified.) <i>/I=1:</i> Interactive even if the source folder is specified and it exists. <i>/I=2:</i> Interactive even if <i>destFolderStr</i> is specified. <i>/I=3:</i> Interactive even if the source folder is specified, the source folder exists, and <i>destFolderStr</i> is specified. Same as <i>/I</i> only.
<i>/M=messageStr</i>	Specifies the prompt message in the Select (source) Folder dialog. If <i>/S</i> is not used, then <i>messageStr</i> will be used for the Select Folder dialog and for the Create Folder dialog. But see <b>Prompt Does Not Work on Macintosh</b> on page IV-137.
<i>/O</i>	Overwrite existing destination folder, if any.  On Macintosh, a Macintosh-style overwrite-move is performed in which the source folder completely replaces the destination folder.  On Windows, a Windows-style mix-in move is performed in which the contents of the source folder are moved into the destination folder, replacing any same-named files but leaving other files in place.
<i>/P=pathName</i>	Specifies the folder to look in for the source folder. <i>pathName</i> is the name of an existing symbolic path.  If <i>srcFolderStr</i> is not specified, the folder associated with <i>pathName</i> is copied.  Using <i>/P</i> means that <i>srcFolderStr</i> (if specified) and <i>destFolderStr</i> must be either simple folder names or paths relative to the folder specified by <i>pathName</i> .
<i>/S=saveMessageStr</i>	Specifies the prompt message in the Create Folder dialog.

<code>/Z [=z]</code>	Prevents procedure execution from aborting if it attempts to copy a file that does not exist. Use <code>/Z</code> if you want to handle this case in your procedures rather than aborting execution.
<code>/Z=0:</code>	Same as no <code>/Z</code> .
<code>/Z=1:</code>	Copies a folder only if it exists. <code>/Z</code> alone has the same effect as <code>/Z=1</code> .
<code>/Z=2:</code>	Copies a folder if it exists or displays a dialog if it does not exist.

### Variables

The CopyFolder operation returns information in the following variables:

<code>V_flag</code>	Set to zero if the folder was copied, to -1 if the user cancelled either the Select Folder or Create Folder dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
<code>S_fileName</code>	Stores the full path to the folder that was copied, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.
<code>S_path</code>	Stores the full path to the folder copy, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.

### Details

You can use only `/P=pathName` (without `srcFolderStr`) to specify the source folder to be copied.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

### Examples

Copy the folder that the current experiment is stored in:

```
CopyFile/P=home as "HD:Copy Of Folder Experiment Is In"
```

Copy the Igor Extensions Folder to the Windows desktop:

```
CopyFile/D/P=Igor ":Igor Extensions" as "C:WINDOWS:Desktop"
```

Ask the user to select a folder, starting with the Igor folder, and then make a copy of that folder in the Igor Pro 7 folder:

```
CopyFile/I=2/P=Igor as "::Folder Copy"
```

Copy an entire disk inside a folder:

```
CopyFolder/O/D "Floppy" as "HD:Desktop Folder:Copy Into Here"
```

### See Also

**Open**, **MoveFile**, **DeleteFile**, **MoveFolder**, **NewPath**, and **IndexedDir** operations, and **Symbolic Paths** on page II-21.

## CopyScales

**CopyScales** [`/I/P`] *srcWaveName*, *waveName* [, *waveName*]...

The CopyScales operation copies the x, y, z, and t scaling, x, y, z, and t units, the data Full Scale and data units from *srcWaveName* to the other waves.

### Flags

<code>/I</code>	Copies the x, y, z, and t scaling in inclusive format.
<code>/P</code>	Copies the x, y, z, and t scaling in slope/intercept format (x0, dx format).

### Details

Normally the x, y, z, and t (dimension) scaling is copied in min/max format. However, if you use `/P`, the dimension scaling is copied in slope/intercept format so that if *srcWaveName* and the other waves have differing dimension size (number of points if the wave is a 1D wave), then their dimension values will still match for the points they have in common. Similarly, `/I` uses the inclusive variant of the min/max format. See **SetScale** for a discussion of these dimension scaling formats.

If a wave has only one point, `/I` mode reverts to `/P` mode.

## Correlate

---

CopyScales copies scales only for those dimensions that *srcWaveName* and *waveName* have in common.

### See Also

**x**, **y**, **z**, and **t** scaling functions.

## Correlate

**Correlate** [/AUTO/C/NODC] *srcWaveName*, *destWaveName* [, *destWaveName*]...

The Correlate operation correlates *srcWaveName* with each destination wave, putting the result of each correlation in the corresponding destination wave.

### Flags

- /AUTO** Auto-correlation scaling. This forces the X scaling of the destination wave's center point to be  $x=0$ , and divides the destination wave by the center point's value so that the center value is exactly 1.0.
- If *srcWaveName* and *destWaveName* do not have the same number of points, this flag is ignored.
- /AUTO** is not compatible with **/C**.
- /C** Circular correlation. (See **Compatibility Note**.)
- /NODC** Removes the mean from the source and destination waves before computing the correlations. Removing the mean results in the un-normalized auto- or cross-covariance.
- "DC" is an abbreviation of "direct current", an electronics term for the non-varying average value component of a signal.

### Details

**Note:** To compute a single-value correlation number use the **StatsCorrelation** function which returns the Pearson's correlation coefficient of two same-length waves.

Correlate performs linear correlation unless the **/C** flag is used.

Depending on the type of correlation, the length of the destination may increase. *srcWaveName* is not altered unless it also appears as a destination wave.

If the source wave is real-valued, each destination wave must be real-valued and if the source wave is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; calculations are performed in the higher precision.

The linear correlation equation is:

$$destWaveOut[p] = \sum_{m=0}^{N-1} srcWave[m] \cdot destWaveIn[p + m]$$

where  $N$  is the number of points in the longer of *destWaveIn* and *srcWave*.

For circular correlation, the index  $[p + m]$  is wrapped around when it exceeds the range of  $[0, \text{numpts}(\text{destWaveIn}) - 1]$ . For linear correlation, when  $[p + m]$  exceeds the range a zero value is substituted for *destWaveIn* $[p + m]$ . When  $m$  exceeds  $\text{numpts}(\text{srcWave}) - 1$ , 0 is used instead of *srcWave* $[m]$ .

Comparing this with the **Convolve** operation, which is the linear convolution:

$$destWaveOut[p] = \sum_{m=0}^{N-1} destWaveIn[m] \cdot srcWave[p - m]$$

you can see that the only difference is that for correlation the source wave is *not* reversed before shifting and combining with the destination wave.

The Correlate operation is not multidimensional aware. For details, see **Analysis on Multidimensional Waves** on page II-86 and in particular **Analysis on Multidimensional Waves** on page II-86.

### Compatibility Note

Prior to Igor Pro 5, Correlate/C scaled and rotated the results improperly (the result was often rotated left by one and the X scaling was entirely negative).

Now the destination wave's X scaling is unaltered and it does not rotate the result. You can force the old behavior for compatibility with old procedures that depend on the old behavior by setting `root:V_oldCorrelationScaling=1`.

A better way to get identical Correlate/C results with all versions of Igor Pro is to use this code, which rotates the result so that `x=0` is always the first point in *destWave*, no matter which Igor Pro version runs this code (currently, it doesn't change anything and runs extremely quickly because it does no rotation):

```
Correlate/C srcWave, destWave
Variable pointAtXEqualZero= x2pnt(destWave,0)      // 0 for Igor Pro 5
Rotate -pointAtXEqualZero,destWave
SetScale/P x, 0, DimDelta(destWave,0), "", destWave
```

### Applications

A common application of correlation is to measure the similarity of two input signals as they are shifted by one another.

Often it is desirable to normalize the correlation result to 1.0 at the maximum value where the two inputs are most similar. To normalize *destWaveOut*, compute the RMS values of the input waves and the number of points in each wave:

```
WaveStats/Q srcWave
Variable srcRMS = V_rms
Variable srcLen = numpnts(srcWave)

WaveStats/Q destWave
Variable destRMS = V_rms
Variable destLen = numpnts(destWave)

Correlate srcWave, destWave          // overwrites destWave

// now normalize to max of 1.0
destWave /= (srcRMS * sqrt(srcLen) * destRMS * sqrt(destLen))
```

Another common application is using autocorrelation (where *srcWaveName* and *destWaveName* are the same) to determine Power Spectral Density. In this case it better to use the **DSPPeriodogram** operation which provides more options.

### See Also

**Convolution** on page III-253 and **Correlation** on page III-255 for illustrated examples. See the **Convolve** operation for algorithm implementation details, which are identical except for the lack of source wave reversal, and the lack of the /A (acausal) flag.

The **MatrixOp**, **StatsCorrelation**, **StatsCircularCorrelationTest**, **StatsLinearCorrelationTest**, and **DSPPeriodogram** operations.

### References

An explanation of autocorrelation and Power Spectral Density (PSD) can be found in Chapter 12 of Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

WaveMetrics provides Igor Technical Note 006, "DSP Support Macros" that computes the PSD with options such as windowing and segmenting. See the Technical Notes folder. Some of the techniques discussed there are available as Igor procedure files in the "WaveMetrics Procedures:Analysis:" folder.

## COS

### `cos (angle)`

The `cos` function returns the cosine of *angle* which is in radians.

In complex expressions, *angle* is complex, and `cos (angle)` returns a complex value:

$$\cos(x + iy) = \cos(x)\cosh(y) - i\sin(x)\sinh(y).$$

See Also

acos, sin, tan, sec, csc, cot

## cosh

**cosh (num)**

The cosh function returns the hyperbolic cosine of *num*:

$$\cosh(x) = \frac{e^x + e^{-x}}{2}.$$

In complex expressions, *num* is complex, and **cosh (num)** returns a complex value.

See Also

sinh, tanh, coth

## CosIntegral

**CosIntegral (z)**

The CosIntegral(z) function returns the cosine integral of *z*.

If *z* is real, a real value is returned. If *z* is complex then a complex value is returned.

The CosIntegral function was added in Igor Pro 7.00.

**Details**

The cosine integral is defined by

$$Ci(z) = \gamma + \ln(z) + \int_0^z \frac{\cos(t) - 1}{t} dt, \quad (|\arg(z)| < \pi)$$

where  $\gamma$  is the Euler-Mascheroni constant 0.5772156649015328606065.

IGOR computes the CosIntegral using the expression:

$$Ci(z) = -\frac{Z^2}{4} {}_2F_3\left(1, 1; 2, 2, \frac{3}{2}; -\frac{z^2}{4}\right) + \ln(z) + \gamma,$$

**References**

Abramowitz, M., and I.A. Stegun, "Handbook of Mathematical Functions", Dover, New York, 1972. Chapter 5.

See Also

SinIntegral, ExpIntegralE1, hyperGPFQ

## cot

**cot (angle)**

The cot function returns the cotangent of *angle* which is in radians.

In complex expressions, *angle* is complex, and **cot(angle)** returns a complex value.

See Also

sin, cos, tan, sec, csc

## coth

**coth** (*num*)

The coth function returns the hyperbolic cotangent of *num*:

$$\coth(x) = \frac{e^x + e^{-x}}{e^x - e^{-x}}.$$

In complex expressions, *num* is complex, and coth(*num*) returns a complex value.

**See Also**

sinh, cosh, tanh

## CountObjects

**CountObjects** (*sourceFolderStr*, *objectType*)

The CountObjects function returns the number of objects of the specified type in the data folder specified by the string expression.

**CountObjectsDFR** is preferred.

**Parameters**

*sourceFolderStr* can be either " : " or " " to specify the current data folder. You can also use a full or partial data folder path. *objectType* should be one of the following values:

- 1 Waves
- 2 Numeric variables
- 3 String variables
- 4 Data folders

**See Also**

Chapter II-8, **Data Folders**, and the **GetIndexedObjName** function.

## CountObjectsDFR

**CountObjectsDFR** (*dfr*, *objectType*)

The CountObjectsDFR function returns the number of objects of the specified type in the data folder specified by the data folder reference *dfr*.

CountObjectsDFR is the same as CountObjects except the first parameter, *dfr*, is a data folder reference instead of a string containing a path.

**Parameters**

*objectType* is one of the following values:

- 1 Waves
- 2 Numeric variables
- 3 String variables
- 4 Data folders

**See Also**

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-72.

**GetIndexedObjNameDFR**

## cpowi

**cpowi** (*num*, *ipow*)

This function is obsolete as the exponentiation operator  $^$  handles complex expressions with any combination of real, integer and complex arguments. See **Operators** on page IV-5. The cpowi function returns a complex number resulting from raising complex *num* to integer-valued power *ipow*. *ipow* can be positive or negative, but if it is not an integer cpowi returns (NaN, NaN).

## CreateAliasShortcut

**CreateAliasShortcut** [*flags*] [*targetFileDirStr*] [*as aliasFileStr*]

The CreateAliasShortcut operation creates an alias (*Macintosh*) or shortcut (*Windows*) file on disk. The alias can point to either a file or a folder. The file or folder pointed to is called the “target” of the alias or shortcut.

### Parameters

*targetFileDirStr* can be a full path to the file or folder to make an alias or shortcut for, a partial path relative to the folder associated with */P=pathName*, or the name of a file or folder in the folder associated with *pathName*.

If Igor can not determine the location of the file or folder from *targetFileDirStr* and *pathName*, it displays a dialog allowing you to specify a target file. Use */D* to select a folder as the alias target, instead.

*aliasFileStr* can be a full path to the created alias file, a partial path relative to the folder associated with *pathName* if specified, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the alias or shortcut file from *aliasFileStr* and *pathName*, it displays a File Save dialog allowing you to create the file.

If you use a full or partial path for either *targetFileDirStr* or *aliasFileStr*, see **Path Separators** on page III-401 for details on forming the path.

Folder paths should not end with single path separators. See the **MoveFolder Details** section.

### Flags

<i>/D</i>	Uses the Select Folder dialog rather than Open File dialog when <i>targetFileDirStr</i> is not fully specified.								
<i>/I [=i]</i>	Specifies the level of user interactivity. <table> <tr> <td><i>/I=0:</i></td><td>Interactive only if one or <i>targetFileDirStr</i> or <i>aliasFileStr</i> is not specified or if the target file is missing. (Same as if <i>/I</i> was not specified.)</td></tr> <tr> <td><i>/I=1:</i></td><td>Interactive even if <i>targetFileDirStr</i> is fully specified and the target file exists.</td></tr> <tr> <td><i>/I=2:</i></td><td>Interactive even if <i>targetFileDirStr</i> is specified.</td></tr> <tr> <td><i>/I=3:</i></td><td>Interactive even if <i>targetFileDirStr</i> is specified and the target file exists. Same as <i>/I</i> only.</td></tr> </table>	<i>/I=0:</i>	Interactive only if one or <i>targetFileDirStr</i> or <i>aliasFileStr</i> is not specified or if the target file is missing. (Same as if <i>/I</i> was not specified.)	<i>/I=1:</i>	Interactive even if <i>targetFileDirStr</i> is fully specified and the target file exists.	<i>/I=2:</i>	Interactive even if <i>targetFileDirStr</i> is specified.	<i>/I=3:</i>	Interactive even if <i>targetFileDirStr</i> is specified and the target file exists. Same as <i>/I</i> only.
<i>/I=0:</i>	Interactive only if one or <i>targetFileDirStr</i> or <i>aliasFileStr</i> is not specified or if the target file is missing. (Same as if <i>/I</i> was not specified.)								
<i>/I=1:</i>	Interactive even if <i>targetFileDirStr</i> is fully specified and the target file exists.								
<i>/I=2:</i>	Interactive even if <i>targetFileDirStr</i> is specified.								
<i>/I=3:</i>	Interactive even if <i>targetFileDirStr</i> is specified and the target file exists. Same as <i>/I</i> only.								
<i>/M=messageStr</i>	Specifies the prompt message in the Open File or Select Folder dialog. If <i>/S</i> is not specified, then <i>messageStr</i> will be used for Open File (or Select Folder) and for Save File dialogs. But see <b>Prompt Does Not Work on Macintosh</b> on page IV-137.								
<i>/O</i>	Overwrites any existing file with the alias or shortcut file.								
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.								
<i>/S=saveMessageStr</i>	Specifies the prompt message in the Save File dialog when creating the alias or shortcut file.								

<code>/Z[=z]</code>	Prevents procedure execution from aborting the procedure tries to create an alias or shortcut for a file or folder that does not exist. Use <code>/Z</code> if you want to handle this case in your procedures rather than aborting execution.
<code>/Z=0:</code>	Same as no <code>/Z</code> .
<code>/Z=1:</code>	Creates an alias to a file or folder only if it exists. <code>/Z</code> alone has the same effect as <code>/Z=1</code> .
<code>/Z=2:</code>	Creates an alias to a file or folder only if it exists and displays a dialog if it does not exist.

### Variables

The CreateAliasShortcut operation returns information in the following variables:

<code>V_flag</code>	Status output:
0	Created an alias or shortcut file.
1	User cancelled any of the Open File, Select Folder, or Save File dialogs.
Other:	An error occurred, such as the target file does not exist.
<code>S_fileName</code>	Full path to the target file or folder. If an error occurred or if the user cancelled, it is an empty string.
<code>S_path</code>	Full path to the created alias or shortcut file. If an error occurred or if the user cancelled, it is an empty string.

### Examples

Create a shortcut (*Windows*) to the current experiment, on the desktop:

```
String target= Igorinfo(1)+".pxp" // experiments are usually .pxp on Windows
CreateAliasShortcut/O/P=home target as "C:WINDOWS\Desktop:"+target
```

Create an alias (*Macintosh*) to the VDT XOP in the Igor Extensions folder:

```
String target= ":More Extensions:Data Acquisition:VDT"
CreateAliasShortcut/O/P=Igor target as ":Igor Extensions:VDT alias"
```

Create an alias to the "HD 2" disk. Put the alias on the desktop:

```
CreateAliasShortcut/D/O "HD 2" as "HD:Desktop Folder:Alias to HD 2"
```

### See Also

**Symbolic Paths** on page II-21.

The **Open**, **MoveFile**, **DeleteFile**, and **GetFileFolderInfo** operations. The **IgorInfo** and **ParseFilePath** functions.

## CreateBrowser

```
CreateBrowser [/M] [keyword = value [, keyword = value ...]]
```

The CreateBrowser operation creates a data browser window.

Documentation for the CreateBrowser operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "CreateBrowser"
```

## CreationDate

```
CreationDate(waveName)
```

Returns creation date of wave as an Igor date/time value, which is the number of seconds from 1/1/1904.

The returned value is valid for waves created with Igor Pro 3.0 or later. For waves created in earlier versions, it returns 0.

### See Also

**ModDate**.

## Cross

**Cross** [/DEST=*destWave* /FREE /T /Z] *vectorA*, *vectorB* [, *vectorC*]

The Cross operation computes the cross products *vectorA* × *vectorB* and *vectorA* × (*vectorB* × *vectorC*). Each vector is a 1D real wave containing 3 rows. Stores the result in the wave W\_Cross in the current data folder.

### Flags

/DEST= <i>destWave</i>	<p>Stores the cross product in the wave specified by <i>destWave</i>.</p> <p>The destination wave is overwritten if it exists.</p> <p>The destination wave must be different from the input waves.</p> <p>The operation creates a wave reference for the destination wave if called in a user-defined function. See <b>Automatic Creation of WAVE References</b> on page IV-66 for details.</p> <p>If you omit /DEST, the operation stores the result in the wave W_Cross in the current data folder.</p> <p>Requires Igor7 or later.</p>
/FREE	<p>When used with /DEST, the destination wave is created as a free wave. See <b>Free Waves</b> on page IV-84 for details on free waves.</p> <p>/FREE is allowed in user-defined functions only.</p> <p>Requires Igor7 or later.</p>
/T	Stores output in a row instead of a column in W_Cross.
/Z	Generates no errors for any unsuitable inputs.

## csc

**csc** (*angle*)

The csc function returns the cosecant of *angle* which is in radians.

$$\text{csc}(x) = \frac{1}{\sin(x)}.$$

In complex expressions, *angle* is complex, and csc(*angle*) returns a complex value.

**See Also**

sin, cos, tan, sec, cot

## csch

**csch** (*x*)

The csch function returns the hyperbolic cosecant of *x*.

$$\text{csch}(x) = \frac{1}{\sinh(x)} = \frac{2}{e^x - e^{-x}}.$$

In complex expressions, *x* is complex, and csch(*x*) returns a complex value.

**See Also**

cosh, tanh, coth, sech

## CsrInfo

**CsrInfo**(*cursorName* [, *graphNameStr*])

The CsrInfo function returns a keyword-value pair list of information about the specified cursor (*cursorName* is A through J) in the top graph or graph specified by *graphNameStr*. It returns "" if the cursor is not in the graph.

### Details

The returned string contains information about the cursor in the following format:

```
TNAME:traceName; ISFREE:freeNum;POINT:xPointNumber;[YPOINT:yPointNumber;]
RECREATION:command;
```

The *traceName* value is the name of the graph trace or image to which it is attached or which supplies the x (and y) values even if the cursor isn't attached to it.

If TNAME is empty, fields POINT, ISFREE, and YPOINT are not present.

The *freeNum* value is 1 if the cursor is not attached to anything, 0 if attached to a trace or image.

The POINT value is the same value **pcsr** returns.

The YPOINT keyword and value are present only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot or when the cursor is free. Its value is the same as returned by **qcsr**.

If cursor is free, POINT and YPOINT values are fractional relative positions (see description in the **Cursor** command).

The RECREATION keyword contains the Cursor commands (including /W) necessary to regenerate the current settings.

### Examples

```
Variable aExists= strlen(CsrInfo(A)) > 0    // A is a name, not a string
Variable bIsFree= NumberByKey("ISFREE",CsrInfo(B,"Graph0"))
```

### See Also

**Programming With Cursors** on page II-249.

**Cursors — Moving Cursor Calls Function** on page IV-316.

**Trace Names** on page II-216, **Programming With Trace Names** on page IV-81.

## CsrWave

**CsrWave**(*cursorName* [, *graphNameStr* [, *wantTraceName*]])

The CsrWave function returns a string containing the name of the wave the specified cursor (A through J) is on in the top (or named) graph. If the optional *wantTraceName* is nonzero, the trace name is returned. A trace name is the wave name with optional instance notation (see **ModifyGraph (traces)**).

### Details

The name of a wave by itself is not sufficient to identify the wave because it does not specify what data folder contains the wave. Thus, if you are calling CsrWave for the purpose of passing the wave name to other procedures, you should use the **CsrWaveRef** function instead. Use CsrWave if you want the name of the wave to use in an annotation or a notebook.

### Examples

```
String waveCursorAIsOn = CsrWave(A)           // not CsrWave("A")
String waveCursorBIsOn = CsrWave(B,"Graph0")  // in specified graph
String traceCursorBIsOn = CsrWave(B,"",1)     // trace name in top graph
```

### See Also

**Programming With Cursors** on page II-249.

**Trace Names** on page II-216, **Programming With Trace Names** on page IV-81.

### CsrWaveRef

**CsrWaveRef**(*cursorName* [, *graphNameStr*])

The CsrWaveRef function returns a wave reference to the wave the specified cursor (A through J) is on in the top (or named) graph.

#### Details

The wave reference can be used anywhere Igor is expecting the name of a wave (not a string containing the name of a wave).

CsrWaveRef should be used in place of the CsrWave() string function to work properly with data folders.

#### Examples

```
Print CsrWaveRef(A) [50]           // not CsrWaveRef("A")
Print CsrWaveRef(B, "Graph0") [50] // in specified graph
```

#### See Also

**Programming With Cursors** on page II-249.

**Wave Reference Functions** on page IV-186.

### CsrXWave

**CsrXWave**(*cursorName* [, *graphNameStr*])

The CsrXWave function returns a string containing the name of the wave supplying the X coordinates for an XY plot of the Y wave the specified cursor (A through J) is attached to in the top (or named) graph.

#### Details

CsrXWave returns an empty string ("" ) if the wave the cursor is on is not plotted versus another wave providing the X coordinates (that is, if the wave was not plotted with a command such as `Display theWave vs anotherWave`).

The name of a wave by itself is not sufficient to identify the wave because it does not specify what data folder contains the wave. Thus, if you are calling CsrXWave for the purpose of passing the wave name to other Igor procedures, you should use the **CsrXWaveRef** function instead. Use CsrXWave if you want the name of the wave to use in an annotation or a notebook.

#### Examples

`Display ywave vs xwave`

ywave supplies the Y coordinates and xwave supplies the X coordinates for this XY plot.

```
Cursor A ywave,0
Print CsrXWave(A)           // prints xwave
```

#### See Also

**Programming With Cursors** on page II-249.

### CsrXWaveRef

**CsrXWaveRef**(*cursorName* [, *graphNameStr*])

The CsrXWaveRef function returns a wave reference to the wave supplying the X coordinates for an XY plot of the Y wave the specified cursor (A through J) is attached to in the top (or named) graph.

#### Details

The wave reference can be used anywhere Igor is expecting the name of a wave (not a string containing the name of a wave).

CsrXWaveRef returns a null reference (see **WaveExists**) if the wave the cursor is on is not plotted versus another wave providing the X coordinates (that is, if the wave was not plotted with a command such as `Display theWave vs anotherWave`). CsrXWaveRef should be used in place of the CsrXWave string function to work properly with data folders.

#### Examples

`Display ywave vs xwave`

ywave supplies the Y coordinates and xwave supplies the X coordinates for this XY plot.

```
Cursor A ywave,0
Print CsrXWaveRef(A) [50]           // prints value of xwave at point #50
```

### See Also

**Programming With Cursors** on page II-249.

**Wave Reference Functions** on page IV-186.

## CTabList

### CTabList()

The CTabList string function returns a semicolon-separated list of the names of built-in color tables. This can be useful when creating pop-up menus in control panels.

Color tables available through version 4:

Grays	Rainbow	YellowHot	BlueHot	BlueRedGreen
RedWhiteBlue	PlanetEarth	Terrain		

Additional color tables added for version 5:

Grays256	Rainbow256	YellowHot256	BlueHot256	BlueRedGreen256
RedWhiteBlue256	PlanetEarth256	Terrain256	Grays16	Rainbow16
Red	Green	Blue	Cyan	Magenta
Yellow	Copper	Gold	CyanMagenta	RedWhiteGreen
BlueBlackRed	Geo	Geo32	LandAndSea	LandAndSea8
Relief	Relief19	PastelsMap	PastelsMap20	Bathymetry9
BlackBody	Spectrum	SpectrumBlack	Cycles	Fiddle
Pastels				

Additional color tables added for version 6:

RainbowCycle	Rainbow4Cycles	GreenMagenta16	dBZ14	dBZ21
Web216	BlueGreenOrange	BrownViolet	ColdWarm	Mocha
VioletOrangeYellow	SeaLandAndFire			

Additional color tables added for version 6.2:

Mud	Classification
-----	----------------

### See Also

See **Image Color Tables** on page II-305 and **ColorTab2Wave**.

## CtrlBackground

### CtrlBackground [key [= value]]...

The CtrlBackground operation controls the unnamed background task.

CtrlBackground works only with the unnamed background task. New code should use named background tasks instead. See **Background Tasks** on page IV-298 for details.

### Parameters

dialogsOK=1 or 0	If 1, your task will be allowed to run while an Igor dialog is present. This can potentially cause crashes unless your task is well-behaved.
noBurst=1 or 0	Normally (or noBurst=0), your task will be called at maximum rate if a delay causes normal run times to be missed. Using noBurst=1, will suppress this burst catch up mode.
period=deltaTicks	Sets the minimum number of ticks that must pass between invocations of the background task.

start[= <i>startTicks</i> ]	Starts the background task (designated by SetBackground) when the tick count reaches <i>startTicks</i> . If you omit <i>startTicks</i> the task starts immediately.
stop	Stops the background task.

**See Also**

The **BackgroundInfo**, **SetBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and **Background Tasks** on page IV-298.

CtrlNamedBackground

**CtrlNamedBackground** *taskName*, **keyword** = *value* [, **keyword** = *value* ...]

The CtrlNamedBackground operation creates and controls named background tasks.

We recommend that you see **Background Tasks** on page IV-298 for an orientation before working with background tasks.

**Important:** Unlike the unnamed background task, by default named tasks run when a dialog window is active. This can cause a crash if the background task does things the dialog does not expect. See **Background Tasks and Dialogs** on page IV-300 for details.

**Parameters**

<i>taskName</i>	<i>taskName</i> is the name of the background task or <i>_all_</i> to control all named background tasks. You can use any valid standard Igor object name as the background task name.
burst [= <i>b</i> ]	Enable burst catch up mode (off by default, <i>b</i> =0). When on ( <i>b</i> =1), the task is called at the maximum rate if a delay misses normal run times.
dialogsOK [= <i>d</i> ]	Use dialogsOK=0 to prevent the background task from running when a dialog window is active. By default, dialogsOK=1 is in effect. See <b>Background Tasks and Dialogs</b> on page IV-300 for details.
kill [= <i>k</i> ]	Stops and releases task memory for reuse ( <i>k</i> =1; default) or continues ( <i>k</i> =0).
period= <i>deltaTicks</i>	Sets the minimum number of ticks ( <i>deltaTicks</i> ) that must pass between background task invocations. <i>deltaTicks</i> is truncated to an integer and clipped to a value greater than zero. See <b>Background Task Period</b> on page IV-299 for details.
proc= <i>funcName</i>	Specifies name of a background user function (see <b>Details</b> ).
start [= <i>startTicks</i> ]	Starts when the tick count reaches <i>startTicks</i> . A task starts immediately without <i>startTicks</i> .
status	Returns background task information in the S_info string variable.
stop [= <i>s</i> ]	Stops the background task ( <i>s</i> =1; default) or continues ( <i>s</i> =0).

**Details**

The user function you specify via the proc keyword must have the following format:

```
Function myFunc(s)
    STRUCT WMBBackgroundStruct &s
    ...
```

The members of the WMBBackgroundStruct are:

**Base WMBBackgroundStruct Structure Members**

Member	Description
char name [MAX_OBJ_NAME+1]	Background task name.
uint32 curRunTicks	Tick count when task was called.
int32 started	TRUE when CtrlNamedBackground start is issued. You may clear or set to desired value.
uint32 nextRunTicks	Precomputed value for next run but user functions may change this.

You may also specify a user function that takes a user-defined STRUCT as long as the first elements of the structure match the WMBBackgroundStruct or, preferably, if the first element is an instance of WMBBackgroundStruct. Use the started field to determine when to initialize the additional fields. Your structure may not include any String, WAVE, NVAR, DFREF or other fields that reference memory that is not part of the structure itself.

If you specify a user-defined structure that matches the first fields rather than containing an instance of WMBBackgroundStruct, then your function will fail if, in the future, the size of the built-in structure changes. The value of MAX\_OBJ\_NAME is 31 but this may also change.

Your function should return zero unless it wants to stop in which case it should return 1.

You can call CtrlNamedBackground within your background function. You can even switch to a different function if desired.

Use the status keyword to obtain background task information via the S\_info variable, which has the format:

NAME: name; PROC: fname; RUN: r; PERIOD: p; NEXT: n; QUIT: q; FUNCERR: e;

When parsing S\_info, do not rely on the number of key-value pairs or their order. RUN, QUIT, and FUNCERR values are 1 or 0, NEXT is the tick count for the next firing of the task. QUIT is set to 1 when your function returns a nonzero value and FUNCERR is set to 1 if your function could not be used for some reason.

### See Also

See **Background Tasks** on page IV-298 for examples.

### Demos

Choose File→Example Experiments→Programming→ Background Task Demo.

## CtrlFIFO

**CtrlFIFO FIFOName** [, **key = value**]...

The CtrlFIFO operation controls various aspects of the named FIFO.

### Parameters

close	Closes the FIFO's output or review file (if any).
deltaT=dt	Documents the data acquisition rate.
doffset=dataOffset	Used only with rdfile. Offset to data. If not provided offset is zero.
dsize=dataSize	Used only with rdfile. Size of data in bytes. If not provided, then data size is assumed to be the remainder of file. If this assumption is not valid then unexpected results may be observed.
flush	New data in FIFO is flushed to disk immediately.
file=oRefNum	File reference number for the FIFO's output file. You obtain this reference number from the <b>Open</b> operation used to create the file.
note=noteStr	Stores the note string in the file header. It is limited to 255 bytes.
rdfile=rRefNum	Like rfile but for review of raw data (use Open/R command). Channel data must match raw data in file. Offset from start of file to start of data can be provided using doffset given in same command. If data does not extend all the way to the end of the file, then the number of bytes of data can be provided using dsize in the same command.
rfile=rRefNum	File reference number for the FIFO's review file. Use a review file when you are using a FIFO to review existing data. Obtain the reference number from the Open/R operation used to open the file. File may be either unified header/data or a split format where the header contains the name of a file containing the raw data.
size=s	Sets number of chunks in the FIFO. The default is 10000. A chunk of data consists of a single data point from each of the FIFO's channels.

start	Starts the FIFO running by setting the time/date in the FIFO header, writing the header to the output file and marking the FIFO active.
stop	Stops the FIFO by flushing data to disk and marking the FIFO as inactive.
swap	Used only with rdfile. Indicates that the raw data file requires byte-swapping when it is read. This would be the case if you are running on a Macintosh, reading a binary file from a PC, or vice versa.

### Details

Once start has been issued, the FIFO can accept no further commands except stop.

The FIFO must be in the valid state for you to access its data (using a chart control or using the **FIFO2Wave** operation). When you create a FIFO, using **NewFIFO**, it is initially invalid. It becomes valid when you issue the start command via the CtrlFIFO operation. It remains valid until you change a FIFO parameter using CtrlFIFO.

FIFOs are used for data acquisition.

The **NewFIFO** and **FIFO2Wave** operations, and **FIFOs and Charts** on page IV-291.

## Cursor

```
Cursor [flags] cursorName traceName x_value
Cursor /F [flags] cursorName traceName x_value, y_value
Cursor /K [/W=graphName] cursorName
Cursor /I [/F] [flags] cursorName imageName x_value, y_value
Cursor /M [flags] cursorName
```

The Cursor operation moves the cursor specified by *cursorName* onto the named trace at the point whose X value is *x\_value*, or the coordinates of an image pixel or free cursor position at *x\_value* and *y\_value*.

### Parameters

*cursorName* is one of ten cursors A through J.

### Flags

/A= <i>a</i>	Activates ( <i>a</i> =1) or deactivates ( <i>a</i> =0) the cursor. Active cursors move with arrow keys or the cursor panel.
/C=( <i>r,g,b[,a]</i> )	Sets the cursor color (default is black). <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue in the color of the waves as an integer from 0 to 65535.  In Igor Pro 7.00 or later, optionally provide <i>a</i> to set transparency, with 0 being fully transparent (invisible) and 65535 being fully opaque (default).
/F	Cursor roams free. The trace or image provides the axis pair that defines x and y coordinates for the setting and readout. Use /P to set in relative coordinates, where 0,0 is the top left corner of the rectangle defined by the axes and 1,1 is the right bottom corner.
/H= <i>h</i>	Specifies crosshairs on cursors. <i>h</i> =0: Full crosshairs off. <i>h</i> =1: Full crosshairs on. <i>h</i> =2: Vertical hairline. <i>h</i> =3: Horizontal hairline.
/I	Places cursor on specified image.
/K	Removes the named cursor from the top graph.
/L= <i>lStyle</i>	Line style for crosshairs (full or small). <i>lStyle</i> =0: Solid lines. <i>lStyle</i> =1: Alternating color dash.

<code>/M</code>	Modifies properties without having to specify trace or image coordinates. Does not work with the <code>/F</code> or <code>/I</code> flags.
<code>/N=noKill</code>	Determines if the cursor is removed ("killed") if the user drags it outside of the plot area: <code>noKill=0:</code> Remove the cursor (default). <code>noKill=1:</code> Do not remove the cursor.
<code>/NUML=n</code>	Used in conjunction with <code>/H</code> when $h$ is non-zero. Sets the number of crosshair lines to draw. $n$ must be between 1 and 3. When $n$ is greater than 1, the line separation is set by the <code>/T=t</code> flag. If $n = 2$ or $3$ and $t$ is less than 3, the line appears as if $n$ is 1. If $n = 3$ and $t$ is less than 5, the appearance reverts to $n = 2$ . Lines are symmetrically disposed around the cursor position. When $n = 3$ , $t$ sets the separation of the outer pair of lines. <code>/NUML</code> was added in Igor Pro 7.00.
<code>/P</code>	Interpret $xNum$ as a point number rather than an X value.
<code>/S=s</code>	Sets cursor style. <code>s=0:</code> Original square or circle. <code>s=1:</code> Small crosshair with letter. <code>s=2:</code> Small crosshair without letter.
<code>/T=t</code>	Sets the thickness of crosshair lines for <code>/H</code> when $h$ is non-zero. If <code>/NUML</code> sets the number of lines greater than 1 then <code>/T</code> sets the separation of the outer pair of lines. $t$ is the line thickness or separation distance in units of pixels. The default is <code>/T=1</code> . The form <code>/T={mode, t1, t2}</code> provides finer control. <code>/T</code> was added in Igor Pro 7.00.
<code>/T={mode,t1,t2}</code>	Sets the thickness of crosshair lines for <code>/H</code> when $h$ is non-zero. If <code>/NUML</code> sets the number of lines greater than 1 then <code>/T</code> sets the separation of the outer pair of lines. If <code>mode=1</code> then $t1$ and $t2$ are in units of screen pixels. $t1$ is the vertical line thickness or separation distance and $t2$ is the horizontal line thickness or separation distance. The default crosshair appearance is equivalent to <code>/T={1,1,1}</code> . If <code>mode=0</code> then $t1$ and $t2$ are in units of axis coordinates and consequently track changes in axis range and graph size. Normally $t1$ is the vertical line thickness or separation distance and $t2$ is the horizontal line thickness or separation distance but they are swapped if the trace or graph is in swap XY mode. <code>/T</code> was added in Igor Pro 7.00.
<code>/W=graphName</code>	Specifies a particular named graph window or subwindow. When omitted, action will affect the active window or subwindow. When identifying a subwindow with <i>graphName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

Usually *traceName* is the same as the name of the wave displayed by that trace, but it could be a name in instance notation. See **ModifyGraph (traces)** and **Instance Notation** on page IV-19 for discussions of trace names and instance notation.

A string containing *traceName* can be used with the `$` operator to specify the trace name.

$x\_value$  is an X value in terms of the X scaling of the wave displayed by *traceName*. If *traceName* is graphed as an XY pair, then  $x\_value$  is *not* the same as the X axis coordinate. Since the X scaling is ignored when displaying an XY pair in a graph, we recommend you use the `/P` flag and use a point number for  $x\_value$ .

*cursorName* is a name, *not* a string.

To get a cursor readout, choose ShowInfo from the Graph menu.

Moving a cursor in a macro or function does not immediately erase the old cursor. DoUpdate has to be explicitly called.

### Examples

```
Display myWave // X coordinates from X scaling of myWave
Cursor A, myWave, leftx(myWave) //cursor A on first point of myWave

AppendToGraph yWave vs xWave //X coordinates from xWave, not X scaling
Cursor/P B,yWave,numpts(yWave)-1 //cursor B on last point of yWave
DoUpdate // erase any old A or B cursors
```

### See Also

**Programming With Cursors** on page II-249 and the **DoUpdate** operation.

## CursorStyle

### CursorStyle

CursorStyle is a procedure subtype keyword that puts the name of the procedure in the “Style function” submenu of the Cursor Info pop-up menu. It is automatically used when Igor creates a cursor style function. To create a cursor style function, choose “Save style function” in the “Style function” submenu of the Cursor Info pop-up menu.

See also **Programming With Cursors** on page II-249.

## CurveFit

**CurveFit** [*flags*] *fitType*, [*kwCWave=coefWaveName*,] *waveName* [*flag parameters*]

The CurveFit operation fits one of several built-in functions to your data (for user-defined fits, see the **FuncFit** operation). When with CurveFit and built-in fit functions, automatic initial guesses will provide a good starting point in most cases.

The results of the fit are returned in a wave, by default W\_coef. In addition, the results are put into the system variables K0, K1 ... K<sub>n</sub> but the use of the system variables is limited and considered obsolete.

You can specify your own wave for the coefficient wave instead of W\_coef using the kwCWave keyword.

Virtually all waves specified to the CurveFit operation can be a sub-range of a larger wave using the same sub-range syntax as the Display operation uses for graphing. See **Wave Subrange Details** on page V-113.

See Chapter III-8, **Curve Fitting** for detailed information including the use of the Curve Fit dialog.

CurveFit operation parameters are grouped in the following categories: flags, fit type, parameters (kwCWave=coefWaveName and waveName), and flag parameters. The sections below correspond to these categories. Note that flags must precede the fit type and flag parameters must follow waveName.

### Flags

- |                   |  |
|-------------------|--|
| /B=pointsPerCycle | Used when <i>type</i> is sin; <i>pointsPerCycle</i> is the estimated number of data points per sine wave cycle. This helps provide initial guesses for the fit. You may need to try a few different values on either side of your estimated points/cycle.                          |
| /C                | Makes constraint matrix and vector. This only applies if you use the /C=constraintSpec parameter to specify constraints (see below). Creates the M_FitConstraint matrix and the W_FitConstraint vector. For more information, see <b>Fitting with Constraints</b> on page III-198. |
| /G                | Use values in variables K0, K1 ... K <sub>n</sub> as starting guesses for a fit. If you specify a coefficient wave with the kwCWave keyword, the starting guesses will be read from the coefficient wave.  |
| /H="hhh..."       | Specifies coefficients to hold constant.<br><i>h</i> is 1 for coefficients to hold, 0 for coefficients vary.<br>For example, /H="100" holds K0 constant, varies K1 and K2.   |

<code>/K={constants}</code>	<p>Sets values of constants (not fit coefficients) in certain fitting functions. For instance, the <code>exp_XOffset</code> function contains an X offset constant. Built-in functions will set the constant automatically, but the automatic value can be overridden using this flag.</p> <p><i>constants</i> is a list of constant values, e.g., <code>/K={1,2,3}</code>. The length of the list must match the number of constants used by the chosen fit function.</p> <p>This flag is not currently supported by the Curve Fit dialog. Use the To Cmd button and add the flag on the command line.</p>
<code>/L=destLen</code>	<p>Sets the length of the wave created by the AutoTrace feature, that is, <code>/D</code> without destination wave (see the <code>/D</code> parameter above). The length of the wave <code>fit_waveName</code> will be set to <i>destLen</i>. This keyword also sets the lengths of waves created for confidence and prediction bands.</p>
<code>/M</code>	<p>Generates the covariance matrix, the waves <code>CM_Kn</code>, where <i>n</i> is from 0 (for <code>K0</code>) to the number of coefficients minus one.</p>
<code>/M=doMat</code>	<p>Generates the covariance matrix. If <i>doMat</i> =2, the covariance matrix is put into a 2D matrix wave called <code>M_Covar</code>. If <i>doMat</i> =1 or is missing, the covariance matrix is generated as the 1D waves <code>CM_Kn</code>, where <i>n</i> is from 0 (for <code>K0</code>) to the number of coefficients minus one. If <i>doMat</i> =0, the covariance matrix is not generated. <i>doMat</i> =1 is included for compatibility with previous versions; it is better to use <i>doMat</i> =2.</p>
<code>/N[=dontUpdate]</code>	<p>If <i>dontUpdate</i> = 1, suppresses updates during the fit. This can make the curve fit go much faster; all graphs, tables, etc. will be updated when the fit finishes. <code>/N</code> is the same as <code>/N=1</code>.</p> <p>The default is <code>/N=1</code>. Prior to Igor Pro 7.00 it was <code>/N=0</code>. To update every iteration, use <code>/N=0</code>.</p>
<code>/NTHR = nthreads</code>	<p>This flag is accepted but is obsolete and does nothing. See <b>Curve Fitting with Multiple Processors</b> on page III-218 for further information.</p>
<code>/O</code>	<p>Only generates initial guesses; doesn't actually do the fit.</p> <p>Unless <code>/ODR=2</code>, this flag is ignored when used with linear fit types (line, poly, <code>poly_XOffset</code>, and <code>poly2D</code>). The <b>FuncFit</b> operation also ignores this flag.</p>
<code>/ODR=fitMethod</code>	<p>Selects a fitting method. Values for <i>fitMethod</i> are:</p> <ol style="list-style-type: none"> <li>0: Default Levenberg-Marquardt least-squares method using old code.</li> <li>1: Trust-region Levenberg-Marquardt ordinary least-squares method implemented using ODRPACK95 code. See <b>Curve Fitting References</b> on page III-236.</li> <li>2: Trust-region Levenberg-Marquardt least orthogonal distance method implemented using ODRPACK95 code. This method is appropriate for fitting when there are measurement errors in the independent variables, sometimes called "errors in variables fitting", "random regressor models," or "measurement error models".</li> <li>3: Implicit fit. No dependent variable is specified; instead fitting attempts to adjust the fit coefficients such that the fit function returns zero for all dependent variables.</li> </ol> <p>Implicit fitting will be of almost no use with the built-in fitting functions. Instead, use <b>FuncFit</b> and a user-defined fit function designed for an implicit fit.</p> <p>Note that fitting with non-zero <i>fitMethod</i> is not threadsafe. Since the basic curve fitting operations are threadsafe, using <code>/ODR=&lt;nonzero&gt;</code> in a threadsafe user function will compile, but will result in a run-time error.</p>
<code>/Q[=quiet]</code>	<p>If <i>quiet</i> = 1, prevents results from being printed in history. <code>/Q</code> is the same as <code>/Q=1</code>.</p>

/TBOX =  
*textboxSpec*

Adds an annotation to the graph containing the fit data (see the **TextBox** operation, or Chapter III-2, **Annotations**). The textbox contains a customizable set of information about the fit. The argument *textboxSpec* is a bitfield to select various elements to be included in the textbox:

1	Title "Curve Fit Results"
2	Date
4	Time
8	Fit Type (Least Squares, ODR, etc.)
16	Fit function name
32	Model Wave, the autodeestination wave (includes a symbol for the trace if appropriate)
64	Y Wave, with trace symbol
128	X Wave
256	Coefficient value report
512	Include errors in the coefficient value report

Request inclusion of various parts by adding up the values for each part you want. Setting *textboxSpec* to zero will remove the textbox. Default is *textboxSpec* = 0.

/X

Sets the X scaling of the auto-trace destination wave to match the appropriate X axis on the graph when the Y data wave is on the top graph. This is useful when you want to extrapolate the curve outside the range of X data being fit.

/W=*wait*

Specifies behavior for the curve fit results window.

<i>wait</i> =1:	Wait till user clicks OK button before dismissing curve fit results window. This is the default behavior from the command line or dialog.
<i>wait</i> =0:	Display the curve fit window but do not wait for the user to click the OK button.
<i>wait</i> =2:	Do not display the curve fit results window at all. This is the default for fits run from a procedure.

### Fit Types

*fitType* is one of the built-in curve fit function types:

gauss	Gaussian peak: $y = K_0 + K_1 \exp \left[ -\left( \frac{x - K_2}{K_3} \right)^2 \right]$ .
lor	Lorentzian peak: $y = K_0 + \frac{K_1}{(x - K_2)^2 + K_3}$ .
exp	Exponential: $y = K_0 + K_1 \exp(-K_2 x)$ .
dblexp	Double exponential: $y = K_0 + K_1 \exp(-K_2 x) + K_3 \exp(-K_4 x)$ .
sin	Sinusoid: $y = K_0 + K_1 \sin(K_2 x + K_3)$ .
line	Line: $y = K_0 + K_1 x$ .
poly <i>n</i>	Polynomial: $y = k_0 + K_1 x + K_2 x^2 + \dots$ .  <i>n</i> is from 3 to 20. <i>n</i> is the number of terms or the degree plus one.
poly_XOffset <i>n</i>	Polynomial: $y = K_0 + K_1(x - x_0) + K_2(x - x_0)^2 + \dots$

	<p><math>n</math> is from 3 to 20. <math>n</math> is the number of terms or the degree plus one.</p> <p><math>x_0</math> is a constant; by default it is set to the minimum X value involved in the fit. Inclusion of <math>x_0</math> prevents problems with floating-point roundoff errors when you have large values of X in your data set.</p>
hillequation	<p>Hill's Equation: <math>y = K_0 + \frac{(K_1 - K_0)}{1 + (K_3/x)^{K_2}}</math> .</p> <p>This is a sigmoidal function. Note that X values must be greater than 0.</p>
sigmoid	<p><math>y = K_0 + \frac{K_1}{1 + \exp(K_2 - x/K_3)}</math> .</p>
power	<p>Power law: <math>y = K_0 + K_1 x^{K_2}</math> . Note that X values must be greater than 0.</p>
lognormal	<p>Log normal: <math>y = K_0 + K_1 \exp\left[-\left(\frac{\ln(x/K_2)}{K_3}\right)^2\right]</math> . X values must be greater than 0.</p>
gauss2D	<p>2D Gaussian: <math>z = K_0 + K_1 \exp\left[\frac{-1}{2(1 - K_6^2)}\left(\left(\frac{x - K_2}{K_3}\right)^2 + \left(\frac{y - K_4}{K_5}\right)^2 - \frac{2K_6(x - K_2)(y - K_4)}{K_3 K_5}\right)\right]</math> .</p> <p>The cross-correlation coefficient (<math>K_6</math>) must be between -1 and 1. This coefficient is automatically constrained to lie in that range. If you are confident that the correlation is zero, it may greatly speed the fit to hold it at zero.</p>
poly2D $n$	<p>Two-dimensional polynomial: <math>z = K_0 + K_1 x + K_2 y + K_3 x^2 + K_4 xy + K_5 y^2 + \dots</math> .</p> <p>where <math>n</math> is the degree of the polynomial. All terms up to degree <math>n</math> are included, including cross terms. For instance, degree 3 terms are <math>x^3</math>, <math>x^2 y</math>, <math>xy^2</math>, and <math>y^3</math>.</p>
exp_XOffset	<p>Exponential: <math>y = K_0 + K_1 \exp(-(x - x_0)/K_2)</math> .</p> <p><math>x_0</math> is a constant; by default it is set to the minimum <math>x</math> value involved in the fit. Inclusion of <math>x_0</math> prevents problems with floating-point roundoff errors that can afflict the exp function.</p>
dblexp_XOffset	<p>Double exponential: <math>y = K_0 + K_1 \exp(-(x - x_0)/K_2) + K_3 \exp(-(x - x_0)/K_{4(2)})</math> .</p> <p><math>x_0</math> is a constant; by default it is set to the minimum <math>x</math> value involved in the fit. Inclusion of <math>x_0</math> prevents problems with floating-point roundoff errors that can afflict the exp function.</p>

### Parameters

`kwCWave=coefWaveName` specifies an optional coefficient wave. If present, the specified coefficient wave is set to the final coefficients determined by the curve fit. If absent, a wave named `W_coef` is created and is set to the final coefficients determined by the curve fit.

If you use `kwCWave=coefWaveName` and you include the `/G` flag, initial guesses are taken from the specified coefficient wave.

`waveName` is the wave containing the Y data to be fit to the selected function *type*. You can fit to a subrange of the wave by supplying `(startX,endX)` after the wave name. Though not shown in the syntax description, you can also specify the subrange in points by supplying `[startP,endP]` after the wave name. See **Wave Subrange Details** on page V-113 for more information on subranges of waves in curve fitting.

If you are using one of the two-dimensional fit functions (`gauss2D` or `poly2D`) either `waveName` must name a matrix wave or you must supply a list of X waves via the `/X` flag.

### Flag Parameters

These flag parameters must follow *waveName*.

<i>/A=appendResid</i>	<i>appendResid</i> =1 (default) appends the automatically-generated residual to the graph and <i>appendResid</i> =0 prevents appending (see <i>/R[=residwaveName]</i> ). With <i>appendResid</i> =0, the wave is generated and filled with residual values, but not appended to the graph.
<i>/AD[=doAutoDest]</i>	If <i>doAutoDest</i> is 1, it is the same as <i>/D</i> alone. <i>/AD</i> is the same as <i>/AD=1</i> .
<i>/C=constraintSpec</i>	Applies linear constraints during curve fitting. Constraints can be in the form of a text wave containing constraint expressions ( <i>/C=textWaveName</i> ) or a suitable matrix and vector ( <i>/C={constraintMatrix, constraintVector}</i> ). See <b>Fitting with Constraints</b> on page III-198. <b>Note:</b> Constraints are not available for the built-in line, poly and poly2D fit functions. To apply constraints to these fit functions you must create a user-defined fit function.
<i>/D [=destwaveName]</i>	<p><i>destwaveName</i> is evaluated based on the equation resulting from the fit. <i>destwaveName</i> must have the same length as <i>waveName</i>.</p> <p>If only <i>/D</i> is specified, an automatically named wave is created. The name is based on the <i>waveName</i> with "fit_" as a prefix. This automatically named wave will be appended (if necessary) to the top graph if <i>waveName</i> is graphed there. The X scaling of the fit_ wave is set from the range of x data used during the fit.</p> <p>By default the length of the automatically-created wave is 200 points (or 2 points for a straight line fit). This can be changed with the <i>/L</i> flag.</p> <p>If <i>waveName</i> is a 1D wave displayed on a logarithmic X axis, Igor also creates an X wave with values exponentially spaced. The name is based on <i>waveName</i> with "fitX_" as a prefix.</p>
<i>/F={confLevel, confType [, confStyleKey [, waveName...]]}</i>	<p>Calculates confidence intervals for a confidence level of <i>confLevel</i>. The value of <i>confLevel</i> must be between 0 and 1 corresponding to confidence levels of 0 to 100 per cent.</p> <p><i>confType</i> selects what to calculate:</p> <ul style="list-style-type: none"> <li>1: Confidence bands for the model.</li> <li>2: Prediction bands for the model.</li> <li>4: Confidence intervals for the fit coefficients.</li> </ul> <p>These values can be added together to select multiple options. That is, to select both a confidence band and fit coefficient confidence intervals, set <i>confType</i> to 5.</p> <p>Confidence and prediction bands can be shown as waves contouring a given confidence level (use "Contour" for <i>confStyleKey</i>) or as error bars (use "ErrorBar" for <i>confStyleKey</i>). The default is Contour.</p> <p>If no waves are specified, waves to contain the results are automatically generated and appended to the top graph (if the top graph contains the fitted data). See <b>Confidence Band Details</b> for details on the waves for confidence bands.</p> <p><b>Note:</b> Confidence bands and prediction bands are not available for multivariate curve fits.</p>
<i>/I [=weightType]</i>	If <i>weightType</i> is 1, the weighting wave (see <i>/W</i> parameter) contains standard deviations. If <i>weightType</i> is 0, the weighting wave contains reciprocal of the standard deviation. If the <i>/I</i> parameter is not present, the default is <i>/I=0</i> .
<i>/M=maskWaveName</i>	Specifies that you want to use the wave named <i>maskWaveName</i> to select points to be fit. The mask wave must match the dependent variable wave in number of points and dimensions. Setting a point in the mask wave to zero or NaN (blank in a table) eliminates that point from the fit.

<code>/R [=residwaveName]</code>	<p>Calculates elements of <i>residwaveName</i> by subtracting model values from the data values. <i>residwaveName</i> must have the same length as <i>waveName</i>.</p> <p>If only <code>/R</code> is specified, an automatically named wave is created with the same number of points as <i>waveName</i>. The name is based on <i>waveName</i> with "Res_" as a prefix.</p> <p>The automatically created residual wave will be appended (if necessary) to the top graph if <i>waveName</i> is graphed there. The residual wave is appended to a new free axis named by prepending "Res_" to the name of the vertical axis used for plotting <i>waveName</i>. To the extent possible, the new free axis is formatted nicely.</p> <p>If the graph containing the data to be fit has very complex formatting, you may not wish to automatically append the residual to the graph. In this case, use <code>/A=0</code>.</p>
<code>/AR=doAutoResid</code>	If <i>doAutoResid</i> is 1, it is the same as <code>/R</code> alone. <code>/AR</code> is the same as <code>/AR=1</code> .
<code>/W=wghtwaveName</code>	<i>wghtwaveName</i> contains weighting values applied during the fit, and must have the same length as <i>waveName</i> . These weighting values can be either the reciprocal of the standard errors, or the standard errors. See the <code>/I</code> parameter above for details.
<code>/X=xwaveName</code>	<p>The X values for the data to fit come from <i>xwaveName</i>, which must have the same length and type as <i>waveName</i>.</p> <p>If you are fitting to one of the two-dimensional fit functions and <i>waveName</i> is a matrix wave, <i>xwaveName</i> supplies independent variable data for the X dimension. In this case, <i>xwaveName</i> must name a 1D wave with the same number of rows as <i>waveName</i>.</p>
<code>/X={xwave1, xwave2}</code>	For fitting to one of the two-dimensional fit functions when <i>waveName</i> is a 1D wave. <i>xwave1</i> and <i>xwave2</i> must have the same length as <i>waveName</i> .
<code>/Y=ywaveName</code>	For fitting using one of the 2D fit functions if <i>waveName</i> is a matrix wave. <i>ywaveName</i> must be a 1D wave with length equal to the number of columns in <i>waveName</i> .
<code>/NWOK</code>	<p>Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to CurveFit is normally treated as an error. By using <code>/NWOK</code>, you are telling CurveFit that a null wave reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls CurveFit with optional waves.</p> <p>The waves affected are the X wave or waves (<code>/X</code>), weight wave (<code>/W</code>), mask wave (<code>/M</code>) and constraint text wave (<code>/C</code>). The destination wave (<code>/D=wave</code>) and residual wave (<code>/R=wave</code>) are also affected, but the situation is more complicated because of the dual use of <code>/D</code> and <code>/R</code> to mean "do autodeestination" and "do autoresidual". See <code>/AR</code> and <code>/AD</code>.</p> <p>If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.</p> <p><b>Note:</b> To work properly this flag must be the last one in the command.</p>

### Flag Parameters for Nonzero /ODR

`/XW=xWeightWave`  
`/XW={xWeight1, xWeight2}`

/ODR=2 or 3 only.

Specifies weighting values for the independent variables using *xWeightWave*, which must have the same length as *waveName*. When fitting to one of the multivariate fit functions such as poly2D or Gauss2D, you must supply a weight wave for each independent variable using the second form.

Weighting values can be either the reciprocal of the standard errors, or the standard errors. The choice of standard error or reciprocal standard error must be the same for both /W and /XW. See /I for details.

/XHLD=*holdWave*

/XHLD={*holdWave1*, *holdWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to hold the values of the independent variables fixed during orthogonal distance regression. The waves must match the input X data; a one in a wave element fixes the value of the corresponding X value.

/CMAG=*scaleWave*

Specifies a wave that indicates the expected scale of the fit coefficients at the solution. If different coefficients have very different orders of magnitude of expected values, this can improve the efficiency and accuracy of the fit.

/XD=*xDestWave*

/XD={*xDestWave1*, *xDestWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to receive the fitted values of the independent variables during a least orthogonal distance regression.

/XR=*xResidWave*

/XR={*xResidWave1*, *xResidWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to receive the differences between fitted values of the independent variables and the starting values during a least orthogonal distance regression. That is, they will be filled with the X residuals.

## Details

CurveFit gets initial guesses from the Kn system variables when user guesses (/G) are specified, unless a coefficient wave is specified using the kwCWave keyword. Final curve fit parameters are written into a wave name W\_coef, unless you specify a coefficient wave with the kwCWave keyword.

Other output waves are M\_Covar (see the /M flag), M\_FitConstraint and W\_FitConstraint (see /C parameter and **Fitting with Constraints** on page III-198) and W\_sigma.

For compatibility with earlier versions of Igor, the parameters are also stored in the system variables Kn. This can be a source of confusion. We suggest you think of W\_coef as the **output** coefficients and Kn as **input** coefficients that get overwritten.

Other output waves are M\_Covar (see the /M flag), M\_FitConstraint and W\_FitConstraint (see /C parameter and **Fitting with Constraints** on page III-198), W\_sigma. If you have selected coefficient confidence limits using the /F parameter, a wave called W\_ParamConfidenceInterval is created with the confidence intervals for the fit coefficients.

CurveFit stores other curve fitting statistics in variables whose names begin with "V\_". CurveFit also looks for certain V\_ variables which you can use to modify its behavior. These are discussed in **Special Variables for Curve Fitting** on page III-202.

When fitting with /ODR=nonzero, fitting with constraints is limited to simple "bound constraints." That is, you can constrain a fit coefficient to be greater than or less than some value. Constraints involving combinations of fit coefficients are supported only with /ODR=0. The constraints are entered in the same way, using an expression like  $K0 > 1$ .

## Wave Subrange Details

Almost any wave you specify to CurveFit can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command (see **Subrange Display Syntax** on page II-250 for details). However, the Display command allows only one dimension to have a range (multiple elements from the dimension); if a multidimensional wave is appropriate for CurveFit, you may use a range for more than one dimension.

Some waves must have the same number of points as other waves. For instance, a one-dimensional Y wave must have the same number of points as any X waves. Thus, if you use a subrange for an X wave, the number of points in the subrange must match the number of points being used in the Y wave (but see **Subrange Backward Compatibility** on page V-114 for a complication to this rule).

A common use of wave subranges might be to package all your data into a single multicolumn wave, along with the residuals and model values. For a univariate fit, you might need X and Y waves, plus a destination (model) wave and a residual wave. You can achieve all of that using a 4 column wave. For example:

```
Make/D/N=(100, 4) Data
... fill column zero with X data and column one with Y data ...
CurveFit poly 3, Data[] [1] /X=Data[] [0]/D=Data[] [2]/R=Data[] [3]
```

Note that because all the waves are full columns from a single multicolumn wave, the number of points is guaranteed to be the same.

The number of points used for X waves (*xwaveName* or {*xwave1*, *xwave2*, ...}), weighting wave (*wghtwaveName*), mask wave (*maskWaveName*), destination wave (*destwaveName*) and residual wave (*residwaveName*) must be the same as the number of points used for the Y wave (*waveName*). If you specify your own confidence band waves (/F flag) they must match the Y wave; you cannot use subranges with confidence band waves. If you set /ODR = nonzero, the X weight, hold, destination and residuals waves must match the Y wave.

The total number of points in each wave does not need to match other waves, just the number of points in the specified subrange.

When fitting to a univariate fit function (that includes almost all the fit types) the Y wave must have effectively one dimension. That means the Y wave must either be a 1D wave, or it must have a subrange that makes the data being used one dimensional. For instance:

```
Make/N=(100,100) Ydata // 2D wave
CurveFit gauss Ydata[] [0] // OK- a single column is one-dimensional
CurveFit gauss Ydata[2] [] // OK- a single row is one-dimensional
CurveFit gauss Ydata // not OK- Ydata is two-dimensional
CurveFit gauss Ydata[] [0,1] // not OK- two columns makes 2D subrange
```

When fitting a multivariate function (**poly2D** or **Gauss2D**) you have the choice of making the Y data either one-dimensional or two-dimensional. If it is one-dimensional, then you must be fitting XYZ (or Y,X1,X2) triplets. In that case, you must provide a one-dimensional Y wave and two one-dimensional X waves, or 2 columns from a multicolumn wave. For instance:

These are OK:

```
Make/N=(100,3) myData
CurveFit Gauss2D myData[] [0] /X={myData[] [1],myData[] [2]}
CurveFit Gauss2D myData[] [0] /X=myData[] [1,2]
```

These are not OK:

```
CurveFit Gauss2D myData /X={myData[] [1],myData[] [2]} // 2D Y wave with 1D X waves
CurveFit Gauss2D myData[] [0] /X=myData // too many X columns
```

If you use a 2D Y wave, the X1 and X2 data can come from the grid positions and the Y wave's X and Y index scaling, or you can use one-dimensional waves or wave subranges to specify the X1 and X2 positions of the grid:

```
Make/N=(20,30) yData
CurveFit Gauss2D yData //OK- 2D Y data, X1 and X2 from scaling
Make/N=20 x1Data
Make/N=30 x2Data
// OK: 2D effective Y data, matching 1D X and Y flags
CurveFit Gauss2D yData[0,9] [0,19] /X=x1Data[0,9]/Y=x2data[10,29]
// OK: effective 2D Y data
Make/N=(10,20,3) Y data
CurveFit Gauss2D yData[] [] [0]
```

There are, of course, lots of possible combinations, too numerous to enumerate.

### Subrange Backward Compatibility

Historically, a Y wave could have a subrange. The same subrange applied to all other waves. For backward compatibility, if you use a subrange with the Y wave only, and other waves lack a subrange, these other waves must have either: 1) The same total number of points as the total number of points in the Y wave in which case the Y wave subrange will be applied; or 2) The same total number of points as the Y wave's subrange.

In addition, the Y wave can take a subrange in parentheses to indicate that the subrange refers to the Y wave's scaled indices (X scaling). If you use parentheses to specify an X range, you must satisfy the old subrange rules: All waves must have the same number of points. Subrange is allowed for the Y wave only. The Y wave subrange is applied to all other waves.

### Confidence Band Details

Automatic generation of confidence and prediction bands occurs if the `/F={...}` parameter is used with no wave names. One to four waves are generated, or you can specify one to four wave names yourself depending on the `confKind` and `confStyle` settings.

Waves auto-generated by `/F={confLevel, confKind, confStyle}`:

<i>confKind</i>	<i>confStyle</i>	What You Get	Auto Wave Names
1	"Contour"	upper and lower confidence contours	UC_ <i>dataName</i> , LC_ <i>dataName</i>
2	"Contour"	upper and lower prediction contours	UP_ <i>dataName</i> , LP_ <i>dataName</i>
3	"Contour"	upper and lower confidence contours and prediction contours	UC_ <i>dataName</i> , LC_ <i>dataName</i> , UP_ <i>dataName</i> , LP_ <i>dataName</i>
1	"ErrorBar"	confidence interval wave	CI_ <i>dataName</i>
2	"ErrorBar"	prediction interval wave	PI_ <i>dataName</i>
3	"ErrorBar"	confidence and prediction interval waves	CI_ <i>dataName</i> , PI_ <i>dataName</i>

Note that `confKind` may have 4 added to it if you want coefficient confidence limits calculated as well.

The contour waves are appended to the top graph as traces if the data wave is displayed in the top graph. The wave names have *dataName* replaced with the name of the wave containing the Y data for the fit.

Waves you must supply for `/F={confLevel, confKind, confStyle, wave, wave...}`:

<i>confKind</i>	<i>confStyle</i>	You Supply
1	"Contour"	2 waves to receive upper and lower confidence contours.
2	"Contour"	2 waves to receive upper and lower prediction contours.
3	"Contour"	4 waves to receive upper and lower confidence and upper and lower prediction contours.
1	"ErrorBar"	1 wave to receive values of confidence band width.
2	"ErrorBar"	1 wave to receive values of prediction band width.
3	"ErrorBar"	2 waves to receive values of confidence and prediction band widths.

The waves you supply must have the same number of points as the dependent variable data wave. The band intervals will be calculated at the X values of the input data. These waves are not automatically appended to a graph; it is expected that you will display the contour waves as traces or use the error bar waves to make error bars on the model fit wave.

### Residual Details

Residuals are calculated only for elements corresponding to elements of `waveName` that are included in the fit. Thus, you can calculate residuals automatically for a piecewise fit done in several steps.

The automatic residual wave will be appended to the top graph if the graph displays the Y data. It is appended to a new free axis positioned directly above the axis used to display the Y data, making a stacked graph. Other axes are shortened as necessary to make room for the new axis. You can alter the axis formatting later. See **Creating Stacked Plots** on page II-253 for details.

While Igor will go to some lengths to make a nicely formatted stacked graph, the changes made to the graph formatting may be undesirable in certain cases. Use /A=0 to suppress the automatic append to the graph. The automatic residual wave will be created and filled with residual values, but not appended to the graph.

When fitting to a user-specified function, see **FuncFit**. For multivariate user-specified fitting functions, see **FuncFit** and **FuncFitMD**. See **Confidence Bands and Coefficient Confidence Intervals** on page III-193 for a detailed description of confidence and prediction bands.

### References

An explanation of the Levenberg-Marquardt nonlinear least squares optimization can be found in Chapter 14.4 of Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

## CustomControl

**CustomControl** [/Z] *ctrlName* [**keyword** = *value* [, **keyword** = *value* ...]]

The CustomControl operation creates or modifies a custom control in the target window. A CustomControl starts out as a generic button, but you can customize both its appearance and its action.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the CustomControl to be created or changed. See **Button** for standard default parameters.

The following keyword=value parameters are supported:

- |                                 |   |
|---------------------------------|---|
| fColor=( <i>r,g,b</i> )         | Sets color of the button only when picture is not used and frame=1.<br><i>r</i> , <i>g</i> , and <i>b</i> can range from 0 to 65535.  |
| focusRing= <i>fr</i>            | Enables or disables the drawing of a rectangle indicating keyboard focus:<br><i>fr</i> =0: Focus rectangle will not be drawn.<br><i>fr</i> =1: Focus rectangle will be drawn (default).<br>On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.  |
| frame= <i>f</i>                 | Sets frame style used only when picture is not used:<br><i>f</i> =0: No frame (only the title is drawn).<br><i>f</i> =1: Default, a button is drawn with a centered title. Set fColor to something other than black to colorize the button.<br><i>f</i> =2: Simple box.<br><i>f</i> =3: 3D sunken frame. On Macintosh, when "native GUI appearance" is enabled for the control, the frame is filled with the proper operating system color.<br><i>f</i> =4: 3D raised frame.<br><i>f</i> =5: Text well. |
| labelBack=( <i>r,g,b</i> ) or 0 | Sets background color for the control only when a picture is not used and frame is not 1 and is not 3 on Macintosh.<br><i>r</i> , <i>g</i> and <i>b</i> specify the amount of red, green and blue in the color as an integer from 0 to 65535. If not set (or labelBack=0), then background is transparent (not erased).   |

<code>mode=<i>m</i></code>	Notifies the control that something has happened. Can be used for any purpose. See <b>Details</b> discussion of the <code>kCCE_mode</code> event.
<code>noPROC</code>	Specifies that no procedure will execute when clicking the custom control.
<code>picture=<i>pict</i></code>	Uses the named Proc Pictures to draw the control. The picture is taken to be three side-by-side frames, which show the control appearance in the normal state, when the mouse is down, and in the disabled state.  The control action function can overwrite the picture number using the <code>picture={<i>pict</i>,<i>n</i>}</code> syntax.  The picture size overrides the size keyword.
<code>picture={<i>pict</i>,<i>n</i>}</code>	Uses the specified Proc Picture to draw the control. The picture is <i>n</i> side-by-side frames instead of the default three frames.
<code>pos={<i>left</i>,<i>top</i>}</code>	Sets the position of the control in pixels.
<code>pos+=<i>dx</i>,<i>dy</i>}</code>	Offsets the position of the control in pixels.
<code>proc=<i>procName</i></code>	Specifies the name of the action function for the control. The function must not kill the control or the window.
<code>size={<i>width</i>,<i>height</i>}</code>	Sets size of the control in pixels but only when not using a Proc Picture.
<code>title=<i>titleStr</i></code>	Specifies text that appears in the control.  Using escape codes you can change the font, size, style, and color of the title. See <b>Annotation Escape Codes</b> on page III-53 or details.
<code>userdata(<i>UDName</i>)=<i>UDStr</i></code>	Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.
<code>userdata(<i>UDName</i>)+=<i>UDStr</i></code>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .
<code>value=<i>varName</i></code>	Sets the numeric variable, string variable, or wave that is associated with the control. With a wave, specify a point using the standard bracket notation with either a point number ( <code>value=awave[4]</code> ) or a row label ( <code>value=awave[%alabel]</code> ).
<code>valueColor=(<i>r</i>,<i>g</i>,<i>b</i>)</code>	Sets initial color of the title for the button drawn only when picture is not used and frame=1.  <i>r</i> , <i>g</i> , and <i>b</i> range from 0 to 65535. <i>valueColor</i> defaults to black (0,0,0). To further change the color of the title text, use escape sequences as described for <code>title=<i>titleStr</i></code> .

### Flags

<code>/Z</code>	No error reporting.
-----------------	---------------------

### Details

When you create a custom control, your action procedure gets information about the state of the control using the `WMCustomControlAction` structure. See **WMCustomControlAction** for details on the `WMCustomControlAction` structure.

Although the return value is not currently used, action procedures should always return zero.

When you call a function with the `kCCE_draw` event, the basic button picture (custom or default) will already have been drawn. You can use standard draw commands such as **DrawLine** to draw on top of the basic picture. Unlike the normal situation when draw commands merely add to a draw list, which only later is drawn, `kCCE_draw` event draw commands are executed directly. The coordinate system, which you can not change, is pixels with (0,0) being the top left corner of the control. Most drawing commands are legal but because of the immediate nature of drawing, the /A (append) flag of **DrawPoly** is not allowed.

The `kCCE_mode` event can be used for any purpose, but it mainly serves as a notification to the control that something has happened. For example, to send information to a control, you can set a named (or the unnamed) userdata and then set the mode to indicate that the control should examine the userdata. For this signaling purpose, you should use a mode value of 0 because this value will not become part of the recreation macro.

The `kCCE_frame` event is sent just before drawing one of the *pict* frames, as set by the picture parameter. On input, the `curFrame` field is set to 0 (normal or mouse down outside button), to 1 (mouse down in button), or to 2 (disable). You may modify `curFrame` as desired but your value will be clipped to a valid value.

When you specify a *pict* with the picture parameter, you will get a `kCCE_drawOSBM` event when that *pict* is drawn into an offscreen bitmap. Once it is created, all updates use the offscreen bitmap until you specify a new picture parameter. Thus the custom drawing done at this event is static, unlike drawing done during the `kCCE_draw` event, which can be different each time the control is drawn. Because the *pict* can contain multiple side-by-side frames, the width of the offscreen bitmap is the width derived from the `ctrlRect` field multiplied by the number of frames.

Because the action function is called in the middle of various control events, it must not kill the control or the window. Doing so will almost certainly cause a crash.

### Examples

See **Creating Custom Controls** on page III-377 for some examples of custom controls.

For a demonstration of custom controls, see the Custom Control Demo.pxp example experiment, which is located in your Igor Pro 7 Folder in the Examples:Feature Demos 2: folder.

The **TextBox**, **DrawPoly** and **DefaultGUIControls** operations.

## CWT

### CWT [*flags*] *srcWave*

The CWT operation computes the continuous wavelet transform (CWT) of a 1D real-valued input wave (*srcWave*). The input can be of any numeric type. The computed CWT is stored in the wave `M_CWT` in the current data folder. `M_CWT` is a double precision 2D wave which, depending on your choice of mother wavelet and output format, may also be complex. The dimensionality of `M_CWT` is determined by the specifications of offsets and scales. The operation sets the variable `V_flag` to zero if successful or to a nonzero number if it fails for any reason.

### Flags

<code>/ENDM=method</code>	Selects the method used to handle the two ends of the data array with direct integration ( <code>/M=1</code> ).
<code>method=0:</code>	Padded on both sides by zeros.
<code>method=1:</code>	Reflected at both the start and end.
<code>method=2:</code>	Entered with cyclical repetition.
<code>/FSCL</code>	Use correction factor to the wave scaling of the second dimension of the output wave so that the numbers are more closely related to Fourier wavelength. See <b>References</b> for more information on the calculation of these correction factors. This flag does not affect the output from the Haar wavelet.
<code>/M=method</code>	Specifies the CWT computation method.
<code>method=0:</code>	Fast method uses FFT (default).
<code>method=1:</code>	Slower method using direct integration.

You should mostly use the more efficient FFT method. The direct method should be reserved to situations where the FFT is not producing optimal results. Theoretically, when the FFT method fails, the direct method should also be fairly inaccurate, e.g., in the case of undersampled signal. The main advantage in the direct method is that you can use it to investigate edge effects.

*/OUT=format*

Sets the format of the output wave M\_CWT:

*format=1:*     Complex.

*format=2:*     Real valued.

*format=4:*     Real and contains the magnitude.

Depending on the method of calculation and the choice of mother wavelet, the “native” output of the transform may be real or complex. You can force the output to have a desired format using this flag.

*/Q*

Quiet mode; no results printed to the history.

*/R1={startOffset, delta1, numOffsets}*

Specifies offsets for the CWT. Offsets are the first dimension in a CWT. Normally you will calculate the CWT for the full range of offsets implied by *srcWave* so you will not need to use this flag. However, when using the slow method, this flag restricts the output range of offsets and save some computation time. *startOffset* (integer) is the point number of the first offset in *srcWave*. *delta1* is the interval between two consecutive CWT offsets. It is expressed in terms of the number *srcWave* points. *numOffsets* is the number of offsets for which the CWT is computed.

By default *startOffset=0*, *delta1=1*, and *numOffsets* is the number of points in *srcWave*. If you want to specify just the *startOffset* and *delta1*, you can set *numOffsets=0* to use the same number of points as the source wave.

*/R2={startScale, scaleStepSize, numScales}*

Specifies the range of scales for the CWT is computation. Scales are the second dimension in the output wave. Note however that there are limitations on the minimum and maximum scales having to do with the sampling of your data. Because there is a rough correspondence between a Fourier spatial frequency and CWT scale it should be understood that there is also a maximum theoretical scale. This is obvious if you compute the CWT using an FFT but it also applies to the slow method. If you specify a range outside the allowed limits, the corresponding CWT values are set to NaN.

Use NaN if you want to use the default value for any parameter.

The default value for *startScale* is determined by sampling of the source wave and the wavelet parameter or order.

At a minimum you must specify either *scaleStepSize* or *numScales*.

*/SMP1=offsetMode*

Determines computation of consecutive offsets. Currently supporting only *offsetMode=1* for linear, user-provided partial offset limits (see */R1* flag):  
*val1=startOffset+numOffsets\*delta1*.

*/SMP2=scaleMode* Determines computation of consecutive scales. *scaleMode* is 1 by default if you specify the */R2* flag.

*format=1:* Linear:  
 $theScale = startScale + index * scaleStepSize$   
*format=2:* User-provided scaling wave.  
*format=4:* Power of 2 scaling interval:  
 $theScale = startScale * 2.^{(index * scaleStepSize)}$

When using *scaleMode=4* the operation saves the consecutive scale values in the wave *W\_CWTScaling*. Note also that if you use *scaleMode=4* without specifying a corresponding */R2* flag, the default *scaleStepSize* of 1 and 64 scale values gives rise to scale values that quickly exceed the allowed limits.

(See */R2* flag for details about the different parameters used in the equations above.)

*/SW2=sWave* Provides specific scale values at which the transform is evaluated. Use instead of */R2* flag. It is your responsibility to make sure that the entries in the wave are appropriate for the sampling density of *srcWave*.

*/WBI1={Wavelet [, order]}*

Specifies the built-in wavelet (mother) function. *Wavelet* is the name of a wavelet function: Morlet (default), MorletC (complex), Haar, MexHat, DOG, and Paul.

Morlet: 
$$\Psi_0(x) = \frac{1}{\pi^{1/4}} \cos(\omega x) \exp\left(-\frac{x^2}{2}\right).$$

By default,  $\omega=5$ . Use the */WPR1* flag to specify other values for  $\omega$ .

MorletC: 
$$\Psi_0(x) = \frac{1}{\pi^{1/4}} \exp(i\omega x) \exp\left(-\frac{x^2}{2}\right).$$

By default,  $\omega=5$ . Use the */WPR1* flag to specify other values for  $\omega$ .

Haar: 
$$\Psi_0(x) = \begin{cases} 1 & 0 \leq x < 0.5 \\ -1 & 0.5 \leq x < 1 \end{cases}.$$

DOG: 
$$\Psi_0(x) = \frac{(-1)^{m+1}}{\sqrt{\Gamma\left(m + \frac{1}{2}\right)}} \frac{d^m}{dx^m} \left( \exp\left(-\frac{x^2}{2}\right) \right).$$

MexHat: Special case of DOG with  $m=2$ .

Paul: 
$$\Psi_0(m, x) = \frac{2^m i^m m!}{\sqrt{\pi (2m)!}} (1 - ix)^{-(m+1)}.$$

*order* applies to DOG and Paul wavelets only and specifies  $m$ , the particular member of the wavelet family.

The default wavelet is the Morlet.

*/WPR1={param1}* *param1* is a wavelet-specific parameter for the wavelet function selected by */WBI1*. For example, use */WPR1={6}* to change the Morlet frequency from the default (5).

/Z No error reporting. If an error occurs, sets V\_flag to -1 but does not halt function execution.

### Details

The CWT can be computed directly from its defining integral or by taking advantage of the fact that the integral represents a convolution which in turn can be calculated efficiently using the fast Fourier transform (FFT).

When using the FFT method one encounters the typical sampling problems and edge effects. Edge effects are also evident when using the slow method but they only significant in high scales.

From sampling considerations it can be shown that the maximum frequency of a discrete input signal is  $1/2dt$  where  $dt$  is the time interval between two samples. It follows that the smallest CWT scale is  $2dt$  and the largest scale is  $Ndt$  where  $N$  is the total number of samples in the input wave.

The transform in M\_CWT is saved with the wave scaling. *startOffset* and *delta1* are used for the X-scaling. Both *startOffset* and *delta1* are either specified by the /R1 flag or copied from *srcWave*. The Y-scaling of M\_CWT depends on your choice of /SMP2. If the CWT scaling is linear then the wave scaling is based on *startScale* and *scaleStepSize*. If you are using power of 2 scaling interval then the Y wave scaling of M\_CWT has a *start*=0 and *delta*=1 and the wave W\_CWTScaling contains the actual scale values for each column of M\_CWT. Note that W\_CWTScaling has one extra data point to make it suitable for display using an operation like:

```
AppendImage M_CWT vs {*, W_CWTScaling}
```

We have encountered two different definitions for the Morlet wavelet in the literature. The first is a complex function (MorletC) and the second is real (Morlet). Instead of choosing one of these definitions we implemented both so you may choose the appropriate wavelet.

<<http://paos.colorado.edu/research/wavelets/>>.

## DataFolderDir

**DataFolderDir**(*mode* [, *dfr* ])

The DataFolderDir function returns a string containing a listing of some or all of the objects contained in the current data folder or in the data folder referenced by *dfr*.

### Parameters

*mode* is a bitwise flag for each type of object. Use -1 for all types. Use a sum of the bit values for multiple types.

Desired Type	Bit Number	Bit Value
All		-1
Data folders	0	1
Waves	1	2
Numeric variables	2	4
String variables	3	8

*dfr* is a data folder reference.

**Details**

The returned string has the following format:

1. FOLDERS:*name,name,...*;<CR>
2. WAVES:*name,name,...*;<CR>
3. VARIABLES:*name,name,...*;<CR>
4. STRINGS:*name,name,...*;<CR>

Where <CR> represents the carriage return character.

**Tip**

This function is mostly useful during debugging, used in a **Print** command. For finding the contents of a data folder programmatically, it will be easier to use the functions **CountObjects** and **GetIndexedObjName**.

**Examples**

```
Print DataFolderDir(8+4)      // prints variables and strings
Print DataFolderDir(-1)      // prints all objects
```

**See Also**

Chapter II-8, **Data Folders**.

**Setting Bit Parameters** on page IV-12 for information about bit settings.

## DataFolderExists

**DataFolderExists** (*dataFolderNameStr*)

The DataFolderExists function returns the truth that the specified data folder exists.

*dataFolderNameStr* can be a full path or partial path relative to the current data folder.

If *dataFolderNameStr* is null DataFolderExists returns 1 because, for historical reasons, a null data folder path is taken to refer to the current data folder.

**See Also**

Chapter II-8, **Data Folders**.

## DataFolderRefsEqual

**DataFolderRefsEqual** (*dfr1*, *dfr2*)

The DataFolderRefsEqual function returns the truth the two data folder references are the same.

**See Also**

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-72.

The **DataFolderRefStatus** function.

## DataFolderRefStatus

**DataFolderRefStatus** (*dfr*)

The DataFolderRefStatus function returns the status of a data folder reference.

**Details**

DataFolderRefStatus returns zero if the data folder reference is invalid or non-zero if it is valid.

DataFolderRefStatus returns a bitwise result with bit 0 indicating if the reference is valid and bit 1 indicating if the reference data folder is free. Therefore the returned values are:

- 0: The data folder reference is invalid.
- 1: The data folder reference refers to a regular global data folder.
- 3: The data folder reference refers to a free data folder.

A data folder reference is invalid if it was never assigned a value or if it is assigned an invalid value. For example:

## dateToJulian

---

```
DFREF dfr                                // dfr is invalid
DFREF dfr = root:                        // dfr is valid
DFREF dfr = root:NonExistentDataFolder  // dfr is invalid
```

A data folder reference can be valid and yet point to a non-existent data folder:

```
NewDataFolder/O root:MyDataFolder
DFREF dfr = root:MyDataFolder          // dfr is valid
KillDataFolder root:MyDataFolder       // dfr is still valid
```

After the KillDataFolder, dfr is still a valid data folder reference but points to a non-existent data folder.

You should use DataFolderRefStatus to test any DFREF variables that might not be valid, such as after assigning a reference when you are not sure that the referenced data folder exists. For historical reasons, an invalid DFREF variable will often act like root.

### See Also

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-72.

## dateToJulian

**dateToJulian(year, month, day)**

The dateToJulian function returns the Julian day number for the specified date. The Julian day starts at noon. Use negative number for BC years and positive numbers for AD years. To exclude any ambiguity, there is no year zero in this calendar. For general orientation, Julian day 2450000 corresponds to October 9, 1995.

### See Also

The **JulianToDate** function.

For more information about the Julian calendar see:

<<http://www.tondering.dk/claus/calendar.html>>.

## date

**date()**

The date function returns a string containing the current date.

Formatting of dates depends on your operating system and on your preferences entered in the Date & Time control panel (*Macintosh*) or the Regional Settings control panel (*Windows*).

### Examples

```
Print date()          // Prints Mon, Mar 15, 1993
```

### See Also

The **Secs2Date**, **Secs2Time**, and **time** functions.

## date2secs

**date2secs(year, month, day)**

The date2secs function returns the number of seconds from midnight on 1/1/1904 to the specified date.

Note that the month and day parameters are one-based, so these series start at one.

If *year*, *month*, and *day* are all -1 then date2secs returns the offset in seconds from the local time to the UTC (Universal Time Coordinate) time.

### Examples

```
Print Secs2Date(date2secs(1993,3,15),1)          // Ides of March, 1993
```

Prints the following, depending on your system's date settings, in the history area:

```
Monday, March 15, 1993
```

This next example sets the X scaling of a wave to 1 day per point, starting January 1, 1993:

```
Make/N=125 myData = 100 + gnoise(50)
SetScale/P x,date2secs(1993,1,1),24*60*60,"dat",myData
Display myData;ModifyGraph mode=5
```

### See Also

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-78.

The **Secs2Date**, **Secs2Time**, and **time** functions.

## DateTime

### **DateTime**

The DateTime function returns number of seconds from 1/1/1904 to current local date and time.

To get the UTC date and time, subtract Date2Secs(-1,-1,-1) from the value returned by DateTime.

Unlike most Igor functions, DateTime is used without parentheses.

### **Examples**

```
Variable localNow = DateTime
```

### **See Also**

The **Secs2Date**, **Secs2Time** and **time** functions.

## dawson

### **dawson(x)**

The dawson function returns the value of the Dawson integral:

$$F(x) = \exp(-x^2) \int_0^x \exp(t^2) dt.$$

### **References**

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 298 pp., Dover, New York, 1972.

## DDEExecute

### **DDEExecute(refNum, cmdStr [, timeout])**

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEExecute function sends a string of commands, *cmdStr*, to the server for execution. The format of the commands depends on the server application.

*refNum* is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEExecute returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

In some situations, you may want to use a zero *timeout* and then use DDEStatus to monitor when the server is finished. You would do this if the server might take a long time to accomplish the commands and you want Igor to continue working at the same time.

### **See Also**

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

## DDEInitiate

### **DDEInitiate(serverName, topicName)**

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEInitiate function opens a DDE session and returns a reference number for use by the rest of the DDE routines. Returns zero if failure.

If the desired application is not running, DDEInitiate will return zero. If this occurs, you can use the ExecuteScriptText operation to start the server application.

## DDEPokeString

---

Refer to your application's documentation for the *serverName* and *topicName*. See the following example for usage with Excel.

### Examples

```
Variable ch= DDEInitiate("excel","book1")
```

### See Also

The **ExecuteScriptText** operation. For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

## DDEPokeString

**DDEPokeString(refNum, itemString, string [, timeout])**

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEPokeString function sends *string* to the server.

*itemString* is a string specifying the server application's DDE item name for the location into which to store the string. For example, "R1C1" specifies the first cell in an Excel spreadsheet.

*refNum* is the DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEPokeString returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

### See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

## DDEPokeWave

**DDEPokeWave(refNum, itemString, wave [, timeout [, format]])**

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEPokeWave function sends data from a *wave* to the server.

*itemString* is a string specifying the server application's DDE item name for the location into which to store the string. For example, "R1C1:R10C10" specifies a 10x10 block of cells in an Excel spreadsheet.

*refNum* is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEPokeWave returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the *timeout* period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *format* parameter can be 0 to send the data as tab-delimited text (default) or can be 1 to specify Microsoft's XLTable (excel) format. To specify *format* without specifying *timeout*, the latter may be completely missing ( , , ) or a \* symbol may be used:

```
err= DDEPokeWave(ch,"R1C1:R10C10",*,1)
```

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

### Examples

A session using Microsoft Excel:

```
Variable ch,err1,err2  
ch= DDEInitiate("excel","book1")  
Make/O/N=(5,5) jack= P+10*Q  
err1= DDEPokeWave(ch,"R1C1:R5C5",jack)  
err2= DDETerminate(ch)
```

### See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

## DDERequestString

**DDERequestString(refNum, itemString [, timeout])**

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDERequestString string function returns a string of requested data or null handle in case of failure.

*itemString* is a string specifying the server application's DDE item name for the data being requested. For example, "R1C1" specifies the first cell in an Excel spreadsheet.

*refNum* is a DDE session reference number returned by DDEInitiate to start a particular session.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

### See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

## DDERequestWave

**DDERequestWave(refNum, itemString, destWave [, timeout])**

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDERequestWave function loads a preexisting wave with data from the server. The provided destination wave, *destWave*, can be either text or numeric. Data from the server must be a tab delimited array. It is analyzed to determine the dimensions of the wave but the numeric type (or string type) of the wave is not changed.

*itemString* is a string specifying the server application's DDE item name for the requested data. For example, "R1C1:R10C10" specifies a 10x10 block of cells in an Excel spreadsheet.

*refNum* is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDERequestWave returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

### See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

## DDEStatus

**DDEStatus(refNum)**

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEStatus function returns the status of the DDE session defined by *refNum* from a previous DDEInitiate.

Returns zero if *refNum* is not valid or if the session has been closed.

Returns nonzero if session is valid where the individual bits have the following meanings:

- Bit 0: Set if the session is valid and not busy.
- Bit 1: Set if waiting for an ack from the server for a previous DDEPoke or DDEExecute that timed out. (bit 0 and 1 are exclusive).
- Bit 2: Set if the ack from the server for a previous poke or execute command was negative. Only applies to timed out commands.

### See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

### DDETerminate

**DDETerminate** (*refNum*)

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDETerminate function closes the DDE session defined by *refNum* from a previous DDEInitiate. Returns truth session was valid.

Pass zero to terminate all client sessions.

#### See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

### Debugger

**Debugger**

The Debugger operation breaks into the debugger if it is enabled.

#### See Also

The **Debugger** on page IV-198 and the **DebuggerOptions** operation.

### DebuggerOptions

**DebuggerOptions** [*enable=en*, *debugOnError=doe*, *NVAR\_SVAR\_WAVE\_Checking=nvwc*]

The DebuggerOptions operation programmatically changes the user-level debugger settings. These are the same three settings that are available in the Procedure menu (and the debugger source pane contextual menu)

#### Parameters

All parameters are optional. If none are specified, no action is taken, but the output variables are still set.

*enable=en*                      Turns the debugger on (*en=1*) or off (*en=0*).  
If the debugger is disabled then the other settings are cleared even if other settings are on.

*debugOnError=doe*      Turns Debugging On Error on or off.  
*doe=0*:                      Disables Debugging On Error (see **Debugging on Error** on page IV-199).  
*doe=1*:                      Enables Debugging On Error and also enables the debugger (implies *enable=1*).

*NVAR\_SVAR\_WAVE\_Checking=nvwc*  
Turns NVAR, SVAR, and WAVE checking on or off.  
*nvwc=0*:                      Disables “NVAR SVAR WAVE Checking”. See **Accessing Global Variables and Waves** on page IV-59 for more details.  
*nvwc=1*:                      Enables this checking and also enables the debugger (implies *enable=1*).

#### Details

DebuggerOptions sets the following variables to indicate the Debugger settings that are in effect *after* the command is executed. A value of zero means the setting is off, nonzero means the setting is on.

*V\_enable*                      *V\_debugOnError*                      *V\_NVAR\_SVAR\_WAVE\_Checking*

#### See Also

The **Debugger** on page IV-198 and the **Debugger** operation.

## default

### default:

The default flow control keyword is used in switch and strswitch statements. When none of the case labels in the switch or strswitch match the evaluation expression, execution will continue with code following the default label, if it is present.

### See Also

**Switch Statements** on page IV-41.

## DefaultFont

**DefaultFont** [/U] "*fontName*"

The DefaultFont operation sets the default font to be used in graphs for axis labels, tick mark labels and annotations, and in page layouts for annotations.

### Parameters

"*fontName*" should be a font name, optionally in quotes. The quotes are not required if the font name is one word.

### Flags

/U            Updates existing graphs and page layouts immediately to use the new default font.

## DefaultGUIControls

**DefaultGUIControls** [/Mac/W=*winName*/Win] [*appearance*]

The DefaultGUIControls operation changes the appearance of user-defined controls.

**Note:**        The recommended way to change the appearance of user-defined controls is to use the Miscellaneous Settings dialog's Native GUI Appearance for Controls checkbox in the Compatibility tab, which is equivalent to `DefaultGUIControls native` when checked, and to `DefaultGUIControls os9` when unchecked.

Use `DefaultGUIControls/W=winName` to override that setting for individual windows.

### Parameters

*appearance* may be one of the following:

- |         |   |
|---------|---|
| native  | Creates standard-looking controls for the current computer platform. This is the default value.                 |
| os9     | Igor Pro 5 appearance (quasi-Macintosh OS 9 controls that look the same on Macintosh and Windows).              |
| default | Inherits the window appearance from either a parent window or the experiment-wide default (only valid with /W). |

### Flags

- |                    |   |
|--------------------|---|
| /Mac               | Changes the appearance of controls only on Macintosh, and it affects the experiment whenever it is used on Macintosh.   |
| /W= <i>winName</i> | Affects the named window or subwindow. When omitted, sets an experiment-wide default.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy. |
| /Win               | Changes the appearance of controls only on Windows, and it affects the experiment whenever it is used on Windows.   |

### Details

If *appearance* is not specified, nothing is changed. The current value for appearance is returned in `S_value`.

If *appearance* is specified the previous appearance value for the window- or experiment-wide default is returned in *S\_value*.

With */W*, the control appearance applies only to the specified window (Graph or Panel). If it is not used, then the settings are global to experiments on the current computer. **Tip:** Use */W=#* to refer to the current active subwindow.

The */Mac* and */Win* flags specify the affected computer platform. If the current platform other than specified, then the settings are not used, but (if native or OS9) are remembered for use in window recreation macros or experiment recreation. This means you can create an experiment that with different appearances depending on the current platform.

If neither */Mac* nor */Win* are used, it is implied by the current platform. To set native appearance on both platforms, use two commands:

```
DefaultGUIControls/W=Panel0/Mac native
```

```
DefaultGUIControls/W=Panel0/Win native
```

**Note:** The setting for DefaultGUIControls without */W* is not stored in the experiment file; it is a user preference set by the Miscellaneous Settings dialog's Native GUI Appearance for Controls checkbox in the Compatibility tab. If you use DefaultGUIControls native or DefaultGUIControls os9 commands, the checkbox will not show the current state of the experiment-wide setting. Clicking Save Settings in the Miscellaneous Settings dialog will overwrite the DefaultGUIControls setting (but not the per-window settings).

In addition to the experiment-wide appearance setting and the window-specific appearance setting, an individual control's appearance can be set with the appropriate control command's appearance keyword (or a ModifyControl appearance keyword). A control-specific appearance setting overrides a window-specific appearance, which in turn overrides the experiment-wide appearance setting.

Although meant to be used before controls are created, calling DefaultGUIControls will update all open windows.

DefaultGUIControls does not change control fonts or font sizes, which means you can create controls that look "native-ish" without having to readjust their positions to avoid avoid shifting or overlap. However, the smooth font rendering that the Native GUI uses on Macintosh does change the length of text slightly, so some shifting will occur that affects mostly controls that were aligned on their right sides.

The native appearance affects the way that controls are drawn in **TabControl** and **GroupBox** controls.

### TabControl Background Details

Unlike the os9 appearance which draws only an outline to define the tab region (leaving the center alone) the native tab appearance fills the tab region. Fortunately, TabControls are drawn before all other kinds of controls which allows enclosed controls to be drawn on top of a tab control regardless of the order in which the buttons are defined in the window recreation macro.

However the drawing order of native TabControls does matter: the top-most TabControls draws over other TabControls. (The top-most TabControl is listed last in the window recreation macro.) The os9 appearance allows a smaller (nested) TabControl to be underneath the later (enclosing) TabControl because tabs normally aren't filled. Converting these tabs to native appearance will cause nested tab to be hidden.

To fix the drawing order problem in an existing panel, turn on the drawing tools, select the arrow tool, right-click the enclosing TabControl, and choose Send to Back to correct this situation. If the TabControl itself is inside another TabControl, select that enclosing TabControl and also choose Send to Back, etc.

To fix the window recreation macro or function that created the panel, arrange the enclosing TabControl commands to execute before the commands that create the enclosed TabControls.

A natively-drawn TabControl draws any drawing objects that are entirely enclosed by the tab region so that it behaves the same as an os9 unfilled TabControl with drawing objects inside.

### GroupBox Control Background Details

GroupBox controls, unlike TabControls, are not drawn before all other controls, so the drawing order always matters if the GroupBox specifies a background (fill) color and it contains other controls.

You may find that enabling native appearance hides some controls inside the GroupBox. They are probably underneath (before) the GroupBox in the drawing order.

To fix this in an existing panel, turn on the drawing tools, right-click on the GroupBox and choose Send to Back. To fix the window recreation macro or function that created the panel, arrange the GroupBox commands to execute before the commands that create the enclosed controls.

A natively-drawn GroupBox draws any drawing objects that are entirely enclosed by the box; an os9 filled GroupBox does not.

#### See Also

The **DefaultUIFont**, **ModifyControl**, **Button**, **GroupBox**, and **TabControl** operations.

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

## DefaultUIFont

**DefaultUIFont** [/W=*winName* /Mac/Win] *group* = {*fNameStr*, *fSize*, *fStyle*} [,...]

The DefaultUIFont operation changes the default font for user-defined controls and other Graphical User Interface elements.

#### Parameters

*fNameStr* is the name of a font, *fSize* is the font size, and *fStyle* is a bitwise parameter with each bit controlling one aspect of the font style. See **Button** for details about these parameters.

*group* may be one of the following:

all	All controls
button	Button and default CustomControl
checkbox	CheckBox controls
tabcontrol	TabControl controls
popup	Affects the icon (not the title) of a PopupMenu control. The text in the popped state is set by the system and can not be changed. The title of a PopupMenu is affected by the all group but the icon text is not.
panel	Draw text in a panel.
graph	Overlay graphs. Size is used only if ModifyGraph <i>gfSize</i> = -1; style is not used.
table	Overlay tables.

#### Flags

/Mac	Changes control fonts only on Macintosh, and it affects the experiment whenever it is used on Macintosh.
/W= <i>winName</i>	Affects the named window or subwindow. When omitted, sets an experiment-wide default.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.
/Win	Changes control fonts only on Windows, and it affects the experiment whenever it is used on Windows.

#### Details

Although designed to be used before controls are created, calling DefaultUIFont will update all affected windows with controls. This makes it easy to experiment with fonts. Keep in mind that fonts can cause compatibility problems when moving between machines or platforms.

The /Mac and /Win flags indicate the platform on which the fonts are to be used. If the current platform is not the one specified then the settings are not used but are remembered for use in window recreation macros or experiment recreation. This allows a user to create an experiment that will use different fonts depending on the current platform.

If the /W flag is used then the font settings apply only to the specified window (Graph or Panel.) If the /W flag is not used, then the settings are global to the experiment. Tip: Use /W=# to refer to the current active subwindow.

*fNameStr* may be an empty string ("" ) to clear a group. Setting the font name to "\_IgorSmall", "\_IgorMedium", or "\_IgorLarge" will use Igor's own defaults. The standard defaults for controls are the equivalent to setting all to "\_IgorSmall", tabcontrol to "\_IgorMedium", and button to "\_IgorLarge". Use a *fSize* of zero to also get the standard default for size. On Windows, the three default fonts and sizes are all the same.

Although designed to be used before controls are created, calling DefaultUIFont will update all affected windows with controls. This makes it easy to experiment with fonts. Keep in mind that fonts can cause compatibility problems when moving between machines or platforms.

To read back settings, use DefaultUIFont [/W=winName/Mac/Win/OVR] *group* to return the current font name in *S\_name*, the size in *V\_value*, and the style in *V\_flag*. With /OVR or if /Mac or /Win is not current, it returns only override values. Otherwise, values include Igor built-in defaults. If *S\_name* is zero length, values are not defined.

Default Fonts and Sizes

The standard defaults for controls is the equivalent to setting all to "\_IgorSmall", tabcontrol to "\_IgorMedium", and button to "\_IgorLarge". Use a *fSize* of zero to also get the standard default for size. On Windows, the three default fonts and sizes are all the same.

Control	Macintosh		Windows	
	Font	Font Size	Font	Font Size
Button	Lucida Grande	13	MS Shell Dlg*	12
Checkbox	Geneva	9	MS Shell Dlg	12
GroupBox	Geneva	9	MS Shell Dlg	12
ListBox	Geneva	9	MS Shell Dlg	12
PopupMenu†	Geneva	9	MS Shell Dlg	12
SetVariable	Geneva	9	MS Shell Dlg	12
Slider	Geneva	9	MS Shell Dlg	12
TabControl	Geneva	12	MS Shell Dlg	12
TitleBox	Geneva	9	MS Shell Dlg	12
ValDisplay	Geneva	9	MS Shell Dlg	12

\* MS Shell Dlg is a "virtual font name" which maps to Tahoma on Windows XP, to MS Sans Serif on Windows 7, and to Segoe UI on Windows 8 and Windows 10.

† On Macintosh, the PopupMenu font is Geneva 9 for the title and Lucida Grande 12 for the popup menu itself. On Windows, both fonts are MS Shell Dlg 12.

Examples

```
DefaultUIFont/Mac all={"Zapf Chancery",12,0},panel={"geneva",12,3}
DefaultUIFont/Win all={"Century Gothic",12,0},panel={"arial",12,3}
NewPanel
Button b0
DrawText 40,43,"Some text"
```

See Also

The **DefaultGUIControls** operation. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

**Window Position Coordinates** on page III-405 and **Points Versus Pixels** on page III-404 for explanations of how font sizes in panels are interpreted for various screen resolutions.

Demos

Choose File→Example Experiments→Feature Demos 2→All Controls Demo.

## DefaultTextEncoding

**DefaultTextEncoding** [**encoding**=*textEncoding*, **overrideDefault**=*override*]

The DefaultTextEncoding operation programmatically changes the default text encoding and experiment text encoding override settings. These settings, which are discussed under **The Default Text Encoding** on page III-415, are also accessible via the Misc→Text Encoding→Default Text Encoding menu.

DefaultTextEncoding is rarely needed because typically you will change the default text encoding manually using the menu, if at all.

The DefaultTextEncoding operation was added in Igor Pro 7.00.

### Parameters

All parameters are optional. If none are specified, no action is taken, but the output variables are still set.

**encoding**=*textEncoding*

*textEncoding* specifies the new default text encoding. See **Text Encoding Names and Codes** on page III-434 for a list of codes.

Pass 0 to set the default text encoding to the equivalent of selecting "Western" from the Default Text Encoding submenu.

The value 255, corresponding to the binary text encoding type, is treated as an invalid value for the *textEncoding* parameter.

**overrideDefault**=*override*

Turns overriding of the experiment's text encoding off or on.

0: Turns override off

1: Turns override on

### Details

The default text encoding affects Igor's behavior when opening a file whose text encoding is unknown. See **The Default Text Encoding** on page III-415 for details.

The experiment text encoding affects how files are loaded during experiment loading only. The override setting allows you to override the experiment text encoding stored in the experiment file. Normally you will not need to do this. See **The Default Text Encoding** on page III-415 for further discussion.

You may occasionally find it necessary to change the default text encoding because an Igor operation lacks a /ENCG flag that allows you to specify the text encoding and instead uses the current default text encoding. In such cases it is a good idea to save the original default text encoding, change it as necessary, and then change it back to the original text encoding. The example below demonstrates this technique.

### Output Variables

DefaultTextEncoding sets the following output variables to indicate the settings that are in effect after the command executes:

V\_defaultTextEncoding     A text encoding code.

V\_overrideExperiment     A value of zero means the setting is off, nonzero means the setting is on.

### Example

```
Function DemoDefaultTextEncoding()
    // Store the original default text encoding
    DefaultTextEncoding
    Variable originalTextEncoding = V_defaultTextEncoding

    // Set new default text encoding
    DefaultTextEncoding encoding = 3      // 3= Windows-1252

    [ Do something that depends on the default text encoding ]

    // Restore the original default text encoding
    DefaultTextEncoding encoding = originalTextEncoding
End
```

See Also

The Default Text Encoding on page III-415, Text Encoding Names and Codes on page III-434

## defined

**defined**(*symbol*)

The defined function returns 1 if the symbol is defined 0 if the symbol is not defined.

*symbol* is a symbol possibly created by a #define statement or by SetIgorOption poundDefine=*symbol*.

*symbol* is a name, not a string. However you can use \$ to convert a string expression to a name.

### Details

The defined function can be used in three ways:

Outside of a procedure using a #if statement

Inside a procedure using a #if statement

Inside a procedure using an if statement

For example:

```
#define DEBUG

#if defined(DEBUG)                                // Outside of a function with #if
    Constant kSomeConstant = 100
#else
    Constant kSomeConstant = 50
#endif

Function Test1()                                  // Inside a function with #if
    #if defined(DEBUG)
        Print "Debugging"
    #else
        Print "Not debugging"
    #endif
End

Function Test1()                                  // Inside a function with if
    if (defined(DEBUG))
        Print "Debugging"
    else
        Print "Not debugging"
    endif
End
```

In these examples, we could have just as well used #ifdef instead of the defined function. For logical combinations of conditions however, only defined will do:

```
#if (defined(SYMBOL1) && defined(SYMBOL2))
.
.
#endif
```

When used in a procedure window, defined(symbol) returns 1 if symbol is defined at the time the line is compiled. In a given procedure file, only the following symbols are visible:

Symbols defined earlier in that procedure file \*

Symbols defined in the built-in procedure window †

Predefined symbols (see **Predefined Global Symbols** on page IV-101)

Symbols defined by SetIgorOption poundDefine=*symbol*

\* When used in the body of a procedure, as opposed to outside of a procedure, a symbol defined anywhere in a given procedure window is visible. However, to avoid depending on this confusing exception, you should define all symbols before they are referenced in a procedure file.

† Symbols defined in the built-in procedure window are not available to independent modules.

When the defined function is used from the command line, only symbols defined in the built-in procedure window, predefined symbols, and symbols defined using SetIgorOption are visible.

**See Also**

**#define**, **Conditional Compilation** on page IV-100, **Predefined Global Symbols** on page IV-101

## DefineGuide

**DefineGuide** [/W= *winName*] *newGuideName* = {[*guideName1*, *val* [, *guideName2*]]} [,...]

The DefineGuide operation creates or overwrites a user-defined guide line in the target or named window or subwindow. Guide lines help with the positioning of subwindows in a host window.

**Parameters**

*newGuideName* is the name for the newly created guide. When it is the name of an existing guide, the guide will be moved to the new position.

*guideName1*, *guideName2*, etc., must be the names of existing guides.

The meaning of *val* depends on the form of the command syntax. When using only one guide name, *val* is an absolute distance offset from to the guide. The directionality of *val* is to the right or below the guide for positive values. The units of measure are points except in panels where they are in pixels. When using two guide names, *val* is the fractional distance between the two guides.

**Flags**

/W=*winName*      Defines guides in the named window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

**Details**

The names for the built-in guides are as defined in the following table:

	Left	Right	Top	Bottom
Host Window Frame	FL	FR	FT	FB
Host Graph Rectangle	GL	GR	GT	GB
Inner Graph Plot Rectangle	PL	PR	PT	PB

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows.

To delete a guide use *guideName*={}.

**See Also**

The **Display**, **Edit**, **NewPanel**, **NewImage**, and **NewWaterfall** operations.

The **GuideInfo** function.

## DelayUpdate

**DelayUpdate**

The DelayUpdate operation delays the updating of graphs and tables while executing a macro.

**Details**

Use DelayUpdate at the end of a line in a macro if you want the next line in the macro to run before graphs or tables are updated.

This has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the **DoUpdate** operation.

**See Also**

The **DoUpdate**, **PauseUpdate**, and **ResumeUpdate** operations.

### DeleteAnnotations

**DeleteAnnotations** [*flags*] [*tagOffscreen*, *tagTraceHidden*, *invisible*,  
*offsetOffscreen*, *tooSmall* [=*size*]]

The DeleteAnnotations operation lists, in the S\_name output variable, and optionally deletes annotations that are hidden for reasons specified by the flags and keywords.

The operation affects the window or subwindow specified by the /W flag or, if /W is omitted, the active window or subwindow.

Do not use DeleteAnnotations to programmatically delete a specific, single annotation. Instead use:

TextBox/W=winName/K/N=annotationName

The /LIST flag limits the action to only listing, instead of deleting, the annotations.

The DeleteAnnotations operation was added in Igor Pro 7.00.

#### Keywords

The keywords identify annotations based on the reasons for their being hidden:

invisible	Deletes or lists annotations hidden with /V=0.
offsetOffscreen	Deletes or lists annotations that are offscreen, usually because of excessive /X and /Y offsets.
tagOffscreen	Deletes or lists tags hidden because they are attached to trace points that are offscreen. This affects trace tags, axis tags, and image tags if their "if offscreen" setting, as set in the Position tab of the Modify Annotation dialog, is set to "hide the tag".
tagTraceHidden	Deletes or lists tags hidden because the tagged trace is hidden.
tooSmall [=size]	Deletes or lists annotations whose height or width is <i>size</i> points or smaller. <i>size</i> is expressed in points and defaults to 8. This is useful for deleting annotations that are too small to see or to double-click.

#### Flags

/A	All annotations, whether hidden or not, are listed or deleted. All keywords are ignored.
/LIST	Specifies that annotations identified by the other parameters are to be listed in the S_name output variable but not deleted.
/W=winName	Annotations in the named window or subwindow are considered. When omitted, annotations in the active window or subwindow are considered.  When identifying a subwindow with winName, see Subwindow Syntax for details on forming the window hierarchy.

#### Output Variables

S_name	A semicolon-separated list of the annotations that match the criteria set by the keywords and flags.
V_flag	Set to the number of annotations deleted or listed.

#### Examples

```
Function DeleteAnnotationsInWin(win)
    String win           // Specifies a top-level window or a subwindow

    // Handle specified top-level window or subwindow
    DeleteAnnotations/W=$win/A
    Variable numDeleted = V_Flag

    // Now handle subwindows, if any
    String children = ChildWindowList(win)
    Variable n = ItemsInList(children)
    Variable i
```

```
    for(i=0; i<n; i+=1)
        String child = StringFromList(i, children)
        numDeleted += DeleteAnnotationsInWin(child) // Recurse
    endfor

    return numDeleted
End
```

**See Also****TextBox, StringFromList, AnnotationList**

## DeleteFile

**DeleteFile** [*flags*] [*fileNameStr*]

The DeleteFile operation deletes a file on disk.

**Parameters**

*fileNameStr* can be a full path to the file to be deleted (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not locate the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file to be deleted.

If you use a full or partial path for either file, see **Path Separators** on page III-401 for details on forming the path.

**Flags**

/I	Interactive mode displays the Open File dialog even if <i>fileNameStr</i> is specified and the file exists.
/M= <i>messageStr</i>	Specifies the prompt message for the Open File dialog. But see <b>Prompt Does Not Work on Macintosh</b> on page IV-137.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/Z[= <i>z</i> ]	Prevents procedure execution from aborting if it attempts to delete a file that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort. /Z=0: Same as no /Z. /Z=1: Deletes a file only if it exists. /Z alone has the same effect as /Z=1. /Z=2: Deletes a file if it exists or displays a dialog if it does not exist.

**Variables**

The DeleteFile operation returns information in the following variables:

V_flag	Set to zero if the file was deleted, to -1 if the user cancelled the Open File dialog, and to some nonzero value if an error occurred, such as the specified file does not exist.
S_path	Stores the full path to the file that was deleted. If an error occurred or if the user cancelled, it is set to an empty string.

**See Also****DeleteFolder, MoveFile, CopyFile, NewPath, and Symbolic Paths** on page II-21.

### DeleteFolder

**DeleteFolder** [*flags*] [*folderNameStr*]

The DeleteFolder operation deletes a disk folder and all of its contents.

**Warning:** *The DeleteFolder command destroys data!* The deleted folder and the contents are not moved to the Trash or Recycle Bin.

DeleteFolder will delete a folder only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category.

If permission is denied, the folder will not be deleted and V\_Flag will return 1088 (Command is disabled) or 1276 (You denied permission to delete a folder). Command execution will cease unless the /Z flag is specified.

#### Parameters

*folderNameStr* can be a full path to the folder to be deleted, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a folder within the folder associated with *pathName*.

If Igor can not determine the location of the folder from *folderNameStr* and *pathName*, it displays a Select Folder dialog allowing you to specify the folder to be deleted.

If /P=*pathName* is given, but *folderNameStr* is not, then the folder associated with *pathName* is deleted.

If you use a full or partial path for either folder, see **Path Separators** on page III-401 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

#### Flags

/I	Interactive mode displays a Select Folder dialog even if <i>folderNameStr</i> is specified and the folder exists.
/M= <i>messageStr</i>	Specifies the prompt message for the Select Folder dialog. But see <b>Prompt Does Not Work on Macintosh</b> on page IV-137.
/P= <i>pathName</i>	Specifies the folder to look in for the folder. <i>pathName</i> is the name of an existing symbolic path.
/Z[= <i>z</i> ]	Prevents procedure execution from aborting if it attempts to delete a folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort. /Z=0: Same as no /Z. /Z=1: Deletes a folder only if it exists. /Z alone has the same effect as /Z=1. /Z=2: Deletes a folder if it exists or displays a dialog if it does not exist.

#### Variables

The DeleteFolder operation returns information in the following variables:

V_flag	Set to zero if the folder was deleted, to -1 if the user cancelled the Select Folder dialog, and to some nonzero value if an error occurred, such as the specified folder does not exist.
S_path	Stores the full path to the folder that was deleted, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.

#### Details

You can use only /P=*pathName* (without *folderNameStr*) to specify the source folder to be deleted.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

**See Also**

The **DeleteFile**, **MoveFolder**, **CopyFolder**, **NewPath**, and **IndexedDir** operations. **Symbolic Paths** on page II-21.

**DeletePoints**

**DeletePoints** [/M=*dim*] *startElement*, *numElements*, *waveName*  
[, *waveName*]...

The DeletePoints operation deletes *numElements* elements from the named waves starting from element *startElement*.

**Flags**

/M=*dim*     *dim* specifies the dimension from which elements are to be deleted. Values are:

- 0:           Rows.
- 1:           Columns.
- 2:           Layers.
- 3:           Chunks.

If /M is omitted, DeletePoints deletes from the rows dimension.

**Details**

A wave may have any number of points, including zero. Removing all elements from any dimension removes all points from the wave, leaving a 1D wave with zero points.

Except for the case of removing all elements, DeletePoints does not change the dimensionality of a wave. Use **Redimension** for that.

**See Also**

The **Redimension** operation.

**deltax**

**deltax** (*waveName*)

The deltax function returns the named wave's dx value. deltax works with 1D waves only.

**Details**

This is equal to the difference of the X value of point 1 minus the X value of point 0.

**See Also**

The **leftx** and **rightx** functions.

When working with multidimensional waves, use the **DimDelta** function.

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-63.

**DFREF**

**DFREF** *localName* [= *path* or *dfr*], [*localName1* [= *path* or *dfr*]]

DFREF is used to define a local data folder reference variable or input parameter in a user-defined function.

The syntax of the DFREF is:

```
DFREF localName [= path or dfr ][, localName1 [= path or dfr ]]
```

where *dfr* stands for "data folder reference". The optional assignment part is used only in the body of a function, not in a parameter declaration.

Unlike the **WAVE** reference, a DFREF in the body without the assignment part does not do any lookup. It simply creates a variable whose value is null.

**Examples**

```
Function Test(dfr)
  DFREF dfr
```

```
  Variable dfrStatus = DataFolderRefStatus(dfr)
```

```

if (dfrStatus == 0)
    Print "Invalid data folder reference"
    return -1
endif

if (dfrStatus & 2)           // Bit 1 set means free data folder
    Print "Data folder reference refers to a free data folder"
endif

if (dfrStatus == 1)
    Print "Data folder reference refers a global data folder"
    DFREF dfSav = GetDataFolderDFR()
    Print GetDataFolder(1)    // Print data folder path
    SetDataFolder dfSav
endif

Make/O dfr:jack=sin(x/8)     // Make a wave in the referenced data folder

return 0
End

```

### See Also

For information on programming with data folder references, see **Data Folder References** on page IV-72.

## Differentiate

**Differentiate** [*type flags*] [*flags*] *yWaveA* [/X = *xWaveA*]  
 [/D = *destWaveA*] [, *yWaveB* [/X = *xWaveB*] [/D = *destWaveB*] [, ...]

The Differentiate operation calculates the 1D numerical derivative of a wave.

Differentiate is multi-dimension-aware in the sense that it computes a 1D differentiation along the dimension specified by the /DIM flag or along the rows dimension if you omit /DIM.

Complex waves have their real and imaginary components differentiated individually.

### Flags

/DIM= <i>d</i>	Specifies the wave dimension along which to differentiate when <i>yWave</i> is multi-dimensional.  <i>d</i> =-1: Treats entire wave as 1D (default). <i>d</i> =0: Differentiates along rows. <i>d</i> =1: Differentiates along columns. <i>d</i> =2: Differentiates along layers. <i>d</i> =3: Differentiates along rows.  For example, for a 2D wave, /DIM=0 differentiates each row and /DIM=1 differentiates each column.
/EP= <i>e</i>	Controls end point handling.  <i>e</i> =0: Replaces undefined points with an approximation (default). <i>e</i> =1: Deletes the point(s).
/METH= <i>m</i>	Sets the differentiation method.  <i>m</i> =0: Central difference (default). <i>m</i> =1: Forward difference. <i>m</i> =2: Backward difference.
/P	Forces point scaling.

### Type Flags (used only in functions)

Differentiate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave

assignment. See **WAVE Reference Types** on page IV-67 and **WAVE Reference Type Flags** on page IV-68 for a complete list of type flags and further details.

For example, when the input (and output) waves are complex, the output wave will be complex. To get the Igor compiler to create a complex output wave reference, use the /C type flag with /D=destwave:

```
Make/O/C cInput=cmplx(sin(p/8), cos(p/8))
Make/O/C/N=0 cOutput
Differentiate/C cInput /D=cOutput
```

### Wave Parameters

**Note:** All wave parameters must follow *yWave* in the command. All wave parameter flags and type flags must appear immediately after the operation name.

/D=*destWave* Specifies the name of the wave to hold the differentiated data. It creates *destWave* if it does not already exist or overwrites it if it exists.

/X=*xWave* Specifies the name of the corresponding X wave.

### Details

If the optional /D = *destWave* flag is omitted, then the wave is differentiated in place overwriting the original data.

When using a method that deletes points (/EP=1) with a multidimensional wave, deletion is not done if no dimension is specified.

When using an X wave, the X wave must match the Y wave data type (excluding the complex type flag) and it must be 1D with the number points matching the size of the dimension being differentiated. X waves are not used with integer source waves.

Differentiate/METH=1/EP=1 is the inverse of Integrate/METH=2, but Integrate/METH=2 is the inverse of Differentiate/METH=1/EP=1 only if the original first data point is added to the output wave.

Differentiate applied to an XY pair of waves does not check the ordering of the X values and doesn't care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves using **Sort**.

### See Also

The **Integrate** operation.

## digamma

### digamma(x)

The digamma function returns the digamma, or psi function of  $x$ . This is the logarithmic derivative of the gamma function:

$$\Psi(z) \equiv \frac{d}{dz} \ln(\Gamma(z)) = \frac{\Gamma'(z)}{\Gamma(z)}.$$

In complex expressions,  $x$  is complex, and digamma( $x$ ) returns a complex value.

Limited testing indicates that the accuracy is approximately 1 part in  $10^{16}$ , at least for moderately-sized values of  $x$ .

## Dilogarithm

### Dilogarithm(z)

Returns the Dilogarithm function for real or complex argument  $z$ . The dilogarithm is a special case of the polylogarithm defined by

$$Li_2(z) = \sum_{k=1}^{\infty} \frac{z^k}{k^2}.$$

## DimDelta

---

The dilogarithm function was added in Igor Pro 7.00.

### See Also

**zeta**

### Reference

Wood, D.C. (June 1992). "The Computation of Polylogarithms. Technical Report 15-92". Canterbury, UK: University of Kent Computing Laboratory.

The function based on an algorithm by Didier Clamond.

## DimDelta

**DimDelta**(*waveName*, *dimNumber*)

The DimDelta function returns the scale factor delta of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks. If *dimNumber*=0 this is identical to `deltax(waveName)`.

### See Also

**DimOffset**, **DimSize**, **SetScale**, **WaveUnits**, **ScaleToIndex**

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-63.

## DimOffset

**DimOffset**(*waveName*, *dimNumber*)

The DimOffset function returns the scaling offset of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. If *dimNumber*=0 this is identical to `leftx(waveName)`.

### See Also

**DimDelta**, **DimSize**, **SetScale**, **WaveUnits**, **ScaleToIndex**

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-63.

## DimSize

**DimSize**(*waveName*, *dimNumber*)

The DimSize function returns the size of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. For a 1D wave, `DimSize(waveName, 0)` is identical to `numpts(waveName)`.

### See Also

**DimDelta**, **DimOffset**, **SetScale**, **WaveUnits**

## Dir

**Dir** [*dataFolderSpec*]

The Dir operation returns a listing of all the objects in the specified data folder.

### Parameters

If you omit *dataFolderSpec* then the current data folder is used.

If present, *dataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

### Details

The format of the printed information is the same as the format used by the string function **DataFolderDir**. Igor programmers may find it more convenient to use **CountObjects** and **GetIndexedObjName**.

Usually it is easier to use the Data Browser (Data menu). However, **Dir** is useful when you want to copy a name into the command line or when you want to document the current state of the folder in the history.

## See Also

Chapter II-8, **Data Folders**.

## Display

```
Display [flags] [waveName [, waveName ]...[vs xwaveName]]  
[as titleStr]
```

The Display operation creates a new graph window or subwindow, and appends the named waves, if any. Waves are displayed as 1D traces.

By default, waves are plotted versus the left and bottom axes. Use the /L, /B, /R, and /T flags to plot the waves against other axes.

### Parameters

Up to 100 *waveNames* may be specified, subject to the 1000 byte command line length limit. If no wave names are specified, a blank graph is created and the axis flags are ignored.

If you specify "*vs xwaveName*", the Y values of the named waves are plotted versus the Y values of *xwaveName*. If you don't specify "*vs xwaveName*", the Y values of each *waveName* are plotted versus its own X values.

If *xwaveName* is a text wave, the resulting plot is a category plot. Each element of *waveName* is plotted by default in bars mode (`ModifyGraph mode=5`) against a category labeled with the text of the corresponding element of *xwaveName*.

The Y waves for a category plot should have point scaling (see **Changing Dimension and Data Scaling** on page II-63); this is how category plots were intended to work. However, if all the Y waves have the same scaling, it will work correctly.

*titleStr* is a string expression containing the graph's title. If not specified, Igor will provide one which identifies the waves displayed in the graph.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-250.

You can provide a custom name for a trace by appending /TN=traceName to the waveName specification. This is useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-82 for more information.

### Flags

/B[=*axisName*]      Plots X coordinates versus the standard or named bottom axis.

/FG=(*gLeft*, *gTop*, *gRight*, *gBottom*)

Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use \* to specify a default guide name.

Guides may override the numeric positioning set by /W.

/HIDE=*h*      Hides (*h* = 1) or shows (*h* = 0, default) the window.

/HOST=*hcSpec*      Embeds the new graph in the host window or subwindow specified by *hcSpec*.

When identifying a subwindow with *hcSpec*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

/I      Specifies that /W coordinates are in inches.

<code>/K=k</code>	<p>Specifies window behavior when the user attempts to close it.</p> <p><i>k</i>=0: Normal with dialog (default).</p> <p><i>k</i>=1: Kills with no dialog.</p> <p><i>k</i>=2: Disables killing.</p> <p><i>k</i>=3: Hides the window.</p> <p>If you use <code>/K=2</code> or <code>/K=3</code>, you can still kill the window using the <b>KillWindow</b> operation.</p>
<code>/L[=axisName]</code>	Plots Y coordinates versus the standard or named left axis.
<code>/M</code>	Specifies that <code>/W</code> coordinates are in centimeters.
<code>/N=name</code>	Requests that the created graph have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, <i>S_name</i> is set to the chosen graph name. Use <code>DoWindow/K name</code> to ensure that <i>name</i> is available.
<code>/NCAT</code>	In Igor Pro 6.37 or later, allows subsequent appending of a category trace to a numeric plot. See <b>Combining Numeric and Category Traces</b> on page II-322 for details.
<code>/PG=(gLeft, gTop, gRight, gBottom)</code>	<p>Specifies the inner plot rectangle of the graph subwindow inside its host window.</p> <p>The standard plot rectangle guide names are PL, PR, PT, and PB, for the left, right, top, and bottom plot rectangle guides, respectively, or user-defined guide names as defined by the host. Use <code>*</code> to specify a default guide name.</p> <p>Guides may override the numeric positioning set by <code>/W</code>.</p>
<code>/R[=axisName]</code>	Plots Y coordinates versus the standard or named right axis.
<code>/T[=axisName]</code>	Plots Y coordinates versus the standard or named top axis.
<code>/TN=traceName</code>	Allows you to provide a custom trace name for a trace. This is useful when displaying waves with the same name but from different data folders. See <b>User-defined Trace Names</b> on page IV-82 for details.
<code>/W=(left,top,right,bottom)</code>	<p>Gives the graph a specific location and size on the screen. Coordinates for <code>/W</code> are in points unless <code>/I</code> or <code>/M</code> are specified before <code>/W</code>.</p> <p>When used with the <code>/HOST</code> flag, the specified location coordinates of the sides can have one of two possible meanings:</p> <ol style="list-style-type: none"> <li>1: When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.</li> <li>2: When any value is greater than 1, coordinates are taken to be fixed locations measured in points relative to the top left corner of the host frame.</li> </ol> <p>When the subwindow position is fully specified using guides (using the <code>/HOST</code>, <code>/FG</code>, or <code>/PG</code> flags), the <code>/W</code> flag may still be used although it is not needed.</p>

### Details

If `/N` is not used, Display automatically assigns to the graph a name of the form “Graph*n*”, where *n* is some integer. In a function or macro, the assigned name is stored in the *S\_name* string. This is the name you can use to refer to the graph from a procedure. Use the **RenameWindow** operation to rename the graph.

### Examples

To make a contour plot, use:

```
Display; AppendMatrixContour waveName
```

or

```
Display; AppendXYZContour waveName
To display an image, use:
Display; AppendImage waveName
or
NewImage waveName
```

### See Also

The **AppendToGraph** operation.

The operations **AppendImage**, **AppendMatrixContour**, **AppendXYZContour**, and **NewImage**. For more information on Category Plots, see Chapter II-13, **Category Plots**.

The operations **ModifyGraph**, **ModifyContour**, and **ModifyImage** for changing the characteristics of graphs.

The **DoWindow** operation for changing aspects of the graph window.

## DisplayHelpTopic

**DisplayHelpTopic** [/K=*k* /Z] *TopicString*

The DisplayHelpTopic operation displays a help topic as if a help link had been clicked in an Igor help file.

### Parameters

*TopicString* is string expression containing the topic. It may be in one of three forms: <topic name>, <subtopic name>, <topic name>[<subtopic name>]. These forms are illustrated by the examples.

Make sure that your topic string is specific to minimize the likelihood that Igor will find the topic in a help file other than the one you intended. To avoid this problem, it is best to use the <topic name>[<subtopic name>] form if possible.

### Flags

/K= <i>k</i>	Determines when the help file is closed.
<i>k</i> =0:	Leaves the help file open indefinitely (default). Use this if the help topic may be of interest in any experiment.
<i>k</i> =1:	If the found topic is in a closed help file, the help file closes with the current experiment. Use this if the help topic is tightly associated with the current experiment.
/Z	Ignore errors. If /Z is used, DisplayHelpTopic sets V_flag to 0 if the help topic was found or to a nonzero error code if it was not found. V_flag is set only when /Z is used.

### Details

DisplayHelpTopic first searches for the specified topic in the open help files. If the topic is not found, it then searches all help files in the Igor Pro 7 folder and subfolders.

If the topic is still not found, it then searches all help files in the current experiment's home folder, but not in subfolders. This puts a help file that is specific to a particular experiment in the experiment's home folder.

If the topic is still not found and if DisplayHelpTopic was called from a procedure and if the procedure resides in a stand-alone file on disk (i.e., it is not in the built-in procedure window or in a packed procedure file), Igor then searches all help files in the procedure file's folder, but not in subfolders. This puts a help file that is specific to a particular set of procedures in the same folder as the procedure file.

If Igor finds the topic, it displays it. If Igor can not find the topic, it displays an error message, unless /Z is used.

### Examples

```
// This example uses the topic only.
DisplayHelpTopic "Waves"

// This example uses the subtopic only.
DisplayHelpTopic "Waveform Arithmetic and Assignment"

// This example uses the topic[subtopic] form.
DisplayHelpTopic "Waves[Waveform Arithmetic and Assignment]"
```

### See Also

Chapter II-1, **Getting Help** for information about Igor help files and formats.

## DisplayProcedure

**DisplayProcedure** [**flags**] [**functionOrMacroNameStr**]

The DisplayProcedure operation displays the named function, macro or line by bringing the procedure window it is defined in to the front with the function, macro or line highlighted.

### Parameters

*functionOrMacroNameStr* is a string expression containing the name of the function or macro to display. If you omit *functionOrMacroNameStr* then you must use /W or /L.

*functionOrMacroNameStr* may be a simple name or may include independent module and/or module name prefixes to display static functions.

If you use /L to display a particular line then you must omit *functionOrMacroNameStr*.

To display a procedure window without changing its scrolling or selection, use /W and omit *functionOrMacroNameStr*.

### Flags

*/B=winTitleOrName* Brings up the procedure window just behind the window with this name or title.

*/L=lineNum* If /W is specified, *lineNum* is a zero-based line number in the specified window.  
If /W is not specified, *lineNum* is a “global” line number. Each procedure window line has a unique global line number as if all of the procedure files were concatenated into one big file. The order of concatenation of files can change when procedures are recompiled.

If you use /L then you must omit *functionOrMacroNameStr*.

*/W=procWinTitle* Searches in the procedure window with this title.

*procWinTitle* is a name, not a string, so you construct /W like this:

*/W=\$"New Polar Graph.ipf"*

If you omit /W, DisplayProcedure searches all open (nonindependent module) procedure windows.

### Details

If a procedure window has syntax errors that prevent Igor from determining where functions and macros start and end, then DisplayProcedure may not be able to locate the procedure.

*winTitleOrName* is not a string; it is a name. To position the found procedure window behind a window whose title has a space in the name, use the \$ operator as in the second example, below.

If *winTitleOrName* does not match any window, then the found procedure window is placed behind the top target window.

*lineNum* is a zero-based line number: 0 is the first line of the window. Because each line of a procedure window is a paragraph, line numbers and paragraph numbers are the same. You can use the Procedure→Info menu item to show a selection's starting and ending paragraph/line number.

*procWinTitle* is also a name. Use */W=\$"New Polar Graph.ipf"* to search for the function or macro in only that procedure file.

Don't specify both *functionOrMacroNameStr* and */L=lineNum* as this is ambiguous and not allowed.

### Advanced Details

If SetIgorOption IndependentModuleDev=1, *procWinTitle* can also be a title followed by a space and, in brackets, an independent module name. In such cases searches for the function or macro are in the specified procedure window and independent module. (See **Independent Modules** on page IV-224 for independent module details.)

For example, if any procedure file contains these statements:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

The command

```
DisplayProcedure/W=$"Axis Utilities.ipf [myIM] " "HVAxisList"
```

opens the procedure window that contains the HVAxisList function, which is in the Axis Utilities.ipf file and the independent module myIM. The command uses the \$" " syntax because space and bracket characters interfere with command parsing.

Similarly, if SetIgorOption IndependentModuleDev=1 then *functionOrMacroNameStr* may also contain an independent module prefix followed by the # character. The preceding command can be rewritten as:

```
DisplayProcedure/W=$"Axis Utilities.ipf " "myIM#HVAxisList"
```

or more simply

```
DisplayProcedure "myIM#HVAxisList"
```

You can use the same syntax to display a static function in a non-independent module procedure file using a module name instead of (or in addition to) the independent module name.s

*procWinTitle* can also be just an independent module name in brackets to retrieve the text from *any* procedure window that belongs to named independent module:

```
DisplayProcedure/W=$" [myIM] " "HVAxisList"
```

### Examples

```
DisplayProcedure "Graph0"
DisplayProcedure/B=Panel0 "MyOwnUserFunction"
DisplayProcedure/W=Procedure           // Shows the main Procedure window
DisplayProcedure/W=Procedure/L=5       // Shows line 5 (the sixth line)
DisplayProcedure/W=$"Wave Lists.ipf"
DisplayProcedure "moduleName#myStaticFunctionName"
SetIgorOption IndependentModuleDev=1
DisplayProcedure "WMGP#GizmoBoxAxes#DrawAxis"
```

### See Also

**Independent Modules** on page IV-224.

**MacroList**, **FunctionList**, and **ProcedureText**, **HideProcedures**, **DoWindow**.

## do-while

do

*<loop body>*

**while** (*<expression>*)

A do-while loop executes *loop body* until *expression* evaluates as FALSE (zero) or until a break statement is executed.

### See Also

**Do-While Loop** on page IV-42 and **break** for more usage details.

## DoAlert

```
DoAlert [/T=titleStr] alertType, promptStr
```

The DoAlert operation displays an alert dialog and waits for user to click button.

### Parameters

<i>alertType=t</i>	Controls the type of alert dialog:
<i>t=0:</i>	Dialog with an OK button.
<i>t=1:</i>	Dialog with Yes button and No buttons.
<i>t=2:</i>	Dialog with Yes, No, and Cancel buttons.
<i>promptStr</i>	Specifies the text that is displayed in the alert dialog.

### Flags

*/T=titleStr* Changes the title of the dialog window from the default title.

### Details

DoAlert sets the variable *V\_flag* as follows:

- 1: Yes clicked.
- 2: No clicked.
- 3: Cancel clicked.

### See Also

The **Abort** operation.

## DoIgorMenu

**DoIgorMenu** [*/C* */OVRD*] *MenuNameStr*, *MenuItemStr*

The DoIgorMenu operation allows an Igor programmer to invoke Igor's built-in menu items. This is useful for bringing up Igor's built-in dialogs under program control.

### Parameters

*MenuNameStr* The name of an Igor menu, like "File", "Graph", or "Load Waves".

*MenuItemStr* The text of an Igor menu item, like "Copy" (in the Edit menu) or "New Graph" (in the Windows menu).

### Flags

Using both the */C* and the */OVRD* flag in one command is not permitted.

- /C* Just Checking. The menu item is not invoked, but *V\_flag* is set to 1 if the item was enabled or to 0 if it was not enabled.
- /OVRD* Tells Igor to skip checks that it normally does before executing the menu command specified by *MenuNameStr* and *MenuItemStr*. You are responsible for ensuring that the menu command you are invoking is appropriate under conditions existing at runtime.
- The main use for the */OVRD* flag is to allow an advanced programmer to invoke a menu command for a menu that is currently hidden when dealing with subwindows. For example, if you have a graph subwindow in a control panel which is in operate mode, the Graph menu is not visible in the menu bar. Normally the user could not invoke an item, such as Modify Trace Appearance.
- /OVRD* allows you to invoke the menu command, but it is up to you to verify that it is appropriate. In the Modify Trace Appearance example, you should invoke the menu command only if the active window or subwindow is a graph that contains at least one trace.
- /OVRD* was added in Igor Pro 7.00.

### Details

All menu names and menu item text are in English to ensure that code developed for a localized version of Igor Pro will run on all versions. Note that no trailing "..." is used in *MenuItemStr*.

*V\_flag* is set to 1 if the corresponding menu item was enabled, which usually means the menu item was successfully selected. Otherwise *V\_flag* is 0. *V\_flag* does not reflect the success or failure of the resulting dialog, if any.

If the menu item selection displays a dialog that generates a command, clicking the Do It button executes the command immediately without using the command line as if Execute/Z operation had been used. Clicking the To Cmd Line button appends the command to the command line rather than inserting the command at the front.

The DoIgorMenu operation will not attempt to select a menu during curve fitting. Doubtless there are other times during which using DoIgorMenu would be unwise.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the *MenuItemStr* parameter. Use "Save Window", "Save Window As", "Save Window Copy", "Adopt Window", and "Revert Window" instead of "Save Notebook" or "Save Procedure", etc. Use "Page Setup" instead of "Page Setup For All Graphs", etc. Use "Print" instead of "Print Graph", etc.

#### See Also

The **SetIgorMenuMode** and **Execute** operations.

## DoPrompt

**DoPrompt** [/HELP=*helpStr*] *dialogTitleStr*, *variable* [, *variable*]...

The DoPrompt statement in a function invokes the simple input dialog. A DoPrompt specifies the title for the simple input dialog and which input variables are to be included in the dialog.

#### Flags

*/HELP=helpStr*      Sets the help topic or help text that appears when the dialog's Help button is pressed. *helpStr* can be a help topic and subtopic such as is used by `DisplayHelpTopic/K=1 helpStr`, or it can be text (255 characters max) that is displayed in a subdialog just as if `DoAlert 0, helpStr` had been called, or *helpStr* can be "" to remove the Help button.

#### Parameters

*variable* is the name of a dialog input variable, which can be real or complex numeric local variable or local string variable, defined by a Prompt statement. You can specify as many as 10 variables.

*dialogTitleStr* is a string or string expression containing the text for the title of the simple input dialog.

#### Details

Prompt statements are required to define what variables are to be used and the text for any string expression to accompany or describe the input variable in the dialog. When a DoPrompt variable is missing a Prompt statement, you will get a compilation error. Pop-up string data can not be continued across multiple lines as can be done using Prompt in macros. See **Prompt** for further usage details.

Prompt statements for the input variables used by DoPrompt must come before the DoPrompt statement itself, otherwise, they may be used anywhere within the body of a function. The variables are not required to be input parameters for the function (as is the case for Prompt in macros) and they may be declared within the function body. DoPrompt can accept as many as 10 variables.

Functions can use multiple DoPrompt statements, and Prompt statements can be reused or redefined.

When the user clicks the Cancel button, any new input parameter values are not stored in the variables.

DoPrompt sets the variable `V_flag` as follows:

0:	Continue button clicked.
1:	Cancel button clicked.

#### See Also

The **Simple Input Dialog** on page IV-132, the **Prompt** keyword, and **DisplayHelpTopic**.

## Double

**double** *localName*

Declares a local 64-bit double-precision variable in a user-defined function or structure.

Double is another name for Variable. It is available in Igor Pro 7 and later.

### DoUpdate

**DoUpdate** [/E=*e* /W=*targWin* /SPIN=*ticks* ]

The DoUpdate operation updates windows and dependent objects.

#### Flags

/E= <i>e</i>	Used with /W, /E=1 marks window as a progress window that can accept mouse events while user code is executing. Currently, only control panel windows can be used as a progress window.
/W= <i>targWin</i>	Updates only the specified window. Does not update dependencies or do any other updating.  Currently, only graph and panel windows honor the /W flag.  V_Flag is set to the truth the window exists. See <b>Progress Windows</b> on page IV-144 for other values for V_Flag.
/SPIN= <i>ticks</i>	Sets the delay between the start of a control procedure and the spinning beachball. <i>ticks</i> is the delay in ticks (60th of a second.) Unless used with the /W flag, /SPIN just sets the delay and an update is not done.

#### Details

Call DoUpdate from an Igor procedure to force Igor to update any objects that need updating. Igor updates any graphs, tables or page layouts that need to be updated and also any objects (string variables, numeric variables, waves, controls) that depend on other objects that have changed since the last update.

Igor performs updates automatically when:

- No user-procedure is running.
- An interpreted procedure (Macro, Proc, Window type procedures) is running and PauseUpdate or DelayUpdate is not in effect.

An automatic DoUpdate is not done while a user-defined function is running. You can call DoUpdate from a user-defined function to force an update.

#### See Also

The **DelayUpdate**, **PauseUpdate**, and **ResumeUpdate** operations, **Progress Windows** on page IV-144.

### DoWindow

**DoWindow** [*flags*] [*windowName*]

The DoWindow operation controls various window parameters and aspects. There are additional forms for DoWindow when the /S or /T flags are used; see the following DoWindow entries.

#### Parameters

*windowName* is the name of a graph, table, page layout, notebook, panel, Gizmo, camera, or XOP target window.

A window's name is *not* the same as its title. The title is shown in the window's title bar. The name is used to manipulate the window from Igor commands. You can check both the name and the title using the Window Control dialog (in the Arrange submenu of the Window menu).

#### Flags

/B[= <i>bname</i> ]	Moves the specified window to the back (to the bottom of desktop) or behind window <i>bname</i> .
/C	Changes the name of the target window to the specified name. The specified name must not be used for any other object except that it can be the name of an existing window macro.
/C/N	Changes the target window name and creates a new window macro for it. However, /N does nothing if a macro or function is running. /N is not applicable to notebooks.
/D	Deletes the file associated with window, if any (for notebooks only).

/F	Brings the window with the given name to the front (top of desktop).
/H	Specifies the command window as the target of the operation. When using /H, <i>windowName</i> must not be specified and only the /B and /HIDE flags are honored. Use /H to bring the command window to the front (top of desktop). Use /H/B to send the command window to the bottom of the desktop. Use /H/HIDE to hide or show the command window.
/HIDE= <i>h</i>	Sets hidden state of a window. <i>h</i> =0: Visible. <i>h</i> =1: Hidden. <i>h</i> =?: Sets the variable V_flag as follows: 0: The window does not exist. 1: The window is visible. 2: The window is hidden.  You can also read the hidden state using <b>GetWindow</b> and set it using <b>SetWindow</b> .
/K	Kills the window with the given name. <b>KillWindow</b> is preferred.
/N	Creates a new window macro for the window with the given name. However, /N does nothing if a macro or function is running. /N is not applicable to notebooks.
/R	Replaces (updates) the window macro for the named window or creates it if it does not yet exist. However, /R does nothing if a macro or function is running. /R is not applicable to notebooks.
/R/K	Replaces (updates) the window macro for the named window or creates it if it does not yet exist and then kills the window. However, /R does nothing if a macro or function is running. /R is not applicable to notebooks.
/W= <i>targWin</i>	Designates <i>targWin</i> as the target window; it also requires that you specify <i>windowName</i> . Use this mainly with floating panels, which are always on top. You can use a subwindow specification of an external subwindow only with the /T flag or without any flags.

### Details

DoWindow sets the variable V\_flag to 1 if there was a window with the specified name after DoWindow executed, to 0 if there was no such window, or to 2 if the window is hidden.

Call DoWindow with no flags to check if a window exists.

When used with the /N flag, *windowName* must not conflict with the name of any other object. When used with the /C flag, *windowName* must not conflict with the name of any other object except that it can be the name of an existing window macro.

The /R and /N flags do nothing when executed while a macro or function is running. This is necessary because changing procedures while they are executing causes unpredictable and undesirable results. However you can use the Execute/P operation to cause the DoWindow command to be executed after procedures are finished running. For example:

```
Function SaveWindowMacro(windowName)
    String windowName                // "" for top graph or table
    if (strlen(windowName) == 0)
        windowName = WinName(0, 3)    // Name of top graph or table
    endif
    String cmd
    sprintf cmd, "DoWindow/R %s", windowName
    Execute/P cmd
End
```

You can use the /D flag in conjunction with the /K flag to kill a notebook window and delete its associated file, if any. /D has no effect on any other type of window and has no effect if the /K flag is not present.

## DoWindow/T

---

### Examples

```
DoWindow Graph0           // Set V_flag to 1 if Graph0 window exists.
DoWindow/F Graph0         // Make Graph0 the top/target window.
DoWindow/C MyGraph        // Target window (Graph0) renamed MyGraph.
DoWindow/K Panel0         // Kill the Panel0 window.
DoWindow/H/B              // Put the command window in back.
DoWindow/D/K Notebook2    // Kill Notebook2, delete its file.
```

### See Also

**RenameWindow, MoveWindow, MoveSubwindow, SetActiveSubwindow, KillWindow**

**HideProcedures, IgorInfo**

## DoWindow/T

**DoWindow /T *windowName*, *windowTitleStr***

The DoWindow/T operation sets the window title for the named window to the specified title.

### Details

The title is shown in the window's title bar, and listed in the appropriate Windows submenu. The window *name* is still used to manipulate the window, so, for example, the window name (if *windowName* is a graph or table) is listed in the New Layout dialog; not the title.

You can check both the name and the title using the Window Control dialog (in the Control submenu of the Windows menu).

*windowName* is the name of the window or a special keyword, kwTopWin or kwFrame.

If *windowName* is kwTopWin, DoWindow retitles the top target window.

If *windowName* is kwFrame, DoWindow retitles the "frame" or "application" window that Igor has only under Windows. This is the window that contains Igor's menus and status bar. On Macintosh, kwFrame is allowed, but the command does nothing.

The Window Control dialog does not support kwFrame. The frame title persists until Igor quits or until it is restored as shown in the example. Setting *windowTitleStr* to "" will restore the normal frame title.

### Examples

```
DoWindow/T MyGraph, "My Really Neat Graph"
DoWindow/T kwFrame, "My Igor-based Application"
DoWindow/T kwFrame, ""           // restore normal frame title
```

## DoWindow/S

**DoWindow /N/S=*styleMacroName* *windowName***

**DoWindow /R/S=*styleMacroName* *windowName***

The DoWindow/S operation creates a new "style macro" for the named window, using the specified style macro name. Does not create or replace the window macro for the specified window.

### Flags

<i>/N/S=styleMacroName</i>	Creates a new style macro with the given name based on the named window.
<i>/R/S=styleMacroName</i>	Creates or replaces the style macro with the given name based on the named window.

### Details

The /R or /N flag must appear before the /S flag.

If the /S flag is present, the DoWindow operations does *not* create or replace the window macro for the specified window.

The /R and /N flags do nothing when executed while a macro or function is running. This is necessary because changing procedures while they are executing causes unpredictable and undesirable results.

## DoXOPIdle

### DoXOPIdle

The DoXOPIdle operation sends an IDLE event to all open XOPs. This operation is very specialized. Generally, only the author of an XOP will need to use this operation.

### Details

Some XOPs (External Operation code modules) require IDLE events to perform certain tasks.

Igor does not automatically send IDLE events to XOPs while an Igor program is running. You can call DoXOPIdle from a user-defined program to force Igor to send the event.

## DPSS

### DPSS [*flags*] *numPoints*, *numWindows*

The DPSS operation generates Slepian's Discrete Prolate Spheroidal Sequences.

The DPSS operation was added in Igor Pro 7.00.

### Flags

<i>/DEST=destWave</i>	Saves the DPSS in a wave specified by <i>destWave</i> . The destination wave is overwritten if it exists.  Creates a wave reference for the destination wave in a user function. See <b>Automatic Creation of WAVE References</b> on page IV-66 for details.  If you omit <i>/DEST</i> the operation saves the result in the wave M_DPSS in the current data folder.
<i>/EV=evWave</i>	Saves the first <i>numWindows</i> eigenvalues in a wave specified by <i>evWave</i> . The eigenvalues are computed for a symmetric tridiagonal matrix. They are real, positive and close to 1. They can be used to estimate bias in multitaper calculations.
<i>/FREE</i>	Creates output waves as free waves.  <i>/FREE</i> is permitted in user-defined functions only, not from the command line or in macros.  If you use <i>/FREE</i> then <i>destWave</i> , <i>evWave</i> and <i>sumsWave</i> must be simple names, not paths.  See <b>Free Waves</b> on page IV-84 for details on free waves.
<i>/NW=nw</i>	Specifies the time-bandwidth product. This value should typically be in the range [2,6]. Given a time-bandwidth product <i>nw</i> it is recommended to use no more than 2*nw tapers in order to maximize variance efficiency. The default value of the time-bandwidth product is 3.
<i>/DTPS=sumsWave</i>	Saves the sums of the generated DPSS windows in a wave specified by <i>sumsWave</i> .
<i>/Q</i>	Suppress printing information in the history.
<i>/Z</i>	Suppress errors. The variable V_Flag is set to 0 if successful and to -1 otherwise.

### Details

DPSS generates Slepian's Discrete Prolate Spheroidal Sequences in a 2D double-precision wave of dimensions *numPoints* by *numWindows*.

If you do omit */DEST* the operation creates the output wave M\_DPSS in the current data folder. The sequences/tapers are arranged as columns in the output wave.

### Examples

```
DPSS/DEST=dpss5 1000,5
Display dpss5[] [0], dpss5[] [1], dpss5[] [2], dpss5[] [3], dpss5[] [4]
ModifyGraph rgb(dpss5#1)=(0,65535,0), rgb(dpss5#2)=(1,16019,65535)
ModifyGraph rgb(dpss5#3)=(65535,0,52428), rgb(dpss5#4)=(0,0,0)

// Different sequences are orthogonal
```

## DrawAction

---

```
MatrixOp/o aa=col(dpss5,1)*col(dpss5,4)
Integrate/METH=1 aa/D=W_INT
Print W_INT[numpts(W_INT)-1]
```

### See Also

## DrawAction

**DrawAction** [/L=*layerName*/W=*winName*] *keyword* = *value* [, *keyword* = *value* ...]

The DrawAction operation deletes, inserts, and reads back a named drawing object group or the entire draw layer.

### Parameters

DrawAction accepts multiple *keyword* = *value* parameters on one line.

beginInsert [= <i>index</i> ]	Inserts draw commands before or at <i>index</i> position or at position specified by getgroup or delete parameters; position otherwise is zero.
commands [= <i>start,stop</i> ]	Stores commands in S_recreation for draw objects between <i>start</i> and <i>stop</i> index values, range defined by getgroup, or entire layer otherwise.
delete [= <i>start,stop</i> ]	Deletes draw objects between <i>start</i> and <i>stop</i> index values, range defined by getgroup, or entire layer otherwise.
extractOutline [= <i>start,stop</i> ]	Stores polygon outline between <i>start</i> and <i>stop</i> index values, range defined by getgroup, or entire layer otherwise. Waves W_PolyX and W_PolyY contain coordinates with NaN separators. V_npnts contains the number of objects. Coordinates are for the first object encountered.
endInsert	Terminates insert mode.
getgroup= <i>name</i>	Stores first and last index of named group in V_startPos and V_endPos. Use <i>_all_</i> to specify the entire layer. Sets V_flag to truth group exists.

### Flags

/L= <i>layerName</i>	Specifies the drawing layer on which to act. <i>layerName</i> is one of the drawing layers as specified in <b>SetDrawLayer</b> .
/W= <i>winName</i>	Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

Commands stored in S\_recreation are the same as those that would be generated for the range of objects in the recreation macro for the window but also have comment lines preceding each object of the form:

```
// ;ITEMNO:n;
```

where *n* is the item number of the draw object.

### Examples

Create a drawing with a named group:

```
NewPanel /W=(455,124,936,413)
SetDrawEnv fillfgc= (65535,0,0)
DrawRect 58,45,132,103
SetDrawEnv gstart,gname= fred
SetDrawEnv fillfgc= (65535,43690,0)
DrawRect 79,62,154,120
```

```
SetDrawEnv arrow= 1
DrawLine 139,70,219,70
SetDrawEnv gstop
SetDrawEnv fillfgc= (0,65535,65535)
DrawRect 95,77,175,138
SetDrawEnv fillfgc= (0,0,65535)
DrawRect 111,91,191,156
```

Get and print commands for the “fred” group:

```
DrawAction getgroup=fred,commands
Print S_recreation
```

prints:

```
// ;ITEMNO:3;
SetDrawEnv gstart,gname= fred
// ;ITEMNO:4;
SetDrawEnv fillfgc= (65535,43690,0)
// ;ITEMNO:5;
DrawRect 79,62,154,120
// ;ITEMNO:6;
SetDrawEnv arrow= 1
// ;ITEMNO:7;
DrawLine 139,70,219,70
// ;ITEMNO:8;
SetDrawEnv gstop
```

Replace group fred (the orange rectangle and the arrow) with a different object. First delete the group and enter insert mode:

```
DrawAction getgroup=fred, delete, begininsert
```

Next draw the replacement:

```
SetDrawEnv gstart,gname= fred
SetDrawEnv fillfgc= (65535,65535,0)
DrawOval 82,62,161,123
SetDrawEnv gstop
```

Lastly exit insert mode:

```
DrawAction endinsert
```

### See Also

The **SetDrawEnv** operation and Chapter III-3, **Drawing**.

## DrawArc

**DrawArc** [/W=*winName*/X/Y] *xOrg*, *yOrg*, *arcRadius*, *startAngle*, *stopAngle*

The DrawArc operation draws a circular counterclockwise arc with center at *xOrg* and *yOrg*.

### Parameters

(*xOrg*, *yOrg*) defines the center point for the arc in the currently active coordinate system.

Angles are measured in degrees increasing in a counterclockwise direction. The *startAngle* specifies the starting angle for the arc and *stopAngle* specifies the end. If *stopAngle* is equal to *startAngle*, 360° is added to *stopAngle*. Thus, a circle can be drawn using *startAngle* = *stopAngle*.

The *arcRadius* is the radial distance measured in points from (*xOrg*, *yOrg*).

### Flags

/W= <i>winName</i>	Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.
/X	Measures <i>arcRadius</i> using the current X-coordinate system. If /Y is also used, the arc may be elliptical.
/Y	Measures <i>arcRadius</i> using the current Y-coordinate system. If /X is also used, the arc may be elliptical.

### Details

Arcs honor the current dash pattern and arrowhead setting in the same way as polygons and Beziers. In fact, arcs are implemented using Bezier curves.

Normally, you would create arcs programmatically. If you need to sketch an arc-like object, you should probably use a Bezier curve because it is more flexible and easier to adjust. However, there is one handy feature of arcs that make them useful for manual drawing: the origin can be in any of the supported coordinate systems and the radius is in points.

To draw an arc interactively, see **Arcs and Circles** on page III-63 for instructions.

### See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv** and **SetDrawLayer** operations.

The **DrawBezier**, **DrawOval** and **DrawAction** operations.

## DrawBezier

```
DrawBezier [/W=winName /ABS] xOrg, yOrg, hScaling, vScaling, {x0, y0, x1, y1 ...}
```

```
DrawBezier [/W=winName /ABS] xOrg, yOrg, hScaling, vScaling, xWaveName,  
yWaveName
```

```
DrawBezier/A [/W=winName] {xn, yn, xn+1, yn+1 ...}
```

The DrawBezier operation draws a Bezier curve with first point of the curve positioned at *xOrg* and *yOrg*.

### Parameters

(*xOrg*, *yOrg*) defines the starting point for the Bezier curve in the currently active coordinate system.

*hScaling* and *vScaling* set the horizontal and vertical scale factors about the origin, with 1 meaning 100%.

The *xWaveName*, *yWaveName* version of DrawBezier gets data from the named X and Y waves. This connection is maintained so that any changes to either wave will result in updates to the Bezier curve.

To use the version of DrawBezier that takes a literal list of vertices, you place as many vertices as you like on the first line and then use as many /A versions as necessary to define all the vertices.

### Flags

/A	Appends the given vertices to the currently open Bezier (freshly drawn or current selection).
/ABS	Suppresses the default subtraction of the first point from the rest of the data.
/W=winName	Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

Data waves defining Bezier curves must have  $1+3*n$  data points. Every third data point is an anchor point and lies on the curve; intervening points are control points that define the direction of the curve relative to the adjacent anchor point.

Normally, you should create and edit a Bezier curve using drawing tools, and not calculate values. See **Polygon Tool** on page III-63 for instructions.

You can include the /ABS flag to suppress the default subtraction of the first point. Also, you can now insert NaN values to break a bezier into pieces.

To change just the origin and scale without respecifying the data use:

```
DrawBezier xOrg, yOrg, hScaling, vScaling, { }
```

To delete an anchor point, press Option (*Macintosh*) or Alt (*Windows*) and then click on the anchor. To insert a new anchor, click on the curve between anchor points.

### Example

Create a half circle approximation from three anchor points starting at the 12 o'clock position, with an anchor at the 3 o'clock position, and the last at the 6 o'clock position using explicit values:

```
// Set plot relative coords, 0-1, no fill
SetDrawEnv xcoord=prel, ycoord=prel, fillpat= 0, save

Variable len= 0.275          // control point length = 0.55 * radius for a circle
// Starting anchor point has only a trailing control point
Variable anchor0x= 0.5, anchor0y=1          // starting point at 6 o'clock
Variable t0x= 0.5+len, t0y= 1              // trailing control point

// second anchor point has both leading and trailing control points
Variable l1x=1, l1y = 0.5+len              // leading control point
Variable anchor1x= 1, anchor1y= 0.5        // 3 o'clock anchor
Variable t1x=1, t1y = 0.5-len              // trailing control point

// Last (3rd) anchor point has only a leading control point
Variable l2x=0.5+len, l2y = 0              // leading control point
Variable anchor2x= 0.5, anchor2y= 0        // 6 o'clock

// One command per anchor for clarity
DrawBezier anchor0x, anchor0y, 1,1, {anchor0x, anchor0y, t0x, t0y}
DrawBezier/A {l1x, l1y, anchor1x, anchor1y, t1x, t1y}
DrawBezier/A {l2x, l2y, anchor2x, anchor2y}
```

To draw using waves:

```
Make/O bezierX= {anchor0x, t0x, l1x, anchor1x, t1x, l2x, anchor2x }
Make/O bezierY= {anchor0y, t0y, l1y, anchor1y, t1y, l2y, anchor2y }
DrawBezier anchor0x, anchor0y, 1,1, bezierX, bezierY
```

The **DrawArc**, **DrawPoly** and **DrawAction** operations.

## DrawLine

**DrawLine** [/W=*winName*] *x0*, *y0*, *x1*, *y1*

The DrawLine operation draws a line in the target graph, layout or control panel from (*x0,y0*) to (*x1,y1*).

### Flags

<i>/W=winName</i>	Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
	When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

The coordinate system as well as the line's thickness, color, dash pattern and other properties are determined by the current drawing environment. The line is drawn in the current draw layer for the window, as determined by SetDrawLayer.

### See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

### DrawOval

**DrawOval** [/W=*winName*] *left, top, right, bottom*

The DrawOval operation draws an oval in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right*, and *bottom*.

#### Flags

*/W=winName*                Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

#### Details

The coordinate system as well as the oval's thickness, color, dash pattern and other properties are determined by the current drawing environment (note that you cannot draw dashed ovals). The oval is drawn in the current draw layer for the window, as determined by SetDrawLayer.

#### See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

### DrawPICT

**DrawPICT** [/W=*winName*] [/RABS] *left, top, hScaling, vScaling, pictName*

The DrawPICT operation draws the named picture in the target graph, layout or control panel. The *left* and *top* parameters set the position of the top/left corner of the picture. *hScaling* and *vScaling* set the horizontal and vertical scale factors with 1 meaning 100%.

#### Flags

*/RABS*                      Draws the named picture using absolute scaling. In this mode, it draws the picture in the rectangle defined by *left* and *top* for point (x0,y0), and by *hScaling* and *vScaling* for point (x1,y1), respectively.

*/W=winName*                Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

#### Details

The coordinate system for the left and top parameters is determined by the current drawing environment. The PICT is drawn in the current draw layer for the window, as determined by SetDrawLayer.

#### See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

### DrawPoly

**DrawPoly** [/W=*winName*] /ABS] *xorg, yorg, hScaling, vScaling, xWaveName, yWaveName*

**DrawPoly** [/W=*winName*] /ABS] *xorg, yorg, hScaling, vScaling, {x<sub>0</sub>, y<sub>0</sub>, x<sub>1</sub>, y<sub>1</sub> ...}*

**DrawPoly/A** [/W=*winName*] {*x<sub>n</sub>, y<sub>n</sub>, x<sub>n+1</sub>, y<sub>n+1</sub> ...*}

The DrawPoly operation draws a polygon in the target graph, layout or control panel.

#### Parameters

(*xorg, yorg*) defines the starting point for the polygon in the currently active coordinate system.

*hScaling* and *vScaling* set the horizontal and vertical scale factors, with 1 meaning 100%.

The *xWaveName*, *yWaveName* version of DrawPoly gets data from those X and Y waves. This connection is maintained so that changes to either wave will update the polygon.

The DrawPoly operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

To use the version of DrawPoly that takes a literal list of vertices, you place as many vertices as you like on the first line and then use as many /A versions as necessary to define all the vertices.

### Flags

/A	Appends the given vertices to the currently open polygon (freshly drawn or current selection).
/ABS	Suppresses the default subtraction of the first point from the rest of the data.
/W= <i>winName</i>	Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

Because *xorg* and *yorg* define the location of the starting vertex of the poly, adding or subtracting a constant from the vertices will have no effect. The first XY pair in the {*x0*, *y0*, *x1*, *y1*,...} vertex list will appear at (*xorg*,*yorg*) regardless of the value of *x0* and *y0*. *x0* and *y0* merely serve to set a reference point for the list of vertices. Subsequent vertices are relative to (*x0*,*y0*).

To keep your mental health intact, we recommend that you specify (*x0*,*y0*) as (0,0) so that all the following vertices are offsets from that origin. Then (*xorg*,*yorg*) sets the position of the polygon and all of the vertices in the list are relative to that origin.

An alternate method is to use the same values for (*x0*,*y0*) as for (*xorg*,*yorg*) if you consider the vertices to be “absolute” coordinates.

You can include the /ABS flag to suppress the subtraction of the first point. Also, you can now insert NaN values to break a polygon into pieces.

To change just the origin and scale of the currently open polygon — without having to respecify the data — use:

```
DrawPoly xorg, yorg, hScaling, vScaling, { }
```

The coordinate system as well as the polygon’s thickness, color, dash pattern and other properties are determined by the current drawing environment. The polygon is drawn in the current draw layer for the window, as determined by SetDrawLayer.

### Examples

Here are some commands to draw some small triangles using absolute drawing coordinates (see **SetDrawEnv**).

```
Display // make a new empty graph
//Draw one triangle, starting at 50,50 at 100% scaling
SetDrawEnv xcoord= abs,ycoord= abs
DrawPoly 50,50,1,1, {0,0,10,10,-10,10,0,0}
//Draw second triangle below and to the right, same size and shape
SetDrawEnv xcoord= abs,ycoord= abs
DrawPoly 100,100,1,1, {0,0,10,10,-10,10,0,0}
```

### See Also

Chapter III-3, **Drawing**.

### DrawRect

**DrawRect** [/W=*winName*] *left, top, right, bottom*

The DrawRect operation draws a rectangle in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right*, and *bottom*.

#### Flags

/W=*winName*

Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

#### Details

The coordinate system as well as the rectangle's thickness, color, dash pattern and other properties are determined by the current drawing environment. The rectangle is drawn in the current draw layer for the window, as determined by SetDrawLayer.

#### See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

### DrawRRect

**DrawRRect** [/W=*winName*] *left, top, right, bottom*

The DrawRRect operation draws a rounded rectangle in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right*, and *bottom*.

#### Flags

/W=*winName*

Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

#### Details

The coordinate system as well as the rectangle's rounding, thickness, color, dash pattern and other properties are determined by the current drawing environment. The rounded rectangle is drawn in the current draw layer for the window, as determined by SetDrawLayer.

#### See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

### DrawText

**DrawText** [/W=*winName*] *x<sub>0</sub>, y<sub>0</sub>, textStr*

The DrawText operation draws the specified text in the target graph, layout or control panel. The position of the text is determined by (*x<sub>0</sub>*, *y<sub>0</sub>*) along with the current textjust, textyjust and textrot settings as set by SetDrawEnv.

## Flags

*/W=winName*      Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

## Details

The coordinate system as well as the text's font, size, style and other properties are determined by the current drawing environment. The text is drawn in the current draw layer for the window, as determined by SetDrawLayer.

## See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

# DrawUserShape

**DrawUserShape** [*/W=winName /MO=options*] *x0, y0, x1, y1, userFuncName, textString, privateString*

The DrawUserShape operation is similar to built-in drawing operations except the shape is defined by a user-defined function which is executed when the shape is drawn.

DrawUserShape was added in Igor Pro 7.00.

## Parameters

For rectangular shapes (*x0,y0*) defines the top left corner while (*x1,y1*) defines the lower right corner in the currently active coordinate system. For line-like shapes, (*x0,y0*) specifies the start of the line while(*x1,y1*) specifies the end.

*userFuncName* specifies your user-defined function that uses built-in drawing operations to define the shape and provides information about it to Igor.

*textString* specifies text to be drawn over the shape by Igor. Pass "" if you do not need text. Using escape codes you can change the font, size, style, and color of the text. See **Annotation Escape Codes** on page III-53 or details.

*privateString* is text or binary data used by the user-defined function for any purpose. It is typically used to maintain state information and is saved in recreation macros using a method that supports binary. Pass "" if you do not need this.

To support modifying an existing shape, each of the last three parameters above can be `_NoChange_`. The *x0, y0, x1, y1* parameters can be all zero for no change. Using `_NoChange_` when there is no existing shape is an error. To target an existing shape, it must be selected by the drawing tools.

## Flags

*/W=winName*      Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

*/M=options*      An integer that Igor passes to your user-defined drawing function for use for any purpose.

## Details

The user-defined function must have the following form and structure parameter.

```
Function MyUserShape(s) : DrawUserShape // Optional ": DrawUserShape" indicates
                                         // that this function should be added
    STRUCT WMDrawUserShapeStruct &s      // to the menu of shapes in the drawing palette

    Variable returnValue= 1
```

```
StrSwitch(s.action)
case "draw":
    Print "Put DrawXXX commands here"
    break
case "drawSelected":
    Print "Put Draw commands when selected (may be same as normalDraw) here"
    break
case "hitTest":
    Print "Put code to test if mouse is over a control point here"
    // Set doSetCursor and optionally cursorCode if so"
    // Set returnValue to zero if not over control point or, if in operate
    // mode and you don't want to start a button operation.
    break
case "mouseDown":
    if( s.operateMode )
        Print "Mouse down in button mode."
    else
        // Code similar or same as hitTest.
        Print "User is starting a drag of a control point."
    endif
    // Set returnValue to zero if if no action or redraw needed
    break
case "mouseMove":
    if(s.operateMode)
        Print "Roll-over mode and mouse is inside shape."
    else
        Print "Mouse has been captured and user is dragging a control point."
    endif
    // Set returnValue to zero if if no action or redraw needed
    break
case "mouseUp":
    if(s.operateMode)
        Print "Mouse button released."
    else
        Print "User finished dragging control point."
    endif
    break
case "getInfo":
    Print "Igor is requesting info about this shape."
    s.textString= "category for shape"
    s.privateString= "shape name"
    s.options= 0// Or set bits 0, 1 and/or 2
    break
EndSwitch

return returnValue
End
```

WMDrawUserShapeStruct is a built-in structure with the following members:

### WMDrawUserShapeStruct Structure Members

Member	Description
char action[32]	Input: Specifies what action is requested.
SInt32 options	Input: Value from /MO flag. Output: When action is getInfo, set bits as follows: Set bit 0 if the shape should behave like a simple line. When resizing end-points, you will get live updates. Set bit 1 if the shape is to act like a button; you will get mouse down in normal operate mode. Set bit 2 to get roll-over action. You will get hitTest action and if 1 is returned, the mouse will be captured.
SInt32 operateMode	Input: If 0, the shape is being edited; if 1, normal operate mode (only if options bit 1 or 2 was set during getInfo).
PointF mouseLoc	Input: The location of the mouse in normalized coordinates.

## WMDrawUserShapeStruct Structure Members

Member	Description
SInt32 doSetCursor	Output: If action is hitTest, set true to use the following cursor number. Also used for mouseMoved in rollover mode.
SInt32 cursorCode	Output: If action is hitTest and doSetCursor is set, then set this to the desired Igor cursor number.
double x0,y0,x1,y1	Input: Coordinates of the enclosing rectangle of the shape.
RectF objectR	Input: Coordinates of the enclosing rectangle of the shape in device units.
char winName[MAX_HostChildSpec+1]	Full path to host subwindow
// Information about the coordinate system	
Rect drawRect	Draw rect in device coordinates
Rect plotRect	In a graph, this is the plot area
char xcName[MAX_OBJ_NAME+1]	Name of X coordinate system, may be axis name
char ycName[MAX_OBJ_NAME+1]	Name of Y coordinate system, may be axis name
double angle	Input: Rotation angle, use when displaying text
String textString	Input: Use or ignore; special output for getInfo
String privateString	Input and output: Maintained by Igor but defined by user function; may be binary; special output for getInfo

The constants used to size the char arrays, MAX\_HostChildSpec and MAX\_OBJ\_NAME, are defined internally in Igor and are subject to change in future versions.

The drawing commands you provide for the draw and drawSelected actions must use normalized coordinates ranging from (0,0) to (1,1). For example, to draw a rectangle you would use

```
DrawRect 0,0,1,1
```

Generally, you will not set drawing environment parameters such as color or fill mode but will leave that to the user of your shape just as they would for built-in shapes such as a Rectangle.

You will get the drawSelected action when the user has selected your shape with the arrow draw tool. For simple shapes, this can use the same code as the draw action but if you want the shape to be editable, you can draw control points such as a yellow dot. You would then provide code in the hitTest and mouseDown actions that determines if the user has moved over or clicked on a control point. For an example of this, see the FatArrows procedure file in the User Draw Shapes demo experiment.

Your function should respond to the getInfo action by setting the textString field to a category name and the privateString field to a shape name. A category name might be "Arrows" and a shape name might be "Right Arrow". These names are used to populate the menus you get when right-clicking the user shapes icon in the drawing tools palette. You can also set bits in the options field to enable certain special actions. For examples of these, see the LineCallout and button procedure windows in the User Draw Shapes demo experiment.

**Note:** To support button-like shapes in graphs and layouts, an additional drawing layer named Overlay was added in Igor Pro 7.00. This layer is drawn over the top of everything else and is not printed or exported. Objects in the Overlay draw layer can update without the need to redraw the entire window as would be the case if one of the previously existing layers were used. For consistency, this layer is also available in control panels.

Chapter III-3, **Drawing**.

**SetDrawEnv, SetDrawLayer, DrawBezier, DrawPoly, DrawAction**

### DSPDetrend

**DSPDetrend** [*flags*] *srcWave*

The DSPDetrend operation removes from *srcWave* a trend defined by the best fit of the specified function to the data in *srcWave*.

#### Flags

/A	Subtracts the average of <i>srcWave</i> before performing any fitting. Added in Igor Pro 7.00.
/F= <i>function</i>	<i>function</i> is the name of a built-in curve fitting function: gauss, lor, exp, dblexp, sin, line, poly (requires /P flag), hillEquation, sigmoid, power, lognormal, poly2d (requires /P flag), gauss2d. If <i>function</i> is unspecified, the defaults are line if <i>srcWave</i> is 1D or poly2d if <i>srcWave</i> is 2D.
/M= <i>maskWave</i>	Detrending will only affect points that are nonzero in <i>maskWave</i> . Note that <i>maskWave</i> must have the same dimensionality as <i>srcWave</i> .
/P= <i>n</i>	Specifies polynomial order for poly or poly2d functions (see <b>CurveFit</b> for details). When used with the 1D poly function <i>n</i> specifies the number of terms in the polynomial. By default <i>n</i> =3 for the 1D case and <i>n</i> =1 for poly2d.
/Q	Quiet mode; no error reporting.

#### Details

DSPDetrend sets V\_flag to zero when the operation succeeds, otherwise it will be set to -1 or will contain an error code from the curve fitting routines. Results are saved in the wave W\_Detrend (for 1D input) or M\_Detrend (for 2D input) in the current data folder. If a wave by that name already exists in the current data folder it will be overwritten.

#### See Also

**CurveFit** for more information about V\_FitQuitReason and the built-in fitting functions.

### DSPPeriodogram

**DSPPeriodogram** [*flags*] *srcWave* [*srcWave2*]

The DSPPeriodogram operation calculates the periodogram, cross-spectral density or the degree of coherence of the input waves. The result of the operation is stored in the wave W\_Periodogram in the current data folder.

To compute the cross-spectral density or the degree of coherence, you need to specify the second wave using the optional *srcWave2* parameter. In this case, W\_Periodogram will be complex and the /DB and /DBR flags do not apply.

#### Flags

/DB	Expresses results in dB using the maximum value as reference.
/DBR= <i>ref</i>	Express the results in dB using the specified <i>ref</i> value.
/COHR	Computes the degree of coherence. This flag applies when the input consists of two waves.
/DLSG	When computing the periodogram, cross-spectral density or the degree of coherence using multiple segments the operation by default pads the last segment with zeros as necessary. If you specify this flag, an incomplete last segment is dropped and not included in the calculation.

<code>/NODC=val</code>	<p>Suppresses the DC term:</p> <p><code>val=1:</code> Removes the DC by subtracting the average value of the signal before processing and before applying any window function (see <code>/Win</code> below).</p> <p><code>val=2:</code> Suppresses the DC term by setting it equal to the second term in the FFT array.</p> <p><code>val=0:</code> Computes the DC term using the FFT (default).</p>
<code>/NOR=N</code>	<p>Sets the normalization, <i>N</i>, in the periodogram equation. By default, it is the number of data points times the square norm of the window function (if any).</p> <p><i>N</i>=0 or 1: Skips default normalization.</p> <p>Any other value of <i>N</i> is used as the only normalization.</p>
<code>/Q</code>	Quiet mode; suppresses printing in the history area.
<code>/SEGN={ptsPerSegment, overlapPts}</code>	<p>Use this flag to compute the periodogram, cross-spectral density or degree of coherence by averaging over multiple segments taken from the input waves. The size of each interval is <i>ptsPerSegment</i>. <i>overlapPts</i> determines the number of points at the end of each interval that are included in the next segment.</p>
<code>/R=[startPt, endPt]</code>	Calculates the periodogram for a limited range of the wave. <i>startPt</i> and <i>endPt</i> are expressed in terms of point numbers in <i>srcWave</i> .
<code>/R=(startX, endX)</code>	Calculates the periodogram for a limited range of the wave. <i>startX</i> and <i>endX</i> are expressed in terms of x-values. Note that this option will convert your x-specifications to point numbers and some roundoff may occur.
<code>/WIN=windowKind</code>	<p>Specifies the window type. If you omit the <code>/W</code> flag, DSPPeriodogram uses a rectangular window for the full wave or the range of data selected by the <code>/R</code> flag.</p> <p>Choices for <i>windowKind</i> are:</p> <p>Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.</p> <p>See <b>FFT</b> for window equations and details.</p>
<code>/Z</code>	Do not report errors. When an error occurs, <i>V_flag</i> is set to -1.

### Details

The default periodogram is defined as

$$Periodogram = \frac{|F(s)|^2}{N},$$

where *F* (*s*) is the Fourier transform of the signal *s* and *N* is the number of points.

In most practical situations you need to account for using a window function (when computing the Fourier transform) which takes the form

$$Periodogram = \frac{|F(s \cdot w)|^2}{N_p N_w},$$

where *w* is the window function, *N<sub>p</sub>* is the number of points and *N<sub>w</sub>* is the normalization of the window function.

If you compute the periodogram by subdividing the signal into multiple segments (with any overlap) and averaging the results over all segments, the expression for the periodogram is

$$Periodogram = \frac{\sum_{i=1}^M |F(s_i \cdot w)|^2}{MN_s N_w},$$

where  $s_i$  is the  $i$ th segment  $s$ ,  $N_s$  is the number of points per segment and  $M$  is the number of segments. When calculating the cross-spectral density (csd) of two waves  $s_1$  and  $s_2$ , the operation results in a complex valued wave

$$csd = \frac{F(s_A)[F(s_B)]^*}{N},$$

which contains the normalized product of the Fourier transform of the first wave  $S_A$  with the complex conjugate of the Fourier transform of the second wave  $S_B$ . The extension of the csd calculation to segment averaging has the form

$$csd = \frac{\sum_{i=0}^M F(s_{Ai})[F(s_{Bi})]^*}{MN_s N_w},$$

where  $S_{Ai}$  is the  $i$ th segment of the first wave,  $M$  is the number of segments and  $N_s$  is the number of points in a segment.

The degree of coherence is a normalized version of the cross-spectral density. It is given by

$$\gamma = \frac{\sum_{i=0}^M F(s_{Ai})[F(s_{Bi})]^*}{\sqrt{\sum_{i=0}^M F(s_{Ai})[F(s_{Ai})]^* \sum_{i=0}^M F(s_{Bi})[F(s_{Bi})]^*}}.$$

The bias in the degree of coherence is calculated using the approximation

$$B = \frac{1}{M} [1 - |\gamma|^2]^2.$$

The bias is stored in the wave  $W\_Bias$ .

If you use the `/SEGN` flag the actual number of segments is reported in the variable `V_numSegments`.

Note that `DSPPeriodogram` does not test the dimensionality of the wave; it treats the wave as 1D. When you compute the cross-spectral density or the degree of coherence the number-type, dimensionality and the scaling of the two waves must agree.

## Duplicate

**Duplicate** [*flags*] [*type flags*] *srcWaveName*, *destWaveName* [, *destWaveName*]...

The Duplicate operation creates new waves, the names of which are specified by *destWaveNames* and the contents, data type and scaling of which are identical to *srcWaveName*.

### Parameters

*srcWaveName* must be the name of an existing wave.

The *destWaveNames* should be wave names not currently in use unless the /O flag is used to overwrite existing waves.

### Flags

- /FREE                      Creates a free wave (see **Free Waves** on page IV-84).  
/FREE is allowed only in functions and only if a simple name or wave reference structure field is specified as the destination wave name.
- /O                          Overwrites existing waves with the same name as *destWaveName*.
- /R=(startX,endX)        Specifies an X range in the source wave from which the destination wave is created.  
See Details for further discussion of /R.
- /R=(startX,endX)(startY,endY)        Specifies both X and Y range. Further dimensions are constructed analogously.  
See Details for further discussion of /R.
- /R=[startP,endP]        Specifies a row range in the source wave from which the destination wave is created.  
Further dimensions are constructed just like the scaled dimension ranges.  
See Details for further discussion of /R.
- /RMD=[firstRow,lastRow][firstColumn,lastColumn][firstLayer,lastlayer][firstChunk,lastChunk]  
Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 7.00.  
You can include all higher dimensions by leaving off the corresponding brackets. For example:  
/RMD= [firstRow, lastRow]  
includes all available columns, layers and chunks.  
You can use empty brackets to include all of a given dimension. For example:  
/RMD= [] [firstColumn, lastColumn]  
means "all rows from column A to column B".  
You can use a \* to specify the end of any dimension. For example:  
/RMD= [firstRow, \*]  
means "from firstRow through the last row".

### Type Flags (*used only in functions*)

When used in user-defined functions, Duplicate can also take the /B, /C, /D, /I, /S, /U, /W, /T, /DF and /WAVE flags. This does not affect the result of the Duplicate operation - these flags are used only to identify what kind of wave is expected at runtime.

This information is used if, later in the function, you create a wave assignment statement using a duplicated wave as the destination:

## DuplicateDataFolder

---

```
Function DupIt(wv)
    Wave/C wv //complex wave

    Duplicate/O/C wv,dupWv //tell Igor that dupWv is complex
    dupWv[0]=cmplx(5.0,1.0) //no error, because dupWv known complex
    ...
```

If Duplicate did not have the /C flag, Igor would complain with a “function not available for this number type” message when it tried to compile the assignment of dupWv to the result of the cmplx function.

These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-67 and **WAVE Reference Type Flags** on page IV-68 for a complete list of type flags and further details.

### Details

If /R is omitted, the entire wave is duplicated.

In the range specifications used with /R, a \* for the end means duplicate to the end. You can also simply leave out the end specification. To include all of a given dimension, use /R= [ ] . If you leave off higher dimensions, all those dimensions are duplicated. That is, /R= [ 1 , 5 ] for a 2D wave is equivalent to /R= [ 1 , 5 ] [ ] .

The destination wave will always be unlocked, even if the source wave was locked.

### Warning:

Under some circumstances, such as in loops in user-defined functions, Duplicate may exhibit undesired behavior. When you use

```
Duplicate/O srcWave, DestWaveName
```

in a user-defined function, it creates a local WAVE variable named *DestWaveName* at compile time. At runtime, if the WAVE variable is NULL, it creates a wave of the same name in the current data folder. If, however, the WAVE variable is not NULL, as it would be in a loop, then the referenced wave will be overwritten no matter where it is located. If the desired behavior is to create (or overwrite) a wave in the current data folder, you should use one of the following two methods:

```
Duplicate/O srcWave, $"DestWaveName"
WAVE DestWaveName // only if you need to reference dest wave
```

or

```
Duplicate/O srcWave, DestWaveName
// then after you are finished using DestWaveName...
WAVE DestWaveName=$"
```

### See Also

Rename, Concatenate, SplitWave

## DuplicateDataFolder

**DuplicateDataFolder** *sourceDataFolderSpec*, *destDataFolderSpec*

The DuplicateDataFolder operation makes a copy of the source data folder and everything in it and places the copy at the specified location with the specified name.

### Parameters

*sourceDataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

*destDataFolderSpec* can be just a data folder name, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name. If just a data folder name is used then the new data folder is created in the current data folder.

### Details

An error is issued if the destination is contained within the source data folder.

### Examples

Create a copy of foo named foo2 in bar:

```
DuplicateDataFolder foo,:bar:foo2
```

**See Also**

See the **MoveDataFolder** operation. Chapter II-8, **Data Folders**.

**DWT**

**DWT** [*flags*] *srcWaveName*, *destWaveName*

The DWT operation performs discrete wavelet transform on the input wave *srcWaveName*. The operation works on one or more dimensions only as long as the number of elements in each dimension is a power of 2 or when the /P flag is specified

**Flags**

- /D      Denoises the source wave. Performs the specified wavelet transform in the forward direction. It then zeros all transform coefficients whose magnitude fall below a given percentage (specified by the /V flag) of the maximum magnitude of the transform. It then performs the inverse transform placing the result in *destWaveName*. The /I flag is incompatible with the /D flag.
- /I      Perform the inverse wavelet transform. The /S and /D flags are incompatible with the /I flag.
- /N=*num*      Specifies the number of wavelet coefficients. See /T flag for supported combinations.
- /P=*num*      Controls padding:
- num=1:      Adds zero padding to the end of the dimension up to nearest power of 2 when the number of data elements in a given dimension of *srcWaveName* is not a power of 2.
- num=2:      Uses zero padding to compute the transform, but the resulting wave is truncated to the length of the input wave.
- /S      Smooths the source wave. This performs the specified wavelet transform in the forward direction. It then zeros all transform coefficients except those between 0 and the cut-off value (specified in % by /V flag). It then performs the inverse transform placing the result in *destWaveName*. The /I flag is incompatible with the /S flag.
- /T=*type*      Performs the wavelet transform specified by *type*. The following table gives the transform name with the *type* code for the transform and the allowed values of the *num* parameter used with the /N flag. "NA" means that the /N flag is not applicable to the corresponding transform.
- | <b>Wavelet Transform</b> | <b><i>type</i></b> | <b><i>num</i></b>                  |
|--------------------------|--------------------|------------------------------------|
| Daubechies               | 1 (default)        | 4, 6, 8, 10, 12, 20                |
| Haar                     | 2                  | NA                                 |
| Battle-Lemarie           | 4                  | NA                                 |
| Burt-Adelson             | 8                  | NA                                 |
| Coifman                  | 16                 | 2, 4, 6                            |
| Pseudo-Coifman           | 32                 | NA                                 |
| splines                  | 64                 | 1 (2-2), 2 (2-4), 3 (3-3), 4 (3-7) |
- /V=*value*      Specifies the degree of smoothing with the /S and /D flags only.
- For /S, *value* gives the cutoff as a percentage of data points above which coefficients are set to zero. For /D, *value* specifies the percentage of the maximum magnitude of the transform such that coefficients smaller than this value are set to zero.

**Details**

If *destWaveName* exists, DWT overwrites it; if it does not exist, DWT creates it.

When used in a function, the DWT operation automatically creates a wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-66 for details.

If *destWaveName* is not specified, the DWT operation stores the results in W\_DWT for 1D waves and M\_DWT for higher dimensions.

When working with 1D waves, the transform results are packed such that the higher half of each array contains the detail components and the lower half contains the smooth components and each successive scale is packed in the lower elements. For example, if the source wave contains 128 points then the lowest scale results are stored in elements 64-127, the next scale (power of 2) are stored from 32-63, the following scale from 16-31 etc.

### Example

```
Make/O/N=1024 testData=sin(x/100)+gnoise(0.05)
DWT /S/N=20/V=25 testData, smoothedData
```

### See Also

For continuous wavelet transforms use the **CWT** operation. See the **FFT** operation.

For further discussion and examples see **Discrete Wavelet Transform** on page III-252.

## e

### e

The e function returns the base of the natural logarithm system (2.7182818...).

## EdgeStats

**EdgeStats** [*flags*] *waveName*

The EdgeStats operation produces simple statistics on a region of a wave that is expected to contain a single edge. If more than one edge exists, EdgeStats works on the first one found.

### Flags

<i>/A=avgPts</i>	Determines <i>startLevel</i> and <i>endLevel</i> automatically by averaging <i>avgPts</i> points at centered at <i>startX</i> and <i>endX</i> . Default is <i>/A=1</i> .
<i>/B=box</i>	Sets box size for sliding average. This should be an odd number. If <i>/B=box</i> is omitted or <i>box</i> equals 1, no averaging is done.
<i>/F=frac</i>	Specifies levels 1, 2 and 3 as a fraction of ( <i>endLevel-startLevel</i> ): $\text{level1} = \text{frac} * (\text{endLevel} - \text{startLevel}) + \text{startLevel}$ $\text{level2} = 0.5 * (\text{endLevel} - \text{startLevel}) + \text{startLevel}$ $\text{level3} = (1 - \text{frac}) * (\text{endLevel} - \text{startLevel}) + \text{startLevel}$ <p>The default value for <i>frac</i> is 0.1 which makes level1 the 10% level, level2 the 50% level and level3 the 90% level.</p> <p><i>frac</i> must be between 0 and 0.5.</p>
<i>/L=(startLevel, endLevel)</i>	Sets <i>startLevel</i> and <i>endLevel</i> explicitly. If omitted, they are determined automatically. See <i>/A</i> .
<i>/P</i>	Output edge locations (see <b>Details</b> ) are returned as point numbers. If <i>/P</i> is omitted, edge locations are returned as X values.
<i>/Q</i>	Prevents results from being printed in history and prevents error if edge is not found.
<i>/R=(startX, endX)</i>	Specifies an X range of the wave to search. You may exchange <i>startX</i> and <i>endX</i> to reverse the search direction.
<i>/R=[startP, endP]</i>	Specifies a point range of the wave to search. You may exchange <i>startP</i> and <i>endP</i> to reverse the search direction. If <i>/R</i> is omitted, the entire wave is searched.
<i>/T=dx</i>	Forces search in two directions for a possibly more accurate result. <i>dx</i> controls where the second search starts.

### Details

The */B=box*, */T=dx*, */P*, and */Q* flags behave the same as for the **FindLevel** operation.

EdgeStats considers a region of the input wave between two X locations, called *startX* and *endX*. *startX* and *endX* are set by the */R=(startX,endX)* flag. If this flag is missing, *startX* and *endX* default to the start and end of the entire wave. *startX* can be greater than *endX* so that the search for an edge can proceed from the “right” to the “left”.

The diagram above shows the default search direction, from the “left” (lower point numbers) of the wave toward the “right” (higher point numbers).

The *startLevel* and *endLevel* values define the base levels of the edge. You can explicitly set these levels with the */L=(startLevel,endLevel)* flag or you can let EdgeStats find the base levels for you by using the */A=avgPts* flag which averages points around *startX* and *endX*.

Given *startLevel* and *endLevel* and a *frac* value (see the */F=frac* flag) EdgeStats defines level1, level2 and level3 as shown in the diagram above. With the default *frac* value of 0.1, level1 is the 10% point, level2 is the 50% point and level3 is the 90% point.

With these levels defined, EdgeStats searches the wave from *startX* to *endX* looking for level2. Having found it, it then searches for level1 and level3. It returns results via variables described below.

EdgeStats sets the following variables:

V_flag	0: All three level crossings were found. 1: One or two level crossings were found. 2: No level crossings were found.
V_EdgeLoc1	X location of level1.
V_EdgeLoc2	X location of level2.
V_EdgeLoc3	X location of level3.
V_EdgeLv10	<i>startLevel</i> value.
V_EdgeLv11	level1 value.
V_EdgeLv12	level2 value.
V_EdgeLv13	level3 value.
V_EdgeLv14	<i>endLevel</i> value.
V_EdgeAmp4_0	Edge amplitude ( <i>endLevel</i> - <i>startLevel</i> ).
V_EdgeDLoc3_1	Edge width (x distance between point 1 and point 3).
V_EdgeSlope3_1	Edge slope (straight line slope from point 1 and point 3).

These X locations and distances are in terms of the X scaling of the named wave unless you use the */P* flag, in which case they are in terms of point number.

The EdgeStats operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

# Edit

**Edit** [*flags*] [*columnSpec* [, *columnSpec*]...] [**as** *titleStr*]

The Edit operation creates a table window or subwindow containing the specified columns.

**Parameters**

*columnSpec* is usually just the name of a wave. If no *columnSpecs* are given, Edit creates an empty table.

Column specifications are wave names optionally followed by one of the suffixes:

Suffix	Meaning
.i	Index values.
.l	Dimension labels.
.d	Data values.
.id	Index and data values.
.ld	Dimension labels and data values.

If the wave is complex, the wave names may be followed by .real or .imag suffixes. However, as of Igor Pro 3.0, both the real and imaginary columns are added to the table together — you can not add one without the other — so using these suffixes is discouraged.

**Historical Note:** Prior to Igor Pro 3.0, only 1D waves were supported. We called index values “X values” and used the suffix “.x” instead of “.i”. We called data values “Y values” and used the suffix “.y” instead of “.d”. For backward compatibility, Igor accepts “.x” in place of “.i” and “.y” in place of “.d”.

*titleStr* is a string expression containing the table’s title. If not specified, Igor will provide one which identifies the columns displayed in the table.

**Flags**

/HIDE= <i>h</i>	Hides ( <i>h</i> = 1) or shows ( <i>h</i> = 0, default) the window.
/HOST= <i>hcSpec</i>	Embeds the new table in the host window or subwindow specified by <i>hcSpec</i> . When identifying a subwindow with <i>hcSpec</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.
/I	Specifies that /W coordinates are in inches.
/K= <i>k</i>	Specifies window behavior when the user attempts to close it. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing. <i>k</i> =3: Hides the window.  If you use /K=2 or /K=3, you can still kill the window using the <b>KillWindow</b> operation.
/M	Specifies that /W coordinates are in centimeters.
/N= <i>name</i>	Requests that the created table have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen table name. Use DoWindow/K <i>name</i> to ensure that <i>name</i> is available.
/W=( <i>left,top,right,bottom</i> )	

Gives the table a specific location and size on the screen. Coordinates for /W are in points unless /I or /M are specified before /W.

When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings:

When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.

When any value is greater than 1, coordinates are taken to be fixed locations measured in points relative to the top left corner of the host frame.

### Details

You can not change dimension index values shown in a table. Use the Change Wave Scaling dialog or the **SetScale** operation.

If /N is not used, Edit automatically assigns to the table window a name of the form "Tablen", where  $n$  is some integer. In a function or macro, the assigned name is stored in the S\_name string. This is the name you can use to refer to the table from a procedure. Use the **RenameWindow** operation to rename the graph.

### Examples

These examples assume that the waves are 1D.

```
Edit myWave,otherWave      // 2 columns: data values from each wave
Edit myWave.id             // 2 columns: x and data values
Edit cmplxWave             // 2 columns: real and imaginary data values
Edit cmplxWave.i          // One column: x values
```

The following examples illustrates the use of column name suffixes in procedures when the name of the wave is in a string variable.

```
Macro TestEdit()
  String w = "wave0"
  Edit $w           // edit data values
  Edit $w.i         // show index values
  Edit $w.id        // index and data values
End
```

Note that the suffix, if any, must not be stored in the string. In a user-defined function, the syntax would be slightly different:

```
Function TestEditFunction()
  Wave w = $"wave0"
  Edit w           // no $, because w is name, not string
  Edit w.i         // show index values
  Edit w.id        // index and data values
End
```

### See Also

## endtry

### endtry

The endtry flow control keyword marks the end of a try-catch-entry flow control construct.

### See Also

The **try-catch-endtry** flow control statement for details.

## enoise

### enoise(num [, RNG])

The enoise function returns a random value drawn from a uniform distribution having a range of  $[-num, num]$ .

The random number generator is initialized using the system clock when you start Igor, virtually guaranteeing that you will never repeat the same sequence. If you want repeatable “random” numbers, use **SetRandomSeed**.

The optional parameter *RNG* selects one of two different pseudo-random number generators. If omitted, the default is 1. The *RNG*’s are:

<i>RNG</i>	Description
1	Linear Congruential generator by L’Ecuyer with added Bayes-Durham shuffle. The algorithm is described in <i>Numerical Recipes</i> as the function <code>ran2()</code> . This option has nearly $2^{32}$ distinct values and the sequence of random numbers has a period in excess of $10^{18}$ .
2	Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of $2^{19937}-1$ .

In a complex expression, the enoise function returns a complex value, as if you had called:

```
cmplx(enoise(num), enoise(num))
```

Except for `gnoise`, other noise functions do not have complex implementations.

### Example

```
// Generate uniformly-distributed integers on the interval [from,to] with from<to
Function IntNoise(from, to)
    Variable from, to
    Variable amp = to - from
    return floor(from + mod(abs(enoise(100*amp)), amp+1))
End
```

**EqualWaves**

**EqualWaves(waveA, waveB, selector [, tolerance])**

The **EqualWaves** function compares *waveA* to *waveB*. Each wave can be of any data type. It returns 1 for equality and zero otherwise.

Use the *selector* parameter to determine which aspects of the wave are compared. You can add *selector* values to test more than one field at a time or pass -1 to compare all aspects.

<i>selector</i>	Field Compared
1	Wave data
2	Wave data type
4	Wave scaling
8	Data units
16	Dimension units
32	Dimension labels
64	Wave note
128	Wave lock state
256	Data full scale
512	Dimension sizes

If you use the selectors for wave data, wave scaling, dimension units, dimension labels or dimension sizes, **EqualWaves** will return zero if the waves have unequal dimension sizes. The other selectors do not require equal dimension sizes.

**Details**

If you are testing for equality of wave data and if the *tolerance* is specified, it must be a positive number. The function returns 1 for equality if the data satisfies:

$$\sum_i (waveA[i] - waveB[i])^2 < tolerance.$$

If *tolerance* is not specified, it defaults to  $10^{-8}$ .

If *tolerance* is set to zero and *selector* is set to 1 then the data in the two waves undergo a binary comparison (byte-by-byte).

If *tolerance* is non-zero then the presence of NaNs at a given point in both waves does not contribute to the sum shown in the equation above when both waves contain NaNs at the same point. A NaN entry that is present in only one of the waves is sufficient to flag inequality. Similarly, INF entries are excluded from the tolerance calculation when they appear in both waves at the same position and have the same signs.

If you are comparing wave data (*selector* = 1) and both waves contain zero points the function returns 1.

**See Also**

The **MatrixOp** operation equal keyword.

**erf**

**erf(num [, accuracy])**

The erf function returns the error function of *num*.

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.$$

Optionally, *accuracy* can be used to specify the desired fractional accuracy.

In complex expressions the error function is

$$\operatorname{erf}(z) = \frac{2z}{\sqrt{\pi}} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -z^2\right),$$

where

$${}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -z^2\right)$$

is the confluent hypergeometric function of the first kind HyperG1F1. In this case the accuracy parameter is ignored.

**Details**

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

For backwards compatibility, in the absence of *accuracy* an alternate calculation method is used that achieves fractional accuracy better than about  $2 \times 10^{-7}$ .

If *accuracy* is present, erf can achieve fractional accuracy better than  $8 \times 10^{-16}$  for *num* as small as  $10^{-3}$ . For smaller *num* fractional accuracy is better than  $5 \times 10^{-15}$ .

Higher accuracy takes somewhat longer to calculate. With *accuracy* set to  $10^{-16}$  erfc takes about 50% more time than with *accuracy* set to  $10^{-7}$ .

**See Also**

The **erfc**, **erfcw**, **dawson**, **inverseErf**, and **inverseErfc** functions.

**erfc**

**erfc(num [, accuracy])**

The erfc function returns the complementary error function of *num* ( $\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$ ). Optionally, *accuracy* can be used to specify the desired fractional accuracy.

In complex expressions the complementary error function is

$$\operatorname{erfc}(z) = 1 - \operatorname{erf}(z) = 1 - \frac{2z}{\sqrt{\pi}} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -z^2\right) \text{ where } {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -z^2\right)$$

is the confluent hypergeometric function of the first kind HyperG1F1. In this case the accuracy parameter is ignored.

**Details**

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

For backwards compatibility, in the absence of *accuracy* an alternate calculation method is used that achieves fractional accuracy better than  $2 \times 10^{-7}$ .

If *accuracy* is present, erfc can achieve fractional accuracy better than  $2 \times 10^{-16}$  for *num* up to 1. From *num* = 1 to 10 fractional accuracy is better than  $2 \times 10^{-15}$ .

Higher accuracy takes somewhat longer to calculate. With *accuracy* set to  $10^{-16}$  erfc takes about 50% more time than with *accuracy* set to  $10^{-7}$ .

#### See Also

The **erf**, **erfcw**, **inverseErfc**, and **dawson** functions.

## erfcw

### erfcw(z)

The erfcw is a complex form of the error function defined by

$$\text{erfcw}(z) = \exp[-z^2] \text{erfc}(-iz),$$

where

$$\text{erfc}(z) = \frac{2}{\sqrt{\pi}} \int_z^{\infty} \exp[-t^2] dt.$$

The function is computed with accuracy of 0.5e-10. It is particularly useful for large |z| where the computation of erfc(z) starts encountering numerical instability.

## ErrorBars

### ErrorBars [flags] traceName, mode [errorSpecification]

The ErrorBars operation adds or removes error bars to or from the named trace in the specified graph.

The "error bars" are lines that extend from each data point to "caps". The length of the line (or "bar") is usually used to bracket a measured value by the amount of uncertainty, or "error" in the measurement.

#### Parameters

*traceName* is usually the name of a wave. If a wave is displayed more than once in a graph, the instance number can be appended to identify which instance to apply error bars to. For instance, wave0#2 refers to the third instance of wave0 displayed in the top graph (wave0, or wave0#0, is the first instance).

A string containing *traceName* can be used with the \$ operator to specify *traceName*.

*mode* is one of the following keywords:

OFF	No error bars.
X	Horizontal error bars only.
Y	Vertical error bars only.
XY	Horizontal and vertical error bars.
BOX	Box error bars.

SHADE={options, fillMode, fgColor, bkColor [ , negFillMode, negFgColor, negBkColor ]}

SHADE was added in Igor Pro 7.00.

*options* is reserved for future use and must be zero

*fillMode* sets the fill pattern.

- n*=0: No fill.
- n*=1: Erase.
- n*=2: Solid black.
- n*=3: 75% gray.
- n*=4: 50% gray.
- n*=5: 25% gray.
- n*>=6: See **Fill Patterns** on page III-441.

*fgColor* is (r,g,b) or (r,g,b,a). If all zeros including alpha, i.e., (0,0,0,0), then the actual color will be the trace color with an alpha of 20000.

*bkColor* is used for patterns only and can be simply (0,0,0) for solid fills.

*negFillMode* is the same as *fillMode* but for negative error shading.

*negFgColor* is the same as *fgColor* but for negative error shading.

*negBkColor* is the same as *bkColor* but for negative error shading.

The *errorSpecification*, described below, affects only the Y amplitude of error shading.

See **Error Shading** on page II-234 for more information and examples. See **Color Blending** on page III-440 for information on the alpha color parameter.

For any *mode* other than OFF, there is an *errorSpecification* whose format is **keyword** [= *value*]. The *errorSpecification* keywords are:

- pct      Percent.
- sqrt     Square root.
- const    Constant.
- wave     Arbitrary error values. You can use subranges; see **Subrange Display Syntax** on page II-250.

See the examples for the values that correspond to these *mode* and *errorSpecification* keywords. See the diagram below. *mode* and *errorSpecification* control only the lengths of the horizontal and vertical lines (the “bars”) to the “caps”. All other sizes and thicknesses are controlled by the flags.

Sizes controlled by *mode* and *errorSpecification*

Sizes controlled by flag values

### XY mode Error Bars

#### Flags

- /L=lineThick*      Specifies the thickness of both the X and Y error bars drawn from the point on the wave to the caps.
- /T=thick*          Specifies the thickness of both the X and Y error bar “caps”.

<i>/W=winName</i>	Changes error bars in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.
<i>/X=xWidth</i>	Specifies the width (height, actually) of the caps to the left or right of the point.
<i>/Y=yWidth</i>	Specifies the width of the caps above or below the point.

The thicknesses and widths are in units of points. The thickness parameters need not be integers. Although only integral thicknesses can be displayed exactly on the screen, nonintegral thicknesses are produced properly on high resolution hard copy devices. Use */T=0* to completely suppress the caps and */L=0* to completely suppress the lines to the caps.

### Details

If a point in *traceName* is not within the graph's axes (because the graph has been expanded) then that point's error bars are not shown. If a wave specifying error values for *traceName* is shorter than the wave displayed by *traceName* then the last value of the error wave is used for the unavailable points. If a point in an error wave contains NaN (Not a Number) then the half-bar associated with that point is not shown.

### Examples

<code>ErrorBars wave1,XY pct=10,pct=5</code>	X and Y error bars, X is 10% of wave1, Y is 5%
<code>ErrorBars wave1,X sqrt</code>	X error bars only, square root of wave1
<code>ErrorBars wave1,Y const=4.3</code>	Y error bars only, constant error value = 4.3
<code>ErrorBars wave1,BOX pct=10,pct=5</code>	error box, 10% in horizontal direction 5% in vertical direction
<code>ErrorBars wave1,Y wave=(w1,w2)</code>	Y error bars only, arbitrary error values wave w1 = errors for upper (Y+) bars wave w2 = errors for lower (Y-) bars
<code>ErrorBars wave1,Y wave=(,w2)</code>	Y error bars only, no upper (Y+) error bars wave w2 = errors for lower bars
<code>ErrorBars wave1,OFF</code>	turns error bars for wave1 off

**Trace Names** on page II-216, **Programming With Trace Names** on page IV-81.

## Execute

### Execute [/Q/Z] *cmdStr*

The Execute operation executes the contents of *cmdStr* as if it had been typed in the command line.

The most common use of Execute is to call a macro or an external operation from a user-defined function. This is necessary because Igor does not allow you to make such calls directly.

When the */Z* flag is used, an error code is placed in *V\_flag*. The error code will be -1 if a missing parameter style macro is called and the user clicks Quit Macro, or zero if there was no error.

### Flags

<i>/Q</i>	Command is not printed in the command line or history area.
<i>/Z</i>	Errors are not fatal and error dialogs are suppressed.

### Details

Because the command line and command buffer are limited to 1000 bytes on a single line, *cmdStr* is likewise limited to a maximum of 1000 executable bytes.

Do not reference local variables in *cmdStr*. The command is not executed in the local environment provided by a macro or user-defined function.

## Execute/P

---

Execute can accept a string expression containing a macro. The string must start with Macro, Proc, or Window, and must follow the normal rules for macros. All lines must be terminated with carriage returns including the last line. The name of the macro is not important but must exist. Errors will be reported except when using the /Z flag, which will assign V\_Flag a nonzero number in an error condition.

### Examples

It is a good idea to compose the command to be executed in a local string variable and then pass that string to the Execute operation. This prints the string to the history for debugging:

```
String cmd
sprintf cmd, "GBLoadWave/P=%s/S=%d \"%s\"", pathName, skipCount, fileName
Print cmd          // For debugging
Execute cmd

// Execute with a macro:
Execute "Macro junk(a,b)\rvariable a=1,b=2\r\rprint \"hello from macro\",a,b\rEnd\r"
```

### See Also

**The Execute Operation** on page IV-190 for other uses.

## Execute/P

**Execute/P** [/Q/Z] *cmdStr*

Execute/P is similar to Execute except the command string, *cmdStr*, is not immediately executed but rather is posted to an operation queue. Items in the operation queue execute only when nothing else is happening. Macros and functions must not be running and the command line must be empty.

### Flags

/Q	Command is not printed in the command line or history area.
/Z	No error reporting.

### See Also

**Operation Queue** on page IV-263 for more details on using Execute/P with the operation queue.

## ExecuteScriptText

**ExecuteScriptText** [*flags*] *textStr*

The ExecuteScriptText operation passes your text to Apple's scripting subsystem for compilation and execution or to the Windows command line.

If the /Z flag is used then a variable named V\_flag is created and is set to a nonzero value if an error was generated by the script or zero if no error. The error is not reported to Igor if the /Z flag is used.

On Macintosh:	Any results, including error messages, are placed in a string variable named S_value. String values returned in S_value often have double-quote characters at the start and end. Use /UNQ to remove them.
	The /B flag is ignored.
	The /W flag is ignored and ExecuteScriptText does not return until the script is finished.
	The current directory will be / and the PATH environment variable will be the system default, not the user default. Usually PATH=/usr/bin:/bin:/usr/sbin:/sbin.

On Windows: *textStr* contains the name of the executable file with optional Windows-style path and optional arguments:

```
[path]executableName [.exe] [arg1]...
```

If *path* is not given and *executableName* ends with ".exe" or with no extension, Igor locates the executable by searching first the registry and then along the PATH environment variable. If not found, then the Igor Pro 7 Folder directory is assumed.

```
ExecuteScriptText "calc" // calc.exe, calculator
```

When calling a batch file or other non-\*.exe file, supply the full path. If the path (or file name) contains spaces put quotes in the string:

```
ExecuteScriptText "\"C:\\Program Files\\my.bat\""
```

If you use the /W=*waitTime* flag with a positive value for *waitTime*, ExecuteScriptText waits up to that many seconds after submitting the command for the process started by the command to terminate. If the process fails to terminate within that period of time, ExecuteScriptText returns an error.

If you omit the /W flag or if you pass zero for *waitTime*, for GUI programs, ExecuteScriptText returns when the program begins processing messages. For non-GUI programs, ExecuteScriptText returns as soon as the OS returns control to Igor after Igor submits the script text to the OS.

Igor currently can not write to a console application's standard input nor read from its standard output.

Use the /B flag to run the command in the background, keeping Igor as the active application.

S\_value is always set to "".

### Parameters

*textStr* must contain a valid AppleScript program or Windows command line.

### Flags

/B	Execute Windows command line as a background task.
/W= <i>waitTime</i>	This flag is accepted on any platform but has an effect only on Windows. See the description above.
/UNQ	Removes any leading and trailing double-quote characters from S_value. This is useful on Macintosh only and has no effect on Windows. The /UNQ flag was added in Igor Pro 7.00.
/Z	Script errors are not fatal.

### Examples

```
// Macintosh: Convert file.PICT to file.GIF:
String ae = "tell application \"clip2gif\" "
ae += "to save file \"HD:file.PICT\" \"r\"
ExecuteScriptText/Z ae
```

```
// Macintosh: Execute a Unix shell command:
Function/S DemoUnixShellCommand()
// Paths must be POSIX paths (using /).
// Paths containing spaces or other nonstandard characters must be single-quoted.
// See Apple Technical Note TN2065 for more on shell scripting via AppleScript.
String unixCmd
unixCmd = "ls '/Applications/Igor Pro 7 Folder'"

String igorCmd
sprintf igorCmd, "do shell script \"%s\"", unixCmd
Print igorCmd // For debugging only.
```

## ExecuteScriptText

---

```
ExecuteScriptText/UNQ igorCmd
Print S_value           // For debugging only.
return S_value
End

// Windows: Open MatLab in the background:
ExecuteScriptText/B "C:\\Matlab\\bin\\matlab.exe myFile.m"

// Windows: Pass a script to Windows Script Host:
ExecuteScriptText/W=5 "WScript.exe \"C:\\Test Script.vbs\""

// Windows: Execute a batch file and leave the command window open
ExecuteScriptText "cmd.exe /K \"C:\\mybatch.bat\""

// Windows: Execute a DOS command and get output, if any
// ExecutedDOSCommand(command, maxSecondsToWait)
// Executes a DOS command and returns any output text as the function result.
// Returns "" if the DOS command returns no text.
// maxSecondsToWait is the maximum number of seconds to wait for DOS to finish
// the command. If it takes longer than that, an error is generated.
// This function creates files in the Igor Pro User Folder:
//   igorBatch.bat           Holds command that DOS is to execute
//   igorBatchOutput.txt     Holds output generated by DOS command, if any
// Example:
//   Print ExecutedDOSCommand("echo %PATH%", 3)
Function/S ExecutedDOSCommand(command, maxSecondsToWait)
String command           // e.g., "echo %PATH%"
Variable maxSecondsToWait // Error if DOS takes longer than this

String quoteStr = "\""

// Get path to batch file in "Igor Pro User Files"
String dirPath = SpecialDirPath("Igor Pro User Files", 0, 0, 0)
dirPath = ParseFilePath(5, dirPath, "\\ ", 0, 0) // Convert to Windows path
String batchFilePath = dirPath + "igorBatch.bat"
String batchOutputFilePath = dirPath + "igorBatchOutput.txt"

DeleteFile/Z batchOutputFilePath

// Write DOS command to batch file
String dosCommand = command + " > " + quoteStr + batchOutputFilePath + quoteStr
Variable refNum
Open refNum as batchFilePath
FBinWrite refNum, dosCommand
Close refNum

// Execute batch file
// The DOS command must complete in the number of seconds specified via /W
// /C means cmd.exe quits after executing the command
String text
sprintf text, "cmd.exe /C \"%s\"", batchFilePath
ExecuteScriptText/W=(maxSecondsToWait) text

// Get output
String result = ""
Open/R/Z refNum as batchOutputFilePath
if (V_flag != 0)
    result = ""
    // result = "<No output was generated by batch file>" // For debugging
else
    // Read contents of batch file into string
    FStatus refNum
    Variable numBytesInFile = V_logEOF
    result = PadString("", numBytesInFile, 0x20)
    FBinRead refNum, result
    Close refNum
endif

return result
End
```

### See Also

See **AppleScript** on page IV-249.

## exists

### **exists** (*objNameStr*)

The exists function returns a number which indicates if *objNameStr* contains the name of an Igor object, function or operation.

#### **Details**

*objNameStr* can optionally include a full or partial path to the object. If the name does not include a path, exists checks for waves, strings and variables in the current data folder.

*objNameStr* can optionally include a module name or independent module name prefix such as "ProcGlobal#" to check for the existence of functions. This works for macros as well.

The return values are:

- 0: Name not in use, or does not conflict with a wave, numeric variable or string variable in the specified data folder.
- 1: Name of a wave in the specified data folder.
- 2: Name of a numeric or string variable in the specified data folder.
- 3: Function name.
- 4: Operation name.
- 5: Macro name.
- 6: User-defined function name.

exists is not aware of local variables or parameters in user-defined functions, however it is aware of local variables and parameters in macros.

*objNameStr* is a string or string expression, *not* a name.

#### **Examples**

```
// Prints 2 if V_flag exists as a global variable in the current data folder:
Print exists("V_Flag")
```

```
// Prints 5 if a macro named Graph0 exists.
Print exists("ProcGlobal#Graph0")
```

#### **See Also**

The **DataFolderExists** and **WaveExists** functions and the **WinType** operation.

## exp

### **exp** (*num*)

The exp function returns  $e^{num}$ . In complex expressions, *num* is complex, and exp(*num*) returns a complex value.

## ExperimentModified

### **ExperimentModified** [*newModifiedState*]

The ExperimentModified operation gets and optionally sets the modified (save) state of the current experiment.

Use this command to prevent Igor from asking you to save the current experiment after you have made changes you do not need to save or, conversely, to force Igor to ask about saving the experiment even though Igor would not normally do so.

The variable V\_flag is always set to the experiment-modified state that was in effect before the ExperimentModified command executed: 1 for modified, 0 for not modified.

#### **Parameters**

If *newModifiedState* is present, it sets the experiment-modified state as follows:

*newModifiedState* = 0: Igor will not ask to save the experiment before quitting or opening another experiment, and the Save Experiment menu item will be disabled.

`newModifiedState = 1:` Igor will ask to save the experiment before quitting or opening another experiment, and the Save Experiment menu item will be enabled.

If `newModifiedState` is omitted, the state of experiment-modified state is not changed.

**Details**

Executing `ExperimentModified 0` on the command line will not work because the command will be echoed to the history area, marking the experiment as modified. Use the command in a function or macro that does not echo text to the history area.

**Examples**

The `/Q` flag is vital: it suppresses printing into the history area which would mark the experiment as modified again.

```
Menu "File"
    "Mark Experiment Modified",/Q,ExperimentModified 1    // Enables "Save Experiment"
    "Mark Experiment Saved",/Q,ExperimentModified 0       // Disables "Save Experiment"
End
```

**See Also**

The `SaveExperiment` operation, **Menu Definition Syntax** on page IV-118.

**expInt**

**expInt** (*n*, *x*)

The `expInt` function returns the value of the exponential integral  $E_n(x)$ :

$$E_n(x) = P \int_1^{\infty} \frac{e^{-xt}}{t^n} dt \quad (x > 0; n = 0, 1, 2 \dots).$$

**See Also**

`ei`, `ExpIntegralE1`

**References**

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

**ExpIntegralE1**

**ExpIntegralE1** (*z*)

The `ExpIntegralE1(z)` function returns the exponential integral of *z*.

If *z* is real, a real value is returned. If *z* is complex then a complex value is returned.

The `ExpIntegralE1` function was added in Igor Pro 7.00.

**Details**

The exponential integral is defined by

$$E_1(z) = \int_z^{\infty} \frac{e^{-t}}{t} dt, \quad (|\arg(z)| < \pi).$$

**References**

Abramowitz, M., and I.A. Stegun, "Handbook of Mathematical Functions", Dover, New York, 1972. Chapter 5.

**See Also**

`expInt`, `CosIntegral`, `SinIntegral`, `hyperGPFQ`

## expnoise

### expnoise(*b*)

The expnoise function returns a pseudo-random value from an exponential distribution whose average and standard deviation are *b* and the probability distribution function is

$$f(x) = \frac{1}{b} \exp\left(-\frac{x}{b}\right).$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

### See Also

The **SetRandomSeed** operation.

**Noise Functions** on page III-344.

Chapter III-12, **Statistics** for a function and operation overview.

## ExportGizmo

### ExportGizmo [*flags*] keyword [=value]

The ExportGizmo operation is obsolete but is still partially supported for partial backward compatibility.

As of Igor7 you can export Gizmo graphics using File→Save Graphics which generates a **SavePICT** command. The ExportGizmo operation is only partially supported. It can export to the clipboard or to an Igor wave and it can print but it can no longer export to a file. Use SavePICT instead.

Documentation for the ExportGizmo operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "ExportGizmo"
```

## Extract

### Extract [*type flags*] [/INDX/O] *srcWave*, *destWave*, *LogicalExpression*

The Extract operation finds data in *srcWave* wherever *LogicalExpression* evaluates to TRUE and stores the matching data sequentially in *destWave*, which will be created if it does not already exist.

### Parameters

*srcWave* is the name of a wave.

*destWave* is the name of a new or existing wave that will contain the result.

*LogicalExpression* can use any comparison or logical operator in the expression.

### Flags

- /FREE      Creates a free *destWave* (see **Free Waves** on page IV-84).  
/FREE is allowed only in functions and only if a simple name or wave reference structure field is specified for *destWave*.
- /INDX      Stores the index in *destWave* instead of data from *srcWave*.
- /O          Allows *destWave* to be the same as *srcWave* (overwrite source).

### Type Flags (used only in functions)

Extract also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-67 and **WAVE Reference Type Flags** on page IV-68 for a complete list of type flags and further details.

### Details

*srcWave* may be of any type including text.

*destWave* has the same type as *srcWave*, but it is always one dimensional. With /INDX, the *destWave* type is set to unsigned 32-bit integer and the values represent a linear index into *srcWave* regardless of its dimensionality.

### Example

```
Make/O source= x
Extract/O source,dest,source>10 && source<20
print dest
```

Prints the following to the history area:

```
dest [0] = { 11, 12, 13, 14, 15, 16, 17, 18, 19 }
```

### See Also

The **Duplicate** operation.

## factorial

### factorial(*n*)

The factorial function returns  $n!$ , where  $n$  is assumed to be a positive integer.

Note that while factorial is an integer-valued function, a double-precision number has 53 bits for the mantissa. This means that numbers over  $2^{52}$  will be accurate to about one part in about  $2 \times 10^{16}$ . Values of  $n$  greater than 170 result in overflow and return Inf.

## FakeData

### FakeData(*waveName*)

The FakeData function puts fake data in the named wave, which must be single-precision float. This is useful for testing things that require changing data before you have the source for the eventual real data. FakeData can be useful in a background task expression.

The FakeData function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

### Examples

```
Make/N=200 wave0; Display wave0
SetBackground FakeData(wave0)           // define background task
CtrlBackground period=60, start         // start background task
// observe the graph for a while
CtrlBackground stop                     // stop the background task
```

## FastGaussTransform

### FastGaussTransform [*flags*] *srcLocationsWave*, *srcWeightsWave*

The FastGaussTransform operation implements an efficient algorithm for evaluating the discrete Gauss transform, which is given by

$$G(y_j) = \sum_{i=0}^{N-1} q_i \exp \left( -\frac{\|y_j - x_i\|^2}{h} \right),$$

where  $G$  is an  $M$ -dimensional vector,  $y$  is an  $N$ -dimensional vector representing the observation position,  $\{q_i\}$  are the  $M$ -dimensional weights,  $\{x_i\}$  are  $N$ -dimensional vectors representing source locations, and  $h$  is the Gaussian width. The wave `M_FGT` contains the output in the current data folder.

### Flags

/AERR= <i>aprxErr</i>	Sets the approximate error, which determines how many terms of the Taylor expansion of the Gaussian are used by the calculation. Default value is 1e-5.
/WDTH= <i>h</i>	Sets the Gaussian width. Default value is 1.
/OUTW= <i>locWave</i>	Specifies the locations at which the output is computed. <i>locWave</i> must have the same number of columns as <i>srcLocationsWave</i> . The other /OUT flags are mutually exclusive; you should use only one at any time.

/OUT1={x1,nx,x2}	
/OUT2={x1,nx,x2,y1,ny,y2}	
/OUT3={x1,nx,x2,y1,ny,y2,z1,nz,z2}	
	Specifies gridded output of the required dimension. In each case you set the starting and ending values together with the number of intervals in that dimension. You cannot specify an output that does not match the dimensions of the input source.
/Q	No results printed in the history area.
/RX=rx	Sets the maximum radius of any cluster. The clustering algorithm terminates when the maximum radius is less than <i>rx</i> . Without /RX, the maximum radius is the same as the maximum radius encountered.
/RY=ry	Sets the upper bound for the distance between an observation point and a cluster center for which the cluster contributes to the transform value. Default is $5h$ .
/TET= <i>nTerms</i>	Sets the number of terms in the Taylor expansion. Use /TET to set the number of terms and bypass the default error estimate, which is estimated from the approximate error value (/AERR).
/Z	No error reporting.

### Details

The discrete Gauss transform can be computed as a direct sum. An exact calculation is practical only for moderate number of sources and observation points and for low spatial dimensionality. With increasing dimensionality and increasing number of sources it is more efficient to take advantage of some properties of the Gaussian function. The FastGaussianTransform operation does so in two ways: It first arranges the sources in N-dimensional spatial clusters so that it is not necessary to compute the contributions of all source points that belong to remote clusters (see **FPClustering**). The second component of the algorithm is an approximation that factorizes the sum into a factor that depends only on source points and a factor that depends only on observation points. The factor that depends only on source points is computed only once while the factor that depends on observation points is evaluated once for each observation point.

The trade-off between computation efficiency and accuracy can be adjusted using multiple parameters. By default, the operation calculates the number of terms it needs to use in the Taylor expansion of the Gaussian. You can modify the default approximate error value using /AERR or you can directly set the number of terms in the expansion using /TET.

FastGaussianTransform supports calculations in dimensions that may exceed the maximum allowed wave dimensionality. *srcLocationsWave* must be a 2D, real-valued single- or double-precision wave in which each row corresponds to a single source position and columns represent the components in each dimension (e.g., a triplet wave would represent 3D source locations). *srcWeightsWave* must have the same number of rows as *srcLocationsWave* and it must be a real-valued single- or double-precision wave. In most applications *srcWeightsWave* will have a single column so that the output *G* will be scalar. However, if *srcWeightsWave* has multiple columns then *G* is a vector. This can be handy if you need to test multiple sets of coefficients at one time. If you specify observation points using /OUTW then *locWave* must have the same number of columns as *srcLocationsWave* (the number of rows in the output is arbitrary). The operation does not support wave scaling.

## FastOp

**FastOp** [/C] *destwave* = *prod1* [ $\pm$  *prod2* [ $\pm$  *prod3*]]

The FastOp operation can be used to get improved speed out of certain wave assignment statements. The syntax was designed so that you can simply insert FastOp in front of any wave assignment statement that meets the syntax requirements.

## Parameters

<i>destWave</i>	An existing destination wave for the assignment expression. An error will be reported at runtime if the waves are not all the same length or number type.
<i>prod1, prod2, prod3</i>	Products with the following formats:  $constexpr * wave1 * wave2$ or $constexpr / wave2$ <i>constexpr</i> may be a literal numeric constant or a constant expression in parentheses. Such expressions are evaluated only once. Any component in a prod expression may be omitted.

## Flags

/C	Specifies a complex expression. Only applicable to floating point waves.
----	--

## Details

Certain combinations are evaluated using faster specific code rather than more general but slower generic code. The following specific formats are given special consideration:

Single or Double Precision Real	Integer
$waved = C0$	$waved = C0$
$waved = C0 * waveA + C1$	$waved = waveA + C1$
$waved = waveA + C1$	$waved = waveA + waveB + C2$

In the above, pluses may be minuses and the trailing constant (*C0*, *C1*, *C2*) may be omitted.

**Note:** Integer waves are evaluated using double precision intermediate values except for the aforementioned special cases which are evaluated using the native format.

Typically, FastOp will improve performance by 10 to 40 times. The speed increase will be dependent on the computer and on the length of the waves, with the greatest improvement for waves having 1000 to 100,000 points.

This operation replaces the obsolete FastWaveOps XOP. It has all the capabilities of the XOP and then some and has an easier to read syntax.

## Examples

Valid expressions:

```
FastOp waved= 3
FastOp waved= waveA + waveB
FastOp waved= 0.5*waveA + 0.5*waveB
FastOp waved= waveA*waveB
FastOp waved= (2*3)*waveA + 6
FastOp waved= (locvar)*waveA
```

Expressions that are **not** valid:

```
FastOp waved= 3*4
FastOp waved= (waveA + waveB)
FastOp waved= waveA*0.5 + 0.5*waveB
FastOp waved= waveA*waveB/2
FastOp waved= 2*3*waveA + 6
FastOp waved= locvar*waveA
```

## See Also

The **MatrixOp** operation for more efficient matrix operations.

## faverage

**faverage**(waveName [, x1, x2])

The faverage function returns the trapezoidal average value of the named wave from  $x=x1$  to  $x=x2$ .

If your data are in the form of an XY pair of waves, see **faverageXY**.

### Details

If  $x1$  and  $x2$  are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

If  $x1$  or  $x2$  are not within the X range of *waveName*, faverage limits them to the nearest X range limit of *waveName*.

faverage returns the area divided by  $(x2-x1)$ . In other words, the X scaling of *waveName* is eliminated when computing the average.

If any Y values in the specified X range are NaN, faverage returns NaN.

Unlike the **area** function, reversing the order of  $x1$  and  $x2$  does *not* change the sign of the returned value.

The faverage function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

The faverage function returns a complex result for a complex input wave. The real part of the result is the average of the real components in the input wave and the imaginary part of the result is the average of the imaginary components.

### Examples

Comparison of area, faverage and mean functions over interval (12.75,13.32)

```
area(wave,12.75,13.32) = 0.05 * (43+55) / 2 // first trapezoid
                      + 0.20 * (55+88) / 2 // second trapezoid
                      + 0.20 * (88+100) / 2 // third trapezoid
                      + 0.12 * (100+92.2) / 2 // fourth trapezoid
                      = 47.082
```

```
faverage(wave,12.75,13.32) = area(wave,12.75,13.32) / (13.32-12.75)
                          = 47.082/0.57 = 82.6
```

```
mean(wave,12.75,13.32) = (55+88+100+87)/4 = 82.5
```

### See Also

Integrate, area, areaXY, faverageXY and PolygonArea

## faverageXY

**faverageXY**(XWaveName, YWaveName [, x1, x2])

The faverageXY function returns the trapezoidal average value of *YWaveName* from  $x=x1$  to  $x=x2$ , using X values from *XWaveName*.

This function operates identically to faverage, except that it uses an XY pair of waves for X and Y values and it does not work with complex waves.

### Details

If  $x1$  and  $x2$  are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

If  $x1$  or  $x2$  are not within the X range of *XWaveName*, faverageXY limits them to the nearest X range limit of *XWaveName*.

faverageXY returns the area divided by  $(x2-x1)$ .

If any values in the X range are NaN, faverageXY returns NaN.

Reversing the order of  $x1$  and  $x2$  does not change the sign of the returned value.

The values in *XWaveName* may be increasing or decreasing. *faverageXY* assumes that the values in *XWaveName* are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any *X* values are NaN, the result is NaN.

The *faverageXY* function is not multidimensional aware. See Chapter II-6, **Multidimensional Waves** for details on multidimensional waves, particularly **Analysis on Multidimensional Waves** on page II-86.

**See Also**

**Integrate, area, areaXY, faverage and PolygonArea**

## FBinRead

**FBinRead** [*flags*] *refNum*, *objectName*

The FBinRead operation reads binary data from the file specified by *refNum* into the named object.

For simple applications of loading binary data into numeric waves you may find the *GBLoadWave* operation simpler to implement.

### Parameters

*refNum* is a file reference number from the Open operation used to open the file.

*objectName* is the name of a wave, numeric variable, string variable, or structure.

### Flags

*/B[=b]* Specifies file byte ordering.

*b=0*: Native (same as no */B*).

*b=1*: Reversed (same as */B*).

*b=2*: Big-endian (Motorola).

*b=3*: Little-endian (Intel).

*/F=f* Controls the number of bytes read and how the bytes are interpreted.

*f=0*: Native binary format of the object (default).

*f=1*: Signed byte; one byte.

*f=2*: Signed 16-bit word; two bytes.

*f=3*: Signed 32-bit word; four bytes.

*f=4*: 32-bit IEEE floating point; four bytes.

*f=5*: 64-bit IEEE floating point; eight bytes.

*f=6*: 64-bit integer; eight bytes. Requires Igor Pro 7.00 or later.

*/U* Integer formats (*/F=1, 2, or 3*) are unsigned. If */U* is omitted, integers are signed.

### Details

If *objectName* is the name of a string variable then */F* doesn't apply. The number of bytes read is the number of bytes in the string *before* the FBinRead operation is called. You can use the **PadString** function to set the size of a string.

The binary format that FBinRead uses for numeric variables or waves depends on the */F* flag. If no */F* flag is present, the native binary format of the named object is used.

Byte ordering refers to the order in which a multibyte datum is read from a file. For example, a 16-bit word (sometimes called a "short") consists of a high-order byte and a low-order byte. Under big-endian byte ordering, which is commonly used on Macintosh, the high-order byte is read from the file first. Under little-endian byte ordering, which is commonly used on Windows, the low-order byte is read from the file first.

FBinRead will read an entire structure from a disk file. The individual fields of the structure will be byte-swapped if the */B* flag is designated.

The FBinRead operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

**See Also****FBinWrite, Open, FGetPos, FSetPos, FStatus, GBLoadWave****FBinWrite****FBinWrite** [*flags*] *refNum*, *objectName*

The FBinWrite operation writes the named object in binary to a file.

**Parameters***refNum* is a file reference number from the **Open** operation used to open the file.*objectName* is the name of a wave, numeric variable, string variable, or structure.**Flags****/B[=b]** Specifies file byte ordering.*b*=0: Native (same as no /B).*b*=1: Reversed (same as /B).*b*=2: Big-endian (Motorola).*b*=3: Little-endian (Intel).**/F=f** Controls the number of bytes written and how the bytes are formatted.*f*=0: Native binary format of the object (default).*f*=1: Signed byte; one byte.*f*=2: Signed 16-bit word; two bytes.*f*=3: Signed 32-bit word; four bytes.*f*=4: 32-bit IEEE floating point; four bytes.*f*=5: 64-bit IEEE floating point; eight bytes.*f*=6: 64-bit integer; eight bytes. Requires Igor Pro 7.00 or later.**/P** Adds an IgorBinPacket to the data. This is used for PPC or Apple event result packets (*refNum* = 0) and is not normally of use when writing to a file.**/U** Integer formats (/F=1, 2, or 3) are unsigned. If /U is omitted, integers are signed.**Details**

A zero value of *refNum* is used in conjunction with Program-to-Program Communication (PPC) or Apple events (*Macintosh*) or DDE (*Windows*). The data that would normally be written to a file is appended to the PPC or Apple event or DDE result packet.

If the object is a string variable then /F doesn't apply. The number of bytes written is the number of bytes in the string.

The binary format that FBinWrite uses for numeric variables or waves depends on the /F flag. If no /F flag is present, FBinWrite uses the native binary format of the named object.

Byte ordering refers to the order in which a multibyte datum is written to a file. For example, a 16-bit word (sometimes called a "short") consists of a high-order byte and a low-order byte. Under big-endian byte ordering, which is commonly used on Macintosh, the high-order byte is written to the file first. Under little-endian byte ordering, which is commonly used on Windows, the low-order byte is written to the file first.

FBinWrite will write an entire structure to a disk file. The individual fields of the structure will be byte-swapped if the /B flag is designated.

The FBinWrite operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

**See Also****FBinRead, Open, FGetPos, FSetPos, FStatus, GBLoadWave**

## FetchURL

### FetchURL(*urlStr*)

The FetchURL function returns a string containing the server's response to a request to get the contents of the URL specified by *urlStr*. If *urlStr* contains a URL that uses the file:// scheme, the contents of the local file is returned.

### Parameters

*urlStr* is a string containing the URL to retrieve. You can include a username, password, and server port number as part of the URL.

FetchURL expects that *urlStr* has been percent-encoded if it contains reserved characters. See **Percent Encoding** on page IV-253 for additional information on when percent-encoding is necessary and how to do it.

See **URLs** on page IV-252 for details about how to correctly specify the URL.

FetchURL supports only the http://, https://, ftp://, and file:// schemes. See **Supported Network Schemes** on page IV-253 for details.

There are two special values of *urlStr* that can be used to get information about the network library that Igor uses. The keyword=value pairs returned when *urlStr* is "curl\_version\_info" may be useful to programmers in that the features and protocols available in the library are specified.

```
FetchURL("curl_version")
FetchURL("curl_version_info")
```

### Details

If FetchURL encounters an error, it returns a NULL string. You should check for errors before using the returned string. In a user-defined function, use the **GetRTErr** function.

```
String urlStr = "http://www.badserver"
String response = FetchURL(urlStr)
Variable error = GetRTErr(1)           // Check for error before using response
if (error != 0)
    // FetchURL produced an error
    // so don't try to use the response.
endif
```

### Limitations

It is possible for FetchURL to return a valid server response even though the URL you requested does not exist on the server or requires a username and password that you did not provide. In this situation, the response returned by the server will usually be a web page stating that the page was not found or another error message. You can check for this kind of error in your own code by examining the response.

FetchURL does not support advanced features such as network proxies, file or data uploads, setting the timeout period, or saving the server's response directly to a file. When using the http:// scheme, only the GET method is supported. This means that you cannot use FetchURL to submit form data to a web server that requires using the http POST method. Use the **URLRequest** operation if you need any of these features.

Igor Pro is not capable of displaying the contents of a URL in a rendered form like a web browser.

### Examples

```
// Retrieve the contents of the WaveMetrics home page.
String response
response = FetchURL("http://www.wavemetrics.com")

// Get a binary image file from a web server and then
// save the image to a file on the desktop.
String url = "http://www.wavemetrics.net/images/tbg.gif"
String imageBytes = FetchURL(url)
Variable error = GetRTErr(1)
if (error != 0)
    Print "Error downloading image."
else
    Variable refNum
    String localPath = SpecialDirPath("Desktop", 0, 0, 0) + "tbg.gif"
    Open/T=".gif" refNum as localPath
    FBinWrite refNum, imageBytes
    Close refNum
endif
```

## FFT

**FFT** [*flags*] *srcWave*

The FFT operation computes the Discrete Fourier Transform of *srcWave* using a multidimensional prime factor decomposition algorithm. By default, *srcWave* is overwritten by the FFT.

### Output Wave Name

For compatibility with earlier versions of Igor, if you use FFT with no flags or with just the /Z flag, the operation overwrites *srcWave*.

If you use any flag other than /Z, FFT uses default output wave names: W\_FFT for a 1D FFT and M\_FFT for a multidimensional FFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting *srcWave*.

### Flags

/COLS

Computes the 1D FFT of 2D *srcWave* one column at a time, storing the results in the destination wave.

$$I[t_1][n] = \sum_{k=0}^{N-1} f[t_1][k] \exp(i2\pi kn / N).$$

You must specify a destination wave using the /DEST flag. No other flags are allowed with this flag. The number of rows must be even. If *srcWave* is a real (N×M) wave, the output matrix will be (1+N/2,M) in analogy with 1D FFT. To avoid changes in the number of points you can convert *srcWave* to complex data type. This flag applies only to 2D source waves. See also the /ROWS flag.

/DEST=*destWave*

Specifies the output wave created by the FFT operation.

It is an error to attempt specify the same wave as both *srcWave* and *destWave*.

The default output wave name is W\_FFT for a 1D FFT and M\_FFT for a multidimensional FFT.

When used in a function, the FFT operation by default creates a complex wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-66 for details.

/FREE

Creates *destWave* as a free wave.

/FREE is allowed only in functions and only if *destWave*, as specified by /DEST, is a simple name or wave reference structure field.

See **Free Waves** on page IV-84 for more discussion.

The /FREE flag was added in Igor Pro 7.00.

/HCC

Hypercomplex transform (cosine). Computes the integral

$$I_c(\omega_1, \omega_2) = \int \int_{-\infty}^{\infty} f(t_1, t_2) \cos(t_1 \omega_1) \exp(it_2 \omega_2) dt_1 dt_2$$

using the 2D FFT (see **Details**).

/HCS	Hypercomplex transform (sine). Computes the integral $I_s(\omega_1, \omega_2) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(t_1, t_2) \sin(t_1 \omega_1) \exp(it_2 \omega_2) dt_1 dt_2$ using the 2D FFT (see <b>Details</b> ).
/MAG	Saves just the magnitude of the FFT in the output wave. See comments under /OUT.
/MAGS	Saves the squared magnitude of the FFT in the output wave. See comments under /OUT.
/OUT=mode	Sets the output wave format. <p> mode=1: Default for complex output.  mode=2: Real output.  mode=3: Magnitude.  mode=4: Magnitude square.  mode=5: Phase.  mode=6: Scaled magnitude.  mode=7: Scaled magnitude squared. </p> <p>You can also identify modes 2-4 using the convenience flags /REAL, /MAG, and /MAGS. The convenience flags are mutually exclusive and are overridden by the /OUT flag.</p> <p>The scaled quantities apply to transforms of real valued inputs where the output is normally folded in the first dimension (because of symmetry). The scaling applies a factor of 2 to the squared magnitude of all components except the DC. The scaled transforms should be used whenever Parseval's relation is expected to hold.</p>
/PAD={dim1 [, dim2, dim3, dim4]}	Converts <i>srcWave</i> into a padded wave of dimensions <i>dim1, dim2, ..., dim4</i> . The padded wave contains the original data at the start of the dimension and adds zero entries to each dimension up to the specified dimension size. The <i>dim1...dim4</i> values must be greater than or equal to the corresponding dimension size of <i>srcWave</i> . If you need to pad just the lowest dimension(s) you can omit the remaining dimensions; for example, /PAD= <i>dim1</i> will set <i>dim2</i> and above to match the dimensions in <i>srcWave</i> .
/REAL	Saves just the real part of the transform in the output wave. See comments under /OUT.
/ROWS	Calculates the FFT of only the first dimension of a 2D <i>srcWave</i> . It thus computes the 1D FFT of one row at a time, storing the results in the destination wave. $N[n][t_2] = \sum_{k=0}^{M-1} f[k][t_2] \exp(i2\pi kn / M)$
	You must specify a destination wave using the /DEST flag. No other flags are allowed with this flag. The number of columns must be even. If <i>srcWave</i> is a real (N×M) wave, the output matrix will be (N,1+M/2) in analogy with 1D FFT. To avoid changes in the number of points you can convert <i>srcWave</i> to complex data type. See also /COLS flag.
/RP=[startPoint, endPoint]	
/RX=(startX, endX)	Defines a segment of a 1D <i>srcWave</i> that will be transformed. By default the operation transforms the whole wave. It is sometimes useful to take advantage of this feature in order to transform just the defined interval, which includes both end points. You can define the interval using wave point indexing with the /RP flag or using the X-values with the /RX flag. The interval must include at least four data points and the total number of points must be an even number.

*/WINF=windowKind*

Premultiplies a 1D *srcWave* with the selected window function.

If you include the */PAD* flag, the window function is applied to the pre-padded data.

See **Window Functions** below for details.

*/Z*

Disables rotation of the FFT of a complex wave. Igor normally rotates the FFT result (which is also complex) by  $N/2$  so that  $x=0$  is at the center point ( $N/2$ ). When */Z* is specified, Igor does not perform this rotation and leaves  $x=0$  at the first point (0).

### Details

The data type of *srcWave* is arbitrary. The first dimension of *srcWave* must be an even number and the minimum length of *srcWave* is four points. When *srcWave* is a double precision wave, the FFT is computed in double precision. All other data types are transformed using single precision calculations. The result of the FFT operation is always a floating point number (single or double precision).

Depending on your choice of outputs, you may not be able to invert the transform in order to obtain the original *srcWave*.

*srcWave* or any of its intervals must have at least four data points and must not contain NaNs or INFs.

The FFT algorithm is based on prime number decomposition, which decomposes the number of points in each dimension of the wave into a product of prime numbers. The FFT is optimized for primes  $< 5$ . In time consuming applications it is frequently worthwhile to pad the data so that the total number of points factors into small prime numbers.

The hypercomplex transforms are computed by writing the sine and cosine as a sum of two exponentials. Let the 2D Fourier transform of the input signal be

$$F[n_1][n_2] = \sum_{k_1=0}^{N_1-1} \sum_{k_2=0}^{N_2-1} f[k_1][k_2] \exp\left(i2\pi k_1 \frac{n_1}{N_1}\right) \exp\left(i2\pi k_2 \frac{n_2}{N_2}\right)$$

then the two hypercomplex transforms are given by

$$I_c[n_1][n_2] = \frac{1}{2} (F[n_1][n_2] + F[-n_1][n_2])$$

and

$$I_s[n_1][n_2] = \frac{1}{2i} (F[n_1][n_2] - F[-n_1][n_2])$$

### Window Functions

The */F=windowKind* flag premultiplies a 1D *srcWave* with the selected window function.

In the following window definitions,  $w(n)$  is the value of the window function that multiplies the signal,  $N$  is the number of points in the signal wave (or range if */R* is specified), and  $n$  is the wave point index. With */R*,  $n=0$  for the first datum in the range.

Choices for *windowKind* are in bold.

#### **Bartlett:**

A synonym for Bartlett.

**Bartlett:**

$$w(n) = \begin{cases} \frac{2n}{N} & n = 0, 1, \dots, \frac{N}{2} \\ 2 - \frac{2n}{N} & n = \frac{N}{2}, \dots, N-1 \end{cases}$$

**Blackman367, Blackman361, Blackman492, Blackman474:**

$$w(n) = a_0 - a_1 \cos\left(\frac{2\pi}{N}n\right) + a_2 \cos\left(\frac{2\pi}{N}2n\right) - a_3 \cos\left(\frac{2\pi}{N}3n\right).$$

$$n = 0, 1, 2, \dots, N-1.$$

<i>windowKind</i>	$a_0$	$a_1$	$a_2$	$a_3$

## FGetPos

### FGetPos *refNum*

The FGetPos operation returns the file position for a file.

FGetPos is a faster alternative to FStatus if the only thing you are interested in is the file position.

The FGetPos operation was added in Igor Pro 7.00.

### Parameters

*refNum* is a file reference number obtained from the **Open** operation.

### Details

FGetPos supports very big files theoretically up to about 4.5E15 bytes in length.

FGetPos sets the following variables:

V_flag	Nonzero (true) if <i>refNum</i> is valid.
V_filePos	Current file position for the file in bytes from the start.

### See Also

**Open**, **FSetPos**, **FStatus**

## FIFO2Wave

### FIFO2Wave [/R/S] *FIFOName*, *channelName*, *waveName*

The FIFO2Wave operation copies FIFO data from the specified channel of the named FIFO into the named wave. FIFOs are used for data acquisition.

### Flags

/R=[ <i>startPoint</i> , <i>endPoint</i> ]	Dumps the specified FIFO points into the wave.
/S=s	Controls the wave's X scaling and number type: s=0: Same as no /S. s=1: Sets the wave's X scaling x0 value to the number of the first sample in the FIFO. s=2: Changes the wave's number type to match the FIFO channel's type. s=3: Combination of s=1 and s=2.

### Details

The FIFO must be in the valid state for FIFO2Wave to work. When you create a FIFO, using NewFIFO, it is initially invalid. It becomes valid when you issue the start command via the CtrlFIFO operation. It remains valid until you change a FIFO parameter using CtrlFIFO.

If you specify a range of FIFO data points, using /R=[*startPoint*,*endPoint*] then FIFO2Wave dumps the specified FIFO points into the wave after clipping *startPoint* and *endPoint* to valid point numbers.

The valid point numbers depend on whether the FIFO is running and on whether or not it is attached to a file. If the FIFO is running then *startPoint* and *endPoint* are truncated to number of points in the FIFO. If the FIFO is buffering a file then the range can include the full extent of the file.

If you specify no range then FIFO2Wave transfers the most recently acquired FIFO data to the wave. The number of points transferred is the smaller of the number of points in the FIFO and number of points in the wave.

FIFO2Wave may or may not change the wave's X scaling and number type, depending on the current X scaling and on the /S flag.

Think of the wave's X scaling as being controlled by two values,  $x_0$  and  $dx$ , where the X value of point  $p$  is  $x_0 + p \cdot dx$ . FIFO2Wave always sets the wave's  $dx$  value equal to the FIFO's  $\Delta T$  value (as set by the CtrlFIFO operation). If you use no /S flag, FIFO2Wave does not set the wave's  $x_0$  value nor does it set the wave's number type.

If you are using FIFO2Wave to update a wave in a graph as quickly as possible, the /S=0 flag gives the highest update rate. The other /S values trigger more recalculation and slow down the updating.

If the wave's number type (possibly changed to match the FIFO channel) is a floating point type, FIFO2Wave scales the FIFO data before transferring it to the wave as follows:

$$\text{scaled\_value} = (\text{FIFO\_value} - \text{offset}) * \text{gain}$$

If the FIFO channel's gain is one and its offset is zero, the scaling would have no effect so FIFO2Wave skips it.

If the specified FIFO channel is an image strip channel (one defined using the optional vectPnts parameter to NewFIFOChan), then the resultant wave will be a matrix with the number of rows set by vectPnts and the number of columns set by the number of points described above for one-dimensional waves. To create an image plot that looks the same as the corresponding channel in a Chart, you will need to transpose the wave using **MatrixTranspose**.

#### See Also

## FIFOStatus

**FIFOStatus** [/Q] *FIFOName*

The FIFOStatus operation returns miscellaneous information about a FIFO and its channels. FIFOs are used for data acquisition.

#### Flags

/Q                      Doesn't print in the history area.

#### Details

FIFOStatus sets the variable *V\_flag* to nonzero if a FIFO of the given name exists. If the named FIFO does exist then FIFOStatus stores information about the FIFO in the following variables:

<i>V_FIFORunning</i>	Nonzero if FIFO is running.
<i>V_FIFOChunks</i>	Number of chunks of data placed in FIFO so far.
<i>V_FIFOn chans</i>	Number of channels in the FIFO.
<i>S_Info</i>	Keyword-packed information string.

The keyword-packed information string consists of a sequence of sections with the following form: *keyword:value*;

You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions. Here are the keywords for *S\_Info*:

In addition, FIFOStatus writes fields to *S\_Info* for each channel in the FIFO. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named "Pressure" then the following would appear in the *S\_Info* string: NAME4:Pressure.

In the following table, the channel's number is represented by "#".

## FilterFIR

Keyword	Type	Meaning
DATE	Number	The date/time when start was issued via CtrlFIFO.
DELTAT	Number	The FIFO's deltaT value as set by CtrlFIFO.
DISKTOT	Number	Current number of chunks written to the FIFO's file.
FILENUM	Number	The output file refNum or review file refNum as set by CtrlFIFO. This will be zero if the FIFO is connected to no file.
NOTE	String	The FIFO's note string as set by CtrlFIFO.
VALID	Number	Zero if FIFO is not valid.

Keyword	Type	Meaning
FSMINUS#	Number	Channel's minus full scale value as set by NewFIFOChan.
FSPLUS#	Number	Channel's plus full scale value as set by NewFIFOChan.
GAIN#	Number	Channel's gain value as set by NewFIFOChan.
NAME#	String	Name of channel.
OFFSET#	Number	Channel's offset value as set by NewFIFOChan.
UNITS#	String	Channel's units as set by NewFIFOChan.

The **NumberByKey** and **StringByKey** functions for parsing keyword-value strings.

## FilterFIR

**FilterFIR** [*flags*] *waveName* [, *waveName*]...

The FilterFIR operation convolves each *waveName* with automatically-designed filter coefficients or with *coefsWaveName* using time-domain methods.

The automatically-designed filter coefficients are simple lowpass and highpass window-based filters or a maximally-flat notch filter. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first *waveName* or just used to filter the data in *waveName*.

FilterFIR filters data faster than **Convolve** when there are many fewer filter coefficient values than data points in *waveName*.

**Note:** FilterFIR replaces the obsolete **SmoothCustom** operation.

### Parameters

*waveName* is a destination wave that is overwritten by the convolution of itself and the filter.

*waveName* may be multidimensional, but only one dimension selected by /DIM is filtered (for two-dimensional filtering, see **MatrixFilter**).

If *waveName* is complex, the real and imaginary parts are filtered independently.

### Flags

/COEF [=coefsWaveName]

Replaces the first output *waveName* by the filter coefficients instead of the filtered results or, when *coefsWaveName* is specified, replaces the output wave(s) by the result of convolving *waveName* with coefficients in *coefsWaveName*.

*coefsWaveName* must not be one of the destination *waveNames*. It must be single- or double-precision numeric and one-dimensional.

To avoid shifting the output with respect to the input, *coefsWaveName* must have an odd length with the “center” coefficient in the middle of the wave.

The coefficients are usually symmetrical about the middle point, but FilterFIR does not enforce this.

/DIM=*d*

Specifies the wave dimension to filter.

- d*=-1: Treats entire wave as 1D (default).
- d*=0: Operates along rows.
- d*=1: Operates along columns.
- d*=2: Operates along layers.
- d*=3: Operates along chunks.

Use /DIM=0 to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all of the sound samples at a particular time.

/E=*endEffect*

Determines how the ends of the wave (*w*) are handled when fabricating missing neighbor values. *endEffect* has values:

- 0: Bounce method (default). Uses  $w[i]$  in place of the missing  $w[-i]$  and  $w[n-i]$  in place of the missing  $w[n+i]$ .
- 1: Wrap method. Uses  $w[n-i]$  in place of the missing  $w[-i]$  and vice versa.
- 2: Zero method. Uses 0 for any missing value.
- 3: Fill method. Uses  $w[0]$  in place of the missing  $w[-i]$  and  $w[n]$  in place of the missing  $w[n+i]$ .

/HI={*f1*, *f2*, *n*}

Creates a high-pass filter based on the windowing method, using the Hanning window unless another window is specified by /WINF.

*f1* and *f2* are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

*f1* is the end of the reject band, and *f2* is the start of the pass band:

$$0 < f1 < f2 < 0.5$$

*n* is the number of FIR filter coefficients to generate. A larger number gives better stop-band rejection. A good number to start with is 101.

Use both /HI and /LO to create a bandpass filter.

/LO={*f1*, *f2*, *n*}

Creates a low-pass filter. *f1* is the end of the pass band, *f2* is the start of the reject band, and *n* is the number of FIR filter coefficients. See /HI for more details.

/NMF={*fc*, *fw* [, *eps*, *nMult*]}

Creates a maximally-flat notch filter centered at  $fc$  with a -3dB width of  $fw$ .  $fc$  and  $fw$  are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

The longest filter length allowed is 4001 points, which requires  $fw \geq 0.0079$  (1.58% of the sampling frequency).

The longest filter length allowed is 2,147,483,647 points, which requires  $fw \geq 1.07644\text{e-}05$  (0.00107644 % of the sampling frequency).

Coefficients at the ends that are smaller than the optional *eps* parameter are removed, making the filter shorter (and faster), though less accurate. The default is  $2^{-40}$ . Use 0 to retain all coefficients, no matter how small, even zero coefficients.

*nMult* specifies how much longer the filter may be to obtain the most accurate notch frequency. The default is 2 (potentially twice as many coefficients). Set *nMult*  $\leq 1$  to generate the shortest possible filter.

The maximally flat notch filter design is based on Zahradník and Vlcek, and uses arbitrary precision math (see **APMath**) to compute the coefficients.

*/WINF=windowKind*

Applies the named “window” to the filter coefficients. Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when many filter coefficients are used.

If */WINF* is not specified, the Hanning window is used. For no coefficient filtering, use */WINF=None*.

Choices for *windowKind* are:

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.

See **FFT** for window equations and details.

### Details

If *coefsWaveName* is specified, then */HI*, */LO*, and */NMF* are ignored.

If more than one of */HI*, */LO*, and */NMF* are specified, the filters are combined using linear convolution. The length of the combined filter is slightly less than the sum of the individual filter lengths.

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length should be small in comparison to the destination waves.

FilterFIR assumes that the middle point of *coefsWaveName* corresponds to the delay = 0 point. The “middle” point number =  $\text{trunc}(\text{numpts}(\text{coefsWaveName}) - 1) / 2$ . *coefsWaveName* usually contains the two-sided impulse response of a filter, and usually contains an odd number of points. This is the kind of coefficients data generated by */HI*, */LO*, and */NMF*.

FilterFIR ignores the X scaling of all waves, except when */COEF* creates a coefficients wave, which preserves the X scale *deltax* and alters the *leftx* value so that the zero-phase (center) coefficient is located at *x=0*.

### Examples

```
// Make test sound from three sine waves
Variable/G fs= 44100 // Sampling frequency
Variable/G seconds= 0.5 // Duration
Variable/G n= 2*round(seconds*fs/2)
Make/O/W/N=(n) sound // 16-bit integer sound wave
SetScale/p x, 0, 1/fs, "s", sound
Variable/G f1= 200, f2= 1000, f3= 7000
Variable/G a1=100, a2=3000, a3=1500
sound= a1*sin(2*pi*f1*x)
sound += a2*sin(2*pi*f2*x)
sound += a3*sin(2*pi*f3*x)+gnoise(10) // Add a noise floor
```

```

// Compute the sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundMag sound
soundMag= 20*log(soundMag)
SetScale d, 0, 0, "dB", soundMag

// Apply a 5 kHz low-pass filter to the sound wave
Duplicate/O sound, soundFiltered
FilterFIR/E=3/LO={4000/fs, 6000/fs, 101} soundFiltered

// Compute the filtered sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundFilteredMag soundFiltered
soundFilteredMag= 20*log(soundFilteredMag)
SetScale d, 0, 0, "dB", soundFilteredMag

// Compute the filter's frequency response in dB
Make/O/D/N=0 coefs // Double precision is recommended
SetScale/p x, 0, 1/fs, "s", coefs
FilterFIR/COEF/LO={4000/fs, 6000/fs, 101} coefs
FFT/MAG/WINF=Hanning/PAD={ (2*numpts(coefs)) }/DEST=coefsMag coefs
coefsMag= 20*log(coefsMag)
SetScale d, 0, 0, "dB", coefsMag

// Graph the frequency responses
Display/R/T coefsMag as "FIR Lowpass Example";DelayUpdate
AppendToGraph soundMag, soundFilteredMag;DelayUpdate
ModifyGraph axisEnab(left)={0,0.6}, axisEnab(right)={0.65,1}

## FilterIIR

**FilterIIR** [*flags*] [*waveName*,...]

The **FilterIIR** operation applies to each *waveName* either the automatically-designed IIR filter coefficients or the IIR filter coefficients in *coefsWaveName*. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first *waveName* or just used to filter the data in *waveName*.

The automatically-designed filter coefficients are bilinear transforms of the Butterworth analog prototype with an optional variable-width notch filter.

To design more advanced IIR filters, see **Designing the IIR Coefficients**.

### Parameters

*waveName* may be multidimensional, but only the one dimension selected by /DIM is filtered (for two-dimensional filtering, see **MatrixFilter**).

*waveName* may be omitted for the purpose of checking the format of *coefsWaveName*. If the format is detectably incorrect an error code will be returned in V\_flag. Use /Z to prevent command execution from stopping.

### Flags

/CASC	Specifies that <i>coefsWaveName</i> contains cascaded bi-quad filter coefficients. The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form 1 filtering. See <b>Cascade Details</b> .
/COEF [=coefsWaveName]	<p>Replaces the first output <i>waveName</i> by the filter coefficients instead of the filtered results or, when <i>coefsWaveName</i> is specified, replaces the output wave(s) by the result of filtering <i>waveName</i> with the IIR coefficients in <i>coefsWaveName</i>.</p> <p><i>coefsWaveName</i> must not be one of the destination <i>waveNames</i>. It must be single- or double-precision numeric and two-dimensional.</p> <p>When used with /CASC, <i>coefsWaveName</i> must have 6 columns, containing real-valued coefficients for a product of ratios of second-order polynomials (cascaded bi-quad sections).</p> <p>If /ZP is specified, it must be complex, otherwise it must be real.</p> <p>See <b>Details</b> for the format of the coefficients in <i>coefsWaveName</i>.</p>
/DIM= <i>d</i>	<p>Specifies the wave dimension to filter.</p> <p><i>d</i>=-1: Treats entire wave as 1D (default).</p> <p><i>d</i>=0: Operates along rows.</p> <p><i>d</i>=1: Operates along columns.</p> <p><i>d</i>=2: Operates along layers.</p> <p><i>d</i>=3: Operates along chunks.</p> <p>Use /DIM=0 to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional <i>waveName</i> where each row comprises all of the sound samples at a particular time.</p>
/HI= <i>fHigh</i>	<p>Creates a high-pass Butterworth filter with the -3dB corner at <i>fHigh</i>. The order of the filter is controlled by the /ORD flag.</p> <p><i>fHigh</i> is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).</p>
/LO= <i>fLow</i>	<p>Creates a low-pass Butterworth filter with the -3dB corner at <i>fLow</i>. The /ORD flag controls the order of the filter.</p> <p><i>fLow</i> is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).</p> <p>Create bandpass and bandreject filters by specifying both /HI and /LO. For a bandpass filter, set <i>fLow</i> &gt; <i>fHigh</i>, and for a band reject filter, set <i>fLow</i> &lt; <i>fHigh</i>.</p>

<i>/N={fNotch, notchQ}</i>	Creates a notch filter with the center frequency at <i>fNotch</i> and a -3dB width of <i>fNotch/notchQ</i> .  <i>fNotch</i> is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).  <i>notchQ</i> is a number greater than 1, typically 10 to 100. Large values produce a filter that “rings” a lot.
<i>/ORD=order</i>	Sets the order of the Butterworth filter(s) created by <i>/HI</i> and <i>/LO</i> . The default is 2 (second order), and the maximum is 100.
<i>/Z=z</i>	Prevents procedure execution from aborting when an error occurs. Use <i>/Z=1</i> to handle this case in your procedures using <b>GetRTError(1)</b> rather than having execution abort. <i>/Z=0</i> is the same as no <i>/Z</i> at all.
<i>/ZP</i>	Specifies that <i>coefsWaveName</i> contains complex z-domain zeros (in column 0) and poles (in column 1) or, if <i>coefsWaveName</i> is not specified, that the first output <i>waveName</i> is to be replaced by filter coefficients in the zero-pole format. See <b>Zeros and Poles Details</b> .

### Details

FilterIIR sets *V\_flag* to 0 on success or to an error code if an error occurred. Command execution stops if an error occurs unless the */Z* flag is set. Omit */Z* and call **GetRTError** and **GetRTErrorMessage** under similar circumstances to see what the error code means.

### Direct Form 1 Details

Unless */CASC* or */ZP* are specified, the coefficients in *coefsWaveName* describe a ratio of two polynomials of the Z transform:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2} + \dots}{b_0 + b_1 z^{-1} + b_2 z^{-2} + \dots}$$

Direct Form I Implementation

$$y_i = \frac{a_0 x_i + a_1 x_{i-1} + a_2 x_{i-2} + \dots - b_1 y_{i-1} - b_2 y_{i-2} + \dots}{b_0}$$

where *x* is the input wave *waveName* and *y* is the output wave (either *waveName* again or *destWaveName*).

FilterIIR computes the filtered result using the Direct Form I implementation of *H(z)*.

The rational polynomial numerator (*a<sub>i</sub>*) coefficients in are column 0 and denominator (*b<sub>i</sub>*) coefficients in column 1 of *coefsWaveName*.

The coefficients in row 0 are the nondelayed coefficients *a<sub>0</sub>* (in column 0) and *b<sub>0</sub>* (in column 1).

The coefficients in row 1 are the *z<sup>-1</sup>* coefficients, *a<sub>1</sub>* and *b<sub>1</sub>*.

The coefficients in row *n* are the *z<sup>-n</sup>* coefficients, *a<sub>n</sub>* and *b<sub>n</sub>*.

The number of coefficients for the numerator can differ from the number of coefficients for the denominator. In this case, specify 0 for unused coefficients.

**Note:** If all the coefficients of the denominator are 0 ( $b_i = 0$  except  $b_0 = 1$ ), then the filter is actually a causal FIR filter (Finite Impulse Response filter with delay of  $n-1$ ). In this sense, FilterIIR implements a superset of the FilterFIR operation.

### Alternate Direct Form 1 Notation

The designation of  $a_i$ , etc. as the numerator is at odds with many textbooks such as *Digital Signal Processing*, which uses  $b$  for the numerator coefficients of the rational function,  $a$  for the denominator coefficients with an implicit  $a_0 = 1$ , in addition to reversing the signs of the remaining denominator coefficients so that they can write  $H(z)$  as:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{\sum_{i=0}^n b_i z^{-i}}{1 - \sum_{i=1}^n a_i z^{-i}}.$$

Coefficients derived using this notation need their denominator coefficients sign-reversed before putting them into rows 1 through  $n$  of column 1 (the second column), and the “missing” nondelayed denominator coefficient of 1.0 placed in row 0, column 1.

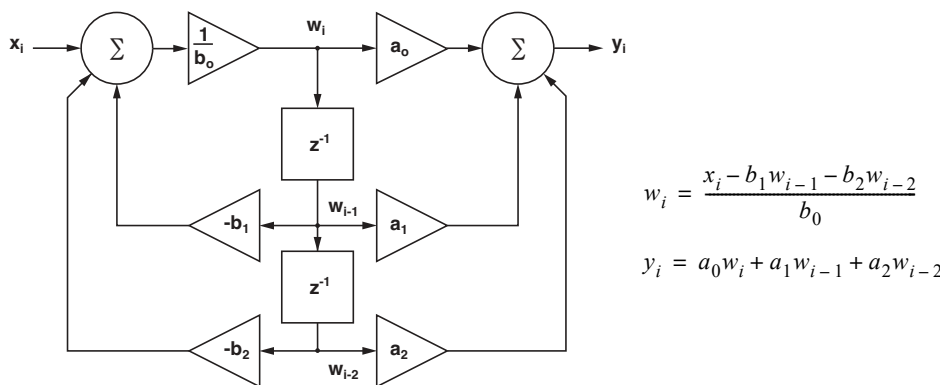

### Cascade Details

When using /CASC, coefficients in *coefsWaveName* describe the product of one or more ratios of two quadratic polynomials of the Z transform:

$$H(z) = \frac{Y(z)}{X(z)} = \prod_{k=1}^K \frac{a_{0_k} + a_{1_k} z^{-1} + a_{2_k} z^{-2}}{b_{0_k} + b_{1_k} z^{-1} + b_{2_k} z^{-2}}.$$

Each product term implements a “cascaded bi-quad section”, and  $H(z)$  can be realized by feeding the output of one section to the next one.

The cascade coefficients filter the data using a Direct Form II cascade implementation:

### Cascaded Bi-Quad Direct Form II Implementation

The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form I filtering. Cascade IIR filtering is recommended when the filter order exceeds 16 (a 16th-order Direct Form I filter has 17 numerator coefficients and 17 denominator coefficients).

*coefsWaveName* must be a six-column real-valued numeric wave. Each row describes one bi-quad section. The coefficients for the second term (or “section”) of the product ( $k=2$ ) are in the following row, etc.:

<i>k</i>	Row	Col 0	Col 1	Col 2	Col 3	Col 4	Col 5
1	0	$a_{0_1}$	$a_{1_1}$	$a_{2_1}$	$b_{0_1}$	$b_{1_1}$	$b_{2_1}$
2	1	$a_{0_2}$	$a_{1_2}$	$a_{2_2}$	$b_{0_2}$	$b_{1_2}$	$b_{2_2}$
...							

The number of coefficients for the numerator ( $a$ 's) is allowed to differ from the number of coefficients for the denominator ( $b$ 's). In this case, specify 0 for unused coefficients.

For example, a third order filter (three poles and three zeros) cascade implementation is a single-order section combined with a second order section. The values for  $a_{2_k}$ ,  $b_{2_k}$  for that section ( $k$ ) would be 0. Here the second section is specified as the first-order section:

<i>k</i>	Row	Col 0	Col 1	Col 2	Col 3	Col 4	Col 5
1	0	$a_{0_1}$	$a_{1_1}$	$a_{2_1}$	$b_{0_1}$	$b_{1_1}$	$b_{2_1}$
2	1	$a_{0_2}$	$a_{1_2}$	0	$b_{0_2}$	$b_{1_2}$	0

### Alternate Cascade Notation

In the DSP literature, the  $b_{0_k}$  gain values are typically one and the  $H(z)$  expression contains an overall gain value, usually  $K$ . Here each product term (or “section”) has a user-settable gain value. Computing the correct gain values to control overflow in integer implementations is the responsibility of the user. For floating implementations, you might as well set all  $b_{0_k}$  values to one except, say,  $b_{0_1}$ , to control the overall gain.

### Zeros and Poles Details

When using /ZP, coefficients in *coefsWaveName* contains complex zeros and poles in the (also complex) Z transform domain:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{(z - z_0)(z - z_1)(z - z_2) \dots}{(z - p_0)(z - p_1)(z - p_2) \dots}$$

*coefsWaveName* must be a two-column complex wave with zero0, zero1,... zeroN in the first column of N+1 rows, and pole0, pole1,... poleN in the second column of those same rows:

<i>k</i>	Row	Col 0	Col 1
1	0	(zero0Real, zero0Imag)	(pole0Real, pole0Imag)
2	1	(zero1Real, zero1Imag)	(pole1Real, pole1Imag)
3	2	(zero2Real, zero2Imag)	(pole2Real, pole2Imag)
...			

If a zero or pole has a nonzero imaginary component, the conjugate zero or pole must be included in *coefsWaveName*. For example, if a zero is placed at (0.7, 0.5), the conjugate is (0.7, -0.5), and that value must also appear in column 0. These two zeros form what is known as a “conjugate pair”. The conjugate values must match within the greater of 1.0e-6 or  $1.0e-6 * |\text{zeroOrPole}|$ .

Use (0,0) for unused poles or zeros, as a zero or pole at  $z = (0,0)$  has no effect on the filter frequency response.

The /ZP format for the coefficients is internally converted into the Direct Form 1 implementation, or into the Cascade Direct Form 2 implementation if /CASC is specified. There is no option for returning these implementation-dependent coefficients in a wave.

### Designing the IIR Coefficients

Simple IIR filters can be used or created by specifying the /LO, /HI, /ORD, /N, /CASC, and /ZP flags. Use /COEF without *coefsWaveName* to put these simple IIR filter coefficients into the first *waveName*.

More advanced IIR filters (Bessel, Chebyshev) can be designed using the separate IFDL package. IFDL is a suite of extensions and macros that you use to design FIR (Finite Impulse Response) and IIR (Infinite Impulse Response) filters and to apply them to your data. The IIR design software creates IIR coefficients based on bilinear transforms of analog prototype filters such as Bessel, Butterworth, and Chebyshev. See the WaveMetrics web site for more about IFDL.

Even without IFDL, you can create custom IIR filters by manually placing poles and zeros in the Z plane using the Pole and Zero Filter Design procedures. Copy the following line to your Procedure window and click the Compile button at the bottom of the procedure window:

```
#include <Pole And Zero Filter Design>
```

Then choose Pole and Zero Filter Design from the Analysis menu.

### Examples

```
// Make test sound from three sine waves
Variable/G fs= 44100 // Sampling frequency
Variable/G seconds= 0.5 // Duration
Variable/G n= 2*round(seconds*fs/2)
Make/O/W/N=(n) sound // 16-bit integer sound wave
SetScale/p x, 0, 1/fs, "s", sound

## FindContour

**FindContour** [*flags*] *matrixWave*, *level*

The FindContour operation creates an XY pair of waves representing the locus of the solution to *matrixWave*=*level*.

The FindContour operation was added in Igor Pro 7.00.

## FindDimLabel

---

### Flags

<code>/DSTX=destX</code>	Saves the output X data in the specified destination wave. The destination wave is created or overwritten if it already exists.
<code>/DSTY=destY</code>	Saves the output Y data in the specified destination wave. The destination wave is created or overwritten if it already exists.

### Details

FindContour uses a contour-following algorithm to generate a pair of waves describing the locus of the solution to *matrixWave=level*.

If you omit `/DSTX` the output X data is written to `W_XContour` in the current data folder.

If you omit `/DSTY` the output Y data is written to `W_YContour` in the current data folder.

The output waves are written as double-precision floating point. They use NaNs to separate different contiguous solution points.

### Example

```
Make/N=(100,200) dataWave = 1e4*gauss(x,50,10,y,100,20)
FindContour dataWave,4      // Find solution to dataWave=4
NewImage dataWave
AppendToGraph/T W_YContour vs W_XContour
```

### See Also

**AppendMatrixContour, ContourZ**

## FindDimLabel

**FindDimLabel(waveName, dimNumber, labelString)**

Returns the index value corresponding to the label for the given dimension. Returns -1 if the label is for the entire dimension. Returns -2 if the label is not found.

Use *dimNumber* =0 for rows, 1 for columns, 2 for layers, or 3 for chunks.

### See Also

**GetDimLabel, SetDimLabel**

## FindDuplicates

**FindDuplicates [flags] srcWave**

The FindDuplicates operation identifies duplicate values in a wave and optionally creates various output waves. *srcWave* can be either numeric or text.

When *srcWave* is numeric, the `/DN`, `/INDX`, `/RN` and `/SN` flags create output waves as described below. If you omit all of these flags then FindDuplicates does nothing.

When *srcWave* is text, the `/DT`, `/INDX`, `/RT` and `/ST` flags create output waves as described below. If you omit all of these flags then FindDuplicates does nothing.

The FindDuplicates operation was added in Igor Pro 7.

### Flags

<code>INDX=indexWave</code>	Creates a numeric output wave containing the index of each encountered duplicate. The index is the point number in <i>srcWave</i> where a duplicate value was encountered. This flag applies to both numeric and text inputs.
<code>/Z</code>	Do not report any errors.

### Flags for Numeric Source Wave

<code>/DN=dupsWave</code>	Creates a numeric output wave that contains the duplicates.
<code>/RN=dupsRemovedWave</code>	

	Creates a numeric output wave that contains the source data with all duplicates removed.
<i>/SN=replacement</i>	Creates a numeric output wave with all duplicates replaced with <i>replacement</i> . <i>replacement</i> can be any numeric value including NaN or INF.  The output wave is W_ReplacedDuplicates in the current data folder unless you specify a different output wave using the /SNDS flag.
<i>/SNDS=dupsReplacedWave</i>	Specifies the output wave generated by /SN. If you omit /SNDS then the output wave created by /SN is W_ReplacedDuplicates in the current data folder. /SNDS without /SN has no effect.
<i>/TOL=tolerance</i>	Specifies the tolerance value for single-precision and double-precision numeric source waves.  Two values are considered duplicates if $\text{abs}(\text{value1} - \text{value2}) \leq \text{tolerance}$ By default <i>tolerance</i> is zero.

### Flags for Text Source Wave

<i>/DT=dupsWave</i>	Creates a text output wave that contains the duplicates.
<i>/RT=dupsRemovedWave</i>	Creates a text output wave that contains the source data with all duplicates removed.
<i>/ST=replacementStr</i>	Creates a text output wave with all duplicates replaced with <i>replacementStr</i> . <i>replacementStr</i> can be any text value including "".  The output wave is T_ReplacedDuplicates in the current data folder unless you specify a different output wave using the /STDS flag.
<i>/STDS=dupsReplacedWave</i>	Specifies the output wave generated by /ST. If you omit /STDS then the output wave created by /ST is T_ReplacedDuplicates in the current data folder. /STDS without /ST has no effect.

### Details

FindDuplicates scans *srcWave* and identifies duplicate values. The first instance of any value is not considered a duplicate. Duplicates are either identical, as is the case with integer or text waves, or values that are within a specified tolerance in the case of single-precision or double-precision numeric waves.

Text comparison is case-sensitive.

The operation creates wave references for the waves specified by the various flags above. See **Automatic Creation of WAVE References** on page IV-66 for details.

### See Also

**FindLevels**, **FindValue**, **Sort**

## FindLevel

**FindLevel** [*flags*] *waveName*, *level*

The FindLevel operation searches the named wave to find the X value at which the specified Y *level* is crossed.

### Flags

<i>/B=box</i>	Sets box size for sliding average. If <i>/B=box</i> is omitted or <i>box</i> equals 1, no averaging is done. If you specify an even box size then the next higher (odd) integer is used. If you use a box size greater than 1, FindLevel will be unable to find a level crossing that occurs in the first or last $(box-1)/2$ points of the wave since these points don't have enough neighbors for computing the derived average wave values.
<i>/EDGE=e</i>	Specifies searches for either increasing or decreasing level crossing. <i>e=1:</i> Searches only for crossing where Y values are increasing as <i>level</i> is crossed from wave start towards wave end. <i>e=2:</i> Searches only for crossing where the Y values are decreasing as <i>level</i> is crossed from wave start towards wave end. <i>e=0:</i> Same as no <i>/EDGE</i> flag (searches for either increasing and decreasing level crossing).
<i>/P</i>	Computes the X crossing location in terms of point number. If <i>/P</i> is omitted, the level crossing location is computed in terms of X values.
<i>/Q</i>	Don't print results in history and don't report error if <i>level</i> is not found.
<i>/R=(startX,endX)</i>	Specifies an X range of the wave to search. You may exchange <i>startX</i> and <i>endX</i> to reverse the search direction.
<i>/R=[startP,endP]</i>	Specifies a point range of the wave to search. You may exchange <i>startP</i> and <i>endP</i> to reverse the search direction. If you specify the range as <i>/R=[startP]</i> then the end of the range is taken as the end of the wave. If <i>/R</i> is omitted, the entire wave is searched.
<i>/T=dx</i>	Search for two level crossings. <i>dx</i> must be less than <i>minWidthX</i> , so you must also specify <i>/M</i> if you use <i>/T</i> . (FindLevel limits <i>dx</i> so that second search start isn't beyond where the first search for next edge will be.)
<i>/T=dx</i>	Performs a second search after finding the initial level crossing. The second search starts <i>dx</i> units beyond the initial level crossing and looks back in the direction of the initial crossing. If FindLevel finds a second level crossing, it sets <i>V_LevelX</i> to the average of the initial and second crossings. Otherwise, it sets <i>V_LevelX</i> to the initial crossing.

### Details

FindLevel scans through the wave comparing *level* to values derived from the Y values of the wave. Each derived value is a sliding average of the Y values.

FindLevel searches for two derived wave values that straddle *level*. If it finds these values it computes the X value at which *level* is located by linearly interpolating between the straddling Y values.

**Note:** FindLevel does not locate values exactly equal to *level*; it locates transitions through *level*. See **BinarySearch** for one method of locating exact values.

FindLevel reports its results by setting these variables:

<i>V_flag</i>	0: <i>level</i> was found. 1: <i>level</i> was not found.
<i>V_LevelX</i>	Interpolated X value at which <i>level</i> was found, or the corresponding point number if <i>/P</i> is specified.
<i>V_rising</i>	0: Y values at the crossing are decreasing from wave start towards wave end. 1: Y values at the crossing are increasing.

If you omit the /Q flag then FindLevel also reports its results by printing them in the history area.

If *level* is not found, and if you omit the /Q flag, FindLevel generates an error which puts up an error alert and halts execution of any command line or macro that is in progress.

V\_LevelX is returned in terms of the X scaling of the named wave unless you use the /P flag, in which case it is in terms of point number.

The FindLevel operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

## FindLevels

**FindLevels** [*flags*] *waveName*, *level*

The FindLevels operation searches the named wave to find one or more X values at which the specified Y *level* is **crossed**.

To find where the wave is equal to a given value, use **FindValue** instead.

### Flags

/B= <i>box</i>	Sets box size for sliding average. See the <b>FindLevel</b> operation.
/D= <i>destWaveName</i>	Specifies wave into which FindLevels is to store the level crossing values. If /D and /DEST are omitted, FindLevels creates a wave named W_FindLevels to store the level crossing values in.
/DEST= <i>destWaveName</i>	Same as /D. Both /D and /DEST create a real wave reference for the destination wave in a user function. See <b>Automatic Creation of WAVE References</b> on page IV-66 for details.
/EDGE= <i>e</i>	Specifies searches for either increasing or decreasing level crossing. <i>e</i> =1: Searches only for crossings where the Y values are increasing as level is crossed from wave start towards wave end. <i>e</i> =2: Searches only for crossings where the Y values are decreasing as level is crossed from wave start towards wave end. <i>e</i> =0: Same as no /EDGE flag (searches for both increasing and decreasing level crossings).
/M= <i>minWidthX</i>	Sets the minimum X distance between level crossings. This determines where FindLevels searches for the next crossing after it has found a level crossing. The search starts <i>minWidthX</i> X units beyond the crossing. The default value for <i>minWidthX</i> is 0.
/N= <i>maxLevels</i>	Sets a maximum number of crossings that FindLevels is to find. The default value for <i>maxLevels</i> is the number of points in the specified range of <i>waveName</i> .
/P	Compute crossings in terms of points. See the <b>FindLevel</b> operation.
/Q	Doesn't print to history and doesn't abort if no levels are found.
/R=( <i>startX,endX</i> )	Specifies X range. See the <b>FindLevel</b> operation.
/R=[ <i>startP,endP</i> ]	Specifies point range. See the <b>FindLevel</b> operation.
/T= <i>dx</i>	Search for two level crossings. <i>dx</i> must be less than <i>minWidthX</i> , so you must also specify /M if you use /T. (FindLevels limits <i>dx</i> so that second search start isn't beyond where the first search for next edge will be.) See <b>FindLevel</b> for more about /T.

### Details

The algorithm for finding a level crossing is the same one used by the **FindLevel** operation.

## FindListItem

---

If FindLevels finds *maxLevels* crossings or can not find another level crossing, it stops searching.

FindLevels sets the following variables:

V\_flag                    0: *maxLevels* level crossings were found.  
                          1: At least one but less than *maxLevels* level crossings were found.  
                          2: No level crossings were found.

V\_LevelsFound    Number of level crossings found.

### Examples

```
Make/O/D/N=0 destWave
FindLevels/Q/D=destWave data, 5
if (V_LevelsFound)
    Print destWave[0]    // First crossing X location

FindLevels/Q/D=destWave data, 5
if (V_LevelsFound)
    Print destWave[0]    // First crossing X location
```

### See Also

The **FindLevel** operation for details about the level crossing detection algorithm and the /B, /P, /Q, /R, and /T flag values.

The FindLevels operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

## FindListItem

**FindListItem**(*itemStr*, *listStr* [, *listSepStr* [, *start* [, *matchCase* ]]])

The FindListItem function returns a numeric offset into *listStr* where *itemStr* begins. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use FindListItem to locate the start of an item in a string containing a "wave0;wave1;" style list such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

Use WhichListItem to determine the index of an item in the list.

If *itemStr* is not found, if *listStr* is "", or if *start* is not within the range of 0 to strlen(*listStr*)-1, then -1 is returned.

*listSepStr*, *startIndex*, and *matchCase* are optional; their defaults are ";", 0, and 1 respectively.

### Details

*ItemStr* may have any length.

*listStr* is searched for the first instance of the item string bound by a *listSepStr* on the left and a *listSepStr* on the right. The returned number is the character index where the first character of *itemStr* was found in *listSepStr*.

The search starts from the character position in *listStr* specified by *start*. A value of 0 starts with the first character in *listStr*, which is the default if *start* is not specified.

*listString* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are always case-sensitive. The comparison of *itemStr* to the contents of *listStr* is usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparison case insensitive.

In Igor6, only the first byte of *listSepStr* was used. In Igor7 and later, all bytes are used.

If *startIndex* is specified, then *listSepStr* must also be specified. If *matchCase* is specified, *startIndex* and *listSepStr* must be specified.

### Examples

```
Print FindListItem("w1", "w0;w1;w2," )                    // prints 3
Print FindListItem("v2", "v1,v2,v3,", ",")               // prints 3
Print FindListItem("v2", "v0,v2,v2,", ",", 4)            // prints 6
Print FindListItem("C", "a;c;C;")                        // prints 4
Print FindListItem("C", "a;c;C;", ",", 0, 0)             // prints 2
```

## FindPeak

**FindPeak** [*flags*] *waveName*

The FindPeak operation searches for a minimum or maximum by analyzing the smoothed first and second derivatives of the named wave. Information about the peak position, amplitude, and width are returned in the output variables.

### Flags

Some of the flags have the same meaning as for the FindLevel operation.

/B= <i>box</i>	Sets box size for sliding average.
/I	Modify the search criteria to accommodate impulses (peaks of one sample) by requiring only one value to exceed <i>minLevel</i> .  The default criteria requires that two successive values exceed <i>minLevel</i> for a peak to be found (or two successive values be less than the /M level when searching for negative peaks).  Impulses can also be found by omitting <i>minLevel</i> , in which case /I is superfluous.
/M= <i>minLevel</i>	Defines minimum level of a peak. /N changes this to maximum level (see <b>Details</b> ).
/N	Searches for a negative peak (minimum) rather than a positive peak (maximum).
/P	Location output variables (see <b>Details</b> ) are reported in terms of (floating point) point numbers. If /P is omitted, they are reported as X values.
/Q	Doesn't print to history and doesn't abort if no peak is found.
/R=( <i>startX,endX</i> )	Specifies X range and direction for search.
/R=[ <i>startP,endP</i> ]	Specifies point range and direction for search.

### Details

FindPeak sets the following variables:

V_flag	Set only when using the /Q flag.  0: Peak was found.  Any nonzero value means the peak was not found.
V_LeadingEdgeLoc	Interpolated location of the peak edge closest to <i>startX</i> or <i>startP</i> . If you use the /P flag, V_LeadingEdgeLoc is a point number rather than to an X value. If the edge was not found, this value is NaN.
V_PeakLoc	Interpolated X value at which the peak was found. If you use the /P flag, FindPeak sets V_PeakLoc to a point number rather than to an X value. Set to NaN if peak wasn't found.
V_PeakVal	The <i>approximate</i> Y value of the found peak. If the peak was not found, this value is NaN (Not a Number).
V_PeakWidth	Interpolated peak width. If you use the /P flag, V_PeakWidth is expressed in point numbers rather than as an X value. V_PeakWidth is never negative. If either peak edge was not found, this value is NaN.
V_TrailingEdgeLoc	Interpolated location of the peak edge closest to <i>endX</i> or <i>endP</i> . If you use the /P flag, V_TrailingEdgeLoc is a point number rather than to an X value. If the edge was not found, this value is NaN.

FindPeak computes the sliding average of the input wave using the BoxSmooth algorithm with the *box* parameter. The peak center is found where the derivative of this smoothed result crosses zero. The peak edges are found where the second derivative of the smoothed result crosses zero. Linear interpolation of the derivatives is used to more precisely locate the center and edges. The peak value is simply the greater of the two unsmoothed values surrounding the peak center (if /N, then the lesser value).

## FindPointsInPoly

---

FindPeak is not a high-accuracy measurement routine; it is intended as a simple peak-finder. Use the **PulseStats** operation for more precise statistics.

Without /M, a peak is found where the derivative crosses zero, regardless of the peak height.

If you use the /M=*minLevel* flag, FindPeak ignores peaks that are lower than *minLevel* (i.e., the Y value of a found peak will exceed *minLevel*) in the box-smoothed input wave. If /N is also specified (search for minimum), FindPeak ignores peaks whose amplitude is greater than *minLevel* (i.e., the Y value of a found peak will be less than *minLevel*).

Without /I, a peak must have two successive values that exceed *minLevel*. Use /I when you are searching for peaks that may have only one value exceeding *minLevel*.

The search for the peak begins at *startX* (or the first point of the wave if /R is not specified), and ends at *endX* (or the last point of the wave if no /R). Searching backwards is permitted, and exchanges the values of V\_LeadingEdgeLoc and V\_TrailingEdgeLoc.

A simple automatic peak-finder is implemented in the procedure file:

```
#include <Peak AutoFind>
```

one of the #include <Multi-peak fitting 1.3> procedures that provides support for Gaussian, Lorentzian, and Voigt fitting functions. See the “Multi-peak fit” example experiment for details (:Examples:Curve Fitting: folder).

The FindPeak operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

### See Also

The **PulseStats** operation, the **FindLevel** operation for details about the /B, /P, /Q, and /R flag values.

## FindPointsInPoly

**FindPointsInPoly** *xWaveName*, *yWaveName*, *xPolyWaveName*, *yPolyWaveName*

The FindPointsInPoly operation determines if points fall within a certain polygon. It can be used to write procedures that operate on a subset of data identified graphically in a graph.

### Details

FindPointsInPoly determines which points in *yWaveName* vs *xWaveName* fall within the polygon defined by *yPolyWaveName* vs *xPolyWaveName*.

*xWaveName* must have the same number of points as *yWaveName* and *xPolyWaveName* must have the same number of points as *yPolyWaveName*.

FindPointsInPoly creates an output wave named W\_inPoly with the same number of points as *xWaveName*. FindPointsInPoly indicates whether the point *yWaveName*[p] vs *xWaveName*[p] falls within the polygon by setting W\_inPoly [p] =1 if it is within the polygon, or W\_inPoly [p] =0 if it is not.

FindPointsInPoly uses integer arithmetic with a precision of about 1 part in 1000. This should be good enough for visually determined (hand-drawn) polygons but might not be sufficient for mathematically generated polygons.

The FindPointsInPoly operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

### See Also

The **GraphWaveDraw** operation.

## FindRoots

**FindRoots** [*flags*] *funcspec*, *pWave* [, *funcspec*, *pwave* [, ...]]

**FindRoots** /P=*PolyCoefsWave*

The FindRoots operation determines roots or zeros of a specified nonlinear function or system of functions. The function or system of functions must be defined in the form of Igor user procedures.

Using the second form of the command, FindRoots finds all the complex roots of a polynomial with real coefficients. The polynomial coefficients are specified by *PolyCoefsWave*.

**Flags for roots of nonlinear functions**

<i>/B [= doBracket]</i>	Specifies bracketing for roots of a single nonlinear function only. <i>doBracket=0:</i> Skips an initial check of the root bracketing values and the possible search for bracketing values. This means that you must provide good bracketing values via the <i>/L</i> and <i>/H</i> flags. See <i>/L</i> and <i>/H</i> flags for details on bracketing of roots. <i>/B</i> alone is the same as <i>/B=0</i> . <i>doBracket=1:</i> Uses default root bracketing.
<i>/F=trustRegion</i>	Sets the expansion factor of the trust region for the search algorithm when finding roots of systems of functions. Smaller numbers will result in a more stable search, although for some functions larger values will allow the search to zero in on a root more rapidly. Default is 1.0; useful values are usually between 0.1 and 100.
<i>/I=maxIters</i>	Sets the maximum number of iterations in searching for a root to <i>maxIters</i> . Default is 100.
<i>/L=lowBracket</i> <i>/H=highBracket</i>	<i>/L</i> and <i>/H</i> are used only when finding roots of a single nonlinear function. <i>lowBracket</i> and <i>highBracket</i> are X values that bracket a zero crossing of the function. A root is found between the bracketing values.  If <i>lowBracket</i> and <i>highBracket</i> are on the same side of zero, it will try to find a minimum or maximum between <i>lowBracket</i> and <i>highBracket</i> . If it is found, and it is on the other side of zero, Igor will find two roots.  If <i>lowBracket</i> and <i>highBracket</i> are on the same side of zero, but no suitable extreme point is found between, it will search outward from these values looking for a zero crossing. If it is found, Igor determines one root.  If <i>lowBracket</i> and <i>highBracket</i> are equal, it adds 1.0 to <i>highBracket</i> before looking for a zero crossing.  The default values for <i>lowBracket</i> and <i>highBracket</i> are zero. Thus, not using either <i>lowBracket</i> or <i>highBracket</i> is the same as <i>/L=0/H=1</i> .
<i>/Q</i>	Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.
<i>/T=tol</i>	Sets the acceptable accuracy to <i>tol</i> . That is, the reported root should be within $\pm tol$ of the real root.
<i>/X=xWave</i> <i>/X={x1, x2, ...}</i>	Sets the starting point for searching for a root of a system of functions. There must be as many X values as functions. The starting point can be specified with a wave having as many points as there are functions, or you can write out a list of X values in braces. If you are finding roots of a single function, use <i>/L</i> and <i>/H</i> instead.  If you specify a wave, this wave is also used to receive the result of the root search.
<i>/Z=yValue</i>	Finds other solutions, that is, places where $f(x) = yValue$ . FindRoots usually finds zeroes — places where $f(x) = 0$ .

**Flag for roots of polynomials**

<i>/P=PolyCoefsWave</i>	Specifies a wave containing real polynomial coefficients. With this flag, it finds polynomial roots and does not expect to find user function names on the command line.  The <i>/P</i> flag causes all other flags to be ignored.  Use of this flag is not permitted in a thread-safe function.
-------------------------	--

**Parameters**

*func* specifies the name of a user-defined function.

*pwave* gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified. It is intended for your private use to pass adjustable constants to your function.

These parameters occur in pairs. For a one-dimensional problem, use a single *func, pwave* pair. An N-dimensional problem requires N pairs unless you use the combined function form (see **Combined Format for Systems of Functions**).

### Function Format for 1D Nonlinear Functions

Finding roots of a nonlinear function or system of functions requires that you realize the function in the form of an Igor user function of a certain form. In the FindRoots command you then specify the functions with one or more function names paired with parameter wave names. See **Finding Function Roots** on page III-290 for detailed examples.

The functions must have a particular form. If you are finding the roots of a single 1D function, it should look like this:

```
Function myFunc(w,x)
    Wave w
    Variable x
    return f(x)          // an expression ...
End
```

Replace “f (x)” with an appropriate expression. The FindRoots command might then look like this:

```
FindRoots /L=0 /H=1 myFunc, cw          // cw is a parameter wave for myFunc
```

### Function Format for Systems of Multivariate Functions

If you need to find the roots of a system of multidimensional functions, you can use either of two forms. In one form, you provide N functions with N independent variables. You must have a function for each independent variable. For instance, to find the roots of two 2D functions, the functions must have this form:

```
Function myFunc1(w, x1, x2)
    Wave w
    Variable x1, x2
    return f1(x1, x2)    // an expression ...
End

Function myFunc2(w, x1, x2)
    Wave w
    Variable x1, x2
    return f2(x1, x2)    // an expression ...
End
```

In this case, the FindRoots command might look like this (where cw1 and cw2 are parameter waves that must be made before executing FindRoots):

```
FindRoots /X={0,1} myFunc1, cw1, myFunc2, cw2
```

You can also use a wave to pass in the X values. Make sure you have the right number of points in the X wave — it must have N points for a system of N functions.

```
Function myFunc1(w, xW)
    Wave w, xW
    return f1(xW[0], xW[1]) // an expression ...
End

Function myFunc2(w, xW)
    Wave w, xW
    return f2(xW[0], xW[1]) // an expression ...
End
```

### Combined Format for Systems of Functions

For large systems of equations it may get tedious to write a separate function for each equation, and the FindRoots command line will get very long. Instead, you can write it all in one function that returns N Y values through a Y wave. The X values are passed to the function through a wave with N elements. The parameter wave for such a function must have N columns, one column for each equation. The parameters for equation N are stored in column N-1. FindRoots will complain if any of these waves has other than N rows.

Here is an template for such a function:

```
Function myCombinedFunc(w, xW, yW)
    Wave w, xW, yW
    yW[0] = f1(w[0][...], xW[0], xW[1],..., xW[N-1])
    yW[1] = f2(w[1][...], xW[0], xW[1],..., xW[N-1])
```

```

...
yW[N-1] = fN(w[N-1][...], xW[0], xW[1], ..., xW[N-1])
End

```

When you use this form, you only have one function and parameter wave specification in the FindRoots command:

```

Make/N=(nrows, nequations) paramWave
fill in paramWave with values
Make/N=(number of equations) guessWave
guessWave = {x0, x1, ..., xN}
FindRoots /X=guessWave myCombinedFunc, paramWave

```

FindRoots has no idea how many actual equations you have in the function. If it doesn't match the number of rows in your waves, your results will not be what you expect!

### Coefficients for Polynomials

To find the roots of a polynomial, you first create a wave with the correct number of points. For a polynomial of degree N, create a wave with N+1 points. For instance, to find roots of a cubic equation you need a four-point wave.

The first point (row zero) of the wave contains the constant coefficient, the second point contains the coefficient for X, the third for  $X^2$ , etc.

There is no hard limit on the maximum degree, but note that there are significant numerical problems associated with computations involving high-degree polynomials. Round-off error most likely limits reasonably accurate results to polynomials with degree limited to 20 to 30.

Ultimately, if you are willing to accept very limited accuracy, the numerical problems will result in a failure to converge. In limited testing, we found no failures to converge with polynomials up to at least degree 100. At degree 150, we found occasional failures. At degree 200 the failures were frequent, and at degree 500 we found no successes.

Note that you really can't evaluate a polynomial with such high degree, and we have no idea if the computed roots for a degree-100 polynomial have any practical relationship to the actual roots.

While FindRoots is a thread-safe operation, finding polynomial roots is not. Using FindRoots/P=polyWave in a ThreadSafe function results in a compile error.

### Results for Nonlinear Functions and Systems of Functions

The FindRoots operation reports success or failure via the V\_flag variable. A nonzero value of V\_flag indicates the reason for failure:

V_flag=0:	Successful search for a root. Otherwise, the value indicates what went wrong:
V_flag=1:	User abort.
V_flag=3:	Exceeded maximum allowed iterations
V_flag=4:	/T=tol was too small. Reported by the root finder for systems of nonlinear functions.
V_flag=5:	The search algorithm wasn't making sufficient progress. It may mean that /T=tol was set to too low a value, or that the search algorithm has gotten trapped at a false root. Try restarting from a different starting point.
V_flag=6:	Unable to bracket a root. Reported when finding roots of single nonlinear functions.
V_flag=7:	Fewer roots than expected. Reported by the polynomial root finder. This may indicate that roots were successfully found, but some are doubled. Happens only rarely.
V_flag=8:	Decreased degree. Reported by the polynomial root finder. This indicates that one or more of the highest-order coefficients was zero, and a lower degree polynomial was solved.
V_flag=9:	Convergence failure or other numerical problem. Reported by the polynomial root finder. This indicates that a numerical problem was detected during the computation. The results are not valid.

## FindSequence

---

The results of finding roots of a single 1D function are put into several variables:

V_numRoots	The number of roots found. Either 1 or 2.
V_Root	The root.
V_YatRoot	The Y value of the function at the root. <i>Always</i> check this; some discontinuous functions may give an indication of success, but the Y value at the found root isn't even close to zero.
V_Root2	Second root if FindRoots found two roots.
V_YatRoot2	The Y value at the second root.

Results for roots of a system of nonlinear functions are reported in waves:

W_Root	X values of the root of a system of nonlinear functions. If you used /X=xWave, the root is reported in your wave instead.
W_YatRoot	The Y values of the functions at the root of a system of nonlinear functions. Only one root is found during a single call to FindRoots.

Roots of a polynomial are reported in a wave:

W_polyRoots	A complex wave containing the roots of a polynomial. The number of roots should be equal to the degree of the polynomial, unless a root is doubled.
-------------	---

### See Also

**Finding Function Roots** on page III-290.

The FindRoots operation uses the Jenkins-Traub algorithm for finding roots of polynomials:

Jenkins, M.A., Algorithm 493, Zeros of a Real Polynomial, *ACM Transactions on Mathematical Software*, 1, 178-189, 1975. Used by permission of ACM (1998).

## FindSequence

**FindSequence** [*flags*] *srcWave*

The FindSequence operation finds the location of the specified sequence starting the search from the specified start point. The result of the search stored in V\_value is the index of the entry in the wave where the first value is found or -1 if the sequence was not found.

### Flags

/FNAN	Specifies searching for a NaN value when srcWave is floating point. This flag was added in Igor Pro 7.00.
/I=wave	Specifies an integer sequence wave for integer search.
/M=val	If there are repeating entries in the match sequence, <i>val</i> is a tolerance value that specifies the maximum difference between the number of repeats. So, for example, if the match sequence is aaabbccc and the <i>srcWave</i> contains a sequence aabbcc then the sequence will not be considered a match if <i>val</i> =0 but will be considered a match if <i>val</i> =1.
/S=start	Sets starting point of the search. If /S is not specified, start is 0.
/T=tolerance	Defines the tolerance (value $\pm$ <i>tolerance</i> will be accepted) when comparing floating point numbers.
/U=uValue	Specifies the match sequence wave in case of unsigned long range.
/V=rValue	Specifies the match sequence wave in the case of single/double precision numbers.
/Z	No error reporting.

**Details**

If the match sequence is specified via the /V flag, it is considered to be a floating point wave (i.e., single or double precision) in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the /T flag, the default value  $1.0^{-7}$ .

If the match sequence is specified via the /I flag, the sequence is assumed to be an integer wave (this includes both signed and unsigned char, signed and unsigned short as well as long). In this case *srcWave* must also be of integer type and the operation searches for the sequence based on exact equality between the match sequence and entries in the wave as signed long integers.

If the match sequence is unsigned long wave use the /U flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

```
col=floor(V_value/rowsInWave)
row=V_value-col*rowsInWave
```

**See Also**

The **FindValue** operation.

**FindValue**

**FindValue** [*flags*] *srcWave*

**FindValue** [*flags*] *txtWave*

This operation finds the location of the specified value starting the search from the specified start point. The result of the search stored in *V\_value* is the index of the entry in the wave where the value is found or -1 if not found.

**Flags**

/I= <i>ival</i>	Specifies an integer value for integer search.
/S= <i>start</i>	Sets start of search in the wave. If /S is not specified, start is set to 0.
/T= <i>tolerance</i>	Use this flag when comparing floating point numbers to define a non-negative tolerance such that the specified value $\pm$ <i>tolerance</i> will be accepted.
/TEXT= <i>templateString</i>	Specifies a template string that will be searched for in <i>txtWave</i> .
/TXOP= <i>txOptions</i>	Specifies the search options using a combination of binary values. <ul style="list-style-type: none"> <li>1: Case sensitive</li> <li>2: Whole word</li> <li>4: Whole wave element</li> </ul>
/U= <i>uValue</i>	Specifies the match value in case of unsigned long range.
/V= <i>rValue</i>	Specifies the match value in the case of single/double precision numbers. For most purposes you should also use /T to specify the tolerance.
/Z	No error reporting.

**Details**

If the match value is specified via the /V flag, it is considered to be a floating point value in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the /T flag, the value  $10^{-7}$  is used.

If the match value is specified via the /I flag, the value is assumed to be an integer. In this case *srcWave* must be of integer type and the operation searches for the value based on exact equality between the match value and entries in the wave as signed long integers.

If the match value is unsigned long use the /U flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

```
col=floor(V_value/rowsInWave)
row=V_value-col*rowsInWave
```

When searching for text in a text wave the operation creates the variable `V_value` as above but it also creates the variable `V_startPos` to specify the position of *templateString* from the start of the particular wave element.

### Example

```
Make jack = sin(x/8)          // Single-precision floating point
Display jack

// This prints -1 because 0.5 +/- 1.0E-7 does not occur in wave jack
FindValue /V=.5 jack; Print V_value

// This prints 21 because 0.5 +/- 0.01 does occur in wave jack
FindValue /V=.5 /T=.01 jack; Print V_value

// The value of jack(21), to 6 decimal digits of precision, is 0.493920
Print jack(21)
```

## FitFunc

### FitFunc

Marks a user function as a user-defined curve fit function. By default, only functions marked with this keyword are displayed in the Function menu in the Curve Fit dialog.

If you wish other functions to be displayed in the Function menu, you can select the checkbox labelled "Show old-style functions (missing FitFunc keyword)".

### See Also

**User-Defined Fitting Functions** on page III-219.

## floor

### floor(*num*)

The floor function returns the closest integer less than or equal to *num*.

### See Also

The **round**, **ceil**, and **trunc** functions.

## FontList

### FontList(*separatorStr* [, *options*])

The FontList function returns a list of the installed fonts, separated by the characters in *separatorStr*.

### Parameters

A maximum of 10 bytes from *separatorStr* are appended to each font name as the output string is generated. *separatorStr* is usually ";".

Use *options* to limit the returned font list according to font type. It is restricted to returning only scalable fonts (TrueType, PostScript, or OpenType), which you can do with *options* = 1.

To get a list of nonscalable fonts (bitmap or raster), use:

```
String bitmapFontList = RemoveFromList(FontList(";",1), FontList(";""))
```

(Most Mac OS X fonts are scalable, so bitmapFontList may be empty.)

### Examples

```
Function SetFont(fontName)
    String fontName
    Prompt fontName,"font name:",popup,FontList(";")+ "default;"
    DoPrompt "Pick a Font", fontName

    Print fontName

    Variable type= WinType("")          // target window type
    String windowName= WinName(0,127)
    if((type==1) || (type==3) || (type==7)) // graph, panel, layout
```

```

        Print "Setting drawing font for "+windowName
        Execute "SetDrawEnv fname=\""+fontName+"\" "
    else
        if( type == 5 )                                // notebook
            Print "Setting font for selection in "+windowName
            Notebook $windowName font=fontName
        endif
    endif
End

```

### See Also

The **FontSizeStringWidth**, **FontSizeHeight**, and **WinType** functions, and the **Execute**, **SetDrawEnv**, and **Notebook Operations**.

## FontSizeHeight

**FontSizeHeight**(*fontNameStr*, *fontSize*, *fontstyle* [,*appearanceStr*])

The FontSizeHeight function returns the line height in pixels of any string when rendered with the named font and the given font style and size.

### Parameters

*fontNameStr* is the name of the font, such as "Helvetica".

*fontSize* is the size (height) of the font in pixels.

*fontStyle* is text style (bold, italic, etc.). Use 0 for plain text.

### Details

The returned height is the sum of the font's ascent and descent heights. Variations in *fontStyle* and typeface design cause the actual font height to be different than *fontSize* would indicate. (Typically a font "height" refers to only the ascent height, so the total height will be slightly larger to accommodate letters that descend below the baseline, such as g, p, q, and y).

*FontSize* is in pixels. To obtain the height of a font specified in points, use the **ScreenResolution** function and the conversion factor of 72 points per inch (see Examples).

If the named font is not installed, FontSizeHeight returns NaN.

FontSizeHeight understands "default" to mean the current experiment's default font.

*fontStyle* is a binary coded integer with each bit controlling one aspect of the text style as follows:

Bit 0:	Bold
Bit 1:	Italic
Bit 2:	Underline
Bit 4:	Strikethrough

To set bit 0 and bit 2 (bold, underline), use  $2^0 + 2^2 = 1 + 4 = 5$  for *fontStyle*. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

The optional *appearanceStr* parameter has no effect on Windows.

On Macintosh, the *appearanceStr* parameter is used for determining the height of a string drawn by a control. Set *appearanceStr* to "native" if you are measuring the height of a string drawn by a "native GUI" control or to "os9" if not.

Set *appearanceStr* to "default" to use the appearance set by the user in the Miscellaneous Settings dialog. "os9" is the default value.

Usually you will want to set *appearanceStr* to the S\_Value output of **DefaultGUIControls**/W=winName when determining the height of a string drawn by a control.

### Examples

```

Variable pixels= 12 * ScreenResolution/72           // convert 12 points to pixels
Variable pixelHeight= FontSizeHeight("Helvetica",pixels,0)
Print "Height in points= ", pixelHeight * 72/ScreenResolution

```

```
Function FontIsInstalled(fontName)
    String fontName
    if( numtype(FontSizeHeight(fontName,10,0)) == 2 )
        return 0          // NaN returned, font not installed
    else
        return 1
    endif
End
```

### See Also

The **FontList**, **FontSizeStringWidth**, **numtype**, **ScreenResolution**, and **DefaultGUIControls** functions.

## FontSizeStringWidth

**FontSizeStringWidth**(*fontNameStr*, *fontSize*, *fontstyle*, *theStr* [,*appearanceStr*])

The **FontSizeStringWidth** function returns the width of *theStr* in pixels, when rendered with the named font and the given font style and size.

### Parameters

*fontNameStr* is the name of the font, such as "Helvetica".

*fontSize* is the size (height) of the font in pixels.

*fontStyle* is text style (bold, italic, etc.). Use 0 for plain text.

*theStr* is the string whose width is being measured.

The optional *appearanceStr* parameter has no effect on Windows.

On Macintosh, the *appearanceStr* parameter is used for determining the width of a string drawn by a control. Set *appearanceStr* to "native" if you are measuring the width of a string drawn by a "native GUI" control or to "os9" if not.

Set *appearanceStr* to "default" to use the appearance set by the user in the Miscellaneous Settings dialog. "os9" is the default value.

Usually you will want to set *appearanceStr* to the *S\_Value* output of **DefaultGUIControls**/W=winName when determining the width of a string drawn by a control.

### Details

If the named font is not installed, **FontSizeStringWidth** returns NaN.

**FontSizeStringWidth** understands "default" to mean the current experiment's default font.

*FontSize* is in pixels. To obtain the width of a font specified in points, use the **ScreenResolution** function and the conversion factor of 72 points per inch (see Examples).

*fontStyle* is a binary coded integer with each bit controlling one aspect of the text style as follows:

Bit 0:	Bold
Bit 1:	Italic
Bit 2:	Underline
Bit 4:	Strikethrough

To set bit 0 and bit 2 (bold, underline), use  $2^0 + 2^2 = 1 + 4 = 5$  for *fontStyle*. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

### Examples

#### Example 1

```
Variable fsPix= 10 * ScreenResolution/72          // 10 point text in pixels
String text= "How long is this text?"
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text)
Print "width in inches= ", WidthPix / ScreenResolution
```

#### Example 2

```
Variable fsPix= 13 * ScreenResolution/72          // 13 point text in pixels
String text= "text for a control"
```

```
DefaultGUIControls/W=Panel0 // Sets S_Value
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text,S_Value)
Print "width in points= ", WidthPix / ScreenResolution * 72
```

#### See Also

The **FontList**, **FontSizeHeight**, **ScreenResolution** and **DefaultGUIControls** functions.

## for-endfor

```
for(<initialize>;<exit test>;<update>)
    <loop body>
endfor
```

A for-endfor loop executes *loop body* code until *exit test* evaluates as FALSE, zero, or until a break statement is executed within the body code. When the loop starts, the *initialize* expressions are evaluated once. For each iteration, the *exit test* is evaluated at the beginning, and the *update* expressions are evaluated at the end.

#### See Also

For **Loop** on page IV-43 and **break** for more usage details.

## FPClustering

**FPClustering** [*flags*] *srcWave*

The FPClustering operation performs cluster analysis using the farthest-point clustering algorithm. The input for the operation *srcWave* defines M points in N-dimensional space. Outputs are the waves W\_FPCenterIndex and W\_FPClusterIndex.

#### Flags

/CAC	Computes all the clusters specified by /MAXC.
/CM	Computes the center of mass for each cluster. The results are stored in the wave M_clustersCM in the current data folder. Each row corresponds to a single cluster with columns providing the respective dimensional components.
/INCD	Computes the inter-cluster distances. The result is stored in the current data folder in the wave M_InterClusterDistance, a 2D wave in which the [i][j] element contains the distance between cluster <i>i</i> and cluster <i>j</i> .
/MAXC= <i>nClusters</i>	Terminates the calculation when the number of clusters reaches the specified value. Note that this termination condition is sufficient but not necessary, i.e., the operation can terminate earlier if the farthest distance of an element from a hub is less than the average distance.
/MAXR= <i>maxRad</i>	Terminates the calculation when the maximum distance is less than or equal to <i>maxRad</i> .
/NOR	Normalizes the data on a column by column basis. The normalization makes each columns of the input span the range [0,1] so that even when <i>srcWave</i> contains columns that may be different by several orders of magnitude, the algorithm is not biased by a larger implied cartesian distance.
/Q	Don't print information to the history area.
/SHUB= <i>sHub</i>	Specifies the row which is used as a starting hub number. By default the operation uses the first row in <i>srcWave</i> .
/Z	No error reporting.

#### Details

The input for FPClustering is a 2D wave *srcWave* which consists of M rows by N columns where each row represents a point in N-dimensional space. *srcWave* can contain only finite real numbers and must be of type SP or DP. The operation computes the clustering and produces the wave W\_FPCenterIndex which contains the centers or “hubs” of the clusters. The hubs are specified by the zero-based row number in *srcWave* which contains the cluster center. In addition, the operation creates the wave W\_FPClusterIndex where each entry maps the corresponding input point to a cluster index. By default, the operation continues to add clusters

## fprintf

---

as long as the largest possible distance is greater than the average intercluster distance. You can also stop the processing when the operation has formed a specified number of clusters (see /MAXC).

The variable `V_max` contains the maximum distance between any element and its cluster hub.

It is possible that in some circumstances you can get slightly different clustering depending on your starting point. The default starting hub is row zero of *srcWave* but you can use the /SHUB flag to specify a different starting point.

FPClustering computes the Cartesian distance between points. As a result, if the scale of any dimension is significantly larger than other dimensions it might bias the clustering towards that dimension. To avoid this situation you can use the /NOR flag which normalizes each column to the range [0,1] and hence equalizes the weight of each dimension in the clustering process.

### See Also

The **KMeans** operation.

### References

Gonzalez, T., Clustering to minimize the maximum intercluster distance, *Theoretical Computer Science*, 38, 293-306, 1985.

## fprintf

**fprintf** *refNum*, *formatStr* [, *parameter*]...

The fprintf operation prints formatted output to a text file.

### Parameters

*refNum* is a file reference number from the **Open** operation used to open the file.

*formatStr* is the format string, as used by the **printf** operation.

*parameter* varies depending on *formatStr*.

### Details

If *refNum* is 1, fprintf will print to the history area instead of to a file, as if you used printf instead of fprintf. This useful for debugging purposes.

A zero value of *refNum* is used in conjunction with Program-to-Program Communication (PPC), Apple events (*Macintosh*) or DDE (*Windows*). Data that would normally be written to a file is appended to the PPC, Apple event or DDE result packet.

The fprintf operation supports numeric (real only) and string fields from structures. All other field types will cause a compile error.

### See Also

The **printf** operation for complete format and parameter descriptions. The **Open** operation and **Creating Formatted Text** on page IV-244.

## FReadLine

**FReadLine** [/N/T] *refNum*, *stringVarName*

The FReadLine operation reads bytes from a file into the named string variable. The read starts at the current file position and continues until a terminator character is read, the end of the file is reached, or the maximum number of bytes is read.

### Parameters

*refNum* is a file reference number from the **Open** operation used to create the file.

## Flags

<code>/N=<i>n</i></code>	Specifies the maximum number of bytes to read.
<code>/T=<i>termcharStr</i></code>	Specifies the terminator character. <code>/T= (num2char (13) )</code> specifies carriage return (CR, ASCII code 13). <code>/T= (num2char (10) )</code> specifies linefeed (LF, ASCII code 10). <code>/T=" ; "</code> specifies the terminator as a semicolon. <code>/T=" "</code> specifies the terminator as null (ASCII code 0). See <b>Details</b> for default behavior regarding the terminator.

## Details

If `/N` is omitted, there is no maximum number of bytes to read. When reading lines of text from a normal text file, you will not need to use `/N`. It may be of use in specialized cases, such as reading text embedded in a binary file.

If `/T` is omitted, `FReadLine` will terminate on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.) `FReadLine` reads whichever of these appears in the file, terminates the read, and returns just a CR in the output string. This default behavior transparently handles files that use CR, LF, CRLF, or LFCR as the terminator and will be suitable for most cases.

If you use the `/T` flag, then `FReadLine` will terminate on the specified character only and will return the specified character in the output string.

Once you have read all of the bytes in the file, `FReadLine` will return zero bytes via *stringVarName*. The example below illustrates testing for this.

In Igor Pro 7.00 or later, if the file data begins with the UTF-8 byte order mark (BOM) then `FReadLine` skips those bytes. In UTF-8, the BOM is the byte sequence 0xEF, 0xBB, 0xBF. If you want to check for the presence of the BOM, use **FBinRead** instead of `FReadLine`.

## Example

```
Function PrintAllLinesInFile()
    Variable refNum
    Open/R refNum as ""           // Display dialog
    if (refNum == 0)
        return -1                // User canceled
    endif

    Variable lineNumber, len
    String buffer
    lineNumber = 0
    do
        FReadLine refNum, buffer
        len = strlen(buffer)
        if (len == 0)
            break                // No more lines to be read
        endif
        Printf "Line number %d: %s", lineNumber, buffer
        if (CmpStr(buffer[len-1], "\r") != 0) // Last line has no CR ?
            Printf "\r"
        endif
        lineNumber += 1
    while (1)

    Close refNum
    return 0
End
```

The **Open** and **FBinRead** operations.

## fresnelCos

### **fresnelCos** (*x*)

The `fresnelCos` function returns the Fresnel cosine function  $C(x)$ .

$$C(x) = \int_0^x \cos\left(\frac{\pi}{2}t^2\right)dt.$$

### See Also

The **fresnelSin** and **fresnelCS** functions.

### References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

## fresnelCS

### **fresnelCS**(*x*)

The **fresnelCS** function returns both the Fresnel cosine in the real part of the result and the Fresnel sine in the imaginary part of the result.

### See Also

The **fresnelSin** and **fresnelCos** functions.

## fresnelSin

### **fresnelSin**(*x*)

The **fresnelSin** function returns the Fresnel sine function  $S(x)$ .

$$S(x) = \int_0^x \sin\left(\frac{\pi}{2}t^2\right)dt.$$

### See Also

The **fresnelCos** and **fresnelCS** functions.

### References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

## FSetPos

### **FSetPos** *refNum*, *filePos*

The **FSetPos** operation attempts to set the current file position to the given position.

### Parameters

*refNum* is a file reference number obtained from the **Open** operation when the file was opened.

*filePos* is the desired position of the file in bytes from the start of the file.

### Details

**FSetPos** generates an error if *filePos* is greater than the number of bytes in the file. You can ascertain this limit with the **FStatus** operation.

When a file that is open for writing is closed, any bytes past the end of the current file position are deleted by the operating system. Therefore, if you use **FSetPos**, make sure to set the current file position properly before closing the file.

**FSetPos** supports files of any length.

### See Also

**Open**, **FGetPos**, **FStatus**

## FStatus

### **FStatus** *refNum*

The FStatus operation provides file status information for a file.

#### Parameters

*refNum* is a file reference number obtained from the **Open** operation.

#### Details

FStatus supports files of any length.

FStatus sets the following variables:

V_flag	Nonzero (true) if <i>refNum</i> is valid, in which case FStatus sets the other variables as well.
V_filePos	Current file position for the file in bytes from the start. In Igor7 or later, if you only want to know the current file position, use <b>FGetPos</b> instead of FStatus, which is slower.
V_logEOF	Total number of bytes in the file.
S_fileName	Name of the file.
S_path	Path from the volume to the folder containing the file. For example, "hd:Folder1:Folder2:". This is suitable for use as an input to the <b>NewPath</b> operation. Note that on the Windows operating system Igor uses a colon between folders instead of the Windows-standard backslash to avoid confusion with Igor's use of backslash to start an escape sequence (see <b>Escape Sequences in Strings</b> on page IV-13).
S_info	Keyword-packed information string.

The keyword-packed information string for S\_info consists of a sequence of sections with the following form: *keyword:value*; You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions.

Here are the keywords for S\_info:

Keyword	Type	Meaning
PATH	string	Name of the symbolic path in which the file is located. This will be empty if there is no such symbolic path.
WRITEABLE	number	1 if file can be written to, 0 if not.

#### See Also

**Open**, **FGetPos**, **FSetPos**

## FTPCreateDirectory

### **FTPCreateDirectory** [*flags*] *urlStr*

The FTPCreateDirectory operation creates a directory on an FTP server on the Internet.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-257.

FTPCreateDirectory sets V\_flag to zero if the operation succeeds or to a non-zero error code if it fails.

If the directory specified by *urlStr* already exists on the server, the server contents are not touched and V\_flag is set to -1. This is not treated as an error.

#### Parameters

*urlStr* specifies the directory to create. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/test/newDirectory"). For example:

```
"ftp://ftp.wavemetrics.com/test/newDirectory"
```

*urlStr* must always end with a directory name, and must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test/newDirectory
```

If you do not specify that the path in *urlStr* is absolute, it is interpreted as relative to the FTP user's base directory. Since *pub* is the base directory for an anonymous user at *wavemetrics.com*, these URLs reference the same directory for an anonymous user:

```
ftp://ftp.wavemetrics.com//pub/test/newDirectory // Absolute path
ftp://ftp.wavemetrics.com/test/newDirectory      // Relative to base directory
```

Special characters, such as punctuation, that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-253 for additional information.

### Flags

<i>/N=portNumber</i>	Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, the default will be correct so you won't need to use the <i>/N</i> flag.
<i>/U=usernameStr</i>	Specifies the user name to be used when logging in to the FTP server. If <i>/U</i> is omitted or if <i>usernameStr</i> is "", the login is done as an anonymous user. Use <i>/U</i> if you have an account on the FTP server.
<i>/V=diagnosticMode</i>	<p>Determines what kind of diagnostic messages <b>FTPCreateDirectory</b> will display in the history area. <i>diagnosticMode</i> is a bitwise parameter, with the bits defined as follows:</p> <ul style="list-style-type: none"><li>Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.</li><li>Bit 1: Show errors. This displays additional information when errors occur.</li><li>Bit 2: Show status. This displays commands sent to the server and the server's response.</li></ul> <p>The default value for <i>diagnosticMode</i> is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.</p> <p>See <b>FTP Troubleshooting</b> on page IV-260 for other troubleshooting tips.</p>
<i>/W=passwordStr</i>	<p>Specifies the password to be used when logging in to the FTP server. Use <i>/W</i> if you have an account on the FTP server.</p> <p>If <i>/W</i> is omitted, the login is done using a default password that will work with most anonymous FTP servers.</p> <p>See <b>Safe Handling of Passwords</b> on page IV-255 for information on handling sensitive passwords.</p>
<i>/Z</i>	<p>Errors are not fatal. Will not abort procedure execution if an error occurs.</p> <p>Your procedure can inspect the <i>V_flag</i> variable to see if the transfer succeeded. <i>V_flag</i> will be zero if it succeeded, -1 if the specified directory already exists, or another nonzero value if an error occurred.</p>

### Examples

```
// Create a directory.
String url = "ftp://ftp.wavemetrics.com/pub/test/newDirectory"
FTPCreateDirectory url
```

### See Also

**File Transfer Protocol (FTP)** on page IV-257.

**FTPDelete**, **FTPDownload**, **FTPUpload**, **URLEncode**

## FTPDelete

**FTPDelete** [*flags*] *urlStr*

The FTPDelete operation deletes a file or a directory from an FTP server on the Internet.

**Warning:** If you delete a directory on an FTP server, all contents of that directory and any subdirectories are also deleted.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-257.

FTPDelete sets *V\_flag* to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the */Z* flag, can be used to allow procedures to continue to execute if an FTP error occurs.

### Parameters

*urlStr* specifies the file or directory to delete. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/test/TestFile1.txt"

*urlStr* must always end with a file name if you are deleting a file or with a directory name if you are deleting a directory. In the case of a directory, *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is absolute, it is interpreted as relative to the FTP user's base directory. Since pub is the base directory for an anonymous user at wavemetrics.com, these URLs reference the same directory for an anonymous user:

```
ftp://ftp.wavemetrics.com//pub/test
```

```
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-253 for additional information

### Flags

<i>/D</i>	Deletes a complete directory and all its contents. Omit <i>/D</i> if you are deleting a file.
<i>/N=portNumber</i>	Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, the default will be correct so you won't need to use the <i>/N</i> flag.
<i>/U=usernameStr</i>	Specifies the user name to be used when logging in to the FTP server. If <i>/U</i> is omitted or if <i>usernameStr</i> is "", the login is done as an anonymous user. Use <i>/U</i> if you have an account on the FTP server.
<i>/V=diagnosticMode</i>	<p>Determines what kind of diagnostic messages FTPDelete will display in the history area. <i>diagnosticMode</i> is a bitwise parameter, with the bits defined as follows:</p> <p>Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.</p> <p>Bit 1: Show errors. This displays additional information when errors occur.</p> <p>Bit 2: Show status. This displays commands sent to the server and the server's response.</p>

The default value for *diagnosticMode* is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.

See **FTP Troubleshooting** on page IV-260 for other troubleshooting tips.

<code>/W=passwordStr</code>	<p>Specifies the password to be used when logging in to the FTP server. Use <code>/W</code> if you have an account on the FTP server.</p> <p>If <code>/W</code> is omitted, the login is done using a default password that will work with most anonymous FTP servers.</p> <p>See <b>Safe Handling of Passwords</b> on page IV-255 for information on handling sensitive passwords.</p>
<code>/Z</code>	<p>Errors are not fatal. Will not abort procedure execution if an error occurs.</p> <p>Your procedure can inspect the <code>V_flag</code> variable to see if the transfer succeeded. <code>V_flag</code> will be zero if it succeeded, or a nonzero value if an error occurred.</p>

### Examples

```
// Delete a file.  
String url = "ftp://ftp.wavemetrics.com/test/TestFile1.txt"  
FTPDelete url
```

```
// Delete a directory.  
String url = "ftp://ftp.wavemetrics.com/test/TestDir1"  
FTPDelete/D url
```

### See Also

**File Transfer Protocol (FTP)** on page IV-257.

**FTPCreateDirectory**, **FTPDownload**, **FTPUpload**, **URLEncode**

## FTPDownload

**FTPDownload** [*flags*] *urlStr*, *localPathStr*

The **FTPDownload** operation downloads a file or a directory from an FTP server on the Internet.

**Warning:** When you download a file or directory using the path and name of a file or directory that already exists on your local hard disk, all previous contents of the local file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-257.

**FTPDownload** sets a variable named `V_flag` to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the `/Z` flag, can be used to allow procedures to continue to execute if a FTP error occurs.

If the operation succeeds, **FTPDownload** sets a string named `S_Filename` to the full file path of the downloaded file or, if the `/D` flag was used, the full path to the base directory that was downloaded. This is useful in conjunction with the `/I` flag.

If the operation fails, `S_Filename` is set to "".

### Parameters

*urlStr* specifies the file or directory to download. It consists of a naming scheme (always `ftp://`), a computer name (e.g., `ftp.wavemetrics.com` or `38.170.234.2`), and a path (e.g., `/Test/TestFile1.txt`). For example: `ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt`.

*urlStr* must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra `/` character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is an absolute path, it is interpreted as a path relative to the FTP user's base directory. Since `pub` is the base directory for an anonymous user, this URL references the same directory:

```
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-253 for additional information.

*localPathStr* and *pathName* specify the name to use for the file or directory that will be created on your hard disk. If you use a full or partial path for *localPathStr*, see **Path Separators** on page III-401 for details on forming the path.

*localPathStr* must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, *localPathStr* must not end with a colon or backslash.

FTPDownload displays a dialog through which you can identify the local file or directory in the following cases:

1. You have used the /I (interactive) flag.
2. You did not completely specify the location of the local file or directory via *pathName* and *localPathStr*.
3. There is an error in *localPathStr*. This can be either a syntactical error or a reference to a nonexistent file or directory.
4. The specified local file or directory exists and you have not used the /O (overwrite) flag.

See **Examples** for examples of constructing a URL and local path.

### Flags

/D	Downloads a complete directory. Omit it if you are downloading a file.
/I	Interactive mode which will prompt you to specify the name and location of the file or directory to be created on the local hard disk.
/M= <i>messageStr</i>	Specifies the prompt message used by the dialog in which you specify the name and location of the file or directory to be created. But see <b>Prompt Does Not Work on Macintosh</b> on page IV-137.
/N= <i>portNumber</i>	Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won't need to use the /N flag.
/O[= <i>mode</i> ]	Controls whether a local file or directory whose name is in conflict with the file or directory being downloaded is overwritten without prompting the user. <div style="margin-left: 20px;"> <i>mode</i>=0: Prompts the user to allow the overwrite. This is the default behavior if /O is omitted.  <i>mode</i>=1: Overwrites without prompting the user. If the /D flag is also used, all contents of the destination directory are deleted if it already exists. /O=1 is the same as /O.  <i>mode</i>=2: Merges files and subdirectories downloaded with the contents of the destination directory. Unlike /O=1, the contents of the destination directory are not deleted, however files and directories downloaded from the server will overwrite existing files and directories of the same name. When downloading a file this mode is accepted but has the same effect as /O=1.           </div>
/P= <i>pathName</i>	Contributes to the specification of the file or directory to be created on your hard disk. <i>pathName</i> is the name of an existing symbolic path. See <b>Examples</b> .
/S= <i>showProgress</i>	Determines if a progress dialog is displayed. <div style="margin-left: 20px;"> 0: No progress dialog.  1: Show a progress dialog (default).           </div>
/T= <i>transferType</i>	Controls the FTP transfer type. <div style="margin-left: 20px;"> 0: Image (binary) transfer (default).  1: ASCII transfer.           </div>

See **FTP Transfer Types** on page IV-260 for more discussion.

<code>/U=<i>userNameStr</i></code>	Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if <i>userNameStr</i> is "", you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.
<code>/V=<i>diagnosticMode</i></code>	<p>Determines what kind of diagnostic messages FTPDownload will display in the history area. <i>diagnosticMode</i> is a bitwise parameter, with the bits defined as follows:</p> <p>Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.</p> <p>Bit 1: Show errors. This displays additional information when errors occur.</p> <p>Bit 2: Show status. This displays commands sent to the server and the server's response.</p> <p>The default value for <i>diagnosticMode</i> is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.</p> <p>See <b>FTP Troubleshooting</b> on page IV-260 for other troubleshooting tips.</p>
<code>/W=<i>passwordStr</i></code>	<p>Specifies the password to be used when logging in to the FTP server. Use this flag if you have an account on the FTP server.</p> <p>If this flag is omitted, "nopassword" will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the <code>/W="&lt;your email address&gt;"</code> flag.</p> <p>If <code>/W</code> is omitted, the login is done using a default password that will work with most anonymous FTP servers.</p> <p>See <b>Safe Handling of Passwords</b> on page IV-255 for information on handling sensitive passwords.</p>
<code>/Z</code>	<p>Errors are not fatal. Will not abort procedure execution if an error occurs.</p> <p>Your procedure can inspect the <code>V_flag</code> variable to see if the transfer succeeded. <code>V_flag</code> will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.</p>

### Examples

Download a file using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test Folder:TestFile1.txt"
FTPDownload url, localPath
```

Download a file using a local symbolic path and file name:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String pathName = "Igor" // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPDownload/P=$pathName url, fileName
```

Download a directory using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPDownload/D url, localPath
```

### See Also

**File Transfer Protocol (FTP)** on page IV-257.

**FTPCreateDirectory**, **FTPDelete**, **FTPUpload**, **URLEncode**, **FetchURL**.

## FTPUpload

**FTPUpload** [*flags*] *urlStr*, *localPathStr*

The FTPUpload operation uploads a file or a directory to an FTP server on the Internet.

**Warning:** When you upload a file or directory to an FTP server, all previous contents of the server file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-257.

FTPUpload sets a variable named *V\_flag* to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the */Z* flag, can be used to allow procedures to continue to execute if a FTP error occurs.

If the operation succeeds, FTPUpload sets a string named *S\_Filename* to the full file path of the uploaded file or, if the */D* flag was used, to the full path to the base directory that was uploaded. This is useful in conjunction with the */I* flag.

If the operation fails, *S\_Filename* is set to "".

### Parameters

*urlStr* specifies the file or directory to create. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/Test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt".

*urlStr* must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory, in which case *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is an absolute path, it is interpreted as a path relative to the FTP user's base directory. Since pub is the base directory for an anonymous user, this URL references the same directory:

```
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-253 for additional information.

*localPathStr* and *pathName* specify the name and location on your hard disk of the local file to be uploaded. If you use a full or partial path for *localPathStr*, see **Path Separators** on page III-401 for details on forming the path.

*localPathStr* must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory. In the case of a directory, *localPathStr* must not end with a colon or backslash.

FTPUpload displays a dialog that you can use to identify the file or directory to be uploaded in the following cases:

1. You used the */I* (interactive) flag.
2. You did not completely specify the location of the file or folder to be uploaded via *pathName* and *localPathStr*.
3. There is an error in *localPathStr*. This can be either a syntactical error or a reference to a nonexistent directory.

See **Examples** for examples of constructing a URL and local path.

### Flags

<i>/D</i>	Uploads a complete directory. Omit it if you are uploading a file.
<i>/I</i>	Interactive mode which displays a dialog for choosing the local file or directory to be uploaded.

<i>/M=messageStr</i>	Specifies the prompt message used by the dialog in which you choose the local file or directory to be uploaded. But see <b>Prompt Does Not Work on Macintosh</b> on page IV-137.
<i>/N=portNumber</i>	Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won't need to use the <i>/N</i> flag.
<i>/O[=mode]</i>	<p>Overwrite. FTPUpload <i>always</i> overwrites the specified server file or directory, whether <i>/O</i> is used or not.</p> <p>If <i>/O=2</i> is <i>not</i> used, all files and subdirectories in the destination directory on the server are first deleted and then the local files and directories are uploaded to the server.</p> <p>If <i>/O=2</i> is used, the existing contents the contents of the local source directory are merged into the remote directory instead of completely overwriting it.</p>
<i>/P=pathName</i>	Contributes to the specification of the file or directory to be uploaded. <i>pathName</i> is the name of an existing symbolic path. See <b>Examples</b> .
<i>/S=showProgress</i>	<p>Determines if a progress dialog is displayed.</p> <p>0: No progress dialog.</p> <p>1: Show a progress dialog (default).</p>
<i>/T=transferType</i>	<p>Controls the FTP transfer type.</p> <p>0: Image (binary) transfer (default).</p> <p>1: ASCII transfer.</p> <p>See <b>FTP Transfer Types</b> on page IV-260 for more discussion.</p>
<i>/U=usernameStr</i>	Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if <i>usernameStr</i> is "", you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.
<i>/V=diagnosticMode</i>	<p>Determines what kind of diagnostic messages FTPUpload will display in the history area. <i>diagnosticMode</i> is a bitwise parameter, with the bits defined as follows:</p> <p>Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.</p> <p>Bit 1: Show errors. This displays additional information when errors occur.</p> <p>Bit 2: Show status. This displays commands sent to the server and the server's response.</p> <p>The default value for <i>diagnosticMode</i> is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.</p> <p>See <b>FTP Troubleshooting</b> on page IV-260 for other troubleshooting tips.</p>
<i>/W=passwordStr</i>	<p>Specifies the password used when logging in to the FTP server. Use this flag if you have an account on the FTP server.</p> <p>If this flag is omitted, "nopassword" will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the <i>/W="&lt;your email address&gt;"</i> flag.</p> <p>If <i>/W</i> is omitted, the login is done using a default password that will work with most anonymous FTP servers.</p> <p>See <b>Safe Handling of Passwords</b> on page IV-255 for information on handling sensitive passwords.</p>

/Z Errors are not fatal. Will not abort procedure execution if an error occurs.

Your procedure can inspect the `V_flag` variable to see if the transfer succeeded. `V_flag` will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.

### Examples

Upload a file using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test Folder:TestFile1.txt"
FTPUpload url, localPath
```

Upload a file using a local symbolic path and file name:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String pathName = "Igor" // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPUpload/P=$pathName url, fileName
```

Upload a directory using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPUpload/D url, localPath
```

## FuncFit

**FuncFit** [*flags*] *fitFuncName*, *cwaveName*, *waveName* [*flag parameters*]

**FuncFit** [*flags*] {*fitFuncSpec*}, *waveName* [*flag parameters*]

The FuncFit operation performs a curve fit to a user defined function, or to a sum of fit functions using the second form (see **Fitting Sums of Fit Functions** on page V-237). Fitting can be done using any method that can be selected using the /ODR flag (see **CurveFit** for details).

FuncFit operation parameters are grouped in the following categories: flags, parameters (*fitFuncName*, *cwaveName*, *waveName* or {*fitFuncSpec*}, *waveName*), and flag parameters. The sections below correspond to these categories. Note that flags must precede the *fitFuncName* or *fitFuncSpec* and flag parameters must follow *waveName*.

### Flags

See **CurveFit** for all available flags.

### Parameters

<i>fitFuncName</i>	The user-defined function to fit to, which can be a function taking multiple independent variables (see also <b>FuncFitMD</b> ). Multivariate fitting with FuncFit <i>requires</i> /X= <i>xwaveSpec</i> .
<i>cwaveName</i>	Wave containing the fitting coefficients.
<i>waveName</i>	The wave containing the dependent variable data to be fit to the specified function. For functions of just one independent variable, the dependent variable data is often referred to as "Y data". You can fit to a subrange of the wave by supplying ( <i>startX,endX</i> ) or [ <i>startP,endP</i> ] after the wave name. See <b>Wave Subrange Details</b> below for more information on subranges of waves in curve fitting.
<i>fitFuncSpec</i>	List of fit functions and coefficient waves, with some optional information. Using this format fits a model consisting of the sum of the listed fit functions. Intended for fitting multiple peaks, but probably useful for other applications as well. See <b>Fitting Sums of Fit Functions</b> on page V-237.

### Flag Parameters

These flag parameters must follow *waveName*.

<i>/E=ewaveName</i>	A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave.
<i>/STRC=structureInstance</i>	Used only with <b>Structure Fit Functions</b> on page III-229. When using a structure fit function, you must specify an instance of the structure to FuncFit. This will be an instance that has been initialized by a user-defined function that you write in order to invoke FuncFit.
<i>/X=xwaveSpec</i>	An optional wave containing X values for each of the input data values. If the fitting function has more than one independent variable, <i>xwaveSpec</i> is required and must be either a 2D wave with a column for each independent variable, or a list of waves, one for each independent variable. A list must be in braces: <i>/X={xwave0, xwave1,...}</i> . There must be exactly one column or wave for each independent variable in the fitting function.
<i>/NWOK</i>	<p>Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to FuncFit is normally treated as an error. By using <i>/NWOK</i>, you are telling FuncFit that a null wave reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls FuncFit with optional waves.</p> <p>The waves affected are the X wave or waves (<i>/X</i>), weight wave (<i>/W</i>), epsilon wave (<i>/E</i>) and mask wave (<i>/M</i>). The destination wave (<i>/D=wave</i>) and residual wave (<i>/R=wave</i>) are also affected, but the situation is more complicated because of the dual use of <i>/D</i> and <i>/R</i> to mean "do autodeestination" and "do autoresidual". See <i>/AR</i> and <i>/AD</i>.</p> <p>If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.</p> <p><b>Note:</b> To work properly this flag must be the last one in the command.</p>

Other parameters are used as for the **CurveFit** operation, with some exceptions for multivariate fits.

### Details for Multivariate Fits

The dependent variable data wave, *waveName*, must be a 1D wave even for multivariate fits. For fits to data in a multidimensional wave, see **FuncFitMD**.

For multivariate fits, the auto-residual (*/R* with no wave specified) is calculated and appended to the top graph if the dependent variable data wave is graphed in the top graph as a simple 1D trace. Auto residuals are calculated but not displayed if the data are displayed as a contour plot.

The autodest wave (*/D* with no wave specified) for multivariate fits has the same number of points as the data wave, with a model value calculated at the X values contained in the wave or waves specified with */X=xwaveSpec*.

Confidence bands are not supported for multivariate fits.

### Wave Subrange Details

Almost any wave you specify to FuncFit can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command (see **Subrange Display Syntax** on page II-250 for details). See **Wave Subrange Details** on page V-113 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for CurveFit apply to FuncFit as well.

In addition to the waves discussed in the CurveFit documentation, it is possible to use subranges when specifying the coefficient wave and the epsilon wave. Since the coefficient wave and epsilon wave must have the same number of points, it might make sense to make them two columns from a single multicolumn wave. For instance, here is an example in which the first column is used as the coefficient wave, the second is used as the epsilon wave, and the third is used to save a copy of the initial guesses for future reference:

```
Make/D/N=(5, 3) myCoefs
myCoefs[] [0] = {1,2,3,4,5}           // hypothetical initial guess
myCoefs[] [1] = 1e-6                 // reasonable epsilon values
```

```
myCoefs[][2] = myCoefs[p][0] // save copy of initial guess
FuncFit myFitFunc, myCoefs[][0] myData /E=myCoefs[][1] ...
```

You might have a fit function that uses a subset of the coefficients that are used by another. It might be useful to use a single wave for both. Here is an example in which a function that takes four coefficients is used to fit a subset of the coefficients, and then that solution is used as the initial guess for a function that takes six coefficients:

```
Make/D/N=6 Coefs6={1,2,3,4,5,6}
FuncFit Fit4Coefs, Coefs6[0,3] fitfunc4Coefs ...
FuncFit Fit6Coefs, Coefs6 ...
```

Naturally, the two fit functions must be worked out carefully to allow this.

### Fitting Sums of Fit Functions

If Igor encounters a left brace at the beginning of the fit function name, it expects a list of fit functions to be summed during the fit. This is useful for, for instance, fitting several peaks in a data set to a sum of peak functions.

The fit function specification includes at least the name of the fitting function and an associated coefficient wave. A sum of fit functions requires multiple coefficient waves, one for each fit function. Any coefficient wave-related options must be specified in the fit function specification via keyword-value pairs.

The syntax of the sum-of-fit-functions specification is as follows:

```
{ {func1, coef1, keyword=value}, {func2, coef2, keyword=value}, ... }
```

or

```
{ string=fitSpecStr }
```

Within outer braces, each fit function specification is enclosed within inner braces. You can use one or more fit function specifications, with no intrinsic limit on the number of fit functions.

The second format is available to overcome limitations on the length of a command line in Igor. This format is just like the first, but everything inside the outer braces is contained in a string expression (which may be just a single string variable).

You can use any fit function that can be used for ordinary fitting, including the built-in functions that are available using the CurveFit operation. If you should write a user-defined fitting function with the same name as a built-in fit function, the user-defined function will be used (this is strongly discouraged).

Every function specification must include an appropriate coefficient wave, pre-loaded with initial guesses.

The comma between each function specification is optional.

The keyword-value pairs are optional, and are used to communicate further options on a function-by-function basis. Available keywords are:

<b>HOLD=holdstr</b>	Indicates that a fit coefficient should be held fixed during fitting. <i>holdstr</i> works just like the hold string specified via the /H flag for normal fitting, but applies only to the coefficient wave associated with the fit function it appears with.  If you include HOLD in a string expression (the {string=fitSpecStr} syntax), you must escape the quotation marks around the hold string.  If you use the command-line syntax { {func1, coef1, HOLD=holdStr}, ... }, <i>holdStr</i> may be a reference to a global variable acquired using SVAR, or it may be a quoted literal string.  If you use {string=fitSpecStr}, <i>fitSpecStr</i> is parsed at run-time outside the context of any running function. Consequently, you cannot use a general string expression. You can use either HOLD="quotedLiteralString" or HOLD=root:globalString.
<b>CONST={constants}</b>	Sets the values of constants in the fitting function. So far, only two built-in functions take constants: exp_XOffset and dblexp_XOffset. They each take just one constant (the X offset), so you will have a "list" of one number inside the braces.
<b>EPSW=epsilonWave</b>	Specifies a wave holding epsilon values. Use only with a user-defined fitting function to set the differencing interval used to calculate numerical estimates of derivatives of the fitting function.

**STRC=structureInstance** Specifies an instance of the structure to FuncFit when using a structure fit function. *structureInstance* is an instance that was initialized by a user-defined function that invokes FuncFit. This keyword (and structure fitting functions) can be used only when calling FuncFit from within a user-defined function. See **Structure Fit Functions** on page III-229 for more details.

For more details, and for examples of sums of fit functions in use, **Fitting Sums of Fit Functions** on page III-214.

### See Also

The **CurveFit** operation for parameter details. See also **FuncFitMD** for user-defined multivariate fits to data in a multidimensional wave.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See **Using the Curve Fitting Dialog** on page III-155, especially the section **Fitting to a User-Defined Function** on page III-163.

For details on the form of a user-defined function, see **User-Defined Fitting Functions** on page III-219.

## FuncFitMD

**FuncFitMD** [*flags*] *fitFuncName*, *cwaveName*, *waveName* [*flag parameters*]

The FuncFitMD operation performs a curve fit to the specified multivariate user defined *fitFuncSpec*. FuncFitMD handles gridded data sets in multidimensional waves. Most parameters and flags are the same as for the **CurveFit** and **FuncFit** operations; differences are noted below.

*cwaveName* is a 1D wave containing the fitting coefficients, and *functionName* is the user-defined fitting function, which has 2 to 4 independent variables.

FuncFitMD operation parameters are grouped in the following categories: flags, parameters (*fitFuncName*, *cwaveName*, *waveName*), and flag parameters. The sections below correspond to these categories. Note that flags must precede the *fitFuncName* and flag parameters must follow *waveName*.

### Flags

*/L=dimSize* Sets the dimension size of the wave created by the auto-trace feature, that is, /D without destination wave. The wave *fit\_waveName* will be a multidimensional wave of the same dimensionality as *waveName* that has *dimSize* elements in each dimension. That is, if you are fitting to a matrix wave, *fit\_waveName* will be a square matrix that has dimensions *dimSize* X *dimSize*. **Beware:** *dimSize* = 100 requires 100 million points for a 4-dimensional wave!

### Parameters

*fitFuncName* User-defined function to fit to, which must be a function taking 2 to 4 independent variables.

*cwaveName* 1D wave containing the fitting coefficients.

*waveName* The wave containing the dependent variable data to be fit to the specified function. For functions of just one independent variable, the dependent variable data is often referred to as "Y data". You can fit to a subrange of the wave by supplying (*startX,endX*) or [*startP,endP*] for each dimension after the wave name. See **Wave Subrange Details** below for more information on subranges of waves in curve fitting.

### Flag Parameters

These flag parameters must follow *waveName*.

*/E=ewaveName* A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave.

*/T=twaveName* Like /X except for the T independent variable. This is a 1D wave having as many elements as *waveName* has chunks.

*/X=xwaveName* The X independent variable values for the data to fit come from *xwaveName* instead of from the X scaling of *waveName*. This is a 1D wave having as many elements as *waveName* has rows.

<code>/Y=ywaveName</code>	Like <code>/X</code> except for the Y independent variable. This is a 1D wave having as many elements as <i>waveName</i> has columns.
<code>/Z=ywaveName</code>	Like <code>/X</code> except for the Z independent variable. This is a 1D wave having as many elements as <i>waveName</i> has layers.
<code>/NWOK</code>	<p>Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to FuncFitMD is normally treated as an error. By using <code>/NWOK</code>, you are telling FuncFitMD that a null wave reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls FuncFitMD with optional waves.</p> <p>The waves affected are the X wave or waves (<code>/X</code>), the Y spacing wave (<code>/Y</code>), the Z spacing wave (<code>/Z</code>) the T spacing wave (<code>/T</code>), weight wave (<code>/W</code>), epsilon wave (<code>/E</code>) and mask wave (<code>/M</code>). The destination wave (<code>/D=wave</code>) and residual wave (<code>/R=wave</code>) are also affected, but the situation is more complicated because of the dual use of <code>/D</code> and <code>/R</code> to mean "do autodeestination" and "do autoresidual". See <code>/AR</code> and <code>/AD</code>.</p> <p>If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.</p> <p><b>Note:</b> To work properly this flag must be the last one in the command.</p>

### Details

Auto-residual (`/R` with no wave specified) and auto-trace (`/D` with no wave specified) for functions having two independent variables are plotted in a separate graph window if *waveName* is plotted as a contour or image in the top graph. An attempt is made to plot the model values and residuals in the same way as the input data.

By default the auto-trace and auto-residual waves are 50x50 or 25x25x25 or 15x15x15x15. Use `/L=dimSize` for other sizes. Make your own wave and use `/D=waveName` or `/R=waveName` if you want a wave that isn't square. In this case, the wave dimensions must be the same as the dependent data wave.

Confidence bands are not available for multivariate fits.

### Wave Subrange Details

Almost any wave you specify to FuncFitMD can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command; see **Subrange Display Syntax** on page II-250 for details. Note that the dependent variable data (*waveName*) must be a multidimensional wave; this requires an extension of the subrange syntax to allow a multidimensional subrange. See **Wave Subrange Details** on page V-236 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for **CurveFit** apply to FuncFitMD as well.

A subrange could be used to pick a plane from a 3D wave for fitting using a fit function taking two independent variables:

```
Make/N=(100,100,3) DepData
FuncFitMD fitfunc2D, myCoefs, DepData[] [] [0] ...
```

The **CurveFit** operation for parameter details.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See **Using the Curve Fitting Dialog** on page III-155, especially the section **Fitting to a User-Defined Function** on page III-163.

For details on the form of a user-defined function, see **User-Defined Fitting Functions** on page III-219.

## FUNCREF

**FUNCREF** *protoFunc func* [= *funcSpec*]

Within a user function, FUNCREF is a reference that creates a local reference to a function or a variable containing a function reference.

When passing a function as an input parameter to a user function, the syntax is:

```
FUNCREF protoFunc func
```

## FuncRefInfo

---

In this FUNCREF reference, *protoFunc* is a function that specifies the format of the function that can be passed by the FUNCREF, and *func* is a function reference used as an input parameter.

When you declare a function reference variable within a user function, the syntax is:

```
FUNCREF protoFunc func = funcSpec
```

Here, the local FUNCREF variable, *func*, is assigned a *funcSpec*, which can be a literal function name, a \$ string expression that evaluates at runtime, or another FUNCREF variable.

### See Also

**Function References** on page IV-98 for an example and further usage details.

## FuncRefInfo

### FuncRefInfo ( *funcRef* )

The FuncRefInfo function returns information about a FUNCREF.

### Parameters

*funcRef* is a function reference variable declared by a FUNCREF statement in a user-defined function.

### Details

FuncRefInfo returns a semicolon-separated keyword/value string containing the following information:

Keyword	Information
NAME	The name of the reference function or "" if the FUNCREF variable has not been assigned to point to a function.
ISPROTO	0 if the FUNCREF variable has been assigned to point to a function. 1 if it has not been assigned and therefore still points to the prototype function.
ISXFUNC	0 if it points to a user-defined function. 1 if the FUNCREF points to an external function.

### See Also

**Function References** on page IV-98 and **FUNCREF** on page V-239.

## Function

**Function** [ [/C /D /S /DF /WAVE] *functionName* ( [ *parameters* ] )

The Function keyword introduces a user-defined function in a procedure window.

The optional flags specify the return value type, if any, for the function.

### Flags

/C	Returns a complex number.
/D	Returns a double-precision number. Obsolete, accepted for backward compatibility.
/S	Returns a string.
/DF	Returns a data folder reference. See <b>Data Folder Reference Function Results</b> on page IV-75.
/WAVE	Returns a wave reference. See <b>Wave Reference Function Results</b> on page IV-70.

### Details

If you omit all flags, the result is a scalar double-precision number.

The /D flag is not needed because all numeric return values are double-precision.

### See Also

Chapter IV-3, **User-Defined Functions** and **Function Syntax** on page IV-31 for further information.

## FunctionInfo

**FunctionInfo**(*functionNameStr* [, *procedureWinTitleStr*])

The FunctionInfo function returns a keyword-value pair list of information about the user-defined or external function name in *functionNameStr*.

### Parameters

*functionNameStr* a string expression containing the name or multipart name of a user-defined or external function. *functionNameStr* is usually just the name of a function.

To return information about a static function, supply both the module name and the function name in MyModule#MyFunction format (see **Regular Modules** on page IV-222), or specify the function name and *procedureWinTitleStr* (see below).

To return information about a function in a different independent module, supply the independent module name in addition to any module name and function name (a double or triple name):

Name	What It Refers To
MyIndependentModule#MyFunction	Refers to a non-static function in an independent module.
MyIndependentModule#MyModule#MyFunction	Refers to a static function in a procedure file with #pragma moduleName=MyModule in an independent module.

(See **Independent Modules** on page IV-224 for details on independent modules.)

The optional *procedureWinTitleStr* can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf") in which to search for the named user-defined function. The information about the named function in the specified procedure window is returned.

The *procedureWinTitleStr* parameter makes it possible to select one of several static functions with identical names among different procedure windows, even if they do not contain a #pragma moduleName=myModule statement.

If you execute this command:

```
SetIgorOption IndependentModuleDev=1
```

then *procedureWinTitleStr* can also be a title followed by an independent module name in brackets to return information about the named function in the procedure window of the given title that belongs to named independent module.

*procedureWinTitleStr* can also be just an independent module name in brackets to return information about the named nonstatic function in any procedure window that belongs to named independent module.

### Details

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

#### User-Defined and External Functions

Keyword	Information Following Keyword
NAME	The name of the function. Same as contents of <i>functionNameStr</i> in most cases. Just the function name if you use the module#function format.
TYPE	Value is "UserDefined" or "XFunc".
THREADSAFE	Either "yes" or "no". See <b>ThreadSafe Functions</b> on page IV-97.
RETURNTYPE	Number giving the return type of the function. See the table <b>Return Type and Parameter Type Codes</b> on page V-242.
N_PARAMS	Number of parameters for this function.
PARAM_n_TYPE	Number encoding the type of each parameter. There will be N of these keywords, one for each parameter. The part shown as <i>n</i> will be a number from 0 to N.

See **Examples** for a method for decoding these keywords.

**User-Defined Functions Only**

<b>Keyword</b>	<b>Information Following Keyword</b>
PROCWIN	Title of procedure window containing the function definition.
MODULE	Module containing function definition (see <b>Regular Modules</b> on page IV-222).
INDEPENDENTMODULE	Independent module containing function definition (see <b>Independent Modules</b> on page IV-224).
SPECIAL	The value part has one of three values:  no: Not a “special” function.  static: Is a static function. Use the module#function format to get info about static functions.  override: Function is an override function. See <b>Function Overrides</b> on page IV-98.
SUBTYPE	The function subtype, for instance <b>FitFunc</b> . See <b>Procedure Subtypes</b> on page V-13 for others.
PROCLINE	Line number within the procedure window of the function definition.
VISIBLE	Either "yes" or "no". Set to "no" in the unlikely event that the function is defined in an invisible file.
N_OPT_PARAMS	Number of optional parameters. Usually zero.

**External Functions Only**

<b>Keyword</b>	<b>Information Following Keyword</b>
XOP	Name of the XOP module containing the function.

**Return Type and Parameter Type Codes**

<b>Type</b>	<b>Code</b>	<b>Code in Hex</b>
Complex	1	0x1
Single Precision	2	0x2
Variable	4	0x4
Double Precision	4	0x4
Byte	8	0x8
16-bit Integer	16	0x10
32-bit Integer	32	0x20
Single Precision	2	0x2
/WAVE	128	0x80
Data folder reference	256	0x100
Structure	512	0x200
Function reference	1024	0x400
Pass by reference parameter	4096	0x1000

## Return Type and Parameter Type Codes

Type	Code	Code in Hex
String	8192	0x2000
Wave	16384	0x4000
/Z	-32768	0xFFFF8000

Igor functions can return a numeric value, a string value, a wave reference, or a data folder reference.

A returned numeric value is always double precision and may be complex. The return type for a normal numeric function is 4, for a complex function (Function/C) is 5 (4 for number +1 for complex).

A string function (Function/S) is 8192 (string). A Function/WAVE has a return type of 16384.

The return and parameter codes may be combined to indicate combinations of attributes. For instance, the code for a variable is 4 and the code for complex is 1. Consequently, the code for a complex variable parameter is 5. The code for a complex variable parameter passed by reference is  $(4+1+4096) = 4101$ .

Variables are always double-precision, hence the code of 4.

Waves may have a variety of codes. Numeric waves will combine with one of the number type codes such as 2 or 16. This does not reflect the numeric type of any actual wave, but rather any flag you may have used in the Wave reference. Thus, if the beginning of your function looks like

```
Function myFunc(w)
    Wave w
```

the code for the parameter w will be 16386 (16384 + 2) indicating a single-precision wave. You can use a numeric type flag with the Wave reference:

```
Function myFunc(w)
    Wave/I w
```

In this case, the code will be 16416 (16384 + 32).

Such codes are not very useful, as it is very rare to use a numeric type flag because the numeric type will be resolved correctly at runtime regardless of the flag.

A text wave has no numeric type, so its code is exactly 16384 (or -16384 if /Z is also specified.) Thus, the numeric type part of the code for a numeric wave serves to distinguish a numeric wave from a text wave. And a Wave/WAVE (a wave that contains references to other waves) has a code of 16512 (16384 + 128), unless /Z is also specified, which subtracts 32768, resulting in a code of -16256.

### Examples

This function formats function information nicely and prints it in the history area in an organized fashion. You can copy it into the Procedure window to try it out. It uses the function `InterpretType()` below to print a human-readable version of the parameter and return types. To try `PrintFuncInfo()`, you will need to copy the code for `InterpretType()` as well.

```
Function PrintFuncInfo(functionName)
    String functionName

    String infostr = FunctionInfo(functionName)
    if (strlen(infostr) == 0)
        print "The function \""+functionName+"\" does not exist."
        return -1
    endif

    print "Name: ", StringByKey("NAME", infostr)

    String typeStr = StringByKey("TYPE", infostr)
    print "Function type: ", typeStr
    Variable IsUserDefined = CmpStr(typeStr, "UserDefined")==0

    // It's not really necessary to use an IF statement here;
    // it simply prevents lines with blank information being
    // printed for an XFUNC.

    if (IsUserDefined)
        print "Module: ", StringByKey("MODULE", infostr)
```

```

    print "Procedure window: ", StringByKey("PROCWIN", infostr)
    print "Subtype: ", StringByKey("SUBTYPE", infostr)
    print "Special? ", StringByKey("SPECIAL", infostr)

    // Note use of NumberByKey to get a numeric key value
    print "Line number: ", NumberByKey("PROCLINE", infostr)
endif

// See function InterpretType() below for example of
// interpreting type information.

Variable returnType = NumberByKey("RETURNTYPE", infostr)

String returnTypeStr = InterpretType(returnType, 1)
printf "Return type: %d (0x%X) %s\r", returnType, returnType, returnTypeStr

Variable nparams = NumberByKey("N_PARAMS", infostr)
print "Number of Parameters: ", nparams

Variable nOptParams = 0
if (IsUserDefined)
    nOptParams = NumberByKey("N_OPT_PARAMS", infostr)
    print "Optional Parameters: ", nOptParams
endif

Variable i
for (i = 0; i < nparams; i += 1)
    // Note how the PARAM_n TYPE keyword string is constructed here:
    String paramKeyStr = "PARAM_" + num2istr(i) + "_TYPE"
    Variable ptype = NumberByKey(paramKeyStr, infostr)

    String ptypeStr = InterpretType(ptype, 0)
    String format = "Parameter %d; type as number: %g (0x%X); type as string: %s"
    String output
    sprintf output, format, i, ptype, ptype, ptypeStr
    print output
endfor

return 0
End

```

Function that creates a human-readable string with information about parameter and return types. Note that various attributes of the type info is tested using the bitwise AND operator (&) to test for individual bits. The constants are expressed as hexadecimal values (prefixed with "0x") to make them more readable (at least to a programmer). Otherwise, 0x4000 would be 16384; at least, 0x4000 is clearly a single-bit constant.

```

Function/S InterpretType(type, isReturnType)
    Variable type
    Variable isReturnType      // 0: type is parameter type; 1: type is return type.

    String typeStr = ""

    // limit type to unsigned 16-bit values (remove sign extensions caused by 0x8000)
    type = type & 0xFFFF

    // isNumeric is flag to tell whether to print out "complex" and "real";
    // we don't want that information on strings, text waves or wave of wave references.
    Variable isNumeric = 1

    if (type & 0x4000)          // test for WAVE bit set
        typeStr += "Wave"

        if ( !isReturnType )
            if (type & 0x80)    // test for WAVE/WAVE bit set
                typeStr += "/WAVE"
                // don't print "real" or "complex" for wave waves
                isNumeric = 0
            endif
            if (type & 0x8000)   // test for WAVE/Z bit set
                typeStr += "/Z"
            endif
        endif
        typeStr += " "
    endif

```

```

        if( (type == 0x4000) || (type == (0x4000 | 0x8000)) )    // WAVE/T or WAVE/Z/T
            if( !isReturnType )
                // For parameter types, if no numeric bits are set, it is a text wave.
                // A numeric wave has some other bits set causing the value
                // to be different from 0x4000 or 0xC000.
                typeStr += "text "
            endif
            // Function/WAVE doesn't (cannot) specify whether the returned wave
            // is text or numeric.
            // Don't print "real" or "complex" for text or unknown wave types.
            isNumeric = 0
        endif
        elseif (type & 0x2000)    // test for STRING bit set
            typeStr += "String "
            isNumeric = 0
        elseif (type & 4)    // test for VARIABLE bit
            typeStr += "Variable "
        elseif (type & 0x100)    // test for DFREF bit
            typeStr += "Data folder reference "
            isNumeric = 0
        elseif (type & 0x200)    // test for STRUCTURE bit
            typeStr += "Struct "
            isNumeric = 0
        elseif (type & 0x400)    // test for FUNCREF bit
            typeStr += "FuncRef "
            isNumeric = 0
        endif

        // print "real" or "complex" for numeric objects only
        if (isNumeric)
            if (type & 1)    // test for COMPLEX bit
                typeStr += "cmplx "
            else
                typeStr += "real "
            endif
        endif

        if( !isReturnType && (type & 0x1000) )    // test for PASS BY REFERENCE bit
            typeStr += "reference "
        endif

        return typeStr
    End

```

The **StringByKey** and **NumberByKey** functions.

**StringByKey**, **NumberByKey**, and **FunctionList** functions.

**Regular Modules** on page IV-222 and **Independent Modules** on page IV-224.

## FunctionList

**FunctionList**(*matchStr*, *separatorStr*, *optionsStr*)

The **FunctionList** function returns a string containing a list of built-in or user-defined function names satisfying certain criteria. This is useful for making a string to list functions in a pop-up menu control. Note that if the procedures need to be compiled, then **FunctionList** will not list user-defined functions.

**Parameters**

Only functions having names that match *matchStr* string are listed. Use "\*" to match all names. See **WaveList** for examples.

The first character of *separatorStr* is appended to each function name as the output string is generated. *separatorStr* is usually ";" for list processing (See **Processing Lists of Waves** on page IV-187 for details on list processing).

## FunctionList

---

Use *optionsStr* to further qualify the list of functions. *optionsStr* is a string containing keyword-value pairs separated by commas. Available options are:

KIND: <i>nk</i>	Controls the kinds of functions returned. <i>nk</i> =1: List built-in functions. <i>nk</i> =2: List normal and override user-defined functions. <i>nk</i> =4: List external functions (defined by an XOP). <i>nk</i> =8: List only curve fitting functions; must be summed with 1, 2, 4, or 16. For example, use 10 to list user-defined fitting functions. <i>nk</i> =16: Include static user-defined functions; requires WIN: option, must be summed with 1, 2, or 8. To list only static functions, subtract the non-static functions using RemoveFromList.
SUBTYPE: <i>typeName</i>	Lists functions that have the type <i>typeName</i> . That is, you could use ButtonControl as <i>typeName</i> to list only functions that are action procedures for buttons.
VALTYPE: <i>nv</i>	Restricts list to functions whose return type is a certain kind. <i>nv</i> =1: Real-valued functions. <i>nv</i> =2: Complex-valued functions. <i>nv</i> =4: String functions. <i>nv</i> =8: WAVE functions <i>nv</i> =16: DFREF functions.  Use a sum of these values to include more than one type. The return type is not restricted if this option is omitted.
NPARAMS: <i>np</i>	Restricts the list to functions having exactly <i>np</i> parameters. Omitting this option lists functions having any number of parameters.
NINDVARS: <i>ni</i>	Restricts the list to fitting functions for exactly <i>ni</i> independent variables. NINDVARS is ignored if you have not elected to list curve fitting functions using the KIND option. Functions for any number of independent variables are listed if the NINDVARS option is omitted.
WIN: <i>windowTitle</i>	Lists functions that are defined in the procedure window with the given title. "Procedure" is the title of the built-in procedure window.  <b>Note:</b> Because the <i>optionsStr</i> keyword-value pairs are comma separated and procedure window names can have commas in them, the WIN:keyword must be the last one specified.
WIN: <i>windowTitle</i> [ <i>independentModuleName</i> ]	Lists functions that are defined in the named procedure window that belongs to the independent module <i>independentModuleName</i> . See <b>Independent Modules</b> on page IV-224 for details. Requires SetIgorOption IndependentModuleDev=1, otherwise no functions are listed.  Requires <i>independentModuleName</i> =ProcGlobal or SetIgorOption independentModuleDev=1, otherwise no functions are listed.  <b>Note:</b> The syntax is literal and strict: the window title must be followed by one space and a left bracket, followed directly by the independent module name and a closing right bracket.
WIN:[ <i>independentModuleName</i> ]	

Lists functions that are defined in any procedure file that belongs to the named independent module.

Requires *independentModuleName*=ProcGlobal or SetIgorOption independentModuleDev=1, otherwise no functions are listed.

**Note:** The syntax is literal and strict: 'WIN:' must be followed by a left bracket, followed directly by the independent module name and a closing right bracket, like this:

```
FunctionList(..., "WIN: [myIndependentModuleName] ")
```

### Examples

To list user-defined fitting functions for two independent variables:

```
Print FunctionList("*", ";", "KIND:10,NINDVARS:2")
```

To list button-control functions that start with the letter *b* (note that button-control functions are user-defined):

```
Print FunctionList("b*", ";", "KIND:2,SUBTYPE:ButtonControl")
```

### See Also

**Independent Modules** on page IV-224.

For details on procedure subtypes, see **Procedure Subtypes** on page IV-193, as well as **Button**, **CheckBox**, **SetVariable**, and **PopupMenu**.

The **DisplayProcedure** operation and the **MacroList**, **OperationList**, **StringFromList**, and **WinList** functions.

## FunctionPath

**FunctionPath**(*functionNameStr*)

The FunctionPath function returns a path to the file containing the named function. This is useful in certain specialized cases, such as if a function needs access to a lookup table of a large number of values.

The most likely use for this is to find the path to the file containing the currently running function. This is done by passing "" for *functionNameStr*, as illustrated in the example below.

The returned path uses Macintosh syntax regardless of the current platform. See **Path Separators** on page III-401 for details.

If the procedure file is a normal standalone procedure file, the returned path will be a full path to the file such as "hd:Igor Pro 7 Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf".

If the function resides in the built-in procedure window the returned path will be ":Procedure". If the function resides in a packed procedure file, the returned path will be "<packed procedure window title>".

If FunctionPath is called when procedures are in an uncompiled state, it returns ":",.

### Parameters

If *functionNameStr* is "", FunctionPath returns the path to the currently executing function or "" if no function is executing.

Otherwise FunctionPath returns the path to the named function or "" if no function by that name exists.

### Examples

This example loads a lookup table into memory. The lookup table is stored as a wave in an Igor binary file.

```
Function LoadMyLookupTable()
    String path

    path = FunctionPath("") // Path to file containing this function.
    if (CmpStr(path[0],":") == 0)
        // This is the built-in procedure window or a packed procedure
        // file, not a standalone file. Or procedures are not compiled.
        return -1
    endif

    // Create path to the lookup table file.
    path = ParseFilePath(1, path, ":", 0, 0) + "MyTable.ibw"
```

```
DFREF dfSave = GetDataFolderDFR()  
// A previously-created place to store my private data.  
SetDataFolder root:Packages:MyData  
  
// Load the lookup table.  
LoadWave/O path  
  
SetDataFolder dfSave  
return 0  
End
```

### See Also

The **FunctionList** function.

## GalleryGlobal

### **GalleryGlobal#pictureName**

The GalleryGlobal keyword is used in an independent module to reference a picture in the global picture gallery which you can view by choosing Misc→Pictures.

### See Also

See **Independent Modules and Pictures** on page IV-230.

## gamma

### **gamma (num)**

The gamma function returns the value of the gamma function of *num*. If *num* is complex, it returns a complex result. Note that the return value for *num* close to negative integers is NaN, not ±Inf.

### See Also

The **gammln** function.

## gammaEuler

### **gammaEuler**

The gammaEuler function returns the Euler-Mascheroni constant 0.5772156649015328606065.

The gammaEuler function was added in Igor Pro 7.00.

## gammaInc

### **gammaInc(a, x [, upperTail])**

The gammaInc function returns the value of the incomplete gamma function, defined by the integral

$$\Gamma(a, x) = \int_x^\infty e^{-t} t^{a-1} dt.$$

If *upperTail* is zero, the limits of integration are 0 to x. If *upperTail* is absent, it defaults to 1, and the limits of integration are x to infinity, as shown. Note that `gammaInc(a, x) = gamma(a) - gammaInc(a, x, 0)`.

Defined for  $x > 0$ ,  $a \geq 0$  (*upperTail* = zero or absent) or  $a > 0$  (*upperTail* = 0).

### See Also

The **gamma**, **gammp**, and **gammq** functions.

## gammaNoise

### **gammaNoise(a [, b])**

The gammaNoise function returns a pseudo-random value from the gamma distribution

$$f(x) = \frac{x^{a-1} \exp\left(-\frac{x}{b}\right)}{b^a \Gamma(a)}, \quad x > 0, a > 0, b > 0,$$

whose mean is  $ab$  and variance is  $ab^2$ . For backward compatibility you can omit the parameter  $b$  in which case its value is set to 1. When  $a \rightarrow 1$  gammaNoise reduces to **expnoise**.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

### References

Marsaglia, G., and W. W. Tsang, *ACM*, 26, 363-372, 2000.

### See Also

The **SetRandomSeed** operation.

**Noise Functions** on page III-344.

Chapter III-12, **Statistics** for a function and operation overview.

## gammln

**gammln**(*num* [, *accuracy*])

The gammln function returns the natural log of the gamma function of *num*, where *num* > 0. If *num* is complex, it returns a complex result. Optionally, *accuracy* can be used to specify the desired fractional accuracy. If *num* is complex, it returns a complex result. In this case, *accuracy* is ignored.

### Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

For backward compatibility, if you don't include *accuracy*, gammln uses older code that achieves an accuracy of about  $2 \times 10^{-10}$ .

With *accuracy*, newer code is used that is both faster and more accurate. The output has fractional accuracy better than  $1 \times 10^{-15}$  except for values near zero, where the absolute accuracy  $(f_{\text{actual}} - f_{\text{returned}})$  is better than  $2 \times 10^{-16}$ .

The speed of calculation depends only weakly on accuracy. Higher accuracy is significantly slower than lower accuracy only for *num* between 6 and about 10.

### See Also

The **gamma** function.

## gammq

**gammq**(*a*, *x* [, *accuracy*])

The gammq function returns the regularized incomplete gamma function  $P(a, x)$ , where  $a > 0$ ,  $x \geq 0$ . Optionally, *accuracy* can be used to specify the desired fractional accuracy. Same as  $\text{gammaInc}(a, x, 0) / \text{gamma}(a)$ .

### Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

For backward compatibility, if you don't include *accuracy*, gammq uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

The ability of gammq to return a value having full fractional accuracy is limited by double-precision calculations. This means that it will mostly have fractional accuracy better than about  $10^{-15}$ , but this is not guaranteed, especially for extreme values of  $a$  and  $x$ .

### See Also

The **gammaInc** and **gammq** functions.

## gammq

**gammq(a, x [, accuracy])**

The gammq function returns the regularized incomplete gamma function  $1-P(a,x)$ , where  $a > 0, x \geq 0$ . Optionally, *accuracy* can be used to specify the desired fractional accuracy. Same as `gammaInc(a, x)/gamma(a)`.

### Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

For backward compatibility, if you don't include *accuracy*, gammq uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

The ability of gammq to return a value having full fractional accuracy is limited by double-precision calculations. This means that it will mostly have fractional accuracy better than about  $10^{-15}$ , but this is not guaranteed, especially for extreme values of  $a$  and  $x$ .

### See Also

The **gammaInc** and **gammp** functions.

## Gauss

**Gauss(x,xc,wx [,y,yc,wy [,z,zc,wz [,t,tc,wt]]])**

The Gauss function returns a normalized Gaussian for the specified dimension.

$$Gauss(\mathbf{r}, \mathbf{c}, \mathbf{w}) = \prod_{i=1}^n \frac{1}{w_i \sqrt{2\pi}} \exp \left[ -\frac{1}{2} \left( \frac{r_i - c_i}{w_i} \right)^2 \right],$$

where  $n$  is the number of dimensions.

### Parameters

$xc, yc, zc$ , and  $tc$  are the centers of the Gaussian in the X, Y, Z, and T directions, respectively.

$wx, wy, wz$ , and  $wt$  are the widths of the Gaussian in the X, Y, Z, and T directions, respectively.

Note that  $w_i$  here is the standard deviation of the Gaussian. This is different from the width parameter in the gauss curve fitting function, which is  $\sqrt{2}$  times the standard deviation.

Note also that the Gauss function lacks the cross-correlation parameter that is included in the Gauss2D curve fitting function.

### Examples

```
Make/n=100 eee=gauss(x,50,10)
Print area(eee,-inf,inf)
0.999999

Make/n=(100,100) ddd=gauss(x,50,10,y,50,15)
Print area(ddd,-inf,inf)
0.999137
```

## Gauss1D

**Gauss1D(w, x)**

The Gauss1D function returns the value of a Gaussian peak defined by the coefficients in the wave  $w$ . The equation is the same as the Gauss curve fit:

$$w[0] + w[1] \exp \left[ -\left( \frac{x - w[2]}{w[3]} \right)^2 \right].$$

### Examples

Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range:

```

Make/O/N=100 junkg // fake data wave
Setscale/I x -1,1,junkg
Display junkg
junkg = 1+2.5*exp(-(x-.5)/.3)^2)+gnoise(.1)
Duplicate/O junkg, junkgfit
junkgfit = NaN
AppendToGraph junkgfit
CurveFit gauss junkg[50,99] /D=junkgfit
// now extend the model trace
junkgfit = Gauss1D(w_coef, x)

```

#### See Also

The **CurveFit** operation.

## Gauss2D

### Gauss2D(*w*, *x*, *y*)

The Gauss2D function returns the value of a two-dimensional Gaussian peak defined by the coefficients in the wave *w*. The equation is the same as the Gauss2D curve fit:

$$w[0] + w[1] \exp \left\{ \frac{-1}{2(1-w[6]^2)} \left[ \left( \frac{x-w[2]}{w[3]} \right)^2 + \left( \frac{y-w[4]}{w[5]} \right)^2 - \left( \frac{2w[6](x-w[2])(y-w[4])}{w[3]w[5]} \right) \right] \right\}.$$

#### Examples

Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range (watch out for the very long wave assignment to junkg2D):

```

Make/O/N=(100,100) junkg2D // fake data wave
Setscale/I x -1,1,junkg2D
Setscale/I y -1,1,junkg2D
Display; AppendImage junkg2D
//Caution! Next command wrapped to fit page:
junkg2D = -1 + 2.5*exp((-1/(2*(1-.4^2)))*((x-.1)/.2)^2+((y+.2)/.35)^2+2*.4*
((x-.1)/.2)*((y+.2)/.35)))
junkg2D += gnoise(.01)
Duplicate/O junkg2D, junkg2Dfit
junkg2Dfit = NaN
AppendMatrixContour junkg2Dfit
CurveFit gauss2D junkg2D[20,80] [10,70] /D=junkg2Dfit[20,80] [10,70]
// now extend the model trace
junkg2Dfit = Gauss2D(w_coef, x, y)

```

#### See Also

The **CurveFit** operation.

## GBLoadWave

### GBLoadWave [*flags*] [*fileNameStr*]

The GBLoadWave operation loads data from a binary file into waves.

For more complex applications such as loading structured data into Igor structures see the **FBinRead** operation.

Prior to Igor7, GBLoadWave was implemented as an XOP. It is now a built-in operation.

#### Parameters

If *fileNameStr* is omitted or is "", or if the /I flag is used, GBLoadWave presents an Open File dialog from which you can choose the file to load.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-401 for details on forming the path.

### Flags

/A	Automatically assigns arbitrary wave names using "wave" as the base name. Skips names already in use.
/A= <i>baseName</i>	Same as /A but it automatically assigns wave names of the form <i>baseName0</i> , <i>baseName1</i> .
/D= <i>d</i>	New programming should use the /I flag instead of the /D, /L and /F flags. <i>d</i> =0: Creates single-precision waves. <i>d</i> =1: Creates double-precision waves. /D by itself is equivalent to /D=1.
/F= <i>f</i>	New programming should use the /I flag instead of the /D, /L and /F flags. <i>f</i> specifies the data format of the file: <i>f</i> =1: Signed integer (8, 16, 32 bits allowed) <i>f</i> =2: Creates double-precision waves <i>f</i> =3: Floating point (default, 32, 64 bits allowed)
/FILT= <i>fileFilterStr</i>	Provides control over the file filter menu in the Open File dialog. This flag was added in Igor Pro 7.00. The construction of the <i>fileFilterStr</i> parameter is the same as for the /F= <i>fileFilterStr</i> flag of the Open operation. See <b>Open File Dialog File Filters</b> on page IV-137 for details.
/I [{ <i>macFilterStr</i> , <i>winFilterStr</i> }]	Specifies interactive mode which displays the Open File dialog. In Igor7, the <i>macFilterStr</i> and <i>winFilterStr</i> parameters are ignored. Use the /FILT flag instead.
/J= <i>j</i>	Specifies how input floating point data is interpreted. <i>j</i> =0: IEEE floating point (default) <i>j</i> =1: VAX floating point
/L= <i>length</i>	New programming should use the /T flag instead of the /D, /L and /F flags. <i>length</i> specifies the data length of the data in the file in bits (default = 32). Allowable data lengths are 8, 16, 32, 64.
/N	Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.
/N= <i>baseName</i>	Same as /N except that it automatically assigns wave names of the form <i>baseName0</i> , <i>baseName1</i> .
/O= <i>o</i>	Controls overwriting of waves in case of a name conflict. <i>o</i> =0: Use unique wave names. <i>o</i> =1: Overwrite existing waves. /O by itself is equivalent to /O=1.
/P= <i>pathName</i>	Specifies the folder to look in for <i>fileNameStr</i> . <i>pathName</i> is the name of an existing symbolic path.
/Q= <i>q</i>	Controls messages written to the history area of the command window. <i>q</i> =0: Write messages. <i>q</i> =1: Suppress messages. /Q by itself is equivalent to /Q=1.
/S= <i>s</i>	<i>s</i> is the number of bytes at the start of the file to skip. It defaults to 0.

<i>/T={fType,wType}</i>	Specifies the data type of the file ( <i>fType</i> ) and the data type of the wave or waves to be created ( <i>wType</i> ). The allowed codes for both <i>fType</i> and <i>wType</i> are: 2: Single-precision floating point 4: Double-precision floating point 8: 8-bit signed integer 16: 16-bit signed integer 32: 32-bit signed integer 64: 64-bit signed integer (Igor7 or later) 72: 8-bit unsigned integer (8+64) 80: 16-bit unsigned integer (16+64) 96: 32-bit unsigned integer (32+64) 192: 64-bit unsigned integer (128+64) (Igor7 or later)
<i>/U=u</i>	Specifies the number of points of data per array in the file. The default is 0 which means "auto". In this case GBLoadWave calculate the number of data pointers per array based on the number of bytes in the file, the number of bytes to be skipped at the start of the file ( <i>/S</i> flag), and the number of arrays in the file ( <i>/W</i> flag).
<i>/V=v</i>	Specifies interleaving of data in the file. <i>v=0</i> : Data in file is not interleaved (default) <i>v=1</i> : Data in file is interleaved <i>/V</i> by itself is equivalent to <i>/V=1</i> .
<i>/W=w</i>	Specifies the number of arrays in the file. The default is 1. If you omit <i>/W</i> but specify the number of points per data array in the file via <i>/U</i> then GBLoadWave calculates the number of waves to be loaded based on the number of bytes in the file, the number of bytes to be skipped at the start of the file ( <i>/S</i> flag), and the specified number of points per data array in the file ( <i>/U</i> flag). Therefore, if you specify <i>/U</i> and want to load just one wave you must also specify <i>/W=1</i> .
<i>/Y={offset, mult}</i>	Data loaded into waves is scaled using offset and mult: output data = (input data + offset) * multiplier This is useful to convert integer data into scaled, real numbers.

### Details

The */N* flag instructs Igor to automatically name new waves "wave" (or *baseName* if */N=baseName* is used) plus a number. The number starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The */A* flag is like */N* except that Igor skips names already in use.

The */T* flag allows you to specify a data type for both the input (data in the file) and the output (data in the waves). You should use the */T* flag instead of the */D*, */L* and */F* flags. These flags are obsolete but are still supported.

### GBLoadWave Open File Dialog

If you include the */I* flag, or if the */P=pathName* and *fileNameStr* parameters do not fully specify the file to be loaded, GBLoadWave displays the Open File dialog.

The */FILT=fileFilterStr* flag provides control over the file filter menu in the Open File dialog. This flag was added in Igor Pro 7.00. The construction of the *fileFilterStr* parameter is the same as for the */F=fileFilterStr* flag of the Open operation. See **Open File Dialog File Filters** on page IV-137 for details.

In Igor7, the *macFilterStr* and *winFilterStr* parameters of the */I* flag are ignored. Use the */FILT* flag instead.

**Output Variables**

GBLoadWave sets the following output variables:

V_flag	Number of waves loaded or -1 if an error occurs during the file load.
S_fileName	Name of the file being loaded.
S_path	File system path to the folder containing the file.
S_waveNames	Semicolon-separated list of the names of loaded waves.

S\_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

When GBLoadWave presents an Open File dialog and the user cancels, V\_flag is set to 0 and S\_fileName is set to "".

**Example**

```
// Load 128 point single precision version 2 Igor binary file
GBLoadWave/S=126/U=128 "fileName"

// Load 8 256 point arrays of 16 bit signed integers into single-precision waves
// after skipping 128 byte header
GBLoadWave/S=128/T={16,2}/W=8/U=256 "fileName"

// Load n 100 point arrays of double-precision floating point numbers
// into double-precision Igor waves with names like temp0, temp1, etc,
// overwriting existing waves. n is determined by the number of bytes
// in the file.
GBLoadWave/O/N=temp/T={4,4}/U=100 "fileName"

// Load a file containing a 1024 byte header followed by a 512 row
// by 384 column array of unsigned bytes into an unsigned byte matrix
// wave and display it as an image
GBLoadWave/S=1024/T={8+64,8+64}/N=temp "fileName"
Rename temp0, image
Redimension/N=(512,384) image
if (<file uses row-major order>)
    MatrixTranspose image
endif
Display; AppendImage image
```

"Row-major order" relates to how a 2D array is stored in memory. In row-major order, all data for a given row is stored contiguously in memory. In column-major order, all data for a given column is stored contiguously in memory. Igor uses column-major order but row-major is more common.

**See Also**

**Loading General Binary Files** on page II-146.

**FBinRead** operation for more complex applications such as loading structured data into Igor structures.

**gcd****gcd(A, B)**

The gcd function calculates the greatest common divisor of *A* and *B*, which are both assumed to be integers.

**Examples**

Compute least common multiple (LCM) of two integers:

```
Function LCM(a,b)
    Variable a, b
    return((a*b)/gcd(a,b))
End
```

## GetAxis

**GetAxis** [/W=*winName* /Q] *axisName*

The GetAxis operation determines the axis range and sets the variables V\_min and V\_max to the minimum and maximum values of the named axis.

### Parameters

*axisName* is usually "left", "right", "top" or "bottom", though it may also be the name of a free axis such as "VertCrossing".

### Flags

/Q	Prevents values of V_flag, V_min, and V_max from being printed in the history area. The results are still stored in the variables.
/W= <i>winName</i>	Retrieves axis info from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

GetAxis sets V\_min according to the bottom of vertical axes or left of horizontal axes and V\_max according to the top of vertical axes or right of horizontal axes. It also sets the variable V\_flag to 0 if the specified axis is actually used in the graph, or to 1 if it is not.

### See Also

The **AxisInfo** function.

## GetBrowserLine

**GetBrowserLine**(*fullPathStr* [, *mode*])

The GetBrowserLine function returns the zero-based line number of the data folder referenced by *fullPathStr*.

Documentation for the GetBrowserLine function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GetBrowserLine"
```

## GetBrowserSelection

**GetBrowserSelection**(*index* [, *mode*])

The GetBrowserSelection returns a string containing the full path, quoted if necessary, to a selected Data Browser item.

Documentation for the GetBrowserSelection function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GetBrowserSelection"
```

## GetCamera

**GetCamera** [*flags*] [*keywords*]

The GetCamera operation provides information about a camera window.

Documentation for the GetCamera operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GetCamera"
```

### GetDataFolder

**GetDataFolder(mode [, dfr])**

The GetDataFolder function returns a string containing the name of or full path to the current data folder or, if *dfr* is present, the specified data folder.

GetDataFolderDFR is preferred.

#### Parameters

If *mode*=0, it returns just the name of the data folder.

If *mode*=1, GetDataFolder returns a string containing the full path to the data folder.

*dfr*, if present, specifies the data folder of interest.

#### Details

GetDataFolder can be used to save and restore the current data folder in a procedure. However GetDataFolderDFR is preferred for that purpose.

#### Examples

```
String savedDataFolder = GetDataFolder(1)           // Save
SetDataFolder root:
Variable/G gGlobalRootVar
SetDataFolder savedDataFolder                      // and restore
```

#### See Also

Chapter II-8, **Data Folders**.

The **SetDataFolder** operation and **GetDataFolderDFR** function.

### GetDataFolderDFR

**GetDataFolderDFR()**

The GetDataFolderDFR function returns the data folder reference for the current data folder.

#### Details

GetDataFolderDFR can be used to save and restore the current data folder in a procedure. It is like GetDataFolder but returns a data folder reference rather than a string.

#### Example

```
DFREF saveDFR = GetDataFolderDFR()                 // Save
SetDataFolder root:
Variable/G gGlobalRootVar
SetDataFolder saveDFR                             // and restore
```

#### See Also

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-72.

The **SetDataFolder** operation.

### GetDefaultFont

**GetDefaultFont(winName)**

The GetDefaultFont function returns a string containing the name of the default font for the named window or subwindow.

#### Parameters

If *winName* is null (that is, " ") returns the default font for the experiment.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

#### Details

Only graph windows and the experiment as a whole have default fonts. If *winName* is the name of a window other than a graph (e.g., a layout), or if *winName* is not the name of any window, GetDefaultFont returns the experiment default font.

In user-defined functions, font names are usually evaluated at compile time. To use the output of `GetDefaultFont` in a user-defined function, you will usually need to build a command as a string expression and execute it with the **Execute** operation.

#### Examples

```
String fontName = GetDefaultFont("Graph0")
String command= "SetDrawEnv fname=\"\" + fontName + "\", save"
Execute command
```

#### See Also

The `GetDefaultFontSize`, `GetDefaultFontStyle`, `FontSizeHeight`, and `FontSizeStringWidth` functions.

## GetDefaultFontSize

**GetDefaultFontSize**(*graphNameStr*, *axisNameStr*)

The `GetDefaultFontSize` function returns the default font size of the graph or of the graph's axis (in points) in the specified window or subwindow.

#### Details

If *graphNameStr* is "" the top graph is examined.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

If *axisNameStr* is "", the font size of the default font for the graph is returned.

If named axis exists, the default font size for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

#### See Also

The `GetDefaultFont`, `GetDefaultFontStyle`, `FontSizeHeight`, and `FontSizeStringWidth` functions.

## GetDefaultFontStyle

**GetDefaultFontStyle**(*graphNameStr*, *axisNameStr*)

The `GetDefaultFontStyle` function returns the default font style of the graph or of the graph's axis in the specified window or subwindow.

#### Details

If *graphNameStr* is "" the top graph is examined.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

If *axisNameStr* is "", the font style of the default font for the graph is returned.

If named axis exists, the default font style for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

The function result is a bitwise value with each bit identifying one aspect of the font style as follows:

Bit 0:	Bold
Bit 1:	Italic
Bit 2:	Underline
Bit 4:	Strikethrough

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

#### See Also

The `GetDefaultFont`, `GetDefaultFontSize`, `FontSizeHeight`, and `FontSizeStringWidth` functions.

### GetDimLabel

**GetDimLabel**(*waveName*, *dimNumber*, *dimIndex*)

The GetDimLabel function returns a string containing the label for the given dimension or dimension element.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks.

If *dimIndex* is -1, it returns the label for the entire dimension. If *dimIndex* is  $\geq 0$ , it returns the dimension label for that element of the dimension.

**See Also**

**SetDimLabel**, **FindDimLabel**

**Dimension Labels** on page II-85 for further usage details and examples.

### GetEnvironmentVariable

**GetEnvironmentVariable**(*varName*)

The GetEnvironmentVariable function returns a string containing the current value of the specified environment variable for the currently running Igor process. If the variable does not exist, an empty string ("" ) is returned.

The GetEnvironmentVariable function was added in Igor Pro 7.00.

#### Parameters

<i>varName</i>	The name of an environment variable which may or may not exist. It must not be an empty string and may not contain an equals sign (=).  As a special case, if a single equals sign ("=") is passed for <i>varName</i> , a carriage return (\r) separated list of all current key=value environment variable pairs is returned.
----------------	--

#### Details

The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables.

Any child process created by calling ExecuteScriptText inherits the environment variables of Igor's process.

On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

GetEnvironmentVariable returns an empty string if *varName* does not exist or if it does exist but its value is empty. If you need to know whether or not the environment variable itself actually exists, you can use the following function:

```
Function EnvironmentVariableExists(varName)
    String varName
    String varList = GetEnvironmentVariable("=")

    // Replace \r with \n because GrepString treats \n only as line separator, not \r.
    varList = ReplaceString("\r", varList, "\n")
    String regExp = "(?m)^[ ]*" + varName + "="
    return GrepString(varList, regExp)
End
```

#### Examples

```
String currentUser = GetEnvironmentVariable("USER")
String varList = GetEnvironmentVariable("=")
```

**See Also**

**SetEnvironmentVariable**, **UnsetEnvironmentVariable**

### GetErrorMessage

**GetErrorMessage**(*errorCode* [, *substitutionOption*])

GetErrorMessage returns a string containing an explanation of the error associated with *errorCode*.

## Details

*errorCode* is a value sometimes returned in *V\_Flag*, as per the documentation of the an Igor function or operation; the **Execute** operation is an example.

For a few error codes, the corresponding error message is designed to be combined with "substituted" information available only immediately after the error occurs. An example is the "parameter out of range" error which produces an error message such as "expected number between *x* and *y*". To get the correct error message, you must call `GetErrMsg` immediately after calling the function or operation that generated the error and you must pass the appropriate value for *substitutionOption* as explained below.

## Substitution

Igor maintains two environments which store the substitution information: one for macros created using the Macro, Proc and Window keywords and another for user-defined functions created with the Function keyword. The optional *substitutionOption* parameter gives you the ability to choose between those environments or to not substitute at all. Set *substitutionOption* to one of:

<i>substitutionOption</i>	GetErrMsg Action
0	Substitution values are filled in with "_Not Available_". This is the default when <i>substitutionOption</i> is not specified.
1	Substitution values are blank.
2	Substitution is performed based on the presumption that the error was received while executing a macro or a command using Igor's command line. This includes a command executed via the Execute operation even from a user-defined function because such commands are executed as if entered in the command line.
3	Substitution is performed based on the presumption that the error was received while executing a user-defined function.

For most purposes you should pass 3 for *substitutionOption* when the error was generated in a user-defined function other than through the Execute operation and pass 2 otherwise.

## Examples

```
// Macro, Execute or command line
Execute/Q/Z "Duplicate/O nonexistentWave, dup"
Print GetErrMsg(V_Flag,2)
```

Prints:

```
expected wave name
```

```
// Function example
Function Test()
  Make/O/N=(2,2) data= 0
  FilterIIR/COEF=data/LO=999/Z data // purposely wrong /LO value
  Print GetErrMsg(V_Flag)
  Print GetErrMsg(V_Flag,1)
  Print GetErrMsg(V_Flag,2)
  Print GetErrMsg(V_Flag,3)
End
```

Executing Test () prints:

```
expected _Not Available_ between _Not Available_ and _Not Available_
expected between and
expected between and
expected /LO frequency between 0 and 0.5
```

## See Also

The **GetRTErrMsg** and **GetRTError** functions.

### GetFileFolderInfo

**GetFileFolderInfo** [*flags*] [*fileOrFolderNameStr*]

The GetFileFolderInfo operation returns information about a file or folder.

#### Parameters

*fileOrFolderNameStr* specifies the file (or folder) for which information is returned. It is optional if */P=pathName* and */D* are specified, in which case information about the directory associated with *pathName* is returned.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-401 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

If Igor can not determine the location of the file from *fileOrFolderNameStr* and *pathName*, it displays a dialog allowing you to specify the file to be examined. Use */D* to select a folder.

#### Flags

<i>/D</i>	Uses the Select Folder dialog rather than Open File dialog when <i>pathName</i> and <i>fileOrFolderNameStr</i> do not specify an existing file or folder.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/Q</i>	No information printed to the history area.
<i>/Z[=z]</i>	Prevents procedure execution from aborting if GetFileFolderInfo tries to get information about a file or folder that does not exist. Use <i>/Z</i> if you want to handle this case in your procedures rather than having execution abort. <i>/Z=0:</i> Same as no <i>/Z</i> . <i>/Z=1:</i> Used for getting information for a file or folder only if it exists. <i>/Z</i> alone has the same effect as <i>/Z=1</i> . <i>/Z=2:</i> Used for getting information for a file or folder if it exists and displaying a dialog if it does not exist.

#### Variables

GetFileFolderInfo returns information in the following variables:

<i>V_flag</i>	0: File or folder was found. -1: User cancelled the Open File dialog. Other: An error occurred, such as the specified file or folder does not exist.
<i>S_path</i>	File system path of the selected file.
<i>V_isFile</i>	1: <i>fileOrFolderNameStr</i> is a file.
<i>V_isFolder</i>	1: <i>fileOrFolderNameStr</i> is a folder.
<i>V_isInvisible</i>	1: File is invisible ( <i>Macintosh</i> ) or Hidden ( <i>Windows</i> ).
<i>V_isReadOnly</i>	Set if the file is locked ( <i>Macintosh</i> ) or is read-only ( <i>Windows</i> ).  On <i>Macintosh</i> , <i>V_isReadOnly</i> is either 0 (unlocked) or 1 (locked). To set this manually, display the Finder Info window for the file and then check or uncheck the "Locked" checkbox.  On <i>Windows</i> , <i>V_isReadOnly</i> is either 0 (unlocked) or 1 (locked). To set this manually, display the Properties window for the file and then check or uncheck the "Read-only" checkbox.  On both <i>Macintosh</i> and <i>Windows</i> , <i>V_isReadOnly</i> tells you only about the property set in the Finder or <i>Windows</i> desktop. It does not tell you if you have write permission for the file or for the folder containing the file. If your goal is to determine if you can write to the file, the only way to do that is to try to write to it and catch any resulting error.

V_creationDate	Number of seconds since midnight on January 1, 1904 when the file or folder was first created. Use <b>Secs2Date</b> to get a text format date.
V_modificationDate	Number of seconds since midnight on January 1, 1904 when the file or folder was last modified. Use <b>Secs2Date</b> to get a text format date.
V_isAliasShortcut	1: File is an alias ( <i>Macintosh</i> ) or a shortcut ( <i>Windows</i> ) and S_aliasPath is also set.

If *fileOrFolderNameStr* refers to a file (not a folder), GetFileFolderInfo returns additional information in the following variables:

S_aliasPath	Full path to the file or folder that is the source for an alias ( <i>Macintosh</i> ) or a shortcut ( <i>Windows</i> ).  When the source is a folder, S_aliasPath ends with a “:” character.
V_isStationery	1: The stationery bit is set ( <i>Macintosh</i> ) or ( <i>Windows</i> ) the file type is one of the stationery file types (.pxt, .uxt, .ift).
S_fileType	Four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment). On Windows, these codes are fabricated by translating from the equivalent file name extensions, such as .txt and .pxp.
S_creator	Four-character creator code, such as 'IGR0' (Igor Pro creator code).  On Windows, S_creator is set to 'IGR0' if the file name extensions is one of those registered to Igor Pro, such as .pxp or .bwav (but not .txt). For other registered extensions, S_creator is set to the full file path of the registered application. Otherwise it is set to "".
V_logEOF	Number of bytes in the file data fork. For other forks, use <b>Open/F</b> and <b>FStatus</b> .
V_version	Version number of the file. On Macintosh, this is the value in the vers(1) resource. On Windows, a file version such as 3.10.2.1 is returned as 4.021: use S_fileVersion to avoid the problem of the second digit overflowing into the first digit.  “0”: File version can’t be determined, or the file can’t be examined because it is already open.
S_fileVersion	The file version as a string.  On Macintosh, this is just a string representation of V_Version. On Windows, a file version such as 3.10.2.1 is returned as “3.10.2.1”.  “0”: ( <i>Macintosh</i> ) file version can’t be determined.  “0.0.0.0”: ( <i>Windows</i> ) file version can’t be determined.

## Details

You can change some of the file information by using **SetFileFolderInfo**.

## Examples

Print the modification date of a file:

```
GetFileFolderInfo/Z "Macintosh HD:folder:afile.txt"
if( V_Flag == 0 && V_isFile )           // file exists
    Print Secs2Date(V_modificationDate,0), Secs2Time(V_modificationDate,0)
endif
```

Determine if a folder exists (easier than creating a path with NewPath and then using PathInfo):

```
GetFileFolderInfo/Z "Macintosh HD:folder:subfolder"
if( V_Flag && V_isFolder )
    Print "Folder Exists!"
endif
```

Find the source for a shortcut or alias:

```
GetFileFolderInfo/Z "Macintosh HD:fileThatIsAlias"
if( V_Flag && V_isAliasShortcut )
```

## GetFormula

---

```
Print S_aliasPath
endif
```

### See Also

The **SetFileFolderInfo**, **PathInfo**, and **FStatus** operations. The **IndexedFile**, **Secs2Date**, and **ParseFilePath** functions.

## GetFormula

**GetFormula** (*objName*)

The GetFormula function returns a string containing the named object's dependency formula. The named object must be a wave, numeric variable or string variable.

### Details

Normally an object will have an empty dependency formula and GetFormula will return an empty string (" "). If you assign an expression to an object using the := operator or the SetFormula operation, the text on the right side of the := or the parameter to SetFormula is the object's dependency formula and this is what GetFormula will return.

### Examples

```
Variable/G dependsOnIt
Make/O wave0 := dependsOnIt*2 //wave0 changes when dependsOnIt does
Print GetFormula(wave0)
```

Prints the following in the history area:

```
dependsOnIt*2
```

### See Also

See **Dependency Formulas** on page IV-214, and the **SetFormula** operation.

## GetGizmo

**GetGizmo** [*flags*] *keyword* [=*value*]

The GetGizmo operation provides information about a Gizmo display window.

Documentation for the GetGizmo operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GetGizmo"
```

## GetIndependentModuleName

**GetIndependentModuleName** ()

The GetIndependentModuleName function returns the name of the currently running Independent Module. If no independent module is running, it returns "ProcGlobal".

### See Also

**Independent Modules** on page IV-224.

**IndependentModuleList**.

## GetIndexedObjName

**GetIndexedObjName** (*sourceFolderStr*, *objectType*, *index*)

The GetIndexedObjName function returns a string containing the name of the indexth object of the specified type in the data folder specified by the string expression.

**GetIndexedObjNameDFR** is preferred.

### Parameters

*sourceFolderStr* can be either " : " or " " to specify the current data folder. You can also use a full or partial data folder path. *index* starts from zero. If no such object exists a zero length string (" ") is returned.

*objectType* is one of the following values:

### Examples

```
Function PrintAllWaveNames()
String objName
```

<i>objectType</i>	What You Get
1	Waves
2	Numeric variables
3	String variables
4	Data folders

```

Variable index = 0
do
    objName = GetIndexedObjName(":", 1, index)
    if (strlen(objName) == 0)
        break
    endif
    Print objName
    index += 1
while(1)
End

```

**See Also**

The **CountObjects** function, and Chapter II-8, **Data Folders**.

## GetIndexedObjNameDFR

**GetIndexedObjNameDFR(*dfr*, *objectType*, *index*)**

The GetIndexedObjNameDFR function returns a string containing the name of the *index*th object of the specified type in the data folder referenced by *dfr*.

GetIndexedObjNameDFR is the same as GetIndexedObjName except the first parameter, *dfr*, is a data folder reference instead of a string containing a path.

**Parameters**

*index* starts from zero. If no such object exists a zero length string (" ") is returned.

*objectType* is one of the following values:

<i>objectType</i>	What You Get
1	Waves
2	Numeric variables
3	String variables
4	Data folders

**Examples**

```

Function PrintAllWaveNames()
    String objName
    Variable index = 0
    DFREF dfr = GetDataFolderDFR()    // Reference to current data folder
    do
        objName = GetIndexedObjNameDFR(dfr, 1, index)
        if (strlen(objName) == 0)
            break
        endif
        Print objName
        index += 1
    while(1)
End

```

**See Also**

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-72.

The **CountObjectsDFR** function.

### GetKeyState

#### **GetKeyState ( flags )**

The GetKeyState function returns a bitwise numeric value that indicates the state of certain keyboard keys.

To detect keyboard events directed toward a window that you have created, such as a panel window, use the window hook function instead of GetKeyState. See **Window Hook Functions** on page IV-276 for details.

GetKeyState is normally called from a procedure that is invoked directly through a user-defined button or user-defined menu item. The procedure tests the state of one or more modifier keys and adjusts its behavior accordingly.

Another use for GetKeyState is to determine if Escape is pressed. This can be used to detect that the user wants to stop a procedure.

GetKeyState tests the keyboard at the time it is called. It does not tell you if keys were pressed between calls to the function. Consequently, when a procedure uses the escape key to break a loop, the user must press Escape until the running procedure gets around to calling the function.

#### **Parameters**

*flags* is a bitwise parameter interpreted as follows:

Bit 0:	If set, GetKeyState reports keys even if Igor is not the active application. If cleared, GetKeyState reports keys only if Igor is the active application.
--------	---

All other bits are reserved and must be zero.

#### **Details**

When set, the return value is interpreted bitwise as follows:

Bit 0:	Command ( <i>Macintosh</i> ) or Ctrl ( <i>Windows</i> ) pressed.
Bit 1:	Option ( <i>Macintosh</i> ) or Alt ( <i>Windows</i> ) pressed.
Bit 2:	Shift pressed.
Bit 3:	Caps Lock pressed.
Bit 4:	Control pressed ( <i>Macintosh only</i> ).
Bit 5:	Escape pressed.
Bit 6:	Left arrow key pressed. Supported in Igor Pro 7.00 or later.
Bit 7:	Right arrow key pressed. Supported in Igor Pro 7.00 or later.
Bit 8:	Up arrow key pressed. Supported in Igor Pro 7.00 or later.
Bit 9:	Down arrow key pressed. Supported in Igor Pro 7.00 or later.

To test if a particular key is pressed, do a bitwise AND of the return value with the mask value 1, 2, 4, 8, 16, 32, 64, 128, 256 and 512 for bits 0 through 9 respectively. To test if a particular key and only that key is pressed compare the return value with the mask value.

On Macintosh, it is currently possible to define a keyboard shortcut for a user-defined menu item and then, in the procedure invoked by the keyboard shortcut, to use GetKeyState to test for modifier keys. This is not possible on Windows because the keyboard shortcut will not be activated if a modifier key not specified in the keyboard shortcut is pressed. It is also possible that this ability on Macintosh will be compromised by future operating system changes. On both operating systems, however, you can test for a modifier key when the user chooses a user-defined menu item or clicks a user-defined button using the mouse.

#### **Examples**

```
Function ShiftKeyExample()  
  Variable keys = GetKeyState(0)  
  if (keys == 0)  
    Print "No modifier keys are pressed."  
  endif
```

```
    if (keys & 4)
        if (keys == 4)
            Print "The Shift key and only the Shift key is pressed."
        else
            Print "The Shift key is pressed."
        endif
    endif
End

Function EscapeKeyExample()
    Variable keys

    do
        keys = GetKeyState(0)
        if ((keys & 32) != 0)           // User is pressing escape?
            break
        endif
    while(1)
End
```

## GetLastUserMenuInfo

**GetLastUserMenuInfo**

The GetLastUserMenuInfo operation sets variables in the local scope to indicate the value of the last selected user-defined menu item.

**Details**

GetLastUserMenuInfo creates and sets these special variables:

V\_flag    The kind of menu that was selected:

V_flag	Menu Kind
0	Normal text menu item, including <b>Optional Menu Items</b> (see page IV-122) and <b>Multiple Menu Items</b> (see page IV-122).
3	"*FONT*"
6	"*LINESTYLEPOP*"
7	"*PATTERNPOP*"
8	"*MARKERPOP*"
9	"*CHARACTER*"
10	"*COLORPOP*"
13	"*COLORTABLEPOP*"

See **Specialized Menu Item Definitions** on page IV-123 for details about these special user-defined menus.

V\_value Which menu item was selected. The value also depends on the kind of menu the item was selected from:

V_flag	V_value meaning
0	Text menu item number (the first menu item is number 1).
3	Font menu item number (use S_Value, instead).
6	Line style number (0 is solid line)
7	Pattern number (1 is the first selection, a SW-NE light diagonal).
8	Marker number (1 is the first selection, the X marker).
9	Character as an integer, = char2num(S_Value). Use S_Value instead.
10	Color menu item (use V_Red, V_Green, V_Blue, and V_Alpha instead).
13	Color table list menu item (use S_Value instead).

S\_value The menu item text, depending on the kind of menu it was selected from:

V_flag	S_value meaning
0	Text menu item text.
3	Font name or "default".
6	Name of the line style menu or submenu.
7	Name of the pattern menu or submenu.
8	Name of the marker menu or submenu.
9	Character as string.
10	Name of the color menu or submenu.
13	Color table name.

In the case of **Specialized Menu Item Definitions** (see page IV-123), S\_value will be the title of the menu or submenu, etc.

V\_Red, V\_Green, V\_Blue, V\_Alpha

If a user-defined color menu ("\*COLORPOP\*" menu item) was chosen then these values hold the red, green, and blue values of the selected color. The values range from 0 to 65535.

Will be 0 if the last user-defined menu selection was not a color menu selection.

S\_graphName, S\_traceName

These are set only when any user-defined menu is chosen from a graph's trace contextual menu. (Menu "TracePopup" or Menu "AllTracesPopup" definitions).

Initially " " until a user-defined menu selection was made from one of these contextual menus, these are not reset for each user-defined menu selection.

S\_graphName is the full host-child specification for the graph. If the graph is embedded into a host window, S\_graphName might be something like "Panel0#G0". See **Subwindow Syntax** on page III-87.

S\_traceName is name of the trace that was selected by the trace contextual menu, or " " if the AllTracesPopup menu was chosen. See **Subwindow Syntax** on page III-87.

### Examples

A Multiple Menu Items menu definition:

```
Menu "Wave List", dynamic
  "Menu Item 1", <some command>
  "Menu Item 2", <some command>
  WaveList("*", ";", ""), DoSomethingWithWave()
End
```

If the user selects one of the (many) menu items created by the “Wave List” menu item definition, the DoSomethingWithWave user function can call GetLastUserMenuInfo to determine which wave was selected:

```
Function DoSomethingWithWave()
  GetLastUserMenuInfo
  WAVE/Z selectedWave = $$_value
  ...use selectedWave for something...
End
```

A trivial user-defined color menu definition:

```
Menu "Color"
  "*COLORPOP*", DoSomethingWithColor()
End

Function DoSomethingWithColor()
  GetLastUserMenuInfo
  ... do something with V_Red, V_Green, V_Blue, V_Alpha ...
End
```

See **Specialized Menu Item Definitions** on page IV-123 for another color menu example.

A Trace contextual menu Items menu definition:

```
Menu "TracePopup", dynamic          // menu when a trace is right-clicked
  "- "                             // separator divides this from built-in menu items
  ExportTraceName(), ExportSelectedTrace()
End

Function/S ExportTraceName()
  GetLastUserMenuInfo              // only S_graphName, S_traceName are set.
  Return "Export " + S_traceName
End

Function ExportSelectedTrace()
  GetLastUserMenuInfo
  ...do something with S_graphName, S_traceName...
End
```

Chapter IV-5, **User-Defined Menus** and especially the sections **Optional Menu Items** on page IV-122, **Multiple Menu Items** on page IV-122, and **Specialized Menu Item Definitions** on page IV-123.

**Trace Names** on page II-216, **Programming With Trace Names** on page IV-81.

## GetMarquee

**GetMarquee** [/K/W=winName/Z] [*axisName* [, *axisName*]]

The GetMarquee operation provides a way for you to use the marquee as an input mechanism in graphs and page layout windows. It puts information about the marquee into variables.

### Parameters

If you specify *axisName* (allowed only for graphs) the coordinates are in axis units. If you specify an axis that does not exist, Igor generates an error.

If you specify only one axis then Igor sets only the variables appropriate to that axis. For example, if you execute “GetMarquee left” then Igor sets the V\_bottom and V\_top variables but does *not* set V\_left and V\_right.

### Flags

/K	Kills the marquee. Usually you will want to kill the marquee when you call GetMarquee, so you should use the /K flag. This is modeled after what happens when you create a marquee in a graph and then choose Expand from the Marquee menu. There may be some situations in which you want the marquee to persist. Igor also automatically kills the marquee anytime the window containing the marquee is deactivated, including when a dialog is summoned.
----	---

<i>/W=winName</i>	Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.
<i>/Z</i>	No runtime error generated if the target window isn't a graph or layout, but <i>V_flag</i> will be zero. <i>/Z</i> does not prevent other kinds of problems from generating a runtime error.

### Details

GetMarquee is intended to be used in procedures invoked through user menu items added to the graph Marquee menu and the layout Marquee menu.

GetMarquee sets the following variables and strings:

<i>V_flag</i>	0: There was no marquee when GetMarquee was invoked. 1: There was a marquee when GetMarquee was invoked.
<i>V_left</i>	Marquee left coordinate.
<i>V_right</i>	Marquee right coordinate.
<i>V_top</i>	Marquee top coordinate.
<i>V_bottom</i>	Marquee bottom coordinate.
<i>S_marqueeWin</i>	Name of window containing the marquee, or " " if no marquee. If subwindow, subwindow syntax will be used.

When called from the command line, GetMarquee sets global variables and strings in the current data folder. When called from a procedure, it sets local variables and strings.

In addition, creating, adjusting, or removing a marquee may set additional marquee global variables (see the **Marquee Globals** section, below).

The target window must be a layout or a graph. Use */Z* to avoid generating a runtime-error (*V\_flag* will be 0 if the target window was not a layout or graph).

If the target is a layout then Igor sets the variables in units of points relative to the top/left corner of the paper.

If the target is a graph then Igor sets *V\_left* and *V\_right* based on the specified horizontal axis. If no horizontal axis was specified, *V\_left* and *V\_right* are set relative to the left edge of the base window in points.

If the target is a graph then Igor sets *V\_bottom* and *V\_top* based on the specified vertical axis. If no vertical axis was specified, *V\_top* and *V\_bottom* are set relative to the top edge of the base window in points.

If there is no marquee when you invoke GetMarquee then Igor sets *V\_left*, *V\_top*, *V\_right*, *V\_bottom* based on the last time the marquee was active.

### GetMarquee Example

```
Menu "GraphMarquee"
    "Print Marquee Coordinates", PrintMarqueeCoords()
End

Function PrintMarqueeCoords()
    GetMarquee left, bottom
    if (V_flag == 0)
        Print "There is no marquee"
    else
        printf "marquee left in bottom axis terms: %g\r", V_left
        printf "marquee right in bottom axis terms: %g\r", V_right
        printf "marquee top in left axis terms: %g\r", V_top
        printf "marquee bottom in left axis terms: %g\r", V_bottom
    endif
End
```

You can run this procedure by putting it into the procedure window, making a marquee in a graph, clicking in the marquee and choosing Print Marquee Coordinates:

The procedure calls GetMarquee to set the local marquee variables and then prints their values in the history area:

```
PrintMarqueeCoords()
marquee left in bottom axis terms: 32.1149
marquee right in bottom axis terms: 64.7165
marquee top in left axis terms: 0.724075
marquee bottom in left axis terms: -0.131061
```

### Marquee Globals

You can cause Igor to update global marquee variables whenever the user adjusts the marquee (without the need for you to invoke GetMarquee) by creating a global variable named V\_marquee in the root data folder:

```
Variable/G root:V_marquee = 1 //Creates V_marquee and sets bit 0 only
```

When the user adjusts the marquee Igor checks to see if root:V\_marquee exists and which bits are set, and updates (and creates if necessary) these globals:

Variable/G root:V_left	Marquee left coordinate.
Variable/G root:V_right	Marquee right coordinate.
Variable/G root:V_top	Marquee top coordinate.
Variable/G root:V_bottom	Marquee bottom coordinate.
String/G root:S_marqueeWin	Name of window that contains marquee, or "" if no marquee. Set only if root:V_Marquee has bit 15 (0x8000) set.

Unlike the local variables, for graphs these global variables are never in points. Root:V\_left and V\_right will be axis coordinates based on the first bottom axis created for the graph (if none, then for the first top axis). The axis creation order is the same as is returned by **AxisList**. Similarly, root:V\_top and root:V\_bottom will be axis coordinates based on the first left axis or the first right axis.

Igor examines the global root:V\_marquee for bitwise flags to decide which globals to update, and when:

root:V_marquee Bit Meaning	Bit Number	Bit Value
Update global variables for graph marquees	0	1
Update global variables for layout marquees	2	4
Update S_marqueeWin when updating global variables	15	0x8000

### Marquee Globals Example

By creating the global variable root:V\_marquee this way:

```
Variable/G root:V_marquee = 1 + 4 + 0x8000
```

whenever the user creates, adjusts, or removes a marquee in any graph or layout Igor will create and update the global root:V\_left, etc. coordinate variables and set the global string root:S\_marqueeWin to the name of the window which has the marquee in it. When the marquee is removed, root:S\_marqueeWin will be set to "".

This mechanism does neat things by making a **ValDisplay** or **SetVariable** control depend on any of the globals. See the Marquee Demo experiment in the Examples:Feature Demos folder for an example.

## GetMouse

---

You can also cause a function to run whenever the user creates, adjusts, or removes a marquee by setting up a dependency formula using **SetFormula** to bind one of the marquee globals to one of the function's input arguments:

```
Variable/G root:dependencyTarget
SetFormula root:dependencyTarget, "MyMarqueeFunction(root:S_marqueeWin) "
Function MyMarqueeFunction(marqueeWindow)
    String marqueeWindow          // this will be root:S_marqueeWin
    if( strlen(marqueeWindow) )
        NVAR V_left= root:V_left, V_right= root:V_right
        NVAR V_top= root:V_top, V_bottom= root:V_bottom
        Printf marqueeWindow + " has a marquee at: "
        Printf "%d, %d, %d, %d\r", V_left, V_right, V_top, V_bottom
    else
        Print "The marquee has disappeared."
    endif
    return 0                      // return value doesn't really matter
End
```

### See Also

The **SetMarquee** and **SetFormula** operations. **Setting Bit Parameters** on page IV-12 for information about bit settings.

## GetMouse

### GetMouse [/W=winName]

The GetMouse operation returns information about the position of the input mouse, and the state of the mouse buttons.

GetMouse is useful in situations such as background tasks where the mouse position and state aren't available as they are in control procedures and window hook functions.

### Flags

/W=winName	Returns the mouse position relative to the named window or subwindow. When identifying a subwindow with winName, see <b>Subwindow Syntax</b> on page III-87.
/W=kwTopWin	Returns the mouse position relative to the currently frontmost non-floating window.
/W=kwCmdHist	Returns the mouse position relative to the command window.
/W=Procedure	Returns the mouse position relative to the main Procedure window.

### Details

GetMouse returns the mouse position in local coordinates relative to the specified window unless /W is omitted in which case the returned coordinates are global.

On Windows, global coordinates are actually relative to the frame window. See **GetWindow** wsizeDC kwFrameInner.

Information is returned via the following string and numeric variables:

V_left	Horizontal mouse position, in pixels.
V_top	Vertical mouse position, in pixels.
V_flag	Mouse button state. V_flag is a bitwise value with each bit reporting the mouse button states:  Bit 0: 1 if the primary mouse button (usually the left) is down, 0 if it is up. Bit 1: 1 if the secondary mouse button (usually the right) is down, 0 if it is up.  On Macintosh, the secondary mouse button can be invoked by pressing the control key while clicking the primary (often the only) mouse button, but GetMouse does not report this with bit 1 set. Use <b>GetKeyState</b> 's bit 4 to test if the control key is pressed.  See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.

**S\_name** Name of the window or subwindow which the position is relative to, or "" if not a nameable window or if /W was omitted. Most useful with /W=kwTopWin. The result can be kwCmdHist or Procedure, or the name of a target window.

## GetRTError

### **GetRTError (flag)**

The GetRTError function returns information about the error state of Igor's user-defined function runtime execution environment.

If *flag* is 0, GetRTError returns an error code if an error has occurred or 0 if no error has occurred.

If *flag* is 1, GetRTError returns an error code if an error has occurred or 0 if no error has occurred and it clears the error state of Igor's runtime execution environment. Use this if you want to detect and handle runtime errors yourself.

If *flag* is 2, GetRTError returns the state of Igor's internal abort flag but does not clear it.

For *flag*=0 and *flag*=1, you can call **GetErrMsg** to obtain the error message associated with the returned error code, if any.

In Igor Pro 7.00 or later, using GetRTError(1) on the same line as a command that causes an error overrides the debugger "debug on error" setting and prevents the debugger from activating for that error.

### Example

```
// This illustrates how to detect and handle a runtime error
// rather than allowing it to cause Igor to abort execution.
Function Demo()
    <Call an Igor operation or a user-defined function>
    Variable err = GetRTError(0)
    if (err != 0)
        String message = GetErrMsg(err)
        Printf "Error in Demo: %s\r", message
        err = GetRTError(1) // Clear error state
        Print "Continuing execution"
    endif
    <Call an Igor operation or a user-defined function>
End
```

### See also

The **GetErrMsg** and **GetRTErrMessage** functions.

## GetRTErrMessage

### **GetRTErrMessage ()**

In a user function, GetRTErrMessage returns a string containing the name of the operation that caused the error, a semicolon, and an error message explaining the cause of the error. This is the same information that appears in the alert dialog displayed. If no error has occurred, the string will be of zero length. GetRTErrMessage must be called before the error is cleared by calling GetRTError with a nonzero argument.

### See also

The **GetRTError** and **GetErrMsg** functions.

## GetRTLLocation

### **GetRTLLocation (sleepMS)**

GetRTLLocation is used for profiling Igor procedures.

You will typically not call GetRTLLocation directly but instead will use it through FunctionProfiling.ipf which you can access using this include statement:

```
#include <FunctionProfiling>
```

## GetRTLInfo

---

GetRTLInfo is called from an Igor preemptive thread to monitor the main thread. It returns a code that identifies the current location in the procedure files corresponding to the procedure line that is executing in the main thread.

### Parameters

*sleepMs* is the number of milliseconds to sleep the preemptive thread after fetching a value.

### Details

The result from GetRTLInfo is passed to **GetRTLInfo** to determine the location in the procedures. This samples the main thread only and the location becomes meaningless after any procedure editing.

### See Also

**GetRTLInfo**

## GetRTLInfo

### GetRTLInfo (code)

GetRTLInfo is used for profiling Igor procedures.

You will typically not call GetRTLInfo directly but instead will use it through FunctionProfiling.ipf which you can access using this include statement:

```
#include <FunctionProfiling>
```

GetRTLInfo is called from an Igor preemptive thread to monitor the main thread. It returns a key/value string containing information about the procedure location associated with code or "" if the location could not be found.

### Parameters

*code* is the result from a very recent call to **GetRTLInfo**.

### Details

The format of the result string is:

```
"PROCNAME:name;LINE:line;FUNCNAME:name;"
```

As of Igor Pro 7.03, if the code is in an independent module other than ProcGlobal then this appears at the beginning of the result string:

```
IMNAME:inName;
```

The line number is padded with zeros to facilitate sorting.

### See Also

**GetRTLInfo**

## GetRTLStackInfo

### GetRTLStackInfo (selector)

The GetRTLStackInfo function returns information about “runtime stack” (the chain of macros and functions that are executing).

### Details

If *selector* is 0, GetRTLStackInfo returns a semicolon-separated list of the macros and procedures that are executing. This list is the same you would see in the debugger’s stack list.

The currently executing macro or function is the last item in the list, the macro or function that started execution is the first item in the list.

If *selector* is 1, it returns the name of the currently executing function or macro.

If *selector* is 2, it returns the name of the calling function or macro.

If *selector* is 3, GetRTLStackInfo returns a semicolon-separated list of routine names, procedure file names and line numbers. This is intended for advanced debugging by advanced programmers only.

For example, if RoutineA in procedure file ProcA.ipf calls RoutineB in procedure file ProcB.ipf, and RoutineB calls GetRTLStackInfo(3), it will return:

```
RoutineA, ProcA.ipf, 7; RoutineB, ProcB.ipf, 12;
```

The numbers 7 and 12 would be the actual numbers of the lines that were executing in each routine. Line numbers are zero-based.

GetRTStackInfo does not work correctly with string macros executed via the Execute operation.

In future versions of Igor, *selector* may request other kinds of information.

### Examples

```
Function Called()
    Print "Called by " + GetRTStackInfo(2) + "()"
    Print "Routines in calling chain: " + GetRTStackInfo(0)
End

Function Calling()
    Called()
End

Macro StartItUp()
    Calling()
End

// Executing StartItUp() prints:
// Called by Calling()
// Routines in calling chain: StartItUp;Calling;Called;
```

### See Also

**StringFromList**, **ItemsInList**, and **GetRTError** functions. **The Stack and Variables Lists** on page IV-202.

## GetScrapText

### GetScrapText()

The GetScrapText function returns a string containing any plain text on the Clipboard (aka “scrap”). This is the text that would be pasted into a text document if you used Paste in the Edit menu.

### See Also

The **PutScrapText** and **LoadPICT** operations.

## GetSelection

### GetSelection winType, winName, bitflags

The GetSelection operation returns information about the current selection in the specified window.

### Parameters

*winType* is one of the following keywords:

graph, panel, table, layout, notebook, procedure

*winName* is the name of a window of the specified type.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

If *winType* is procedure then *winName* is actually a procedure window title inside a "\$" wrapper, such as:

```
GetSelection procedure $"DemoLoader.ipf", 3
```

*bitflags* is a bitwise parameter that is used in different ways for different window types, as described in **Details**. You should use 0 for undefined bits. **Setting Bit Parameters** on page IV-12 for further details about bit settings.

### Details

For all window types, GetSelection sets *V\_flag*:

<i>V_flag</i>	0: No selection when GetSelection was invoked.
	1: There was a selection when GetSelection was invoked.

Here is a description of what GetSelection does for each window type:

### Examples

In a new experiment, make a table named “Table0” with some columns, and select some combination of rows and columns:

## GetUserData

<i>winType</i>	<i>bitFlags</i>	Action
graph		Does nothing.
panel		Does nothing.
table	1	Sets V_startRow, V_startCol, V_endRow, and V_endCol based on the selected cells in the table. The top/left cell, not including the Point column, is (0, 0).
	2	Sets S_selection to a semicolon-separated list of column names.
	4	Sets S_dataFolder to a semicolon-separated list of data folders, one for each column.
layout	2	Sets S_selection to a semicolon separated list of selected objects in the layout layer (not any drawing layers). S_selection will be "" if no objects are selected.
notebook	1	Sets V_startParagraph, V_startPos, V_endParagraph, and V_endPos based on the selected text in the notebook.
	2	Sets S_selection to the selected text.
procedure	1	Sets V_startParagraph, V_startPos, V_endParagraph, V_endPos based on the selected text in the procedure window.
	2	Sets S_selection to the selected text.

```
Make wave0 = p
Make wave1 = p + 1
Edit wave0, wave1
ModifyTable selection = (3,0,8,1,3,0)
```

Now execute these commands in a procedure or in the command line:

```
GetSelection table, Table0, 3
Print V_flag, V_startRow, V_startCol, V_endRow, V_endCol
Print S_selection
```

This will print the following in the history area:

```
1 3 0 8 1
wave0.d;wave1.d;
```

## GetUserData

**GetUserData(winName, objID, userDataName)**

The GetUserData function returns a string containing the user data for a window or subwindow. The return string will be empty if no user data exists.

### Parameters

*winName* may specify a window or subwindow name. Use "" for the top window.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

*objID* is a string specifying the name of a control or graph trace. Use "" for a window or subwindow.

*userDataName* is the name of the user data or "" for the default unnamed user data.

### See Also

The **ControlInfo**, **GetWindow**, and **SetWindow** operations.

## GetWavesDataFolder

**GetWavesDataFolder(waveName, kind)**

The GetWavesDataFolder function returns a string containing the name of a data folder containing the wave named by *waveName*. Variations on the theme are selected by *kind*.

The most common use for this is in a procedure, when you want to create a wave or a global variable in the data folder containing a wave passed as a parameter.

**GetWavesDataFolderDFR** is preferred.

**Details**

<i>kind</i>	<b>GetWavesDataFolder Returns</b>
0	Only the name of the data folder containing <i>waveName</i> .
1	Full path of data folder containing <i>waveName</i> , without wave name.
2	Full path of data folder containing <i>waveName</i> , including possibly quoted wave name.
3	Partial path from current data folder to the data folder containing <i>waveName</i> .
4	Partial path including possibly quoted wave name.

Kinds 2 and 4 are especially useful in creating command strings to be passed to **Execute**.

**Examples**

```
Function DuplicateWaveInDataFolder(w)
    Wave w
    DFREF dfSav = GetDataFolderDFR()
    SetDataFolder GetWavesDataFolder(w,1)
    Duplicate/O w, $(NameOfWave(w) + "_2")
    SetDataFolder dfSav
End
```

**See Also**

Chapter II-8, **Data Folders**.

## GetWavesDataFolderDFR

**GetWavesDataFolderDFR (waveName)**

The GetWavesDataFolderDFR function returns a data folder reference for the data folder containing the specified wave.

GetWavesDataFolderDFR is the same as GetWavesDataFolder except that it returns a data folder reference instead of a string containing a path.

**See Also**

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-72.

## GetWindow

**GetWindow [/Z] winName, keyword**

The GetWindow operation provides information about the named window or subwindow. Information is returned in variables, strings, and waves.

**Parameters**

*winName* can be the name of graph, table, panel, page layout, notebook, or any subwindow. It can also be the title of a procedure window or one of these four special keywords:

kwTopWin	Specifies the topmost graph, table, panel, page layout, or notebook window.
kwCmdHist	Specifies the command history area.
kwFrameOuter	Specifies the “frame” or “application” window that Igor Pro has only under Windows. This is the window that contains Igor’s menus and status bar.
kwFrameInner	Specifies the inside of the same “frame” window under Windows. This is the window that all other Igor windows are inside.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

Only one of the following keywords may follow *winName*. The keyword chosen determines the information stored in the output variables:

active	Sets V_Value to 1 if the window is active or to 0 otherwise. Active usually means the window is the frontmost window.
activeSW	Stores the window “path” of currently active subwindow in S_Value. See <b>Subwindow Syntax</b> on page III-87 for details on the window hierarchy.
backRGB	<p>Sets V_Red, V_Green, V_Blue, and V_Alpha to the background color of the window. The values range from 0 to 65535. The background color is set with <b>ModifyGraph (colors)</b> wbRGB, <b>ModifyLayout</b> bgRGB, and <b>Notebook</b> backRGB. Also returns the background color of procedure windows and the command/history windows. Other windows set these values to 65535 (opaque white).</p> <p>Added in Igor Pro 7.00.</p>
exterior	Sets V_value to 1 if the window is an exterior panel window or to 0 otherwise. Useful for window hook functions that must work for both regular windows and exterior panel windows, since exterior panels use their own hook function.
bgRGB	<p>Another name for backRGB.</p> <p>Added in Igor Pro 7.00.</p>
cbRGB	<p>Sets V_Red, V_Green, V_Blue, and V_Alpha to the control panel area background color of the window in graphs or panel windows, as set by <b>ModifyGraph (colors)</b> cbRGB and <b>ModifyPanel</b> cbRGB. Other windows set these values to 65535 (opaque white).</p> <p>Added in Igor Pro 7.00.</p>
drawLayer	<p>If the specified window is a graph, layout, or panel window then the window's current drawing layer is returned in S_value. S_value is set to "" for other windows. See <b>Drawing Layers</b> on page III-68.</p> <p>Added in Igor Pro 7.00.</p>
expand	<p>For graph windows, sets V_Value to the expand value set by <b>ModifyGraph (general)</b> expand=value, a value normally 0 or 1, where 1.5 means 150%.</p> <p>For notebook, procedure and command windows, sets V_Value to the magnification, normally 100. See the <b>Notebook</b> magnification=m documentation for details.</p> <p>For layout windows, sets V_Value to the <b>ModifyLayout</b> mag=m value, usually 0.5 (50%).</p> <p>Table windows set V_Value to 0, panels and other unsupported windows to NaN.</p> <p>Added in Igor Pro 7.00.</p>
file	<p>Works for notebook and procedure windows only.</p> <p>Returns via S_value a semicolon-separated list containing:</p> <ul style="list-style-type: none"><li>- the file name</li><li>- the Mac path to the folder containing the file with a colon at the end</li><li>- the name of a symbolic path pointing to that folder, if any</li></ul> <p>If the window was never saved to a standalone file then "" is returned in S_value. If the specified window is not a notebook or procedure window then "" is returned in S_value.</p>

gbRGB	<p>Sets V_Red, V_Green, V_Blue, and V_Alpha to the plot area background color of the window in graph windows, as set by <b>ModifyGraph (colors)</b> gbRGB. Other windows set these values to 65535 (opaque white).</p> <p>Use wbRGB to get the color of window background (the area outside of the axes). Added in Igor Pro 7.00.</p>
gsize	<p>Reads graph outer dimensions into V_left, V_right, V_top, and V_bottom in local coordinates. This includes axes but not the tool palette, control bar, or info panel. Dimensions are in points.</p>
gsizeDC	<p>Same as gsize but dimensions are in device coordinates (pixels).</p>
hide	<p>Sets V_Value bit 0 if the window or subwindow is hidden.</p> <p>Sets bit 1 if the host window is minimized.</p> <p>Sets bit 2 if the subwindow is hidden only because an ancestor window or subwindow is hidden. Added in Igor Pro 7.00.</p> <p>On Macintosh, if you execute <code>MoveWindow 0,0,0,0</code> to minimize a window to the dock, and then you immediately call <code>GetWindow hide</code>, bit 1 may not be correctly set because of the delay caused by the animation of the window sliding into the dock.</p>
hook	<p>Copies name of window hook function to S_value. See <b>Unnamed Window Hook Functions</b> on page IV-286.</p>
hook(hName)	<p>For the given named hook <i>hName</i>, copies name of window hook function to S_value. See <b>Named Window Hook Functions</b> on page IV-277.</p>
logicalpapersize	<p>Returns logical paper size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points.</p> <p>If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page. V_left and V_top are 0 and correspond to the left top corner of the physical page.</p> <p>On the Macintosh, using a Scale of 50% multiplies all of these dimensions by 2.</p>
logicalprintablesize	<p>Returns logical printable size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points.</p> <p>If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page minus the margins. V_left and V_top are the number of points from the left top corner of the physical page to the left top corner of the printable area of page.</p> <p>On the Macintosh, using a page setup scale of 50% multiplies all of these dimensions by 2.</p>
magnification	<p>Sets V_Value exactly the same way that expand does.</p> <p>Added in Igor Pro 7.00.</p>
maximize	<p>Sets V_Value to 1 if the window is maximized, 0 otherwise. On Macintosh, V_Value is always 0.</p>
needUpdate	<p>Sets V_Value to 1 if window or subwindow is marked as needing an update.</p>
note	<p>Copies window note to S_value.</p>
psize	<p>Reads graph plot area dimensions (where the traces are) into V_left, V_right, V_top, and V_bottom in local coordinates. Dimensions are in points.</p>
psizeDC	<p>Same as psize but dimensions are in device coordinates (pixels).</p>

sizeLimit	<p>Returns the size limits imposed on a window via <code>SetWindow sizeLimit</code> in the <code>V_minWidth</code>, <code>V_minHeight</code>, <code>V_maxWidth</code> and <code>V_maxHeight</code>. The values are scaled for screen resolution to the same units as <code>GetWindow wsize</code>, which is points. Very large limits are returned as INF.</p> <p>The <code>sizeLimit</code> keyword was added in Igor Pro 7.00.</p> <p>Also returns a <code>sizeLimit</code> status value in <code>V_Value</code>. 0 means no <code>SetWindow sizeLimit</code> command will appear in the window's recreation macro, usually because no <code>SetWindow sizeLimit</code> command was applied to the window. 1 means a <code>SetWindow sizeLimit</code> command will appear in the window's recreation macro. -1 means it won't appear because of conflicts with graph absolute sizing modes.</p>
title	<p>Gets the title (set by as <i>titleStr</i> with <code>NewPanel</code>, <code>Display</code>, etc., or by the Window Control dialog) and puts it into <code>S_value</code>. <code>S_value</code> is set to "" if <i>winName</i> specifies a subwindow. See also the <code>wtitle</code> keyword, below.</p>
userdata	<p>Returns the primary (unnamed) user data for a window in <code>S_value</code>. Use <b>GetUserData</b> to obtain any named user data.</p>
wavelist	<p>Creates a 3 column text wave called <code>W_WaveList</code> containing a list of waves used in the graph in <i>winName</i>. Each wave occupies one row in <code>W_WaveList</code>. This list includes all waves that can be in a graph, including the data waves for contour plots and images.</p>
wbRGB	<p>Another name for <code>backRGB</code>.</p> <p>Added in Igor Pro 7.00.</p>
wsize	<p>Reads window dimensions into <code>V_left</code>, <code>V_right</code>, <code>V_top</code>, and <code>V_bottom</code> in points from the top left of the screen. For subwindows, values are local coordinates in the host.</p>
wsizeDC	<p>Same as <code>wsize</code> but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle.</p>
wsizeOuter	<p>Reads window dimensions into <code>V_left</code>, <code>V_right</code>, <code>V_top</code>, and <code>V_bottom</code> in points from the top left of the screen. Dimensions are for the entire window including any frame and title bar. For subwindows, values are for the host window.</p>
wsizeOuterDC	<p>Same as <code>wsizeOuter</code> but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle, so <code>V_top</code> will be negative for a window with a title bar. <code>V_left</code> will be negative for windows with a frame; windows on Macintosh OS X have no frame, so <code>V_left</code> will be zero.</p>
wsizeRM	<p>Generally the same as <code>wsize</code>, but these are the coordinates that would actually be used by a recreation macro except that the coordinates are in points even if the window is a panel. Also, if the window is minimized or maximized, the coordinates represent the window's restored location.</p> <p>On Windows, <code>GetWindow kwFrameOuter wsizeRM</code> returns the pixel coordinates of the MDI frame even when the frame is maximized. <code>wsizeDC</code> returns 2,2,2,2 in this case.</p>
wtitle	<p>Gets the actual window title displayed in the window's title bar, regardless of whether it was set by the user (see the <code>title</code> keyword above) or is the default title created by Igor, and puts it into <code>S_value</code>.</p> <p><code>S_value</code> is set to "" if <i>winName</i> specifies a subwindow.</p> <p>If <i>winName</i> is <code>kwFrameOuter</code> or <code>kwFrameInner</code>, on Macintosh <code>S_Value</code> is set to the name of the Igor application. On Windows it is set to the full title of the application as seen on the frame's window, which can be altered using <code>DoWindow/T kwFrame</code>.</p>

## Flags

`/Z` Suppresses error if, for instance, *winName* doesn't name an existing window. `V_flag` is set to zero if no error occurred or to a non-zero error code.

## Details

*winName* can be the title of a procedure window. If the title contains spaces, use:

```
GetWindow $"Title With Spaces" wsize
```

However, if another window has a name which matches the given procedure window title, that window's properties are returned instead of the procedure window.

The *wsize* parameter is appropriate for all windows.

The *gsize*, *psize*, *gbRGB*, and *wavelist* parameters are appropriate only for graph windows.

The *logicalpapersize*, *logicalprintablesizes* and *expand/magnification* parameters are appropriate for all printable windows except for control panels and Gizmo plots.

## Local Coordinates

"Local coordinates" are relative to the top left of the graph area, regardless of where that is on the screen or within the graph window. All dimensions are reported in units of points (1/72 inch) regardless of screen resolution. On the Macintosh, this is the same as screen pixels.

## Frame Window Coordinates

`kwCmdHist`, `kwFrameInner`, and `kwFrameOuter` may be used with only the *wsize* keyword.

On Windows computers, `kwFrameInner` and `kwFrameOuter` return coordinates into `V_left`, `V_right`, `V_top`, and `V_bottom`. On the Macintosh, they always return 0, because Igor has no frame on the Macintosh.

`kwFrameOuter` coordinates are the location of the outer edges of Igor's application window, expressed in screen (pixel) coordinates suitable for use with `MoveWindow/F` to restore, minimize, or maximize the Igor application window.

If Igor is currently minimized, `kwFrameOuter` returns 0 for all values. If maximized, it returns 2 for all values. Otherwise, the screen (pixel) coordinates of the frame are returned in `V_left`, `V_right`, `V_top`, and `V_bottom`. This is consistent with `MoveWindow/F`.

`kwFrameInner` coordinates, however, are the location of the inner edges of the application window, expressed in Igor window coordinates (points) suitable for positioning graphs and other windows with **MoveWindow**.

If Igor is currently minimized, `kwFrameInner` returns the inner frame coordinates Igor would have if Igor were "restored" with `MoveWindow/F 1,1,1,1`.

`V_left` and `V_top` will always both be 0, and `V_Bottom` and `V_Right` will be the maximum visible (or potentially visible) window (not screen) coordinates in points.

## The Wavelist Keyword

The format of `W_WaveList`, created with the *wavelist* keyword, is as follows:

Column 1	Column 2	Column 3
Wave name	partial path to the wave	special ID number

The wave name in column 1 is simply the name of the wave with no path. It may be the same as other waves in the list, if there are waves from different data folders.

The partial path in column 2 includes the wave name and can be used with the `$` operator to get access to the wave.

The special ID number in column 3 has the format `##<number>##`. A version of the recreation macro for the graph can be generated that uses these ID numbers instead of wave names (see the **WinRecreation** function). This makes it relatively easy to find every occurrence of a particular wave using a function like **strsearch**.

## Examples

```
// These commands draw a red foreground rectangle framing
// the printable area of a page layout window.
GetWindow Layout0 logicalpapersize
DoWindow/F Layout0
```

```
SetDrawLayer/K userFront
SetDrawEnv linefgc=(65535,0,0), fillpat=0           // Transparent fill
DrawRect V_left+1, V_top+1, V_right-1, V_bottom-1

// These commands demonstrate the difference between title and wtitle.
Make/O data=x
Display/N=MyGraph data
GetWindow MyGraph title;Print S_Value                // Prints nothing (S_Value = "")
GetWindow MyGraph wtitle;Print S_Value               // Prints "MyGraph:data"
DoWindow/T MyGraph, "My Title for My Graph"
GetWindow MyGraph title;Print S_Value                // Prints "My Title for My Graph"
GetWindow MyGraph wtitle;Print S_Value               // Prints "My Title for My Graph"
```

### See Also

The **SetWindow**, **GetUserData**, **MoveWindow** and **DoWindow** operations.

The **IgorInfo** function.

## GizmoInfo

**GizmoInfo**(*nameStr*, *key*)

The **GizmoInfo** function is used to determine if a particular name is valid and unique as a Gizmo item names.

Documentation for the **GizmoInfo** function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GizmoInfo"
```

## GizmoPlot

**GizmoPlot**

**GizmoPlot** is a procedure subtype keyword that identifies a macro as being a Gizmo recreation macro. It is automatically used when Igor creates a window recreation macro for a Gizmo plot. See **Procedure Subtypes** on page IV-193 and **Saving and Recreating Graphs** on page II-261 for details.

## GizmoScale

**GizmoScale**(*dataValue*, *dimNumber* [, *gizmoNameStr*] )

The **GizmoScale** function returns a scaled *dataValue* for the specified dimension. The scaled values are used to position non-data drawing objects in the Gizmo window.

Documentation for the **GizmoScale** function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GizmoScale"
```

## gnoise

**gnoise**(*num* [, *RNG*] )

The **gnoise** function returns a random value from a Gaussian distribution such that the standard deviation of an infinite number of such values would be *num*.

The random number generator is initialized using the system clock when you start Igor, virtually guaranteeing that you will never get the same sequence twice. If you want repeatable “random” numbers, use **SetRandomSeed**.

The Gaussian distribution is achieved using a Box-Muller transformation of uniform random numbers.

The optional parameter *RNG* selects one of two different pseudo-random number generators used to create the uniformly-distributed random numbers used as the input to the Box-Muller transformation. If omitted, the default is 1. The *RNG*’s are:

<i>RNG</i>	Description
1	Linear Congruential generator by L’Ecuyer with added Bayes-Durham shuffle. The algorithm is described in <i>Numerical Recipes</i> (2nd edition) as the function <code>ran2 ( )</code> . This RNG has nearly $2^{32}$ distinct values and the sequence of random numbers has a period in excess of $10^{18}$ .
2	Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of $2^{19937}-1$ .

In a complex expression, the `gnoise` function returns a complex value, as if you had called:

```
cmplx(gnoise(num), gnoise(num))
```

Except for `ennoise`, other noise functions do not have complex implementations.

## Graph

### Graph

**Graph** is a procedure subtype keyword that identifies a macro as being a graph recreation macro. It is automatically used when Igor creates a window recreation macro for a graph. See **Procedure Subtypes** on page IV-193 and **Saving and Recreating Graphs** on page II-261 for details.

## GraphMarquee

### GraphMarquee

**GraphMarquee** is a procedure subtype keyword that puts the name of the procedure in the graph Marquee menu. See **Marquee Menu as Input Device** on page IV-151 for details.

## GraphNormal

### GraphNormal [/W=winName]

The **GraphNormal** operation returns the target or named graph to the normal mode, exiting any drawing mode that it may be in.

You would usually enter normal mode by choosing ShowTools from the Graph menu and clicking the crosshair tool.

### Flags

<code>/W=winName</code>	Reverts the named graph window. This must be the first flag specified when used in a Proc or Macro or on the command line.
-------------------------	--

#### See Also

The **GraphWaveDraw** and **GraphWaveEdit** operations.

## GraphStyle

### GraphStyle

**GraphStyle** is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Graph dialog and in the Graph Macros menu. See **Graph Style Macros** on page II-262 for details.

## GraphWaveDraw

### GraphWaveDraw [flags] [yWaveName, xWaveName]

The **GraphWaveDraw** operation initiates drawing a curve composed of *yWaveName* vs *xWaveName* in the target or named graph. The user draws the curve using the mouse, and the values are stored in a pair of waves as XY data.

Normally, you would initiate drawing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using **GraphWaveDraw**.

### Parameters

*yWaveName* and *xWaveName* will contain the y and x values of the curve drawn by the user with the mouse.

If *yWaveName* and *xWaveName* do not already exist, they are created with two points which are initially set to NaN (Not a Number) and appended to the target.

If *yWaveName* and *xWaveName* already exist, an error is generated unless the /O (overwrite) flag is present. If /O is present, the waves are re-created — with two points which are initially set to NaN — and appended to the target if they are not already in it.

If *yWaveName* and *xWaveName* are omitted then waves called W\_YPolyn and W\_XPolyn are created with two points set to NaN and appended to the target (*n* is some digit, so Igor might create a wave named W\_YPoly0, for example).

### Flags

/F[=f]	Initiates freehand drawing. In normal drawing, you click where you want a data point. In freehand drawing, you click once and then draw with the mouse button held down. If present, <i>f</i> specifies the smoothing factor. Max value is 8 (which is really slow), min value is 0 (default). The drawing tools use a value of 3 which is the recommended value.
/L/R/B/T	Specifies which axes to use (Left, Right, Bottom, Top). Bottom and Left axes are used by default. Can specify free axes using /L= <i>axis name</i> type notation. See <b>AppendToGraph</b> for details. If necessary, the specified axes will be created. If an axis is created its range is set to -1 to 1.
/M	Specifies that the curve being edited must be monotonic in the X dimension. The user is not allowed drag points so that they cross horizontally.
/O	Overwrites <i>yWaveName</i> and <i>xWaveName</i> if they already exist.
/W= <i>winName</i>	Draws in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

### Details

Once drawing starts no other user actions are allowed.

In normal mode, drawing stops when you double-click or when you click the first point (in which case the last point is set equal to the first point). When drawing finishes, the edit mode is entered.

In freehand mode, drawing stops when the mouse is released or when 10000 points have been drawn.

If /O is used and the waves are already on the graph then the first instance on the graph will be used even if they use a different pair of axes than specified.

### See Also

The **GraphNormal**, **GraphWaveEdit** and **DrawAction** operations.

## GraphWaveEdit

**GraphWaveEdit** [*flags*] *traceName*

The GraphWaveEdit operation initiates editing a wave trace in a graph. The wave trace must already be in the graph.

Normally, you would initiate editing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using GraphWaveEdit.

### Parameters

*traceName* is a wave name, optionally followed by the # character and an instance number: “myWave#1” is the *second* instance of myWave appended to the graph (“myWave” is the first).

If *traceName* is omitted then you get to pick the wave trace to edit by clicking it.

**Flags**

<code>/M</code>	Specifies that the edited trace must be monotonic in the X dimension. You cannot drag points so that they cross horizontally.
<code>/NI</code>	Suppresses automatic new point insertion when clicking between points.
<code>/T=t</code>	Sets the trace mode.  <code>t=0</code> : Lines and small square markers (default). <code>t=1</code> : User settings unchanged.
<code>/W=winName</code>	Edits traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-87 for details on forming the window hierarchy.

**Details**

The GraphWaveEdit operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details.

**See Also**

## Grep

```
Grep [flags] [srcFileStr ] [srcTextWaveName] [ as [destFileOrFolderStr]
      [destTextWaveName] ]
```

The Grep operation copies lines matching a search expression from a file on disk, the Clipboard, or rows from a text wave to a new or existing file, an existing text wave, the History area, the Clipboard, or to S\_value as a string list.

**Source Parameters**

The optional *srcFileStr* can be

- The full path to the file to copy lines from (in which case `/P` is not needed).
- The partial path relative to the folder associated with *pathName*.
- The name of a file in the folder associated with *pathName*.
- “Clipboard” to read lines of text from the Clipboard (in which case `/P` is ignored).

If Igor can not determine the location of the source file from *srcFileStr* and *pathName*, it displays a dialog allowing you to specify the source file.

The optional *srcTextWaveName* is the name or path to a text wave.

Only one of *srcFileStr* or *srcTextWaveName* may be specified. If neither is specified then an Open File dialog is presented allowing you to specify a source file.

**Destination Parameters**

The optional *destFileOrFolderStr* can be

- The name of (or path to) an existing folder when `/D` is specified.
- The name of (or path to) a possibly existing file.
- “Clipboard”, in which case the matching lines are copied to the Clipboard (and `/P` and `/D` are ignored). The text can be retrieved with the **GetScrapText** function.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with *pathName*.

If `/D` is specified, the source file is created inside the folder using the source file name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

The optional *destTextWaveName* is the name or path to an existing text wave. It may be the same wave as *srcTextWaveName*.

Only one of *destFileOrFolderStr* or *destTextWaveName* may be specified.

If no destination file or text wave is specified then matching lines are printed in the history area, unless the /Q flag is specified, in which case the matching lines aren't printed or copied anywhere (though the output variables are still set).

Use /LIST to set S\_value to a string list containing the matching lines or rows.

Use /INDX to create a wave W\_index containing the zero-based row or line number where matches were found.

### Parameter Details

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-401 for details on forming the path.

Folder paths should not end with single path separators. See **MoveFolder's** Details section.

### Flags

- /A Appends matching lines to the destination file, creating it if necessary, appends text to the Clipboard if the *destFileOrFolderStr* is "Clipboard", or appends rows to the destination text wave. Has no effect on output to the History area.
- /D Interprets *destFileOrFolderStr* as the name of (or path to) an existing folder (or directory). Without /D, *destFileOrFolderStr* is the name of (or path to) a file. It is ignored if the destination is a text wave, the Clipboard, or the History area.  
If *destFileOrFolderStr* is not a full path to a folder, it is relative to the folder associated with *pathName*.
- /DCOL={colNum} Useful only when the destination is *destTextWaveName*.  
Copies matching lines of text from the source file, Clipboard, or *srcTextWaveName* to column *colNum* of *destTextWaveName*, with any terminator characters removed.  
The default when the source is a file or the Clipboard is /DCOL={ 0 }, which copies matching lines into the first column of *destTextWaveName*.  
The default when the source is *srcTextWaveName* is to copy each column of a matched row to the corresponding column in *destTextWaveName*.  
/DCOL must be used with the /A flag, otherwise the destination wave will have only 1 column.
- /DCOL=[{colNum} [, delimStr], ...] Useful only when the source is *srcTextWaveName* and the destination is a file, the Clipboard, History area, or S\_value.  
Copies multiple columns in any order from matching rows of *srcTextWaveName* to the destination file, Clipboard, History area, or S\_value.  
Construct the line by appending the contents of the numbered column and the *delimStr* parameters in the order specified. The output line is terminated as described in **Line Termination**.
- /E=regExprStr Specifies the Perl-compatible regular expression string. A line must match the regular expression to be copied to the output file. See **Regular Expressions**.  
Multiple /E flags may be specified, in which case a line is copied only if it matches every regular expression.
- /E={regExprStr, reverse}

Specifies the Perl-compatible regular expression string, *regExprStr*, for which the sense of the match can be changed by *reverse*.

*reverse*=1: Matching expressions are taken to **not** match, and vice versa. For example, use */E={ "CheckBox" , 1 }* to list all lines that do not contain "CheckBox".

*reverse*=0: Same as */E=regExprStr*.

*/ENCG=textEncoding*

Specifies the text encoding of named text file. This flag applies if the source is a file and is ignored if the source is the clipboard or a text wave.

See **Text Encoding Names and Codes** on page III-434 for a list of accepted values for *textEncoding*.

If you omit */ENCG*, Grep uses the default text encoding as specified by the Misc→Text Encoding→Default Text Encoding menu.

Passing 0 for *textEncoding* acts as if */ENCG* were omitted. Passing 255 (binary) for *textEncoding* is treated as an error because the source text must be internally converted to UTF-8 and there is no valid conversion from binary to UTF-8.

*/GCOL=grepCol*

Greps the specified column of *srcTextWaveName*, which is a two-dimensional text wave. The default search is on the first column (*grepCol*=0). Use *grepCol*=-1 to match against any column of *srcTextWaveName*.

Does not apply if the source is a file or Clipboard.

*/I*

Requires interactive searching even if *srcFileStr* and *destFileOrFolderStr* are specified and if the source file exists. Same as */I*=3.

*/I=i*

Specifies the degree of file search interactivity with the user.

*i*=0: Default; interactive only if *srcFileStr* is not specified or if the source file is missing. Same as if */I* were not specified.

**Note:** This is different behavior than other commands such as **CopyFile**.

*i*=1: Interactive even if *srcFileStr* is specified and the source file exists.

*i*=2: Interactive even if *destFileOrFolderStr* is specified.

*i*=3: Interactive even if *srcFileStr* is specified, the source file exists, and *destFileOrFolderStr* is specified.

*/INDX*

Creates in the current data folder an output wave *W\_Index* containing the line numbers (or row numbers) where matching lines were found. If this is the only output you need, also use the */Q* flag.

*/LIST[=listSepStr]*

Creates an output string variable *S\_value* containing a semicolon-separated list of the matching lines. If *listSepStr* is specified, then it is used to separate the list items. See **StringFromList** for details on string lists. If this is the only output you need, also use the */Q* flag.

*/M=messageStr*

Specifies the prompt message in any Open File dialog. If */S* is not specified, then *messageStr* will be used for both the Open File and Save File dialogs. But see **Prompt Does Not Work on Macintosh** on page IV-137.

*/O*

Overwrites any existing destination file.

*/P=pathName*

Specifies the folder containing the source file or the folder into which the file is copied. *pathName* is the name of an existing symbolic path.

Both *srcFileStr* and *destFileOrFolderStr* must be either simple file or folder names, or paths relative to the folder specified by *pathName*.

<i>/Q</i>	Prevents printing results to an output file, text wave, History, or Clipboard. Use <i>/Q</i> to check for a match to <i>regExprStr</i> by testing the value of <i>V_flag</i> , <i>V_value</i> , <i>S_value</i> ( <i>/LIST</i> ), or <i>W_Index</i> ( <i>/INDX</i> ) without generating any other matching line output.  <b>Note:</b> When using <i>/Q</i> neither <i>destFileOrFolderStr</i> nor <i>destTextWaveName</i> may be specified.
<i>/S=saveMessageStr</i>	Specifies the prompt message in any Save File dialog.
<i>/T=termCharStr</i>	Specifies the terminator character.  <i>/T= (num2char (13) )</i> Carriage return (CR, ASCII code 13). <i>/T= (num2char (10) )</i> Linefeed (LF, ASCII code 10). <i>/T= " ; "</i> Semicolon. <i>/T= " "</i> Null (ASCII code 0).  See <b>Line Termination</b> for the default behavior of the terminator character.
<i>/Z[=z]</i>	Prevents aborting of procedure execution when attempting to open a nonexistent file for searching. Use <i>/Z</i> if you want to handle this case in your procedures rather than having execution abort.  <i>z=0:</i> Same as no <i>/Z</i> at all. <i>z=1:</i> Open file only if it exists. <i>/Z</i> alone is the same as <i>/Z=1</i> . <i>z=2:</i> Open file if it exists and display a dialog if it does not exist.

### Line Termination

Line termination applies mostly to source and destination files. (The Clipboard and history area delimit lines with CR, and text waves have no line terminators.)

If */T* is omitted, Grep will break file lines on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.)

Grep reads whichever of these terminator(s) appear in the source file and use them to write lines to any output file.

The terminator(s) are removed before the line is matched against the regular expression.

For lines that match *regExprStr*, terminator(s) in the input file are transferred to the output file unless the output is the Clipboard or history area, in which case the output terminator is always only CR (like **LoadWave**). This means you can transparently handle files that use CR, LF, CRLF, or LFCR as the terminator, and omitting */T* will be suitable for most cases.

If you use the */T* flag, then Grep will terminate line-from-file reads on the specified character only and will output the specified character into any output file.

### “Lines” in One-dimensional Text Waves

Grep considers each row of *srcTextWaveName* or *destTextWaveName* to be a “line” of input or output.

When the destination is a file, the Clipboard, or the History area, Grep copies all of the text in a matching row of *srcTextWaveName* to the file and terminates the line. See **Line Termination** for the rules on line terminators.

When the destination is a *destTextWaveName*, Grep simply copies all the text in a matching row to a row in *destTextWaveName*, without adding or omitting any terminators.

### “Lines” and Columns in Two-Dimensional Text Waves

Grep by default *matches* against only the first column (column 0) of each row of *srcTextWaveName*. You can use the */GCOL=grepCol* flag to specify a different column to match against. Use */GCOL=-1* to match against any column of *srcTextWaveName*.

When the source is a text wave and the destination is a file, the Clipboard, or the History area, Grep by default *copies* only the first column (column 0) to the destination.

Use the */DCOL={colNum1, delimStr1, colNum2, delimStr2, ... colNumN}* to print multiple columns (in any order) with delimiters after each column (the last column number need not be followed by a delimiter string). The output line is terminated with CR or *termcharStr* as described in **Line Termination**.

When both the source and destination are text waves and append (/A) is *not* specified, the destination text wave is redimensioned to have the same number of columns as the source text wave, and all columns of matching rows of *srcTextWaveName* are copied to *destTextWaveName*.

When both the source and destination are text waves and append /A is specified, then the number of columns in *destTextWaveName* is left unchanged, and each column of *srcTextWaveName* is copied to the corresponding column of *destTextWaveName*.

If the destination is a text wave and the source is a file or the Clipboard, each line (without the terminator) is copied to the first column of the destination text wave, or use /DCOL={ *destColNum* } to put the text into a different column.

### Output Variables

The Grep operation returns information in the following variables. When running in a user-defined function these are created as local variables. Otherwise they are created as global variables in the current data folder.

V_flag	0: Output successfully generated. -1: User cancelled either the Open File or Save File dialogs. Other: An error occurred, such as the specified file does not exist.
V_value	The number of input lines that matched the regular expression.
V_startParagraph	Zero-based line number into the file or Clipboard (or the row number of a source text wave) where the first regular expression was matched. Also see the /INDX flag.
S_fileName	Full path to the source file, the source text wave, or "Clipboard". If an error occurred or if the user cancelled, it is an empty string.
S_path	Full path to the destination file or destination text wave. "Clipboard": If <i>destFileOrFolderStr</i> was the Clipboard. "History": If the output was printed to the history area of the window. "": If an error occurred, if the user cancelled, or if /Q was specified.
S_value	Contains matching lines as a string list only if /LIST is specified.

### Regular Expressions

A regular expression is a pattern that is matched against a subject string from left to right. Most characters stand for themselves in a pattern, and match the corresponding characters in the "subject".

In the case of Grep, the "subject" is each line of the source file or Clipboard, or each row in the source text wave.

The regular expression syntax supported by Grep, **GrepList**, and **GrepString** is based on the "Perl-Compatible Regular Expression" (PCRE) library.

The syntax is similar to regular expressions supported by various UNIX and POSIX `egrep(1)` commands. See **Regular Expressions** on page IV-164 for more details.

As a trivial example, the pattern "Fred" as specified here:

```
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
```

matches lines that contain the string "Fred" anywhere on the line.

Character matching is *case-sensitive* by default, similar to `strsearch`. Prepend the Perl 5 modifier `(?i)` to match upper and lower-case versions of "Fred":

```
// Copy lines that contain "Fred", "fred", "FRED", "fRed", etc
Grep/P=myPath/E="( ?i)fred" "afile.txt" as "AnyFredFile.txt"
```

To copy lines that do *not* match the regular expression, set the /E flag's reverse parameter:

```
// Copy lines that do NOT contain "Fred", "fred", "fRed", etc.
Grep/P=myPath/E="{ ( ?i)fred",1} "afile.txt" as "NotFredFile.txt"
```

**Note:** Igor doesn't use the opening and closing regular expression delimiters that UNIX `grep` or Perl use: they would have used `"/Fred/"` and `"/(?i)fred/"`.

Regular expressions in Igor support the expected metacharacters and character classes that make the whole grep paradigm so useful. For example:

```
// Copy lines that START with a space or tab character
Grep/P=myPath/E="^[ \t]" "afile.txt" as "LeadingTabsFile.txt"
```

For a complete description of regular expressions, see **Regular Expressions** on page IV-164, especially for a description of the many uses of the regular expression backslash character (see **Backslash in Regular Expressions** on page IV-167).

**Note:** Because Igor Pro also has special uses for backslash (see **Escape Sequences in Strings** on page IV-13), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes identifies a single backslash for the Grep command.

For example, to copy lines that contain “\z”, the Perl pattern would be `\z`, but the equivalent Grep expression would be `/E="\\z"`.

See **Backslash in Regular Expressions** on page IV-167 for a more complete description of backslash behavior in Igor Pro.

### Examples

```
// Copy lines in afile.txt containing "Fred" (case sensitive)
// to an output file named "AnyFredFile.txt" in the same directory.
Grep/P=myPath/E="Fred" "afile.txt" as "AnyFredFile.txt"

// Copy lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)
// to a text wave (which must exist and is overwritten):
Make/O/N=0/T outputTextWave
Grep/P=myPath/E="( ?i)fred"/E="( ?i)wilma" "afile.txt" as outputTextWave

// Print lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)
// to the history area
Make/O/N=0/T outputTextWave
Grep/P=myPath/E="( ?i)fred"/E="( ?i)wilma" "afile.txt"

// Test whether afile.txt contains the word "boondoggle", and if so,
// on which line the first occurrence was found, WITHOUT creating any output.
//
// Note: the \\b sequences limit matches to a word boundary before and after
// "boondoggle", so "boondoggles" and "aboondoggle" won't match.
//
Grep/P=myPath/Q/E="( ?i)\\bBoondoggle\\b" "afile.txt"
if( V_value ) // at least one instance was found
    Print "First instance of \"boondoggle\" was found on line", V_startParagraph
endif

// Create in S_value a string list of the lines as \r - separated list items:
Grep/P=myPath/LIST="\r"/Q/E="( ?i)\\bBoondoggle\\b" "afile.txt"
if( V_value ) // some were found
    Print S_value
endif

// Create in W_index a list of the 0-based line numbers where "boondoggle"
// or "boondoggles", etc was found in afile.txt.
Grep/P=myPath/INDX/Q/E="( ?i)boondoggle" "afile.txt"
if( V_flag == 0 ) // grep succeeded, perhaps none were found; let's see where
    WAVE W_Index // needed if in a function
    Edit W_Index // show line numbers in a table.
endif

// (Create a string list and text wave for the following examples.)
String list= CTabList() // "Grays;Rainbow;YellowHot;..."
Variable items= ItemsInList(list)
Make/O/T/N=(items) textWave= StringFromList(p,list)

// Copy rows of textWave that contain "Red" (case sensitive)
// to the Clipboard as carriage-return separated lines.
Grep/E="Red" textWave as "Clipboard"
```

```
// Copy lines of the Clipboard that do NOT contain "Blue"
// (case in-sensitive) back to the Clipboard, overwriting what was there:
Grep/E={"(?i)blue",1} "Clipboard" as "Clipboard"

// Format matching text wave row to the history area
Grep/E=("Red")/DCOL={"prefix text --- ", 0, " --- suffix text"} textWave
// Printed output:
prefix text --- BlueRedGreen --- suffix text
prefix text --- RedWhiteBlue --- suffix text
prefix text --- BlueRedGreen256 --- suffix text
prefix text --- RedWhiteBlue256 --- suffix text
prefix text --- Red --- suffix text
prefix text --- RedWhiteGreen --- suffix text
prefix text --- BlueBlackRed --- suffix text

// Re-copy rows of textWave that contain "Red" (case sensitive)
// to the Clipboard as carriage-return separated lines.
Grep/E="Red" textWave as "Clipboard"
// Create a 2-column text wave whose column 1 (the second column)
// contains the matching text from the Clipboard
Make/O/N=(0,2)/T outputTextWave
// Grep with /A to preserve 2 columns of outputTextWave
Grep/A/E="Red"/GCOL=1/DCOL={1} "Clipboard" as outputTextWave
Edit outputTextWave

// Examples with two-dimensional source text waves
Make/O/T/N=(10, 3) sourceTW= StringFromList(p+10*q,list)
Edit sourceTW

// Copy rows of textWave that contain "Red" in column 2 to outputTextWave.
Make/O/N=0/T outputTextWave
Grep/E="Red"/GCOL=2 sourceTW as outputTextWave
Edit outputTextWave

// Format matching text wave columns to the history area.
// Match lines that contain "Red" in any column of sourceTW:
Grep/E=("Red")/GCOL=-1/DCOL={0," ", "1," ", "2} sourceTW
// Printed output:
YellowHot, BlueRedGreen256, Magenta
BlueHot, RedWhiteBlue256, Yellow
BlueRedGreen, PlanetEarth256, Copper
RedWhiteBlue, Terrain256, Gold

## References

The regular expression syntax supported by Grep, **GrepString**, and **GrepList** is based on the *PCRE — Perl-Compatible Regular Expression Library* by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.

Visit <http://pcre.org/> for more information about the PCRE library, and <http://www.perldoc.com/> for more about Perl regular expressions. The description of regular expressions above is taken from the PCRE documentation.

A good book on regular expressions is: Friedl, Jeffrey E. F., *Mastering Regular Expressions*, 2nd ed., 492 pp., O'Reilly Media, 2002.

A helpful web site is: <http://www.regular-expressions.info>

## See Also

**Regular Expressions** on page IV-164 and **Symbolic Paths** on page II-21.

**Demo**, **CopyFile**, **PutScrapText**, **LoadWave** operations. The **GrepString**, **GrepList**, **StringMatch**, and **CmpStr** functions.

### GrepList

**GrepList(listStr, regExprStr [,reverse [, listSepStr]])**

The GrepList function returns each list item in *listStr* that matches the regular expression *regExprStr*.

*ListStr* should contain items separated by the *listSepStr* character, such as in "abc;def;".

*regExprStr* is a regular expression such as is used by the UNIX grep (1) command. It is much more powerful than the wildcard syntax used for **ListMatch**. See **Regular Expressions** on page IV-164 for *regExprStr* details.

*reverse* is optional. If missing, it is taken to be 0. If *reverse* is nonzero then the sense of the match is reversed. For example, if *regExprStr* is "^abc" and *reverse* is 1, then all list items that do not start with "abc" are returned.

*listSepStr* is optional; the default is ";". In order to specify *listSepStr*, you must precede it with *reverse*.

#### Examples

To list ColorTables containing "Red", "red", or "RED" (etc.):

```
Print GrepList(CTabList(), "(?i)red")           // case-insensitive matching
```

To list window recreation commands starting with "\tCursor":

```
Print GrepList(WinRecreation("Graph0", 0), "\t\tCursor", 0, "\r")
```

#### See Also

**Regular Expressions** on page IV-164.

**ListMatch**, **StringFromList**, and **WhichListItem** functions and the **Grep** operation.

### GrepString

**GrepString(string, regExprStr)**

The GrepString function tests *string* for a match to the regular expression *regExprStr*. Returns 1 to indicate a match, or 0 for no match.

#### Details

*regExprStr* is a regular expression such as is used by the UNIX grep(1) command. It is much more powerful than the wildcard syntax used for **StringMatch**. See **Regular Expressions** on page IV-164 for *regExprStr* details.

Character matching is case-sensitive by default, similar to **strsearch**. Prepend the Perl 5 modifier "(?i)" to match upper and lower-case text

#### Examples

Test for truth that the string contains at least one digit:

```
if( GrepString(str, "[0-9]+") )
```

Test for truth that the string contains at least one "abc", "Abc", "ABC", etc.:

```
if( GrepString(str, "(?i)abc") )           // case-insensitive test
```

#### See Also

**Regular Expressions** on page IV-164.

The **StringMatch**, **CmpStr**, **strsearch**, **ListMatch**, and **ReplaceString** functions and the **Demo** and **sscanf** operations.

### GridStyle

**GridStyle**

GridStyle is a procedure subtype keyword that puts the name of the procedure in the Grid->Style Function submenu of the mover pop-up menu in the drawing tool palette. You can have Igor automatically create a grid style function for you by choosing Save Style Function from that submenu.

### GroupBox

**GroupBox [/Z] ctrlName [keyword = value [, keyword = value ...]]**

The GroupBox operation creates a box to surround and group related controls.

For information about the state or status of the control, use the **ControlInfo** operation.

## Parameters

*ctrlName* is the name of the GroupBox control to be created or changed.

The following keyword=value parameters are supported:

<code>appearance={kind [, platform]}</code>	<p>Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings.</p> <p><i>kind</i> can be one of <code>default</code>, <code>native</code>, or <code>os9</code>.</p> <p><i>platform</i> can be one of <code>Mac</code>, <code>Win</code>, or <code>All</code>.</p> <p>See <b>DefaultGUIControls Default Fonts and Sizes</b> for how enclosed controls are affected by native groupbox appearance.</p> <p>See <b>Button</b> for more appearance details.</p>
<code>disable=d</code>	<p>Sets user editability of the control.</p> <p><i>d=0</i>: Normal.</p> <p><i>d=1</i>: Hide.</p> <p><i>d=2</i>: Draw in gray state.</p>
<code>fColor=(r,g,b)</code>	Sets color of the title text. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>font="fontName"</code>	Sets font used for the box title, e.g., <code>font="Helvetica"</code> .
<code>frame=f</code>	Sets frame mode. If 1 (default), the frame has a 3D look. If 0, then a simple gray line is used. Generally, you should not use <code>frame=0</code> with a title if you want to be in accordance with human interface guidelines.
<code>fsize=s</code>	Sets font size for box title.
<code>fstyle=fs</code>	<p>Sets the font style of the title text. <i>fs</i> is a bitwise parameter with each bit controlling one aspect of the font style for the tick mark labels as follows:</p> <p>Bit 0: Bold</p> <p>Bit 1: Italic</p> <p>Bit 2: Underline</p> <p>Bit 4: Strikethrough</p> <p>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.</p>
<code>labelBack=(r,g,b) or 0</code>	Sets fill color for the interior. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. If not set, then interior is transparent. Note that if a fill color is used, draw objects can not be used because they will be covered up. Also, you will have to make sure the GroupBox is drawn before any interior controls.
<code>pos={left,top}</code>	Sets the position of the box in pixels.
<code>pos+={dx,dy}</code>	Offsets the position of the box in pixels.
<code>size={width,height}</code>	Sets box size in pixels.
<code>userdata(UDName)=UDStr</code>	Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.
<code>userdata(UDName)+=UDStr</code>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .
<code>title=titleStr</code>	Sets title to <i>titleStr</i> . Use "" for no title.

## GuideInfo

---

`win=winName` Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

### Flags

`/Z` No error reporting.

### Details

If no title is given and the width is less than 11 or height is specified as less than 6, then a vertical or horizontal separator line will be drawn rather than a box.

**Note:** Like `TabControls`, you need to click near the top of a `GroupBox` to select it.

### See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

## GuideInfo

**GuideInfo**(*winNameStr*, *guideNameStr*)

The `GuideInfo` function returns a string containing a semicolon-separated list of information about the named guide line in the named host window or subwindow.

### Parameters

*winNameStr* can be "" to refer to the top host window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

*guideNameStr* is the name of the guide line for which you want information.

### Details

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
NAME	Name of the guide.
WIN	Name of the window or subwindow containing the guide.
TYPE	The value associated with this keyword is either <i>User</i> or <i>Builtin</i> . A <i>User</i> type denotes a guide created by the <code>DefineGuide</code> operation, equivalent to dragging a new guide from an existing one.
HORIZONTAL	Either 0 for a vertical guide, or 1 for a horizontal guide.
POSITION	The position of the guide in points. This is the actual position relative to the left or bottom edge of the window, not the relative position specified to <code>DefineGuide</code> .

The following keywords will be present only for user-defined guides:

Keyword	Information Following Keyword
GUIDE1	The guide is positioned relative to GUIDE1.
GUIDE2	In some cases, the guide is positioned at a fractional position between GUIDE1 and GUIDE2. If the guide does not use GUIDE2, the value will be "".
RELPOSITION	The position relative to GUIDE1 (and GUIDE2 if applicable). This is the same as the <i>val</i> parameter in <code>DefineGuide</code> . The returned value is in units of points if only GUIDE1 is used, or a fractional value if both GUIDE1 and GUIDE2 are used.

**See Also**

The **GuideNameList**, **StringByKey** and **NumberByKey** functions; the **DefineGuide** operation.

## GuideNameList

**GuideNameList**(*winNameStr*, *optionsStr*)

The **GuideNameList** function returns a string containing a semicolon-separated list of guide names from the named host window or subwindow.

**Parameters**

*winNameStr* can be "" to refer to the top host window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

*optionsStr* is used to further qualify the list of guides. It is a string containing keyword-value pairs separated by commas. Use "" to list all guides. Available options are:

TYPE:type	type = Builtin: List only built-in guides. type = User: List only user-defined guides, those created by the <b>DefineGuide</b> operation or by manually dragging a new guide from an existing one.
HORIZONTAL:h	h = 0: List only non-horizontal (that is, vertical) guides. h = 1: List only horizontal guides.

**Example**

```
String list = GuideNameList("Graph0", "TYPE:Builtin,HORIZONTAL:1")
```

**See Also**

The **DefineGuide** operation and the **GuideInfo** function.

## Hanning

**Hanning** *waveName* [, *waveName*]...

**Note:** The **WindowFunction** operation has replaced the Hanning operation.

The Hanning operation multiplies the named waves by a Hanning window (which is a raised cosine function).

You can use Hanning in preparation for performing an FFT on a wave if the wave is not an integral number of cycles long.

The Hanning operation is not multidimensional aware. See Chapter II-6, **Multidimensional Waves**, particularly **Analysis on Multidimensional Waves** on page II-86 for details.

**See Also**

The **WindowFunction** operation implements the Hanning window as well as other forms such as Hamming, Parzen, and Bartlet (triangle).

**ImageWindow**, **DPSS**

## Hash

**Hash**(*inputStr*, *method*)

The **Hash** function returns a cryptographic hash of the data in *inputStr*.

**Parameters**

*inputStr* is string of length up to 2<sup>31</sup> bytes. *inputStr* can contain binary or text data.

*method* is a number indicating the hash algorithm to use:

1	SHA-256 (SHA-2)
2	MD4
3	MD5

---

4	SHA-1
5	SHA-224 (SHA-2)
6	SHA-384 (SHA-2)
7	SHA-512 (SHA-2)

---

Prior to Igor Pro 7.00, only method 1 was supported.

## **hcsr**

**hcsr**(*cursorName* [, *graphNameStr*])

The **hcsr** function returns the horizontal coordinate of the named cursor (A through J) in the coordinate system of the top (or named) graph's X axis.

### **Parameters**

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

### **Details**

The X axis used is the one that controls the trace on which the cursor is placed.

### **Examples**

```
Variable xAxisValueAtCursorA = hcsr(A)           // not hcsr("A")
String str="A"
Variable xA= hcsr($str,"Graph0")                 // $str is a name, too
```

### **See Also**

The **pcsr**, **qcsr**, **vcsr**, **xcsr**, and **zcsr** functions.

**Programming With Cursors** on page II-249.

## **hermite**

**hermite**(*n*, *x*)

The **hermite** function returns the Hermite polynomial of order *n*:

$$H_n(x) = (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2).$$

The first few polynomials are:

$$1$$

$$2x$$

$$4x^2 - 2$$

$$8x^3 - 12x$$

### **See Also**

The **hermiteGauss** function.

## hermiteGauss

**hermiteGauss** (*n*, *x*)

The hermiteGauss function returns the normalized Hermite polynomial of order *n*:

$$H_n(x) = \frac{1}{\sqrt{\sqrt{\pi} 2^n n!}} (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2).$$

Here the normalization was chosen such that

$$\int_{-\infty}^{\infty} e^{-x^2} H_n(x) H_m(x) dx = \delta_{nm},$$

where  $\delta_{nm}$  is the Kronecker symbol.

You can verify the Hermite-Gauss normalization using the following functions:

```
Function TestNormalization(order)
  Variable order

  Variable/G theOrder = order
  // The integrand vanishes in double-precision outside [-30,30]
  Print/D Integrate1D(hermiteIntegrand, -30, 30, 2)
End

Function HermiteIntegrand(inX)
  Variable inX

  NVAR n = root:theOrder
  return HermiteGauss(n, inX)^2*exp(-inX*inX)
End
```

### See Also

The **hermite** function.

## hide

**#pragma hide = value**

The hide pragma allows you to make a procedure file invisible.

### See Also

The **The hide Pragma** on page IV-50 and **#pragma**.

## HideIgorMenus

**HideIgorMenus** [*MenuNameStr* [, *MenuNameStr* ]...

The HideIgorMenus operation hides the named built-in menus or, if none are explicitly named, hides all built-in menus in the menu bar.

The effect of HideIgorMenus is lost when a new experiment is opened. The state of HideIgorMenus is saved with the experiment.

User-defined menus are not hidden by HideIgorMenus unless attached to built-in menus and the menu definition uses the hideable keyword.

### Parameters

*MenuNameStr*      The name of an Igor menu, like “File”, “Data”, or “Graph”.

### Details

The optional menu names are in English and not abbreviated. This ensures that code developed for a localized version of Igor will run on all versions.

The built-in menus that can be shown or hidden (the Help menu can be hidden only on Windows) are those that appear in the menu bar:

## HideInfo

---

File	Edit	Data	Analysis	Macros	Windows	Graph
Layout	Notebook	Panel	Procedure	Table	Misc	Help

Hiding a built-in menu to which a user-defined menu is attached results in a built-in menu with only the user-defined items. For example, if this menu definition attaches items to the built-in Graph menu:

```
Menu "Graph"  
    "Do My Graph Thing", ThingFunction()  
End
```

Calling `HideIgorMenus "Graph"` will still leave a Graph menu showing (when a Graph is the top-most target window) with only the user-defined menu(s) in it: in this example the one “Do My Graph Thing” item.

Hiding the Macros menu hides menus created from Macro definitions like:

```
Macro MyMacro()  
    Print "Hello, world."  
End
```

but does not hide normal user-defined “Macros” definitions like:

```
Menu "Macros"  
    "Macro 1", MyMacro(1)  
End
```

You can set user-defined menus to hide and show along with built-in menus by adding the optional `hideable` keyword to the menu definition:

```
Menu "Graph", hideable  
    "Do My Graph Thing", ThingFunction()  
End
```

Then `HideIgorMenus "Graph"` will hide those items, too. If all user-defined Graph menu definitions use the `hideable` keyword, then no Graph menu will appear in the menu bar.

Some WaveMetrics procedures use the `hideable` keyword so that only customer-defined menus remain when `HideIgorMenus` is executed.

### See Also

Chapter IV-5, **User-Defined Menus**.

The **ShowIgorMenus**, **DoIgorMenu**, and **SetIgorMenuMode** operations.

## HideInfo

**HideInfo** [/W=*winName*]

The `HideInfo` operation removes the info panel from a graph if it was previously shown by the **ShowInfo** operation.

### Flags

*/W=winName*            Hides the info panel in the named window.

### See Also

The **ShowInfo** operation.

**Programming With Cursors** on page II-249.

## HideProcedures

**HideProcedures**

The `HideProcedures` operation hides all procedure windows without closing or killing them.

### See Also

The **DisplayProcedure** and **DoWindow** operations.

## HideTools

**HideTools** [/A/W=*winName*]

The HideTools operation hides the tool palette in the top graph or control panel if it was previously shown by the ShowTools operation.

### Flags

/A	Sizes the window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.
/W= <i>winName</i>	Hides the tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

### See Also

The ShowTools operation.

## HilbertTransform

**HilbertTransform** [/Z] [/O] [/DEST=*destWave*] *srcWave*

The HilbertTransform operation computes the Hilbert transformation of *srcWave*, which is a real or complex (single or double precision) wave of 1-3 dimensions. The result of the HilbertTransform is stored in *destWave*, or in the wave W\_Hilbert (1D) or M\_Hilbert in the current data folder.

### Flags

/DEST= <i>destWave</i>	Creates a real wave reference for the destination wave in a user function. See <b>Automatic Creation of WAVE References</b> on page IV-66 for details.
/O	Overwrites <i>srcWave</i> with the transform.
/PAD={ <i>dim1</i> [, <i>dim2</i> , <i>dim3</i> , <i>dim4</i> ]}	Converts <i>srcWave</i> into a padded wave of dimensions <i>dim1</i> , <i>dim2</i> .... The padded wave contains the original data at the start of the dimension and adds zero entries to each dimension up to the specified dimension size. The <i>dim1</i> ... values must be greater than or equal to the corresponding dimension size of <i>srcWave</i> . If you need to pad just the lowest dimension(s) you can omit the remaining dimensions; for example, /PAD= <i>dim1</i> will set <i>dim2</i> and above to match the dimensions in <i>srcWave</i> .  This flag was added in Igor Pro 7.00.
/Z	No error reporting.

### Details

The Hilbert transform of a function  $f(x)$  is defined by:

$$F(t) = \frac{1}{\pi t} \int_{-\infty}^{\infty} \frac{f(x) dx}{x - t}.$$

Theoretically, the integral is evaluated as a Cauchy principal value. Computationally one can write the Hilbert transform as the convolution:

$$F(t) = \frac{-1}{\pi t} * f(t),$$

which by the convolution theorem of Fourier transforms, may be evaluated as the product of the transform of  $f(x)$  with  $-i*\text{sgn}(x)$  where:

## Histogram

---

$$\text{sgn}(x) = \begin{cases} -1 & x < 0 \\ 0 & x = 0 \\ 1 & x > 0 \end{cases} .$$

Note that the Hilbert transform of a constant is zero. If you compute the Hilbert transform in more than one dimension and one of the dimensions does not vary (is a constant), the transform will be zero (or at least numerically close to zero).

There are various definitions for the extension of the Hilbert transform to more than one dimension. In two dimensions this operation computes the transform by multiplying the 2D Fourier transform of the input by the factor  $(-i)\text{sgn}(x)(-i)\text{sgn}(y)$  and then computing the inverse Fourier Transform. A similar procedure is used when the input is 3D.

### Examples

Extract the instantaneous amplitude and frequency of a narrow-band signal.

```
Make/O/N=1000 w0,amp,phase
SetScale/I x 0,50,"", w0,amp,phase
w0 = exp(-x/10)*cos(2*pi*x)
HilbertTransform /DEST=w0h w0 // w0+i*w0h is the "analytic signal", i=cplx(0,1)
amp = sqrt(w0^2 + w0h^2) // extract the envelope
phase = atan2(-w0h,w0) // extract the phase [SIGN CONVENTION?]
Unwrap 2*pi, phase // eliminate the 2*pi phase jumps
Differentiate phase /D=freq // would have less noise if fit to a line
// over interior points
freq /= 2*pi // phase = 2*pi*freq*time
Display w0,amp // original waveform and its envelope; note boundary effects
Display freq // instantaneous frequency estimate, with boundary effects
```

### See Also

The FFT operation.

### References

Bracewell, R., *The Fourier Transform and Its Applications*, McGraw-Hill, 1965.

## Histogram

**Histogram** [*flags*] *srcWaveName*, *destWaveName*

The Histogram operation generates a histogram of the data in *srcWaveName* and puts the result in *destWaveName* or in *W\_Histogram* or in the wave specified by */DEST*.

### Parameters

*srcWaveName* specifies the wave containing the data to be histogrammed.

For historical reasons the meaning and use of *destWaveName* depend on the binning mode as specified by */B*. See **Histogram Destination Wave** on page V-300 below for details.

### Flags

*/A* Accumulates the histogram result with the existing values in the destination wave instead of replacing the existing values with the result. Assumes */B=2* unless the */B* flag is present.

**Note:** The result will be incorrect if you also use */P*.

/B=mode	<p>Controls binning:</p> <p><i>mode=1:</i> Semi-automatic mode that sets the bin range based on the range of the Y values in <i>srcWaveName</i>. The number of bins is determined by the number of points in the destination wave.</p> <p><i>mode=2:</i> Uses the bin range and number of bins determined by the X scaling and number of points in the destination wave.</p> <p><i>mode=3:</i> Uses Sturges' method to determine optimal number of bins and redimensions the destination wave as necessary. By this method</p> $\text{numBins} = 1 + \log_2(N)$ <p>where N is the number of data points in <i>srcWaveName</i>. The bins will be distributed so that they include the minimum and maximum values.</p> <p><i>mode=4:</i> Uses a method due to Scott, which determines the optimal bin width as</p> $\text{binWidth} = 3.49 * \sigma * N^{-1/3}$ <p>where N is the number of data points in <i>srcWaveName</i> and <math>\sigma</math> is the standard deviation of the distribution. The bins will be distributed so that they include the minimum and maximum values.</p> <p><i>method=5:</i> Uses the Freedman-Daiconis method where</p> $\text{binWidth} = 2 * \text{IQR} * N^{-1/3}$ <p>where IQR is the interquartile distance (see <b>StatsQuantiles</b>) and the bins are evenly distributed between the minimum and maximum values.</p>
/B={binStart,binWidth,numBins}	<p>Sets the histogram bins from these parameters rather than from <i>destWaveName</i>. Changes the X scaling and length of the destination wave.</p>
/C	<p>Sets the X scaling so that X values are in the centers of the bins, which is required when you do a curve fit to the histogram output. Ordinarily, wave scaling of the output wave is set with X values at the left bin edges.</p>
/CUM	<p>Requests a cumulative histogram in which each bin is the sum of bins to the left. The last bin will contain the total number of input data points, or, with /P, 1.0.</p> <p>/CUM cannot be used with a weighted histogram (/W flag).</p> <p>When used with /A, the destination wave must be the result of a histogram created with /CUM.</p> <p>Note that if you use a binning mode (/B flag) that sets a bin range that does not include the entire range of the input data, then the output will not count all of input points and the last bin will not contain the total number of input points. Input points whose values fall below the left edge of the first bin or above the right edge of the last bin will not be counted.</p>
/DEST=destWave	<p>Saves the histogram output in a wave specified by <i>destWave</i>. The destination wave is created or overwritten if it already exists.</p> <p>Creates a wave reference for the destination wave in a user function. See <b>Automatic Creation of WAVE References</b> on page IV-66 for details.</p> <p>See <b>Histogram Destination Wave</b> on page V-300 below for further discussion.</p> <p>The /DEST flag was added in Igor Pro 7.00.</p>
/N	<p>Creates a wave (W_SqrtN) containing the square root of the number of counts in each bin. This is an appropriate wave to use as a weighting wave when doing a curve fit to the histogram results.</p>

## Histogram

---

<code>/NLIN=<i>binsWave</i></code>	<p>Computes a non-linear histogram using the bins specified in the wave <i>binsWave</i>. This option is not compatible with the flags <code>/A</code>, <code>/B</code>, <code>/C</code>, <code>/CUM</code>, <code>/N</code>, <code>/P</code>, <code>/W</code>.</p> <p>The bins must be contiguous and non-overlapping so that <i>binsWave</i> contains monotonically increasing values with no NaNs and INFs. For example, if you want the 3 bins <code>[1,10)</code>, <code>[10,100)</code>, <code>[100,1000)</code>, execute:</p> <p>Make <code>O/N=4 bins={1,10,100,1000}</code></p> <p>The upper end of each bin is open.</p> <p>The <code>/NLIN</code> flag was added in Igor Pro 7.00.</p>
<code>/P</code>	<p>Normalizes the histogram as a probability distribution function, and shifts wave scaling so that data correspond to the bin centers.</p> <p>When using the results with <b>Integrate</b>, you must use <code>/METH=0</code> or <code>/METH=2</code> to select rectangular integration methods.</p>
<code>/R=(<i>startX</i>,<i>endX</i>)</code>	<p>Specifies the range of X values of <i>srcWaveName</i> over which the histogram is to be computed.</p>
<code>/R=[<i>startP</i>,<i>endP</i>]</code>	<p>Specifies the range of points of <i>srcWaveName</i> over which the histogram is to be computed.</p>
<code>/RMD=[<i>firstRow</i>,<i>lastRow</i>][<i>firstColumn</i>,<i>lastColumn</i>][<i>firstLayer</i>,<i>lastlayer</i>][<i>firstChunk</i>,<i>lastChunk</i>]</code>	<p>Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 7.00.</p> <p>You can include all higher dimensions by leaving off the corresponding brackets. For example:</p> <p><code>/RMD=[firstRow, lastRow]</code></p> <p>includes all available columns, layers and chunks.</p> <p>You can use empty brackets to include all of a given dimension. For example:</p> <p><code>/RMD=[] [firstColumn, lastColumn]</code></p> <p>means "all rows from column A to column B".</p> <p>You can use a <code>*</code> to specify the end of any dimension. For example:</p> <p><code>/RMD=[firstRow, *]</code></p> <p>means "from firstRow through the last row".</p>
<code>/W=<i>weightWave</i></code>	<p>Creates a "weighted" histogram. In this case, instead of adding a single count to the appropriate bin, the corresponding value from <i>weightWave</i> is added to the bin. <i>weightWave</i> may be any number type, and it may be complex. If it is complex, then the destination wave will be complex.</p> <p><code>/W</code> cannot be used with a cumulative histogram (<code>/CUM</code> flag).</p>

### Histogram Destination Wave

For historical reasons there are multiple ways to specify the destination wave and the meaning and use of *destWaveName* depend on the binning mode as specified by `/B`. This section explains the details and then provides guidance and when to use which mode.

In binning modes 1 and 2 (`/B=1` and `/B=2`, described above), the destination wave plays a role in determining the binning and *destWaveName* must be the name of an existing wave. If you omit `/DEST` then the output is written to *destWaveName*. If you provide `/DEST` then the output is written to the wave specified by `/DEST`.

In binning modes 3, 4 and 5 (`/B=3`, `/B=4` and `/B=5`, described above), the destination wave plays no role in determining the binning. If you omit *destWaveName* and `/DEST`, Histogram stores its output in a wave named `W_Histogram` in the current data folder. If you omit `/DEST` and provide *destWaveName*, then *destWaveName* must name an existing wave to which the output is written. If you provide `/DEST`, you can omit *destWaveName*. If you provide both `/DEST` and *destWaveName* then *destWaveName* must name an existing wave but the operation ignores it.

Here is the recommended usage:

If you want to use specific binning that you have determined, use `/B={binStart,binWidth,numBins}`, use `/DEST` to specify the destination wave, and omit `destWaveName`.

If you want Igor to determine the binning, use `/B=3`, `/B=4` or `/B=5`, use `/DEST` to specify the destination wave, and omit `destWaveName`.

For backward compatibility with Igor Pro 6, use `/B=1`, `/B=2`, `/B=3`, `/B=4` or `/B={binStart,binWidth,numBins}`, create a destination wave, use it as `destWaveName` and omit `/DEST`.

### Details

If you use `/B={binStart, binWidth, numBins}`, then the initial number of data points in the wave is immaterial since the Histogram operation changes the number of points.

Only one `/B` and only one `/R` flag is allowed.

If both `/A` and `/B` flags are missing, the bin range and number of bins is calculated as if `/B=1` had been specified.

When accumulating multiple histograms in one output wave, typically you will want to use `/B={binStart,binWidth,numBins}` for the first histogram, and `/A` for successive histograms.

The Histogram operation works on single precision floating point destination waves. If necessary, Histogram redimensions the destination wave to be single precision floating point. However, Histogram/`A` requires that the destination wave already be single precision floating point.

For a weighted histogram, the destination wave will be double-precision.

If you specify the range as `/R=(start)`, then the end of the range is taken as the end of `srcWaveName`.

In an ordinary histogram, input data is examined one data point at a time. The operation determines which bin a data value falls into and a single count is added to that bin. A weighted histogram works similarly, except that it adds to the bin a value from another wave in which each row corresponds to the same row in the input wave.

Normal Histogram

Weighted Histogram

The Histogram operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-86 for details. In fact, the Histogram operation can be usefully applied to multidimensional waves, such as those that represent images. The `/R` flag will not work as expected, however.

### Examples

```
// Create histogram of two sets of data.
Make/N=1000 data1=gnoise(1), data2=gnoise(1)
Make/N=1 histResult
```

## hyperG0F1

---

```
// Sets bins, does histogram.  
Histogram/B={-5,1,10} data1, histResult  
Display histResult; ModifyGraph mode=5  
  
// Accumulates into existing bins.  
Histogram/A data2, histResult
```

## hyperGNoise

**hyperGNoise**(*m*, *n*, *k*)

The hyperGNoise function returns a pseudo-random value from the hypergeometric distribution whose probability distribution function is

$$f(x, m, n, k) = \frac{\binom{n}{x} \binom{m-n}{k-x}}{\binom{m}{k}}$$

where  $m$  is the total number of items,  $n$  is the number of marked items, and  $k$  is the number of items in a sample.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

## i

### i

The i function returns the loop index of the inner most iterate loop in a macro. Not to be used in a function. iterate loops are archaic and should not be used.

## ICA

### ICA [*flags*] *srcWave*

The ICA operation performs independent component analysis using the FastICA algorithm. Input data is in the form of a 2D wave where each column represents the equivalent of a single data acquisition channel. The results of the operation are stored in the waves M\_ICAComponents, M\_ICAUnMix and M\_matrixW in the current data folder.

The ICA operation was added in Igor Pro 7.00.

#### Flags

/A= <i>alpha</i>	<p><i>alpha</i> is a constant used as a factor in the argument of the logCosh function. It is not used with the exp function.</p> <p><i>alpha</i> is in the range [1,2] and its default value is 1.</p> <p>You will rarely need to change this value to affect the rate of convergence or the quality of the results.</p>
/CF=num	<p>Specifies the contrast function, also called the non-quadratic function, used by ICA.</p> <p><i>num</i>=0: logCosh (default)</p> <p><i>num</i>=1: exp</p>
/COLS	<p>Preconditions the input by subtracting the mean and then normalizing the input on a column-by-column basis. The algorithm appears to converge and produce better results when this flag is used.</p>
/DFLT	<p>Use the deflation/vector method where iterations solve for a single vector of the "unmixing" matrix at a time. By default the operation uses the matrix method which solves for the complete unmixing matrix at one time.</p>
/PCA	<p>Save the output of the "PCA" stage which is also the form of the data before the fastICA iterations. The data are saved in the wave M_PCA in the current data folder.</p>
/Q	<p>Quiet mode; do not print anything in the history.</p>
/TOL= <i>tolerance</i>	<p>The tolerance value is used to determine when iterations converge.</p> <p>In the deflation/vector method the tolerance measures the difference between the values of vectors in consecutive iterations.</p> <p>In the matrix method the tolerance measures the average deviation of all components.</p> <p>By default tolerance = 1e-5 for both methods.</p>

`/WINT=w` Provides an initial unmixing matrix *W*. If you do not provide this matrix the algorithm initializes using `enose`.  
 The wave *w* must be 2D having the same number type as *srcWave* and having dimensions *nCols* x *nCols*, where *nCols* is the number of columns of *srcWave*. Providing an initial matrix is useful if you have obtained one from a previous set of iterations which may have converged using inadequate tolerance.

`/Z` No error reporting.

### Details

*srcWave* is a 2D wave of *nRows* by *nCols*. It must be a single or double precision real-valued wave containing no NaNs or INFs. Each column of *srcWave* corresponds to a single data acquisition channel that is assumed to consist of a linear superposition of independent components. This can be expressed as a matrix product

$$\mathbf{X} = \mathbf{A} (\mathbf{S}^t)$$

where **S** is an *nRows* by *nCols* matrix of independent components, <sup>t</sup> denotes the transpose, **A** is an *nCols* by *nCols* mixing matrix and **X** is the "mixed" input. The ICA operation attempts to find the independent components of **S** from the transformation

$$\mathbf{S} = \mathbf{W} \mathbf{X}$$

so that the mutual information between the resulting columns of **S** is minimized. Since mutual information is not affected by a multiplication of components by scalar constants, the resulting independent components can be specified up to a scalar factor.

The operation uses the FastICA algorithm to compute the independent components.

The algorithm has two available methods for computation. The default is to attempt to evaluate the full **W** matrix at once. The second method (`/DFLT` flag) also known as "deflation" computes one row of **W** at a time. The deflation method might have advantages in cases where there are fewer independent components than there are columns in the input.

### Example

```
// Create the source
Make/O/N=(1000,3) ddd
ddd[] [0]=sin(2*pi*x/13)
ddd[] [1]=sin(2*pi*x/17)
ddd[] [2]=sin(2*pi*x/23)

// Create mixing matrix
Make/O/N=(3,3) AA
AA[0] [0] = { 0.291, 0.6557, -0.5439 }
AA[0] [1] = { 0.5572, 0.3, -0.2 }
AA[0] [2] = { -0.1, -0.7, 0.4 }

// Do the mixing
MatrixOp/O xx=ddd x AA

// Try the ICA
ICA/DFLT/COLS xx
Wave ICARes
Display M_ICAComponents[] [0]
Display M_ICAComponents[] [1]
Display M_ICAComponents[] [2]
```

PCA

## if-elseif-endif

```

if ( <expression1> )
    <TRUE part 1>
elseif ( <expression2> )
    <TRUE part 2>
[...]
[else
    <FALSE part>]
endif

```

In an if-elseif-endif conditional statement, when an expression first evaluates as TRUE (nonzero), then only code corresponding to the TRUE part of that expression is executed, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then *FALSE part* is executed when present. After executing code in any TRUE part or the FALSE part, execution will next continue with any code following the if-elseif-endif statement.

### See Also

If-Elseif-Endif on page IV-38 for more usage details.

## if-endif

```

if ( <expression> )
    <TRUE part>
[else
    <FALSE part>]
endif

```

An if-endif conditional statement evaluates *expression*. If *expression* is TRUE (nonzero) then the code in *TRUE part* is executed, or if FALSE (zero) then the optional *FALSE part* is executed.

### See Also

If-Else-Endif on page IV-37 for more usage details.

## IFFT

**IFFT** [*flags*] *srcWave*

The IFFT operation calculates the Inverse Discrete Fourier Transform of *srcWave* using a multidimensional fast prime factor decomposition algorithm. This operation is the inverse of the FFT operation.

### Output Wave Name

For compatibility with earlier versions of Igor, if you use IFFT without /ROWS or /COLS, the operation overwrites *srcWave*.

If you use the /ROWS flag, IFFT uses the default output wave name M\_RowFFT and if you use the /COLS flag, IFFT uses the default output wave name M\_ColFFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting *srcWave*.

### Parameters

*srcWave* is a complex wave. The IFFT of *srcWave* is either a real or complex wave, according to the length and flags.

### Flags

- |       |  |
|-------|--|
| /C    | Forces the result of the IFFT to be complex. Normally, the IFFT produces a real result unless certain special conditions are detected as described in <b>Details</b> .   |
| /COLS | Computes the 1D IFFT of 2D <i>srcWave</i> one column at a time, storing the results in the destination wave. You must specify a destination wave using the /DEST flag (no other flags are allowed). See the /ROWS flag and corresponding flags of the FFT operation. |

<code>/DEST=destWave</code>	<p>Specifies the output wave created by the IFFT operation.</p> <p>It is an error to specify the same wave as both <i>srcWave</i> and <i>destWave</i>.</p> <p>In a function, IFFT by default creates a real wave reference for the destination wave. See <b>Automatic Creation of WAVE References</b> on page IV-66 for details.</p>
<code>/FREE</code>	<p>Creates <i>destWave</i> as a free wave.</p> <p><code>/FREE</code> is allowed only in functions and only if <i>destWave</i>, as specified by <code>/DEST</code>, is a simple name or wave reference structure field.</p> <p>See <b>Free Waves</b> on page IV-84 for more discussion.</p> <p>The <code>/FREE</code> flag was added in Igor Pro 7.00.</p>
<code>/R</code>	<p>Forces real output when, due to a power of 2 number of points, IFFT would otherwise automatically produce a complex result.</p>
<code>/ROWS</code>	<p>Calculates the IFFT of only the first dimension of 2D <i>srcWave</i>. It computes the 1D FFT one row at a time. You must specify a destination wave using the <code>/DEST</code> flag (no other flags are allowed). See the <code>/COLS</code> flag and corresponding flags of the <b>FFT</b> operation.</p>
<code>/Z</code>	<p>Will not rotate <i>srcWave</i> when computing the IDFT of a complex wave whose length is an integral power of 2.</p> <p>This length indicates that the Inverse DFT result will also be a complex wave. When the result is complex, <i>and</i> the x scaling of <i>srcWave</i> is such that the first point is <i>not</i> x=0, it normally rotates <i>srcWave</i> by -N/2 points before performing the IFFT. This inverts the process of performing an FFT on a complex wave. However when <code>/Z</code> is specified, it does not perform this rotation.</p>

### Details

The data type of *srcWave* must be complex and must not be an integer type. You should be aware that an IFFT on a number of points that is prime can be slow.

By default, IFFT assumes you are performing an inverse transform on data that was originally real and therefore it produces a real result. However, for historical and compatibility reasons, IFFT detects the special conditions of a one-dimensional wave containing an integral power of 2 data points and automatically creates a complex result.

When the result is complex, the number of points (N) in the resulting wave will be of the same length. Otherwise the resulting wave will be real and of length (N-1)\*2.

In either the complex or real case the X units of the output wave are changed to "s". The X scaling also is changed appropriately, cancelling out the adjustments made by the **FFT** operation. When the data is multidimensional, the same considerations apply to the additional dimensions. The scaling description and IDFT equation below pretend that the IFFT is not performed in-place. After computing the IFFT values, the X scaling of *waveOut* is changed as if Igor had executed these commands:

```
Variable points // time-domain points, NtimeDomain
if( waveIn was complex wave )
    points= numpnts(waveIn)
else
    points= (numpnts(waveIn) - 1) * 2 // waveIn was real wave
endif
Variable deltaT= 1 / (points*deltaX(waveIn)) // 1/(NtimeDomaindx)
SetScale/P waveOut 0,deltaT,"s"
```

The IDFT equation is:

$$waveOut[n] = \frac{1}{N} \sum_{k=0}^{N-1} waveIn[k] \exp\left(\frac{2\pi i k n}{N}\right), \quad \text{where } i = \sqrt{-1}.$$

## IgorInfo

### IgorInfo(*selector*)

The IgorInfo function returns information about the Igor application and the environment in which it is running.

### Details

*selector* is a number from 0 to 6.

Always pass 0, 1, 2, 3, 4, 5, 6 or 7 as the input parameter. In future versions of Igor Pro, this parameter may request other kinds of information.

If *selector* is 0, IgorInfo returns a collection of assorted information. The result string contains five kinds of information. Each group is prefaced by a keyword and a colon, and terminated with a semicolon.

Keyword	Information Following Keyword For IgorInfo(0)
FREEMEM	The amount of free memory available to Igor.
PHYSMEM	The amount of total physical memory available to Igor. Added in Igor Pro 7.00.
USEDPHYSMEM	The amount of used physical memory available to Igor. Added in Igor Pro 7.00.
IGORKIND	<p>The type of Igor application:</p> <p>"pro": Igor Pro 32-bit</p> <p>"pro demo": Igor Pro 32-bit in demo mode</p> <p>"pro64": Igor Pro 64-bit</p> <p>"pro64 demo": Igor Pro 64-bit in demo mode</p> <p>"pro64" and "pro64 demo" are returned by the 64-bit of Igor Pro 7.00 or later.</p> <p>The presence of "demo" indicates that Igor is running in demo mode, either because the user's fully-functional demo period has expired or because the user chose to run in demo mode using the License dialog.</p>
IGORVERS	The version number of the Igor application. Also see IGORFILEVERSION returned by IgorInfo(3).
NSCREEN	Number of screens currently attached to the computer and used for the desktop.
SCREEN1	<p>A description of the characteristics of screen 1.</p> <p>The format of the SCREEN1 description is:</p> <p>SCREEN1:DEPTH=<i>bitsPerPixel</i>,RECT=<i>left,top,right,bottom</i>;</p> <p><i>left</i>, <i>top</i>, <i>right</i>, and <i>bottom</i> are all in pixels.</p> <p>If there are multiple screens, there will be additional SCREEN keywords, such as SCREEN2 and SCREEN3.</p>

If *selector* is 1, IgorInfo returns the name of the current Igor experiment.

If *selector* is 2, IgorInfo returns the name of the current platform: "Macintosh" or "Windows".

If *selector* is 3, IgorInfo returns a collection of more detailed information about the operating system, localization information, and the actual file version of the Igor executable. The keywords are OS, OSVERSION, LOCALE, and IGORFILEVERSION.

Keyword	Information Following Keyword For IgorInfo(3)
IGORFILEVERSION	<p>The actual version number of the Igor application file.</p> <p>On Macintosh, the version number is a floating point number with a possible suffix. Igor Pro 7.00, for example, returns "7.00". Igor Pro 7.02A returns "7.02A".</p> <p>On Windows, the version format is a period-separated list of four numbers. Igor Pro 7.02 returns "7.0.2.0". A revision to Igor Pro 7.02 would be indicated in the last digit, such as "7.0.2.12".</p>

Keyword	Information Following Keyword For IgorInfo(3)
LOCALE	Country for which this version of Igor Pro is localized. "US" for most versions, "Japan" for the Japanese versions.
OS	On Mac OS X, this will be "Macintosh OS X". On Windows, this might be "Windows XP (Build 1234)". The actual build number and format of the text will vary with the operating system.
OSVERSION	Operating system number. On Macintosh, this is something like "10.9.5". On Windows, this is something like "6.3.10586".

If *selector* is 4, IgorInfo returns the name of the current processor architecture. Currently this is always "Intel".

If *selector* is 5, IgorInfo returns, as a string, the serial number of the program if it is registered or "\_none\_" if it isn't registered. Use **str2num** to store the result in a numeric variable. str2num returns NaN if the program isn't registered.

If *selector* is 6, IgorInfo returns, as a string, the version of the Qt library under which Igor is running, for example "5.6.1". This selector value was added in Igor Pro 7.00.

If *selector* is 7, IgorInfo returns, as a string, the name of the current user. This selector value was added in Igor Pro 7.00.

#### Examples

```
Print NumberByKey("NSCREENS", IgorInfo(0))      // Number of active displays
Function RunningWindows()                        // Returns 0 if Macintosh, 1 if Windows
    String platform = UpperStr(IgorInfo(2))
    Variable pos = strsearch(platform, "WINDOWS", 0)
    return pos >= 0
End
```

## IgorVersion

**#pragma IgorVersion = versNum**

When a procedure file contains the directive, **#pragma IgorVersion=versNum**, an error will be generated if *versNum* is greater than the current Igor Pro version number. It prevents procedures that use new features added in later versions from running under older versions of Igor in which these features are missing. However, this version check is limited because it does not work with versions of Igor older than 4.0.

#### See Also

The **The IgorVersion Pragma** on page IV-50 and **#pragma**.

## IgorVersion

The IgorVersion function returns version number of the Igor application as a floating point number. Igor Pro 7.00 returns 7.00, as does Igor Pro 7.00A.

#### Details

Because floating point numbers are not precise, exact comparisons to floating point values often behave in unexpected ways. For example:

```
Variable result = 6 + 0.1
if (result == 6.1)
    Print "result == 6.1"           // this is not printed!
else
    Print "difference = ", result - 6.1 // prints "difference = -8.88178e-16"
endif
```

However, IgorVersion compensates for this so that the following will work as expected:

```
if (IgorVersion() == 6.1)
    Print "result == 6.1" // this is printed to the history area
endif
```

You can use `IgorVersion` in conditionally compile code expressions, which can be used to omit calls to new Igor features or to provide backwards compatibility code.

```
#if (IgorVersion() >= 7.00)
    [Code that compiles only on Igor Pro 7.00 or later]
#else
    [Code that compiles only on earlier versions of Igor]
#endif
```

If at all possible, it is better to require your users to use a later version of Igor rather than writing conditional code. Attempting this kind of backward-compatibility multiplies your testing requirements and the chances for bugs.

#### See Also

**IgorInfo**, **Conditional Compilation** on page IV-100, **The IgorVersion Pragma** on page IV-50

## ilim

### **ilim**

The `ilim` function returns the ending loop count for the inner most iterate loop. Not to be used in a function. Iterate loops are archaic and should not be used.

## imag

### **imag (z)**

The `imag` function returns the imaginary component of the complex number `z` as a real (not complex) number.

#### See Also

The **cmplx**, **conj**, **p2rect**, **r2polar**, and **real** functions.

## ImageAnalyzeParticles

### **ImageAnalyzeParticles** [*flags*] *keyword imageMatrix*

The `ImageAnalyzeParticles` operation performs one of two particle analysis operations on a 2D or 3D source wave *imageMatrix*. The source image wave must be binary, i.e., an unsigned char format where the particles are designated by 0 and the background by 255 (the operation will produce erroneous results if your data uses the opposite designation). Note that all nonzero values in the source image will be considered part of the background. Grayscale images must be thresholded before invoking this operation (you may need to use the `/I` flag with the **ImageThreshold** operation).

**Note:** `ImageAnalyzeParticles` does not take into account wave scaling. All image metrics are in pixels and all pixels are assumed to be square.

#### Parameters

*keyword* is one of the following names:

- |       |  |
|-------|--|
| mark  | Creates a masking image for a single particle, which is specified by an internal (seed) pixel using the <code>/L</code> flag. The masking image is stored in the wave <code>M_ParticleMarker</code> , which is an unsigned char wave. All points in <code>M_ParticleMarker</code> are set to 64 (image operations on binary waves use the value 64 to designate the equivalent of NaN) except points in the particle which are set to the 0. This wave is designed to be used as an overlay on the original image (using the <code>explicit=1</code> mode of <code>ModifyImage</code> ). This keyword is superseded by the <b>ImageSeedFill</b> operation. |
| stats | Measures the particles in the image. See <b>ImageAnalyzeParticles Stats</b> on page V-313 for details.   |

## Flags

<i>/A=minArea</i>	<p>Specifies a minimum area as a threshold that must be exceeded for a particle to be counted (e.g., use <i>minArea</i>=0 to find single pixel particles). The minimum area is measured in pixels; its default value is <i>minArea</i>=5.</p> <p>When the source wave is 3D, <i>minArea</i> specifies the minimum number of voxels that constitute a particle.</p> <p><i>/A</i> has no effect when used with the <i>mark</i> method.</p>
<i>/B</i>	Erases a 1 pixel wide frame inset from the boundary. This insures that no particles will have boundary pixels (see <i>/EBPC</i> below) and all boundary waves will describe close contours.
<i>/CIRC={minCircularity,maxCircularity}</i>	<p>Use this flag to filter the output so that only particles in the range of the specified circularity are counted.</p>
<i>/D=dataWave</i>	Specify a wave from which the minimum, maximum, and total particle intensity are sampled when used with the stats keyword. <i>dataWave</i> must be of the same dimensions as the input binary image <i>imageMatrix</i> . It can be of any real numeric type. Results are returned in the waves <i>W_IntMax</i> , <i>W_IntMin</i> , and <i>W_IntAvg</i> .
<i>/E</i>	<p>Calculates an ellipse that best fits each particle. The equivalent ellipse is calculated by first finding the moments of the particle (i.e., average x-value, average y-value, average <math>x^2</math>, average <math>y^2</math>, and average <math>x*y</math>), and then requiring that the area of the ellipse be equal to that of the particle. The resulting ellipses are saved in the wave <i>M_Moments</i>. When <i>imageMatrix</i> is a 2D wave, the results returned in <i>M_Moments</i> are the columns: the X-center of the ellipse, the Y-center of the ellipse, the major axis, the minor axis, and the angle (radians) that the major axis makes with the X-direction. When <i>imageMatrix</i> is a 3D wave, the results in <i>M_Moments</i> include the sum of the X, Y, and Z components as well as all second order permutations of their products. They are arranged in the order: <i>sumX</i>, <i>sumY</i>, <i>sumZ</i>, <i>sumXX</i>, <i>sumYY</i>, <i>sumZZ</i>, <i>sumXY</i>, <i>sumXZ</i>, and <i>sumYZ</i>.</p>
<i>/EBPC</i>	Use this flag to exclude from counting any particle that has one or more pixels on any boundary of the image.
<i>/F</i>	<p>Fills 2D particles having internal holes and adjusts their area measure for the removal of holes. Internal boundaries around the holes are also eliminated. When the boundary of the particle consists of thin elements that cannot be traversed as a single closed path which passes each boundary pixel only once, the particle will not be filled. Note that filling particles may increase execution time considerably and on some images it may require large amount of memory. It is likely that a more efficient approach would be to preprocess the binary image and remove holes using morphology operations. This flag is not supported when <i>imageMatrix</i> is a 3D wave.</p>
<i>/FILL</i>	<p>Use <i>/FILL</i> to fill holes inside particles. The reported values of area and perimeter are computed as if there are no holes. The filling algorithm could fail if, for example, there is a closed contour of zeros around the particles.</p> <p>If you specify both <i>/F</i> and <i>/FILL</i> the operation used <i>/FILL</i> only.</p> <p>Added in Igor Pro 7.00.</p>
<i>/L= (row,col)</i>	Specifies a 2D particle location in connection with the mark method. ( <i>row</i> , <i>col</i> ) is a seed value corresponding to any pixel inside the particle. If the seed belongs to the particle boundary, the particle will not be filled. This flag is not supported when <i>imageMatrix</i> is a 3D wave.

<i>/M=markerVal</i>	<p>Use this flag with the stats mode for 2D images. See <b>stats</b> keyword for a full description of the following waves:</p> <p><i>markerVal=0:</i> No marker waves. <i>markerVal=1:</i> M_ParticlePerimeter. <i>markerVal=2:</i> M_ParticleArea. <i>markerVal=3:</i> M_Particle.</p> <p>This flag does not apply to 3D waves.</p>
<i>/MAXA=maxArea</i>	<p>Specifies an upper limit of the area of an acceptable particle when used with the stats keyword. The area is measured in pixels and the default value of <i>maxArea</i> is the number of pixels in the image. In 3D the maximum value applies to the number of voxels.</p>
<i>/NSW</i>	<p>Creates the marker wave (see <i>/M</i> flag) but not the particle statistics waves when used with the stats keyword. This should reduce execution time in images containing many particles.</p>
<i>/P=plane</i>	<p>Specifies the plane when operating on a single layer of a 3D wave.</p>
<i>/PADB</i>	<p>Use this flag with the stats keyword to pad the image with a 1 pixel wide background. This has the effect that particles touching the image boundary are now interior particles with closed perimeter (that extend one pixel beyond the original image frame). In addition, entries in the wave W_ObjPerimeter will be longer for all boundary particles which will also affect other derived parameters such as circularity.</p> <p><i>/PADB</i> is different from <i>/B</i> in that it takes into account all pixels belonging to the particle that lie on the boundary of the image. The two flags are mutually exclusive.</p> <p><i>/PADB</i> was added in Igor Pro 7.00.</p>
<i>/Q</i>	<p>Quiet flag, does not report the number of particles to the history area.</p>
<i>/R=roiWave</i>	<p>Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u) that has the same number of rows and columns as <i>imageMatrix</i>. The ROI itself is defined by the entries or pixels in the <i>roiWave</i> with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When <i>imageMatrix</i> is a 3D wave, <i>roiWave</i> can be either a 2D wave (matching the number of rows and columns in <i>imageMatrix</i>) or it can be a 3D wave that must have the same number of rows, columns and layers as <i>imageMatrix</i>. When using a 2D <i>roiWave</i> with a 3D <i>imageMatrix</i> the ROI is understood to be defined by <i>roiWave</i> for each layer in the 3D wave.</p> <p>See <b>ImageGenerateROIMask</b> for more information on creating 2D ROI waves.</p>
<i>/U</i>	<p>Saves the wave M_ParticleMarker as an 8-bit unsigned instead of the default 16-bit when used with the mark keyword.</p>
<i>/W</i>	<p>Creates boundary waves W_BoundaryX, W_BoundaryY, and W_BoundaryIndex for a 2D <i>imageMatrix</i> wave. W_BoundaryX and W_BoundaryY contain the pixels along the particle boundaries. The boundary of each particle ends with a NaN entry in both waves. Each entry in W_BoundaryIndex is the index to the start of a new particle in W_BoundaryX and W_BoundaryY, so that you can quickly locate the boundary of each particle.</p> <p>When there are holes in particles, the entries in W_BoundaryX and W_BoundaryY start with the external boundary followed by all the internal boundaries for that particle. There are no index entries for internal boundaries.</p> <p>This flag is not supported when <i>imageMatrix</i> is a 3D wave.</p>

### Details

Particle analysis is accomplished by first converting the data from its original format into a binary representation where the particle is designated by zero and the background by any nonzero value. The algorithm searches for the first pixel or voxel that belongs to a particle and then grows the particle from that seed while keeping count

of the area, perimeter and count of pixels or voxels in the particle. If you use additional flags, the algorithm must compute additional quantities for each pixel or voxel belonging to the particle.

If your goal is to mask only the particle, a more efficient approach is to use the **ImageSeedFill** operation, which similarly follows the particle but does not spend processing time on computing unrelated particle properties. ImageSeedFill also has the additional advantage of not requiring that the input wave be binary, which will save time on performing the initial threshold and, in fact, may produce much better results with the adaptive/fuzzy features that are not available in ImageAnalyzeParticles.

### ImageAnalyzeParticles Stats

The ImageAnalyzeParticles stats keyword measures the particles in the image. Results of the measurements are reported for all particles whose area exceeds the *minArea* specified by the /A flag. The results of the measurements are:

V_NumParticles	Number of particles that exceed the <i>minArea</i> limit.
W_ImageObjArea	Area (in pixels) for each particle.
W_ImageObjPerimeter	Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.
W_circularity	Ratio of the square of the perimeter to ( $4*\pi*$ objectArea). This value approaches 1 for a perfect circle.
W_rectangularity	Ratio of the area of the particle to the area of the inscribing (nonrotated) rectangle. This ratio is $\pi/4$ for a perfectly circular object and unity for a nonrotated rectangle.
W_SpotX and W_SpotY	Contain a single x, y point from each object. There is one entry per particle and the entries follow the same order as all other waves created by this operation. Each (x,y) point from these waves can be used to define the position of a tag or annotation for a particle. Points can also be used as seed pixels for the associated <i>mark</i> method or for the ImageSeedFill operation.
W_xmin, W_xmax, W_ymin, W_ymax	Contain a single point for each particle defining an inscribing rectangular box with axes along the X and Y directions.

One of the following waves can be created depending on the /M specification. The waves are designed to be used as an overlay on the original image (using the explicit=1 mode of **ModifyImage**). **Note:** the additional time required to create these waves is negligible compared with the time it takes to generate the stats data.

M_ParticlePerimeter	Masking image of particle boundaries. It is an unsigned char wave that contains 0 values for the object boundaries and 64 for all other points.
M_ParticleArea	Masking image of the area occupied by the particles. It is an unsigned char wave containing 0 values for the object boundaries and 64 for all other points. It is also different from the input image in that particles smaller than the minimum size, specified by /A, are absent.
M_Particle	Image of both the area and the boundary of the particles. It is an unsigned char wave that contains the value 16 for object area, the value 18 for the object boundaries and the value 64 for all other points.
M_rawMoments	Contains five columns. The first column is the raw sum of the x values for each particle, and the second column contains the sum of the y values. To obtain the average or “center” of a particle divide these values by the corresponding area. The third column contains the sum of $x^2$ , the fourth column the sum of $y^2$ , and the fifth column the sum of $x*y$ . The entries of this wave are used in calculating a fit to an ellipse (using the /E flag).

## ImageBlend

---

When *imageMatrix* is a 3D wave, the different results are packed into a single 2D wave *M\_3DParticleInfo*, which consists of one row and 11 columns for each particle. Columns are arranged in the following order: *minRow*, *maxRow*, *minCol*, *maxCol*, *minLayer*, *maxLayer*, *xSeed*, *ySeed*, *zSeed*, *volume*, and *area*. Use `Edit M_3DParticleInfo.1d` to display the results in a table with dimension labels describing the different columns.

### Examples

Convert a grayscale image (blobs) into a proper binary input:

```
ImageThreshold/M=4/Q/I blobs
```

Get the statistics on the thresholded image of blobs and create an image mask output wave for the perimeter of the particles:

```
ImageAnalyzeParticles/M=1 stats M_ImageThresh
```

Display an image of the blobs with a red overlay of the perimeter image:

```
NewImage/F blobs; AppendImage M_ParticlePerimeter  
ModifyImage M_ParticlePerimeter explicit=1, eval={0,65000,0,0}
```

### See Also

The **ImageThreshold**, **ImageGenerateROIMask**, **ImageSeedFill**, and **ModifyImage** operations. For more usage details see **Particle Analysis** on page III-328.

## ImageBlend

**ImageBlend** [/A=*alpha* /W=*alphaWave*] *srcWaveA*, *srcWaveB* [, *destWave*]

The **ImageBlend** operation takes two RGB images (3D waves) in *srcWaveA* and *srcWaveB* and computes the alpha blending so that

$$destWave = srcWaveA * (1 - alpha) + srcWaveB * alpha$$

for each color component. If *destWave* is not specified or does not already exist, the result is saved in the current data folder in the wave *M\_alphaBlend*.

The source and destination waves must be of the same data types and the same dimensions. The *alphaWave*, if used, must be a single precision (SP) float wave and it must have the same number of rows and columns as the source waves.

### Flags

/A= <i>alpha</i>	Specifies a single alpha value for the whole image
/W= <i>alphaWave</i>	Single precision wave that specifies an alpha value for each pixel.

## ImageBoundaryToMask

**ImageBoundaryToMask** width=*w*, height=*h*, xwave=*xwavename*, ywave=*ywavename* [, *scalingWave=scalingWaveName*, [*seedX=xVal*, *seedY=yVal*]]

The **ImageBoundaryToMask** operation scan-converts a pair of XY waves into an ROI mask wave.

### Parameters

height = <i>h</i>	Specifies the mask height in pixels.
scalingWave = <i>scalingWaveName</i>	2D or 3D wave that provides scaling for the mask. If specified, the scaling of the first two dimensions of <i>scalingWave</i> are copied to <i>M_ROIMask</i> , and both the X and Y waves are assumed to describe pixels in the scaled domain.
seedX = <i>xVal</i>	Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires <i>seedY</i> .
seedY = <i>yVal</i>	Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires <i>seedX</i> .

<code>width = w</code>	Specifies the mask width in pixels.
<code>xwave = xwavename</code>	Name of X wave for mask region.
<code>ywave = ywavename</code>	Name of Y wave for mask region.

### Details

`ImageBoundaryToMask` generates an unsigned char 2D wave named `M_ROIMask`, of dimensions specified by width and height. The wave consists of a background pixels that are set to 0 and pixels representing the mask that are set to 1.

The x and y waves can be of any type. However, if the waves describe disjoint regions there must be at least one NaN entry in each wave corresponding to the discontinuity, which requires that you use either single or double precision waves. The values stored in the waves must correspond to zero-based integer pixel values.

If the x and y waves include a vertex that lies outside the mask rectangle, the offending vertex is moved to the boundary before the associated line segment is scan converted.

If you want to obtain a true ROI mask in which closed regions are filled, you can specify the `seedX` and `seedY` keywords. The ROI mask is set with zero outside the boundary of the domain and 1 everywhere inside the domain.

### Examples

```
Make/O/N=(100,200) src=gnnoise(5)           // create a test image
SetScale/P x 500,1,"", src;DelayUpdate      // give it some funny scaling
SetScale/P y 600,1,"", src
Display; AppendImage src
Make/O/N=201 xxx,yyy                        // create boundary waves
xxx=550+25*sin(p*pi/100)                    // representing a close ellipse
yyy=700+35*cos(p*pi/100)
AppendToGraph yyy vs xxx
```

Now create a mask from the ellipse and scale it so that it will be appropriate for src:

```
ImageBoundaryToMask ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src
```

To generate an ROI masked filled with 1 in a region defined by a seed value and the boundary curves:

```
ImageBoundaryToMask
    ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src,seedx=550,seedy=700
```

## ImageEdgeDetection

**ImageEdgeDetection** [*flags*] **Method** *imageMatrix*

The `ImageEdgeDetection` operation performs one of several standard image edge detection operations on the source wave *imageMatrix*.

Unless the `/O` flag is specified, the resulting image is saved in the wave `M_ImageEdges`.

The edge detection methods produce binary images on output; the background is set to 0 and the edges to 255. This is due, in most cases to a thresholding performed in the final stage.

Except for the case of marr and shen detectors, you can use the `/M` flag to specify a method for automatic thresholding; see the **ImageThreshold** `/M` flag.

### Parameters

*Method* selects type of edge detection. *Method* is one of the following names:

<code>canny</code>	Canny edge detector uses smoothing before edge detection and thresholding. You can optionally specify the threshold using the <code>/T</code> flag and the smoothing factor using <code>/S</code> .
<code>frei</code>	Calculates the Frei-Chen edge operator (see Pratt p. 503) using only the row and column filters.
<code>kirsch</code>	Kirsch edge detector (see Pratt p. 509). Performs convolution with 8 masks calculating gradients.

marr	Marr-Hildreth edge detector. Performs two convolutions with Laplacian of Gaussian and then detects zero crossings. Use the /S flag to define the width of the convolution kernel.
prewitt	Calculates the Prewitt compass gradient filters. Returns the result for the largest filter response.
roberts	Calculates the square root of the magnitude squared of the convolution with the Robert's row and column edge detectors.
shen	Shen-Castan optimized edge detector. Supposed to be effective in the presence of noise. The flags that modify this operation are: /F for the threshold ratio (0.9 by default), /S for smoothness factor (0.9 by default), /W for window width (default is 10), /H for thinning factor which by default is 1.
sobel	Sobel edge detector using convolutions with row and column edge gradient masks (see Pratt p. 501).

### Flags

/F=fraction	Determines the threshold value for the shen algorithm by starting from the histogram of the image and choosing a threshold such that <i>fraction</i> specifies the portion of the image pixels whose values are below the threshold. Valid values are in the interval ( $0 < fraction < 1$ ).
/H=thinning	Thins edges when used with shen edge detector. By default the thinning value is 1. Higher values produce thinner edges.
/I	Inverts the output, i.e., sets the edges to 255 and the background to 0.
/M=threshMethod	See the <b>ImageThreshold</b> automatic methods for obtaining a threshold value. Methods 1, 2, 4 and 5 are supported in this operation. If you use <i>threshMethod</i> = -1, threshold is not applied.  If you want to apply your own thresholding algorithm, use /M=6 to bypass the thresholding completely. The wave M_RawCanny contains the result regardless of any other flags you may have used.
/N	Sets the background level to 64 (i.e., NaN)
/O	Overwrites the source image with the output image.
/P=layer	Applies the operation to the specified layer of a 3D wave. /P is incompatible with /O. /P was added in Igor Pro 7.00.
/R=roiSpec	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by entries/pixels whose values are 0. Pixels outside the ROI can be any nonzero value. The ROI does not have to be contiguous and can be any arbitrary shape. See <b>ImageGenerateROIMask</b> for more information on creating ROI waves.  In general, the <i>roiSpec</i> has the form { <i>roiWaveName</i> , <i>roiFlag</i> }, where <i>roiFlag</i> can take the following values: <i>roiFlag</i> =0: Set pixels outside the ROI to 0. <i>roiFlag</i> =1: Set pixels outside the ROI as in original image. <i>roiFlag</i> =2: Set pixels outside the ROI to NaN (=64).  By default <i>roiFlag</i> is set to 1 and it is then possible to use the /R flag using the abbreviated form /R= <i>roiWave</i> .
/S= smoothVal	Specifies the standard deviation or the width of the smoothing filter. By default the operation uses 1. Larger values require longer computation time. In the shen operation the default value is 0.9 and the valid range is ( $0 < smoothVal < 1$ ).

<code>/T=thresh</code>	Sets a manual threshold for any method above that uses a single threshold. This is faster than using <code>/M</code> .
<code>/W=width</code>	Specifies window width when used in the shen operation. By default width is set to 10 and it is clipped to 49.

## ImageFileInfo

**ImageFileInfo** [`/P=pathName`] *fileNameStr*

As of Igor Pro 7, ImageFileInfo is no longer supported and always returns an error.

It is obsolete because it used QuickTime to obtain graphics file information and Apple is phasing out QuickTime.

## ImageFilter

**ImageFilter** [*flags*] *Method dataMatrix*

The ImageFilter operation is identical to **MatrixFilter**, accepting the same parameters and flags, with the exception of the additional features described below.

### Parameters

*Method* selects the filter type. *Method* is one of the following names:

<code>avg3d</code>	<i>n</i> $\times$ <i>n</i> $\times$ <i>n</i> average filter for 3D waves.
<code>gauss3d</code>	<i>n</i> $\times$ <i>n</i> $\times$ <i>n</i> gaussian filter for 3D waves.
<code>hybridmedian</code>	Implements ranking pixel values between two groups of pixels in a 5x5 neighborhood. The first group includes horizontal and vertical lines through the center, the second group includes diagonal lines through the center, and both groups include the center pixel itself. The resulting median value is the ranked median of both groups and the center pixel.
<code>max3d</code>	<i>n</i> $\times$ <i>n</i> $\times$ <i>n</i> maximum rank filter for 3D waves.
<code>median3d</code>	<i>n</i> $\times$ <i>n</i> $\times$ <i>n</i> median filter for 3D waves where <i>n</i> must be of the form 3 <sup><i>r</i></sup> (integer <i>r</i> ), e.g., 3x3x3, 9x9x9 etc. The filter does not change the value of the voxel it is centered on if any of the filter voxels lies outside the domain of the data.
<code>min3d</code>	<i>n</i> $\times$ <i>n</i> $\times$ <i>n</i> minimum rank filter for 3D waves.
<code>point3d</code>	<i>n</i> $\times$ <i>n</i> $\times$ <i>n</i> point finding filter using normalized $(n^3 - 1) * center - outer$ for 3D waves.

### Flags

<code>/N=<i>n</i></code>	Specifies the filter size. By default <i>n</i> = 3. In most situations it will be useful to set <i>n</i> to an odd number in order to preserve the symmetry in the filters.
<code>/O</code>	Overwrites the source image with the output image. Used only with the hybridmedian filter, which does not automatically overwrite the source wave.

### Details

You can operate on 3D waves using the 3D filters listed above. These filters are extensions of the 2D filters available under MatrixFilter. The avg3d, gauss3d, and point3d filters are implemented by a 3D convolution that uses an averaging compensation at the edges.

This operation does not support complex waves.

**MatrixFilter** for descriptions of the other available parameters and flags.

**MatrixConvolve** for information about convolving your own 3D kernels.

### References

Russ, J., *Image Processing Handbook*, CRC Press, 1998.

## ImageFocus

**ImageFocus** [*flags*] *stackWave*

The ImageFocus operation creates in focus image(s) from a stack of images that contain in and out of focus regions. It computes the variance in a small neighborhood around each pixel and then takes the pixel value from the plane in which the highest variance is found.

### Flags

/ED= <i>edepth</i>	Sets the effective depth in planes. For example, an effective depth of one means that it computes the best focus for each plane using a stack of three planes, which includes the current plane and any one adjacent plane above and below it. Does not affect the default method (/METH=0).
/METH= <i>method</i>	Specifies the calculation method. <i>method</i> =0: Computes a single plane output for the stack (default). <i>method</i> =1: Computes the best image for each plane using /ED.
/Q	Quiet mode; no output to history area.
/Z	No error reporting.

Chapter III-11, **Image Processing** contains links to and descriptions of other image operations.

## ImageFromXYZ

**ImageFromXYZ** [*flags*] *xyzWave*, *dataMatrix*, *countMatrix*

**ImageFromXYZ** [*flags*] {*xWave*,*yWave*,*zWave*}, *dataMatrix*, *countMatrix*

ImageFromXYZ converts XYZ data to matrix form. You might use it, for example, to convert a "sparse matrix" to an actual matrix for easier display and processing.

You provide the input data in the XYZ triplet *xyzWave* or in 1D waves *xwave*, *ywave*, and *zwave*.

*dataMatrix* and *countMatrix* receive output data but you must create them prior to calling ImageFromXYZ.

For each XY location in the input data, ImageFromXYZ adds the corresponding Z value to an element of *dataMatrix*. The element is determined based on the input XY location and the X and Y scaling of *dataMatrix*.

For each XY location in the input data, ImageFromXYZ increments the corresponding element of *countMatrix*. This permits you to obtain an average Z value if multiple input values fall into a given element of *dataMatrix*.

### Parameters

*xyzWave* is a triplet wave containing the input XYZ data.

*xWave*, *yWave* and *zWave* are 1D input waves containing XYZ data.

You specify either *xyzWave* by itself or *xWave*, *yWave* and *zWave* in braces.

*dataMatrix* is a 2D wave to which the Z values are added. It must be either single-precision or double-precision floating point. The X and Y scaling of *dataMatrix* determines how input values are mapped to output matrix elements.

*countMatrix* is a 2D wave the elements of which store the number of Z values added to each corresponding element of *dataMatrix*. ImageFromXYZ sets it to 32-bit integer if it is not already so.

**Flags**

*/AS* If */AS* (autoscale) is specified, ImageFromXYZ clears both *dataMatrix* and *countMatrix* and sets the X and Y scaling of *dataMatrix* based on the range of X and Y input values.

**Details**

For each point in the XYZ input data, ImageFromXYZ adds the Z value to the appropriate element of *dataMatrix* and increments the corresponding element of *countMatrix*. Normally you will clear *dataMatrix* and *countMatrix* before calling it.

You can combine multiple XYZ datasets in one matrix by calling ImageFromXYZ multiple times with different input data and the same *dataMatrix* and *countMatrix*. In this case you would clear *dataMatrix* and *countMatrix* before the first call to ImageFromXYZ only.

What you do with the output is up to you but one technique is to divide *dataMatrix* by *countMatrix* to get the average and then use **MatrixFilter** NanZapMedian to eliminate any NaN values that result from zero divided by zero.

**Example**

```
Make /N=1000 /O wx=enoise(2), wy= enoise(2), wz= exp(-(wx^2+wy^2))
Make /O /N=(100,100) dataMat=0
SetScale x,-2,2,dataMat
SetScale y,-2,2,dataMat
Duplicate /O dataMat,countMat
ImageFromXYZ /AS {wx,wy,wz}, dataMat, countMat

// Execute these one at a time
NewImage dataMat
dataMat /= countMat // Replace cumulative z value with average
MatrixFilter NanZapMedian, dataMat // Apply median filter, zapping NaNs
```

**See Also**

**SetScale, Image X and Y Coordinates** on page II-301.

## ImageGenerateROIMask

**ImageGenerateROIMask** [*/W=winName/E=e/I=i*] *imageInstance*

The ImageGenerateROIMask operation creates a Region Of Interest (ROI) mask for use with other ImageXXX commands. It assumes the top (or */W* specified) graph contains an image and that the user has drawn shapes using Igor's drawing tools in a specific manner.

ImageGenerateROIMask creates an unsigned byte mask matrix with the same x and y dimensions and scaling as the specified image. The mask is initially filled with zeros. Then the drawing layer, *progFront*, in the graph is scanned for suitable fillable draw objects. The area inside each shape is filled with ones unless the fill mode for the shape is set to erase in which case the area is filled with zeros.

**Flags**

*/E=e* Changes value used for the exterior from the default zero values to *e*.

*/I=i* Changes value used for the interior from the default one values to *i*.

*/W=winName* Looks for the named graph window or subwindow containing appropriate image masks drawn by the user. If */W* is omitted, ImageGenerateROIMask uses the top graph window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

**Details**

To generate an ROI wave for use with most image processing operations you need to set the values of interior pixels to zero and exterior pixels to one using */E=1/I=0*.

Suitable objects are those that can be filled (rectangles, ovals, etc.) and which are plotted in axis coordinate mode specified using the same axes by which the specified image instance is displayed. Objects plotted in plot relative mode are also used, However, this is not recommended because it will give correct results only

if the image exactly fills the plot rectangle. If you use axis coordinate mode then you can zoom in or out as desired and the resulting mask will still be correct.

Note that the shapes can have their fill mode set to none. This still results in a fill of ones. This is to allow the drawn ROI to be visible on the graph without obscuring the image. However cutouts (fills with erase mode) will obscure the image.

Note also that nonfill drawing objects are ignored. You can use this fact to create callouts and other annotations.

In a future version of Igor, we may create a new drawing layer in graphs dedicated to ROIs.

The mask generated is named M\_ROIMask and is generated in the current data folder.

Variable V\_flag is set to 1 if the top graph contained draw objects in the correct layer and 0 if not. If 0 then the M\_ROIMask wave was not generated.

### Examples

```
Make/O/N=(200,400) jack=x*y; NewImage jack; ShowTools
SetDrawLayer ProgFront
SetDrawEnv linefgc=(65535,65535,0),fillpat=0,xcoord=top,ycoord=left,save
DrawRect 63.5,79.5,140.5,191.5
DrawRRect 61.5,206.5,141.5,280.5
SetDrawEnv fillpat= -1
DrawOval 80.5,169.5,126.5,226.5
ImageGenerateROIMask jack
NewImage M_ROIMask
AutoPositionWindow/E
```

### See Also

For another example see **Generating ROI Masks** on page III-331.

## ImageGLCM

### ImageGLCM [*flags*] *srcWave*

The ImageGLCM operation calculates the gray-level co-occurrence matrix for an 8-bit grayscale image and optionally evaluates Haralick's texture parameters.

The ImageGLCM operation was added in Igor Pro 7.00.

### Flags

- |                            |  |
|----------------------------|--|
| <i>/D=distance</i>         | Sets the offset in pixels for which the co-occurrence matrix is calculated. The default value is 1.  |
| <i>/DEST=destGLCM</i>      | Specifies the wave to hold the co-occurrence matrix. If you omit <i>/DEST</i> the operation stores the matrix in the wave M_GLCM in the current data folder.   |
| <i>/DETP=destParamWave</i> | <p>Specifies the wave to hold the computed texture parameters. If you omit <i>/DETP</i> the operation stores the texture parameters in the wave W_TextureParams in the current data folder.</p> <p>If the destination wave already exists it is overwritten. Note that you must specify the <i>/HTFP</i> flag to compute the texture parameters.</p> |
| <i>/E=structureBits</i>    | <p><i>structureBits</i> is a bitwise setting that lets you control the combination of co-occurrences that you want to compute.</p> <p>Consider a wave displayed in a table and a pixel at position x</p>   |

0	3	5
1	x	6
2	4	7

The *structureBits* corresponding to co-occurrence between *x* and any direction is simply  $2^{\text{direction}}$ . By default the operation computes all combinations. This is equivalent to *structureBits*=255.

Note that the *structureBits* only define directions. The combination of the distance (/D) and the *structureBits* define the full co-occurrence calculation.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

/FREE	Creates output waves as free waves.  /FREE is permitted in user-defined functions only, not from the command line or in macros.  If you use /FREE then <i>destGLCM</i> and <i>destParamWave</i> must be simple names, not paths.  See <b>Free Waves</b> on page IV-84 for details on free waves.
/HTFP	Computes Haralick's texture parameters. See the discussion in the Details section below for more information about the texture parameters.
/P=plane	If the image consists of more than one plane you can use this flag to determine which plane in <i>srcWave</i> is analysed. By default it is plane zero.
/Z	No error reporting.

### Details

ImageGLCM computes the co-occurrence matrix for the image in *srcWave* and optionally evaluates Haralick's texture parameters. The operation supports 8-bit grayscale images and generates a 256x256 single-precision floating point co-occurrence matrix.

The elements of the matrix  $P[i][j]$  are defined as the normalized number of pixels that have a spatial relationship defined by the distance (/D) and the structure (/E) such that the first pixel has gray-level *i* and the second pixel has gray-level *j*. The matrix is normalized so that the sum of all its elements is 1.

If you specify the /HTFP flag the operation computes the 13 Haralick texture parameters and stores them sequentially in the destination wave (see /DETP). The wave is saved with dimension labels defining each element. The expressions for the texture parameters are:

$$f_1 = \sum_i \sum_j (p[i][j])^2,$$

$$f_2 = \sum_{n=0}^{254} n^2 \left\{ \sum_{i=0}^{255} \sum_{\substack{j=0 \\ |i-j|=n}}^{255} p[i][j] \right\},$$

$$f_3 = \sum_i \sum_j \frac{(i - \mu_x)(j - \mu_y)p[i][j]}{\sigma_x \sigma_y},$$

$$f_4 = \sum_i \sum_j (i - \mu)^2 p[i][j],$$

$$f_5 = \sum_i \sum_j \frac{1}{1 + (i - j)^2} p[i][j],$$

$$f_6 = \sum_i i p_{x+y}(i),$$

$$f_7 = \sum_i (i - f_6)^2 p_{x+y}(i),$$

$$f_8 = - \sum_i p_{x+y}(i) \log(p_{x+y}(i)),$$

$$f_9 = - \sum_i \sum_j p[i][j] \log(p[i][j]),$$

$$f_{10} = \text{Variance}(p_{x-y}),$$

$$f_{11} = \sum_i p_{x-y}(i) \log(p_{x-y}(i)),$$

$$f_{12} = \frac{f_9 - HXY1}{\max(HX, HY)},$$

$$f_{13} = \sqrt{1 - \exp(-2(HXY2 - f_9))}.$$

Here

$$p_x(i) = \sum_j p[i][j], \quad p_y(j) = \sum_i p[i][j],$$

$$\mu_x = \sum_i i p_x(i), \quad \mu_y = \sum_i i p_y(i), \quad \mu = (\mu_x + \mu_y) / 2.$$

$$\sigma_x = \sqrt{\sum_i (1 - \mu_x)^2 p_x(i)}, \quad \sigma_y = \sqrt{\sum_i (1 - \mu_y)^2 p_y(i)},$$

$$p_{x+y}(k) = \sum_i \sum_{\substack{j \\ i+j=k}} p[i][j],$$

$$p_{x-y}(k) = \sum_i \sum_{\substack{j \\ |i-j|=k}} p[i][j],$$

$$HXY1 = - \sum_i \sum_j p[i][j] \log(p_x(i)p_y(j)),$$

$$HXY2 = - \sum_i \sum_j p_x(i)p_y(j) \log(p_x(i)p_y(j)),$$

$$HX = - \sum_i p_x(i) \log(p_x(i)), \quad HY = - \sum_i p_y(i) \log(p_y(i)).$$

There are at least two versions of f7 used in the literature and in software. We know of at least three versions of f14 so ImageGLCM does not compute it.

## ImageHistModification

**ImageHistModification** [*flags*] *imageMatrix*

The ImageHistModification operation performs a modification of the image histogram and saves the results in the wave *M\_ImageHistEq*. If /W is not specified, the operation is a simple histogram equalization of *imageMatrix*. If /W is specified, the operation attempts to produce an image with a histogram close to *waveName*. If /A is specified, the operation performs an adaptive histogram equalization. *imageMatrix* is a wave of any noncomplex numeric type. Adaptive histogram equalization applies only to 2D waves and the other parts apply to both 2D and 3D waves.

#### Flags

/A	Performs an adaptive histogram equalization by subdividing the image into a minimum of 4 rectangular domains and using interpolation to account for the boundaries between adjacent domains. When the /C flag is specified with contrast factor greater than 1, this operation amounts to contrast-limited adaptive histogram equalization. By default the operation divides the image into 8 horizontal and 8 vertical regions. See /H and /V.
/B= <i>bins</i>	Specifies the number of <i>bins</i> used with the /A flag. If not specified, this value defaults to 256.
/C= <i>cFactor</i>	Specifies a contrast factor (or clipping value) above which pixels are equally distributed over the whole range. <i>cFactor</i> must be greater than 1, in the limit as <i>cFactor</i> approaches 1 the operation is a regular adaptive histogram equalization. <b>Note:</b> this flag is used only with the /A flag.
/H= <i>hRegions</i>	Specifies the number of horizontal subdivisions to be used with the /A feature. Note, the number of image pixels in the horizontal direction must be an integer multiple of <i>hRegions</i> .
/I	Extends the standard histogram equalization by using $2^{16}$ bins instead of $2^8$ when calculating histogram equalization. This feature does not apply to the adaptive histogram equalization (/A flag).

<code>/O</code>	Overwrites the source image. If this flag is not specified, the resulting image is saved in the wave <code>M_ImageHistEq</code> .
<code>/R=roiSpec</code>	<p>Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (<code>/b/u</code>). The ROI wave must have the same number of rows and columns as <i>imageMatrix</i>. The ROI itself is defined by the entries whose values are 0. Regions outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape.</p> <p>In general, the <i>roiSpec</i> has the form <code>{roiWaveName, roiFlag}</code>, where <i>roiFlag</i> can take the following values:</p> <ul style="list-style-type: none"><li><code>roiFlag=0</code>: Set pixels outside the ROI to 0.</li><li><code>roiFlag=1</code>: Set pixels outside the ROI as in original image (default).</li><li><code>roiFlag=2</code>: Set pixels outside the ROI to NaN (=64).</li></ul> <p>By default <i>roiFlag</i> is set to 1 and it is then possible to use the <code>/R</code> flag with the abbreviated form <code>/R=roiWave</code>. When <i>imageMatrix</i> is a 3D wave, <i>roiWave</i> can be either a 2D wave (matching the number of rows and columns in <i>imageMatrix</i>) or it can be a 3D wave which must have the same number of rows, columns, and layers as <i>imageMatrix</i>. When using a 2D <i>roiWave</i> with a 3D <i>imageMatrix</i>, the ROI is understood to be defined by <i>roiWave</i> for each layer in the 3D wave.</p> <p>See <b>ImageGenerateROIMask</b> for more information on creating ROI waves.</p>
<code>/V=vRegions</code>	Specifies the number of vertical subdivisions to be used with the <code>/A</code> flag. The number of image pixels in the horizontal direction must be an integer multiple of <i>vRegions</i> . If the image dimensions are not divisible by the number of regions that you want, you can pad the image using <b>ImageTransform padImage</b> .
<code>/W=waveName</code>	Specifies a 256-point wave that provides the desired histogram. The operation will attempt to produce an image having approximately the desired histogram values. This flag does not apply to the adaptive histogram equalization ( <code>/A</code> flag)

## ImageHistogram

**ImageHistogram** [*flags*] *imageMatrix*

The **ImageHistogram** operation calculates the histogram of *imageMatrix*. The results are saved in the wave `W_ImageHist`. If *imageMatrix* is an RGB image stored as a 3D wave, the resulting histograms for each color plane are saved in `W_ImageHistR`, `W_ImageHistG`, `W_ImageHistB`.

*imageMatrix* must be a real-valued numeric wave.

### Flags

<code>/I</code>	Calculates a histogram with 65536 bins evenly distributed between the minimum and maximum data values. The operation first finds the extrema and then calculates the bins and the resulting histogram. Data can be a 2D wave of any type including float or double.
<code>/P=plane</code>	Restricts the calculation of the histogram to a specific plane when <i>imageMatrix</i> is a non RGB 3D wave.

<i>/R=roiWave</i>	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u) that has the same number of rows and columns as <i>imageMatrix</i> . The ROI itself is defined by the entries of pixels in the <i>roiWave</i> with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When <i>imageMatrix</i> is a 3D wave, <i>roiWave</i> can be either a 2D wave (matching the number of rows and columns in <i>imageMatrix</i> ) or it can be a 3D wave that must have the same number of rows, columns and layers as <i>imageMatrix</i> . When using a 2D <i>roiWave</i> with a 3D <i>imageMatrix</i> the ROI is understood to be defined by <i>roiWave</i> for each layer in the 3D wave.  See <b>ImageGenerateROIMask</b> for more information on creating 2D ROI waves.
<i>/S</i>	Computes the histogram for a whole 3D wave possibly subject to 2D or 3D ROI masking. The <i>/S</i> and <i>/P</i> flags are mutually exclusive.

### Details

The ImageHistogram operation works on images, but it handles both 2D and 3D waves of any data type. Unless you use one of the special features of this operation (e.g., ROI or /P or /I) you could alternatively use the **Histogram** operation, which computes the histogram for the full wave and includes additional options for controlling the number of bins.

If the data type of *imageMatrix* is single byte, the histogram will have 256 bins from 0 to 255. Otherwise, the 256 bins will be distributed between the minimum and maximum values encountered in the data. Use the */I* flag to increase the number of bins to 65536, which may be useful for unsigned short (/W/U) data.

## ImageInfo

**ImageInfo**(*graphNameStr*, *imageWaveNameStr*, *instanceNumber*)

The ImageInfo function returns a string containing a semicolon-separated list of information about the specified image in the named graph window or subwindow.

### Parameters

*graphNameStr* can be "" to refer to the top graph.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-87 for details on forming the window hierarchy.

*imageWaveNameStr* contains either the name of a wave displayed as an image in the named graph, or an image instance name (wave name with "#n" appended to distinguish the nth image of the wave in the graph). You might get an image instance name from the **ImageNameList** function.

If *imageWaveNameStr* contains a wave name, *instanceNumber* identifies which instance you want information about. *instanceNumber* is usually 0 because there is normally only one instance of a wave displayed as an image in a graph. Set *instanceNumber* to 1 for information about the second image of the wave, etc. If *imageWaveNameStr* is "", then information is returned on the *instanceNumber*th image in the graph.

If *imageWaveNameStr* contains an instance name, and *instanceNumber* is zero, the instance is taken from *imageWaveNameStr*. If *instanceNumber* is greater than zero, the wave name is extracted from *imageWaveNameStr*, and information is returned concerning the *instanceNumber*th instance of the wave.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon for ease of use with **StringByKey**. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
COLORMODE	A number indicating how the image colors are derived: 1: Color table (see <b>Image Color Tables</b> on page II-305). 2: Scaled color index wave (see <b>Indexed Color Details</b> on page II-312). 3: Point-scaled color index (See <b>Example: Point-Scaled Color Index Wave</b> on page II-313). 4: Direct color (see <b>Direct Color Details</b> on page II-313). 5: Explicit Mode (See <b>ModifyImage</b> explicit keyword).
RECREATION	Semicolon-separated list of <i>keyword=modifyParameters</i> commands for the ModifyImage command.
XAXIS	X axis name.
XWAVE	X wave name if any, else blank.
XWAVEDF	The full path to the data folder containing the X wave or blank if there is no X wave.
YAXIS	Y axis name.
YWAVE	Y wave name if any, else blank.
YWAVEDF	The full path to the data folder containing the Y wave or blank if there is no Y wave.
ZWAVE	Name of wave containing Z data used to calculate the image plot.
ZWAVEDF	The full path to the data folder containing the Z data wave.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “;”, prepend “ModifyImage ”, replace the “x” with the name of a image plot (“data#1” for instance) and then **Execute** the resultant string as a command.

Example 1

This example gets the image information for the second image plot of the wave "jack" (which has an instance number of 1) and applies its **ModifyImage** settings to the first image plot.

```
#include <Graph Utility Procs>, version=6.1 // For WMGetRECREATIONFromInfo
// Make two image plots of the same data on different left and right axes
Make/O/N=(20,20) jack=sin(x/5)+cos(y/4)
Display;AppendImage jack // bottom and left axes
AppendImage/R jack // bottom and right axes
// Put image plot jack#0 above jack#1
ModifyGraph axisEnab(left)={0.5,1},axisEnab(right)={0,0.5}
// Set jack#1 to use the Rainbow color table instead of the default Grays
ModifyImage jack#1 ctab={*,*,Rainbow,0}
```

Now we peek at some of the image information for the second image plot of the wave "jack" (which has an instance number of 1) displayed in the top graph:

```
Print ImageInfo("", "jack", 1) [69, 148]           // Just the interesting stuff
;ZWAVE:jack;ZWAVEDF:root;;COLORMODE:1;RECREATION:ctab= {*,*,Rainbow,0};plane= 0;
// Apply the color table, etc from jack#1 to jack:
String info= WMGetRECREATIONFromInfo(ImageInfo("", "jack", 1))
info= RemoveEnding(info)                        // Remove trailing semicolon
// Use comma instead of semicolon separators
String text = ReplaceString(";", info, ",")
Execute "ModifyImage jack " + text
```

### Example 2

This example gets the full path to the wave containing the Z data from which the first image plot in the top graph was calculated.

```
String info= ImageInfo("", "", 0)           // 0 is index of first image plot
String pathToZ= StringByKey("ZWAVEDF", info)+StringByKey("ZWAVE", info)
Print pathToZ
      root:jack
```

**Image Plots** on page II-297.

**Image Instance Names** on page II-314.

## ImageInterpolate

**ImageInterpolate** [*flags*] *Method srcWave*

The ImageInterpolate operation interpolates the source *srcWave* and stores the results in the wave M\_InterpolatedImage in the current data folder unless you specify a different destination wave using the /DEST flag.

### Parameters

*Method* selects type of interpolation. *Method* is one of the following names:

**Affine2D** Performs an affine transformation on *srcWave* using parameters specified by the /APRM flag. The transformation applies to a general combination of rotation, scaling, and translation represented by a 3x3 matrix

$$M = \begin{bmatrix} r_{11} & r_{12} & t_x \\ r_{21} & r_{22} & t_y \\ 0 & 0 & w \end{bmatrix}.$$

The upper 2x2 matrix is a composite of rotation and scaling,  $t_x$  and  $t_y$  are composite translations and  $w$  is usually 1. It computes the dimensions of the output wave and then uses the inverse transformation and bilinear interpolation to compute the value of each output pixel. When an output pixel does not map back into the source domain it is set to the user-specified background value. It supports 2D and 3D input waves. If *srcWave* is a 3D wave it applies on a layer by layer basis.

The output is stored in the wave M\_Affine in the current data folder.

**/ATOL** Allows ImageInterpolate to use a tolerance value if the result of the interpolation at any point is NaN. The algorithm returns the first non-NaN value it finds by adding or subtracting 1/10000th of the size of the X or Y interpolation step. At worst this algorithm is 5 times slower than the default algorithm if the interpolation is performed in a region which is completely outside the convex source domain.

/ATOL was added in Igor Pro 7.00.

**/CMSH** Use this flag in Voronoi interpolation to create a triangle mesh surface representing the input data. After triangulating the X, Y locations (in a plane  $z=\text{const}$ ), the mesh is generated from a sequence of XYZ vertices of all the resulting triangles. The output is stored in the wave M\_ScatterMesh in the current data folder. It is in the form of a triplet wave where every consecutive 3 rows represent a disjoint triangle.

If the input contains a NaN or INF in any column, the corresponding row is excluded from the triangulation.

If you want to generate this mesh without generating the interpolated matrix you can omit the /S flag.

/CMSH was added in Igor Pro 7.00.

**Bilinear** Performs a bilinear interpolation subject to the specified flag. You can use either the /F or /S flag, but not both.

**Kriging** Uses Kriging to generate an interpolated matrix from a sparse data set. Kriging calculates interpolated values for a rectangular domain specified by the /S flag. The Kriging parameters are specified via the /K flag.

Kriging is computed globally for a single user-selected variogram model. If there are significant spatial variances within the domain occupied by the data, you should consider subdividing the domain along natural boundaries and use a single variogram model in each subdivision.

If there are N data points, the algorithm first computes the NxN matrix containing the distances between the data and then inverts an associated matrix of similar size to compute the result for the selected variogram model. Because inversion of an NxN matrix can be computationally expensive, you should consider restricting the calculation to regions that are similar to the range implied by the variogram. Such an approach can also be justified in the sense that the local interpolation should not be affected by a remote datum.

**Note:** Kriging does not support data containing NaNs or INFs. Wave scaling has no effect.

- Pixelate** Creates a lower resolution (pixelated) version of *srcWave* by averaging the pixels inside domain specified by /PXSZ flag. The results are saved in the wave M\_PixelatedImage in the current data folder.
- The computed wave has the same numeric type as *srcWave* so the averaging may be inaccurate in the case of integer waves.
- When *srcWave* is a 3D wave you have the option of averaging only over data in each layer using /PXSZ={nx,ny} or averaging over data in a rectangular cube using /PXSZ={nx,ny,nz}.
- When not averaging over layers, the number of rows and columns of the new image are obtained by integer division of the original number by the respective size of the averaging rectangle and adding one more pixel for any remainder.
- When averaging over layers the resulting rows and columns are obtained by truncated integer division ignoring remainders (if any).
- Resample** Computes a new image based on the selected interpolation function and transformation parameters. Set the interpolation function with the /FUNC flag. Use the /TRNS flag to specify transformation parameters for grayscale images, or /TRNR, /TRNG, and /TRNB for the red, green, and blue components, respectively, of RGB images. M\_InterpolatedImage contains the output image in the current data folder.
- There are currently two transformation functions: the first magnifies an image and the second applies a radial polynomial sampling. The radial polynomial affects pixels based on their position relative to the image center. A linear polynomial reproduces the same image. Any nonlinear terms contribute to distortion (or correction thereof).
- Spline** Computes a 2D spline interpolation for 2D matrix data. The degree of the spline is specified by the /D flag.
- Voronoi** Generates an interpolated matrix from a sparse data set (*srcWave* must be a triplet wave) using Voronoi polygons. It calculates interpolated values for a rectangular domain as specified by the /S or /RESL flags.
- It first computes the Delaunay triangulation of X, Y locations in the Z=0 plane (assuming that X, Y positions occupy a convex domain in the plane). It then uses the Voronoi dual to interpolate the Z values for X and Y pairs from the grid defined by the /S flag. The computed grid may exceed the bounds of the convex domain defined by the triangulation. Interpolated values for points outside the convex domain are set to NaN or the value specified by the /E flag.
- Use the /I flag to iterate to finer triangulation by subdividing the original triangles into smaller domains. Each iteration increases computation time by approximately a factor of two, but improves the smoothness of the interpolation.
- If you have multiple sets of data in which X,Y locations are unchanged, you can use the /STW flag to store one triangulation and then use the /PTW flag to apply the precomputed triangulation to a new interpolation. To use this option you should use the Voronoi keyword first with a triplet wave for *srcWave* and set xn = x0 and yn = y0. The operation creates the wave W\_TriangulationData that you use in the next triangulation with a 1D wave as *srcWave*.
- Voronoi interpolation is similar to what can be accomplished with the **ContourZ** function except that it does not require an existing contour plot, it computes the whole output matrix in one call, and it has the option of controlling the subdivision iterations.
- See **Voronoi Interpolation Example** below.
- XYWaves** Performs bilinear interpolation on a matrix scaled using two X and Y 1D waves (specified by /W). The interpolation range is defined by /S. The data domain is defined between the centers of the first and last pixels (X in this example):
- ```
xmin= (xWave[0] + xWave[1]) / 2
xmax= (xWave[last] + xWave[last-1]) / 2
```
- Values outside the domain of the data are set to NaN. The interpolation is contained in the M\_InterpolatedImage wave, which is single precision floating point or double precision if *srcWave* is double precision.

**Warp** Performs image warping interpolation using a two step algorithm with three optional interpolation methods. The operation warps the image based on the relative positions of source and destination grids. The warped image has the same size as the source image. The source and destination grids are each specified by a pair of 2D X and Y waves where the rows and columns correspond to the relative location of the source grid. The smallest supported dimensions of grid waves are 2x2. All grid waves must be double-precision floating point and must have the same number of points corresponding to pixel positions within the image. Grid waves must not contain NaNs or INFs. Wave scaling is ignored.

### Flags

*/APRM={r11,r12,tx,r21,r22,ty,w,background}*

Sets elements of the affine transformation matrix and the background value.

*/D=splineDeg*

Specifies the spline degree with the Spline method. The default spline degree is 2. Supported values are 2, 3, 4, and 5.

*/DEST=destWave*

Specifies the wave to contain the output of the operation. If the specified wave already exists, it is overwritten.

Creates a wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-66 for details.

*/E=outerValue*

Assigns *outerValue* to all points outside the convex domain of the Delaunay triangulation. By default *outerValue* = NaN.

*/F={fx,fy}*

Calculates a bilinear interpolation of all the source data. Here *fx* is the sampling factor for the X-direction and *fy* is the sampling factor in the Y-direction. The output number of points in a dimension is  $\text{factor} \times (\text{number of data intervals}) + 1$ . The number of data intervals is one less than the number of points in that dimension.

For example, if *srcWave* is a 2x2 matrix (you have a single data interval in each direction) and you use */F={2,2}*, then the output wave is a 3x3 matrix (i.e., 2x2 intervals) which is a factor of 2 of the input. Sampling factors can be noninteger values.

*/FDS*

Performs spline interpolation to a “local” cubic spline that depends only on the 2D neighboring data. The interpolation goes exactly through the original data and provides continuity of the function and its first derivative. The second derivative is set to vanish on the boundary. The implemented algorithm was provided by Francis Dalaudier. */FDS* was added in Igor Pro 7.00.

*/FUNC=funcName*

Specifies the interpolation function. *funcName* can be:

- nn** Nearest neighbor interpolation uses the value of the nearest neighbor without interpolation. This is the fastest function.
- bilinear** Bilinear interpolation uses the immediately surrounding pixels and computes a linear interpolation in each dimension. This is the second fastest function.
- cubic** Cubic polynomial (photoshop-like) uses a 4x4 neighborhood value to compute the sampled pixel value.
- spline** Spline smoothed sampled value uses a 4x4 neighborhood around the pixel.
- sinc** Slowest function using a 16x16 neighborhood.

*/I=iterations*

Specifies the number of times the original triangulation is subdivided with the Voronoi interpolation method. By default the Voronoi interpolation computes the original triangulation without subdivision.

*/K={model, nugget, sill, range}*

Specifies the variogram parameters for kriging using standard notation, models are expressed in terms of the nugget value  $C_0$ , sill value  $C_0+C_1$ , and range  $a$ .

*model* Selects the variogram model. Values and models are:

1: Spherical.  $\gamma(h) = C_0 + C_1 \cdot (3h/2a - 0.5 \cdot h^3/a^3)$

2: Exponential.  $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot h/a])$

3: Gaussian.  $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot (h/a)^2])$

*nugget* Specifies the lowest value in the variogram.

*sill* Specifies the maximum (plateau) value in the variogram range the characteristic length of the different variogram models.

Wave scaling has no effect on kriging calculations.

*/PFTL=tol*

In Voronoi interpolation, controls the rectangular neighborhood about each datum position XY where the algorithm returns the original Z-value. The tolerance value  $0 \leq tol < 1$  is tested separately in X and Y (i.e., it is not a geometric distance) when both X and Y are normalized to the range [0,1]. By default  $tol=1e-15$ .

Added in Igor Pro 7.00.

*/PTW=tWave*

Uses a previous triangulation wave with Voronoi interpolation. *tWave* will be the wave saved by the */STW* flag. You can't use a triangulation wave that was computed and saved on a different computer platform.

See **PTW Flag Example** on page V-333.

*/PXSZ={nx,ny}*

Specifies the size in pixels of the averaging rectangle used by the Pixelate operation. *nx* is the number of rows and *ny* is the number of columns that are averaged to yield a single output pixel. If *srcWave* is a 3D wave the resulting wave has the same number of layers as *srcWave* with pixelation computed on a layer-by-layer basis.

*/PXSZ={nx,ny,nz}*

Specifies the size in pixels of the averaging rectangle used by the Pixelate operation. *nx* is the number of rows and *ny* is the number of columns and *nz* is the number of layers that are averaged to yield a single output pixel.

This form of the */PXSZ* flag was added in Igor Pro 7.00.

*/RESL={nx, ny}*

Specifies resampling the full input image to an output image having *nx* rows by *ny* columns.

*/S={x0,dx,xn,y0,dy,yn}*

Calculates a bilinear interpolation of a subset of the source data. Here *x0* is the starting point in the X-direction, *dx* is the sampling increment, *xn* is the end point in the X-direction and the corresponding values for the Y-direction. If you set *x0* equal to *xn* the operation will compute the triangulation but not the interpolation.

- /SPRT** Skips the XY perturbation step. The perturbation step is designed to break degeneracies that originate when the XY data are sampled on a rectangular grid. If your data are not sampled on a rectangular grid you can skip the perturbation and get better accuracy in reproducing the Z-values at the sampled locations. See also **ModifyContour** with the keyword Perturbation.  
Added in Igor Pro 7.00.
- /STW** Saves the triangulation information in the wave W\_TriangulationData in the current data folder. W\_TriangulationData can only be used on the computer platform where it was created.
- /SV** Saves the Voronoi interpolation in the 2D wave M\_VoronoiEdges, which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle containing the convex domain.

**/TRNS={transformFunc,p1,p2,p3,p4}**

Determines the mapping between a pixel in the destination image and the source pixel. *transformFunc* can be:

- scaleShift** Sets image scaling which could be anamorphic if the X and Y scaling are different.
- radialPoly** Corrects both color as well as barrel and pincushion distortion. In **radialPoly** the mapping from a destination pixel to a source pixel is a polynomial in the pixel's radius relative to the center of the image.

A source pixel, *sr*, satisfies the equation:

$$sr = ar + br^2 + cr^3 + dr^4,$$

where *r* is the radius of a destination pixel having an origin at the center of the destination image.

The corresponding parameters are:

| <i>transformFunc</i> | <i>p1</i> | <i>p2</i> | <i>p3</i> | <i>p4</i> |
|----------------------|-----------|-----------|-----------|-----------|
| <b>scaleShift</b>    | xOffset   | xScale    | yOffset   | yScale    |
| <b>radialPoly</b>    | 0         | 1         | 2         | 3         |

- /U=uniformScale** Calculates a bilinear interpolation of all the source data as with the /F flag but with two exceptions: A single uniform scale factor applies in both dimensions, and the scale factor applies to the number of points — not the intervals of the data.
- /W={xWave,yWave}** Provides the scaling waves for XYWaves interpolation. Both waves must be monotonic and must have one more point than the corresponding dimension in *srcWave*. The waves contain values corresponding to the edges of data points in *srcWave*, so that the X value at the first data point is equal to  $(xWave[0] + xWave[1]) / 2$ .

## Flags for Warp

- /dgrx=wave** Sets the wave containing the destination grid X data.
- /dgry=wave** Sets the wave containing the destination grid Y data.
- /sgrx=wave** Sets the wave containing the source grid X data.
- /sgry=wave** Sets the wave containing the source grid Y data.

/WM=*im*                Sets the interpolation method for warping an image.

*im*=1:            Fast selection of original data values.

*im*=2:            Linear interpolation.

*im*=3:            Smoothing interpolation (slow)

### Details

When computing Bilinear or Spline interpolation *srcWave* can be a 2D or a 3D wave. When *srcWave* is a 3D wave the interpolation is computed on a layer by layer basis and the result is stored in a corresponding 3D wave. When the interpolation method is Kriging or Voronoi, *srcWave* is a 2D triplet wave (3-column wave) where each row specifies the X, Y, Z values of a datum. *srcWave* can be of any real data type. Results are stored in the wave M\_InterpolatedImage. If *srcWave* is double precision so is M\_InterpolatedImage; otherwise M\_InterpolatedImage is a single precision wave.

### Voronoi Interpolation Example

```
Function DemoVoronoiInterpolation()
    Make/O/N=(100,3) sampleTriplet
    sampleTriplet[] [0]=enoise(5)
    sampleTriplet[] [1]=enoise(5)
    sampleTriplet[] [2]=sqrt(sampleTriplet[p] [0]^2+sampleTriplet[p] [1]^2)

    // Interpolate the data to a rectangular grid of 50x50 pixels
    ImageInterpolate/RESL={50,50}/DEST=firstImage voronoi, sampleTriplet

    // Triangulate the XY locations and save the triangulation wave
    ImageInterpolate/STW voronoi, sampleTriplet

    // Use the previous triangulation on the Z column of the sample
    MatrixOp/O zData=col(sampleTriplet,2)
    Wave W_TriangulationData
    ImageInterpolate/PTW=W_TriangulationData/RESL={50,50}/DEST=secondImage voronoi, zData
End
```

### PTW Flag Example

```
Function DemoPTW()
    // Create some random data
    Make/O/N=(100,3) eee = enoise(5)

    // Compute triangulation wave
    ImageInterpolate/RESL={1,1}/STW voronoi, eee
    Wave W_TriangulationData

    // Copy the Z-column to a 1D wave
    MatrixOp/O e3 = col(eee,2)

    // Use the previous triangulation with 1D wave
    ImageInterpolate/PTW=W_TriangulationData /RESL={100,100} voronoi, e3
    Wave M_InterpolatedImage
    Duplicate/O M_InterpolatedImage, oneD

    // Direct computation for comparison
    ImageInterpolate/RESL={100,100} voronoi, eee

    // Display
    NewImage M_InterpolatedImage
    NewImage oneD
End
```

## ImageLineProfile

```
ImageLineProfile [flags] xWave=xwave, yWave=ywave, srcWave=srcWave [,  
    width=value, widthWave=wWave]
```

The ImageLineProfile operation provides sampling of a source image along an arbitrary path specified by the two waves: *xWave* and *yWave*. The arbitrary path is made of line segments between every two consecutive vertices of *xWave* and *yWave*. In each segment the profile is calculated at a number of points (profile points) equivalent to the sampling density of the original image (unless the /V flag is used). Both *xWave* and *yWave* should have the same scaling as *srcWave*. If *srcWave* does not have the same scaling in both dimensions you should remove the scaling to compute an accurate profile.

At each profile point, the profile value is calculated by averaging samples along the normal to the profile line segment. The number of samples in the average is determined by the keyword *width*. The operation actually averages the interpolated values at  $N$  equidistant points on the normal to profile line segment, with  $N=2(\text{width}+0.5)$ . Samples outside the domain of the source image do not contribute to the profile value.

The profile values are stored in the wave *W\_ImageLineProfile*. The actual locations of the profile points are stored in the waves *W\_LineProfileX* and *W\_LineProfileY*. When the averaging *width* is greater than zero, the operation can also calculate at each profile point the standard deviation of the values sampled for that point (see /S flag). The results are then stored in the wave *W\_LineProfileStdv*. When using this operation on 3D RGB images, the profile values are stored in the 3 column waves *M\_ImageLineProfile* and *M\_LineProfileStdv* respectively.

### Parameters

|                                 |                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>srcWave</i> = <i>srcWave</i> | Specifies the image for which the line profile is evaluated. The image may be a 2D wave of any type or a 3D wave or RGB data.                                                                                                                                                                                                                       |
| <i>xWave</i> = <i>xwave</i>     | Specifies the wave containing the x coordinate of the line segments along the path.                                                                                                                                                                                                                                                                 |
| <i>yWave</i> = <i>ywave</i>     | Specifies the wave containing the y coordinate of the line segments along the path.                                                                                                                                                                                                                                                                 |
| <i>width</i> = <i>value</i>     | Specifies the width (diameter) in pixels (need not be an integer value) in a direction perpendicular to the path over which the data is interpolated and averaged for each path point. If you do not specify <i>width</i> or use <i>width</i> =0, only the interpolated value at the path point is used.                                            |
| <i>widthWave</i> = <i>wWave</i> | Specifies the width of the profile (see definition above) on a segment by segment basis. <i>wWave</i> should be a 1D wave that has the same number of entries as <i>xWave</i> and <i>yWave</i> . If you provide a <i>widthWave</i> any value assigned with the <i>width</i> keyword is ignored. All values in the wave must be positive and finite. |

### Flags

|                  |                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /P= <i>plane</i> | Specifies which plane (layer) of a 3D wave is to be profiled. By default <i>plane</i> = -1 and the profiles are of either the single layer of a 2D wave or all three layers of a 3D RGB wave. Use <i>plane</i> = -2 if you want to profile all layers of a 3D wave. |
| /S               | Calculates standard deviations for each profile point.                                                                                                                                                                                                              |
| /SC              | Saves <i>W_LineProfileX</i> and <i>W_LineProfileY</i> using the X and Y scaling of <i>srcWave</i> .                                                                                                                                                                 |
| /V               | Calculate profile points only at the vertices of <i>xWave</i> and <i>yWave</i> .                                                                                                                                                                                    |

### Examples

```
Make/N=(50, 50) sampleData  
sampleData = sin((x-25) / 10) * cos((y-25) / 10)  
NewImage sampleData  
Make/n=2 xTrace={0,50} ,yTrace={20,20}  
ImageLineProfile srcWave=sampleData, xWave=xTrace, yWave=yTrace  
AppendtoGraph/T yTrace vs xTrace  
Display W_ImageLineProfile
```

**See Also**

For additional examples see **ImageLineProfile Operation** on page III-325.

**ImageLoad**

**ImageLoad** [*flags*] [*fileNameStr*]

The ImageLoad operation loads an image file into an Igor wave. It can load PNG, JPEG, BMP, TIFF, and Sun Raster Files.

**Parameters**

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-401 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter or pass "" for it.

**Flags**

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
